# Expressing integers in the form $a^{2}-b^{2}$ 

Dr Richard Kenderdine

Kenderdine Maths Tutoring

One of the problems given in `Teaching Problem-solving in Undergraduate Mathematics` [A] is the following:

## Which numbers can be written as the difference of two perfect squares, e.g. $6^{2}-2^{2}=32$ ?

## I interpret `number` to mean integer (whole number).

An initial investigation of the values of $a^{2}-b^{2}$ for $2 \leq a \leq 12$ and $1 \leq b \leq a-1$ yielded the output:

|  | $\mathrm{b}=\mathrm{a}-1$ | a-2 | a-3 | a-4 | a-5 | a-6 | a-7 | a-8 | a-9 | a-10 | a-11 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{a}=2$ | 3 |  |  |  |  |  |  |  |  |  |  |
| 3 | 5 | 8 |  |  |  |  |  |  |  |  |  |
| 4 | 7 | 12 | 15 |  |  |  |  |  |  |  |  |
| 5 | 9 | 16 | 21 | 24 |  |  |  |  |  |  |  |
| 6 | 11 | 20 | 27 | 32 | 35 |  |  |  |  |  |  |
| 7 | 13 | 24 | 33 | 40 | 45 | 48 |  |  |  |  |  |
| 8 | 15 | 28 | 39 | 48 | 55 | 60 | 63 |  |  |  |  |
| 9 | 17 | 32 | 45 | 56 | 65 | 72 | 77 | 80 |  |  |  |
| 10 | 19 | 36 | 51 | 64 | 75 | 84 | 91 | 96 | 99 |  |  |
| 11 | 21 | 40 | 57 | 72 | 85 | 96 | 105 | 112 | 117 | 120 |  |
| 12 | 23 | 44 | 63 | 80 | 95 | 108 | 119 | 128 | 135 | 140 | 143 |

For example, the entries in the third row, where $a=4$, are obtained from $4^{2}-3^{2}=7,4^{2}-2^{2}=12$ and $4^{2}-1^{2}=15$.

The first column consists of all the odd numbers greater than 1 . Hence the numbers differ by 2 . The numbers in the second column differ by 4 , those in the third column by 6 and so on. Note that some numbers can be represented in more than one way eg $24=5^{2}-1^{2}=7^{2}-5^{2}$.

We can see from the table that all the odd numbers greater then 1 and all even numbers greater than 4 that are multiples of 4 can be expressed as the difference of two squares.

This leaves us with the question: why cannot even numbers that are not multiples of 4 be expressed as the difference of two squares?

Consider these points:
(1) even numbers can be expressed as $2 n$ and odd numbers as $2 n+1$, for integer $n \geq 0$.
(2) multiples of 4 can be expressed as $4 n$, even numbers that are not multiples of 4 can be expressed as $4 n+2$ and odd numbers as one of $4 n+1$ or $4 n-1$, for integer $n \geq 0$. Note that numbers of the form $4 n-1$ have a remainder of 3 when divided by 4 (in the language of modulus arithmetic they are said to be congruent to $3 \bmod 4$ ).

Now consider the forms that $a^{2}-b^{2}$ can take for the possible combinations of parity of $a$ and $b$ :
(1) both $a$ and $b$ even. Let $a=2 n$ and $b=2 m$ then $a^{2}-b^{2}=4\left(n^{2}-m^{2}\right)$
(2) $a$ even and $b$ odd. Let $a=2 n$ and $b=2 m+1$ then $a^{2}-b^{2}=4\left(n^{2}-m-m^{2}\right)-1$
(3) $a$ odd and $b$ even. Let $a=2 n+1$ and $b=2 m$ then $a^{2}-b^{2}=4\left(n^{2}+n-m^{2}\right)+1$
(4) both $a$ and $b$ odd. Let $a=2 n+1$ and $b=2 m+1$ then $a^{2}-b^{2}=4(n-m)(n+m+1)$

We see that when both $a$ and $b$ have the same parity $a^{2}-b^{2}$ is a multiple of 4 greater than 4 , whereas when they are of different parity $a^{2}-b^{2}$ is an odd number. None of the expressions were of the form $4 n+2$.

Note that the first even number that can be expressed in the form $a^{2}-b^{2}$ is 8 , using combination (4) with $n=1$ and $m=0$, giving $4(1-0)(1$ $+0+1)=4(1)(2)=8$.

Hence we agree with the conclusion given above:
All odd numbers greater than 1 and multiples of 4 greater than 4 can be expressed in the form $a^{2}-b^{2}$.
