

Fibroblast/JPlasma Pen Mole and or Skin Tag Removal

Typically, healing takes 5-14 days. During this time the skin will behave like a superficial graze/superficial burn that may ooze and scab. It is better to keep the skin moist with Vaseline, Anti-biotic Ointment (preferred) during this time.

Clean your wound two times a day with gentle soap and water, or just water if you feel stinging from a cleanser. Don't use hydrogen peroxide or alcohol, which can slow healing. Make sure your hands are clean when you care for the wound.

Avoid scratching or rubbing your wound during recovery. As your wound heals, it may itch. Keeping the area moist with a thin layer of petroleum jelly (Vaseline) or Anti-biotic Ointment (preferred) will help relieve the itching.

If clothing irritates the site where a skin tag or mole has been removed, cover it with a bandage to prevent rubbing and bleeding.

A scab may form and will usually peel away within 1 to 3 weeks, depending on the area treated.

Prevent the wound from re-opening by keeping strenuous activity to a minimum.

Take proper care of your wound to prevent further scarring and promote better healed results.

When to call your doctor:

There is any redness, pain, or yellow pus around the injury. This could mean there is an infection.

There is bleeding at the injury site that will not stop after 10 minutes of direct pressure. You have a fever greater than 100°F (37.8°C).

There is pain at the site that will not go away, even after taking pain medicine.
