RELIABILITY
REDUNDANCY

- ▶ A reliability block diagram (RBD) provides a success oriented view of the system.
- ▶ RBD's provide a framework for understanding redundancy.
- ▶ RBDs facilitate the computation of system reliability from component reliabilities.
- ▶ RBDs and fault trees provide essentially the same information.
- ▶ Below is the RBD for the backup power supply.

RELIABILITY
REDUNDANCY

A **reliability block diagram (RBD)** is defined as follows:

- ▶ A reliability block diagram is a graph whose edges are the system components.
- ▶ There are a pair of nodes called *terminal nodes* – (a) and (b) in the backup power supply diagram.
- ▶ If there is a path between the terminal nodes which contains only edges with functional components, the entire system is functional. Otherwise it is not functional.

SERIAL & PARALLEL CONFIGURATIONS

FUNCTIONS
PATHS AND CUTSETS

QUANTITATIVE
ANALYSIS

RELIABILITY
REDUNDANCY

- ▶ In the serial configuration, failure of either component, A_1 or A_2 causes system failure.
- ▶ In the parallel configuration, both components must fail in order for the system to fail – redundancy

EXAMPLE: FIRE PUMP SYSTEM

- ▶ A system with n components is called a system of **order n** .

- ▶ x_i denotes the state of component or subsystem i ,

$$x_i = \begin{cases} 1 & \text{the component is functioning} \\ 0 & \text{the component is failed} \end{cases}, \quad i = 1, \dots, n$$

- ▶ x denotes the state of the entire system,

$$x = \begin{cases} 1 & \text{the system is functioning} \\ 0 & \text{the system is failed} \end{cases}$$

- ▶ The **structure function** is a function $\phi(x_1, \dots, x_n)$ associated with a given system, such that

$$x = \phi(x_1, \dots, x_n)$$

QUANTITATIVE
ANALYSIS

RELIABILITY
REDUNDANCY

- ▶ A component is **irrelevant** if it has no effect on the functioning of the system, i.e., the i^{th} component is irrelevant if

$$\phi(x_1, \dots, x_{i-1}, 0, x_{i+1}, \dots, x_n) = \phi(x_1, \dots, x_{i-1}, 1, x_{i+1}, \dots, x_n)$$

for all $x_1, \dots, x_{i-1}, x_{i+1}, \dots, x_n$

Otherwise it is called relevant.

- ▶ Assumption: the system will not run worse if a failed component is replaced by a functional component
 $\Rightarrow \phi(x_1, \dots, x_n)$ is a nondecreasing function of each of the variables x_1, \dots, x_n .
- ▶ A system is **coherent** if all of its components are relevant and its structure function is nondecreasing.
- ▶ By focusing on coherent structures we rule out certain pathologies.

PATHS AND CUTSETS

ENGINEERING
RELIABILITY

- ▶ The set of components of a system of order n is

$$C = \{1, 2, \dots, n\}$$

- ▶ A **path set**, P , is a subset of C which by functioning ensures that the system is functioning. A path set is minimal if it cannot be reduced without losing its status as a path set.
- ▶ A **cut set**, K , is a subset of C which by failing causes the system to fail. A cut set is minimal if it cannot be reduced without losing its status as a cut set.

► Note:

- $A = A_1 \cap A_2 \cap \dots \cap A_n \Leftrightarrow A^c = A_1^c \cup A_2^c \cup \dots \cup A_n^c$
- $A \subset A_i, i = 1, \dots, n \Rightarrow R(t) \leq R_i(t)$

- A serial system reliability is no greater than the reliability of any subsystem!
- Suppose that the failure events A_i are mutually independent, then

$$R(t) = P(A) = P(\cap_{i=1}^n A_i) = \prod_{i=1}^n P(A_i) = \prod_{i=1}^n R_i(t)$$

PARALLEL STRUCTURE

ENGINEERING
RELIABILITY

RELIABILITY
BLOCK
DIAGRAMS

▶ $A = A_1 \cup A_2 \cup \dots \cup A_n$

▶ If the subsystem failure events are independent:

▶ $A^c = A_1^c \cap A_2^c \cap \dots \cap A_n^c$

▶ $P(A^c) = P(A_1^c) P(A_2^c) \dots P(A_n^c)$

▶ $P(A) = 1 - P(A^c) = 1 - \prod_{i=1}^n P(A_i^c) = 1 - \prod_{i=1}^n [1 - P(A_i)]$

▶ Consequently, for independent events:

$$R(t) = 1 - \prod_{i=1}^n (1 - R_i(t))$$

- ▶ Consider identical components,
- ▶ The probability of failure over a specified time period for a single component is p , so the component reliability is $r = 1 - p$,
- ▶ Let M denote the number of components that fail in the specified time period, then

$$P(M = m) = \underbrace{C_m^n}_{\substack{\# \text{ ways to} \\ \text{get } m/n}} \underbrace{p^m}_m \underbrace{(1-p)^{n-m}}_{\substack{n-m \\ \text{survivors}}} = C_m^n (1-r)^m r^{n-m}$$

- ▶ The k/n system will survive if there are no more than $n - k$ failures, so

$$R = \sum_{m=0}^{n-k} C_m^n (1-r)^m r^{n-m}$$

- ▶ Consider a redundant (parallel) combination of two identical components.
- ▶ Let T_1 , T_2 , T denote the failure times of component 1, component 2, and the system, respectively.
 - ▶ the units are identical, so $R_1(t) = R_2(t)$
 - ▶ assume the failures of the two units are independent events.
- ▶ The system reliability of the active parallel structure is

$$\begin{aligned}R_a(t) &= P(T_1 > t \cup T_2 > t) \\ &= P(T_1 > t) + P(T_2 > t) - P(T_1 > t)P(T_2 > t) \\ R_a(t) &= R_1(t) + R_2(t) - R_1(t)R_2(t)\end{aligned}$$

RELIABILITY
REDUNDANCY

- ▶ The standby system does not start operating until the primary unit fails.
- ▶ The system can survive until time t if the primary unit survives until time t or the primary unit fails before time t , but the second unit survives until time t :

$$R_s(t) = P(T_2 > t | T_2 > T_1) = P(T_1 > t) + P(T_1 < t \cap T_2 > t)$$

- ▶ The two possibilities can be restated as $T_1 > t$ or T_1 occurs at $\tau < t$ and $T_2 > t - \tau$. Notice that

$$P(\tau < T_1 < \tau + d\tau) = f_1(\tau) d\tau$$

$$P(\tau < T_1 < \tau + d\tau \cap T_2 > t) = R_2(t - \tau) f_1(\tau) d\tau$$

$$P(T_1 < t \cap T_2 > t) = \int_0^t R_2(t - \tau) f_1(\tau) d\tau$$

$$R_s(t) = R_1(t) + \int_0^t R_2(t - \tau) f_1(\tau) d\tau$$

EXAMPLE: CONSTANT FAILURE RATE

ENGINEERING
RELIABILITY

- ▶ Components with constant failure rate λ have reliability

$$R(t) = e^{-\lambda t}$$

- ▶ An active parallel structure has reliability

$$R_a(t) = 2e^{-\lambda t} - e^{-2\lambda t}$$

- ▶ A standby parallel structure has reliability

$$R_s(t) = (1 + \lambda t) e^{-\lambda t}$$

RELIABILITY
REDUNDANCY

- ▶ Consider a system with state vector $\mathbf{x} = \{x_1, \dots, x_n\}$ and structure function $\phi_1(\mathbf{x})$, and a second system with state vector $\mathbf{y} = \{y_1, \dots, y_m\}$ and structure function $\phi_2(\mathbf{y})$.
- ▶ if these systems are connected in series then the whole system is of order $n + m$, and its structure function is

$$\phi(\mathbf{x}, \mathbf{y}) = \phi_1(\mathbf{x}) \phi_2(\mathbf{y})$$

- ▶ if these systems are connected in parallel then the whole system is of order $n + m$, and its structure function is

$$\phi(\mathbf{x}, \mathbf{y}) = \max \{ \phi_1(\mathbf{x}), \phi_2(\mathbf{y}) \}$$

SYSTEM LEVEL VS COMPONENT LEVEL REDUNDANCY

BLOCK
DIAGRAMS

RBD DEFINITION
RBDs AND FAULT
TREES
SYSTEM STRUCTURE

QUALITATIVE
ANALYSIS

STRUCTURE
FUNCTIONS
PATHS AND CUTSETS

QUANTITATIVE
ANALYSIS

RELIABILITY
REDUNDANCY

- ▶ Suppose the two systems in the parallel structure are identical, i.e., we have a system level redundant configuration. In this case,

$$\phi_S(\mathbf{x}, \mathbf{y}) = \max \{ \phi_1(\mathbf{x}), \phi_1(\mathbf{y}) \} \leq \phi_1(x_1y_1, \dots, x_ny_n)$$

- ▶ Consider a component level redundant configuration of system one, the structure function is

$$\phi_C(\mathbf{x}, \mathbf{y}) = \phi_1(\max \{x_1, y_1\}, \dots, \max \{x_n, y_n\})$$

But, for coherent systems,

$$\phi_1(\max \{x_1, y_1\}, \dots, \max \{x_n, y_n\}) \geq \phi_1(x_1y_1, \dots, x_ny_n)$$

So,

$$\phi_C(\mathbf{x}, \mathbf{y}) \geq \phi_S(\mathbf{x}, \mathbf{y})$$

- ▶ Thus, in general, we get a better (more reliable?) system through component redundancy rather than system redundancy.
