.....Answer 3.....: On this Google Earth image of part of the Democratic Republic of Congo, the 5 random points in each 160x160 km grid cell are shown.

NOTE: For planning your country's geochemical baseline mapping, the size of the grid cells can be modified to suit your budget. *I mean national, not global-scale geochemical mapping.*

"Everything in and on the Earth - mineral, animal and vegetable - is made from one, or generally some combination of, the natural chemical elements occurring in the rocks of the Earth's crust and the surficial materials derived from them. Everything that is grown, or made, depends upon the availability of the appropriate elements. The existence, quality and survival of life depends upon the availability of elements in the correct proportions and combinations. Because natural processes and human activities are continuously modifying the chemical composition of our environment, it is important to determine the present abundance and spatial distribution of the elements across the Earth's surface in a much more systematic manner than has been attempted hitherto" (Darnley et al., 1965, p. x). Although such a global database is urgently needed for multi-purpose use, the systematic attempt is still in its infancy because of the non-existence of a manual of comprehensive and standardised methods of sampling and other supporting procedures. The current 'International Union of Geological Sciences Manual of Standard Methods for Establishing the Global Geochemical Reference Network' fills this gap. The Manual follows the concept of 7350 Global Terrestrial Network grid cells of 160x160m, covering the land surface of Earth, with five random sites within each grid cell for the collection of samples. This allows the establishment of the standardised Global Geochemical Reference Network with respect to rock, residual soil, humus, overbank sediment, stream water, stream sediment and floodplain sediment. Apart from the instructions for the collection of samples, the Manual covers sample preparation and storage, development of reference materials, geoanalytical methods, quality control procedures, geodetic and parametric levelling of existing data sets, data conditioning for the generation of time-independent geochemical data, management of data and map production, and finally project management. The methods described herein, apart from their use for Establishing the Global Geochemical Reference Network, can be used in other geochemical surveys at any mapping scale.

ISBN: 978-618-85049-1-2

Question 4: Which procedures should be followed for the production of internally consistent quality-controlled global geochemical databases for multipurpose use?

THE KEY IS STANDARDISATION OF ALL PROCEDURES FROM SAMPLING, SAMPLE PREPARATION, TO ANALYTICAL METHODS AND INSTALLATION OF A STRICT QUALITY CONTROL PROCEDURE AT ALL STAGES

Production of High Quality Harmonised Geochemical Databases at any mapping scale

Sampling

- These are the two most crucial stages of any geochemical survey.
- Any errors during these two stages is carried forward, and can result in the failure of the whole survey.

Sample preparation

Laboratory analysis

- Errors can be corrected by re-analysis of samples, provided enough sample material is available.

Standardised detailed instructions are given for sampling:

Detailed instructions are given for the collection of each sample type

Rock

Residual soil

Unfiltered

Humus

Stream water:-

Filtered

Stream sediment

Floodplain sediment

Overbank sediment

From the five (5) randomly selected catchment basins of each 160x160km grid cell, representative samples of

- Rock,**
- Residual soil (top & bottom),**
- Humus,**
- Stream water,**
- Stream sediment, and**
- Overbank sediment (top & bottom)**

are collected from the 2nd order catchment basin, and

- Floodplain sediment (top & bottom)**

is collected from the 3rd order catchment basin.

Note: Numbers 1, 2 & 3 refer to 1st, 2nd & 3rd order streams, respectively, at a map scale of 1:50,000.

Samples to be collected from 2nd order catchment basin:

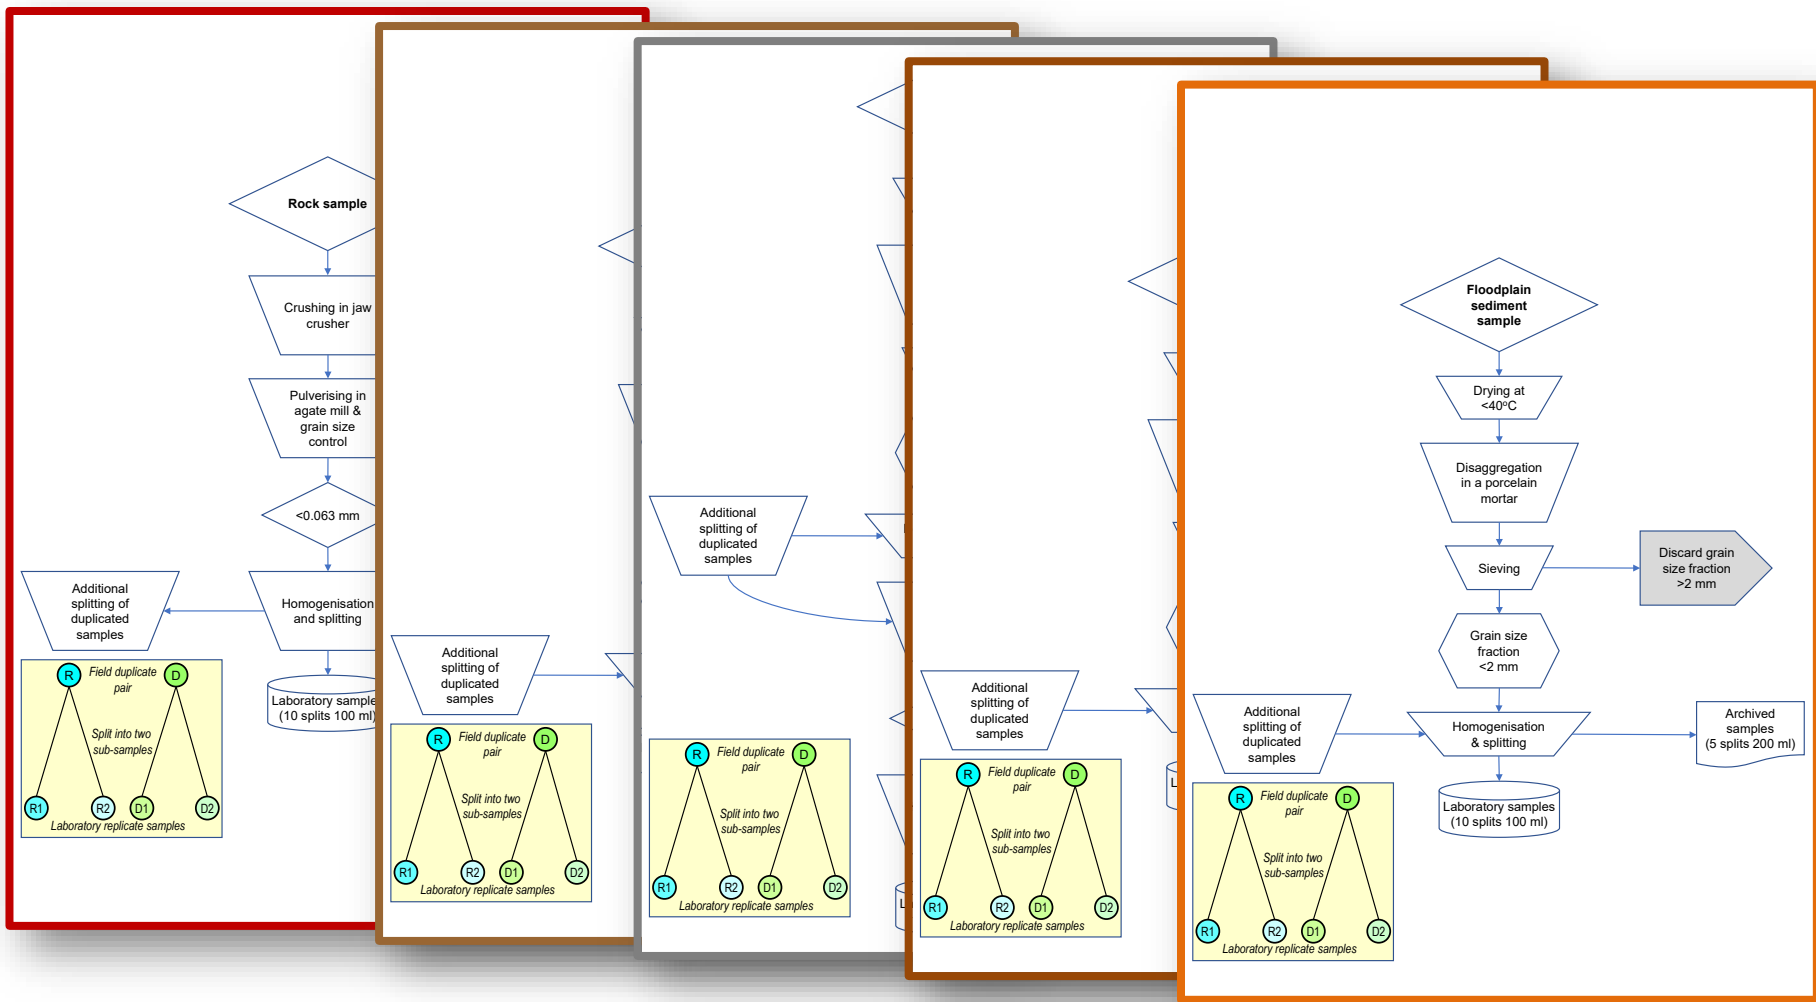

- Rock: N26E14R3
- Residual topsoil: N26E14T3
- Residual bottomsoil: N26E14C3
- Humus: N26E14H3 (where available)

- Overbank sediment - top: N26E14K3
- Overbank sediment - bottom: N26E14N3
- Stream sediment: N26E14S3
- Stream water: N26E14W3

Samples to be collected from 3rd order catchment basin:

- Floodplain sediment - top: N26E14F3
- Floodplain sediment - bottom: N26E14L3

Detailed instructions are given for sample preparation:

Detailed instructions are given for sample homogenisation, splitting, archiving, and randomisation of samples with insertion of duplicate-replicate sample splits, and external secondary reference materials for submission to the analytical laboratory

Standardisation is the key to harmonisation of geochemical databases

Laboratory analysis of collected samples: All samples of each medium type **MUST BE analysed** by the same analytical method at the same laboratory and, if possible, within a short time period. If the project runs for a long time, then other conditions must be followed by using the project reference samples to level the data. Methods of data conditioning for producing seamless geochemical maps are described in Chapter 8.

Checking of analytical data: Detailed instructions are given of how to conduct a thorough check of the received analytical data, and in case errors are identified, the particular batches should be reanalysed, and in the worst-case scenario it may be necessary to demand the reanalysis of the whole sample suite.

Chapter 7 - Quality Control Procedures

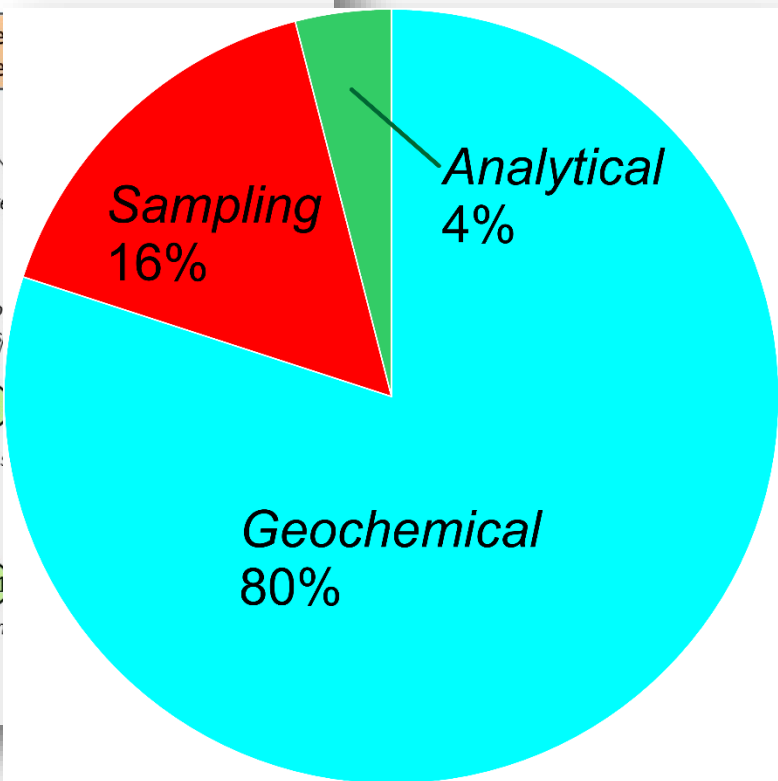

Alecios Demetriades, Christopher C. Johnson, Ariadne Argyraki

Quality control report: For each set of analytical data, it is stressed that a well-documented quality control report should be written, and problems encountered and solutions given must be clearly mentioned.

Quality control, and data conditioning when necessary

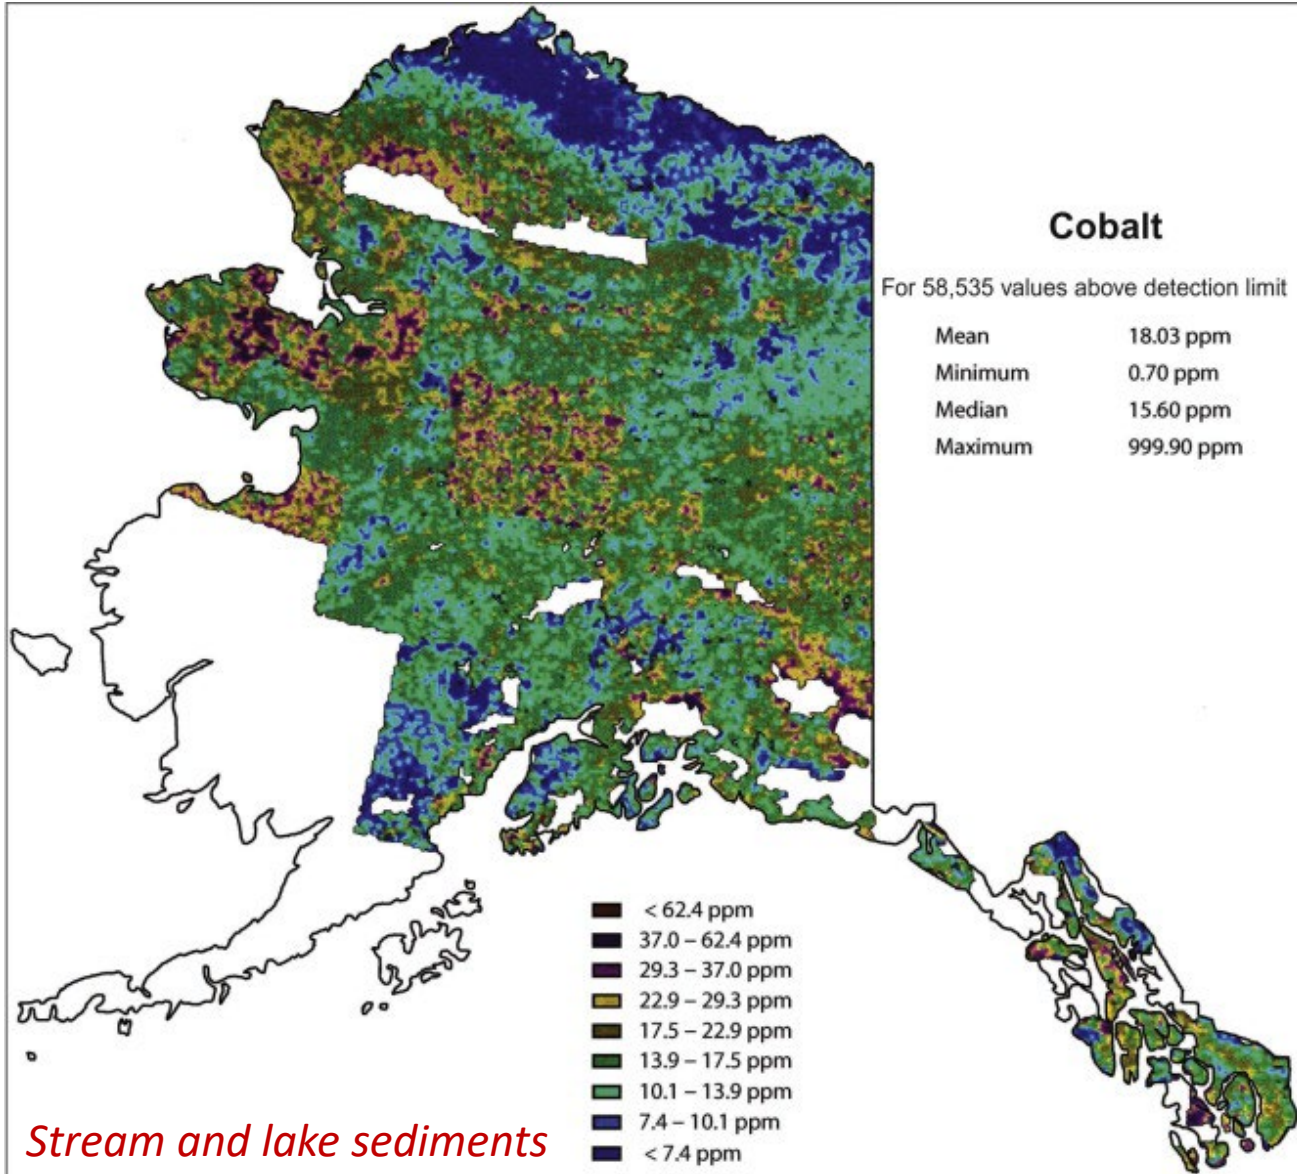

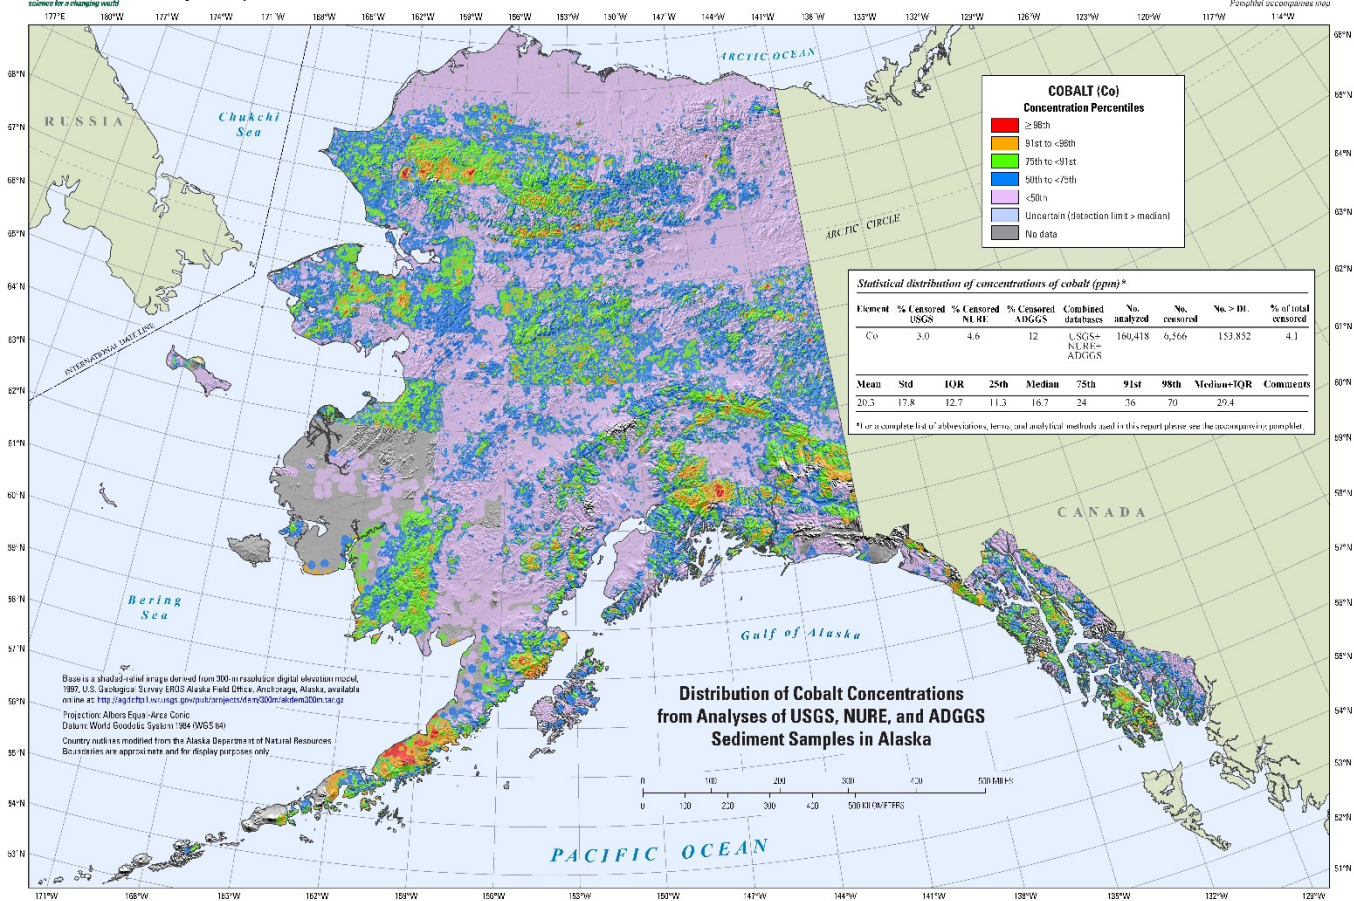

(a) Balanced ANOVA design

Chapter 8

Figure 8.1 on page 433. Cobalt distribution map from the original Geochemical Atlas of Alaska (Weaver *et al.*, 1983) modified by Smith *et al.* (2013, Fig. 4, p.172). Large blocks of unlevelled data, identifiable by their straight-edge boundaries (map sheet boundaries), show the effects of uncorrected bias in the analytical results.

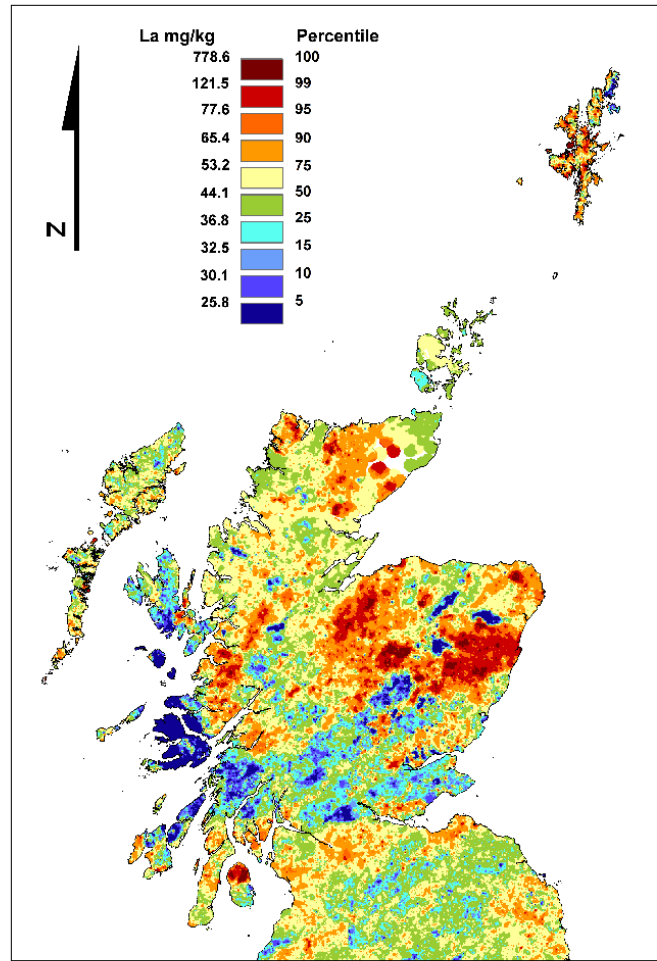

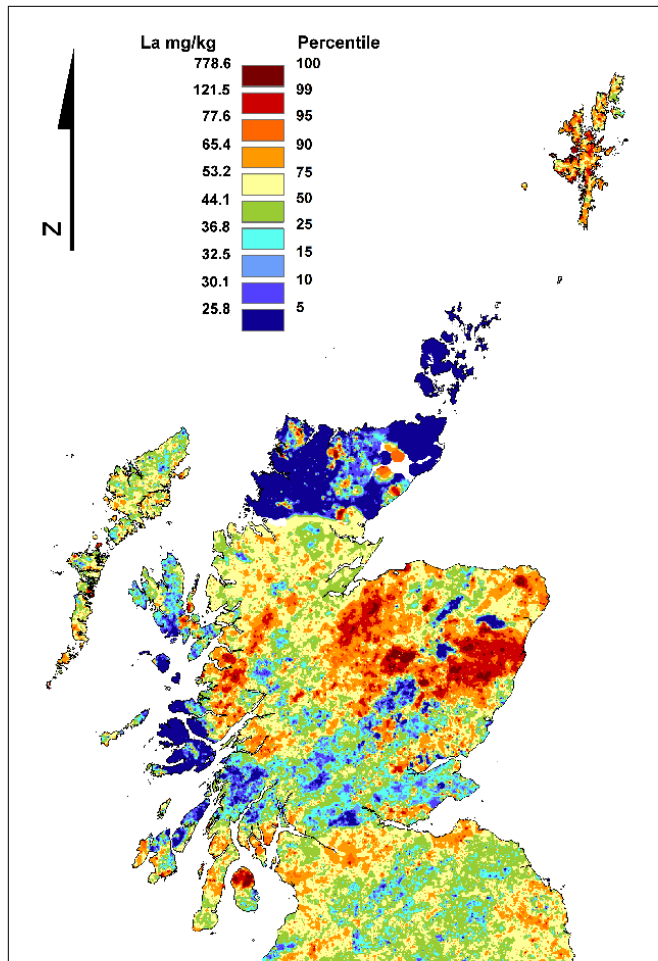

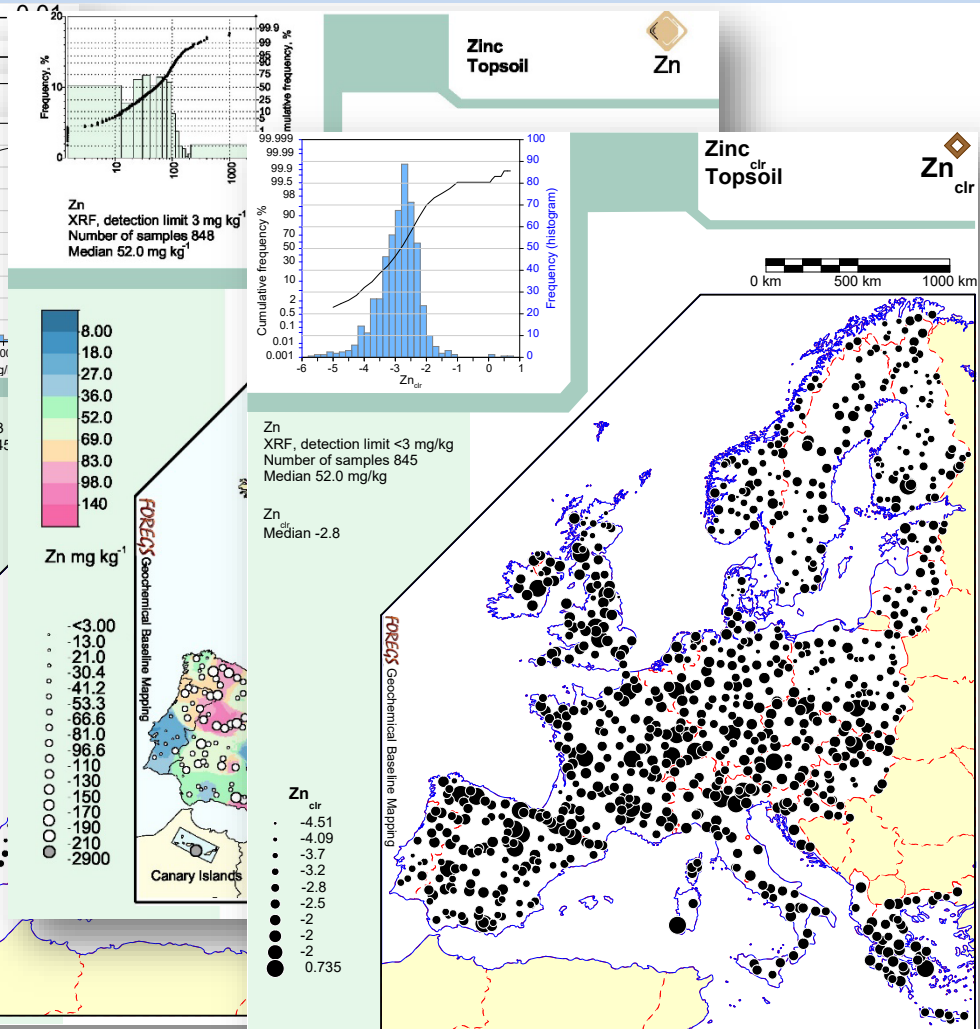

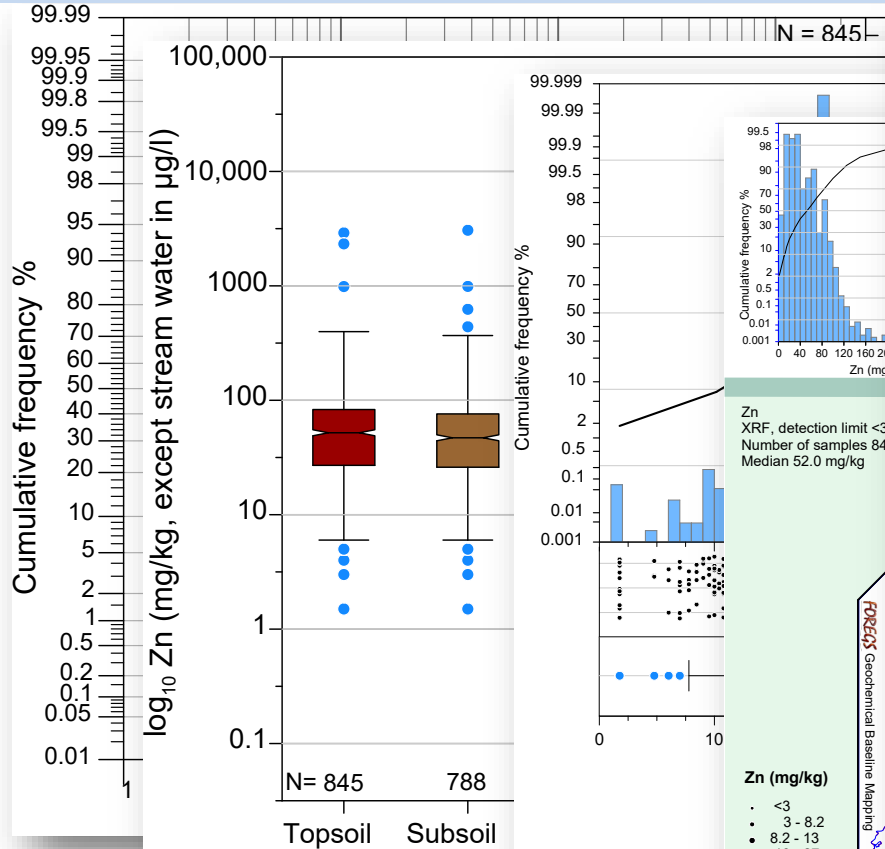

Cobalt distribution map from the new compilation of the stream and lake sediment geochemical data set of Alaska (Wang *et al.*, 2020). As you can observe the large blocks of unlevelled data are still identifiable by their straight-edge boundaries (map sheet boundaries).

Chapter 9

As you may appreciate, it is impossible in one lecture to present in detail the 515 pages of the [***International Union of Geological Sciences Manual of Standard Methods for Establishing the Global Geochemical Reference Network***](#). Therefore, I urge you to download it and study it at your leisure. We are certain that you will find something to help you in your work. If you have any questions you can contact me at: alecos.demetriades@gmail.com or any other co-author.

All the Chapters describing the procedure of sampling Rock, Residual soil, Humus, Stream water, Stream sediment, Overbank sediment and Floodplain sediment start with an Introduction, Required equipment, Cautions where necessary, and the sampling procedure is well-illustrated. As sampling of residual soil is the most difficult, the next few slides will show you an overall view.
