$$\sum \dot{P}_k\,\delta\theta_k + \sum P_k[(\delta\theta_k)^{\cdot} - \delta\omega_k] - \sum\Big(\sum A_{lk}(\partial T^*/\partial q_l)\Big)\,\delta\theta_k = \sum \Theta_k\,\delta\theta_k,$$

with the help of the transitivity equations (ex. 2.13.2: d–i), yields

$$\dot{P}_1\,\delta\theta_1 + \dot{P}_2\,\delta\theta_2 + \dot{P}_3\,\delta\theta_3$$
$$+ P_1(-\omega_3\,\delta\theta_2 + \omega_2\,\delta\theta_3) + P_2(\omega_3\,\delta\theta_1 - \omega_1\,\delta\theta_3) + P_3(0) = \Theta_1\,\delta\theta_1 + \Theta_2\,\delta\theta_2 + \Theta_3\,\delta\theta_3, \tag{t4}$$

or, collecting $(\ldots)\,\delta\theta_k$ terms:

$$(\dot{P}_1 + P_2\,\omega_3 - \Theta_1)\,\delta\theta_1 + (\dot{P}_2 - P_1\,\omega_3 - \Theta_2)\,\delta\theta_2 + (\dot{P}_3 + P_1\,\omega_2 - \Theta_3)\,\delta\theta_3 = 0. \tag{t5}$$

Finally, adjoining to this variational equation the constraint

$$\delta\theta_1 = 0, \qquad \text{or} \qquad (1)\,\delta\theta_1 + (0)\,\delta\theta_2 + (0)\,\delta\theta_3 = 0, \tag{t6}$$

via the method of Lagrangean multipliers yields the three earlier equations (s4–6):

$$\dot{P}_1 + P_2\,\omega_3 = \Theta_1 + \lambda_1: \qquad m(b\,\dot{\omega}_3 + \omega_2\,\omega_3) = N + \lambda, \tag{t7}$$

$$\dot{P}_2 - P_1\,\omega_3 = \Theta_2: \qquad m(\dot{\omega}_2 - b\,\omega_3{}^2) = K, \tag{t8}$$

$$\dot{P}_3 + P_1\,\omega_2 = \Theta_3: \qquad I_C\,\dot{\omega}_3 + m\,b\,\omega_2\,\omega_3 = M. \tag{t9}$$

The above clearly demonstrate the usefulness of the nonholonomic form of LP (t4, 5) over any particular set of *equations*.

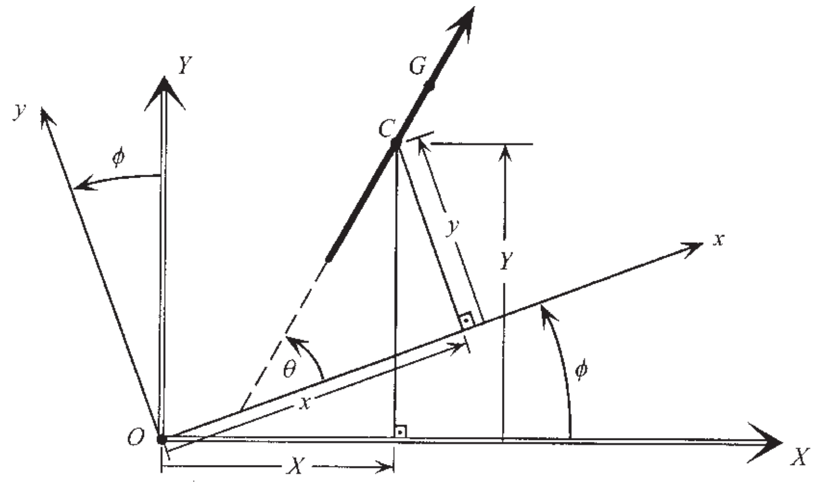

Figure 3.50 Geometry of sled on a uniformly spinning turntable. *Inertial coordinates*: $q_1 = X, q_2 = Y, q_3 = \psi \equiv \phi + \theta, \phi = \omega t$; *rotating coordinates*: $q_1 = x, q_2 = y, q_3 = \theta$.

Problem 3.18.1 Formulate the constraint of a sled in plane motion on a turntable spinning with constant (inertial) angular velocity Ω, in both inertial and rotating coordinates (fig. 3.50).

HINT

Formulate the constraint in the (moving) O–xy axes, and then use the transformation equations: $x = X \cos\phi - Y \sin\phi$, $y = X \sin\phi + Y \cos\phi$, and their $(\ldots)^{\cdot}$-derivatives for the (fixed) O–XY axes.

Problem 3.18.2 Continuing from the preceding problem, write down its transitivity equations and calculate (read off) their Hamel coefficients. Then obtain its equations of motion in both holonomic and nonholonomic variables.

Example 3.18.2 *Dynamics of a Rolling Sphere on a Fixed Plane.* Let us determine the forces and equations of motion of a homogeneous sphere S, of mass m and radius r, rolling on a rough horizontal fixed plane P (fig. 3.51).

The relevant kinematics has already been discussed in exs. 2.13.4–2.13.6. We recall that $q_1 = X_G \equiv X$, $q_2 = Y_G = Y$; $q_3 = \phi$, $q_4 = \theta, q_5 = \psi$ (coordinates of center of mass G and Eulerian angles of sphere-fixed axes G–xyz relative to translating/nonrotating axes G–XYZ), and that the constraints are

$$\dot{X} - (r \sin\phi)\dot{\theta} + (r \sin\theta \cos\phi)\dot{\psi} = 0, \quad \dot{Y} + (r \cos\phi)\dot{\theta} + (r \sin\theta \sin\phi)\dot{\psi} = 0; \qquad \text{(a)}$$

that is, here, $n = 5, m = 2 \;\Rightarrow\; f \equiv n - m = 3$ (# *local*) *DOF*.

The Routh–Voss Equations

By König's theorem and the results of §1.17, the (double) kinetic energy of S is

$$2T = m[(\dot{X})^2 + (\dot{Y})^2] + \left(I_X{}^2 \omega_X{}^2 + I_Y{}^2 \omega_Y{}^2 + I_Z{}^2 \omega_Z{}^2\right)$$

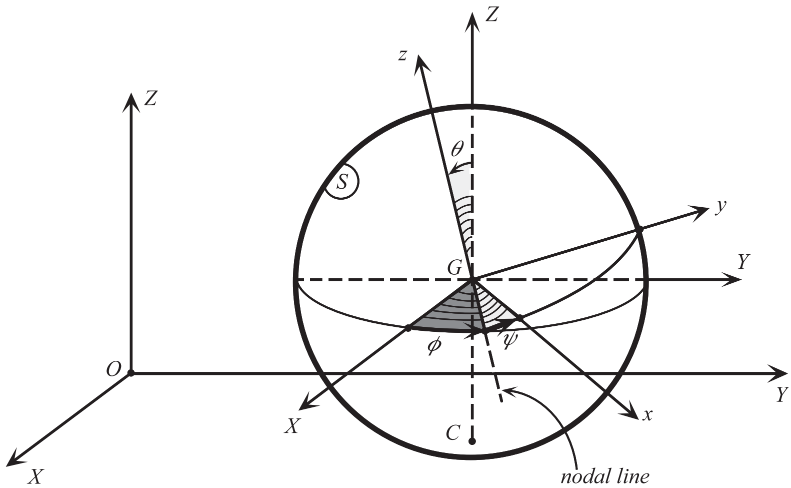

Figure 3.51 Geometry of sphere rolling on a fixed horizontal plane. Axes: O–XYZ: inertial (fixed); G–XYZ: translating (nonrotating); G–xyz: body-fixed.

(the *second* term can be expressed in either *body* or *space* axes at G; $I_X = I_Y = I_Z \equiv I = 2mr^2/5$)

$$= m[(\dot{X})^2 + (\dot{Y})^2] + I[(\dot{\phi})^2 + (\dot{\theta})^2 + (\dot{\psi})^2 + 2\dot{\phi}\,\dot{\psi}\cos\theta], \tag{b}$$

and, therefore, the corresponding five Routh–Voss equations,

$$E_k(T) = Q_k + \sum \lambda_D a_{Dk} \quad (k = 1, \ldots, 5 \equiv X, Y, \phi, \theta, \psi;\; D = 1, 2),$$

with $\lambda_1 \to \lambda$ and $\lambda_2 \to \mu$, are

$$m\ddot{X} = Q_X + \lambda \qquad (\text{i.e., } R_X = \lambda), \tag{b1}$$

$$m\ddot{Y} = Q_Y + \mu \qquad (\text{i.e., } R_Y = \mu); \tag{b2}$$

$$I(\ddot{\phi} + \ddot{\psi}\cos\theta - \dot{\theta}\,\dot{\psi}\sin\theta) = Q_\phi \qquad (\text{i.e., } R_\phi = 0), \tag{b3}$$

$$I(\ddot{\theta} + \dot{\phi}\,\dot{\psi}\sin\theta) = Q_\theta - r(\lambda\sin\phi - \mu\cos\phi) \quad (\equiv Q_\theta + R_\theta), \tag{b4}$$

$$I(\ddot{\psi} + \ddot{\phi}\cos\theta - \dot{\phi}\,\dot{\theta}\sin\theta) = Q_\psi + r\sin\theta(\lambda\cos\phi + \mu\sin\phi) \quad (\equiv Q_\psi + R_\psi). \tag{b5}$$

Equation (b3) shows that if $Q_\phi = 0$, then $\dot{\omega}_Z = \ddot{\phi} + \ddot{\psi}\cos\theta - \dot{\theta}\,\dot{\psi}\sin\theta = 0 \Rightarrow \omega_Z = \dot{\phi} + \cos\theta\,\dot{\psi}$ (= *total vertical spin*) = *constant*, as expected. [See also Bahar (1970–1980, pp. 446–450) and Roy (1965, vol. I, pp. 380–385) for additional insights and special cases.]

Next:

- Eliminating λ and μ among (b1–5) [e.g., solving (b1) for λ and (b2) for μ and inserting these values into (b4, 5)], we obtain the following *three* coupled kinetic

Maggi-like equations:

$$I(\ddot{\phi} + \ddot{\psi}\cos\theta - \dot{\theta}\,\dot{\psi}\sin\theta) = Q_\phi, \tag{b6}$$

$$I(\ddot{\theta} + \dot{\phi}\,\dot{\psi}\sin\theta) + mr(\ddot{X}\sin\phi - \ddot{Y}\cos\phi) = Q_\theta + r(Q_X\sin\phi - Q_Y\cos\phi), \tag{b7}$$

$$\begin{aligned} &I(\ddot{\psi} + \ddot{\phi}\cos\theta - \dot{\phi}\,\dot{\theta}\sin\theta) - mr(\ddot{X}\cos\phi + \ddot{Y}\sin\phi) \\ &\qquad = Q_\psi - r\sin\theta(Q_X\cos\phi + Q_Y\sin\phi); \end{aligned} \tag{b8}$$

which, along with the *two* constraints (a) constitute a determinate system of five equations in the five Lagrangean coordinates: $X(t), Y(t); \phi(t), \theta(t), \psi(t)$. After these latter have been found, we can easily determine the multipliers/reactions $\lambda(t), \mu(t)$ from (b1, 2), respectively.

• If, further, with the help of the constraints (a) we eliminate $\dot{X} \to \ddot{X} = \ddot{X}(\phi, \theta;\ \dot{\phi}, \dot{\theta}, \dot{\psi};\ \ddot{\theta}, \ddot{\psi})$ and $\dot{Y} \to \ddot{Y} = \ddot{Y}(\phi, \theta;\ \dot{\phi}, \dot{\theta}, \dot{\psi};\ \ddot{\theta}, \ddot{\psi})$, or any other *two* out of the five $\dot{q}$'s, among (b6–8), we will obtain the *three* (kinetic) Chaplygin–Voronets equations of the problem, coupled in $\dot{\phi}, \dot{\theta}, \dot{\psi}$ and their $(\ldots)^{\cdot}$-derivatives—see below.

• Equations (b1–5) can, of course, also be obtained by *adjoining to LP*:

$$\sum [(\partial T/\partial\dot{q}_k)^{\cdot} - \partial T/\partial q_k]\,\delta q_k = \sum Q_k\,\delta q_k, \tag{b9}$$

the constraints (a) in virtual form [i.e., with $(\ldots)^{\cdot}$ replaced, in them, by $\delta(\ldots)$], via multipliers λ and μ, and then setting of the coefficients of the (now) free δq's equal to zero.

The Hamel Equations

Recalling (ex. 2.13.6: a ff., with $\Omega = 0$):

$$\omega_1 = \dot{X} - r\,\omega_Y = \dot{X} - r\,\omega_4\ (= 0)\ \Rightarrow\ \dot{X} = \omega_1 + r\,\omega_4, \tag{c1}$$

$$\omega_2 = \dot{Y} + r\,\omega_X = \dot{Y} + r\,\omega_3\ (= 0)\ \Rightarrow\ \dot{Y} = \omega_2 - r\,\omega_3, \tag{c2}$$

$$\omega_3 = \omega_X\ \Rightarrow\ \omega_X = \omega_3, \tag{c3}$$

$$\omega_4 = \omega_Y\ \Rightarrow\ \omega_Y = \omega_4, \tag{c4}$$

$$\omega_5 = \omega_Z\ \Rightarrow\ \omega_Z = \omega_5, \tag{c5}$$

we readily find (no constraint enforcement yet)

$$(\dot{X})^2 + (\dot{Y})^2 = \cdots = {\omega_1}^2 + {\omega_2}^2 + r^2({\omega_3}^2 + {\omega_4}^2) + 2r(\omega_1\,\omega_4 - \omega_2\,\omega_3),$$

$$r^2({\omega_X}^2 + {\omega_Y}^2 + {\omega_Z}^2) = r^2({\omega_1}^2 + {\omega_2}^2 + {\omega_3}^2),$$

and, therefore, (b) becomes

$$\begin{aligned} 2T \to 2T(\omega) \equiv 2T^* = \cdots = m[&{\omega_1}^2 + {\omega_2}^2 + (7r^2/5)({\omega_3}^2 + {\omega_4}^2) \\ &+ (2r^2/5){\omega_5}^2 + 2r(\omega_1\,\omega_4 - \omega_2\,\omega_3)], \end{aligned} \tag{c6}$$

or, to within "*Hamel-important terms*" [i.e., dropping the *quadratic* terms in $\omega_1\ (= 0)$ and $\omega_2\ (= 0)$, but *not* the linear ones]:

$$2T^* = m[(7r^2/5)({\omega_3}^2 + {\omega_4}^2) + (2r^2/5){\omega_5}^2 + 2r(\omega_1\,\omega_4 - \omega_2\,\omega_3)]. \tag{c7}$$

From this, we readily find [with the notation $(\ldots)_o \equiv (\ldots)$ *evaluated for* $\omega_{1,2} = 0$]

$$P_1 \equiv (\partial T^*/\partial\omega_1)_o = m\,r\,\omega_4, \tag{c8}$$

$$P_2 \equiv (\partial T^*/\partial\omega_2)_o = -3m\,r\,\omega_3, \tag{c9}$$

$$P_3 \equiv (\partial T^*/\partial\omega_3)_o = (7mr^2/5)\omega_3, \tag{c10}$$

$$P_4 \equiv (\partial T^*/\partial\omega_4)_o = (7mr^2/5)\omega_4, \tag{c11}$$

$$P_5 \equiv (\partial T^*/\partial\omega_5)_o = (2mr^2/5)\omega_5 = I\,\omega_5. \tag{c12}$$

Next, to the virtual work of the impressed forces. Recalling (ex. 2.13.6: i1–6), we obtain, successively,

$$\begin{aligned}
\delta' W &= Q_X\,\delta X + Q_Y\,\delta Y + Q_\phi\,\delta\phi + Q_\theta\,\delta\theta + Q_\psi\,\delta\psi \\
&= Q_X(\delta\theta_1 + r\,\delta\theta_4) + Q_Y(\delta\theta_2 - r\,\delta\theta_3) \\
&\quad + Q_\phi(-\cot\theta\,\sin\phi\,\delta\theta_3 + \cot\theta\,\cos\phi\,\delta\theta_4 + \delta\theta_5) \\
&\quad + Q_\theta(\cos\phi\,\delta\theta_3 + \sin\phi\,\delta\theta_4) + Q_\psi[(\sin\phi/\sin\theta)\,\delta\theta_3 - (\cos\phi/\sin\theta)\,\delta\theta_4] \\
&= (Q_X)\,\delta\theta_1 + (Q_Y)\,\delta\theta_2 + [-r\,Q_Y - \cot\theta\,\sin\phi\,Q_\phi + \cos\phi\,Q_\theta + (\sin\phi/\sin\theta)Q_\psi]\,\delta\theta_3 \\
&\quad + [r\,Q_X + \cot\theta\,\cos\phi\,Q_\phi + \sin\phi\,Q_\theta - (\cos\phi/\sin\theta)Q_\psi]\,\delta\theta_4 + Q_\phi\,\delta\theta_5,
\end{aligned} \tag{c13}$$

and, therefore,

$$\Theta_1 = Q_X, \qquad \Theta_2 = Q_Y, \tag{c14, 15}$$

$$\Theta_3 = -r\,Q_Y - \cot\theta\,\sin\phi\,Q_\phi + \cos\phi\,Q_\theta + (\sin\phi/\sin\theta)Q_\psi, \tag{c16}$$

$$\Theta_4 = r\,Q_X + \cot\theta\,\cos\phi\,Q_\phi + \sin\phi\,Q_\theta - (\cos\phi/\sin\theta)Q_\psi, \tag{c17}$$

$$\Theta_5 = Q_\phi. \tag{c18}$$

[If no reactions are sought, we only need $\Theta_{3,4,5}$. Then we can enforce the constraints in $\delta' W = \Theta_3\,\delta\theta_3 + \Theta_4\,\delta\theta_4 + \Theta_5\,\delta\theta_5$.]

In view of the above, noting that, here, $\partial T^*/\partial q_k = 0$ and $\gamma^r{}_{I,n+1} = 0$, and recalling (ex. 2.13.6: l1–m, with $\Omega = 0$), the *kinetic* Hamel equations $\dot{P}_I + \sum\sum \gamma^r{}_{II'} P_r\,\omega_{I'} \equiv \dot{P}_I - \Gamma_I = \Theta_I$ $(I, I' = 3, 4, 5;\ r = 1, \ldots, 5)$ yield

$$\begin{aligned}
I = 3: \quad & (7mr^2/5)\dot\omega_3 - \Gamma_3 \\
&= (7mr^2/5)\dot\omega_3 + \gamma^1{}_{34}P_1\,\omega_4 + \gamma^1{}_{35}P_1\,\omega_5 + \gamma^2{}_{34}P_2\,\omega_4 + \gamma^2{}_{35}P_2\,\omega_5 \\
&\qquad + \gamma^4{}_{35}P_4\,\omega_5 + \gamma^5{}_{34}P_5\,\omega_4 \\
&\qquad (\text{only the } \textit{first, third, sixth, and seventh} \text{ terms survive}) \\
&= (7mr^2/5)\dot\omega_3 - P_5\,\omega_4 + (P_4 - rP_1)\omega_5 \\
&= (7mr^2/5)\dot\omega_3 - (I\omega_5)\omega_4 + [(7mr^2/5)\omega_4 - r(m\,r\,\omega_4)]\omega_5 \\
&= (7mr^2/5)\dot\omega_3 + 0 \qquad (\text{recalling that } I = 2mr^2/5);
\end{aligned} \tag{c19}$$

and similarly for $I = 4, 5$. The final results are (recalling §3.15)

$I = 3$: $\quad (7mr^2/5)\dot{\omega}_3 = \Theta_3,$

or

$$(7mr^2/5)\dot{\omega}_X = -r\,Q_Y - \cot\theta\,\sin\phi\,Q_\phi + \cos\phi\,Q_\theta + (\sin\phi/\sin\theta)Q_\psi = M_X - r\,Q_Y; \tag{c20}$$

$I = 4$: $\quad (7mr^2/5)\dot{\omega}_4 = \Theta_4,$

or

$$(7mr^2/5)\dot{\omega}_Y = r\,Q_X + \cot\theta\,\cos\phi\,Q_\phi + \sin\phi\,Q_\theta - (\cos\phi/\sin\theta)Q_\psi = M_Y + r\,Q_X; \tag{c21}$$

$I = 5$: $\quad (2mr^2/5)\,\dot{\omega}_5 = \Theta_5,$

or

$$(2mr^2/5)\,\dot{\omega}_Z = Q_\phi. \tag{c22}$$

These three (first-order) equations, plus the *three* kinematic relations $\omega_{X,Y,Z} \Leftrightarrow \dot{\phi}, \dot{\theta}, \dot{\psi}$ (§1.12) and the *two* constraints (a), constitute a determinate system in the eight functions: $X(t), Y(t);\ \phi(t), \theta(t), \psi(t);\ \omega_{X,Y,Z}(t)$.

Instead of the *space-fixed* ω-components $\omega_{X,Y,Z}$, we could just as well have used its *body-fixed* components $\omega_{x,y,z}$; or, we can always invoke the $\omega_{X,Y,Z} \Leftrightarrow \omega_{x,y,z}$ relations. However, because of the complete *symmetry* of this problem, the space-fixed axes seems the best choice.

The Appell Equations

Since

$$\begin{aligned} a_G{}^2 &= (\ddot{X})^2 + (\ddot{Y})^2 = [(\omega_1 + r\,\omega_4)^{\cdot}]^2 + [(\omega_2 - r\,\omega_3)^{\cdot}]^2 \\ &= (\dot{\omega}_1)^2 + (\dot{\omega}_2)^2 + r^2[(\dot{\omega}_3)^2 + (\dot{\omega}_4)^2] + 2r(\dot{\omega}_1\,\dot{\omega}_4 - \dot{\omega}_2\,\dot{\omega}_3), \end{aligned} \tag{d1}$$

and, as in the preceding example (*à la* König),

$$S = S_G + S_{/G}, \qquad 2S_G = m\,a_G{}^2, \qquad 2S_{/G} \equiv \int dm\,\boldsymbol{a}_{/G}\cdot\boldsymbol{a}_{/G} = \int dm\,a_{/G}{}^2, \tag{d2}$$

it is not too hard to see that S^* equals the earlier T^*, but with the ω's replaced by the corresponding $\dot{\omega}$'s; that is,

$$\begin{aligned} 2S^* = 2T^*(\dot{\omega}) = m\Big\{&(\dot{\omega}_1)^2 + (\dot{\omega}_2)^2 + (7r^2/5)[(\dot{\omega}_3)^2 + (\dot{\omega}_4)^2] \\ &+ (2r^2/5)(\dot{\omega}_5)^2 + 2r(\dot{\omega}_1\dot{\omega}_4 - \dot{\omega}_2\,\dot{\omega}_3)\Big\}. \end{aligned} \tag{d3}$$

Also, as the theory shows (3.5.25a ff.), if we are not interested in finding the constraint reactions, we can enforce the constraints $\omega_{1,2} = 0 \Rightarrow \dot{\omega}_{1,2} = 0$ in S^* right from the start; that is, we can neglect from it not just the quadratic terms in $\dot{\omega}_{1,2}$ but also the linear ones. Thus, we can take $2S^*(\dot{\omega}_{1,2} = 0) \equiv 2S^*{}_o$:

$$2S^*{}_o = m\Big\{(7r^2/5)[(\dot{\omega}_3)^2 + (\dot{\omega}_4)^2] + (2r^2/5)(\dot{\omega}_5)^2\Big\}, \tag{d4}$$

and therefore the kinetic Appellian equations are

$$\partial S^*{}_o/\partial\dot{\omega}_3 = (7r^2/5)\dot{\omega}_3 = \Theta_3, \tag{d5}$$

$$\partial S^*{}_o/\partial\dot{\omega}_4 = (7r^2/5)\dot{\omega}_4 = \Theta_4, \tag{d6}$$

$$\partial S^*{}_o/\partial\dot{\omega}_5 = (2r^2/5)\dot{\omega}_5 = \Theta_5; \tag{d7}$$

and, of course, these coincide with the earlier kinetic Hamel equations.

The Chaplygin Equations (3.8.13a ff.)

We recall that here the (double) kinetic energy equals

$$2T = m[(\dot{X})^2 + (\dot{Y})^2] + I[(\dot{\phi})^2 + (\dot{\theta})^2 + (\dot{\psi})^2 + 2\dot{\phi}\,\dot{\psi}\cos\theta], \tag{e1}$$

while the constraints (a), rewritten in the Chaplygin form — that is,

$$\dot{q}_D = \sum b_{DI}\,\dot{q}_I, \qquad \text{where} \qquad q_D = X, Y;\ q_I = \phi, \theta, \psi,$$

are

$$\dot{X} = (r\sin\phi)\dot{\theta} - (r\cos\phi\sin\theta)\dot{\psi} \quad \text{and} \quad \dot{Y} = -(r\cos\phi)\dot{\theta} - (r\sin\phi\sin\theta)\dot{\psi}. \tag{e2}$$

Therefore, in this problem, the "Chaplygin coefficients" are (with some easily understood ad hoc notation)

$$\begin{aligned} &b_{13} \equiv b_{X\phi} = 0, && b_{14} \equiv b_{X\theta} = r\sin\phi, && b_{15} \equiv b_{X\psi} = -r\cos\phi\sin\theta,\\ &b_{23} \equiv b_{Y\phi} = 0, && b_{24} \equiv b_{Y\theta} = -r\cos\phi, && b_{25} \equiv b_{Y\psi} = -r\sin\phi\sin\theta. \end{aligned} \tag{e3}$$

Clearly, since (α) the constraints (e2, 3) are stationary, and (β) the chosen "dependent" coordinates X, Y do not appear either in the constraint coefficients b_{DI} or in T (i.e., $\partial T/\partial X = 0$, $\partial T/\partial Y = 0$), this is a Chaplygin system, and, therefore, Chaplygin's equations hold; and, for this problem, they coincide with Voronets' equations. Let us find them.

(i) Eliminating $\dot{X}$ and $\dot{Y}$ from T with the help of the constraints (e2), we obtain the "Chaplygin constrained kinetic energy"

$$\begin{aligned} 2T &= 2T[\theta, \dot{X}(\phi,\theta;\,\dot{\theta},\dot{\psi}),\ \dot{Y}(\phi,\theta;\,\dot{\theta},\dot{\psi}),\ \dot{\phi},\dot{\theta},\dot{\psi}]\\ &= \cdots = (mr^2)\big[(2/5)(\dot{\phi})^2 + (7/5)(\dot{\theta})^2 + \big((2/5)+\sin^2\theta\big)(\dot{\psi})^2 + (4\cos\theta/5)\dot{\phi}\dot{\psi}\big]\\ &= 2T_o(\phi,\theta;\,\dot{\phi},\dot{\theta},\dot{\psi}) \equiv 2T_o, \end{aligned} \tag{e4}$$

and, therefore,

$$
\begin{aligned}
E_3(T_o) &\equiv E_\phi(T_o) \equiv (\partial T_o/\partial\dot{\phi})^{\cdot} - \partial T_o/\partial\phi = (2mr^2/5)(\ddot{\phi} + \ddot{\psi}\,\cos\theta - \dot{\theta}\,\dot{\psi}\,\sin\theta),\\
E_4(T_o) &\equiv E_\theta(T_o) \equiv (\partial T_o/\partial\dot{\theta})^{\cdot} - \partial T_o/\partial\theta\\
&= (mr^2)[(7/5)\ddot{\theta} - (\dot{\psi})^2\,\sin\theta\,\cos\theta + (2/5)\dot{\phi}\,\dot{\psi}\,\sin\theta],\\
E_5(T_o) &\equiv E_\psi(T_o) \equiv (\partial T_o/\partial\dot{\psi})^{\cdot} - \partial T_o/\partial\psi\\
&= (mr^2)\Big\{(2/5)\ddot{\phi}\cos\theta + \big[(2/5) + \sin^2\theta\big]\ddot{\psi} + 2\dot{\theta}\dot{\psi}\sin\theta\cos\theta\\
&\qquad - (2/5)\dot{\phi}\dot{\theta}\sin\theta\Big\}. \qquad \text{(e5, 6, 7)}
\end{aligned}
$$

(ii) Next, let us calculate the corresponding "Chaplygin corrective terms"

$$
\begin{aligned}
-\Gamma_{Io} &\equiv \sum\sum (\partial b_{DI'}/\partial q_I - \partial b_{DI}/\partial q_{I'})(\partial T/\partial\dot{q}_D)_o\,\dot{q}_{I'}\\
&\equiv \sum\sum t^D{}_{I'I}(\partial T/\partial\dot{q}_D)_o\,\dot{q}_{I'} \equiv \sum\sum t^D{}_{I'I}\,p_{Do}\,\dot{q}_{I'}. \qquad \text{(e8)}
\end{aligned}
$$

Using commas for partial derivatives relative to the q_I, we obtain, successively,

$$
\begin{aligned}
-\Gamma_{3o} \equiv -\Gamma_{\phi o} &\equiv \sum\sum t^D{}_{I3}\,p_{Do}\,\dot{q}_I = \sum\Big(\sum t^D{}_{I3}\,\dot{q}_I\Big)p_{Do}\\
&= [(b_{13,3} - b_{13,3})\dot{q}_3 + (b_{14,3} - b_{13,4})\dot{q}_4 + (b_{15,3} - b_{13,5})\dot{q}_5]p_{1o}\\
&\quad + [(b_{23,3} - b_{23,3})\dot{q}_3 + (b_{24,3} - b_{23,4})\dot{q}_4 + (b_{25,3} - b_{23,5})\dot{q}_5]p_{2o}\\
&= [(b_{X\theta,\phi} - b_{X\phi,\theta})\dot{\theta} + (b_{X\psi,\phi} - b_{X\phi,\psi})\dot{\psi}]p_{Xo}\\
&\quad + [(b_{Y\theta,\phi} - b_{Y\phi,\theta})\dot{\theta} + (b_{Y\psi,\phi} - b_{Y\phi,\psi})\dot{\psi}]p_{Yo},
\end{aligned}
$$

or, since,

$$
\begin{aligned}
p_{1o} &\equiv p_{Xo} \equiv (\partial T/\partial\dot{X})_o = (m\dot{X})_o = mr(\dot{\theta}\,\sin\phi - \dot{\psi}\,\cos\phi\,\sin\theta),\\
p_{2o} &\equiv p_{Yo} \equiv (\partial T/\partial\dot{Y})_o = (m\dot{Y})_o = -mr(\dot{\theta}\,\cos\phi + \dot{\psi}\,\sin\phi\,\sin\theta),
\end{aligned}
$$

finally,

$$
\begin{aligned}
-\Gamma_{3o} &\equiv -\Gamma_{\phi o}\\
&= [(r\,\cos\phi - 0)\dot{\theta} + (r\,\sin\phi\,\sin\theta - 0)\dot{\psi}](mr)(\dot{\theta}\,\sin\phi - \dot{\psi}\,\cos\phi\,\sin\theta)\\
&\quad + [(r\,\sin\phi - 0)\dot{\theta} + (-r\,\cos\phi\,\sin\theta - 0)\dot{\psi}](-mr)(\dot{\theta}\,\cos\phi + \dot{\psi}\,\sin\phi\,\sin\theta)\\
&= \cdots = 0; \qquad \text{(e9)}
\end{aligned}
$$

and similarly, after some careful algebra,

$$
-\Gamma_{4o} \equiv -\Gamma_{\theta o} = \sum\Big(\sum t^D{}_{I4}\,\dot{q}_I\Big)p_{Do} = \cdots = mr^2(\dot{\phi} + \dot{\psi}\,\cos\theta)(\dot{\psi}\,\sin\theta), \qquad \text{(e10)}
$$

$$
-\Gamma_{5o} \equiv -\Gamma_{\psi o} = \sum\Big(\sum t^D{}_{I5}\,\dot{q}_I\Big)p_{Do} = \cdots = -mr^2(\dot{\phi} + \dot{\psi}\,\cos\theta)(\dot{\theta}\,\sin\theta). \qquad \text{(e11)}
$$

The above show that the *nonvanishing* Chaplygin coefficients are

$$t^1{}_{43} \equiv t^X{}_{\theta\phi} = r\cos\phi \quad (= -t^1{}_{34} \equiv -t^X{}_{\phi\theta}), \tag{e12}$$

$$t^1{}_{53} \equiv t^X{}_{\psi\phi} = r\sin\phi\,\sin\theta \quad (= -t^1{}_{35} \equiv -t^X{}_{\phi\psi}), \tag{e13}$$

$$t^1{}_{54} \equiv t^X{}_{\psi\theta} = -r\cos\phi\,\cos\theta \quad (= -t^1{}_{45} \equiv -t^X{}_{\theta\psi}); \tag{e14}$$

$$t^2{}_{43} \equiv t^Y{}_{\theta\phi} = r\sin\phi \quad (= -t^2{}_{34} \equiv -t^Y{}_{\phi\theta}), \tag{e15}$$

$$t^2{}_{53} \equiv t^Y{}_{\psi\phi} = -r\cos\phi\,\sin\theta \quad (= -t^2{}_{35} \equiv -t^Y{}_{\phi\psi}), \tag{e16}$$

$$t^2{}_{54} \equiv t^Y{}_{\psi\theta} = -r\sin\phi\,\cos\theta \quad (= -t^2{}_{45} \equiv -t^Y{}_{\theta\psi}). \tag{e17}$$

(iii) Finally, let us calculate the "Chaplygin impressed forces" $Q_{Io} \equiv Q_I + \sum b_{DI}\,Q_D$. With some obvious ad hoc notation, we find

$$Q_{3o} \equiv Q_{\phi o} = Q_3 + b_{13}Q_1 + b_{23}Q_2 = Q_3 \equiv Q_\phi, \tag{e18}$$

$$\begin{aligned} Q_{4o} \equiv Q_{\theta o} = Q_4 + b_{14}Q_1 + b_{24}Q_2 &= Q_4 + (r\sin\phi)Q_1 + (-r\cos\phi)Q_2 \\ &= Q_\theta + r(Q_X\sin\phi - Q_Y\cos\phi), \end{aligned} \tag{e19}$$

$$\begin{aligned} Q_{5o} \equiv Q_{\psi o} = Q_5 + b_{15}Q_1 + b_{25}Q_2 &= Q_5 + (-r\cos\phi\,\sin\theta)Q_1 + (-r\sin\phi\,\sin\theta)Q_2 \\ &= Q_\psi - r\sin\theta(Q_X\cos\phi + Q_Y\sin\phi). \end{aligned} \tag{e20}$$

Inserting now all the above partial results into Chaplygin's equations (3.8.13o):

$$(\partial T_o/\partial\dot{q}_I)^{\cdot} - \partial T_o/\partial q_I - \Gamma_{Io} = Q_{Io} \tag{e21}$$

(with I: $3 \to \phi, 4 \to \theta, 5 \to \psi$), and, simplifying a little, we obtain the following three kinetic equations:

$$\phi: \qquad (2mr^2/5)(\ddot{\phi} + \ddot{\psi}\cos\theta - \dot{\theta}\dot{\psi}\sin\theta) = Q_\phi, \tag{e22}$$

$$\theta: \qquad (7mr^2/5)(\ddot{\theta} + \dot{\phi}\dot{\psi}\sin\theta) = Q_\theta + r(Q_X\sin\phi - Q_Y\cos\phi), \tag{e23}$$

$$\begin{aligned} \psi: \qquad &(mr^2)[(2/5)\ddot{\phi}\cos\theta + (2/5)\ddot{\psi} + \ddot{\psi}\sin^2\theta - (7/5)\dot{\phi}\dot{\theta}\sin\theta \\ &+ \dot{\theta}\dot{\psi}\sin\theta\cos\theta] = Q_\psi - r\sin\theta(Q_X\cos\phi + Q_Y\sin\phi). \end{aligned} \tag{e24}$$

These latter, of course, coincide (i) with the earlier-found kinetic Maggi equations (b6–8), after we eliminate in them $\ddot{X}$ and $\ddot{Y}$ using the $(\ldots)^{\cdot}$-differentiated constraints (a); and (ii) with the earlier kinetic Hamel equations (c20–22), after we express $\dot{\phi}, \ldots, \ddot{\phi}, \ldots,$ in terms of $\omega_{3,4,5}$ and $\dot{\omega}_{3,4,5}$, and $Q_{\phi,\theta,\psi;o}$ in terms of $\Theta_{3,4,5}$; and similarly with the Appell equations (d5–7). The details are left to the reader.

REMARK

(May be omitted in a first reading.) A safer way to calculate the $-\Gamma_{Io}$ — and, in fact, the entire set of Chaplygin's equations — is by direct application of the *Chaplygin form of the master variational equation* [specialization of the corresponding equation of Hamel (§3.6.12)]

$$\sum (\partial T_o/\partial\dot{q}_I)^{\cdot}\,\delta q_I - \sum (\partial T_o/\partial q_I)\,\delta q_I - \sum \Gamma_{Io}\,\delta q_I = \sum Q_{Io}\,\delta q_I, \tag{e25}$$

where

$$-\sum \Gamma_{Io}\,\delta q_I = \sum\Big(\sum\sum t^D{}_{I'I}\,p_{Do}\,\dot{q}_{I'}\Big)\,\delta q_I$$
$$= \sum\Big(\sum\sum t^D{}_{I'I}\,\dot{q}_{I'}\,\delta q_I\Big)p_{Do} = -\sum p_{Do}\big[(\delta q_D)^{\cdot} - \delta(\dot{q}_D)\big]. \qquad \text{(e26)}$$

The reason for this is that here we have, in effect, adopted the *Suslov viewpoint* according to which

$$(\delta\theta_k)^{\cdot} - \delta\omega_k = 0 \qquad \text{and} \qquad (\delta q_I)^{\cdot} - \delta(\dot{q}_I) = 0, \qquad \text{(e27)}$$

but, successively,

$$(\delta q_D)^{\cdot} - \delta(\dot{q}_D) = \Big(\sum b_{DI}\,\delta q_I\Big)^{\cdot} - \delta\Big(\sum b_{DI'}\,\dot{q}_{I'}\Big)$$
$$= \sum\sum (b_{DI,I'}\,\dot{q}_{I'}\,\delta q_I - b_{DI',I}\,\dot{q}_{I'}\,\delta q_I)$$
$$= \sum\sum (b_{DI,I'} - b_{DI',I})\dot{q}_{I'}\,\delta q_I$$
$$\equiv \sum\sum t^D{}_{II'}\,\dot{q}_{I'}\,\delta q_I = -\sum\sum t^D{}_{I'I}\,\dot{q}_{I'}\,\delta q_I; \qquad \text{(e28)}$$

whereas in the customary, and more general, viewpoint of Hamel (§2.12): $(\delta q_k)^{\cdot} - \delta(\dot{q}_k) = 0$, $(k = 1, \ldots, n)$, but

$$(\delta\theta_D)^{\cdot} - \delta\omega_D = \sum\sum \gamma^D{}_{I\alpha}\,\omega_\alpha\,\delta\theta_I \;\Rightarrow\; \sum\sum t^D{}_{I'I}\,\dot{q}_{I'}\,\delta q_I \neq 0, \qquad \text{(e29)}$$

and, accordingly, the term corresponding to $-\sum \Gamma_{Io}\,\delta q_I$ is [recalling (§3.6.11)]

$$\sum P_k[(\delta\theta_k)^{\cdot} - \delta\omega_k] \rightarrow \sum p_{Do}[(\delta\theta_D)^{\cdot} - \delta\omega_D]$$
$$= \sum p_{Do}\Big(\sum\sum t^D{}_{I'I}\,\dot{q}_{I'}\,\delta q_I\Big) = \sum\Big(\sum\sum t^D{}_{I'I}\,p_{Do}\,\dot{q}_{I'}\Big)\,\delta q_I; \qquad \text{(e30)}$$

that is, the two interpretations may be different, but, if utilized consistently, both lead to the same equations of motion [and similarly for the case of Voronets (3.8.14a ff.)].

In our problem, adopting the Suslov viewpoint, we obtain, successively [recalling (e2), etc.],

$$-\sum p_{Do}[(\delta q_D)^{\cdot} - \delta(\dot{q}_D)] = -p_{Xo}[(\delta X)^{\cdot} - \delta(\dot{X})] - p_{Yo}[(\delta Y)^{\cdot} - \delta(\dot{Y})]$$
$$= -[mr(\dot{\theta}\,\sin\phi - \dot{\psi}\,\cos\phi\,\sin\theta)]\;\{[(r\,\sin\phi)\,\delta\theta - (r\,\cos\phi\,\sin\theta)\,\delta\psi]^{\cdot}$$
$$- \delta[(r\,\sin\phi)\dot{\theta} - (r\,\cos\phi\,\sin\theta)\dot{\psi}]\}$$
$$- [-mr(\dot{\theta}\,\cos\phi + \dot{\psi}\,\sin\phi\,\sin\theta)]\;\{[(-r\,\cos\phi)\,\delta\theta + (-r\,\sin\phi\,\sin\theta)\,\delta\psi]^{\cdot}$$
$$- \delta[(-r\cos\phi)\dot{\theta} + (-r\,\sin\phi\,\sin\theta)\dot{\psi}]\}$$
$$= \cdots = (0)\,\delta\phi + [mr^2(\dot{\psi}\,\sin\theta)(\dot{\phi} + \dot{\psi}\,\cos\theta)]\,\delta\theta$$
$$+ [(-mr^2)(\dot{\theta}\,\sin\theta)(\dot{\phi} + \dot{\psi}\,\cos\theta)]\,\delta\psi$$
$$= -(\Gamma_{\phi o}\,\delta\phi + \Gamma_{\theta o}\,\delta\theta + \Gamma_{\psi o}\,\delta\psi), \qquad \text{(e31)}$$

as (e26) requires; and, of course, in agreement with the earlier (e9–11).

The above make clear that the methods of Chaplygin, and Voronets, are rather complicated and error prone, even in this relatively simple problem; and the only reason for working it out completely was [just like Chaplygin's original effort (1895/1897)] to demonstrate concretely that, *in general*,

$$E_I(T_o) \equiv (\partial T_o/\partial \dot{q}_I)^{\cdot} - \partial T_o/\partial q_I \neq Q_{Io}; \tag{e32}$$

although, in this case, the equality *does* hold for $q_I = \phi$ [see also Beghin, 1967, I, pp. 436–438), and "a famous error" in our *rolling coin* example 3.18.5 (below)].

The Hadamard Equations

$E_I(T) + \sum b_{DI} E_D(T) = Q_I + \sum b_{DI} Q_D$ $(\equiv Q_{Io})$. The $E_k(T)$ $(k = 1, \ldots, 5)$, b_{DI}, and Q_{Io} have already been calculated. It is not hard to show that the final result would be the earlier kinetic Maggi equations (b6–8); while for $D = 1, 2$ we would simply have [recalling (3.8.11a ff.)]

$$E_D(T) = Q_D + \lambda_D = Q_D + R_D. \tag{f}$$

Constraint Reactions

In view of the above, we obtain, successively,

$$R_1 \equiv R_X = m\ddot{X} - Q_X \qquad \text{and} \qquad R_2 \equiv R_Y = m\ddot{Y} - Q_Y; \tag{g1}$$

and [recalling (3.8.11l)] $R_I = \sum \lambda_D a_{DI} = \sum \lambda_D(-b_{DI}) = -\sum b_{DI}[E_D(T) - Q_D]$:

$$\begin{aligned}
R_3 = R_\phi &= -b_{13}[E_1(T) - Q_1] - b_{23}[E_2(T) - Q_2] = -(0)(\ldots) - (0)(\ldots) = 0,\\
R_4 = R_\theta &= -b_{14}[E_1(T) - Q_1] - b_{24}[E_2(T) - Q_2]\\
&= -r\sin\phi(m\ddot{X} - Q_X) - (-r\cos\phi)(m\ddot{Y} - Q_Y)\\
&= r[-m(\ddot{X}\sin\phi - \ddot{Y}\cos\phi) + (Q_X\sin\phi - Q_Y\cos\phi)],\\
R_5 = R_\psi &= -b_{15}[E_1(T) - Q_1] - b_{25}[E_2(T) - Q_2]\\
&= -(-r\cos\phi\sin\theta)(m\ddot{X} - Q_X) - (-r\sin\phi\sin\theta)(m\ddot{Y} - Q_Y)\\
&= r[m(\ddot{X}\cos\phi + \ddot{Y}\sin\phi) - (Q_X\cos\phi + Q_Y\sin\phi)];
\end{aligned} \tag{g2, 3, 4}$$

so that once the motion has been found, the reactions can be readily determined.

Example 3.18.3 *Dynamics of a Sphere Rolling on a Uniformly Spinning Plane.*

Introduction: Hamel's Equations

Continuing from the preceding example, let us find the motion of that sphere if the plane P is revolving about the fixed (vertical) axis OZ with *constant* angular velocity Ω. The relevant kinematics has already been discussed in ex. 2.13.5 and ex. 2.13.6. It was shown there that the rolling constraints are (note additional *acatastatic* terms)

$$\begin{aligned}
&\dot{X} - (r\sin\phi)\dot{\theta} + (r\cos\phi\sin\theta)\dot{\psi} + \Omega Y = 0,\\
&\dot{Y} + (r\cos\phi)\dot{\theta} + (r\sin\phi\sin\theta)\dot{\psi} - \Omega X = 0.
\end{aligned} \tag{a1}$$

Since the catastatic coefficients $[a_{Dk};\ D = 1, 2;\ k = 1, \ldots, 5]$ and kinetic energy have the same form as in the previous catastatic case, the equations of motion of Routh–Voss and Maggi–Hadamard are the same *in form* as before; their *solutions*, however, will be different because these equations must now be joined with the different constraints (a1).

Similarly, LP and the *virtual* form of the constraints (a) remain the same. But since T in quasi variables, T^*, is not the same as before, Hamel's equations (which incorporate the new constraints) will be different; and so will be those of Appell. Indeed, and remembering *not* to enforce the constraints $\omega_{1,2} = 0$ until the final stage, we find

$$2T \to 2T^* = m[(\omega_1 + r\,\omega_4 - \Omega\, Y)^2 + (\omega_2 - r\,\omega_3 + \Omega\, X)^2] + I({\omega_3}^2 + {\omega_4}^2 + {\omega_5}^2). \quad \text{(a2)}$$

The γ's have already been calculated in (ex. 2.13.6: 11–m); we have also found that

$$A_{13} = 0, \quad A_{14} = r, \quad A_{15} = 0; \qquad A_{23} = -r, \quad A_{24} = 0, \quad A_{25} = 0. \qquad \text{(a3)}$$

Therefore, Hamel's kinetic equations

$$(\partial T^*/\partial \omega_I)^{\cdot} - \sum A_{DI}(\partial T^*/\partial q_D) + \sum\sum {\gamma^k}_{II'}(\partial T^*/\partial \omega_k)\omega_{I'} + \sum {\gamma^k}_I(\partial T^*/\partial \omega_k) = \Theta_I, \qquad \text{(a4)}$$

yield, after some straightforward and careful algebra,

$$\dot{P}_3 - \partial T^*/\partial\theta_3 + P_4\,\omega_5 - P_5\,\omega_4 + P_1\,r(\Omega - \omega_5) = \Theta_3, \qquad \text{(a5)}$$

$$\dot{P}_4 - \partial T^*/\partial\theta_4 + P_5\,\omega_3 - P_3\,\omega_5 + P_2\,r(\Omega - \omega_5) = \Theta_4, \qquad \text{(a6)}$$

$$\dot{P}_5 - \partial T^*/\partial\theta_5 + P_3\,\omega_4 - P_4\,\omega_3 + P_1 r\,\omega_3 + P_2\,r\,\omega_4 = \Theta_5; \qquad \text{(a7)}$$

or, explicitly,

$$(7mr^2/5)\dot{\omega}_X - m\,r\,\Omega(r\,\omega_Y - \Omega Y) = \Theta_X, \qquad \text{(a8)}$$

$$(7mr^2/5)\dot{\omega}_Y + m\,r\,\Omega(r\,\omega_X - \Omega X) = \Theta_Y, \qquad \text{(a9)}$$

$$(2mr^2/5)\dot{\omega}_Z = \Theta_Z; \qquad \text{(a10)}$$

we notice the Ω-proportional terms [in addition to those of eqs. (c20–22) of the preceding example]. The extension to the general case $\Omega = \Omega(t)$ involves only some algebraic complications; in particular, eqs. (a5–7) still hold.

Hamel's Equations via the Master Variational Equation

$$\sum \dot{P}_k\,\delta\theta_k + \sum P_k[(\delta\theta_k)^{\cdot} - \delta\omega_k] - \sum \Big[\sum A_{lk}(\partial T^*/\partial q_l)\Big]\,\delta\theta_k = \sum \Theta_k\,\delta\theta_k. \quad \text{(b1)}$$

The direct application of (b1), for the derivation of Hamel equations of motion, is recommended in order to minimize the probability of errors. Its main advantage lies in the calculation of the *second* (noncommutative) term. Let us carry this out explicitly: Recalling the transitivity relations (ex. 2.13.6: j ff.), we find, successively,

$$\begin{aligned}
&P_1[(-\Omega)\,\delta\theta_2 + r(\Omega - \omega_5)\,\delta\theta_3 + (r\,\omega_3)\,\delta\theta_5]\\
&\quad + P_2[(\Omega)\,\delta\theta_1 + r(\Omega - \omega_5)\,\delta\theta_4 + (r\,\omega_4)\,\delta\theta_5]\\
&\quad + P_3[(\omega_4)\,\delta\theta_5 + (-\omega_5)\,\delta\theta_4]\\
&\quad + P_4[(\omega_5)\,\delta\theta_3 + (-\omega_3)\,\delta\theta_5]\\
&\quad + P_5[(\omega_3)\,\delta\theta_4 + (-\omega_4)\,\delta\theta_3]\\
&= (P_2\,\Omega)\,\delta\theta_1 + (-P_1\,\Omega)\,\delta\theta_2 + [P_4\,\omega_5 - P_5\,\omega_4 + P_1 r(\Omega - \omega_5)]\,\delta\theta_3\\
&\quad + [P_5\,\omega_3 - P_3\,\omega_5 + P_2\,r(\Omega - \omega_5)]\,\delta\theta_4\\
&\quad + [P_3\,\omega_4 - P_4\,\omega_3 + r(P_1\,\omega_3 + P_2\,\omega_4)]\,\delta\theta_5.
\end{aligned} \tag{b2}$$

In the above, we notice that (a) the first and second terms, are needed in the *kinetostatic* equations ($\delta\theta_{1,2} = 0$); while the rest are needed in the *kinetic* equations ($\delta\theta_{3,4,5} = 0$); and (b) the constraints have been enforced in the velocity form $\omega_{1,2} = 0$, but not in the virtual form $\delta\theta_{1,2} = 0$ (unless we are not interested in the reactions).

Let the reader verify that by collecting $(\ldots)\,\delta\theta_k$ terms, and so on, and applying the method of multipliers, eqs. (b1, 2) lead to the following full set of equations of motion:

Kinetostatic equations:

$$\delta\theta_1: \qquad \dot{P}_1 - A_{11}P_1 - A_{21}P_2 + \Omega\,P_2 = \Theta_1 + \Lambda_1, \tag{b3}$$

$$\delta\theta_2: \qquad \dot{P}_2 - A_{12}P_1 - A_{22}P_2 - \Omega\,P_1 = \Theta_2 + \Lambda_2; \tag{b4}$$

Kinetic equations:

$$\delta\theta_3: \qquad \dot{P}_3 - A_{13}P_1 - A_{23}P_2 + P_4\,\omega_5 - P_5\,\omega_4 + P_1\,r(\Omega - \omega_5) = \Theta_3, \tag{b5}$$

$$\delta\theta_4: \qquad \dot{P}_4 - A_{14}P_1 - A_{24}P_2 + P_5\,\omega_3 - P_3\,\omega_5 + P_2\,r(\Omega - \omega_5) = \Theta_4, \tag{b6}$$

$$\delta\theta_5: \qquad \dot{P}_5 - A_{15}P_1 - A_{25}P_2 + P_3\,\omega_4 - P_4\,\omega_3 + r(P_1\,\omega_3 + P_2\,\omega_4) = \Theta_5; \tag{b7}$$

the last three in complete agreement with the earlier-found equations (a5–7).

The Appell Equations (Kinetic Equations Only)

Using the customary notations, we find

$$2S^* = m\,a_G{}^2 + 2S^*{}_{/G}, \tag{c1}$$

where

$$2S^*_{/G} = I[(\dot\omega_X)^2 + (\dot\omega_Y)^2 + (\dot\omega_Z)^2] = I[(\dot\omega_3)^2 + (\dot\omega_4)^2 + (\dot\omega_5)^2], \tag{c2}$$

$$\begin{aligned} a_G{}^2 &= (\ddot X)^2 + (\ddot Y)^2 = [(r\,\omega_4 - \Omega\,Y + \omega_1)^{\cdot}]^2 + [(-r\,\omega_3 + \Omega\,X + \omega_2)^{\cdot}]^2 \\ &= [r\,\dot\omega_4 + \Omega(r\,\omega_3 - \Omega\,X)]^2 + [-r\,\dot\omega_3 + \Omega(r\,\omega_4 - \Omega\,Y)]^2 \\ &= r^2[(\dot\omega_3)^2 + (\dot\omega_4)^2] + 2r\,\Omega[(r\,\omega_3 - \Omega\,X)\dot\omega_4 - (r\,\omega_4 - \Omega\,Y)\dot\omega_3] \\ &\quad + \textit{non–Appell-important terms}. \end{aligned} \tag{c3}$$

Therefore, to within *Appell-important terms*, and since $I = 2mr^2/5$, the *constrained* (double) Appellian of the sphere equals

$$\begin{aligned} 2S^* \to 2S^*{}_o &= m\{(7r^2/5)[(\dot\omega_3)^2 + (\dot\omega_4)^2] + (2r^2/5)(\dot\omega_5)^2\} \\ &\quad + 2m\,r\,\Omega[(r\,\omega_3 - \Omega\,X)\dot\omega_4 - (r\,\omega_4 - \Omega\,Y)\dot\omega_3], \end{aligned} \tag{c4}$$

where the *second*, Ω-proportional, group of terms is due to the rotation of the plane. Differentiating this Appellian relative to $\dot\omega_{3,4,5}$ yields the left sides of the earlier kinetic equations (a5–7, b5–7).

Example 3.18.4 *Power Equations/Energetics of Rolling Sphere on Uniformly Spinning Plane*. Let us begin by collecting all needed analytical results; already calculated in exs. 2.13.5 and 2.13.6, and the preceding examples 3.18.2 and 3.18.3. [Here, too, the case $\Omega = constant$ was chosen for its algebraic simplicity; the general case $\Omega = given\ function\ of\ time$ would not have offered any theoretical difficulties. We have (with $I \equiv 2mr^2/5$)

(i)
$$\begin{aligned} 2T &= m[(\dot X)^2 + (\dot Y)^2] + (I_X{}^2\omega_X{}^2 + I_Y{}^2\omega_Y{}^2 + I_Z{}^2\omega_Z{}^2) \\ &= m[(\dot X)^2 + (\dot Y)^2] + I[(\dot\phi)^2 + (\dot\theta)^2 + (\dot\psi)^2 + 2\dot\phi\,\dot\psi\cos\theta]. \end{aligned} \tag{a1}$$

That here $T_1 = T_0 = 0 \ \Rightarrow\ T = T_2$, should come as no surprise. The holonomic coordinates chosen here — namely, X, Y, ϕ, θ, ψ — are *inertial*.

(ii)
$$\begin{aligned} 2T^* &= m[(\omega_1 + r\,\omega_4 - \Omega\,Y)^2 + (\omega_2 - r\,\omega_3 + \Omega\,X)^2] + I(\omega_3{}^2 + \omega_4{}^2 + \omega_5{}^2) \\ &= (\textit{expanding and grouping appropriately}) = 2T^*{}_2 + 2T^*{}_1 + 2T^*{}_0, \end{aligned} \tag{a2}$$

$$\begin{aligned} 2T^*{}_2 &= m[\omega_1{}^2 + \omega_2{}^2 + r^2(\omega_3{}^2 + \omega_4{}^2) + 2r(\omega_1\omega_4 - \omega_2\,\omega_3)] \\ &\quad + I(\omega_3{}^2 + \omega_4{}^2 + \omega_5{}^2) \\ &= (\textit{double})\ \textit{kinetic energy of motion of sphere relative to plane}, \end{aligned} \tag{a3}$$

$$\begin{aligned} T^*{}_1 &= m[(-Y\Omega)\,\omega_1 + (-rY\Omega)\,\omega_4 + (X\Omega)\,\omega_2 + (-rX\Omega)\,\omega_3] \\ &= \textit{kinetic energy of ``coupling'' of motion of plane and sphere/plane}, \end{aligned} \tag{a4}$$

$$\begin{aligned} 2T^*{}_0 &= m\,\Omega^2(X^2 + Y^2) \\ &= (\textit{double})\ \textit{kinetic energy of sphere when at rest relative the plane}; \end{aligned} \tag{a5}$$

and no constraints have been enforced yet.

(iii) Since the only impressed force here is gravity (i.e., $\Theta_I = 0$), the corresponding potential energy is constant; say, $V = V^* = mgr$, and, therefore,

$$\partial V/\partial q_k = 0 \;\Rightarrow\; \partial V^*/\partial\theta_k \equiv \sum A_{lk}(\partial V/\partial q_l) = 0, \tag{b1}$$

and [recalling (2.9.34 ff.) and (3.9.12f)]

$$\partial V^*/\partial\theta_{n+1} \equiv \partial V^*/\partial t + \sum A_k(\partial V^*/\partial q_k) \;=\; 0 + \sum A_k(0) = 0; \tag{b2}$$

(iv) The *nonvanishing* Hamel coefficients are [recalling ex. 2.13.6: (l1–m)]

$$\begin{aligned}
&\gamma^1{}_{35} = -\gamma^1{}_{53} = -r, \qquad \gamma^1{}_{36} = -\gamma^1{}_{63} \equiv \gamma^1{}_3 = r\,\Omega, \qquad \gamma^1{}_{26} = -\gamma^1{}_{62} \equiv \gamma^1{}_2 = -\Omega;\\
&\gamma^2{}_{45} = -\gamma^2{}_{54} = -r, \qquad \gamma^2{}_{46} = -\gamma^2{}_{64} \equiv \gamma^2{}_4 = r\,\Omega, \qquad \gamma^2{}_{16} = -\gamma^2{}_{61} \equiv \gamma^2{}_1 = \Omega;\\
&\gamma^3{}_{54} = -\gamma^3{}_{45} = 1, \qquad \gamma^4{}_{35} = -\gamma^4{}_{53} = 1, \qquad \gamma^5{}_{43} = -\gamma^5{}_{34} = 1;
\end{aligned} \tag{c}$$

and from these only $\gamma^1{}_3 = r\,\Omega$ and $\gamma^2{}_4 = r\,\Omega$ will be needed in the power equation below.

Nonholonomic Power Equation

From the above, and with an eye toward (3.9.12h ff.), we find, successively,

(i)
$$\begin{aligned}
\partial L^*/\partial\theta_{n+1} &= \partial T^*/\partial\theta_{n+1} \equiv \partial T^*/\partial t + \sum A_k(\partial T^*/\partial q_k)\\
&= m[\Omega(X^2 + Y^2) - r(X\omega_X + Y\omega_Y)]\,\dot{\Omega} + A_1(\partial T^*/\partial X)\\
&\qquad + A_2(\partial T^*/\partial Y),\\
&= (-\Omega Y)[(m\,\Omega)(\Omega X - r\,\omega_3)] + (\Omega X)[(m\,\Omega)(\Omega Y - r\,\omega_4)]\\
&= \cdots = m\,r\,\Omega^2(Y\omega_X - X\omega_Y);
\end{aligned} \tag{d1}$$

(ii)
$$\begin{aligned}
R &\equiv \sum\sum \gamma^b{}_I(\partial T^*/\partial\omega_b)\,\omega_I \qquad [\text{and with } (\ldots)_o \equiv (\ldots) \textit{ evaluated at } \omega_{1,2} = 0]\\
&= \gamma^1{}_3(\partial T^*/\partial\omega_1)_o\,\omega_3 + \gamma^2{}_4(\partial T^*/\partial\omega_2)_o\,\omega_4\\
&= (r\,\Omega)[m(r\,\omega_Y - \Omega Y)]\omega_X + (r\,\Omega)[m(-r\,\omega_X + \Omega X)]\omega_Y\\
&= m\,r\,\Omega^2(X\omega_Y - Y\omega_X).
\end{aligned} \tag{d2}$$

In view of these partial results (in particular, the mutual canceling of the rheonomic effects of the nonholonomic constraints $\partial L^*/\partial\theta_{n+1} + R = 0$), the general nonholonomic power equation (3.9.12i)

$$dh^*/dt = -\,\partial L^*/\partial\theta_{n+1} + \sum \Theta_I\,\omega_I - R, \tag{e1}$$

where $h^* \equiv \sum(\partial L^*/\partial\omega_I)\omega_I - L^* = T^*{}_2 + (V^* - T^*{}_0)$, reduces to the nonholonomic *Jacobi–Painlevé* integral (3.9.12n)

$$h^* = T^*{}_2 - T^*{}_0 = \textit{constant}; \tag{e2}$$

or, further, since [upon enforcing the constraints $\omega_{1,2} = 0$ in (a3–5)]

$$\begin{aligned} 2T^*{}_2 &= m\,r^2({\omega_3}^2 + {\omega_4}^2) + I({\omega_3}^2 + {\omega_4}^2 + {\omega_5}^2) \\ &= \cdots = (mr^2/5)[7({\omega_X}^2 + {\omega_Y}^2) + 2\,{\omega_Z}^2], \end{aligned} \tag{e3}$$

$$T^*{}_1 = -m\,r\,\Omega(Y\omega_4 + X\omega_3) = -m\,r\,\Omega(X\omega_X + Y\omega_Y), \tag{e4}$$

$$2T^*{}_0 = m\,\Omega^2(X^2 + Y^2), \tag{e5}$$

that integral assumes the final form

$$7({\omega_X}^2 + {\omega_Y}^2) + 2{\omega_Z}^2 = 5(\Omega^2/r^2)(X^2 + Y^2) + constant \tag{e6}$$

[by the z-equation, (a10), $I\,\dot{\omega}_Z = \Theta_Z = 0 \;\Rightarrow\; \omega_Z = constant$]. We notice that, due to (e2),

$$\begin{aligned} E^* \equiv T^* + V^* &= T^*{}_2 + T^*{}_1 + T^*{}_0 + V^* = T^*{}_2 + T^*{}_1 + T^*{}_0 + constant \\ &= 2T^*{}_2 + T^*{}_1 + constant = T^*{}_1 + 2T^*{}_0 + constant \neq constant; \end{aligned} \tag{e7}$$

that is, the generalized energy h^* is conserved, but the classical one $E(= E^*)$ is not.

Next, eq. (e6) was obtained *without recourse to the equations of motion*. It is instructive to rederive it, or its equivalent $\dot{T}^*{}_2 = \dot{T}^*{}_0$, directly from expressions (a3–5, e3–5) and the kinetic equations of motion and constraints [see preceding example, eqs. (a8–10) and (a1), respectively]:

$$\dot{\omega}_X = (5/7)(\Omega/r)(r\,\omega_Y - \Omega\,Y), \tag{f1}$$

$$\dot{\omega}_Y = -(5/7)(\Omega/r)(r\,\omega_X - \Omega\,X), \tag{f2}$$

$$\dot{\omega}_Z = 0; \tag{f3}$$

$$\dot{X} = r\,\omega_Y - \Omega\,Y, \qquad \dot{Y} = -r\,\omega_X + \Omega\,X. \tag{f4}$$

Indeed, $(\ldots)^{\cdot}$-differentiating $T^*{}_2$ and $T^*{}_0$, eqs. (a3, 5), and then utilizing (f1–4) yields

$$\begin{aligned} \dot{T}^*{}_2 &= (m\,r^2/5)[7(\omega_X\,\dot{\omega}_X + \omega_Y\,\dot{\omega}_Y) + 2\omega_Z\,\dot{\omega}_Z] \\ &= \cdots = m\,r\,\Omega^2(X\omega_Y - Y\omega_X); \end{aligned} \tag{f5}$$

$$\begin{aligned} \dot{T}^*{}_0 &= m\,\Omega(X^2 + Y^2)\dot{\Omega} + m\,\Omega^2(X\dot{X} + Y\dot{Y}) \\ &= \cdots = m\,r\,\Omega^2(X\omega_Y - Y\omega_X), \quad \text{Q.E.D.} \end{aligned} \tag{f6}$$

Holonomic Power Equation

For a more complete understanding of the energetics of this problem, let us also formulate its power equation in holonomic variables, eq. (3.9.11d ff.):

$$dh/dt = -\partial L/\partial t + \sum Q_k \dot{q}_k - \sum \lambda_D a_D, \tag{g1}$$

where $h \equiv \sum (\partial L/\partial \dot{q}_k)\dot{q}_k - L = T_2 + (V - T_0)$. Here, $T = T_2$ is given by (a1), $V = constant$, $Q_k = 0$ (i.e., no impressed nonpotential forces), and, from the constraints (ex. 3.18.3: a1), $a_1 \to a_X = \Omega Y$, $a_2 \to a_Y = -\Omega X$; while $\lambda_1 = \Lambda_1 \to \lambda_X$ and $\lambda_2 = \Lambda_2 \to \lambda_Y$ are, respectively, the OX and OY components of the rolling constraint reaction, from the plane to the sphere, at its contact point $C(X, Y, 0)$. In view of these partial results, eq. (g1) becomes

$$dh/dt = dT_2/dt = -a_1\lambda_1 - a_2\lambda_2 = -(\Omega Y)\lambda_X - (-\Omega X)\lambda_Y$$
$$= \Omega(X\lambda_Y - Y\lambda_X) \equiv M_O\,\Omega, \qquad \text{(g2)}$$

where $M_O = X\lambda_Y - Y\lambda_X =$ *moment of* (*tangential*) *rolling reactions at C about OZ*; and, of course, agrees with what would have resulted by "elementary" (Newton–Euler) considerations: the sphere is an "open" system, and, therefore, *the rate of change of its total classical (inertial) energy* $E \equiv T + V$ $(= h)$ *must equal the (inertial) power of all external forces on it*. Since this latter is none other than the rolling reaction (and, clearly, the power of its component *normal* to O-XY vanishes), we obtain

$$dE/dt = M_O\,\Omega \ (= \textit{externally supplied power, needed to keep the plane spinning at the constant rate } \Omega). \qquad \text{(g3)}$$

Finally, invoking the principle of linear momentum for the sphere, we find

$$M_O = X\lambda_Y - Y\lambda_X = X(m\ddot{Y}) - Y(m\ddot{X}) = dH_O/dt, \qquad \text{(g4)}$$

where

$$H_O \equiv [m(X\dot{Y} - Y\dot{X})] = X(m\dot{Y}) - Y(m\dot{X})$$
$$= \textit{inertial angular momentum of particle of mass } m\textit{, located at the sphere center}, \qquad \text{(g5)}$$

and this, combined with (g3) and the constancy of Ω, readily yields the integral

$$E - H_O\Omega = \textit{constant}, \qquad \text{or} \qquad T - H_O\Omega = \textit{constant}. \qquad \text{(g6)}$$

It is not hard to show the equivalence of (e2) and (g6). Indeed, from the latter, recalling (3.9.12t), we obtain, successively,

$$H_O\Omega = E - \textit{constant} = E^* - \textit{constant} = (h^* + 2T^*{}_0 + T^*{}_1) - \textit{constant}$$
$$= 2T^*{}_0 + T^*{}_1 + (h^* - \textit{constant}). \qquad \text{(g7)}$$

On the other hand, by direct calculation [invoking the constraints (f4) in the definition (g5)], we find

$$H_O = X[m(-r\omega_X + \Omega X)] - Y[m(r\omega_Y - \Omega Y)]$$
$$= m\,\Omega(X^2 + Y^2) - m\,r(X\omega_X + Y\omega_Y),$$

and, therefore,

$$H_O\Omega = m\,\Omega^2(X^2 + Y^2) + [-m\,\Omega\,r(X\omega_X + Y\omega_Y)] = 2T^*{}_0 + T^*{}_1. \qquad \text{(g8)}$$

From (g7, 8), the integral (e2) follows immediately.

Concluding Remarks

That the holonomic power equation does not produce a conservation theorem of the same form as the nonholonomic power equation should not come as a surprise. It is intimately connected with our choice of holonomic coordinates: if the q's were *noninertial*, the rolling constraint would be

$$\boldsymbol{v}_{C,\ \text{relative to plane-fixed axes } O\text{–}xyz} = \mathbf{0}; \tag{h}$$

instead of the earlier $\boldsymbol{v}_{C,\ \text{of sphere}} = \boldsymbol{v}_{C,\ \text{of plane}}$, and it would produce *homogeneous* (i.e., catastatic) Pfaffian equations in these noninertial Lagrangean velocities, that is, $a_{1,2} = 0$. Then, $T = T_2 + T_1 + T_0$, and the holonomic power equation would reduce to the holonomic Jacobi–Painlevé integral [recalling (3.9.11n)] $h = T_2 - T_0 = constant$. A convenient set of such noninertial coordinates are the two (horizontal) coordinates of the center of the sphere relative to *plane-fixed* rectangular Cartesian axes, say $O\text{–}x'y'z'$, and the three Eulerian angles between them and the earlier *sphere-fixed* axes $G\text{–}xyz$; and Ω would *not* appear in the constraints, but it *would* appear in T.

In sum: (a) Only T must be calculated relative to inertial axes, here $O\text{–}XYZ$; *the constraints can be expressed relative to any convenient axes, in terms of any convenient system coordinates*; and since during virtual work the time is assumed frozen, the forces involved are frame independent.

(b) Energy conservation depends on both the *system* and the *frame of reference*.

Problem 3.18.3 Derive the power equations of a sled moving on a uniformly rotating, horizontal, and rough turntable (probs. 3.18.1 and 3.18.2), in both holonomic and nonholonomic variables, and in both inertial and turntable-fixed coordinates. Proceed either from the general energetic theory (§3.9), or from their equations of motion (i.e., multiply each of them with the corresponding velocity, then add together, etc.). Compare with the elementary method.

Problem 3.18.4 Formulate the constraints of a sphere rolling on a uniformly rotating, horizontal, and rough plane in terms of *plane-fixed* (noninertial) system coordinates. Then (i) write down the corresponding transitivity equations, and read off the Hamel coefficients; (ii) obtain its corresponding Hamel equations; and (iii) derive its power equations in both holonomic and nonholonomic variables.

Problem 3.18.5 Consider the problem of rolling *and pivoting* of a homogeneous sphere on a fixed, horizontal, and rough plane. Formulate its constraints, transitivity equations and read off its Hamel coefficients; obtain its kinetic and kinetostatic equations of motion of Routh–Voss, Maggi, Hamel, and Appell; and, finally, derive its power equations, in both holonomic and nonholonomic variables.

Problem 3.18.6 Extend the preceding problem to the case where the plane, on which the rolling and pivoting sphere moves, rotates with a constant angular velocity Ω.

Problem 3.18.7 Consider a sphere S with *eccentric* center of mass G, in slippingless rolling on a fixed, horizontal, and rough plane P (fig. 3.52).

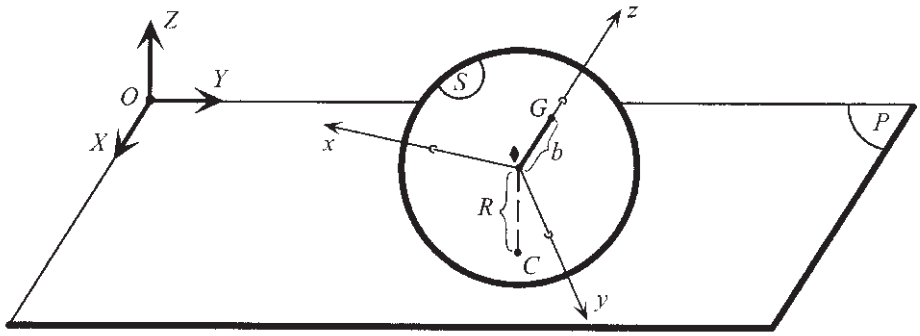

Figure 3.52 Eccentric (nonhomogeneous) sphere rolling on fixed plane.
O–XYZ/$\mathbf{IJK}$: plane-fixed (inertial) axes/basis;
G: eccentric center of mass of sphere, $\mathbf{OG} = \mathbf{r}_G = (X_G, Y_G, Z_G)$;
$\blacklozenge$: geometrical center of sphere, $O\blacklozenge = (X_\blacklozenge, Y_\blacklozenge, Z_\blacklozenge) \equiv (X, Y, R)$;
C: contact point between sphere and plane, $\mathbf{OC} = (X, Y, 0)$;
$\blacklozenge$–xyz/$\mathbf{ijk}$: sphere-fixed (noninertial) axes/basis,
chosen so that $\blacklozenge\mathbf{G} \equiv \mathbf{r}_{G/\blacklozenge} \equiv (x, y, z) = (0, 0, b)$.

Here, using standard notations, we have the following:

(a) Velocity of a generic sphere point:

$$\boldsymbol{v} = \boldsymbol{v}_\blacklozenge + \boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge} = (\dot{X}, \dot{Y}, 0) + (\omega_X, \omega_Y, \omega_Z) \times (X_{/\blacklozenge}, Y_{/\blacklozenge}, Z_{/\blacklozenge}); \tag{a1}$$

(b) Velocity of contact point C:

$$\begin{aligned} \boldsymbol{v}_C &= \boldsymbol{v}_\blacklozenge + \boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge} = (\dot{X}, \dot{Y}, 0) + (\omega_X, \omega_Y, \omega_Z) \times (0, 0, -R) \\ &= (\dot{X} - R\,\omega_Y, \dot{Y} + R\,\omega_X, 0); \end{aligned} \tag{a2}$$

(c) Relation of $(\omega_X, \omega_Y, \omega_Z)$ with the time rates of the Eulerian angles between O–XYZ and $\blacklozenge$–xyz, ϕ, θ, ψ (recalling results from §1.12):

$$\begin{aligned} \omega_X &= (\cos\phi)\dot{\theta} + (\sin\phi\,\sin\theta)\dot{\psi}, \\ \omega_Y &= (\sin\phi)\dot{\theta} + (-\cos\phi\,\sin\theta)\dot{\psi}, \qquad \omega_Z = \dot{\phi} + (\cos\theta)\dot{\psi}. \end{aligned} \tag{a3}$$

We also have the related coordinate transformation relations [§1.12, with $\sin(\ldots) \equiv s(\ldots)$, etc.]:

$$\begin{aligned} X_{G/\blacklozenge} &\equiv X_G - X_\blacklozenge \equiv X_G - X \\ &= (c\phi\,c\psi - s\phi\,c\theta\,s\psi)x + (-c\phi\,s\psi - s\phi\,c\theta\,c\psi)y + (s\phi\,s\theta)z, \end{aligned} \tag{a4}$$

$$\begin{aligned} Y_{G/\blacklozenge} &\equiv Y_G - Y_\blacklozenge \equiv Y_G - Y \\ &= (s\phi\,c\psi + c\phi\,c\theta\,s\psi)x + (-s\phi\,s\psi + c\phi\,c\theta\,c\psi)y + (-c\phi\,s\theta)z, \end{aligned} \tag{a5}$$

$$\begin{aligned} Z_{G/\blacklozenge} &\equiv Z_G - Z_\blacklozenge \equiv Z_G - R \\ &= (s\theta\,s\psi)x + (s\theta\,c\psi)y + (c\theta)z, \end{aligned} \tag{a6}$$

from which, since here $(x, y, z) = (0, 0, b)$, we obtain

$$\boldsymbol{r}_{G/\blacklozenge} = \big(X_{G/\blacklozenge}, Y_{G/\blacklozenge}, Z_{G/\blacklozenge}\big) - \big((s\phi\, s\theta)b, -(c\phi\, s\theta)b, (c\theta)b\big). \tag{a7}$$

(d) In view of (a2, 3), the rolling constraint $\boldsymbol{v}_C = \mathbf{0}$ assumes the Pfaffian forms

$$\dot{X} - R\,\omega_Y = \dot{X} - R[(\sin\phi)\dot{\theta} + (-\cos\phi\,\sin\theta)\dot{\psi}] = 0, \tag{b1}$$

$$\dot{Y} + R\,\omega_X = \dot{Y} + R[(\cos\phi)\dot{\theta} + (\sin\phi\,\sin\theta)\dot{\psi}] = 0. \tag{b2}$$

(i) With the help of the above, show that the (double) kinetic energy of the sphere equals

$$\begin{aligned} 2T &= \mathcal{S}\, dm\, \mathbf{v}^2 = \cdots = m\,\mathbf{v}_\blacklozenge{}^2 + 2m\,\mathbf{v}_\blacklozenge \cdot (\boldsymbol{\omega} \times \boldsymbol{r}_{G/\blacklozenge}) + \mathcal{S}\, dm(\boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge})^2 \\ &= \cdots = m[(\dot{X})^2 + (\dot{Y})^2] \\ &\qquad + 2m\,b\big\{\dot{X}[(s\phi\, c\theta)\dot{\theta} + (c\phi\, s\theta)\dot{\phi}] + \dot{Y}[(-c\phi\, c\theta)\dot{\theta} + (s\phi\, s\theta)\dot{\phi}]\big\} \\ &\qquad + A[(\dot{\theta})^2 + \sin^2\theta(\dot{\phi})^2] + C[(\cos\theta)\dot{\phi} + \dot{\psi}]^2 \\ &= 2T(\dot{X}, \dot{Y}, \dot{\phi}, \dot{\theta}, \dot{\psi}); \end{aligned} \tag{c}$$

where A and $C =$ *moments of inertia of sphere about* $\blacklozenge x$ (or $\blacklozenge y$) *and* $\blacklozenge z$*, respectively*.

(ii) Using the expression (c), the constraints (b1, 2), and noting that the only impressed force (gravity) has potential equal to

$$V = m\,g\,Z_G = m\,g(Z_\blacklozenge + Z_{G/\blacklozenge}) = m\,g(R + b\cos\theta) = m\,g\,b\cos\theta + \textit{constant}, \tag{d}$$

verify that the Routh–Voss equations of motion of the sphere are (with $\lambda_X \equiv \lambda$ and $\lambda_Y \equiv \mu$):

$$X\!: \qquad m\{\dot{X} + b[(\sin\phi\,\cos\theta)\dot{\theta} + (\cos\phi\,\sin\theta)\dot{\phi}]\}^{\cdot} = \lambda, \tag{e1}$$

$$Y\!: \qquad m\{\dot{Y} + b[(-\cos\phi\,\cos\theta)\dot{\theta} + (\sin\phi\,\sin\theta)\dot{\phi}]\}^{\cdot} = \mu, \tag{e2}$$

$$\begin{aligned} \phi\!: \qquad & [A\,\dot{\phi}\,\sin^2\theta + C(\cos\theta\,\dot{\phi} + \dot{\psi})\cos\theta - m\,b\,R\,\sin^2\theta\,\dot{\psi}]^{\cdot} \\ & \qquad + m\,b\,R\,\dot{\theta}\,\dot{\psi}\,\sin\theta\,\cos\theta + m\,bR\,\dot{\phi}\,\dot{\theta}\,\sin\theta = 0, \end{aligned} \tag{e3}$$

$$\begin{aligned} \theta\!: \qquad & (A\,\dot{\theta} + m\,bR\,\cos\theta\,\dot{\theta})^{\cdot} - A(\dot{\phi})^2\,\sin\theta\,\cos\theta + C(\cos\theta\,\dot{\phi} + \dot{\psi})\dot{\phi}\,\sin\theta \\ & \qquad + m\,bR(\dot{\theta})^2\,\sin\theta + m\,bR\,\dot{\phi}\,\dot{\psi}\,\cos\theta\,\sin\theta \\ & = \lambda(-R\sin\phi) + \mu(R\cos\phi) + m\,g\,b\,\sin\theta, \end{aligned} \tag{e4}$$

$$\psi\!: \qquad [C(\cos\theta\,\dot{\phi} + \dot{\psi})]^{\cdot} = \lambda(R\cos\phi\,\sin\theta) + \mu(R\,\sin\phi\,\sin\theta). \tag{e5}$$

(iii) Verify that by solving (e1, 2) for λ and μ, respectively, and substituting the results into (e3–5), we obtain the (kinetic Maggi) equations:

ϕ: remains unchanged, since it did not contain any multipliers, (f1)

$$\begin{aligned}\theta:\quad &(A\dot{\theta} + mbR\cos\theta\,\dot{\theta})^{\cdot} - A(\dot{\phi})^2 \sin\theta\cos\theta + C(\dot{\phi}\cos\theta + \dot{\psi})\dot{\phi}\sin\theta\\ &\quad + mbR(\dot{\theta})^2 \sin\theta + mbR\,\dot{\phi}\dot{\psi}\cos\theta\sin\theta\\ &\quad + mR\sin\phi[\dot{X} + b(\dot{\theta}\sin\phi\cos\theta + \dot{\phi}\cos\phi\sin\theta)]^{\cdot}\\ &\quad - mR\sin\phi[\dot{Y} + b(-\dot{\theta}\cos\phi\cos\theta + \dot{\phi}\sin\phi\sin\theta)]^{\cdot}\\ &= mgb\sin\theta, \end{aligned} \tag{f2}$$

$$\begin{aligned}\psi:\quad &[C(\dot{\phi}\cos\theta + \dot{\psi})]^{\cdot} - mR\cos\phi\sin\theta[\dot{X} + b(\dot{\theta}\sin\phi\cos\theta + \dot{\phi}\cos\phi\sin\theta)]^{\cdot}\\ &\quad - mR\sin\phi\sin\theta[\dot{Y} + b(-\dot{\theta}\cos\phi\cos\theta + \dot{\phi}\sin\phi\sin\theta)]^{\cdot} = 0. \end{aligned} \tag{f3}$$

Problem 3.18.8 Continuing from the preceding problem, verify that by eliminating the (chosen as) dependent velocities $\dot{X}$ and $\dot{Y}$ from its eqs. (f2, 3), using the constraints (b1, 2), we eventually obtain the following Chaplygin–Voronets equations of the problem:

$$\begin{aligned}\phi:\quad &[A\dot{\phi}\sin^2\theta + C(\dot{\phi}\cos\theta + \dot{\psi})\cos\theta - mbR\sin^2\theta\,\dot{\psi}]^{\cdot}\\ &+ mbR\dot{\theta}\sin\theta(\dot{\psi}\cos\theta + \dot{\phi}) = 0, \end{aligned} \tag{a1}$$

$$\begin{aligned}\theta:\quad &[(A + 2mbR\cos\theta + mR^2)\dot{\theta}]^{\cdot} + mbR\sin\theta[(\dot{\theta})^2 + \dot{\phi}\dot{\psi}\cos\theta - (\dot{\phi})^2]\\ &+ mR^2\dot{\phi}\dot{\psi}\sin\theta - A(\dot{\phi})^2\sin\theta\cos\theta + C(\dot{\phi}\cos\theta + \dot{\psi})\dot{\phi}\sin\theta\\ &- mgb\sin\theta = 0, \end{aligned} \tag{a2}$$

$$\begin{aligned}\psi:\quad &[C(\dot{\phi}\cos\theta + \dot{\psi}) + mR^2\dot{\psi}\sin^2\theta - mbR\dot{\phi}\sin^2\psi]^{\cdot}\\ &- mR^2\dot{\theta}\sin\theta(\dot{\psi}\cos\theta + \dot{\phi}) = 0. \end{aligned} \tag{a3}$$

HINTS

In the Maggi equations (f1–3), the terms deriving from λ and μ can be combined with the remaining terms to produce equations of the form $[\ldots]^{\cdot} + \cdots = 0$, like (a1–3), first, by application of the familiar differentiation rule: $f\dot{g} = (fg)^{\cdot} - f\dot{g}$ (where $f, g =$ arbitrary functions); and then by use of the constraints (b1, 2), but rewritten in the equivalent forms

$$\dot{X}\sin\phi - \dot{Y}\cos\phi = R\dot{\theta}, \qquad \dot{X}\cos\phi + \dot{Y}\sin\phi = -R\dot{\psi}\sin\theta, \tag{b}$$

Problem 3.18.9 Continuing from the preceding problem, show that its eqs. (a1) and (a3) combine to produce the (*linear*) integral

$$AR\dot{\phi}\sin^2\theta + C(b + R\cos\theta)(\dot{\phi}\cos\theta + \dot{\psi}) - mb^2R\dot{\phi}\sin^2\theta = \textit{constant}. \tag{a}$$

HINT

Multiply (a1) by R and (a3) by b, then combine, simplify, and, finally, integrate.

Problem 3.18.10 Continuing from the preceding problems, show that the Chaplygin–Voronets equations (a1–3) of prob. 3.18.8, possess the (*quadratic*) energy integral

$$mR^2[(\dot\theta)^2 + (\dot\psi)^2 \sin^2\theta] + 2mbR[(\dot\theta)^2 \cos\theta - \dot\phi\,\dot\psi \sin^2\theta] \\ + A[(\dot\theta)^2 + (\dot\phi)^2 \sin^2\theta] + C(\dot\phi\cos\theta + \dot\psi)^2 + 2mgb\cos\theta = 2h; \tag{a}$$

in addition to (a) of prob. 3.18.9.

REMARKS

(i) Since the five equations (prob. 3.18.8: a1–3), (prob. 3.18.9: a), and (prob. 3.18.10: a) do not contain explicitly either ϕ or ψ, we can, for example, solve the last two of them for $\dot\phi$ and $\dot\psi$ *in terms of* θ *and* $\dot\theta$; that is, $\dot\phi = \dot\phi(\theta, \dot\theta)$ and $\dot\psi = \dot\psi(\theta, \dot\theta)$, and then insert these expressions into any one of the first three equations (of motion), say the simplest of them. The result would be a *single* second-order differential equation for θ; and since *the time does not appear explicitly*, this can be further reduced to a *first*-order problem.

(ii) If, next, our sphere shrinks to a particle of mass m, then $A = mb^2$ and $C = 0$, and the linear integral (prob. 3.18.9: a) degenerates to the trivial equality $0 = constant$ $(= 0)$; that is, one of our equations disappears! For a detailed discussion and explanation of this interesting mathematical "paradox," see the masterful treatment of Hamel (1949, pp. 760–766).

Problem 3.18.11 Continuing from the above problems of the eccentric sphere:

(i) Introduce the following convenient quasi velocities:

$$\omega_1 \equiv \dot X - R\,\omega_Y = \dot X - (R\sin\phi)\dot\theta + (R\cos\phi\sin\theta)\dot\psi \quad (= 0), \tag{a1}$$

$$\omega_2 \equiv \dot Y + R\,\omega_X = \dot Y + (R\cos\phi)\dot\theta + (R\sin\phi\sin\theta)\dot\psi \quad (= 0); \tag{a2}$$

$$\omega_3 \equiv \dot\theta, \tag{a3}$$

$$\omega_4 \equiv \dot\phi, \tag{a4}$$

$$\omega_5 \equiv \dot\psi; \tag{a5}$$

which invert easily (no constraint enforcement yet), as follows:

$$\dot X = \omega_1 + R\sin\phi\,\omega_3 - R\cos\phi\sin\theta\,\omega_5, \tag{b1}$$

$$\dot Y = \omega_2 - R\cos\phi\,\omega_3 - R\sin\phi\sin\theta\omega_5, \tag{b2}$$

$$\dot\theta = \omega_3, \tag{b3}$$

$$\dot\phi = \omega_4, \tag{b4}$$

$$\dot\psi = \omega_5. \tag{b5}$$

(ii) Using (a1–b5), verify the transitivity equations (no constraint enforcement yet)

$$(\delta\theta_1)^{\cdot} - \delta\omega_1 = R\cos\phi(\omega_3\,\delta\theta_4 - \omega_4\,\delta\theta_3) - R\sin\phi\sin\theta(\omega_4\,\delta\theta_5 - \omega_5\,\delta\theta_4) + R\cos\phi\,\cos\theta(\omega_3\,\delta\theta_5 - \omega_5\,\delta\theta_3); \tag{c1}$$

$$(\delta\theta_2)^{\cdot} - \delta\omega_2 = R\sin\phi(\omega_3\,\delta\theta_4 - \omega_4\,\delta\theta_3) + R\cos\phi\,\sin\theta(\omega_4\,\delta\theta_5 - \omega_5\,\delta\theta_4) + R\sin\phi\,\cos\theta(\omega_3\,\delta\theta_5 - \omega_5\,\delta\theta_3); \tag{c2}$$

$$(\delta\theta_3)^{\cdot} - \delta\omega_3 = 0, \qquad (\delta\theta_4)^{\cdot} - \delta\omega_4 = 0, \qquad (\delta\theta_5)^{\cdot} - \delta\omega_5 = 0; \tag{c3}$$

since $\theta_{3,4,5}$ are holonomic coordinates. From the above, we read off the (nonvanishing) Hamel coefficients:

$$\gamma^1{}_{43} = -\gamma^1{}_{34} = R\cos\phi, \qquad \gamma^1{}_{54} = -\gamma^1{}_{45} = -R\sin\phi\,\sin\theta,$$
$$\gamma^1{}_{53} = -\gamma^1{}_{35} = R\cos\phi\,\cos\theta; \tag{d1}$$

$$\gamma^2{}_{43} = -\gamma^2{}_{34} = R\sin\phi, \qquad \gamma^2{}_{54} = -\gamma^2{}_{45} = R\cos\phi\,\sin\theta,$$
$$\gamma^2{}_{53} = -\gamma^2{}_{35} = R\sin\phi\,\cos\theta; \tag{d2}$$

$$\gamma^3{}_{..} = 0, \qquad \gamma^4{}_{..} = 0, \qquad \gamma^5{}_{..} = 0. \tag{d3}$$

(iii) Using (b1–5), show that the kinetic energy expression (prob. 3.18.7: c), or, equivalently,

$$\begin{aligned}2T &= m[(\dot{X})^2 + (\dot{Y})^2] \\ &\quad + 2mb\{\dot{\theta}\cos\theta(\dot{X}\sin\phi - \dot{Y}\cos\phi) + \dot{\phi}\sin\theta(\dot{X}\cos\phi + \dot{Y}\sin\phi)\} \\ &\quad + A[(\dot{\theta})^2 + \sin^2\theta(\dot{\phi})^2] + C[(\cos\theta)\dot{\phi} + \dot{\psi}]^2,\end{aligned} \tag{e1}$$

becomes, in the chosen quasi velocities (no constraint enforcement yet),

$$\begin{aligned}2T^* &= m[\omega_1{}^2 + \omega_2{}^2 + R^2\omega_3{}^2 + R^2\sin^2\theta\,\omega_5{}^2 + 2R\sin\phi\,\omega_1\omega_3 \\ &\quad - 2R\cos\phi\,\omega_2\,\omega_3 - 2R\cos\phi\,\sin\theta\,\omega_1\,\omega_5 - 2R\sin\phi\,\sin\theta\,\omega_2\,\omega_5] \\ &\quad + 2mb[\omega_3\cos\theta(\omega_1\sin\phi - \omega_2\cos\phi + R\,\omega_3) \\ &\quad + \omega_4\sin\theta(\omega_1\cos\phi + \omega_2\sin\phi - R\sin\theta\,\omega_5)] \\ &\quad + A[\omega_3{}^2 + (\sin^2\theta)\omega_4{}^2] + C[(\cos\theta)\omega_4 + \omega_5]^2.\end{aligned} \tag{e2}$$

[*Quadratic* terms in the constrained, or dependent, quasi velocities $\omega_{1,2}$ *can* be omitted from (e2) at this stage, without affecting the equations of motion; but *linear* terms in them *cannot* — explain].

(iv) Using the above results and noting that (after enforcing the constraints $\omega_{1,2} = 0$)

$$\partial T^*/\partial\theta_{1,2,4,5} = 0, \qquad \partial T^*/\partial\theta_3 = \partial T^*/\partial\theta = \cdots,$$
$$\partial V^*/\partial\theta_{1,2,4,5} = 0, \qquad \partial V^*/\partial\theta_3 = \partial V^*/\partial\theta = -m\,g\,b\,\sin\theta, \tag{e3}$$

show that the Hamel equations of this problem are (with $P_k \equiv \partial T^*/\partial\omega_k$, $k = 1, \ldots, 5$).

Kinetic equations:

$$\dot{P}_3 - \partial T^*/\partial\theta_3 + \gamma^1{}_{34}P_1\,\omega_4 + \gamma^1{}_{35}P_1\,\omega_5 + \gamma^2{}_{34}P_2\,\omega_4 + \gamma^2{}_{35}P_2\,\omega_5 = -(\partial V^*/\partial\theta_3),$$
$$\dot{P}_4 + \gamma^1{}_{43}P_1\,\omega_3 + \gamma^1{}_{45}P_1\,\omega_5 + \gamma^2{}_{43}P_2\,\omega_3 + \gamma^2{}_{45}P_2\,\omega_5 = 0,$$
$$\dot{P}_5 + \gamma^1{}_{53}P_1\,\omega_3 + \gamma^1{}_{54}P_1\,\omega_4 + \gamma^2{}_{53}P_2\,\omega_3 + \gamma^2{}_{54}P_2\,\omega_4 = 0; \qquad \text{(f1, 2, 3)}$$

or, explicitly, respectively,

$$[\omega_3(A + 2m\,bR\,\cos\theta + m\,R^2)]^{\bullet} + mR^2\,\sin\theta\,\omega_4\,\omega_5$$
$$+ m\,bR\,\sin\theta(-\omega_4{}^2 + \cos\theta\,\omega_4\,\omega_5 + \omega_3{}^2)$$
$$- A\,\sin\theta\,\cos\theta\,\omega_4{}^2 + C(\cos\theta\,\omega_4 + \omega_5)\,\sin\theta = m\,g\,b\,\sin\theta, \qquad \text{(f4)}$$

$$[A\,\sin^2\theta\,\omega_4 + C(\cos\theta\,\omega_4 + \omega_5)\,\cos\theta - m\,bR\,\sin^2\theta\,\omega_5]^{\bullet}$$
$$+ m\,bR\,\sin\theta\,\omega_3(\omega_4 + \cos\theta\,\omega_5) = 0, \qquad \text{(f5)}$$

$$[mR^2\,\sin^2\theta\,\omega_5 - m\,bR\,\sin^2\theta\,\omega_4 + C(\cos\theta\,\omega_4 + \omega_5)]^{\bullet}$$
$$- m\,R^2\sin\theta\,\cos\theta\,\omega_3\,\omega_5 - mR^2\,\sin\theta\,\omega_3\,\omega_4 = 0; \qquad \text{(f6)}$$

and, as can be verified easily, these equations coincide with the earlier (prob. 3.18.8: a1–3), respectively; *but, unlike them, they have been derived without elimination of the dependent velocities*;

Kinetostatic equations:

$$\dot{P}_1 = \Lambda_1(\equiv \lambda_1), \qquad \dot{P}_2 = \Lambda_2(\equiv \lambda_2), \qquad \text{(f7, 8)}$$

[since, as (d1–3) show, all the $\gamma^k{}_{1I}$ and $\gamma^k{}_{2I}$ ($k = 1, \ldots, 5;\ I = 3, 4, 5$) vanish]

or, explicitly, respectively,

$$[mR\,\sin\phi\,\omega_3 - mR\,\cos\phi\,\sin\theta\,\omega_5 + m\,b(\omega_3\,\sin\phi\,\cos\theta + \omega_4\,\cos\phi\,\sin\theta)]^{\bullet} = \Lambda_1,$$
$$[-mR\,\cos\phi\,\omega_3 - mR\,\sin\phi\,\sin\theta\,\omega_5 + m\,b(-\omega_3\,\cos\phi\,\cos\theta + \omega_4\,\sin\phi\,\sin\theta)]^{\bullet} = \Lambda_2. \qquad \text{(f9, 10)}$$

Example 3.18.5 *Dynamics of a Rolling Hoop (or Disk, or Coin).* Let us determine the forces and equations of motion of a thin homogeneous hoop H, of mass m and radius r, rolling on a rough, horizontal, and fixed plane P (fig. 3.53).

The relevant kinematics has already been detailed in ex. 2.13.7. We recall that

$$q_1 \equiv X_G \equiv X, \quad q_2 \equiv Y_G \equiv Y; \qquad q_3 \equiv \phi, \quad q_4 \equiv \theta, \quad q_5 \equiv \psi; \qquad \text{(a1)}$$

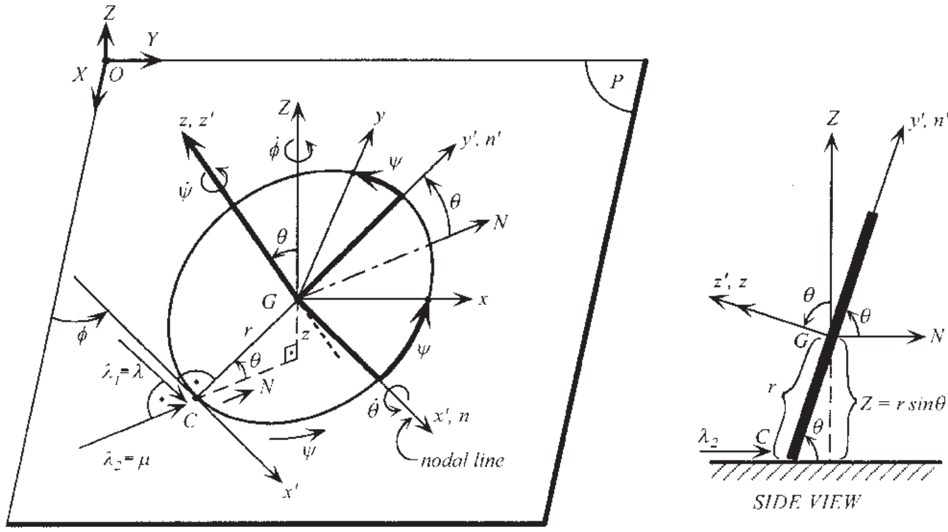

Figure 3.53 Geometry of a homogeneous hoop rolling on rough, horizontal, and fixed plane. *G*: geometrical center and center of mass of hoop, *C*: contact point between hoop and plane. *Axes/bases*:
*O–XYZ/***IJK**: plane-fixed (inertial) axes/basis;
$G\text{–}x'y'z'/\mathbf{i'j'k'} \equiv G\text{–}nn'z'/\mathbf{u}_n\mathbf{u}_{n'}\mathbf{k}'$: semimobile (noninertial) axes/basis;
$G\text{–}x'NZ/\mathbf{i}'\mathbf{u}_N\mathbf{K} \equiv G\text{–}nNZ/\mathbf{u}_n\mathbf{u}_N\mathbf{K}$: semifixed (noninertial) axes/basis;
*G–xyz/***ijk**: disk-fixed (noninertial) axes/basis;
ϕ, θ, ψ: Eulerian angles between *O–XYZ/***IJK** (or *G–XYZ/***IJK**) and *G–xyz/***ijk**.

since $Z_G \equiv Z = r\,\sin\theta$, Z is not independent (i.e., here, $f \equiv n - m = 5 - 2 = 3$ — see below)

$$\boldsymbol{\omega} = (\omega_{x'}, \omega_{y'}, \omega_{z'}) = (\dot{\theta}, \dot{\phi}\,\sin\theta, \dot{\psi} + \dot{\phi}\,\cos\theta) \qquad (\textit{semimobile components})$$

$$= (\omega_{x'}, \omega_N, \omega_Z) = (\dot{\theta}, -\dot{\psi}\,\sin\theta, \dot{\phi} + \dot{\psi}\,\cos\theta) \qquad (\textit{semifixed components}), \quad \text{(a2)}$$

$$\boldsymbol{GC} = (0, -r\,\cos\theta, -r\,\sin\theta) \qquad (\textit{semifixed components}), \quad \text{(a3)}$$

$$\Rightarrow \boldsymbol{\omega} \times \boldsymbol{GC} = \big(r(\dot{\psi} + \dot{\phi}\cos\theta), -r\,\dot{\theta}\,\sin\theta, -r\,\dot{\theta}\,\cos\theta\big); \quad \text{(a4)}$$

and therefore the rolling constraint $\boldsymbol{v}_C = \mathbf{0}$ translates to the two Pfaffian conditions

$$(\boldsymbol{v}_C)_{x'} = \dot{X}\,\cos\phi + \dot{Y}\,\sin\phi + r(\dot{\psi} + \dot{\phi}\,\cos\theta) = 0, \quad \text{(a5)}$$

$$(\boldsymbol{v}_C)_N = -\dot{X}\,\sin\phi + \dot{Y}\,\cos\phi + r\,\dot{\theta}\,\sin\theta = 0. \quad \text{(a6)}$$

The Routh–Voss Equations

Since, by König's theorem and the above geometry/kinematics,

$$2T = m[(\dot{X})^2 + (\dot{Y})^2 + (\dot{Z})^2] + (I_{x'}\,\omega_{x'}{}^2 + I_{y'}\,\omega_{y'}{}^2 + I_{z'}\,\omega_{z'}{}^2)$$

$$= m[(\dot{X})^2 + (\dot{Y})^2 + r^2(\dot{\theta})^2\,\cos^2\theta] + (mr^2/2)(\dot{\theta})^2 + (mr^2/2)(\dot{\phi})^2\,\sin^2\theta$$

$$+ (m\,r^2)(\dot{\psi} + \dot{\phi}\,\cos\theta)^2, \quad \text{(b1)}$$

and $V = mgZ = mgr\sin\theta$ (and with $\lambda_1 \equiv \lambda, \lambda_2 \equiv \mu$), the Routh–Voss equations of the hoop are

$$X: \qquad m\ddot{X} = \lambda\cos\phi - \mu\sin\phi, \tag{b2}$$

$$Y: \qquad m\ddot{Y} = \lambda\sin\phi + \mu\cos\phi; \tag{b3}$$

$$\phi: \qquad [(mr^2/2)(\dot{\phi}\sin^2\theta)]^\cdot + [(mr^2)\cos\theta(\dot{\phi}\cos\theta + \dot{\psi})]^\cdot = \lambda r\cos\theta, \tag{b4}$$

$$\begin{aligned}\theta: \qquad & [(mr^2)(\dot{\theta}\cos^2\theta)]^\cdot + (mr^2/2)\ddot{\theta} + (mr^2)(\dot{\theta})^2\sin\theta\cos\theta \\ & - (mr^2/2)(\dot{\phi})^2\sin\theta\cos\theta + (mr^2)\dot{\phi}(\dot{\phi}\cos\theta + \dot{\psi})\sin\theta \\ & = \mu r\sin\theta - mgr\cos\theta,\end{aligned} \tag{b5}$$

$$\psi: \qquad [(mr^2)(\dot{\psi} + \dot{\phi}\cos\theta)]^\cdot = \lambda r. \tag{b6}$$

Equations (b2, 3) express the principle of *linear* momentum along the axes X and Y, respectively; while eqs. (b4–6) express that of *angular* momentum about G, and the corresponding (nonorthogonal!) axes of rotation through it.

Determination of the Reactions; and the Equations of Maggi and Chaplygin–Voronets

To determine and/or eliminate the multipliers (reactions) we, first, solve (b2, 3) for them:

$$\lambda = m(\ddot{X}\cos\phi + \ddot{Y}\sin\phi), \qquad \mu = m(\ddot{Y}\cos\phi - \ddot{X}\sin\phi). \tag{c1}$$

Then, $(\ldots)^\cdot$-differentiating the constraints (a5, 6), to generate $\ddot{X}$ and $\ddot{Y}$, we find

$$\ddot{X}\cos\phi + \ddot{Y}\sin\phi + \dot{\phi}(\dot{Y}\cos\phi - \dot{X}\sin\phi) + r(\dot{\phi}\cos\theta + \dot{\psi})^\cdot = 0, \tag{c2}$$

$$-\ddot{X}\sin\phi + \ddot{Y}\cos\phi - \dot{\phi}(\dot{X}\cos\phi + \dot{Y}\sin\phi) + r(\dot{\theta}\sin\theta)^\cdot = 0; \tag{c3}$$

or, invoking (c1),

$$(\lambda/m) + \dot{\phi}(\dot{Y}\cos\phi - \dot{X}\sin\phi) + r(\dot{\phi}\cos\theta + \dot{\psi})^\cdot = 0, \tag{c4}$$

$$(\mu/m) - \dot{\phi}(\dot{X}\cos\phi + \dot{Y}\sin\phi) + r(\dot{\theta}\sin\theta)^\cdot = 0; \tag{c5}$$

and, finally, eliminating the *second sum/term* in each of them via the constraints (a5, 6) and then solving for the multipliers, we obtain these latter in terms of ϕ, θ, ψ and their rates of change:

$$\lambda = mr[\dot{\phi}\dot{\theta}\sin\theta - (\dot{\phi}\cos\theta + \dot{\psi})^\cdot], \tag{c6}$$

$$\mu = -mr[\dot{\phi}(\dot{\phi}\cos\theta + \dot{\psi}) + (\dot{\theta}\sin\theta)^\cdot]. \tag{c7}$$

Now:

(a) Inserting (c1) into (b4–6) results in the three kinetic Maggi equations of our problem, which, along with the two constraints (a5, 6), constitutes a determinate system for $X(t), Y(t), \phi(t), \theta(t), \psi(t)$; then $\lambda(t)$ and $\mu(t)$ can be immediately found from (c1); whereas

(b) Inserting (c6, 7) into (b4–6) results in its three (kinetic only) Chaplygin–Voronets equations for $\phi(t), \theta(t), \psi(t)$:

$$\phi: \quad [(m\,r^2/2)(\dot{\phi}\,\sin^2\theta)]^{\cdot} + [(m\,r^2)\,\cos\theta(\dot{\phi}\,\cos\theta + \dot{\psi})]^{\cdot}$$
$$= m\,r^2\,\cos\theta[\dot{\phi}\,\dot{\theta}\,\sin\theta - (\dot{\phi}\,\cos\theta + \dot{\psi})^{\cdot}], \tag{c8}$$

$$\theta: \quad [(m\,r^2)(\dot{\theta}\,\cos^2\theta)]^{\cdot} + (m\,r^2/2)\ddot{\theta} + (m\,r^2)(\dot{\theta})^2\,\sin\theta\,\cos\theta$$
$$- (m\,r^2/2)(\dot{\phi})^2\,\sin\theta\,\cos\theta + (mr^2)\dot{\phi}\,(\dot{\phi}\,\cos\theta + \dot{\psi})\,\sin\theta + m\,g\,r\,\cos\theta$$
$$= -m\,r^2\,\sin\theta[\dot{\phi}\,(\dot{\phi}\,\cos\theta + \dot{\psi}) + (\dot{\theta}\,\sin\theta)^{\cdot}], \tag{c9}$$

$$\psi: \quad [(m\,r^2)(\dot{\psi} + \dot{\phi}\,\cos\theta)]^{\cdot} = m\,r^2[\dot{\phi}\,\dot{\theta}\,\sin\theta - (\dot{\phi}\,\cos\theta + \dot{\psi})^{\cdot}]. \tag{c10}$$

Once $\phi(t), \theta(t), \psi(t)$ have been found from the above, then $\lambda(t)$ and $\mu(t)$ can be immediately calculated from (c6, 7).

(c) As shown a little later, eqs. (c8–10), when expressed in terms of the *semimobile* angular velocity components, eq. (a2), are none other than the corresponding kinetic Hamel equations (with $\omega_{x',y',z'} \to \omega_{3,4,5}$).

A Famous and Instructive Error

The rolling hoop offers a good opportunity to demonstrate concretely that, in general, $E_I(T_o) \neq Q_{Io}$. Indeed, eliminating the two dependent velocities $\dot{X}$ and $\dot{Y}$ ($n = 5, m = 2 \Rightarrow f \equiv 5 - 2 = 3$) from (b1) with the help of the constraints (a5, 6), while noting that, then, $(\dot{X})^2 + (\dot{Y})^2 = r^2(\dot{\psi} + \dot{\phi}\,\cos\theta)^2 + r^2(\dot{\theta})^2\,\sin^2\theta$, we bring the (double) kinetic energy to the constrained (or *nonlegitimate*) form,

$$2T \to 2T_o \equiv 2T_o(\theta; \dot{\phi}, \dot{\theta}, \dot{\psi})$$
$$= (3mr^2/2)(\dot{\theta})^2 + (mr^2/2)(\dot{\phi})^2\,\sin^2\theta + (2mr^2)(\dot{\psi} + \dot{\phi}\,\cos\theta)^2. \tag{d1}$$

Therefore, and since here, too, $V = V_o = mgZ = mgr\,\sin\theta \Rightarrow Q_{Io} = -\partial V_o/\partial q_I$, the *incorrect* Lagrangean equations — that is, $(\partial T_o/\partial \dot{q}_I)^{\cdot} - \partial T_o/\partial q_I = -\partial V_o/\partial q_I$ ($q_I = \phi, \theta, \psi$) — are

$$d/dt\big[(mr^2/2)(\dot{\phi})^2\,\sin^2\theta + (2m\,r^2)\,\cos\theta(\dot{\psi} + \dot{\phi}\,\cos\theta)\big] = 0, \tag{d2}$$

$$(3mr^2/2)\ddot{\theta} - (mr^2/2)(\dot{\phi})^2\,\sin\theta\,\cos\theta + (2mr^2)\dot{\phi}\,\sin\theta(\dot{\psi} + \dot{\phi}\,\cos\theta)$$
$$= -m\,g\,r\,\cos\theta, \tag{d3}$$

$$d/dt(\dot{\psi} + \dot{\phi}\,\cos\theta) = 0. \tag{d4}$$

On the history of this error (committed by some distinguished scientists in the 1890s), see, for example, Stäckel (1905, pp. 596–597); also Campbell (1971, pp. 102–108).

The Hamel Equations

We recall that (ex. 2.13.7)

$$\omega_1 \equiv \dot{X}\cos\phi + \dot{Y}\sin\phi + r(\dot{\psi} + \dot{\phi}\cos\theta) \quad (=0), \tag{e1}$$

$$\omega_2 \equiv -\dot{X}\sin\phi + \dot{Y}\cos\phi + r\dot{\theta}\sin\theta \quad (=0); \tag{e2}$$

$$\omega_3 \equiv \omega_{x'} = \dot{\theta}, \qquad \omega_4 \equiv \omega_{y'} = \dot{\phi}\sin\theta, \qquad \omega_5 \equiv \omega_{z'} = \dot{\psi} + \dot{\phi}\cos\theta; \tag{e3–5}$$

and

$$(\delta\theta_1)^{\cdot} - \delta\omega_1 = (\omega_4/\sin\theta)\,\delta\theta_2 + (-\omega_2/\sin\theta)\,\delta\theta_4, \tag{e6}$$

$$(\delta\theta_2)^{\cdot} - \delta\omega_2 = (-\omega_4/\sin\theta)\,\delta\theta_1 + [(\omega_1/\sin\theta) - (r\omega_5/\sin\theta)]\,\delta\theta_4 + (r\omega_4/\sin\theta)\,\delta\theta_5, \tag{e7}$$

$$(\delta\theta_3)^{\cdot} - \delta\omega_3 = 0 \qquad (\theta\text{: holonomic coordinate}), \tag{e8}$$

$$(\delta\theta_4)^{\cdot} - \delta\omega_4 = (\omega_3\cot\theta)\,\delta\theta_4 + (-\omega_4\cot\theta)\,\delta\theta_3, \tag{e9}$$

$$(\delta\theta_5)^{\cdot} - \delta\omega_5 = (\omega_4)\,\delta\theta_3 + (-\omega_3)\,\delta\theta_4. \tag{e10}$$

Therefore, and since here $\boldsymbol{I}_G = diagonal\ (A = mr^2/2, B = A = mr^2/2, C = mr^2)$,

(a)
$$\begin{aligned} 2T = 2T^* &= m\,v_G{}^2 + \boldsymbol{\omega}\cdot\boldsymbol{I}_G\cdot\boldsymbol{\omega} \qquad \text{(no constraint enforcement yet!)} \\ &= m[(\omega_1 - r\,\omega_5)^2 + (\omega_2 - r\,\omega_3\sin\theta)^2 + r^2\omega_3{}^2\cos^2\theta] \\ &\qquad + (m\,r^2)[(\omega_3{}^2/2) + (\omega_4{}^2/2) + \omega_5{}^2] \\ &= m\{r^2[(3\omega_3{}^2/2) + (\omega_4{}^2/2) + 2\omega_5{}^2] - 2r\,\omega_1\,\omega_5 - 2r\,\omega_2\,\omega_3\sin\theta \\ &\qquad + \omega_1{}^2 + \omega_2{}^2\}, \end{aligned} \tag{e11}$$

(the last *two* terms can be safely neglected at this stage—why?) and from this we readily obtain

(b)
$$P_1 = (\partial T^*/\partial\omega_1)_o = (-m\,r\,\omega_5 + m\,\omega_1)_o = -m\,r\,\omega_5 \Rightarrow \dot{P}_1 = -m\,r\,\dot{\omega}_5, \tag{e12}$$

$$P_2 = (\partial T^*/\partial\omega_2)_o = -m\,r\,\omega_3\sin\theta \Rightarrow \dot{P}_2 = -m\,r(\dot{\omega}_3\sin\theta + \omega_3{}^2\cos\theta), \tag{e13}$$

$$P_3 = \cdots = m[-r\,\omega_2\sin\theta + (3r^2\omega_3/2)]_o = (3m\,r^2/2)\omega_3 \Rightarrow \dot{P}_3 = (3m\,r^2/2)\dot{\omega}_3, \tag{e14}$$

$$P_4 = \cdots = (m\,r^2/2)\omega_4 \Rightarrow \dot{P}_4 = (m\,r^2/2)\dot{\omega}_4, \tag{e15}$$

$$P_5 = \cdots = 2m\,r^2\omega_5 \Rightarrow \dot{P}_5 = 2m\,r^2\dot{\omega}_5; \tag{e16}$$

also (check it!),

(c)
$$\partial T^*/\partial\theta_k \equiv \sum A_{lk}(\partial T^*/\partial q_l) = [A_{4k}(\partial T^*/\partial\theta)]_o = 0 \qquad (k = 1, \ldots, 5); \tag{e17}$$

while the fundamental noncommutative term $\Gamma \equiv \sum P_k[(\delta\theta_k)^{\cdot} - \delta\omega_k]$ becomes

$$\begin{aligned}
\text{(d)}\quad \Gamma &= P_1[(\omega_4/\sin\theta)\,\delta\theta_2 - (\omega_2/\sin\theta)\,\delta\theta_4] + \cdots \\
&\qquad \text{(we } can \text{ enforce the constraints } \omega_{1,2} = 0; \\
&\qquad \text{but } not\ \delta\theta_{1,2} = 0, \text{if we want to calculate the constraint reactions)} \\
&= -P_2(\omega_4/\sin\theta)\,\delta\theta_1 + P_1(\omega_4/\sin\theta)\,\delta\theta_2 + (P_5\,\omega_4 - P_4\,\omega_4\cot\theta)\,\delta\theta_3 \\
&\quad + [P_4\,\omega_3\cot\theta - P_2\,r(\omega_5/\sin\theta) - P_5\,\omega_3]\,\delta\theta_4 + P_2 r(\omega_4/\sin\theta)\,\delta\theta_5. \qquad \text{(e18)}
\end{aligned}$$

Collecting all these results into the master variational equation

$$\sum (\dot{P}_k - \partial T^*/\partial\theta_k)\,\delta\theta_k + \Gamma = \sum \Theta_k\,\delta\theta_k,$$

and applying to it the method of Lagrangean multipliers, we obtain the *two* kineto-static equations

$$k = 1:\quad \dot{P}_1 - (\omega_4/\sin\theta)P_2 = \Theta_1 + \lambda_1, \quad \text{or} \quad mr(-\dot{\omega}_5 + \omega_3\,\omega_4) = \Theta_1 + \lambda_1, \qquad \text{(e19)}$$

$$\begin{aligned}
k = 2:\quad &\dot{P}_2 + (\omega_4/\sin\theta)P_1 = \Theta_2 + \lambda_2, \\
&\text{or} \quad -m\,r[\dot{\omega}_3\sin\theta + \omega_3{}^2\cos\theta + (\omega_4\,\omega_5/\sin\theta)] = \Theta_2 + \lambda_2, \qquad \text{(e20)}
\end{aligned}$$

and the *three* kinetic equations

$$\begin{aligned}
k = 3:\quad &\dot{P}_3 - \omega_4\cot\theta P_4 + \omega_4 P_5 = \Theta_3, \\
&\text{or} \qquad (3m\,r^2/2)\dot{\omega}_3 - (m\,r^2/2)\cot\theta\,\omega_4{}^2 + (2m\,r^2)\omega_4\,\omega_5 = \Theta_3, \\
&\text{or, further,} \qquad m\,r^2[(3/2)\dot{\omega}_3 + 2\omega_4\,\omega_5 - (1/2)\cot\theta\,\omega_4{}^2] = \Theta_3, \qquad \text{(e21)} \\
k = 4:\quad &\dot{P}_4 - (r\,\omega_5/\sin\theta)P_2 + \omega_3\cot\theta\,P_4 - \omega_3 P_5 = \Theta_4, \\
&\text{or} \qquad m\,r^2[(1/2)\dot{\omega}_4 + (1/2)\cot\theta\,\omega_3\,\omega_4 - \omega_3\,\omega_5] = \Theta_4, \qquad \text{(e22)} \\
k = 5:\quad &\dot{P}_5 + (r\,\omega_4/\sin\theta)P_2 = \Theta_5, \\
&\text{or} \qquad m\,r^2(2\dot{\omega}_5 - \omega_3\,\omega_4) = \Theta_5. \qquad \text{(e23)}
\end{aligned}$$

If the only impressed force is gravity (sole case to be examined here), then

$$V = V^* = m\,g\,Z = m\,g\,r\sin\theta_3 \;\Rightarrow\; \Theta_{1,2,4,5} = 0 \quad \text{and} \quad \Theta_3 = -\partial V^*/\partial\theta_3 = -m\,g\,r\cos\theta,$$

and therefore the three kinetic equations (e21–23) reduce, respectively, to

$$(3/2)(d\omega_3/dt) + 2\omega_4\,\omega_5 - (1/2)\cot\theta\,\omega_4{}^2 = -(g/r)\cos\theta, \qquad \text{(e24)}$$

$$(1/2)(d\omega_4/dt) + (1/2)\cot\theta\,\omega_3\,\omega_4 - \omega_3\,\omega_5 = 0, \qquad \text{(e25)}$$

$$2(d\omega_5/dt) - \omega_3\,\omega_4 = 0. \qquad \text{(e26)}$$

We leave it to the reader to show, with the help of the above, that the corresponding equations in terms of the components of $\boldsymbol{\omega}$ along the *body-fixed* axes G–xyz, $\omega_{x,y,z}$, are

$$3(d\omega_x/dt) + \omega_y(4\omega_z - \omega_y \cot\theta) = -2(g/r)\cos\theta, \tag{e27}$$

$$d\omega_y/dt + \omega_x(\omega_y \cot\theta - 2\omega_z) = 0, \tag{e28}$$

$$2(d\omega_x/dt) - \omega_x\,\omega_y = 0. \tag{e29}$$

HINT

Use the $\omega_{x',y',z'} \Leftrightarrow \omega_{x,y,z}$ transformation equations (§1.12) in eqs. (e24–26).

The Appell Equations (No Reactions, only motion)

Here, all the difficulty lies in calculating the (constrained) Appellian in terms of the q's; $\omega_{3,4,5}$; $\dot{\omega}_{3,4,5}$; and t; that is, $S \to S^* \to S^*{}_o$. To this end, we will utilize the Appellian counterpart of König's theorem (3.14.3a ff.),

$$S^* = S^*{}_G + S^*{}_{/G},$$

where

$$2S^*{}_G \equiv m(\boldsymbol{a}_G \cdot \boldsymbol{a}_G),$$
$$2S^*{}_{/G} \equiv \int dm(\boldsymbol{a}_{/G} \cdot \boldsymbol{a}_{/G}) = \boldsymbol{\alpha} \cdot \boldsymbol{I}_G \cdot \boldsymbol{\alpha} + 2(\boldsymbol{\alpha} \times \boldsymbol{\omega}) \cdot (\boldsymbol{I}_G \cdot \boldsymbol{\omega}). \tag{f1}$$

Let us calculate these parts of S^* separately, as follows.

(a) Using the convenient *semifixed axes/basis* G–$x'NZ/\boldsymbol{i}'\boldsymbol{u}_N\boldsymbol{K} \equiv G$–$nNZ/\boldsymbol{u}_n\boldsymbol{u}_N\boldsymbol{K}$, and invoking the $\omega \Leftrightarrow \dot{q}$ relations (and then enforcing the constraints $\omega_{1,2} = 0$ there) yields, successively,

$$\begin{aligned}
\boldsymbol{v}_G &= \dot{X}\boldsymbol{I} + \dot{Y}\boldsymbol{J} + \dot{Z}\boldsymbol{K} \\
&= \dot{X}(\cos\phi\,\boldsymbol{u}_n - \sin\phi\,\boldsymbol{u}_N) + \dot{Y}(\sin\phi\,\boldsymbol{u}_n + \cos\phi\,\boldsymbol{u}_N) + \dot{Z}\boldsymbol{K} \\
&= (\dot{X}\cos\phi + \dot{Y}\sin\phi)\boldsymbol{u}_n + (-\dot{X}\sin\phi + \dot{Y}\cos\phi)\boldsymbol{u}_N + \dot{Z}\boldsymbol{K} \\
&= -r(\dot{\psi} + \dot{\phi}\cos\theta)\boldsymbol{u}_n + (-r\,\dot{\theta}\sin\theta)\boldsymbol{u}_N + (r\,\dot{\theta}\cos\theta)\boldsymbol{K} \\
&= (\omega_1 - r\,\omega_5)\boldsymbol{u}_n + (\omega_2 - r\sin\theta\,\omega_3)\boldsymbol{u}_N + (r\cos\theta\,\omega_3)\boldsymbol{K} \\
&= (-r\,\omega_5)\boldsymbol{u}_n + (-r\sin\theta\,\omega_3)\boldsymbol{u}_N + (r\cos\theta\,\omega_3)\boldsymbol{K},
\end{aligned} \tag{f2}$$

and since $\boldsymbol{\omega}_{\text{semifixed}} \equiv \boldsymbol{\omega}_{SF} = (0)\boldsymbol{u}_n + (0)\boldsymbol{u}_N + (\dot{\phi})\boldsymbol{K}$, from which it follows that

$$d\boldsymbol{u}_n/dt = \boldsymbol{\omega}_{SF} \times \boldsymbol{u}_n = (0, 0, \dot{\phi}) \times (1, 0, 0) = \dot{\phi}\,\boldsymbol{u}_N = (\omega_4/\sin\theta)\boldsymbol{u}_N, \tag{f3}$$

$$d\boldsymbol{u}_N/dt = \boldsymbol{\omega}_{SF} \times \boldsymbol{u}_N = (0, 0, \dot{\phi}) \times (0, 1, 0) = -\dot{\phi}\,\boldsymbol{u}_n = (-\omega_4/\sin\theta)\boldsymbol{u}_n, \tag{f4}$$

$$d\boldsymbol{K}/dt = \boldsymbol{\omega}_{SF} \times \boldsymbol{K} = (0, 0, \dot{\phi}) \times (0, 0, 1) = \boldsymbol{0}, \tag{f5}$$

we, therefore, obtain (with some easily understood moving axes notations)

$$\begin{aligned}\boldsymbol{a}_G = d\boldsymbol{v}_G/dt &= (d\boldsymbol{v}_G/dt)_{SF} + \boldsymbol{\omega}_{SF} \times \boldsymbol{v}_G \\ &= \cdots = -r\big[(\dot{\omega}_5 - \omega_3\omega_4)\boldsymbol{u}_n + (\dot{\omega}_3 \sin\theta + \omega_3{}^2 \cos\theta + \omega_4\omega_5/\sin\theta)\boldsymbol{u}_N \\ &\qquad - (\dot{\omega}_3 \cos\theta - \omega_3{}^2 \sin\theta)\boldsymbol{K}\big],\end{aligned} \tag{f6}$$

and so, *to within Appell-important terms* (i.e., those containing $\dot{\omega}$'s),

$$a_G{}^2 \equiv \boldsymbol{a}_G \cdot \boldsymbol{a}_G = r^2[(\dot{\omega}_3)^2 + (\dot{\omega}_4)^2] + 2r^2\omega_4(\dot{\omega}_3\,\omega_5 - \omega_3\,\dot{\omega}_5). \tag{f7}$$

(b) To calculate the relative Appellian $S^*{}_{/G}$ we need $\boldsymbol{\alpha}$. Here, it is more convenient to work with the *semimobile axes/basis* $G{-}x'y'z'/\boldsymbol{i}'\boldsymbol{j}'\boldsymbol{k}' \equiv G{-}nn'z'/\boldsymbol{u}_n\boldsymbol{u}_{n'}\boldsymbol{k}'$. Since

$$\boldsymbol{\omega} = (\dot{\theta})\boldsymbol{i}' + (\dot{\phi}\sin\theta)\,\boldsymbol{j}' + (\dot{\psi} + \dot{\phi}\cos\theta)\boldsymbol{k}' = \omega_3\,\boldsymbol{i}' + \omega_4\,\boldsymbol{j}' + \omega_5\,\boldsymbol{k}', \tag{f8}$$

and

$$\boldsymbol{\omega}_{\text{semimobile}} \equiv \boldsymbol{\omega}_{SM} = (\dot{\theta})\boldsymbol{i}' + (\dot{\phi}\sin\theta)\boldsymbol{j}' + (\dot{\phi}\cos\theta)\boldsymbol{k}', \tag{f9}$$

from which

$$\begin{aligned} d\boldsymbol{i}'/dt &= \boldsymbol{\omega}_{SM} \times \boldsymbol{i}' = (\dot{\theta},\, \dot{\phi}\sin\theta,\, \dot{\phi}\cos\theta) \times (1, 0, 0) \\ &= \dot{\phi}(\cos\theta\,\boldsymbol{j}' - \sin\theta\,\boldsymbol{k}') = \omega_4(\cot\theta\,\boldsymbol{j}' - \boldsymbol{k}'), \end{aligned} \tag{f10}$$

$$\begin{aligned} d\boldsymbol{j}'/dt &= \boldsymbol{\omega}_{SM} \times \boldsymbol{j}' = (\dot{\theta},\, \dot{\phi}\sin\theta,\, \dot{\phi}\cos\theta) \times (0, 1, 0) \\ &= -\dot{\phi}\cos\theta\,\boldsymbol{i}' + \dot{\theta}\,\boldsymbol{k}' = -\omega_4\cot\theta\,\boldsymbol{i}' + \omega_3\,\boldsymbol{k}', \end{aligned} \tag{f11}$$

$$\begin{aligned} d\boldsymbol{k}'/dt &= \boldsymbol{\omega}_{SM} \times \boldsymbol{k}' = (\dot{\theta},\, \dot{\phi}\sin\theta,\, \dot{\phi}\cos\theta) \times (0, 0, 1) \\ &= \dot{\phi}\sin\theta\,\boldsymbol{i}' - \dot{\theta}\,\boldsymbol{j}' = \omega_4\,\boldsymbol{i}' - \omega_3\,\boldsymbol{j}'; \end{aligned} \tag{f12}$$

we, therefore, find

$$\begin{aligned} \boldsymbol{\alpha} \equiv d\boldsymbol{\omega}/dt &= (d\boldsymbol{\omega}/dt)_{SM} + \boldsymbol{\omega}_{SM} \times \boldsymbol{\omega} = (d\boldsymbol{\omega}/dt)_{SM} + \boldsymbol{\omega}_{SM} \times (\boldsymbol{\omega}_{SM} + \dot{\psi}\,\boldsymbol{k}') \\ &= \cdots = [\dot{\omega}_3 + \omega_4(\omega_5 - \omega_4\cot\theta)]\boldsymbol{i}' \\ &\qquad + [\dot{\omega}_4 - \omega_3(\omega_5 - \omega_4\cot\theta)]\boldsymbol{j}' + \dot{\omega}_5\,\boldsymbol{k}', \end{aligned} \tag{f13}$$

and so, *to within Appell-important terms,*

$$\begin{aligned} \boldsymbol{\alpha} \times \boldsymbol{\omega} &= \cdots = (\dot{\omega}_4\,\omega_5 - \omega_4\,\dot{\omega}_5)\boldsymbol{i}' + (\dot{\omega}_5\,\omega_3 - \omega_5\,\dot{\omega}_3)\,\boldsymbol{j}' \\ &\qquad + (\dot{\omega}_3\,\omega_4 - \omega_3\,\dot{\omega}_4)\boldsymbol{k}', \end{aligned} \tag{f14}$$

$$\boldsymbol{I}_G \cdot \boldsymbol{\omega} = (mr^2/2)(\omega_3\,\boldsymbol{i}' + \omega_4\boldsymbol{j}' + 2\omega_4\,\boldsymbol{k}'), \tag{f15}$$

and, accordingly,

$$(\boldsymbol{\alpha} \times \boldsymbol{\omega}) \cdot (\boldsymbol{I}_G \cdot \boldsymbol{\omega}) = (mr^2/2)\omega_5(\dot{\omega}_3\omega_4 - \omega_3\dot{\omega}_4). \tag{f16}$$

Next, with the help of the decomposition (again, in semimobile components)

$$\begin{aligned}
&\boldsymbol{\alpha} = \boldsymbol{\alpha}' + \boldsymbol{\alpha}'',\\
&\qquad \boldsymbol{\alpha}' \equiv (\dot{\omega}_3, \dot{\omega}_4, \dot{\omega}_5),\\
&\qquad \boldsymbol{\alpha}'' \equiv \big(\omega_4(\omega_5 - \omega_4 \cot\theta), -\omega_3(\omega_5 - \omega_4 \cot\theta), 0\big),
\end{aligned} \tag{f17}$$

we find that, *to within Appell-important terms*,

$$\begin{aligned}
\boldsymbol{\alpha} \cdot \boldsymbol{I}_G \cdot \boldsymbol{\alpha} &= \boldsymbol{\alpha}' \cdot \boldsymbol{I}_G \cdot \boldsymbol{\alpha}' + 2(\boldsymbol{\alpha}'' \cdot \boldsymbol{I}_G \cdot \boldsymbol{\alpha}')\\
&= \cdots = mr^2\big\{[(\dot{\omega}_3/2)^2 + (\dot{\omega}_4/2)^2 + (\dot{\omega}_5)^2]\\
&\qquad + (\dot{\omega}_3\omega_4 - \omega_3\dot{\omega}_4)(\omega_5 - \omega_4 \cot\theta)\big\}.
\end{aligned} \tag{f18}$$

Finally, utilizing all the above results in (f1) we deduce that

$$\begin{aligned}
2S^*{}_o &= m{a_G}^2 + \boldsymbol{\alpha} \cdot \boldsymbol{I}_G \cdot \boldsymbol{\alpha} + 2(\boldsymbol{\alpha} \times \boldsymbol{\omega}) \cdot (\boldsymbol{I}_G \cdot \boldsymbol{\omega})\\
&= mr^2[3(\dot{\omega}_3)^2/2 + (\dot{\omega}_4)^2/2 + 2(\dot{\omega}_5)^2\\
&\quad + 2\omega_4(\dot{\omega}_3\omega_5 - \omega_3\dot{\omega}_5) + 2\omega_5(\dot{\omega}_3\omega_4 - \omega_3\dot{\omega}_4)\\
&\quad - \omega_4(\dot{\omega}_3\omega_4 - \omega_3\dot{\omega}_4)\cot\theta].
\end{aligned} \tag{f19}$$

(c) Hence, the three kinetic Appell equations are

$$\partial S^*{}_o/\partial\dot{\omega}_3 = mr^2[(3/2)\dot{\omega}_3 + 2\omega_4\,\omega_5 - (1/2)\cot\theta\,{\omega_4}^2] = \Theta_3, \tag{f20}$$

$$\partial S^*{}_o/\partial\dot{\omega}_4 = mr^2[(1/2)\dot{\omega}_4 + (1/2)\cot\theta\,\omega_3\,\omega_4 - \omega_3\,\omega_5] = \Theta_4, \tag{f21}$$

$$\partial S^*{}_o/\partial\dot{\omega}_5 = mr^2(2\dot{\omega}_5 - \omega_3\,\omega_4) = \Theta_5, \tag{f22}$$

and, of course, these coincide with the earlier (e21–23).

- To find the reactions, we need the *relaxed* Appellian $S^* = S^*(t; q_{1,\dots,5}; \omega_{1,\dots,5}; \dot{\omega}_{1,\dots,5})$; then, $(\partial S^*/\partial\dot{\omega}_1)_o = \Theta_1 + \lambda_1$, $(\partial S^*/\partial\dot{\omega}_2)_o = \Theta_2 + \lambda_2$, and these equations would, of course, coincide with the earlier (e19–20). The details are left to the reader.
- In view of the kinematico-inertial identity (3.5.25c): $(\partial S^*/\partial\dot{\omega}_{3,4,5})_o = \partial S^*{}_o/\partial\dot{\omega}_{3,4,5}$, if no reactions are sought there is no need to calculate S^*; $S^*{}_o$ will suffice.
- The above, hopefully, show the advantages of the (essentially Lagrangean) method of Hamel over that of Appell. The explicit calculation of accelerations is a rather expensive step! For alternative Appellian derivations of this problem, see also (alphabetically): Neimark and Fufaev (1972, pp. 149–156), Pérès (1953, pp. 224–226), Routh [1905(a), pp. 352–353].

Brief Analytical Discussion of the Kinetic Hoop Equations (e24–26)

The solution of these equations is facilitated by the introduction of the nutation angle θ as the independent variable, instead of the time t. Then, since $\dot{\theta} = \omega_3$, and with the notation $d(\dots)/d\theta \equiv (\dots)'$, we have

$$d\omega_I/dt = (d\omega_I/d\theta)(d\theta/dt), \qquad \text{or} \qquad \dot{\omega}_I = \omega_3\,{\omega_I}' \qquad (I = 3, 4, 5), \tag{g1}$$

and so the last two kinetic equations (e25, 26) transform, respectively, to

$$\omega_4{}' + (\cot\theta)\omega_4 - 2\omega_5 = 0, \qquad 2\omega_5{}' - \omega_4 = 0; \tag{g2}$$

and eliminating ω_4 between them yields the single θ-equation

$$\omega_5{}'' + (\cot\theta)\omega_5{}' - \omega_5 = 0. \tag{g3}$$

With the initial conditions

$$t = 0: \qquad \theta = \theta_o, \quad \omega_3 = \omega_{3o}, \quad \omega_4 = \omega_{4o} = 2\omega_{5o}{}', \quad \omega_5 = \omega_{5o},$$

the general solution of this linear and homogeneous but *variable coefficient* equation, to be obtained via *hypergeometric series*, will have the form

$$\omega_5 = \omega_5(\theta; \theta_o, \omega_{5o}, \omega_{5o}{}') = \omega_5(\theta; \theta_o, \omega_{5o}, \omega_{4o}/2) \equiv \omega_5(\theta; \theta_o, \omega_{4o}, \omega_{5o}). \tag{g4}$$

Then, ω_4 can be found by θ-differentiation; and since

$$\begin{aligned} d(\omega_3{}^2)/d\theta &= 2\omega_3(d\omega_3/d\theta) \\ &= 2\omega_3(d\omega_3/dt)(dt/d\theta) = 2[\omega_3(1/\dot{\theta})](d\omega_3/dt) = 2\dot{\omega}_3, \end{aligned} \tag{g5}$$

the first kinetic equation (e24) reduces to

$$d(3\omega_3{}^2/4)/d\theta = -(g/r)\cos\theta + (\cot\theta/2)\omega_4{}^2 - 2\omega_4\,\omega_5 = \text{known function of } \theta,$$

from which $\omega_3(\theta)$ may be found by a quadrature. Then, a final integration of $\dot{\theta} = \omega_3$ yields $\theta(t)$.

For full analytical treatments of these interesting equations, see, for example (alphabetically): Appell (1953, pp. 253–258, 386–388), Grammel (1950, pp. 235–245), MacMillan (1936, pp. 276–282), Neimark and Fufaev (1972, pp. 55–60, 155–156), Pars (1965, pp. 120–122), Webster (1912, pp. 307–316), Winkelmann and Grammel (1927, pp. 434–437).

Finally, for derivations of the equations of motion of this problem, in terms of the *coordinates of the contact point* of the hoop with the plane (instead of those of its mass center), and ϕ, θ, ψ, see, for example, Hamel [1949, pp. 470–471 (Routh–Voss equations), 448–479, 489–492, 778–781 (Hamel equations, stability of motion, etc.)], Rosenberg (1977, pp. 265–268, 338–340).

Brief Discussion of the Kinetostatic Hoop Equations (e19, 20)

Substituting into eqs. (e19, 20) $\dot{\omega}_3$ and $\dot{\omega}_5$ from the first and last of the kinetic equations, respectively, and recalling that $\Theta_{1,2} = 0$, we obtain the constraint reactions on the hoop, at its contact point C (figure 3.53):

Along Cx': $\qquad \Lambda_1 = \lambda_1 \equiv \lambda = (mr/2)\omega_3\,\omega_4, \qquad$ (h1)

Along CN:

$$\begin{aligned} \Lambda_2 = \lambda_2 \equiv \mu = -mr\{&\cos\theta(\omega_3{}^2 + \omega_4{}^2/3) \\ &+ [(1/\sin\theta) - (4\sin\theta/3)]\omega_4\,\omega_5 - (2g/3r)\sin\theta\cos\theta\}. \end{aligned} \tag{h2}$$

Once the (rotational) motion has been determined from the kinetic equations — that is, once $\omega_{3,4,5}$ and θ have been found as functions of t and the initial conditions — then (h1, 2) immediately yield the reactions as functions of the same variables. Of course, these forces can also be calculated by direct application of the Newton–Euler principle of linear momentum to the hoop, along the semifixed axes $G - x'NZ \equiv G - nNZ$—see, for example, Lur'e (1968, pp. 409–410).

Problem 3.18.12 Continuing from the preceding example, show that (under gravity only) the power, or energy rate, theorem yields the *first-order integral*

$$mr^2({\omega_3}^2 + {\omega_5}^2) + A({\omega_3}^2 + {\omega_4}^2) + C{\omega_5}^2 = -2m\,g\,r\sin\theta + constant, \tag{a}$$

or, since here $A = mr^2/2$ and $C = m\,r^2$,

$$3{\omega_3}^2 + {\omega_4}^2 + 4{\omega_5}^2 + 4(g/r)\sin\theta = constant. \tag{b}$$

Problem 3.18.13 Continuing from the preceding example, assume that, in addition to rolling, the hoop is constrained to remain *vertical*; that is, $\theta(t) = \pi/2$.

(i) Find its constraints and its Routh–Voss equations of motion.

(ii) For the special (constraint-satisfying) initial conditions

$$\begin{aligned} &\phi(0) = 0, \quad \dot\phi(0) = \dot\phi_o; \qquad \psi(0) = 0, \quad \dot\psi(0) = \dot\psi_o; \\ &x(0) = 0, \quad \dot x(0) = -r\,\dot\psi_o; \qquad y(0) = r, \quad \dot y(0) = 0, \end{aligned} \tag{a}$$

show that:

- The Lagrangean multiplier associated with the *tangential* direction Cx' vanishes; while
- The multiplier associated with the *normal* direction CN equals $mr\dot\phi_o\dot\psi_o/3 = constant$; and
- The hoop center G traces a circle of radius $r(\dot\psi_o/\dot\phi_o)$, with constant speed $(\dot X)^2 + (\dot Y)^2 = r^2(\dot\psi_o)^2$, and normal acceleration of magnitude $r\dot\phi_o\dot\psi_o$.

Problem 3.18.14 Continuing from the preceding example, consider its key kinetic equation (g3):

$$d^2\omega_5/d\theta^2 + (\cot\theta)(d\omega_5/d\theta) - \omega_5 = 0, \qquad \text{where} \ \ \omega_5 \equiv \dot\psi + \dot\phi\cos\theta = \omega_{z'}. \tag{a}$$

Show that the independent variable change $\theta \to \zeta = \cos^2\theta$ transforms the above to the *hypergeometric* equation

$$2\zeta(1-\zeta)(d^2\omega_5/d\zeta^2) + (1 - 3\zeta)(d\omega_5/d\zeta) - (1/2)\omega_5 = 0. \tag{b}$$

Then, show that a particular *infinite series* solution of this famous equation is

$$\omega_5 = \sum a_k\zeta^k = a_0 + a_1\zeta + a_2\zeta^2 + \cdots, \tag{c}$$

where

$$a_k/a_{k-1} = (4k^2 - 6k + 3)/2k(2k-1) \qquad (k = 1, 2, \ldots).$$

Problem 3.18.15 Consider again the hoop, but now rolling on a plane P, which *translates* with given (inertial) velocity (fig. 3.54)

$$\boldsymbol{v}_{\text{plane}} \equiv \boldsymbol{v}_P = \boldsymbol{v}_C = \big(v_X(t), v_Y(t), v_X(t)\big). \tag{a}$$

Also, assume for algebraic simplicity, but no loss in generality, that P is (and remains) horizontal.

(i) If X, Y, Z = inertial coordinates of the hoop center G [i.e., $Z = h(t) + r\sin\theta$, $v_Z(t) = dh(t)/dt$], show that the rolling constraints are (recall prob. 2.13.3)

$$[\dot{X} - v_X(t)]\cos\phi + [\dot{Y} - v_Y(t)]\sin\phi + r\,\dot{\phi}\cos\theta + r\,\dot{\psi} = 0, \tag{b}$$

$$-[\dot{X} - v_X(t)]\sin\phi + [\dot{Y} - v_Y(t)]\cos\phi + r\,\dot{\theta}\sin\theta = 0. \tag{c}$$

(ii) Show that the (inertial) potential and kinetic energies of the hoop are, respectively,

$$V = -m\,g[h(t) + r\sin\theta], \tag{d}$$

$$2T = m\{(\dot{X})^2 + (\dot{Y})^2 + [\dot{h}(t) + r\cos\theta\,\dot{\theta}]^2\}$$
$$+ A[(\dot{\theta})^2 + (\dot{\phi})^2\sin^2\theta] + C(\dot{\psi} + \dot{\phi}\cos\theta)^2 \qquad (C = 2A = 2B = m\,r^2); \tag{e}$$

and, therefore, verify that the corresponding Routh–Voss equations are (with $\lambda_{1,2}$ = multipliers)

$$m\ddot{X} = \lambda_1\cos\phi - \lambda_2\sin\phi, \tag{f}$$

$$m\ddot{Y} = \lambda_1\sin\phi + \lambda_2\cos\phi, \tag{g}$$

$$[A\,\dot{\phi}\sin^2\theta + C(\dot{\psi} + \dot{\phi}\cos\theta)\cos\theta]^{\cdot} = \lambda_1 r\cos\theta, \tag{h}$$

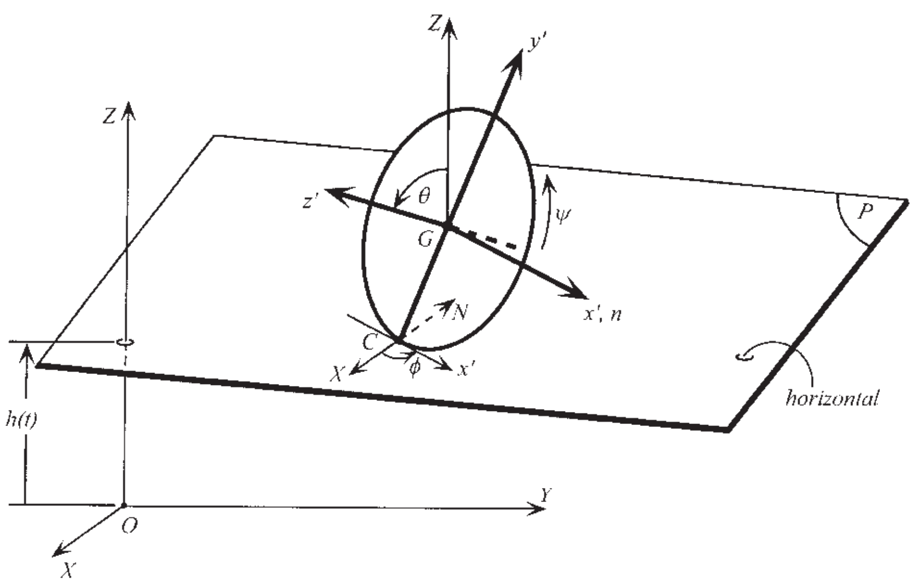

Figure 3.54 Hoop rolling on a translating horizontal plane.

$$m\,r\cos\theta\,[\ddot{h} + r(\sin\theta)^{\cdot\cdot}\,] + A[\ddot{\theta} - (\dot{\phi})^2\sin\theta\cos\theta]$$
$$+\, C(\dot{\psi} + \dot{\phi}\cos\theta)\dot{\phi}\sin\theta = -m\,g\,r\cos\theta + \lambda_2\,r\sin\theta, \tag{i}$$
$$C(\dot{\psi} + \dot{\phi}\cos\theta)^{\cdot} = \lambda_1\,r. \tag{j}$$

(iii) Eliminating $\lambda_{1,2}$ from the above Routh–Voss equations (f–j), and then $\ddot{X}$, $\ddot{Y}$ via the [once $(\ldots)^{\cdot}$-differentiated] constraints (b, c), verify that the three (kinetic) Chaplygin–Voronets equations of this problem are

$$A\,\ddot{\phi}\sin\theta - C\,\dot{\theta}\,\dot{\psi} = 0, \tag{k}$$
$$(C + m\,r^2)(\dot{\phi}\cos\theta + \dot{\psi})^{\cdot} - m\,r^2\dot{\phi}\,\dot{\theta}\sin\theta$$
$$= m\,r[\dot{v}_X(t)\cos\phi + \dot{v}_Y(t)\sin\phi], \tag{l}$$
$$(A + m\,r^2)\ddot{\theta} - A(\dot{\phi})^2\sin\theta\cos\theta + (C + m\,r^2)\sin\theta\,\dot{\phi}(\dot{\phi}\cos\theta + \dot{\psi})$$
$$= -m\,g\,r\cos\theta - m\,r[\dot{v}_X(t)\sin\phi\sin\theta - \dot{v}_Y(t)\cos\phi\sin\theta + \dot{v}_Z(t)\cos\theta]; \tag{m}$$

and that along, with the constraints (b, c), they constitute a determinate system for $X(t)$, $Y(t)$, $\phi(t)$, $\theta(t)$, $\psi(t)$. Then, in both (ii) and here, $Z(t) = h(t) + r\sin\theta(t)$. Notice that (a) the terms due to the translation of the plane appear as additional "forces" on the right sides of (l) and (m), and equal, respectively, $mr\boldsymbol{a}_P(t)\cdot\boldsymbol{i}'$ and $-mr\boldsymbol{a}_P(t)\cdot\boldsymbol{k}'$, where $\boldsymbol{a}_P(t) \equiv d\boldsymbol{v}_P(t)/dt = (\dot{v}_X(t),\ \dot{v}_Y(t),\ \dot{v}_Z(t))$, $\boldsymbol{i}' \equiv \boldsymbol{u}_n = (\cos\phi,\ \sin\phi,\ 0)$, $\boldsymbol{k}' = (\sin\phi\sin\theta,\ -\cos\phi\sin\theta,\ \cos\theta)$; and that (b) here, too, the Lagrangean method shows its superiority over the momentum method of Newton–Euler.

Problem 3.18.16 Continuing from the preceding problem, examine the special motion where *P remains fixed* [or, equivalently, translates *uniformly*: $dv_{X,Y,Z}(t)/dt = 0 \Rightarrow v_{X,Y,Z}(t) = constant \equiv c_{X,Y,Z}$*], and the hoop rolls at a constant nutation angle* $\theta(t) = constant \equiv \theta_o$.

(i) After verifying that such a motion is possible, show that, then, the first two Chaplygin–Voronets equations, (k, l), yield

$$\dot{\phi} = constant \equiv \dot{\phi}_o, \qquad \dot{\psi} = constant \equiv \dot{\psi}_o; \tag{a}$$

while the third of them, (m), reduces to

$$-A(\dot{\phi}_o)^2\sin\theta_o\cos\theta_o + (C + mr^2)\sin\theta_o\,\dot{\phi}_o(\dot{\phi}_o\cos\theta_o + \dot{\psi}_o) = -m\,g\,r\cos\theta_o. \tag{b}$$

(ii) Then, using the constraints, eqs. (b, c) of the preceding problem, show that

$$\dot{X} - c_X = -r(\dot{\phi}_o\cos\theta_o + \dot{\psi}_o)\cos(\dot{\phi}_o\,t), \qquad \dot{Y} - c_Y = -r(\dot{\phi}_o\cos\theta_o + \dot{\psi}_o)\sin(\dot{\phi}_o\,t). \tag{c}$$

Discuss particular cases of this special motion; for example, $\theta_o = \pi/2$ $(\Rightarrow, \dot{\phi}_o, \dot{\psi}_o = \cdots)$, $\theta_o \neq \pi/2\ (\Rightarrow \dot{\phi}_o, \dot{\psi}_o = \cdots)$.

Problem 3.18.17 Examine the problem of a hoop rolling on a *uniformly rotating horizontal and rough platform*; that is, formulate its constraints in any convenient set of coordinates, write down its transitivity equations, and then obtain its Routh–Voss, Hamel, and Appell equations, with or without reactions.

Problem 3.18.18 Examine the earlier problems of the (sliding) sled and (rolling) sphere, but on a *translating* platform; that is, obtain their constraints, transitivity equations, and various equations of motion.

Example 3.18.6 *Dynamics of Pair of Rolling Wheels on an Axle.* Let us determine the motion and reactions of a system consisting of two identical homogeneous wheels, mounted on a light axle, and each capable of turning freely about it, and rolling on a fixed, horizontal, and rough plane (fig. 3.55).

The kinematics of this system has already been discussed in ex. 2.13.8. It was found there that $q_{1,\ldots,5} = X,\ Y,\ \phi,\ \psi',\ \psi''$, and that the rolling constraints are

$$\dot{X}\cos\phi + \dot{Y}\sin\phi = 0, \tag{a1}$$

$$-\dot{X}\sin\phi + \dot{Y}\cos\phi + b\,\dot{\phi} + r\,\dot{\psi}' = 0, \tag{a2}$$

$$-\dot{X}\sin\phi + \dot{Y}\cos\phi - b\,\dot{\phi} + r\,\dot{\psi}'' = 0; \tag{a3}$$

or, since the last two of them yield the *integrable* combination (with $c =$ integration constant, depending on the initial values of $\phi,\ \psi',\ \psi''$)

$$2b\dot{\phi} + r(\dot{\psi}' - \dot{\psi}'') = 0 \ \Rightarrow\ 2b\phi = c - r(\psi' - \psi''), \tag{a4}$$

we may take, as the two independent Pfaffian constraints,

$$\dot{X}\cos\phi + \dot{Y}\sin\phi = 0, \tag{b1}$$

$$-\dot{X}\sin\phi + \dot{Y}\cos\phi + (r/2)(\dot{\psi}' + \dot{\psi}'') = 0. \tag{b2}$$

For the purposes of the Routh–Voss equations (see below), a further simplification of these constraints is possible: (a) multiplying the first of them by $\sin\phi$ and the second by $\cos\phi$ and adding together yields

$$\dot{Y} + (r/2)(\dot{\psi}' + \dot{\psi}'')\cos\phi = 0; \tag{b3}$$

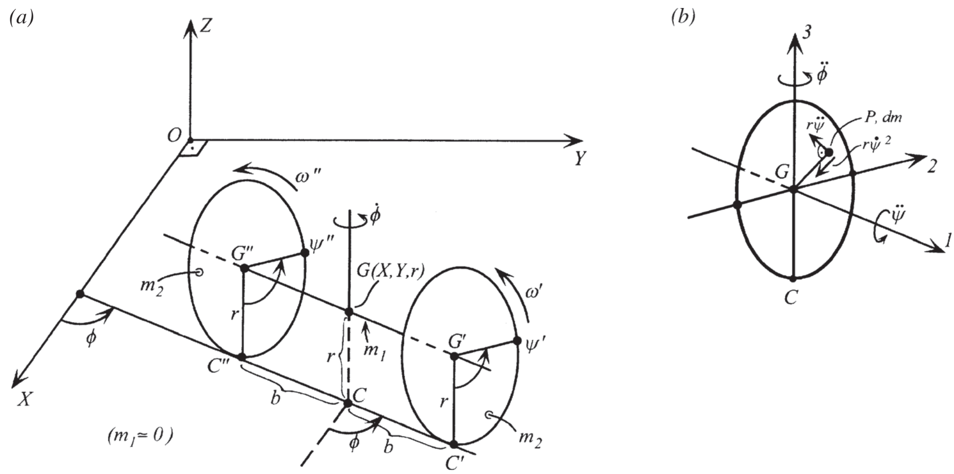

Figure 3.55 (a) Rolling of two wheels on an axle, on a fixed plane; (b) acceleration components needed for calculation of Appellian.

while (b) multiplying the first of them by $\cos\phi$ and the second by $-\sin\phi$ and adding together yields

$$\dot{X} - (r/2)(\dot{\psi}' + \dot{\psi}'')\sin\phi = 0; \tag{b4}$$

and then (c) eliminating $\dot{\psi}''$ from these two with the help of the integrable relation (a4, for $b = r$): $2b\,\dot{\phi} + r(\dot{\psi}' - \dot{\psi}'') = 0 \Rightarrow \dot{\psi}'' = 2\dot{\phi} + \dot{\psi}'$, finally results in the two new Pfaffian constraints

$$\dot{X} - r(\dot{\psi}' + \dot{\phi})\sin\phi = 0, \qquad \dot{Y} + r(\dot{\psi}' + \dot{\phi})\cos\phi = 0. \tag{b5}$$

In view of the above, we introduce the following quasi velocities:

$$\omega_1 \equiv \dot{\theta}_1 \equiv \dot{X}\cos\phi + \dot{Y}\sin\phi \qquad (= 0), \tag{c1}$$

$$\omega_2 \equiv \dot{\theta}_2 \equiv -\dot{X}\sin\phi + \dot{Y}\cos\phi \quad (\neq 0), \tag{c2}$$

$$\omega_3 \equiv \dot{\theta}_3 \equiv \dot{\phi} \qquad (\neq 0), \tag{c3}$$

$$\begin{aligned}\omega_4 \equiv \dot{\theta}_4 &\equiv r(\dot{\psi} + \dot{\psi}'') + 2(-\dot{X}\sin\phi + \dot{Y}\cos\phi) \\ &= r(\dot{\psi}' + \dot{\psi}'') + 2\omega_2 \quad (= 0),\end{aligned} \tag{c4}$$

$$\omega_5 \equiv \dot{\theta}_5 \equiv 2b\,\dot{\phi} + r(\dot{\psi}' - \dot{\psi}'') \quad (= 0). \tag{c5}$$

The above invert easily to

$$\dot{X} = (\cos\phi)\omega_1 + (-\sin\phi)\omega_2, \tag{c6}$$

$$\dot{Y} = (\sin\phi)\omega_1 + (\cos\phi)\omega_2, \tag{c7}$$

$$\dot{\phi} = (0)\omega_1 + (0)\omega_2 + (1)\omega_3, \tag{c8}$$

$$\dot{\psi}' = (1/2r)(-2\omega_2 - 2r\,\omega_3 + \omega_4 - \omega_5), \tag{c9i}$$

$$\dot{\psi}'' = (1/2r)(-2\omega_2 + 2r\,\omega_3 + \omega_4 - \omega_5). \tag{c9ii}$$

From (c1–9i), we readily obtain the following transitivity equations:

$$(\delta\theta_1)^{\cdot} - \delta\omega_1 = (\omega_3)\,\delta\theta_2 + (-\omega_2)\,\delta\theta_3, \tag{d1}$$

$$(\delta\theta_2)^{\cdot} - \delta\omega_2 = (-\omega_3)\,\delta\theta_1 + (\omega_1)\,\delta\theta_3, \tag{d2}$$

$$(\delta\theta_3)^{\cdot} - \delta\omega_3 = 0, \tag{d3}$$

$$(\delta\theta_4)^{\cdot} - \delta\omega_4 = (-2\omega_3)\,\delta\theta_1 + (2\omega_1)\,\delta\theta_3, \tag{d4}$$

$$(\delta\theta_5)^{\cdot} - \delta\omega_5 = 0. \tag{d5}$$

The Routh–Voss Equations

Applying König's theorem (plus parallel axis theorem for moments of inertia), we obtain

$$\begin{aligned}2T = (m_1 + 2m_2)[(\dot{X})^2 + (\dot{Y})^2] + (m_1 b^2/3)(\dot{\phi})^2 \\ + 2[(m_2 r^2/4) + m_2 b^2](\dot{\phi})^2 + (m_2 r^2/2)[(\dot{\psi}')^2 + (\dot{\psi}'')^2],\end{aligned} \tag{e1}$$

or, for the special case, to be examined here for algebraic simplicity, $m_1 = 0$, $m_2 \equiv m$ (= mass of *each* wheel), $b = r$:

$$T = m[(\dot{X})^2 + (\dot{Y})^2] + (mr^2/4)[(\dot{\psi}')^2 + (\dot{\psi}'')^2 + 5(\dot{\phi})^2]. \tag{e2}$$

Hence, the *five* Routh–Voss equations corresponding to (e1) and (b5) are (with multipliers $\lambda_1 \equiv \lambda$ and $\lambda_2 \equiv \mu$; and with impressed force components to be calculated from the invariant differential $\delta' W = Q_X \,\delta X + Q_Y \,\delta Y + Q_\phi \,\delta\phi + Q_{\psi'} \,\delta\psi' + Q_{\psi''} \,\delta\psi''$, as if the δq's were unconstrained)

$$X: \qquad (2m)\ddot{X} = Q_X + \lambda, \tag{e3}$$

$$Y: \qquad (2m)\ddot{Y} = Q_Y + \mu, \tag{e4}$$

$$\phi: \qquad (5mr^2/2)\,\ddot{\phi} = Q_\phi + r(-\lambda \sin\phi + \mu\cos\phi), \tag{e5}$$

$$\psi': \qquad (mr^2/2)\,\ddot{\psi}' = Q_{\psi'} + r(-\lambda \sin\phi + \mu\cos\phi), \tag{e6}$$

$$\psi'': \qquad (mr^2/2)\,\ddot{\psi}'' = Q_{\psi''}. \tag{e7}$$

If all Q's vanish (*free* motion), the above yield the *two* obvious integrals

$$\dot{\psi}'' = constant,$$

$$(5mr^2/2)\dot{\phi} - (mr^2/2)\dot{\psi}' = constant \;\Rightarrow\; 5\dot{\phi} - \dot{\psi}' = constant. \tag{e8}$$

A *third* integral results as follows: first, we rewrite the two Pfaffian constraints as

$$\dot{X}\cos\phi + \dot{Y}\sin\phi = 0, \tag{e9}$$

$$\dot{X}\sin\phi - \dot{Y}\cos\phi = r(\dot{\phi} + \dot{\psi}'); \tag{e10}$$

then we $(\ldots)^{\cdot}$-differentiate the first of them and take into account the second. The result is

$$\ddot{X}\sin\phi - \ddot{Y}\cos\phi = r(\ddot{\phi} + \ddot{\psi}')$$

$$= (1/2m)(\lambda\sin\phi - \mu\cos\phi) = -[mr/2(2m)]\ddot{\psi}' = -(r/4)\ddot{\psi}';$$

and from this, by rearrangement and integration, it follows that

$$(4m)\dot{\phi} + (5m)\dot{\psi}' = constant \;\Rightarrow\; 4\dot{\phi} + 5\dot{\psi}' = constant.$$

These integrals show that the angles ϕ, ψ', ψ'' vary *linearly* in time; in which case, the constraints integrate easily to

$$\dot{X} = r(constant)\sin\phi = (constant)\;Y, \tag{e11}$$

$$\dot{Y} = -r(constant)\cos\phi = -(constant)\;X; \tag{e12}$$

that is, the path of G is a *circle*, parallel to the plane $Z = 0$, of radius $R = r|(\dot{\phi}_o + \dot{\psi}_o{}')/\dot{\phi}_o|$, described at the *uniform* rate $\dot{\phi}_o$. Indeed, we have

$$v_G{}^2 = (\dot{X})^2 + (\dot{Y})^2 = (R\dot{\phi}_o)^2 \;\Rightarrow\; (\dot{\phi}_o + \dot{\psi}_o{}')^2 r^2 = (\dot{\phi}_o)^2 R^2, \quad \text{Q.E.D.}$$

[The third integral also results, more simply, from the *constancy of T* (by energy conservation; and since, here, λ and μ are workless), if in there [eq. (e2)] using the constraints (b5), we replace $(\dot{X})^2 + (\dot{Y})^2$ with $r^2(\dot{\phi} + \dot{\psi}')^2$. Then, we obtain a *constant coefficient* relation between $(\dot{\phi})^2$ and $(\dot{\psi}')^2$, from which it follows that $\dot{\phi}$ and $\dot{\psi}'$ are constants, like $\dot{\psi}''$. The earlier argument, however, may apply to more general problems.]

Finally, inserting $\dot{X}$ and $\dot{Y}$ from (e11, 12) into the first two equations of motion, (e3, 4), yields the two constraint reactions λ and μ. For additional insights, see, for example, Pérès (1953, pp. 213–214), Rosenberg (1977, pp. 340–345).

The Hamel Equations

From the $\dot{q} \leftrightarrow \omega$ relations (c6–9), we easily find

$$(\dot{X})^2 + (\dot{Y})^2 = {\omega_1}^2 + {\omega_2}^2, \tag{f1}$$

$$(\dot{\psi}')^2 + (\dot{\psi}'')^2 = (1/2r^2)[(\omega_4 - 2\omega_2)^2 + (\omega_5 - 2r\,\omega_3)^2], \tag{f2}$$

$$(\dot{\phi})^2 = {\omega_3}^2, \tag{f3}$$

and, therefore,

$$T \to T^* = \cdots = (m){\omega_1}^2 + (3m/2){\omega_2}^2 + (7mr^2/4){\omega_3}^2 + (m/8)({\omega_4}^2 + {\omega_5}^2) + (-m/2)\omega_2\,\omega_4 + (-mr/2)\omega_3\,\omega_5, \tag{f4}$$

with no constraint enforcement yet. However, in view of the constraints $\omega_{1,4,5} = 0$, the (quadratic) *first* and *fourth* terms/summands in (f4) can be safely neglected at this stage; that is, finally, to within *Hamel-important terms*,

$$T^* = (3m/2){\omega_2}^2 + (7mr^2/4){\omega_3}^2 + (-m/2)\omega_2\omega_4 + (-mr/2)\omega_3\omega_5. \tag{f5}$$

Next:

(a) The *nonholonomic momenta* $P_k \equiv (\partial T^*/\partial\omega_k)_o$ $(k = 1, \ldots, 5)$ and their $(\ldots)^{\cdot}$-derivatives are

$$P_1 = 0 \;\Rightarrow\; \dot{P}_1 = 0, \tag{f6}$$

$$P_2 = (3m)\omega_2 \;\Rightarrow\; \dot{P}_2 = (3m)\dot{\omega}_2, \tag{f7}$$

$$P_3 = (7mr^2/2)\omega_3 \;\Rightarrow\; \dot{P}_3 = (7mr^2/2)\dot{\omega}_3, \tag{f8}$$

$$P_4 = (-m/2)\omega_2 \;\Rightarrow\; \dot{P}_4 = (-m/2)\dot{\omega}_2, \tag{f9}$$

$$P_5 = (-mr/2)\omega_3 \;\Rightarrow\; \dot{P}_5 = (-mr/2)\dot{\omega}_3. \tag{f10}$$

(b) Since $(\partial T^*/\partial q_k)_o = 0$ $(k = 1, \ldots, 5)$, we will have

$$\partial T^*/\partial\theta_l \equiv \sum A_{kl}(\partial T^*/\partial q_k) = 0 \qquad (l = 1, \ldots, 5). \tag{f11}$$

(c) In view of (d1–5) and (f6–10), the fundamental noncommutativity term $\Gamma \equiv \sum P_k[(\delta\theta_k)^{\cdot} - \delta\omega_k]$, upon enforcing the constraints $\omega_{1,4,5} = 0$ (but *not* $\delta\theta_{1,4,5} = 0$, since we want reactions too) becomes

$$\begin{aligned}\Gamma &= P_1(\omega_3\,\delta\theta_2 - \omega_2\,\delta\theta_3) + P_2(-\omega_3\,\delta\theta_1 + \omega_1\,\delta\theta_3) + P_3(0)\\ &\quad + P_4(-2\omega_3\,\delta\theta_1 + 2\omega_1\,\delta\theta_3) + P_5(0)\\ &= -(P_2 + 2P_4)\omega_3\,\delta\theta_1. \end{aligned} \tag{f12}$$

(d) The nonholonomic impressed force components, Θ_k, are obtained as follows [with use of virtual form of (c6–9), and calculated as if the constraints $\delta\theta_{1,4,5} = 0$ did not exist]:

$$\begin{aligned}\delta' W &= Q_X\,\delta X + Q_Y\,\delta Y + Q_\phi\,\delta\phi + Q_{\psi'}\,\delta\psi' + Q_{\psi''}\,\delta\psi''\\ &= Q_X(\cos\phi\,\delta\theta_1 - \sin\phi\,\delta\theta_2) + Q_Y(\sin\phi\,\delta\theta_1 + \cos\phi\,\delta\theta_2) + Q_\phi\,\delta\theta_3\\ &\quad + Q_{\psi'}(1/2r)(-2\,\delta\theta_2 - 2r\,\delta\theta_3 + \delta\theta_4 + \delta\theta_5)\\ &\quad + Q_{\psi''}(1/2r)(-2\,\delta\theta_2 + 2r\,\delta\theta_3 + \delta\theta_4 - \delta\theta_5)\\ &= (Q_X\cos\phi + Q_Y\sin\phi)\,\delta\theta_1 + [-Q_X\sin\phi + Q_Y\cos\phi - r^{-1}(Q_{\psi'} + Q_{\psi''})]\,\delta\theta_2\\ &\quad + [Q_\phi - (Q_{\psi'} - Q_{\psi''})]\,\delta\theta_3 + (2r)^{-1}(Q_{\psi'} + Q_{\psi''})\,\delta\theta_4\\ &\quad + (2r)^{-1}(Q_{\psi'} - Q_{\psi''})\,\delta\theta_5\\ &\equiv \Theta_1\,\delta\theta_1 + \Theta_2\,\delta\theta_2 + \Theta_3\,\delta\theta_3 + \Theta_4\,\delta\theta_4 + \Theta_5\,\delta\theta_5. \end{aligned} \tag{f13}$$

Substituting all these results into the, by now, well-known nonholonomic version of LP, and applying to it the method of Lagrangean multipliers for $(\ldots)\,\delta\theta_{1,4,5}$, we eventually obtain the Hamel equations (nonholonomic variables), and, next to them, the Maggi equations (holonomic variables):

$$\begin{aligned} &\theta_1\!: \quad -(P_2 + 2P_4)\omega_3 = \Theta_1 + \lambda_1 \;\Rightarrow\; -2m\,\omega_2\,\omega_3 = -2m(-\dot{X}\sin\phi + \dot{Y}\cos\phi)\dot{\phi} = \Theta_1 + \lambda_1,\\ &\theta_2\!: \quad \dot{P}_2 + P_1\omega_3 = \Theta_2 \;\Rightarrow\; 3m\,\dot{\omega}_2 = 3m(-\dot{X}\sin\phi + \dot{Y}\cos\phi)^{\cdot} = \Theta_2,\\ &\theta_3\!: \quad \dot{P}_3 - P_1\omega_2 = \Theta_3 \;\Rightarrow\; (7mr^2/2)\,\dot{\omega}_3 = (7mr^2/2)\ddot{\phi} = \Theta_3,\\ &\theta_4\!: \quad \dot{P}_4 = \Theta_4 + \lambda_4 \;\Rightarrow\; (-m/2)\,\dot{\omega}_2 = (-m/2)(-\dot{X}\sin\phi + \dot{Y}\cos\phi)^{\cdot} = \Theta_4 + \lambda_4,\\ &\theta_5\!: \quad \dot{P}_5 = \Theta_5 + \lambda_5 \;\Rightarrow\; (-mr/2)\,\dot{\omega}_3 = (-mr/2)\ddot{\phi} = \Theta_5 + \lambda_5. \end{aligned} \tag{f14–18}$$

Again, for the *force–free* motion (i.e., all Θ_k's $= 0$), and recalling the constraints (a2): $-\dot{X}\sin\phi + \dot{Y}\cos\phi + r(\dot{\phi} + \dot{\psi}') = 0$, and (a4): $2\dot{\phi} + (\dot{\psi}' - \dot{\psi}'') = 0$, we conclude from the $\theta_{2,3}$-equations that $\dot{\phi} + \dot{\psi}' = constant$, $\dot{\phi} = constant \Rightarrow \dot{\psi}' = constant$, $(\psi'')^{\cdot} = constant$. Further, it follows that, here, θ_5-equation: $\lambda_5 = 0$; θ_4-equation: $\lambda_4 = 0$; θ_1-equation: $\lambda_1 = constant$.

For the related problem of the *two-wheeled street vendor's cart* (where only the algebra is slightly more complicated than here), see, for example, Hamel (1949, pp. 471–472, 479, 484–485).

The Appell Equations

(No reactions, only motion; i.e., equations for $k \to I = 2, 3$; not $k \to D = 1, 4, 5$.)

(i) *Elementary nonvectorial solution*. Here, with $(X_{G''}, Y_{G''}) =$ (inertial) coordinates of G'' and $(X_{G'}, Y_{G'}) =$ (inertial) coordinates of G', we have [fig. 3.55(a) and (b)]

$$X_{G''} = X - r\cos\phi \;\Rightarrow\; (X_{G''})^{\cdot\cdot} = \ddot{X} + r\cos\phi(\dot{\phi})^2 + r\sin\phi\,\ddot{\phi}, \tag{g1}$$

$$Y_{G''} = Y - r\sin\phi \;\Rightarrow\; (Y_{G''})^{\cdot\cdot} = \ddot{Y} + r\sin\phi(\dot{\phi})^2 - r\cos\phi\,\ddot{\phi}, \tag{g2}$$

$$X_{G'} = X + r\cos\phi \;\Rightarrow\; (X_{G'})^{\cdot\cdot} = \ddot{X} - r\cos\phi(\dot{\phi})^2 - r\sin\phi\,\ddot{\phi}, \tag{g3}$$

$$Y_{G'} = Y + r\sin\phi \;\Rightarrow\; (Y_{G'})^{\cdot\cdot} = \ddot{Y} - r\sin\phi(\dot{\phi})^2 + r\cos\phi\,\ddot{\phi}, \tag{g4}$$

and, therefore, using the Appellian version of König's theorem, we find the Appellians

$$G''\text{ wheel:}\qquad 2S_{G''} = m[(\ddot{X}_{G''})^2 + (\ddot{Y}_{G''})^2] + \{(mr^2/2)(\ddot{\psi}'')^2 + (mr^2/4)(\ddot{\phi})^2\},$$

$$G'\text{ wheel:}\qquad 2S_{G'} = m[(\ddot{X}_{G'})^2 + (\ddot{Y}_{G'})^2] + \{(mr^2/2)(\ddot{\psi}')^2 + (mr^2/4)(\ddot{\phi})^2\}.$$

From the above, it follows that, to *within Appell-important terms* and with constraints enforced,

$$\begin{aligned}
2S_{\text{entire system}} &= 2S_{G''} + 2S_{G'} \\
&= \cdots = m[(\ddot{X})^2 + (\ddot{Y})^2 + r^2(\ddot{\phi})^2 + 2r\,\ddot{\phi}(\ddot{X}\cos\phi + \ddot{Y}\sin\phi) \\
&\qquad + 2r\,\ddot{\phi}(\ddot{X}\sin\phi - \ddot{Y}\cos\phi)] \\
&\qquad + (mr^2/2)\{(\ddot{\psi}'')^2 + (1/2)(\ddot{\phi})^2\} \\
&\qquad + m[(\ddot{X})^2 + (\ddot{Y})^2 + r^2(\ddot{\phi})^2 + 2r\ddot{\phi}(-\ddot{X}\cos\phi + \ddot{Y}\sin\phi) \\
&\qquad - 2r\,\ddot{\phi}(\ddot{X}\cos\phi + \ddot{Y}\sin\phi)] \\
&\qquad + (mr^2/2)\big[(\ddot{\psi}')^2 + (1/2)(\ddot{\phi})^2\big] \\
&= 2m[(\ddot{X})^2 + (\ddot{Y})^2] \\
&\qquad + 2(mr^2/4)\big[(\ddot{\psi}'')^2 + (\ddot{\psi}')^2 + 5(\ddot{\phi})^2\big];
\end{aligned} \tag{g5}$$

that is, $2T$, eq. (e2), but with the $\dot{q}$'s replaced by the corresponding $\ddot{q}$'s (= *homogeneous* quadratic in the $\ddot{q}$'s). Next, since $\partial\ddot{q}/\partial\dot{\omega} = \partial\dot{q}/\partial\omega$, and recalling the $\dot{q} \Leftrightarrow \omega$ relations (c6–9), we find

$$
\begin{aligned}
\partial S^*/\partial\dot{\omega}_2 &= (\partial S/\partial\ddot{X})(\partial\dot{X}/\partial\omega_2) + (\partial S/\partial\ddot{Y})(\partial\dot{Y}/\partial\omega_2) + (\partial S/\partial\ddot{\phi})(\partial\dot{\phi}/\partial\omega_2) \\
&\quad + (\partial S/\partial\ddot{\psi}'')(\partial\dot{\psi}''/\partial\omega_2) + (\partial S/\partial\ddot{\psi}')(\partial\dot{\psi}'/\partial\omega_2) \\
&= (2m\ddot{X})(-\sin\phi) + (2m\ddot{Y})(\cos\phi) + (5mr^2\ddot{\phi}/2)(0) \\
&\quad + (mr^2\ddot{\psi}''/2)(-r^{-1}) + (mr^2\ddot{\psi}'/2)(-r^{-1}) \\
&= 2m(-\ddot{X}\sin\phi + \ddot{Y}\cos\phi) - (mr/2)(\ddot{\psi}'' + \ddot{\psi}') \\
&= 2m(-r\ddot{\phi} - r\ddot{\psi}') - (mr/2)(\ddot{\psi}'' + \ddot{\psi}') \\
&= -2mr[(\ddot{\psi}'' - \ddot{\psi}')/2] - 2mr\ddot{\psi}' - (mr/2)\ddot{\psi}' - (mr/2)\ddot{\psi}'' \\
&= -(3mr/2)(\ddot{\psi}'' + \dot{\psi}') \\
&= -(3mr/2)[(-r^{-1}\dot{\omega}_2 - \dot{\omega}_3) + (-r^{-1}\dot{\omega}_2 + \dot{\omega}_3)] \\
&= -(3mr/2)(-2r^{-1}\dot{\omega}_2) = 3m\,\dot{\omega}_2, \qquad \text{(g6)}
\end{aligned}
$$

and, similarly,

$$
\begin{aligned}
\partial S^*/\partial\dot{\omega}_3 &= (2m\ddot{X})(0) + (2m\ddot{Y})(0) \\
&\quad + (5mr^2\ddot{\phi}/2)(1) + (mr^2\ddot{\psi}''/2)(-1) + (mr^2\ddot{\psi}'/2)(1) \\
&= (mr^2/2)(\ddot{\psi}'' - \ddot{\psi}' + 5\ddot{\phi}) \\
&= (mr^2/2)(2\ddot{\phi} + 5\ddot{\phi}) = (7mr^2/2)\ddot{\phi} = (7mr^2/2)\dot{\omega}_3; \qquad \text{(g7)}
\end{aligned}
$$

and these are precisely the left (i.e., inertia) sides of the earlier *second* and *third* equations of Hamel. To derive the *first, fourth,* and *fifth* Appellian equations, we use again S, apply the chain rule

$$
\partial S^*/\partial\dot{\omega}_k = \sum (\partial S/\partial\ddot{q}_l)(\partial\dot{q}_l/\partial\omega_k) \qquad (l = 1, \ldots, 5), \qquad \text{(g8)}
$$

and then impose the constraints $\omega_{1,4,5} = 0$; that is, *after* the differentiations—not before them! The details are left to the reader.

(ii) *Vectorial solution*. For *each* wheel, we shall have [recalling (3.14.4a ff.)]:

$$
2S = m\,a_G{}^2 + \boldsymbol{\alpha}\cdot(\boldsymbol{I}_G\cdot\boldsymbol{\alpha}) + (\boldsymbol{\alpha}\times\boldsymbol{\omega})\cdot(\boldsymbol{I}_G\cdot\boldsymbol{\omega}). \qquad \text{(g9)}
$$

But here (using the notation of the first Appellian solution):

$$
a_G{}^2 = (\ddot{X}_{G''})^2 + (\ddot{Y}_{G''})^2, \qquad \text{or} \qquad (\ddot{X}_{G'})^2 + (\ddot{Y}_{G'})^2, \qquad \text{(g10)}
$$

and along the *intermediate* but principal axes G–123 (fig. 3.55b), which have inertial angular velocity $(0, 0, \dot{\phi})$, we easily find

$$
\begin{aligned}
&\boldsymbol{\omega} = (\dot{\psi}, 0, \dot{\phi}) \\
&\Rightarrow \boldsymbol{\alpha} = d\boldsymbol{\omega}/dt = (\ddot{\psi}, 0, \ddot{\phi}) + (0, 0, \dot{\phi}) \times (\dot{\psi}, 0, \dot{\phi}) = (\ddot{\psi}, -\dot{\psi}\,\dot{\phi}, \ddot{\phi}), \\
&\boldsymbol{I}_G = \mathit{diagonal}\,(mr^2/2, mr^2/4, mr^2/4), \qquad \text{(g11)}
\end{aligned}
$$

and, therefore,

$$(\boldsymbol{\alpha} \times \boldsymbol{\omega}) \cdot (\boldsymbol{I}_G \cdot \boldsymbol{\omega}) = [(\ddot{\psi}, -\dot{\psi}\dot{\phi}, \ddot{\phi}) \times (\dot{\psi}, 0, \dot{\phi})] \cdot (mr^2\dot{\psi}/2, 0, mr^2\dot{\phi}/4)$$
$$= \cdots = -(mr^2/2)(\dot{\psi})^2(\dot{\phi})^2 = \textit{non–Appell-important}\ \text{term}, \quad \text{(g12)}$$

and

$$\boldsymbol{\alpha} \cdot (\boldsymbol{I}_G \cdot \boldsymbol{\alpha}) = [(\ddot{\psi}, -\dot{\psi}\dot{\phi}, \ddot{\phi}) \cdot (mr^2\ddot{\psi}/2, -mr^2\dot{\psi}\dot{\phi}/4, mr^2\ddot{\phi}/4)$$
$$= mr^2(\ddot{\psi})^2/2 + mr^2(\dot{\psi})^2(\dot{\phi})^2/4 + mr^2(\ddot{\phi})^2/4$$
$$= (mr^2/2)\left[(\ddot{\psi})^2 + (1/2)(\ddot{\phi})^2\right] + \textit{non–Appell-important}\ \text{term}; \quad \text{(g13)}$$

that is, *for each wheel, and to within Appell-important terms*,

$$2S = m{a_G}^2 + (mr^2/2)[(\ddot{\psi})^2 + (1/2)(\ddot{\phi})^2], \quad \text{(g14)}$$

and, adding these partial results, we re-establish the earlier entire system Appellian.

Example 3.18.7 *Dynamics of Pair of Rolling Wheels on an Inclined Plane.* Continuing from the preceding example, let us specialize it to the case where $m_{\text{wheel}} = 0$ but $m_{\text{axle}} \equiv m \neq 0$; and, in addition, the whole system rolls on a plane inclined by an angle χ to the horizontal (fig. 3.56).

We saw in the previous example that the constraints are

$$\dot{X}\cos\phi + \dot{Y}\sin\phi = 0, \quad \text{(a1)}$$

$$-\dot{X}\sin\phi + \dot{Y}\cos\phi + b\dot{\phi} + r\dot{\psi}' = 0, \quad \text{(a2)}$$

$$-\dot{X}\sin\phi + \dot{Y}\cos\phi - b\dot{\phi} + r\dot{\psi}'' = 0. \quad \text{(a3)}$$

It is not hard to see that, in this case,

$$2T = m[(\dot{X})^2 + (\dot{Y})^2] + (mb^2/3)(\dot{\phi})^2, \quad \text{(b)}$$

and, therefore, to within Appell-important terms,

$$2S = m[(\ddot{X})^2 + (\ddot{Y})^2] + (mb^2/3)(\ddot{\phi})^2, \quad \text{(c)}$$

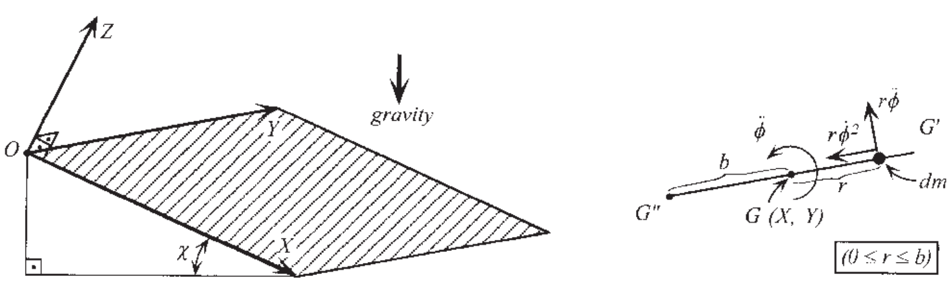

Figure 3.56 Rolling wheels on an axle, on an inclined plane.

and

$$\delta' W = mg(\delta X \sin\chi) \equiv Q_X\,\delta X \;\Rightarrow\; Q_X = mg\sin\chi. \tag{d}$$

Let us use the constraints to eliminate, say $\ddot{Y}$, from S: $(\ldots)^{\cdot}$-differentiating (a1) we obtain

$$\dot{Y} = -\dot{X}(\cos\phi/\sin\phi) \;\Rightarrow\; \ddot{Y} = -\ddot{X}(\cos\phi/\sin\phi) + \dot{X}\dot{\phi}(1/\sin^2\phi). \tag{e}$$

Substituting (e) into (c), we obtain $S = S_o(\ddot{X}, \ddot{\phi}) \equiv S_o = \cdots$. We remark that in building Appell's equations, *there is no need to square* $\ddot{Y}$ of (e). Indeed, since $S = S[\ddot{X}, \ddot{Y}(\ddot{X}, \ldots), \ddot{\phi}; \ldots] = S_o$, the chain rule yields

$$\begin{aligned}
\partial S_o/\partial\ddot{X} &= \partial S/\partial\ddot{X} + (\partial S/\partial\ddot{Y})(\partial\ddot{Y}/\partial\ddot{X}) = \partial S/\partial\ddot{X} + (\partial S/\partial\ddot{Y})(\partial\dot{Y}/\partial\dot{X})\\
&= (m\ddot{X}) + (m\ddot{Y})(-\cos\phi/\sin\phi) \quad (= mg\sin\chi),
\end{aligned} \tag{f}$$

$$\begin{aligned}
\partial S_o/\partial\ddot{\phi} &= \partial S/\partial\ddot{\phi} + (\partial S/\partial\ddot{Y})(\partial\ddot{Y}/\partial\ddot{\phi}) = \partial S/\partial\ddot{\phi} + (\partial S/\partial\ddot{Y})(\partial\dot{Y}/\partial\dot{\phi})\\
&= (mb^2/3)\ddot{\phi} + (m\ddot{Y})(0) \quad (= 0).
\end{aligned} \tag{g}$$

From (g), and with $\omega_o/\phi_o =$ *initial angular velocity/angle* of bar $G''G'$, we immediately find

$$\dot{\phi} = \omega_o \;\Rightarrow\; \phi = \omega_o t + \phi_o. \tag{h}$$

Then, with the choice $\phi_o = 0$, (f) reduces to

$$\ddot{X}\sin(\omega_o t) - \ddot{Y}\cos(\omega_o t) = g\sin\chi\sin(\omega_o t); \tag{i}$$

and along with (e) they constitute a system for $X(t)$ and $Y(t)$. Indeed, eliminating $\ddot{Y}$ between (i) and (e) yields

$$\ddot{X}\big\{\sin(\omega_o t) + \big[\cos^2(\omega_o t)/\sin(\omega_o t)\big]\big\} - \dot{X}\omega_o[\cos(\omega_o t)/\sin^2(\omega_o t)] = g\sin\chi\sin(\omega_o t). \tag{j}$$

Integrating (j) twice {while noticing that its left side equals $[\dot{X}/\sin(\omega_o t)]^{\cdot}$}, we obtain, after some elementary integrations (and with $c_{1,2} =$ *integration constants*),

$$X = (g\sin\chi/4\omega_o{}^2)\cos(2\omega_o t) - (c_1/\omega_o)\cos(\omega_o t) + c_2. \tag{k}$$

Then, substituting from (k) into (a1) and integrating, we finally get (with $c_3 =$ *integration constant*)

$$Y = (g\sin\chi/4\omega_o{}^2)[\sin(2\omega_o t) + 2\omega_o t] - (c_1/\omega_o)\sin(\omega_o t) + c_3; \tag{l}$$

that is, G traces a curve parallel to a *cycloid* with base(line) parallel to OY.

For additional insights, see Delassus [(1913(b), pp. 406–409), which investigates the above system but with an additional particle of mass m placed at G, and then of the limit as $m_{\text{wheels}}, m_{\text{bar}} \to 0$], Pérès (1953, p. 214); also Bahar (1998).

APPENDIX 3.A1

REMARKS ON THE HISTORY OF THE HAMEL-TYPE EQUATIONS OF ANALYTICAL MECHANICS

Below, and continuing from the Introduction and the early sections of this chapter, we discuss the historical evolution of the Hamel-type equations; that is, of T-based *equations of nonholonomically constrained systems in nonholonomic variables*.

We begin with the following, highly selective but adequate for our purposes, summaries of the main theoretical developments of Lagrangean mechanics; see tables 3.A1.1–3.A1.3.

Table 3.A1.1 **Global Picture**

Newton (2nd half of 17th cent.)	Physical foundations of mechanics (fundamental law); particle
Euler (18th cent.)	Physical and mathematical foundations of mechanics (momentum mechanics); rigid body, ***rotation***
Lagrange (2nd half of 18th cent.)	Mathematical deepening of mechanics (energetic mechanics); ***constraints***, Lagrangean equations
Cauchy (1st half of 19th cent.)	Continuum mechanics; ***deformation*** (strain), stress
Hamilton (1830's)	Canonical formalism; Hamilton's equations
Jacobi (1840's)	Integration theory of dynamics
Kelvin/Helmholtz/Routh (2nd half of 19th cent.)	Ignorable (cyclic) coordinates; gyroscopic systems
Appell (late 19th-early 20th cent.)	Nonholonomic systems; Appell's equations (acceleration-based equations)
Heun (early 20th cent.)	Theoretical engineering dynamics
Hamel (1st half of 20th cent.)	Nonholonomic systems, axiomatics of classical (discrete + continuum) mechanics; Hamel's equations (kinetic energy-based equations)

Table 3.A1.2 **Prehistory of Lagrangean Mechanics**

Mersenne (1646)	Find the period of a mathematical pendulum with several masses
Huygens (1673)	Center of oscillation (''Horologium oscillatorium'')
Jacob Bernoulli (1686–1703)	Physical pendulum; earliest form of d'Alembert's principle
D'Alembert (1743)	Earliest monograph on constrained system dynamics

Table 3.A1.3 **Historical Synthesis (mid-to-late 18th Century)**

D'Alembert's decomposition (Ansatz): $df = dF + dR$		Laws of Simple Machines: Ancient Greeks (Aristotle, Archimedes et al.), Del Monte (1577), Galileo (1594), Torricelli (1644) et al.
$\downarrow$		$\downarrow$
D'Alembert's Principle: The $\{-dR\}$ are in equilibrium (1743)	$+$	Johann Bernoulli Statical Principle of Virtual Work (1717, 1725): Equilibrium $\Leftrightarrow$ zero virtual work
	$\downarrow$	
Lagrange: Principle of least action (1760); Lagrange's principle (1764); Lagrange's equations (1780); Méchanique Analitique (1788)		$S(-d\boldsymbol{R})\cdot\delta\boldsymbol{r} = 0 \;\Rightarrow\; S\, dm\, \boldsymbol{a}\cdot\delta\boldsymbol{r} = S\, d\boldsymbol{F}\cdot\delta\boldsymbol{r}$

From the Prehistory of the Hamel-Type Equations

Let us now discuss, *in "our" notation*, some additional special forms of Hamel-type equations of motion (early 1870s to the early 1900s). It is through the acquaintance with such historical curiosities that we deepen our understanding of *contemporary* Lagrangean mechanics, both holonomic and nonholonomic; and appreciate better the importance of the fundamental contributions of Heun and Hamel (1901–1914) to our subject.

(i) Equations of Ferrers (early 1870s, publ. 1873)

Let us assume for algebraic simplicity, but no loss in generality, a scleronomic system with Chaplygin-type constraints (3.8.13a)

$$\dot{q}_D = \sum b_{DI}(q_{m+1}, \dots, q_n)\dot{q}_I = \sum b_{DI}\dot{q}_I \qquad (I = m+1, \dots, n). \tag{3.A1.1}$$

Then, Ferrers' equations are

$$I_{Io} \equiv d/dt(\partial T_o/\partial \dot{q}_I) - S\, dm\, \boldsymbol{v}_o \cdot (d\boldsymbol{\beta}_I/dt) = Q_{Io}, \tag{3.A1.2}$$

where

$$\boldsymbol{v} = \sum \boldsymbol{e}_k \dot{q}_k = \cdots \equiv \sum \boldsymbol{\beta}_I \dot{q}_I \equiv \sum (\partial \boldsymbol{v}_o/\partial \dot{q}_I)\dot{q}_I \equiv \boldsymbol{v}_o(q, \dot{q}_I) \equiv \boldsymbol{v}_o. \tag{3.A1.2a}$$

We recall [(2.9.37), also prob. 2.11.1] that since, in general, the $\boldsymbol{\beta}_I$ are *nongradient*

$$E_I(\boldsymbol{v}_o) \equiv d/dt(\partial \boldsymbol{v}_o/\partial \dot{q}_I) - \partial \boldsymbol{v}_o/\partial q_I \equiv d\boldsymbol{\beta}_I/dt - \partial \boldsymbol{v}_o/\partial q_I \neq \boldsymbol{0}, \tag{3.A1.3a}$$

even though (2.5.10)

$$E_I(\boldsymbol{v}) \equiv d/dt(\partial \boldsymbol{v}/\partial \dot{q}_I) - \partial \boldsymbol{v}/\partial q_I = \boldsymbol{0}. \tag{3.A1.3b}$$

Indeed, in view of the above, we obtain, successively (with I, $I' = m+1, \dots, n$),

$$\begin{aligned} E_I(\boldsymbol{v}_o) &= d\boldsymbol{\beta}_I/dt - \partial \boldsymbol{v}_o/\partial q_I \\ &= \sum (\partial \boldsymbol{\beta}_I/\partial q_{I'})(dq_{I'}/dt) - \sum (\partial \boldsymbol{\beta}_{I'}/\partial q_I)(dq_{I'}/dt) \\ &= \sum (\partial \boldsymbol{\beta}_I/\partial q_{I'} - \partial \boldsymbol{\beta}_{I'}/\partial q_I)\dot{q}_{I'} \neq \boldsymbol{0} \qquad \text{(in general)}; \end{aligned} \tag{3.A1.3c}$$

and, therefore, in the nonholonomic case,

$$R_I \equiv S\, dm\, \boldsymbol{v}_o \cdot (\partial \boldsymbol{v}_o/\partial \dot{q}_I)^{\cdot} \equiv S\, dm\, \boldsymbol{v}_o \cdot (d\boldsymbol{\beta}_I/dt) \neq S\, dm\, \boldsymbol{v}_o \cdot (\partial \boldsymbol{v}_o/\partial q_I) = \partial T_o/\partial q_I. \tag{3.A1.3d}$$

Also, Carvallo (1900–1901), in his classic studies of the *mono*- and *bi-cycle*, and most likely independently of Ferrers, introduced essentially equivalent equations of motion. Clearly, the method of Ferrers can be extended to the most general rheonomic nonholonomic constraints; even nonlinear ones (chap. 5).

REMARKS

(a) Such an extension of (3.A1.2) has been given (independently) by Greenwood [1994, p. 83 ff., eqs. (3.98)]. With (our notation): $\dot{q}_k = \sum A_{kI}\omega_I + A_k$, $\boldsymbol{v} = \cdots = \boldsymbol{v}^*{}_o(t, q, \omega_I) \Rightarrow T^* = T^*{}_o(t, q, \omega_I)$, or

$$T[t, q, \dot{q}_I, \dot{q}_D(t, q, \dot{q}_I)] = T_o(t, q, \dot{q}_I) = T_o[t, q, \dot{q}_I(t, q, \omega_I)] = T^*{}_o(t, q, \omega_I),$$

and with $\delta' W = \sum Q_k \, \delta q_k = \sum \Theta_I \, \delta\theta_I$, we obtain the *Greenwood equations*:

$$(\partial T^*{}_o/\partial\dot{\omega}_I)^{\cdot} - S\, dm\, \boldsymbol{v}^*{}_o \cdot (\partial \boldsymbol{v}^*{}_o/\partial\omega_I) = \Theta_I. \tag{3.A1.3e}$$

Actually, (3.A1.3e) also holds for nonlinear nonholonomic transformations: $\dot{q}_I = \dot{q}_I(t, q, \omega_I)$.

(b) A certain unclear historical statement by Whittaker (1937, p. 215, footnote) seems to have caused a number of other (less famous) authors to call, *erroneously*, Ferrers equations the Routh–Voss (multiplier) equations; for example, Fox (1967, p. 351), Hand and Finch (1998, p. 62, footnote), Rose (1938, p. 16). The record is corrected in Routh 1905(a), p. 348, footnote.

(c) For complementary expositions on the Ferrers equations, and so on, see, for example (alphabetically): Auerbach (1908, p. 327, eq. (68)), Gray (1918, pp. 411–418), Marcolongo (1912, pp. 104–105), Voss (1901/1908, pp. 82–83).

(ii) T-Equations of Appell (1899) and Boltzmann (1902)

These result from further transformations of the key R_I term, (3.A1.3d). Indeed, we obtain, successively [recalling (3.3.11a ff.)],

$$\begin{aligned}
R_I &\equiv S\, dm\, \boldsymbol{v}_o \cdot (d\boldsymbol{\beta}_I/dt) = S\, dm\, \boldsymbol{v}_o \cdot [d/dt(\partial \boldsymbol{v}_o/\partial\dot{q}_I)] \\
&= S\, dm\boldsymbol{v}_o \cdot [d/dt(\partial \boldsymbol{v}_o/\partial\dot{q}_I) - \partial \boldsymbol{v}_o/\partial q_I] + S\, dm\, \boldsymbol{v}_o \cdot (\partial \boldsymbol{v}_o/\partial q_I) \\
&= S\, dm\, \boldsymbol{v}_o \cdot \Big(\sum (\partial \boldsymbol{\beta}_I/\partial q_{I'})(dq_{I'}/dt) - \sum (\partial \boldsymbol{\beta}_{I'}/\partial q_I)(dq_{I'}/dt)\Big) + \partial T_o/\partial q_I \\
&= \Gamma_{Io} + \partial T_o/\partial q_I \qquad (\Rightarrow R_I - \partial T_o/\partial q_I = \Gamma_{Io}),
\end{aligned} \tag{3.A1.4}$$

where

$$\begin{aligned}
\Gamma_{Io} &\equiv S\, dm\, \boldsymbol{v}_o \cdot E_I(\boldsymbol{v}_o) \\
&= \sum \Big\{ S\, dm\, \boldsymbol{v}_o \cdot (\partial \boldsymbol{\beta}_I/\partial q_{I'} - \partial \boldsymbol{\beta}_{I'}/\partial q_I) \Big\}\, \dot{q}_{I'}
\end{aligned} \tag{3.A1.4a}$$

an expression that shows clearly the *gyroscopicity* of this nonholonomic "correction term." Hence, Ferrers' equations take the Appell form

$$E_I(T_o) - \Gamma_{Io} \equiv d/dt(\partial T_o/\partial\dot{q}_I) - \partial T_o/\partial q_I - \Gamma_{Io} = Q_{Io}. \tag{3.A1.5}$$

When the fundamental term Γ_{Io} is expressed exclusively in *system* variables, say $\Gamma_{Io} = \sum c_{II'}\, \dot{q}_{I'} = quadratic$ in the $\dot{q}_I$ (where $c_{II'} = -c_{I'I}$), eqs. (3.A1.5) are none other than the Chaplygin equations (3.8.13a ff.); which, as we have seen, are a special case of the Hamel equations.

From the above, we conclude, with Appell, that for Lagrange's equations to apply for a particular q_I [i.e., $(\partial T_o/\partial\dot{q}_I)^{\cdot} - \partial T_o/\partial q_I = Q_{Io}$], it is necessary and sufficient that $\Gamma_{Io} = 0$, identically in t, q_I's, $\dot{q}_I$'s. In holonomic systems this holds for *all* $I = m+1, \ldots, n$; but in nonholonomic ones, it may hold for some of them; e.g., in the rolling coin problem it does hold for the *nutation* angle θ [ex. 3.18.5, and Ferrers (1873, pp. 3–4)]. Appell calls the number of *nonvanishing* Γ_{Io}'s the "order of nonholonomicity" of the system; and also, he points out the errors resulting from the indiscriminate use of Lagrange's equations $E_I(T_o) = Q_{Io}$.

However, Appell (1899) did not pursue the transformation of R_I and Γ_I any further, and thus missed arriving at the equations of Chaplygin (1895, publ. 1897) and Voronets (1901). Instead, seeing an apparent dead-end in the direction of Lagrange-type equations, like (3.A1.5) with (3.A1.4a), he turned his energies to the development of his other, now famous, *acceleration-based* S-equations (1899, 1900):

$$\partial S_o/\partial \ddot{q}_I = Q_{Io}. \tag{3.A1.6}$$

Comparing (3.A1.5) and (3.A1.6), we immediately deduce the following basic kinematico-inertial identity:

$$\begin{aligned} \Gamma_{Io} &= [(\partial T_o/\partial \dot{q}_I)^{\cdot} - \partial T_o/\partial q_I] - \partial S_o/\partial \ddot{q}_I \equiv E_I(T_o) - \partial S_o/\partial \ddot{q}_I \\ &\equiv [(\textit{constrained})\ \textit{Euler–Lagrange}]_I - [(\textit{constrained})\ \textit{Appell}]_I \neq 0 \qquad \text{(in general);} \end{aligned} \tag{3.A1.7}$$

see, for example, Appell [1899(a), pp. 39–45; 1925, pp. 12–17; 1953, pp. 383–388].

The form (3.A1.5), but for general rheonomic nonholonomic systems [i.e., a form that when brought to *system variables* would be *none other than the Voronets equations* (1901) — (3.8.14a ff.)] was also arrived at, independently, by Boltzmann (1902; 1904, pp. 104–105), who, among mechanicians, gave the first geometrical interpretation of the ("Ricci–Boltzmann–Hamel") *rotation coefficients*: $\partial\boldsymbol{\beta}_I/\partial q_{I'} - \partial\boldsymbol{\beta}_{I'}/\partial q_I$. An additional, related, derivation of the Boltzmann equations, based on Hertz's "principle of the straightest path" (§6.7), was given a little later by Boltzmann's famous student Ehrenfest [1904]. See also, Krutkov (1928: vectorial/dyadic treatment of Boltzmann's equations), MacMillan (1936, pp. 332–341: clear derivation of Boltzmann's equations; unique and virtually unknown/unnoticed in the English literature); and Klein (1970, pp. 53–74: critical summary of Ehrenfest's dissertation). [See also Mei (1984; 1985, pp. 108–114) for an extension of the MacMillan equations to nonlinear nonholonomic constraints.]

To summarize: the main drawback of these equations of Ferrers–Appell–Boltzmann–MacMillan is that they are *mixed*; that is, some of their terms $[E_I(T_o), Q_{Io}]$ are expressed in *system* variables, and some (Γ_{Io}) in *particle* variables. Perhaps this explains why they have not been used much in concrete problems, let alone theoretical arguments. The equations that result by expressing the nonholonomic term Γ_{Io} too in system variables (a qualitatively higher step in the evolution of Lagrangean-type equations!) are the equations of Chaplygin and Voronets; schematically:

- Equations of Ferrers (1873)/Appell (1899) $\xrightarrow[\text{variables}]{\text{system}}$ Equations of Chaplygin (1895–1897),
- Equations of Boltzmann (1902)/MacMillan (1936)] $\xrightarrow[\text{variables}]{\text{system}}$ Equations of Voronets (1901).

(3.A1.8)

Last, a special case of the Chaplygin–Voronets equations (rolling of convex body on rough plane) was first given by Neumann (1885).

(iii) Boltzmann versus Hamel

In the light of this historical record, the widely used term "Boltzmann–Hamel equations" (probably originated by readers of Whittaker (1904, §30), and parroted by the rest, except Hamel and his school) is inaccurate. There is a very big difference between these two sets of equations, although they appeared only about a year apart from each other (Boltzmann: 1902; Hamel: 1903, 1904).

(iv) Volterra versus Hamel

The only other Lagrange-type equations of motion that can stand next to Hamel's are those by Volterra (1898; corrections: 1899). However, even Volterra *never discussed constraints*, just equations of motion in terms of nonholonomic *variables* (what he called "parameters," or "motion characteristics"); and, more importantly, Hamel's treatment is far more comprehensive and deep.

(v) Gibbs versus Appell

The S-equations of Appell under Pfaffian constraints are sometimes called "Gibbs–Appell equations"; for example, Pars (1965). However, a careful study of the original memoirs of these two masters reveals that Appell's contributions (several weighty papers, a monograph exclusively devoted to these equations, plus extensive parts of his famous treatise) completely overshadow by several orders of magnitude those of Gibbs (two pages at the end of his single paper on theoretical dynamics). The main difference between the two is that: Appell dealt with *both nonholonomic coordinates and constraints*, whereas Gibbs dealt *only with nonholonomic coordinates*. Also, their approaches are distinctly different: Gibbs derives his equations from the differential form of the (lesser known) Gauss' principle, whereas Appell obtains his from (the simpler) Lagrange's principle.

For these objective and incontrovertible reasons, we have decided to call them *Appell's equations*. In this practice, we are accompanied by the overwhelming majority of the best mechanicians of the 20th century; for example, (in approximate chronological order of appearance of their works on this subject): Voss, Heun, Routh, Whittaker, Gray, Hamel, Nordheim, Johnsen, Prange, Ames and Murnaghan, Levi-Civita and Amaldi, MacMillan, Rose, Lanczos, Beghin, Pérès, Synge, Lur'e, Gantmacher, Novoselov, Dobronravov, Neimark and Fufaev, Mei et al.

In view of the above, the situation in (iv) and (v) can be fairly summed up as follows: Volterra's equations stand relative to Hamel's the same way that Gibbs' equations stand relative to Appell's (S-equations), and vice versa. In both cases, the relevant contributions of Hamel and Appell exceed by several quantitative and qualitative orders of magnitude those of Volterra and Gibbs, respectively. This is shown schematically in table 3.A1.4.

The foregoing history helps us to build the following summaries and table of the equations of motion of analytical dynamics:

Table 3.A1.4 Volterra vs. Hamel, and Gibbs vs. Appell

	Nonholonomic Coordinates		
	No Constraints		Constraints
***T*-equations:**	Volterra (1898)	<	Hamel (1903, 1904)
***S*-equations:**	Gibbs (1879)	<	Appell (1899, 1900)

Lagrange's Principle (LP)

Particle/vector variables: $\displaystyle S\, dm\, \boldsymbol{a} \cdot \delta \boldsymbol{r} = S\, d\boldsymbol{F} \cdot \delta \boldsymbol{r}$

Holonomic system variables: $\sum E_k(T)\, \delta q_k = \sum Q_k\, \delta q_k$

Nonholonomic system variables: $\sum [E_k{}^*(T^*) - \Gamma_k]\, \delta\theta_k = \sum \Theta_k \delta\theta_k.$

General Remarks

Additional Pfaffian constraints (holonomic and/or nonholonomic) are either (a) *adjoined* to LP via *multipliers*, in which case the resulting equations are, in general, *coupled* in the motion and reactions. However, under finite (geometrical) constraints, the equations of motion can always be uncoupled by special choices of "equilibrium" coordinates; or they are (b) *embedded* to LP (or *eliminated*) via *quasi coordinates*, in which case the resulting equations of motion can always be uncoupled by special choices of such quasi variables into *kinetic* (reactionless, motion only) and *kineto-static* (reaction-containing).

Table 3.A1.5 summarizes the equations of constrained dynamics.

Table 3.A1.5 Global (Panoramic) Map of the Equations of Constrained Dynamics

	T-Based Equations (velocities)
Multipliers:	Routh (1879)/Voss (1884–1885) — holonomic variables
	↓
Projection:	Maggi (1896, 1901) — holonomic variables Special cases: Hadamard (1895, 1899), Korteweg (1899)
	↓
Quasi variables:	Hamel (1903–1904) — nonholonomic variables
Special cases:	(i) Ferrers (1873), Appell (1899), Carvallo (1900), Boltzmann (1902), Auerbach (1908), MacMillan (1936), Greenwood (1994); (ii) C. Neumann (1885), Chaplygin (1895–1897) → Voronets (1901); (iii) Volterra (1898); (iv) Poincaré (1901)
	S-Based Equations (accelerations)
In view of the kinematico-inertial identities:	
Holonomic variables:	$\partial S/\partial \ddot{q}_k = (\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k$
Nonholonomic variables:	$\partial S^*/\partial \dot{\omega}_k = (\partial T^*/\partial \omega_k)^{\cdot} - \partial T^*/\partial \theta_k - \Gamma_k$
there exist Appellian counterparts to all the above equations. Here, in general, both T and S are unconstrained; if the additional Pfaffian constraints are holonomic, they can be constrained.	
(For the less common (dT/dt)-based equations, see §6.3 ff.)	

APPENDIX 3.A2

CRITICAL COMMENTS ON VIRTUAL DISPLACEMENTS/WORK; AND LAGRANGE'S PRINCIPLE

Some Common Misunderstandings Regarding d'Alembert's Principle (d'AP)

As pointed out in §3.2 and elsewhere, d'AP is, in spite of its simplicity, one of the most misunderstood principles in the history of physics. Although the whole matter was finally and fully clarified, qualitatively and quantitatively, in the early years of the 20th century by such mechanics greats as Heun and Hamel, considerable confusion and misunderstanding still persists even today, especially among English language texts and, more specifically, those written by physicists. (The most likely culprits for such a tradition of error must be the very influential Victorian treatises of Thomson/Tait, Routh, Whittaker, Lamb, et al.; which, in spite of their overall greatness, are pretty incomplete on this fundamental topic.) Let us try to identify and dispel the most common of these intellectual malignancies.

(i) A frequent misrepresentation of d'AP runs as follows: one starts with the Newton–Euler law:

$$d\boldsymbol{f} = dm\,\boldsymbol{a}, \tag{3.A2.1}$$

then one moves the inertia term $dm\,\boldsymbol{a}$ to the left/force side of the equation, and calls the trivial result: $d\boldsymbol{f} + (-dm\,\boldsymbol{a}) = \boldsymbol{0}$, d'AP. In words: during the motion, the sum of all forces, real ($d\boldsymbol{f}$) and "reversed effective" ($-dm\,\boldsymbol{a}$) are in dynamic (?!) equilibrium; see, for example, (alphabetically): Halfman (1962, p. 62), Housner and Hudson (1959, pp. 253–254), Meriam and Kraige (1986, p. 223), to name a few contemporary (otherwise quite decent and worthwhile) expositions. Many more examples of this physically vacuous formulation appear in other areas of engineering dynamics; for example, vibrations, fluid mechanics, and so on.

(ii) Some authors talk about d'AP in so many places and (in, mostly, qualitative) forms, including the correct one, that the reader ends up confused as to the true meaning of the principle and unable to apply it to new and nontrivial circumstances. Others confuse d'AP with the Newton–Euler principle (better, constitutive postulate) of action–reaction for the *internal* forces, while limiting themselves to rigid bodies/systems; for example, Marris and Stoneking (1967, pp. 95–96). But if d'AP simply meant equilibrium of all *internal* forces, in the Newton–Euler sense, that is,

$$S\, d\boldsymbol{f}_{internal} = \boldsymbol{0} \qquad \text{and} \qquad S\, \boldsymbol{r} \times d\boldsymbol{f}_{internal} = \boldsymbol{0}, \tag{3.A2.2}$$

then how would one apply the principle to constrained systems that do not possess such forces? [As we have already seen (§3.2), in general, $d\boldsymbol{f}_{internal} \neq d\boldsymbol{R}$ (= *total* constraint reaction); $d\boldsymbol{f}_{internal} = d\boldsymbol{R}_{internal}$, in a rigid body, and $d\boldsymbol{f}_{internal} = d\boldsymbol{R}$, in a free (i.e., *externally* unconstrained) rigid body.] For example, in the following simple systems the constraint reactions are neither internal nor do they satisfy (3.A2.2): (a) particle on, say a smooth, surface; (b) mathematical pendulum. Indeed, here we have

$$\textit{Newton–Euler}\text{ principles:}\quad S\, d\boldsymbol{R} \neq \boldsymbol{0} \quad \text{and} \quad S\,(\boldsymbol{r} \times d\boldsymbol{R}) \neq \boldsymbol{0} \quad (\text{for a general } \boldsymbol{r}); \tag{3.A2.3a}$$

but

$$\textit{D'Alembert–Lagrange} \text{ principle:} \quad \mathcal{S}\, d\boldsymbol{R} \cdot \delta \boldsymbol{r} = 0; \tag{3.A2.3b}$$

that is, it is not the constraint reactions that must vanish [individually or in the sense of (3.A2.2), although that may happen in some problems], but the *sum* of their projections in certain directions. In other words, to say that d'AP requires that the constraint reactions be "in equilibrium," or constitute a "null system" of forces, is correct provided that *equilibrium* is understood in the *generalized total virtual work sense of* (3.A2.3b), *not* (3.A2.3a). Then, it is meaningful even for a *single* reaction, external or internal. Let us clarify this.

Following Hamel (1927; 1949, p. 217): we call two force (and/or couple) systems, acting separately on the same mechanical system, *equivalent* if, and only if, starting from the same initial kinematical state (i.e., time, positions, and velocities) they communicate to it the same acceleration. In particular: a system of forces is said to be in *equilibrium* (or be a *null system*) if the accelerations communicated by it to a mechanical system are the same as those that would occur if no impressed forces acted on it.

In this light it becomes clear why the earlier-mentioned pendulum tension is in equilibrium; it may not vanish, but it does not affect the acceleration of the pendulum's bob; that is done by gravity, an impressed force.

(iii) A related misconception is to confuse d'AP with the spatial integral forms of the Newton–Euler principles of linear/angular momentum. Thus, we read that "the sum of the forces and the sum of the moments of the forces [including those of the 'inertia forces' $-dm\,\boldsymbol{a}$] about *any* point vanish" and "d'Alembert's principle leaves one free to take moments about *any* point, whereas the angular momentum principle restricts one in this regard" (Kane and Levinson, 1980, pp. 102–103). In our notation, the above read simply

$$\mathcal{S}\,(d\boldsymbol{f} - dm\,\boldsymbol{a}) = \boldsymbol{0} \qquad \text{and} \qquad \mathcal{S}\,\boldsymbol{r}_{/\bullet} \times (d\boldsymbol{f} - dm\,\boldsymbol{a}) = \boldsymbol{0}, \tag{3.A2.4}$$

where $\boldsymbol{r}_{/\bullet}$ = position vector of generic system particle relative to the completely arbitrary (fixed or moving, not necessarily body-) point $\bullet$.

But eqs. (3.A2.4) follow immediately from the local Newton–Euler principle (3.A2.1) by the simple mathematical operations indicated above. Generally, starting with (3.A2.1), we can perform to it any kind of mathematically meaningful operation; for example, dot it or cross it with an arbitrary scalar/vector/tensor, and so on, differentiate/integrate it in space/time, and so on. Nothing *physically new* will result from such analytical (logical) rearrangements. One does not need any special permission from Newton–Euler (i.e., a *new postulate*) to go from (3.A2.1) to (3.A2.4); and the latter is not d'AL, anyway, but a trivial rearrangement of the Newton–Euler principle. Let us elaborate on this matter.

Detour on Angular Momentum

As already described in §1.6, to obtain an angular momentum principle we cross (3.A2.1) with $\boldsymbol{r}_{/\bullet}$ and then integrate/sum it, for a fixed time, over the material system:

$$\boldsymbol{M}_{\bullet} \equiv \mathcal{S}\,\boldsymbol{r}_{/\bullet} \times d\boldsymbol{f} = \mathcal{S}\,\boldsymbol{r}_{/\bullet} \times dm\,\boldsymbol{a}. \tag{3.A2.5}$$

However, the right (inertia) side of (3.A2.5) can be transformed further either as

(a)
$$\begin{aligned} \mathcal{S}\, \boldsymbol{r}_{/\bullet} \times dm\, \boldsymbol{a} &= \left(\mathcal{S}\, \boldsymbol{r}_{/\bullet} \times dm\, \boldsymbol{v}\right)^{\cdot} - \mathcal{S}\, \boldsymbol{v}_{/\bullet} \times dm\, \boldsymbol{v} \\ &= \left(\mathcal{S}\, \boldsymbol{r}_{/\bullet} \times dm\, \boldsymbol{v}\right)^{\cdot} - \mathcal{S}\, (\boldsymbol{v} - \boldsymbol{v}_\bullet) \times dm\, \boldsymbol{v} \\ &= d\boldsymbol{H}_\bullet/dt + \boldsymbol{v}_\bullet \times m\, \boldsymbol{v}_G, \end{aligned} \tag{3.A2.5a}$$

where

$$\boldsymbol{H}_{\bullet,\text{absolute}} \equiv \boldsymbol{H}_\bullet \equiv \mathcal{S}\, \boldsymbol{r}_{/\bullet} \times dm\, \boldsymbol{v} = \textit{Absolute angular momentum} \text{ about } \bullet, \tag{3.A2.5b}$$

and G = *center of mass of the system*; that is, in general, the sum of the moments of the rate of linear momenta about $\bullet$ [left side of (3.A2.5a)] is not equal to the rate of change of the sum of moments of the linear momenta about $\bullet$ [first term in right side of (3.A2.5a)]; or, in terms of $\bullet$ – *relative* quantities as

(b)
$$\begin{aligned} \mathcal{S}\, \boldsymbol{r}_{/\bullet} \times dm\, \boldsymbol{a} &= \left(\mathcal{S}\, \boldsymbol{r}_{/\bullet} \times dm\, \boldsymbol{v}\right)^{\cdot} + \boldsymbol{v}_\bullet \times m\, \boldsymbol{v}_G \\ &= \left\{\mathcal{S}\, [\boldsymbol{r}_{/\bullet} \times dm(\boldsymbol{v}_\bullet + \boldsymbol{v}_{/\bullet})]\right\}^{\cdot} + \boldsymbol{v}_\bullet \times m\, \boldsymbol{v}_G \\ &= \left[\mathcal{S}\, (\boldsymbol{r}_{/\bullet} \times dm\, \boldsymbol{v}_\bullet)\right]^{\cdot} + \left[\mathcal{S}\, (\boldsymbol{r}_{/\bullet} \times dm\, \boldsymbol{v}_{/\bullet})\right]^{\cdot} + \boldsymbol{v}_\bullet \times m\, \boldsymbol{v}_G \\ &= \mathcal{S}\, (\boldsymbol{v}_{/\bullet} \times dm\, \boldsymbol{v}_\bullet) + \mathcal{S}\, (\boldsymbol{r}_{/\bullet} \times dm\, \boldsymbol{a}_\bullet) + \left[\mathcal{S}\, (\boldsymbol{r}_{/\bullet} \times dm\, \boldsymbol{v}_{/\bullet})\right]^{\cdot} \\ &\qquad + \boldsymbol{v}_\bullet \times m\, \boldsymbol{v}_G \\ &= \boldsymbol{v}_{G/\bullet} \times m\, \boldsymbol{v}_\bullet + \boldsymbol{r}_{G/\bullet} \times m\, \boldsymbol{a}_\bullet + \left[\mathcal{S}\, (\boldsymbol{r}_{/\bullet} \times dm\, \boldsymbol{v}_{/\bullet})\right]^{\cdot} + \boldsymbol{v}_\bullet \times m\, \boldsymbol{v}_G \\ &\quad \text{[since } \boldsymbol{v}_{G/\bullet} \equiv \boldsymbol{v}_G - \boldsymbol{v}_\bullet, \text{ the } \textit{first} \text{ and } \textit{last} \text{ terms, in the above,} \\ &\quad \text{add up to zero]} \\ &= d\boldsymbol{h}_\bullet/dt + \boldsymbol{r}_{G/\bullet} \times m\, \boldsymbol{a}_\bullet, \end{aligned} \tag{3.A2.5c}$$

where

$$\begin{aligned} \boldsymbol{H}_{\bullet,\text{relative}} \equiv \boldsymbol{h}_\bullet &\equiv \mathcal{S}\, \boldsymbol{r}_{/\bullet} \times dm\, \boldsymbol{v}_{/\bullet} = \textit{Relative angular momentum} \text{ about } \bullet \\ &= \mathcal{S}\, [\boldsymbol{r}_{/\bullet} \times dm(\boldsymbol{v} - \boldsymbol{v}_\bullet)] = \cdots = \boldsymbol{H}_\bullet - m\boldsymbol{r}_{G/\bullet} \times \boldsymbol{v}_\bullet. \end{aligned} \tag{3.A2.5d}$$

From eqs. (3.A2.5a–d) it clearly follows that
(a) If $\bullet$ = *fixed point*, say O ($\Rightarrow \boldsymbol{v}_\bullet = \boldsymbol{0}$), or $\boldsymbol{v}_G = \boldsymbol{0}$, or if $\boldsymbol{v}_\bullet$ parallel to $\boldsymbol{v}_G$, then

$$\mathcal{S}\, \boldsymbol{r}_{/\bullet} \times dm\, \boldsymbol{a} = d\boldsymbol{H}_\bullet/dt; \tag{3.A2.5e}$$

(b) If $\bullet$ = *fixed point*, say O ($\Rightarrow \boldsymbol{a}_\bullet = \boldsymbol{0}$), or $\bullet = G$, or $\boldsymbol{r}_{G/\bullet}$ is parallel to $\boldsymbol{a}_\bullet$, then

$$\mathcal{S}\, \boldsymbol{r}_{/\bullet} \times dm\, \boldsymbol{a} = d\boldsymbol{h}_\bullet/dt. \tag{3.A2.5f}$$

In sum, and since, generally,

$$\begin{aligned} \boldsymbol{H}_O &\equiv \mathcal{S}\,[(\boldsymbol{r}_\bullet + \boldsymbol{r}_{/\bullet}) \times dm\, \boldsymbol{v}] \\ &= \cdots = \boldsymbol{H}_\bullet + \boldsymbol{r}_\bullet \times m\, \boldsymbol{v}_G = (\boldsymbol{h}_\bullet + m\, \boldsymbol{r}_{G/\bullet} \times \boldsymbol{v}_\bullet) + \boldsymbol{r}_\bullet \times m\, \boldsymbol{v}_G, \end{aligned} \tag{3.A2.5g}$$

we will have the following two, most useful (and memorable!) expressions of the principle of angular momentum:

$$\mathcal{S}\,\boldsymbol{r} \times dm\, \boldsymbol{a} = \left(\mathcal{S}\,\boldsymbol{r} \times dm\, \boldsymbol{v}\right)^{\cdot} = d\boldsymbol{H}_O/dt = d\boldsymbol{h}_O/dt \quad (= \boldsymbol{M}_O), \tag{3.A2.5h}$$

$$\mathcal{S}\,\boldsymbol{r}_{/G} \times dm\, \boldsymbol{a} = \left(\mathcal{S}\,\boldsymbol{r}_{/G} \times dm\, \boldsymbol{v}\right)^{\cdot} = d\boldsymbol{H}_G/dt = d\boldsymbol{h}_G/dt \quad (= \boldsymbol{M}_G). \tag{3.A2.5i}$$

Back to d'AP. But all these, kinematico-inertial identities and corresponding mutually equivalent forms of the principle of angular momentum (and many more presented in §1.6) are only half the story; *the other half is the forces and their moments*. Without the *additional* constitutive postulate of *action–reaction* for the *internal* forces $\{d\boldsymbol{f}_i\}$, where $d\boldsymbol{f} = d\boldsymbol{f}_{\text{external}} + d\boldsymbol{f}_{\text{internal}} \equiv d\boldsymbol{f}_e + d\boldsymbol{f}_i$, in either local or integral form, the moment side of (3.A2.5, 5h, 5i) would still contain the moments of the (generally unknown) $d\boldsymbol{f}_i$; and thus the solution of problems via these principles would, in general, be *indeterminate* (i.e., # *unknowns* > # *equations*). Adopting that postulate, as we will do, amounts to replacing in the above $\boldsymbol{M}_{\ldots}$ with $\boldsymbol{M}_{\ldots,\text{external}} \equiv \boldsymbol{M}_{\ldots,e}$:

$$\boldsymbol{M}_{\bullet,e} \equiv \mathcal{S}\,\boldsymbol{r}_{/\bullet} \times d\boldsymbol{f}_e = \mathcal{S}\,\boldsymbol{r}_{/\bullet} \times dm\, \boldsymbol{a}, \tag{3.A2.6a}$$

$$\boldsymbol{M}_{O,e} \equiv \mathcal{S}\,\boldsymbol{r} \times d\boldsymbol{f}_e = d\boldsymbol{H}_O/dt = d\boldsymbol{h}_O/dt, \tag{3.A2.6b}$$

$$\boldsymbol{M}_{G,e} \equiv \mathcal{S}\,\boldsymbol{r}_{/G} \times d\boldsymbol{f}_e = d\boldsymbol{H}_G/dt = d\boldsymbol{h}_G/dt; \tag{3.A2.6c}$$

because now $\boldsymbol{M}_{\bullet,\text{internal}} \equiv \mathcal{S}\,\boldsymbol{r}_{/\bullet} \times d\boldsymbol{f}_i = \boldsymbol{0}$ (and $\boldsymbol{f}_i \equiv \mathcal{S}\,d\boldsymbol{f}_i = \boldsymbol{0}$). [If the $\{d\boldsymbol{f}_e\}$ contain unknown constraint reactions, then the problem is still indeterminate; i.e., we need a new postulate to supply the additional independent equations.] Other forms of the above result from the purely geometrical (statical) relation: $\boldsymbol{M}_\bullet = \boldsymbol{M}_O + \boldsymbol{r}_{O/\bullet} \times \boldsymbol{f}$, $\boldsymbol{f} = \mathcal{S}\,d\boldsymbol{f}$ (acting through O), and then use of linear momentum:

$$\boldsymbol{f} = m\, \boldsymbol{a}_G, \text{ and action–reaction:} \boldsymbol{f} = \mathcal{S}\,(d\boldsymbol{f}_e + d\boldsymbol{f}_i) = \mathcal{S}\,d\boldsymbol{f}_e \equiv \boldsymbol{f}_e.$$

Now, the principle of d'Alembert (d'AP) $\to$ Lagrange (LP), and its associated "bothersome" virtual concepts, play a similar role with action–reaction *but for the constraint reactions*. By postulating the new and nontrivial constitutive (i.e., physical) postulate (3.A2.3b) for these forces, where

$$\begin{aligned} \delta\boldsymbol{r} &= \sum (\partial\boldsymbol{r}/\partial q_k)\, \delta q_k \equiv \sum \boldsymbol{e}_k\, \delta q_k \qquad (\textit{holonomic}\text{ coordinates}), \\ &= \sum (\partial\boldsymbol{r}/\partial\theta_k)\, \delta\theta_k \equiv \sum \boldsymbol{\varepsilon}_k\, \delta\theta_k \qquad (\textit{nonholonomic}\text{ coordinates}), \end{aligned} \tag{3.A2.6d}$$

Lagrangean mechanics succeeds in generating as many equations as needed to render its problem determinate. That the virtual variations of the system coordinates $\{\delta q_k, \delta\theta_k\}$ are arbitrary (unless they, later, become constrained) is not a weakness or vagueness of the Lagrangean method, as some ignoramuses claim, but, on the contrary, its strength: it allows us to *obtain as many independent reactionless* *equations as there are independent* δq's/$\delta\theta$'s $(= \#DOF)$, contrary to *actual* power equations that produce only *one* dependent equation. It is the fundamental *particle and system* vectors $\{\boldsymbol{e}_k, \boldsymbol{\varepsilon}_k\}$ that enter the equations of motion; for example, if the δq's are independent, LP yields

$$\text{\textit{Particle/vector} variables:} \qquad \mathcal{S}\, dm\, \boldsymbol{a}\cdot\boldsymbol{e}_k = \mathcal{S}\, d\boldsymbol{F}\cdot\boldsymbol{e}_k, \tag{3.A2.6e}$$

$$\text{Holonomic \textit{system} variables:} \qquad E_k(T) = Q_k. \tag{3.A2.6f}$$

To further clarify the meaning of virtualness, and thus quell the irrational fears of all those uncomfortable with "very small quantities," and so on (residues of a precalculus mindset?!), we add the following passage from a Victorian master's text on introductory statics:

> This [LP or Virtual Work] is an equation between infinitesimals, and it is to be understood on the ordinary conventions of the Differential Calculus ... $\delta' W$ vanishes [in Statics, or $\delta' W = \delta I$ in Kinetics], not because the quantities δq [or $\delta\boldsymbol{r}$] themselves tend to the limit zero, but in virtue of the *ratios* which these quantities bear to one another. The equation $[\delta' W_R = 0]$ therefore holds if the resolved displacements δq are replaced by any finite quantities having to one another the ratios in question. (Lamb, 1928, p. 113)

A related theme advanced by some antivirtual authors goes as follows: well, if you stretch the definitions and concepts of virtual displacement long enough, "when $\delta\boldsymbol{r}$ [our notation] are chosen properly," then you will arrive at "their" equations. However, as the fundamental definitions (3.A2.6d), or

$$\delta\boldsymbol{r} \equiv \textit{linear and homogeneous (in } \delta q\textit{) part of } \boldsymbol{r}(q+\delta q, t) - \boldsymbol{r}(q, t), \tag{3.A2.6g}$$

and LP show, such a coincidence is hardly some accidental ad hoc result out of the blue; but, instead, the only kind of equations flowing directly, logically, and uniquely, out of the application of LP to Pfaffianly constrained systems. A true principle leads, it does not follow; that is, it is not a conceptual rubber-band that stretches ("chosen properly") to fit the facts of the moment, after the latter have occurred!

In sum: *it is the force side of the equations of motion that compels us to introduce LP*. Equation (3.A2.3b) is a practical and theoretical necessity forced (!) upon us by the particular decomposition of the total force into impressed and reaction—a fact that is peculiar to Lagrangean mechanics; it is not an alternative to action–reaction. The famous kinematico-inertial identity of Lagrange:

$$\mathcal{S}\, dm\; \boldsymbol{a}\cdot(\partial\boldsymbol{r}/\partial q_k) \equiv \mathcal{S}\, dm\; \boldsymbol{a}\cdot\boldsymbol{e}_k = (\partial T/\partial\dot{q}_k)^{\cdot} - \partial T/\partial q_k \equiv E_k(T), \tag{3.A2.6h}$$

(that holds always, independently of subsequent constraints and constitutive postulates, as long as the q's are *holonomic* coordinates), is a *most welcome and useful but secondary result*.

The preoccupation with (3.A2.6h), at the expense of the forces, $Q_k \equiv \mathcal{S}\, d\boldsymbol{F}\cdot(\partial\boldsymbol{r}/\partial q_k) \equiv \mathcal{S}\, d\boldsymbol{F}\cdot\boldsymbol{e}_k$, $\quad R_k \equiv \mathcal{S}\, d\boldsymbol{R}\cdot(\partial\boldsymbol{r}/\partial q_k) \equiv \mathcal{S}\, d\boldsymbol{R}\cdot\boldsymbol{e}_k$ [= 0, in (3.A2.6e, f)], is perhaps best reflected in the seemingly innocuous but revealing fact that, although in "elementary" (Newton–Euler) mechanics most of us are taught to write *force = (mass)* × *(acceleration)*—that is, place the force on the *left* side of the equation—as soon as we graduate to advanced dynamics (d'Alembert–Lagrange), we suddenly switch to the form (*mass*) × (*acceleration*) = *force*—that is, place the force on the *right* side of the equation! Thus, many beginners in

Lagrangean mechanics get the superficial impression that the latter is just an exercise in differentiation of scalar energetic functions; the price one must pay for the transition from rectangular to curvilinear, or "generalized" coordinates (a pretty primitive term, in view of differential geometry and tensors). Even classics like Routh (1905(a), pp. 45–48) or Whittaker (1937, pp. 34–37) reinforce this misrepresentation.

(iv) Finally, there are those who, failing to understand the fundamental, simple, and natural kinematical representation (3.A2.6d), and in a complete breach with rational discourse, furiously and ignorantly trivialize and/or dismiss everything virtual (displacements, work, etc.) as "ill-defined," "nebulous," and "hence objectionable"; or complain "But it can hardly be gainsaid that maximum clarity is guaranteed by defining $\delta \boldsymbol{r}$ [our notation] *mathematically* in terms of more fundamental quantities" and "Consequently, for the formulation of equations of motion, the use of principles represented by LP [our term] is contraindicated, at least for systems possessing a finite number of degrees of freedom" [Kane and Levinson (1983, p. 1077), and rebuttal to Desloge (1986)]; and [virtual concepts are] "the closest thing in dynamics to black magic," "If you can construct a good virtual displacement vector, you can do good business with it,.... The difficulty is constructing it in the first place. It's like catching a bird by sprinkling salt on its tail. Virtual displacement is the salt on the bird's tail" (Radetsky, 1986, pp. 55–56); and "It should be acknowledged at this point that the traditional concepts of virtual displacement and virtual work are not necessary to the derivation of [our 3.A2.6e, f, h)]. It is quite sufficient (and more straightforward) simply to dot multiply $d\boldsymbol{f} = dm\,\boldsymbol{a}$ by [our] $\partial \boldsymbol{v}/\partial \dot{q}_j$ and add these equations together, accomplishing this for each of these n values of j" (Likins, 1973, pp. 297–298). The falsehood and misleadingness of these criticisms should be clear in the light of the above, and chapters 2 and 3. But we also point out the following, in favor of virtualness:

(a) As (3.A2.6d) shows, $\delta \boldsymbol{r}$ is *invariant* under $\delta q \leftrightarrow \delta\theta$ transformations, whereas the $\{\boldsymbol{e}_k, \boldsymbol{\varepsilon}_k\}$ are not; and similarly for $\delta' W$, $\delta' W_R$, δI, and so on.

(b) The $\delta \boldsymbol{r}$ admits of a far simpler and direct geometrical *visualization* than the $\partial \boldsymbol{v}/\partial \dot{q}_j \equiv \boldsymbol{e}_j$ (and $\partial \boldsymbol{v}^*/\partial \omega_j \equiv \boldsymbol{\varepsilon}_j$). In general, *differentials are far easier to visualize than derivatives*, and this explains their dominant presence in most figures of free-body diagrams, control volumes, and so on, even though the final equations do not contain lone differentials but derivatives.

(c) What is the motivation for dotting $d\boldsymbol{f} - dm\,\boldsymbol{a}$ with $\partial \boldsymbol{v}/\partial \dot{q}_j$? Why not dot it with its equal but simpler $\partial \boldsymbol{r}/\partial q_j$? Or, why not, say, cross it with them, or with $\partial \boldsymbol{v}/\partial q_j$, and so on? Or, why does not $\partial \boldsymbol{r}/\partial t \equiv \boldsymbol{e}_{n+1} \equiv \boldsymbol{e}_0$ appear in the equations of motion, although it appears in both $\boldsymbol{v}$ and $\boldsymbol{a}$?

(d) We would like to see such (supposedly) virtual-less authors try to:

- Extend their ad hoc techniques, rigorously, to *nonlinear* nonholonomic velocity constraints, without virtual displacements, or something mathematically equivalent (chap. 5). Fortunately for them, their constraints are *linear* in the velocities; that is, they are Pfaffian.
- Teach (even discrete) analytical *statics* (S) to students with no knowledge of dynamics (D), without virtual displacements/work! What does one do with their $\partial \boldsymbol{v}/\partial \dot{q}_j$ there? On the other hand, the definitions presented here are *uniformly* valid for both D and S alike.

(e) And if the use of differential variational principles, such as LP, is "contraindicated," how is one going to make the transition to the rest of the *differential* variational principles of Jourdain, Gauss et al. (chap. 6), and the *integral* variational principles of Hamilton, Voronets, Hamel, et al. (chap. 7), with their increasingly important role for approximate (analytical and numerical) solutions (chap. 7), as well as *invariance/conservation* theorems (e.g., Noether's theorem, §8.13)? Why such scientific provincialism and short-sightedness? [On the numerical advantages of some of these principles, see, e.g., Schiehlen (1981); for Gauss' principle, in particular, see, for example, Udwadia and Kalaba (1996)].

Such antivirtual attitudes artificially distance themselves from the tried and true mainstream dynamics, built over several centuries by some of the greatest names in mathematics and mechanics; such antihistorical and antitraditional attitudes contribute to a dynamical tower of Babel!

So, to recapitulate, we think that the whole problem with the earlier "antivirtual crowd" begins with their failure to acknowledge that in mechanics *the crux of the matter is the force*; that Newton–Euler splits forces into *internal* and *external* ("apples"), whereas d'Alembert–Lagrange splits them into *impressed* and *reactions* ("oranges"); and that the basic goal of AL is to *uncouple* the equations of motion into *kinetic* (*motion only, no reactions*) and *kinetostatic* (*reactions*). This failure also hampers the extension of their dynamics to new types of constraints and associated forces (e.g., servoconstraints, §3.17), let alone the application of its methodology to other areas of engineering and physics (such as electromechanical analogies and nonholonomic rotating electrical machinery; see, for example, Arczewski and Pietrucha (1993), Maißer (1981), Neimark and Fufaev (1972).

Appell versus Kane

In our notation, the so-called "Kane's equations" (1961, 1965, 1985) read simply (with $I = m+1, \ldots, n$):

$$\mathcal{S}\, d\boldsymbol{F}\cdot(\partial\boldsymbol{v}^*/\partial\omega_I) + \mathcal{S}\,(-dm\,\boldsymbol{a}^*)\cdot(\partial\boldsymbol{v}^*/\partial\omega_I) = 0,$$

or

$$(\textit{Generalized active force})_I + (\textit{Generalized inertial "force"})_I = 0. \tag{3.A2.7}$$

But in view of the fundamental kinematical identities (2.9.35 ff.)

$$\partial\boldsymbol{r}^*/\partial\theta_I = \partial\boldsymbol{v}^*/\partial\omega_I = \partial\boldsymbol{a}^*/\partial\dot{\omega}_I = \partial\dot{\boldsymbol{a}}^*/\partial\ddot{\omega}_I = \cdots \equiv \boldsymbol{\varepsilon}_I, \tag{3.A2.7a}$$

eqs. (3.A2.7) can be immediately rewritten as

$$\mathcal{S}\, d\boldsymbol{F}\cdot(\partial\boldsymbol{a}^*/\partial\dot{\omega}_I) + \mathcal{S}\,(-dm\,\boldsymbol{a}^*)\cdot(\partial\boldsymbol{a}^*/\partial\dot{\omega}_I) = 0, \tag{3.A2.7b}$$

or, finally, after some very simple rearrangements,

$$\partial/\partial\dot{\omega}_I\Big(\mathcal{S}\,(1/2)dm\,\boldsymbol{a}^*\cdot\boldsymbol{a}^*\Big) = \mathcal{S}\, d\boldsymbol{F}\cdot(\partial\boldsymbol{a}^*/\partial\dot{\omega}_I), \tag{3.A2.7c}$$

which are none other than Appell's equations! Here is a partial (alphabetical) list of readable textbooks/treatises/encyclopedias, and so on, on eqs. (3.A2.7–7c) [*all* of them from before 1961 (year of first Kane paper), and several from before Kane was born!]:

Appell [1899(a), (b); 1900(a), (b); 1925; 1953, pp. 388–395, eqs. (3.A2.6). Leisurely component presentation]

Coe [1938, pp. 386–390, eqs. (7). Earliest vectorial treatment in U.S. literature]

Hamel (1927, pp. 30–32; especially equations on 17th line from top of p. 32. Force-free case)

Hamel (1949, pp. 361–363; especially equations on 7th line from top of p. 362. Best concise presentation)

Lur'e [1961/1968, pp. 389–395. Equations (8.5.18) and (8.6.10) are, respectively, Kane's equations of 1961 and 1965]

MacMillan [1936, pp. 341–343, eqs. (3). Earliest (component) appearance in a U. S. treatise]

Marcolongo (1912, pp. 104–105; especially equations on 3rd line from bottom of p. 104)

Neimark and Fufaev [1967/1972, pp. 147–149, eqs. (8.3). Based completely on virtual concepts]

Pérès [1953, pp. 219–222. Excellent concise (vectorial) treatment including Kane's equations of both 1961 and 1965]

Platrier (1954, pp. 170–173, 323–324, 343–344)

Routh [1905(a), pp. 348–353, eqs. (5). Earliest appearance in English]

Schaefer [1919, p. 74, eq. (212)], similar treatment to Routh's and MacMillan's; well known in the German-speaking world.

Schaefer [1951, eqs. (12). Earliest *nonlinear* generalization of "Kane's equations" of 1965. Incidentally, in 1962 (in discussion of Kane (1961)) Schaefer warned Kane, in vain, that any further improvement on the methods/equations of the classical masters of dynamics (Appell, Heun, Hamel, Prange, Johnsen et al.) "is not imaginable."

Voss (1901–1908, pp. 82–83; and connection with Ferrers' equations)

(i) To make matters worse, Kane uses the following arcane terminology/notation:

(a) Our ω's he calls "generalized speeds," despite the fact that these are the (contravariant) *nonholonomic* components of the system velocity vector, in configuration/event space; a vector whose *holonomic* components are none other than the $\dot{q}$'s (what most reasonable authors call "generalized velocities," but Kane leaves nameless!). In other words, the $\dot{q}$'s and ω's are components of the *same* (system) vector, but along different types of bases: one *gradient*, one *nongradient*. However, and this is the essence of the method of quasi coordinates in constrained dynamics, *a proper choice of ω's uncouples the equations of motion into kinetic and kinetostatic; and, roughly, the n q's embed the (original) holonomic constraints, while the $n - m$ ω's embed the (additional) Pfaffian constraints.*

But there is another problem with "generalized speeds." According to time-honored and standard mechanics practices, *speed is the magnitude (or length) of the velocity vector,* and, as such, a *nonnegative scalar,* whereas the $\dot{q}$'s and ω's, being *components*, may have any sign—in automobiles, speedometers never show negative speeds! (Actually, the speed is an *invariant* under coordinate transformations; in tensor language: an absolute tensor of rank zero.) Therefore, from the viewpoint of tensors/differential geometry, and the traditions and practices of dynamics, the term "generalized speeds" is archaic, erroneous, and confusing.

(b) Kane's term "partial velocities," for our $\boldsymbol{e}_k$ and $\boldsymbol{\varepsilon}_k$, is entirely capricious and hides more than it reveals. In view of the identity (3.A2.7a), and a similar one for holonomic coordinates, we could just as well have called them "partial positions," or "partial accelerations," or even ... "partial jerks," and so on. A better term, though a long one, would be "accompanying (particle and system) vectors," that is the *begleitvektoren* of Heun; but we would welcome a more concise terminology.

(ii) To avoid virtual displacements, and so on, Kane (1961; 1968, p. 52) talks about instantaneous constraints, or about dividing $\delta\boldsymbol{r}$ with δt, the latter understood as "... any quantity having the dimensions of time." But since $\delta t = 0$ {in order to eliminate reactions, i.e. so that $\left[\mathsf{S}\, d\boldsymbol{R}\cdot(\partial\boldsymbol{r}/\partial t)\right]\delta t \equiv R_0\,\delta t = 0$, even though $R_0 \neq 0$}, such statements are likely to cause more confusion (division by a zero!), plus they are irrelevant to the final result—that is, the equations of motion. Why not use the simpler and rigorous definition (3.A2.6d, g).

(iii) In his frantic attempts to artificially distance himself from Appell, Kane (1986) states that the Appellian S is "a quantity of no interest in its own right." Well, most concepts of mechanics and physics derive their importance not "in their own right," but from their relation to the current edifice of those sciences; like a stone in relation to a building it belongs. Such narrow, positivistic (?), undialectical, objections can be raised against the Lagrangean, the Hamiltonian, the entropy, and so on. When was the last time anyone saw a stress, or a strain or even an acceleration?! During the 17th century, similar short-sighted complaints were raised against Leibniz's "vis viva" (= twice the kinetic energy). Tomorrow, perhaps, some other quantity, involving still higher derivatives (again "of no interest in its own right") might be introduced, in order to combine many new and old phenomena under one simple conceptual roof.

(iv) An alleged advantage (of the bean-counting type) of Kane over Appell is that in applying the latter one needs to square the accelerations $\boldsymbol{a}$ (or $\boldsymbol{a}^*$), then build the Appellian S (S^*), and then differentiate it with respect to the quasi accelerations $\dot{\omega}_k$, whereas Kane's approach dispenses with all that—compare (3.A2.7) with (3.A2.7c).

However, as Professor L.Y. Bahar has pointed out, the calculation of $\boldsymbol{a}^*$ and $\partial\boldsymbol{a}^*/\partial\dot{\omega}_k$ and subsequent formation of their dot product, in (3.A2.7b), is standard procedure in engineering science *whenever a quadratic form has to be partially differentiated.* For example, to calculate the static deflection p of a thin linearly elastic Euler/Bernoulli beam, of length l, flexural rigidity EI, and bending moment M, under a concentrated load P, we can use Castigliano's well-known theorem:

$$p = \partial V/\partial P = \partial/\partial P\left(\int_0^l M^2 dx/2EI\right), \tag{3.A2.8a}$$

where V is the *strain energy* of the beam (see any book on structural analysis). It is well known that, in practice, we never compute the integrand explicitly, then integrate it, and then differentiate the resulting function of P; but, instead, we first carry out the differentiation under the integral, and then integrate the result:

$$p = \partial V/\partial P = \int_0^l [M(\partial M/\partial P)/EI]\, dx; \tag{3.A2.8b}$$

that is, the step from (3.A2.8a) to (3.A2.8b) is conceptual rather than practical. Here, clearly, we have the correspondences $\boldsymbol{a}^* \to M$, $\partial\boldsymbol{a}^*/\partial\dot{\omega}_k \to \partial M/\partial P$. As with everything else, practice with Appell's equations helps one develop shortcuts and other special labor-saving skills. Finally, why use $\partial\boldsymbol{v}^*/\partial\omega_k$ or $\partial\boldsymbol{a}^*/\partial\dot{\omega}_k$, and not their equal but simpler expression (2.9.27)

$$\partial\boldsymbol{r}^*/\partial\theta_k \equiv \sum A_{lk}(\partial\boldsymbol{r}/\partial q_l),$$

and analogously for holonomic variables. Such flexibilities are absent from Kane's scheme.

In sum, Kane's equations are just a special implementation (or "raw" form) of Appell's kinetic equations, along the way from LP; one that completely ignores the long-term and big picture aspects of mechanics: namely, our understanding of its *underlying mathematical structure and physical ideas*, and their *interconnections with other areas of natural science,* which are the hallmarks of genuine education. Moreover, the whole Kaneian approach is conceptually unmotivated, isolating and primitive, historically ignorant and flat, intellectually stifling and wasteful. Indeed, it is a degraded and sterile type of mechanics that soon leads its practitioners down a dynamical dead-end. Ultimately, and this *applies to most of the contemporary multibody dynamics expositions*, such schemes discourage *active* learning, with its new and unpredictable turns, diversity and change. Like the currently promoted antipluralistic "expert systems," they assume that there is "a" best way to do dynamics, which is best determined by whomever designs the relevant books/computer programs. This is not normal human learning; it is not a presentation based on a *continuous* historical evolution; namely, one that respects and expands the dynamics traditions and practices. The brains of the readers (or users) are treated as pieces of equipment (hardware), where one inserts *abruptly* a set of computer instructions and commands (software). As a result, the majority of users of such "dynamics" will never be able to raise that edifice even by one inch; they will have been transformed from thinking engineers to (highly expendable) filing clerks! [We are indebted to B. Garson's *The Electronic Workshop: How Computers are Transforming the Office of the Future into the Factory of the Past* (Simon and Schuster, 1988, p. 126) for some of these insights.]

4

Impulsive Motion

4.1 INTRODUCTION

In this chapter, we present the Lagrangean principles and equations of *impulsive, or discontinuous,* motion of constrained systems. The relevant ‘‘elementary’’ Newton–Euler definitions and equations are summarized in §4.2. Then we cover, in sequence: the impulsive version of Lagrange’s principle (§4.3); the Appellian classification of impulsive constraints and corresponding equations of impulsive motion (§4.4); the formulation of kinetic and kinetostatic impulsive equations, in both holonomic and nonholonomic variables (§4.5; impulsive counterparts of the equations of Maggi, Hamel, and Appell); and, finally, the various impulsive energetic/extremum theorems of Carnot, Kelvin, Bertrand, Robin et al. (§4.6). As in the rest of the book, the discussion is complemented with a number of examples and problems.

Impulsive motion is a topic of intense and rapidly expanding research. Hence, a number of its aspects (e.g., role of *friction, deformation*), since they cannot be dealt with definitively here, are omitted.

For complementary reading on this engineeringly important subject, we recommend (alphabetically): Bouligand (1954, pp. 129–157, 444–483), Brach (1991), Easthope (1964, pp. 268–306), Goldsmith (1960), Hamel (1949, pp. 395–402), Kilmister and Reeve (1966, pp. 178–195, 217–221, 235–242, and Exercises), Kilmister (1967, pp. 98–108), Lainé (1946, pp. 185–201, 259–278), Loitsianskii and Lur’e (1983, pp. 131–143, 237–245, 276–280), Panovko (1977), Pöschl (1928), Routh (1905(a), pp. 136–164, 254–268, 302–313, 323–327), Smart (1951, vol. 2, pp. 376–390), Suslov (1946, pp. 607–645); also Bahar (1994), for instructive applications of Jourdain’s variational principle (§6.3) to impact.

4.2 BRIEF OVERVIEW OF THE NEWTON–EULER IMPULSIVE THEORY

Below, we summarize a few basic definitions and concepts. [Some of our differentials will be in *time* and some in *space*; we hope that their differences will be clear from the context, and no confusion will arise.]

Integrating the fundamental equation of motion of a particle P of mass dm (§1.4 ff.):

$$dm\,\boldsymbol{a} = d\boldsymbol{f}, \qquad \text{or} \qquad dm(d\boldsymbol{v}/dt) = d\boldsymbol{f}, \tag{4.2.1}$$

from an arbitrary time t' to an arbitrary time $t''(> t')$ yields

$$\Delta(dm\,\boldsymbol{v}) \equiv \Delta(d\boldsymbol{p}) = \int_{'}^{''} d\boldsymbol{f}\, dt, \tag{4.2.2}$$

where

$$\Delta(\ldots) = (\ldots)_{t''} - (\ldots)_{t'}, \qquad \int_{'}^{''} \ldots\, dt \equiv \int_{t'}^{t''} \ldots\, dt. \tag{4.2.2a}$$

Equation (4.2.2) states that the change of the linear momentum $d\boldsymbol{p} = dm\,\boldsymbol{v}$ of a (system) particle P during an arbitrary time interval $t'' - t' \equiv \tau$ equals the impulse of the total force $d\boldsymbol{f}$ acting on P, during that interval. Now, if τ is *finite*, the above is just the first time-integral of the Newton–Euler equation of motion; and, therefore, represents nothing new. If, however, τ is *very small*, or *infinitesimal*, then an independent and rather interesting chapter of dynamics, known as *impulsive motion* (IM; or *impact*, or *shock*), emerges. More specifically, IM occurs whenever *a very large* (or *infinite*, or *delta function-like*) *force acts on P for a very short time*; i.e., for $\tau \to 0$. As a result of this, at the end of τ: (i) the particle's *momentum* has changed by a *finite* instantaneous, that is, discontinuous, *jump* $\Delta(d\boldsymbol{p}) \equiv (d\boldsymbol{p})^+ - (d\boldsymbol{p})^- \neq \boldsymbol{0}$, where $(\ldots)^+/(\ldots)^-$: values of $(\ldots)$ just *after/before* the shock, respectively, or *right/left* limits of $(\ldots)$; or, since $dm = constant$,

$$\Delta\boldsymbol{v} \equiv \boldsymbol{v}^+ - \boldsymbol{v}^- \neq \boldsymbol{0}, \tag{4.2.3}$$

while (ii) the particle's *position* $\boldsymbol{r}$ has remained essentially *unchanged*; that is,

$$\Delta\boldsymbol{r} = \boldsymbol{0}. \tag{4.2.4}$$

Symbolically, in the IM case, eq. (4.2.2) reads

$$\Delta(dm\,\boldsymbol{v}) = \widehat{d\boldsymbol{f}}, \tag{4.2.5}$$

where

$$\widehat{(\ldots)} \equiv \lim_{\tau\to 0} \int_{t'}^{t'+\tau} (\ldots)\, dt \quad (\text{“}hat\text{” notation}). \tag{4.2.5a}$$

REMARKS

(i) The “hat” notation should not be confused with that notation occasionally employed for unit vectors.

(ii) We point out that, here, and contrary to the finite force case, as $\tau \to 0$,

$$\lim \int (\ldots)\,\mathrm{d}t \neq \int \lim\,(\ldots)\, dt, \quad \text{in general.} \tag{4.2.5b}$$

Clearly, impulsive “forces” (or *percussions*, or *blows*) $\widehat{d\boldsymbol{f}}$ are not defined as ordinary (or finite) forces at every instant of time, but, instead, only through the *instantaneous and finite jump*, or *discontinuity*, $\Delta(d\boldsymbol{p}) = \Delta(dm\,\boldsymbol{v}) = dm\,\Delta\boldsymbol{v}$ that they produce; for finite forces, such as gravity, the limit (4.2.5a) is, clearly, zero [and for an arbitrary continuous function $f = f(t, q)$: $\Delta f = 0$ and $\hat{f} = 0$]. The result of these approximations [i.e., $\Delta(positions) = 0$, $\Delta(velocities) \neq 0$, see ex. 2.4.1, below] is an impulsive theory of, admittedly, reduced practical value, but one of conceptual clarity and simplicity.

Application of this same idea to the Newton–Euler principles of linear and angular momentum, for a general system [i.e., multiplication of its, generally, *differential* equations of (finite) motion by dt, integration over τ, and then taking of the limit as $\tau \to 0$; while assuming that not all acting forces are finite, and that the "principle of action–reaction" for the internal loads holds for IM too], leads to *the impulsive forms of these two principles*, at time t, that are *algebraic* (finite difference; i.e., nondifferential!) equations.

As in finite motion, here, too, two possibilities arise: (i) either our theory generates enough such algebraic equations to determine the system's *postimpact state*; that is, the $\Delta \boldsymbol{v}$'s or the $\boldsymbol{v}^+$'s, and therefore the problem is *impulsively determinate*; or (ii) we have more unknowns than available equations, and thus the problem is *impulsively indeterminate*, in which case we need (in *addition* to the already utilized kinematical and kinetical equations) special *physical, or constitutive, equations/postulates*, as in continuum mechanics (e.g., Hooke's law in elasticity, Navier–Stokes law in fluid dynamics, etc.) — see §4.4.

Work–Energy in Impulsive Motion

Integrating the (rate of) work–(kinetic) energy equation, $dT/dt = \mathcal{S}\, d\boldsymbol{f} \cdot \boldsymbol{v}$, between t' and $t''(> t')$ yields the familiar integral form

$$\Delta T \equiv T'' - T' \equiv T^+ - T^- = \int_{'}^{''} \left(\mathcal{S}\, d\boldsymbol{f} \cdot \boldsymbol{v} \right) dt, \tag{4.2.6}$$

from which, passing to the impulsive limit ($t'' \to t'$) and invoking the mean value theorem of integral calculus, we obtain

$$\Delta T = \mathcal{S}\, \widehat{d\boldsymbol{f}} \cdot \langle \boldsymbol{v} \rangle \equiv \textit{Impulsive ``work.''} \tag{4.2.7}$$

where

$$\langle \boldsymbol{v} \rangle: \textit{mean/average} \text{ value of (generally unknown) impact velocity.} \tag{4.2.7a}$$

However, since impact involves *friction* and *deformation* — that is, phenomena accompanied by conversion of mechanical energy into heat — and since the latter lies outside pure mechanics, we should *not view* (4.2.7) as an *ordinary work–energy theorem*; impulsive "work" is not connected with increase in energy; and so, unlike momentum relations, in the case of energy there is no simple mathematical transition from ordinary (continuous, or finite, motion) to impulsive dynamics. [For some energetic aspects of impact, see, e.g., Roy (1965, pp. 176–179).]

Example 4.2.1 *Proof that Under Impulsive Forces:*

$$\Delta(\text{positions}) = 0, \qquad \text{but} \qquad \Delta(\text{velocities}) \neq 0.$$

Let us consider the motion of a particle P of mass m, along the axis Ox, with initial conditions (at, say, $t_o = 0$): $x(0) = 0$ and $\dot{x}(0) = 0$, under the 2τ – periodic total force:

$$X = X_o \sin(\pi t/\tau), \qquad 0 \le t \le \tau,$$
$$X = 0, \qquad \tau < t < \infty, \tag{a}$$

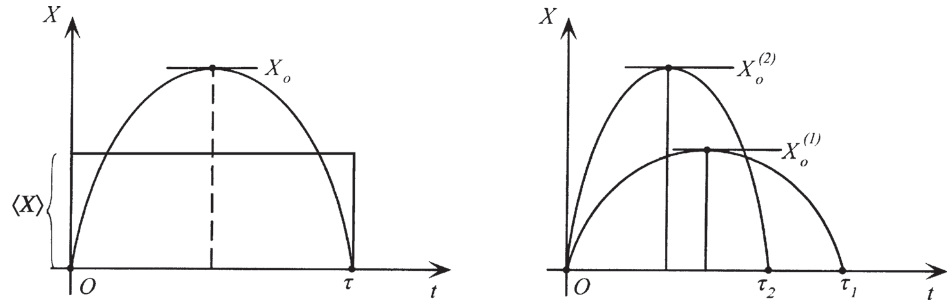

Figure 4.1 On the concept of impulsive force.

where $X_o =$ *force amplitude, a constant*; and $\tau =$ *duration* of action of X (fig. 4.1). Integrating the equation of motion of P:

$$m\ddot{x} = X_o \sin(\pi t/\tau), \tag{b}$$

twice, while choosing the integration constants to satisfy the given initial conditions, we obtain

$$\dot{x} \equiv v = (X_o\tau/\pi m)\big[1 - \cos(\pi t/\tau)\big], \tag{c}$$

$$x = (X_o\tau/\pi m)t - (X_o\tau^2/\pi^2 m)\sin(\pi t/\tau). \tag{d}$$

Hence,

$$\Delta x \equiv x(\tau) - x(0) = (X_o\tau^2)/(\pi m) = (X_o\tau)\tau/\pi m = \big(\langle X\rangle\tau/2m\big)\tau, \tag{e}$$

$$\Delta(\dot{x}) \equiv \Delta v = \dot{x}(\tau) - \dot{x}(0) = 2(X_o\tau)/(\pi m) = \big(\langle X\rangle\tau\big)/m, \tag{f}$$

where

$$\langle X\rangle \equiv (1/\tau)\int_0^\tau X(t)\,dt = (1/\tau)\int_0^\tau X_o \sin(\pi t/\tau)\,dt = 2X_o/\pi:$$

$$\textit{Mean value of force in } \tau. \tag{g}$$

The above show that as long as the product $\langle X\rangle\tau = \int_0^\tau X(t)\,dt$ remains fixed (even though τ, and hence $\langle X\rangle$, may vary) so does Δv. Hence, in the particular, "impact limit": $X_o \to \infty$ (and generally as $|X_o| \to \infty) \Rightarrow \langle X\rangle \to \infty$, *and* $\tau \to 0$, so that $\langle X\rangle\tau =$ *fixed nonzero value* $\equiv C$, eqs. (e, f) yield

$$\Delta x = 0 \quad \text{and} \quad \Delta v = C/m \Rightarrow \Delta(mv) = C; \tag{h}$$

that is, in the limiting case of a very large ("infinite") force acting for a very short ("infinitesimal") time, the momentum changes ("instantaneously/discontinuously") by the finite amount C, while the position does not!

4.3 THE LAGRANGEAN IMPULSIVE THEORY; NAMELY, CONSTRAINED DISCONTINUOUS MOTION

Let us now examine impulsive motion from the viewpoint of analytical mechanics. Summing eqs. (4.2.2, 5) over all the material particles of the system, $\mathcal{S}(\ldots)$, yields the *impulsive linear momentum principle*:

$$S\,\Delta(dm\,\boldsymbol{v}) = \Delta\Big(S\,dm\,\boldsymbol{v}\Big) = S\,\widehat{d\boldsymbol{f}} = \widehat{S\,d\boldsymbol{f}} = \hat{\boldsymbol{f}}, \tag{4.3.1}$$

since, clearly, $S(\ldots)$ and $\Delta(\ldots)$ can be interchanged; and, recalling the *d'Alembert decomposition* (§3.2): $d\boldsymbol{f} = d\boldsymbol{F} + d\boldsymbol{R}$, we can rewrite (4.3.1), with some easily understood notations, as

$$\Delta\Big(S\,dm\,\boldsymbol{v}\Big) = \hat{\boldsymbol{F}} + \hat{\boldsymbol{R}}. \tag{4.3.2}$$

This is the *constrained impulsive linear momentum* "*principle*." A similar constrained impulsive equation/theorem results if we cross both members of the Newton–Euler law of motion for a typical particle, *under d'Alembert's decomposition*, with its position vector (relative to some fixed origin, or some other position vector), sum the resulting angular momentum equations over the entire system, multiply the result with dt, integrate it over τ, and then, as before, take its limit as $\tau \to 0$. The result would be the *constrained impulsive angular momentum principle*, featuring on its right side the sums of the moments of the *impressed impulsive forces* $\{\widehat{d\boldsymbol{F}}\}$, and *impulsive constraint reactions* $\{\widehat{d\boldsymbol{R}}\}$ [i.e., "forces" caused either by the $\widehat{d\boldsymbol{F}}$'s, or by the sudden introduction of constraints (in addition to the already existing ones, which are called *permanent*, or *primitive*), cause discontinuous changes (jumps) to the system holonomic and/or nonholonomic velocities — these are detailed below].

Now, the objective of Lagrangean impulsive theory — namely, *the impulsive theory of constrained mechanical systems* — is to develop system impulsive equations *with or without the* $\widehat{d\boldsymbol{R}}$'s. To this end, we proceed as in the case of finite motion (chap. 3): dotting the constrained impulsive linear momentum equation for a typical system particle P,

$$\Delta(dm\,\boldsymbol{v}) = \widehat{d\boldsymbol{F}} + \widehat{d\boldsymbol{R}}, \tag{4.3.3}$$

with its virtual displacement $\delta\boldsymbol{r}$ (at the shock instant $t = t'$), and then summing over the system particles, yields

$$S\big[\Delta(dm\,\boldsymbol{v}) - \widehat{d\boldsymbol{F}}\,\big]\cdot\delta\boldsymbol{r} = S\,\widehat{(-d\boldsymbol{R})}\cdot\delta\boldsymbol{r}; \tag{4.3.3a}$$

and, next, assuming that for bilateral "ideal" constraints the $\widehat{d\boldsymbol{R}}$'s satisfy the constitutive postulate/definition (while assuming that $\widehat{\delta\boldsymbol{r}} = \boldsymbol{0}$; e.g., by choosing *time-independent/constant virtual displacements*, for $t' \le t \le t''$)

$$\widehat{-\,\delta' W_R} \equiv \widehat{S(-d\boldsymbol{R})\cdot\delta\boldsymbol{r}} = S\,\widehat{(-d\boldsymbol{R})}\cdot\delta\boldsymbol{r} = 0, \tag{4.3.3b}$$

we readily obtain the *fundamental impulsive variational equation* (*impulsive principle of Lagrange — LIP*)

$$\widehat{\delta I} = \widehat{\delta' W}, \tag{4.3.4}$$

where

$$\widehat{\delta I} \equiv \widehat{S\, dm\, \boldsymbol{a} \cdot \delta \boldsymbol{r}} = S\, \Delta(dm\, \boldsymbol{v}) \cdot \delta \boldsymbol{r}:$$

(first-order) *virtual work of impulsive momenta*, (4.3.4a)

$$\widehat{\delta' W} \equiv \widehat{S\, d\boldsymbol{F} \cdot \delta \boldsymbol{r}} = S\, \widehat{d\boldsymbol{F}} \cdot \delta \boldsymbol{r}:$$

(first-order) *virtual work of impressed "forces."* (4.3.4b)

From (4.3.3–4b), we can obtain all kinds of special impulsive equations: with/without impulsive reactions (i.e., kinetostatic/kinetic/mixed impulsive equations), in particle/system form, in holonomic/nonholonomic variables, and so on.

We begin by substituting into (4.3.3b, 4) the *holonomic* variable representation (§2.5 ff.): $\delta \boldsymbol{r} = \sum \boldsymbol{e}_k\, \delta q_k$ $(k = 1, \ldots, n)$. Since [in complete analogy with the finite motion case (§3.2 ff.), and assuming that $\hat{\boldsymbol{e}}_k = \boldsymbol{0}$, $\widehat{\delta q_k} = 0 \Rightarrow \widehat{\delta \boldsymbol{r}} = \boldsymbol{0}$]

$$\widehat{\delta' W_R} = S\, \widehat{d\boldsymbol{R}} \cdot \delta \boldsymbol{r} = \sum \Big(S\, \widehat{d\boldsymbol{R}} \cdot \boldsymbol{e}_k \Big)\, \delta q_k \equiv \sum \widehat{R_k}\, \delta q_k, \tag{4.3.5a}$$

$$\widehat{\delta' W} = S\, \widehat{d\boldsymbol{F}} \cdot \delta \boldsymbol{r} = \sum \Big(S\, \widehat{d\boldsymbol{F}} \cdot \boldsymbol{e}_k \Big)\, \delta q_k \equiv \sum \widehat{Q_k}\, \delta q_k, \tag{4.3.5b}$$

$$\begin{aligned} \widehat{\delta I} &= S\, \Delta(dm\, \boldsymbol{v}) \cdot \delta \boldsymbol{r} = \sum \Big(S\, dm\, \Delta \boldsymbol{v} \cdot \boldsymbol{e}_k \Big)\, \delta q_k \\ &= \sum \Delta \Big(S\, dm\, \boldsymbol{v} \cdot \boldsymbol{e}_k \Big)\, \delta q_k \equiv \sum \Delta p_k\, \delta q_k, \end{aligned} \tag{4.3.5c}$$

and

$$p_k \equiv S\, (dm\, \boldsymbol{v} \cdot \boldsymbol{e}_k) \equiv \partial T / \partial \dot{q}_k$$

$$\Rightarrow \Delta p_k = \Delta \Big(S\, dm\, \boldsymbol{v} \cdot \boldsymbol{e}_k \Big) = S\, \Delta(dm\, \boldsymbol{v}) \cdot \boldsymbol{e}_k:$$

[holonomic (k)th component of] impulsive system *momentum change*, (4.3.6a)

$$\widehat{Q_k} \equiv \widehat{S\, d\boldsymbol{F} \cdot \boldsymbol{e}_k} = S\, \widehat{d\boldsymbol{F} \cdot \boldsymbol{e}_k} = S\, \widehat{d\boldsymbol{F}} \cdot \boldsymbol{e}_k:$$

[holonomic (k)th component of] impulsive system *impressed* force;
or, simply, impressed system *impulse*, (4.3.6b)

$$\widehat{R_k} \equiv \widehat{S\, d\boldsymbol{R} \cdot \boldsymbol{e}_k} = S\, \widehat{d\boldsymbol{R} \cdot \boldsymbol{e}_k} = S\, \widehat{d\boldsymbol{R}} \cdot \boldsymbol{e}_k:$$

[holonomic (k)th component of] impulsive system *constraint reaction* force, (4.3.6c)

we finally obtain LIP, eqs. (4.3.3b, 4), in *holonomic system variables*:

$$\sum \widehat{R_k}\, \delta q_k = 0, \qquad \sum \Delta(\partial T / \partial \dot{q}_k)\, \delta q_k = \sum \widehat{Q_k}\, \delta q_k; \tag{4.3.7}$$

and similarly for *quasi variables* (§4.5).

These are the fundamental (differential) variational equations of Lagrangean impulsive theory. All equations of impulsive motion, compatible with our finite-number-of-degrees-of-freedom model (i.e., impulsive counterparts of the equations of Routh–Voss, Maggi, Hamel, etc.), flow from (4.3.7) by *appropriate specializations of the virtual displacements;* and these latter depend on the nature of the imposed constraints. This process is detailed in the following sections.

Example 4.3.1 *"Work–energy" theorem in Constrained Impulsive Motion; or, Impressed Impulsive Forces Applied to a Moving System.* Let us begin with the LIP, eqs. (4.3.4–4b):

$$\mathsf{S}\, dm(\boldsymbol{v}^+ - \boldsymbol{v}^-) \cdot \delta\boldsymbol{r} = \mathsf{S}\, \widehat{d\boldsymbol{F}} \cdot \delta\boldsymbol{r}. \tag{a}$$

Choosing in there, first $\delta\boldsymbol{r} \to \boldsymbol{v}^-$ and then $\delta\boldsymbol{r} \to \boldsymbol{v}^+$ (since, here, time is considered fixed), we obtain, respectively,

$$\mathsf{S}\, dm(\boldsymbol{v}^+ - \boldsymbol{v}^-) \cdot \boldsymbol{v}^- = \mathsf{S}\, \widehat{d\boldsymbol{F}} \cdot \boldsymbol{v}^-, \tag{b}$$

$$\mathsf{S}\, dm(\boldsymbol{v}^+ - \boldsymbol{v}^-) \cdot \boldsymbol{v}^+ = \mathsf{S}\, \widehat{d\boldsymbol{F}} \cdot \boldsymbol{v}^+. \tag{c}$$

Adding (b) and (c) side by side, and then dividing by 2, we obtain the sought energetic theorem

$$\Delta T \equiv T^+ - T^- = W_{-/+}, \tag{d}$$

where

$$2T^+ \equiv \mathsf{S}\, dm\, \boldsymbol{v}^+ \cdot \boldsymbol{v}^+, \qquad 2T^- \equiv \mathsf{S}\, dm\, \boldsymbol{v}^- \cdot \boldsymbol{v}^-, \tag{e}$$

and

$$W_{-/+} \equiv \mathsf{S}\, \widehat{d\boldsymbol{F}} \cdot (\boldsymbol{v}^+ + \boldsymbol{v}^-)/2 \equiv \mathsf{S}\, \widehat{d\boldsymbol{F}} \cdot \langle \boldsymbol{v} \rangle. \tag{f}$$

In words: The sudden change of the kinetic energy of a moving system, due to arbitrary impressed impulses, equals the sum of the dot products of these impulses with the mean (average) velocities of their material points of application, immediately before and after their action.

4.4 THE APPELLIAN CLASSIFICATION OF IMPULSIVE CONSTRAINTS, AND CORRESPONDING EQUATIONS OF IMPULSIVE MOTION

As mentioned earlier, to proceed further from the impulsive variational equation (§4.3.7), we must specify the n δq's; that is, specify the (variational form of the) impulsive constraints of the particular problem. And this brings us to Appell's fundamental *classification of impulsive constraints*. [See Appell (1896, p. 6 ff.; 1953, pp. 505–544); also (alphabetically): Bouligand (1954, pp. 129–157) and Roy (1965, p. 171 ff.). For a related classification, but with different terminology, see Pars (1965, pp. 228–248) and Rosenberg (1977, pp. 391–411). Also, all impulsive constraints dealt with here are assumed ideal; that is, $\widehat{\delta' W_R} = 0$].

According to his approach, which we follow here, the most general way of viewing a shock or percussion is as follows: at a given initial instant t' new constraints are suddenly introduced into the system and/or some old constraints are removed, or suppressed. As a result, percussions are generated, which, in the very short time interval

$\tau \equiv t'' - t'$, over which they are supposed to act and during which the shock lasts, produce finite velocity changes, but, according to our "first" approximation negligible position changes; that is, for $\tau \to 0$: $\Delta q = 0$, $\Delta(dq/dt) \equiv \Delta v \neq 0$ (ex. 4.2.1).

Now, *the constraints existing at the shock moment* are either *persistent* or *nonpersistent*. By persistent, we mean constraints that, existing at the shock "moment," exist also after it, so that the actual postimpact displacements are incompatible with them; whereas by nonpersistent we mean constraints that, existing at the shock moment, do not exist after it, so that the actual postimpact displacements are incompatible with them.

As a result of this, impulsive constraints can be classified into the following *four* distinct kinds or types:

1. Constraints existing *before, during, and after the shock*; that is, the latter neither introduces new constraints, nor does it change the old ones; the system, however, is acted on by impulsive forces. An example of such a constraint is the striking of a physical pendulum with a nonsticking (or, nonplastic) hammer at one of its points, and resulting communication to it of a specified impressed impulsive force; while the impulsive reactions, generated at the pendulum support, satisfy (4.3.3b) and first of (4.3.7).
2. Constraints existing *during and after the shock, but not before it*; that is, the latter introduces suddenly new constraints to the system. Examples: (a) A rigid bar falling freely, until the two inextensible slack strings connecting its endpoints to a fixed ceiling get taut (during) and do not break (after); (b) The inelastic central collision of two solid spheres ("coefficient of restitution" $\equiv e = 0$—see (4.4.1)); (c) In a ballistic pendulum (see prob. 4.4.9) the pendulum is constrained to rotate about a fixed axis; which is a constraint existing before, during and after the percussion of the pendulum with a projectile (i.e., first-type constraint). The projectile, however, originally independent of the pendulum, strikes it and becomes embedded into it; which is a case of a new constraint whose sudden realization produces the shock, and which exists during and after the shock but not before it (i.e., second-type constraint).
3. Constraints existing *before and during the shock, but not after it*. For example, let us imagine a system consisting of two particles connected by a light and inextensible bar, or thread, thrown up into the air. Then, let us assume that one of these particles is suddenly seized (persistent constraint introduced abruptly; i.e., second type) and, at the same time, the bar breaks (constraint existing before the shock does not exist after it; i.e., third type).
4. Constraints existing *only during the shock, but neither before nor after it*. For example, when two solids collide, since their bounding surfaces come into contact, a constraint is abruptly introduced into this two body system. If these bodies are *elastic* ($e = 1$—see coefficient of restitution, below), they separate after the collision; which is a case of a constraint existing during the percussion but neither before nor after it (i.e., fourth type); while if they are *plastic* ($e = 0$) they do not separate (projectile and pendulum, above; i.e., second type). (If $0 < e < 1$, the bodies separate; i.e., we have a fourth-kind constraint.)

This classification is summarized in table 4.1; clearly, the first two types contain the persistent constraints, while the last two contain the nonpersistent ones.

REMARKS

(i) Types 1, 2, 3, 4 are also referred to, respectively, as *permanent, persistent, preexisting*, and *instantaneous* (*direct shock*). Also, for obvious reasons, type 1 is referred to as *continuous*; and types 2, 3, and 4, as *discontinuous*.

Table 4.1 Appellian Classification of Impulsive Constraints

	Preshock (before)	Shock (during)	Postshock (after)
1 (persistent)	▬	▬	▬
2 (persistent)		▬	▬
3 (nonpersistent)	▬	▬	
4 (nonpersistent)		▬	

(ii) These concepts are of paramount importance because, as shown below, in an impulsive problem, the excess of the number of unknowns (postimpact velocities and constraint reactions) over that of the available equations [those obtained from Lagrange's impulsive principle; plus preimpact velocities, impressed impulsive forces, constraints, and sometimes knowledge of the postimpact state (second type; e.g., $e = 0$)]—that is, the degree of its indeterminacy—equals the number of its constraints that, having existed before or during the shock, cease to do so at the end of it; that is,

$$\textit{Degree of indeterminacy} = \textit{Number of nonpersistent constraints};$$

hence, the persistent types 1 and 2 are *determinate*, while the nonpersistent ones 3 and 4 are indeterminate.

(iii) Generally, problems of *collision* among solid bodies are indeterminate. For example, in the collision of two *smooth* solids, A and B, with respective mass centers G_A and G_B, we have thirteen unknowns: $3 + 3 = 6$ from the postimpact velocities of G_A and G_B, $3 + 3 = 6$ from the postimpact angular velocities of A and B, and 1 from the magnitude of the mutual *normal* impact force; and only twelve equations: $6 + 6 = 12$ from the theorems of impulsive linear/angular momenta. (For *nonsmooth* solids, things get more complicated.) To make the problem determinate, we introduce Newton's *coefficient of restitution, e*. This latter is defined by

$$e = -\frac{(\boldsymbol{v}_{2/1}\cdot\boldsymbol{n})^+}{(\boldsymbol{v}_{2/1}\cdot\boldsymbol{n})^-} \equiv -\frac{{\nu_{2/1,n}}^+}{{\nu_{2/1,n}}^-} = -\frac{\text{Relative velocity of } \textit{separation}}{\text{Relative velocity of } \textit{approach}}, \tag{4.4.1}$$

where 1 and 2 are the two points of A and B that come into contact during the collision, and $\boldsymbol{n}$ is the unit vector along the common normal to their bounding surfaces there, say from A to B (see also exs. 4.4.1 and 4.4.2 below). The coefficient ranges from 0 (*plastic* impact, no separation) to 1 (*elastic* impact, no energy loss); that is, $0 \le e \le 1$.

(iv) The case of the removal of a constraint (e.g., the sudden snapping of one or more of the taut strings supporting an originally motionless bar from a ceiling), is *not* an impulsive motion problem (of the third kind) but one of *initial* motion; that is,

$$\Delta(\textit{positions}) = 0, \qquad \Delta(\textit{velocities}) = 0, \qquad \text{but} \quad \Delta(\textit{accelerations}) \neq 0.$$

However, if the rupture is the result of an impulsive force (a blow), the problem falls under type 3 (see comments on rupture later in this section).

Analytical Expression of the Appellian Classification; Persistency versus Determinacy

Let us express analytically all these types of constraints. We begin with a discussion of this issue in terms of *elementary* dynamics. Let us consider a system consisting of

N solids, in contact with each other at K points, out of which C are of the nonpersistent type, and/or with a number of foreign solid obstacles that are either fixed or have *known* motions. Assuming *frictionless* collisions, we will have a total of $6N + K$ *unknowns* ($6N$ postshock velocities, plus K percussions at the smooth contacts, along the common normals); and $6N + K - C$ *equations* ($6N$ impulsive momentum equations, plus $K - C$ persistent-type constraints); and therefore *the degree of indeterminacy equals the number of nonpersistent contacts* C (i.e., the kind that disappear after the shock). Hence: (i) a *free* (*i.e., unconstrained*) solid subjected to *given* percussions, and/or (ii) a system subjected only to *persistent* constraints are impulsively determinate.

Let us now discuss the problem from the Lagrangean viewpoint. We recall (§2.4 ff.) that a number of holonomic constraints, imposed on a system originally defined by n Lagrangean coordinates, can *always* be put in the *equilibrium* form:

$$q_1 = 0, q_2 = 0, \ldots, q_m = 0 \qquad (m\text{: number of such constraints} < n) \tag{4.4.1a}$$

REMARKS

(i) It is shown later in this section, that, *within our impulsive approximations,* even Pfaffian constraints (including nonholonomic ones) can be brought to the holonomic form; that is, in impulsive motion *all* constraints behave as holonomic! However, as elaborated in the next section, quasi variables *can* be used to advantage in impulsive problems.

(ii) Briefly, if the system is, originally, described by the Lagrangean coordinates $q \equiv (q_1, \ldots, q_n)$, and if the $m(< n)$ new constraints are expressed by

$$\phi_1(t, q) = 0, \ldots, \phi_m(t, q) = 0, \tag{4.4.1b}$$

then, by replacing $q_1, \ldots, q_m$ with the new Lagrangean coordinates,

$$\chi_1 \equiv \phi_1(t, q), \ldots, \chi_m \equiv \phi_m(t, q); \qquad \chi_{m+1} = q_{m+1}, \ldots, \chi_n = q_n, \tag{4.4.1c}$$

we can express the new constraints (b) by the "equilibrium" equations:

$$\chi_1 = 0, \ldots, \chi_m = 0. \tag{4.4.1d}$$

Assuming, henceforth, such a choice of Lagrangean coordinates for all our impulsive constraints (and, for convenience, redenoting these new equilibrium coordinates by $q_1, \ldots, q_m; \ldots, q_n$), we can quantify the four Appellian types of impulsive constraints as follows:

- *First-type constraints* (existing *before, during, and after* the shock). As a result of these constraints, let the system configurations depend on n, hitherto independent, Lagrangean parameters: $q \equiv (q_1, \ldots, q_n)$. During the shock interval (t', t''), the corresponding velocities $\dot{q} \equiv (\dot{q}_1, \ldots, \dot{q}_n)$, pass suddenly from the known values $(\dot{q})^-$, at t', to other values $(\dot{q})^+$, while the q's remain practically unchanged; that is, here we have

$$(q_k)_{\text{before}} = 0, \qquad (q_k)_{\text{during}} = 0, \qquad (q_k)_{\text{after}} = 0; \tag{4.4.2a}$$

$$\Delta\dot{q}_k \equiv (\dot{q}_k)^+ - (\dot{q}_k)^- \neq 0 \qquad \big[(\dot{q}_k)^+\text{: unknown}, (\dot{q}_k)^-\text{: known}\big]. \tag{4.4.2b}$$

• *Second-type constraints* (additional constraints, existing *during and after* the shock, but *not before it*). Here, with $q_{D''} \equiv (q_1, \ldots, q_{m''})$, where $m'' < n$, we have

$$(q_{D''})_{\text{before}} \neq 0, \qquad (q_{D''})_{\text{during}} = 0, \qquad (q_{D''})_{\text{after}} = 0; \tag{4.4.3a}$$

$$(\dot{q}_{D''})^- \neq 0, \quad (\dot{q}_{D''})^+ = 0 \;\Rightarrow\; \Delta(\dot{q}_{D''}) = -(\dot{q}_{D''})^- \neq 0. \tag{4.4.3b}$$

[Equations like $q_{\text{after}} - q_{\text{before}} \neq 0$ i.e., (4.4.3a, 4a) in no way contradict our earlier assumption (first approximation): $\Delta(\textit{configuration}) \equiv \Delta q \equiv q^+ - q^- = 0$. As with the finite motion case (chap. 2), any new holonomic constraints must be consistent with the system configuration.]

• *Third-type constraints* (additional constraints existing *before and during*, but *not after* the shock). Here, with $q_{D'''} \equiv (q_{m''+1}, \ldots, q_{m'''})$, where $m''' < n$, we have

$$(q_{D'''})_{\text{before}} = 0, \qquad (q_{D'''})_{\text{during}} = 0, \qquad (q_{D'''})_{\text{after}} \neq 0; \tag{4.4.4a}$$

$$(\dot{q}_{D'''})^- = 0, \;\; (\dot{q}_{D'''})^+ \neq 0 \;\Rightarrow\; \Delta(\dot{q}_{D'''}) = (\dot{q}_{D'''})^+ \neq 0. \tag{4.4.4b}$$

• *Fourth-type constraints* (additional constraints existing only *during*, but *neither before nor after* the shock). Here, with $q_{D''''} \equiv (q_{m'''+1}, \ldots, q_{m''''})$, where $m'''' < n$, we have

$$(q_{D''''})_{\text{before}} \neq 0, \qquad (q_{D''''})_{\text{during}} = 0, \qquad (q_{D''''})_{\text{after}} \neq 0; \tag{4.4.5a}$$

$$(\dot{q}_{D''''}) \neq 0, \quad (\dot{q}_{D''''})^- \neq 0 \;\Rightarrow\; \Delta(\dot{q}_{D''''}) = (\dot{q}_{D''''})^+ - (\dot{q}_{D''''})^- \neq 0. \tag{4.4.5b}$$

Hence, if no fourth-type constraints exist, $m''' = m''''$; and if no third-type constraints exist, $m'' = m'''$; and so on. Now, arguing as in the case of continuous motion (chap. 3), during the shock interval, we may view the constraints of the *second, third*, and *fourth* types as absent, provided that, in the spirit of the *impulsive principle of relaxation* [see also discussion below, after (4.4.16b)], we add to the system the corresponding constraint reactions. All relevant equations of motion are contained in the LIP (second of 4.3.7),

$$\sum \Delta(\partial T/\partial \dot{q}_k)\, \delta q_k = \sum \hat{Q}_k\, \delta q_k \qquad (k = 1, \ldots, n). \tag{4.4.6}$$

If the *virtual displacements* $\delta q \equiv (\delta q_1, \ldots, \delta q_n)$ are arbitrary, the right side of the above contains the impulsive virtual works of the reactions stemming from the *second, third*, and *fourth*-type constraints, and operating during the shock interval $[t', t'']$. Therefore, to eliminate these "forces," and thus produce $n - m''''$ reactionless, or kinetic, impulsive equations, we choose δq's that are compatible with *all constraints holding at the shock moment;* that is, we take

$$\delta q_1, \ldots, \delta q_{m''}; \qquad \delta q_{m''+1}, \ldots, \delta q_{m'''}; \qquad \delta q_{m'''+1}, \ldots, \delta q_{m''''} = 0; \tag{4.4.6a}$$

$$\delta q_{m''''+1}, \ldots, \delta q_n \neq 0. \tag{4.4.6b}$$

Applying the method of Lagrangean multipliers to the variational equation (4.4.6), under the virtual constraints (4.4.6a, b), we readily obtain the *two* (uncoupled) sets of equations:

Impulsive kinetostatic: $\quad \Delta(\partial T/\partial \dot{q}_D) = \hat{Q}_D + \hat{\lambda}_D \quad (D = 1, \ldots, m'''')$, (4.4.7a)

Impulsive kinetic: $\quad \Delta(\partial T/\partial \dot{q}_I) = \hat{Q}_I \quad (I = m'''' + 1, \ldots, n)$. (4.4.7b)

Further, since the velocity jumps $\Delta\dot{q}$ are produced only by the very large impulsive constraint reactions, operating during the very small interval $t'' - t'$, within our approximations, the $\hat{Q}_I$ [since they derive only from ordinary (i.e., finite, nonimpulsive) forces, like gravity] vanish: $\hat{Q}_I = 0$; and so (4.4.7b) reduce to *Appell's rule*:

$$\Delta(\partial T/\partial \dot{q}_I) = 0 \;\Rightarrow\; (\partial T/\partial \dot{q}_I)^+ = (\partial T/\partial \dot{q}_I)^-. \tag{4.4.8}$$

In words: *The partial derivatives of the kinetic energy relative to the velocities of those system coordinates q's that are not forced to vanish at the shock instant (i.e., $q_{\text{during}} \neq 0$) have the same values before and after the impact; or these $n - m''''$ unconstrained momenta, $p_I \equiv \partial T/\partial \dot{q}_I$, are conserved.*

Now, since T is quadratic in the $\dot{q}$'s, eqs. (4.4.8) are *linear and* (as explained below, under "Frame of Reference Effects on Impulsive Motion") *homogeneous* in the $n\ \Delta\dot{q}$'s. In there:

(i) The $q_1, \ldots, q_n$, have their constant shock instant values; that is,

$$q_D\colon\ q_{D''}, q_{D'''}, q_{D''''} = 0; \qquad \text{while} \qquad q_I\colon\ q_{m''''+1}, \ldots, q_n = \textit{known}; \tag{4.4.9a}$$

(ii) The $(\dot{q}_1)^-, \ldots, (\dot{q}_n)^-$ are *known*; in particular, $(\dot{q}_{D'''})^- = 0$; (4.4.9b)

(iii) The $(\dot{q}_1)^+, \ldots, (\dot{q}_n)^+$ are the *unknowns* of the problem; except that, since the constraints $(q_{D''})_{\text{after}} = 0$ are persistent,

$$(\dot{q}_{D''})^+ = 0. \tag{4.4.9c}$$

Hence, we have $n - m''''$ linear equations (4.4.8) for the $n - m''$ unknowns: $(\dot{q}_{m''+1})^+, \ldots, (\dot{q}_n)^+$; and therefore the *degree of indeterminacy* of the impulsive problem equals

$$\begin{aligned}(n - m'') - (n - m'''') &= m'''' - m'' \quad (> 0, \text{assumed})\\ &= \textit{number of nonpersistent constraints}\ (= \text{number of 3rd and 4th types}).\end{aligned} \tag{4.4.9d}$$

In sum: the impulsive problem (4.4.8) is, in general, *indeterminate* [unlike its ordinary motion counterpart which *is* determinate (§3.5, §3.8)]: the m'''' kinetostatic equations (4.4.7a) introduce the m'''' *additional* unknown $\hat{\lambda}_D$'s. If, however, only persistent constraints are present ($m'''' = m''$), the impulsive problem (4.4.8) is *determinate*.

To make the problem determinate, in the presence of nonpersistent type constraints, we must make particular *constitutive* (i.e., *physical*) *hypotheses*; for example, elasticity assumptions about the postshock state. For example, in the well-known problem of central (or direct) collision of two solid spheres that separate after the shock (fourth-type constraint), Newton–Euler mechanics provides only *one* equation for the two postimpact velocities of the spheres' centers: $\Delta v_{\text{center of mass of system}} = 0$. A *second* equation is furnished by constitutive assumptions; for example, for perfect elasticity, $\Delta T = 0$. The most common constitutive equations for such third and/or fourth type $(\dot{q})^+$'s are

$$(\dot{q}_{D''',D''''})^+ = -e(\dot{q}_{D''',D''''})^- \quad (D''' = m'' + 1, \ldots, m'''; D'''' = m''' + 1, \ldots, m''''); \tag{4.4.10a}$$

where e is the earlier *coefficient of restitution*. Then, the corresponding velocity jumps equal

$$\Delta(\dot{q}_{D''',D''''}) \equiv (\dot{q}_{D''',D''''})^+ - (\dot{q}_{D''',D''''})^- = -(1+e)(\dot{q}_{D''',D''''})^-. \tag{4.4.10b}$$

REMARKS

(i) If the constraints have the *general* (*nonequilibrium*) *form*

$$\phi_D(t, q) = 0 \Rightarrow \delta\phi_D = \sum (\partial\phi_D/\partial q_k)\,\delta q_k = 0 \qquad [D = 1, \ldots, m(< n)], \tag{4.4.11a}$$

then combination ("adjoining") of the above with (4.4.6), via *impulsive Lagrangean multipliers* $\hat{\lambda}_D$ yields the *n impulsive Routh–Voss equations*

$$\Delta p_k = \hat{Q}_k + \hat{R}_k, \qquad \text{with} \qquad \hat{R}_k = \sum \hat{\lambda}_D(\partial\phi_D/\partial q_k). \tag{4.4.11b}$$

As in the finite motion case (§3.8), these equations are *coupled* in the $(\dot{q})^+$'s and $\hat{\lambda}$'s, because the q's employed are *coupled*; i.e., eqs. (4.4.11a); whereas the earlier eqs. (4.4.7a, b; 8), corresponding to the uncoupled (equilibrium) coordinates (4.4.1a–d) are uncoupled.

In *first-type problems*, the above equations along with the m postshock forms of (4.4.11a),

$$\phi_D = 0 \Rightarrow \dot{\phi}_D = \sum (\partial\phi_D/\partial q_k)\dot{q}_k + \partial\phi_D/\partial t = 0, \tag{4.4.11c}$$

with the partial derivatives of the ϕ's evaluated at the shock configuration and instant, constitute a set of $n + m$ algebraic equations for the n postshock velocities $(\dot{q})^+$ and the m impulsive multipliers $\hat{\lambda}$. And since such constraints also hold, in form, for the preshock velocities $(\dot{q})^-$, only $n - m$ of the latter need be known.

In *second-type problems,* eqs. (4.4.11b) also hold, and the impulsive constraints (4.4.11a) are imposed at the beginning of the shock and continue to hold during and after, but not before, it. Therefore, we can apply (4.4.11c) for the $(\dot{q})^+$'s.

(ii) Equations (4.4.11b) can, of course, result directly by integration of the finite Routh–Voss equations of the system (§3.5) in time, then taking the limit as $\tau \equiv t'' - t' \to 0$, and noticing that since $\partial T/\partial q_k = \textit{finite}$ during τ ($\Delta q_k = 0$ and $\dot{q}_k = \textit{finite}$, hence $\Delta\dot{q}_k = \textit{finite}$),

$$\widehat{(\partial T/\partial q_k)} = 0; \tag{4.4.12}$$

and the partial ϕ-derivatives, within our approximations, remain constant.

(iii) If the third- and fourth-type constraints have the general form (4.4.11a), then (4.4.10a, b) must be replaced by

$$(\dot{\phi})^+ = -e(\dot{\phi})^- \Rightarrow \Delta\dot{\phi} \equiv (\dot{\phi})^+ - (\dot{\phi})^- = -(1+e)(\dot{\phi})^-. \tag{4.4.10c, d}$$

Further, due to the compatibility of velocities with the constraint, $\dot{\phi} \sim \boldsymbol{v}_{2/1} \cdot \boldsymbol{n} = (v_{2/1})_n$, and so

$$\text{at } t'\text{:} \quad (\dot{\phi})^- < 0 \qquad \text{(beginning of ``approach'' period)},$$

$$\text{at } t''\text{:} \quad (\dot{\phi})^+ > 0 \qquad \text{(ending of ``restitution'' period)}. \tag{4.4.10e}$$

In sum: the $n\,(\dot{q})^+$'s can be determined from the $n - m''''$ kinetic equations (4.4.8), the m'' kinematical equations (4.4.3b), and the $m'''' - m''$ constitutive equations (4.4.10a, b); that is, a total of $(n - m'''') + (m'') + (m'''' - m'') = n$ equations. Once all the $(\dot{q})^+$'s have been found, the m'''' kinetostatic equations (4.4.7a) immediately yield the m'''' impulsive reactions $\hat{\lambda}_D$.

For instance, in an impact problem with the *three* constraints $q_1 = q_2 = q_3 = 0$ (i.e., $m'''' = 3$), the impulsive multipliers will appear only in the first three equations:

$$\Delta(\partial T/\partial \dot{q}_D) = \hat{Q}_D + \hat{\lambda}_D \qquad (D = 1, 2, 3); \tag{4.4.10f}$$

while, by Appell's rule, the remaining kinetic equations will be

$$\Delta(\partial T/\partial \dot{q}_I) = 0 \qquad (I = 4, 5, \ldots, n). \tag{4.4.10g}$$

If we are only interested in the $(\dot{q})^+$'s and not the $\hat{\lambda}$'s, then we must add to the $n - 3$ equations (4.4.10g) the three postimpact conditions for $(\dot{q}_{1,2,3})^+$. For example, if the *first* and *second* constraints hold after the shock (persistent) while the *third* one does not (nonpersistent), then these conditions are

$$(\dot{q}_1)^+ = (\dot{q}_2)^+ = 0, \qquad (\dot{q}_3)^+ = -e(\dot{q}_3)^-; \tag{4.4.10h}$$

and along with (4.4.10g) these constitute a determinate system for the $n\ (\dot{q})^+$.

(iv) In applying impulsive equations, like (4.4.7a, b; 8; 11b), or any other form involving $\partial T/\partial \dot{q}_k$, there is no need to start with the general (configuration and velocity) expression for T, then $(\partial \ldots /\partial \dot{q})$-differentiate it, and finally evaluate the results for the shock configuration(s) and time, as in the finite motion case. It is simpler, and leads to the same final results, if we *calculate T only at the shock configuration and time and proceed from there to calculate the momenta, and so on*. [Why? Explain using a Taylor expansion of T around the shock configuration, and then taking the partial *q-derivatives* of both sides. See, for example, Beghin (1967, pp. 472–473).]

(v) *Frame of reference effects on impulsive motion*. We begin by pointing out that the impulsive theorems of linear and angular momentum are independent of the frame of reference used; that is, *they hold unchanged in form even in noninertial frames* (*moving axes*), provided that the latter's inertial motions remain continuous and involve only finite accelerations. Then, the "inertial," or "fictitious" forces on a typical particle—that is, the "force" of *transport* (due to the translational and rotational inertial accelerations of the noninertial frame), and *the complementary, or Coriolis,* "force" (due to the coupling of the relative velocity of the particle with the inertial angular velocity of the frame—recalling §1.7)—remain *finite* and therefore give zero impulses. [This also follows from the fact that the impulsive momentum equations involve only velocity *jumps* $\Delta\mathbf{v}$; and these latter are *frame-independent*, as long as, during the shock, the transport velocities of the noninertial frames *do not undergo finite jumps*; it is like adding and subtracting the same frame velocity (after and before the shock, respectively) to all system particles! (Explain, quantitatively, using the frame transformation equations for velocities.) Question: During a shock, does the velocity of *body-fixed* axes, say at G, undergo finite changes (i.e., velocity discontinuities)? If it does, then the above reasoning does not apply to these axes.] The above are easy to see from the viewpoint of analytical mechanics: in all pertinent impulsive derivations, we may consider only the *quadratic* and *homogeneous* part of T (§3.9), $T_2 = 1/2 \sum\sum M_{kl}\dot{q}_k\dot{q}_l$; under our impulsive approximations, its *linear* and *homogeneous* part, $T_1 = \sum M_k \dot{q}_k$ (which, we recall, arises from the nonstationary/

noninertial contributions $\partial\mathbf{r}/\partial t$), makes a zero contribution to Δp_k:

$$\Delta(\partial T/\partial\dot{q}_k) = \Delta(\partial T_2/\partial\dot{q}_k) = 0. \tag{4.4.13}$$

In sum: In impulsive (not finite) motion problems we can always replace the inertial kinetic energy with the relative one; that is, take $T \approx T_2$, and then proceed as in the inertial case. Clearly, this results in considerable algebraic simplification.

(vi) *Holonomic versus nonholonomic constraints in impulsive motion.* We saw earlier, eqs. (4.4.1a–d), that any set of $m(< n)$ holonomic constraints,

$$\phi_D(t, q) = 0 \qquad (D = 1, \ldots, m), \tag{4.4.14a}$$

can be brought to the equilibrium form

$$\chi_D \equiv \phi_D(t, q) = 0 \qquad (D = 1, \ldots, m); \tag{4.4.14b}$$

and $\chi_I \equiv q_I(\neq 0)$. It follows that the associated generalized velocities and virtual variations, from 1 to m, will satisfy, respectively (with $k = 1, \ldots, n$),

$$\dot{\chi}_D = \sum (\partial\phi_D/\partial q_k)\dot{q}_k + \partial\phi_D/\partial t = 0 \qquad \text{and} \qquad \delta\chi_D = \sum (\partial\phi_D/\partial q_k)\,\delta q_k = 0. \tag{4.4.14c}$$

Now, since we assume that during the shock the coordinates and time remain essentially constant, we can replace in there the Pfaffian constraints (first of 4.4.14c) with their approximate time integral

$$\psi_D \equiv \sum \Phi_{Dk} q_k + \Phi_D t - C_D = 0, \tag{4.4.15}$$

where

$$\Phi_{Dk} \equiv \partial\phi_D/\partial q_k,\ \Phi_D \equiv \partial\phi_D/\partial t,\ C_D\text{: } \textit{constants}, \text{for } t' \leq t \leq t''; \tag{4.4.15a}$$

and thus replace $q_1, \ldots, q_m$ with the equilibrium coordinates $\psi_D(= 0)$. The same reasoning applied to the holonomic and/or nonholonomic Pfaffian impulsive constraints,

$$\sum a_{Dk}\dot{q}_k + a_D = 0, \tag{4.4.16a}$$

allows us to *approximate* them, in $[t', t'']$, with

$$\beta_D \equiv \sum a_{Dk} q_k + a_D t - \alpha_D = 0, \qquad \alpha_D = \textit{integration constants}; \tag{4.4.16b}$$

that is, replace $q_1, \ldots, q_m$ with the new equilibrium variables $\beta_D(= 0)$.

In sum: In impulsive problems, we may disregard the holonomic versus nonholonomic difference—*during the shock, all constraints are approximately holonomic*—and to solve them, either we use impulsive multipliers, or avoid them by choosing the above equilibrium coordinates, or use quasi variables (see §4.5).

Impulsive Principle of Relaxation (RIP)

To calculate impulsive reactions due to pre-existing constraints, say in a *first*-type constraint problem (e.g., determine the impulsive bending moment at a certain point of a physical pendulum caused by a given blow at another point of it), either we use the impulsive forms of linear and angular momentum, after solving the Lagrangean impulsive equations of the given (unrelaxed) system, say (4.4.7a, b), and so on; or, in the spirit of an *impulsive principle of relaxation of the constraints*, we may endow the system with an *additional* n' Lagrangean coordinates $q_{k'}(k' = 1, \ldots, n')$, equal in number to that of the sought reactions and satisfying the persistent equilibrium constraints

$$q_{k'} = constant;\ \text{say} = 0, \tag{4.4.17a}$$

then calculate the "relaxed" kinetic energy

$$T = T(t, q_{1'}, \ldots, q_{n'};\ q_1, \ldots, q_n;\ \dot{q}_{1'}, \ldots, \dot{q}_{n'};\ \dot{q}_1, \ldots, \dot{q}_n), \tag{4.4.17b}$$

from that calculate $\partial T/\partial \dot{q}_{k'}$ and $\partial T/\partial \dot{q}_k$, and so on, and reasoning as before for the new relaxed problem, arrive at the uncoupled system

Kinetostatic equations: $\quad (\Delta p_{k'})_o = (\hat{Q}_{k'})_o + \hat{\lambda}_{k'} \qquad (k' = 1, \ldots, n'),$ (4.4.17c)

Kinetic equations: $\quad (\Delta p_k)_o = (\hat{Q}_k)_o \qquad (k = 1, \ldots, n);$ (4.4.17d)

where $(\ldots)_o \equiv (\ldots)$ *evaluated for* $q_{k'} = constant$ (e.g., for 0) and $\dot{q}_{k'} = 0$. We can easily show that the relaxed T, (4.4.17b), is needed only for the kinetostatic (4.4.17c); for the kinetic ones, (4.4.17d), we can use the original (unrelaxed, or constrained) kinetic energy T_o (why?). Finally, the whole method of RIP can be applied without theoretical complications to *second/third/fourth*-types of impulsive problems.

Sudden Rupture of Constraints

As mentioned earlier, this is *not* an impulsive problem but one of *initial (finite) motion*; the jumps appear in the $\ddot{q}$'s. If, *after* the rupture, the system has n Lagrangean coordinates, its postrupture equations of motion are (with the usual notations)

$$E_k(T) = Q_k \qquad (k = 1, \ldots, n), \tag{4.4.18a}$$

and, if the suppressed (broken) constraints are

$$\sum a_{Dk}\, \delta q_k = 0 \qquad [D = 1, \ldots, m(< n)], \tag{4.4.18b}$$

then the prerupture equations are

$$E_k(T) = Q_k + \sum \lambda_D a_{Dk} \qquad (k = 1, \ldots, n). \tag{4.4.18c}$$

Solving these sets of equations (e.g., subtracting them side by side, etc.), we can calculate the *acceleration jumps*: $\Delta\ddot{q} \equiv (\ddot{q})^+ - (\ddot{q})^-$.

Example 4.4.1 *Elementary (Newton–Euler) Theory of Rigid-Body Collisions.* Let us consider two rigid bodies, B_1 and B_2, with respective masses m_1 and m_2, mass centers G_1 and G_2, colliding at a certain instant t^- at the contact point C (fig. 4.2). Then, by the impulsive principles of linear and angular momentum, applied to B_1 and B_2 separately, we obtain

$$m_1(\boldsymbol{v}_1{}^+ - \boldsymbol{v}_1{}^-) = -\hat{\boldsymbol{f}}, \qquad \boldsymbol{H}_1{}^+ - \boldsymbol{H}_1{}^- = \boldsymbol{r}_1 \times (-\hat{\boldsymbol{f}}) = -\boldsymbol{r}_1 \times \hat{\boldsymbol{f}}, \tag{a1, 2}$$

$$m_2(\boldsymbol{v}_2{}^+ - \boldsymbol{v}_2{}^-) = \hat{\boldsymbol{f}}, \qquad \boldsymbol{H}_2{}^+ - \boldsymbol{H}_2{}^- = \boldsymbol{r}_2 \times \hat{\boldsymbol{f}}; \tag{a3, 4}$$

where $\hat{\boldsymbol{f}}$ = impulsive force, at C, say from B_1 to B_2, and $\boldsymbol{H}_{1,2}$ = angular momenta of $B_{1,2}$ about $G_{1,2}$, respectively. Now, since the precollision velocities are assumed

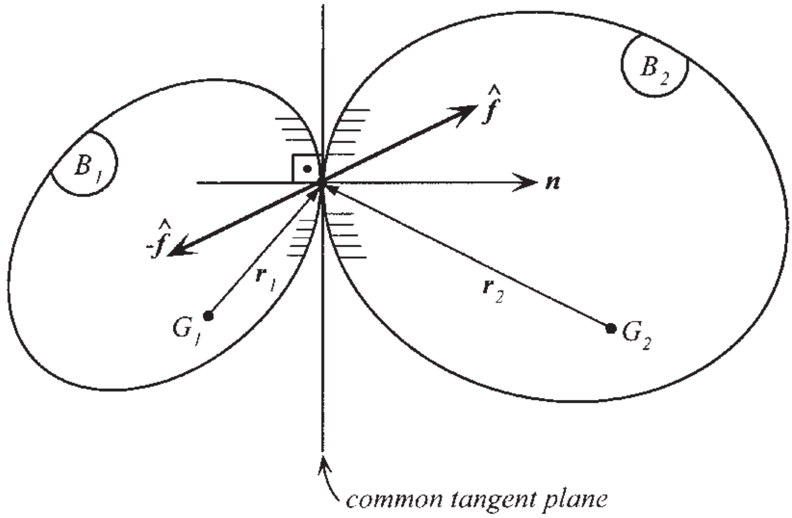

Figure 4.2 Collision of two rigid bodies. $\boldsymbol{n}$: Common unit normal (from B_1 to B_2); $\boldsymbol{H}_{G_1} \equiv \boldsymbol{H}_1$, $\boldsymbol{H}_{G_2} \equiv \boldsymbol{H}_2$.

known, the above constitutes a system of 4×3 scalar equations for the 5×3 unknown components of $\boldsymbol{v}_1{}^+, \boldsymbol{v}_2{}^+$; $\boldsymbol{H}_1{}^+$, $\boldsymbol{H}_2{}^+$; $\hat{\boldsymbol{f}}$ [from $\boldsymbol{H}_1{}^+$, $\boldsymbol{H}_2{}^+$ we can determine the postcollision angular velocities $\boldsymbol{\omega}_1{}^+$ and $\boldsymbol{\omega}_2{}^+$ via inversion of $\boldsymbol{H} = \mathbf{I} \cdot \boldsymbol{\omega}$, $\mathbf{I}$ = inertia tensor at G (known), for each body].

Hence, *the principles of mechanics alone do not suffice to solve the impact problem*; we need additional *physical hypotheses* to remove the $(15 - 12 =)$ 3-fold indeterminacy.

REMARK

The indeterminacy is due to our simple/idealized model of the impact problem; that is, to the *rigid* bodies and impulsive forces; a model that has also led to indeterminacy in ordinary/finite motion, for example, statical indeterminacy. As there, determinacy is here attained by adoption of the more realistic (and more "expensive") model of the *deformable* body. Then, the contact point C becomes a contact *surface* $C = C(t)$; while the impulsive force $\hat{\boldsymbol{f}}$ is replaced by the following resultant of a complicated distribution of surface tractions $\boldsymbol{t}_{(n)}$ over C: $\hat{\boldsymbol{f}} = \int dt(\int_C \boldsymbol{t}_{(n)}\, dC)$. For details, see works on dynamic elasticity, and so on.

Here, we remove the indeterminacy with the following two *empirical* hypotheses:

(i) B_1 and B_2 are *smooth*, so that $\hat{\boldsymbol{f}} = \hat{f}\boldsymbol{n}$, where $\hat{f} > 0$ and $\boldsymbol{n}$ = unit vector at C, along the common *normal*, say from B_1 to B_2; a hypothesis that reduces the number of unknowns to 13: $\boldsymbol{v}_1{}^+$, $\boldsymbol{v}_2{}^+$; $\boldsymbol{H}_1{}^+$, $\boldsymbol{H}_2{}^+$; $\hat{f}$, and

(ii) *Conservation of* (*kinetic*) *energy*: $\Delta T \equiv T^+ - T^- = 0$; which, since T^- is known and T^+ can be expressed in terms of $\boldsymbol{v}_1{}^+$, $\boldsymbol{v}_2{}^+$; $\boldsymbol{H}_1{}^+$, $\boldsymbol{H}_2{}^+$, reduces the number of unknowns to 12, and thus makes the problem determinate.

Speed of Compression; Coefficient of Restitution

Let us generalize a bit. If the velocities of the two particles of B_1 and B_2 in contact at C are $\boldsymbol{u}_1$ and $\boldsymbol{u}_2$, so that before, during, and after the collision, $\boldsymbol{u}_1 = \boldsymbol{v}_1 + \boldsymbol{\omega}_1 \times \boldsymbol{r}_1$ and

$\boldsymbol{u}_2 = \boldsymbol{v}_2 + \boldsymbol{\omega}_2 \times \boldsymbol{r}_2$, then the *speed of compression c* is defined as

$$c \equiv (\boldsymbol{u}_1 - \boldsymbol{u}_2)\cdot\boldsymbol{n} = \textit{normal component of relative velocity at } C$$
$$\text{(initially positive, since } B_1 \text{ and } B_2 \text{ tend to overlap).} \qquad \text{(b)}$$

Now, with the help of c, the collision process is decomposed into the following two stages:

(i) a *period of compression* (approaching of B_1 and B_2): $c > 0$;

(ii) a *period of restitution* (separation of B_1 and B_2): $c < 0$;

since, at the end of the compression period, the impact forces $-\hat{\boldsymbol{f}} \to -\hat{I}\boldsymbol{n}$ and $\hat{\boldsymbol{f}} \to \hat{I}\boldsymbol{n}$ reduce c to zero. If $(\ldots)^* \equiv (\ldots)$ *at the end of the compression period,* then applying again linear and angular momentum on B_1 and B_2, *between the beginning and the end of the compression period*, we obtain

$$m_1(\boldsymbol{v}_1{}^* - \boldsymbol{v}_1{}^-) = -\hat{I}\boldsymbol{n}, \qquad \boldsymbol{H}_1{}^* - \boldsymbol{H}_1{}^- = \boldsymbol{r}_1 \times (-\hat{I}\boldsymbol{n}) = -\boldsymbol{r}_1 \times \hat{I}\boldsymbol{n}, \qquad \text{(c1, 2)}$$

$$m_2(\boldsymbol{v}_2{}^* - \boldsymbol{v}_2{}^-) = \hat{I}\boldsymbol{n}, \qquad \boldsymbol{H}_2{}^* - \boldsymbol{H}_2{}^- = \boldsymbol{r}_2 \times \hat{I}\boldsymbol{n}, \qquad \text{(d1, 2)}$$

$$c^* \equiv (\boldsymbol{u}_1{}^* - \boldsymbol{u}_2{}^*)\cdot\boldsymbol{n} = 0; \qquad \text{(e)}$$

which constitutes a determinate system of $(4 \times 3) + 1 = 13$ scalar equations for the 13 scalar unknowns of the end of the compression period: $\boldsymbol{v}_1{}^*$, $\boldsymbol{v}_2{}^*$; $\boldsymbol{H}_1{}^*$, $\boldsymbol{H}_2{}^*$; $\hat{I}$. Having found $\hat{I}$, and assuming that the impulsive forces during the restitution period are proportional to those forces during the compression period, the factor of that proportionality called *coefficient of restitution*, e, we can then write in (a1–4),

$$\hat{\boldsymbol{f}} = (1 + e)\hat{I}\boldsymbol{n}, \qquad \text{(f)}$$

and thus reduce its number of scalar unknowns to 13: $\boldsymbol{v}_1{}^+$, $\boldsymbol{v}_2{}^+$; $\boldsymbol{H}_1{}^+$, $\boldsymbol{H}_2{}^+$; e. Therefore, the problem becomes determinate by specifying the value of e. We have the following three cases: $e = 0$: *inelastic collision*; $e = 1$: *elastic collision*; $0 < e < 1$: *semielastic collision*. It can be shown that the elastic case, $e = 1$, implies the conservation condition $T^+ = T^-$.

Example 4.4.2 *Specialization of the Above to the Case of the Collision of Two, Originally Nonrotating, Smooth and Homogeneous Spheres.* Here, since $-\boldsymbol{r}_1 \times \hat{\boldsymbol{f}} = \boldsymbol{0}$ and $\boldsymbol{r}_2 \times \hat{\boldsymbol{f}} = \boldsymbol{0}$, eqs. (c1–e) of the preceding example reduce to

$$m_1(\boldsymbol{v}_1{}^* - \boldsymbol{v}_1{}^-) = -\hat{I}\boldsymbol{n}, \qquad m_2(\boldsymbol{v}_2{}^* - \boldsymbol{v}_2{}^-) = \hat{I}\boldsymbol{n}, \qquad (\boldsymbol{u}_1{}^* - \boldsymbol{u}_2{}^*)\cdot\boldsymbol{n} = 0, \qquad \text{(a)}$$

and $\boldsymbol{H}_1{}^* - \boldsymbol{H}_1{}^- = \boldsymbol{0}$, $\boldsymbol{H}_2{}^* - \boldsymbol{H}_2{}^- = \boldsymbol{0}$ (since $\boldsymbol{\omega}_1{}^- = \boldsymbol{0}$ and $\boldsymbol{\omega}_2{}^- = \boldsymbol{0}$, and, hence, also $\boldsymbol{u}_1{}^* = \boldsymbol{v}_1{}^*$ and $\boldsymbol{u}_2{}^* = \boldsymbol{v}_2{}^*$; and $\boldsymbol{\omega}_1{}^+ = \boldsymbol{0}$ and $\boldsymbol{\omega}_2{}^+ = \boldsymbol{0}$). Solving the system (a) we obtain

$$\hat{I} = [m_1 m_2/(m_1 + m_2)][(\boldsymbol{v}_1{}^- - \boldsymbol{v}_2{}^-)\cdot\boldsymbol{n}] = (m_1 m_2 c)/(m_1 + m_2), \qquad \text{(b1)}$$

that is,

$$\hat{\boldsymbol{f}} = \big[m_1 m_2 c(1 + e)/(m_1 + m_2)\big]\boldsymbol{n}, \qquad \text{(b2)}$$

where $c =$ known initial (preimpact) value of compression speed (> 0). As a result, eqs. (a1–4, f) of the preceding example yield

$$m_1({\boldsymbol v_1}^+ - {\boldsymbol v_1}^-) = -(1+e)\hat{I}\boldsymbol{n}, \qquad m_2({\boldsymbol v_2}^+ - {\boldsymbol v_2}^-) = (1+e)\hat{I}\boldsymbol{n}, \tag{c}$$

and from these we readily obtain the postimpact velocities

$${\boldsymbol v_1}^+ = {\boldsymbol v_1}^- - \{c/[1 + (m_2/m_1)]\}(1+e)\boldsymbol{n}, \tag{d1}$$

$${\boldsymbol v_2}^+ = {\boldsymbol v_2}^- + \{c/[1 + (m_2/m_1)]\}(1+e)\boldsymbol{n}. \tag{d2}$$

We leave it to the reader to show that the kinetic energy change equals

$$\Delta T \equiv T^+ - T^- = -[m_1 m_2 c^2/2(m_1+m_2)](1-e^2) \le 0, \tag{e}$$

that is, $T^+ \le T^-$, in general (since $0 \le e \le 1$) an energy *loss*! Special cases are:

(i) $e = 1$ (elastic impact): $\Delta T = 0$: energy of compression = energy of restitution;

(ii) $e = 0$ (inelastic impact): $\Delta T = -(m_1 m_2 c^2)/2(m_1+m_2)$.

For an elementary, but instructive and rare, treatment of the role of *friction* in impact, see, for example, Hamel ([1922(a)] 1912, pp. 447–450).

Example 4.4.3 A thin, straight, and homogeneous bar AB, of mass m and length $2b$, moves on a fixed, horizontal, and smooth plane p. At a certain moment, the bar strikes a fixed peg O located a distance c from the center of mass of the bar G. Let us calculate the postimpact velocities in the following two cases: (i) the point of the bar that strikes O stays fixed relative to the latter, and (ii) the bar remains in contact with O and slides without friction on it (fig. 4.3) (Lainé, 1946, pp. 188–191).

On p, let us choose axes O–xy such that $x = c$, $y = 0$, $\phi = 0$. Now, by König's theorem, the (double) kinetic energy of the bar is

$$2T = m\big[(\dot{x})^2 + (\dot{y})^2\big] + (mb^2/3)(\dot{\phi})^2; \tag{a}$$

and since, obviously, $\widehat{\delta' W} = 0$, the impulsive Lagrangean principle (LIP) yields

$$\Delta(\partial T/\partial \dot{x})\,\delta x + \Delta(\partial T/\partial \dot{y})\,\delta y + \Delta(\partial T/\partial \dot{\phi})\,\delta\phi = 0$$
$$\Rightarrow (\Delta\dot{x})\,\delta x + (\Delta\dot{y})\,\delta y + (b^2\Delta\dot{\phi}/3)\,\delta\phi = 0. \tag{b}$$

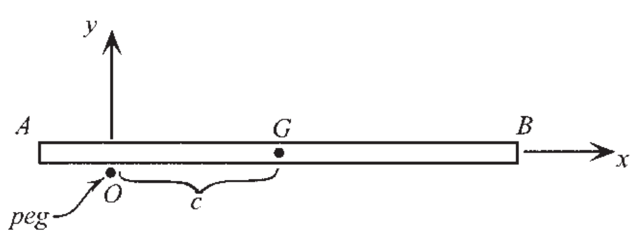

Figure 4.3 Geometry of bar *AB* moving on a fixed, horizontal, and smooth plane *p*, and striking a fixed peg *O*. $|\boldsymbol{AB}| = 2b$, $\boldsymbol{OG} = (x, y) \Rightarrow |\boldsymbol{OG}| = c$, and *angle* $(AB, Ox) \equiv \phi \to 0$.

Let us find the restrictions among δx, δy, $\delta\phi$.

(i) When the bar point sticks to O, the constraints are

$$x = c\cos\phi \Rightarrow \ \delta x = -c\sin\phi\,\delta\phi\big|_{\phi=0} = 0, \tag{c1}$$

$$y = c\sin\phi \Rightarrow \ \delta y = c\cos\phi\,\delta\phi\big|_{\phi=0} = c\,\delta\phi; \tag{c2}$$

and, therefore, LIP, eq. (b), reduces to

$$(\varDelta\dot{y})(c\,\delta\phi) + (b^2/3)\,\varDelta\dot{\phi}\,\delta\phi = 0 \ \Rightarrow \ c\,\varDelta\dot{y} + (b^2/3)\,\varDelta\dot{\phi} = 0; \tag{d1}$$

or, explicitly [with $(\dot{\phi})^+ \equiv \omega$],

$$c[(\dot{y})^+ - (\dot{y})^-] + (b^2/3)(\omega - \omega^-) = 0. \tag{d2}$$

However, from the *velocity* form of the constraints, evaluated at the impact configuration, we find the following postimpact velocities [with $(\dot{x})^+ \equiv \dot{x}$, $(\dot{y})^+ \equiv \dot{y}$]:

$$\dot{x} = -c\sin\phi\,\dot{\phi}\big|_{\phi=0} = 0, \qquad \dot{y} = c\cos\phi\,\dot{\phi}\big|_{\phi=0} = c\,\omega; \tag{e}$$

and so (d2) yields

$$\begin{aligned} &c[c\,\omega - (\dot{y})^-] + (b^2/3)(\omega - \omega^-) = 0 \\ &\Rightarrow \omega = [c(\dot{y})^- + (b^2/3)\omega^-]\big/[c^2 + (b^2/3)]. \end{aligned} \tag{f}$$

[Elementary solution: applying angular momentum conservation about O we get

$$H_O{}^- = H_O{}^+\text{: } (mb^2/3)\omega^- + mc(\dot{y})^- = m[(b^2/3) + c^2]\omega^- \Rightarrow \omega^- = \ldots, \text{eq. (f).]}$$

(ii) When the bar is obliged to slide on O, the *component of* $\boldsymbol{v}_{O'} = \boldsymbol{v}_G + \boldsymbol{\omega}\times\boldsymbol{r}_{O'/G}$ (O': bar point, instantaneously adjacent to peg O) *normal to Ox must vanish*:

$$\begin{aligned} \boldsymbol{v}_{O'}\cdot\boldsymbol{j} &= \boldsymbol{v}_G\cdot\boldsymbol{j} + (\boldsymbol{\omega}\times\boldsymbol{r}_{O'/G})\cdot\boldsymbol{j} \\ &= (\dot{x},\dot{y},0)\cdot(0,1,0) + [(0,0,\dot{\phi})\times(-c,0,0)]\cdot(0,1,0) \\ &= (\dot{y} - c\dot{\phi},0,0) = (0,0,0) \qquad [\text{since at the impact moment: } x = c], \end{aligned} \tag{g1}$$

that is,

$$\dot{y} - c\dot{\phi} = 0 \Rightarrow \ \delta y - c\,\delta\phi = 0 \qquad [\text{since this constraint is scleronomic}]; \tag{g2}$$

which, we notice, is the same as (c2).

Hence, in this case, we have the following two variational equations:

$$(\varDelta\dot{x})\,\delta x + (\varDelta\dot{y})\,\delta y + (b^2\varDelta\dot{\phi}/3)\,\delta\phi = 0, \tag{h1}$$

$$(0)\,\delta x + (1)\,\delta y + (-c)\,\delta\phi = 0; \tag{h2}$$

from which we obtain immediately

$$\varDelta\dot{x} = 0 \Rightarrow \dot{x} = (\dot{x})^- \qquad [\text{different from first of (e), since here } \delta x \neq 0], \tag{i1}$$

$$c\,\varDelta\dot{y} + (b^2/3)\,\varDelta\dot{\phi} = 0 \ \Rightarrow \ c[\dot{y} - (\dot{y})^-] + (b^2/3)[\dot{\phi} - (\dot{\phi})^-] = 0, \tag{i2}$$

from which, since $\dot{y} = c\,\dot{\phi} \equiv c\,\omega$, finally,

$$\omega = [c(\dot{y})^- + (b^2/3)\omega^-]\big/[c^2 + (b^2/3)] \qquad \text{[same as in the preceding case, eq. (f)].} \tag{i3}$$

Problem 4.4.1 Consider a two-DOF holonomic system with (double) kinetic energy:

$$2T = A(\dot{x})^2 + 2B\,\dot{x}\,\dot{y} + C(\dot{y})^2, \tag{a}$$

where $x, y =$ Lagrangean coordinates; $A, B, C =$ inertia coefficients (functions of x, y). Show that its *postimpact* kinetic energy, from a motionless preimpact state defined by $x, y = 0$; $(\dot{x})^-$, $(\dot{y})^- = 0$; $A, B, C \to A_o$, B_o, C_o, under the Lagrangean impulsive forces X and Y, equals

$$2T^+ = (C_o X^2 - 2B_o XY + A_o Y^2)\big/(A_o C_o - B_o{}^2). \tag{b}$$

HINT

Solve the impulsive Lagrangean equations $(\partial T/\partial \dot{x})^+ - (\partial T/\partial \dot{x})^- = X$, and so on, for $(\dot{x})^+$, $(\dot{y})^+$ in terms of X, Y; A_o, B_o, C_o.

Problem 4.4.2 Apply the result (b) of the preceding problem to the impact of a double pendulum (fig. 4.4) consisting of two equal and homogeneous rods, AB and BC, each of mass m and length l, smoothly hinged at A to a fixed object (a ceiling) and to each other at B, initially in vertical equilibrium and struck at C by a horizontal blow of magnitude $\hat{\boldsymbol{P}}$.

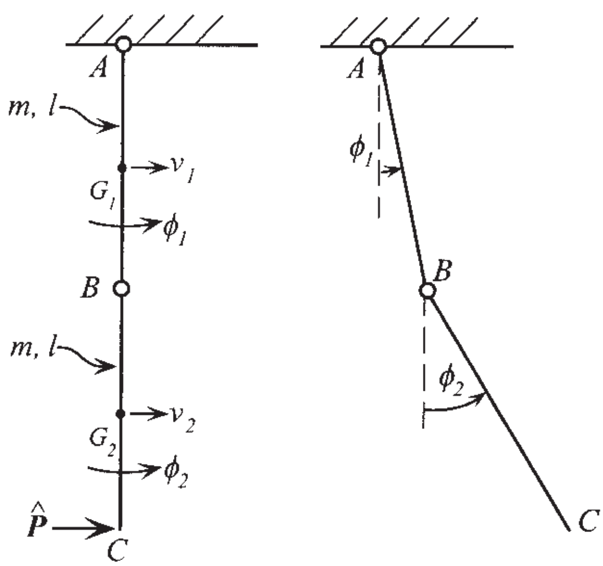

Figure 4.4 Impact at tip of a double pendulum.

HINT

The postimpact kinetic energy equals [omitting the $(\ldots)^+$ for convenience]

$$2T = m({v_1}^2 + {v_2}^2) + I[(\dot{\phi}_1)^2 + (\dot{\phi}_2)^2];$$

where: $I = ml^2/12$, $v_1 = (l/2)\dot{\phi}_1$, $v_2 = l\dot{\phi}_1 + (l/2)\dot{\phi}_2$, $v_{1,2} =$ velocities of centers of mass of AB and BC, respectively, in vertical configuration. (See, e.g., Lamb, 1923, pp. 321–322.)

Problem 4.4.3 Assuming that the δq's are independent, show that *the Lagrangean system momenta equal the corresponding Lagrangean system impulses that would, instantaneously, create the motion from rest.*

Problem 4.4.4 (Lainé, 1946, pp. 196–200). An articulated rhombus R, $ABCD$, formed of four identical thin and homogeneous rigid bars, each of length $2b$ and mass m (fig. 4.5), falls freely *translating* so that its diagonal AC is vertical; also, let *angle* $(BAD) \equiv 2\phi$ $(0 < \phi < \pi/2)$. At the instant of impact of A with the smooth horizontal ground, its translational velocity (including that of its mass center G) is v_o, vertically and downwards. Finally, let e be the coefficient of restitution, and assume that the impulse at A is distributed symmetrically between AB and AD.

For convenience, but no loss in generality, take axes O–xy (Ox: vertical, Oy: horizontal) such that, at the impact moment; $A = O$; R is also shown in an arbitrary configuration $A'B'C'D'$ [fig. 4.5(b)]. The latter can, clearly, be specified by the following *four* Lagrangean coordinates: (x, y) for G, *angle*$(Ax, A'C') \equiv \theta$, and *angle*$(A'C', A'D') \equiv \phi$.

(i) Show that the (double) kinetic energy of R equals

$$2T = 4m\left[(\dot{x})^2 + (\dot{y})^2\right] + (16mb^2/3)\left[(\dot{\theta})^2 + (\dot{\phi})^2\right]. \qquad \text{(a)}$$

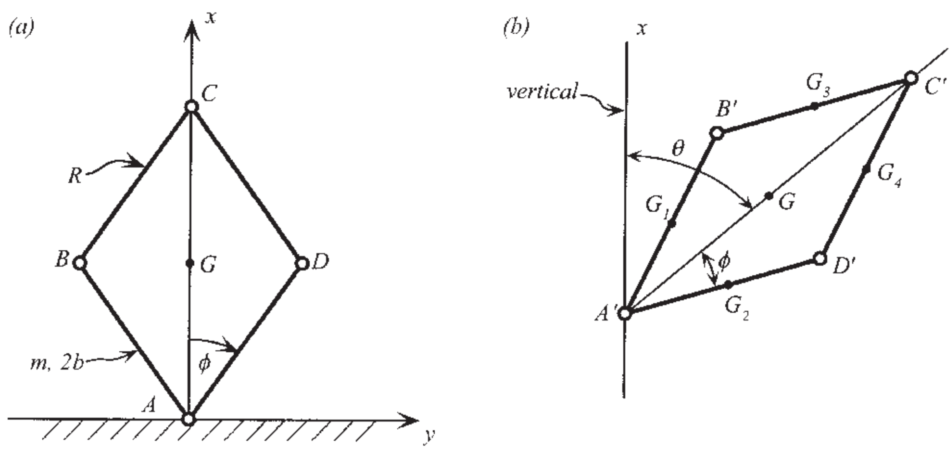

Figure 4.5 (a) Geometry of rhombus R, $ABCD$, falling freely translating with velocity v_o, so that AC is vertical, and then hitting the smooth ground at A; (b) rhombus in arbitrary configuration.

HINTS

Let 1, 2, 3, 4 be, respectively, the centers of mass (midpoints) of the bars $A'B'$, $A'D'$, $B'C'$, $D'C'$. Next, notice (or prove) that (a) 1 describes a circle of center G and radius b, with angular velocity $\dot{\theta} + \dot{\phi}$, while (b) the bar $A'B'$ rotates about 1 with angular velocity $\dot{\theta} - \dot{\phi}$. Hence, its (double) kinetic energy *relative to G* is

$$2T_{A'B',\text{relative}} = mb^2(\dot{\theta} + \dot{\phi})^2 + (mb^2/3)(\dot{\theta} - \dot{\phi})^2, \tag{a1}$$

and this clearly equals the kinetic energy of $D'C'$; that is, $2T_{C'D',\text{relative}} = 2T_{A'B',\text{relative}}$; while reasoning analogously for the bars $A'D'$, $B'C'$ one finds

$$2T_{A'D',\text{relative}} = 2T_{B'C',\text{relative}} = mb^2(\dot{\theta} - \dot{\phi})^2 + (mb^2/3)(\dot{\theta} + \dot{\phi})^2. \tag{a2}$$

Finally, applying König's theorem to this nonrigid system (i.e., $T = T_{\text{of } G} + T_{\text{relative to } G}$) yields (a).

(ii) Since the constraints are (with some easily understood notations)

$$\begin{aligned}
\boldsymbol{v}_{A'} &= \boldsymbol{v}_1 + \boldsymbol{\omega}_{A'B'} \times \boldsymbol{r}_{A'/1} = (\boldsymbol{v}_{G'} + \boldsymbol{v}_{1/G'}) + \boldsymbol{\omega}_{A'B'} \times \boldsymbol{r}_{A'/1} \\
&\qquad \big[\text{notice that } \boldsymbol{v}_{1/G'} = (dx_{1/G'}/dt, dy_{1/G'}/dt) \text{ (only } x \text{ and } y \text{ components shown)} \\
&\qquad \text{where } x_{1/G'} \equiv x_1 - x_{G'} = -b\cos(\theta + \phi),\ y_{1/G'} \equiv y_1 - y_{G'} = -b\sin(\theta + \phi)\big] \\
&= (\dot{x}, \dot{y}) + \big(b(\dot{\theta} + \dot{\phi})\sin(\theta + \phi), -b(\dot{\theta} + \dot{\phi})\cos(\theta + \phi)\big) \\
&\qquad + [(\dot{\theta} - \dot{\phi})\boldsymbol{k}] \times \big(-b\cos(\theta - \phi), b\sin(\theta - \phi)\big) \\
&= \big(\dot{x} + b(\dot{\theta} + \dot{\phi})\sin(\theta + \phi) + b(\dot{\theta} - \dot{\phi})\sin(\theta - \phi), \\
&\qquad \dot{y} - b(\dot{\theta} + \dot{\phi})\cos(\theta + \phi) - b(\dot{\theta} - \dot{\phi})\cos(\theta - \phi)\big) \\
&= \big(\dot{x} + 2b\,\dot{\theta}\cos\phi\sin\theta + 2b\,\dot{\phi}\sin\phi\cos\theta, \\
&\qquad \dot{y} - 2b\,\dot{\theta}\cos\phi\cos\theta + 2b\,\dot{\phi}\sin\phi\sin\theta\big) \\
&\qquad [\text{evaluated at } \theta = 0, \dot{\theta} = 0] \\
&= (\dot{x} + 2b\,\dot{\phi}\sin\phi,\ \dot{y}) = v_{Ax}\,\boldsymbol{i} + v_{Ay}\,\boldsymbol{j}, \qquad\qquad \text{(b)} \\
&\Rightarrow \textit{vertical virtual displacement of } A \textit{ should vanish}\text{: } \delta x + (2b\sin\phi)\,\delta\phi = 0, \qquad \text{(c)}
\end{aligned}$$

(although, in general, $v_{Ax} = \textit{nonzero constant}$), and since $\widehat{\delta' W} = 0$, verify that the impulsive Lagrangean principle, under (c), yields the following equations of motion:

$$y\text{:} \quad \Delta(\partial T/\partial \dot{y}) = 0 \Rightarrow (\dot{y})^+ \equiv \dot{y} = (\dot{y})^- = 0, \tag{c1}$$

$$\theta\text{:} \quad \Delta(\partial T/\partial \dot{\theta}) = 0 \Rightarrow (\dot{\theta})^+ \equiv \dot{\theta} = (\dot{\theta})^- = 0; \tag{c2}$$

$$x, \phi\text{:} \quad \hat{\lambda} = -\Delta(\partial T/\partial \dot{x}) = -(2b\sin\phi)^{-1}\Delta(\partial T/\partial \dot{\phi}) \qquad (\hat{\lambda}\text{: impulsive multiplier}) \tag{c3}$$

$$\Rightarrow \Delta\dot{x} = (2b/3\sin\phi)\,\Delta\dot{\phi} \ \Rightarrow\ 3(\dot{x} + v_o)\sin\phi = 2b\,\dot{\phi}. \tag{c4}$$

[Since $\Delta\dot{x} \equiv (\dot{x})^+ - (\dot{x})^- \equiv \dot{x} - (\dot{x})^- = \dot{x} - (-v_o) = \dot{x} + v_o$,

$\Delta\dot{\phi} \equiv (\dot{\phi})^+ - (\dot{\phi})^- \equiv \dot{\phi} - (\dot{\phi})^- = \dot{\phi} - 0 = \dot{\phi}$].

(iii) Verify that (c4) and the constitutive relation $\dot{x} + 2b\,\dot{\phi}\sin\phi = -e(-v_o)$ yield the values

$$\dot{x} = \left[(e - 3\sin^2\phi)/(1 + 3\sin^2\phi)\right]v_o, \tag{d1}$$

$$\dot{\phi} = \left[3(1+e)\sin\phi/2b(1 + 3\sin^2\phi)\right]v_o; \tag{d2}$$

and from these, and (c3), that

$$\hat{\lambda} = -4m\left[\dot{x} - (\dot{x})^-\right] = -4m(\dot{x} + v_o) = \cdots. \tag{d3}$$

Since $(\dot{\theta})^- = 0$, then, by symmetry, we may set $\dot{\theta} = 0$, $\theta = 0$, $\dot{y} = 0$, $y = 0$, for all t.

REMARK

The *inelastic* case $e = 0$ can be treated like a problem with a *new* constraint. Here, too, $\delta x + (2b\sin\phi)\,\delta\phi = 0$, but now (taking the limit of the above values as $e \to 0$)

$$\dot{x} = \left[-3\sin^2\phi/(1 + 3\sin^2\phi)\right]v_o, \qquad \dot{y} = 0, \qquad \dot{\theta} = 0, \tag{e1}$$

$$\dot{\phi} = \left[3\sin\phi/2b(1 + 3\sin^2\phi)\right]v_0, \qquad \hat{\lambda} = -\left[4m/(1 + 3\sin^2\phi)\right]v_o. \tag{e2}$$

Similarly, for the *elastic* case $e = 1$: $\dot{x} + 2b\,\dot{\phi}\sin\phi = v_o$.

For a solution based on the theorem of Carnot (§4.6), see Lainé (1946, p. 201).

Problem 4.4.5 (Lainé, 1946, pp. 193–194). A particle P of mass m is forced to slide on a smooth moving circle (i.e., a circular, rigid, and light wire) C of center O and radius r (fig. 4.6). The axis of C (perpendicular to the plane of the circle) coincides

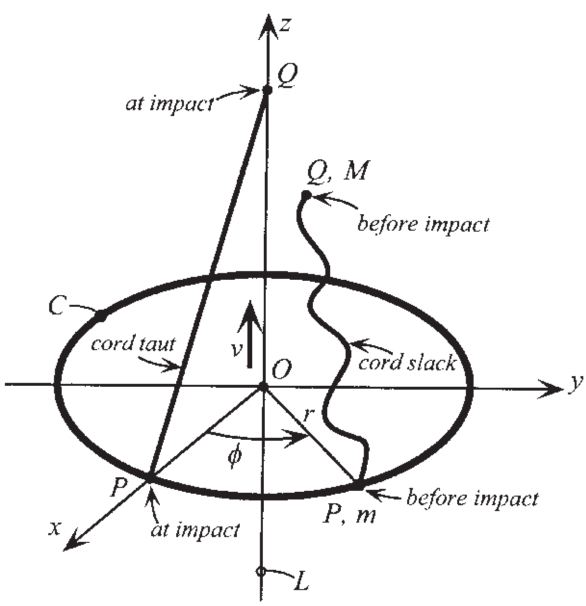

Figure 4.6 Geometry of two-particle system, P and Q, connected by a light and inextensible cord, which at some point in time gets suddenly taut. P can slide on a uniformly translating circle, while Q, before the impact, moves freely in space.

continuously with a fixed line L, on which O is forced to move with constant translational velocity v. A *second* particle Q of mass M moves freely in space. The two particles are connected by an inextensible and massless cord whose length l, in the beginning, is longer than the distance PQ; that is, the cord is slack. At a certain moment, during the motion, the distance PQ becomes equal to the length of the cord, which thus finds itself suddenly taut. Assume that, at that moment, the positions and (preimpact) velocities of P and Q are known, and that Q is on L.

For convenience, but no loss in generality, choose axes O–xyz such that, at the impact moment, O coincides with the center of C, Oz with L and along the circle velocity v, and Ox with $OP(=+r)$. In these axes, the *generic* preimpact coordinates of P are

$$x = r\cos\phi, \quad y = r\sin\phi, \quad z = vt \qquad [(r, \phi)\text{: plane polar coordinates of } P], \tag{a}$$

and, therefore, its corresponding velocity components are

$$\dot{x} = -r\sin\phi\,\dot{\phi}, \qquad \dot{y} = r\cos\phi\,\dot{\phi}, \qquad \dot{z} = v. \tag{b}$$

Hence, just before the impact ($t = 0$, $\phi = 0$),

$$x^- = r, \quad y^- = 0, \quad z^- = 0; \qquad (\dot{x})^- = 0, \quad (\dot{y})^- = r(\dot{\phi})^-, \quad \dot{z} = v. \tag{c1}$$

Similarly, let the preimpact position and velocity of Q be, respectively,

$$X^-, \quad Y^-, \quad Z^-; \qquad (\dot{X})^-, \quad (\dot{Y})^-, \quad (\dot{Z})^-. \tag{c2}$$

From the above it follows that, before the shock, the Lagrangean coordinates of the system are $q_{1,\ldots,4} = \phi, X, Y, Z$.

(i) Show that its (double) kinetic energy equals

$$2T = m[(r\dot{\phi})^2 + v^2] + M(\dot{X}^2 + \dot{Y}^2 + \dot{Z}^2), \tag{d}$$

while its impressed impulsive virtual work vanishes: $\widehat{\delta' W} = 0$; and so the impulsive Lagrangean principle becomes (dropping, for convenience, all *superscript minuses* from $q_{1,\ldots,4}$)

$$\Delta(\partial T/\partial\dot{X})\,\delta X + \Delta(\partial T/\partial\dot{Y})\,\delta Y + \Delta(\partial T/\partial\dot{Z})\,\delta Z + \Delta(\partial T/\partial\phi^{\cdot})\,\delta\phi = 0. \tag{e}$$

Now, the tightening of the cord is equivalent to the sudden introduction of the constraint $|\boldsymbol{PQ}| = l$ (*constant*), or, in terms of $q_{1,\ldots,4}$,

$$(X - r\cos\phi)^2 + (Y - r\sin\phi)^2 + (Z - vt)^2 = l^2, \tag{f1}$$

or, rearranging,

$$(X^2 + Y^2 + Z^2) - 2r(X\cos\phi + Y\sin\phi) - 2Z(vt) + (vt)^2 = l^2 - r^2; \tag{f2}$$

and $\delta(\ldots)$-varying this (while recalling to set $\delta t = 0$, and $\delta v = 0$), we obtain the *virtual* form of the constraint:

$$\begin{aligned} &X\,\delta X + Y\,\delta Y + Z\,\delta Z \\ &\quad - r(\cos\phi\,\delta X + \sin\phi\,\delta Y) - r(-X\sin\phi + Y\cos\phi)\,\delta\phi - (vt)\,\delta Z = 0. \end{aligned} \tag{f3}$$

Therefore, *at the impact moment* (i.e., $t = 0$, $\phi = 0$), the $\delta q_{1,\ldots,4}$ satisfy

$$(X - r)\,\delta X + Y\,\delta Y + Z\,\delta Z - rY\,\delta\phi = 0. \tag{f4}$$

(ii) Show that the variational equation (e), under (f4), produces [with the help of the multiplier $\hat{\lambda}$ (proportional to the impulsive cord reaction)] the following *four* equations:

$$M\,\Delta\dot{X} = \hat{\lambda}(X - r), \qquad M\,\Delta\dot{Y} = \hat{\lambda}Y, \qquad M\,\Delta\dot{Z} = \hat{\lambda}Z,$$
$$(mr^2)\,\Delta\dot{\phi} = -\hat{\lambda}\,rY; \tag{g}$$

and these, along with the $(\ldots)^{\cdot}$-form of the constraint (f1, 2) (evaluated at $t = 0$, $\phi = 0$; and, for convenience, without the *superscript pluses* in the postimpact $\dot{q}_{1,\ldots,4}$)

$$(X - r\cos\phi)\dot{X} + (Y - r\sin\phi)\dot{Y} + (Z - vt)\dot{Z}$$
$$- r(-X\sin\phi + Y\cos\phi)\dot{\phi} - vZ + v^2 t = 0, \tag{h1}$$

$$\Rightarrow (X - r)\dot{X} + (Y)\dot{Y} + (Z)\dot{Z} - (rY)\dot{\phi} - vZ = 0, \tag{h2}$$

yield a system of *five* equations for $\dot{X}$, $\dot{Y}$, $\dot{Z}$, $\dot{\phi}$; $\hat{\lambda}$.

For example, if at $t = 0$, Q is on L (i.e., X, $Y = 0$), verify that eqs. (g) and (h2) reduce, respectively, to

$$\dot{X} = (\dot{X})^- - \hat{\lambda}(r/M), \quad \dot{Y} = (\dot{Y})^-, \quad \dot{Z} = (\dot{Z})^- + \hat{\lambda}(Z/M), \quad \dot{\phi} = (\dot{\phi})^-, \tag{i1}$$

$$(-r)\dot{X} + (Z)\dot{Z} - vZ = 0; \tag{i2}$$

and, upon elimination of $\hat{\lambda}$, yield the postimpact velocities

$$\dot{X} = Z\{Z(\dot{X})^- + r[(\dot{Z})^- - v]\}/(r^2 + Z^2), \qquad \dot{Y} = (\dot{Y})^-,$$
$$\dot{Z} = \{r^2(\dot{Z})^- + Z[r(\dot{X})^- + vZ]\}/(r^2 + Z^2), \qquad \dot{\phi} = (\dot{\phi})^-; \tag{i3}$$

and when these results are substituted back into the *first* or *third* of (i1), they supply $\hat{\lambda}$. The details are left to the reader.

Problem 4.4.6 Consider a regular hexagon consisting of six identical and homogeneous bars *ABCDEF* (fig. 4.7), each of mass m and length $2b$, smoothly joined at their mutual hinges *A, B, C, D, E, F,* and originally resting on a smooth horizontal table. The system is struck by an impulse $\hat{I}$, normal to AF at its midpoint, which communicates to it a postimpact velocity $\dot{x}$. Show that the postimpact velocity of the opposite bar CD, $\dot{y}$, equals $\dot{x}/10$.

HINTS

In this configuration $\phi = \pi/6 = 30^\circ$, and, therefore,

$$2T = m[6(\dot{x})^2 - 12b\,\dot{x}\,\dot{\phi} + (40/3)b^2(\dot{\phi})^2], \;\; \widehat{\delta' W} = \hat{I}\,\delta x \Rightarrow \partial T/\partial\dot{\phi} = 0:$$
$$\dot{x} = \cdots = (20/9)b\,\dot{\phi};$$

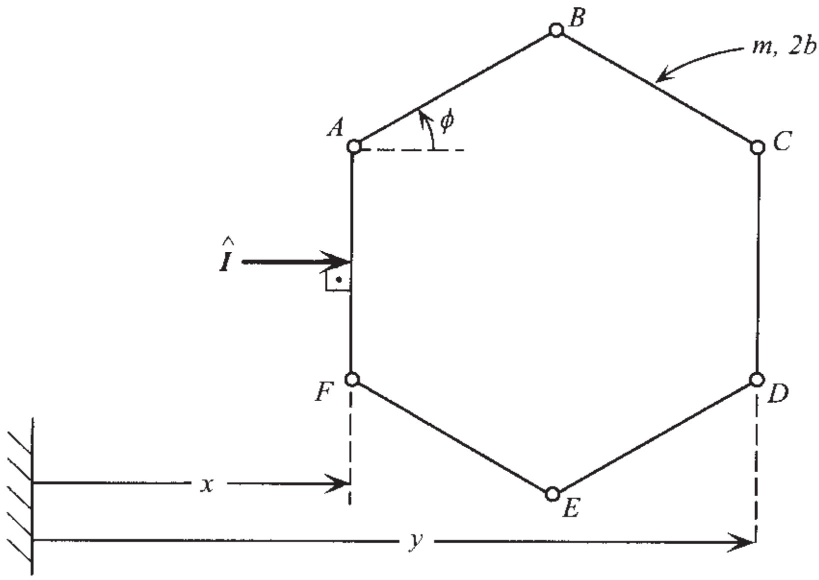

Figure 4.7 Smoothly hinged regular hexagon under a normal impulse $\hat{I}$ at the midpoint of its bar *FA*.

and so

$$\dot{y} = [x + 2(2b\cos\phi)]^{\cdot} = (\dot{x} - 4b\sin\phi\,\dot{\phi})\big|_{\phi=\pi/6} = \cdots = (2/9)b\,\dot{\phi}.$$

Example 4.4.4 Consider a circular homogeneous disk D, of mass m and radius r, moving in the vertical plane $O\text{–}xy$. At a certain instant, D strikes the fixed axis (ground) Ox and is ready to begin rolling on it (fig. 4.8). Let us determine the postimpact velocities.

Before the shock, the system positions depend on the following three parameters: (x, y): coordinates of D's center/center of mass G, angle of rotation ϕ (from Oy toward Ox – negative sense). At the shock moment, the following two (obviously) persistent constraints are introduced:

(i) $y = r$ (*contact* of D with axis Ox), (a)
(ii) $x = r\phi$ (*rolling* of D on Ox; with proper origin choice); (b)

or, in terms of the new, convenient equilibrium coordinates

$$q_1 \equiv y - r, \qquad q_2 \equiv x - r\,\phi, \qquad q_3 \equiv x, \tag{c}$$

simply

$$q_1 = 0, \qquad q_2 = 0 \qquad (\text{while } \ q_3 \neq 0). \tag{d}$$

Next, by König's theorem, the (unconstrained) kinetic energy of D (doubled; with $mk^2 \equiv I =$ moment of inertia of D about its mass center G) is

$$\begin{aligned} 2T &= m\big[(\dot{x})^2 + (\dot{y})^2\big] + I(\dot{\phi})^2 = m\big[(\dot{x})^2 + (\dot{y})^2 + k^2(\dot{\phi})^2\big] \\ &= m\big[(\dot{q}_1)^2 + (\dot{q}_3)^2 + (k/r)^2(\dot{q}_3 - \dot{q}_2)^2\big]. \end{aligned} \tag{e}$$

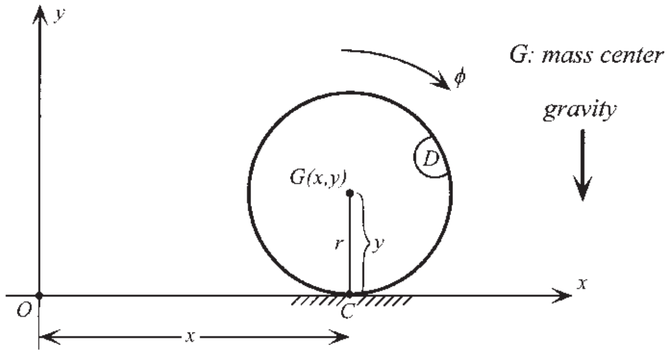

Figure 4.8 Impact of circular disk on horizontal fixed axis.

Now, since q_3 is the only unconstrained coordinate, *Appell's rule,* (4.4.8), yields

$$(\partial T/\partial \dot{q}_3)^+ = (\partial T/\partial \dot{q}_3)^-: \qquad \Delta\dot{q}_3 + (k/r)^2(\Delta\dot{q}_3 - \Delta\dot{q}_2) = 0; \tag{f}$$

from which, since $q_2 = 0 \Rightarrow (\dot{q}_2)^+ = 0$ (second-type constraint) $\Rightarrow (\dot{x})^+ = r(\dot{\phi})^+$, we obtain, successively,

$$[(\dot{x})^+ - (\dot{x})^-] + (k/r)^2\{[(\dot{x})^+ - (\dot{x})^-] - [[(\dot{x})^+ - r(\dot{\phi})^+] - [(\dot{x})^- - r(\dot{\phi})^-]]\} = 0,$$

or, simplifying,

$$[(\dot{x})^+ - (\dot{x})^-] + (k/r)^2[(\dot{x})^+ - r(\dot{\phi})^-] = 0$$
$$\Rightarrow (\dot{x})^+ = [r^2(\dot{x})^- + k^2 r(\dot{\phi})^-]/(r^2 + k^2); \tag{g}$$

an equation that expresses conservation of angular momentum about the contact point C.

The above shows that if $r(\dot{x})^- + k^2(\dot{\phi})^- = 0$, then $(\dot{x})^+ = 0$; that is, the sudden impact stops the disk! It is left to the reader to obtain the impulsive equations for q_1 and q_2, and thus calculate the impulsive multipliers corresponding to the two constraints (d).

Problem 4.4.7 Continuing from the preceding example, show that under the coordinate choice $q_1 = x$, $q_2 = y$, $q_3 = \phi$, the impulsive Routh–Voss equations, (4.4.11b), yield

$$\Delta(m\dot{x}) = \hat{\lambda}_2, \qquad \Delta(m\dot{y}) = \hat{\lambda}_1, \qquad \Delta(I\dot{\phi}) = \hat{\lambda}_2(-r), \tag{a}$$

where $\hat{\lambda}_1$ and $\hat{\lambda}_2$ are impulsive multipliers corresponding to the two constraints (d) of that example, but, here, in these new q's; that is, $q_2 - r = 0$ and $q_1 - rq_3 = 0$.

Then, solving this new system, show that $\hat{\lambda}_1 = -m(\dot{y})^-$, and $\hat{\lambda}_2 = m[(\dot{x})^+ - (\dot{x})^-] = -(mk^2/r)[(\dot{\phi})^+ - (\dot{\phi})^-]$; and, further, by eliminating $(\dot{\phi})^+$, obtain (g) of the preceding example.

Problem 4.4.8 *Central* (*or Direct*) *Collision of Two Spheres.* Consider two homogeneous spheres, S_1 and S_2, both translating along the fixed axis Ox. Let their respective *centers of mass/masses/radii/center of mass coordinates be* $G_1/m_1/r_1/x_1$ and $G_2/m_2/r_2/x_2$.

(i) Show that if S_1 and S_2 collide, the sole equation furnished by the Appellian theory is

$$\Delta(\partial T/\partial \dot{q}_1) = 0: \qquad m_1 \Delta\dot{q}_1 + m_2(\Delta\dot{q}_1 + \Delta\dot{q}_2) = 0, \tag{a}$$

where $q_1 \equiv x_1$ and $q_2 \equiv x_2 - x_1 - (r_1 + r_2)$ ($= 0$, constraint introduced at the shock moment); and this expresses the conservation of *total linear momentum* along Ox.

(ii) Show that if we assume that $(q_2)_{\text{after shock}} = 0$ (plastic spheres) $\Rightarrow (\dot{q}_2)^+ = 0$ (second-type constraint; i.e., plastic impact) then

$$(\dot{x}_1)^+ = \left[m_1(\dot{x}_1)^- + m_2(\dot{x}_2)^-\right]/(m_1 + m_2).$$

Problem 4.4.9 *Ballistic Pendulum.* Consider a projectile (e.g., bullet) B of mass m (fig. 4.9), in rectilinear translation in a vertical plane, and a physical (ballistic) pendulum P, of mass m and center of mass G, capable of rotating about a fixed axis perpendicular to that plane through an origin O. Let the polar coordinates of B be ($r = OB$, $\phi = angle(O\text{–}vertical, OB)$) and $\theta = angle(O\text{–}vertical, OG)$; that is, before the shock, the system positions depend on the three parameters r, ϕ, θ. At a certain instant, B strikes P and becomes embedded into it, and from then on both move as one body [i.e., plastic impact: $r \to constant \equiv r_o$ and $\phi \to \theta$ ($\pm$ *constant*) assume zero]. Show that, if $(\dot{\theta})^- = 0$ and I is the moment of inertia of P about O, then

$$(\dot{\theta})^+ = \left[m{r_o}^2/(I + m{r_o}^2)\right](\dot{\phi})^- \tag{a}$$

[$r_o(\dot{\phi})^-$: (known) component of velocity of B along perpendicular to OB, at shock moment].

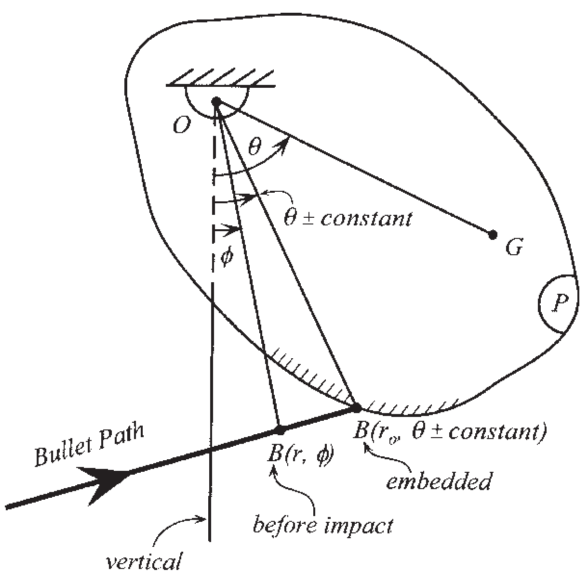

Figure 4.9 Impact in ballistic pendulum.

HINT

Introduce the new equilibrium parameters: $q_1 \equiv r - r_o$, $q_2 \equiv \theta - \phi$, $q_3 \equiv \theta$. Then the suddenly introduced persistent constraints are simply $q_1 = 0$, $q_2 = 0 \Rightarrow (\dot{q}_1)^+ = 0$, $(\dot{q}_2)^+ = 0$ (second type); also $(\dot{q}_3)^- \equiv (\dot{\theta})^- = 0$; and by Appell's rule, for q_3, $\Delta(\partial T/\partial \dot{q}_3) = 0$.

Example 4.4.5 *Impact of a Rigid Body B on a Fixed Obstacle, at a Common Contact Point C.*

Taking axes C–xyz, where Cz is along the common normal of the impacting surfaces, and, say, toward B, and with

$$(u, v, w): \quad \text{components of velocity of contact point of } B \text{ at } C, \boldsymbol{v}_C; \tag{a1}$$

$$(\omega_x, \omega_y, \omega_z): \text{ components of angular velocity of } B, \boldsymbol{\omega}; \tag{a2}$$

$$(x, y, z): \quad \text{coordinates of mass center of } B, G, \tag{a3}$$

and since

$$\boldsymbol{v}_G = \boldsymbol{v}_C + \boldsymbol{\omega} \times \boldsymbol{r}_{G/C}, \tag{b}$$

applying König's theorem, we find (with I_{kl}: moments/products of inertia of B at G)

$$\begin{aligned} 2T &= m\big[(u + \omega_y z - \omega_z y)^2 + (v + \omega_z x - \omega_x z)^2 + (w + \omega_x y - \omega_y x)^2\big] \\ &\quad + (I_x {\omega_x}^2 + I_y {\omega_y}^2 + I_z {\omega_z}^2 + 2I_{xy}\, \omega_x \omega_y + 2I_{xz}\, \omega_x \omega_z + 2I_{yz}\, \omega_y \omega_z) \\ &= m(u^2 + v^2 + w^2) + 2m\big[\omega_x(yw - zv) + \omega_y(zu - xw) + \omega_z(xv - yu)\big] \\ &\quad + (I_x {\omega_x}^2 + I_y {\omega_y}^2 + I_z {\omega_z}^2 + 2I_{xy}\, \omega_x \omega_y + 2I_{xz}\, \omega_x \omega_z + 2I_{yz}\, \omega_y \omega_z). \end{aligned} \tag{c}$$

We also have the *constitutive equation*

$$w^+ = -e\, w^- \;\Rightarrow\; \Delta w = -(1 + e) w^- \qquad (> 0, \text{ since } \; w^- < 0). \tag{d}$$

Now, we consider the following *two* cases:

(i) *Smooth obstacle*: Then the sole constraint is $w = 0$ (during the impact), and so only the w-equation of motion contains a *multiplier*. The postimpact state will be determined from (d) and the remaining (kinetic) equations

$$\Delta(\partial T/\partial u) = 0, \qquad \Delta(\partial T/\partial v) = 0; \tag{e1}$$

$$\Delta(\partial T/\partial \omega_x) = 0, \qquad \Delta(\partial T/\partial \omega_y) = 0, \qquad \Delta(\partial T/\partial \omega_z) = 0. \tag{e2}$$

(ii) *Rough surfaces*: In this case, the constraints are $u = 0, v = 0, w = 0$ (during the impact), and, therefore [assuming that a (d)-like relation still holds],

$$u^+ = 0 \Rightarrow \Delta u = -u^-, \qquad v^+ = 0 \Rightarrow \Delta v = -v^-, \qquad \Delta w = -(1 + e) u^-. \tag{f}$$

The values $\varDelta\omega_{x,y,z}$ will be determined from the three (kinetic) equations

$$\varDelta(\partial T/\partial\omega_x) = 0: \qquad I_x\,\varDelta\omega_x + I_{xy}\,\varDelta\omega_y + I_{xz}\,\varDelta\omega_z + m(y\,\varDelta w - z\,\varDelta v) = 0, \tag{g1}$$

$$\varDelta(\partial T/\partial\omega_y) = 0: \qquad I_{yx}\,\varDelta\omega_x + I_y\,\varDelta\omega_y + I_{yz}\,\varDelta\omega_z + m(z\,\varDelta u - x\,\varDelta w) = 0, \tag{g2}$$

$$\varDelta(\partial T/\partial\omega_z) = 0: \qquad I_{zx}\,\varDelta\omega_x + I_{zy}\,\varDelta\omega_y + I_z\,\varDelta\omega_z + m(x\,\varDelta v - y\,\varDelta u) = 0. \tag{g3}$$

If the axes G–xyz are *principal*, the above simplify somewhat; that is, the products of inertia vanish.

Problem 4.4.10 A heavy rigid body of revolution (axis Oz) moves in space about the *fixed point* O. At time t_o its nutation angle θ equals θ_o, and its Eulerian angle rates are $\dot\phi_o, \dot\theta_o, \dot\psi_o$. At that moment, the axis Oz hits a fixed obstacle, thus introducing the *nonpersistent* constraint ϕ (precession) $=$ *constant*. Show that

$$\varDelta\dot\theta = 0 \;\Rightarrow\; (\dot\theta)^+ = (\dot\theta)^-, \tag{a}$$

$$\varDelta(\dot\psi + \dot\phi\cos\theta) = 0 \;\Rightarrow\; (\dot\psi)^+ = (\dot\psi)^- + (1+e)(\dot\phi)^-\cos\theta_o, \tag{b}$$

$$\varDelta\big[(A\sin^2\theta)\dot\phi + C(\dot\psi + \dot\phi\cos\theta)\cos\theta\big] = R_\phi. \tag{c}$$

HINTS

Here (recalling §1.15 ff.):

(i)
$$2T = A\big[(\dot\theta)^2 + (\dot\phi)^2\sin^2\theta\big] + C(\dot\psi + \dot\phi\cos\theta)^2, \tag{d}$$

where

$$A/C:\ \textit{transverse/axial}\text{ moments of inertia of body at }O; \tag{e}$$

(ii)
$$\hat{Q}_{\phi,\theta,\psi} = 0; \tag{f}$$

(iii)
$$(\dot\phi)^+ = -e(\dot\phi)^-; \tag{g}$$

and, therefore,

(iv)
$$\varDelta(\partial T/\partial\dot\theta) = 0,$$
$$\varDelta(\partial T/\partial\dot\psi) = 0 \;\Rightarrow\; \varDelta\dot\psi = -\varDelta(\dot\phi\cos\theta) \;\Rightarrow\; (\dot\psi)^+ = (\dot\psi)^- + \cdots,$$
$$\varDelta(\partial T/\partial\dot\phi) = R_\phi\ \text{(impulsive multiplier)}. \tag{h}$$

Example 4.4.6 A homogeneous sphere S, of center and center of mass G, mass M and radius R, rests on a rough fixed horizontal plane p. Then, a given impulse $\hat{\boldsymbol{F}}$ is applied at a specified S-point A. Let us find its postimpact velocities.

Relative to *space-fixed* axes O–xyz (coinciding with *sphere-fixed* axes G–$\xi\eta\zeta$ at the impact instant; and such that O–xy: parallel to plane $p, Oz =$ perpendicular to p, positive upwards), let

$$\text{Coordinates of } G\text{: } (\xi, \eta, \zeta)_{\text{at impact instant}} = (0, 0, 0), \tag{a1}$$

$$\text{Coordinates of } A\text{: } (x, y, z), \tag{a2}$$

$$\text{Coordinates of contact point } C\text{: } (x_C, y_C, z_C)_{\text{at impact instant}} = (0, 0, -R), \tag{a3}$$

$$\text{Components of angular velocity of } S\text{: } (\omega_{x,y,z}), \tag{a4}$$

$$\text{Components of } \hat{\boldsymbol{F}}\text{: } (X, Y, Z). \tag{a5}$$

[Instead of the $(\omega_{x,y,z})$ we could have chosen the rates of the $3 \to 1 \to 3$ Eulerian angles of G–$\xi\eta\zeta$ relative to O–xyz: $(\dot{\phi}, \dot{\theta}, \dot{\psi})$; even though $(\phi, \theta, \psi)_{\text{impact instant}} = (0, 0, 0)$.] Then, by König's theorem (and with the constraint $\dot{\zeta} = v_{G,z} = 0$ enforced in it),

$$2T = M[(\dot{\xi})^2 + (\dot{\eta})^2] + Mk^2({\omega_x}^2 + {\omega_y}^2 + {\omega_z}^2); \tag{b}$$

where $k^2 \equiv 2R^2/5$; also, and since $\boldsymbol{v}_A = \boldsymbol{v}_G + \boldsymbol{\omega} \times \boldsymbol{r}_{A/G} \Rightarrow \delta\boldsymbol{r}_A = \delta\boldsymbol{r}_G + \delta\boldsymbol{\chi} \times \boldsymbol{r}_{A/G}$, or, in components,

$$\dot{x} = \dot{\xi} + z\omega_y - y\omega_z, \qquad \dot{y} = \dot{\eta} + x\omega_z - z\omega_x, \qquad \dot{z} = \dot{\zeta} + y\omega_x - x\omega_y, \tag{c}$$

the percussive virtual work is (with $\boldsymbol{OA} \equiv \boldsymbol{r}_A$)

$$\begin{aligned}
\widehat{\delta' W} &= \hat{\boldsymbol{F}} \cdot \delta\boldsymbol{r}_A = X\,\delta x + Y\,\delta y + Z\,\delta z \\
&= X(\delta\xi + z\,\delta\theta_y - y\,\delta\theta_z) + Y(\delta\eta + x\,\delta\theta_z - z\,\delta\theta_x) + Z(0 + y\,\delta\theta_x - x\,\delta\theta_y) \\
&= (X)\,\delta\xi + (Y)\,\delta\eta + (Z)0 \\
&\qquad + (yZ - zY)\,\delta\theta_x + (zX - xZ)\,\delta\theta_y + (xY - yX)\,\delta\theta_z,
\end{aligned} \tag{d}$$

where $\omega_{x,y,z} \equiv \dot{\theta}_{x,y,z}$; and, since at the end of the impact

$$\boldsymbol{v}_{\text{contact of } S \text{ with } p} \equiv \boldsymbol{v}_C = \boldsymbol{v}_G + \boldsymbol{\omega} \times \boldsymbol{r}_{C/G} = \boldsymbol{0},$$

or, in components,

$$\begin{aligned}
(\dot{x}_C, \dot{y}_C, \dot{z}_C)_{\text{at impact instant}} &= (\dot{\xi}, \dot{\eta}, \dot{\zeta}) + (\omega_x, \omega_y, \omega_z) \times (0, 0, -R) = (0, 0, 0): \\
&\Rightarrow \dot{\xi} - R\,\omega_y = 0, \qquad \dot{\eta} + R\,\omega_x = 0, \\
\text{and} \qquad &\dot{\zeta} = 0 \;\Rightarrow\; \zeta = \textit{constant} = 0 \text{ (as expected)},
\end{aligned} \tag{e}$$

we will have (with $\hat{\lambda}$ and $\hat{\mu}$ as impulsive multipliers along x_C and y_C, respectively)

$$\widehat{\delta' W_R} = \hat{\lambda}\,\delta x_C + \hat{\mu}\,\delta y_C = \hat{\lambda}(\delta\xi - R\,\delta\theta_y) + \hat{\mu}(\delta\eta + R\,\delta\theta_x) = 0. \tag{f}$$

Utilizing the above in the impulsive principle of Lagrange {plus method of multipliers (i.e., adjoining δ [first/second of eqs. (e)] to it via $\hat{\lambda}, \hat{\mu}$); or, equivalently, and in the spirit of impulsive relaxation, adding (f) to $\widehat{\delta' W}$}, we readily obtain the following *five* equations of impulsive motion:

$$\varDelta(\partial T/\partial\dot{\xi}) = X + \hat{\lambda}(1) + \hat{\mu}(0): \qquad \varDelta(M\dot{\xi}) = X + \hat{\lambda}, \tag{g1}$$

$$\varDelta(\partial T/\partial\dot{\eta}) = Y + \hat{\lambda}(0) + \hat{\mu}(1): \qquad \varDelta(M\dot{\eta}) = Y + \hat{\mu}; \tag{g2}$$

$$\varDelta(\partial T/\partial\omega_x) = yZ - zY + \hat{\lambda}(0) + \hat{\mu}(R): \quad \varDelta(Mk^2\omega_x) = yZ - zY + \hat{\mu}R, \tag{g3}$$

$$\varDelta(\partial T/\partial\omega_y) = zX - xZ + \hat{\lambda}(-R) + \hat{\mu}(0): \quad \varDelta(Mk^2\omega_y) = zX - xZ - \hat{\lambda}R, \tag{g4}$$

$$\varDelta(\partial T/\partial\omega_z) = xY - yX + \hat{\lambda}(0) + \hat{\mu}(0): \quad \varDelta(Mk^2\omega_z) = xY - yX; \tag{g5}$$

which, along with the *two* constraints (e) constitute a determinate system of *seven* algebraic equations for $\varDelta\dot{\xi}, \varDelta\dot{\eta}, \varDelta\omega_{x,y,z}, \hat{\lambda}, \hat{\mu}$. Finally, application of the Newton–Euler impulsive linear momentum theorem in the vertical direction yields the vertical impulsive reaction at C, if needed [instead of using relaxation in T, eq. (b), and an extra multiplier].

An Introduction to Kinetic Impulsive Equations

To obtain multiplierless (i.e., kinetic impulsive) equations we may proceed as follows:

(i) Eliminate $\hat{\lambda}$ and $\hat{\mu}$ from (g3–5), with the help of (g1, 2); that is,

$$\hat{\lambda} = M\varDelta\dot{\xi} - X, \qquad \hat{\mu} = M\varDelta\dot{\eta} - Y, \tag{h}$$

thus obtaining the following *three kinetic impulsive Maggi* equations:

$$-(MR)\,\varDelta\dot{\eta} + (Mk^2)\,\varDelta\omega_x = yZ - (z+R)\,Y, \tag{i1}$$

$$(MR)\,\varDelta\dot{\xi} + (Mk^2)\,\varDelta\omega_y = -xZ + (z+R)X, \tag{i2}$$

$$(Mk^2)\,\varDelta\omega_z = xY - yX \qquad \text{(unchanged)}; \tag{i3}$$

which, along with the *two* constraints (e), constitute a determinate system of *five* algebraic equations for $\varDelta\dot{\xi}, \varDelta\dot{\eta}, \varDelta\omega_{x,y,z}$; then $\hat{\lambda}, \hat{\mu}$ follow immediately from (h). [Equations (i1–3) also result by applying the principle of impulsive angular momentum about C.]

Further, using (e) to eliminate, say $\varDelta\dot{\xi}$ and $\varDelta\dot{\eta}$, from (i1–3) would result in the *three kinetic impulsive Chaplygin–Voronets equations* in $\varDelta\omega_{x,y,z}$ (see §4.5).

(ii) Or, introduce the following "equilibrium" (quasi) velocities:

$$\omega_1 \equiv \dot{\theta}_1 \equiv \dot{\xi} - R\,\omega_y\ (=0) \Rightarrow \dot{\xi} = \dot{\theta}_1 + R\,\omega_y, \qquad \delta\xi = \delta\theta_1 + R\,\delta\theta_y, \tag{j1}$$

$$\omega_2 \equiv \dot{\theta}_2 \equiv \dot{\eta} + R\,\omega_x\ (=0) \Rightarrow \dot{\eta} = \dot{\theta}_2 - R\,\omega_x, \qquad \delta\eta = \delta\theta_2 - R\,\delta\theta_x; \tag{j2}$$

in terms of which the expressions (b), (d), and (f) become, respectively,

$$2T \to 2T^* = M\big[(\omega_1 + R\,\omega_y)^2 + (\omega_2 - R\,\omega_x)^2\big] + (Mk^2)(\omega_x{}^2 + \omega_y{}^2 + \omega_z{}^2); \tag{k1}$$

$$\begin{aligned}\widehat{\delta' W} \to \widehat{(\delta' W)^*} &= \cdots = X\,\delta\theta_1 + Y\,\delta\theta_2 + \big[Zy - (R+z)Y\big]\,\delta\theta_x \\ &\quad + \big[X(R+z) - Zx\big]\,\delta\theta_y + \big[Yx - Xy\big]\,\delta\theta_z \\ &\equiv \hat{\Theta}_1\,\delta\theta_1 + \hat{\Theta}_2\,\delta\theta_2 + \hat{\Theta}_x\,\delta\theta_x + \hat{\Theta}_y\,\delta\theta_y + \hat{\Theta}_z\,\delta\theta_z,\end{aligned} \tag{k2}$$

$$\widehat{\delta' W_R} \to \widehat{(\delta' W_R)^*} = \hat{\lambda}\,\delta\theta_1 + \hat{\mu}\,\delta\theta_2 \equiv \hat{\Lambda}_1\,\delta\theta_1 + \hat{\Lambda}_2\,\delta\theta_2 = 0; \tag{k3}$$

and then, using the above in the impulsive principle of Lagrange, obtain the following *five Hamel equations of impulsive motion*:

$$\textit{Kinetostatic:} \qquad \Delta(\partial T^*/\partial\omega_k) = \hat{\Theta}_k + \hat{\Lambda}_k \qquad (k = 1, 2), \tag{l1}$$

$$\textit{Kinetic:} \qquad \Delta(\partial T^*/\partial\omega_k) = \hat{\Theta}_k \qquad (k = x, y, z). \tag{l2}$$

The details are left to the reader; and the entire process of elimination of impulsive multipliers is treated in full generality in §4.5.

4.5 IMPULSIVE MOTION VIA QUASI VARIABLES

Here the previous results are extended to nonholonomic "coordinates" and velocities, and in the process show that, contrary to the finite motion case (§3.5), *the Lagrangean impulsive equations retain the same form in both holonomic and nonholonomic variables.*

Let us assume, with no loss of generality, that our system is subjected to m Pfaffian (holonomic and/or nonholonomic) constraints:

$$\sum a_{Dk}\,dq_k + a_D\,dt = 0 \quad \text{(kinematically admissible form)}, \tag{4.5.1a}$$

$$\sum a_{Dk}\,\delta q_k = 0 \quad \text{(virtual form)} \quad [D = 1, \ldots, m(< n);\ k = 1, \ldots, n]. \tag{4.5.1b}$$

Introducing the n quasi coordinates θ (as detailed in §2.9 ff.) via

$$d\theta_D \equiv \sum a_{Dk}\,dq_k + a_D\,dt \quad (= 0), \qquad d\theta_I \equiv \sum a_{Ik}\,dq_k + a_I\,dt \quad (\neq 0), \tag{4.5.2a}$$

$$\delta\theta_D \equiv \sum a_{Dk}\,\delta q_k \quad (= 0), \qquad \delta\theta_I \equiv \sum a_{Ik}\,\delta q_k \quad (\neq 0); \tag{4.5.2b}$$

$$d\theta_{n+1} \equiv dq_{n+1} \equiv dt; \qquad \delta\theta_{n+1} \equiv \delta q_{n+1} \equiv \delta t = 0 \qquad (I = m+1, \ldots, n); \tag{4.5.2c}$$

and their n quasi velocities ω via

$$\omega_D \equiv d\theta_D/dt \quad (= 0), \quad \omega_I \equiv d\theta_I/dt \quad (\neq 0), \quad \omega_{n+1} \equiv d\theta_{n+1}/dt = \dot{t} = 1, \tag{4.5.2d}$$

we can write for the virtual displacement of a typical particle:

$$\delta\boldsymbol{r} = \sum \boldsymbol{e}_k\,\delta q_k \equiv \sum \boldsymbol{\varepsilon}_I\,\delta\theta_I. \tag{4.5.3}$$

The Impulsive Hamel Equations

Substituting the second of (4.5.3) into the LIP, eqs. (4.3.3b–4b), and since the $n - m \ \delta\theta_I$ are unconstrained, and $\Delta(\ldots)$ and $\widehat{(\ldots)}$ commute with $S(\ldots)$ [assuming, of course, that $\hat{\boldsymbol{\varepsilon}}_I = \Delta\boldsymbol{\varepsilon}_I = \mathbf{0}$], we easily obtain, respectively,

$$\hat{\Lambda}_I \equiv S\, \widehat{d\boldsymbol{R}} \cdot \boldsymbol{\varepsilon}_I \equiv (I)\text{th } \textit{nonholonomic} \text{ component of system } \textit{constraint reaction}$$
$$= 0, \tag{4.5.4a}$$

and the $n - m$ *nonholonomic kinetic impulsive equations*:

$$S\, \Delta(dm\, \boldsymbol{v}) \cdot \boldsymbol{\varepsilon}_I = \Delta\Big(S\, dm\, \boldsymbol{v} \cdot \boldsymbol{\varepsilon}_I\Big) = S\, \widehat{d\boldsymbol{F}} \cdot \boldsymbol{\varepsilon}_I; \tag{4.5.4b}$$

or, in *system* variables, and with $P_I \equiv S\, dm\, \boldsymbol{v} \cdot \boldsymbol{\varepsilon}_I = P_I(t, q, \omega) = \partial T^*/\partial\omega_I = (I)$th *nonholonomic component of system momentum*,

$$\Delta P_I = \hat{\Theta}_I \qquad (I = m+1, \ldots, n). \tag{4.5.5a}$$

It is not hard to show (e.g., invoking the relaxation principle/Lagrangean multipliers; in a completely analogous way with the finite motion case — recall §3.5), that the corresponding *m impulsive nonholonomic kinetostatic equations* are

$$\Delta P_D = \hat{\Theta}_D + \hat{\Lambda}_D, \qquad \hat{\Lambda}_D \equiv \hat{\lambda}_D \quad (\neq 0) \qquad (D = 1, \ldots, m). \tag{4.5.5b}$$

These *uncoupled* algebraic equations are the *impulsive counterparts of Hamel's equations* (§3.3 ff.).

The Impulsive Maggi Equations

Multiplying the impulsive Routh–Voss equations corresponding to (4.5.1a, b),

$$\Delta p_k = \hat{Q}_k + \sum \hat{\lambda}_D a_{Dk} \qquad (D = 1, \ldots, m), \tag{4.5.6}$$

with $A_{kl} = A_{kl}(q, t)$, where (A_{kl}) is the *inverse* of the (augmented) $n \times n$ matrix (a_{kl}), as in chapters 2 and 3, and summing over k from 1 to n, we find, successively,

$$\begin{aligned} \Delta\Big(\sum A_{kl} p_k\Big) &= \sum A_{kl} \hat{Q}_k + \sum \Big[A_{kl}\Big(\sum \hat{\lambda}_D a_{Dk}\Big)\Big] \\ &= \sum A_{kl} \hat{Q}_k + \sum \Big[\hat{\lambda}_D\Big(\sum a_{Dk} A_{kl}\Big)\Big] \\ &= \sum A_{kl} \hat{Q}_k + \sum \hat{\lambda}_D\, \delta_{Dl}, \end{aligned}$$

or, finally, since $\Delta A_{kl} = 0$, the above split into the following two groups:

$$\sum A_{kD} \Delta p_k = \sum A_{kD} \hat{Q}_k + \hat{\lambda}_D \qquad (\equiv \hat{\Theta}_D + \hat{\Lambda}_D) \qquad (D = 1, \ldots, m), \tag{4.5.6a}$$
$$\sum A_{kI} \Delta p_k = \sum A_{kI} \hat{Q}_k \qquad (\equiv \hat{\Theta}_I) \qquad (I = m+1, \ldots, n); \tag{4.5.6b}$$

since $\hat{\lambda}_I \equiv \hat{\Lambda}_I = 0$. Equations (4.5.6a) and (4.5.6b) are, respectively, the *impulsive kinetostatic and kinetic Maggi's equations*.

REMARKS

(i) The kinetic impulsive equations (4.5.5a) can also be obtained by integration of the corresponding kinetic equations of ordinary continuous motion (§3.5) in time, and then taking the impulsive limit $\tau \to 0$, while noting that [as in (4.4.12)]:

$$\widehat{\partial T^*/\partial\theta_I} \equiv \sum A_{kI}\,\widehat{(\partial T^*/\partial q_k)} = 0 \quad \text{and} \quad -\widehat{\Gamma_I} \equiv \widehat{\sum\sum \gamma^k{}_{II'}(\partial T^*/\partial\omega_k)\omega_{I'}} = 0; \tag{4.5.7}$$

and similarly for the kinetostatic equations (4.5.5b). The above allow us to rewrite (4.5.5a) as

$$\Delta(\partial T^*{}_o/\partial\omega_I) = \hat{\Theta}_I, \qquad (I = m+1,\ldots,n), \tag{4.5.8}$$

where, as usual,

$$\begin{aligned} T^*{}_o &\equiv T^*(q;\ \omega_1 = 0,\ldots,\omega_m = 0;\ \omega_{m+1},\ldots,\omega_n;\ t) \\ &= T^*(q;\ \omega_{m+1},\ldots,\omega_n;\ t) \equiv T^*{}_o(q,\omega_I,t)\text{: } \textit{constrained } T^*; \end{aligned} \tag{4.5.8a}$$

that is, here, and *contrary to the Hamel equations for ordinary motion* (§3.5), *if no impulsive reactions are sought*, we can enforce the m nonholonomic constraints $\omega_D = 0$ in T^* (and Θ_I) *before* the partial differentiations; and this simplifies the calculations somewhat. [Justification: expanding $T^* = T^*(\omega_I, \omega_D)$ à la Taylor around $\omega_D = 0$, we obtain (with some easily understood calculus notations)

$$\begin{aligned} T^*(\omega_I,\omega_D) &= T^*(\omega_I,0) + (\partial T^*/\partial\omega_D)_o\omega_D + O_2(\omega_D) \\ \Rightarrow [\partial T^*(\omega_I,\omega_D)/\partial\omega_I]_o &= \partial T^*(\omega_I,0)/\partial\omega_I + \big\{\partial/\partial\omega_I[(\partial T^*/\partial\omega_D)_o]\omega_D + O_2(\omega_D)\big\}_o \\ &= \partial T^*(\omega_I,0)/\partial\omega_I + 0, \end{aligned}$$

that is, simply,

$$(\partial T^*/\partial\omega_I)_o = \partial T^*{}_o/\partial\omega_I.\big]$$

However, for problems with *second*-type constraints, where, clearly [recalling (§4.4.3b)],

$$\omega_D{}^+ = 0 \qquad \text{but} \qquad \omega_D{}^- \neq 0, \tag{4.5.8b}$$

eqs. (4.5.8) do *not* hold: even if no impulsive reactions are sought, still, we must express $T \to T^*$ as function of *all* the ω's, carry out all differentiations, and *then* enforce the m constraints, first of (8b), on the *postimpact* momenta; the *preimpact* momenta will be calculated using the known ω^-. In sum, for *second*-type constraint problems, (4.5.5b/8, 5c) will be replaced, respectively, by

$$(\partial T^*/\partial\omega_I)^+ - (\partial T^*/\partial\omega_I)^- = \hat{\Theta}_I \qquad (I = m+1,\ldots,n), \tag{4.5.9a}$$

$$(\partial T^*/\partial\omega_D)^+ - (\partial T^*/\partial\omega_D)^- = \hat{\Theta}_D + \hat{\Lambda}_D \qquad (D = 1,\ldots,m); \tag{4.5.9b}$$

although for the *independent postimpact momenta* we still have $(\partial T^*/\partial\omega_I)^+ = (\partial T^*{}_o/\partial\omega_I)^-$.

(ii) The *special* independent quasi-velocity choice $\omega_I = \dot{q}_I$, in (4.5.8), produces what might be called *the impulsive Chaplygin–Voronets (kinetic) equations*:

$$\Delta(\partial T_o/\partial \dot{q}_I) = \hat{Q}_{Io}, \tag{4.5.10}$$

where $T \equiv T^*{}_o(q;\, \dot{q}_{m+1}, \ldots, \dot{q}_n;\, t) \equiv T^*{}_o(q;\, \dot{q}_I;\, t) \equiv T_o(q, \dot{q}_I;\, t)$; in which case, $\partial T^*/\partial \omega_I$ becomes $\partial T_o/\partial \dot{q}_I = \partial T/\partial \dot{q}_I + \sum b_{DI}(\partial T/\partial \dot{q}_D)$, a specialization of $P_I = \sum A_{kI} p_k$; and the $(n-m)$ $\hat{Q}_{Io}$ are defined from

$$\widehat{\delta' W} \equiv \sum \hat{Q}_k\, \delta q_k = \sum \left(\hat{Q}_I + \sum b_{DI} \hat{Q}_D\right) \delta q_I \equiv \sum \hat{Q}_{Io}\, \delta q_I, \tag{4.5.10a}$$

a specialization of $\hat{\Theta}_I = \sum A_{kI} \hat{Q}_k$ [see also (4.5.12b, c)].

Equations (4.5.10) show that Lagrange's impulsive equations in holonomic variables hold *unchanged in form, even for nonholonomically constrained systems*, provided we use, in there, the constrained quantities T_o and $\hat{Q}_{Io}$, instead of their unconstrained (relaxed) counterparts T and $\hat{Q}_k$; and, by comparing them with eqs. (4.5.5a, 8) we conclude that, due to (4.5.7), *the Lagrangean impulsive equations have the same form in both holonomic and nonholonomic variables*. Of course, (4.5.10) can also be obtained by direct application of the impulsive limiting process to the Chaplygin–Voronets equations (§3.8), with invocation of (4.5.7)-like results. [We recall (§3.8) that here too, just like with eqs. (4.5.8), the situation is in sharp contrast to its ordinary motion counterpart; that is, if the special Pfaffian constraints (4.5.1a) are nonholonomic, then $E_I(T_o) \neq Q_{Io}$.] In view of the earlier remark (i), these equations do *not* hold (without appropriate modifications) for *second*-type constraint problems; and, obviously, cannot be used to calculate impulsive reactions.

Historical: equations (4.5.10) seem to be due to Beghin and Rousseau (1903), who obtained them using the impulsive counterpart of the method of their teacher P. Appell (1899, 1900); that is, independently of any Chaplygin–Voronets equation considerations. In the past, they have been used by various authors [e.g., Beer (1963)], but without the proper theoretical justification given here, or in the Beghin/Rousseau paper.

(iii) Due to the vectorial transformations $P_l = \sum A_{kl} p_k$, and $\hat{\Theta}_l = \sum A_{kl} \hat{Q}_k$ (via chain rule), the impulsive Maggi equations (4.5.6a, b) are identical to the impulsive Hamel equations (4.5.5c, b), respectively; but the former are in *holonomic* variables while the latter are in *nonholonomic* variables. Also, Maggi's equations can result directly from the LIP, eqs. (second of 4.3.7), by inserting in it the inverse of (4.5.2a–c):

$$\delta q_k = \sum A_{kD}(1 \cdot \delta\theta_D) + \sum A_{kI}\, \delta\theta_I \quad \left(= \sum A_{kI}\, \delta\theta_I\right); \tag{4.5.11}$$

the details can be easily carried out by the reader.

(iv) In case the constraints (4.5.1a, b) have the special form (recalling results from §2.11)

$$dq_D = \sum b_{DI}\, dq_I + b_D\, dt, \qquad \delta q_D = \sum b_{DI}\, \delta q_I, \tag{4.5.12a}$$

the Maggi equations (4.5.6a, b) specialize, respectively, to

$$\Delta p_D = \hat{Q}_D + \hat{\lambda}_D \qquad \text{and} \qquad \Delta p_I = \hat{Q}_I - \sum b_{DI} \hat{\lambda}_D; \tag{4.5.12b}$$

and by eliminating the m λ's between these two sets of equations, we obtain the $n - m$ *impulsive kinetic Hadamard equations*

$$\Delta p_I + \sum b_{DI} \Delta p_D = \hat{Q}_I + \sum b_{DI} \hat{Q}_D \equiv \hat{Q}_{Io}; \qquad (4.5.12c)$$

which, along with the n constraints (first of 4.5.12a) (*evaluated at the postimpact instant*—assuming, of course, that they hold there), constitute a determinate set of $(n - m) + m = n$ equations for the n $(\dot{q})^+$; the m $\hat{\lambda}_D$ can then be found from (first of 4.5.12b). [We notice the similarity between the first of (4.5.12b) and the earlier equations (4.4.7a).]

With the notation $\hat{M}_k \equiv \Delta p_k - \hat{Q}_k$, eqs. (4.5.12b, c) can be rewritten, respectively, as

$$\textit{Kinetostatic}: \quad \hat{M}_D = \hat{\lambda}_D \qquad \text{and} \qquad \textit{Kinetic}: \quad \hat{M}_I + \sum b_{DI} \hat{M}_D = 0. \qquad (4.5.12d)$$

For *second*-type constraint problems, clearly, the above impulsive equations of Routh–Voss, Maggi, and Hadamard still hold; and the n $(\dot{q})^-$ have known values, unrelated to the constraints (4.5.1a).

Appell's Equations and Impulsive Motion

Since these equations contain the accelerations explicitly, in general, they are not very useful in impulsive problems. Nevertheless, an Appell-like form of impulsive equations can be formulated. To this end, first, we define the *kinetic energy of the velocity jumps*, or *impulsive Appellian* function:

$$\hat{S} \equiv \int dm\ \Delta\boldsymbol{v} \cdot \Delta\boldsymbol{v}/2 \qquad \left[\neq \Delta T \equiv \int dm\ (\boldsymbol{v}^+ \cdot \boldsymbol{v}^+ - \boldsymbol{v}^- \cdot \boldsymbol{v}^-)/2\right], \qquad (4.5.13a)$$

[in *exception* to the earlier *hat notation*, eqs. (4.2.5a)!)] and then notice that, since $\Delta\boldsymbol{\varepsilon}_I = \mathbf{0}$ *and* $\Delta\boldsymbol{\varepsilon}_{n+1} = \mathbf{0}$, we have

$$\Delta\boldsymbol{v} = \sum \boldsymbol{\varepsilon}_I \Delta\omega_I \ \Rightarrow\ \partial(\Delta\boldsymbol{v})/\partial(\Delta\omega_I) = \boldsymbol{\varepsilon}_I, \qquad (4.5.13b)$$

and therefore, successively,

$$\begin{aligned} \partial\hat{S}/\partial(\Delta\omega_I) &= \int (dm/2) 2\, \Delta\boldsymbol{v} \cdot \left[\partial(\Delta\boldsymbol{v})/\partial(\Delta\omega_I)\right] \\ &= \int dm\ \Delta\boldsymbol{v} \cdot \boldsymbol{\varepsilon}_I = \Delta\Big(\int dm\ \boldsymbol{v} \cdot \boldsymbol{\varepsilon}_I\Big) \equiv \Delta P_I; \end{aligned}$$

that is, finally, the kinetic equations of impulsive motion take the "Appellian" form

$$\partial\hat{S}/\partial(\Delta\omega_I) = \Delta(\partial T^*/\partial\omega_I) = \hat{\Theta}_I \qquad (I = m+1, \ldots, n), \qquad (4.5.13c)$$

due to Arrighi (1939); see also Pars (1965, pp. 238–242). It is not hard to see, by invoking the impulsive principle of relaxation and a relaxed S, that the corresponding kinetostatic equations are

$$\left[\partial\hat{S}/\partial(\Delta\omega_D)\right]_o = \hat{\Theta}_D + \hat{\Lambda}_D \qquad (D = 1, \ldots, m). \qquad (4.5.13d)$$

Example 4.5.1 One extremity of the major axis (point P) and one extremity of the minor axis (point Q) of a thin homogeneous elliptical disk of (principal) semiaxes,

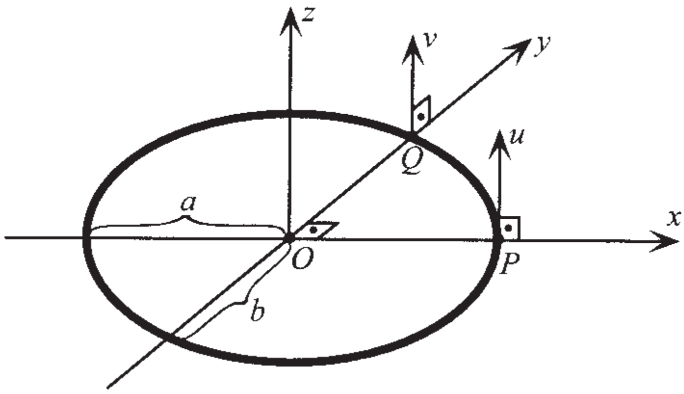

Figure 4.10 Elliptical disk, initially at rest, is given the velocities u and v at the endpoints of its axes, perpendicular to its plane. Semiaxes of the ellipse: $a = |\boldsymbol{OP}|, b = |\boldsymbol{OQ}|$.

a, b, and mass m, initially at rest, are imparted prescribed velocities, u (at P) and ν (at Q), perpendicular to the plane of the disk (fig. 4.10). Let us find its *postimpact* linear and angular velocities.

By König's theorem, the (double) kinetic energy of the disk is

$$2T \to 2T^* = m({v_x}^2 + {v_y}^2 + {v_z}^2) + (A{\omega_x}^2 + B{\omega_y}^2 + C{\omega_z}^2), \qquad \text{(a)}$$

where

$$\boldsymbol{v}_G = (v_x, v_y, v_z)\text{: velocity of mass center of disk, } G,$$

$$\boldsymbol{\omega} \;= (\omega_x, \omega_y, \omega_z)\text{: angular velocity of disk,}$$

$$(I_x, I_y, I_z) = \big(mb^2/4, ma^2/4, m(a^2+b^2)/4\big)\text{: principal moments of inertia of disk at } G. \qquad \text{(b)}$$

From rigid-body kinematics, we have

$$\boldsymbol{v}_P = \boldsymbol{v}_G + \boldsymbol{\omega} \times \boldsymbol{r}_{P/G}, \qquad \boldsymbol{v}_Q = \boldsymbol{v}_G + \boldsymbol{\omega} \times \boldsymbol{r}_{Q/G}; \qquad \text{(c)}$$

or, in components,

$$u\,\boldsymbol{k} = (v_x, v_y, v_z) + (\omega_x, \omega_y, \omega_z) \times (a, 0, 0), \qquad \text{(c1)}$$

$$v\,\boldsymbol{k} = (v_x, v_y, v_z) + (\omega_x, \omega_y, \omega_z) \times (0, b, 0); \qquad \text{(c2)}$$

respectively, from which, equating, we obtain the velocity compatibility conditions

$$v_x = 0 \text{ (also, by symmetry)}, \qquad v_y + a\,\omega_z = 0, \qquad v_z - a\,\omega_y = u, \qquad \text{(c3)}$$

$$v_x - b\,\omega_z = 0, \qquad v_y = 0 \text{ (also, by symmetry)}, \qquad v_z + b\,\omega_x = v. \qquad \text{(c4)}$$

In view of the above, we choose the following convenient set of six quasi velocities:

$$\omega_1 \equiv v_x = 0, \tag{c5}$$

$$\omega_2 \equiv v_y = 0, \tag{c6}$$

$$\omega_3 \equiv \omega_z = 0, \tag{c7}$$

$$\omega_4 \equiv v_z - a\,\omega_y - u = 0, \tag{c8}$$

$$\omega_5 \equiv v_z + b\,\omega_x - v = 0, \tag{c9}$$

$$\omega_6 \equiv v_z \neq 0 \tag{c10}$$

(we could have chosen as ω_6 either ω_x or ω_y, or any linear combination of $\omega_{x,y,z}$); which invert readily to

$$v_x = \omega_1 = 0, \tag{c11}$$

$$v_y = \omega_2 = 0, \tag{c12}$$

$$v_z = \omega_6 \neq 0, \tag{c13}$$

$$\omega_x = (1/b)(\omega_5 - v_z + v) = (1/b)(0 - \omega_6 + v) = (1/b)(v - \omega_6) \neq 0, \tag{c14}$$

$$\omega_y = (1/a)(v_z - u - \omega_4) = (1/a)(\omega_6 - u - 0) = (1/a)(\omega_6 - u) \neq 0, \tag{c15}$$

$$\omega_z = \omega_3 = 0. \tag{c16}$$

Hence the kinetic energy, (a) [with (b)], becomes, successively,

$$\begin{aligned} 2T^* \to 2T^{**} &= m{v_z}^2 + A[(v/b) - (v_z/b)]^2 + B[(v_z/a) - (u/a)]^2 \\ &= \cdots = (m/2)\left[3{v_z}^2 - (u+v)v_z + (u^2 + v^2)/2\right]. \end{aligned} \tag{c17}$$

Since the preimpact state is one of rest, the v_z-impulsive equation becomes

$$\begin{gathered} \Delta(\partial T^{**}/\partial v_z) = (\partial T^{**}/\partial v_z)^+ \equiv \partial T^{**}/\partial v_z = \hat{\Theta}_z \ (= 0, \text{ explain}): \\ (m/4)[6v_z - (u+v)] = 0 \ \Rightarrow \ v_z = (u+v)/6, \end{gathered} \tag{d1}$$

and combined with (c3, 4) yields the following postimpact angular velocities:

$$\omega_x = (v - v_z)/b = (5v - u)/6b, \qquad \omega_y = (v_z - u)/a = (v - 5u)/6a. \tag{d2}$$

See also Bahar [1987, via Jourdain's impulsive principle (see example below)] and Byerly [1916, pp. 72–75, via Kelvin's theorem (§4.6 and next problem)].

Problem 4.5.1 Continuing from the preceding example, by (c3, 4):

$$\omega_x = (v - v_z)/b, \qquad \omega_y = (v_z - u)/a, \tag{a}$$

so that the (constrained) kinetic energy [eq. (a) of ex. 4.5.1], becomes

$$T = (1/2)m{v_z}^2 + (mb^2/8)[(v - v_z)/b]^2 + (ma^2/8)[(v_z - u)/a]^2 = T(v_z;\, u, v). \tag{b}$$

Then show that the earlier equation (d1) results from

$$\partial T/\partial v_z = 0. \tag{c}$$

REMARK

This also constitutes an application of Kelvin's theorem (§4.6).

Problem 4.5.2 Continuing from the preceding example and problem, show by any means that the impulses at P and Q (i.e., the ones communicating to the disk the above velocities), $\hat{I}_P$ and $\hat{I}_Q$, respectively, equal

$$\hat{I}_P = (m/24)(5u - v), \qquad \hat{I}_Q = (m/24)(5v - u); \tag{a}$$

also,

$$v_z = (\hat{I}_P + \hat{I}_Q)/m, \qquad \omega_x = 4\hat{I}_Q/mb, \qquad \omega_y = -4\hat{I}_P/ma. \tag{b}$$

Example 4.5.2 A homogeneous sphere of center and center of mass G, mass m, and radius r, rotating with angular velocity $\boldsymbol{\omega}^- = (\omega_x{}^-, \omega_y{}^-, \omega_z{}^-)$ is suddenly placed on a perfectly rough horizontal plane (fig. 4.11). Let us find its postimpact velocities

$$\boldsymbol{\omega}^+ \equiv \boldsymbol{\omega} = (\omega_x, \omega_y, \omega_z) \qquad \text{and} \qquad \boldsymbol{v}_G{}^+ \equiv \boldsymbol{v} = (v_x, v_y, v_z).$$

By kinematics we have

$$\boldsymbol{v}_{\text{contact point}} \equiv \boldsymbol{v}_C = \boldsymbol{v} + \boldsymbol{\omega} \times \boldsymbol{r}_{C/G} = \mathbf{0}, \tag{a}$$

or, in components,

$$(0, 0, 0) = (v_x, v_y, v_z) + (\omega_x, \omega_y, \omega_z) \times (0, 0, -r), \tag{b}$$

and from this we obtain the three Pfaffian constraints

$$v_x - r\,\omega_y = 0, \qquad v_y + r\,\omega_x = 0, \qquad v_z = 0. \tag{c}$$

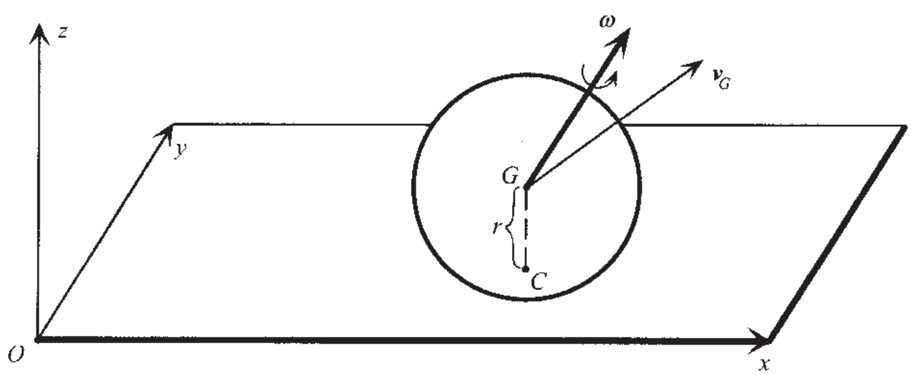

Figure 4.11 Sphere placed suddenly in contact with a rough plane.

Hence, introducing the *six* quasi velocities ω_k:

$$\omega_1 \equiv v_x - r\,\omega_y = 0, \tag{d1}$$

$$\omega_2 \equiv v_y + r\,\omega_x = 0, \tag{d2}$$

$$\omega_3 \equiv v_z = 0, \tag{d3}$$

$$\omega_4 \equiv \omega_x \neq 0, \tag{d4}$$

$$\omega_5 \equiv \omega_y \neq 0, \tag{d5}$$

$$\omega_6 \equiv \omega_z \neq 0 \tag{d6}$$

(or any other linear and invertible combination of $v_x, v_y, v_z, \omega_{x,y,z}$); and their inverses,

$$v_x = \omega_1 + r\,\omega_y = \omega_1 + r\,\omega_5 = r\,\omega_5, \tag{d7}$$

$$v_y = \omega_2 - r\,\omega_x = \omega_2 - r\,\omega_4 = -r\,\omega_4, \tag{d8}$$

$$v_z = \omega_3 = 0, \tag{d9}$$

$$\omega_x = \omega_4 \neq 0, \tag{d10}$$

$$\omega_y = \omega_5 \neq 0, \tag{d11}$$

$$\omega_z = \omega_6 \neq 0, \tag{d12}$$

we can express the (double) kinetic energy of the sphere as follows:

$$\begin{aligned} 2T &= m({v_x}^2 + {v_y}^2 + {v_z}^2) + mk^2({\omega_x}^2 + {\omega_y}^2 + {\omega_z}^2) \\ &= m[(\omega_1 + r\,\omega_5)^2 + (\omega_2 - r\,\omega_4)^2 + {\omega_3}^2 + k^2({\omega_4}^2 + {\omega_5}^2 + {\omega_6}^2)] \quad (= 2T^*), \end{aligned}$$

[where $k^2 \equiv (2/5)r^2$: (squared) radius of gyration of sphere about G] or

$$\begin{aligned} 2T^* = m\big[&(r^2 + k^2){\omega_4}^2 + (r^2 + k^2){\omega_5}^2 + k^2{\omega_6}^2 \\ &+ {\omega_1}^2 + {\omega_2}^2 + {\omega_3}^2 + 2r\,\omega_1\omega_5 - 2r\,\omega_2\omega_4\big], \end{aligned} \tag{e}$$

where the last *five* terms represent the "relaxed (i.e., unconstrained)" contributions to T^*. As a result of the above, the *postimpact* nonholonomic momenta $(\partial T^*/\partial\omega_k)^+$ are found to be [with the notation $(\ldots)|^+ = (\ldots)_{\text{postimpact constraints enforced after differentiations}}$]

$$1:\quad m(\omega_1 + r\,\omega_5)|^+ = m\,r\,\omega_5, \tag{f1}$$

$$2:\quad m(\omega_2 - r\,\omega_4)|^+ = -m\,r\,\omega_4, \tag{f2}$$

$$3:\quad m\,\omega_3|^+ = m\,\omega_3, \tag{f3}$$

$$4:\quad m[(r^2 + k^2)\omega_4 - r\,\omega_2]|^+ = m(r^2 + k^2)\omega_4, \tag{f4}$$

$$5:\quad m[(r^2 + k^2)\omega_5 + r\,\omega_1]|^+ = m(r^2 + k^2)\omega_5, \tag{f5}$$

$$6:\quad m\,k^2\omega_6|^+ = m\,k^2\omega_6; \tag{f6}$$

and similarly for the *preimpact* nonholonomic momenta $(\partial T^*/\partial\omega_k)^-$:

$$1:\ 0,\qquad 2:\ 0,\qquad 3:\ 0,\qquad 4:\ m\,k^2{\omega_4}^-,\qquad 5:\ m\,k^2{\omega_5}^-,\qquad 6:\ m\,k^2{\omega_6}^-. \tag{f7}$$

Next, let us calculate the nonholonomic impulsive forces, $\hat{\Theta}_k$ (impressed) and $\hat{\Lambda}_D$ (reactions) [where, in view of (d1–6), $k = 1, \ldots, 6$; $D = 1, 2, 3$] and their relations with their holonomic counterparts $\hat{Q}_{x,y,z;\ldots}$ and $\hat{R}_{x,y,z}, \hat{M}_{x,y,z}$. With $d\theta_k/dt \equiv \omega_k$, we obtain

$$\widehat{\delta' W} = \sum \hat{\Theta}_k\,\delta\theta_k = 0, \qquad \hat{\Theta}_k = 0 \;\Rightarrow\; \hat{Q}_{x,y,z;\,\ldots} = 0; \tag{g1}$$

$$\begin{aligned}
\widehat{\delta' W_R} &= \sum \hat{\Lambda}_k\,\delta\theta_k = \sum \hat{\Lambda}_D\,\delta\theta_D \\
&= \hat{\Lambda}_1\,\delta\theta_1 + \hat{\Lambda}_2\,\delta\theta_2 + \hat{\Lambda}_3\,\delta\theta_3 \\
&= \hat{\Lambda}_1(\delta x - r\,\delta\theta_y) + \hat{\Lambda}_2(\delta y + r\,\delta\theta_x) + \hat{\Lambda}_3\,\delta z \\
&= \hat{\Lambda}_1\,\delta x + \hat{\Lambda}_2\,\delta y + \hat{\Lambda}_3\,\delta z + (\hat{\Lambda}_2\,r)\,\delta\theta_x + (-\hat{\Lambda}_1\,r)\,\delta\theta_y + (0)\,\delta\theta_z \qquad \text{(g2)} \\
&\equiv \hat{R}_x\,\delta x + \hat{R}_y\,\delta y + \hat{R}_z\,\delta z + \hat{M}_x\,\delta\theta_x + \hat{M}_y\,\delta\theta_y + \hat{M}_z\,\delta\theta_z, \qquad \text{(g3)} \\
&\Rightarrow\; \hat{R}_x = \hat{\Lambda}_1,\; \hat{R}_y = \hat{\Lambda}_2,\; \hat{R}_z = \hat{\Lambda}_3;\; \hat{M}_x = r\hat{\Lambda}_2,\; \hat{M}_y = -r\hat{\Lambda}_1,\; \hat{M}_x = 0. \qquad \text{(g4)}
\end{aligned}$$

With the help of the above results, and the notational $\Delta P_k \equiv (\partial T^*/\partial\omega_k)^+ - (\partial T^*/\partial\omega_k)^-$: *impulsive jumps* of the nonholonomic momenta, the Hamel equations of impulsive motion become

1: $\quad \Delta P_1 = \hat{\Theta}_1 + \hat{\Lambda}_1$: $\qquad m\,r\,\omega_5 = m\,r\,\omega_y = \hat{\Lambda}_1,$ (h1)

or, due to the $k = 5$ equation (see below),

$$m\,r[k^2/(r^2 + k^2)]\omega_y{}^- = \hat{\Lambda}_1; \tag{h2}$$

2: $\quad \Delta P_2 = \hat{\Theta}_2 + \hat{\Lambda}_2$: $\qquad -\,m\,r\,\omega_4 = -m\,r\,\omega_x = \hat{\Lambda}_2,$ (h3)

or, due to the $k = 4$ equation (see below),

$$-\,m\,r[k^2/(r^2 + k^2)]\omega_x{}^- = \hat{\Lambda}_2; \tag{h4}$$

3: $\quad \Delta P_3 = \hat{\Theta}_3 + \hat{\Lambda}_3$: $\qquad m\,\omega_3 = m\,v_z = \hat{\Lambda}_3 = 0;$ (h5)

4: $\quad \Delta P_4 = \hat{\Theta}_4$: $\qquad m(r^2 + k^2)\omega_4 - m\,k^2\omega_4^- = 0,$ (h6)

or

$$\omega_x = [k^2/(r^2 + k^2)]\omega_x{}^-, \quad \text{and then} \quad v_y = -r\,\omega_x = \cdots; \tag{h7}$$

5: $\quad \Delta P_5 = \hat{\Theta}_5$: $\qquad m(r^2 + k^2)\omega_5 - m\,k^2\omega_5{}^- = 0,$ (h8)

or

$$\omega_y = [k^2/(r^2 + k^2)]\omega_y{}^-, \quad \text{and then} \quad v_x = r\,\omega_y = \cdots; \tag{h9}$$

6: $\quad \Delta P_6 = \hat{\Theta}_6$: $\qquad m\,k^2\omega_6 - m\,k^2\omega_6{}^- = 0,$ (h10)

or

$$\omega_6 = \omega_6{}^- \;\Rightarrow\; \omega_z = \omega_z{}^-. \tag{h11}$$

Finally, let us compare the above with the "elementary" Newton–Euler impulsive theory. With $\boldsymbol{v}_G{}^- = (v_x{}^-, v_y{}^-, v_z{}^-) = \mathbf{0}$, and recalling (g4), we readily find

$$m\,v_x = \hat{R}_x\ (= \hat{\Lambda}_1) \Rightarrow \hat{R}_x = m\,r\,\omega_y = m\,r[k^2/(r^2+k^2)]\omega_y{}^-, \tag{i1}$$

$$m\,v_y = \hat{R}_y\ (= \hat{\Lambda}_2) \Rightarrow \hat{R}_y = -m\,r\,\omega_x = -m\,r[k^2/(r^2+k^2)]\omega_x{}^-, \tag{i2}$$

$$m\,v_z = \hat{R}_z\ (= \hat{\Lambda}_3) \Rightarrow \hat{R}_z = 0; \tag{i3}$$

$$\hat{M}_x = r\,\hat{R}_y = \cdots, \quad \hat{M}_y = -r\,\hat{R}_x = \cdots, \quad \hat{M}_z = 0 \quad \text{(angular momentum about } G). \tag{i4}$$

[To obtain reactionless equations we could apply the impulsive angular momentum principle (here, conservation) about the contact point C.]

Finally, it is not hard to show that if $(v_x{}^-, v_y{}^-, v_z{}^-) \neq \mathbf{0}$, (h7, 9) would be replaced, respectively, by

$$\omega_x = (k^2\omega_x{}^- + r\,v_y{}^-)/(r^2+k^2) \qquad \text{and} \qquad \omega_y = (k^2\omega_y{}^- + r\,v_x{}^-)/(r^2+k^2). \tag{j}$$

See also Bahar [1987, via Jourdain's impulsive principle (see example below)] and Byerly [1916, pp. 72–75, via Kelvin's theorem (§4.6)].

Example 4.5.3 A homogeneous straight rigid bar AB of length $l = 2b$ and mass m falls freely in the vertical plane O–xy and strikes a smooth and inelastic floor at A (fig. 4.12). Find the postimpact velocities and forces.

We choose as Lagrangean coordinates $q_{1,2,3}$ (i) the coordinates of the mass center of the bar G: x and y, and (ii) the bar angle with the vertical (positive upward): θ. Clearly, this is a *second*-kind problem; that is, one of *suddenly applied* and *persistent* constraints. The *preimpact* velocities are

$$(\dot{x})^- = 0, \qquad (\dot{y})^- = -v, \qquad (\dot{\theta})^- = \omega, \qquad \text{all given;} \tag{a}$$

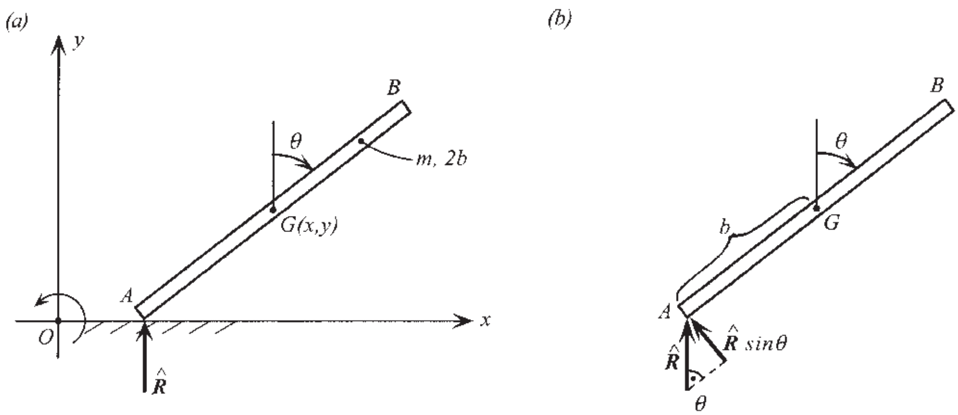

Figure 4.12 (a) Impact of bar AB (length $2b$, mass m) on smooth, inelastic floor; (b) components of floor reaction.

while the *unknowns* of the problem are the *postimpact* velocities:

$$(\dot{x})^+ \equiv \dot{x} = 0 \quad \text{(by inspection—see below)}, \qquad (\dot{y})^+ = \dot{y}, \qquad (\dot{\theta})^+ = \dot{\theta}; \tag{b}$$

and the impulsive ground reaction $\hat{R}$. Below we present *two* solutions.

1. First Solution: Holonomic Coordinates

We have (double) *kinetic energy* (with $I \equiv mb^2/3$: moment of inertia of bar about G):

$$2T = m[(\dot{x})^2 + (\dot{y})^2] + I(\dot{\theta})^2; \tag{c}$$

constraint:

$$\begin{aligned}\boldsymbol{v}_A = \boldsymbol{v}_G + \boldsymbol{\omega} \times \boldsymbol{r}_{A/G} &= (\dot{x}, \dot{y}, 0) + (-\dot{\theta}\,\boldsymbol{k}) \times (-b\,\sin\theta, b\,\cos\theta, 0)\\ &= (\dot{x} - b\,\dot{\theta}\,\cos\theta,\ \dot{y} + b\,\dot{\theta}\,\sin\theta,\ 0)\\ &= (v_{Ax}, v_{Ay}, 0);\end{aligned} \tag{d}$$

and, since the floor is *inelastic*,

$$v_{Ay} = \dot{y} + b\,\dot{\theta}\,\sin\theta = 0 \qquad \text{(i.e., } n - m = 3 - 1 = 2), \tag{e1}$$

and, in virtual form (with $v_{Ay} \equiv \dot{y}_A$),

$$\delta y_A = \delta y + b\,\sin\theta\,\delta\theta = 0 \qquad \text{(i.e., the vertical virtual displacement of } A \text{ vanishes)}; \tag{e2}$$

an equation that holds whether the inelastic floor is *stationary* (case discussed here), or moves with a *prescribed* motion [generalization of (e1)].

Impulsive Lagrange's principle:

$$\Delta(\partial T/\partial\dot{x})\,\delta x + \Delta(\partial T/\partial\dot{y})\,\delta y + \Delta(\partial T/\partial\dot{\theta})\,\delta\theta = 0, \tag{f1}$$

under the constraint eq. (e2), rewritten as

$$(0)\,\delta x + (1)\,\delta y + (b\,\sin\theta)\,\delta\theta = 0. \tag{f2}$$

Since δx is *unconstrained*, (f1) gives

$$\Delta(\partial T/\partial\dot{x}) = \Delta(m\,\dot{x}) = m\,\dot{x} - m(\dot{x})^- = 0 \ \Rightarrow\ \dot{x} = 0. \tag{g1}$$

Then (f1, 2) reduce, respectively, to

$$\Delta(\partial T/\partial\dot{y})\,\delta y + \Delta(\partial T/\partial\dot{\theta})\,\delta\theta = \Delta(m\dot{y})\,\delta y + \Delta(I\,\dot{\theta})\,\delta\theta = 0, \tag{g2}$$

$$(1)\ \delta y + (b\sin\theta)\,\delta\theta = 0; \tag{g3}$$

and, via an impulsive multiplier $-\hat{\lambda}$, combine, in well-known ways, to the single *unconstrained* variational equation

$$\big[\Delta(m\,\dot{y}) - \hat{\lambda}(1)\big]\,\delta y + \big[\Delta(I\,\dot{\theta}) - \hat{\lambda}(b\,\sin\theta)\big]\,\delta\theta = 0. \tag{g4}$$

This yields, immediately, the two Routh–Voss impulsive equations

$$\Delta(m\dot{y}) = \hat{\lambda}, \qquad \Delta(I\dot{\theta}) = \hat{\lambda}(b\sin\theta); \tag{h1}$$

or, invoking the preimpact velocities (a),

$$m(\dot{y} + v) = \hat{\lambda}, \qquad I(\dot{\theta} - \omega) = \hat{\lambda}\, b\sin\theta, \tag{h2}$$

which, along with the constraint equation (e1) (evaluated at the postimpact instant) constitute a system of three equations for $\dot{y}, \dot{\theta}, \hat{\lambda}$. Solving them, we find

$$\dot{\theta} = (b\,\omega + 3v\sin\theta)\big/ b(1 + 3\sin^2\theta), \tag{i1}$$

$$\dot{y} = -\sin\theta(b\,\omega + 3v\sin\theta)\big/(1 + 3\sin^2\theta). \tag{i2}$$

Then, from the first of (h2),

$$\hat{\lambda} = m(\dot{y} + v) = m(v - b\,\omega\sin\theta)\big/(1 + 3\sin^2\theta); \tag{i3}$$

and [fig. 4.12(b)]

$$\begin{aligned}\widehat{\delta' W_R} = \hat{R}\,\delta y_A = \hat{R}\,(\delta y + b\sin\theta\,\delta\theta) &= \hat{R}\,\delta y + (\hat{R}\,b\sin\theta)\,\delta\theta\\ &\equiv \hat{R}_y\,\delta y + \hat{R}_\theta\,\delta\theta \quad (= 0),\end{aligned} \tag{j1}$$

that is,

$$\hat{R}_y = \hat{R} = \hat{\lambda}, \qquad \hat{R}_\theta = \hat{R}\,b\sin\theta = \hat{\lambda}\,b\sin\theta, \qquad \hat{R}_x = 0. \tag{j2}$$

The (two) kinetic impulsive Maggi equations of this problem are (g1) and the equation obtained by eliminating $\hat{\lambda}$ between (h2):

$$I(\dot{\theta} - \omega) - b\sin\theta\,\big[m(\dot{y} + v)\big] = 0, \tag{k1}$$

or, simplifying,

$$3\sin\theta(\dot{y} + v) - b(\dot{\theta} - \omega) = 0. \tag{k2}$$

Solving (g1), (k2), and (e1) for $\dot{x}, \dot{y}, \dot{\theta}$, we recover the second of (g1) and (i1, 2). These results are rederived more systematically below.

2. Second Solution: Nonholonomic Coordinates

Due to the constraints (e1, 2), we introduce the following set of quasi velocities:

$$\omega_1 \equiv \dot{y} + (b\sin\theta)\dot{\theta} \quad (= 0), \qquad \omega_2 \equiv \dot{y}, \qquad \omega_3 \equiv \dot{x}. \tag{l1}$$

Their inverse is readily found to be

$$\dot{x} = \omega_3, \qquad \dot{y} = \omega_2, \qquad \dot{\theta} = (\omega_1 - \omega_2)/b\sin\theta; \tag{l2}$$

that is, the corresponding transformation matrices are

$$(a_{kl}) = \begin{pmatrix} 0 & 1 & b\sin\theta \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{pmatrix},$$

$$(A_{kl}) = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ (b\cos\theta)^{-1} & -(b\cos\theta)^{-1} & 0 \end{pmatrix}. \tag{l3}$$

Then:

(i) Maggi's *kinetic* equations: $\sum A_{kI}\Delta p_k = \sum A_{kI}\hat{Q}_k$ $(k = 1, 2, 3;\ I = 2, 3)$, with some (hopefully obvious) ad hoc notations, become

$I = 2$: $$A_{x2}(\Delta p_x - \hat{Q}_x) + A_{y2}(\Delta p_y - \hat{Q}_y) + A_{\theta 2}(\Delta p_\theta - \hat{Q}_\theta) = 0,$$

or $$(0)\,(\Delta p_x - 0) + (1)\,(\Delta p_y - 0) + (-1/b\sin\theta)(\Delta p_\theta - 0) = 0,$$

or, finally, $$\Delta p_\theta = (b\,\sin\theta)\Delta p_y. \tag{m1}$$

$I = 3$: $$A_{x3}(\Delta p_x - \hat{Q}_x) + A_{y3}(\Delta p_y - \hat{Q}_y) + A_{\theta 3}(\Delta p_\theta - \hat{Q}_\theta) = 0,$$

or $$(1)\,(\Delta p_x - 0) + (0)\,(\Delta p_y - 0) + (0)\,(\Delta p_\theta - 0) = 0,$$

or, finally, $$\Delta p_x = 0; \tag{m2}$$

(ii) Maggi's *kinetostatic* equations: $\sum A_{kD}\Delta p_k = \sum A_{kD}\hat{Q}_k$ $(k = 1, 2, 3;\ D = 1;$ i.e., here only *one* such equation) become

$D = 1$: $$A_{x1}(\Delta p_x - \hat{Q}_x) + A_{y1}(\Delta p_y - \hat{Q}_y) + A_{\theta 1}(\Delta p_\theta - \hat{Q}_\theta) = \hat{\lambda}_1 \equiv \hat{\lambda},$$

or $$(0)\ (\Delta p_x - 0) + (0)\ (\Delta p_y - 0) + (1/b\ \sin\theta)(\Delta p_\theta - 0) = \hat{\lambda},$$

or, finally, $$\Delta p_\theta = (b\ \sin\theta)\hat{\lambda}. \tag{m3}$$

Equations (m1–3), naturally, coincide with the earlier equations (k2), (g1), (second of h2), respectively.

(iii) Next, let us formulate the *impulsive Hamel* equations. In terms of the above ω's, the *preimpact* state is

$$\omega_1{}^- = -v + \omega b\ \sin\theta \quad (\neq 0,\ \text{but}\ \omega_1{}^+ \equiv \omega = 0),$$
$$\omega_2{}^- = (\dot{y})^- = -v, \qquad \omega_3{}^- = (\dot{x})^- = 0; \tag{n1}$$

and, further,

$$2T \to 2T^* = m(\omega_2{}^2 + \omega_3{}^2) + (m/3\ \sin^2\theta)(\omega_1 - \omega_2)^2 \quad [\text{substituting (l2) into (c)}], \tag{n2}$$

$$\Rightarrow\ 2T^*{}_o = m(\omega_2{}^2 + \omega_3{}^2) + (m/3\ \sin^2\theta)\omega_2{}^2 \quad (\textit{constrained}\ 2T^*); \tag{n3}$$

$$\widehat{\delta' W} \to \widehat{(\delta' W)^*} = \hat{\Theta}_1\,\delta\theta_1 + \hat{\Theta}_2\,\delta\theta_2 + \hat{\Theta}_3\,\delta\theta_3 = 0$$

$$[\text{where } \omega_{1,2,3} \equiv d\theta_{1,2,3}/dt;\ \text{since } \hat{Q}_{x,y,\theta} = 0 \ \Rightarrow\ \hat{\Theta}_{1,2,3} = 0]; \qquad \text{(n4)}$$

$$\begin{aligned}\widehat{\delta' W_R} \to \widehat{(\delta' W_R)^*} &= \hat{\Lambda}_1\,\delta\theta_1 + \hat{\Lambda}_2\,\delta\theta_2 + \hat{\Lambda}_3\,\delta\theta_3 \\ &= \hat{\Lambda}_1(\delta y + b\,\sin\theta\,\delta\theta) + \hat{\Lambda}_2\,\delta y + \hat{\Lambda}_3\,\delta x \\ &= \hat{\Lambda}_3\,\delta x + (\hat{\Lambda}_1 + \hat{\Lambda}_2)\,\delta y + (\hat{\Lambda}_1 b\,\sin\theta)\,\delta\theta \quad (= 0), \qquad \text{(n5)}\end{aligned}$$

from which [and (j2)] it follows that

$$\hat{R}_x = \hat{\Lambda}_3 = 0, \qquad \hat{R}_y = \hat{\Lambda}_1 + \hat{\Lambda}_2 = \hat{\lambda} \Rightarrow \hat{\Lambda}_2 = 0 \quad \text{(by next equation)},$$

$$\hat{R}_\theta = \hat{\Lambda}_1 b\,\sin\theta = \hat{\lambda}\,b\,\sin\theta \ \Rightarrow\ \hat{\Lambda}_1 = \hat{\lambda} = \hat{R}; \quad \text{i.e., } \hat{\Lambda}_1 \neq 0, \quad \hat{\Lambda}_2 = 0, \quad \hat{\Lambda}_3 = 0. \quad \text{(n6)}$$

In view of the above, the Hamel impulsive equations are (we recall to set, after the differentiations, $\omega_1 = 0$)

$$\omega_3\!: \qquad \Delta(\partial T^*/\partial\omega_3) = \hat{\Lambda}_3\!: \qquad m\,\omega_3 - 0 = 0 \Rightarrow \omega_3 \equiv \dot{x} = 0, \qquad \text{(o1)}$$

$$\begin{aligned}\omega_2\!: \qquad & \Delta(\partial T^*/\partial\omega_2) = \hat{\Lambda}_2\!: \\ & [m\,\omega_2 + (m/3\,\sin^2\theta)(\omega_2 - \omega_1)] \\ & \qquad - [m(-v) + (m/3\,\sin^2\theta)(-v - b\,\omega\,\sin\theta + v)], \\ & \Rightarrow m(\omega_2 + v) + (m/3\,\sin\theta)[(\omega_2/\sin\theta) + b] = 0 \\ & \Rightarrow \omega_2 \equiv \dot{y} = -\sin\theta(b\,\omega + 3v\sin\theta)\big/(1 + 3\,\sin^2\theta), \qquad \text{(o2)}\end{aligned}$$

$$\begin{aligned}\omega_1\!: \qquad & \Delta(\partial T^*/\partial\omega_1) = \hat{\Lambda}_1\!: \\ & \quad [m(\omega_1 - \omega_2)/3\,\sin^2\theta]_o - [m(b\,\omega\,\sin\theta - v + v)/3\,\sin^2\theta]_o \\ & \quad = (-m\,\omega_2/3\,\sin^2\theta) - (m\,b\,\omega/3\,\sin\theta) = \hat{\Lambda}_1 = \hat{\lambda}, \\ & \Rightarrow -(m/3\,\sin\theta)\big[(\omega_2/\sin\theta) + b\,\omega\big] = \hat{\lambda}, \\ & \Rightarrow \hat{\Lambda}_1 = m(v - b\,\omega\,\sin\theta)/(1 + 3\,\sin^2\theta) \qquad \text{[invoking (o2)]}; \qquad \text{(o3)}\end{aligned}$$

and, finally, from (l2)

$$\dot{\theta} = -\omega_2/b\,\sin\theta = -\dot{y}/b\,\sin\theta = (b\,\omega + 3v\,\sin\theta)\big/b(1 + 3\,\sin^2\theta), \qquad \text{(o4)}$$

as before.

CLOSING REMARKS

(i) This is a problem of the *second* kind; that is, suddenly introduced persistent constraints. Due to $\omega_1{}^- \neq 0$, in expressions like $(\partial T^*/\partial\omega_D)^+$ and $(\partial T^*/\partial\omega_D)^-$, we must keep *all* the ω's in $T^+\!: T^* = T^*(\omega_1, \omega_2, \omega_3)$, and enforce the constraint $\omega_1^+ \equiv \omega_1 = 0$ only *after all differentiations have been carried out*. However, the reader may easily verify that

$$(\partial T^*/\partial\omega_I)^+ = (\partial T^*{}_o/\partial\omega_I)^+.$$

(ii) This problem is treated in Timoshenko and Young (1948, p. 226). Their solution is, however, *conceptually* incorrect, since they treat $\hat{R}$ as an *impressed* impulsive force; even though, clearly, all Q's vanish. Their final results, however, are correct. The same error is repeated in several other (mostly British) texts: for example, Ramsey (1937, pp. 220–221), Smart (1951, pp. 262–263). Other authors do not commit such errors only because they restrict their treatments to *first*-kind problems.

Problem 4.5.3 (D. T. Greenwood, private communication, 1997). Continuing from the preceding example, and in order to avoid calculating undesired impulsive constraint reactions, choose as velocity variables $\dot{x}_A \equiv v_{Ax}$, $\dot{y}_A \equiv v_{Ay}$, $\dot{\theta} \equiv \Omega$ (i.e., $\omega_1 \equiv v_{Ay}$, $\omega_2 \equiv v_{Ax}$, $\omega_3 \equiv \dot{\theta}$). Then the initial conditions are

$$v_{Ax}{}^- = -b\,\omega\cos\theta, \qquad v_{Ay}{}^- = b\,\omega\sin\theta - \nu, \qquad \Omega^- = \omega, \tag{a}$$

while after the impact with the floor,

$$v_{Ay} = 0, \qquad v_{Ax},\ \Omega\text{:}\quad \text{independent} \qquad (\text{i.e., } \omega_1 = 0, \quad \omega_2,\ \omega_3\text{: independent}). \tag{b}$$

(i) Show that the unconstrained kinetic energy of the bar is

$$T = (m/2)(v_{Ax}{}^2 + v_{Ay}{}^2) + (2m\,b^2/3)\Omega^2 + m\,b\,\Omega(v_{Ax}\cos\theta - v_{Ay}\sin\theta) \quad (= T^*). \tag{c}$$

(ii) Verify that Appell's rule (i.e., conservation of system momenta corresponding to v_{Ax}, Ω) gives

$$\Delta(\partial T/\partial v_{Ax}) = \Delta(\partial T^*/\partial\omega_2) = 0\text{:} \quad m\,v_{Ax} + m\,b\,\Omega\cos\theta = \textit{constant} \quad (= 0), \tag{d1}$$

$$\Delta(\partial T/\partial\Omega) = \Delta(\partial T^*/\partial\omega_3) = 0\text{:}$$

$$(4/3)m\,b^2\Omega + m\,b(v_{Ax}\cos\theta - v_{Ay}\sin\theta) = \textit{constant} \quad [= (4/3)m\,b^2\omega - m\,b^2\omega + m\,b\,v\sin\theta]; \tag{d2}$$

from which, eliminating v_{Ax}, while recalling the first of (b), we obtain Ω [ex. 4.5.3: (i1)].

(iii) Show that the vertical constraint impulse $\hat{\lambda} = \hat{R}_y$ is found from the impulsive Routh–Voss equation

$$\Delta(\partial T/\partial v_{Ay}) = \hat{R}_y\text{:}$$

$$\Delta(m v_{Ay} - m\,b\,\Omega\sin\theta) = -m\sin\theta\big[(b\,\omega + 3v\sin\theta)/(1 + 3\sin^2\theta)\big] + mv = \hat{R}_y, \tag{e}$$

in agreement with the earlier expressions (i3) and (o3) of ex. 4.5.3.

Example 4.5.4 A homogeneous straight rigid bar AB of length L and mass M can rotate freely about a fixed pin at A. A particle of mass m strikes the bar and then *slides along it*. The entire figure lies on a smooth horizontal plane O–xy (fig. 4.13). Find the postimpact velocities and forces (reactions) if the bar is initially at rest; the particle strikes at a distance $\alpha L\,(0 < \alpha < 1)$, when the bar makes an angle $\theta = \theta_o$ with the positive x-axis, with preimpact velocity components $(\dot{x})^- = 0$, $(\dot{y})^- = v_o \equiv v$ (Bahar, 1970–1980; Greenwood, 1977, p. 118).

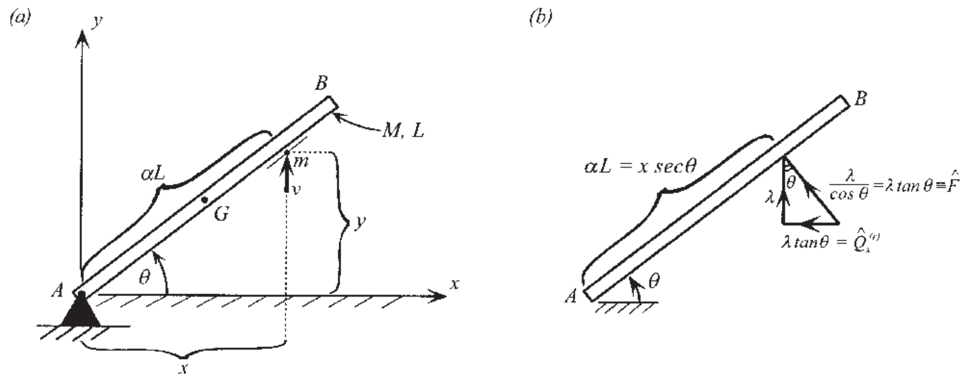

Figure 4.13 (a) Particle impacting on a straight rigid bar *AB*, at a distance αL from *A*; (b) corresponding constraint reaction, and its components. $\alpha L = x\sec\theta$; $\hat{\lambda}\sec\theta \equiv \hat{F}, \hat{\lambda}\tan\theta = \hat{R}_x$.

By König's theorem,

$$\begin{aligned} 2T &= M(L\dot{\theta}/2)^2 + (ML^2/12)(\dot{\theta})^2 + m[(\dot{x})^2 + (\dot{y})^2] \\ &= M[L^2(\dot{\theta})^2/3] + m[(\dot{x})^2 + (\dot{y})^2]; \end{aligned} \tag{a1}$$

also,

$$\widehat{\delta' W} = 0, \qquad \hat{Q}_{x,y,\theta} = 0. \tag{a2}$$

1. First Solution: Holonomic Coordinates

By $(\ldots)^{\cdot}$-differentiating the holonomic and stationary constraint $y = x\tan\theta$ [fig. 4.13(a)], we find

$$\dot{y} = \dot{x}\tan\theta + x\dot{\theta}\sec^2\theta \;\Rightarrow\; (\tan\theta)\dot{x} + (-1)\dot{y} + (x\sec^2\theta)\dot{\theta} = 0, \tag{b1}$$

and, since this system is scleronomic,

$$(\tan\theta)\,\delta x + (-1)\,\delta y + (x\sec^2\theta)\,\delta\theta = 0. \tag{b2}$$

Further, we have

$$\textit{Particle configuration:} \qquad x = (\alpha L)\cos\theta, \qquad y = (\alpha L)\sin\theta, \tag{b3}$$

$$\textit{Preimpact velocities:} \qquad (\dot{x})^- = 0, \qquad (\dot{y})^- = v, \qquad (\dot{\theta})^- = 0, \tag{b4}$$

$$\textit{Postimpact velocities:} \qquad (\tan\theta)\dot{x} + (-1)\dot{y} + (x\sec^2\theta)\dot{\theta} = 0. \tag{b5}$$

Therefore, the impulsive principle of Lagrange yields

$$\begin{aligned} 0 &= \Delta(\partial T/\partial\dot{x})\,\delta x + \Delta(\partial T/\partial\dot{y})\,\delta y + \Delta(\partial T/\partial\dot{\theta})\,\delta\theta \\ &= [m\dot{x} - m(\dot{x})^-]\,\delta x + [m\dot{y} - m(\dot{y})^-]\,\delta y + (ML^2/3)[\dot{\theta} - (\dot{\theta})^-]\,\delta\theta \\ &= (m\dot{x})\,\delta x + m(\dot{y} - v)\,\delta y + (ML^2/3)\dot{\theta}\,\delta\theta, \end{aligned} \tag{c}$$

under (b2). Applying the multiplier rule to (c), with (b2), we readily obtain

$$m\dot{x} = \hat{\lambda}\tan\theta, \qquad m(\dot{y} - v) = -\hat{\lambda}, \qquad (ML^2/3)\dot{\theta} = \hat{\lambda}(x\sec^2\theta), \qquad \text{(d1, 2, 3)}$$

which along with (b1) [or (b5)] constitutes an algebraic system of *four* equations for $\dot{x}, \dot{y}, \dot{\theta}, \hat{\lambda}$. Solving it, we find (with $\beta \equiv m/M$)

$$\dot{x} = (\sin\theta\cos\theta/3\alpha^2\beta)v, \qquad \text{(e1)}$$

$$\dot{y} = [(\sin^2\theta + 3\alpha^2\beta)/(1 + 3\alpha^2\beta)]v, \qquad \text{(e2)}$$

$$L\dot{\theta} = [(3\alpha\cos\theta)/(\beta^{-1} + 3\alpha^2)]v; \qquad \text{(e3)}$$

$$\hat{\lambda} = m(v - \dot{y}) = \left[\cos^2\theta/(1 + 3\alpha^2\beta)\right]m\,v$$
$$= [\cos^2\theta/(\beta^{-1} + 3\alpha^2)]Mv. \qquad \text{(e4)}$$

From the above, and figure 4.13(b), we find that the holonomic components of the impulsive constraint reactions equal

$$\hat{R}_x = \hat{\lambda}\tan\theta = \hat{F}\sin\theta = (\sin\theta/\alpha L)\hat{R}_\theta, \qquad \text{(f 1)}$$

$$\hat{R}_y = -\hat{\lambda} = -(\cos\theta/\alpha L)\hat{R}_\theta, \qquad \text{(f 2)}$$

$$\hat{R}_\theta = \widehat{(\delta' W_R)_o}/\delta\theta = [(\hat{\lambda}\sec\theta)(x\sec\theta)\,\delta\theta]/\delta\theta = \hat{\lambda}\,x\sec^2\theta. \qquad \text{(f 3)}$$

2. Second Solution: Nonholonomic Coordinates

In view of the constraint (b1), and recalling (b3), we introduce the following quasi velocities:

$$\omega_1 \equiv (\tan\theta)\dot{x} + (-1)\dot{y} + (\alpha L/\cos\theta)\dot{\theta} \quad (= 0), \qquad \omega_2 \equiv \dot{x}, \qquad \omega_3 \equiv \dot{y}; \qquad \text{(g1)}$$

with inverses (unconstrained, since we want to calculate the impulsive reactions)

$$\dot{x} = \omega_2, \qquad \dot{y} = \omega_3, \qquad \dot{\theta} = (\cos\theta/\alpha L)\omega_1 + (\cos\theta/\alpha L)\omega_3 + (-\sin\theta/\alpha L)\omega_2. \quad \text{(g2)}$$

Then:

(i) The, also unconstrained, (double) kinetic energy is

$$2T \to 2T^* = (M/3\alpha^2)\left[(\omega_1 + \omega_3)\cos\theta - \omega_2\sin\theta\right]^2 + m(\omega_2{}^2 + \omega_3{}^2); \qquad \text{(h)}$$

(ii) The *preimpact* velocities are

$$(\dot{\theta})^- = 0, \qquad (\dot{x})^- = 0, \qquad (\dot{y})^- = v \quad \Rightarrow \quad \omega_1{}^- = -v, \qquad \omega_2{}^- = 0, \qquad \omega_3{}^- = v, \text{(i)}$$

$\omega_1 \equiv \omega_1{}^+ \ (= 0) \neq \omega_1{}^-$ (sudden $\to$ persistent constraints; i.e., *second*-type problem);

(j)

(iii) The (unconstrained) impulsive virtual works are

$$\widehat{(\delta' W)^*} \equiv \hat{\Theta}_1\, \delta\theta_1 + \hat{\Theta}_2\, \delta\theta_2 + \hat{\Theta}_3\, \delta\theta_3 = 0 \Rightarrow \hat{\Theta}_{1,2,3} = 0, \tag{k1}$$

$$0 = \widehat{(\delta' W_R)^*} \equiv \hat{\Lambda}_1\, \delta\theta_1 + \hat{\Lambda}_2\, \delta\theta_2 + \hat{\Lambda}_3\, \delta\theta_3 \qquad \text{[invoking the virtual form of (g2)]}$$

$$= \hat{\Lambda}_1[(\tan\theta)\, \delta x - \delta y + (\alpha L/\cos\theta)\, \delta\theta] + \hat{\Lambda}_2\, \delta x + \hat{\Lambda}_3\, \delta y$$

$$= \cdots = \hat{R}_x\, \delta x + \hat{R}_y\, \delta y + \hat{R}_\theta\, \delta\theta \equiv \widehat{\delta' W_R}, \tag{k2}$$

$$\Rightarrow \hat{R}_x = (\tan\theta)\hat{\Lambda}_1 + \hat{\Lambda}_2 = (\tan\theta)\hat{\Lambda}_1 \quad [= (\sin\theta/\alpha L)\hat{R}_\theta] \qquad (\text{since } \hat{\Lambda}_2 = 0), \tag{k3}$$

$$\hat{R}_y = (-1)\hat{\Lambda}_1 + \hat{\Lambda}_3 = -\hat{\Lambda}_1 \quad [= -(\cos\theta/\alpha L)\hat{R}_\theta] \qquad (\text{since } \hat{\Lambda}_3 = 0), \tag{k4}$$

$$\hat{R}_\theta = (\alpha L/\cos\theta)\hat{\Lambda}_1 \qquad (\text{where } \hat{\Lambda}_1 = \hat{\lambda}). \tag{k5}$$

Therefore, the Hamel impulsive equations are (we recall to set $\omega_1^+ \equiv \omega_1 = 0$, *after* the differentiations)

$$\omega_1: \qquad \Delta(\partial T^*/\partial\omega_1) = \hat{\Lambda}_1:$$

$$(M/3\alpha^2)(\omega_3 \cos^2\theta - \omega_2 \sin\theta\cos\theta) = \hat{\Lambda}_1, \tag{l1}$$

$$\omega_2: \qquad \Delta(\partial T^*/\partial\omega_2) = 0:$$

$$(M/3\alpha^2)(\omega_2 \sin^2\theta - \omega_3 \sin\theta\cos\theta) + m\,\omega_2 = 0, \tag{l2}$$

$$\omega_3: \qquad \Delta(\partial T^*/\partial\omega_3) = 0:$$

$$(M/3\alpha^2)(\omega_3 \cos^2\theta - \omega_2 \sin\theta\cos\theta) + m(\omega_3 - v) = 0. \tag{l3}$$

Solving this algebraic system for $\omega_{2,3}$ and $\hat{\Lambda}_1$ we find

$$\omega_2 = \dot{x} = [\varepsilon \sin\theta\cos\theta/(1+\varepsilon)]v, \tag{m1}$$

$$\omega_3 = \dot{y} = [(1 + \varepsilon \sin^2\theta)/(1+\varepsilon)]v, \tag{m2}$$

$$\hat{\Lambda}_1 = \hat{\lambda} = (M/3\alpha^2)[\cos^2\theta/(1+\varepsilon)]v, \tag{m3}$$

where

$$\varepsilon \equiv M/3m\alpha^2 = (M/m)(1/3\alpha^2) = 1/3\alpha^2\beta, \tag{m4}$$

$$\Rightarrow \dot{\theta} = (\cos\theta/\alpha L)\omega_3 - (\sin\theta/\alpha L)\omega_2 = [\cos\theta/\alpha L(1+\varepsilon)]v; \tag{m5}$$

which, naturally, coincide with the earlier values.

CLOSING REMARKS

If the problem was one of the *first* kind (i.e., only impressed impulsive forces, no change of constraints), then $\Delta\omega_1 \equiv \omega_1{}^+ - \omega_1{}^- = 0 - 0$, and since always $(\partial T^*/\partial\omega_I)_o = \partial T^*{}_o/\partial\omega_I$, the *kinetic* impulsive equations can be written as $\Delta(\partial T^*{}_o/\partial\omega_I) = \hat{\Theta}_I$ $(I = 2, 3)$. But in *second* kind problems, like this one, since $\omega_1{}^- \neq 0$, the notation $(\ldots)_o$ can only mean setting $\omega_1{}^+ = 0$, after all differentiations; that is, we must start with T^*, even if we do not seek the impulsive reactions. Then,

$$(\partial T^*/\partial\omega_I)^+ = (\partial T^*{}_o/\partial\omega_I)^+ \qquad \text{but} \qquad (\partial T^*/\partial\omega_I)^- \neq (\partial T^*{}_o/\partial\omega_I)^-, \tag{n1, 2}$$

and the kinetic (reactionless) impulsive equations can be written as $(\partial T^*{}_o/\partial\omega_I)^+ - (\partial T^*/\partial\omega_I)^- = \hat{\Theta}_I$. Clearly, these are general results.

Let us verify them for our problem. Equation (h) yields

$$2T^* \to 2T^*{}_o = (M/3\alpha^2)(\omega_3\cos\theta - \omega_2\sin\theta)^2 + m(\omega_2{}^2 + \omega_3{}^2), \tag{o}$$

$$\Rightarrow\ \partial T^*{}_o/\partial\omega_2 = (M/3\alpha^2)(\omega_3\cos\theta - \omega_2\sin\theta)(-\sin\theta) + m\,\omega_2, \tag{p1}$$

$$(\partial T^*{}_o/\partial\omega_2)^- = (M/3\alpha^2)(v\cos\theta)(-\sin\theta), \tag{p2}$$

but

$$(\partial T^*/\partial\omega_2)^- = (M/3\alpha^2)\big[(-v+v)\cos\theta - 0\big](-\sin\theta) + 0 = 0; \tag{p3}$$

that is,

$$(\partial T^*/\partial\omega_2)^- \neq (\partial T^*{}_o/\partial\omega_2)^-;$$

and

$$(\partial T^*{}_o/\partial\omega_2)^+ = (M/3\alpha^2)(\omega_3\cos\theta - \omega_2\sin\theta)(-\sin\theta) + m\,\omega_2, \tag{p4}$$

$$(\partial T^*/\partial\omega_2)^+ = (M/3\alpha^2)(\omega_3\cos\theta - \omega_2\sin\theta)(-\sin\theta) + m\,\omega_2; \tag{p5}$$

that is,

$$(\partial T^*{}_o/\partial\omega_2)^+ = (\partial T^*/\partial\omega_2)^+,\ \text{and similarly for } \omega_3.$$

In sum: the replacement of T^* with $T^*{}_o$ in the kinetic impulsive equations is allowed *only when the constraints* $\omega_D = 0$ *hold.*

Example 4.5.5 Three slender homogeneous bars, AB, BC, CD, each of mass m and length $2b$, are pinned together at B and C, and pivoted at A to a fixed horizontal table. The end D receives an impulse $\hat{P}$ [fig. 4.14a]. Let us find the translational and rotational (angular) velocities of the mass center of each rod (Bahar, 1987; Chorlton, 1983, pp. 227–229; also Beghin, 1967, pp. 472–473).

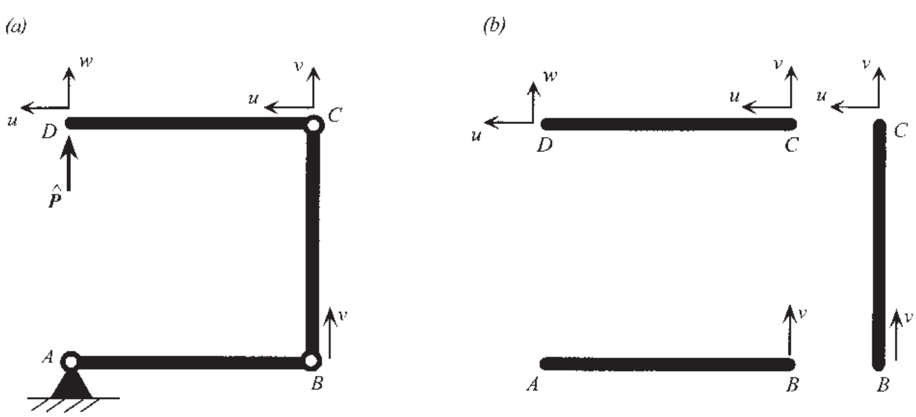

Figure 4.14 (a) System consisting of three homogeneous bars AB, BC, CD, impacted at D; (b) quasi velocities chosen to describe its velocities. ''British theorem'': the kinetic energy of a thin homogeneous bar AB, of mass m, equals $T = (m/6)(v_A{}^2 + v_B{}^2 + \mathbf{v}_A \cdot \mathbf{v}_B)$.

1. Kinetic Equations

Although, clearly, this is a holonomic system, we choose to describe it by the quasi velocities shown in fig. 4.14(a, b), compatible with plane and rigid kinematics. Using the "British theorem" [(1.17.8)] and some easily understood ad hoc notation, we find that the kinetic energy of the system, *at the impact configuration*, is

$$
\begin{aligned}
T &= T_{AB} + T_{BC} + T_{CD} \\
&= (m/6)(0 + v^2) + (m/6)(v^2 + u^2 + v^2 + v^2) + (m/6)(u^2 + v^2 + u^2 + w^2 + u^2 + w\,v) \\
&= (m/6)(5v^2 + 4u^2 + w^2 + w\,v). \qquad \text{(a)}
\end{aligned}
$$

[For comparison purposes, we point out that the König theorem-based calculation would have given

$$2T_{AB} = m(v/2)^2 + (mb^2/3)(v/2b)^2 = m\,v^2/3, \qquad \text{(a1)}$$

$$2T_{BC} = m[v^2 + (u^2/4)] + (mb^2/3)(u/2b)^2 = m\,v^2 + m\,u^2/3, \qquad \text{(a2)}$$

$$
\begin{aligned}
2T_{CD} &= m\{u^2 + [(w+v)/2]^2\} + (m\,b^2/3)[(w-v)/2b]^2 \\
&= (m/3)(3u^2 + v^2 + w^2 + w\,v), \quad \text{etc.}] \qquad \text{(a3)}
\end{aligned}
$$

The impressed impulsive forces are calculated from the corresponding virtual work expression (as if u, v, w were quasi coordinates):

$$\widehat{\delta' W} = \hat{\Theta}_u\,\delta u + \hat{\Theta}_v\,\delta v + \hat{\Theta}_w\,\delta w = \hat{P}\,\delta w \;\Rightarrow\; \hat{\Theta}_u = 0, \hat{\Theta}_v = 0, \hat{\Theta}_w = \hat{P}. \qquad \text{(b)}$$

In view of the above, the Hamel equations of motion are (with T instead of the customary T^*, and $\omega^+ \equiv \omega$ for all *postimpact* velocities)

$$\Delta(\partial T/\partial u) = 0 \Rightarrow (m/6)(8u) = 0, \qquad \text{(c1)}$$

$$\Delta(\partial T/\partial v) = 0 \Rightarrow (m/6)(10v + w) = 0, \qquad \text{(c2)}$$

$$\Delta(\partial T/\partial w) = \hat{P} \Rightarrow (m/6)(v + 2w) = \hat{P}; \qquad \text{(c3)}$$

and their solution is easily found to be

$$u = 0, \qquad v = -(6/19)(\hat{P}/m), \qquad w = (60/19)(\hat{P}/m). \qquad \text{(d)}$$

Then, by simple kinematics,

$$
\begin{aligned}
&\omega_{AB} = v/2b = -(3/19)(\hat{P}/mb) \quad \text{(clockwise)}, \qquad \omega_{BC} = 0, \\
&\omega_{DC} = (w - v)/2b = (33/19)(\hat{P}/mb) \quad \text{(clockwise)}; \qquad \text{(e1)}
\end{aligned}
$$

and

$$
\begin{aligned}
&\boldsymbol{v}_{\text{center of mass of } AB} = v/2 = -(3/19)(\hat{P}/m) \qquad \text{(downwards)}, \\
&\boldsymbol{v}_{\text{center of mass of } BC} = v = -(6/19)(\hat{P}/m) \qquad \text{(downwards)}, \\
&\boldsymbol{v}_{\text{center of mass of } DC} = (v + w)/2 = (27/19)(\hat{P}/m) \qquad \text{(upwards)}. \qquad \text{(e2)}
\end{aligned}
$$

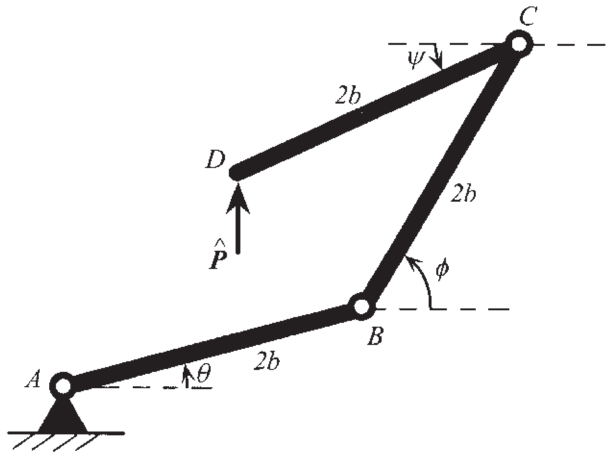

Figure 4.15 Geometry of impact problem of fig. 4.14, but for a *generic* configuration, defined by the bar angles $q_{1,2,3}$: ϕ, θ, ψ (see Beghin, 1967, pp. 472–473; Chorlton, 1983, pp. 227–229).

Note the simplicity of the quasi-velocity approach, as compared with Lagrangean (holonomic) coordinates in connection with the calculation of T for a *general* configuration (fig. 4.15).

2. Kinetostatic Equations

Next, let us use the *impulsive relaxation principle* to calculate the (*external*) impulsive reaction at A. Since that "force" has components in both directions, we must allow A to move both *up/down* and *left/right* (fig. 4.16).

We notice the additional horizontal velocity component x at B, due to another x at A; and a vertical one y at A; and two "force" components at A that go along with x, y: X, Y. The *relaxed* kinetic energy is

$$\begin{aligned} T_{\text{relaxed}} \equiv T_{rx} &= (m/6)(w^2 + u^2 + u^2 + v^2 + u^2 + wv + u^2 + v^2 + v^2 \\ &\qquad + x^2 + v^2 + ux + x^2 + y^2 + x^2 + v^2 + x^2 + yv) \\ &= (m/6)(w^2 + 4u^2 + 5v^2 + 4x^2 + y^2 + wv + ux + yv), \end{aligned} \tag{f}$$

and so the equations of motion are

$$\Delta\big[(\partial T_{rx}/\partial \omega_k)_o\big] = \hat{\Theta}_k + \hat{\Lambda}_k, \tag{g1}$$

where

$$\{\omega_k\colon\ u, v, w;\ x = 0, y = 0\}, \qquad \{\hat{\Theta}_k\colon\ 0, 0, \hat{P};\ 0, 0\}, \qquad \{\hat{\Lambda}_k\colon\ 0, 0, 0;\ X, Y\}; \tag{g2}$$

and $(\ldots)_o$ means enforcement of the constraints $x = 0, y = 0$, in $(\ldots)$. Thus, and

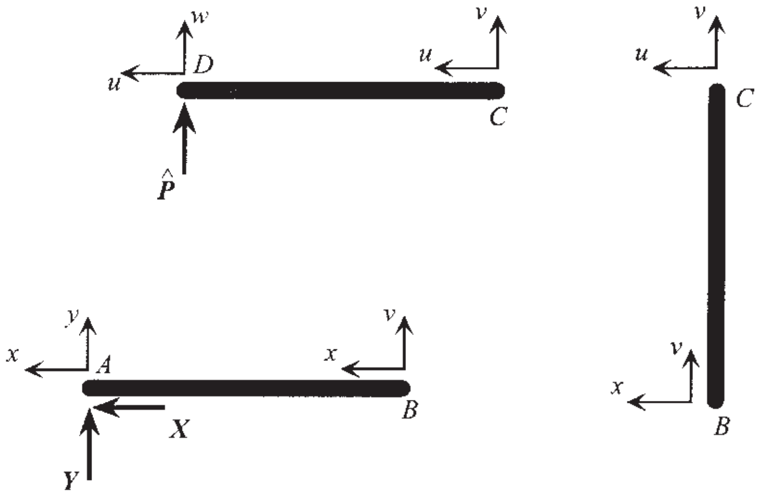

Figure 4.16 Velocities and *external* impulsive forces of impact problem of fig. 4.14.

dropping the subscript rx from T, for simplicity, we find

$$(\partial T/\partial u)_o = 0: \qquad (m/6)(8u + x)_o = (m/6)(8u) = 0, \tag{h1}$$

$$(\partial T/\partial v)_o = 0: \qquad (m/6)(10v + w + y)_o = (m/6)(10v + w) = 0, \tag{h2}$$

$$(\partial T/\partial w)_o = \hat{P}: \qquad (m/6)(2w + v)_o = (m/6)(2w + v) = \hat{P}, \tag{h3}$$

$$(\partial T/\partial x)_o = X: \qquad (m/6)(8x + u)_o = (m/6)(u) = X, \tag{h4}$$

$$(\partial T/\partial y)_o = Y: \qquad (m/6)(2y + v)_o = (m/6)(v) = Y; \tag{h5}$$

from which, since $u = 0$, we obtain

$$X = mu/6 = 0,$$

$$Y = mv/6 = (m/6)(-6/19)(\hat{P}/m) = (-1/19)\hat{P} \qquad \text{(i.e., downward, at } A). \tag{i}$$

These results can be easily confirmed via the elementary (Newton–Euler) methods: by linear momentum for the entire system, in the + *vertical* direction, we get

$$\hat{P} + Y = m\big[(v/2) + v + (w + v)/2\big] = m[2v + (w/2)], \tag{j}$$

from which, and the earlier values (d) [obtained by use of the kinetic equations (c1–3)], we find $Y = \cdots = (-1/19)\hat{P}$; and similarly for the horizontal direction, we find $X = 0$.

Problem 4.5.4 (Smart, 1951, pp. 264–265). Four equal straight homogeneous rods, AB, BC, CD, and DE, each of length l and mass m, are smoothly joined together at B, C, D, and rest on a smooth horizontal table so that consecutive rods are perpendicular to each other (fig. 4.17). The midpoints of all rods are collinear, and the end E is fixed. Then, the end A is struck by a blow $\hat{P}$ parallel to the line joining the midpoints of the rods (i.e., along ACE).

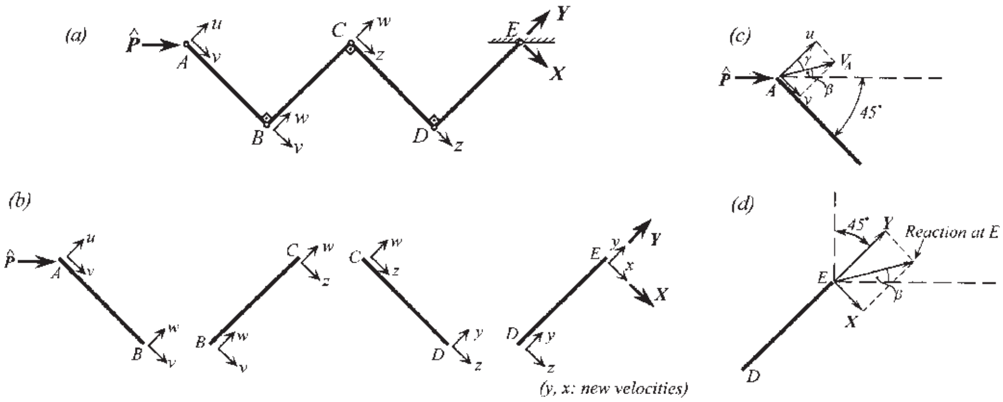

Figure 4.17 System of four, originally motionless, straight and mutually perpendicular rods, AB, BC, CD, and DE, (B, C, D: hinged; E: fixed) struck by a blow $\hat{P}$ at its end A, along ACE. (a) General view of problem; (b) free-body diagram of each rod; (c) detail of application of blow $\hat{P}$, at A; (d) detail of impulsive reaction, at E.

(i) Using the kinematically compatible (postimpact) quasi velocities u, v, w, z (fig. 4.17), and the earlier "British theorem," show that the (double) kinetic energy and (impressed) impulsive virtual work, at the impact configuration, equal, respectively,

$$2T = (m/3)(u^2 + 4v^2 + 5w^2 + 5z^2 + u\,w + z\,v), \tag{a}$$

$$\begin{aligned}\widehat{\delta' W} &= \hat{\Theta}_u\,\delta u + \hat{\Theta}_v\,\delta v + \hat{\Theta}_w\,\delta w \\ &= (\hat{P}/\sqrt{2})\,\delta u + (\hat{P}/\sqrt{2})\,\delta v + (0)\,\delta w + (0)\,\delta z \\ &\qquad \text{(as if } u, v, w, z \text{ were quasi coordinates).}\end{aligned} \tag{b}$$

(ii) Since the preimpact state is one of rest — that is, $\Delta(\partial T/\partial\omega) = \partial T/\partial\omega$ (ω: u, v, w, z) — show that the equations of impulsive motion are

$$u:\quad (m/6)(2u + w) = \hat{P}/\sqrt{2}, \qquad v:\quad (m/6)(8v + z) = \hat{P}/\sqrt{2}, \tag{c1, 2}$$

$$w:\quad 10w + u = 0, \qquad z:\quad 10z + v = 0; \tag{c3, 4}$$

with solutions

$$u = (30\sqrt{2}\,/19)(\hat{P}/m), \qquad v = (30\sqrt{2}\,/79)(\hat{P}/m), \tag{c5, 6}$$

$$w = -(3\sqrt{2}\,/19)(\hat{P}/m), \qquad z = -(3\sqrt{2}\,/79)(\hat{P}/m). \tag{c7, 8}$$

(iii) Show that A begins to move in a direction making an angle $\tan^{-1}(30/49)$ with that of the blow, and find the angle between the impulsive external reaction at E and the blow $\hat{P}$.

HINTS

(i) If the angle between $\hat{P}$ and $\boldsymbol{v}_A$ is β, then $\tan\beta = (u - v)/(u + v) = \cdots = 30/49$.

[From trigonometry: tan (*angle between u and* $\boldsymbol{v}_A$) $\equiv \tan\gamma = v/u$, and $\tan(\beta + \gamma) = \tan 45^\circ = 1 = (\tan\beta + \tan\gamma)/(1 - \tan\beta\tan\gamma) \Rightarrow \tan\beta = \cdots$.]

(ii) The components of the reaction at E, X (perpendicular to DE), and Y (along DE) can be found, either from the impulsive principle of relaxation (see next problem), or from the principle of linear momentum applied to the entire (nonrigid) system, in these two directions:

$$\text{Along } DE: \qquad Y + (\hat{P}/\sqrt{2}) = m\big[(w/2) + w + ((u+w)/2)\big], \tag{d1}$$

$$\text{Perpendicular to } DE: \qquad X + (\hat{P}/\sqrt{2}) = m\big[(z/2) + z + ((z+v)/2) + v\big]. \tag{d2}$$

Verify that the above, with the help of (c1–4), yield

$$X = \hat{P}\sqrt{2}\big[-(1/2) + (39/79)\big], \qquad Y = \hat{P}\sqrt{2}\big[-(1/2) + (9/19)\big], \tag{d3}$$

and, therefore,

$$\begin{aligned}\tan\,&(\text{angle between reaction at } E \text{ and horizontal}) = (Y - X)/(Y + X) = 30/49\\ &= \tan\,(\text{angle between } \boldsymbol{v}_A \text{ and horizontal}) \equiv \tan\beta, \quad \text{Q.E.D.}\end{aligned} \tag{e}$$

Problem 4.5.5 Continuing from the preceding problem, calculate the *external* reaction components X, Y via the impulsive principle of relaxation; allow E to move with corresponding velocities x (perpendicular to DE; i.e., parallel to X) and y (along DE; i.e., parallel to Y). Formulate the equations of the relaxed system, and then set, at the end, $x = 0, y = 0$ [fig. 4.17(b)].

HINTS

Show that the (double) kinetic energy of the so-relaxed system is

$$2T_{\text{relaxed}} = (m/3)(u^2 + 4v^2 + 5w^2 + 5z^2 + uw + 4y^2 + zv + x^2 + wy + xz), \tag{a}$$

and, therefore, (a) the *kinetic* equations remain the same as in the preceding (constrained) case; while (b) the additional *kinetostatic* equations are

$$(mw/6) = Y \;\Rightarrow\; Y = \cdots = -(\sqrt{2}/38)\hat{P}, \quad (mz/6) = X \;\Rightarrow\; X = \cdots = -(\sqrt{2}/158)\hat{P}; \tag{b}$$

in agreement with the values found in the previous problem.

Problem 4.5.6 (Synge and Griffith, 1959, pp. 429–430). Two uniform rods, AB and BC, each of mass m and length $2b$, are smoothly hinged at B and, initially, rest on a smooth horizontal table, so that A, B, C are collinear. Then, a horizontal blow $\hat{P}$ is struck at C in a direction perpendicular to BC (fig. 4.18).

(i) *Holonomic coordinates*. Show that, in terms of the Lagrangean coordinates, (x, y): coordinates of B (positive to the right and upward, respectively) and (θ_1, θ_2): angles of AB, BC, respectively, with horizontal (both positive counterclockwise), and with $k^2 \equiv b^2/3$, the postimpact (double) kinetic energy and (impressed) impulsive virtual work, at the impact configuration (i.e., x, y; θ_1, $\theta_2 = 0$), equal, respectively

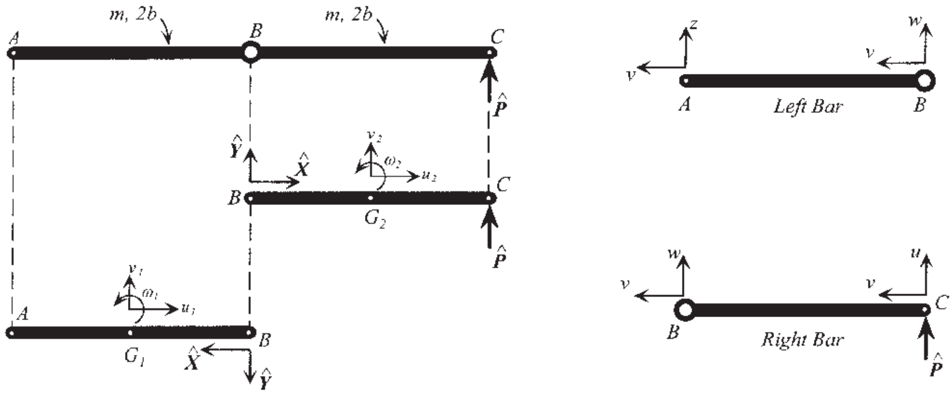

Figure 4.18 System of two, originally motionless, straight rods, *AB*, *BC* (*C*: hinged; *A*, *B*, *C*: collinear) struck by a blow $\hat{P}$ at its end *C*, at a right angle to *ABC*.

(with $\dot{\theta}_1 \equiv \omega_1$, $\dot{\theta}_2 \equiv \omega_2$),

$$\begin{aligned} 2T &= m[(\dot{x})^2 + (\dot{y} - b\,\omega_1)^2 + k^2{\omega_1}^2] \\ &\quad + m[(\dot{x})^2 + (\dot{y} + b\,\omega_2)^2 + k^2{\omega_2}^2], \end{aligned} \tag{a}$$

$$\widehat{\delta' W} = \hat{X}\,\delta x + \hat{Y}\,\delta y + \hat{\Theta}_1\,\delta\theta_1 + \hat{\Theta}_2\,\delta\theta_2 = \hat{P}(\delta y + 2b\,\delta\theta_2) \tag{b}$$

$$[\text{i.e., } \hat{X} = 0, \qquad \hat{Y} = \hat{P}, \qquad \hat{\Theta}_1 = 0, \qquad \hat{\Theta}_2 = 2b\hat{P}]$$

and, therefore, verify that the equations of impulsive motion are,

$$x: \qquad 2m\dot{x} = 0, \tag{c1}$$

$$y: \qquad m(\dot{y} - b\,\omega_1) + m(\dot{y} + b\,\omega_2) = \hat{P}, \tag{c2}$$

$$\theta_1: \qquad -\,m\,b(\dot{y} - b\,\omega_1) + (m\,k^2)\omega_1 = 0, \tag{c3}$$

$$\theta_2: \qquad m\,b(\dot{y} + b\,\omega_2) + (m\,k^2)\omega_2 = 2b\hat{P}; \tag{c4}$$

with solutions

$$\dot{x} \ = 0, \qquad \dot{y} = -(\hat{P}/m) \qquad (\text{i.e., initially, } B \text{ moves downward only}), \tag{c5}$$

$$\omega_1 = -(3/4)(\hat{P}/mb) \ \ (\text{i.e., clockwise}), \quad \omega_2 = (9/4)(\hat{P}/mb) \ \ (\text{i.e., counterclockwise}). \tag{c6}$$

(ii) *Nonholonomic coordinates*. Show that in terms of the kinematically compatible quasi velocities *u, v, w, z* (fig. 4.18), again at the impact configuration,

$$2T = (m/3)(u^2 + 6v^2 + 2w^2 + z^2 + u\,w + z\,w), \tag{d}$$

$$\widehat{\delta' W} = \hat{P}\,\delta\theta \qquad (\text{where } \ \dot{\theta} \equiv u), \tag{e}$$

and, therefore, verify that the equations of impulsive motion are

$$(m/6)(2u + w) = \hat{P}, \quad (m/6)(12v) = 0, \quad (m/6)(u + 4w + z) = 0, \quad (m/6)(w + 2z) = 0; \tag{f}$$

with solutions

$$u = (7/2)(\hat{P}/m), \qquad v = 0, \qquad w = -(\hat{P}/m), \qquad z = (1/2)(\hat{P}/m). \tag{g}$$

(iii) Show that as the number of bars goes to infinity (to the left of C, B, A), $u = 2\sqrt{3}(\hat{P}/m)$.

Problem 4.5.7 Continuing from the preceding problem (figs. 4.18, 4.19), calculate the *internal* reaction components at B: $\hat{X}$ (assumed upward on the left bar, downward on the right) and $\hat{Y}$ (assumed leftward on the left bar, rightward on the right bar), via the impulsive principle of relaxation: allow $B_{left\,\mathrm{bar}}$ to move with corresponding velocities x (upward) and y (leftward), and $B_{right\,\mathrm{bar}}$ to move with corresponding velocities w (upward) and v (leftward). Formulate the equations of the relaxed system, and then set, at the end, $x = w$, $y = v$.

HINTS

Show that for the so-relaxed system,

$$2T_{\mathrm{relaxed}} = (m/3)(u^2 + 3v^2 + w^2 + x^2 + 3y^2 + z^2 + uw + xz), \tag{a}$$

$$\widehat{\delta' W} = \hat{P}\,\delta\upsilon - \hat{Y}\,\delta\varpi - \hat{X}\,\delta\omega + \hat{X}\,\delta\xi + \hat{Y}\,\delta\zeta, \tag{b}$$

where

$$\dot{\upsilon} \equiv u, \qquad \dot{\varpi} \equiv v, \qquad \dot{\omega} \equiv w, \qquad \dot{\xi} \equiv x, \qquad \dot{\zeta} \equiv y; \tag{b1}$$

and, hence, verify that [with the notations: $T_{\mathrm{relaxed}} \equiv T$ and $(\ldots)_o \equiv (\ldots)_{\mathrm{constraints\ enforced}}$] the equations of motion are

$$u: \quad (\partial T/\partial u)_o = \hat{P} \Rightarrow 2u + w = 6\hat{P}/m; \tag{c1}$$

$$v: \quad (\partial T/\partial v)_o = -\hat{Y} \Rightarrow v = -(\hat{Y}/m); \tag{c2}$$

$$w: \quad (\partial T/\partial w)_o = -\hat{X} \Rightarrow 2w + u = -(6\hat{X}/m); \tag{c3}$$

$$x: \quad (\partial T/\partial x)_o = \hat{X} \Rightarrow 2w + z = 6\hat{X}/m; \tag{c4}$$

$$y: \quad (\partial T/\partial y)_o = \hat{Y} \Rightarrow v = \hat{Y}/m; \tag{c5}$$

$$z: \quad (\partial T/\partial z)_o = 0 \Rightarrow 2z + w = 0; \tag{c6}$$

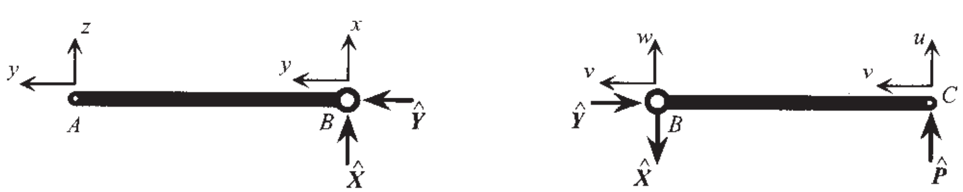

Figure 4.19 System of two, originally motionless straight rods, *AB*, *BC* (*C*: hinged; *A*, *B*, *C*: collinear) struck by a blow $\hat{P}$ at its end C, at a right angle to *ABC*, specially relaxed at *B* in order to calculate the internal reactions there.

with solutions

$$u = (7/2)(\hat{P}/m), \quad v = 0, \quad w = -(\hat{P}/m), \quad z = (1/2)(\hat{P}/m), \quad \hat{X} = -(\hat{P}/4), \quad \hat{Y} = 0, \tag{d}$$

in agreement with the values found (for the postimpact velocities) in the preceding problem.

REMARK

Note that $(\partial T/\partial w)_o + (\partial T/\partial x)_o = 0$, $(\partial T/\partial v)_o + (\partial T/\partial y)_o = 0$; that is, *the sum of the internal reactions vanishes,* like a Lagrangean form of impulsive action–reaction.

For additional aspects of this problem, see Kilmister and Reeve (1966, pp. 220–221, 229, 235–250).

Problem 4.5.8 (Beer, 1963; Kane, 1962; Raher, 1954, 1955). Two identical, homogeneous, circular, and thin (sharp-edged) wheels, W' and W'' (fig. 4.20), each of radius r and mass m, are capable of rotating freely about the ends of a common axle A, of mass M and length $2b$, so that the entire assembly can roll on a fixed, perfectly rough, and horizontal plane P. The system is struck (set in motion) by an impulse $\hat{I}$, acting for the very short time interval $[t', t'']$, at the axle point S located a distance $i\,(< 2b)$ from the center of W' (with no loss in generality), perpendicularly to A and parallel to P.

The *kinematics* of this problem has been discussed in ex. 2.13.8; while the *kinetics* of its ordinary (continuous) motion has been detailed in ex. 3.18.6. It was found there that, with the Lagrangean coordinates,

(x, y): coordinates of axle midpoint, G;

ϕ: angle (of precession) of line joining the contact points of W' and W'', C' and C'', respectively, with the $+x$-axis; and

(ψ', ψ''): angles of rolling (or, of proper rotation) of W' and W'',

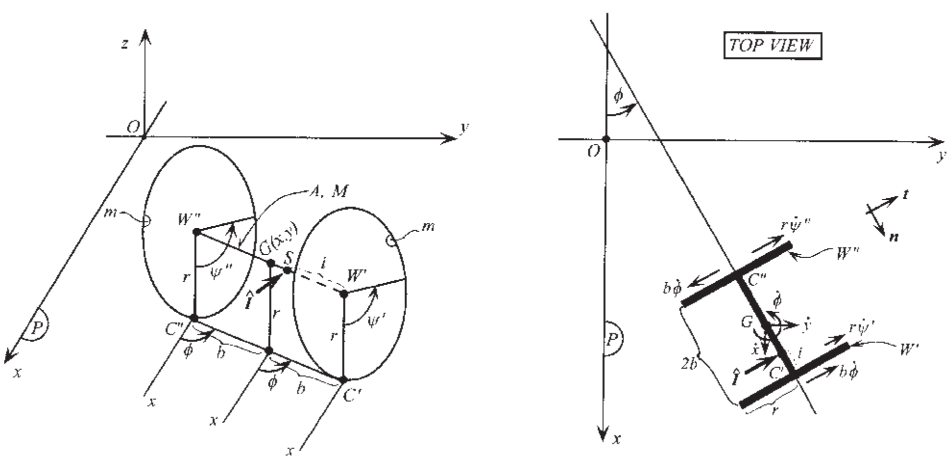

Figure 4.20 Geometry of a system of two identical, homogeneous, circular, and thin wheels, rotating freely at the ends of an axle, and rolling on a fixed, rough, and horizontal plane, struck by an impulse $\hat{I}$ at the axle point S.

the three constraint equations are (i.e., here $n = 5$, $m = 2$)

$$v_{C',n} = v_{C'',n} = \dot{x}\cos\phi + \dot{y}\sin\phi = 0, \tag{a1}$$

$$v_{C',t} = -\dot{x}\sin\phi + \dot{y}\cos\phi + b\,\dot{\phi} + r\,\dot{\psi}' = 0, \tag{a2}$$

$$v_{C'',t} = -\dot{x}\sin\phi + \dot{y}\cos\phi - b\,\dot{\phi} + r\,\dot{\psi}'' = 0; \tag{a3}$$

$$\{\Rightarrow\ \dot{x} = (b\,\dot{\phi} + r\dot{\psi}')\sin\phi,\ \ \dot{y} = (b\dot{\phi} + r\dot{\psi}')\cos\phi\}, \tag{a4}$$

or, since (a2, 3) yield the *integrable* combination (with $c =$ integration constant, depending on the initial values of ϕ, ψ', ψ''),

$$2b\,\dot{\phi} + r(\dot{\psi}' - \dot{\psi}'') = 0\ \Rightarrow\ 2b\,\phi = c - r(\psi' - \psi''); \tag{b}$$

we may take as independent Lagrangean coordinates: x, y; ψ', ψ'' (i.e., actually, $n = 4$, $m = 2$) under (a1–3), of which only *two* are independent. Finally, since this is an impact problem, we can choose, with no loss in generality, the $+x$-axis so that $\phi = 0$ (or $\phi = \pi/2$); in which case, eqs. (a1–2) $\Rightarrow$ (a4) and (a3) simplify, respectively, to

$$\dot{x} = 0, \qquad \dot{y} + b\dot{\phi} + r\dot{\psi}' = 0, \qquad \dot{y} - b\dot{\phi} + r\dot{\psi}'' = 0; \tag{c}$$

or, adding the last two,

$$\dot{x} = 0, \qquad 2\dot{y} + r(\dot{\psi}' + \dot{\psi}'') = 0. \tag{d}$$

(i) Show that the (double) kinetic energy of the entire system is

$$\begin{aligned} 2T &= (M + 2m)[(\dot{x})^2 + (\dot{y})^2] + (Mb^2/3)(\dot{\phi})^2 \\ &\quad + (mr^2/2)\{[(\dot{\psi}')^2 + (\dot{\psi}'')^2] + [1 + 4(b/r)^2](\dot{\phi})^2\}, \end{aligned} \tag{e}$$

and, therefore, for the special case where $b = r$ and $M \approx 0$,

$$2T = 2m[(\dot{x})^2 + (\dot{y})^2] + (mr^2/2)[(\dot{\psi}')^2 + (\dot{\psi}'')^2 + 5(\dot{\phi})^2], \tag{f}$$

or, thanks to (c), $T = T(\dot{x}, \dot{y}; \dot{\phi}, \dot{\psi}', \dot{\psi}'')\ \Rightarrow\ T_o(\dot{\phi}, \dot{\psi}') = T_o$,

$$2T \Rightarrow 2T_o = (mr^2/2)\big[13(\dot{\phi})^2 + 6(\dot{\psi}')^2 + 12\dot{\phi}\,\dot{\psi}'\big]; \tag{g}$$

while the impressed impulsive virtual work is

$$\widehat{\delta' W} = (-i\,\hat{I})\,\delta\phi + (-r\,\hat{I})\,\delta\psi'\ \Rightarrow\ \hat{Q}_\phi = -i\,\hat{I},\ \hat{Q}_{\psi'} = -i\,\hat{I}. \tag{h}$$

(ii) With the help of the above, deduce that, under the initial conditions (i.e., at $t = t'$)

$$(\dot{\phi})^- = 0, \qquad (\dot{\psi}')^- = 0, \tag{i}$$

the (*Hamel* $\Rightarrow$) *Chaplygin–Voronets* impulsive equations of this *first*-type problem:

$$\varDelta(\partial T_o/\partial\dot{\phi}) = \hat{Q}_\phi, \qquad \varDelta(\partial T_o/\partial\dot{\psi}') = \hat{Q}_{\psi'}, \tag{j}$$

yield the postimpact velocities (i.e., at $t = t''$)

$$(\dot{\phi})^+ = (2/7)(\hat{I}/mr^2)(r - i), \qquad (\dot{\psi}')^+ = (2/7)(\hat{I}/mr^2)[i - (13/6)r]. \tag{k}$$

Combining these results with those of the ordinary motion case, ex. 3.18.6, we readily see that after the impact (i.e., $t \geq t''$), the system rolls with

$$\dot{\phi} = (\dot{\phi})^+ = constant \equiv \Omega, \qquad \dot{\psi}' = (\dot{\psi}')^+ = constant \equiv \omega'; \tag{l}$$

in which case, the general constraints (a4) (with $b = r$) can be integrated to yield

$$x = R[\cos(\Omega t) - \cos(\Omega t'')], \qquad y = R[\sin(\Omega t) - \sin(\Omega t'')], \tag{m}$$

where

$$R = -r[1 + (\omega'/\Omega)] \ \Rightarrow\ |R| = (7/6)r^2|r - i|^{-1} \qquad \text{[invoking (k)]}. \tag{n}$$

Finally, eliminating the time between eqs. (m), we easily obtain

$$[x + R\cos(\Omega t'')]^2 + [y + R\sin(\Omega t'')]^2 = R^2, \tag{o}$$

that is, *the postimpact path of the axle midpoint G is a circle of radius* $|R|$; as predicted in ex. 3.18.6.

Problem 4.5.9 Continuing from the preceding problem:

(i) Show that under the choice of $\dot{\psi}'$ and $\dot{\psi}''$ as independent (quasi) velocities, since in that case $\dot{\psi}'' = \dot{\psi}' + 2\dot{\phi}$,

$$T = T(\dot{x}, \dot{y}; \dot{\phi}, \dot{\psi}', \dot{\psi}'') \Rightarrow T_o(\dot{\psi}', \dot{\psi}'') = T_o:$$

$$2T_o = (mr^2/2)\big[(13/4)(d\psi'/dt)^2 + (13/4)(d\psi''/dt)^2 - (1/2)(d\psi'/dt)(d\psi''/dt)\big]; \tag{a}$$

$$\widehat{\delta' W} = \hat{Q}_\phi\,\delta\phi + \hat{Q}_{\psi'}\,\delta\psi' = \hat{Q}_{\psi'}\,\delta\psi' + \hat{Q}_{\psi''}\,\delta\psi''$$

$$\Rightarrow\ \hat{Q}_\phi\,\delta\phi = \hat{Q}_{\psi''}\,\delta\psi'' \ \Rightarrow\ \hat{Q}_\phi = (\partial\dot{\psi}''/\partial\dot{\phi})\hat{Q}_{\psi''} \ \Rightarrow\ \hat{Q}_{\psi''} = (-i/2)\hat{I}. \tag{b}$$

(ii) The corresponding impulsive *Chaplygin–Voronets* equations are

$$\Delta(\partial T_o/\partial\dot{\psi}') = \hat{Q}_{\psi'}, \qquad \Delta(\partial T_o/\partial\dot{\psi}'') = \hat{Q}_{\psi''}, \tag{c}$$

where

$$\partial T_o/\partial\dot{\psi}' = (mr^2/8)(13\dot{\psi}' - \dot{\psi}''), \tag{d1}$$

$$\partial T_o/\partial\dot{\psi}'' = (mr^2/8)(13\dot{\psi}'' - \dot{\psi}'). \tag{d2}$$

REMARKS

(i) This and the previous problem illustrate the earlier-made observation that, in *first*-kind problems, like this one, and in sharp contrast to the case of ordinary motion (§3.8), we *can* enforce the Pfaffian constraints in T, that is, $T \to T_o$ right from the start, and then form the $n - m$ multiplierless (kinetic) impulsive Hamel-like equations; that is, in such impulsive problems, the equations of Hamel and Lagrange have similar forms.

(ii) Additional convenient choices of quasi velocities (of which only *two* are independent) would have been the following:

(a) $$\omega_1 \equiv \dot{x} = 0, \qquad \omega_2 \equiv \dot{y} + b\,\dot{\phi} + r\,\dot{\psi}' = 0;$$

$$\omega_3 \equiv \dot{y} - b\,\dot{\phi} + r\,\dot{\psi}'' = 0, \qquad \omega_4 = \dot{\psi}' \neq 0, \qquad \omega_5 = \dot{\phi} \neq 0; \tag{e}$$

with inverses

$$\dot{x} = \omega_1 = 0, \qquad \dot{y} = (\omega_2 - r\,\omega_4 - b\,\omega_5)|_{b=r} = -r(\omega_4 + \omega_5); \qquad \dot{\phi} = \omega_5,$$
$$\dot{\psi}' = \omega_4, \qquad \dot{\psi}'' = (1/r)(-\omega_2 + \omega_3 + r\omega_4 + 2b\omega_5)|_{b=r} = \omega_4 + 2\omega_5; \tag{f}$$

and

(b)
$$\omega_1 \equiv \dot{x} = 0, \qquad \omega_2 \equiv \dot{y} + r\dot{\phi} + r\dot{\psi}' = 0,$$
$$\omega_3 \equiv \dot{\psi}' \neq 0, \qquad \omega_4 \equiv \dot{\phi} \neq 0; \tag{g}$$

with inverses

$$\dot{x} = \omega_1 = 0, \qquad \dot{y} = \cdots = -r(\omega_3 + \omega_4); \qquad \dot{\psi}' = \omega_3, \qquad \dot{\phi} = \omega_4. \tag{h}$$

Problem 4.5.10 Continuing from the preceding two problems:

(i) Show that under the choice of $v_G \equiv v \equiv ds/dt$ [parallel to the impulse $\hat{I}$; i.e., $\dot{x} = -v\sin\phi$, $\dot{y} = v\cos\phi$ (for a general angle ϕ), s: quasi coordinate] and $\dot{\phi} \equiv \omega$ as independent (quasi) velocities, since then

$$\dot{\psi}' \equiv \omega_1 = -(1/r)(v + b\,\omega), \qquad \dot{\psi}'' \equiv \omega_2 = -(1/r)(v - b\,\omega), \tag{a}$$

the (double) kinetic energy and impulsive impressed virtual work are, respectively,

$$2T = (M + 2m)v^2 + [(Mb^2/3) + 2mb^2 + (mr^2/2)]\omega^2 + [(mr^2/2)({\omega_1}^2 + {\omega_2}^2)]$$
$$= \cdots = (M + 3m)v^2 + [(Mb^2/3) + 3mb^2 + (mr^2/2)]\omega^2 = T_o(v, \omega) = T_o, \tag{b}$$
$$\widehat{\delta' W} = \hat{Q}_s\,\delta s + \hat{Q}_\phi\,\delta\phi = \hat{I}\,\delta s + (\hat{I}i)\,\delta\phi \;\Rightarrow\; \hat{Q}_s = \hat{I},\; \hat{Q}_\phi = i\,\hat{I}. \tag{c}$$

(ii) Verify that the corresponding *Chaplygin–Voronets* impulsive equations are

$$\partial T_o/\partial v = \hat{Q}_s: \qquad (M + 3m)v = \hat{I} \;\Rightarrow\; v = \cdots, \tag{d1}$$
$$\partial T_o/\partial \omega = \hat{Q}_\phi: \qquad \big[(Mb^2/3) + 3mb^2 + (mr^2/2)\big]\omega = i\,\hat{I} \;\Rightarrow\; \omega = \cdots. \tag{d2}$$

Example 4.5.6 *Jourdain's Principle in Impulsive Motion* (to be read after §6.3). We begin with the general "raw" (i.e., particle variable) form of Jourdain's principle for ordinary, continuous motion (6.2.4) and (6.3.15):

$$\mathsf{S}\,(dm\,\boldsymbol{a} - d\boldsymbol{F}) \cdot \delta'\boldsymbol{v} = 0, \tag{a}$$

where $\delta'\boldsymbol{v} \equiv \delta\boldsymbol{v}|_{\text{with}\,\delta t = 0\text{ and }\delta\boldsymbol{r} = \boldsymbol{0}}$ is the *Jourdain variation* of $\boldsymbol{v}$ (6.3.5). Next, integrating (a) between t and $t + \tau$, and then taking the limit as $\tau \to 0$ (or, integrating "between" t^- and t^+), and using the notations introduced in §4.2, we obtain the "raw" form of the impulsive Jourdain principle:

$$\mathsf{S}\,(dm\,\Delta\boldsymbol{v} - \widehat{d\boldsymbol{F}}) \cdot \delta'\boldsymbol{v} = 0 \qquad [\Delta\boldsymbol{v} \equiv \boldsymbol{v}^+ - \boldsymbol{v}^-]. \tag{b}$$

Now, substituting into (b) the basic representation of $\delta'\boldsymbol{v}$,

$$\delta'\boldsymbol{v} = \delta'\Big(\sum \omega_I \boldsymbol{\varepsilon}_I + \boldsymbol{\varepsilon}_{n+1}\Big) = \sum \boldsymbol{\varepsilon}_I\,\delta\omega_I = \sum (\partial\boldsymbol{v}/\partial\omega_I)\,\delta\omega_I \tag{c}$$

[recalling § 2.9ff.; and that, since the $\boldsymbol{\varepsilon}_I, \boldsymbol{\varepsilon}_{n+1}$ $(I = m+1, \ldots, n)$ are functions of t and q, their Jourdain variations vanish: $\delta'(\boldsymbol{\varepsilon}_I, \boldsymbol{\varepsilon}_{n+1}) = \mathbf{0}$], we obtain, successively,

$$
\begin{aligned}
0 &= \mathbf{S}\,(dm\,\Delta\boldsymbol{v} - \widehat{d\boldsymbol{F}})\cdot\Big(\sum \boldsymbol{\varepsilon}_I\,\delta\omega_I\Big)\\
&= \sum\Big(\mathbf{S}\,(dm\,\Delta\boldsymbol{v} - \widehat{d\boldsymbol{F}})\cdot\boldsymbol{\varepsilon}_I\Big)\,\delta\omega_I\\
&= \sum\Big\{\mathbf{S}\,[dm(\partial\boldsymbol{v}/\partial\omega_I)\cdot\Delta\boldsymbol{v} - \widehat{d\boldsymbol{F}}\cdot\boldsymbol{\varepsilon}_I]\Big\}\,\delta\omega_I\\
&= \sum\Big\{\Delta\Big(\mathbf{S}\,dm(\partial\boldsymbol{v}/\partial\omega_I)\cdot\boldsymbol{v}\Big) - \mathbf{S}\,\widehat{d\boldsymbol{F}}\cdot\boldsymbol{\varepsilon}_I\Big\}\,\delta\omega_I \qquad (\text{since } \Delta\boldsymbol{\varepsilon}_I = \mathbf{0})\\
&= \sum\,\big[\Delta(\partial T^*/\partial\omega_I) - \hat{\Theta}_I\big]\,\delta\omega_I \qquad \Big(\text{since } \ 2T^* \equiv \mathbf{S}\,dm\,\boldsymbol{v}\cdot\boldsymbol{v}, \text{etc.}\Big), \qquad \text{(d)}
\end{aligned}
$$

from which, since the $n-m$ $\delta\omega_I$'s are independent, we immediately obtain the earlier $n-m$ impulsive kinetic Hamel equations,

$$\Delta(\partial T^*/\partial\omega_I) = \hat{\Theta}_I. \qquad \text{(e)}$$

For instructive applications of (c) and (e) to impulsive problems, see Bahar (1994).

Example 4.5.7 *A Direct Method for the Determination of the Impulsive Reactions* (may be omitted in a first reading). Let us consider the earlier (§4.4) "Routh–Voss impulsive equations" of a system subjected to the *single* Pfaffian constraint

$$\sum a_k(t,q)\dot{q}_k + a_0(t,q) = 0, \qquad \text{(a)}$$

that is,

$$\Delta(\partial T/\partial\dot{q}_k) = \hat{Q}_k + \hat{\lambda}\,a_k. \qquad \text{(b)}$$

Since [with the usual notations (§3.9)]

$$2T = 2(T_2 + T_1 + T_0) = \sum\sum M_{kl}\dot{q}_k\dot{q}_l + \sum 2M_k\dot{q}_k + M_0, \qquad \text{(c)}$$

and the M_{kl}, M_k are functions of t, q: $\Delta(M_{kl}, M_k) = 0$, and, therefore,

$$\Delta(\partial T/\partial\dot{q}_k) = \Delta\Big(\sum M_{kl}\dot{q}_l + M_k\Big) = \sum M_{kl}\Delta\dot{q}_l \quad (= \Delta p_k), \qquad \text{(d)}$$

eqs. (b) assume the explicit form

$$\sum M_{kl}\,\Delta\dot{q}_l = \hat{Q}_k + \hat{\lambda}\,a_k. \qquad \text{(e)}$$

Let us isolate (uncouple) the $\Delta\dot{q}_l$: multiplying (e) with $m_{rk} = m_{kr}$, where

$$\sum M_{kl}m_{kr} = \delta_{lr}, \qquad \text{(f)}$$

and summing over k yields the general $\Delta\dot{q}_r$-expressions

$$\Delta\dot{q}_r = \sum m_{rk}\hat{Q}_k + \hat{\lambda}\Big(\sum m_{rk}a_k\Big). \qquad \text{(g)}$$

[In tensor calculus, the m_{rk} are called *conjugate* to the M_{kl} (and vice versa); and are denoted by M^{rk}. See, for example, Papastavridis (1999, chap. 2), Sokolnikoff (1964, p. 76 ff.), Synge and Schild (1949, p. 29 ff.).]

Next, multiplying (g) with a_r and summing over r, we get

$$\sum a_r\, \Delta\dot{q}_r = \sum\sum m_{rk} a_r \hat{Q}_k + \hat{\lambda} a^2, \tag{h}$$

where

$$\sum\sum m_{rk} a_r a_k \equiv a^2 \qquad \text{[magnitude (squared) of vector } (a_r)\text{]}, \tag{i}$$

and solving for $\hat{\lambda}$,

$$\hat{\lambda} = \left(\sum a_r\, \Delta\dot{q}_r - \sum\sum m_{rk} a_r \hat{Q}_k\right)\Big/ a^2. \tag{j}$$

Now:

(i) For *first*-kind impulsive problems (i.e., constraints holding before, during, and after the shock), eq. (a) yields

$$\Delta\left(\sum a_k \dot{q}_k + a_0\right) = \sum a_k\, \Delta\dot{q}_k = 0, \tag{k}$$

and so (j) reduces to

$$\hat{\lambda} = -\sum\sum m_{rk} a_r \hat{Q}_k \Big/ a^2. \tag{l}$$

Then, substituting (l) into (g) and solving for $(\dot{q}_r)^+$, we obtain (with some dummy-index changes)

$$(\dot{q}_r)^+ = (\dot{q}_r)^- + \sum m_{rk} \hat{Q}_k - \left(\sum\sum m_{lk} a_l \hat{Q}_k / a^2\right)\left(\sum m_{rs} a_s\right). \tag{m}$$

(ii) For *second*-kind impulsive problems (i.e., constraints suddenly introduced at the impact moment), the $(\dot{q}_r)^-$ do *not* obey (a). Then, invoking the latter, we get

$$\sum a_r\, \Delta\dot{q}_r = \sum a_r (\dot{q}_r)^+ - \sum a_r (\dot{q}_r)^- = -a_0 - \sum a_r (\dot{q}_r)^- \quad (\neq 0), \tag{n}$$

and so (j) reduces to

$$\hat{\lambda} = -\left[a_0 + \sum a_r (\dot{q}_r)^- + \sum\sum m_{rk} a_r \hat{Q}_k\right]\Big/ a^2. \tag{o}$$

Once $\hat{\lambda}$ is found, then (g) yield immediately (with some dummy-index changes)

$$\begin{aligned} \Delta\dot{q}_r &\equiv (\dot{q}_r)^+ - (\dot{q}_r)^- \\ &= \sum m_{rk} \hat{Q}_k - \left\{\left[a_0 + \sum a_k (\dot{q}_k)^- + \sum\sum m_{lk} a_l \hat{Q}_k\right]\Big/ a^2\right\}\left(\sum m_{rs} a_s\right), \\ &\Rightarrow (\dot{q}_r)^+ = \ldots . \end{aligned} \tag{p}$$

Equations (l) and (o) yield $\hat{\lambda}$ in terms of initially known quantities; that is, a_0, a_r, $M_{kl} \to m_{kl}$, and $\hat{Q}_k$ (unlike the earlier impulsive kinetostatic equations of Maggi, Hamel, Appell, et al.).

The n equations (m) and n equations (p) might be called *the impulsive Jacobi–Synge equations* of the corresponding problem (unlike the earlier $n - m$ kinetostatic and m kinetic impulsive equations of Maggi, Hamel, Appell, et al.; recall ex. 3.10.2).

We leave it to the reader to extend this method to the case of $m(< n)$ Pfaffian constraints.

Application of the above to Example 4.5.3

We recall that in this, *second*-kind, problem,

$$q_{1,2,3}\colon\ x, y, \theta; \qquad a_1 = 0, \quad a_2 = 1, \quad a_3 = b \sin\theta, \quad a_0 = 0; \qquad \hat{Q}_k = 0; \tag{q1}$$

and the nonvanishing inertia coefficients of T are

$$M_{kl}\colon\ M_{11} = M_{22} = m;\ \ M_{33} = I\ \Rightarrow\ m_{kl}\colon\ m_{11} = m_{22} = m^{-1};\ \ m_{33} = I^{-1}, \tag{q2}$$

Therefore,

$$\sum m_{1s}a_s = m_{11}a_1 + m_{12}a_2 + m_{13}a_3 = (m^{-1})(0) + (0)(1) + (0)(b\sin\theta) = 0,$$

$$\sum m_{2s}a_s = m_{21}a_1 + m_{22}a_2 + m_{23}a_3 = (0)(0) + (m^{-1})(1) + (0)(b\sin\theta) = m^{-1},$$

$$\sum m_{3s}a_s = m_{31}a_1 + m_{32}a_2 + m_{33}a_3 = (0)(0) + (0)(1) + (I^{-1})(b\sin\theta) = I^{-1}b\sin\theta,$$

$$\begin{aligned}\Rightarrow\ a^2 \equiv \sum\Big(\sum m_{rs}a_s\Big)a_r &= (0)(0) + (m^{-1})(1) + (I^{-1}b\sin\theta)(b\sin\theta)\\ &= m^{-1} + [(mb^2/3)^{-1}(b\sin\theta)](b\sin\theta) = m^{-1}(1 + 3\sin^2\theta);\end{aligned} \tag{q3}$$

$$\sum\Big(\sum m_{rk}\hat{Q}_k\Big)a_r = \cdots = 0, \tag{q4}$$

and so, finally, eq. (o) yields

$$\begin{aligned}\hat{\lambda} &= -[a_1(\dot{x})^- + a_2(\dot{y})^- + a_3(\dot{\theta})^-]\big/a^2\\ &= -[(0)(0) + (1)(-v) + (b\sin\theta)(\omega)]\big/[m^{-1}(1 + 3\sin^2\theta)]\\ &= m(v - b\,\omega\sin\theta)/(1 + 3\sin^2\theta),\end{aligned} \tag{r}$$

that is, (i3) of ex. 4.5.3. Similarly for $(\dot{q}_r)^+$ via eq. (p); the details are left to the reader.

4.6 EXTREMUM THEOREMS OF IMPULSIVE MOTION (OF CARNOT, KELVIN, BERTRAND, ROBIN, ET AL.)

Since the impulsive equations are algebraic equations in the shock velocities — that is, of the first order — *no proper integral variational principles exist for them*. However, by appropriate specializations of the *differential* variational principles (chap. 6), a host of interesting and useful *extremum* propositions (i.e., maxima/minima in the sense of ordinary mathematical analysis) of sufficient generality can be obtained. These theorems, summarized below, constitute impulsive counterparts of the energetic theorems of ordinary (i.e., continuous) motion. [Carnot's theorems (see below) are included here, although they are neither variational nor extremum, but simply energetic; that is, just like their ordinary motion counterparts, they deal with *actual* motions (velocities), and yield only *one* equation. For proofs of these theorems in general *system* variables, see ex. 4.6.7.]

For complementary reading, we recommend the following older British texts (alphabetically): Chirgwin and Plumpton (1966, pp. 329–343), Easthope (1964, pp. 285–304), Kilmister and Reeve (1966, pp. 247–248), Milne (1948, pp. 370–378), Ramsey (1937, pp. 185–195), Smart (1951, pp. 376–390).

4.6.1 Theorem of Carnot (1803)

1. First Part (Collisions)

In the absence of impressed impulses, the sudden introduction of (ideal) stationary and persistent constraints that change some velocity reduces the kinetic energy; hence, by the collision of inelastic bodies, some kinetic energy is always lost.

2. Second Part (Explosions)

The sudden removal of (ideal and) stationary constraints that break bonds of rigidity (e.g., explosion of a shell, or breaking of the rope in a tug-of-war contest) increases the kinetic energy.

Their proofs utilize the following auxiliary and purely kinematico-inertial identity: Let $\{\boldsymbol{v}_1\}$ and $\{\boldsymbol{v}_2\}$ be any two possible sets of velocities, with corresponding kinetic energies T_1 and T_2; that is, $2T_1 \equiv S\, dm\, \boldsymbol{v}_1 \cdot \boldsymbol{v}_1,\ 2T_2 \equiv S\, dm\, \boldsymbol{v}_2 \cdot \boldsymbol{v}_2$. Then, by simple algebra,

$$2\boldsymbol{v}_2 \cdot (\boldsymbol{v}_2 - \boldsymbol{v}_1) = {\boldsymbol{v}_2}^2 - {\boldsymbol{v}_1}^2 + (\boldsymbol{v}_2 - \boldsymbol{v}_1)^2 \ \Rightarrow\ 2K_{12} = T_1 + T_2 - T_{12}; \qquad (4.6.1a1)$$

also,

$$2\boldsymbol{v}_1 \cdot (\boldsymbol{v}_1 - \boldsymbol{v}_2) = {\boldsymbol{v}_1}^2 - {\boldsymbol{v}_2}^2 + (\boldsymbol{v}_1 - \boldsymbol{v}_2)^2 \ \Rightarrow\ 2K_{12} = T_1 + T_2 - T_{12}; \qquad (4.6.1a2)$$

where

$$2K_{12} = 2K_{21} \equiv S\, dm\, \boldsymbol{v}_1 \cdot \boldsymbol{v}_2, \qquad (4.6.1b1)$$

$$2T_{12} = 2T_{21} \equiv S\, dm(\boldsymbol{v}_2 - \boldsymbol{v}_1) \cdot (\boldsymbol{v}_2 - \boldsymbol{v}_1): \qquad (4.6.1b2)$$

Kinetic energy of relative motion ≥ 0.

(a) To prove the first part, we begin with LIP, eqs. (4.3.4) ff.), or

$$\widehat{\delta' W_R} = 0 \ \Rightarrow\ \widehat{\delta I} = \widehat{\delta' W}, \qquad (4.6.1c)$$

where

$$\widehat{\delta' W_R} \equiv S\, \widehat{d\boldsymbol{R}} \cdot \delta\boldsymbol{r}, \qquad \widehat{\delta I} \equiv S\, dm(\boldsymbol{v}^+ - \boldsymbol{v}^-) \cdot \delta\boldsymbol{r}, \qquad \widehat{\delta' W} \equiv S\, \widehat{d\boldsymbol{F}} \cdot \delta\boldsymbol{r}, \qquad (4.6.1d)$$

and in there we make the identifications $\boldsymbol{v}^- = \boldsymbol{v}_1$, $\boldsymbol{v}^+ = \boldsymbol{v}_2$ (i.e., velocities just before and after additional workless constraints), and [since the new constraints are stationary and the $\delta\boldsymbol{r}$ are compatible with both primitive (i.e., existing) and additional constraints] we choose $\delta\boldsymbol{r} \to d\boldsymbol{r} = \boldsymbol{v}^+\, dt \sim \boldsymbol{v}^+ = \boldsymbol{v}_2$, and notice that, here, $\widehat{\delta' W} \to S\, \widehat{d\boldsymbol{F}} \cdot \boldsymbol{v}^+ \equiv S\, \widehat{d\boldsymbol{F}} \cdot \boldsymbol{v}_2 = 0$. Thus, we obtain

$$S\, dm(\boldsymbol{v}^+ - \boldsymbol{v}^-) \cdot \boldsymbol{v}^+ = S\, \widehat{d\boldsymbol{F}} \cdot \boldsymbol{v}^+ = 0,$$

or

$$\mathop{S} dm(\boldsymbol{v}_2 - \boldsymbol{v}_1) \cdot \boldsymbol{v}_2 = \mathop{S} \widehat{d\boldsymbol{F}} \cdot \boldsymbol{v}_2 = 0,$$
$$\Rightarrow \mathop{S} dm\, \boldsymbol{v}_2 \cdot \boldsymbol{v}_2 = \mathop{S} dm\, \boldsymbol{v}_2 \cdot \boldsymbol{v}_1; \qquad \text{i.e., } T_2 = K_{12}, \tag{4.6.1e}$$

and so (4.6.1a) becomes

$$2T_2 = T_1 + T_2 - T_{12} \Rightarrow T_2 - T_1 = -T_{12} < 0; \text{ i.e.,}$$
$$T_2 < T_1; \tag{4.6.1f}$$

[we exclude the case(s) where the introduction of new constraint(s) does not change the kinetic energy] or, reverting to our standard notation,

$$\begin{aligned} \Delta T \equiv T^+ - T^- &\equiv \mathop{S} (dm/2)\boldsymbol{v}^+ \cdot \boldsymbol{v}^+ - \mathop{S} (dm/2)\boldsymbol{v}^- \cdot \boldsymbol{v}^- \\ &= -\mathop{S} (dm/2)(\boldsymbol{v}^+ - \boldsymbol{v}^-) \cdot (\boldsymbol{v}^+ - \boldsymbol{v}^-) \\ &\equiv -\mathop{S} (dm/2)\, \Delta\boldsymbol{v} \cdot \Delta\boldsymbol{v} \\ &\equiv -T_{\text{jump}}:\ -\left[\textit{Kinetic energy of jump (or of lost) motion}\right] < 0, \end{aligned}$$

or

$$T^- - T^+ = T_{\text{jump}} > 0, \quad \text{Q.E.D.} \tag{4.6.1g}$$

[Recalling (4.5.13a), we see that, here, $\hat{S} = -\Delta T$.]

(b) To prove the *second* part, similarly, we identify $\boldsymbol{v}^- = \boldsymbol{v}_1$, $\boldsymbol{v}^+ = \boldsymbol{v}_2$, choose $\delta\boldsymbol{r} \to d\boldsymbol{r} = \boldsymbol{v}^-\, dt \sim \boldsymbol{v}^- = \boldsymbol{v}_1$, and notice that, here, $\mathop{S} \widehat{d\boldsymbol{F}} \cdot \boldsymbol{v}^- \equiv \mathop{S} \widehat{d\boldsymbol{F}} \cdot \boldsymbol{v}_1 = 0$. The result is

$$\mathop{S} dm(\boldsymbol{v}^+ - \boldsymbol{v}^-) \cdot \boldsymbol{v}^- = \mathop{S} dm(\boldsymbol{v}_2 - \boldsymbol{v}_1) \cdot \boldsymbol{v}_1 = 0,$$
$$\Rightarrow \mathop{S} dm\, \boldsymbol{v}_2 \cdot \boldsymbol{v}_1 = \mathop{S} dm\, \boldsymbol{v}_1 \cdot \boldsymbol{v}_1; \qquad \text{i.e., } T_1 = K_{12}, \tag{4.6.1h}$$

and so (4.6.1a) yields

$$2T_1 = T_1 + T_2 - T_{12} \Rightarrow T_1 - T_2 = -T_{12} < 0; \text{ i.e.,}$$
$$T_1 < T_2; \tag{4.6.1i}$$

or, in terms of our standard notation,

$$\begin{aligned} \Delta T \equiv T^+ - T^- &\equiv \mathop{S} (dm/2)\boldsymbol{v}^+ \cdot \boldsymbol{v}^+ - \mathop{S} (dm/2)\boldsymbol{v}^- \cdot \boldsymbol{v}^- \\ &= \mathop{S} (dm/2)(\boldsymbol{v}^+ - \boldsymbol{v}^-) \cdot (\boldsymbol{v}^+ - \boldsymbol{v}^-) \\ &\equiv \mathop{S} (dm/2)\, \Delta\boldsymbol{v} \cdot \Delta\boldsymbol{v} \equiv T_{\text{jump}} > 0, \quad \text{Q.E.D.} \end{aligned} \tag{4.6.1j}$$

REMARKS

(i) The above can also be easily obtained by combining the identities

$$\mathop{S} dm(\boldsymbol{v}^+ - \boldsymbol{v}^-) \cdot \boldsymbol{v}^+ = \Delta T + T_{\text{jump}}, \qquad \mathop{S} dm(\boldsymbol{v}^+ - \boldsymbol{v}^-) \cdot \boldsymbol{v}^- = \Delta T - T_{\text{jump}}, \tag{4.6.1k}$$

[which follow at once from (4.6.1a, b) with the earlier identifications] with LIP, (4.6.1c, d). Thus, the first of (4.6.1k) yields $\Delta T + T_{\text{jump}} = 0$ (*first theorem*, while the second of (4.6.1k) yields $\Delta T - T_{\text{jump}} = 0$ (*second theorem*).

(ii) For Carnot's first theorem under *nonpersistent* constraints, see Appell (1896, p. 15 ff.).

(iii) If the bodies in question are *elastic*, then their collision consists of (a) a period of *compression* (as if the bodies were inelastic), and (b) a period of explosion-like *restitution*. Since the corresponding forces are equal and opposite, *the kinetic energy lost in compression balances exactly the kinetic energy gained in restitution*. This is sometimes called the *third theorem of Carnot*.

4.6.2 Theorem of Kelvin (1863)

If an originally motionless system is suddenly set in motion by (unknown) impressed impulses acting at specified points of it and communicating to them prescribed (i.e., given) velocities, then the resulting (or actual) postimpact kinetic energy is less than that of any other kinematically possible (or comparison, or hypothetical) motion; that is, one in which the specified points have the same prescribed velocities as in the actual motion, and all other external and/or internal system constraints are respected (which is why this theorem is occasionally referred to as a "principle of laziness"); that is, with some obvious notations:

$$T(\boldsymbol{v}_{\text{postimpact } comparison}) > T(\boldsymbol{v}_{\text{postimpact } actual}). \tag{4.6.2a}$$

Hence, this result allows us to find the actual postimpact velocities in terms of the prescribed velocities.

To prove it, and since *such comparison motions may differ from each other infinitesimally,* we let $\boldsymbol{v}^+{}_{\text{actual}} \equiv \boldsymbol{v}^+$ and $\boldsymbol{v}^+{}_{\text{comparison}} \equiv \boldsymbol{v}^+ + \delta\boldsymbol{v}^+ \equiv \boldsymbol{v}^+ + \delta_K \boldsymbol{v} \equiv \boldsymbol{v}$; where, of course, both $\boldsymbol{v}^+$ and $\boldsymbol{v}$ are kinematically admissible, and, at the specified points, $\delta_K \boldsymbol{v} = \mathbf{0}$. Then, with $\delta \boldsymbol{r} \sim \delta_K \boldsymbol{v}$, and since, at these points, $\delta_K \boldsymbol{v} = \mathbf{0}$, while for the rest of them $\widehat{d\boldsymbol{F}} = \mathbf{0}$,

$$\mathsf{S}\, \widehat{d\boldsymbol{F}} \cdot \delta_K \boldsymbol{v} = 0 \qquad \text{and} \qquad \mathsf{S}\, \widehat{d\boldsymbol{R}} \cdot \delta_K \boldsymbol{v} = 0. \tag{4.6.2b}$$

• *Stationarity*: Next, setting $\boldsymbol{v}^- = \mathbf{0}$ (since the system is initially at rest) and the rest of the above specializations into the master equations (4.6.1c, d) yields the *stationarity* condition

$$\mathsf{S}\, dm\, \boldsymbol{v}^+ \cdot \delta_K \boldsymbol{v} = 0, \qquad \text{or} \qquad \mathsf{S}\, dm\, \boldsymbol{v}^+ \cdot \boldsymbol{v} = \mathsf{S}\, dm\, \boldsymbol{v}^+ \cdot \boldsymbol{v}^+; \tag{4.6.2c}$$

that is,

$$\delta_K \Big(\mathsf{S}\, (dm/2) \boldsymbol{v}^+ \cdot \boldsymbol{v}^+ \Big) \equiv \delta_K T(\boldsymbol{v}^+) = 0; \tag{4.6.2d}$$

that is, *the actual postimpact motion makes the kinetic energy stationary*.

- *Minimality*: As a result of the above we have, successively,

$$\begin{aligned}
\Delta T &\equiv T(\boldsymbol{v}) - T(\boldsymbol{v}^+) \equiv T(\boldsymbol{v}^+ + \delta_K \boldsymbol{v}) - T(\boldsymbol{v}^+) \\
&\equiv \mathbf{S}(dm/2)\boldsymbol{v}\cdot\boldsymbol{v} - \mathbf{S}(dm/2)\boldsymbol{v}^+\cdot\boldsymbol{v}^+ \\
&= \mathbf{S}(dm/2)\big[(\boldsymbol{v}^+ + \delta_K\boldsymbol{v})\cdot(\boldsymbol{v}^+ + \delta_K\boldsymbol{v}) - \boldsymbol{v}^+\cdot\boldsymbol{v}^+\big] \qquad \text{[invoking (4.6.2c, d)]} \\
&= \mathbf{S}(dm/2)\,\delta_K\boldsymbol{v}\cdot\delta_K\boldsymbol{v} \equiv \mathbf{S}(dm/2)(\boldsymbol{v}-\boldsymbol{v}^+)\cdot(\boldsymbol{v}-\boldsymbol{v}^+) \\
&\equiv (1/2)\,\delta^2{}_K T(\boldsymbol{v}^+) \geq 0 \qquad \text{(with the equality holding for } \delta_K\boldsymbol{v} = \mathbf{0}) \\
&\qquad\qquad \Rightarrow T(\boldsymbol{v}^+) = \textit{minimum}, \quad \text{Q.E.D.} \qquad (4.6.2e)
\end{aligned}$$

However, in concrete problems, it is the stationarity rather than the minimality that is invoked.

REMARKS

(i) Equation (4.6.2c) also results, most simply, by setting in the master equations (4.6.1c, d): (a) $\boldsymbol{v}^- = \mathbf{0}$ and (b) first, $\delta\boldsymbol{r} \sim \boldsymbol{v}^+$, and, second, $\delta\boldsymbol{r} \sim \boldsymbol{v} \equiv \boldsymbol{v}^+ + \delta_K\boldsymbol{v}$, and then noting that

$$0 = \mathbf{S}\,\widehat{d\boldsymbol{F}}\cdot\delta_K\boldsymbol{v} \;\Rightarrow\; \mathbf{S}\,\widehat{d\boldsymbol{F}}\cdot\boldsymbol{v} = \mathbf{S}\,\widehat{d\boldsymbol{F}}\cdot\boldsymbol{v}^+.$$

(ii) For proofs utilizing (4.6.1a1, 1a2), see ex. 4.6.7; also Chirgwin and Plumpton (1966, p. 330 ff.).

(iii) For applications of Kelvin's theorem to hydrodynamics, and so on, see, for example, Byerly (1916, pp. 76–80), and, of course, Thomson and Tait (1912, §312–317, pp. 286–301).

4.6.3 Theorem of Bertrand (1853) and Delaunay (1840)

Consider a system in motion acted upon by prescribed impressed impulses applied to it: (a) with its existing (i.e., original) ideal constraints and, separately, (b) with additional (also ideal) constraints. Then, the actual postimpact kinetic energy under the existing constraints is greater than that under the additional constraints, where, in both cases, the impulses, as well as the initial motion of the system, are the same; or, these additional constraints reduce the kinetic energy; that is,

$$T(\boldsymbol{v}_{\text{postimpact } \textit{existing constraints}}) > T(\boldsymbol{v}_{\text{postimpact } \textit{additional constraints}}). \qquad (4.6.3a)$$

REMARKS

(i) Originally established by Lagrange; generalized by Sturm (1841) and Bertrand [in his notes to the 3rd ed. of Lagrange's *Mécanique Analytique* (1853–1855)]. The maximum property is due to Delaunay (1840).

(ii) We notice the similarities with Carnot's first theorem: in there, the system is acted upon by given impulses, and *then* ideal impulsive constraints are imposed; while in the Bertrand–Delaunay theorem, in the competing motion both impulses and constraints are applied *simultaneously*. (On the latter, see also "Remarks" following the theorem of Robin, below.)

To prove it, we let $\boldsymbol{v}^+$ and $\boldsymbol{v}$ be, respectively, the existing and additionally constrained postimpact velocities, and $\boldsymbol{v}^-$ be the common preimpact velocity. If the corresponding impulsive reactions are $\{\widehat{d\boldsymbol{R}^+}\}$ and $\{\widehat{d\boldsymbol{R}}\}$, then, by the first parts of (4.6.1c, d) with $\delta\boldsymbol{r} \sim \boldsymbol{v}^+$,

$$\mathcal{S}\, \widehat{d\boldsymbol{R}^+} \cdot \boldsymbol{v}^+ = 0 \qquad \text{and} \qquad \mathcal{S}\, \widehat{d\boldsymbol{R}} \cdot \boldsymbol{v}^+ = 0, \tag{4.6.3b}$$

and so the second parts of (4.6.1c, d), with $\{\widehat{d\boldsymbol{F}}\}$ the common impressed forces and, again, $\delta\boldsymbol{r} \sim \boldsymbol{v}$, and $\boldsymbol{v}^+ \to \boldsymbol{v}^+$, $\boldsymbol{v}$, yield

$$\mathcal{S}\, dm(\boldsymbol{v}^+ - \boldsymbol{v}^-) \cdot \boldsymbol{v} = \mathcal{S}\, \widehat{d\boldsymbol{F}} \cdot \boldsymbol{v},$$

and

$$\mathcal{S}\, dm(\boldsymbol{v} - \boldsymbol{v}^-) \cdot \boldsymbol{v} = \mathcal{S}\, \widehat{d\boldsymbol{F}} \cdot \boldsymbol{v}, \tag{4.6.3c}$$

from which, subtracting side by side, we obtain

$$\mathcal{S}\, dm(\boldsymbol{v}^+ - \boldsymbol{v}) \cdot \boldsymbol{v} = 0, \tag{4.6.3d}$$

and from this it follows readily [as in the corresponding steps of the previous theorems of Carnot and Kelvin, eqs. (4.6.1g–1j, 2e)]:

$$\begin{aligned} T^+ - T &\equiv \mathcal{S}\,(dm/2)\boldsymbol{v}^+ \cdot \boldsymbol{v}^+ - \mathcal{S}\,(dm/2)\boldsymbol{v} \cdot \boldsymbol{v} \\ &= \mathcal{S}\,(dm/2)(\boldsymbol{v}^+ - \boldsymbol{v}) \cdot (\boldsymbol{v}^+ - \boldsymbol{v}) > 0; \qquad \text{i.e., } T^+ > T, \quad \text{Q.E.D.} \end{aligned} \tag{4.6.3e}$$

• *Continuous case, variational formulation*. If, further, the additionally constrained (postimpact) motion depends continuously on its deviation from the (postimpact) motion under existing constraints, then setting in the above $\boldsymbol{v} - \boldsymbol{v}^+ = \delta\boldsymbol{v}^+ \equiv \delta_{B/D}\boldsymbol{v}$, we obtain [as in Kelvin's theorem, (4.6.2d)], the *stationarity* equation

$$\delta_{B/D}T^+ \equiv \delta_{B/D}T(\boldsymbol{v}^+) \equiv \delta_{B/D}\Big(\mathcal{S}\,(dm/2)\boldsymbol{v}^+ \cdot \boldsymbol{v}^+\Big) = \mathcal{S}\, dm\, \boldsymbol{v}^+ \cdot \delta_{B/D}\boldsymbol{v} = 0; \tag{4.6.3f}$$

that is, for constrained variations, the actual motion makes the kinetic energy *stationary; and the maximality* inequality (with the equality holding for $\delta_{B/D}\boldsymbol{v} = \boldsymbol{0}$)

$$\begin{aligned} \varDelta_{B/D}T(\boldsymbol{v}^+) &\equiv T - T^+ = \cdots \\ &= -(1/2)\,\delta^2{}_{B/D}T^+ \;=\; -\mathcal{S}\,(dm/2)\,\delta_{B/D}\boldsymbol{v} \cdot \delta_{B/D}\boldsymbol{v} \le 0. \end{aligned} \tag{4.6.3g}$$

Since, here, the impressed impulses are assumed to be *the same* for all kinematically possible (comparison) postimpact velocities, Bertrand's theorem can be reformulated as follows: The postimpact velocities of the existing constraints (actual problem) $\boldsymbol{v}^+$ make either $T = \mathcal{S}\,(dm/2)\boldsymbol{v} \cdot \boldsymbol{v}$, or $T = T^- + \mathcal{S}\,\widehat{d\boldsymbol{F}} \cdot (\boldsymbol{v} + \boldsymbol{v}^-)/2$ [resulting from the impulsive work–energy theorem," ex. 4.3.1, eqs. (d–f), with $\boldsymbol{v}^+ \to \boldsymbol{v}$] *stationary* (a *maximum*, since T is positive definite), *under the constraint* (expressing the sameness of the impulses for all comparison motions)

$$2(T - T^-) - \mathcal{S}\,\widehat{d\boldsymbol{F}} \cdot (\boldsymbol{v} + \boldsymbol{v}^-) = 0, \tag{4.6.3h}$$

or

$$\mathbf{S}\, dm\, \boldsymbol{v} \cdot \boldsymbol{v} - \mathbf{S}\, \widehat{d\boldsymbol{F}} \cdot (\boldsymbol{v} + \boldsymbol{v}^-) - 2T^- = 0. \tag{4.6.3i}$$

The Bertrand–Delaunay theorem, in spite of its conceptual elegance, has two serious drawbacks:

(i) The earlier continuity requirement significantly limits its usefulness; and

(ii) As one might expect, its practical implementation is, usually, mathematically laborious. [Convenient alternatives, for the determination of the motion of constrained systems resulting from the sudden imposition of impulses, are the stationarity/extremum theorems of Robin and Gauss, presented below.]

Relationship Between the Theorems of Kelvin and Bertrand–Delaunay, Theorem of Taylor (1922)

Let us consider a straight rigid rod AB, initially at rest on a horizontal smooth table, and then set in motion by a given impulse $\hat{I}_B$ applied perpendicularly to it at its end B; and, hence, communicating to it a specified velocity v_B, also perpendicular to the rod at B. Then, we repeat the experiment with a point of the rod C permanently fixed/hinged; something that forces it to rotate about C. Now: (a) If the *impulse* at B is the same in both experiments, then the hinge *decreases* the kinetic energy (Bertrand–Delaunay); in fact, since the value of $\hat{I}_B$ remains fixed, as C approaches B the angular velocity of the rod decreases (and for $C \to B \;\Rightarrow\; \omega \to 0$), and so does its kinetic energy; whereas (b) If the *velocity* of B is the same in both experiments, then the hinge *increases* the kinetic energy (Kelvin); in fact, since the value of v_B remains fixed, as C approaches B the angular velocity of the rod increases indefinitely, and so does its kinetic energy!

The relationship between the kinetic energy *increase* of Kelvin's theorem, and the kinetic energy *decrease* of the Bertrand–Delaunay theorem is answered by the following interesting theorem.

THEOREM OF TAYLOR

Let us consider an originally motionless system S and then apply to its points impulses $\widehat{d\boldsymbol{F}}$, which produce velocities $\boldsymbol{v}^+$, and result in a reference kinetic energy T^+. Next, we introduce to S given constraints. To this new, motionless, system, S_c, we:

(a) *First*, apply the earlier $\widehat{d\boldsymbol{F}}$ at the same points, which results in a kinetic energy $T^+{}_{c,\,impulses}$. By the theorem of Bertrand–Delaunay, $T^+{}_{c,\,impulses} < T^+$.

(b) *Second*, we apply the earlier velocities at the same points, which results in a kinetic energy $T^+{}_{c,\,velocities}$. By Kelvin's theorem: $T^+{}_{c,\,velocities} > T^+$.

Now, Taylor's theorem states that

$$|T^+{}_{c,\,velocities} - T^+| \; > \; |T^+{}_{c,\,impulses} - T^+|; \tag{4.6.3j}$$

or

$$\Delta T_K > |\Delta T_{B/D}|,$$

$$\Delta T_K \equiv T(\boldsymbol{v}_{\text{postimpact } \textit{comparison}}) - T(\boldsymbol{v}_{\text{postimpact } \textit{actual}}) \quad (>0),$$

$$\Delta T_{B/D} \equiv T(\boldsymbol{v}_{\text{postimpact } \textit{additional constraints}}) - T(\boldsymbol{v}_{\text{postimpact } \textit{existing constraints}}) \quad (<0); \quad (4.6.3\text{k})$$

where

$$T(\boldsymbol{v}_{\text{postimpact } \textit{actual}}) = T(\boldsymbol{v}_{\text{postimpact } \textit{existing constraints}}) = T^+.$$

In words: *the increase in energy due to the imposition of constraints in the Kelvin case is greater than the (absolute value of the) reduction in energy due to the imposition of the same constraints in the Bertrand–Delaunay case.*

[For proofs and applications, see, for example, Kilmister (1967, pp. 105–107), Milne (1948, pp. 374–378), Pars (1965, p. 238), Ramsey (1937, pp. 216–219), Rosenberg (1977, p. 408). Also, for a combined formulation of the theorems of Kelvin and Bertrand–Delaunay, due to Gray (1901), see Stäckel (1905, p. 517).]

4.6.4 Theorem of Robin (1887)

The actual postimpact velocities $\{\boldsymbol{v}^+\}$ *of a moving system subjected simultaneously to given impressed impulses* $\{\widehat{d\boldsymbol{F}}\}$, *and to sudden ideal impulsive constraints make the following expression:*

$$P = P(\boldsymbol{v}; \boldsymbol{v}^-, \widehat{d\boldsymbol{F}}) \equiv \int (dm/2)(\boldsymbol{v} - \boldsymbol{v}^-)^2 - \int \widehat{d\boldsymbol{F}} \cdot (\boldsymbol{v} - \boldsymbol{v}^-), \qquad (4.6.4\text{a})$$

(stationary and) a minimum, among $\{\boldsymbol{v}\}$: *kinematically possible (or comparison) postimpact velocities; that is,*

$$P(\boldsymbol{v};\ \boldsymbol{v}^-, \widehat{d\boldsymbol{F}}) \geq P(\boldsymbol{v}^+;\ \boldsymbol{v}^-, \widehat{d\boldsymbol{F}}) \equiv P_{\min},$$

$$P_{\min} = \int (dm/2)(\boldsymbol{v}^+ - \boldsymbol{v}^-)^2 - \int \widehat{d\boldsymbol{F}} \cdot (\boldsymbol{v}^+ - \boldsymbol{v}^-). \qquad (4.6.4\text{b})$$

Indeed, setting in the master equations (4.6.1c, d) $\delta\boldsymbol{r} \sim \boldsymbol{v}^+$ and $\delta\boldsymbol{r} \sim \boldsymbol{v}$ (to distinguish them from the $\boldsymbol{v}^+$ of Bertrand's theorem) yields

$$\int dm(\boldsymbol{v}^+ - \boldsymbol{v}^-) \cdot \boldsymbol{v}^+ = \int \widehat{d\boldsymbol{F}} \cdot \boldsymbol{v}^+,$$

$$\int dm(\boldsymbol{v}^+ - \boldsymbol{v}^-) \cdot \boldsymbol{v} = \int \widehat{d\boldsymbol{F}} \cdot \boldsymbol{v} \qquad \left[= \int dm(\boldsymbol{v} - \boldsymbol{v}^-) \cdot \boldsymbol{v}\right]; \qquad (4.6.4\text{c})$$

the last equation holding because, if we denote by $\widehat{d\boldsymbol{R}}$ and $\widehat{d\boldsymbol{R}'}$ the constraint reactions of $\boldsymbol{v}^+$ and $\boldsymbol{v}$, respectively and *since the* $\boldsymbol{v}$ *are compatible with both* $\widehat{d\boldsymbol{R}}$ *and* $\widehat{d\boldsymbol{R}'}$ (i.e., with all constraints — since the $\boldsymbol{v}^+$ are a subset of the $\boldsymbol{v}$, they must also be compatible with both the $\widehat{d\boldsymbol{R}}$ and $\widehat{d\boldsymbol{R}'}$), we shall have $\int \widehat{d\boldsymbol{R}} \cdot \boldsymbol{v} = \int \widehat{d\boldsymbol{R}'} \cdot \boldsymbol{v} = 0$. Next, subtracting eqs. (4.6.4c) side by side readily results in

$$\int dm(\boldsymbol{v}^+ - \boldsymbol{v}^-) \cdot (\boldsymbol{v} - \boldsymbol{v}^+) = \int \widehat{d\boldsymbol{F}} \cdot (\boldsymbol{v} - \boldsymbol{v}^+); \qquad (4.6.4\text{d})$$

or, since kinematically admissible postimpact velocities may differ infinitesimally from each other, setting (as in Kelvin's theorem) $\boldsymbol{v} - \boldsymbol{v}^+ = \delta\boldsymbol{v}^+ \equiv \delta_R\boldsymbol{v}$, we can rewrite (4d) as

$$\mathcal{S}\, dm(\boldsymbol{v}^+ - \boldsymbol{v}^-)\cdot\delta_R\boldsymbol{v} = \mathcal{S}\, \widehat{d\boldsymbol{F}}\cdot\delta_R\boldsymbol{v}, \tag{4.6.4e}$$

which is none other than the *stationarity* condition (since $\delta_R\boldsymbol{v}^- = \mathbf{0}$)

$$\delta_R P = \delta_R\Big(\mathcal{S}\,(dm/2)(\boldsymbol{v} - \boldsymbol{v}^-)^2 - \mathcal{S}\,\widehat{d\boldsymbol{F}}\cdot(\boldsymbol{v} - \boldsymbol{v}^-)\Big) = 0. \tag{4.6.4f}$$

Next, to the minimality condition. We obtain, successively, using the above results,

$$\begin{aligned}
P(\boldsymbol{v};\ldots) - P(\boldsymbol{v}^+;\ldots) &\equiv P - P_{\min}\\
&= \mathcal{S}\,(dm/2)\big[(\boldsymbol{v} - \boldsymbol{v}^-)^2 - (\boldsymbol{v}^+ - \boldsymbol{v}^-)^2\big] - \mathcal{S}\,\widehat{d\boldsymbol{F}}\cdot(\boldsymbol{v} - \boldsymbol{v}^+)\\
&= \mathcal{S}\,(dm/2)(\boldsymbol{v} - \boldsymbol{v}^+)\cdot(\boldsymbol{v} + \boldsymbol{v}^+ - 2\boldsymbol{v}^-) - \mathcal{S}\,dm(\boldsymbol{v}^+ - \boldsymbol{v}^-)\cdot(\boldsymbol{v} - \boldsymbol{v}^+)\\
&= \mathcal{S}\,(dm/2)(\boldsymbol{v} - \boldsymbol{v}^+)^2\\
&= \mathcal{S}\,(dm/2)(\delta_R\boldsymbol{v})^2 = (1/2)\,\delta^2{}_R P \geq 0, \quad \text{Q.E.D.}
\end{aligned} \tag{4.6.4g}$$

REMARKS

The final (i.e., postimpact) velocities of a system under sudden prescribed impressed impulses (or velocities), followed immediately by additional constraints, are the same as if the system had the constraints imposed first, followed immediately by the impressed impulses (or velocities); that is, *the order of application of impressed impulses (or velocities) and constraints is immaterial to the postimpact motion, as long as it all occurs within an infinitesimal time interval*. [However, the order of equally sudden imposition of impressed impulses (or velocities) and *removal* of constraints, clearly, *does* make a difference!] And, wherever that order of application is immaterial, the *total* impulse at various system points, impressed and constraint (reaction), must be the same for either order; hence, then, impressed impulses (or velocities) and additional constraints can be thought of as acting simultaneously, in the sense of Robin's theorem. [These remarks are due to Professor D. T. Greenwood (private communication).]

Special (Extreme) Cases

(a) Only the $\{\widehat{d\boldsymbol{F}}\}$ are imposed, but no additional constraints. Then the $\{\boldsymbol{v}^+\}$ make P, (4.6.4a), a minimum.

(b) Only the additional constraints are imposed, but no $\{\widehat{d\boldsymbol{F}}\}$. Then the $\{\boldsymbol{v}^+\}$ make the "comparison relative kinetic energy" P a minimum:

$$P \to \mathcal{S}\,(dm/2)(\boldsymbol{v} - \boldsymbol{v}^-)^2 \to \mathcal{S}\,(dm/2)(\boldsymbol{v}^+ - \boldsymbol{v}^-)^2 = P_{\min}. \tag{4.6.4h}$$

Further, in this case, we obtain, successively,

$$\begin{aligned}\mathcal{S}(dm/2)(\boldsymbol{v}-\boldsymbol{v}^-)^2 &= \mathcal{S}(dm/2)\boldsymbol{v}\cdot\boldsymbol{v}+\mathcal{S}(dm/2)\boldsymbol{v}^-\cdot\boldsymbol{v}^- - \mathcal{S}\,dm\,\boldsymbol{v}\cdot\boldsymbol{v}^-\\ &= \mathcal{S}(dm/2)\boldsymbol{v}\cdot\boldsymbol{v}+\mathcal{S}(dm/2)\boldsymbol{v}^-\cdot\boldsymbol{v}^- - \mathcal{S}\,dm\,\boldsymbol{v}\cdot\boldsymbol{v}\\ &\quad\text{[the third (last) sum transformed with the help of (4.6.4c)]}\\ &= \mathcal{S}(dm/2)\boldsymbol{v}^-\cdot\boldsymbol{v}^- - \mathcal{S}(dm/2)\boldsymbol{v}\cdot\boldsymbol{v}>0;\end{aligned}$$

and, therefore, for $\boldsymbol{v}=\boldsymbol{v}^+$,

$$\begin{aligned}P_{\min} &= \mathcal{S}(dm/2)(\boldsymbol{v}^+-\boldsymbol{v}^-)^2 = \mathcal{S}(dm/2)\boldsymbol{v}^-\cdot\boldsymbol{v}^- - \mathcal{S}(dm/2)\boldsymbol{v}^+\cdot\boldsymbol{v}^+\\ &= T^- - T^+ \equiv -\Delta T>0 \qquad (=\text{kinetic energy } \textit{loss}).\end{aligned}\tag{4.6.4i}$$

In words: *the postshock velocities of a system subjected to sudden ideal impulsive constraints minimize its relative kinetic energy; and that minimum value equals the lost kinetic energy* (i.e., first part of Carnot's theorem!).

(c) The preimpact state is one of rest. Then we simply set in (4.6.4a, b) $\boldsymbol{v}^-=\boldsymbol{0}$.

4.6.5 Theorem of Gauss

[Impulsive Counterpart of Differential Variational Principle of Gauss (§6.4, §6.6).] *The actual postimpact velocities* $\{\boldsymbol{v}^+\}$ *minimize the "impulsive compulsion":*

$$\begin{aligned}\hat{Z}=\hat{Z}(\boldsymbol{v}) &\equiv \mathcal{S}(dm/2)\big[\boldsymbol{v}-\boldsymbol{v}^- - (\widehat{d\boldsymbol{F}}/dm)\big]^2\\ &\Big(=\cdots = P+\mathcal{S}(\widehat{d\boldsymbol{F}})^2/2dm\Big),\end{aligned}\tag{4.6.5a}$$

relative to all kinematically admissible postimpact velocities $\{\boldsymbol{v}\equiv\boldsymbol{v}^+ + \delta_G\boldsymbol{v}\}$*;* that is, $\min\hat{Z}=\hat{Z}(\boldsymbol{v}^+)$. Indeed, from (4.6.5a) we readily obtain

$$\begin{aligned}\Delta_G\hat{Z} &\equiv \hat{Z}(\boldsymbol{v})-\hat{Z}(\boldsymbol{v}^+)\\ &= \mathcal{S}(dm/2)\big[(\boldsymbol{v}^+ + \delta_G\boldsymbol{v}-\boldsymbol{v}^- - \widehat{d\boldsymbol{F}}/dm)^2-(\boldsymbol{v}^+ - \widehat{d\boldsymbol{F}}/dm)^2\big]\\ &\equiv \delta_G\hat{Z}+(1/2)\delta^2{}_G\hat{Z},\end{aligned}\tag{4.6.5b}$$

where

$$\begin{aligned}\delta_G\hat{Z} &\equiv \mathcal{S}\,dm(\boldsymbol{v}^+ - \boldsymbol{v}^- - \widehat{d\boldsymbol{F}}/dm)\cdot\delta_G\boldsymbol{v}\quad(=\delta_R P)=0\\ &\quad\text{[by setting in (4.6.1c, d) } \delta\boldsymbol{r}\to\delta_G\boldsymbol{v}]\end{aligned}\tag{4.6.5c}$$

$$\begin{aligned}\delta^2{}_G\hat{Z} &\equiv \mathcal{S}\,dm(\delta_G\boldsymbol{v})^2\quad(=\delta^2{}_R P)\\ &\equiv \textit{Relative kinetic energy (as in Kelvin's theorem)}>0;\end{aligned}\tag{4.6.5d}$$

that is, $\Delta_G\hat{Z}=(1/2)\delta^2{}_G\hat{Z}\ [=\Delta_R P=(1/2)\delta^2{}_R P)]>0$, Q.E.D. The above clearly show the equivalence of the theorems of Gauss and Robin.

Table 4.2 Extremum Theorems of Impulsive Motion

Master equation (impulsive Lagrange's principle):

$$\mathcal{S}\, dm(\boldsymbol{v}^+ - \boldsymbol{v}^-)\cdot\delta\boldsymbol{r} = \mathcal{S}\, \widehat{d\boldsymbol{F}}\cdot\delta\boldsymbol{r}$$

- Carnot (first part — collisions):

$$\delta\boldsymbol{r} \sim \boldsymbol{v}^+, \qquad \widehat{d\boldsymbol{F}} = \boldsymbol{0} \Rightarrow T^+ - T^- < 0.$$

  Carnot (second part — explosions):

$$\delta\boldsymbol{r} \sim \boldsymbol{v}^-, \qquad \widehat{d\boldsymbol{F}} = \boldsymbol{0} \Rightarrow T^+ - T^- > 0.$$

- Kelvin (prescribed velocities):

$$\delta\boldsymbol{r} \sim \boldsymbol{v}^+, \qquad \delta\boldsymbol{r} \sim \boldsymbol{v}^+ + \delta_K\boldsymbol{v},\ \boldsymbol{v}^- = \boldsymbol{0} \Rightarrow T(\boldsymbol{v}) - T(\boldsymbol{v}^+) > 0, \qquad \delta_K T^+ = 0.$$

- Bertrand–Delaunay (prescribed impulses):

$$\delta\boldsymbol{r} \sim \boldsymbol{v}^+,\ \delta\boldsymbol{r} \sim \boldsymbol{v}^+ + \delta_{B/D}\boldsymbol{v} = \boldsymbol{v} \Rightarrow T(\boldsymbol{v}) - T(\boldsymbol{v}^+) < 0,\ \delta_{B/D}T^+ = 0.$$

  [Taylor: $T_{\text{Kelvin}}(\boldsymbol{v}) - T(\boldsymbol{v}^+) > T(\boldsymbol{v}^+) - T(\boldsymbol{v})_{\text{Bertrand–Delaunay}}$]

- Robin (prescribed impulses and constraints):

$$\delta\boldsymbol{r} \sim \boldsymbol{v}^+, \qquad \delta\boldsymbol{r} \sim \boldsymbol{v}^+ + \delta_R\boldsymbol{v} = \boldsymbol{v}$$

$$P \equiv \mathcal{S}\,(dm/2)(\boldsymbol{v} - \boldsymbol{v}^-)^2 - \mathcal{S}\,\widehat{d\boldsymbol{F}}\cdot(\boldsymbol{v} - \boldsymbol{v}^-):\quad \text{stationary and minimum.}$$

- Gauss (impulsive compulsion):

$$\hat{Z} \equiv \mathcal{S}\,(dm/2)(\boldsymbol{v} - \boldsymbol{v}^- - \widehat{d\boldsymbol{F}}/dm)^2 = P + \mathcal{S}\,(\widehat{d\boldsymbol{F}})^2/2dm:\quad \text{stationary and minimum.}$$

Alternatively, the stationarity condition (4.6.5c), with $\delta_G\boldsymbol{v}^+ = \boldsymbol{v} - \boldsymbol{v}^+$, applied to

$$\begin{aligned}\hat{Z} &\equiv \mathcal{S}(dm/2)\big[(\boldsymbol{v}^+ - \boldsymbol{v}^-) - \widehat{d\boldsymbol{F}}/dm\big]^2\\ &= \mathcal{S}\,(dm/2)\boldsymbol{v}^+\cdot\boldsymbol{v}^+ + \mathcal{S}\,(dm/2)\boldsymbol{v}^-\cdot\boldsymbol{v}^- + \mathcal{S}\,(\widehat{d\boldsymbol{F}})^2/2dm\\ &\qquad - \mathcal{S}\,dm\,\boldsymbol{v}^+\cdot\boldsymbol{v}^- - \mathcal{S}\,\widehat{d\boldsymbol{F}}\cdot(\boldsymbol{v}^+ - \boldsymbol{v}^-),\end{aligned}$$

yields

$$\begin{aligned}\delta_G\hat{Z} &= \mathcal{S}\,dm(\boldsymbol{v}^+ - \boldsymbol{v}^- - \widehat{d\boldsymbol{F}}/dm)\cdot\delta_G(\boldsymbol{v}^+ - \boldsymbol{v}^- - \widehat{d\boldsymbol{F}}/dm)\\ &= \mathcal{S}\,dm\,\boldsymbol{v}^+\cdot\delta_G\boldsymbol{v} - \mathcal{S}\,dm\,\boldsymbol{v}^-\cdot\delta_G\boldsymbol{v} - \mathcal{S}\,\widehat{d\boldsymbol{F}}\cdot\delta_G\boldsymbol{v} = 0,\end{aligned}\tag{4.6.5e}$$

or, rearranging,

$$\mathcal{S}\,dm(\boldsymbol{v}^+ - \boldsymbol{v}^-)\cdot\delta_G\boldsymbol{v} = \mathcal{S}\,\widehat{d\boldsymbol{F}}\cdot\delta_G\boldsymbol{v};\tag{4.6.5f}$$

that is, the master equations (4.6.1c, d) with $\delta\boldsymbol{r} \to \delta_G\boldsymbol{v}$. Also, eq. (4.6.5f) constitutes the impulsive counterpart of *Jourdain's differential variational principle* (§6.3). This latter, in holonomic system variables, reads $\sum(\Delta p_k - \hat{Q}_k)\,\delta\dot{q}_k = 0$, under $\delta t = 0$, $\delta q_k = 0$. For a detailed and lucid treatment of its application to impulsive problems, see, for example, Bahar (1994); also ex. 4.5.6.

To facilitate the understanding of all these — admittedly, similarly sounding and hence hard to differentiate and remember — theorems, we summarize them in table 4.2.

Example 4.6.1 (D. T. Greenwood, 1997, private communication). *On Input Inertia and Impulse Response*. Let us consider a finite and discrete system, and an impulse $\hat{\boldsymbol{f}}_P$, acting at its point P and causing to it a velocity jump $\Delta \boldsymbol{v}_P \equiv \boldsymbol{v}_P{}^+ - \boldsymbol{v}_P{}^-$. Now, the *input inertia coefficient* or *driving-point mass* at P, μ_P, is defined by

$$\mu_P \equiv \hat{f}_P / \Delta v_{P,t} \qquad (P = 1, 2, \ldots), \tag{a}$$

where $\hat{f}_P$ is the magnitude of $\hat{\boldsymbol{f}}_P$ and $\Delta v_{P,t}$ is the component of $\Delta \boldsymbol{v}_P$ in the direction of $\hat{\boldsymbol{f}}_P$. It is not hard to see that $\mu_P > 0$, always (explain!); and, for a given system point P, it is a function of the configuration and the direction of $\hat{\boldsymbol{f}}_P$, but not of the system's state of motion. From the above, it follows that if μ_P is also finite, $\Delta \boldsymbol{v}_P$ has always a component in the direction of $\hat{\boldsymbol{f}}_P$. Now, and recalling the results of ex. 4.3.1 on the impulsive "work–energy" theorem, the work (or, better, power) done by $\hat{\boldsymbol{f}}_P$, $\hat{W}_P$, equals its dot product with the average velocity of $\boldsymbol{v}_P{}^+$ and $\boldsymbol{v}_P{}^-$:

$$\hat{W}_P \equiv \hat{\boldsymbol{f}}_P \cdot [(\boldsymbol{v}_P{}^- + \boldsymbol{v}_P{}^+)/2] = \hat{\boldsymbol{f}}_P \cdot [\boldsymbol{v}_P{}^- + (\Delta \boldsymbol{v}_P{}^+/2)]; \tag{b}$$

and by that theorem, the corresponding kinetic energy change, ΔT_P, is

$$\Delta T_P \equiv T_P{}^+ - T_P{}^- = \hat{W}_P = \hat{\boldsymbol{f}}_P \cdot \boldsymbol{v}_P{}^- + (\hat{f}_P{}^2/2\mu_P). \tag{c}$$

From this, we conclude that ΔT_P can be positive or negative, depending on the preimpact state of motion (i.e., the value of $\hat{\boldsymbol{f}}_P \cdot \boldsymbol{v}_P{}^-$). But, an originally motionless system (i.e., $\boldsymbol{v}_P{}^- = \boldsymbol{0}$) will always exhibit an *increase* in its kinetic energy, inversely proportional to its μ_P's.

Next, let us assume that additional stationary impulsive constraints are suddenly imposed on a moving system. If some particle velocity is changed, and the impact is inelastic, the resulting impulsive constraint reactions will do negative work on the system as a whole, and thus reduce its kinetic energy (Carnot's first theorem). This and (c) imply that additional constraints result in an increase in the system's input masses, μ_P's; a fact confirming our intuitive feeling that *each constraint tends to increase the resistance to velocity changes due to* $\hat{\boldsymbol{f}}_P$, at P.

Appendix: Calculation of $\Delta v_{P,t}$ for a single impressed impulse $\hat{\boldsymbol{f}}_P$

Recalling the results of §4.5 [eqs. 4.5.4a–5b)], let the constraints and kinetic equations of impulsive motion be, respectively,

$$\omega_D \equiv \sum A_{Dk} \dot{q}_k \equiv \sum A_{Dk} v_k = 0,$$

$$\sum M^*{}_{II'} \Delta\omega_{I'} = \Theta_I \;\Rightarrow\; \Delta\omega_I = \sum Y_{II'} \Theta_{I'} \qquad [(Y_{II'})\text{: inverse of } (M^*{}_{II'})], \tag{d}$$

where

$$\omega_I \equiv \sum A_{Ik} \dot{q}_k \equiv \sum A_{Ik} v_k \neq 0, \qquad M^*{}_{II'} \equiv \partial^2 T^*{}_o / \partial\omega_I \, \partial\omega_{I'},$$

$$T^*{}_o = T^*(t, q, \omega_D = 0, \omega_I) = T^*{}_o(t, q, \omega_I) \qquad (D = 1, \ldots, m;\; I, I' = m+1, \ldots, n). \tag{d1}$$

Now, with the earlier notations/definitions, suppose that

$$\Delta v_{P,t} = \sum C_{PI} \, \Delta\omega_I \qquad (P = 1, 2, \ldots, \#\,\text{particles under impressed impulses}). \tag{e1}$$

Hence, for a *single* such impulse $\hat{\boldsymbol{f}}_P$, by equating impulsive virtual works, we find

$$\hat{\Theta}_I = [\partial(\Delta v_{P,t})/\partial(\Delta\omega_I)]\hat{f}_P = C_{PI}\hat{f}_P. \tag{e2}$$

Substituting (e2) into the second of (d), and the result into (e1), we obtain the sought formula

$$\Delta v_{P,t} = \sum C_{PI}\Big(\sum Y_{II'}(C_{PI'}\hat{f}_P)\Big) = \Big(\sum\sum C_{PI}Y_{II'}C_{PI'}\Big)\hat{f}_P. \tag{f1}$$

From (f1), it also follows at once that the corresponding input mass equals

$$\mu_P \equiv \hat{f}_P/\Delta v_{P,t} = \Big(\sum\sum C_{PI}Y_{II'}C_{PI'}\Big)^{-1}. \tag{f2}$$

The extension of the above to include impulsive constraint reactions is straightforward, and is left to the reader. These formulae may find useful applications to structural dynamics.

Example 4.6.2 Let us consider two circular homogeneous wheels, W_1 and W_2 (fig. 4.21), of respective radii r_1 and r_2, rotating with constant and, initially unrelated, angular velocities about their frictionless parallel axes through their respective fixed (geometrical and mass) centers O_1 and O_2. On these wheels, we drop an initially slack, inextensible and massless cable that sticks to them and, then, at a certain instant, becomes taut and thus exerts an impulsive moment on the wheels. Let us calculate their postimpact angular velocities $\omega_1{}^+$ and $\omega_2{}^+$, respectively.

Since the addition of the cable amounts to the *sudden introduction of a constraint, Carnot's first theorem*, (4.6.1e), yields immediately (with I_1 and I_2 denoting, respectively, the moments of inertia of W_1 and W_2 about O_1 and O_2)

$$\begin{aligned} 2(T^+ - T^-) &= [I_1(\omega_1{}^+)^2 + I_2(\omega_2{}^+)^2] - [I_1(\omega_1{}^-)^2 + I_2(\omega_2{}^-)^2] \\ &= -\big[I_1(\omega_1{}^+ - \omega_1{}^-)^2 + I_2(\omega_2{}^+ - \omega_2{}^-)^2\big] < 0, \end{aligned} \tag{a}$$

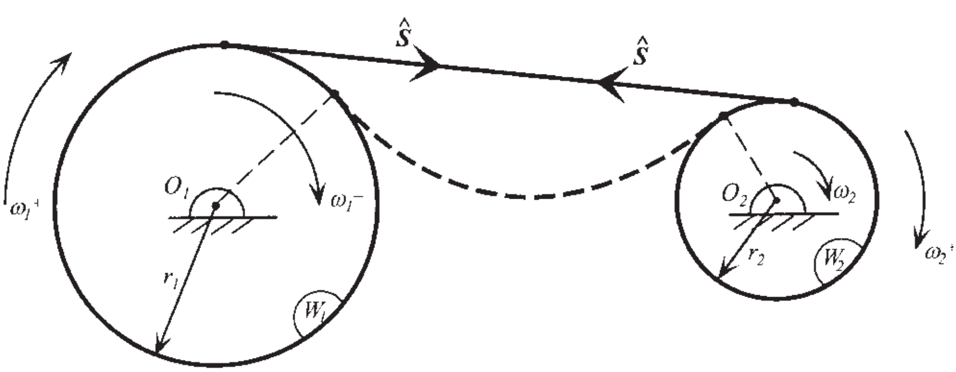

Figure 4.21 Sudden imposition of constraint in a two-wheel system.

or, rearranging and simplifying,

$$I_1[(\omega_1^{-})^2 - (\omega_1^{+})^2] + I_2[(\omega_2^{-})^2 - (\omega_2^{+})^2]$$
$$= I_1(\omega_1^{-} - \omega_1^{+})^2 + I_2(\omega_2^{-} - \omega_2^{+})^2 > 0. \tag{b}$$

From kinematics we have, also,

$$\omega_1^{+} r_1 = \omega_2^{+} r_2. \tag{c}$$

Solving the system (b, c), we obtain the sought postimpact angular velocities

$$\omega_1^{+}/r_2 = \omega_2^{+}/r_1 = (I_1 r_2 \omega_1^{-} + I_2 r_1 \omega_2^{-})/(I_1 r_2^2 + I_2 r_1^2). \tag{d}$$

Then, combining these results with the theorem of impulsive angular momentum, about O_1 and O_2, we obtain the impulsive cable tension $\hat{S}$,

$$\hat{S} r_1 = I_1(\omega_1^{+} - \omega_1^{-}), \qquad -\hat{S} r_2 = I_2(\omega_2^{+} - \omega_2^{-}) \tag{e}$$

$$\Rightarrow \hat{S} = I_1(\omega_1^{+} - \omega_1^{-})/r_1 = -I_2(\omega_2^{+} - \omega_2^{-})/r_2$$
$$= \left[(r_2 \omega_2^{-} - r_1 \omega_1^{-})/(I_1 r_2^2 + I_2 r_1^2)\right] I_1 I_2. \tag{f}$$

Problem 4.6.1 (Bouligand, 1954, pp. 139–142). Consider a thin straight homogeneous rod AB, of mass m and length $2l$, originally suspended in horizontal equilibrium from a fixed ceiling by two vertical identical taut strings, s and s', attached to the bar at points other than its endpoints A and B [fig. 4.22(a)]. A *third* string s'' connects A with the ceiling point O, directly above A. The length of s'' is $2h$, and that is double the distance OA (i.e., originally, s, s' are taut, but s'' is slack). Then, the strings s and s' break simultaneously (or, someone burns them). Calculate the velocity state of AB immediately after the shock produced by the sudden tensioning of s''.

Let [fig 4.22(b)] $OA = r$, $angle(Ox, OA) = \theta$, $angle(Ox, AB) = \phi$. Now, the post s, s'-snap configurations of AB are determined by *three* Lagrangean coordinates; say, r, θ, ϕ; while the shock amounts to the sudden introduction of the persistent constraint $r = constant = 2h$.

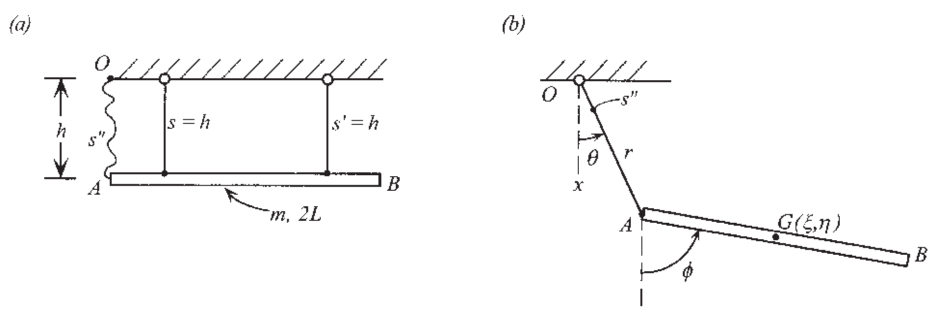

Figure 4.22 Geometry of rod *AB*, of mass *m* and length 2*l*, originally suspended from a fixed ceiling by the two equal and parallel strings *s* and *s'*, of length *h*. A third string *s''*, of length 2*h*, connects *A* with the fixed ceiling point (origin) *O*. Then *s* and *s'* snap, *AB* falls freely until *s''* gets taut and provokes a shock to *AB*.
(a) Equilibrium, (b) generic postshock configuration.

(i) Show that the (double) kinetic energy of AB, for a generic configuration, is

$$2T = m\{r^2(\dot{\theta})^2 + (\dot{r})^2 + (4/3)(l\dot{\phi})^2 + 2l[r\,\dot{\theta}\,\dot{\phi}\cos(\theta-\phi) + \dot{r}\,\dot{\phi}\sin(\theta-\phi)]\}. \qquad \text{(a)}$$

HINT

Let the coordinates of the rod's center and center of mass G be x, y. From geometry,

$$x = r\cos\theta + l\cos\phi, \qquad y = r\sin\theta + l\sin\phi,$$

$$\Rightarrow\ \dot{x} = -r\,\dot{\theta}\sin\theta + \dot{r}\cos\theta - l\,\dot{\phi}\sin\phi, \qquad \dot{y} = r\,\dot{\theta}\cos\theta + \dot{r}\sin\theta + l\,\dot{\phi}\cos\phi. \qquad \text{(b)}$$

Then use König's theorem: $2T = 2T_{\text{with all mass concentrated at } G} + 2T_{\text{relative, about } G}$.

(ii) By applying the fundamental Lagrangean impulsive virtual work equation

$$\Delta(\partial T/\partial\dot{r})\,\delta r + \Delta(\partial T/\partial\dot{\theta})\,\delta\theta + \Delta(\partial T/\partial\dot{\phi})\,\delta\phi = 0, \quad \text{for} \quad \delta r = 0,\ \delta\theta, \delta\phi\text{: } \textit{arbitrary} \quad \text{(c)}$$

(since here $\widehat{\delta' W} = 0$), obtain the *kinetic* impulsive equations:

$$\Delta\big[r\,\dot{\theta} + l\,\dot{\phi}\cos(\theta-\phi)\big] = 0 \qquad \Rightarrow r\Delta\dot{\theta} = 0, \qquad \text{(d1)}$$

$$\Delta\big[(4/3)l\,\dot{\phi} - l\,\dot{\phi}\cos^2(\theta-\phi) + \dot{r}\sin(\theta-\phi)\big] = 0 \Rightarrow (4/3)l\Delta\dot{\phi} - \Delta\dot{r} = 0. \qquad \text{(d2)}$$

(iii) Verify that, since the preshock conditions are (invoking energy conservation)

$$\theta^- = 0,\ \ \phi^- = \pi/2,\ \ r = 2l; \quad (\dot{\theta})^- = 0,\ \ (\dot{\phi})^- = 0,\ \ (\dot{r})^- = (2gh)^{1/2} \quad \text{(free fall)}, \quad \text{(e1)}$$

while, after the shock: $(\dot{r})^+ = 0 \Rightarrow \Delta\dot{r} = -(2gh)^{1/2}$, the above yield the postshock values

$$(\dot{\theta})^+ = 0, \qquad (\dot{\phi})^+ = -3(2gh)^{1/2}/4l. \qquad \text{(e2)}$$

(iv) Verify that the *kinetostatic* impulsive equation is $\Delta(\partial T/\partial\dot{r}) = \hat{\lambda}$ [impulsive multiplier, to adjoin the constraint (1) $\delta r = 0$ to (c), and equal to the tension of s'']. Show that

$$4\hat{\lambda} = (2gh)^{1/2}.$$

(v) Show that if we choose as Lagrangean coordinates, x, y, and ϕ, the (double) kinetic energy and impulsive virtual work equation are, respectively,

$$2T = m[(\dot{x})^2 + (\dot{y})^2] + (ml^2/3)(\dot{\phi})^2; \qquad \text{(f1)}$$

$$\Delta(\partial T/\partial\dot{x})\,\delta x + \Delta(\partial T/\partial\dot{y})\,\delta y + \Delta(\partial T/\partial\dot{\phi})\,\delta\phi = 0, \qquad \text{(f2)}$$

for all δx, δy, $\delta\phi$ constrained by

$$\delta f\,|_{\text{evaluated at } \theta=0,\phi=\pi/2} = 0, \quad \text{where } f \equiv (x - l\cos\phi)^2 + (y - l\sin\phi)^2 = r^2\ \text{(constant)};$$

that is,

$$\delta x + l\,\delta\phi = 0. \qquad \text{(f3)}$$

Verify that the variational equations (f2) and (f3) lead to the kinetic impulsive equations

$$\Delta\dot{x} - (l/3)\,\Delta\dot{\phi} = 0 \qquad \text{and} \qquad \Delta\dot{y} = 0. \qquad \text{(f4)}$$

Then [from (b) evaluated at $\theta = 0$, $\phi = \pi/2$, $r = 2l$], since the preshock velocities are $(\dot{x})^- = 2(gh)^{1/2}$, $(\dot{y})^- = 0$, $(\dot{\phi})^- = 0$, confirm that the postshock velocities will be

$$(\dot{x})^+ = (2gh)^{1/2} + \Delta\dot{x} = (3/4)(2gh)^{1/2}, \quad (\dot{y})^+ = \Delta\dot{y} = 0, \quad (\dot{\phi})^+ = \Delta\dot{\phi}, \tag{f5}$$

[while $(\dot{y})^- = (\dot{y})^+ = 0$], and they will be connected by

$$(df/dt)^+ = 0 \Rightarrow (\dot{x})^+ + l(\dot{\phi})^+ = 0: \qquad (2gh)^{1/2} + \Delta\dot{x} + l\,\Delta\dot{\phi} = 0. \tag{f6}$$

Finally, confirm that combination of (f4) with (f6) yields a $\Delta\dot{\phi}$ value in agreement with (e2); also that the impulsive multiplier needed for adjoining (f3) to (f2) equals $l\,\Delta\dot{\phi}/3$.

(vi) Show that

$$2T^- = 2mgh, \qquad 2T^+ = m[r^2(\dot{\theta})^2 + (4/3)l^2(\dot{\phi})^2], \tag{g1}$$

$$\begin{aligned}
2T_{\text{jump}} &\equiv \mathcal{S}\, dm(\boldsymbol{v}^+ - \boldsymbol{v}^-)\cdot(\boldsymbol{v}^+ - \boldsymbol{v}^-) \qquad \text{(kinetic energy of } \textit{jump} \text{ motion)}\\
&= m[(\Delta\dot{x})^2 + (\Delta\dot{y})^2] + (m\,l^2/3)(\Delta\dot{\phi})^2\\
&= m\{[(\dot{x})^+ - (2gh)^{1/2}]^2 + [(\dot{y})^+]^2 + (l^2/3)[(\dot{\phi})^+]^2\}\\
&= m\{[l(\dot{\phi})^+ + (2gh)^{1/2}]^2 + 4h^2[(\dot{\theta})^+]^2 + (l^2/3)[(\dot{\phi})^+]^2\}.
\end{aligned} \tag{g2}$$

(vii) Show that the *first* theorem of Carnot—that is, $T^- - T^+ = T_{\text{jump}}$—applied to the above yields

$$4h^2[(\dot{\theta})^+]^2 + (4/3)l^2[(\dot{\phi})^+]^2 + l(\dot{\phi})^+(2gh)^{1/2} = 0. \tag{h1}$$

A second equation connecting $(\dot{\theta})^+$ and $(\dot{\phi})^+$ is obtained by applying impulsive angular momentum conservation about O (i.e., Oz—notice that, in our axes, *clockwise is negative*):

$$\begin{aligned}
H_O{}^- = H_O{}^+: \quad -m\,l(2g\,h)^{1/2} &= I_G\,\omega^+ + [\boldsymbol{r}_{G/O} \times (m\boldsymbol{v}_G)]_z\\
&= (ml^2/3)(\dot{\phi})^+ + [-m(\dot{x})^+ l + m(\dot{y})^+(2h)] \quad \text{[using (b)]}\\
&= (ml^2/3)(\dot{\phi})^+ + \{-m[-l(\dot{\phi})^+]l + m[2h(\dot{\theta})^+](2h)\}\\
&= (4/3)(m\,l^2)(\dot{\phi})^+ + m(2h)^2(\dot{\theta})^+,\\
\Rightarrow 4h^2(\dot{\theta})^+(4/3)l^2(\dot{\phi})^+ &+ l(2gh)^{1/2} = 0.
\end{aligned} \tag{h2}$$

Verify that the solution of (h1) and (h2) gives the earlier postshock values.

[The fact that (h1) is a single *nonvariational* equation in the two unknowns—namely, $(\dot{\theta})^+, (\dot{\phi})^+$ (and also that it is *quadratic* in them, thus yielding a *parasitic* solution, in addition to the actual one—a drawback of all *nonvariational/extremum* energetic theorems)—severely limits the practical usefulness of Carnot's theorem(s).]

Example 4.6.3 Let us consider a rigid lamina P, of mass m, originally at rest on a smooth table, one point of which, say A, is suddenly communicated a prescribed velocity (u, v), on the plane of P (fig. 4.23). We will calculate its actual postshock angular velocity, ω^+, via elementary (i.e., Newton–Euler) means, and by Kelvin's

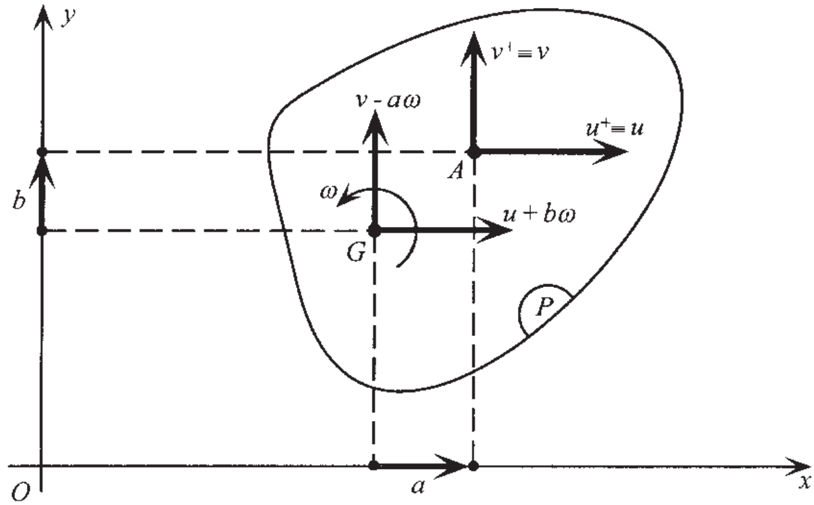

Figure 4.23 Kelvin's theorem for a rigid lamina in plane motion.

theorem; namely, that for ω^+ the kinematically possible postimpact kinetic energy of P becomes both stationary and minimum.

(i) *Via Newton–Euler*. Let (a, b) be the coordinates of A relative to the mass center of P, G. Then, by plane kinematics, the velocity of G has x, y-components: $u + b\,\omega$, $v - a\,\omega$; and so, by impulsive angular momentum about A (with $m\,k^2$: moment of inertia of P about G),

$$0 = (mk^2)\omega^+ + \{[m(u + b\,\omega^+)b] - [m(v - a\,\omega^+)]a\} \tag{a}$$

($=$ angular momentum of P about G + moment of linear momentum of P about A), and solving this for ω^+, we readily obtain

$$\omega^+ = (av - bu)/(k^2 + a^2 + b^2); \tag{b}$$

or, by applying the principle about the *body-fixed* point A, and corresponding moment of inertia

$$I_A = I_G + m(a^2 + b^2) = m(k^2 + a^2 + b^2):$$

$$0 = \Delta\big[I_A\omega - (\boldsymbol{r}_{A/G} \times m\boldsymbol{v}_A)_z\big]:\ 0 = I_A\,\omega^+ - [(mv)a - (mu)b] \ \Rightarrow \text{eq. (b)}. \tag{c}$$

(ii) *Via Kelvin's theorem*. Now, by König's theorem, the postimpact kinetic energy of P for an arbitrary *kinematically possible* postimpact angular velocity ω, equals

$$2T = m\big[(u + b\omega)^2 + (v - a\omega)^2\big] + (mk^2)\omega^2 = 2T(\omega; u, v). \tag{d}$$

Let the reader show that, by Kelvin's theorem, $T \to$ *stationary*; that is, setting $dT/d\omega = 0$ yields $\omega = \omega^+$, eq. (b), and further, that there $d^2T/d\omega^2 > 0$.

Example 4.6.4 Let us consider an initially motionless rigid and homogeneous rod AB, of mass m and length l (fig. 4.24), set in motion by causing its right end B to

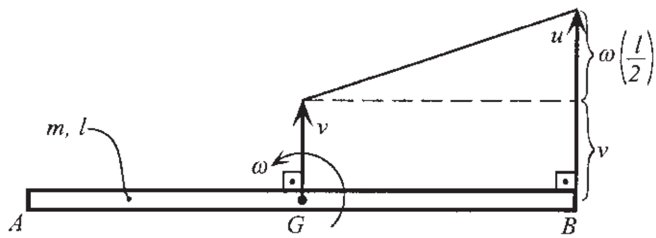

Figure 4.24 Rod under a prescribed velocity u at its end B.

move normally to AB with a specified postimpact velocity u. Let us calculate its postimpact angular velocity ω^+.

Here, by König's theorem, the *kinematically possible* postimpact kinetic energy of the rod [with v: velocity of rod's center of mass G; I: moment of inertia of rod about $G(= ml^2/12)$; and ω: angular velocity of rod] equals

$$2T = mv^2 + I\omega^2; \tag{a}$$

and, by simple kinematics,

$$\boldsymbol{v}_B = \boldsymbol{v}_G + \boldsymbol{\omega} \times \boldsymbol{r}_{B/G} = (0, v, 0) + (0, 0, \omega) \times (l/2, 0, 0) = (0, v + \omega l/2, 0), \tag{b}$$

that is, $u = v + \omega l/2 \Rightarrow v = u - \omega l/2$ (which expresses the kinematic possibility), and, therefore,

$$2T = m(u - \omega l/2)^2 + I\omega^2 \equiv T(\omega; u). \tag{c}$$

Now, according to *Kelvin's theorem*, of all the kinematically possible postimpact motions (i.e., velocities) of the rod with $(v_B)^+ \equiv u =$ *prescribed*, and hence for *any set of values of v and ω satisfying eq. (b)*, the actual, or kinetic, one will make T stationary/minimum; that is, it will be such that

$$\partial T/\partial\omega = -m(l/2)[u - \omega(l/2)] + I\omega = 0 \qquad [\text{with } \omega \to \omega^+]$$
$$\Rightarrow (l/2)\omega^+ = \{m(l/2)^2/[I + m(l/2)^2]\}u; \qquad \text{or, finally,} \ \omega^+ = 3u/2l. \tag{d}$$

Problem 4.6.2 By applying Kelvin's theorem, show that the actual postimpact angular velocities of two identical and homogeneous rods AB and BC (fig. 4.25), ω^+ and Ω^+, each of length l and mass m, smoothly hinged at B and originally at rest so that A, B, C are collinear, and after A is suddenly imparted a specified velocity v, normal to AB, equal

$$\omega^+ = 9v/7l \quad (\text{i.e., clockwise}), \qquad \Omega^+ = -(3v/7l) \quad (\text{i.e., counterclockwise}). \tag{a}$$

HINT

By König's theorem, the postimpact kinetic energy, for any kinematically admissible angular velocities ω and Ω, equals

$$T \equiv T(\omega, \Omega; v) = [(m/2)(v - l\omega/2)^2 + (1/2)(ml^2/12)\omega^2]$$
$$+ \{(m/2)[v - 2(l/2)\omega - (l/2)\Omega]^2 + (1/2)(ml^2/12)\Omega^2\}. \tag{b}$$

Then set $\partial T/\partial\omega = 0$, $\partial T/\partial\Omega = 0$.

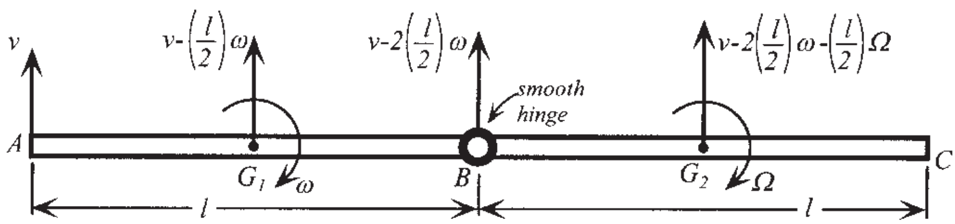

Figure 4.25 Two-rod system set in motion by a normal velocity at one of its endpoints. $v_A = v$, $v_{G_1} = v - (l/2)\omega$, $v_B = v - 2(l/2)\omega$, $v_{G_2} = v - 2(l/2)\omega - (l/2)\Omega$.

Example 4.6.5 (D. T. Greenwood, private communication, 1997).

(i) Let us consider an initially motionless rigid and homogeneous rod AB, of mass m and length l (and, hence, center of mass at the rod midpoint G—fig. 4.26), set in motion by a given transverse impulse $\hat{I}$ at B. Using impulsive principles of linear and angular momentum (about G), we readily find the following postimpact velocities (omitting superscript pluses):

$$v_G = \hat{I}/m, \qquad \omega = \hat{I}(l/2)/(ml^2/12) = 6\hat{I}/ml, \tag{a1}$$

and, therefore, the (also transverse) velocity of B is

$$\boldsymbol{v}_B = \boldsymbol{v}_G + \boldsymbol{\omega} \times \boldsymbol{r}_{B/G} \;\Rightarrow\; v_B = v_G + \omega(l/2) = 4\hat{I}/m. \tag{a2}$$

Hence, by König's theorem, the corresponding kinetic energy equals

$$\begin{aligned} T &= (1/2)m\,{v_G}^2 + (1/2)(m\,l^2/12)\omega^2 = \cdots = 2\hat{I}^2/m \\ &= (1/2)(\hat{I}^2/\mu_B) = (1/2)\mu_B\,{v_B}^2 = (1/2)\hat{I}v_B, \end{aligned} \tag{b1}$$

where (recalling the results/definitions of ex. 4.6.1)

$$\mu_B \equiv \hat{I}/v_B = m/4\text{: } \textit{input inertia coefficient} \text{ (or, } \textit{driving-point mass at } B\text{)}. \tag{b2}$$

(ii) Next, suppose we introduce the constraint $v_A = 0$ (e.g., we hinge A) before the initially motionless rod is struck by the same transverse impulse $\hat{I}$ at B. Now we have

$$\omega = \hat{I}l/(ml^2/3) = 3\hat{I}/ml \;\Rightarrow\; v_B = \omega\,l = 3\hat{I}/m$$

$$\Rightarrow T = (1/2)(ml^2/3)\,\omega^2 = \cdots = 3\hat{I}^2/2m \tag{c}$$

$$= (1/2)(\hat{I}^2/\mu_B) = (1/2)\mu_B\,{v_B}^2 = (1/2)\hat{I}\,v_B, \tag{d1}$$

where

$$\mu_B \equiv \hat{I}/v_B = m/3. \tag{d2}$$

(iii) Comparing the above, we see that the introduction of a constraint (α) has *increased* the value of the input inertia coefficient μ_B, and, since $2T = \hat{I}^2/\mu_B$, (β) has *reduced* the postimpact kinetic energy, in accordance with the Bertrand–Delaunay theorem.

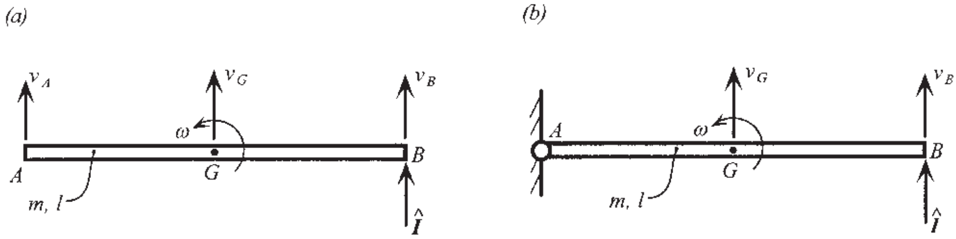

Figure 4.26 Rod under a given transverse impulse $\hat{I}$ at its end B: (a) unconstrained case; (b) constrained case.

If, on the other hand, we had prescribed the velocity v_B, rather than the impulse $\hat{I}$, and kept everything else the same, since also $2T = \mu_B\, {v_B}^2$, the postimpact kinetic energy would have been *increased*, in accordance with the Kelvin theorem.

(iv) Finally, let the values of the input inertia coefficient before the application of the constraint and after it be denoted (for more precision), respectively, as μ_B and $\mu_{B,c}$. Then we can write

$$\mu_{B,c} \equiv \mu_B + \Delta\mu_B = \mu_B + \varepsilon\mu_B = (1+\varepsilon)\mu_B, \tag{e1}$$

where

$$\varepsilon \equiv (\mu_{B,c} - \mu_B)/\mu_B > 0\text{: } \textit{Fractional increase of } \mu_B \textit{ due to the constraint} \tag{e2}$$

(in the above example: $\varepsilon \equiv (m/3 - m/4)\big/(m/4) = 1/3$).

Now, (α) comparing the kinetic energies before and after the constraint, but for the same v_B (i.e., à la Kelvin) we see that (with some easily understood ad hoc notations)

$$\begin{aligned}(T_c - T)_K &\equiv (1/2)\mu_{B,c}{v_B}^2 - (1/2)\mu_B{v_B}^2\\ &= (1/2)\mu_B{v_B}^2(\mu_{B,c} - \mu_B) = (1/2)\mu_B{v_B}^2\varepsilon\\ &\Rightarrow [(T_c - T)/T]_K\text{: Fractional } \textit{increase} \text{ of } T \text{ due to the constraint}\\ &\qquad\qquad (\text{à la Kelvin}) = \varepsilon > 0.\end{aligned} \tag{e3}$$

while (β) comparing the kinetic energies before and after the constraint, but for the same $\hat{I}$ (i.e., à la Bertrand–Delaunay) we see that

$$\begin{aligned}(T - T_c)_{B/D} &\equiv (1/2)(\hat{I}^2/\mu_B) - (1/2)(\hat{I}^2/\mu_{B,c})\\ &= (1/2)\hat{I}^2\big[(1/\mu_B) - (1/\mu_{B,c})\big] = (1/2)(\hat{I}^2/\mu_B)[\varepsilon/(1+\varepsilon)]\\ &\Rightarrow [(T - T_c)/T]_{B/D} > 0\text{: Fractional } \textit{reduction} \text{ of } T \text{ due to the}\\ &\qquad\qquad \text{constraint (à la } \textit{Bertrand–Delaunay})\\ &\qquad\qquad = \varepsilon/(1+\varepsilon) < \varepsilon;\end{aligned} \tag{e4}$$

that is, comparing (e3) and (e4), we immediately conclude that the *T-increase à la Kelvin is greater than the T-decrease à la Bertrand–Delaunay* {by an amount equal to $\varepsilon - [\varepsilon/(1+\varepsilon)](= 1/12$, in the above example)}, in accordance with Taylor's theorem.

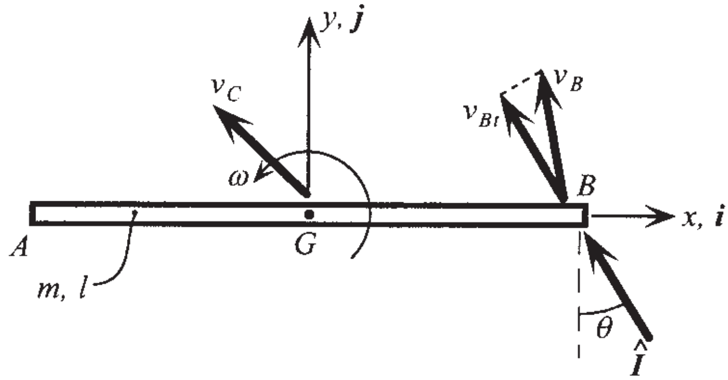

Figure 4.27 Rod AB struck at its right end B by a given nontransverse impulse $\hat{I}$. [$\boldsymbol{i}$, $\boldsymbol{j}$: unit vectors along the positive axes x (parallel to AB), y (perpendicular to AB).]

Problem 4.6.3 (D. T. Greenwood, private communication, 1997). Continuing from the preceding example, consider the response of the unconstrained (and originally motionless) rod AB to an impulse $\hat{\boldsymbol{I}}$ applied to its end B and making an angle θ with the perpendicular to the rod there (fig. 4.27). Let the component of the resulting postimpact velocity at B, $\boldsymbol{v}_B$, along $\hat{\boldsymbol{I}}$ be v_{Bt} (i.e., $\boldsymbol{v}_B$ is neither in the same direction as $\hat{\boldsymbol{I}}$, nor is it perpendicular to the rod at B, as before).

(i) By applying the impulsive principles of linear and angular momentum (about G) show that

$$\boldsymbol{v}_G = (\hat{I}/m)(-\sin\theta\,\boldsymbol{i} + \cos\theta\,\boldsymbol{j}), \qquad \omega = 6\hat{I}\cos\theta/ml, \tag{a1}$$

$$\boldsymbol{v}_B = \boldsymbol{v}_G + \boldsymbol{\omega}\times\boldsymbol{r}_{B/G} = \cdots = (\hat{I}/m)(-\sin\theta\,\boldsymbol{i} + 4\cos\theta\,\boldsymbol{j}) \tag{a2}$$

$$\Rightarrow\; v_{Bt} \equiv \boldsymbol{v}_B\cdot(\hat{\boldsymbol{I}}/\hat{I}) = \cdots = (\hat{I}/m)(1 + 3\cos^2\theta). \tag{a3}$$

(ii) Show that the imparted kinetic energy is

$$T = (\hat{I}^2/2m)(1 + 3\cos^2\theta). \tag{b1}$$

(iii) Verify that T can also be put in the following general forms:

$$T = \hat{I}^2/2\mu_B = (1/2)\hat{I}\,v_{Bt} = (1/2)\mu_B {v_{Bt}}^2, \tag{b2}$$

where

$$\mu_B \equiv \hat{I}/v_{Bt} = m/(1 + 3\cos^2\theta)\text{: input mass at } B. \tag{b3}$$

Problem 4.6.4 Consider an originally motionless and vertical double pendulum consisting of two identical and homogeneous rigid rods, AB and BC (fig. 4.28), each of mass m and length l, smoothly hinged at B and at the fixed support A, and struck by a *given horizontal blow* $\hat{I}$ at C.

(i) Show that the *comparison* postimpact kinetic energy of the system equals

$$T = (m/6)(2u^2 + u\,v + v^2) = (1/2)\hat{I}\,v, \tag{a}$$

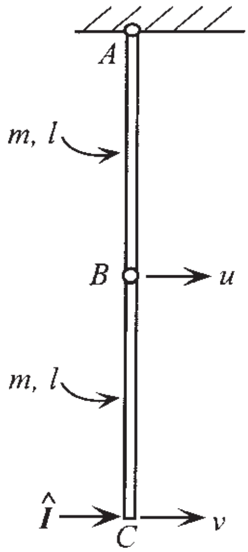

Figure 4.28 Vertical double pendulum struck by a given horizontal impulse.

where u and v are, respectively, the comparison (kinematically admissible) postimpact velocities of B and C, both perpendicular to the pendulum.

(ii) Next, show that application of the Bertrand–Delaunay theorem leads to the (constrained stationarity) conditions $\partial F/\partial u = \partial F/\partial v = 0$, where

$$\begin{aligned} F &\equiv T + \lambda(2T - \hat{I}v) \\ &= (1/2)\hat{I}v + \lambda\big[(m/3)(2u^2 + uv + v^2) - \hat{I}v\big] = F(u, v; \lambda); \\ &\quad \text{constraint:} \quad 2T - \hat{I}v = (m/3)(2u^2 + uv + v^2) - \hat{I}v = 0; \text{ multiplier: } \lambda. \qquad \text{(b)} \end{aligned}$$

(iii) Show that the above equations lead to the following *actual* postimpact velocities:

$$u^+ = -(6/7)\hat{I}/m, \qquad v^+ = (24/7)\hat{I}/m \;\Rightarrow\; T^+ = (1/2)\hat{I}\,v = (12/7)\hat{I}^2/m. \qquad \text{(c)}$$

See also Lamb (1923, p. 321).

Problem 4.6.5 Consider an originally motionless square $ABCD$ consisting of four identical and homogeneous rigid bars (fig. 4.29), each of length $2l$ and mass m, mutually joined by smooth hinges and with corner A fixed, resting on a smooth horizontal table. Then, a *given impressed impulse* $\hat{I}$ acts on the square at B, along BD. Show that the postimpact angular velocities of AB and AD are, respectively,

$$\omega_{AB}{}^+ \equiv \omega_1 = 3\hat{I}/10\sqrt{2}ml, \qquad \omega_{AD}{}^+ \equiv \omega_2 = 0 \quad \text{(i.e., } AD \text{ stationary).} \qquad \text{(a)}$$

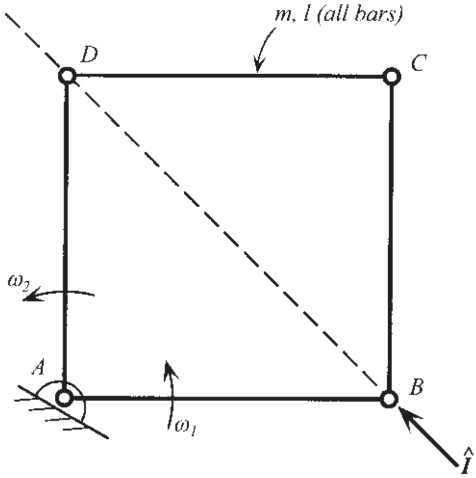

Figure 4.29 Square *ABCD* under given impulse $\hat{I}$ along its diagonal *BD*.

HINT

Apply the Bertrand–Delaunay theorem to the square's postimpact kinetic energy; that is,

$$T = \cdots = \left[(10/3)ml^2\right](\omega_1{}^2 + \omega_2{}^2) = T(\omega_1, \omega_2) \to maximum, \tag{b}$$

under the *constraint* (expressing the impulsive principle of angular momentum about A — explain)

$$\hat{I}(l/\sqrt{2}) = \cdots = \left[(20/3)ml^2\right](\omega_1 + \omega_2) = (specified)\ constant, \tag{c}$$

that is, $T^+ = \cdots = (3/20)(\hat{I}^2/m)$.

Problem 4.6.6 Continuing from the preceding problem, show that the postimpact kinetic energy of the given (*hinged* square) is *twice* as much as the postimpact kinetic energy produced by the *same impulse* $\hat{I}$, but acting on a *rigid* square, as stipulated by the Bertrand–Delaunay theorem.

HINT

In this case, $\omega_1 = \omega_2 \neq 0$ and $T^+ = \cdots = (3/40)(\hat{I}^2/m)$.

[We remark that the preceding problem may also be viewed as a *superposition* of (a) a rigid square ($\omega_1 = \omega_2$) under codirectional impulses $\hat{I}/2$ applied at B and D, and (b) a hinged square with A fixed but C able to slide along AD (i.e., $\omega_1 = -\omega_2$) under an impulse $\hat{I}/2$ applied at B [as in case (a)] and an opposite impulse $-\hat{I}/2$ applied at D.]

Problem 4.6.7 Consider a rhombus $ABCD$ formed by four identical and homogeneous bars, AB, BC, CD, DA (fig. 4.30), each of mass $m/4$, length $2b$, radius of gyration about its own mass center k, and such that $angle(ABC) = 2\phi$, smoothly hinged at A, B, C, D, and originally resting on a frictionless horizontal table. The

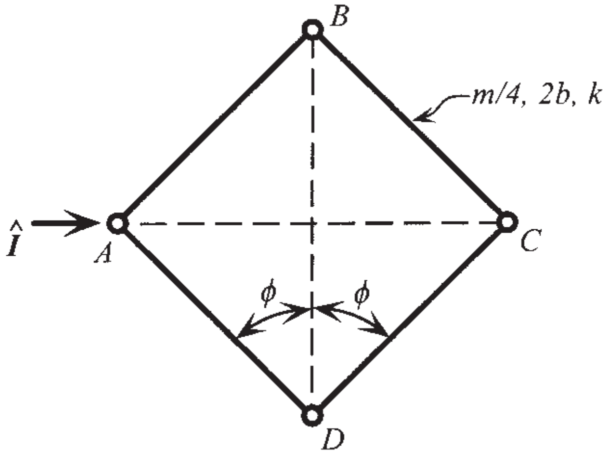

Figure 4.30 Rhombus *ABCD* struck by an impulse $\hat{I}$ along its diagonal *AC*.

rhombus is struck by a blow of intensity $\hat{I}$ at A, along AC. If x is the horizontal coordinate of its mass center G, from some fixed origin along AC, show that:

(i) The (double) kinetic energy of the system, at a generic impact configuration, is

$$2T = m(\dot{x})^2 + m(k^2 + b^2)(\dot{\phi})^2. \tag{a}$$

(ii) The postimpact velocity of A equals

$$(x - 2b\sin\phi)^{\cdot} = \{1 + [4b^2\cos^2\phi/(k^2 + b^2)]\}(\hat{I}/m) \equiv \beta(\hat{I}/m). \tag{b}$$

(iii) The (double) postimpact kinetic energy generated by $\hat{I}$ is $2T = \beta(\hat{I}^2/m) \equiv (2T^+)_{\text{hinged}}$; and, therefore, *the ratio of the actual postimpact kinetic energy to that if the rhombus were rigid*—that is, under the additional constraint $\phi =$ constant $(T_{hinged}/T_{rigid})_{\text{postimpact}}$, equals $\beta(> 1)$; as stipulated by the Bertrand–Delaunay theorem.

Example 4.6.6 Let us calculate the postimpact state of a system having kinetic energy

$$2T = Au^2 + Bv^2 + Cw^2 \tag{a}$$

(where u, v, w: *Lagrangean velocities*), originally moving with velocities $u^- \equiv u_o$, $v^- \equiv v_o$, $w^- \equiv w_o$, after the sudden imposition on it of the constraint

$$au + bv + cw = 0; \tag{b}$$

where both triplets of coefficients A, B, C, and a, b, c have their (approximately) constant impact values.

According to the *Gauss–Robin theorem*, the solution makes the impulsive compulsion,

$$\hat{Z} = A(u - u_o)^2 + B(v - v_o)^2 + C(w - w_o)^2 \equiv \hat{Z}(u, v, w), \tag{c}$$

a minimum, subject to the constraint (b). By differential calculus, we must have

$$d\hat{Z} = 0 \;\Rightarrow\; A(u - u_o)\,du + B(v - v_0)\,dv + C(w - w_o)\,dw = 0, \tag{d}$$

and

$$d[equation(b)] = 0 \;\Rightarrow\; a\,du + b\,dv + c\,dw = 0, \tag{e}$$

from which (using simple analytic geometry arguments in $u/v/w$ space, and fraction properties; thus avoiding Lagrangean multipliers) we obtain successively,

$$\begin{aligned}(u - u_0)/(a/A) &= (v - v_o)/(b/B) = (w - w_o)/(c/C)\\ &= \big[a(u - u_o) + b(v - v_o) + c(w - w_o)\big]/\big[(a^2/A) + (b^2/B) + (c^2/C)\big]\\ &= -(au_o + bv_o + cw_o)/\big[(a^2/A) + (b^2/B) + (c^2/C)\big]\\ &\equiv -\Lambda \qquad [\text{invoking (b)}],\end{aligned} \tag{f}$$

and from this the postimpact velocities follow:

$$u - u_o = -(a/A)\,\Lambda, \qquad v - v_0 = -(b/B)\Lambda, \qquad w - w_o = -(c/C)\,\Lambda. \tag{g}$$

As a result of the above, the kinetic energy *loss* (as *Carnot's first theorem* reminds us) transforms, successively, as follows:

$$\begin{aligned}2(T^- - T^+) \equiv -2\,\Delta T \quad (\geq 0) \;&\equiv\; A({u_o}^2 - u^2) + B({v_o}^2 - v^2) + C({w_o}^2 - w^2)\\ &= A(u_o + u)(a/A)\,\Lambda + B(v_o + v)(b/B)\,\Lambda + C(w_o + w)(c/C)\,\Lambda\\ &= (au_o + bv_o + cw_o)\,\Lambda \qquad [\text{invoking (b)}]\\ &= (au_o + bv_o + cw_o)^2/\big[(a^2/A) + (b^2/B) + (c^2/C)\big] \geq 0,\end{aligned} \tag{h}$$

invoking the Λ-definition (f). The above apply intact, even if u, v, w are quasi velocities.

Example 4.6.7 Let us express some of the earlier extremum theorems in general Lagrangean coordinates.

(i) First, to enhance our understanding, we introduce the following ad hoc (not quite rigorous, but simplifying and convenient) notations and corresponding definitions:

$dq_k/dt \equiv v_k$ (and similarly for any other value of the Lagrangean velocities),

$$p_k \equiv \sum M_{kl} v_l \quad \text{(system momentum); or, } \textit{symbolically},\ p = Mv; \tag{a}$$

$$2T \equiv \sum\sum M_{kl}\dot{q}_k\dot{q}_l \equiv \sum\sum M_{kl} v_k v_l \equiv Mv\,v \equiv p\,v:$$

Initial, or *preimpact*, 2 (kinetic energy), (b1)

$$2T' \equiv \sum\sum M_{kl}{v_k}'{v_l}' \equiv Mv'v' \equiv p'v':$$

Actual postimpact 2 (kinetic energy), (b2)

$$2T'' \equiv \sum\sum M_{kl} v_k{}'' v_l{}'' \equiv M v'' v'' \equiv p'' v'':$$

Comparison, or *kinematically admissible*, *postimpact* 2 (kinetic energy); (b3)

$$2T_{01} = 2T_{10} \equiv \sum\sum M_{kl}(v_k{}' - v_k)(v_l{}' - v_l)$$
$$\equiv M(v' - v)(v' - v) \equiv (p' - p)(v' - v):$$

2(kinetic energy) of *relative* (*or jump*) *motion* $v' - v$, (b4)

$$2T_{02} = 2T_{20} \equiv \sum\sum M_{kl}(v_k{}'' - v_k)(v_l{}'' - v_l)$$
$$\equiv M(v'' - v)(v'' - v) \equiv (p'' - p)(v'' - v):$$

2(kinetic energy) of *relative motion* $v'' - v$, (b5)

$$2T_{12} = 2T_{21} \equiv \sum\sum M_{kl}(v_k{}'' - v_k{}')(v_l{}'' - v_l{}')$$
$$\equiv M(v'' - v')(v'' - v') \equiv (p'' - p')(v'' - v'):$$

2(kinetic) energy of *relative motion* $v'' - v'$; (b6)

$$2K_{01} = 2K_{10} \equiv \sum\sum M_{kl} v_k v_l{}' \equiv M v\, v' \equiv p\, v' \equiv p' v:$$

Impulsive *power of the momenta corresponding to the* v, *times the* v'; and vice versa. (c1)

$$2K_{12} = 2K_{21} \equiv \sum\sum M_{kl} v_k{}' v_l{}'' \equiv M v' v'' \equiv p' v'' \equiv p'' v':$$

Impulsive *power of the momenta corresponding to the* v', *times the* v''; and vice versa. (c2)

(ii) Then, recalling the *symmetry of the inertia coefficients* (i.e., $M_{kl} = M_{lk}$), we readily find that the above are related by

$$2T_{01} \equiv M(v' - v)(v' - v) = \cdots = 2T' + 2T - 2K_{01} - 2K_{01}$$
$$\Rightarrow 2K_{01} = T + T' - T_{01}; \tag{d1}$$

and similarly we derive

$$2K_{02} \equiv M v\, v'' = T + T'' - T_{02}, \tag{d2}$$
$$2K_{12} \equiv M v' v'' = T' + T'' - T_{12}. \tag{d3}$$

(iii) Next, setting in the LIP, (4.3.7), in succession, $\delta q \to v,\ v',\ v''$, we obtain the following formal "impulsive power" expressions:

$$\sum\sum M_{kl}(v_l{}' - v_l) v_k = \sum \hat{Q}_k v_k; \qquad \text{or} \qquad M(v' - v)v = \hat{Q}\, v, \tag{e1}$$
$$\sum\sum M_{kl}(v_l{}' - v_l) v_k{}' = \sum \hat{Q}_k v_k{}'; \qquad \text{or} \qquad M(v' - v)v' = \hat{Q}\, v', \tag{e2}$$
$$\sum\sum M_{kl}(v_l{}' - v_l) v_k{}'' = \sum \hat{Q}_k v_k''; \qquad \text{or} \qquad M(v' - v)v'' = \hat{Q}\, v''; \tag{e3}$$

which, thanks to (d1–3), can be rewritten, respectively, as

$$T' - T - T_{01} = \hat{Q}\, v, \tag{f1}$$

$$T' - T + T_{01} = \hat{Q}\, v', \tag{f2}$$

$$T' - T - T_{12} + T_{02} = \hat{Q}\, v''. \tag{f3}$$

(iv) With the help of the above, we now revisit the earlier extremum theorems:

(iv.a) Adding (f1) and (f2) side by side yields (the system form of ex. 4.3.1

$$2(T' - T) = \hat{Q}(v + v'); \tag{g1}$$

that is, *the change in the kinetic energy of a moving system, due to impressed impulses, equals the power of these impulses on the averaged velocities before and after their application.*

(iv.b) Subtracting (f1) from (f2) yields

$$2T_{01} = \hat{Q}(v' - v); \tag{g2}$$

that is, *the relative kinetic energy of a moving system, due to impressed impulses, equals the power of these impulses on half the velocity jumps due to them.*

(iv.c) If the power of the impressed impulses on the actual postimpact velocities vanishes—that is, if $\hat{Q}\, v' = 0$ (e.g., sudden introduction of ideal impulsive constraints)—then (f2) leads to

$$T' - T + T_{01} = 0 \ \Rightarrow\ T' - T = -T_{01} < 0 \ \Rightarrow\ T' < T : \tag{g3}$$

that is, the introduction of ideal constraints reduces the kinetic energy by an amount equal to the relative (jump) kinetic energy T_{01} [Carnot's *first* theorem, eq. (4.6.1e)].

(iv.d) If the power of the impressed impulses on the preimpact velocities vanishes—that is, if $\hat{Q}\, v = 0$ (e.g., if an explosion occurs in any part of the moving system)—then (f1) leads to

$$T' - T - T_{01} = 0 \ \Rightarrow\ T' - T = T_{01} > 0 \ \Rightarrow\ T' > T; \tag{g4}$$

that is, *in cases of explosion, kinetic energy is always gained by an amount equal to the relative (jump) kinetic energy* T_{01} [Carnot's *second* theorem, eq. (4.6.1h)].

(iv.e) Assume, next, that certain points of the moving system are suddenly seized and, under unknown impressed impulses acting there, are given prescribed velocities; like given constraints. Here, *since the velocities of the points of application of the impressed impulses are prescribed*:

$$\hat{Q}\, v' = \hat{Q}\, v'', \tag{g5}$$

and so the identities (f2, 3), and (b4, 6), immediately yield

$$T_{01} + T_{12} = T_{02} \ \Rightarrow\ T_{01} < T_{02}; \tag{g6}$$

that is, *in the case of impressed impulses acting on a moving system, and imparting to their points of application prescribed velocities, the "actual relative (jump) kinetic energy"* (T_{01}) *is smaller than any other "competing relative kinetic energy"* (T_{02}); in Routh's words: "the actual motion is such that the vis viva [= 2(kinetic energy)] of the relative motion, before and after, is less than if the system took any other course."

In particular, *if the preimpact velocities vanish*—that is, $v = 0$ (initially motionless system)—then $T_{01} \to T'$ and $T_{02} \to T''$, and thus (g6) reduces to the *theorem of Kelvin*:

$$T' < T''; \tag{g7}$$

that is, *in a system initially at rest, and then set in motion by impressed impulses acting at given material points and producing prescribed velocities there, the kinetic energy of the actual velocities* (T') *is less than that of any other competing motion in which these points have the prescribed velocities* (T''). So (g6) constitutes a generalization of Kelvin's theorem to initially generally moving systems.

(iv.f) Finally, assume that given impulses act at specified points, the postimpact velocities of which are, however, unknown. Then, since the impulsive constraint reactions of the so-competing motions v'' are also ideal,

$$M(v' - v)\, v'' = \hat{Q}\, v'' \qquad \text{and} \qquad M(v'' - v)v'' = \hat{Q}\, v'', \tag{h1}$$

or, recalling their forms (e1–f3), and with $v' \to v''$ in (e2) and (f2),

$$\begin{aligned} T' - T - T_{12} + T_{02} &= T'' - T + T_{02} \quad (= \hat{Q}\, v'') \\ \Rightarrow\ T'' + T_{12} &= T' \ \Rightarrow\ T' > T''; \end{aligned} \tag{h2}$$

that is, *theorem of Bertrand–Delaunay*: *in a moving system acted on by given impressed impulses, the actual postimpact kinetic energy is greater than that of any other additionally constrained competing motion, but under the same impulses.*
In sum:

- If the *postimpact velocities* of the points of application of the impressed impulses are *given*, the actual postimpact velocities are found by making the kinetic energy a *minimum* (*Kelvin*); and
- If the *impressed impulses* are *given*, the actual postimpact velocities are found by introducing some constraints and then making the kinetic energy a *maximum* (*Bertrand–Delaunay*).

For complementary derivations, via the so-called *reciprocity* theorems of dynamics, and so on, see, for example, (alphabetically): Kilmister and Reeve (1966, pp. 247–248), Lamb (1929, pp. 184–187, 206, 216–217), Pars (1965, pp. 242–243), Ramsey (1937, pp. 216–218), Rayleigh (1884, p. 91 ff.), Smart (1951, pp. 383–385); also ex. 4.6.8.

Example 4.6.8 *Two Degree of Freedom System: Lagrangean Derivation of Theorems of Kelvin, Bertrand–Delaunay, and of Reciprocity*; as an illustration of *the effect of constraints on the kinetic energy of a mechanical system set in motion in different ways*. We consider a two–Lagrangean coordinate system with (double) kinetic energy

$$2T = a\, {v_x}^2 + 2c\, v_x\, v_y + b\, {v_y}^2: \qquad \textit{positive definite} \text{ in the Lagrangean velocities } v_x, v_y; \tag{a}$$

and a, b, c: inertial coefficients. Hence, its Lagrangean momenta will be

$$p_x \equiv \partial T/\partial v_x = a\, v_x + c\, v_y, \qquad p_y \equiv \partial T/\partial v_y = c\, v_x + b\, v_y. \tag{b}$$

Next, solving the second of (b) for v_y in terms of v_x and p_y, and substituting the result into (a), we obtain the *mixed* T-expression

$$2T = \big[(ab - c^2)/b\big] {v_x}^2 + (1/b){p_y}^2, \tag{c}$$

where $(ab - c^2)/b > 0 \;\Rightarrow\; ab - c^2 > 0$ (positive definiteness of T).

Now, with the help of the above, let us revisit our extremum theorems.

(i) *Theorem of Bertrand–Delaunay*. For the *actual* postimpact state, we have

$$p_x = X = \textit{given}, \quad p_y = 0; \qquad \text{and, therefore, } v_x \neq 0, \quad v_y \neq 0; \tag{d1}$$

while for the *comparison* postimpact state (and denoting the corresponding values of all quantities there with an *accent*),

$${p_x}' = p_x = X, \qquad {p_y}' \neq 0; \qquad {v_x}' \neq 0, \qquad {v_y}' = 0. \tag{d2}$$

Then, the corresponding kinetic energies become

$$2T = \big[(ab - c^2)/b\big] {v_x}^2 \qquad \text{and} \qquad 2T' = a({v_x}')^2. \tag{e}$$

But from (d2), with (b), and then the second of (d1), we find, successively,

$$a\, v_x + c v_y = a\, {v_x}' + c\, {v_y}' = a\, {v_x}'$$
$$\Rightarrow {v_x}' = v_x + (c/a) v_y = v_x + (c/a)[(-c/b) v_x] = \big[1 - (c^2/ab)\big] v_x,$$

and therefore $2T'$ becomes

$$2T' = a({v_x}')^2 = a[1 - (c^2/ab)]^2 {v_x}^2 = \cdots = \big[1 - (c^2/ab)\big] 2T < 2T; \tag{f}$$

that is, the kinetic energy due to a given impulse ($p_x \neq 0$) acting alone ($p_y = 0$) is *greater* than if the other coordinate (y), under the action of a constraining impulse (${p_y}' \neq 0$, but ${p_x}' = p_x \neq 0$), had been prevented from varying (${v_y}' = 0$).

(ii) *Theorem of Kelvin*. For the actual postimpact state, we have

$$p_x \neq 0, \quad p_y = 0; \qquad \text{and} \;\; v_x = \textit{prescribed} \equiv u, \quad v_y \neq 0; \tag{g1}$$

while for the *comparison* postimpact state (accented quantities again),

$${p_x}' \neq 0, \quad {p_y}' \neq 0 \quad \text{(constraining impulse)}; \qquad {v_x}' = v_x = u, \quad {v_y}' = 0. \tag{g2}$$

Then, the corresponding kinetic energies become

$$2T = \big[(ab - c^2)/b\big] {v_x}^2 = \big[a - (c^2/b)\big] {v_x}^2 \qquad \text{and} \qquad 2T' = a({v_x}')^2 = a\, {v_x}^2, \tag{h1}$$

and from these we easily conclude that

$$2T' > 2T; \tag{h2}$$

that is, *the kinetic energy started by a prescribed velocity* (v_x)*, generated by the corresponding impulse acting alone* ($p_x \neq 0$, $p_y = 0$)*, is less than if the other impulse* ${p_y}'(\neq 0)$ *had acted, constraining its associated coordinate* (*i.e.*, ${v_y}' = 0$, *but* ${v_x}' = v_x$).

As Lamb sums it up: *Bertrand–Delaunay theorem*: "A system started from rest by given *impulses* acquires greater energy than if it had been constrained in any way"; *Kelvin theorem*: "A system started with given *velocities* has *less* energy than if it had been constrained" (1923, p. 324). And as remarked by the great British physicist (acoustician, etc.) Rayleigh: "Both theorems are included in the statement that the [moment of] inertia is increased by the introduction of a constraint"; or, "the effect of a constraint is to increase the apparent inertia of the system" (Rayleigh, 1894, p. 100; publ. 1886).

(iii) *Appendix: A theorem of reciprocity*. Let

$$2T = a\,{v_x}^2 + 2c\,v_x\,v_y + b\,{v_y}^2$$
$$\Rightarrow\ p_x \equiv \partial T/\partial v_x = a\,v_x + c\,v_y, \qquad p_y \equiv \partial T/\partial v_y = c\,v_x + b\,v_y, \tag{j}$$

as in (a, b). Now, let us consider *another state of motion,* through the *same configuration*, $(\ldots)'$: ${v_x}'$, ${v_y}'$, ${p_x}'$, ${p_y}'$. Then, it is not hard to see that we will have

$$\begin{aligned} p_x{v_x}' + p_y{v_y}' &= {p_x}'v_x + {p_y}'v_y \\ &= a\,v_x\,{v_x}' + c({v_x}'v_y + v_x\,{v_y}') + b\,v_y{v_y}'. \end{aligned} \tag{k}$$

Therefore, if we set ${p_x}' = 0$, $p_y = 0$, we find $p_x\,{v_x}' = {p_y}'v_y \ \Rightarrow\ v_y/p_x = {v_x}'/{p_y}'$; in words: *if an impulse p_x in the x-coordinate produces a velocity v_y in the y-coordinate, then an equal impulse ${p_y}'$ in the y-coordinate will produce the same velocity ${v_x}'$ in the x-coordinate*. Clearly, such reciprocity relations (a) result from the *symmetry of the inertia coefficients* (inertia tensor, etc.), for any independent set of velocities; and (b) can be easily extended to systems with n Lagrangean coordinates.

EXAMPLE

As an illustration of their use in impulsive motion, let us show the following theorem: *If an impulsive couple $\boldsymbol{C}_1 = C\,\boldsymbol{u}_1 = C(u_{1x}, u_{1y}, u_{1z})$, ($\boldsymbol{u}_1$: unit vector), applied to an originally motionless and unconstrained rigid body generates an angular velocity $\boldsymbol{\omega}_2 = \omega_2\,\boldsymbol{u}_2 = \omega_2(u_{2x}, u_{2y}, u_{2z})$, ($\boldsymbol{u}_2$: another unit vector), then the same couple (magnitude-wise) but applied about $\boldsymbol{u}_2$ (i.e., $\boldsymbol{C}_2 = C\,\boldsymbol{u}_2$) will produce an angular velocity about $\boldsymbol{u}_1$, ω_1, magnitude-wise equal to ω_2 (i.e., $\boldsymbol{\omega}_1 = \omega_1\boldsymbol{u}_1 = \omega_2\boldsymbol{u}_1$, $\omega_1 = \omega_2$); or, the angular velocity ω_2 about axis 2 due to an angular impulse C about axis 1 is equal to the angular velocity ω_1 about axis 1 due to an angular impulse C about axis 2.*

PROOF

Choosing (just for algebraic simplicity, no loss of generality) principal axes at the body's mass center G, with corresponding (principal) moments of inertia $I_{x,y,z}$, we will have (using, for example, the impulsive form of the Eulerian equations, §1.17)

$$\boldsymbol{\omega}_2 = (Cu_{1x}/I_x, Cu_{1y}/I_y, Cu_{1z}/I_z) \equiv (\omega_{2x}, \omega_{2y}, \omega_{2z}), \tag{11}$$
$$\boldsymbol{\omega}_1 = (Cu_{2x}/I_x, Cu_{2y}/I_y, Cu_{2z}/I_z) \equiv (\omega_{1x}, \omega_{1y}, \omega_{1z}), \tag{12}$$
$$\begin{aligned} \Rightarrow \omega_2 = \boldsymbol{\omega}_2 \cdot \boldsymbol{u}_2 &= \omega_1 = \boldsymbol{\omega}_1 \cdot \boldsymbol{u}_1 \\ &= C(u_{1x}u_{2x}/I_x + u_{1y}u_{2y}/I_y + u_{1z}u_{2z}/I_z); \end{aligned} \tag{13}$$

the symmetry of which in $u_{1x,1y,1z;2x,2y,2z}$ proves our proposition. For a treatment based on the Bertrand–Delaunay theorem, see Pöschl (1928, p. 510) and Smart (1951, p. 382). Similar theorems exist in other areas of physics. For further applications and insights, see, for example, Lamb (1929, pp. 276–281) and references cited therein.

Example 4.6.9 Let us consider a system of impulses acting on various points of an arbitrarily moving set of bodies, in such a way that each impulse is perpendicular to the (preimpact) velocity of its point of application. We will show that, as a result, the kinetic energy is increased [Routh, 1905(a), pp. 308–309]. Indeed, because of the above perpendicularity, the power of the impulses on the preimpact velocities vanishes: $T' - T - T_{01} = \hat{Q}\,v = 0$, and so eq. (f1) of ex. 4.6.7 immediately yields

$$T' - T = T_{01} > 0 \;\Rightarrow\; T' > T, \quad \text{Q.E.D.}$$

Example 4.6.10 Let us consider an initially motionless system. If acted on by two different sets of impulses, say A and B, it will take two different postimpact motions. We will show that the power of the impulses A on the velocities B equals the power of the impulses B on the velocities A [Routh, 1905(a), p. 309, example 6].

Indeed, since $T = 0$, we will have $T' = T_{01}$ and $T'' = T_{02}$. Then, the earlier

$$T' - T - T_{12} + T_{02} = \hat{Q}\,v'' \equiv \hat{Q}'v'', \tag{a}$$

and a completely analogous one with T' replaced by T'', and so on; that is,

$$T'' - T - T_{12} + T_{01} = \hat{Q}''v', \tag{b}$$

immediately yield $\hat{Q}'v'' = \hat{Q}''v$, Q.E.D. (a result analogous to a well-known *reciprocal* work proposition in linear elasticity).

Example 4.6.11 Let us, next, extend the above results to the collisions of *inelastic* (but smooth, i.e. frictionless) systems. Here, we introduce the following convenient notation (slightly different from that of ex. 4.6.7):

- v: *preimpact* velocities,
- v': velocities at instant of *maximum compression/contact*,
- v'': *postimpact* velocities (i.e., just after the conclusion of the period of restitution);

and let the corresponding kinetic energies be denoted by T, T', T''; and the *relative* kinetic energies at any two of these instances (with some easily understood notation) be denoted by T_{01}, T_{12}, T_{02}. Because of the smoothness of the colliding surfaces, reasoning à la Carnot (first theorem), we have

$$M(v' - v)v' = \hat{Q}\,v' = 0 \qquad \text{and} \qquad M(v'' - v)v' = \hat{Q}\,v' = 0; \tag{a, b}$$

and since *the ratio of the total impulse to the impulse until the instant of maximum compression* equals $(1 + e)/1$ (where $e \equiv$ *coefficient of restitution*), taking the powers of these impulses over the same velocities (first the preimpact v, and then the postimpact v''); that is, reasoning as in (e1–3) of ex. 4.6.7, we can write

$$M(v'' - v)v = (1 + e)M(v' - v)v, \tag{c}$$

$$M(v'' - v)v'' = (1 + e)M(v' - v)v''. \tag{d}$$

In terms of the *relative* kinetic energies, T_{01}, T_{12}, T_{02}, (a–d) can be rewritten, respectively, as

$$T' - T = -T_{01}, \qquad T'' - T' = T_{12}, \tag{e, f}$$

$$T'' - T'(1+e) + eT = T_{02} - (1+e)T_{01}, \tag{g}$$

$$T'' - T'(1+e) + eT = eT_{02} - (1+e)T_{12}. \tag{h}$$

Now:

(i) Eliminating the three relative kinetic energies, we obtain

$$T'' - T' = -e^2(T' - T); \tag{i}$$

that is, *the kinetic energy increase due to the restitution (or explosion) is e^2 times the kinetic energy decrease due to the compression.*

(ii) Eliminating the three T''s, we obtain

$$T_{01} = T_{02}/(1+e)^2 = T_{12}/e^2. \tag{j}$$

(iii) Finally, eliminating T', T_{01}, and T_{12}, we obtain

$$T'' - T' = -\big[(1-e)/(1+e)\big]T_{02}; \tag{k}$$

thus extending Carnot's "third" theorem to inelastic (but frictionless) systems [discussion after (4.6.1j)]. See also Whittaker (1937, pp. 234–235), for alternative derivations.

For an extension of the above theorems to the collision of *inelastic and rough* solids (i.e., case where, throughout the impact, the contacting surfaces slide on each other and the accompanying friction preserves its direction/sense), see, for example, Routh 1905(a), p. 310).

Example 4.6.12 *Gauss' Principle of Least Impulsive Compulsion (or Constraint)*. To examine the relation of Gauss' impulsive principle, (4.6.5a–f) with the above, let

- T: *actual preimpact* kinetic energy,
- T': *actual postimpact* kinetic energy, under the *existing constraints* and given impulses,
- T'': *comparison postimpact* kinetic energy, under *additional constraints* and given impulses,
- T''': *postimpact* kinetic energy under *zero constraints* (i.e., *free* motion) and given impulses.

Now, by Bertrand's theorem: (i) since the T'''-motion is *less* constrained than both the T'-motion and T''-motion, we will have (with some easily understood notations)

$$T''' = T' + T_{13} \ (\Rightarrow T''' > T') \qquad \text{and} \qquad T''' = T'' + T_{23} \ (\Rightarrow T''' > T''); \tag{a}$$

and (ii) since the T'-motion is *less* constrained than the T''-motion, we will have (fig. 4.31)

$$T' = T'' + T_{12} \ \Rightarrow \ T' > T''. \tag{b}$$

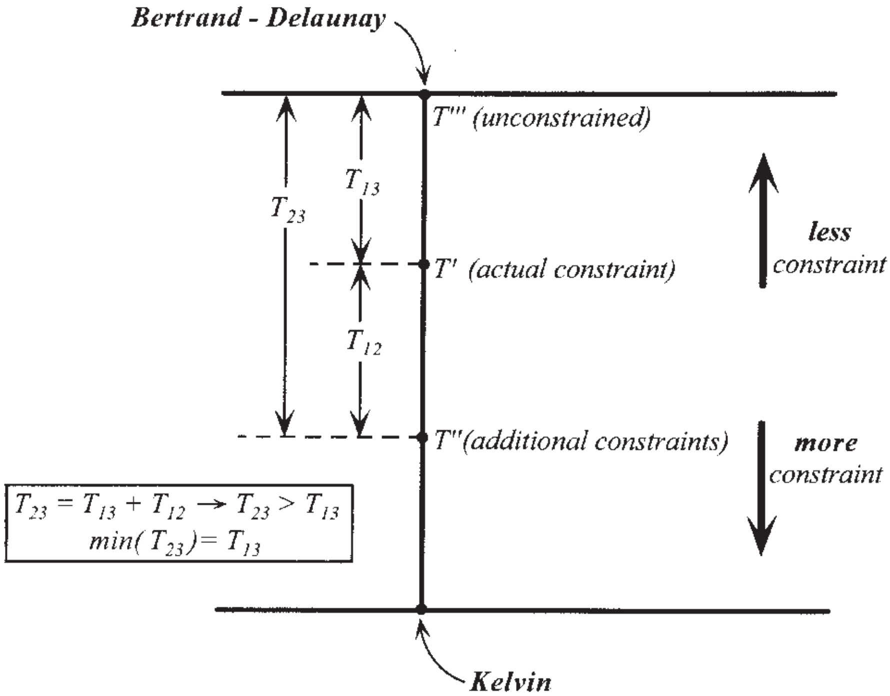

Figure 4.31 Geometrical construction toward the understanding of the impulsive Gauss theorem via the Bertrand–Delaunay theorem.

From (a–b) it follows at once that

$$T_{23} = T_{13} + T_{12} \;\Rightarrow\; T_{23} > T_{13}, \quad \text{i.e., } \min(T_{23}) = T_{13}; \tag{c}$$

and this, since

$$2T_{13} = M(v''' - v')(v''' - v') = M(v' - v''')(v' - v'''), \tag{d}$$

$$\Rightarrow\; \hat{Z} = T_{13} - \hat{Q}\,v' + \cdots \;\Rightarrow\; \Delta\hat{Z} = \Delta T_{13} > 0, \tag{e}$$

(where… "*Gauss constant" terms*) constitutes the impulsive Gauss(/Hertz) theorem: *Make* $2T_{13}$ *minimum for all variations of the* v'*;* the additional constraints are taken into account by attaching their Pfaffian forms to (d) via Lagrangean multipliers, as is well known from the finite motion case (chaps. 3, 5, 6) (see also Pars, 1965, pp. 239–241).

5

Nonlinear Nonholonomic Constraints

If I have had any success in mathematical physics, it is, I think, because I have been able to dodge mathematical difficulties.

(J. W. Gibbs, 1870s)

Experiment never responds with a ''yes'' to theory. At best, it says ''maybe'' and, most frequently, simply ''no.'' When it agrees with theory, this means ''maybe'' and, if it does not, the verdict is ''no.''

Einstein

Nowadays people who for their equations and other statements about nature claim exact and eternal verity are usually dismissed as cranks or lunatics. Nevertheless we lose something in this surrender to lawless uncertainty: Now we must tolerate the youth who blurts out the first, untutored, and uncritical thoughts that come into his head, calls them ''my model'' of something, and supports them by five or ten pounds of paper he calls ''my results,'' gotten by applying his model to some numerical instances which he has elaborated by use of the largest machine he could get hold of, and if you say to him, ''Your model violates NEWTON's laws,'' he replies ''Oh, I don't care about that, I tackle the physics directly, by computer.''

(Truesdell, 1987, p. 74)

Here, as in other important areas of analytical mechanics, English language references are far and few. For concurrent reading, we recommend:

(i) The masterful expositions of Hamel (1938; 1949, pp. 495–507, 524, 782–789);

(ii) The original articles of Johnsen (1936, 1937(a), (b), 1938, 1939, 1941);

(iii) The excellent textbooks/monographs/treatises of Mei (1985; 1987), Mei and Liu (1987), and Mei et al. (1991);

(iv) The compact and clear treatments of Novoselov (1966; 1979);

(v) Also, the fundamental monograph of Neimark and Fufaev (1967 and 1972, pp. 212–237), for a detailed treatment of the controversy over the realizability of nonlinear nonholonomic constraints (NNHC), and the validity of some related limiting processes. On this thorny issue, we, further, recommend the rare and very instructive paper of Bahar (1998);

(vi) *Journal of Applied Mathematics and Mechanics* (PMM, Soviet → Russian);

(vii) *Journal of Applied Mathematics and Mechanics* (Chinese).

5.1 INTRODUCTION

In what follows, we extend Lagrangean kinematics (chap. 2) and kinetics (chap. 3) to mechanical systems originally described by n Lagrangean coordinates $q \equiv (q_1, q_2, \ldots, q_n)$, and subsequently subjected to $m(<n)$ independent *nonlinear* and, generally, *nonintegrable* $\equiv$ *nonholonomic* constraints of the form

$$f_D(t, q, \dot{q}, \ddot{q}, \dddot{q}, \ldots) = 0 \qquad [D = 1, \ldots, m\,(<n)]. \tag{5.1.1}$$

[Here, as in the preceding chapters and the rest of the book, and unless specified otherwise, *Latin* indices range from 1 to n (= *number of original Lagrangean/global positional coordinates*); D (*dependent*), $D', D'', \ldots$ range from 1 to m (= *number of additional constraints, of any kind*); I (*independent*), I', I'', $\ldots$ range from $m+1$ to n; $f \equiv n - m$ (= *number of independent* δq's = *number of independent kinetic equations*).]

In this chapter we concentrate, almost exclusively, on nonlinear nonholonomic *velocity* constraints

$$\begin{aligned} &f_D(t, q, \dot{q}) = 0 \\ &rank(\partial f_D / \partial \dot{q}_k) = m, \qquad \text{in some domain of } t, q, \dot{q}; \end{aligned} \tag{5.1.2}$$

while the more general case (5.1.1) is described briefly later, and is treated more fully in chapter 6. But, once one understands the mechanics of the first-order case (5.1.2), the higher order case (5.1.1) follows without much additional difficulty.

A certain controversy has existed since the early 1910s regarding the *mechanical realizability* of constraints like (5.1.2), let alone (5.1.1), since all known velocity constraints, resulting out of the *passive* rolling among rigid bodies, are *linear/Pfaffian* in the $\dot{q}$'s (or the quasi velocities ω). However, there are important *physical* and *analytical* reasons for studying such nonlinear nonholonomic constraints (NNHC).

• Physically, we can view them as kinematico-physical conditions arising out of nonrolling sources; for example, servoconstraints (§3.17). Consider, for instance, a planar multiple pendulum consisting of n particles connected to a fixed point (say, a ceiling) and to each other via n identical and massless rods, oscillating under gravity; that is, a generalization of the well-known planar double pendulum (ex. 3.5.7). No ordinary springs and/or dampers are attached to the n pendulum joints, but the angles of the first m rods with the vertical, ϕ_D, satisfy the n control constraints $\phi_D = \phi_D(\dot{\phi}_{m+1}, \ldots, \dot{\phi}_n)$, where $\phi_D(\ldots)$ = *nonlinear* functions of their arguments; for example, $\phi_1 \sim (\dot{\phi}_2)^3$, in a double pendulum. These NNHC can be realized either by internal means at the relevant pendulum joints, or by external noncontact means (e.g., electromagnetic action).

• Analytically, as pointed out by Johnsen and Hamel (late 1930s–early 1940s), the general NNHC formalism can help simplify the solution of the equations of motion; that is, even if the constraints are ultimately Pfaffian (nonholonomic or holonomic), they may be analytically easier to handle when in nonlinear form.

REMARK

Some authors view first integrals of the equations of motion, known in advance, as NNHC-like constraints; for example, the integral of energy [either $T + V =$ *constant*, or $h \equiv T_2 + (V_0 - T_0) =$ *constant* (§3.9)], or of linear and angular momentum, or (5.1.2)-like combinations of them [and, conversely, consider (5.1.2)-like constraints as first integrals, not calculated but observed]; and use the formalism of this chapter to reduce the number of the kinetic equations of motion. However, there are *important qualitative differences* between, say, energy constraints and independent (5.1.2)-like constraints: (i) If energy conservation holds, then it is implicitly contained in the equations of motion, and therefore does not need to be imposed separately; whereas, clearly, if those independent constraints are not imposed, the motion will be markedly different. (ii) Energy conservation, being an integral of motion, represents a surface in velocity space, with the coordinates as parameters. Further, since that integral will be quadratic but, generally, nonhomogeneous in the velocities, the shape of the energy constraint surface will be an "ellipsoid" (three-dimensional or generalized), which, again, is different from the shape of, say, holonomic constraint surfaces. For example, for a single particle, the energy constraint surface is a sphere centered at the origin; and hence the particle velocity is codirectional to the sphere normal; while (§2.7), for a holonomic scleronomic constraint applied to that particle, the velocity vector is perpendicular to the constraint surface normal vector. (iii) Last, if a certain set of velocities satisfies a homogeneous holonomic constraint, so will their multiples by an arbitrary scalar constant; something that, clearly, does not happen with energy conservation constraints. [These remarks are due to Professor D. T. Greenwood (private communication, 1996).]

Be that as it may, we believe that, from a practical viewpoint, *familiarity with the general NNHC formalism helps us to understand better the underlying mathematical structure of the various kinematical and kinetic equations of the linear/Pfaffian theory*, chapters 2 and 3; that is, their similarities, differences, special cases, and so on. The reader may find such a nonutilitarian viewpoint quite beneficial.

5.2 KINEMATICS; THE NONLINEAR TRANSITIVITY EQUATIONS

System Kinematics

Equations (5.1.2) imply that out of the n $\dot{q}$'s, only $n-m$ are independent; or, equivalently, the n $\dot{q}$'s can be expressed in terms of $n-m$ independent (i.e., unconstrained) *velocity parameters*, or *nonlinear quasi velocities* $\omega_I \equiv (\omega_{m+1}, \ldots, \omega_n)$:

$$\dot{q}_k = F_k(t, q, \omega_I) \equiv \dot{q}_k(t, q, \omega_I). \tag{5.2.1}$$

In complete analogy with the linear/Pfaffian case (§2.9), we select the following natural, or "equilibrium," set of ω's (choice of Johnsen and Hamel, 1930s):

$$\omega_D \equiv f_D(t, q, \dot{q}) = 0 \qquad [D = 1, \ldots, m\ (< n)] \tag{5.2.2a}$$

$$\omega_I \equiv f_I(t, q, \dot{q}) \neq 0 \qquad [I = m+1, \ldots, n] \tag{5.2.2b}$$

$$\omega_{n+1} \equiv \omega_0 \equiv \dot{q}_{n+1} \equiv \dot{q}_0 = dt/dt = 1. \tag{5.2.2c}$$

The $n-m$ functions $f_I(\ldots)$ are arbitrary, except that when the equations of the system (5.2.2a, b) are solved for the n $\dot{q}$'s in terms of the n ω's $\to$ $n-m$ ω_I's, as in (5.2.1) [assuming, of course, that the Jacobian determinant of the matrix $(\partial f_k/\partial \dot{q}_l) \equiv (\partial \omega_k/\partial \dot{q}_l)$ does not vanish] and these values are inserted back into

(5.1.2), they satisfy them identically. Analytically, this translates to the compatibility conditions

$$\partial\omega_k/\partial q_l + \sum (\partial\omega_k/\partial\dot{q}_r)\,(\partial\dot{q}_r/\partial q_l) = 0, \tag{5.2.3a}$$

$$\partial\dot{q}_k/\partial q_l + \sum (\partial\dot{q}_k/\partial\omega_r)\,(\partial\omega_r/\partial q_l) = 0; \tag{5.2.3b}$$

and

$$\sum (\partial f_k/\partial\dot{q}_r)\,(\partial\dot{q}_r/\partial\omega_l) \equiv \sum (\partial\omega_k/\partial\dot{q}_r)\,(\partial\dot{q}_r/\partial\omega_l) = \partial\omega_k/\partial\omega_l = \delta_{kl}, \tag{5.2.4a}$$

$$\sum (\partial F_k/\partial\omega_r)\,(\partial\omega_r/\partial\dot{q}_l) \equiv \sum (\partial\dot{q}_k/\partial\omega_r)\,(\partial\omega_r/\partial\dot{q}_l) = \partial\dot{q}_k/\partial\dot{q}_l = \delta_{kl}. \tag{5.2.4b}$$

Now, in order to be able to either adjoin or embed (build in) the constraints (5.2.2a) into Lagrange's principle (LP, §3.2), which involves δq_k's and/or the *virtual variations of quasi coordinates*, or *virtual displacement parameters*, $\delta\theta_k$, where $d\theta_k/dt \equiv \omega_k$, we must define these $\delta\theta$'s anew and relate them to the δq's via *linear and homogeneous* transformations:

$$\delta q_k = \sum M_{kI}\delta\theta_I, \qquad M_{kI} = M_{kI}(t, q, \omega); \tag{5.2.5}$$

which would be the virtual counterpart of (5.2.1). But what are the coefficients M_{kI}? To conclude, from (5.2.1) and (5.2.2), that in the nonlinear case

$$\delta q_k = F_k(t, q, \delta\theta) \qquad \text{and} \qquad \delta\theta_k = f_k(t, q, \delta q) \tag{5.2.6}$$

would be meaningless, and unhelpful. So far, the sole requirement is, by (5.2.4a), as in the Pfaffian case,

$$\sum (\partial f_D/\partial\dot{q}_r)\,(\partial\dot{q}_r/\partial\omega_I) \equiv \partial f^*{}_D/\partial\omega_I = \delta_{DI} = 0, \tag{5.2.7}$$

where, and this is a general notation,

$$f_D = f_D(t, q, \dot{q}) = f_D[t, q, \dot{q}(t, q, \omega)] \equiv f_D{}^*(t, q, \omega) \equiv f_D{}^*. \tag{5.2.8}$$

It is shown in the next chapter (on "*Differential* Variational Principles") that the *physical requirement of compatibility* between the principles of Lagrange and Gauss, since there is only one mechanics, leads to the m (nontrivial and nonobvious)

"*Maurer–Appell–Chetaev–Johnsen–Hamel conditions*":

$$\sum (\partial f_D/\partial\dot{q}_k)\,\delta q_k = 0, \tag{5.2.9}$$

among the n δq's; instead of the mathematically correct (from the viewpoint of variational calculus), but *physically inconsistent*, result

$$\delta f_D = \sum [(\partial f_D/\partial q_k)\,\delta q_k + (\partial f_D/\partial\dot{q}_k)\,\delta(\dot{q}_k)] = 0. \tag{5.2.10}$$

To guarantee the identical satisfaction of (5.2.9), under (5.2.7), we introduce $n - m$ independent *virtual displacement parameters* $\delta\theta_I \equiv (\delta\theta_{m+1}, \ldots, \delta\theta_n)$, and set

$$\delta q_k = \sum (\partial\dot{q}_k/\partial\omega_I)\,\delta\theta_I. \tag{5.2.11}$$

Indeed, inserting (5.2.11) into (5.2.9), we obtain

$$0 = \sum (\partial f_D/\partial \dot{q}_k)\Big(\sum (\partial \dot{q}_k/\partial \omega_I)\, \delta\theta_I\Big)$$
$$= \sum\Big(\sum (\partial f_D/\partial \dot{q}_k)\,(\partial \dot{q}_k/\partial \omega_I)\Big)\, \delta\theta_I = \sum (\partial f^*{}_D/\partial \omega_I)\, \delta\theta_I, \qquad (5.2.12)$$

from which, since the $\delta\theta_I$ are independent, eqs. (5.2.7) follow. Then, the virtual form of the constraints (5.1.2), or (5.2.2a), is simply

$$\delta\theta_k = \sum (\partial \omega_k/\partial \dot{q}_l)\, \delta q_l: \qquad \delta\theta_D = 0, \qquad \delta\theta_I \neq 0. \qquad (5.2.13)$$

The Maggi-like representation (5.2.11) and its inverse (5.2.13) are fundamental to all subsequent NNHC developments; for Pfaffian constraints, clearly, they reduce to the forms given in chapter 2. The constraints (5.2.2a, b) establish, in configuration space, a one-to-one correspondence between the ω's and the kinematically admissible $\dot{q}$'s; while (5.2.11, 13) do the same thing for the virtual displacements δq and $\delta\theta$. [The nonvanishing Jacobian of (5.2.2a, b) is the nonvanishing determinant of (5.2.13): $|\partial \omega_k/\partial \dot{q}_l|$.]

From the preceding, we readily conclude that (to be used shortly):

$$\delta\dot{q}_k = \delta F_k = \sum \left[(\partial F_k/\partial q_l)\delta q_l + (\partial F_k/\partial \omega_l)\delta\omega_l\right], \qquad (5.2.14a)$$

$$\delta\dot{\theta}_k \equiv \delta\omega_k = \delta f_k = \sum \left[(\partial f_k/\partial q_l)\delta q_l + (\partial f_k/\partial \dot{q}_l)\delta\dot{q}_l\right]. \qquad (5.2.14b)$$

In what follows, for algebraic convenience, we shall allow the $\delta\theta$ and ω indices to run from 1 to n (like those of the δq's and $\dot{q}$'s). The satisfaction of the constraints $\delta\theta_D = 0, \omega_D = 0$ (and corresponding restrictions on those indices to run only over the independent range $m + 1, \ldots, n$) can be done at any time *after* all differentiations have been carried out. In that case, we may also use the helpful notation $(\ldots)_o \equiv (\ldots, \omega_D = 0, \ldots)$.

Particle Kinematics

So far we have involved *system* variables. Let us now express the above results in *particle*/elementary vector variables.

The (inertial) *virtual displacement, velocity*, and *acceleration* of a typical system particle, whose (inertial) position is expressed as $\boldsymbol{r} = \boldsymbol{r}(t, q)$, are, respectively,

(i)
$$\delta\boldsymbol{r} = \sum (\partial \boldsymbol{r}/\partial q_k)\, \delta q_k = \sum (\partial \boldsymbol{r}/\partial q_k)\, \Big(\sum (\partial \dot{q}_k/\partial \omega_l)\delta\theta_l\Big)$$
$$= \sum\Big(\sum (\partial \boldsymbol{r}/\partial q_k)\,(\partial \dot{q}_k/\partial \omega_l)\Big)\delta\theta_l$$
$$\equiv \sum (\partial \boldsymbol{r}^*/\partial \theta_l)\, \delta\theta_l \equiv \sum \boldsymbol{\varepsilon}_l\, \delta\theta_l \equiv \delta\boldsymbol{r}^*, \qquad (5.2.15)$$

where

$$\boldsymbol{\varepsilon}_l = \sum (\partial \boldsymbol{r}/\partial q_k)\,(\partial \dot{q}_k/\partial \omega_l) \equiv \sum (\partial \dot{q}_k/\partial \omega_l)\boldsymbol{e}_k, \qquad (5.2.16a)$$

$$\boldsymbol{e}_k = \sum (\partial \boldsymbol{r}^*/\partial \theta_l)\,(\partial \omega_l/\partial \dot{q}_k) \equiv \sum (\partial \omega_l/\partial \dot{q}_k)\boldsymbol{\varepsilon}_l; \qquad (5.2.16b)$$

that is,

$$\partial(\ldots)/\partial\theta_l \equiv \sum [\partial(\ldots)/\partial q_k]\,(\partial\dot{q}_k/\partial\omega_l), \tag{5.2.16c}$$

$$\partial(\ldots)/\partial q_k \equiv \sum [\partial(\ldots)/\partial\theta_l]\,(\partial\omega_l/\partial\dot{q}_k) \tag{5.2.16d}$$

[*nonlinear symbolic* (*i.e., nonvectorial/tensorial*) *quasi chain rules*],

(ii)

$$\begin{aligned} \boldsymbol{v} = \boldsymbol{v}(t, q, \dot{q}) = d\boldsymbol{r}/dt &= \sum (\partial\boldsymbol{r}/\partial q_k)\dot{q}_k + \partial\boldsymbol{r}/\partial t \\ &\equiv \sum \dot{q}_k(t, q, \omega)\boldsymbol{e}_k + \boldsymbol{e}_0 \qquad [t \equiv q_{n+1}], \qquad (5.2.17a) \\ &= \sum \omega_k(t, q, \dot{q})\boldsymbol{\varepsilon}_k + \boldsymbol{\varepsilon}_0 \equiv \boldsymbol{v}^*(t, q, \omega) \equiv \boldsymbol{v}^*, \qquad (5.2.17b) \end{aligned}$$

where $\boldsymbol{\varepsilon}_0$ is defined either by (5.2.17b) or, equivalently, extending (5.2.16a–d) for $q_k \to q_{n+1} \equiv t$,

$$\begin{aligned} \boldsymbol{\varepsilon}_0 \equiv \boldsymbol{\varepsilon}_{n+1} \equiv \partial\boldsymbol{r}/\partial\theta_{n+1} &\equiv \sum (\partial\boldsymbol{r}/\partial q_\alpha)\,(\partial\dot{q}_\alpha/\partial\omega_{n+1}) \qquad [\alpha = 1, \ldots, n+1] \\ &= \sum (\partial\boldsymbol{r}/\partial q_k)\,(\partial\dot{q}_k/\partial\omega_{n+1}) + (\partial\boldsymbol{r}/\partial t)\,(\partial\dot{q}_{n+1}/\partial\omega_{n+1}) \\ &= \sum (\partial\dot{q}_k/\partial\omega_{n+1})\boldsymbol{e}_k + \boldsymbol{e}_0 \\ &= \sum (\dot{q}_k\boldsymbol{e}_k - \omega_k\boldsymbol{\varepsilon}_k) + \boldsymbol{e}_0 \qquad [\text{by (5.2.17a, b)}] \\ &= \boldsymbol{e}_0 + \sum \dot{q}_k\boldsymbol{e}_k - \sum \omega_k\Big(\sum (\partial\dot{q}_l/\partial\omega_k)\boldsymbol{e}_l\Big) \\ &= \boldsymbol{e}_0 + \sum \Big(\dot{q}_k - \sum (\partial\dot{q}_k/\partial\omega_l)\omega_l\Big)\boldsymbol{e}_k; \qquad (5.2.17c) \end{aligned}$$

and, inversely,

$$\begin{aligned} \boldsymbol{e}_0 \equiv \boldsymbol{e}_{n+1} \equiv \partial\boldsymbol{r}/\partial t &\equiv \sum (\partial\boldsymbol{r}/\partial\theta_\alpha)\,(\partial\omega_\alpha/\partial\dot{q}_{n+1}) \qquad [\alpha = 1, \ldots, n+1] \\ &= \sum (\partial\boldsymbol{r}/\partial\theta_k)\,(\partial\omega_k/\partial\dot{q}_{n+1}) + (\partial\boldsymbol{r}/\partial\theta_{n+1})\,(\partial\omega_{n+1}/\partial\dot{q}_{n+1}) \\ &= \sum (\partial\omega_k/\partial\dot{q}_{n+1})\boldsymbol{\varepsilon}_k + \boldsymbol{\varepsilon}_0 \\ &= \sum (\omega_k\boldsymbol{\varepsilon}_k - \dot{q}_k\boldsymbol{e}_k) + \boldsymbol{\varepsilon}_0 \qquad [\text{by (5.2.17a, b)}] \\ &= \boldsymbol{\varepsilon}_0 + \sum \omega_k\boldsymbol{\varepsilon}_k - \sum \dot{q}_k\Big(\sum (\partial\omega_l/\partial\dot{q}_k)\boldsymbol{\varepsilon}_l\Big) \\ &= \boldsymbol{\varepsilon}_0 + \sum \Big(\omega_k - \sum (\partial\omega_k/\partial\dot{q}_l)\dot{q}_l\Big)\boldsymbol{\varepsilon}_k. \qquad (5.2.17d) \end{aligned}$$

The above suggest the following definitions, for any function $f^* = f^*(t, q, \omega)$ [in addition to (5.2.16c, d)],

$$\partial f^*/\partial\theta_{n+1} \equiv \sum (\partial f^*/\partial q_k)\Big(\dot{q}_k - \sum (\partial\dot{q}_k/\partial\omega_l)\omega_l\Big) + \partial f^*/\partial t; \tag{5.2.18a}$$

which, in the Pfaffian case, reduces to (2.9.32 ff.)

$$\partial f^*/\partial\theta_{n+1} = \sum (\partial f^*/\partial q_k)A_k + \partial f^*/\partial t \equiv \partial f^*/\partial(t) + \partial f^*/\partial t. \tag{5.2.18b}$$

In particular, for $f^* = q_r$ we find

$$\partial q_r/\partial\theta_s = \partial\dot{q}_r/\partial\omega_s, \tag{5.2.18c}$$

$$\partial q_r/\partial\theta_{n+1} = \partial\dot{q}_r/\partial\omega_{n+1} = \dot{q}_r - \sum(\partial\dot{q}_r/\partial\omega_l)\omega_l$$
$$\left[= \dot{q}_r - \sum A_{rl}\,\omega_l = A_r, \quad \text{in the Pfaffian case}\right]; \tag{5.2.18d}$$

and, inversely,

$$\partial\omega_k/\partial\dot{q}_{n+1} = \partial\theta_k/\partial t = \omega_k - \sum(\partial\omega_k/\partial\dot{q}_l)\dot{q}_l. \tag{5.2.18e}$$

(iii)
$$\begin{aligned} \boldsymbol{a} \equiv d\boldsymbol{v}/dt &= \sum(\partial\boldsymbol{v}/\partial\dot{q}_k)\ddot{q}_k + \cdots \\ &\qquad [\ldots \equiv \text{Terms containing neither } \ddot{q} \text{ nor } \dot{\omega}] \\ &= \sum(\partial\boldsymbol{v}/\partial\dot{q}_k)\left(\sum(\partial\dot{q}_k/\partial\omega_l)\dot{\omega}_l + \cdots\right) + \cdots \\ &= \sum\left(\sum(\partial\boldsymbol{v}/\partial\dot{q}_k)(\partial\dot{q}_k/\partial\omega_l)\right)\dot{\omega}_l + \cdots \\ &\equiv \sum(\partial\boldsymbol{v}^*/\partial\omega_l)\dot{\omega}_l + \cdots \\ &= \sum \boldsymbol{\varepsilon}_l\,\dot{\omega}_l + \cdots = \sum(\partial\boldsymbol{a}^*/\partial\dot{\omega}_l)\dot{\omega}_l + \cdots \\ &\equiv \boldsymbol{a}^*(t, q, \omega, \dot{\omega}) \equiv \boldsymbol{a}^*, \end{aligned} \tag{5.2.19a}$$

where, since $\boldsymbol{v}(t, q, \dot{q}) = \boldsymbol{v}^*(t, q, \omega)$,

$$\partial\boldsymbol{v}^*/\partial\omega_l = \sum(\partial\boldsymbol{v}/\partial\dot{q}_k)(\partial\dot{q}_k/\partial\omega_l), \quad \text{i.e., (5.2.16a, b)} \quad \boldsymbol{\varepsilon}_l = \sum \boldsymbol{e}_k(\partial\dot{q}_k/\partial\omega_l); \tag{5.2.19b}$$

which is a vectorial transformation equation, and not some chain rule, like (5.2.16c, d).

The preceding results readily lead to the fundamental, and purely kinematical, particle–system identities

Holonomic variables: $\quad \partial\boldsymbol{r}/\partial q_k = \partial\boldsymbol{v}/\partial\dot{q}_k = \partial\boldsymbol{a}/\partial\ddot{q}_k = \cdots = \boldsymbol{e}_k, \qquad (5.2.20a)$

Nonholonomic variables: $\quad \partial\boldsymbol{r}^*/\partial\theta_k \equiv \partial\boldsymbol{v}^*/\partial\omega_k = \partial\boldsymbol{a}^*/\partial\dot{\omega}_k = \cdots = \boldsymbol{\varepsilon}_k; \qquad (5.2.20b)$

and their system counterparts

$$\partial q_k/\partial\theta_l \equiv \partial\dot{q}_k/\partial\omega_l = \partial\ddot{q}_k/\partial\dot{\omega}_l = \cdots, \tag{5.2.20c}$$

$$\partial\theta_l/\partial q_k \equiv \partial\omega_l/\partial\dot{q}_k = \partial\dot{\omega}_l/\partial\ddot{q}_k = \cdots. \tag{5.2.20d}$$

With the help of the above, next, we obtain the following basic kinematical result: applying symbolic and real chain rule to $\boldsymbol{v} = \boldsymbol{v}(t, q, \dot{q}) = \boldsymbol{v}^*(t, q, \omega) = \boldsymbol{v}^*$, we find, successively,

(a)
$$\begin{aligned}\partial\boldsymbol{v}^*/\partial\theta_k &= \sum (\partial\boldsymbol{v}^*/\partial q_l)\,(\partial\dot{q}_l/\partial\omega_k)\\ &= \sum \Big[\partial\boldsymbol{v}/\partial q_l + \sum (\partial\boldsymbol{v}/\partial\dot{q}_r)\,(\partial\dot{q}_r/\partial q_l)\Big]\,(\partial\dot{q}_l/\partial\omega_k)\\ &= \sum (\partial\boldsymbol{v}/\partial q_l)\,(\partial\dot{q}_l/\partial\omega_k) + \sum (\partial\boldsymbol{v}/\partial\dot{q}_l)\,(\partial\dot{q}_l/\partial\theta_k), \qquad (5.2.21a)\end{aligned}$$

(b)
$$\begin{aligned}d/dt(\partial\boldsymbol{r}^*/\partial\theta_k) &= d/dt(\partial\boldsymbol{v}^*/\partial\omega_k) = d/dt\Big(\sum (\partial\boldsymbol{v}/\partial\dot{q}_l)\,(\partial\dot{q}_l/\partial\omega_k)\Big)\\ &= \sum \big[\,d/dt\,(\partial\boldsymbol{v}/\partial\dot{q}_l)\big]\,(\partial\dot{q}_l/\partial\omega_k) + \sum (\partial\boldsymbol{v}/\partial\dot{q}_l)\,\big[\,d/dt(\partial\dot{q}_l/\partial\omega_k)\big]. \qquad (5.2.21b)\end{aligned}$$

Therefore, subtracting (5.2.21a, b) side by side, while recalling (5.2.19b), we get

$$\begin{aligned}\gamma_k &\equiv E_k{}^*(\boldsymbol{v}^*) \equiv d/dt(\partial\boldsymbol{v}^*/\partial\omega_k) - \partial\boldsymbol{v}^*/\partial\theta_k \equiv d\boldsymbol{\varepsilon}_k/dt - \partial\boldsymbol{v}^*/\partial\theta_k\\ &= \sum \big[d/dt(\partial\boldsymbol{v}/\partial\dot{q}_l) - \partial\boldsymbol{v}/\partial q_l\big]\,(\partial\dot{q}_l/\partial\omega_k)\\ &\qquad\qquad + \sum \big[d/dt(\partial\dot{q}_l/\partial\omega_k) - \partial\dot{q}_l/\partial\theta_k\big]\,(\partial\boldsymbol{v}/\partial\dot{q}_l)\\ &= \sum E_l(\boldsymbol{v})\,(\partial\dot{q}_l/\partial\omega_k) + \sum E_k{}^*(\dot{q}_l)\,(\partial\boldsymbol{v}/\partial\dot{q}_l)\\ &= \boldsymbol{0} + \sum E_k{}^*(\dot{q}_l)\,(\partial\boldsymbol{v}/\partial\dot{q}_l)\\ &\quad [E_l(\boldsymbol{v}) = \boldsymbol{0},\ \text{since the } q\text{'s are holonomic coordinates (§2.9)}]\\ &= \sum E_k{}^*(\dot{q}_l)\boldsymbol{e}_l = \sum E_k{}^*(\dot{q}_l)\,\Big(\sum (\partial\omega_s/\partial\dot{q}_l)\boldsymbol{\varepsilon}_s\Big), \qquad (5.2.21c)\end{aligned}$$

or finally, and compactly (and in anticipation of later results),

$$\begin{aligned}\gamma_k \equiv E_k{}^*(\boldsymbol{v}^*) &= \sum V^l{}_k\boldsymbol{e}_l = \sum\sum \big[(\partial\omega_s/\partial\dot{q}_l)V^l{}_k\big]\boldsymbol{\varepsilon}_s\\ &= -\sum\sum \big[(\partial\dot{q}_l/\partial\omega_s)H^s{}_k\big]\boldsymbol{e}_l = -\sum H^s{}_k\boldsymbol{\varepsilon}_s:\end{aligned}$$

Nonholonomic deviation; (5.2.21d)

where

$$V^l{}_k \equiv d/dt(\partial\dot{q}_l/\partial\omega_k) - \partial\dot{q}_l/\partial\theta_k \equiv E_k{}^*(\dot{q}_l):$$

Nonlinear Voronets–Chaplygin coefficients, (5.2.21e)

$$H^s{}_k \equiv -\sum (\partial\omega_s/\partial\dot{q}_l)V^l{}_k:$$

Nonlinear Hamel coefficients, (5.2.21f)

$$\Big\{\Leftrightarrow V^l{}_k = -\sum (\partial\dot{q}_l/\partial\omega_s)H^s{}_k \qquad [\text{using (5.2.4a, b)}]\Big\}; \qquad (5.2.21g)$$

also (see prob. 5.2.1, below),

$$H^k{}_s \equiv \sum (\partial\dot{q}_l/\partial\omega_s)\,\big[(\partial\omega_k/\partial\dot{q}_l)^{\cdot} - \partial\omega_k/\partial q_l\big] \equiv \sum (\partial\dot{q}_l/\partial\omega_s)\,E_l(\omega_k). \qquad (5.2.21h)$$

[Clearly, since $|\partial\omega_k/\partial\dot{q}_l| \neq 0$, if the $H^s{}_k$ vanish, so do the $V^s{}_k$; and vice versa.]

These *nonintegrability* relations [actually due to Johnsen and Hamel (in the late 1930s)] result from the nonholonomicity of the "coordinates" θ, and *have nothing to do with constraints*. Further, as these definitions show, in $V^l{}_k$, l is *holonomic*, and k is *nonholonomic*; while, in $H^l{}_k$, both l and k are *nonholonomic*; that is, $V^l{}_k$ is *mixed*, while $H^l{}_k$ is purely nonholonomic.

The Nonlinear Transitivity Equations

By $d/dt(\ldots)$-differentiating (5.2.13), $\delta(\ldots)$-varying (5.2.2a–c) [i.e., (5.2.14b)], and then subtracting side by side, we find, successively,

$$
\begin{aligned}
d/dt(\delta\theta_k) - \delta(d\theta_k/dt) &\equiv (\delta\theta_k)^{\cdot} - \delta\omega_k \\
&= d/dt\Big(\sum (\partial\omega_k/\partial\dot{q}_l)\,\delta q_l\Big) - \delta\omega_k(t, q, \dot{q}) \\
&= \sum \left[(\partial\omega_k/\partial\dot{q}_l)^{\cdot}\,\delta q_l + (\partial\omega_k/\partial\dot{q}_l)\,(\delta q_l)^{\cdot}\right] \\
&\quad - \sum \left[(\partial\omega_k/\partial q_l)\,\delta q_l + (\partial\omega_k/\partial\dot{q}_l)\,\delta(\dot{q}_l)\right] \\
&= \sum (\partial\omega_k/\partial\dot{q}_l)\,[(\delta q_l)^{\cdot} - \delta(\dot{q}_l)] \\
&\quad + \sum \left[(\partial\omega_k/\partial\dot{q}_l)^{\cdot} - \partial\omega_k/\partial q_l\right] \delta q_l;
\end{aligned}
$$

that is, [recalling (5.2.11) and invoking (5.2.21e–h)]

$$
\begin{aligned}
(\delta\theta_k)^{\cdot} - \delta\omega_k &= \sum (\partial\omega_k/\partial\dot{q}_l)\,[(\delta q_l)^{\cdot} - \delta(\dot{q}_l)] \\
&\quad + \sum\sum \left[(\partial\omega_k/\partial\dot{q}_l)^{\cdot} - \partial\omega_k/\partial q_l\right] (\partial\dot{q}_l/\partial\omega_r)\,\delta\theta_r \\
&= \sum (\partial\omega_k/\partial\dot{q}_l)\,[(\delta q_l)^{\cdot} - \delta(\dot{q}_l)] \\
&\quad - \sum\sum \left[(\partial\dot{q}_s/\partial\omega_r)^{\cdot} - \partial\dot{q}_s/\partial\theta_r\right] (\partial\omega_k/\partial\dot{q}_s)\,\delta\theta_r \\
&= \sum (\partial\omega_k/\partial\dot{q}_l)\,\left[(\delta q_l)^{\cdot} - \delta(\dot{q}_l)\right] \\
&\quad - \sum\sum\sum \left[(\partial\dot{q}_s/\partial\omega_r)^{\cdot} - \partial\dot{q}_s/\partial\theta_r\right] (\partial\omega_k/\partial\dot{q}_s)\,(\partial\omega_r/\partial\dot{q}_l)\,\delta q_l,
\end{aligned}
\tag{5.2.22a}
$$

or, compactly,

$$
\begin{aligned}
(\delta\theta_k)^{\cdot} - \delta\omega_k &= \sum (\partial\omega_k/\partial\dot{q}_l)\,[(\delta q_l)^{\cdot} - \delta(\dot{q}_l)] + \sum E_l(\omega_k)\,\delta q_l \\
&= \sum (\partial\omega_k/\partial\dot{q}_l)\,[(\delta q_l)^{\cdot} - \delta(\dot{q}_l)] + \sum H^k{}_r\,\delta\theta_r \\
&= \sum (\partial\omega_k/\partial\dot{q}_l)\,[(\delta q_l)^{\cdot} - \delta(\dot{q}_l)] + \sum\sum H^k{}_r(\partial\omega_r/\partial\dot{q}_l)\,\delta q_l \\
&= \sum (\partial\omega_k/\partial\dot{q}_l)\,[(\delta q_l)^{\cdot} - \delta(\dot{q}_l)] - \sum\sum E_r{}^*(\dot{q}_l)\,(\partial\omega_k/\partial\dot{q}_l)\,\delta\theta_r \\
&= \sum (\partial\omega_k/\partial\dot{q}_l)\,[(\delta q_l)^{\cdot} - \delta(\dot{q}_l)] - \sum\sum V^l{}_r\,(\partial\omega_k/\partial\dot{q}_l)\,\delta\theta_r \\
&= \sum (\partial\omega_k/\partial\dot{q}_l)\,[(\delta q_l)^{\cdot} - \delta(\dot{q}_l)] \\
&\quad - \sum\sum\sum (\partial\omega_k/\partial\dot{q}_s)\,(\partial\omega_r/\partial\dot{q}_l)\,V^s{}_r\,\delta q_l.
\end{aligned}
\tag{5.2.22b}
$$

[Under the m constraints $\delta\theta_D = 0, \delta\theta_r \to \delta\theta_I$ $(r \to I = m+1, \ldots, n)$.]

Similarly, $d/dt(\ldots)$-differentiating (5.2.11), $\delta(\ldots)$-varying (5.2.1) [i.e., (5.2.14a)], with $I \to r = 1, \ldots, n$, and then subtracting side by side, we find, successively,

$$\begin{aligned} d/dt(\delta q_l) - \delta(dq_l/dt) &\equiv (\delta q_l)^{\cdot} - \delta(\dot{q}_l) \\ &= d/dt\Big(\sum (\partial \dot{q}_l/\partial \omega_k)\,\delta\theta_k\Big) - \delta\dot{q}_l(t, q, \omega) \\ &= \sum \big[(\partial \dot{q}_l/\partial \omega_k)^{\cdot}\,\delta\theta_k + (\partial \dot{q}_l/\partial \omega_k)\,(\delta\theta_k)^{\cdot}\big] \\ &\quad - \sum \big[(\partial \dot{q}_l/\partial q_k)\,\delta q_k + (\partial \dot{q}_l/\partial \omega_k)\,\delta\omega_k\big] \\ &= \sum \big[(\partial \dot{q}_l/\partial \omega_k)^{\cdot}\,\delta\theta_k + (\partial \dot{q}_l/\partial \omega_k)\,(\delta\theta_k)^{\cdot}\big] \\ &\quad - \sum \big[(\partial \dot{q}_l/\partial \theta_k)\,\delta\theta_k + (\partial \dot{q}_l/\partial \omega_k)\,\delta\omega_k\big] \\ &= \sum (\partial \dot{q}_l/\partial \omega_k)\,[(\delta\theta_k)^{\cdot} - \delta\omega_k] \\ &\quad + \sum \big[(\partial \dot{q}_l/\partial \omega_k)^{\cdot} - \partial \dot{q}_l/\partial \theta_k\big]\,\delta\theta_k; \end{aligned}$$

that is, [recalling (5.2.13) and invoking (5.2.21e–h)]

$$\begin{aligned} (\delta q_l)^{\cdot} - \delta(\dot{q}_l) &= \sum (\partial \dot{q}_l/\partial \omega_k)\,[(\delta\theta_k)^{\cdot} - \delta\omega_k] \\ &\quad + \sum\sum \big[(\partial \dot{q}_l/\partial \omega_k)^{\cdot} - \partial \dot{q}_l/\partial \theta_k\big]\,(\partial \omega_k/\partial \dot{q}_s)\,\delta q_s \\ &= \sum (\partial \dot{q}_l/\partial \omega_k)\,[(\delta\theta_k)^{\cdot} - \delta\omega_k] \\ &\quad - \sum\sum \big[(\partial \omega_k/\partial \dot{q}_s)^{\cdot} - \partial \omega_k/\partial q_s\big]\,(\partial \dot{q}_l/\partial \omega_k)\,\delta q_s \\ &= \sum (\partial \dot{q}_l/\partial \omega_k)\,[(\delta\theta_k)^{\cdot} - \delta\omega_k] \\ &\quad - \sum\sum\sum \big[(\partial \omega_k/\partial \dot{q}_s)^{\cdot} - \partial \omega_k/\partial q_s\big]\,(\partial \dot{q}_l/\partial \omega_k)\,(\partial \dot{q}_s/\partial \omega_r)\,\delta\theta_r, \end{aligned} \tag{5.2.23a}$$

or, compactly (with some dummy-index changes),

$$\begin{aligned} (\delta q_l)^{\cdot} - \delta(\dot{q}_l) &= \sum (\partial \dot{q}_l/\partial \omega_k)\,[(\delta\theta_k)^{\cdot} - \delta\omega_k] + \sum E_k{}^*(\dot{q}_l)\,\delta\theta_k \\ &\equiv \sum (\partial \dot{q}_l/\partial \omega_k)\,[(\delta\theta_k)^{\cdot} - \delta\omega_k] + \sum V^l{}_k\,\delta\theta_k \\ &= \sum (\partial \dot{q}_l/\partial \omega_k)\,[(\delta\theta_k)^{\cdot} - \delta\omega_k] + \sum\sum E_k{}^*(\dot{q}_l)\,(\partial \omega_k/\partial \dot{q}_s)\,\delta q_s \\ &\equiv \sum (\partial \dot{q}_l/\partial \omega_k)\,[(\delta\theta_k)^{\cdot} - \delta\omega_k] + \sum\sum V^l{}_k\,(\partial \omega_k/\partial \dot{q}_s)\,\delta q_s \\ &= \sum (\partial \dot{q}_l/\partial \omega_k)\,[(\delta\theta_k)^{\cdot} - \delta\omega_k] \\ &\quad - \sum\sum\sum (\partial \dot{q}_l/\partial \omega_r)\,(\partial \omega_k/\partial \dot{q}_s) H^r{}_k\,\delta q_s \\ &= \sum (\partial \dot{q}_l/\partial \omega_k)\,[(\delta\theta_k)^{\cdot} - \delta\omega_k] - \sum\sum (\partial \dot{q}_l/\partial \omega_r) H^r{}_k\,\delta\theta_k. \end{aligned} \tag{5.2.23b}$$

[Under the m constraints $\delta\theta_D = 0, \delta\theta_k \to \delta\theta_I$ $(k \to I = m+1, \ldots, n)$.]

As the above show, and since $|\partial \omega_k/\partial \dot{q}_l| \neq 0$, if the $H^r{}_k$ vanish, so do the $V^r{}_k$; and vice versa. The relations between the $V^l{}_k$ and $H^l{}_k$ can also be found from the equivalence of the transitivity equations (5.2.22) and (5.2.23). Indeed, substituting

$(\delta q_l)^{\cdot} - \delta(\dot{q}_l)$ from (5.2.23a, b) into (5.2.22a, b), simplifying, and invoking (5.2.4a), we get

$$\sum\Big(\sum (\partial\omega_k/\partial\dot{q}_l)\, V^l_{\ r} + H^k_{\ r}\Big)\,\delta\theta_r = 0, \tag{5.2.24}$$

from which we obtain the earlier (5.2.21f, g).

Example 5.2.1 *Alternative Derivation of the Nonintegrability Relations (5.2.21c,d).* We have, successively,

$$\begin{aligned}
\gamma_k &\equiv E_k{}^*(\boldsymbol{v}^*) \equiv d/dt(\partial\boldsymbol{v}^*/\partial\omega_k) - \partial\boldsymbol{v}^*/\partial\theta_k \equiv d\boldsymbol{\varepsilon}_k/dt - \partial\boldsymbol{v}^*/\partial\theta_k\\
&= d/dt\Big(\sum (\partial\dot{q}_l/\partial\omega_k)\boldsymbol{e}_l\Big) - \sum (\partial\boldsymbol{v}^*/\partial q_l)\,(\partial\dot{q}_l/\partial\omega_k)\\
&= \sum (\partial\dot{q}_l/\partial\omega_k)^{\cdot}\boldsymbol{e}_l + \sum (\partial\dot{q}_l/\partial\omega_k)\,(d\boldsymbol{e}_l/dt)\\
&\quad - \sum \Big[(\partial/\partial q_l)\Big(\sum \dot{q}_r\,\boldsymbol{e}_r + \boldsymbol{e}_0\Big)\Big]\,(\partial\dot{q}_l/\partial\omega_k) \qquad [\text{since } \boldsymbol{v}^* = \boldsymbol{v}]\\
&= \sum (\partial\dot{q}_l/\partial\omega_k)^{\cdot}\,\boldsymbol{e}_l + \sum (\partial\dot{q}_l/\partial\omega_k)\,(d\boldsymbol{e}_l/dt)\\
&\quad - \sum\Big\{\sum\ \big[(\partial\dot{q}_r/\partial q_l)\boldsymbol{e}_r + \dot{q}_r(\partial\boldsymbol{e}_r/\partial q_l)\big] + \partial\boldsymbol{e}_0/\partial q_l\Big\}\,(\partial\dot{q}_l/\partial\omega_k)\\
&= \sum (\partial\dot{q}_l/\partial\omega_k)^{\cdot}\boldsymbol{e}_l + \sum (\partial\dot{q}_l/\partial\omega_k)\,(d\boldsymbol{e}_l/dt)\\
&\quad - \sum\sum (\partial\dot{q}_r/\partial q_l)\,(\partial\dot{q}_l/\partial\omega_k)\boldsymbol{e}_r - \sum\sum \dot{q}_r(\partial\dot{q}_l/\partial\omega_k)(\partial\boldsymbol{e}_r/\partial q_l)\\
&\quad - \sum (\partial\dot{q}_l/\partial\omega_k)\,(\partial\boldsymbol{e}_0/\partial q_l)\\
&= \sum (\partial\dot{q}_l/\partial\omega_k)^{\cdot}\boldsymbol{e}_l + \sum (\partial\dot{q}_l/\partial\omega_k)\,(d\boldsymbol{e}_l/dt)\\
&\quad - \sum\Big(\sum \dot{q}_r(\partial\boldsymbol{e}_l/\partial q_r) + (\partial\boldsymbol{e}_l/\partial t)\Big)\,(\partial\dot{q}_l/\partial\omega_k)\\
&\quad - \sum (\partial\dot{q}_r/\partial\theta_k)\boldsymbol{e}_r\\
&\quad [\text{since the } q\text{'s are holonomic: } \partial\boldsymbol{e}_r/\partial q_l = \partial\boldsymbol{e}_l/\partial q_r,\ \partial\boldsymbol{e}_0/\partial q_l = \partial\boldsymbol{e}_l/\partial t]\\
&= \sum (\partial\dot{q}_l/\partial\omega_k)^{\cdot}\boldsymbol{e}_l + \sum (\partial\dot{q}_l/\partial\omega_k)\,(d\boldsymbol{e}_l/dt)\\
&\quad - \sum (\partial\dot{q}_l/\partial\omega_k)\,(d\boldsymbol{e}_l/dt) - \sum (\partial\dot{q}_r/\partial\theta_k)\boldsymbol{e}_r\\
&\quad [\text{the } \textit{second} \text{ and } \textit{third} \text{ sums cancel; and we replace } r \text{ with } l \text{ in the } \textit{last} \text{ term}]\\
&= \sum\ \big[(\partial\dot{q}_l/\partial\omega_k)^{\cdot} - \partial\dot{q}_l/\partial\theta_k\big]\boldsymbol{e}_l; \qquad\qquad \text{(a)}
\end{aligned}$$

that is, eqs. (5.2.21c, d), as before.

Problem 5.2.1 Show, with the help of (5.2.4a, b), that (5.2.21f, g)

$$H^k_{\ r} = -\sum (\partial\omega_k/\partial\dot{q}_l)V^l_{\ r} \ \Leftrightarrow\ V^l_{\ r} = -\sum (\partial\dot{q}_l/\partial\omega_k)H^k_{\ r} \tag{a}$$

lead to the following useful kinematical identities:

$$E_l(\omega_k) = -\sum\sum (\partial\omega_r/\partial\dot{q}_l)\,(\partial\omega_k/\partial\dot{q}_s) E_r{}^*(\dot{q}_s), \tag{b}$$

$$E_r{}^*(\dot{q}_s) = -\sum\sum (\partial\dot{q}_l/\partial\omega_r)\,(\partial\dot{q}_s/\partial\omega_k) E_l(\omega_k)$$
$$\left[\text{i.e., } V^s{}_r = -\sum (\partial\dot{q}_s/\partial\omega_k) H^k{}_r\right]. \tag{c}$$

Problem 5.2.2 Show that in the *Pfaffian* case (§2.9) — that is, when $\omega_l \equiv \sum a_{ld}\dot{q}_d + a_l$ — the nonlinear Hamel coefficients

$$H^l{}_s \equiv \sum \left[(\partial\omega_l/\partial\dot{q}_d)^{\cdot} - \partial\omega_l/\partial q_d\right](\partial\dot{q}_d/\partial\omega_s) \equiv \sum (\partial\dot{q}_d/\partial\omega_s) E_d(\omega_l) \tag{a}$$

reduce to their Pfaffian counterparts (with $\alpha = 1, \ldots, n+1$; and the rest of the notations of §2.10):

$$h^l{}_s = \sum \gamma^l{}_{s\alpha}\,\omega_\alpha = \sum \gamma^l{}_{sr}\,\omega_r + \gamma^l{}_{s,n+1}. \tag{b}$$

Problem 5.2.3 Show that, for a general function $f^* = f^*(t, q, \omega)$, the following *noncommutativity* relations hold:

$$\begin{aligned}
&\partial/\partial\theta_l\,(\partial f^*/\partial\theta_k) - \partial/\partial\theta_k\,(\partial f^*/\partial\theta_l)\\
&\quad = \sum\sum\sum \left[(\partial^2\dot{q}_d/\partial q_s\partial\omega_k)\,(\partial\dot{q}_s/\partial\omega_l)\right.\\
&\qquad\qquad \left. - (\partial^2\dot{q}_d/\partial q_s\partial\omega_l)\,(\partial\dot{q}_s/\partial\omega_k)\right](\partial\omega_p/\partial\dot{q}_d)\,(\partial f^*/\partial\theta_p).
\end{aligned} \tag{a}$$

Then show that in the Pfaffian case (§2.9); that is,

$$\omega_s \equiv \sum a_{sd}\,\dot{q}_d + a_s, \qquad \dot{q}_d = \sum A_{ds}\,\omega_s + A_d, \tag{b}$$

eq. (a) reduces to the noncommutativity equation (2.10.20).

Problem 5.2.4 (i) Show that in the Pfaffian case (§2.9), the nonlinear coefficients

$$E_l(\omega_k) \equiv (\partial\omega_k/\partial\dot{q}_l)^{\cdot} - \partial\omega_k/\partial q_l \tag{a}$$

reduce to

$$\sum (\partial a_{kl}/\partial q_r - \partial a_{kr}/\partial q_l)\dot{q}_r + (\partial a_{kl}/\partial t - \partial a_k/\partial q_l). \tag{b}$$

(ii) Hence show that, in such a case, $E_l(\omega_k) \equiv 0$ translates to the exactness conditions:

$$\partial a_{kl}/\partial q_r = \partial a_{kr}/\partial q_l \qquad \text{and} \qquad \partial a_{kl}/\partial t = \partial a_k/\partial q_l. \tag{c}$$

(iii) Similarly, show that in the Pfaffian case — that is, $\dot{q}_l = \sum A_{lk}\omega_k + A_l$ — the conditions

$$V^l{}_k \equiv E_k{}^*(\dot{q}_l) \equiv (\partial\dot{q}_l/\partial\omega_k)^{\cdot} - \partial\dot{q}_l/\partial\theta_k \equiv 0 \tag{d}$$

become

$$\partial A_{lk}/\partial q_r = \partial A_{lr}/\partial q_k \qquad \text{and} \qquad \partial A_{lk}/\partial t = \partial A_l/\partial q_k. \tag{e}$$

Example 5.2.2 *Special Choices of the Quasi Velocities, and Forms of the Constraints.* Frequently we choose, as in the Pfaffian case, the *last* $n - m$ $\dot{q}$'s as the *independent* quasi velocities. Then (5.2.2a, b) specialize to

$$\omega_D \equiv f_D(t, q, \dot{q}) = 0, \tag{a}$$

$$\omega_I \equiv f_I(t, q, \dot{q}) = \dot{q}_I \neq 0. \tag{b}$$

Solving (a) for the *first* m (dependent) $\dot{q}$'s $\to \dot{q}_D$ in terms of the remaining $n - m$ (independent) $\dot{q}$'s $\to \dot{q}_I$, assuming that $\partial(f_1, \ldots, f_m)/\partial(\dot{q}_1, \ldots, \dot{q}_m) \neq 0$, we obtain

$$\dot{q}_D = \dot{q}_D(t, q, \dot{q}_I) \equiv \phi_D(t, q, \dot{q}_I). \tag{c}$$

System Quantities

In view of the above, the system virtual displacement equation (5.2.11) specializes to

$$\delta q_k\colon \qquad \delta q_D = \sum (\partial\phi_D/\partial\dot{q}_I)\,\delta q_I, \tag{d}$$

$$\delta q_I = \sum (\partial\dot{q}_I/\partial\dot{q}_{I'})\,\delta q_{I'} = \sum (\delta_{II'})\,\delta q_{I'} = \delta q_I; \tag{e}$$

while the corresponding constraint conditions (5.2.9) become

$$\begin{aligned} 0 &= \sum (\partial f_D/\partial\dot{q}_k)\,\delta q_k = \sum \left[(\partial f_D/\partial\dot{q}_{D'})\,\delta q_{D'} + (\partial f_D/\partial\dot{q}_I)\,\delta q_I\right] \\ &= \sum \left\{(\partial f_D/\partial\dot{q}_{D'})\left(\sum (\partial\phi_{D'}/\partial\dot{q}_I)\,\delta q_I\right) + (\partial f_D/\partial\dot{q}_I)\,\delta q_I\right\} \\ &= \sum \left[\partial f_D/\partial\dot{q}_I + \sum (\partial f_D/\partial\dot{q}_{D'})\,(\partial\phi_{D'}/\partial\dot{q}_I)\right]\delta q_I \\ &\equiv \sum [\partial f_D/\partial(\dot{q}_I)]\,\delta q_I. \end{aligned} \tag{f}$$

Particle Quantities

The particle virtual displacement equation (5.2.15) reduces to

$$\begin{aligned} \delta\mathbf{r} &= \sum (\partial\mathbf{r}/\partial q_k)\,\delta q_k = \sum (\partial\mathbf{r}/\partial q_D)\,\delta q_D + \sum (\partial\mathbf{r}/\partial q_I)\,\delta q_I \\ &= \sum (\partial\mathbf{r}/\partial q_D)\left(\sum (\partial\phi_D/\partial\dot{q}_I)\,\delta q_I\right) + \sum (\partial\mathbf{r}/\partial q_I)\,\delta q_I \\ &\equiv \sum [\partial\mathbf{r}/\partial(q_I)]\,\delta q_I \equiv \sum \boldsymbol{B}_I\,\delta q_I, \end{aligned} \tag{g}$$

where

$$\begin{aligned} \boldsymbol{B}_I &\equiv \partial\mathbf{r}/\partial(q_I) \equiv \partial\mathbf{r}/\partial q_I + \sum (\partial\mathbf{r}/\partial q_D)\,(\partial\phi_D/\partial\dot{q}_I) \\ &\equiv \boldsymbol{e}_I + \sum (\partial\phi_D/\partial\dot{q}_I)\boldsymbol{e}_D, \end{aligned}$$

and, in general,

$$\partial \boldsymbol{B}_I/\partial q_{I'} \neq \partial \boldsymbol{B}_{I'}/\partial q_I \qquad \text{(i.e., the } \boldsymbol{B}_I \text{ are } nongradient \text{ vectors);} \tag{h}$$

which is a specialization of the quasi chain rule (5.2.16c) for $\ldots \to \boldsymbol{r}$ and $\theta_I \to (q_I)$.

Similarly, we can show that

$$\boldsymbol{v} \to \boldsymbol{v}_o = \sum \boldsymbol{B}_I \dot{q}_I + \textit{No other } \dot{q} \textit{ terms}, \tag{i}$$

$$\boldsymbol{a} \to \boldsymbol{a}_o = \sum \boldsymbol{B}_I \ddot{q}_I + \textit{No other } \ddot{q} \textit{ terms}; \tag{j}$$

and hence

$$\partial \boldsymbol{r}/\partial(q_I) \equiv \partial \boldsymbol{v}_o/\partial \dot{q}_I \equiv \partial \boldsymbol{a}_o/\partial \ddot{q}_I \equiv \cdots \equiv \boldsymbol{B}_I, \tag{k}$$

which is a specialization of (5.2.20b).

Example 5.2.3 *Special Forms of the Nonlinear Transitivity Equations.* Let us find the form of the transitivity relations for the special quasi-velocity choice of the preceding example. There we saw that [eqs. (c, d)]

$$\delta q_D = \sum (\partial \phi_D/\partial \dot{q}_I)\, \delta q_I \qquad \text{and} \qquad \dot{q}_D = \dot{q}_D(t, q, \dot{q}_I) \equiv \phi_D(t, q, \dot{q}_I). \tag{a}$$

By $(\ldots)^{\cdot}$-differentiating the *first* of them, and $\delta(\ldots)$-varying the *second*, and then subtracting side by side, we obtain, successively,

$$\begin{aligned}
(\delta q_D)^{\cdot} - \delta(\dot{q}_D) &= \sum \left[(\partial \phi_D/\partial \dot{q}_I)^{\cdot}\, \delta q_I + (\partial \phi_D/\partial \dot{q}_I)\, (\delta q_I)^{\cdot}\right] \\
&\quad - \sum \left[\partial \phi_D/\partial q_I + \sum (\partial \phi_D/\partial q_{D'})\, (\partial \phi_{D'}/\partial \dot{q}_I)\right] \delta q_I \\
&\quad - \sum (\partial \phi_D/\partial \dot{q}_I)\, \delta(\dot{q}_I) \\
&= \sum (\partial \phi_D/\partial \dot{q}_I)\, [(\delta q_I)^{\cdot} - \delta(\dot{q}_I)] \\
&\quad + \sum \left[(\partial \phi_D/\partial \dot{q}_I)^{\cdot} - \partial \phi_D/\partial(q_I)\right] \delta q_I,
\end{aligned} \tag{b}$$

where

$$\partial \phi_D/\partial(q_I) \equiv \partial \phi_D/\partial q_I + \sum (\partial \phi_D/\partial q_{D'})\, (\partial \phi_{D'}/\partial \dot{q}_I). \tag{c}$$

Alternatively, applying (5.2.16c), we find, successively,

$$\begin{aligned}
\partial \dot{q}_D/\partial \theta_I &\equiv \sum (\partial \dot{q}_D/\partial q_k)\, (\partial \dot{q}_k/\partial \omega_I) \\
&= \left(\sum (\partial \phi_D/\partial q_{D'})\, (\partial \dot{q}_{D'}/\partial \omega_I) + \sum (\partial \phi_D/\partial q_{I'})\, (\partial \dot{q}_{I'}/\partial \omega_I)\right)_{\omega = \dot{q}} \\
&= \sum (\partial \phi_D/\partial q_{D'})\, (\partial \dot{q}_{D'}/\partial \dot{q}_I) + \sum (\partial \phi_D/\partial q_{I'})\, (\partial \dot{q}_{I'}/\partial \dot{q}_I) \\
&= \sum (\partial \phi_D/\partial q_{D'})\, (\partial \phi_{D'}/\partial \dot{q}_I) + \sum (\partial \phi_D/\partial q_{I'})\, (\delta_{I'I}) \\
&= \partial \phi_D/\partial q_I + \sum (\partial \phi_D/\partial q_{D'})\, (\partial \phi_{D'}/\partial \dot{q}_I) \\
&\equiv \partial \phi_D/\partial(q_I) \qquad \text{[by (c)];}
\end{aligned} \tag{d}$$

that is,

$$\partial\dot{q}_D/\partial\omega_I = \partial\phi_D/\partial\dot{q}_I$$
$$\Rightarrow \omega_I \textit{ can} \text{ be identified with } \dot{q}_I;$$
$$\partial\dot{q}_D/\partial\theta_I = \partial\phi_D/\partial(q_I) \neq \partial\phi_D/\partial q_I$$
$$\Rightarrow \theta_I \textit{ is not} \text{ to be identified with } q_I; \quad \text{hence, the new notation } (q_I). \tag{e}$$

In sum: for this special quasi-variable choice, we can replace in the general expressions

$$\partial(\ldots)/\partial\omega_I \qquad \text{with} \qquad \partial(\ldots)/\partial\dot{q}_I,$$

and

$$\partial(\ldots)/\partial\theta_I \qquad \text{with} \qquad \partial(\ldots)/\partial(q_I) \equiv \partial(\ldots)/\partial q_I + \sum [\partial(\ldots)/\partial q_D]\,(\partial\phi_D/\partial\dot{q}_I). \tag{f}$$

If we now adopt the so-called Suslov viewpoint — that is, $(\delta q_D)^{\cdot} - \delta(\dot{q}_D) \neq 0$, $(\delta q_I)^{\cdot} - \delta(\dot{q}_I) = 0$ [prob. 2.12.5; 3.8.14a ff.] — then (b) leads immediately to the following *nonlinear Suslov* transitivity relations:

$$(\delta q_k)^{\cdot} - \delta(\dot{q}_k): \qquad (\delta q_D)^{\cdot} - \delta(\dot{q}_D) = \sum W^D{}_I\,\delta q_I, \tag{g}$$

$$(\delta q_I)^{\cdot} - \delta(\dot{q}_I) = 0 \qquad (\text{i.e., } W^{I'}{}_I = 0), \tag{h}$$

where

$$W^D{}_I \equiv (\partial\phi_D/\partial\dot{q}_I)^{\cdot} - \partial\phi_D/\partial q_I - \sum (\partial\phi_D/\partial q_{D'})\,(\partial\phi_{D'}/\partial\dot{q}_I)$$
$$\equiv E_I(\phi_D) - \sum (\partial\phi_D/\partial q_{D'})\,(\partial\phi_{D'}/\partial\dot{q}_I)$$
$$\equiv (\partial\phi_D/\partial\dot{q}_I)^{\cdot} - \partial\phi_D/\partial(q_I)$$
$$\equiv E_{(I)}(\phi_D):$$

Special nonlinear Voronets coefficients [specialization of (5.2.21e)]. (i)

If the second of equations (a) have the special form

$$\dot{q}_D = \dot{q}_D(q_I, \dot{q}_I) \equiv \phi_D(q_I, \dot{q}_I): \quad \text{nonlinear Chaplygin system}, \tag{j}$$

then $\partial\phi_D/\partial q_{D'} = 0$, and so (h) reduces to the *nonlinear Chaplygin (or Tsaplygin) coefficients*

$$W^D{}_I \rightarrow T^D{}_I \equiv (\partial\phi_D/\partial\dot{q}_I)^{\cdot} - \partial\phi_D/\partial q_I \equiv E_I(\phi_D). \tag{k}$$

5.3 KINETICS: VARIATIONAL EQUATIONS/PRINCIPLES; GENERAL AND SPECIAL EQUATIONS OF MOTION (OF JOHNSEN, HAMEL, ET AL.)

To derive Lagrangean-type equations, we will use both the central equation (§3.6) in system variables, and Lagrange's principle (§3.2) in both particle and system variables.

The NNHC Central Equation

As discussed in §3.6, the latter is, with the usual notations and assuming that $d(\delta\boldsymbol{r})/dt - \delta(d\boldsymbol{r}/dt) \equiv (\delta\boldsymbol{r})^{\cdot} - \delta\boldsymbol{v} = \boldsymbol{0} \;\Rightarrow\; (\delta q_k)^{\cdot} - \delta(\dot{q}_k) = 0$ (for all holonomic variables, constrained or not),

$$d/dt(\delta P) - \delta T = \delta' W, \tag{5.3.1}$$

where

$$\begin{aligned}\delta P \equiv \mathbf{S}\, dm\,\boldsymbol{v}\cdot\delta\boldsymbol{r} &= \sum (\partial T/\partial \dot{q}_k)\,\delta q_k \equiv \sum p_k\,\delta q_k\\ &= \sum (\partial T^*/\partial\omega_k)\,\delta\theta_k \equiv \sum P_k\,\delta\theta_k,\end{aligned} \tag{5.3.1a}$$

$$\begin{aligned}&\Big[\Rightarrow\; p_k = \sum (\partial\omega_l/\partial\dot{q}_k)P_l \;\Leftrightarrow\; P_l = \sum (\partial\dot{q}_k/\partial\omega_l)p_k,\\ &\text{i.e., } \partial T/\partial\dot{q}_k = \sum (\partial\omega_l/\partial\dot{q}_k)\,(\partial T^*/\partial\omega_l)\\ &\qquad \Leftrightarrow \partial T^*/\partial\omega_l = \sum (\partial\dot{q}_k/\partial\omega_l)\,(\partial T/\partial\dot{q}_k)\Big];\end{aligned} \tag{5.3.1b}$$

$$\begin{aligned}\delta T &\equiv \delta\Big(\mathbf{S}\,(1/2)\,dm\,\boldsymbol{v}\cdot\boldsymbol{v}\Big)\\ &= \sum \big[(\partial T^*/\partial\theta_k)\,\delta\theta_k + (\partial T^*/\partial\omega_k)\,\delta\omega_k\big],\end{aligned} \tag{5.3.1c}$$

$$T = T(t, q, \dot{q}) = T[t, q, \dot{q}(t, q, \omega)] \equiv T^*(t, q, \omega) \equiv T^*; \tag{5.3.1d}$$

$$\begin{aligned}&\delta' W \equiv \mathbf{S}\, d\boldsymbol{F}\cdot\delta\boldsymbol{r} = \sum Q_k\,\delta q_k \equiv \sum \Theta_k\,\delta\theta_k\\ &\quad\Big[\Rightarrow Q_k = \sum (\partial\omega_l/\partial\dot{q}_k)\Theta_l \;\Leftrightarrow\; \Theta_l = \sum (\partial\dot{q}_k/\partial\omega_l)Q_k\Big].\end{aligned} \tag{5.3.1e}$$

Substituting (5.3.1a–e) into (5.3.1), and regrouping appropriately, we obtain the

Central equation in NNH variables:

$$\begin{aligned}\sum (dP_k/dt)\,\delta\theta_k - \sum (\partial T^*/\partial\theta_k)\,\delta\theta_k + \sum P_k[(\delta\theta_k)^{\cdot} - \delta\omega_k]&\\ = \sum \Theta_k\,\delta\theta_k;&\end{aligned} \tag{5.3.2}$$

and from this, invoking the transitivity equations (5.2.22a, b) [under the Hamel viewpoint; i.e., $(\delta q_k)^{\cdot} = \delta(\dot{q}_k)$ for *all* holonomic variables, constrained or not], we finally obtain

Lagrange's principle in NNH variables:

$$\sum \Big(dP_k/dt - \partial T^*/\partial\theta_k + \sum H^s{}_k P_s - \Theta_k\Big)\,\delta\theta_k = 0. \tag{5.3.3}$$

These *variational equations* are fundamental to all subsequent kinetic considerations.

REMARK

As in the Pfaffian case (§3.6), eq. (5.3.3) (and, hence, the equations of motion resulting from it) is independent of any assumptions regarding $d(\delta\boldsymbol{r}) - \delta(d\boldsymbol{r})$ or

$d(\delta q_k) - \delta(dq_k)$. To confirm this, we begin with the most general central equation (3.6.4)

$$d/dt(\delta P) - \delta T - \delta D = \delta' W, \tag{5.3.4}$$

instead of (5.3.1); where, successively,

$$\begin{aligned}
\delta D &\equiv \mathsf{S}\, dm\, \boldsymbol{v} \cdot [(\delta \boldsymbol{r})^{\cdot} - \delta \boldsymbol{v}] = \mathsf{S}\, dm\, \boldsymbol{v} \cdot \Big\{ \sum [(\delta q_k)^{\cdot} - \delta(\dot{q}_k)] \boldsymbol{e}_k \Big\} \\
&= \sum p_k [(\delta q_k)^{\cdot} - \delta(\dot{q}_k)] \\
&= \sum \sum p_k \, (\partial \dot{q}_k / \partial \omega_l) \, [(\delta \theta_l)^{\cdot} - \delta \omega_l] \\
&\quad - \sum \sum \sum p_k (\partial \dot{q}_k / \partial \omega_s) H^s{}_l \, \delta \theta_l \qquad \text{[by (5.2.23b)]} \\
&= \sum P_l [(\delta \theta_l)^{\cdot} - \delta \omega_l] - \sum \sum H^s{}_l P_s \, \delta \theta_l \qquad \text{[by (5.3.1b)]}.
\end{aligned} \tag{5.3.4a}$$

As a result of (5.3.4a) and (5.3.1a–e), eq. (5.3.4) becomes

$$\begin{aligned}
&\sum [(dP_k/dt) \, \delta \theta_k + P_k (\delta \theta_k)^{\cdot}] - \sum \big[(\partial T^* / \partial \theta_k) \, \delta \theta_k + (\partial T^* / \partial \omega_k) \, \delta \omega_k \big] \\
&\quad - \sum P_k [(\delta \theta_k)^{\cdot} - \delta \omega_k] + \sum \sum H^s{}_k P_s \, \delta \theta_k = \sum \Theta_k \, \delta \theta_k,
\end{aligned} \tag{5.3.4b}$$

which, when simplified, as the reader can easily confirm, is none other than (5.3.3).

Equations of Motion

In the presence of $m(< n)$ constraints, in the virtual form (5.2.13): $\delta \theta_D = 0$, application of the method of Lagrangean multipliers to (5.3.3), in exactly the same fashion as in §3.5–3.7, readily produces the following two groups of equations of motion:

Kinetostatic: $$dP_D/dt - \partial T^* / \partial \theta_D + \sum H^k{}_D P_k \;=\; \Theta_D + \lambda_D \qquad (D = 1, \ldots, m), \tag{5.3.5a}$$

Kinetic: $$dP_I/dt - \partial T^* / \partial \theta_I + \sum H^k{}_I P_k \;=\; \Theta_I \qquad (I = m+1, \ldots, n). \tag{5.3.5b}$$

Equations (5.3.5b) are due to Johnsen and Hamel (1936–1941).

In extenso, the kinetic group (5.3.5b) reads

$$\begin{aligned}
&(\partial T^* / \partial \omega_I)^{\cdot} - \partial T^* / \partial \theta_I \\
&\quad + \sum \sum \big[(\partial \omega_l / \partial \dot{q}_s)^{\cdot} - \partial \omega_l / \partial q_s \big] \, (\partial \dot{q}_s / \partial \omega_I) \, (\partial T^* / \partial \omega_l) = \Theta_I,
\end{aligned} \tag{5.3.5c}$$

or

$$E_I(T^*) + \sum \sum E_s(\omega_l) \, (\partial \dot{q}_s / \partial \omega_I) \, (\partial T^* / \partial \omega_l) = \Theta_I; \tag{5.3.5d}$$

and similarly for the kinetostatic group (5.3.5a). Equations (5.3.5b–d) constitute the legitimate generalization of the original Hamel equations (1903–1904, §3.5) to the nonlinear nonholonomic variable and constraint case.

• Using (5.2.21f, h), we easily obtain a *second* form of these equations. Indeed, the kinetic such group is

$$dP_I/dt - \partial T^*/\partial\theta_I - \sum\sum (\partial\omega_l/\partial\dot{q}_k)V^k{}_I P_l = \Theta_I, \tag{5.3.6a}$$

or, in extenso,

$$(\partial T^*/\partial\omega_I)^{\cdot} - \partial T^*/\partial\theta_I - \sum\sum \left[(\partial\dot{q}_k/\partial\omega_I)^{\cdot} - \partial\dot{q}_k/\partial\theta_I\right](\partial\omega_l/\partial\dot{q}_k)(\partial T^*/\partial\omega_l) = \Theta_I, \tag{5.3.6b}$$

or, in operator form,

$$E_I{}^*(T^*) - \sum\sum E_I{}^*(\dot{q}_k)(\partial\omega_l/\partial\dot{q}_k)(\partial T^*/\partial\omega_l) = \Theta_I. \tag{5.3.6c}$$

• Also, since

$$\begin{aligned}\sum (\partial\omega_l/\partial\dot{q}_k)P_l = p_k = p_k(t, q, \dot{q}) &= p_k[t, q, \dot{q}(t, q, \omega)]\\ &\equiv p_k{}^* \equiv (\partial T/\partial\dot{q}_k)^*,\end{aligned} \tag{5.3.7}$$

we can rewrite equations (5.3.6a–c) in the following *mixed* form (i.e., containing both T and T^*):

$$dP_I/dt - \partial T^*/\partial\theta_I - \sum V^k{}_I\, p_k{}^* = \Theta_I, \tag{5.3.8a}$$

$$(\partial T^*/\partial\omega_I)^{\cdot} - \partial T^*/\partial\theta_I - \sum \left[(\partial\dot{q}_k/\partial\omega_I)^{\cdot} - \partial\dot{q}_k/\partial\theta_I\right](\partial T/\partial\dot{q}_k)^* = \Theta_I; \tag{5.3.8b}$$

or, further, with $T^*|_{\text{constraints enforced}} \equiv T^*{}_o$,

$$(\partial T^*{}_o/\partial\omega_I)^{\cdot} - \partial T^*{}_o/\partial\theta_I - \sum V^k{}_I\,(\partial T/\partial\dot{q}_k)^*{}_o = \Theta_I. \tag{5.3.8c}$$

Similarly, (5.3.5b–d) can be replaced by their "constrained" form:

$$(\partial T^*{}_o/\partial\omega_I)^{\cdot} - \partial T^*{}_o/\partial\theta_I + \sum H^k{}_I\,(\partial T^*/\partial\omega_k)_o = \Theta_I. \tag{5.3.8d}$$

REMARKS

Equations (5.3.5b–d, 8d) and (5.3.8a–c) constitute the legitimate nonlinear generalizations of the original "Pfaffian equations" of Hamel (§3.5) and Chaplygin–Voronets (§3.8), respectively. [Although Hamel (1938, p. 48) seems to view (5.3.6a–c), rather than (5.3.5b–d), as the genuine nonlinear generalization of his equations of 1903–1904.] Comparing these two basic kinds of equations we notice the following: The Hamel forms (5.3.5b–d), as well as (5.3.6a–c), contain both $\partial\omega/\partial\dot{q}$ and $\partial\dot{q}/\partial\omega$ derivatives; and (5.3.5b–d) contain both $\ddot{q}$ and $\dot{\omega}$-proportional terms; whereas (5.3.8a–c) involve only $\partial\dot{q}/\partial\omega$ derivatives. On the other hand, the former involve only T^*, while the latter involve both T and T^*. But these differences are superficial: in view of (i) the nonlinear transformation equations $\dot{q} \Leftrightarrow \omega$, (ii) the fact that the matrices $(\partial\dot{q}/\partial\omega)$ and $(\partial\omega/\partial\dot{q})$ are mutually inverse [i.e., by Cramer's rule applied to the "inverseness relations" (5.2.4a, b), *the coefficients* $\partial\omega_l/\partial\dot{q}_k$ appearing in (5.3.6a–c) *equal the minors of the determinant of the matrix* $(\partial\dot{q}/\partial\omega)$ *divided by* $Det(\partial\dot{q}/\partial\omega)$, and can, therefore, be also expressed as functions of t, q, ω without further use of the equations $\dot{q} \Leftrightarrow \omega$; and similarly for expressing the $\partial\dot{q}_k/\partial\omega_l$ appearing in (5.3.8a–c) in terms of $t, q, \dot{q}$] and that, in analogy to (5.3.7), (iii) $P_l \equiv \partial T^*/\partial\omega_l = \sum (\partial\dot{q}_k/\partial\omega_l)(\partial T/\partial\dot{q}_k) = \cdots = P_l(t, q, \dot{q})$, we can express all terms of these two kinds of equations (including the symbols $V^l{}_k$ and $H^l{}_k$) in terms of either $t, q, \dot{q}, \ddot{q}$ or $t, q, \omega, \dot{\omega}$, although, in particular problems, such a choice is conditioned by practical considerations (e.g., amount of labor involved). Finally, reasoning as in §3.4, we see that the Lagrangean multipliers λ_D, in the kinetostatic of the above equations, equal the (covariant) nonholonomic components of the system constraint reactions: $\Lambda_D \equiv S\, d\boldsymbol{R} \cdot \boldsymbol{\varepsilon}_D$, where (§3.2) $dm\, \boldsymbol{a} = d\boldsymbol{F} + d\boldsymbol{R}$. Indeed, assuming that Lagrange's principle (LP) also holds for the reactions enforcing our nonlinear constraints (5.2.2a), we have

$$\delta' W_R \equiv S\, d\boldsymbol{R} \cdot \delta\boldsymbol{r} = \sum R_k\, \delta q_k = \sum \Lambda_k\, \delta\theta_k \quad (= 0), \tag{5.3.9a}$$

from which we immediately obtain the transformation equations

$$\Lambda_k \equiv S\, d\boldsymbol{R} \cdot \boldsymbol{\varepsilon}_k = \sum (\partial \dot{q}_l / \partial \omega_k)\, R_l:$$
$$\Lambda_D \neq 0 \quad (\delta\theta_D = 0) \qquad \text{and} \qquad \Lambda_I = 0 \quad (\delta\theta_I \neq 0), \tag{5.3.9b}$$
$$R_l \equiv S\, d\boldsymbol{R} \cdot \boldsymbol{e}_l = \sum (\partial \omega_k / \partial \dot{q}_l)\, \Lambda_k$$
$$= \sum (\partial \omega_D / \partial \dot{q}_l)\, \Lambda_D = \sum (\partial \phi_D / \partial \dot{q}_l)\, \Lambda_D, \tag{5.3.9c}$$

and comparing with the constitutive equation $R_l = \sum \lambda_D\, (\partial f_D / \partial \dot{q}_l)$, obtained via application of the method of multipliers to LP, we conclude that $\Lambda_D = \lambda_D$.

Lagrange's Principle (LP)

As detailed in §3.2–3.5, LP postulates that

$$\delta I = \delta' W, \tag{5.3.10}$$

where

$$\delta I \equiv S\, dm\, \boldsymbol{a} \cdot \delta\boldsymbol{r} = \sum E_k\, \delta q_k = \sum I_k\, \delta\theta_k, \tag{5.3.10a}$$

$$E_k \equiv S\, dm\, \boldsymbol{a} \cdot \boldsymbol{e}_k = E_k(T), \tag{5.3.10b}$$

$$I_k \equiv S\, dm\, \boldsymbol{a} \cdot \boldsymbol{\varepsilon}_k = E_k{}^*(T^*) + \sum H^l{}_k P_l, \tag{5.3.10c}$$

$$\delta' W \equiv S\, d\boldsymbol{F} \cdot \delta\boldsymbol{r} = \sum Q_k\, \delta q_k = \sum \Theta_k\, \delta\theta_k, \tag{5.3.10d}$$

$$Q_k \equiv S\, d\boldsymbol{F} \cdot \boldsymbol{e}_k, \qquad \Theta_k \equiv S\, d\boldsymbol{F} \cdot \boldsymbol{\varepsilon}_k. \tag{5.3.10e}$$

Holonomic Coordinates

Applying the method of Lagrangean multipliers to (5.3.10) in holonomic system variables:

$$\sum E_k\, \delta q_k = \sum Q_k\, \delta q_k, \tag{5.3.11a}$$

under the m constraints (5.1.2; 5.2.2a), in the virtual form (5.2.9)

$$\sum (\partial f_D / \partial \dot{q}_k)\, \delta q_k = 0, \tag{5.3.11b}$$

we immediately obtain the *nonlinear* (generalization of the) *Routh–Voss* equations:

$$(\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k = Q_k + \sum \lambda_D \, (\partial f_D/\partial \dot{q}_k), \tag{5.3.11c}$$

or, compactly,

$$E_k(T) = Q_k + R_k, \tag{5.3.11d}$$

which, along with the m constraints $f_D = 0$ constitute a determinate system of $n + m$ equations for the $n + m$ unknown functions $\lambda_D(t), q_k(t)$. [Equations (5.3.11c) are due to Routh (1877, 3rd ed. of the *Elementary* part of his classic *Rigid Dynamics*). However, he never applied them to any NNHC problem. It seems certain that he chose that form as a memorable way of writing the equations of motion under Pfaffian [or (5.3.13a)-like] constraints (3.5.15) rather than with the full understanding that equations (5.3.11c) hold for the most general nonlinear first-order (possibly nonholonomic) constraints.]

- In view of the purely kinematico-inertial identity $E_k(T) = \partial S/\partial \ddot{q}_k$, where $S = S(t, q, \dot{q}, \ddot{q})$ is the (unconstrained) Appellian of the system [(3.3.16a)], we will also have the *Appellian form of the nonlinear Routh–Voss equations*:

$$\partial S/\partial \ddot{q}_k = Q_k + \sum \lambda_D \, (\partial f_D/\partial \dot{q}_k). \tag{5.3.12}$$

- If the constraints have the (holonomic) form $g_D \equiv g_D(t, q) = 0$ — that is, if they do not contain the $\dot{q}$'s — it does *not* mean that, since $\partial g_D/\partial \dot{q}_k = 0$, we will have $R_k = 0$. It means, instead, that to apply (5.3.11c) correctly we have to *create a $\dot{q}$-containing constraint from $g_D = 0$*. Indeed, $(\ldots)^{\cdot}$-differentiating $g_D(t, q) = 0$, we obtain

$$0 = dg_D/dt = \partial g_D/\partial t + \sum (\partial g_D/\partial q_k)\dot{q}_k \equiv f_D(t, q, \dot{q}) \equiv f_D, \tag{5.3.13a}$$

from which it follows that

$$\partial f_D/\partial \dot{q}_k = \partial g_D/\partial q_k, \tag{5.3.13b}$$

so that (5.3.11c) become

$$E_k(T) = Q_k + \sum \lambda_D \, (\partial g_D/\partial q_k), \tag{5.3.13c}$$

in complete agreement with earlier results; for example, ex. 3.5.14.

Nonholonomic Coordinates

Applying Lagrangean multipliers to LP, (5.3.10), in nonholonomic variables:

$$\sum I_k \, \delta\theta_k = \sum \Theta_k \, \delta\theta_k, \tag{5.3.14a}$$

under the m constraints $\delta\theta_D = 1 \cdot \delta\theta_D = 0$ (and $0 \cdot \delta\theta_I = 0$ for the rest), we immediately obtain the following two groups of equations:

Kinetostatic: $\quad I_D = \Theta_D + \lambda_D \quad [D = 1, \ldots, m\,(< n)],$ (5.3.14b)

Kinetic: $\quad I_I = \Theta_I \quad [I = m + 1, \ldots, n].$ (5.3.14c)

With the I_k's, Θ_k's, λ_D's defined by (5.3.10c, e, 9b), respectively, the above constitute the so-called "raw" forms of the equations of motion. As in the Pfaffian case (§3.5, §3.8), special choices of the fundamental nonholonomic "accompanying vectors" $\boldsymbol{\varepsilon}_k$ in them, as in (5.2.20b) and ex. 5.2.2, yield special forms of the nonlinear equations of motion (Maggi, Schaefer, Hamel, Appell, et al.). Let us examine them in detail, in order of increasing difficulty.

(i) The choice $\boldsymbol{\varepsilon}_k = \partial \boldsymbol{a}^*/\partial \dot{\omega}_k$ in (5.3.10c) yields, successively,

$$I_k = \mathsf{S}\, dm\, \boldsymbol{a}^* \cdot (\partial \boldsymbol{a}^*/\partial \dot{\omega}_k) = \partial S^*/\partial \dot{\omega}_k, \tag{5.3.15a}$$

where

$$S^* \equiv \mathsf{S}\, (1/2)\, dm\, \boldsymbol{a}^* \cdot \boldsymbol{a}^* = S^*(t, q, \omega, \dot{\omega}): \quad \textit{Nonlinear Appellian}; \tag{5.3.15b}$$

and so (5.3.14b, c) assume the form of the *nonlinear Appell equations*

$$\partial S^*/\partial \dot{\omega}_D = \Theta_D + \lambda_D, \qquad \partial S^*/\partial \dot{\omega}_I = \Theta_I, \tag{5.3.15c}$$

respectively. If we are not interested in the constraint forces, then, as already explained for the Pfaffian case (§3.5), we can replace in the kinetic equations (second of 5.3.15c), the unconstrained Appellian S^* with the constrained one:

$$S^*_o \equiv S^*(t, q, \omega_D = 0, \omega_I, \dot{\omega}_D = 0, \dot{\omega}_I) \equiv S^*_o(t, q, \omega_I, \dot{\omega}_I), \tag{5.3.15d}$$

and similarly for the Θ_I (although we shall still denote them as Θ_I),

$$\partial S^*_o/\partial \dot{\omega}_I = \Theta_I. \tag{5.3.15e}$$

Also, in concrete problems we do not have to first compute S^* and then find $\partial S^*/\partial \dot{\omega}_I \rightarrow (\partial S^*/\partial \dot{\omega}_I)_o = \partial S^*_o/\partial \dot{\omega}_I$ but, instead, we can use I_k in the form of (5.3.15a).

(ii) The choice $\boldsymbol{\varepsilon}_k = \partial \boldsymbol{r}^*/\partial \theta_k \equiv \partial \boldsymbol{r}/\partial \theta_k$ (symbolic gradient) in (5.3.10c) yields, successively,

$$\begin{aligned} I_k &= \mathsf{S}\, dm\, \boldsymbol{a}^* \cdot (\partial \boldsymbol{r}^*/\partial \theta_k) = \mathsf{S}\, dm\, \boldsymbol{a}^* \cdot \Big(\sum (\partial \dot{q}_l/\partial \omega_k)\boldsymbol{e}_l\Big) \\ &= \sum \Big(\mathsf{S}\, dm\, \boldsymbol{a}^* \cdot \boldsymbol{e}_l\Big)\, (\partial \dot{q}_l/\partial \omega_k) \\ &= \sum\, \big[(\partial T/\partial \dot{q}_l)^{\cdot} - \partial T/\partial q_l\big]\, (\partial \dot{q}_l/\partial \omega_k) \qquad \text{[by Lagrange's identity (§3.3)]} \\ &\equiv \sum\, E_l(T)\, (\partial \dot{q}_l/\partial \omega_k) \equiv \sum\, E_l\, (\partial \dot{q}_l/\partial \omega_k); \end{aligned} \tag{5.3.16a}$$

and so (5.3.14b, c) yield the *nonlinear Maggi equations*

$$\sum (\partial \dot{q}_k/\partial \omega_D) E_k = \sum (\partial \dot{q}_k/\partial \omega_D) Q_k + \lambda_D, \tag{5.3.16b}$$

$$\sum (\partial \dot{q}_k/\partial \omega_I) E_k = \sum (\partial \dot{q}_k/\partial \omega_I) Q_k. \tag{5.3.16c}$$

[Equations (5.3.16c) are due to Hamel (1938, p. 45); see also Przeborski (1933) for a particle and component form.] Also, since $E_k = \partial S/\partial \ddot{q}_k$, we can replace in both (5.3.16b, c) E_k with $\partial S/\partial \ddot{q}_k$, and thus obtain the *Appellian form of the nonlinear Maggi equations*.

(iii) The choice $\boldsymbol{\varepsilon}_k = \partial \boldsymbol{v}^*/\partial \omega_k \rightarrow \partial \boldsymbol{v}^*/\partial \omega_I$ in (5.3.10c) yields immediately the *Schaefer equations* (1951):

$$\mathsf{S}\, dm\, \boldsymbol{a}^* \cdot (\partial \boldsymbol{v}^*/\partial \omega_I) = \mathsf{S}\, d\boldsymbol{F} \cdot (\partial \boldsymbol{v}^*/\partial \omega_I), \tag{5.3.17}$$

which, as we show immediately below, constitute a raw form of the earlier nonlinear Johnsen–Hamel equations (5.3.5a ff.). Indeed, I_k transforms, successively, as follows:

$$
\begin{aligned}
I_k &\equiv S\, dm\, \boldsymbol{a}^* \cdot \boldsymbol{\varepsilon}_k = S\, dm\, (d\boldsymbol{v}^*/dt) \cdot (\partial \boldsymbol{v}^*/\partial \omega_k) \\
&= d/dt\Big(S\, dm\, \boldsymbol{v}^* \cdot\ (\partial \boldsymbol{v}^*/\partial \omega_k)\Big) - S\, dm\, \boldsymbol{v}^* \cdot (\partial \boldsymbol{v}^*/\partial \omega_k)^{\cdot} \\
&\quad \Big[\text{adding and subtracting } S\, dm\, \boldsymbol{v}^* \cdot (\partial \boldsymbol{v}^*/\partial \theta_k)\Big] \\
&= d/dt\Big(S\, dm\, \boldsymbol{v}^* \cdot (\partial \boldsymbol{v}^*/\partial \omega_k)\Big) - S\, dm\, \boldsymbol{v}^* \cdot (\partial \boldsymbol{v}^*/\partial \theta_k) \\
&\qquad\qquad - S\, dm\, \boldsymbol{v}^* \cdot \big[(\partial \boldsymbol{v}^*/\partial \omega_k)^{\cdot} - \partial \boldsymbol{v}^*/\partial \theta_k\big] \\
&\quad [\text{if the } \theta \text{ were holonomic coordinates, the } \textit{last (third) sum would vanish}!] \\
&= d/dt\Big[\partial/\partial \omega_k \Big(S\, (1/2)\, dm\, \boldsymbol{v}^* \cdot \boldsymbol{v}^*\Big)\Big] - \Big[\partial/\partial \theta_k \Big(S\, (1/2)\, dm\, \boldsymbol{v}^* \cdot \boldsymbol{v}^*\Big)\Big] \\
&\qquad\qquad - S\, dm\, \boldsymbol{v}^* \cdot E_k{}^*(\boldsymbol{v}^*) \\
&= (\partial T^*/\partial \omega_k)^{\cdot} - \partial T^*/\partial \theta_k - \Gamma_k,
\end{aligned}
\tag{5.3.18a}
$$

where

$$
\begin{aligned}
T &= T(t, q, \dot{q}) = T[t, q, \dot{q}(t, q, \omega)] \\
&\equiv T^*(t, q, \omega) = T^* \equiv S\, (1/2)\, dm\, \boldsymbol{v}^* \cdot \boldsymbol{v}^*,
\end{aligned}
\tag{5.3.18b}
$$

$$
\begin{aligned}
\Gamma_k &\equiv S\, dm\, \boldsymbol{v}^* \cdot \big[(\partial \boldsymbol{v}^*/\partial \omega_k)^{\cdot} - \partial \boldsymbol{v}^*/\partial \theta_k\big] \\
&= S\, dm\, \boldsymbol{v}^* \cdot \big[d/dt\, (\partial \boldsymbol{r}^*/\partial \theta_k) - \partial/\partial \theta_k\, (d\boldsymbol{r}^*/dt)\big] \quad (\neq 0) \\
&\equiv S\, dm\, \boldsymbol{v}^* \cdot E_k{}^*(\boldsymbol{v}^*): \\
&\qquad \textit{Nonlinear nonholonomic correction (or supplementary) term.}
\end{aligned}
\tag{5.3.18c}
$$

Further, recalling the earlier (5.2.21c–h) and the definitions

$$
p_l \equiv \partial T/\partial \dot{q}_l \equiv S\, dm\, \boldsymbol{v} \cdot \boldsymbol{e}_l, \qquad P_l \equiv \partial T^*/\partial \omega_l \equiv S\, dm\, \boldsymbol{v}^* \cdot \boldsymbol{\varepsilon}_l,
$$

we obtain the following mutually equivalent forms in *system* variables:

$$
\begin{aligned}
\Gamma_k &= S\, dm\, \boldsymbol{v}^* \cdot \Big(\sum E_k{}^*(\dot{q}_l)\boldsymbol{e}_l\Big) \\
&= S\, dm\, \boldsymbol{v}^* \cdot \Big(\sum V^l{}_k \boldsymbol{e}_l\Big) = -S\, dm\, \boldsymbol{v}^* \cdot \Big(\sum\sum H^s{}_k (\partial \dot{q}_l/\partial \omega_s)\boldsymbol{e}_l\Big) \\
&= \sum V^l{}_k\, p_l \\
&\quad \Big\{\equiv \sum \big[(\partial \dot{q}_l/\partial \omega_k)^{\cdot} - \partial \dot{q}_l/\partial \theta_k\big]\, (\partial T/\partial \dot{q}_l)^*\Big\} \\
&= -\sum\sum (\partial \dot{q}_l/\partial \omega_s) H^s{}_k\, p_l \\
&\quad \Big\{\equiv -\sum\sum\sum \big[(\partial \omega_s/\partial \dot{q}_b)^{\cdot} - \partial \omega_s/\partial q_b\big]\, (\partial \dot{q}_b/\partial \omega_k)\, (\partial \dot{q}_l/\partial \omega_s)\, (\partial T/\partial \dot{q}_l)^* \\
&= -\sum\sum \big[(\partial \omega_s/\partial \dot{q}_b)^{\cdot} - \partial \omega_s/\partial q_b\big]\, (\partial \dot{q}_b/\partial \omega_k)\, (\partial T^*/\partial \omega_s)\Big\};
\end{aligned}
\tag{5.3.18d}
$$

and

$$
\begin{aligned}
\Gamma_k &= \mathbf{S}\, dm\, \boldsymbol{v}^* \cdot \left(\sum\sum E_k{}^*(\dot{q}_l)\,(\partial\omega_s/\partial\dot{q}_l)\boldsymbol{\varepsilon}_s\right)\\
&= \mathbf{S}\, dm\, \boldsymbol{v}^* \cdot \left(\sum\sum (\partial\omega_s/\partial\dot{q}_l) V^l{}_k \boldsymbol{\varepsilon}_s\right) = -\mathbf{S}\, dm\, \boldsymbol{v}^* \cdot \left(\sum H^s{}_k \boldsymbol{\varepsilon}_s\right)\\
&= \sum\sum (\partial\omega_s/\partial\dot{q}_l) V^l{}_k P_s\\
&\quad \left\{\equiv \sum\sum \left[(\partial\dot{q}_l/\partial\omega_k)^{\cdot} - \partial\dot{q}_l/\partial\theta_k\right](\partial\omega_s/\partial\dot{q}_l)\,(\partial T^*/\partial\omega_s)\right\}\\
&= -\sum H^s{}_k P_s\\
&\quad \left\{\equiv -\sum\sum \left[(\partial\omega_s/\partial\dot{q}_l)^{\cdot} - \partial\omega_s/\partial q_l\right](\partial\dot{q}_l/\partial\omega_k)\,(\partial T^*/\partial\omega_s)\right\}; \qquad (5.3.18\mathrm{e})
\end{aligned}
$$

where

$p_l = p_l(t, q, \dot{q}) = p_l[t, q, \dot{q}(t, q, \omega)] = p_l{}^*(t, q, \omega) \equiv (\partial T/\partial\dot{q}_l)^*$:

holonomic (l)*th component of system momentum, but expressed in nonholonomic variables* [also note that $p_l{}^* \neq P_l$, while $\partial T^*/\partial\dot{q}$ is undefined]. (5.3.18f)

In view of the above, the Schaefer equations (5.3.17) assume the earlier found Lagrangean form of Johnsen–Hamel (5.3.5b ff.):

$$(\partial T^*/\partial\omega_I)^{\cdot} - \partial T^*/\partial\theta_I - \Gamma_I = \Theta_I. \qquad (5.3.19)$$

Below we summarize, for convenience, the various available general particle and system representations of the nonlinear nonholonomic inertia "force" I_k, in operator forms:

$$
\begin{aligned}
I_k &\equiv \mathbf{S}\, dm\, \boldsymbol{a}^* \cdot \boldsymbol{\varepsilon}_k \qquad \text{(Definition; \textit{raw} or particle form)}\\
&= \partial S^*/\partial\dot{\omega}_k \quad \Big[= \sum (\partial S/\partial\ddot{q}_l)\,(\partial\ddot{q}_l/\partial\dot{\omega}_k) = \sum (\partial S/\partial\ddot{q}_l)\,(\partial\dot{q}_l/\partial\omega_k),\\
&\qquad \text{where } 2S^* \equiv \mathbf{S}\, dm\, \boldsymbol{a}^* \cdot \boldsymbol{a}^* = \mathbf{S}\, dm\, \boldsymbol{a} \cdot \boldsymbol{a} \equiv 2S \qquad (\textit{Appell}\ \text{form})\Big]\\
&= \sum (\partial\dot{q}_l/\partial\omega_k)\, E_l(T) \qquad (\textit{Maggi}\ \text{form})\\
&= E_k{}^*(T^*) + \sum\sum E_s(\omega_r)\,(\partial\dot{q}_s/\partial\omega_k)\,(\partial T^*/\partial\omega_r)\\
&= E_k{}^*(T^*) + \sum\sum\sum E_s(\omega_r)\,(\partial\dot{q}_s/\partial\omega_k)\,(\partial\dot{q}_l/\partial\omega_r)\,(\partial T/\partial\dot{q}_l)^*\\
&= E_k{}^*(T^*) - \sum\sum E_k{}^*(\dot{q}_l)\,(\partial\omega_r/\partial\dot{q}_l)\,(\partial T^*/\partial\omega_r)\\
&= E_k{}^*(T^*) - \sum E_k{}^*(\dot{q}_l)\,(\partial T/\partial\dot{q}_l)^* \qquad (\textit{Johnsen–Hamel}\ \text{forms}). \qquad (5.3.20)
\end{aligned}
$$

Also, recalling (5.3.10a), we have the transformation equations between the holonomic and nonholonomic components of the inertia "force":

$$I_k = \sum (\partial\dot{q}_l/\partial\omega_k) E_l \;\Leftrightarrow\; E_l = \sum (\partial\omega_k/\partial\dot{q}_l) I_k, \qquad (5.3.21\mathrm{a})$$

and, of course, the identity:

$$E_l \equiv E_l(T) \equiv \partial S/\partial \ddot{q}_l. \tag{5.3.21b}$$

The above show that, as in the Pfaffian case (§3.2 ff.), $E_k{}^*(T^*)$ does *not* transform as a (covariant) vector under transformations $\delta q \Leftrightarrow \delta\theta$; it is $I_k \equiv E_k{}^*(T) - \Gamma_k$ that does!

REMARKS

(i) Maggi's equations (5.3.16b, c) can also be deduced from the nonlinear Routh–Voss equations (5.3.11c, d):

$$E_k(T) = Q_k + \sum \lambda_D\,(\partial f_D/\partial \dot{q}_k) = Q_k + \sum \lambda_D\,(\partial \omega_D/\partial \dot{q}_k),$$

through multiplication with $\partial \dot{q}_k/\partial \omega_l$, summation over k, and subsequent utilization of (5.2.4a):

$$\sum (\partial \dot{q}_k/\partial \omega_l)\, E_k(T) = \sum (\partial \dot{q}_k/\partial \omega_l) Q_k + A_l,$$

where

$$\begin{aligned} A_l &\equiv \sum\sum \lambda_D(\partial \omega_D/\partial \dot{q}_k)\,(\partial \dot{q}_k/\partial \omega_l) = \sum \lambda_D\,\delta_{Dl} = \lambda_l \\ &= \lambda_D, \qquad\quad \text{if } l \to D = 1, \ldots, m; \\ &= \lambda_I = 0, \qquad \text{if } l \to I = m+1, \ldots, n; \quad \text{Q.E.D.} \end{aligned} \tag{5.3.22}$$

(ii) The preceding show clearly under what conditions $\Gamma_k \to 0$; then $I_k = E_k{}^*(T^*)$ (nonlinear counterpart of pp. 421ff.).

Example 5.3.1 *Holonomic and Nonholonomic Inertial Forces and their Transformation Properties*. Let us find by direct differentiations the relations between the holonomic and nonholonomic inertia "forces" $E_k = E_k(T)$ and $I_k = E_k{}^*(T^*) - \Gamma_k$, respectively.

(i) Applying chain rule to

$$T = T(t, q, \dot{q}) = T^*(t, q, \omega) \equiv T^*, \tag{a}$$

we find

$$\begin{aligned} \partial T^*/\partial q_l &= \partial T/\partial q_l + \sum (\partial T/\partial \dot{q}_r)\,(\partial \dot{q}_r/\partial q_l) \\ \Rightarrow \partial T/\partial q_l &= \partial T^*/\partial q_l - \sum (\partial T/\partial \dot{q}_r)\,(\partial \dot{q}_r/\partial q_l), \end{aligned} \tag{b}$$

and, therefore [recalling the symbolic quasi chain rule (5.2.16c)],

$$\begin{aligned} \sum (\partial T/\partial q_l)\,(\partial \dot{q}_l/\partial \omega_k) &= \sum (\partial T^*/\partial q_l)\,(\partial \dot{q}_l/\partial \omega_k) \\ &\quad - \sum\sum (\partial T/\partial \dot{q}_r)\,(\partial \dot{q}_r/\partial q_l)\,(\partial \dot{q}_l/\partial \omega_k) \\ &= \partial T^*/\partial \theta_k - \sum (\partial T/\partial \dot{q}_r)\,(\partial \dot{q}_r/\partial \theta_k); \end{aligned} \tag{c}$$

and (ii) By $(\ldots)^{\cdot}$-differentiation of the momentum transformation

$$\partial T^*/\partial \omega_k = \sum (\partial T/\partial \dot{q}_l)\,(\partial \dot{q}_l/\partial \omega_k), \tag{d}$$

we obtain

$$(\partial T^*/\partial \omega_k)^{\cdot} = \sum \left[(\partial T/\partial \dot{q}_l)^{\cdot}\,(\partial \dot{q}_l/\partial \omega_k) + (\partial T/\partial \dot{q}_l)\,(\partial \dot{q}_l/\partial \omega_k)^{\cdot}\right],$$

from which, rearranging,

$$\sum \left[(\partial T/\partial \dot{q}_l)^{\cdot}\,(\partial \dot{q}_l/\partial \omega_k)\right] = (\partial T^*/\partial \omega_k)^{\cdot} - \sum \left[(\partial T/\partial \dot{q}_l)\,(\partial \dot{q}_l/\partial \omega_k)^{\cdot}\right]. \qquad \text{(e)}$$

Subtracting (c) from (e) side by side, we obtain the following fundamental kinematico-inertial identity:

$$\sum \left[(\partial T/\partial \dot{q}_l)^{\cdot} - \partial T/\partial q_l\right](\partial \dot{q}_l/\partial \omega_k)$$
$$= (\partial T^*/\partial \omega_k)^{\cdot} - \partial T^*/\partial \theta_k - \sum \left[(\partial \dot{q}_l/\partial \omega_k)^{\cdot} - \partial \dot{q}_l/\partial \theta_k\right](\partial T/\partial \dot{q}_l),$$

or, compactly, while recalling (5.3.18d),

$$\sum (\partial \dot{q}_l/\partial \omega_k)\, E_l(T) = E_k{}^*(T^*) - \Gamma_k \quad (= I_k); \qquad \text{(f)}$$

an equation that, as mentioned earlier, shows that although, individually, neither $E_k{}^*(T^*)$ nor Γ_k transform as (covariant) vectors under $\delta q \Leftrightarrow \delta\theta$, taken together as $I_k \equiv E_k{}^*(T^*) - \Gamma_k$ they do; that is, $I_k = \sum (\partial \dot{q}_l/\partial \omega_k) E_l \;\Leftrightarrow\; E_l = \sum (\partial \omega_k/\partial \dot{q}_l) I_k$.

The above allow us to find the transformation properties of Γ_k under a local quasi-velocity change:

$$\omega = \omega(t, q, \omega') \;\Leftrightarrow\; \omega' = \omega'(t, q, \omega). \qquad \text{(g)}$$

We begin with the invariant virtual work of the inertia "forces":

$$\delta I = \sum I_k\, \delta\theta_k = \sum I_{k'}\, \delta\theta_{k'}, \qquad \text{(h)}$$

where

$$\delta\theta_k = \sum (\partial \omega_k/\partial \omega_{k'})\, \delta\theta_{k'} \;\Leftrightarrow\; \delta\theta_{k'} = \sum (\partial \omega_{k'}/\partial \omega_k)\, \delta\theta_k, \qquad \text{(i)}$$

$$\omega_k \equiv d\theta_k/dt \qquad \text{and} \qquad \omega_{k'} \equiv d\theta_{k'}/dt, \qquad \text{(j)}$$

$$I_k = (\partial T^*/\partial \omega_k)^{\cdot} - \partial T^*/\partial \theta_k - \Gamma_k \equiv E_k{}^*(T^*) - \Gamma_k \equiv E_k{}^* - \Gamma_k, \qquad \text{(k)}$$

$$I_{k'} = (\partial T^*/\partial \omega_{k'})^{\cdot} - \partial T^*/\partial \theta_{k'} - \Gamma_{k'} \equiv E_{k'}{}^*(T^{*\prime}) - \Gamma_{k'} \equiv E_{k'}{}^{*\prime} - \Gamma_{k'}, \qquad \text{(l)}$$

$$T^* = T^*(t, q, \omega), \qquad T^{*\prime} = T^*(t, q, \omega'). \qquad \text{(m)}$$

From the above, we readily obtain the (covariant) vector transformation equations

$$I_{k'} = \sum (\partial \omega_k/\partial \omega_{k'}) I_k \;\Leftrightarrow\; I_k = \sum (\partial \omega_{k'}/\partial \omega_k) I_{k'}. \qquad \text{(n)}$$

Let us find how the constituents of $I_k, E_k{}^*$, and Γ_k, transform individually; that is, how they relate to their accented counterparts.

(a) First, the $E_k{}^*$'s. Applying chain rule to

$$T^* = T^*(t, q, \omega) = T^*[t, q, \omega(t, q, \omega')] = T^{*\prime}(t, q, \omega') \equiv T^{*\prime}, \qquad \text{(o)}$$

we find

(i)
$$\partial T^{*\prime}/\partial\omega_{k'} = \sum (\partial T^*/\partial\omega_k)\,(\partial\omega_k/\partial\omega_{k'}),$$
$$\Rightarrow (\partial T^{*\prime}/\partial\omega_{k'})^{\cdot} = \sum \big[(\partial T^*/\partial\omega_k)^{\cdot}\,(\partial\omega_k/\partial\omega_{k'}) + (\partial T^*/\partial\omega_k)\,(\partial\omega_k/\partial\omega_{k'})^{\cdot}\big]; \qquad \text{(p)}$$

(ii)
$$\begin{aligned}\partial T^{*\prime}/\partial\theta_{k'} &= \sum (\partial T^{*\prime}/\partial q_l)\,(\partial\dot{q}_l/\partial\omega_{k'})\\ &= \sum \big[\partial T^*/\partial q_l + \sum (\partial T^*/\partial\omega_k)\,(\partial\omega_k/\partial q_l)\big]\,(\partial\dot{q}_l/\partial\omega_{k'})\\ &= \sum\Big(\sum (\partial T^*/\partial\theta_k)\,(\partial\omega_k/\partial\dot{q}_l)\Big)\,(\partial\dot{q}_l/\partial\omega_{k'})\\ &\quad + \sum (\partial T^*/\partial\omega_k)\,\Big(\sum (\partial\omega_k/\partial q_l)\,(\partial\dot{q}_l/\partial\omega_{k'})\Big)\\ &= \sum \big[(\partial T^*/\partial\theta_k)\,(\partial\omega_k/\partial\omega_{k'}) + (\partial T^*/\partial\omega_k)\,(\partial\omega_k/\partial\theta_{k'})\big]. \qquad \text{(q)}\end{aligned}$$

Subtracting (q) from (p) side by side, we finally obtain

$$\begin{aligned}(\partial T^{*\prime}/\partial\omega_{k'})^{\cdot} - \partial T^{*\prime}/\partial\theta_{k'} &= \sum \big[(\partial T^*/\partial\omega_k)^{\cdot} - \partial T^*/\partial\theta_k\big]\,(\partial\omega_k/\partial\omega_{k'})\\ &\quad + \sum \big[(\partial\omega_k/\partial\omega_{k'})^{\cdot} - \partial\omega_k/\partial\theta_{k'}\big]\,(\partial T^*/\partial\omega_k);\end{aligned}$$

or, compactly,

$$E_{k'}{}^*(T^{*\prime}) = \sum (\partial\omega_k/\partial\omega_{k'})E_k{}^*(T^*) + \sum (\partial T^*/\partial\omega_k)E_{k'}{}^*(\omega_k); \qquad \text{(r)}$$

which is the general law of transformation of the nonholonomic Euler–Lagrange operator applied to the corresponding kinetic energy (or any other function of t, q, ω).

In particular, if

$$E_{k'}{}^*(\omega_k) \equiv (\partial\omega_k/\partial\omega_{k'})^{\cdot} - \partial\omega_k/\partial\theta_{k'} = 0 \qquad \text{(s)}$$

(in which case, ω and ω' are called *relatively holonomic*), $E_k{}^*(T^*)$ transforms as a vector.

(b) Next, to the Γ_k's (see also next example). In view of (k, l, n), we have

$$E_{k'}{}^* - \Gamma_{k'} = \sum (\partial\omega_k/\partial\omega_{k'})\,(E_k{}^* - \Gamma_k), \qquad \text{(t)}$$

or rearranging, and then using (r),

$$\begin{aligned}\Gamma_{k'} &= \Big[E_{k'}{}^* - \sum (\partial\omega_k/\partial\omega_{k'})E_k{}^*\Big] + \sum (\partial\omega_k/\partial\omega_{k'})\Gamma_k\\ &= \sum (\partial T^*/\partial\omega_k)E_{k'}{}^*(\omega_k) + \sum (\partial\omega_k/\partial\omega_{k'})\Gamma_k,\end{aligned}$$

or, in extenso,

$$\Gamma_{k'} = \sum (\partial\omega_k/\partial\omega_{k'})\Gamma_k + \sum \big[(\partial\omega_k/\partial\omega_{k'})^{\cdot} - \partial\omega_k/\partial\theta_{k'}\big]\,(\partial T^*/\partial\omega_k). \qquad \text{(u)}$$

As the above shows, if ω and ω' are relatively holonomic, Γ_k transforms as a (covariant) vector. [In tensor calculus, nonvectorial (nontensorial) quantities like

$E_k{}^*$ and Γ_k are called *geometrical objects*. Other such examples are the Christoffel symbols (§3.10).] In particular, if $\omega_k = \dot{q}_k$—that is, if the ω are holonomic velocities—then $T^* \to T$, $E_k{}^*(T^*) \to E_k(T)$, and $\Gamma_k \to 0$, and so (u) reduces to

$$\Gamma_{k'} = \sum \left[(\partial \dot{q}_k/\partial \omega_{k'})^{\cdot} - \partial \dot{q}_k/\partial \theta_{k'} \right] (\partial T/\partial \dot{q}_k)' \equiv \sum V^k{}_{k'} p_k{}', \tag{v}$$

where $V^k{}_{k'}$ = nonlinear Voronets coefficients for $\dot{q} = \dot{q}(t, q, \omega') \Leftrightarrow \omega' = \omega'(t, q, \dot{q})$, and $\partial T/\partial \dot{q}_k \equiv p_k \equiv p_k(t, q, \dot{q}) = p_k[t, q, \dot{q}(t, q, \omega')] = p_k{}'(t, q, \omega') \equiv (\partial T/\partial \dot{q}_k)'$.

Example 5.3.2 *Alternative, Particle Vector–Based Derivation of the Transformation Formula (u). Additional Constraints.* By definition (recalling (5.3.18c)

$$\Gamma_{k'} \equiv \mathsf{S}\, dm\, \mathbf{v}^{*\prime} \cdot \left[(\partial \mathbf{v}^{*\prime}/\partial \omega_{k'})^{\cdot} - \partial \mathbf{v}^{*\prime}/\partial \theta_{k'} \right], \tag{a}$$

where

$$\mathbf{v} = \mathbf{v}(t, q, \dot{q}) = \mathbf{v}^*(t, q, \omega) = \mathbf{v}^*[t, q, \omega(t, q, \omega')] = \mathbf{v}^{*\prime}(t, q, \omega') \equiv \mathbf{v}^{*\prime}. \tag{b}$$

But:

(i)
$$\begin{aligned} \boldsymbol{\varepsilon}_{k'} \equiv \partial \mathbf{v}^{*\prime}/\partial \omega_{k'} &= \sum (\partial \mathbf{v}^*/\partial \omega_k)(\partial \omega_k/\partial \omega_{k'}) \equiv \sum (\partial \omega_k/\partial \omega_{k'}) \boldsymbol{\varepsilon}_k, \\ \Rightarrow (\partial \mathbf{v}^{*\prime}/\partial \omega_{k'})^{\cdot} &\equiv d\boldsymbol{\varepsilon}_{k'}/dt \\ &= \sum \left[(\partial \omega_k/\partial \omega_{k'})^{\cdot} \boldsymbol{\varepsilon}_k + (\partial \omega_k/\partial \omega_{k'})(d\boldsymbol{\varepsilon}_k/dt) \right]; \end{aligned} \tag{c}$$

and

(ii)
$$\begin{aligned} \partial \mathbf{v}^{*\prime}/\partial \theta_{k'} &\equiv \sum (\partial \mathbf{v}^{*\prime}/\partial q_l)(\partial \dot{q}_l/\partial \omega_{k'}) \\ &\equiv \sum \left[\partial \mathbf{v}^*/\partial q_l + \sum (\partial \mathbf{v}^*/\partial \omega_k)(\partial \omega_k/\partial q_l) \right] (\partial \dot{q}_l/\partial \omega_{k'}) \\ &= \sum (\partial \mathbf{v}^*/\partial \theta_k) \left(\sum (\partial \omega_k/\partial \dot{q}_l)(\partial \dot{q}_l/\partial \omega_{k'}) \right) \\ &\quad + \sum (\partial \mathbf{v}^*/\partial \omega_k) \left[(\partial \omega_k/\partial q_l)(\partial \dot{q}_l/\partial \omega_{k'}) \right] \\ &\equiv \sum (\partial \mathbf{v}^*/\partial \theta_k)(\partial \omega_k/\partial \omega_{k'}) + \sum (\partial \mathbf{v}^*/\partial \omega_k)(\partial \omega_k/\partial \theta_{k'}). \end{aligned} \tag{d}$$

Inserting the expressions (c, d) in (a), we obtain, successively [recalling that $\mathbf{v}^{*\prime} = \mathbf{v}^*$, $\boldsymbol{\varepsilon}_k = \partial \mathbf{v}^*/\partial \omega_k$, and the definitions of Γ_k and $\partial T^*/\partial \omega_k$],

$$\begin{aligned} \Gamma_{k'} &= \sum (\partial \omega_k/\partial \omega_{k'}) \left\{ \mathsf{S}\, dm\, \mathbf{v}^* \cdot \left[(\partial \mathbf{v}^*/\partial \omega_k)^{\cdot} - \partial \mathbf{v}^*/\partial \theta_k \right] \right\} \\ &\quad + \sum \left[(\partial \omega_k/\partial \omega_{k'})^{\cdot} - \partial \omega_k/\partial \theta_{k'} \right] \left(\mathsf{S}\, dm\, \mathbf{v}^* \cdot (\partial \mathbf{v}^*/\partial \omega_k) \right), \end{aligned}$$

which is none other than eq. (u) of the preceding example.

Additional Constraints

These transformation equations may prove useful if the hitherto independent $n - m$ quasi velocities $\omega_I \equiv (\omega_{m+1}, \ldots, \omega_n)$ are, later, subjected to the $m'\,(< n - m)$ new constraints

$$c_d(t, q, \omega_I) = 0 \qquad (d = 1, \dots, m'). \tag{e}$$

Then, to incorporate (e) to our description, and following the earlier Johnsen–Hamel approach, we may introduce $n - m$ new quasi velocities $\omega' \equiv (\omega_1{}', \dots, \omega'_{n-m})$:

$$\omega_d{}' \equiv c_d(t, q, \omega_I) = 0, \tag{f1}$$

$$\omega_i{}' \equiv c_i(t, q, \omega_I) \neq 0 \qquad (i = m' + 1, \dots, n - m); \tag{f2}$$

where, as in the Pfaffian case (§3.11) the $(n - m) - m'$ $c_i(\dots)$ are arbitrary, except that when the system (f1, 2) is solved for the $\omega_I, \omega_I = \omega_I(t, q, \omega')$, and these expressions are inserted back into (e), they satisfy them identically in the ω'. In this case, Lagrange's principle yields

$$\sum [(\partial T^*/\partial \omega_I)^{\cdot} - \partial T^*/\partial \theta_I - \Gamma_I - \Theta_I]\, \delta\theta_I = 0, \tag{g}$$

where the $n - m$ $\delta\theta_I \equiv (\delta\theta_{m+1}, \dots, \delta\theta_n)$ are subjected to the virtual form of the constraints (e, f1):

$$\delta\theta_d{}' \equiv \sum (\partial c_d/\partial \omega_I)\, \delta\theta_I = 0. \tag{h}$$

From here on, we proceed in well-known ways; that is, either we *adjoin* (h) to (g) via new Lagrangean multipliers ($\rightarrow$ Routh–Voss equations in T^*, ω_I), or we *embed* them via the quasi variables $\delta\theta'/\omega'$ ($\rightarrow$ Maggi equations in $T^*, \omega_I, \partial\omega_I/\partial\omega'$; or Hamel equations in $T^{*\prime} = T^{*\prime}(t, q, \omega'), \omega', \Gamma'$, etc.).

Finally, under $\omega \leftrightarrow \omega'$, Appell's equations (say, under no constraints) become

$$\sum (\partial S^*/\partial \dot{\omega}_k)\, (\partial \dot{\omega}_k/\partial \dot{\omega}_{k'}) = \sum (\partial \dot{\omega}_k/\partial \dot{\omega}_{k'})\Theta_k; \tag{i}$$

that is,

$$\partial S^{*\prime}/\partial \dot{\omega}_{k'} = \Theta_{k'}, \tag{j}$$

where

$$\begin{aligned} S^* = S^*(t, q, \omega, \dot{\omega}) &= S^*\big[t, q, \omega(t, q, \omega'), \dot{\omega}(t, q, \omega', \dot{\omega}')\big] \\ &= S^{*\prime}(t, q, \omega', \dot{\omega}') = S^{*\prime}; \end{aligned} \tag{k}$$

also,

$$\partial\dot{\omega}_k/\partial\dot{\omega}_{k'} = \partial\omega_k/\partial\omega_{k'}, \qquad \partial\dot{\omega}_{k'}/\partial\dot{\omega}_k = \partial\omega_{k'}/\partial\omega_k.$$

Example 5.3.3 *Special Forms of the Equations of Motion: Nonlinear Equations of Hadamard.* Let us specialize the nonlinear Maggi equations to the following quasi-variable choice (recall ex. 5.2.2):

$$\omega_D \equiv f_D(t, q, \dot{q}) = \dot{q}_D - \phi_D(t, q, \dot{q}_I) = 0, \tag{a}$$

$$\omega_I \equiv f_I(t, q, \dot{q}) = \dot{q}_I \neq 0; \tag{b}$$

and its inverse

$$\dot{q}_D = \omega_D + \phi_D(t, q, \dot{q}_I) = \omega_D + \phi_D(t, q, \omega_I), \tag{c}$$

$$\dot{q}_I = \omega_I. \tag{d}$$

With the notation $E_k(T) - Q_k \equiv E_k - Q_k = \partial S/\partial \ddot{q}_k - Q_k \equiv M_k$, and (c, d), we obtain, successively,

$$\begin{aligned}
\sum (\partial \dot{q}_l/\partial \omega_k) M_l &= \sum (\partial \dot{q}_D/\partial \omega_k) M_D + \sum (\partial \dot{q}_I/\partial \omega_k) M_I \\
&= \sum (\partial \dot{q}_D/\partial \omega_{D'}) M_D + \sum (\partial \dot{q}_I/\partial \omega_{D'}) M_I \\
&= \sum (\delta_{DD'}) M_D + \sum (0) M_I = M_{D'} \qquad (D' = 1, \ldots, m); \qquad \text{(e1)} \\
&= \sum (\partial \dot{q}_D/\partial \omega_I) M_D + \sum (\partial \dot{q}_I/\partial \omega_{I'}) M_I \\
&= \sum (\partial \phi_D/\partial \omega_I) M_D + \sum (\delta_{II'}) M_I \\
&= M_I + \sum (\partial \phi_D/\partial \dot{q}_I) M_D \qquad (I = m+1, \ldots, n). \qquad \text{(e2)}
\end{aligned}$$

As a result of the above, Maggi's equations (5.3.16b, c) reduce to the *nonlinear Hadamard equations*.

Kinetostatic:

$$\begin{aligned}
E_D(T) &\equiv \left[(\partial T/\partial \dot{q}_D)^{\cdot} - \partial T/\partial q_D\right] = \partial S/\partial \ddot{q}_D \\
&= Q_D + \lambda_D, \qquad \text{(f1)}
\end{aligned}$$

Kinetic:

$$\begin{aligned}
&E_I(T) + \sum (\partial \phi_D/\partial \dot{q}_I) E_D(T) \\
&\quad \equiv \left[(\partial T/\partial \dot{q}_I)^{\cdot} - \partial T/\partial q_I\right] + \sum (\partial \phi_D/\partial \dot{q}_I) \left[(\partial T/\partial \dot{q}_D)^{\cdot} - \partial T/\partial q_D\right] \\
&\quad = \partial S/\partial \ddot{q}_I + \sum (\partial \phi_D/\partial \dot{q}_I) (\partial S/\partial \ddot{q}_D) \\
&\quad = Q_I + \sum (\partial \phi_D/\partial \dot{q}_I) Q_D. \qquad \text{(f2)}
\end{aligned}$$

Equations (f2), plus the constraints (a), yield the motion; then (f1) give the constraint reactions. [In terms of the constrained Appellian S_o, eqs. (f2) state simply that

$$\partial S_o/\partial \ddot{q}_I = Q_I + \sum (\partial \phi_D/\partial \dot{q}_I) Q_D \quad (\equiv Q_{I,o} \equiv Q_{Io}), \qquad \text{(g)}$$

where

$$S = S(t, q, \dot{q}, \ddot{q}) = \cdots = S_o(t, q, \dot{q}, \ddot{q}) = S_o.]$$

Example 5.3.4 *Special Forms of the Equations of Motion: Nonlinear Equations of Chaplygin and Voronets.* Continuing from the preceding example, let us derive the specialization of the Johnsen–Hamel equations under (a–d) from that example.

First Method

Here, and recalling the notations and results of §3.8, and ex. 5.2.2 and ex. 5.2.3, we have

$$\begin{gathered}
\omega_I \to \dot{q}_I, \quad \theta_I \to (q_I), \quad T^* \to T_o = T_o(t, q, \dot{q}_I) \\
\text{(i.e., no kinetostatic equations, only kinetic);}
\end{gathered}$$

and

$$\partial T^*/\partial\omega_I \to \partial T_o/\partial\dot{q}_I, \tag{a}$$

$$\partial T^*/\partial\theta_I \to \partial T_o/\partial(q_I) \equiv \partial T_o/\partial q_I + \sum (\partial\phi_D/\partial\dot{q}_I)\,(\partial T_o/\partial q_D); \tag{b}$$

$$V^{I'}{}_I \to V^{I'}{}_{I,o} \equiv W^{I'}{}_I = 0 \qquad \text{(Suslov viewpoint)}, \tag{c}$$

$$\begin{aligned} V^D{}_I \to V^D{}_{I,o} \equiv W^D{}_I &= (\partial\phi_D/\partial\dot{q}_I)^{\cdot} - \partial\phi_D/\partial q_I - \sum (\partial\phi_D/\partial q_{D'})\,(\partial\phi_{D'}/\partial\dot{q}_I) \\ &\equiv E_I\ (\phi_D) - \sum (\partial\phi_D/\partial q_{D'})\,(\partial\phi_{D'}/\partial\dot{q}_I) \\ &\equiv (\partial\phi_D/\partial\dot{q}_I)^{\cdot} - \partial\phi_D/\partial(q_I) \\ &\equiv E_{(I)}(\phi_D), \end{aligned} \tag{d}$$

$$\Gamma_I \to \Gamma_{I,o} \equiv W_I = \sum W^D{}_I\,(\partial T/\partial\dot{q}_D)_o \equiv \sum W^D{}_I\, p_{D,o}, \tag{e}$$

$$\begin{aligned} \delta' W \to (\delta' W)_o &= \Big(\sum Q_k\,\delta q_k\Big)_o \\ &= \cdots = \sum \Big(Q_I + \sum (\partial\phi_D/\partial\dot{q}_I) Q_D\Big)\,\delta q_I \equiv \sum Q_{Io}\,\delta q_I. \end{aligned} \tag{f}$$

$\{$For a general function $f = f(t, q, \dot{q}) = f[t, q, \dot{q}_D = \phi_D(t, q, \dot{q}_I), \dot{q}_I] = f_o(t, q, \dot{q}_I) = f_o$, we notice the *difference* between the ordinary *chain rule*:

$$\partial f_o/\partial q_k = \partial f/\partial q_k + \sum (\partial f/\partial\dot{q}_D)\,(\partial\phi_D/\partial q_k),$$

and the *quasi chain rule specialization* (i.e., notation—recall (2.11.15a ff.)):

$$\partial f_o/\partial(q_I) \equiv \partial f_o/\partial q_I + \sum (\partial f_o/\partial q_D)\,(\partial\phi_D/\partial\dot{q}_I).\}$$

As a result of the above, eqs. (5.3.18a–20) yield what should, legitimately, be called the *nonlinear Voronets equations*:

$$\begin{aligned} &\Big\{(\partial T_o/\partial\dot{q}_I)^{\cdot} - \Big[\partial T_o/\partial q_I + \sum (\partial\phi_D/\partial\dot{q}_I)\,(\partial T_o/\partial q_D)\Big]\Big\} - \sum W^D{}_I\,(\partial T/\partial\dot{q}_D)_o \\ &\quad \equiv \big[(\partial T_o/\partial\dot{q}_I)^{\cdot} - \partial T_o/\partial(q_I)\big] - \sum W^D{}_I(\partial T/\partial\dot{q}_D)_o \\ &\quad \equiv E_I(T_o) - \sum (\partial\phi_D/\partial\dot{q}_I)\,(\partial T_o/\partial q_D) - W_I \\ &\quad \equiv E_{(I)}(T_o) - W_I \\ &\quad = Q_{Io}. \end{aligned} \tag{g}$$

In the Chaplygin case, $\dot{q}_D = \dot{q}_D(q_I, \dot{q}_I) \equiv \phi_D(q_I, \dot{q}_I)$ and $T_o = T_o(q_I, \dot{q}_I)$, and so

$$\begin{aligned} &\partial\phi_D/\partial q_{D'} = 0, \qquad \partial T_o/\partial q_D = 0, \\ &\quad \Rightarrow \partial\phi_D/\partial(q_I) = \partial\phi_D/\partial q_I, \\ &\quad \Rightarrow W^D{}_I \equiv E_{(I)}(\phi_D) \to E_I(\phi_D) \equiv (\partial\phi_D/\partial\dot{q}_I)^{\cdot} - \partial\phi_D/\partial q_I \equiv T^D{}_I, \\ &\quad \Rightarrow \Gamma_{I,o} \equiv W_I \to T_I \equiv \sum T^D{}_I(\partial T/\partial\dot{q}_D)_o, \end{aligned} \tag{h}$$

and, accordingly, (g) reduces to what we will be calling the *nonlinear Chaplygin equations*:

$$(\partial T_o/\partial \dot{q}_I)^{\cdot} - \partial T_o/\partial q_I - \sum T^D{}_I\,(\partial T/\partial \dot{q}_D)_o$$
$$\equiv (\partial T_o/\partial \dot{q}_I)^{\cdot} - \partial T_o/\partial q_I - T_I = Q_{Io}. \tag{i}$$

It is not hard to see that in the Pfaffian case, eqs. (g) and (i) reduce, respectively, to the original Voronets and Chaplygin forms (§3.8).

Second Method (By Direct Differentiation)

Here, we have

$$\begin{aligned}\partial T^*/\partial\omega_I &= \sum (\partial T/\partial \dot{q}_k)\,(\partial \dot{q}_k/\partial\omega_I)\\ &= \sum (\partial T/\partial \dot{q}_D)\,(\partial \dot{q}_D/\partial\omega_I) + \sum (\partial T/\partial \dot{q}_{I'})\,(\partial \dot{q}_{I'}/\partial\omega_I)\\ &= \sum (\partial T/\partial \dot{q}_D)\,(\partial \dot{q}_D/\partial \dot{q}_I) + \sum (\partial T/\partial \dot{q}_{I'})\,(\delta_{I'I})\\ &= \partial T/\partial \dot{q}_I + \sum (\partial \dot{q}_D/\partial \dot{q}_I)\,(\partial T/\partial \dot{q}_D) = \partial T_o/\partial \dot{q}_I,\end{aligned} \tag{j}$$

$$\begin{aligned}\partial T^*/\partial\omega_D &\equiv \sum (\partial T/\partial \dot{q}_k)\,(\partial \dot{q}_k/\partial\omega_D)\\ &= \sum (\partial T/\partial \dot{q}_{D'})\,(\partial \dot{q}_{D'}/\partial\omega_D) + \sum (\partial T/\partial \dot{q}_I)\,(\partial \dot{q}_I/\partial\omega_D)\\ &= \sum (\partial T/\partial \dot{q}_{D'})\,(\delta_{D'D}) + \sum (\partial T/\partial \dot{q}_I)\,(0)\\ &= \partial T/\partial \dot{q}_D \ \rightarrow \ (\partial T/\partial \dot{q}_D)^* \rightarrow (\partial T/\partial \dot{q}_D)_o,\end{aligned} \tag{k}$$

$$\begin{aligned}\partial T^*/\partial\theta_I &\equiv \sum (\partial T^*/\partial q_k)\,(\partial \dot{q}_k/\partial\omega_I)\\ &= \sum (\partial T^*/\partial q_D)\,(\partial \dot{q}_D/\partial\omega_I) + \sum (\partial T^*/\partial q_{I'})\,(\partial \dot{q}_{I'}/\partial\omega_I)\\ &= \sum (\partial T^*/\partial q_D)\,(\partial \phi_D/\partial\omega_I) + \sum (\partial T^*/\partial q_{I'})\,(\delta_{I'I})\\ &= \sum (\partial T_o/\partial q_D)\,(\partial \phi_D/\partial \dot{q}_I) + \partial T_o/\partial q_I\\ &\equiv \partial T_o/\partial (q_I),\end{aligned} \tag{l}$$

$$\begin{aligned}H^D{}_I &= \sum \left[(\partial\omega_D/\partial \dot{q}_k)^{\cdot} - \partial\omega_D/\partial q_k\right](\partial \dot{q}_k/\partial\omega_I) \qquad \text{[by (5.2.21h)]}\\ &= \sum \left[(\partial\omega_D/\partial \dot{q}_{D'})^{\cdot} - \partial\omega_D/\partial q_{D'}\right](\partial \dot{q}_{D'}/\partial\omega_I)\\ &\quad + \sum \left[(\partial\omega_D/\partial \dot{q}_{I'})^{\cdot} - \partial\omega_D/\partial q_{I'}\right](\partial \dot{q}_{I'}/\partial\omega_I)\\ &= \sum \left[(\delta_{DD'})^{\cdot} - (-\partial\phi_D/\partial q_{D'})\right](\partial\phi_{D'}/\partial\omega_I)\\ &\quad + \sum \left[(-\partial\phi_D/\partial \dot{q}_{I'})^{\cdot} - (-\partial\phi_D/\partial q_{I'})\right](\delta_{I'I})\\ &= -\left\{(\partial\phi_D/\partial \dot{q}_I)^{\cdot} - \left[\partial\phi_D/\partial q_I + \sum (\partial\phi_D/\partial\phi_{D'})\,(\partial\phi_{D'}/\partial \dot{q}_I)\right]\right\}\\ &= -\left[(\partial\phi_D/\partial \dot{q}_I)^{\cdot} - \partial\phi_D/\partial (q_I)\right]\\ &\equiv -E_{(I)}(\dot{q}_D) = -W^D{}_I,\end{aligned} \tag{m}$$

$$V^k{}_I = (\partial \dot{q}_k/\partial\omega_I)^{\cdot} - \sum (\partial \dot{q}_k/\partial q_l)\,(\partial \dot{q}_l/\partial\omega_I) \qquad \text{[by (5.2.21e)]}; \tag{n}$$

or, proceeding directly from (5.2.21f),

$$\begin{aligned} H^D{}_I &= -\sum (\partial\omega_D/\partial\dot{q}_k) V^k{}_I \\ &= -\sum (\partial\omega_D/\partial\dot{q}_{D'}) V^{D'}{}_I - \sum (\partial\omega_D/\partial\dot{q}_{I'}) V^{I'}{}_I \\ &= -\sum (\delta_{DD'}) V^{D'}{}_I - \sum (-\partial\phi_D/\partial\dot{q}_{I'})\,(0) \\ &= -V^D{}_I \longrightarrow -W^D{}_I \end{aligned} \tag{o}$$

[Either from the Suslov viewpoint, or by direct application of (5.2.21f) to our special case, we easily find $V^{I'}{}_I \to W^{I'}{}_I = 0$, and, therefore,

$$H^{I'}{}_I = -\sum (\partial\omega_{I'}/\partial\dot{q}_k) V^k{}_I = \cdots = 0],$$

$$\begin{aligned} \Theta_I &= \sum (\partial\dot{q}_k/\partial\omega_I) Q_k \\ &= \sum (\partial\dot{q}_D/\partial\omega_I) Q_D + \sum (\partial\dot{q}_{I'}/\partial\omega_I) Q_{I'} \\ &= \sum (\partial\phi_D/\partial\omega_I) Q_D + \sum (\delta_{I'I}) Q_{I'} \\ &= Q_I + \sum (\partial\phi_D/\partial\dot{q}_I) Q_D \equiv Q_{Io}. \end{aligned} \tag{p}$$

Substituting all these special results into (5.3.19), we recover (g), as expected.

Problem 5.3.1 (i) Using the definitions $\Gamma_k = \sum V^l{}_k p_l = -\sum H^b{}_k P_b$, and (5.2.21e–g) in the Γ transformation equation (exs. 5.3.1 and 5.3.2), show that under $\omega(t, q, \omega') \Leftrightarrow \omega'(t, q, \omega)$ the nonlinear Voronets and Hamel coefficients $V^l{}_k$ and $H^b{}_k$ transform as

$$\begin{aligned} V^l{}_{k'} &= \sum (\partial\omega_k/\partial\omega_{k'}) V^l{}_k \\ &\qquad + \sum \left[(\partial\omega_k/\partial\omega_{k'})^{\cdot} - \partial\omega_k/\partial\theta_{k'}\right] (\partial\dot{q}_l/\partial\omega_k), \end{aligned} \tag{a}$$

$$\begin{aligned} H^{b'}{}_{k'} &= \sum (\partial\omega_k/\partial\omega_{k'})\,(\partial\omega_{b'}/\partial\omega_b) H^b{}_k \\ &\qquad - \sum \left[(\partial\omega_k/\partial\omega_{k'})^{\cdot} - \partial\omega_k/\partial\theta_{k'}\right] (\partial\omega_{b'}/\partial\omega_k); \end{aligned} \tag{b}$$

that is, in general, *neither* $V^l{}_k$ nor $H^b{}_k$ *transform as vectors, tensors.*

(ii) Then show that the new (transformed) Voronets and Hamel symbols are related to each other as are the old ones; that is,

$$H^{b'}{}_{k'} = -\sum (\partial\omega_{b'}/\partial\dot{q}_l) V^l{}_{k'} \;\Leftrightarrow\; V^l{}_{k'} = -\sum (\partial\dot{q}_l/\partial\omega_{b'}) H^{b'}{}_{k'}, \tag{c}$$

where $\omega_{r'} = \omega_{r'}(t, q, \dot{q}) \Leftrightarrow \dot{q}_l = \dot{q}_l(t, q, \omega')$.

For alternative, equivalent, expressions to (a, b), see Novoselov (1979, pp. 120–121).

Example 5.3.5 (Mei, 1985, pp. 89–90). Let us obtain the *Routh–Voss* equations of motion of a particle P of mass m moving under the constraint

$$(\dot{q}_1)^2 + (\dot{q}_2)^2 + (\dot{q}_3)^2 = constant \equiv c^2; \tag{a}$$

that is, square of velocity $\boldsymbol{v}$ of $P = \text{constant}$, where $q_{1,2,3} = x, y, z$: rectangular Cartesian coordinates of P. Here, with the usual notations,

$$2T = m[(\dot{q}_1)^2 + (\dot{q}_2)^2 + (\dot{q}_3)^2], \tag{b}$$

$$\begin{aligned} f &\equiv (\dot{q}_1)^2 + (\dot{q}_2)^2 + (\dot{q}_3)^2 - c^2 = 0 \\ &\Rightarrow \partial f/\partial \dot{q}_k = 2\dot{q}_k \qquad (k = 1, 2, 3); \end{aligned} \tag{c}$$

and, therefore, the nonlinear Routh–Voss equations, under impressed forces Q_k, are

$$m\,\ddot{q}_k = Q_k + 2\lambda\,\dot{q}_k, \tag{d}$$

and along with (a) they constitute a determinate system for the $q_k(t)$ and $\lambda(t)$.

To eliminate the multiplier λ, we multiply each of (d) by its $\dot{q}_k$ and add them together, thus obtaining the *power* equation

$$\begin{aligned} &m(\dot{q}_1\ddot{q}_1 + \dot{q}_2\ddot{q}_2 + \dot{q}_3\ddot{q}_3) \\ &\quad = Q_1\dot{q}_1 + Q_2\dot{q}_2 + Q_3\dot{q}_3 + 2\lambda\,[(\dot{q}_1)^2 + (\dot{q}_2)^2 + (\dot{q}_3)^2] \\ &\quad = Q_1\dot{q}_1 + Q_2\dot{q}_2 + Q_3\dot{q}_3 + 2\lambda c^2, \end{aligned} \tag{e}$$

from which, invoking the constraint (c) $f = 0$ and its $(\ldots)^{\cdot}$-derivative

$$\dot{f} = 2\,(\dot{q}_1\ddot{q}_1 + \dot{q}_2\ddot{q}_2 + \dot{q}_3\ddot{q}_3) = 0,$$

we readily get the multiplier

$$\lambda = -(Q_1\dot{q}_1 + Q_2\dot{q}_2 + Q_3\dot{q}_3)\big/2c^2. \tag{f}$$

Finally, substituting λ from (f) back into (d), we obtain the purely *kinetic* ("Jacobi–Synge" type of) equations

$$m\ddot{q}_k = Q_k - \left[(Q_1\dot{q}_1 + Q_2\dot{q}_2 + Q_3\dot{q}_3)/c^2\right]\dot{q}_k. \tag{g}$$

[Recall examples 3.2.6, 3.5.5, and 3.10.2. The general methodology for obtaining such reactionless equations seems to have originated with Jacobi [1842–1843, publ. 1866; p. 51 ff. (esp. p. 55) and p. 132 ff.]; while a more general, tensor calculus-based approach is due to Synge (1926–1927, pp. 53–55).]

Let us examine this problem from the elementary Newton–Euler viewpoint. In view of (a), $v = c$, and so the intrinsic equations of motion of P (§1.2):

$$mv^2/\rho = F_n + R_n, \qquad m\dot{v} = F_t + R_t \tag{h}$$

(ρ: radius of curvature of trajectory of $P, F_{n,t}/R_{n,t}$: normal and tangential components of total impressed/reaction force on P), reduce to

$$\begin{aligned} &mc^2/\rho = F_n + R_n, \\ &\qquad 0 = F_t + R_t \\ &\Rightarrow R_t = -F_t = -\boldsymbol{F}\cdot(\boldsymbol{v}/v) = -(\boldsymbol{F}\cdot\boldsymbol{v})/c \\ &= -\left(\sum Q_k\dot{q}_k\right)\Big/c = 2c\lambda. \end{aligned} \tag{i}$$

For additional details, see Hamel (1949, pp. 709–710).

Example 5.3.6 (Mei, 1985, pp. 91–93). Let us obtain the *Routh–Voss* equations of motion of a particle P of mass m moving in a uniform gravitational field and subject to the Appell–Hamel constraint

$$(\dot{x})^2 + (\dot{y})^2 = (a/b)^2(\dot{z})^2 \qquad (a, b\text{: given; say, positive constants}) \tag{a}$$

where, x, y, z: rectangular Cartesian coordinates of P.

Since here

$$2T = m[(\dot{x})^2 + (\dot{y})^2 + (\dot{z})^2],$$
$$Q_x = 0, \qquad Q_y = 0, \qquad Q_z = -mg \qquad (\text{with } +z \text{ vertically upward}), \tag{b}$$

and with

$$f \equiv (\dot{x})^2 + (\dot{y})^2 - (a/b)^2(\dot{z})^2 = 0, \tag{c}$$

the Routh–Voss equations are

$$m\,\ddot{x} = 2\lambda\,\dot{x}, \qquad m\,\ddot{y} = 2\lambda\,\dot{y}, \qquad m\,\ddot{z} = -m\,g - 2\lambda(a/b)^2\dot{z}; \tag{d}$$

and with (a) they constitute a determinate system for $x(t), y(t), z(t), \lambda(t)$. To obtain reactionless "Jacobi–Synge" equations [like (g) of the preceding example], we $(\ldots)^{\cdot}$-differentiate the constraint (a):

$$\ddot{z} = (b/a)^2[(\dot{x}\ddot{x} + \dot{y}\ddot{y})/\dot{z}], \tag{e}$$

and then substitute it into the third of (d), while using (a) rewritten as

$$\dot{z} = (b/a)\,[(\dot{x})^2 + (\dot{y})^2]^{1/2} \qquad [\dot{z}, a, b > 0], \tag{f}$$

that is, the ratio of vertical velocity to horizontal velocity equals b/a. The result is

$$\begin{aligned} 2\lambda = {} & -m(b/a)^2(\dot{x}\ddot{x} + \dot{y}\ddot{y})\Big/[(\dot{x})^2 + (\dot{y})^2] \\ & - mg(b/a)\Big/[(\dot{x})^2 + (\dot{y})^2]^{1/2}, \end{aligned} \tag{g}$$

and when this is substituted back into the first two of (d), it yields the reactionless equations

$$\begin{aligned} & \ddot{x} + (b/a)^2(\dot{x}\ddot{x} + \dot{y}\ddot{y})\dot{x}\Big/[(\dot{x})^2 + (\dot{y})^2] \\ & \qquad = -g(b/a)\dot{x}\Big/[(\dot{x})^2 + (\dot{y})^2]^{1/2}, \end{aligned} \tag{h}$$

$$\begin{aligned} & \ddot{y} + (b/a)^2(\dot{x}\ddot{x} + \dot{y}\ddot{y})\dot{y}\Big/[(\dot{x})^2 + (\dot{y})^2] \\ & \qquad = -g(b/a)\dot{y}\Big/[(\dot{x})^2 + (\dot{y})^2]^{1/2}. \end{aligned} \tag{i}$$

From these two equations, we readily obtain the equivalent, but simpler, system

$$\begin{aligned} & \dot{y}\,\ddot{x} - \dot{x}\,\ddot{y} = 0, \\ & \dot{x}\,\ddot{x} + \dot{y}\,\ddot{y} = -(g\,a\,b)\,(a^2 + b^2)^{-1}\,[(\dot{x})^2 + (\dot{y})^2]^{1/2}. \end{aligned} \tag{j}$$

The *first* of the above, assuming $\dot{y} \neq 0$, can be rewritten as $(\dot{x}/\dot{y})^{\cdot} = 0$, and integrates immediately to $\dot{y} = c\dot{x}$ (c: integration constant), or further to

$$y - y_o = c(x - x_o) \qquad [x_o = x(0),\ y_o = y(0)]; \tag{k}$$

while the *second*, with the help of the auxiliary variable, $v^2 = (\dot{x})^2 + (\dot{y})^2$, can be rewritten as $\dot{v} = -(g\,a\,b)\,(a^2 + b^2)^{-1}$, and integrates readily to

$$v - v_o = -[(g\,a\,b)\,(a^2 + b^2)^{-1}]\,t \qquad [v_o = v(0)]. \tag{l}$$

In view of this result, the constraint (f) becomes (assuming $\dot{z} > 0$)

$$\dot{z} = (b/a)v = (b/a)v_o - [(g\,b^2)\,(a^2 + b^2)^{-1}]t,$$

and, upon integrating, yields

$$z = z_o + (b/a)v_o\,t - [(g\,b^2)/2\,(a^2 + b^2)]t^2. \tag{m}$$

Finally, with the help of the earlier integral $\dot{y} = c\dot{x}$, v becomes

$$v = [(\dot{x})^2 + (\dot{y})^2]^{1/2} = \dot{x}(1 + c^2)^{1/2} = (\dot{y}/c)\,(1 + c^2)^{1/2}, \tag{n}$$

and so (l) transforms to the following equivalent x, y-equations:

$$(1 + c^2)^{1/2}\dot{x} = v_o - [(g\,a\,b)/(a^2 + b^2)]t, \tag{o}$$

$$(1 + c^2)^{1/2}(\dot{y}/c) = v_o - [(g\,a\,b)/(a^2 + b^2)]t, \tag{p}$$

from which, integrating, we get

$$(1 + c^2)^{1/2}(x - x_o) = v_o\,t - [(g\,a\,b)/2(a^2 + b^2)]t^2, \tag{q}$$

$$c^{-1}(1 + c^2)^{1/2}(y - y_o) = v_o\,t - [(g\,a\,b)/2(a^2 + b^2)]t^2. \tag{r}$$

Comparing the above with (m), we see that we can rewrite all three of them as

$$(1 + c^2)^{1/2}(x - x_o) = c^{-1}(1 + c^2)^{1/2}(y - y_o) = (a/b)(z - z_o), \tag{s}$$

where c can be found from $c = \dot{y}_o/\dot{x}_o$.

Substituting from the above into (g), we can find the constraint reaction $\lambda = \lambda(t;\ v_o, m, g, a, b)$, if needed.

Example 5.3.7 (Mei, 1985, pp. 245–246). Let us obtain the *kinetic* Appellian equations of a particle P of mass m moving under the action of impressed forces Q_k $(k = 1, 2, 3)$ and subject to the Appell–Hamel constraint

$$(\dot{q}_1)^2 + (\dot{q}_2)^2 = (\dot{q}_3)^2 \qquad (q_{1,2,3}\text{: rectangular Cartesian coordinates of } P); \tag{a}$$

that is, vertical velocity equals ($\pm$) of horizontal velocity.

In view of the constraint (a), we introduce the following quasi velocities:

$$2\omega_1 \equiv [(\dot{q}_3)^2 - (\dot{q}_1)^2 - (\dot{q}_2)^2] = 0, \tag{b}$$

$$\omega_2 \equiv \arctan(\dot{q}_2/\dot{q}_1) \neq 0, \tag{c}$$

$$2\omega_3 \equiv [(\dot{q}_1)^2 + (\dot{q}_2)^2 + (\dot{q}_3)^2] \qquad (= 2T/m \neq 0). \tag{d}$$

Adding and subtracting (b) and (d) side by side we obtain, respectively,

$$(\dot{q}_3)^2 = \omega_1 + \omega_3 \ \Rightarrow\ \dot{q}_3 = (\omega_1 + \omega_3)^{1/2}, \tag{e}$$

$$(\dot{q}_1)^2 + (\dot{q}_2)^2 = \omega_3 - \omega_1; \tag{f}$$

and from these and (c), we are readily led to the *inverse* of (b–d):

$$\dot{q}_1 = (\omega_3 - \omega_1)^{1/2}\cos\omega_3, \qquad \dot{q}_2 = (\omega_3 - \omega_1)^{1/2}\sin\omega_3,$$
$$\dot{q}_3 = (\omega_1 + \omega_3)^{1/2}. \tag{g}$$

Now, since we are interested only in the kinetic Appellian equations, we *can* enforce the constraint (b) right at this point; that is, we can work with (g) and its $(\ldots)^{\cdot}$-derivatives evaluated at $\omega_1 = 0$; that is (skipping special notations, such as $(\ldots)_o$, for simplicity),

$$\dot{q}_1 = (\omega_3)^{1/2}\cos\omega_2, \qquad \dot{q}_2 = (\omega_3)^{1/2}\sin\omega_2, \qquad \dot{q}_3 = (\omega_3)^{1/2}; \tag{h}$$

$$\ddot{q}_1 = [\dot{\omega}_3/2\,(\omega_3)^{1/2}]\cos\omega_2 - (\omega_3)^{1/2}\dot{\omega}_2\sin\omega_2,$$

$$\ddot{q}_2 = [\dot{\omega}_3/2\,(\omega_3)^{1/2}]\sin\omega_2 + (\omega_3)^{1/2}\dot{\omega}_2\cos\omega_2,$$

$$\ddot{q}_3 = \dot{\omega}_3/2\,(\omega_3)^{1/2}. \tag{i}$$

Hence, the *constrained* Appellian, S^* for $\omega_1 = 0, \dot{\omega}_1 = 0$ [denoted for convenience by S^*, instead of a more precise notation, such as $S^*{}_o$] equals:

$$\begin{aligned} 2S/m &= [(\ddot{q}_1)^2 + (\ddot{q}_2)^2 + (\ddot{q}_3)^2] \\ &= \cdots = (\dot{\omega}_3)^2/2\omega_3 + \omega_3(\dot{\omega}_2)^2 = S^*(\omega_3, \dot{\omega}_2, \dot{\omega}_3), \end{aligned} \tag{j}$$

and therefore the (constrained) nonholonomic kinetic inertia "forces" are

$$I_2 \equiv \partial S^*/\partial\dot{\omega}_2 = m\,\omega_3\,\dot{\omega}_2, \qquad I_3 \equiv \partial S^*/\partial\dot{\omega}_3 = m\,\dot{\omega}_3/2\omega_3. \tag{k}$$

REMARK

However, as the above and the chain rule show, we could have stopped at the first line of (j) and *not* completed the squares. Indeed, we have

$$
\begin{aligned}
\partial S^*/\partial\dot{\omega}_2 &= (\partial S/\partial\ddot{q}_1)\,(\partial\ddot{q}_1/\partial\dot{\omega}_2) + (\partial S/\partial\ddot{q}_2)\,(\partial\ddot{q}_2/\partial\dot{\omega}_2)\\
&\quad + (\partial S/\partial\ddot{q}_3)\,(\partial\ddot{q}_3/\partial\dot{\omega}_2)\\
&= (\partial S/\partial\ddot{q}_1)\,(\partial\dot{q}_1/\partial\omega_2) + (\partial S/\partial\ddot{q}_2)\,(\partial\dot{q}_2/\partial\omega_2)\\
&\quad + (\partial S/\partial\ddot{q}_3)\,(\partial\dot{q}_3/\partial\omega_2)\\
&= (m\ddot{q}_1)\,[-(\omega_3)^{1/2}\sin\omega_2] + (m\ddot{q}_2)\,[(\omega_3)^{1/2}\cos\omega_2]\\
&\quad + (m\ddot{q}_3)\ (0)\\
&= \cdots = m\,\omega_3\,\dot{\omega}_2 \qquad \text{[using (i)]}, \qquad\qquad (\mathrm{l})\\
\partial S^*/\partial\dot{\omega}_3 &= (\partial S/\partial\ddot{q}_1)\,(\partial\dot{q}_1/\partial\omega_3) + (\partial S/\partial\ddot{q}_2)\,(\partial\dot{q}_2/\partial\omega_3)\\
&\quad + (\partial S/\partial\ddot{q}_3)\,(\partial\dot{q}_3/\partial\omega_3)\\
&= (m\ddot{q}_1)\,[\cos\omega_2/2(\omega_3)^{1/2}] + (m\ddot{q}_2)\,[\sin\omega_2/2(\omega_3)^{1/2}]\\
&\quad + (m\ddot{q}_3)\,[1/2(\omega_3)^{1/2}]\\
&= \cdots = m\,\dot{\omega}_3/2\omega_3, \qquad\qquad (\mathrm{m})
\end{aligned}
$$

as before.

From the above, it follows that the kinetic Appellian equations are

$$I_2 = \sum (\partial\dot{q}_k/\partial\omega_2)Q_k \quad (=\Theta_2), \qquad I_3 = \sum (\partial\dot{q}_k/\partial\omega_3)Q_k \quad (=\Theta_3); \tag{n}$$

or, explicitly,

$$m\,\omega_3\,\dot{\omega}_2 = [-(\omega_3)^{1/2}\sin\omega_2]Q_1 + [(\omega_3)^{1/2}\cos\omega_2]Q_2, \tag{o}$$

and

$$m\,\dot{\omega}_3/2\omega_3 = [\cos\omega_2/2(\omega_3)^{1/2}]Q_1 + [\sin\omega_2/2(\omega_3)^{1/2}]Q_2 + [1/2(\omega_3)^{1/2}]Q_3, \tag{p}$$

or, equivalently,

$$2m(\sqrt{\omega_3})^{\cdot} = (\cos\omega_2)Q_1 + (\sin\omega_2)Q_2 + Q_3. \tag{q}$$

In the special case of a uniform gravitational field — that is,

$$Q_1 = 0, \qquad Q_2 = 0, \qquad Q_3 = -m\,g, \tag{r}$$

eqs. (o) and (q) specialize, respectively, to

$$m\,\omega_3\,\dot{\omega}_2 = 0 \qquad \text{and} \qquad 2m(\sqrt{\omega_3})^{\cdot} = -m\,g, \tag{s}$$

and have the obvious integrals

$$\omega_2 = \omega_{2o} \qquad \text{and} \qquad \sqrt{\omega_3} = \sqrt{\omega_{3o}} - gt/2 \qquad [\omega_{2o} = \omega_2(0), \quad \omega_{3o} = \omega_3(0)]. \tag{t}$$

In the q-variables, the above become [recalling (h)]

$$
\begin{aligned}
&\dot{q}_1 = (-gt/2 + \sqrt{\omega_{3o}})\cos\omega_{2o}, \qquad \dot{q}_2 = (-gt/2 + \sqrt{\omega_{3o}})\sin\omega_{2o},\\
&\dot{q}_3 = -gt/2 + \sqrt{\omega_{3o}},
\end{aligned}
\tag{u}
$$

and integrate readily to

$$q_1 - q_{1o} = (-gt^2/4 + \sqrt{\omega_{3o}}t)\cos\omega_{2o}, \qquad q_2 - q_{2o} = (-gt^2/4 + \sqrt{\omega_{3o}}t)\sin\omega_{2o},$$
$$q_3 - q_{3o} = -gt^2/4 + \sqrt{\omega_{3o}}t \qquad [q_{ko} = q_k(0), \quad k = 1, 2, 3]. \tag{v}$$

Example 5.3.8 (Hamel, 1938, pp. 49–50; 1949, pp. 499–501; Mei, 1985, pp. 178–181). Let us derive the *kinetic* Johnsen–Hamel equations of the preceding example. We saw there that (no constraint enforcement yet!)

$$2\omega_1 \equiv [(\dot{q}_3)^2 - (\dot{q}_1)^2 - (\dot{q}_2)^2] = 0, \tag{a}$$

$$\omega_2 \equiv \arctan(\dot{q}_2/\dot{q}_1) \neq 0, \tag{b}$$

$$2\omega_3 \equiv [(\dot{q}_1)^2 + (\dot{q}_2)^2 + (\dot{q}_3)^2] \qquad (= 2T/m \neq 0); \tag{c}$$

$$\dot{q}_1 = (\omega_3 - \omega_1)^{1/2}\cos\omega_3, \tag{d}$$

$$\dot{q}_2 = (\omega_3 - \omega_1)^{1/2}\sin\omega_3, \tag{e}$$

$$\dot{q}_3 = (\omega_1 + \omega_3)^{1/2}. \tag{f}$$

With the help of the above, we readily find

$$2T = m[(\dot{q}_1)^2 + (\dot{q}_2)^2 + (\dot{q}_3)^2] \;\Rightarrow\; T^* = m\,\omega_3, \tag{g}$$

and, therefore,

$$P_1 \equiv \partial T^*/\partial\omega_1 = 0, \qquad P_2 \equiv \partial T^*/\partial\omega_2 = 0,$$
$$P_3 \equiv \partial T^*/\partial\omega_3 = m \;\Rightarrow\; \dot{P}_3 = 0,$$
$$\partial T^*/\partial q_k = 0 \;\Rightarrow\; \partial T^*/\partial\theta_I = 0 \qquad [k = 1, 2, 3;\; I = 2, 3], \tag{h}$$

and so, as eqs. (5.3.5b) show, we only need to calculate $H^3{}_2$ and $H^3{}_3$.

Indeed, invoking (5.2.21h) and remembering to set $\omega_1 = 0$ *after* all differentiations have been carried out, we find

$$\begin{aligned} H^3{}_2 &\equiv \sum \left[(\partial\omega_3/\partial\dot{q}_k)^{\cdot} - \partial\omega_3/\partial q_k\right](\partial\dot{q}_k/\partial\omega_2) \\ &= [(\partial\omega_3/\partial\dot{q}_1)^{\cdot} - 0]\,(\partial\dot{q}_1/\partial\omega_2) + [(\partial\omega_3/\partial\dot{q}_2)^{\cdot} - 0]\,(\partial\dot{q}_2/\partial\omega_2) \\ &= \cdots = -\sqrt{\omega_3}\,[(\sin\omega_2)\,(\sqrt{\omega_3}\,\cos\omega_2)^{\cdot} - (\cos\omega_2)\,(\sqrt{\omega_3}\,\sin\omega_2)^{\cdot}], \end{aligned} \tag{i}$$

$$\begin{aligned} H^3{}_3 &\equiv \sum \left[(\partial\omega_3/\partial\dot{q}_k)^{\cdot} - \partial\omega_3/\partial q_k\right](\partial\dot{q}_k/\partial\omega_3) \\ &= [(\partial\omega_3/\partial\dot{q}_1)^{\cdot} - 0]\,(\partial\dot{q}_1/\partial\omega_3) + [(\partial\omega_3/\partial\dot{q}_2)^{\cdot} - 0]\,(\partial\dot{q}_2/\partial\omega_3) \\ &\qquad + [(\partial\omega_3/\partial\dot{q}_3)^{\cdot} - 0]\,(\partial\dot{q}_3/\partial\omega_3) \\ &= \cdots = (1/2\sqrt{\omega_3})\,[(\cos\omega_2)\,(\sqrt{\omega_3}\,\cos\omega_2)^{\cdot} + (\sin\omega_2)\,(\sqrt{\omega_3}\,\sin\omega_2)^{\cdot} + (\sqrt{\omega_3})^{\cdot}]; \end{aligned} \tag{j}$$

and [recalling the right sides of eqs. (o, p) of the preceding example]

$$\Theta_2 = (-\sqrt{\omega_3}\,\sin\omega_2)Q_1 + (\sqrt{\omega_3}\,\cos\omega_2)Q_2, \tag{k}$$

$$\Theta_3 = (\cos\omega_2/2\sqrt{\omega_3})Q_1 + (\sin\omega_2/2\sqrt{\omega_3})Q_2 + (1/2\sqrt{\omega_3})Q_3. \tag{l}$$

Let the reader verify that by inserting all these expressions into (5.3.5b) we obtain, after some simple manipulations, eqs. (o) and (p) = (q) of the preceding example; as we should.

REMARK

As pointed out earlier in this section, the Jacobian gradients $\partial\dot{q}/\partial\omega$ $[\partial\omega/\partial\dot{q}]$ can also be found via Cramer's rule from the compatibility conditions (5.2.4a, b), once the $\partial\omega/\partial\dot{q}$ $[\partial\dot{q}/\partial\omega]$ have been calculated from (a–c) [(d–f)]; that is, it is not necessary to invert the nonlinear (a–c) [(d–f)] to obtain (d–f) [(a–c)].

Example 5.3.9 (Dobronravov, 1970, pp. 250–253; Mei, 1985, pp. 241–242; San, 1973, pp. 332–333). Let us derive the kinetic Appellian equations of a particle P of mass m moving in the central Newtonian gravitational field of another (much larger) origin O of mass M; and also subject to the constraint

$$2f \equiv (\dot{r})^2 + (r^2\cos^2\theta)(\dot{\phi})^2 + r^2(\dot{\theta})^2 = \mathit{constant} \equiv c^2; \tag{a}$$

that is, square of velocity of $P = c$; where r, ϕ, θ: (inertial) spherical coordinates of P relative to O (with θ measured from the plane O–xy toward Oz).

The (unconstrained) Appellian of the system is

$$2S = m({a_r}^2 + {a_\phi}^2 + {a_\theta}^2), \tag{b}$$

where $a_{r,\phi,\theta}$ are the (physical) components of the acceleration of P in spherical coordinates (e.g., recalling §1.2, or prob. 3.5.15, with $\theta \to \pi/2 - \theta$):

$$a_r = \ddot{r} - r[(\dot{\theta})^2 + (\dot{\phi})^2\cos^2\theta], \tag{c}$$

$$a_\phi = r\ddot{\phi}\cos\theta + 2\dot{r}\dot{\phi}\cos\theta - 2r\dot{\phi}\dot{\theta}\sin\theta, \tag{d}$$

$$a_\theta = r\ddot{\theta} + 2\dot{r}\dot{\theta} + r(\dot{\phi})^2\sin\theta\cos\theta. \tag{e}$$

In view of (a), we choose as independent q's: $q_2 = r$ and $q_3 = \theta$, and use that constraint to express the dependent $q_1 = \phi$ in terms of r, θ, and so on.

Indeed, solving (a) for $\dot{\phi}$, we obtain

$$(\dot{\phi})^2 = [c^2 - (\dot{r})^2 - r^2(\dot{\theta})^2]\big/r^2\cos^2\theta, \tag{f}$$

$$\Rightarrow \ddot{\phi} = -(\dot{r}\ddot{r} + r^2\dot{\theta}\ddot{\theta})\big/r^2\dot{\phi}\cos^2\theta \quad (+\mathit{Appell\text{-}nonimportant\ terms}), \tag{g}$$

and, therefore,

$$\partial\dot{\phi}/\partial\dot{r} = \partial\ddot{\phi}/\partial\ddot{r} = -\dot{r}/r^2\dot{\phi}\cos^2\theta, \tag{h}$$

$$\partial\dot{\phi}/\partial\dot{\theta} = \partial\ddot{\phi}/\partial\ddot{\theta} = -\dot{\theta}/\dot{\phi}\cos^2\theta. \tag{i}$$

Applying chain rule to

$$
\begin{aligned}
S &= S(a_r, a_\phi, a_\theta) = S[a_r(\ddot{r}, \ddot{\phi}, \ddot{\theta}, \ldots), \ldots] \\
&\equiv S'(\ddot{r}, \ddot{\phi}, \ddot{\theta}, \ldots) = S'[\ddot{r}, \ddot{\phi}(\ddot{r}, \ddot{\theta}, \ldots), \ddot{\theta}, \ldots] \\
&\equiv S_o(\ddot{r}, \ddot{\theta}, \ldots) \equiv S_o \qquad [\text{where } \ldots \equiv \text{no } \ddot{r}, \ddot{\phi}, \ddot{\theta} \text{ terms}],
\end{aligned} \tag{j}
$$

we easily find [no need to complete the squares in (b–e)]

$$
\begin{aligned}
\partial S_o/\partial\ddot{r} = {} & [(\partial S/\partial a_r)\,(\partial a_r/\partial\ddot{r}) + (\partial S/\partial a_\phi)\,(\partial a_\phi/\partial\ddot{r}) \\
& \qquad + (\partial S/\partial a_\theta)\,(\partial a_\theta/\partial\ddot{r})]\,(\partial\ddot{r}/\partial\ddot{r}) \\
& + [(\partial S/\partial a_r)(\partial a_r/\partial\ddot{\phi}) + (\partial S/\partial a_\phi)\,(\partial a_\phi/\partial\ddot{\phi}) \\
& \qquad + (\partial S/\partial a_\theta)\,(\partial a_\theta/\partial\ddot{\phi})]\,(\partial\ddot{\phi}/\partial\ddot{r}) \\
& + [(\partial S/\partial a_r)(\partial a_r/\partial\ddot{\theta}) + (\partial S/\partial a_\phi)\,(\partial a_\phi/\partial\ddot{\theta}) \\
& \qquad + (\partial S/\partial a_\theta)\,(\partial a_\theta/\partial\ddot{\theta})]\,(\partial\ddot{\theta}/\partial\ddot{r}) \\
& [= \partial S'/\partial\ddot{r} + (\partial S'/\partial\ddot{\phi})\,(\partial\ddot{\phi}/\partial\ddot{r}) + (\partial S'/\partial\ddot{\theta})\,(\partial\ddot{\theta}/\partial\ddot{r})] \\
= {} & \cdots = m[\ddot{r} - r(\dot{\theta})^2 - r(\dot{\phi})^2\, \cos^2\theta - (\dot{r}/\dot{\phi})\ddot{\phi} \\
& \qquad - 2(\dot{r})^2/r + 2\dot{r}\,\dot{\theta}\, \tan\theta],
\end{aligned} \tag{k}
$$

$$
\begin{aligned}
\partial S_o/\partial\ddot{\theta} = {} & [(\partial S/\partial a_r)\,(\partial a_r/\partial\ddot{r}) + (\partial S/\partial a_\phi)\,(\partial a_\phi/\partial\ddot{r}) \\
& \qquad + (\partial S/\partial a_\theta)\,(\partial a_\theta/\partial\ddot{r})]\,(\partial\ddot{r}/\partial\ddot{\theta}) \\
& + [(\partial S/\partial a_r)\,(\partial a_r/\partial\ddot{\phi}) + (\partial S/\partial a_\phi)\,(\partial a_\phi/\partial\ddot{\phi}) \\
& \qquad + (\partial S/\partial a_\theta)\,(\partial a_\theta/\partial\ddot{\phi})]\,(\partial\ddot{\phi}/\partial\ddot{\theta}) \\
& + [(\partial S/\partial a_r)\,(\partial a_r/\partial\ddot{\theta}) + (\partial S/\partial a_\phi)\,(\partial a_\phi/\partial\ddot{\theta}) \\
& \qquad + (\partial S/\partial a_\theta)\,(\partial a_\theta/\partial\ddot{\theta})]\,(\partial\ddot{\theta}/\partial\ddot{\theta}) \\
& [= (\partial S'/\partial\ddot{r})\,(\partial\ddot{r}/\partial\ddot{\theta}) + (\partial S'/\partial\ddot{\phi})\,(\partial\ddot{\phi}/\partial\ddot{\theta}) + \partial S'/\partial\ddot{\theta}] \\
= {} & \cdots = m[r^2\ddot{\theta} + r^2(\dot{\phi})^2\, \sin\theta\, \cos\theta \\
& \qquad - r^2(\dot{\theta}/\dot{\phi})\ddot{\phi} + 2r^2(\dot{\theta})^2\, \tan\theta].
\end{aligned} \tag{l}
$$

Next, here (with G denoting the well-known gravitational constant)

$$
Q_r = -mMG/r^2, \qquad Q_\phi = 0, \qquad Q_\theta = 0, \tag{m}
$$

and therefore the independent impressed forces, Q_{Io}, are

$$
Q_{ro} = Q_r + (\partial\dot{\phi}/\partial\dot{r})Q_\phi = -mMG/r^2, \qquad Q_{\theta o} = Q_\theta + (\partial\dot{\phi}/\partial\dot{\theta})Q_\phi = 0. \tag{n}
$$

As a result of the above, the kinetic Appellian equations are

$$\partial S_o/\partial \ddot{r} = Q_{ro}:$$

$$\ddot{r} - r(\dot{\theta})^2 - r(\dot{\phi})^2 \cos^2\theta - (\dot{r}/\dot{\phi})\ddot{\phi} - 2(\dot{r})^2/r + 2\dot{r}\,\dot{\theta}\,\tan\theta \;=\; -MG/r^2, \tag{o}$$

$$\partial S_o/\partial \ddot{\theta} = Q_{\theta o}:$$

$$r^2\ddot{\theta} + r^2(\dot{\phi})^2 \sin\theta\cos\theta - r^2(\dot{\theta}/\dot{\phi})\ddot{\phi} + 2r^2(\dot{\theta})^2 \tan\theta = 0; \tag{p}$$

and along with the constraint (a) these constitute a determinate system for $r(t), \phi(t), \theta(t)$.

Example 5.3.10 (Mei, 1985, pp. 155–156). Let us derive the *general* kinetic Voronets equations (5.3.8a, b) of the preceding example. We introduce the following quasi velocities:

$$\omega_1 \equiv f - c^2/2 \equiv \Big\{[(\dot{r})^2 + (r^2\cos^2\theta)(\dot{\phi})^2 + r^2(\dot{\theta})^2] - c^2\Big\}\Big/2 \quad (=0), \tag{a}$$

$$\omega_2 \equiv \dot{r}\,(\neq 0), \tag{b}$$

$$\omega_3 \equiv r\dot{\theta}\ (\neq 0), \tag{c}$$

and their inverses (with $q_{1,2,3}$: r, ϕ, θ):

$$\dot{r} = \omega_2, \tag{d}$$

$$(\dot{\phi})^2 = [(2\omega_1 + c^2) - (\dot{r})^2 - r^2(\dot{\theta})^2]\Big/r^2\cos^2\theta = [(2\omega_1 + c^2) - \omega_2{}^2 - \omega_3{}^2]\Big/r^2\cos^2\theta, \tag{e}$$

$$\dot{\theta} = \omega_3/r. \tag{f}$$

Hence, the general Voronets symbols needed, $V^k{}_I$, eqs. (5.2.21e; with $k = 1, 2, 3$; $I = 2, 3$) specialize to

$$V^1{}_2 \equiv (\partial\dot{r}/\partial\omega_2)^{\cdot} - \partial\dot{r}/\partial\theta_2 \equiv (\partial\dot{r}/\partial\omega_2)^{\cdot} - \sum(\partial\dot{r}/\partial q_k)\,(\partial\dot{q}_k/\partial\omega_2) = (1)^{\cdot} - 0 = 0, \tag{g}$$

$$V^2{}_2 \equiv (\partial\dot{\phi}/\partial\omega_2)^{\cdot} - \partial\dot{\phi}/\partial\theta_2 \equiv (\partial\dot{\phi}/\partial\omega_2)^{\cdot} - \sum(\partial\dot{\phi}/\partial q_k)\,(\partial\dot{q}_k/\partial\omega_2) = (-\dot{r}/r^2\dot{\phi}\cos^2\theta)^{\cdot} - (-\dot{\phi}/r)(1), \tag{h}$$

$$V^3{}_2 \equiv (\partial\dot{\theta}/\partial\omega_2)^{\cdot} - \partial\dot{\theta}/\partial\theta_2 \equiv (\partial\dot{\theta}/\partial\omega_2)^{\cdot} - \sum(\partial\dot{\theta}/\partial q_k)\,(\partial\dot{q}_k/\partial\omega_2) = (0)^{\cdot} - (-\dot{\theta}/r)(1) = \dot{\theta}/r; \tag{i}$$

$$V^1{}_3 \equiv (\partial\dot{r}/\partial\omega_3)^{\cdot} - \partial\dot{r}/\partial\theta_3 \equiv (\partial\dot{r}/\partial\omega_3)^{\cdot} - \sum(\partial\dot{r}/\partial q_k)\,(\partial\dot{q}_k/\partial\omega_3) = (0)^{\cdot} - 0 = 0, \tag{j}$$

$$V^2{}_3 \equiv (\partial\dot{\phi}/\partial\omega_3)^{\cdot} - \partial\dot{\phi}/\partial\theta_3 \equiv (\partial\dot{\phi}/\partial\omega_3)^{\cdot} - \sum(\partial\dot{\phi}/\partial q_k)\,(\partial\dot{q}_k/\partial\omega_3) = (-\dot{\theta}/r\dot{\phi}\cos^2\theta)^{\cdot} - (\dot{\phi}\tan\theta)\,(r^{-1}), \tag{k}$$

$$V^3{}_3 \equiv (\partial\dot{\theta}/\partial\omega_3)^{\cdot} - \partial\dot{\theta}/\partial\theta_3 \equiv (\partial\dot{\theta}/\partial\omega_3)^{\cdot} - \sum (\partial\dot{\theta}/\partial q_k)\,(\partial\dot{q}_k/\partial\omega_3)$$
$$= (r^{-1})^{\cdot} - (-\dot{\theta}/r)(0) = -\dot{r}/r^2; \tag{l}$$

while the (unconstrained) kinetic energy, in holonomic variables, becomes

$$2T = m[(\dot{r})^2 + (r^2 \cos^2\theta)(\dot{\phi})^2 + r^2(\dot{\theta})^2]$$
$$(= mc^2,\ \text{constrained kinetic energy}), \tag{m}$$
$$\Rightarrow \partial T/\partial\dot{r} = m\,\dot{r}, \qquad \partial T/\partial\dot{\phi} = m\,r^2 \cos^2\theta\dot{\phi}, \qquad \partial T/\partial\dot{\theta} = m\,r^2\dot{\theta}; \tag{n}$$

and, in nonholonomic variables,

$$2T^* = m(2\omega_1 + c^2), \tag{o}$$
$$\Rightarrow \partial T^*/\partial\omega_2 = 0, \qquad \partial T^*/\partial\omega_3 = 0,$$
$$\partial T^*/\partial\theta_2 \equiv \sum (\partial T^*/\partial q_k)\,(\partial\dot{q}_k/\partial\omega_2) = 0, \qquad \partial T^*/\partial\theta_3 = 0; \tag{p}$$

and, finally, the corresponding nonholonomic impressed forces are

$$\Theta_2 \equiv \sum (\partial\dot{q}_k/\partial\omega_2)Q_k = \cdots = -mMG/r^2, \qquad \Theta_3 = \cdots = 0. \tag{q}$$

Substituting all these special results into eqs. (5.3.8a, b) yields

$$\omega_2:\qquad 0 - [V^2{}_2(\partial T/\partial\dot{\phi}) + V^3{}_2(\partial T/\partial\dot{\theta})] = \Theta_2, \tag{r}$$
$$\omega_3:\qquad 0 - [V^2{}_3(\partial T/\partial\dot{\phi}) + V^3{}_3(\partial T/\partial\dot{\theta})] = \Theta_3; \tag{s}$$

and if these two equations are written out, in extenso, they, naturally, coincide with the Appellian equations (o, p) of the preceding example.

Last, by substituting in the above $\dot{r}, \dot{\phi}, \dot{\theta}$ in terms of $\omega_1(= 0), \omega_2, \omega_3$, including $\partial T/\partial\dot{q}_k \to (\partial T/\partial\dot{q}_k)^*$, via (d–f), we may, if needed, express (r, s) in terms of these quasi variables, à la Hamel.

Example 5.3.11 Let us derive the *special* (kinetic) Chaplygin–Voronets equations (ex. 5.3.4: g, i) for the system of ex. 5.3.5. Here, $n = 3$ and $m = 1$, and so with the choice $\dot{q}_D$: $\dot{q}_1$ and $\dot{q}_I$: $\dot{q}_{2,3}$, the constraint

$$(\dot{q}_1)^2 + (\dot{q}_2)^2 + (\dot{q}_3)^2 = constant \equiv c^2 \tag{a}$$

yields

$$\dot{q}_D \to \dot{q}_1 = [c^2 - (\dot{q}_2)^2 + (\dot{q}_3)^2]^{1/2} \equiv \phi_1(\dot{q}_I). \tag{b}$$

Therefore, the kinetic energy becomes

$$2T = m[(\dot{q}_1)^2 + (\dot{q}_2)^2 + (\dot{q}_3)^2]$$
$$= m\Big\{[c^2 - (\dot{q}_2)^2 + (\dot{q}_3)^2] + (\dot{q}_2)^2 + (\dot{q}_3)^2\Big\}$$
$$= mc^2 = T_o(\dot{q}_I) \equiv T_o \quad (\text{constrained kinetic energy}), \tag{c}$$

$$\Rightarrow \partial T/\partial \dot{q}_D\colon\ \partial T/\partial \dot{q}_1 = m\dot{q}_1,$$
$$\partial T_o/\partial \dot{q}_I = 0,$$
$$\partial T_o/\partial (q_I) \equiv \partial T_o/\partial q_I + \sum (\partial T_o/\partial q_D)(\partial \phi_D/\partial \dot{q}_I) = \partial T_o/\partial q_I; \tag{d}$$

the relevant nonlinear Voronets–Chaplygin coefficients $V^D{}_I \to W^D{}_I$ reduce to the following nonlinear Chaplygin coefficients $T^D{}_I$:

$$T^1{}_2 \equiv (\partial \phi_1/\partial \dot{q}_2)^{\cdot} - \partial \phi_1/\partial q_2 = (-\dot{q}_2/\dot{q}_1)^{\cdot} - 0, \tag{e}$$
$$T^1{}_3 \equiv (\partial \phi_1/\partial \dot{q}_3)^{\cdot} - \partial \phi_1/\partial q_3 = (-\dot{q}_3/\dot{q}_1)^{\cdot} - 0; \tag{f}$$

and the constrained impressed forces Q_{Io} become

$$Q_{2o} = Q_2 + (\partial \phi_1/\partial \dot{q}_2)Q_1 = Q_2 - (\dot{q}_2/\dot{q}_1)Q_1, \tag{g}$$
$$Q_{3o} = Q_3 + (\partial \phi_1/\partial \dot{q}_3)Q_1 = Q_3 - (\dot{q}_3/\dot{q}_1)Q_1. \tag{h}$$

Substituting all these special results into the nonlinear Voronets $\to$ Chaplygin equations

$$(\partial T_o/\partial \dot{q}_I)^{\cdot} - \partial T_o/\partial q_I - \sum T^D{}_I(\partial T/\partial \dot{q}_D)_o = Q_{Io}, \tag{i}$$

we find

$$-T^1{}_2(\partial T/\partial \dot{q}_1) = Q_{2o}\colon$$
$$-(-\dot{q}_2/\dot{q}_1)^{\cdot}(m\dot{q}_1) = Q_2 - (\dot{q}_2/\dot{q}_1)Q_1, \tag{j}$$
$$-T^1{}_3(\partial T/\partial \dot{q}_1) = Q_{3o}\colon$$
$$-(-\dot{q}_3/\dot{q}_1)^{\cdot}(m\dot{q}_1) = Q_3 - (\dot{q}_3/\dot{q}_1)Q_1; \tag{k}$$

or, simplifying,

$$m\ddot{q}_2 = Q_2 + (\dot{q}_2/\dot{q}_1)(m\ddot{q}_1 - Q_1), \tag{l}$$
$$m\ddot{q}_3 = Q_3 + (\dot{q}_3/\dot{q}_1)(m\ddot{q}_1 - Q_1), \tag{m}$$

respectively.

To show the equivalence of the above with (g) of ex. 5.3.5, we $(\ldots)^{\cdot}$-differentiate (a),

$$(\dot{q}_1)^2 + (\dot{q}_2)^2 + (\dot{q}_3)^2 = c^2 \ \Rightarrow\ \dot{q}_1\ddot{q}_1 + \dot{q}_2\ddot{q}_2 + \dot{q}_3\ddot{q}_3 = 0,$$

solve the result for $\ddot{q}_1$, and then, invoking (k, l) in it, we obtain, successively,

$$\begin{aligned} m\,\ddot{q}_1 &= -(\dot{q}_2/\dot{q}_1)(m\,\ddot{q}_2) - (\dot{q}_3/\dot{q}_1)(m\,\ddot{q}_3) \\ &= -(\dot{q}_2/\dot{q}_1)[Q_2 + (\dot{q}_2/\dot{q}_1)(m\ddot{q}_1 - Q_1)] \\ &\quad - (\dot{q}_3/\dot{q}_1)[Q_3 + (\dot{q}_3/\dot{q}_1)(m\ddot{q}_1 - Q_1)], \end{aligned}$$

or, reducing further and using (a),

$$m\ddot{q}_1 = Q_1 - \left[(Q_1\dot{q}_1 + Q_2\dot{q}_2 + Q_3\dot{q}_3)/c^2\right]\dot{q}_1, \tag{n}$$

and when this is inserted back into (l, m) it produces equations (ex. 5.3.5: g); as expected, due to the symmetry of the problem in $q_{1,2,3}$.

Problem 5.3.2 In ex. 5.3.9, we saw that

$$(\dot{\phi})^2 = [c^2 - (\dot{r})^2 - r^2(\dot{\theta})^2]/r^2 \cos^2\theta, \qquad \text{i.e., } \dot{q}_D = \phi_D(\dot{q}_I, \ldots). \tag{a}$$

Substituting this into $T(\dot{r}, \dot{\phi}, \dot{\theta}, \ldots)$, obtain $T_o(\dot{r}, \dot{\theta}, \ldots)$, and then find the corresponding *special* (kinetic) Voronets equations (ex. 5.3.4: g). Show that they coincide with the *special* (kinetic) Appellian equations of ex. 5.3.9, and the *general* Voronets equations of ex. 5.3.10.

Problem 5.3.3 Continuing from the system of exs. 5.3.9, and 5.3.10, $(\ldots)^{\cdot}$-differentiate its constraint (a):

$$\dot{f} = \dot{r}\,\ddot{r} + (r^2 \cos^2\theta)\dot{\phi}\,\ddot{\phi} + r^2\dot{\theta}\,\ddot{\theta} + \textit{no other } \ddot{r}, \ddot{\phi}, \ddot{\theta}\textit{-terms}, \tag{a}$$

and introduce the quasi accelerations

$$\dot{\omega}_1 \equiv \dot{f} \quad (= 0), \qquad \dot{\omega}_2 \equiv r^2\dot{\theta}\,\ddot{\theta} \quad (\neq 0), \qquad \dot{\omega}_3 \equiv \dot{r}\,\ddot{r} \quad (\neq 0). \tag{b}$$

Show that the corresponding *general* (kinetic) Appellian equations

$$\partial S^*{}_o/\partial\dot{\omega}_2 = \Theta_2 \qquad \text{and} \qquad \partial S^*{}_o/\partial\dot{\omega}_3 = \Theta_3, \tag{c}$$

where

$$\begin{aligned} S &= S(\ddot{r}, \ddot{\phi}, \ddot{\theta}, \ldots) = \cdots = S^*(\dot{\omega}_1 = 0, \dot{\omega}_2, \dot{\omega}_3, \ldots) \\ &= S^*{}_o(\dot{\omega}_2, \dot{\omega}_3, \ldots) \equiv S^*{}_o(\textit{constrained} \text{ general Appellian}), \end{aligned} \tag{d}$$

coincide with the *special* (kinetic) Appellian equations of ex. 5.3.9.

Problem 5.3.4 Consider the system of ex. 5.3.7; that is, a particle of mass m under impressed forces Q_k, and constrained by $(\dot{q}_1)^2 + (\dot{q}_2)^2 = (\dot{q}_3)^2$.

Obtain its *special* Voronets equations; and show that they coincide with those found in ex. 5.3.7 (general Appell) and ex. 5.3.8 (Johnsen–Hamel).

Example 5.3.12 *Tetherball* (Kitzka, 1986; Fufaev, 1990; also Kuypers, 1993, pp. 66, 388–394). Let us consider a heavy particle P of mass m fastened at the end of a massless (i.e., light) inextensible thread, the other end of which is fixed at a point on the surface of a circular and vertical cylinder C of radius R. As P moves, the thread can be wound up *without slipping* on the surface of C [fig. 5.1 (a)]. [This is an idealization of a toy known as *tetherball*—itself an idealization of Huygens' pendulum, self-regulating its free (i.e., unwound) length.]

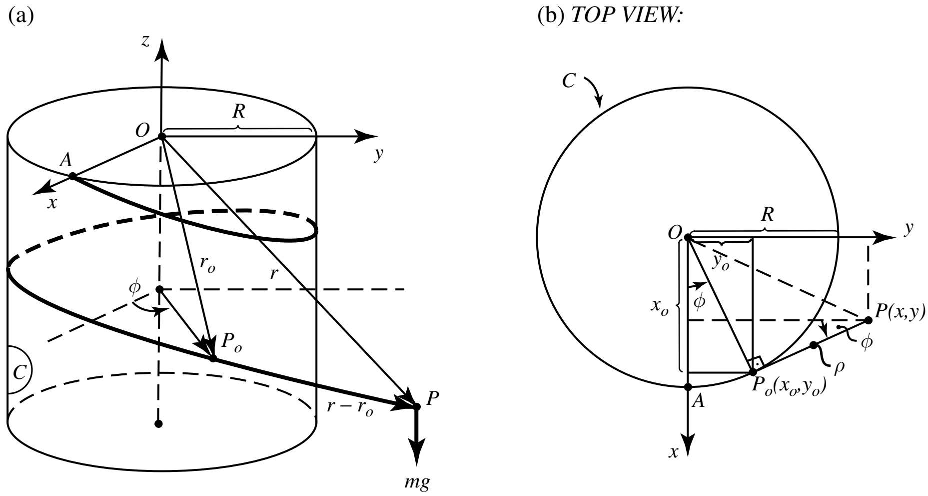

Figure 5.1 (a) Particle P on a thread, wound up on a cylinder C; (b) geometrical details (top view).

Let

$\boldsymbol{r} = (x, y, z)$: position vector of P at a generic time,

$\boldsymbol{r}_o = (x_o, y_o, z_o)$: position vector of point of separation of thread from the cylinder surface P_o, at a generic time,

ρ: length of projection of P_oP on plane O–xy [fig. 5.1(b)]. (a)

The constraints are:

(i) The constancy of the total thread length, as long as its unwound part is taut and its wound part does not slip on C:

$$\int_0^t |\boldsymbol{v}_o|\, dt + |\boldsymbol{r} - \boldsymbol{r}_o| = constant \equiv l_o; \tag{b}$$

that is, *wound length + unwound length* $(l) = l_o$.

(ii) Continuity of thread slope at P_o [fig. 5.1(b)]:

$$(\boldsymbol{r} - \boldsymbol{r}_o)/|\boldsymbol{r} - \boldsymbol{r}_o| = \boldsymbol{v}_o/|\boldsymbol{v}_o| \equiv \boldsymbol{v}_o/v_o; \tag{c}$$

that is, *unit vector along* P_oP = *unit vector along velocity of* P_o.

Also, from geometry, we have

$$x = x_o - \rho \sin\phi = R\cos\phi - \rho\sin\phi, \tag{d1}$$

$$y = y_o + \rho\cos\phi = R\sin\phi + \rho\cos\phi. \tag{d2}$$

Let us translate (b, c) into equivalent scalar forms:

(i) By $(\ldots)^{\cdot}$-differentiating (b), to get rid of the integral, we obtain

$$|\boldsymbol{v}_o| + |\boldsymbol{r} - \boldsymbol{r}_o|^{\cdot} = 0 \;\Rightarrow\; v_o = -|\boldsymbol{r} - \boldsymbol{r}_o|^{\cdot} \equiv -dl/dt, \tag{b1}$$

and so the $(\ldots)^{\cdot}$-derivative of (c), rearranged as

$$\boldsymbol{r} - \boldsymbol{r}_o = \big[|\boldsymbol{r} - \boldsymbol{r}_o|/v_o\big]\boldsymbol{v}_o \;\Rightarrow\; \boldsymbol{r} = \boldsymbol{r}_o + (l/v_o)\boldsymbol{v}_o, \tag{c1}$$

becomes, successively (with $\boldsymbol{v} \equiv \dot{\boldsymbol{r}}$, $\boldsymbol{a}_o \equiv \dot{\boldsymbol{v}}_o$),

$$\boldsymbol{v} = \boldsymbol{v}_o + (l/v_o)\boldsymbol{a}_o + \big[(dl/dt)/v_o\big]\boldsymbol{v}_o - \big[l\,(dv_o/dt)/{v_o}^2\big]\boldsymbol{v}_o$$

$$\text{[by (b1), the } \textit{first} \text{ and } \textit{third} \text{ terms cancel]}$$

$$= \big\{\boldsymbol{a}_o - [(dv_o/dt)/v_o]\boldsymbol{v}_o\big\}(l/v_o), \tag{c2}$$

and dotting this with $\boldsymbol{v}_o$, we get

$$\boldsymbol{v}\cdot\boldsymbol{v}_o = [\boldsymbol{v}_o\cdot\boldsymbol{a}_o - (\dot{v}_o/v_o){v_o}^2]\,(l/v_o) = 0, \tag{c3}$$

since $(\boldsymbol{v}_o\cdot\boldsymbol{v}_o)^{\cdot} = ({v_o}^2)^{\cdot} \Rightarrow 2\boldsymbol{v}_o\cdot\boldsymbol{a}_o = 2v_o\dot{v}_o$. With the help of the $(\ldots)^{\cdot}$-derivatives of (d1, 2), the above assumes the form

$$\boldsymbol{v}\cdot\boldsymbol{v}_o = R\dot{\phi}(\dot{\rho} + R\dot{\phi}) + \dot{z}\,\dot{z}_o = 0. \tag{e1}$$

(ii) Dotting (c) with $\boldsymbol{v}$ and invoking (c3, 4) and (d1, 2), we easily obtain

$$\boldsymbol{v}\cdot(\boldsymbol{r} - \boldsymbol{r}_o) = \rho(\dot{\rho} + R\dot{\phi}) + \dot{z}(z - z_o) = 0. \tag{e2}$$

Instead of the *two* constraints (e1, 2) for the *four* Lagrangean coordinates ϕ, ρ, z, z_o, we can eliminate z_o (and $\dot{z}_o$) between them by $(\ldots)^{\cdot}$-differentiating (e2), multiplying the outcome with $\dot{z}$, and then using (e1, 2). The result is the single *nonlinear* second-order (but linear in its second derivatives) constraint

$$f_o \equiv \rho(\dot{\rho} + R\dot{\phi})\ddot{z} - \rho(\ddot{\rho} + R\ddot{\phi})\dot{z}$$

$$- [(\dot{\rho} + R\dot{\phi})^2 + (\dot{z})^2]\dot{z} = 0, \tag{f}$$

for the *three* coordinates ϕ, ρ, z.

At this point, we could form either (i) the two kinetic Appellian equations (here, $n = 3, m = 1$),

$$\partial S_o/\partial\ddot{\phi} = Q_{\phi o} \qquad \text{and} \qquad \partial S_o/\partial\ddot{\rho} = Q_{\rho o}, \tag{g}$$

where, using (f) (and the notation $\ldots \equiv$ *no* $\ddot{\phi}, \ddot{\rho}, \ddot{z}$ *terms*),

$$S = S(\ddot{\phi}, \ddot{\rho}, \ddot{z}, \ldots) = S[\ddot{\phi}, \ddot{\rho}, \ddot{z}(\ddot{\phi}, \ddot{\rho}, \ldots), \ldots]$$

$$\equiv S_o(\ddot{\phi}, \ddot{\rho}, \ldots) \equiv S_o, \tag{g1}$$

and

$$\delta' W = Q_\phi\,\delta\phi + Q_\rho\,\delta\rho + Q_z\,\delta z = \cdots = Q_{\phi o}\,\delta\phi + Q_{\rho o}\,\delta\rho; \tag{g2}$$

or (ii) the Appellian form of the three mixed (coupled) nonlinear Routh–Voss equations,

$$\partial S/\partial\ddot{q}_k = Q_k + \lambda(\partial f_o/\partial\ddot{q}_k); \qquad q_k = \phi, \rho, z. \tag{h}$$

However, a simpler form of equations of motion results if, following Kitzka (1986), we introduce the following quasi velocities:

$$\omega_1 \equiv R\dot{\phi}, \tag{i1}$$

$$\omega_2 \equiv (\dot{\rho} + R\dot{\phi})/\dot{z} = -\dot{z}_o/R\dot{\phi} = (z_o - z)/\rho \qquad \text{[by (e1, 2)]}, \tag{i2}$$

$$\omega_3 \equiv \dot{z}; \tag{i3}$$

which invert readily to

$$\dot{q}_1 \equiv \dot{\phi} = \omega_1/R, \tag{j1}$$

$$\dot{q}_2 \equiv \dot{\rho} = \omega_2\,\omega_3 - \omega_1, \tag{j2}$$

$$\dot{q}_3 \equiv \dot{z} = \omega_3. \tag{j3}$$

Eliminating z_o from (i2) by $(\ldots)^{\cdot}$-differentiating it: $\dot{z}_o - \dot{z} = (\rho\,\omega_2)^{\cdot} = \dot{\rho}\,\omega_2 + \rho\,\dot{\omega}_2$, and then using (i1, 2) and (j2) in it, we finally obtain the nonlinear (but linear in its second derivative) constraint for $\omega_{1,2,3}$:

$$f \equiv \rho\,\dot{\omega}_2 + (1 + {\omega_2}^2)\omega_3 = 0. \tag{k}$$

Now, let us form the corresponding kinetic Appellian equations

$$\partial S^*_o/\partial\dot{\omega}_1 = \Theta_1 \qquad \text{and} \qquad \partial S^*_o/\partial\dot{\omega}_3 = \Theta_3, \tag{l}$$

where (with the notation $\ldots \equiv$ *no* $\dot{\omega}_{1,2,3}$ *terms*)

$$S^* = S^*(\dot{\omega}_1, \dot{\omega}_2, \dot{\omega}_3, \ldots) = S^*[\dot{\omega}_1, \dot{\omega}_2(\dot{\omega}_1, \dot{\omega}_3, \ldots), \dot{\omega}_3, \ldots]$$
$$\equiv S^*_o(\dot{\omega}_1, \dot{\omega}_3, \ldots) \equiv S^*_o. \tag{11}$$

Indeed, using (k) to eliminate $\dot{\omega}_2$ from $\boldsymbol{a} \equiv \dot{\boldsymbol{v}} \equiv \ddot{\boldsymbol{r}} = (\ddot{x}, \ddot{y}, \ddot{z})$ [(d1, 2) with (j1–3)] we obtain, after some algebra,

$$\ddot{x} = -\Big[\omega_2\,\dot{\omega}_3 - {\omega_3}^2(1 + {\omega_2}^2)/\rho - \rho\,{\omega_1}^2/R^2\Big]\sin\phi$$
$$+ (1/R)[\omega_1(\omega_1 - 2\omega_2\,\omega_3) - \rho\,\dot{\omega}_1]\,\cos\phi, \tag{12}$$

$$\ddot{y} = \Big[\omega_2\,\dot{\omega}_3 - {\omega_3}^2(1 + {\omega_2}^2)/\rho - \rho{\omega_1}^2/R^2\Big]\cos\phi$$
$$+ (1/R)[\omega_1(\omega_1 - 2\omega_2\omega_3) - \rho\dot{\omega}_1]\,\sin\phi, \tag{13}$$

$$\ddot{z} = \dot{\omega}_3, \tag{14}$$

and, therefore,

$$S = (m/2)[(\ddot{x})^2 + (\ddot{y})^2 + (\ddot{z})^2]$$
$$= \cdots = (m/2)\Big\{(1 + {\omega_2}^2)\,(\dot{\omega}_3)^2 - 2\omega_2\,\dot{\omega}_3\,[\omega_3(1 + {\omega_2}^2)/\rho + \rho\,{\omega_1}^2/R^2]$$
$$+ (\rho/R^2)\,[\rho(\dot{\omega}_1)^2 - 2\omega_1\,\dot{\omega}_1(\omega_1 - 2\omega_2\,\omega_3)]\Big\}$$
$$+ \textit{function of } \omega_{1,2,3};\ \rho\ (\text{“}\textit{Appell constant}\text{” } \textit{terms}) = S^*_o; \tag{15}$$

also, by (12–4),

$$\Theta_1 \equiv \mathsf{S}\, d\boldsymbol{F}\cdot(\partial\boldsymbol{a}^*/\partial\dot{\omega}_1) = (-m\,g)(\partial\ddot{z}/\partial\dot{\omega}_1) = 0, \tag{16}$$

$$\Theta_3 \equiv \mathsf{S}\, d\boldsymbol{F}\cdot(\partial\boldsymbol{a}^*/\partial\dot{\omega}_3) = (-m\,g)(\partial\ddot{z}/\partial\dot{\omega}_3) = -m\,g. \tag{17}$$

As a result of the above, Appell's equations (l) become

$$\omega_1: \qquad \rho\,\dot\omega_1 - \omega_1(\omega_1 - 2\omega_2\,\omega_3) = 0, \tag{m1}$$

$$\omega_3: \qquad (1+{\omega_2}^2)\dot\omega_3 - \omega_2\big[(1+{\omega_2}^2){\omega_3}^2/\rho + (\rho/R^2){\omega_1}^2\big] + g = 0, \tag{m2}$$

and along with eqs. (j1–3, k) they constitute a determinate system for the six functions of time: $\omega_{1,2,3}$; ϕ, ρ, z.

Clearly, our system possesses the energy integral

$$\begin{aligned}
E &\equiv T + V = (m/2)\,[(\dot x)^2 + (\dot y)^2 + (\dot z)^2] + m\,g\,z \qquad [\text{using (d1, 2) and (j1–3)}]\\
&= (m/2)\left[(1+{\omega_2}^2){\omega_3}^3 + (\rho/R)^2{\omega_1}^2\right] + m\,g\,z\\
&\equiv T^* + V = constant \equiv E_o,
\end{aligned} \tag{n}$$

which constitutes an indirect proof of the physical correctness of (m1, 2).

REMARKS

(i) Since

$$\begin{aligned}
\partial S^*/\partial\dot\omega_1 &= (\partial S/\partial\ddot x)\,(\partial\ddot x/\partial\dot\omega_1) + (\partial S/\partial\ddot y)(\partial\ddot y/\partial\dot\omega_1)\\
&\quad + (\partial S/\partial\ddot z)\,(\partial\ddot z/\partial\dot\omega_1)\\
&= (\partial S/\partial\ddot x)\,(\partial\dot x/\partial\omega_1) + (\partial S/\partial\ddot y)\,(\partial\dot y/\partial\omega_1)\\
&\quad + (\partial S/\partial\ddot z)\,(\partial\dot z/\partial\omega_1)\\
&= (m\ddot x)\,(\partial\dot x/\partial\omega_1) + (m\ddot y)\,(\partial\dot y/\partial\omega_1) + (m\ddot z)\,(\partial\dot z/\partial\omega_1)\\
&= m[\ddot x(-\rho\,\cos\phi/R) + \ddot y(-\rho\,\sin\phi/R) + \ddot z(0)]\\
&= \cdots = m\rho[\rho\,\dot\omega_1 - \omega_1(\omega_1 - 2\omega_2\,\omega_3)],
\end{aligned} \tag{o1}$$

$$\begin{aligned}
\partial S^*/\partial\dot\omega_3 &= \cdots = (m\ddot x)\,(\partial\ddot x/\partial\dot\omega_1) + \cdots\\
&= m[\ddot x(-\omega_2\,\sin\phi) + \ddot y(\omega_2\,\cos\phi) + \ddot z(1)]\\
&= m\Big\{(1+{\omega_2}^2)\dot\omega_3 - \omega_2[\omega_3(1+{\omega_2}^2)/\rho + (\rho/R^2){\omega_1}^2]\Big\},
\end{aligned} \tag{o2}$$

and

$$\partial S^*/\partial\dot\omega_1 = \partial {S^*}_o/\partial\dot\omega_1, \qquad \partial S^*/\partial\dot\omega_3 = \partial {S^*}_o/\partial\dot\omega_3, \tag{o3}$$

there is no need to find $S^*(\dot\omega_{1,2,3},\ldots)$ or ${S^*}_o(\dot\omega_1,\dot\omega_3,\ldots)$ by expanding the squares of $\ddot x, \ddot y, \ddot z$ in (l5); we can leave it as $S(\ddot x, \ddot y, \ddot z)$.

(ii) In terms of the alternative, convenient, quasi accelerations

$$\dot\Omega_1 \equiv \rho\,\dot\omega_2 + (1+{\omega_2}^2)\omega_3 = 0, \tag{p1}$$

$$\dot\Omega_2 \equiv \dot\omega_1 \neq 0, \tag{p2}$$

$$\dot\Omega_3 \equiv \dot\omega_3 \neq 0, \tag{p3}$$

and the corresponding Appellian

$$S^* \to S^{**} = S^{**}(\dot{\Omega}_1, \dot{\Omega}_2, \dot{\Omega}_3, \ldots) \to S^{**}{}_o = S^{**}{}_o(\dot{\Omega}_2, \dot{\Omega}_3, \ldots), \tag{p4}$$

and impressed forces $\Theta_2 \to \Theta_2{}^*, \Theta_3 \to \Theta_3{}^*$, the kinetic Appellian equations would be

$$\partial S^{**}{}_o/\partial \dot{\Omega}_1 = \Theta_2{}^*, \qquad \partial S^{**}{}_o/\partial \dot{\Omega}_3 = \Theta_3{}^*. \tag{p5}$$

(iii) By looking at the constraints (f) and/or (k), one might conclude that they are nonlinear. However, as Fufaev (1990) has pointed out, this is *not* the case. Indeed, solving (e2) for $\dot{z}$:

$$\dot{z} = \rho(\dot{\rho} + R\dot{\phi})\,(z_o - z)^{-1}, \tag{q1}$$

and substituting this value in (e1), we obtain

$$(\dot{\rho} + R\dot{\phi})\,[R\dot{\phi} + \rho(z_o - z)^{-1}\dot{z}_o] = 0, \tag{q2}$$

from which, since, in general, $\dot{\rho} + R\dot{\phi} \neq 0$, it follows that (e1) is replaced by its equivalent,

$$R\dot{\phi} + \rho(z_o - z)^{-1}\dot{z}_o = 0, \tag{q3}$$

which, just like (e2), is linear (Pfaffian) in the Lagrangean velocities $\dot{\phi}$ and $\dot{z}_o$. Hence, the earlier nonlinearity is not of intrinsic/physical but *analytical* nature: *it resulted from the elimination of z_o and $\dot{z}_o$ between (e1, 2) and associated $(\ldots)^{\cdot}$-differentiations of the first-order constraint (e2).*

This justifies our attitude toward the subject of nonlinear nonholonomic constraints (§5.1): let us learn them; even if they do not exist in any physically meaningful way, we may have to use them for analytical convenience.

For additional physical and numerical aspects, see the earlier given references Kitzka (1986) and Kuypers (1993).

Problem 5.3.5 (Fufaev, 1990; Kitzka, 1986). Continuing from the preceding example of the tetherball, we saw there that its two *nonlinear* constraints, in the *four* Lagrangean coordinates $q_{1,2,3,4} = \phi, \rho, z, z_o$, are

$$\rho(\dot{\rho} + R\dot{\phi}) + (z - z_o)\dot{z} = 0, \tag{a1}$$

$$R\dot{\phi}(\dot{\rho} + R\dot{\phi}) + \dot{z}\,\dot{z}_o = 0, \tag{a2}$$

or, *equivalently* [solving (a1) for $\dot{z}$: $\dot{z} = \rho(\dot{\rho} + R\dot{\phi})\,(z_o - z)^{-1}$ and substituting the result in (a2)], the two *Pfaffian* constraints are

$$(\rho R)\dot{\phi} + (\rho)\dot{\rho} + (z - z_o)\dot{z} = 0, \tag{b1}$$

$$R(z_o - z)\dot{\phi} + \rho\,\dot{z}_o = 0, \tag{b2}$$

and, therefore, in *virtual* form:

$$(\rho R)\,\delta\phi + (\rho)\,\delta\rho + (z - z_o)\,\delta z = 0, \tag{c1}$$

$$[R(z_o - z)]\delta\phi + (\rho)\,\delta z_o = 0. \tag{c2}$$

Setting $m = 1$, for convenience, but no loss in generality,

(i) Show that

$$L \equiv T - V = (1/2)\Big[\rho^2(\dot\phi)^2 + (\dot\rho + R\,\dot\phi)^2 + (\dot z)^2\Big] - gz, \tag{d1}$$

and therefore the corresponding Routh–Voss equations,

$$E_k(L) = \lambda_1 a_{1k} + \lambda_2 a_{2k} \qquad (k = 1, \ldots, 4), \tag{d2}$$

are

$$\phi\!: \qquad R\,\ddot\rho + (R^2 + \rho^2)\ddot\phi - 2\rho\,\dot\rho\,\dot\phi = (R\rho)\lambda_1 + [R(z_o - z)]\lambda_2, \tag{d3}$$

$$\rho\!: \qquad \ddot\rho + R\,\ddot\phi - \rho(\dot\phi)^2 = (\rho)\lambda_1, \tag{d4}$$

$$z\!: \qquad \ddot z + g = (z - z_o)\lambda_1, \tag{d5}$$

$$z_o\!: \qquad 0 = (\rho)\lambda_2 \;\Rightarrow\; \lambda_2 = 0 \qquad [\text{since, in general}, \rho \neq 0]. \tag{d6}$$

(ii) By eliminating $\lambda_{1,2}$ among (d3–6), show that we obtain the two kinetic Maggi equations:

$$\rho\,\ddot\phi + 2\dot\rho\,\dot\phi + R(\dot\phi)^2 = 0, \tag{e1}$$

$$(z_o - z)\big[\ddot\rho + R\,\ddot\phi - \rho(\dot\phi)^2\big] + \rho(\ddot z + g) = 0; \tag{e2}$$

which, along with (b1, 2), constitute a determinate system for the four functions ϕ, ρ, z, z_o.

(iii) Show that for the quasi-velocity choice of the preceding example, eqs. (i1–3), (j1–3),

$$\omega_1 \equiv R\,\dot\phi, \tag{f1}$$

$$\omega_2 \equiv (\dot\rho + R\,\dot\phi)/\dot z = -\dot z_o/R\dot\phi = (z_o - z)/\rho, \tag{f2}$$

$$\omega_3 \equiv \dot z; \tag{f3}$$

$$\dot q_1 \equiv \dot\phi = \omega_1/R, \tag{f4}$$

$$\dot q_2 \equiv \dot\rho = \omega_2\,\omega_3 - \omega_1, \tag{f5}$$

$$\dot q_3 \equiv \dot z = \omega_3, \tag{f6}$$

$$(\Rightarrow \dot z_o = -\omega_1\omega_2), \tag{f7}$$

the above equations (e1, 2) coincide with the Appellian equations (m1, 2) found there.

Problem 5.3.6 Continuing from the preceding example of the tetherball, let us consider its *single* nonlinear second-order constraint in the *three* Lagrangean coordinates $q_{1,2,3} = \phi, \rho, z$, eq. (f):

$$f_o \equiv \rho(\dot{\rho} + R\dot{\phi})\ddot{z} - \rho(\ddot{\rho} + R\ddot{\phi})\dot{z} - [(\dot{\rho} + R\dot{\phi})^2 + (\dot{z})^2]\dot{z} = 0, \tag{a}$$

or, rearranged to show the second derivatives more clearly,

$$-(R\rho\dot{z})\ddot{\phi} - (\rho\dot{z})\ddot{\rho} + \rho(\dot{\rho} + R\dot{\phi})\ddot{z} - [(\dot{\rho} + R\dot{\phi})^2 + (\dot{z})^2]\dot{z} = 0. \tag{b}$$

(i) Show that the corresponding Routh–Voss equations,

$$E_k(L) = \lambda(\partial f_o/\partial\ddot{q}_k) \qquad (k = 1, \ldots, 3), \tag{c}$$

are (again with $m = 1$)

$$\phi: \qquad \ddot{\rho} + R\ddot{\phi} + (\rho^2/R)\ddot{\phi} + 2(\rho/R)\dot{\rho}\dot{\phi} = -(\rho\dot{z})\lambda, \tag{d1}$$

$$\rho: \qquad \ddot{\rho} + R\ddot{\phi} - \rho(\dot{\phi})^2 = -(\rho\dot{z})\lambda, \tag{d2}$$

$$z: \qquad \ddot{z} + g = \rho(\dot{\rho} + R\dot{\phi})\lambda; \tag{d3}$$

and along with (b) they constitute a determinate system for the four functions ϕ, ρ, z, λ.

(ii) From (b, d1–3), deduce that

$$\lambda = \frac{g\rho(\dot{\rho} + R\dot{\phi}) + \dot{z}[(\dot{\rho} + R\dot{\phi})^2 + \rho^2(\dot{\phi})^2 + (\dot{z})^2]}{(\dot{\rho})^2[(\dot{\rho} + R\dot{\phi})^2 + (\dot{z})^2]} = (g\rho\omega_2 + 2E_o - 2gz)\big/\omega_3\rho^2(1 + {\omega_2}^2), \tag{e}$$

where $E_o \equiv T + V$ is the constant total energy [recall eq. (n) of ex. 5.3.12].

(iii) With the help of (e), show that the (physical) constraint force equals

$$\begin{aligned}\boldsymbol{R} &= \lambda[\partial f(t, \boldsymbol{r}, \boldsymbol{v}, \boldsymbol{a})/\partial\boldsymbol{a}] = \sum \lambda\left[\partial f_o(t, q, \dot{q}, \ddot{q})/\partial\ddot{q}_k\right](\partial\ddot{q}_k/\partial\boldsymbol{a}) \\ &= \cdots = -[(1/l)(v^2 + g\rho\omega_2)(\boldsymbol{r} - \boldsymbol{r}_o)]\big/|\boldsymbol{r} - \boldsymbol{r}_o| \\ &= -[(1/l)(v^2 + g\rho\omega_2)/l^2](\boldsymbol{r} - \boldsymbol{r}_o),\end{aligned} \tag{f}$$

where $l^2 = \rho^2 + (z_o - z)^2 = \rho^2(1 + {\omega_2}^2)$ is the instantaneous length (squared) of the *unwound* part of the thread.

(iv) By eliminating λ among (d1–3), obtain the *two* kinetic Maggi equations of the system; which, along with (a) or (b), will constitute a determinate system for ϕ, ρ, z.

Problem 5.3.7 (Fufaev, 1990). Continuing from the preceding example of the tetherball:

(i) Show that if the cylinder surface is *smooth*, the system has the sole *holonomic* constraint

$$(\rho + R\phi)^2 + z^2 = {l_o}^2 \qquad (l_o\text{: thread length}), \tag{a}$$

or, in virtual form,

$$[(\rho + R\,\phi)R]\,\delta\phi + (\rho + R\,\phi)\,\delta\rho + z\,\delta z = 0; \tag{b}$$

that is, it has only *three* Lagrangean coordinates (instead of the four of the *rough*-surface case), but still $n - m = 3 - 1 = 2$.

(ii) Show that, in this case, the Routh–Voss equations for $q_{1,2,3} = \phi, \rho, z$ are

$$E_\phi(L) = \lambda R(\rho + R\,\phi), \qquad E_\rho(L) = \lambda(\rho + R\phi), \qquad E_z(L) = \lambda z, \tag{c}$$

where $E_{\phi,\rho,z}(L)$ can be found via prob. 5.3.5: (d1); and along with (a) these constitute a determinate system for ϕ, ρ, z, λ.

(iii) By eliminating λ among (c), show that we obtain the following two kinetic (holonomic) Maggi equations:

$$\rho\,\ddot{\phi} + 2\dot{\rho}\,\dot{\phi} + R(\dot{\phi})^2 = 0, \tag{d}$$

$$z[\ddot{\rho} + R\,\ddot{\phi} - \rho(\dot{\phi})^2] - (\rho + R\,\phi)\,(\ddot{z} + g) = 0, \tag{e}$$

which, along with (a), constitute a determinate system for ϕ, ρ, z.

(iv) Compare eqs. (d, e), of this smooth case, with the corresponding Maggi equations of the rough case of the preceding problems.

Example 5.3.13 *Reduced, or Routh-like Form of the Equations of Motion of a Nonholonomic and Cyclic/Ignorable System* (Semenova, 1965). (To be studied in connection with §8.4.) Let us consider a scleronomic system under the $m(< n)$ *stationary* Pfaffian constraints

$$\sum a_{Dk}\dot{q}_k = 0, \qquad \text{where} \quad \partial a_{Dk}/\partial t = 0 \qquad [D = 1, \ldots, m;\ k = 1, \ldots, n], \tag{a}$$

and, therefore, having the following Routh–Voss equations of motion:

$$E_k(L) \equiv (\partial L/\partial \dot{q}_k)^{\cdot} - \partial L/\partial q_k = Q_k + R_k, \qquad R_k = \sum \lambda_D a_{Dk}. \tag{b}$$

In addition, let us assume that the first $M\,(< n)$ coordinates are cyclic or *ignorable*; that is,

$$(q_1, \ldots, q_M) \equiv (q_i) \equiv (\psi_i):\ \ \partial L/\partial q_i \equiv \partial L/\partial \psi_i = 0 \qquad [i = 1, \ldots, M], \tag{c}$$

and the corresponding impressed and reaction forces vanish:

$$Q_i = 0 \qquad \text{and} \qquad R_i = 0 \qquad [\text{e.g., if } a_{Di} = 0]. \tag{d}$$

Let us find the Routhian equations of the system; that is, Lagrange-type equations involving only the remaining $n - M$ *noncyclic* or *palpable* or *positional* coordinates $(q_{M+1}, \ldots, q_n) \equiv (q_p)$ and corresponding velocities $(\dot{q}_{M+1}, \ldots, \dot{q}_n) \equiv (\dot{q}_p)$, instead of all the $\dot{q}$'s.

Due to (c, d), eqs. (b) yield

$$p_i \equiv \partial L/\partial \dot{q}_i \equiv \partial L/\partial \dot{\psi}_i = constant \equiv C_i; \quad \text{i.e., } C_i = C_i(q_p, \dot{\psi}_i, \dot{q}_p). \tag{e}$$

Solving these M equations for the M ignorable (but, generally, *variable*) velocities $\dot{q}_i \equiv \dot{\psi}_i$, in terms of the $n - M$ palpable variables q_p and $\dot{q}_p$, we obtain

$$\dot{\psi}_i = \dot{\psi}_i(q_p, \dot{q}_p;\ C_i); \tag{f}$$

which is essentially a Chaplygin-like form of the additional constraints (e).

REMARK

Since T is, at most, *quadratic* in the $\dot{q}$, eqs. (e) are essentially *linear* in the $\dot{q}$, and therefore eqs. (f) are linear in the $\dot{q}_p$ say,

$$p_i = C_i = \sum e_{ik}\,\dot{q}_k + e_i, \qquad e_{ik}, e_i\text{: functions of the } q_p, \tag{g1}$$

from which we find ($i = 1, \ldots, M;\ p = M + 1, \ldots, n$)

$$\dot{q}_i \equiv \dot{\psi}_i = \sum E_{ip}\,\dot{q}_p + E_i, \quad E_{ip}\text{: functions of the } q_p, E_i\text{: functions of the } q_p \text{ and } C_i. \tag{g2}$$

However, here we shall treat both (e) and (f) as *additional* linear and/or nonlinear constraints, because then we can see more clearly the formal structure of the resulting equations.

Let L_o be the Lagrangean resulting from the elimination of the $\dot{\psi}_i$ from L via (f); that is, by enforcing in it the constraints (e):

$$\begin{aligned} L = L(q, \dot{q}) &= L(q_p, \dot{q}_i, \dot{q}_p) \\ &= L\big[q_p, \dot{\psi}_i(q_p, \dot{q}_p;\ C_i), \dot{q}_p\big] \equiv L_o(q_p, \dot{q}_p;\ C_i). \end{aligned} \tag{h}$$

Applying chain rule to the above, we obtain

(i) $$\begin{aligned} \partial L_o/\partial q_p &= \partial L/\partial q_p + \sum (\partial L/\partial\dot{\psi}_i)(\partial\dot{\psi}_i/\partial q_p) = \partial L/\partial q_p + \sum (\partial\dot{\psi}_i/\partial q_p)C_i \\ &\Rightarrow\ \partial L/\partial q_p = \partial L_o/\partial q_p - \sum (\partial\dot{\psi}_i/\partial q_p)C_i, \end{aligned} \tag{i1}$$

(ii) $$\begin{aligned} \partial L_o/\partial\dot{q}_p &= \partial L/\partial\dot{q}_p + \sum (\partial L/\partial\dot{\psi}_i)\,(\partial\dot{\psi}_i/\partial\dot{q}_p) \\ &= \partial L/\partial\dot{q}_p + \sum (\partial\dot{\psi}_i/\partial\dot{q}_p)C_i \\ &\Rightarrow \partial L/\partial\dot{q}_p = \partial L_o/\partial\dot{q}_p - \sum (\partial\dot{\psi}_i/\partial\dot{q}_p)C_i; \end{aligned} \tag{i2}$$

and, therefore, since $\dot{C}_i = 0$,

$$(\partial L/\partial\dot{q}_p)^{\cdot} = (\partial L_o/\partial\dot{q}_p)^{\cdot} - \sum C_i(\partial\dot{\psi}_i/\partial\dot{q}_p)^{\cdot}. \tag{i3}$$

In view of (i1–3), the equations of motion (b) for the $q_p, \dot{q}_p$ can be written in the Chaplygin-like form

$$(\partial L_o/\partial\dot{q}_p)^{\cdot} - \partial L_o/\partial q_p - \sum C_i\Big[(\partial\dot{\psi}_i/\partial\dot{q}_p)^{\cdot} - \partial\dot{\psi}_i/\partial q_p\Big] = \sum \lambda_D a_{Dp}, \tag{j1}$$

or, compactly,

$$E_p(L_o) - \sum C_i E_p(\dot{\psi}_i) = \sum \lambda_D a_{Dp} \equiv R_p; \tag{j2}$$

and along with the constraints (a):

$$\sum a_{Di}\dot{q}_i + \sum a_{Dp}\dot{q}_p = 0$$
$$\Rightarrow \sum (\ldots)_{Dp}\dot{q}_p = \text{known function of the } q_p \text{ and } C_i, \tag{j3}$$

they constitute a determinate system of $(n - M) + m$ equations for the $n - M$ q_p and the m λ_D. Equations (j1) are *coupled* in the q_p and λ_D. To uncouple them into kinetic and kinetostatic equations (assuming that $m < n - M$), we may view them as the Routh–Voss equations of a nonholonomic system under the constraints (j3), and then proceed to derive its uncoupled equations à la Maggi, Hamel, or Appell, as elaborated in chapter 3 and § 5.3. The details are left to the reader.

Problem 5.3.8 (Semenova, 1965). Multiplying each of eqs. (j2) of the preceding example:

$$E_p(L_o) - \sum C_i E_p(\dot{\psi}_i) = R_p \qquad [i = 1, \ldots, M;\ p = M + 1, \ldots, n] \tag{a}$$

by $\dot{q}_p$ and summing over p, obtain the "*noncyclic Jacobi integral*"

$$H_o \equiv \left(\sum (\partial L_o/\partial \dot{q}_p)\dot{q}_p - L_o\right) - \sum C_i\left(\sum (\partial\dot{\psi}_i/\partial\dot{q}_p)\dot{q}_p - \dot{\psi}_i\right):$$
$$\textit{Noncyclic generalized energy} = \textit{constant}. \tag{b}$$

Problem 5.3.9 *Nonlinear and Nonholonomic Power Equation.*

(i) Starting with the kinetic Johnsen–Hamel equations of motion (5.3.5b or 5.3.19), show that the corresponding power equation is

$$d/dt\left(\sum (\partial T^*/\partial\omega_I)\omega_I - T^*\right)$$
$$= -\partial T^*/\partial t + \sum \Theta_I\omega_I - \sum\sum H^k{}_I(\partial T^*/\partial\omega_k)\omega_I, \tag{a}$$

where (symbolically)

$$dT^*/dt \equiv \sum \left[(\partial T^*/\partial\omega_I)\dot{\omega}_I + (\partial T^*/\partial\theta_I)\omega_I\right] + \partial T^*/\partial t, \tag{b}$$

$$\sum (\partial T^*/\partial\theta_I)\omega_I \equiv \sum\sum (\partial T^*/\partial q_k)(\partial\dot{q}_k/\partial\omega_I)\omega_I; \tag{c}$$

instead of the more "orthodox"

$$dT^*/dt = \sum (\partial T^*/\partial\omega_I)\dot{\omega}_I + \sum (\partial T^*/\partial q_k)\dot{q}_k + \partial T^*/\partial t. \tag{d}$$

From these results conclude that:

(ii) If $\dot{q} \Leftrightarrow \omega$ *is linear and homogeneous* in these velocities (e.g., catastatic case), the definitions (b) and (d) coincide; and

(iii) Unless $-\sum\sum H^k{}_I(\partial T^*/\partial\omega_k)\omega_I = 0$ (e.g., by sign properties of $H^k{}_I$, and since the $\partial T^*/\partial\omega_k$ are linear and homogeneous in the ω's), the system will be *nonconservative*, even if all the Θ_I's are potential and all constraints are stationary.

5.4 SECOND- AND HIGHER-ORDER CONSTRAINTS

The foregoing theory can be easily extended to the following case of *second*-order, generally nonholonomic, constraints:

$$f_D(t, q, \dot{q}, \ddot{q}) = 0 \qquad [D = 1, \ldots, m(< n)]. \tag{5.4.1}$$

Here, compatibility among the various differential variational principles (chap. 6) requires that the virtual displacements corresponding to (5.4.1) be constrained by

$$\sum (\partial f_D/\partial \ddot{q}_k)\, \delta q_k = 0, \tag{5.4.2}$$

instead of (5.2.9). Hence, the virtual form of the constraints

$$\dot{\omega}_D \equiv f_D(t, q, \dot{q}, \ddot{q}) = 0 \qquad [D = 1, \ldots, m(< n)], \tag{5.4.3a}$$

$$\dot{\omega}_I \equiv f_I(t, q, \dot{q}, \ddot{q}) \neq 0 \qquad [I = m+1, \ldots, n] \tag{5.4.3b}$$

is

$$\delta\theta_D \equiv \sum (\partial\dot{\omega}_D/\partial\ddot{q}_k)\, \delta q_k = 0, \qquad \delta\theta_I \equiv \sum (\partial\dot{\omega}_I/\partial\ddot{q}_k)\, \delta q_k \neq 0. \tag{5.4.4}$$

It follows that all the previous results hold in this case, too, but with $\partial\dot{q}/\partial\omega$ $(\partial\omega/\partial\dot{q})$ replaced with $\partial\ddot{q}/\partial\dot{\omega}$ $(\partial\dot{\omega}/\partial\ddot{q})$. For example, the second-order counterparts of the, say, kinetic Maggi and Hadamard equations will be

Maggi:

$$\sum (\partial\ddot{q}_k/\partial\dot{\omega}_I) E_k(T) = \sum (\partial\ddot{q}_k/\partial\dot{\omega}_I) Q_k \qquad \text{(Lagrangean form)}, \tag{5.4.5a}$$

$$\begin{aligned} \partial S^*/\partial\dot{\omega}_I &= \sum (\partial\ddot{q}_k/\partial\dot{\omega}_I)\,(\partial S/\partial\ddot{q}_k) \\ &= \sum (\partial\ddot{q}_k/\partial\dot{\omega}_I) Q_k \qquad \text{(Appellian form)}, \end{aligned} \tag{5.4.5b}$$

Hadamard:

$$\begin{aligned} &E_I(T) + \sum (\partial\Phi_D/\partial\ddot{q}_I) E_D(T) \\ &\quad = Q_I + \sum (\partial\Phi_D/\partial\ddot{q}_I) Q_D \qquad \text{(Lagrangean form)}, \end{aligned} \tag{5.4.6a}$$

$$\begin{aligned} \partial S_o/\partial\ddot{q}_I &= \partial S/\partial\ddot{q}_I + \sum (\partial\Phi_D/\partial\ddot{q}_I)\,(\partial S/\partial\ddot{q}_D) \\ &= Q_I + \sum (\partial\Phi_D/\partial\ddot{q}_I) Q_D \qquad \text{(Appellian form)}; \end{aligned} \tag{5.4.6b}$$

where

$$\text{eqs. (5.4.1)} \to \ddot{q}_D = \ddot{q}_D(t, q, \dot{q}, \ddot{q}_I) \equiv \Phi_D(t, q, \dot{q}, \ddot{q}_I), \tag{5.4.7a}$$

$$S(t, q, \dot{q}, \ddot{q}) = \cdots = S^*(t, q, \omega, \dot{\omega}) = \cdots = S_o(t, q, \dot{q}, \ddot{q}_I). \tag{5.4.7b}$$

Similarly, for the *higher*-order constraints:

$$\begin{aligned} &f_D(t, q, \dot{q}, \ddot{q}, \dddot{q}, \ldots, \overset{(s)}{q}) = 0 \\ &[D = 1, \ldots, m(< n);\ s = 1, 2, 3, \ldots], \end{aligned} \tag{5.4.8}$$

eqs. (5.4.2–4) are replaced, respectively, by

$$\sum \left(\partial f_D / \partial \overset{(s)}{q_k} \right) \delta q_k = 0, \tag{5.4.9}$$

$$\overset{(s-1)}{\omega_D} \equiv f_D \left(t, q, \dot{q}, \ddot{q}, \dddot{q}, \ldots, \overset{(s)}{q} \right) = 0, \tag{5.4.10a}$$

$$\overset{(s-1)}{\omega_I} \equiv f_I \left(t, q, \dot{q}, \ddot{q}, \dddot{q}, \ldots, \overset{(s)}{q} \right) \neq 0, \tag{5.4.10b}$$

$$\delta\theta_D \equiv \sum \left(\partial \overset{(s-1)}{\omega_D} \Big/ \partial \overset{(s)}{q_k} \right) \delta q_k = 0, \tag{5.4.10c}$$

$$\delta\theta_I \equiv \sum \left(\partial \overset{(s-1)}{\omega_I} \Big/ \partial \overset{(s)}{q_k} \right) \delta q_k \neq 0. \tag{5.4.10d}$$

In general, starting with $\dot{q}_D = \dot{q}_D(t, q, \dot{q}_I)$ we can easily verify that

$$\partial \dot{q}_D / \partial \dot{q}_I = \partial \ddot{q}_D / \partial \ddot{q}_I = \partial \dddot{q}_D / \partial \dddot{q}_I = \cdots; \tag{5.4.11}$$

and similalry for identities involving $\partial \overset{(s-1)}{\omega_D} / \partial \overset{(s)}{q_k}$.

These topics are examined in detail in chapter 6.

Example 5.4.1 (Mei, 1987, pp. 273–274). Let us derive the equations of motion of a rigid body moving (rotating) about a fixed point and subject to the acceleration (second-order) constraint

$$(\omega_x \dot{\omega}_y - \omega_y \dot{\omega}_x) + ({\omega_x}^2 + {\omega_y}^2)\omega_z - c({\omega_x}^2 + {\omega_y}^2)^{3/2} = 0, \tag{a}$$

where $\omega_{x,y,z}$ are *body-fixed* components of (inertial) angular velocity of the body and c is a constant. If ϕ, θ, ψ are the Eulerian angles between space-fixed and body-fixed axes, then [recalling results from §1.12, and with $s(\ldots) \equiv \sin(\ldots), c(\ldots) \equiv \cos(\ldots)$]

$$\omega_x = (s\theta\, s\psi)\dot{\phi} + (c\psi)\dot{\theta}, \qquad \omega_y = (s\theta\, c\psi)\dot{\phi} + (-s\psi)\dot{\theta}, \qquad \omega_z = (c\theta)\dot{\phi} + (1)\psi, \tag{b}$$

and their inverses,

$$\dot{\phi} = (1/\sin\theta)\,[(s\psi)\omega_x + (c\psi)\omega_y], \qquad \dot{\theta} = (c\psi)\omega_x - (s\psi)\omega_y,$$
$$\dot{\psi} = \omega_z - [(s\psi)\omega_x + (c\psi)\omega_y]\cot\theta. \tag{c}$$

In view of (a), we choose the following *quasi accelerations*:

$$\alpha_1 \equiv (\omega_x \dot{\omega}_y - \omega_y \dot{\omega}_x) + ({\omega_x}^2 + {\omega_y}^2)\omega_z - c({\omega_x}^2 + {\omega_y}^2)^{3/2} = 0, \tag{d1}$$

$$\alpha_2 \equiv (\dot{\omega}_x c\psi - \dot{\omega}_y s\psi) \Big/ (\omega_x c\psi - \omega_y s\psi) \neq 0, \tag{d2}$$

$$\alpha_3 \equiv \dot{\omega}_z \neq 0; \tag{d3}$$

which, upon inverting and enforcing the constraint (d1) yield

$$\dot{\omega}_x = (\omega_x)\alpha_2 + no\ \alpha\text{-}terms, \tag{e1}$$

$$\dot{\omega}_y = (\omega_y)\alpha_2 + no\ \alpha\text{-}terms, \tag{e2}$$

$$\dot{\omega}_z = (1)\alpha_3 + no\ \alpha\text{-}terms. \tag{e3}$$

The Appellian of the body is (recalling the results of §3.14; and with A, B, C: principal moments of inertia of body at fixed point)

$$\begin{aligned} 2S^* = {} & A(\dot{\omega}_x)^2 + B(\dot{\omega}_y)^2 + C(\dot{\omega}_z)^2 + 2(C - B)\omega_y\,\omega_z\,\dot{\omega}_x \\ & + 2(A - C)\omega_x\,\omega_z\,\dot{\omega}_y + 2(B - A)\omega_x\,\omega_y\,\dot{\omega}_z + no\ other\ \dot{\omega}\ terms, \end{aligned} \tag{f}$$

and, therefore, substituting into it (e1–3), we obtain the *constrained* Appellian:

$$\begin{aligned} 2S^* & \Rightarrow 2S^*_o \\ & = A\,\omega_x{}^2\alpha_2{}^2 + B\,\omega_y{}^2\alpha_2{}^2 + C\,\alpha_3{}^2 \\ & \quad + 2(C - B)\omega_x\,\omega_y\,\omega_z\,\alpha_2 + 2(A - C)\omega_x\,\omega_y\,\omega_z\,\alpha_2 + 2(B - A)\omega_x\,\omega_y\,\alpha_3 \\ & \quad + no\ other\ \alpha\ terms, \end{aligned} \tag{g}$$

and from this we get the corresponding constrained inertial "forces":

$$\begin{aligned} \partial S^*_o/\partial\alpha_2 & = A\,\omega_x{}^2\alpha_2 + B\,\omega_y{}^2\alpha_2 + (C - B)\omega_x\,\omega_y\,\omega_z + (A - C)\omega_x\,\omega_y\,\omega_z \\ & = A\,\omega_x\,\dot{\omega}_x + B\,\omega_y\,\dot{\omega}_y + (A - B)\omega_x\,\omega_y\,\omega_z \qquad [\text{with (d2)}], \end{aligned} \tag{h1}$$

$$\begin{aligned} \partial S^*_o/\partial\alpha_3 & = C\alpha_3 + (B - A)\omega_x\,\omega_y \\ & = C(\dot{\omega}_z) + (B - A)\omega_x\,\omega_y \qquad [\text{with (d3)}]. \end{aligned} \tag{h2}$$

Further, with $Q_{\phi,\theta,\psi}$: unconstrained *holonomic* components of impressed force, and using (b), (c), and (e1–3), we obtain its *constrained nonholonomic* components:

$$\begin{aligned} \Theta_2 & = Q_\phi[(\partial\dot{\phi}/\partial\omega_x)\,(\partial\dot{\omega}_x/\partial\alpha_2) + (\partial\dot{\phi}/\partial\omega_y)\,(\partial\dot{\omega}_y/\partial\alpha_2) + (\partial\dot{\phi}/\partial\omega_z)\,(\partial\dot{\omega}_z/\partial\alpha_2)] \\ & \quad + Q_\theta[(\partial\dot{\theta}/\partial\omega_x)\,(\partial\dot{\omega}_x/\partial\alpha_2) + (\partial\dot{\theta}/\partial\omega_y)\,(\partial\dot{\omega}_y/\partial\alpha_2) + (\partial\dot{\theta}/\partial\omega_z)\,(\partial\dot{\omega}_z/\partial\alpha_2)] \\ & \quad + Q_\psi[(\partial\dot{\psi}/\partial\omega_x)\,(\partial\dot{\omega}_x/\partial\alpha_2) + (\partial\dot{\psi}/\partial\omega_y)\,(\partial\dot{\omega}_y/\partial\alpha_2) + (\partial\dot{\psi}/\partial\omega_z)\,(\partial\dot{\omega}_z/\partial\alpha_2)] \\ & = (Q_\phi/\sin\theta)\,(\omega_x\,s\psi + \omega_y\,c\psi) + Q_\theta(\omega_x\,c\psi + \omega_y\,s\psi) - Q_\psi(\omega_x\,s\psi + \omega_y\,c\psi)\cot\theta \\ & = \dot{\phi}\,Q_\phi + \dot{\theta}\,Q_\theta - \dot{\phi}\,Q_\psi\,c\theta, \end{aligned} \tag{i1}$$

$$\Theta_3 = Q_\phi(\ldots) + Q_\theta(\ldots) + Q_\psi(\ldots) = \cdots = Q_\psi. \tag{i2}$$

As a result of (h1, 2), and (i1, 2), Appell's *kinetic* equations $\partial S^*_o/\partial\alpha_I = \Theta_I\ (I = 2, 3)$ become

$$2: \qquad A\,\omega_x\,\dot{\omega}_x + B\,\omega_y\,\dot{\omega}_y + (A - B)\,\omega_x\,\omega_y\,\omega_z = \dot{\phi}\,Q_\phi + \dot{\theta}\,Q_\theta - \dot{\phi}\,Q_\psi\,c\theta, \tag{j1}$$

$$3: \qquad C\,\dot{\omega}_z + (B - A)\omega_x\,\omega_y = Q_\psi; \tag{j2}$$

and along with (b) they constitute a determinate set of five equations for $\dot{\phi}, \dot{\theta}, \dot{\psi};\ \omega_x, \omega_y, \omega_z$.

The remaining kinetostatic equation corresponding to α_1, and based on the *relaxed* Appellian, is

$$(\partial S^*/\partial\alpha_1)_o = \Theta_1 + \Lambda_1; \tag{k}$$

and, once the motion has been determined from (j1, 2), this yields the reaction Λ_1 necessary to maintain the constraint (a). The details of (k) are left to the reader.

Finally, we remark that the above Appellian equations are simpler than those based on $\dot{\omega}_x, \dot{\omega}_y, \dot{\omega}_z$; that is, $\partial S^*/\partial\dot{\omega}_x$, and so on. See, for example, San (1973).

6

Differential Variational Principles

and Associated Generalized Equations of Motion of Nielsen, Tsenov, et al.

The incautious observer might then be tempted to remark: if all mechanics problems can be solved by Newtonian mechanics, is it really economical to introduce a flock of differently stated principles which, after all, can accomplish no more? To this we make a three-fold rejoinder. In the first place, the ease of solving a given problem generally depends on the way in which it is stated, and a method which solves it when it is stated one way may be vastly simpler than that which handles it when the statement is made in another form. In the second place, we can fairly say that *every restatement of the fundamental principles deepens our appreciation of, and feeling for, the whole subject: two methods of solving the same problem mean more in our understanding than the solution of two problems by the same method*. More important in many respects than these answers is, however, the third: it is, by no means, sure that the Newtonian principles are actually competent to describe *all* phenomena in which motion occurs . . . . It seems plausible that alternative points of view may, themselves, suggest fundamental modifications in mechanical principles which will lead to successful attacks on the new problems.

(Lindsay and Margenau, 1936, p. 103, emphasis added)

6.1 INTRODUCTION

This chapter treats (i) the differential variational principles of constrained system dynamics (of Lagrange, Jourdain, Gauss, Hertz, Mangeron–Deleanu, et al.) from a simple and unified viewpoint, and (ii) the associated kinematico-inertial identities and corresponding generalized equations of motion (of Nielsen, Tsenov, Dolaptschiew, et al.).

These topics, until recently viewed by many as academic curiosities, have re-emerged as powerful and versatile tools for the theoretical and numerical handling of problems of nonlinear nonholonomic constraints in the velocities, accelerations, and so on; and also, in impulsive motion and multibody dynamics.

For parallel reading we recommend the following: Mei (1985, 1987), Mei et al. (1991) and references cited therein; and the (Soviet $\rightarrow$) Russian and Chinese journals of *Applied Mathematics and Mechanics*.

6.2 THE GENERAL THEORY

The differential variational principles of mechanics (DVP) are statements to the effect that certain differential expressions, linear and homogeneous in the appropriate kinematical variations from a kinetic state (or first variations of certain scalar energetic functions from it), vanish. The principle of Lagrange (LP) is the simplest and most fundamental of them: as shown below, *excluding singular configurations of the system*, all other DVP derive from it. Here, as with most of the rest of the book, the discussion is limited to bilateral and ideal constraints; that is, we assume that (recalling §3.2 and the notations employed there)

$$\mathcal{S}\, d\boldsymbol{R}\cdot\delta\boldsymbol{r} = 0 \;\Rightarrow\; \mathcal{S}\, dm\,\boldsymbol{a}\cdot\delta\boldsymbol{r} = \mathcal{S}\, d\boldsymbol{F}\cdot\delta\boldsymbol{r}, \tag{6.2.1}$$

where, as detailed earlier (§2.5),

$$\delta\boldsymbol{r} = \sum \boldsymbol{e}_k\,\delta q_k = \sum \boldsymbol{\varepsilon}_k\,\delta\theta_k$$
$$\left(= \sum \boldsymbol{\varepsilon}_I\,\delta\theta_I,\ I = m+1,\ldots,n;\ m\text{: number of } \textit{additional} \text{ Pfaffian constraints}\right). \tag{6.2.1a}$$

Now, $(\ldots)^{\cdot}$-differentiating (6.2.1) once, and recalling that $\mathcal{S}\ldots$ and $(\ldots)^{\cdot}$ commute, we obtain

$$\mathcal{S}\,[(dm\,\boldsymbol{a} - d\boldsymbol{F})^{\cdot}\cdot\delta\boldsymbol{r}] + \mathcal{S}\,[(dm\,\boldsymbol{a} - d\boldsymbol{F})\cdot(\delta\boldsymbol{r})^{\cdot}] = 0. \tag{6.2.2}$$

From this, we readily conclude that the equations of motion of the system can be derived from the variational equation

$$\mathcal{S}\,(dm\,\boldsymbol{a} - d\boldsymbol{F})\cdot(\delta\boldsymbol{r})^{\cdot} = 0, \tag{6.2.3}$$

where the $\delta\boldsymbol{r}$ satisfy not only the familiar $\delta t = 0$, but also $\delta\boldsymbol{r} = \boldsymbol{0}$; and since, as we have already seen (§4.6; also, ex. 6.2.1 below), we can always take $(\delta\boldsymbol{r})^{\cdot} = \delta(\dot{\boldsymbol{r}}) \equiv \delta\boldsymbol{v}$, LP can be replaced by the following DVP:

$$\mathcal{S}\,(dm\,\boldsymbol{a} - d\boldsymbol{F})\cdot\delta\boldsymbol{v} = 0, \qquad \text{with}\quad \delta t = 0 \quad \textit{and} \quad \delta\boldsymbol{r} = \boldsymbol{0}. \tag{6.2.4}$$
$$(\text{constraints on } \delta\boldsymbol{v} \neq \boldsymbol{0}).$$

Next, $(\ldots)^{\cdot}$-differentiating (6.2.4) once yields

$$\mathcal{S}\,[(dm\,\boldsymbol{a} - d\boldsymbol{F})^{\cdot}\cdot\delta\boldsymbol{v}] + \mathcal{S}\,[(dm\,\boldsymbol{a} - d\boldsymbol{F})\cdot(\delta\boldsymbol{v})^{\cdot}] = 0, \tag{6.2.5}$$

and reasoning as earlier, and with $(\delta\boldsymbol{v})^{\cdot} = \delta(\dot{\boldsymbol{v}}) \equiv \delta\boldsymbol{a}$, we see that the equations of motion of the system can be obtained from the variational equation

$$\mathcal{S}\,(dm\,\boldsymbol{a} - d\boldsymbol{F})\cdot\delta\boldsymbol{a} = 0, \qquad \text{with } \delta t = 0,\quad \delta\boldsymbol{r} = \boldsymbol{0},\quad \textit{and}\quad \delta\boldsymbol{v} = \boldsymbol{0} \tag{6.2.6}$$
$$(\text{constraints on } \delta\boldsymbol{a} \neq \boldsymbol{0}).$$

Continuing this process, inductively, we can easily generalize to the following DVP: *The equations of motion of an ideally constrained mechanical system derive from*

$$\mathcal{S}\left(dm\,\boldsymbol{a} - d\boldsymbol{F})\cdot\delta\overset{(s)}{\boldsymbol{r}}\right) = 0 \qquad (s = 0, 1, 2, \ldots), \tag{6.2.7}$$

where the variations satisfy

$$\delta t = 0 \quad and \quad \delta \boldsymbol{r} = \boldsymbol{0}, \quad \delta(\dot{\boldsymbol{r}}) = \boldsymbol{0}, \quad \delta(\ddot{\boldsymbol{r}}) = \boldsymbol{0}, \ldots, \quad \delta\Big(\overset{(s-1)}{\boldsymbol{r}}\Big) = \boldsymbol{0} \quad (s-1 \geq 0). \quad (6.2.7a)$$
$$\left(\text{constraints on } \delta \overset{(s)}{\boldsymbol{r}} \equiv \delta(d^s \boldsymbol{r}/dt^s) \neq \boldsymbol{0}\right).$$

The DVP corresponding to $s = 0, 1, 2$ are called, respectively, principles of *Lagrange* [eq. (6.2.1)] *Jourdain* [eq. (6.2.4)], and *Gauss* (*Gibbs*) [eq. (6.2.6)]; while the case corresponding to a general s, in (6.2.7), is referred to as the principle of *Mangeron–Deleanu* [eqs. (6.2.7, 7a)]; that is, roughly, Jourdain's principle (JP) is Lagrange's principle (LP) with $\delta \boldsymbol{r} \to \delta \boldsymbol{v}$, and Gauss' principle (GP) is LP with $\delta \boldsymbol{r} \to \delta \boldsymbol{a}$, and so on.

[According to Nordheim (1927, pp. 68–69), this unified and simple approach to DVP (which, however, holds only under *differentiable* conditions!) seems to be due to Leitinger (1913) and other members of the "Austrian school" (ca. 1910).]

REMARKS

(i) The equations associated with these variations are an *instantaneous* representation of the system. Otherwise, if, in JP, $\delta \boldsymbol{r}(t) = \boldsymbol{0}$ continuously, one might conclude, incorrectly, that $(\delta \boldsymbol{r})^{\cdot} = \delta(d\boldsymbol{r}/dt) = \boldsymbol{0}$. Rather, *at each succeeding instant*, $\delta \boldsymbol{r}$ *is reset equal to zero, in accordance with the instantaneous viewpoint*. Clearly, this viewpoint does not apply to equations involving time integrals; similarly for GP, and so on.

(ii) In the same spirit, we avoid the occasionally used term *virtual power* for $S\, d\boldsymbol{F} \cdot \delta \boldsymbol{v}$ and the consequent term *principle of virtual power* for JP. Power means work per unit time; that is, $\big(S\, d\boldsymbol{F} \cdot \delta \boldsymbol{r}\big)/\delta t$, but since, here, $\delta t = 0$, such a term could be confusing.

The next step is to transform these DVP to system variables, and then to obtain the corresponding equations of motion. By now, LP is well known (chap. 3), and so we begin with the principle of Jourdain.

Example 6.2.1 *The Significance of the Commutation Rule in Jourdain's Principle* (*JP*). During the formulation of JP, (6.2.3, 4), we invoked the commutation rule:

$$d(\delta \boldsymbol{r}) = \delta(d\boldsymbol{r}) \qquad \text{or} \qquad (\delta \boldsymbol{r})^{\cdot} = (\delta \dot{\boldsymbol{r}}) \equiv \delta \boldsymbol{v}. \tag{a}$$

However, since the derivation of the equations of motion [either from LP or from the central equation (§3.5, §3.6 and §5.3)] is independent of any particular assumptions about $d(\delta \boldsymbol{r}) - \delta(d\boldsymbol{r})$, and since the ultimate purpose and usefulness of JP—in fact, of all DVP—is to produce correct equations of motion, it follows that *JP, too, should be independent of (a)*. Let us see in detail why this is so.

We begin with the most general expression for $\delta \boldsymbol{r}$ (recalling the relevant theory and notations of §2.4–2.9):

$$\delta \boldsymbol{r} = \sum \boldsymbol{e}_k\, \delta q_k = \sum \boldsymbol{\varepsilon}_k\, \delta\theta_k = \sum \boldsymbol{\varepsilon}_I\, \delta\theta_I \qquad (\text{since } \delta\theta_D = 0). \tag{b}$$

Since the $n - m$ vectors $\boldsymbol{\varepsilon}_I$ are independent, the Jourdain requirement $\delta \boldsymbol{r} = \boldsymbol{0}$ applied to (b) yields $\delta\theta_I = 0$; that is, in sum, here we have

$$\delta\theta_k = 0 \qquad (k = 1, 2, 3, \ldots, n). \tag{c}$$

Next, $(\dots)^{\cdot}$-differentiating (a) and *then* enforcing (c), we find

$$\begin{aligned}(\delta\boldsymbol{r})^{\cdot} &= \sum [(d\boldsymbol{\varepsilon}_I/dt)\,\delta\theta_I + \boldsymbol{\varepsilon}_I(\delta\theta_I)^{\cdot}] \\ &= \sum \boldsymbol{\varepsilon}_I(\delta\theta_I)^{\cdot} = \sum (\partial\boldsymbol{v}/\partial\omega_I)(\delta\theta_I)^{\cdot}. \end{aligned} \tag{d}$$

Now, let us calculate $\delta\boldsymbol{v} \Rightarrow (\delta\boldsymbol{v})_{\text{Jourdain variation}} \equiv \delta'\boldsymbol{v}$ [see also (6.3.5) below]. Assuming for simplicity, but no loss of generality, a scleronomic system, we have (omitting superstars on $\boldsymbol{v}$ etc., for simplicity)

$$\boldsymbol{v} = \sum \boldsymbol{\varepsilon}_I\,\omega_I, \tag{e}$$

and, therefore,

$$\delta\boldsymbol{v} = \sum (\delta\boldsymbol{\varepsilon}_I\,\omega_I + \boldsymbol{\varepsilon}_I\,\delta\omega_I) \;\Rightarrow\; \delta'\boldsymbol{v} = \sum \boldsymbol{\varepsilon}_I\,\delta\omega_I, \tag{f}$$

since, *at least for Pfaffian constraints*, $\boldsymbol{\varepsilon}_I = \boldsymbol{\varepsilon}_I(q) \;\Rightarrow\; \delta'\boldsymbol{\varepsilon}_I = \boldsymbol{0}$ [see "Remarks" (i) below].

Subtracting (d) and (f) side by side, we obtain the following *transitivity equation in the sense of Jourdain*:

$$\begin{aligned}(\delta\boldsymbol{r})^{\cdot} - \delta'\boldsymbol{v} &= \sum \boldsymbol{\varepsilon}_I[(\delta\theta_I)^{\cdot} - \delta\omega_I] \\ \Rightarrow (\delta\boldsymbol{r})^{\cdot} &= \delta'\boldsymbol{v} + \sum \boldsymbol{\varepsilon}_I[(\delta\theta_I)^{\cdot} - \delta\omega_I]. \end{aligned} \tag{g}$$

Next, inserting (f) into the $(\dots)^{\cdot}$-derivative of LP under $\delta\boldsymbol{r} = \boldsymbol{0}$; that is (6.2.3),

$$\mathcal{S}\,(dm\,\boldsymbol{a} - d\boldsymbol{F})\cdot(\delta\boldsymbol{r})^{\cdot} = 0, \tag{h}$$

we get

$$\mathcal{S}\,(dm\,\boldsymbol{a} - d\boldsymbol{F})\cdot\delta'\boldsymbol{v} + \mathcal{S}\,(dm\,\boldsymbol{a} - d\boldsymbol{F})\cdot\sum \boldsymbol{\varepsilon}_I[(\delta\theta_I)^{\cdot} - \delta\omega_I] = 0,$$

or, rearranging,

$$\mathcal{S}\,(dm\,\boldsymbol{a} - d\boldsymbol{F})\cdot\delta'\boldsymbol{v} + \sum \Big(\mathcal{S}\,(dm\,\boldsymbol{a} - d\boldsymbol{F})\cdot\boldsymbol{\varepsilon}_I\Big)[(\delta\theta_I)^{\cdot} - \delta\omega_I] = 0; \tag{i}$$

from which, and this is the key step in the entire discussion, since

$$\mathcal{S}\,(dm\,\boldsymbol{a} - d\boldsymbol{F})\cdot\boldsymbol{\varepsilon}_I = 0 \qquad [\text{“raw” form of LP in quasi variables; also (6.3.26)}], \tag{j}$$

we finally obtain the *original* ("Jourdainian") form of JP (1909):

$$\mathcal{S}\,(dm\,\boldsymbol{a} - d\boldsymbol{F})\cdot\delta'\boldsymbol{v} = 0, \qquad \text{under } \delta t = 0 \quad \text{and} \quad \delta\boldsymbol{r} = \boldsymbol{0} \quad [\text{but } (\delta\boldsymbol{r})^{\cdot} \neq \boldsymbol{0}]. \tag{k}$$

In short, the transitivity condition $(\delta\boldsymbol{r})^{\cdot} = \delta\boldsymbol{v}$ is *sufficient but not necessary for the derivation of JP from LP*. Finally, substituting (f) into (k), and since the $n - m$ $\delta\omega_I$ are independent, reproduces (j).

REMARKS

(i) Equation (g) can also result from the general transitivity equation (§2.10):

$$(\delta\theta_k)^{\cdot} - \delta\omega_k = \sum a_{kl}[(\delta q_l)^{\cdot} - \delta(\dot{q}_l)] + \sum\sum \gamma^k_{rs}\,\omega_s\,\delta\theta_r, \tag{11}$$

and its inverse

$$(\delta q_l)^{\cdot} - \delta(\dot{q}_l) = \sum A_{lk}[(\delta\theta_k)^{\cdot} - \delta\omega_k] - \sum\sum\sum A_{lk}\gamma^k{}_{rs}\,\omega_s\,\delta\theta_r. \tag{l2}$$

We have, successively,

$$\begin{aligned}(\delta \boldsymbol{r})^{\cdot} - \delta\boldsymbol{v} &= \sum \boldsymbol{e}_l[(\delta q_l)^{\cdot} - \delta(\dot{q}_l)] \\ &= \sum\Big(\sum A_{lk}\boldsymbol{e}_l\Big)[(\delta\theta_k)^{\cdot} - \delta\omega_k] - \sum\sum\sum\Big(\sum A_{lk}\boldsymbol{e}_l\Big)\gamma^k{}_{rs}\,\omega_s\,\delta\theta_r \\ &= \sum \boldsymbol{\varepsilon}_k[(\delta\theta_k)^{\cdot} - \delta\omega_k] - \sum\sum\sum \boldsymbol{\varepsilon}_k\gamma^k{}_{rs}\,\omega_s\,\delta\theta_r,\end{aligned} \tag{m}$$

from which, due to (c) and since now $\delta\boldsymbol{v} \Rightarrow \delta'\boldsymbol{v}$, we recover (g). Clearly, this derivation is not limited to Pfaffian constraints, and so it avoids the earlier restriction $\boldsymbol{\varepsilon}_I = \boldsymbol{\varepsilon}_I(q)$.

(ii) If we had assumed $(\delta\boldsymbol{r})^{\cdot} = \delta\boldsymbol{v}$, then (g) and (l2) would have led us to $(\delta\theta_k)^{\cdot} = \delta\omega_k$ and also to $(\delta q_k)^{\cdot} = \delta(\dot{q}_k)$, and vice versa. As (l1, 2) readily show, without the Jourdain constraints, *either* $(\delta q_k)^{\cdot} = \delta(\dot{q}_k)$ *or* $(\delta\theta_k)^{\cdot} = \delta\omega_k$, *but not both.*

(iii) The above reasoning extends readily to *higher-order* constraints. For additional insights see also Bremer (1993).

6.3 PRINCIPLE OF JOURDAIN, AND EQUATIONS OF NIELSEN

As detailed in chapters 2 and 5, starting with the general position vector in the Lagrangean variables q,

$$\boldsymbol{r} = \boldsymbol{r}(t, q), \tag{6.3.1}$$

we readily find

$$\boldsymbol{v} = d\boldsymbol{r}/dt = \sum (\partial\boldsymbol{r}/\partial q_k)\dot{q}_k + \partial\boldsymbol{r}/\partial t, \tag{6.3.2}$$

from which

$$\partial\boldsymbol{r}/\partial q_k = \partial\boldsymbol{v}/\partial\dot{q}_k \equiv \partial\dot{\boldsymbol{r}}/\partial\dot{q}_k \equiv \boldsymbol{e}_k \qquad (k = 1, 2, \ldots, n); \tag{6.3.3}$$

and

$$\begin{aligned}\delta\boldsymbol{v} \equiv \delta(\dot{\boldsymbol{r}}) &= \sum (\partial\boldsymbol{r}/\partial q_k)\,\delta(\dot{q}_k) + \sum \delta(\partial\boldsymbol{r}/\partial q_k)\dot{q}_k + \delta(\partial\boldsymbol{r}/\partial t) \\ &= \sum (\partial\dot{\boldsymbol{r}}/\partial\dot{q}_k)\,\delta(\dot{q}_k) + \textit{no other } \delta\dot{q} \textit{ terms} \\ &\equiv \sum \boldsymbol{e}_k\,\delta(\dot{q}_k) + \textit{no other } \delta\dot{q} \textit{ terms} \\ &\equiv \delta'\boldsymbol{v} + \textit{no other } \delta\dot{q} \textit{ terms},\end{aligned} \tag{6.3.4}$$

where

$$\delta'(\ldots) \equiv \sum [\partial(\ldots)/\partial\dot{q}_k]\,\delta(\dot{q}_k):$$

Jourdain variation of $(\ldots)$ [i.e., $\delta(\ldots)$ with $\delta t = 0$ *and* $\delta q_k = 0$]. (6.3.5)

Next, from (6.3.2), we easily obtain

$$\partial\dot{\boldsymbol{r}}/\partial q_k = \sum (\partial^2\boldsymbol{r}/\partial q_k\partial q_l)\dot{q}_l + \partial^2\boldsymbol{r}/\partial q_k\partial t, \tag{6.3.6a}$$

and

$$\begin{aligned}
\boldsymbol{a} = d\boldsymbol{v}/dt = \ddot{\boldsymbol{r}} \\
&= \sum (\partial \boldsymbol{r}/\partial q_k)\ddot{q}_k + \sum\sum (\partial^2 \boldsymbol{r}/\partial q_k \partial q_l)\dot{q}_k \dot{q}_l + 2\sum (\partial^2 \boldsymbol{r}/\partial q_k \partial t)\dot{q}_k \\
&\qquad + \partial^2 \boldsymbol{r}/\partial t^2, \qquad (6.3.6\text{b}) \\
&\Rightarrow \partial \boldsymbol{a}/\partial \dot{q}_k \equiv \partial \ddot{\boldsymbol{r}}/\partial \dot{q}_k = 2\Big(\sum (\partial^2 \boldsymbol{r}/\partial q_k \partial q_l)\dot{q}_l + \partial^2 \boldsymbol{r}/\partial q_k \partial t\Big),
\end{aligned}$$

and, comparing with (6.3.6a), we deduce the following *kinematical identity*:

$$\partial \ddot{\boldsymbol{r}}/\partial \dot{q}_k = 2(\partial \dot{\boldsymbol{r}}/\partial q_k), \qquad \text{or} \qquad \partial \boldsymbol{a}/\partial \dot{q}_k = 2(\partial \boldsymbol{v}/\partial q_k). \tag{6.3.7}$$

The above also reconfirm the already known basic result, extension of (6.3.3),

$$\boldsymbol{e}_k \equiv \partial \boldsymbol{r}/\partial q_k = \partial \dot{\boldsymbol{r}}/\partial \dot{q}_k = \partial \ddot{\boldsymbol{r}}/\partial \ddot{q}_k = \cdots$$

or

$$\partial \boldsymbol{r}/\partial q_k = \partial \boldsymbol{v}/\partial \dot{q}_k = \partial \boldsymbol{a}/\partial \ddot{q}_k = \cdots \qquad (k = 1, 2, \ldots, n). \tag{6.3.8}$$

Next, $(\ldots)^{\cdot}$-differentiating the kinetic energy

$$2T = S\, dm\, \boldsymbol{v} \cdot \boldsymbol{v} = S\, dm\, \dot{\boldsymbol{r}} \cdot \dot{\boldsymbol{r}}, \tag{6.3.9}$$

we readily obtain

$$dT/dt = S\, dm\, \boldsymbol{v} \cdot \boldsymbol{a} = S\, dm\, \dot{\boldsymbol{r}} \cdot \ddot{\boldsymbol{r}}, \tag{6.3.10}$$

and, therefore, invoking (6.3.7) and (6.3.8), and since $\partial T/\partial q_k = S\, dm\, \dot{\boldsymbol{r}} \cdot (\partial \dot{\boldsymbol{r}}/\partial q_k)$,

$$\begin{aligned}
\partial \dot{T}/\partial \dot{q}_k &= S\, dm\, (\partial \dot{\boldsymbol{r}}/\partial \dot{q}_k) \cdot \ddot{\boldsymbol{r}} + S\, dm\, \dot{\boldsymbol{r}} \cdot (\partial \ddot{\boldsymbol{r}}/\partial \dot{q}_k) \\
&= S\, dm\, (\partial \dot{\boldsymbol{r}}/\partial \dot{q}_k) \cdot \ddot{\boldsymbol{r}} + 2 S\, dm\, \dot{\boldsymbol{r}} \cdot (\partial \dot{\boldsymbol{r}}/\partial q_k) \\
&= S\, dm\, (\partial \dot{\boldsymbol{r}}/\partial \dot{q}_k) \cdot \ddot{\boldsymbol{r}} + 2(\partial T/\partial q_k),
\end{aligned} \tag{6.3.11}$$

$$\Rightarrow S\, dm\, \ddot{\boldsymbol{r}} \cdot (\partial \dot{\boldsymbol{r}}/\partial \dot{q}_k) = S\, dm\, \boldsymbol{a} \cdot \boldsymbol{e}_k = \partial \dot{T}/\partial \dot{q}_k - 2(\partial T/\partial q_k); \tag{6.3.12}$$

and combining this with the, by now well-known, Lagrangean identity (§3.3)

$$S\, dm\, \boldsymbol{a} \cdot \boldsymbol{e}_k = (\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k \equiv E_k(T), \tag{6.3.13}$$

we immediately obtain the *Nielsen identity*:

$$d/dt(\partial T/\partial \dot{q}_k) = \partial \dot{T}/\partial \dot{q}_k - \partial T/\partial q_k. \tag{6.3.14}$$

With its help, and (6.3.4, 5), and since $S\, d\boldsymbol{F} \cdot \boldsymbol{e}_k \equiv Q_k$ (§3.4), *Jourdain's principle* (6.2.4), or

$$S\, (dm\, \boldsymbol{a} - d\boldsymbol{F}) \cdot \delta' \boldsymbol{v} = 0, \qquad \text{under } \delta' t = 0 \qquad \textit{and} \qquad \delta' \boldsymbol{r} = \boldsymbol{0}, \tag{6.3.15}$$

assumes the following form in *general holonomic system variables*:

$$\sum [E_k(T) - Q_k]\, \delta(\dot{q}_k) = \sum [N_k(T) - Q_k]\, \delta(\dot{q}_k) = 0, \tag{6.3.16}$$

where the *Nielsen operator* $N_k(\ldots)$, in *holonomic coordinates* (constrained or not), is defined by

$$N_k(T) \equiv \partial\dot{T}/\partial\dot{q}_k - 2(\partial T/\partial q_k) = (\partial T/\partial\dot{q}_k)^{\cdot} - \partial T/\partial q_k \equiv E_k(T). \tag{6.3.17}$$

It is shown below that $N_k(f) = E_k(f)$, for any sufficiently smooth function $f = f(t, q, \dot{q})$. In particular, if the $\delta\dot{q}$'s are *independent* (e.g., holonomic system with n DOF) then (6.3.16) leads immediately to the *Nielsen form of Lagrange's equations* (of the second kind) (Nielsen, 1935, pp. 345–354):

$$\partial\dot{T}/\partial\dot{q}_k - 2(\partial T/\partial q_k) = Q_k. \tag{6.3.18}$$

Here, too, as in the Lagrangean case (§ 3.4 and §3.9), if part of Q_k derives from a potential $V = V(q)$, then (6.3.18) still holds, but with T replaced with $L \equiv T - V$, and Q_k: *nonpotential* part of that force.

If, on the other hand, the δq's are constrained by, say, the m Pfaffian (possibly nonholonomic) constraints

$$\sum a_{Dk}\, \delta q_k = 0 \qquad (D = 1, \ldots, m < n), \tag{6.3.19}$$

or, $(\ldots)^{\cdot}$-differentiating and then $\delta'(\ldots)$-varying them, to bring them to the Jourdain form:

$$\sum \dot{a}_{Dk}\ \delta q_k + \sum a_{Dk}(\delta q_k)^{\cdot} = \sum \dot{a}_{Dk}\ \delta q_k + \sum a_{Dk}\ \delta(\dot{q}_k) = 0,$$

$$\Rightarrow \sum a_{Dk}\ \delta'(\dot{q}_k) = \sum a_{Dk}\ \delta(\dot{q}_k) = 0, \tag{6.3.20}$$

then combining ("adjoining") (6.3.20) to (6.3.16) via the m Lagrangean multipliers λ_D, we obtain

$$N_k(T) = Q_k + \sum \lambda_D a_{Dk}. \tag{6.3.21}$$

Hence, the general rule: *in any set of constrained system equations, in holonomic variables*—for example, equations of Maggi, Hadamard–Appell, Appell—we can replace $E_k(T)$ *(or its identically equal $\partial S/\partial\ddot{q}_k$, S: Appellian) with* $N_k(T)$. Thus, it is not hard to see that

(i) If eqs. (6.3.19) have the Hadamard form (§3.8)

$$\delta q_D = \sum b_{DI}\ \delta q_I \qquad (I = m+1, \ldots, n), \tag{6.3.22}$$

then the "*Nielsen form of the corresponding (kinetic) Hadamard equations*" is

$$\partial\dot{T}/\partial\dot{q}_I - 2(\partial T/\partial q_I) + \sum b_{DI}\big[\partial\dot{T}/\partial\dot{q}_D - 2(\partial T/\partial q_D)\big] = Q_I + \sum b_{DI} Q_D,$$

or, compactly,

$$[N_I(T) - Q_I] + \sum b_{DI}[N_D(T) - Q_D] = 0; \tag{6.3.23}$$

and

(ii) In terms of the general quasi velocities $\omega = \omega(t, q, \dot{q}) \Leftrightarrow \dot{q} = \dot{q}(t, q, \omega)$, discussed in §5.1 and §5.2, the "*Nielsen form of the corresponding kinetic Maggi equations*" is

$$\sum \left[\partial \dot{T}/\partial \dot{q}_k - 2(\partial T/\partial q_k)\right](\partial \dot{q}_k/\partial \omega_I) = \sum Q_k(\partial \dot{q}_k/\partial \omega_I),$$

or, compactly,

$$\sum [N_k(T) - Q_k](\partial \dot{q}_k/\partial \omega_I) = 0; \tag{6.3.24}$$

and similarly for the kinetostatic Maggi equations.

An Application of Jourdain's Principle in Quasi Variables

For such variables, the Jourdain variation requirements result in $\delta\theta_k = 0 \Rightarrow (\delta\theta_k)^{\cdot} - \delta(\dot{\theta}_k) = 0 \Rightarrow (\delta\theta_k)^{\cdot} = \delta\omega_k$ [by the transitivity equations (§2.10, §5.2)], and so eq. (6.3.4) yields the fundamental representation (omitting superstars on $\boldsymbol{v}$ etc., for simplicity)

$$\delta' \boldsymbol{v} = \sum (\partial \boldsymbol{v}/\partial \omega_I)\,(\delta\theta_I)^{\cdot} = \sum (\partial \boldsymbol{v}/\partial \omega_I)\,\delta\omega_I. \tag{6.3.25}$$

Substituting the above into Jourdain's principle, eq. (6.3.15), we immediately obtain the $n - m$ kinetic *Schaefer* equations:

$$S\, dm\, \boldsymbol{a} \cdot (\partial \boldsymbol{v}/\partial \omega_I) = S\, d\boldsymbol{F} \cdot (\partial \boldsymbol{v}/\partial \omega_I). \tag{6.3.26}$$

[These equations were given for the first time by the noted German engineering scientist H. Schaefer, in 1951, for general *nonlinear*, possibly nonholonomic, velocity constraints, in a very insightful and lucid manner via LP (§5.3, recall (5.3.17 ff.)). Fifteen years later, they were reformulated for *linear* (i.e., Pfaffian) velocity constraints by Kane and Wang (1965), and without reference to the correct forms of the principles of mechanics.]

Example 6.3.1 *The Schieldrop–Nielsen Rule.* The following is a systematization of observations aiming at expediting the building of $N_k(T)$. Let us take, for convenience, but no loss of generality, a scleronomic system. By $(\ldots)^{\cdot}$-differentiating its kinetic energy

$$2T = \sum\sum M_{kl}\dot{q}_k\dot{q}_l, \qquad M_{kl} = M_{kl}(q)\text{: } \textit{inertia coefficients}, \tag{a}$$

we get

$$\dot{T} = \sum\sum M_{kl}\ddot{q}_k\dot{q}_l + \sum\sum\sum (1/2)(\partial M_{kl}/\partial q_r)\dot{q}_r\dot{q}_k\dot{q}_l. \tag{b}$$

Now, the $\dot{q}$'s appearing in this $\dot{T}$ are divided in *two* groups: (i) those that were already in T, and (ii) those created by the $(\ldots)^{\cdot}$-operation on the $M_{kl}(q)$. The latter $\dot{q}$ shall, henceforth, be denoted by an *underline*: $\underline{\dot{q}}$.

Next, let us build $N_k(T) \equiv \partial \dot{T}/\partial \dot{q}_k - 2(\partial T/\partial q_k)$. We readily find

$$2\,(\partial T/\partial q_p) = \sum\sum (\partial M_{kl}/\partial q_p)\dot{q}_k\dot{q}_l, \tag{c}$$

$$\partial \dot{T}/\partial \dot{q}_p = \sum M_{pk}\ddot{q}_k + \sum\sum \Big[\partial M_{pk}/\partial q_l + (1/2)\,(\partial M_{kl}/\partial q_p)\Big]\dot{q}_k\dot{q}_l. \qquad \text{(d)}$$

But due to the symmetry of the inertia coefficients, $M_{kl} = M_{lk}$,

$$\begin{aligned}\sum\sum (\partial M_{pk}/\partial q_l)\dot{q}_k\dot{q}_l &= \sum\sum (\partial M_{pl}/\partial q_k)\dot{q}_k\dot{q}_l \\ &= \sum\sum (1/2)\,(\partial M_{pk}/\partial q_l + \partial M_{pl}/\partial q_k)\dot{q}_k\dot{q}_l; \qquad \text{(e)}\end{aligned}$$

and, therefore,

$$\begin{aligned}\partial \dot{T}/\partial \dot{q}_p = {}& \sum M_{pk}\ddot{q}_k \\ &+ \sum\sum (1/2)\,(\partial M_{pk}/\partial q_l + \partial M_{pl}/\partial q_k + \partial M_{kl}/\partial q_p)\dot{q}_k\dot{q}_l. \qquad \text{(f)}\end{aligned}$$

Hence, subtracting (c) from (f) side by side,

$$\begin{aligned}N_p(T) &\equiv \partial \dot{T}/\partial \dot{q}_p - 2(\partial T/\partial q_p) \\ &= \sum M_{pk}\ddot{q}_k + \sum\sum (1/2)(\partial M_{pk}/\partial q_l + \partial M_{pl}/\partial q_k - \partial M_{kl}/\partial q_p)\dot{q}_k\dot{q}_l \\ &[= E_k(T)]. \qquad \text{(g)}\end{aligned}$$

These are standard steps in the derivation of explicit forms for $E_k(T)$ (§3.10). From the viewpoint of Nielsen's operator, however, they allow us to make the following observations:

(i) $\partial \dot{T}/\partial \dot{q}_k$ derives from $\dot{T}$ when every term of it is multiplied by the number (or power) of the $\dot{q}_p$ terms in it, and then the factor $\dot{q}_p$ is omitted from that term;
(ii) $2\,(\partial T/\partial q_p)\dot{q}_p$ is twice of that $\dot{T}$ term which contains the $\dot{q}_p$ generated by the $(\ldots)^{\cdot}$ differentiation.

So we have the following rule [due to E. B. Schieldrop (Nielsen, 1935, pp. 352–354)]:

First, we build $\dot{T}$. Then, to obtain $N_p(T)$ for a particular $p = 1, 2, 3, \ldots,$ we multiply each term of $\dot{T}$ either with an integer $k = 0, 1, 2, 3, \ldots,$ or with $k - 2 = -2, -1, 0, 1, \ldots,$ *depending on whether, from the k factors $\dot{q}_p$ in that term, none or one, respectively, were created by the $\dot{T}$-differentiations*—the underlined $\dot{q}$'s in $\dot{T}$ help us to keep track of that. Finally, in each term of the expression obtained thus far, we omit a term $\dot{q}_p$ or divide it by $\dot{q}_p$; which thus results in $N_p(T)$. In other words:

(i) The parts of $\dot{T}$ that are *linear* in $\dot{q}$ need no underlining and no sign change;
(ii) the parts of $\dot{T}$ that are *cubic* in the $\dot{q}$'s do contain an underlined $\dot{q}$; and so:
  (a) If $\dot{q}_p$ does not appear as a factor in that term, the latter makes no contribution to $N_p(T)$;
  (b) If $\dot{q}_p$ appears *once*, that term appears with *changed* or *unchanged* sign, according as $\dot{q}_p$ is *underlined* or *not*;
  (c) If $\dot{q}_p$ appears *twice* in a $\dot{T}$-factor, that term is multiplied by $k - 2$ when none of the $\dot{q}_p$ is underlined, or is multiplied by $k - 2 = 2 - 2 = 0$ when one of the $\dot{q}_p$ is underlined; *then, there is no contribution from that $\dot{T}$-term*;
  (d) If $\dot{q}_p$ appears *thrice* in a $\dot{T}$-factor, then one of them must be underlined, and so that term is multiplied by $k - 2 = 3 - 2 = 1$; and *its sign remains unchanged.*

Table 6.1

	$\dot{T}$-terms:	$N_r(T)$	$N_\phi(T)$
1.	$m\,\dot{r}\,\ddot{r}$	$k=1 \Rightarrow (1)\,(\ldots)$ $(1)\,(m\,\dot{r}\,\ddot{r})/\dot{r} = m\,\ddot{r}$	$k=0 \Rightarrow (0)\,(\ldots)$ 0
2.	$m\,r^2\,\dot{\phi}\,\ddot{\phi}$	$k=0 \Rightarrow (0)\,(\ldots)$ 0	$k=1 \Rightarrow (1)\,(\ldots)$ $(1)\,m\,r^2\,\dot{\phi}\,\ddot{\phi}/\dot{\phi} = m\,r^2\,\ddot{\phi}$
3.	$m\,r\,\underline{\dot{r}}\,(\dot{\phi})^2$	$k=1 \Rightarrow k-2=-1 \Rightarrow (-1)\,(\ldots)$ $(-1)\,[m\,r\,\dot{r}\,(\dot{\phi})^2]/\dot{r} = -m\,r\,(\dot{\phi})^2$	$k=2 \Rightarrow (2)\,(\ldots)$ $(2)\,[m\,r\,\dot{r}\,(\dot{\phi})^2]/\dot{\phi} = 2\,m\,r\,\dot{r}\,\dot{\phi}$
Totals		$N_r(T) = m\,\ddot{r} - m\,r\,(\dot{\phi})^2$	$N_\phi(T) = m\,r^2\,\ddot{\phi} + 2\,m\,r\,\dot{r}\,\dot{\phi}$

Example 6.3.2 Let us consider the *plane* motion of a particle of mass m, using polar coordinates $q_1 = r,\ q_2 = \phi$. Here,

$$2T = m\,[(\dot{r})^2 + r^2\,(\dot{\phi})^2], \tag{h1}$$

and, therefore,

$$\dot{T} = m\,[\dot{r}\,\ddot{r} + r^2\,\dot{\phi}\,\ddot{\phi} + r\,\underline{\dot{r}}\,(\dot{\phi})^2]; \tag{h2}$$

note the underlined $\dot{r}$ in the last term.

Then, applying the Schieldrop–Nielsen rule, we calculate $N_r(T) = E_r(T)$ and $N_\phi(T) = E_\phi(T)$. The details are shown in table 6.1.

No claims of universal calculational superiority of this clever rule are made here. We do think, however, that *this is something potentially useful, and, hence, worth knowing*. Perhaps, with proper systematization (symbolic programming), it could be used to advantage in more complicated systems. An additional example of its use is given in ex. 6.5.2.

6.4 INTRODUCTION TO THE PRINCIPLE OF GAUSS AND THE EQUATIONS OF TSENOV

(Gauss' principle, due to its fundamental importance, is given an independent extensive treatment in §6.6.)

By $(\ldots)^{\cdot}$-differentiating (6.3.6b), we obtain the *jerk vector* [(1.7.19e)]:

$$\begin{aligned}
\boldsymbol{j} \equiv d\boldsymbol{a}/dt \equiv \dddot{\boldsymbol{r}}
&= \sum (\partial\mathbf{r}/\partial q_k)\dddot{q}_k \\
&\quad + \sum\sum \left[(\partial^2\mathbf{r}/\partial q_k\partial q_l)\ddot{q}_k\dot{q}_l + (\partial^2\mathbf{r}/\partial q_k\partial q_l)\dot{q}_k\ddot{q}_l + (\partial^2\mathbf{r}/\partial q_k\partial q_l)\dot{q}_k\ddot{q}_l\right] \\
&\quad + \sum (\partial^2\mathbf{r}/\partial q_k\partial t)\ddot{q}_k + 2\sum (\partial^2\mathbf{r}/\partial q_k\partial t)\ddot{q}_k + \textit{no other } \ddot{q},\ \dddot{q}\ \textit{terms};
\end{aligned} \tag{6.4.1a}$$

that is,

$$\begin{aligned}
\dddot{\boldsymbol{r}} &= \sum (\partial\mathbf{r}/\partial q_k)\dddot{q}_k \\
&\quad + 3\sum \left(\sum (\partial^2\mathbf{r}/\partial q_k\partial q_l)\ddot{q}_k\dot{q}_l + (\partial^2\mathbf{r}/\partial q_k\partial t)\ddot{q}_k\right) \\
&\quad + \textit{no other } \ddot{q},\ \dddot{q}\ \textit{terms}
\end{aligned} \tag{6.4.1b}$$

from which we easily deduce

$$\partial \dddot{\boldsymbol{r}}/\partial \dddot{q}_k = \partial \ddot{\boldsymbol{r}}/\partial \ddot{q}_k = \partial \boldsymbol{r}/\partial q_k = \boldsymbol{e}_k, \tag{6.4.2}$$

which is an extension of (6.3.8).

Further, and in complete analogy with (6.3.4, 5), we have

$$\begin{aligned}\delta \boldsymbol{a} \equiv \delta \ddot{\boldsymbol{r}} = \cdots &= \sum \boldsymbol{e}_k\, \delta(\ddot{q}_k) + \textit{no other } \delta\ddot{q} \textit{ terms}\\ &\equiv \delta'' \boldsymbol{a} + \textit{no other } \delta\ddot{q} \textit{ terms},\end{aligned} \tag{6.4.3}$$

where

$\delta''(\ldots) \equiv \sum [\partial(\ldots)/\partial \ddot{q}_k]\delta(\ddot{q}_k)$:

Gaussian variation of $(\ldots)$ [i.e., $\delta(\ldots)$ with $\delta t = 0$, $\delta q = 0$ *and* $\delta(\dot{q}_k) = 0$]. (6.4.4)

Next, $(\ldots)^{\cdot}$-differentiating $\dot{T}$, we find

$$\begin{aligned}\ddot{T} &= S\, dm\, \ddot{\boldsymbol{r}} \cdot \ddot{\boldsymbol{r}} + S\, dm\, \dot{\boldsymbol{r}} \cdot \dddot{\boldsymbol{r}}\\ &\left[= S\, dm\, \boldsymbol{a} \cdot \boldsymbol{a} + S\, dm\, \boldsymbol{v} \cdot \boldsymbol{j} \;=\; 2\, S + S\, dm\, \boldsymbol{v} \cdot \boldsymbol{j} \qquad (S:\ \textit{Appellian})\right],\end{aligned} \tag{6.4.5}$$

from which we readily obtain

$$\partial \ddot{T}/\partial \ddot{q}_k = 2 S\, dm\, \ddot{\boldsymbol{r}} \cdot (\partial \ddot{\boldsymbol{r}}/\partial \ddot{q}_k) + S\, dm\, \dot{\boldsymbol{r}} \cdot (\partial \dddot{\boldsymbol{r}}/\partial \ddot{q}_k),$$

or, due to (6.4.2) and

$$\begin{aligned}\partial \dddot{\boldsymbol{r}}/\partial \ddot{q}_k &= 3 \sum \left(\sum (\partial^2 \boldsymbol{r}/\partial q_k \partial q_l)\dot{q}_l + \partial^2 \boldsymbol{r}/\partial q_k \partial t \right)\\ &= 3(\partial \dot{\boldsymbol{r}}/\partial q_k) = 3(\partial \boldsymbol{v}/\partial q_k),\end{aligned} \tag{6.4.6}$$

equivalently,

$$\begin{aligned}\partial \ddot{T}/\partial \ddot{q}_k &= 2 S\, dm\, \boldsymbol{a} \cdot \boldsymbol{e}_k + 3 S\, dm\, \boldsymbol{v} \cdot (\partial \boldsymbol{v}/\partial q_k)\\ &= 2E_k(T) + 3(\partial T/\partial q_k);\end{aligned} \tag{6.4.7}$$

and rearranging this we finally get the kinematico-inertial identity:

$$E_k(T) = (1/2)\left[\partial \ddot{T}/\partial \ddot{q}_k - 3(\partial T/\partial q_k)\right] \equiv C_k^{(2)}(T), \tag{6.4.8}$$

where

$C_k^{(2)}(\ldots) \equiv (1/2)\{\partial(\ldots)^{\cdot\cdot}/\partial \ddot{q}_k - 3[\partial(\ldots)/\partial q_k]\}$:

Tsenov (or Tzénoff, or Tzenov, or Cenov) operator of the *second kind,* in holonomic variables. (6.4.9)

With the help of the above, Gauss principle reads

$$\sum \left[C_k^{(2)}(T) - Q_k\right]\delta \ddot{q}_k = 0; \tag{6.4.10}$$

and, as earlier, if the δq's and hence also the $\delta\ddot{q}$'s are independent, the above leads to *Tsenov's equations of the second kind*, in holonomic variables:

$$C_k^{(2)}(T) = Q_k; \tag{6.4.11}$$

[developed by the Bulgarian mechanician I. Tsenov (1885–1967), originally (in a slightly different form) in 1924, and more systematically in the 1950s and later (1953, 1962)] while, if the $\delta\ddot{q}$ are constrained by the $m(< n)$ Pfaffian constraints

$$\sum a_{Dk}\,\delta q_k = 0, \tag{6.4.12a}$$

then, we first bring them to the Gaussian form:

$$\sum a_{Dk}\,\delta\ddot{q}_k = 0 \tag{6.4.12b}$$

[by $(\ldots)^{\cdot\cdot}$-differentiation and then application of (6.4.4)] and subsequently adjoin (6.4.12b) to (6.4.10) via Lagrangean multipliers, thus obtaining *the Tsenov form of the Routh–Voss equations of motion*:

$$C_k{}^{(2)}(T) = Q_k + \sum \lambda_D a_{Dk}. \tag{6.4.12c}$$

Proceeding similarly to the next step — that is, to $\dddot{T}$, $\overset{(4)}{\boldsymbol{r}} \equiv (\dddot{\boldsymbol{r}})^{\cdot}$, and since, in this case,

$$\partial\dddot{T}/\partial\dddot{q}_k = \cdots = 3E_k(T) + 4(\partial T/\partial q_k), \tag{6.4.13a}$$

we easily obtain, for independent δq's and hence also $\delta\dddot{q}$'s, *Tsenov's equations of the third kind*, in *holonomic* variables:

$$E_k(T) \equiv C_k{}^{(3)}(T) \equiv (1/3)\left[\partial\dddot{T}/\partial\dddot{q}_k - 4(\partial T/\partial q_k)\right] = Q_k. \tag{6.4.13b}$$

Proceeding inductively, from the above, we can easily show that the earlier *Mangeron–Deleanu* principle (6.2.7, 7a), where, in analogy with (6.4.4),

$$\delta\overset{(s)}{\boldsymbol{r}} = \sum\left[\partial\overset{(s)}{\boldsymbol{r}}/\partial\overset{(s)}{q}_k\right]\delta\overset{(s)}{q}_k = \sum \boldsymbol{e}_k\,\delta\overset{(s)}{q}_k, \tag{6.4.14a}$$

becomes, in holonomic system variables,

$$\sum\left[C_k{}^{(s)}(T) - Q_k\right]\delta\overset{(s)}{q}_k = 0, \tag{6.4.14b}$$

where

$$\begin{aligned} C_k{}^{(s)}(T) &\equiv E_k(T) \equiv \textstyle\int dm\,\boldsymbol{a}\cdot\boldsymbol{e}_k \equiv \int dm\,\boldsymbol{a}\cdot\left(\partial\overset{(s)}{\boldsymbol{r}}/\partial\overset{(s)}{q}_k\right) \\ &\equiv (1/s)\left[\partial\overset{(s)}{T}/\partial\overset{(s)}{q}_k - (s+1)\,(\partial T/\partial q_k)\right], \end{aligned} \tag{6.4.14c}$$

is the general *Mangeron–Deleanu operator (in holonomic variables)* applied to T, and, in analogy with the Nielsen identity (6.3.14),

$$d/dt(\partial T/\partial\dot{q}_k) = (1/s)\left[\partial\overset{(s)}{T}/\partial\overset{(s)}{q}_k - \partial T/\partial q_k\right]. \tag{6.4.14d}$$

Again, for unconstrained δq's, eq. (6.4.14b) yields the *Tsenov-type equations of Mangeron–Deleanu (1962) and Dolaptschiew (1966)*:

$$\begin{gathered} (1/s)\left[\partial\overset{(s)}{T}/\partial\overset{(s)}{q} - (s+1)\,(\partial T/\partial q_k)\right] = Q_k \\ (k = 1, \ldots, n;\ s = 1, 2, 3, \ldots); \end{gathered} \tag{6.4.14e}$$

and analogously if the δq's are constrained.

In sum: in all equations of motion in holonomic variables, and whether the δq's are constrained or not, we can replace $E_k(T) \equiv (\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k$ (*Lagrange*) $\equiv \partial S/\partial \ddot{q}_k$ (*Appell*) with any one of its equals:

$$N_k(T) \equiv \partial \dot{T}/\partial \dot{q}_k - 2\,(\partial T/\partial q_k) \qquad (\textit{Nielsen}), \tag{6.4.15a}$$

or

$$\begin{aligned} C_k{}^{(2)}(T) &\equiv (1/2)\,\big[\partial \ddot{T}/\partial \ddot{q}_k - 3\,(\partial T/\partial q_k)\big], \\ C_k{}^{(3)}(T) &\equiv (1/3)\,\big[\partial \dddot{T}/\partial \dddot{q}_k - 4\,(\partial T/\partial q_k)\big] \qquad (\textit{Tsenov}), \end{aligned} \tag{6.4.15b}$$

or

$$C_k{}^{(s)}(T) \equiv (1/s)\left[\partial \overset{(s)}{T}/\partial \overset{(s)}{q_k} - (s+1)\,(\partial T/\partial q_k)\right]$$
$$(\textit{Mangeron–Deleanu–Dolaptschiew}); \tag{6.4.15c}$$

[i.e., $C_k{}^{(1)}(T) = N_k(T)$].

Summary

(i) Analytical Results

Since all the earlier variational principles are equivalent, we can utilize *any of them with any of the above kinematico-inertial expressions*; although, historically, $E_k(T)$ and $N_k(T)$ have been associated with Lagrange's principle, and $\partial S/\partial \ddot{q}_k$ with Gauss' principle. In practice, however, which variational principle and operator will be used in a particular problem depends on the given form of the constraints; some are more natural than others. Thus:

(a) If the constraints have the form $f_D(t,q) = 0$ $[D = 1, \ldots, m(< n)]$, then, since

$$\delta f_D = \sum (\partial f_D/\partial q_k)\,\delta q_k = 0, \tag{6.4.16a}$$

Lagrange's principle, with $E_k(T)$ or $N_k(T)$, is preferred.

(b) If the constraints have the form $f_D(t,q,\dot{q}) = 0$, then, since

$$\delta' f_D = \sum (\partial f_D/\partial \dot{q}_k)\,\delta \dot{q}_k = 0, \tag{6.4.16b}$$

Jourdain's principle, with $E_k(T)$ or $N_k(T)$, is recommended. The formal (i.e., mathematical) $\delta(\ldots)$-variation of f_D,

$$\delta f_D = \sum (\partial f_D/\partial q_k)\,\delta q_k + \sum (\partial f_D/\partial \dot{q}_k)\,\delta(\dot{q}_k) = 0, \tag{6.4.16c}$$

(as also explained in §5.2 ff.) *cannot* be combined with Lagrange's principle,

$$\sum [E_k(T) - Q_k]\,\delta q_k = 0,$$

to produce the correct equations of motion; that is,

$$E_k(T) = Q_k + \sum \lambda_D(\partial f_D/\partial \dot{q}_k). \tag{6.4.16d}$$

Since $\delta'' f_D = \sum (\partial f_D/\partial \ddot{q}_k)\,\delta\ddot{q}_k = 0$, Gauss' principle, say with $E_k(T)$:

$$\sum [E_k(T) - Q_k]\delta\ddot{q}_k = 0, \tag{6.4.16e}$$

cannot be utilized either. But it *can* be applied to $df_D/dt = 0$; indeed, since

$$df_D/dt = \partial f_D/\partial t + \sum (\partial f_D/\partial q_k)\dot{q}_k + \sum (\partial f_D/\partial \dot{q}_k)\ddot{q}_k \\ [\equiv g_D(t, q, \dot{q}, \ddot{q})] = 0,$$

we have

$$\delta''(df_D/dt) = \sum (\partial \dot{f}_D/\partial \ddot{q}_k)\,\delta\ddot{q}_k = \sum (\partial f_D/\partial \dot{q}_k)\,\delta\ddot{q}_k \\ \left[\equiv \delta'' g_D = \sum (\partial g_D/\partial \ddot{q}_k)\,\delta\ddot{q}_k\right] = 0, \tag{6.4.16f}$$

and this combined with Gauss' principle yields the correct equations; that is, (6.4.16d).

(c) Similarly, we can show that for constraints of the form $f_D(t, q, \dot{q}, \ddot{q}) = 0$, to *insure compatibility among the principles of Lagrange, Jourdain and Gauss*, we must set

$$\delta f_D = \sum (\partial f_D/\partial \ddot{q}_k)\,\delta q_k = 0, \tag{6.4.16g}$$

$$\delta' f_D = \sum (\partial f_D/\partial \ddot{q}_k)\,\delta\dot{q}_k = 0, \tag{6.4.16h}$$

$$\delta'' f_D = \sum (\partial f_D/\partial \ddot{q}_k)\,\delta\ddot{q}_k = 0; \tag{6.4.16i}$$

in which case, the correct equations of motion are

$$E_k(T) = Q_k + \sum \lambda_D(\partial f_D/\partial \ddot{q}_k). \tag{6.4.16j}$$

(ii) Geometrical Interpretation

If we think of the constraints $f_D(t, q, \dot{q}) = 0$ as hypersurfaces in velocity space, with t and the q's as parameters (since the velocities can change instantaneously, but the configuration and time cannot), (6.4.16b) states that the virtual velocity change $\delta\dot{q}$ lies in the local tangent plane, just like the δq's lie in the local tangent plane of the surface $f_D(t, q) = 0$ (holonomic constraints) in configuration space. Analogously for $f_D(t, q, \dot{q}, \ddot{q}) = 0$, (6.4.16i) states the conditions. The above show that *JP is a natural for velocity constraints, while GP is a natural for acceleration constraints.*

These results are summarized in tables 6.2 and 6.3.

Table 6.2 Virtual Displacements Needed to Produce the Correct Equations of Motion

Constraints	Lagrange	Jourdain	Gauss
$f(t, q) = 0$: $\partial f/\partial q$	$\delta f = (\partial f/\partial q)\delta q$	$\delta' f = 0$ $\delta' \dot{f} = (\partial f/\partial q)\delta\dot{q}$	$\delta'' f = 0$, $\delta'' \dot{f} = 0$ $\delta'' \ddot{f} = (\partial f/\partial q)\delta\ddot{q}$
$f(t, q, \dot{q}) = 0$: $\partial f/\partial \dot{q}$	—	$\delta' f = (\partial f/\partial \dot{q})\delta\dot{q}$	$\delta'' f = 0$ $\delta'' \dot{f} = (\partial f/\partial \dot{q})\delta\ddot{q}$
$f(t, q, \dot{q}, \ddot{q}) = 0$: $\partial f/\partial \ddot{q}$	—	—	$\delta'' f = (\partial f/\partial \ddot{q})\delta\ddot{q}$

Table 6.3 Correct Equations of Motion

[Notation: $M_k \equiv E_k(T) - Q_k \equiv N_k(T) - Q_k \equiv \partial S/\partial \ddot{q}_k - Q_k$;
Mechanical principle: $\sum M_k\, \delta x_k = 0, \qquad \delta x_k = \delta q_k,\ \delta\dot{q}_k,\ \delta\ddot{q}_k, \ldots$]

Constraints	Virtual Displacements	Equations of Motion
$f_D(t, q) = 0$	$\delta f_D = \sum (\partial f_D/\partial q_k)\delta q_k$	$M_k = \sum \lambda_D(\partial f_D/\partial q_k)$
$f_D(t, q, \dot{q}) = 0$	$\delta' f_D = \sum (\partial f_D/\partial \dot{q}_k)\delta\dot{q}_k$	$M_k = \sum \lambda_D(\partial f_D/\partial \dot{q}_k)$
$f_D(t, q, \dot{q}, \ddot{q}) = 0$	$\delta'' f_D = \sum (\partial f_D/\partial \ddot{q}_k)\delta\ddot{q}_k$	$M_k = \sum \lambda_D(\partial f_D/\partial \ddot{q}_k)$
And analogously for higher-order constraints.		

For the *quasivariable* versions of the preceding, see problem 6.5.6.

Example 6.4.1 Let us derive the impressed force-free equations of motion of a sled (or narrow boat, or skate, or knife, or stiff razor blade, etc.; recalling ex. 2.13.2, ex. 3.18.1, and their notations; also exs. 7.3.2 and 7.3.3) of mass m, *whose mass center G coincides with its contact point C*, on a smooth horizontal plane P, via the various DVP.

(i) *Via Jourdain's principle*. With Lagrangean coordinates $q_{1,2,3} = x, y, \phi$, and since here $V = 0$, $Q_{k,np} = 0$, so that

$$2L = 2T = m[(\dot{x})^2 + (\dot{y})^2] + I(\dot{\phi})^2, \tag{a}$$

and the constraint is (with $\boldsymbol{n}$: unit vector perpendicular to sled, on P)

$$\boldsymbol{v}\cdot\boldsymbol{n} = (\sin\phi)\dot{x} + (-\cos\phi)\dot{y} = 0 \ \Rightarrow\ (\sin\phi)\,\delta x + (-\cos\phi)\,\delta y = 0; \tag{b}$$

that is, $n = 3$, $m = 1$, JP yields the variational equation:

$$\sum E_k(L)\,\delta\dot{q}_k = 0: \qquad (m\ddot{x})\,\delta\dot{x} + (m\ddot{y})\,\delta\dot{y} + (I\ddot{\phi})\,\delta\dot{\phi} = 0, \tag{c}$$

under the constraint (b), *but brought to Jourdain form*; that is,

$$f(t, q, \dot{q}) = 0 \ \Rightarrow\ \delta' f = (\partial f/\partial\dot{q})\,\delta\dot{q}, \tag{d}$$

$$\begin{aligned}
&\delta'[(\sin\phi)\dot{x} + (-\cos\phi)\dot{y}] \\
&= \delta[(\sin\phi)\dot{x} + (-\cos\phi)\dot{y}]\Big|_{\delta x,\,\delta y,\,\delta\phi = 0} \\
&= [(\sin\phi)\,\delta\dot{x} + (-\cos\phi)\,\delta\dot{y} \\
&\quad + (\dot{x}\cos\phi)\,\delta\phi + (\dot{y}\sin\phi)\,\delta\phi]\Big|_{\delta x,\,\delta y,\,\delta\phi = 0} = 0,
\end{aligned} \tag{e}$$

or, carrying out the variations and enforcing the Jourdainian constraints $\delta q_k = 0$,

$$(\sin\phi)\,\delta\dot{x} + (-\cos\phi)\,\delta\dot{y} = 0. \tag{f}$$

Eliminating, say, $\delta\dot{y}$ between (c) and (f), we obtain the *unconstrained* variational equation

$$(m\,\ddot{x}\cos\phi + m\,\ddot{y}\sin\phi)\,\delta\dot{x} + (I\ddot{\phi}\cos\phi)\,\delta\dot{\phi} = 0. \tag{g}$$

from which, since $\delta\dot{x}$ and $\delta\dot{\phi}$ are now independent, we get the two reactionless equations of motion

$$\ddot{x}\cos\phi + \ddot{y}\sin\phi = 0, \qquad \ddot{\phi} = 0. \tag{h, i}$$

The first of them expresses the absence of force in the tangential direction, while the second expresses the absence of moment, about $C = G$, in the direction perpendicular to P.

(ii) *Via Gauss' principle*. Here, the variational equation is

$$\sum E_k(L)\,\delta(\ddot{q}_k) = 0: \qquad (m\,\ddot{x})\,\delta\ddot{x} + (m\,\ddot{y})\,\delta\ddot{y} + (I\ddot{\phi})\,\delta\ddot{\phi} = 0, \tag{j}$$

under the constraint (b), *but brought to Gaussian form*; that is,

$$f(t, q, \dot{q}) = 0 \;\Rightarrow\; \delta''(df/dt) = (\partial f/\partial\dot{q})\,\delta\ddot{q}, \tag{k}$$

$$\begin{aligned}\delta''\Big\{d/dt[(\sin\phi)\dot{x} + (-\cos\phi)\dot{y}]\Big\} &\equiv \delta[(\sin\phi)\ddot{x} + (-\cos\phi)\ddot{y} \\ &\quad + (\dot{x}\cos\phi)\dot{\phi} + (\dot{y}\sin\phi)\dot{\phi}]\Big|_{\delta x,\,\delta y,\,\delta\phi=0;\;\delta\dot{x},\,\delta\dot{y},\,\delta\dot{\phi}=0} = 0,\end{aligned} \tag{l}$$

or, carrying out the variations

$$\begin{aligned}\big\{(\sin\phi)\,\delta\ddot{x} &+ (-\cos\phi)\,\delta\ddot{y} \\ &+ (\delta\dot{x}\cos\phi - \dot{x}\sin\phi\,\delta\phi + \delta\dot{y}\sin\phi + \dot{y}\cos\phi\;\delta\phi)\dot{\phi} \\ &+ (\dot{x}\cos\phi + \dot{y}\sin\phi)\,\delta\dot{\phi}\big\}\Big|_{\delta x,\,\delta y,\,\delta\phi=0;\;\delta\dot{x},\,\delta\dot{y},\,\delta\dot{\phi}=0} = 0,\end{aligned} \tag{m}$$

and then enforcing the Gaussian constraints $\delta q_k = 0$, $\delta\dot{q}_k = 0$,

$$(\sin\phi)\,\delta\ddot{x} + (-\cos\phi)\,\delta\ddot{y} = 0. \tag{n}$$

Similarly, eliminating $\delta\ddot{y}$ between (j) and (n), we find again eqs. (h, i).

For a Gaussian treatment of the related problem of *Prytz's planimeter*, see Brill (1909, pp. 30–33).

Problem 6.4.1 (i) Show that (where, as usual, $k, l = 1, 2, \ldots, n$; and $s = 1, 2, \ldots$)

$$\begin{aligned} d^s\mathbf{r}/dt^s \equiv \overset{(s)}{\mathbf{r}} &= \sum(\partial\mathbf{r}/\partial q_k)\overset{(s)}{q}_k \\ &\quad + s\Big(\sum\sum(\partial^2\mathbf{r}/\partial q_k\,\partial q_l)\overset{(s-1)}{q_k}\,\dot{q}_l + \sum(\partial^2\mathbf{r}/\partial q_k\,\partial t)\overset{(s-1)}{q_k}\Big) \\ &\quad + \textit{no other}\ \overset{(s-1)}{q},\ \overset{(s)}{q}\ \textit{terms}; \\ &= \sum(\partial\mathbf{r}/\partial q_k)\,\overset{(s)}{q}_k + \textit{no other}\ \overset{(s)}{q}\ \textit{terms};\end{aligned} \tag{a}$$

and, therefore,

(ii) $$\delta\overset{(s)}{\mathbf{r}} = \sum\Big[\partial\overset{(s)}{\mathbf{r}}/\partial\overset{(s)}{q}_k\Big]\delta\overset{(s)}{q}_k = \sum \mathbf{e}_k\,\delta\overset{(s)}{q}_k \quad \text{(Mangeron variation)}; \tag{b}$$

(iii) $$\mathbf{e}_k = \partial\mathbf{r}/\partial q_k = \cdots = \partial\overset{(s)}{\mathbf{r}}/\partial\overset{(s)}{q}_k = \partial\overset{(s)}{\mathbf{v}}/\partial\overset{(s+1)}{q_k} = \partial\overset{(s)}{\mathbf{a}}/\partial\overset{(s+2)}{q_k}; \tag{c}$$

(iv) $$\partial \overset{(s)}{\boldsymbol{r}} / \partial \overset{(s-1)}{q_k} = s\Big(\sum (\partial^2 \boldsymbol{r}/\partial q_k\, \partial q_l)\dot{q}_l + \partial^2 \boldsymbol{r}/\partial q_k\, \partial t\Big)$$
$$= s(\partial \dot{\boldsymbol{r}}/\partial q_k) = s(\partial \boldsymbol{v}/\partial q_k) \tag{d}$$
$$\Rightarrow\ \partial \overset{(s)}{\boldsymbol{v}} / \partial \overset{(s)}{q_k} = (s+1)(\partial \boldsymbol{v}/\partial q_k); \tag{e}$$

(v) $$\overset{(s)}{\boldsymbol{v}} = (s+1) \sum (\partial \boldsymbol{v}/\partial q_k)\, \overset{(s)}{q_k} + \textit{no other } \overset{(s)}{q} \textit{ terms.} \tag{f}$$

Problem 6.4.2 (i) Starting with $2T \equiv S\, dm\, \boldsymbol{v} \cdot \boldsymbol{v}$, show that

$$\overset{(s)}{T} = S\, dm\, \boldsymbol{v} \cdot \overset{(s+1)}{\boldsymbol{r}} + s S\, dm\, \boldsymbol{a} \cdot \overset{(s)}{\boldsymbol{r}} + \textit{no other } \overset{(s)}{\boldsymbol{r}},\ \overset{(s+1)}{\boldsymbol{r}} \textit{ terms;}$$
$$= S\, dm\, \overset{(1)}{\boldsymbol{r}} \cdot \overset{(s+1)}{\boldsymbol{r}} + s S\, dm\, \overset{(2)}{\boldsymbol{r}} \cdot \overset{(s)}{\boldsymbol{r}} + \textit{no other } \overset{(s)}{\boldsymbol{r}},\ \overset{(s+1)}{\boldsymbol{r}} \textit{ terms;} \tag{a}$$

and from this deduce the following kinematico-inertial identities:

(a) $$\partial T/\partial q_k = S\, dm\, \dot{\boldsymbol{r}} \cdot (\partial \dot{\boldsymbol{r}}/\partial q_k) = (1/s) S\, dm\, \dot{\boldsymbol{r}} \cdot \left(\partial \overset{(s)}{\boldsymbol{r}} / \partial \overset{(s-1)}{q_k}\right)$$
$$\equiv (1/s) S\, dm\, \boldsymbol{v} \cdot \left(\partial \overset{(s)}{\boldsymbol{r}} / \partial \overset{(s-1)}{q_k}\right), \tag{b}$$

and, generally,

(b) $$\partial \overset{(s)}{T} / \partial \overset{(s)}{q_k} = S\, dm\, \dot{\boldsymbol{r}} \cdot \left(\partial \overset{(s+1)}{\boldsymbol{r}} / \partial \overset{(s)}{q_k}\right) + s S\, dm\, \ddot{\boldsymbol{r}} \cdot \left(\partial \overset{(s)}{\boldsymbol{r}} / \partial \overset{(s)}{q_k}\right)$$
$$= (s+1) S\, dm\, \boldsymbol{v} \cdot (\partial \boldsymbol{v}/\partial q_k) + s S\, dm\, \boldsymbol{a} \cdot \boldsymbol{e}_k$$
$$= (s+1)(\partial T/\partial q_k) + s\, E_k(T), \tag{c}$$

from which, rearranging, we obtain the earlier *Mangeron–Deleanu* identity:

$$E_k(T) = (1/s)\left[\partial \overset{(s)}{T} / \partial \overset{(s)}{q_k} - (s+1)(\partial T/\partial q_k)\right]. \tag{d}$$

($s = 1$: Nielsen eqs., $s = 2$: Tsenov eqs., etc.)

(ii) Prove the *Mangeron–Deleanu* recursive identity:

$$(1/s)\left[\partial \overset{(s)}{T} / \partial \overset{(s)}{q_k}\right] - (1/r)\left[\partial \overset{(r)}{T} / \partial \overset{(r)}{q_k}\right] + \big[(s-r)/(s\,r)\big](\partial T/\partial q_k) = 0,$$
$$(s, r = 1, 2, \ldots;\ k = 1, 2, \ldots; n), \tag{e}$$

and with its help, and the rest, deduce the following identities:

(a) $$\big[1/(s-r)\big]\left[(r+1)\left(\partial \overset{(s)}{T} / \partial \overset{(s)}{q_k}\right) - (s+1)\left(\partial \overset{(r)}{T} / \partial \overset{(r)}{q_k}\right)\right] = E_k(T),$$
$$\big[s, r = 1, 2, \ldots, \text{BUT (this form) } s \neq r;\ k = 1, 2, \ldots, n\big], \tag{f}$$

(b) $$\partial \overset{(s)}{T} / \partial \overset{(s)}{q_k} - \partial \overset{(s-1)}{T} / \partial \overset{(s-1)}{q_k} = \partial T/\partial q_k + E_k(T), \tag{g}$$

$$\partial \overset{(s)}{T}/\partial \overset{(s+1)}{q_k} = \partial \overset{(s-1)}{T}/\partial \overset{(s)}{q_k} = \cdots = \partial T/\partial \dot{q}_k \ (= p_k); \tag{h}$$

(c)
$$\overset{(s)}{\delta I} \equiv \mathsf{S}\, dm\, \boldsymbol{a} \cdot \delta \overset{(s)}{\boldsymbol{r}}$$
$$= \sum \left[\partial \overset{(s)}{T}/\partial \overset{(s)}{q_k} - \partial \overset{(s-1)}{T}/\partial \overset{(s-1)}{q_k} - \partial T/\partial q_k\right] \delta \overset{(s)}{q_k}, \tag{i}$$

sometimes referred to as *the Mićević Dušan–Rusov Lazar* form of Lagrange's identity ($\Rightarrow$ principle, 1984); and for unconstrained $\delta \overset{(s)}{q_k}$'s easily resulting in the equations of motion:

$$\partial \overset{(s)}{T}/\partial \overset{(s)}{q_k} - \partial \overset{(s-1)}{T}/\partial \overset{(s-1)}{q_k} - \partial T/\partial q_k = Q_k. \tag{j}$$

For further related results, see, for example, Shen and Mei (1987).

Example 6.4.2 Let us show, by direct differentiations, that for any sufficiently differentiable function $f(t, q, \dot{q})$: $E_k(f) = N_k(f)$, or, in extenso,

$$(\partial f/\partial \dot{q}_k)^{\cdot} - \partial f/\partial q_k = \partial \dot{f}/\partial \dot{q}_k - 2(\partial f/\partial q_k). \tag{a}$$

We have, successively,

$$\begin{aligned}
N_k(f) &\equiv \partial \dot{f}/\partial \dot{q}_k - 2(\partial f/\partial q_k)\\
&= \partial/\partial \dot{q}_k \left[\partial f/\partial t + \sum (\partial f/\partial q_l)\dot{q}_l + \sum (\partial f/\partial \dot{q}_l)\ddot{q}_l\right] - 2(\partial f/\partial q_k)\\
&= \partial/\partial t(\partial f/\partial \dot{q}_k) + \sum \left[\partial/\partial q_l(\partial f/\partial \dot{q}_k)\right]\dot{q}_l + \sum (\partial f/\partial q_l)\,\delta_{lk}\\
&\qquad + \sum \left[\partial/\partial \dot{q}_l(\partial f/\partial \dot{q}_k)\right]\ddot{q}_l - 2(\partial f/\partial q_k).
\end{aligned}$$

But (i) the *first, second, and fourth* terms combine to $(\partial f/\partial \dot{q}_k)^{\cdot}$; while (ii) the *third* reduces to $\partial f/\partial q_k$, and combines with the *last* term to $-\partial f/\partial q_k$; that is, finally,

$$N_k(f) = (\partial f/\partial \dot{q}_k)^{\cdot} - \partial f/\partial q_k \equiv E_k(f), \quad \text{Q.E.D.} \tag{b}$$

Example 6.4.3 Let us extend the result of the preceding example to *nonholonomic* variables; namely, let us show that

$$E_k{}^*(f^*) \equiv (\partial f^*/\partial \omega_k)^{\cdot} - \partial f^*/\partial \theta_k = \partial \dot{f}^*/\partial \omega_k - 2(\partial f^*/\partial \theta_k) \equiv N_k{}^*(f^*), \tag{a}$$

where (recalling the notations of chaps. 2–5)

$$\partial \ldots/\partial \theta_k \equiv \sum (\partial \ldots/\partial q_l)(\partial \dot{q}_l/\partial \omega_k) \Leftrightarrow \partial \ldots/\partial q_l = \sum (\partial \ldots/\partial \theta_k)(\partial \omega_k/\partial \dot{q}_l), \tag{b}$$

and

$$f = f(t, q, \dot{q}) = f[t, q, \dot{q}(t, q, \omega)] \equiv f^*(t, q, \omega) \equiv f^*. \tag{c}$$

Since $\dot{f}^* \equiv df^*/dt$ is a function of t, q, ω; $\dot{q}(t, q, \omega)$, $\ddot{q}(t, q, \omega, \dot{\omega})$, we find, successively,

$$
\begin{aligned}
N_k{}^*(f^*) &\equiv \partial\dot{f}^*/\partial\omega_k - 2(\partial f^*/\partial\theta_k) \\
&= \partial/\partial\omega_k\Big[\partial f^*/\partial t + \sum (\partial f^*/\partial q_l)\dot{q}_l + \sum (\partial f^*/\partial\omega_l)\dot{\omega}_l\Big] \\
&\qquad\qquad - 2\sum (\partial f^*/\partial q_l)(\partial\dot{q}_l/\partial\omega_k) \\
&= \partial/\partial t(\partial f^*/\partial\omega_k) + \sum \big[\partial/\partial q_l(\partial f^*/\partial\omega_k)\big]\dot{q}_l + \sum (\partial f^*/\partial q_l)(\partial\dot{q}_l/\partial\omega_k) \\
&\qquad\qquad + \sum \big[\partial/\partial\omega_l(\partial f^*/\partial\omega_k)\big]\dot{\omega}_l - 2\sum (\partial f^*/\partial q_l)(\partial\dot{q}_l/\partial\omega_k)
\end{aligned}
$$

[the *first, second, and fourth* terms combine to $(\partial f^*/\partial\omega_k)^{\cdot}$;

while, recalling (b), the *third* and *last* add up to $-\partial f^*/\partial\theta_k$]

$$= (\partial f^*/\partial\omega_k)^{\cdot} - \partial f^*/\partial\theta_k \equiv E_k{}^*(f^*), \quad \text{Q.E.D.} \tag{d}$$

For an alternative proof, see Mei (1983, pp. 630–631).

Example 6.4.4 Using the kinematico-inertial identities of the preceding examples, let us find the Nielsen forms of the two general (say, kinetic) nonlinear nonholonomic equations of Johnsen–Hamel (§5.3):

$$(\partial T^*/\partial\omega_I)^{\cdot} - \partial T^*/\partial\theta_I - \sum \Big[(\partial\dot{q}_k/\partial\dot{\omega}_I)^{\cdot} - \partial\dot{q}_k/\partial\theta_I\Big](\partial T/\partial\dot{q}_k)^* = \Theta_I, \tag{a}$$

where

$$(\partial T/\partial\dot{q}_k)^* = \sum (\partial T^*/\partial\omega_l)(\partial\omega_l/\partial\dot{q}_k), \qquad \text{i.e.,} \quad p_k = p_k(t, q, \dot{q}) = p_k{}^*(t, q, \omega), \tag{b}$$

or, compactly,

$$E_I{}^*(T^*) - \sum E_I{}^*(\dot{q}_k)(\partial T/\partial\dot{q}_k)^* = \Theta_I; \tag{c}$$

and

$$(\partial T^*/\partial\omega_I)^{\cdot} - \partial T^*/\partial\theta_I + \sum\sum \big[(\partial\omega_l/\partial\dot{q}_r)^{\cdot} - \partial\omega_l/\partial q_r\big](\partial\dot{q}_r/\partial\omega_I)(\partial T^*/\partial\omega_l) = \Theta_I, \tag{d}$$

or, compactly,

$$E_I(T^*) + \sum\sum E_r(\omega_l)(\partial\dot{q}_r/\partial\omega_I)(\partial T^*/\partial\omega_l) = \Theta_I. \tag{e}$$

(i) Substituting $N_I{}^*(T^*) = E_I{}^*(T^*)$ and $N_I{}^*(\dot{q}_k) = E_I{}^*(\dot{q}_k)$ in (a, c), we readily obtain their Nielsen forms:

$$\partial\dot{T}^*/\partial\omega_I - 2(\partial T^*/\partial\theta_I) - \sum \Big[\partial\ddot{q}_k/\partial\omega_I - 2(\partial\dot{q}_k/\partial\theta_I)\Big](\partial T/\partial\dot{q}_k)^* = \Theta_I, \tag{f}$$

or, compactly,

$$N_I{}^*(T^*) - \sum N_I{}^*(\dot{q}_k)(\partial T/\partial\dot{q}_k)^* = \Theta_I. \tag{g}$$

(ii) Substituting $N_I{}^*(T^*) = E_I{}^*(T^*)$ and $N_r(\omega_l) = E_r(\omega_l)$ in (d, e), we readily obtain their Nielsen forms:

$$\partial \dot{T}^*/\partial \omega_I - 2(\partial T^*/\partial \theta_I) + \sum\sum \big[(\partial \dot{\omega}_l/\partial \dot{q}_r) - 2(\partial \omega_l/\partial q_r)\big](\partial \dot{q}_r/\partial \omega_I)(\partial T^*/\partial \omega_l) = \Theta_I, \tag{h}$$

or, compactly,

$$N_I{}^*(T^*) + \sum\sum N_r(\omega_l)(\partial \dot{q}_r/\partial \omega_I)(\partial T^*/\partial \omega_l) = \Theta_I. \tag{i}$$

And similarly for the kinetostatic equations.

Here, too, as in chapter 5, we remark that the importance of these equations lies not so much in their ability to solve concrete nonholonomic problems more easily, but in that they help us to understand better the formal kinematico-inertial structure of analytical mechanics; also, they might prove useful in handling higher-order constraints.

Problem 6.4.3 Show that in the Pfaffian case

$$\dot{q}_k = \sum A_{kl}(t, q)\,\omega_l + A_k(t, q) = \sum A_{kI}(t, q)\,\omega_I + A_k(t, q), \tag{a}$$

eqs. (f) of the preceding example reduce to the *Nielsen form of the general nonlinear Voronets equations*:

$$\begin{aligned}\partial \dot{T}^*/\partial \omega_I &- 2(\partial T^*/\partial \theta_I)\\ &+ \sum (\partial T/\partial \dot{q}_k)^*\Big(\sum (\partial A_{kI'}/\partial \theta_I - \partial A_{kI}/\partial \theta_{I'})\,\omega_{I'} + \partial A_k/\partial \theta_I\\ &\qquad - \sum (\partial A_{kI}/\partial q_l)A_l - \partial A_{kI}/\partial t\Big) = \Theta_I.\end{aligned} \tag{b}$$

Equivalent forms can be obtained from (h) of the preceding example, if, instead of (a), we use

$$\omega_l = \sum a_{lk}(t, q)\,\dot{q}_k + a_l(t, q). \tag{c}$$

Problem 6.4.4 (Mei, 1985, pp. 203–207, 211–214). Continuing from the preceding problem, show that if (a) of that problem are stationary (or scleronomic); that is, if

$$\dot{q}_k = \sum A_{kl}(q)\,\omega_l = \sum A_{kI}(q)\,\omega_I, \tag{a}$$

then (b) of that problem reduce to the *Nielsen form of the general nonlinear Chaplygin equations*:

$$\partial \dot{T}^*/\partial \omega_I - 2(\partial T^*/\partial \theta_I) + \sum\sum (\partial T/\partial \dot{q}_k)^*\big[(\partial A_{kI'}/\partial \theta_I - \partial A_{kI}/\partial \theta_{I'})\,\omega_{I'}\big] = \Theta_I. \tag{b}$$

6.5 ADDITIONAL FORMS OF THE EQUATIONS OF NIELSEN AND TSENOV

(i) Following Tsenov, we introduce the function

$$R_{(1)} \equiv \dot{T} - 2\dot{T}_{(o)}, \tag{6.5.1}$$

where $T_{(o)}$ is what results from T *if we regard it as function of t and the q's, but not the* $\dot{q}$*'s*; that is, *for fixed, or frozen, velocities,*

$$T_{(o)} = T_{(o)}(t, q) = T(t, q, \dot{q} = constant). \tag{6.5.2}$$

From the above it follows that

$$\dot{T}_{(o)} = \sum (\partial T/\partial q_k)\dot{q}_k + \partial T/\partial t + no\ other\ \dot{q}\ terms, \tag{6.5.3}$$

and, therefore,

$$\partial \dot{T}_{(o)}/\partial \dot{q}_k = \partial T/\partial q_k. \tag{6.5.4}$$

Then, Nielsen's equations, say (6.3.18), can be written in the Appellian form

$$\partial R_{(1)}/\partial \dot{q}_k = Q_k, \tag{6.5.5}$$

which is slightly simpler than the corresponding Appell's equations $\partial S/\partial \ddot{q}_k = Q_k$. Finally, introducing the new "Tsenov function"

$$K_{(1)} \equiv R_{(1)} - \sum Q_k\, \dot{q}_k, \tag{6.5.6}$$

we can express (6.5.5) in the equilibrium form:

$$\partial K_{(1)}/\partial \dot{q}_k = 0, \qquad \text{under the conditions } \partial Q_l/\partial \dot{q}_k = 0; \tag{6.5.7}$$

in words: *the equations of motion result from the stationarity of the function* $K_{(1)} = K_{(1)}(\dot{q})$. Similarly, for constrained systems: for example, if the constraints are

$$\begin{aligned} &\dot{q}_D = \sum b_{DI}\dot{q}_I + b_D, \qquad b_{DI} = b_{DI}(t, q), \qquad b_D = b_D(t, q) \\ &\Rightarrow \delta q_D = \sum b_{DI}\ \delta q_I, \end{aligned} \tag{6.5.8a}$$

then it is not hard to see that the Nielsen–Tsenov equations of the system take the "Hadamard form":

$$\partial K_{(1)}/\partial \dot{q}_I + \sum b_{DI}\big(\partial K_{(1)}/\partial \dot{q}_D\big) = 0$$

$$(D = 1, 2, \ldots, m;\ I = m+1, \ldots, n); \tag{6.5.8b}$$

or, with $K_{(1)} = K_{(1)}[t, q, \dot{q}_D(t, q, \dot{q}_I), \dot{q}_I] \equiv K_{(1)o}(t, q, \dot{q}_I) = K_{(1)o}$ ("constrained Tsenov function")

$$\begin{aligned} \Rightarrow\ \partial K_{(1)o}/\partial \dot{q}_I &= \partial K_{(1)}/\partial \dot{q}_I + \sum (\partial K_{(1)}/\partial \dot{q}_D)(\partial \dot{q}_D/\partial \dot{q}_I) \\ &= \partial K_{(1)}/\partial \dot{q}_I + \sum b_{DI}(\partial K_{(1)}/\partial \dot{q}_D), \end{aligned} \tag{6.5.8c}$$

simply,

$$\partial K_{(1)o}/\partial \dot{q}_I = 0. \tag{6.5.8d}$$

Other "Maggi-like" forms are also possible.

(ii) Again, following Tsenov, introducing the functions

$$R_{(2)} \equiv (1/2)(\ddot{T} - 3\ddot{T}_{(o)}) \qquad \text{and} \qquad K_{(2)} \equiv R_{(2)} - \sum Q_k \ddot{q}_k, \tag{6.5.9a}$$

and then noting the kinematic identities

$$\dot{T}_{(o)} = \sum (\partial T/\partial q_k)\dot{q}_k + \textit{no other } \dot{q} \textit{ terms} \Rightarrow \ddot{T}_{(o)} = \sum (\partial T/\partial q_k)\ddot{q}_k + \textit{no } \ddot{q} \textit{ terms},$$
$$\Rightarrow \partial \ddot{T}_{(o)}/\partial \ddot{q}_k = \partial T/\partial q_k, \tag{6.5.9b}$$

we can rewrite (6.4.11) in the following Appell-like and "equilibrium forms":

$$\partial R_{(2)}/\partial \ddot{q}_k = Q_k, \tag{6.5.9c}$$
$$\partial K_{(2)}/\partial \ddot{q}_k = 0, \qquad \text{under the conditions } \ \partial Q_l/\partial \ddot{q}_k = 0, \tag{6.5.9d}$$

respectively.

The above are particularly useful for constraints of the acceleration form:

$$f_D(t, q, \dot{q}, \ddot{q}) = 0. \tag{6.5.10a}$$

Then, Gauss' principle yields

$$\sum (\partial K_{(2)}/\partial \ddot{q}_k)\, \delta\ddot{q}_k = \sum (\partial K_{(2)}/\partial \ddot{q}_D)\delta\ddot{q}_D + \sum (\partial K_{(2)}/\partial \ddot{q}_I)\, \delta\ddot{q}_I = 0, \tag{6.5.10b}$$

under the conditions (in Gaussian variation form)

$$\delta'' f_D = \sum (\partial f_D/\partial \ddot{q}_D)\, \delta\ddot{q}_D + \sum (\partial f_I/\partial \ddot{q}_I)\, \delta\ddot{q}_I = 0$$
$$\Rightarrow \delta\ddot{q}_D = \sum (\partial \ddot{q}_D/\partial \ddot{q}_I)\, \delta\ddot{q}_I \equiv \sum b_{DI}\, \delta\ddot{q}_I. \tag{6.5.10c}$$

Combining (6.5.10c) with (6.5.10b), in by now well-known ways, and since the $n - m$ $\delta\ddot{q}_I$ can now be taken as independent, we immediately obtain the *Hadamard form of the second-kind Tsenov equations*:

$$\partial K_{(2)}/\partial \ddot{q}_I + \sum b_{DI}(\partial K_{(2)}/\partial \ddot{q}_D) = 0. \tag{6.5.10d}$$

A (6.5.8d)-like form is also readily available.

(iii) Finally, in the general case of a system subjected to the m (s)th order constraints

$$f_D\left(t, q, \dot{q}, \ddot{q}, \dddot{q}, \ldots, \overset{(s)}{q}\right) = 0, \tag{6.5.11a}$$

we can easily show that the *Hadamard form of its Mangeron–Deleanu equations* is

$$\partial K_{(s)}/\partial \overset{(s)}{q}_I + \sum b_{DI}\left(\partial K_{(s)}/\partial \overset{(s)}{q}_D\right) = 0, \tag{6.5.11b}$$

where

$$\overset{(s)}{q}_D = \sum b_{DI}\, \overset{(s)}{q}_I + \textit{no other } \overset{(s)}{q} \ \textit{ terms} \ \Rightarrow \ \delta\, \overset{(s)}{q}_D = \sum b_{DI}\, \delta\, \overset{(s)}{q}_I, \tag{6.5.11c}$$

and

$$K_{(s)} \equiv R_{(s)} - \sum Q_k \overset{(s)}{q}_k, \qquad \text{under} \quad \partial Q_l / \partial \overset{(s)}{q}_k = 0,$$

$$R_{(s)} \equiv (1/s)\left[\overset{(s)}{T} - (s+1) \sum (\partial T/\partial q_k)\, \overset{(s)}{q}_k\right] + \textit{no other } \overset{(s)}{q} \textit{ terms}$$

$$= (1/s)\left[\overset{(s)}{T} - (s+1)\, \overset{(s)}{T}_{(o)}\right] + \textit{no other } \overset{(s)}{q} \textit{ terms}, \tag{6.5.11d}$$

due to

$$\overset{(s)}{T}_{(o)} = \sum (\partial T/\partial q_k)\, \overset{(s)}{q}_k + \textit{no other } \overset{(s)}{q} \textit{ terms} \Rightarrow \partial \overset{(s)}{T}_{(o)} / \partial \overset{(s)}{q}_k = \partial T / \partial q_k. \tag{6.5.11e}$$

These higher-order Tsenov equations were presented, in a series of papers, by the Romanian mechanicians D. Mangeron and S. Deleanu in the early 1960s. Finally, (a) in terms of the *constrained* $R_{(s)o}$ and corresponding impressed forces Q_{Io}, the equations of motion take the Appellian form

$$\partial R_{(s)o} / \partial \overset{(s)}{q}_I = Q_{Io}; \tag{6.5.11f}$$

while (b) in terms of the *constrained* $K_{(s)o}$, they assume the equilibrium form

$$\partial K_{(s)o} / \partial \overset{(s)}{q}_I = 0. \tag{6.5.11g}$$

GENERAL REMARKS

(i) The relation between all these equations and the Lagrangean ones rests on the key kinematico-inertial identity:

$$(\partial T/\partial \dot{q}_k)^{\cdot} = (1/s)\left[\partial \overset{(s)}{T} / \partial \overset{(s)}{q}_k - \partial T/\partial q_k\right] \qquad (s = 1, 2, 3, \ldots). \tag{6.5.12}$$

(ii) The usefulness of these $\overset{(s)}{T}$-based equations lies in their ability to handle constraints of corresponding order in s. Symbolically,

$$f(t, q, \dot{q}) = 0 \Rightarrow \dot{T} \qquad \text{(Nielsen)},$$

$$f(t, q, \dot{q}, \ddot{q}) = 0 \Rightarrow \ddot{T} \qquad \text{(Tsenov 2nd kind)},$$

$$f(t, q, \dot{q}, \ddot{q}, \dddot{q}) = 0 \Rightarrow \dddot{T} \qquad \text{(Tsenov 3rd kind)},$$

....

$$f\left(t, q, \dot{q}, \ddot{q}, \ldots, \overset{(s)}{q}\right) = 0 \Rightarrow \overset{(s)}{T} \qquad \text{(Mangeron–Deleanu)}.$$

For unconstrained systems (i.e., independent δq's), these types of equations (as well as those by Appell) *do not seem to offer any particular advantage over the ordinary Lagrangean equations.*

(iii) By comparing the preceding $\overset{(s)}{T}$-equations with those by Appell, say for unconstrained systems, we readily conclude that

$$\partial R_{(s)} / \partial \overset{(s)}{q}_k = \partial \overset{(s)}{S} / \partial \overset{(s+2)}{q}_k \qquad (s = 1, 2, 3, \ldots). \tag{6.5.13}$$

(iv) It is not hard to show that, for Pfaffian constraints

$$\sum a_{Dk}\dot{q}_k + a_D = 0 \ \Rightarrow \ \sum a_{Dk}\ \delta q_k = 0, \tag{6.5.14a}$$

some of the earlier principles can be extended so that they hold for *finite* variations, and not just $\delta(\ldots)$:

(a) If both $\dot{q}_k$ and $\dot{q}_k + \Delta\dot{q}_k$ are sets of kinematically admissible velocities, *at the same configuration and time*; that is, if they both satisfy (6.5.14a):

$$\sum a_{Dk}\dot{q}_k + a_D = 0, \qquad \sum a_{Dk}(\dot{q}_k + \Delta\dot{q}_k) + a_D = 0. \tag{6.5.14b}$$

then subtracting them side by side yields

$$\sum a_{Dk}\ \Delta\dot{q}_k = 0, \tag{6.5.14c}$$

for Jourdain-like variations satisfying $\Delta t = 0$ and $\Delta q = 0$. This states that, in the constraints (6.5.14a), *we can replace the virtual δq_k's with the finite-velocity Jourdain jumps $\Delta\dot{q}_k$.*

(b) By $(\ldots)^{\cdot}$-differentiating (6.5.14a), we obtain

$$\sum (\dot{a}_{Dk}\dot{q}_k + a_{Dk}\ddot{q}_k) + \dot{a}_D = \sum a_{Dk}\ddot{q}_k + \textit{no other } \ddot{q} \textit{ terms} = 0, \tag{6.5.15a}$$

and, therefore, if we consider the two admissible acceleration states $\ddot{q}$ and $\ddot{q} + \Delta\ddot{q}$, under the Gaussian restrictions $\Delta t = 0$, $\Delta q = 0$, $\Delta\dot{q} = 0$, substitute them into (6.5.15a), and subtract the resulting equations side by side, we obtain

$$\sum a_{Dk}\ \Delta\ddot{q}_k = 0; \tag{6.5.15b}$$

that is, in (6.5.14a), *we can replace the δq_k's with the finite acceleration Gauss jumps* $\Delta\ddot{q}_k$. The extension to higher-order constraints should be obvious.

(v) Let the impressed forces Q_k be derivable, wholly or partly, from a *generalized potential* $V = V(t, q, \dot{q})$ [§3.9]; that is,

$$V = V(t, q, \dot{q}) = V_0(t, q) + \sum \gamma_k(t, q)\dot{q}_k,$$

and

$$\begin{aligned} Q_{k,\,\text{potential part}} &= E_k(V) \equiv (\partial V/\partial\dot{q}_k)^{\cdot} - \partial V/\partial q_k \\ &= -\partial V_0/\partial q_k + \sum (\partial\gamma_k/\partial q_l - \partial\gamma_l/\partial q_k)\dot{q}_l + \partial\gamma_k/\partial t. \end{aligned} \tag{6.5.16a}$$

Then, it can be easily shown that V satisfies the "Dolaptschiew identities":

$$(\partial V/\partial\dot{q}_k)^{\cdot} = (1/s)\left(\partial \overset{(s)}{V}/\partial \overset{(s)}{q}_k - \partial V/\partial q_k\right), \tag{6.5.16b}$$

and, therefore, with $L \equiv T - V$, the equations of motion, of, say, an unconstrained system, can be rewritten as

$$(1/s)\left[\partial \overset{(s)}{L}/\partial \overset{(s)}{q}_k - (s+1)(\partial L/\partial q_k)\right] = Q_{k,np}, \tag{6.5.16c}$$

$$Q_{k,np}\text{: } \textit{nonpotential} \text{ part of } Q_k. \tag{6.5.16d}$$

Further, introducing $L_{(o)} \equiv L(t, q, \dot{q} = constant)$, and since $\partial \overset{(s)}{L}_{(o)} / \partial \overset{(s)}{q}_k = \partial L / \partial q_k$, the equations of motion assume the following two equivalent forms:

$$\text{Appell-like:} \qquad \partial l_{(s)} / \partial \overset{(s)}{q}_k = Q_{k,np}, \quad \text{where} \quad l_{(s)} \equiv (1/s)\left[\overset{(s)}{L} - (s+1)\overset{(s)}{L}_{(o)}\right], \tag{6.5.16e}$$

$$\text{Equilibrium:} \qquad \partial k_{(s)} / \partial \overset{(s)}{q}_k = 0, \qquad \text{where} \quad k_{(s)} \equiv l_{(s)} - \sum Q_{k,np} \overset{(s)}{q}_k . \tag{6.5.16f}$$

And analogously for constrained systems. For example, the equations of motion of a system constrained by

$$\overset{(s)}{q}_D = \sum b_{DI} \overset{(s)}{q}_I + \textit{no other } \overset{(s)}{q} \textit{ terms} \Rightarrow \delta \overset{(s)}{q}_D = \sum b_{DI} \, \delta \overset{(s)}{q}_I, \tag{6.5.17a}$$

are

$$\partial l_{(s)o} / \partial \overset{(s)}{q}_I = (Q_{I,np})_o \qquad \text{or} \qquad \partial k_{(s)o} / \partial \overset{(s)}{q}_I = 0, \tag{6.5.17b}$$

where $l_{(s)o}, k_{(s)o}$ are, respectively, $l_{(s)}$, $k_{(s)}$ from which the dependent rates $\overset{(s)}{q}_D$ have been eliminated by means of the first of (6.5.17a), and $(Q_{I,np})_o \equiv Q_{I,np} + \sum b_{DI} Q_{D,np}$.

Problem 6.5.1 *Higher Forms of Appell's Equations* [$S = S(t, q, \dot{q}, \ddot{q})$: Appellian function]. Let

$$\overset{(s)}{U} \equiv \overset{(s)}{S} - \sum Q_k \overset{(s)}{q}_k + f\left(t, q, \dot{q}, \ldots, \overset{(s-1)}{q}\right). \tag{a}$$

Show that

(i) Under the $m\ (< n)$ constraints

$$f_D\left(t, q, \dot{q}, \ldots, \overset{(s+2)}{q}\right) = 0, \tag{b}$$

the equations of motion may be expressed in the "Routh–Voss" form:

$$\partial \overset{(s)}{S} / \partial \overset{(s+2)}{q}_k = Q_k + \sum \lambda_D \left(\partial f_D / \partial \overset{(s+2)}{q}_k\right); \tag{c}$$

(ii) Under the $m\ (< n)$ constraints

$$\overset{(s+2)}{q}_D = \sum b_{DI} \overset{(s+2)}{q}_I + \textit{no other } \overset{(s+2)}{q}_k \textit{ terms}, \tag{d}$$

they may be expressed in the "Hadamard" form:

$$\partial \overset{(s)}{S} / \partial \overset{(s+2)}{q}_I + \sum b_{DI} \left(\partial \overset{(s)}{S} / \partial \overset{(s+2)}{q}_D\right) = Q_I + \sum b_{DI} Q_D; \tag{e}$$

and

(iii) Under the $m\ (< n)$ constraints

$$\overset{(s+2)}{q}_D = \overset{(s+2)}{q}_D\left(t, q, \dot{q}, \ldots, \overset{(s+1)}{q}, \overset{(s+2)}{\theta}\right), \tag{f}$$

they may be expressed in the "Maggi" form:

$$\sum (\partial S/\partial \ddot{q}_k)\left[\partial \overset{(s+2)}{q_k} \big/ \partial \overset{(s+2)}{\theta_I}\right] = \sum Q_k \left[\partial \overset{(s+2)}{q_k} \big/ \partial \overset{(s+2)}{\theta_I}\right] = \Theta_I. \tag{g}$$

In all these cases, it is assumed that the constraint forces satisfy the "ideal reactions" postulate (§3.2 ff.):

$$\Lambda_I \equiv \mathbf{S}\, d\boldsymbol{R}\cdot \boldsymbol{\varepsilon}_I = \mathbf{S}\, d\boldsymbol{R}\cdot \left(\partial \overset{(s)}{\boldsymbol{a}} \big/ \partial \overset{(s+2)}{\theta_I}\right) = 0. \tag{h}$$

Example 6.5.1 A charged particle moves in a *homogeneous* electromagnetic field of intensities $\boldsymbol{E}$ (electric) and $\boldsymbol{H}$ (magnetic). It is shown in electrodynamics [see any advanced book on the subject; e.g., Landau and Lifshitz (1971, §8, §16)] that its Lagrangean is

$$L \equiv T - V = (1/2)mv^2 - e\Phi + (e/c)(\boldsymbol{A}\cdot \boldsymbol{v}), \tag{a}$$

where e = electric charge, c = speed of light in vacuum,

$$\Phi = -\boldsymbol{E}\cdot \boldsymbol{r} \text{ is the } \textit{scalar potential of the (electric) field}\text{, and} \tag{b1}$$

$$\boldsymbol{A} = (\boldsymbol{H}\times \boldsymbol{r})/2 \text{ is the } \textit{vector potential of the (magnetic) field.} \tag{b2}$$

Let us choose axes O–xyz so that both fields lie on the O–yz plane, and $\boldsymbol{H}$ is directed along the $+Oz$ axis; that is, $\boldsymbol{E} = (0, E_y, E_z)$ and $\boldsymbol{H} = (0, 0, H_z \equiv H)$. Then L assumes the form:

$$L = (m/2)\left[(\dot{x})^2 + (\dot{y})^2 + (\dot{z})^2\right] + e\left(y E_y + z E_z\right) + (eH/2c)(x\dot{y} - y\dot{x}); \tag{c1}$$

and thus, following Tsenov's concept,

$$L \;\Rightarrow\; L_{(o)} = e(y E_y + z E_z) + (eH/2c)(x\dot{y} - y\dot{x}) + \textit{constant}, \tag{c2}$$

where $\dot{x}$, $\dot{y}$ are viewed as fixed, or frozen, quantities.

Let us apply the Tsenov/Mangeron–Deleanu equations for $s = 1$. Here,

$$\begin{aligned} Q_{k,np} &= 0,\\ R_{(1)} &= K_{(1)} = \dot{L} - 2\dot{L}_{(o)}\\ &\quad = m(\dot{x}\,\ddot{x} + \dot{y}\,\ddot{y} + \dot{z}\,\ddot{z}) - e(E_y\,\dot{y} + E_z\,\dot{z})\\ &\qquad - (eH/2c)(x\,\dot{y} - y\,\dot{x}) + \textit{function of } x, y, \ddot{x}, \ddot{y}, \end{aligned} \tag{d}$$

and, therefore, the equations of motion (6.5.16) are

$$\partial K_{(1)}/\partial \dot{x} = m\,\ddot{x} - (eH/c)\dot{y} = 0, \tag{e}$$

$$\partial K_{(1)}/\partial \dot{y} = m\,\ddot{y} - e\,E_y + (eH/c)\dot{x} = 0, \tag{f}$$

$$\partial K_{(1)}/\partial \dot{z} = m\,\ddot{z} - e\,E_z = 0; \tag{g}$$

and, of course, these coincide with the equations obtained by other means.

Example 6.5.2 (Dolaptschiew, 1969, pp. 181–182). Let us derive the Tsenov, Nielsen, et al. equations of motion of a heavy homogeneous sphere (fig. 6.1), of mass m and radius r, rolling on the rough inner wall of a fixed vertical circular cylinder of radius R $(\geq r)$.

Kinematics, Constraints

Let us introduce the following five Lagrangean coordinates:

$$q_1 = \gamma, \quad q_2 = z; \qquad q_3 = \phi, \quad q_4 = \theta, \quad q_5 = \psi \quad \text{(Eulerian angles)}. \tag{a}$$

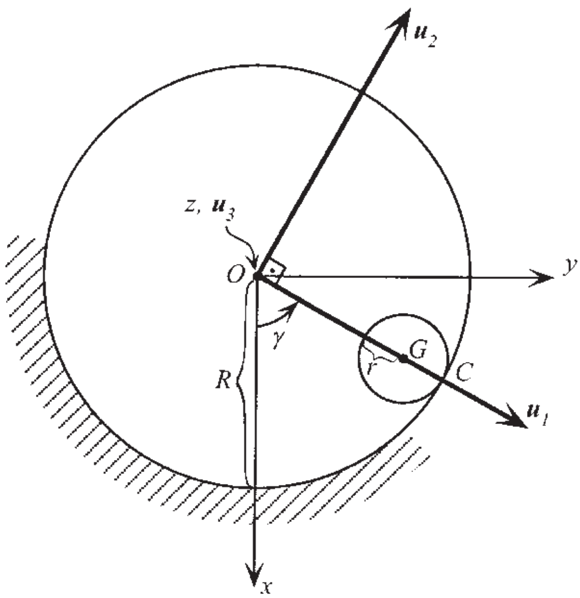

Figure 6.1 Geometry of rolling of a sphere on the rough inner wall of a fixed vertical cylinder (top view).
G: center of mass and centroid of sphere, O: vertical projection of center of typical normal section of cylinder, C: point of contact of sphere with cylinder;
$I = (2/5)mr^2 = mk^2$: moment of inertia of sphere about any axis through G;
O–xyz: fixed axes at ground level, with Oz pointing towards the reader;
(x, y, z): coordinates of C;
Mobile (intermediate) ortho–normal–dextral basis O–$\boldsymbol{u}_{1,2,3}$:
$\boldsymbol{u}_1$: radially outwards (i.e., toward C), making an angle γ with Ox,
$\boldsymbol{u}_2$: perpendicular to $\boldsymbol{u}_1$, in positive γ-sense (counterclockwise),
$\boldsymbol{u}_3$: so that $\boldsymbol{u}_{1,2,3}$ constitutes a dextral basis (points toward the reader).

From fig. 6.1 and §1.12, we see that the components of the angular velocity of the sphere, $\boldsymbol{\omega}$, along the fixed axes ($\omega_{x,y,z}$), and along the intermediate axes ($\omega_{1,2,3}$), are related by

$$\omega_x = \dot{\psi}\, s\theta\, s\phi + \dot{\theta}\, c\phi = \omega_1\, c\gamma - \omega_2\, s\gamma, \tag{b1}$$

$$\omega_y = -\dot{\psi}\, s\theta\, c\phi + \dot{\theta}\, s\phi = \omega_1\, s\gamma + \omega_2\, c\gamma, \tag{b2}$$

$$\omega_z = \dot{\phi} + \dot{\psi}\, c\theta = \omega_3; \tag{b3}$$

[where, as usual, $s(\ldots) \equiv \sin(\ldots)$, $c(\ldots) \equiv \cos(\ldots)$] and so, inverting, we obtain

$$\omega_1 = \dot{\theta}\, c(\phi - \gamma) + \dot{\psi}\, s\theta\, s(\phi - \gamma), \tag{c1}$$

$$\omega_2 = \dot{\theta}\, s(\phi - \gamma) - \dot{\psi}\, s\theta\, c(\phi - \gamma), \tag{c2}$$

$$\omega_3 = \dot{\phi} + \dot{\psi}\, c\theta. \tag{c3}$$

Clearly, $\omega_{1,2,3}$ are quasi velocities; like $\omega_{x,y,z}$.

The rolling constraint at C is

$$\boldsymbol{v}_C = \boldsymbol{v}_G + \boldsymbol{\omega} \times \boldsymbol{r}_{C/G} = \boldsymbol{0}, \tag{d}$$

or, along $\boldsymbol{u}_{1,2,3}$, and with the notation $R - r \equiv \rho$,

$$\begin{aligned} \boldsymbol{v}_C &= d/dt(z\,\boldsymbol{u}_3 + \rho\,\boldsymbol{u}_1) + \boldsymbol{\omega} \times (r\,\boldsymbol{u}_1) \\ &= [\dot{z}\,\boldsymbol{u}_3 + \rho(d\boldsymbol{u}_1/dt)] + (\omega_1, \omega_2, \omega_3) \times (r, 0, 0) \\ &= \dot{z}\,\boldsymbol{u}_3 + \rho(\dot{\gamma}\,\boldsymbol{u}_2) + (0, r\,\omega_3, -r\,\omega_2) \\ &= (\rho\dot{\gamma} + r\,\omega_3)\boldsymbol{u}_2 + (\dot{z} - r\,\omega_2)\boldsymbol{u}_3 = \boldsymbol{0}, \end{aligned}$$

from which we obtain the two scalar constraints

$$\rho\,\dot{\gamma} + r\,\omega_3 = 0, \qquad \dot{z} - r\,\omega_2 = 0; \tag{e}$$

or, thanks to (c2, 3), exclusively in *holonomic* variables,

$$v_{C,\,\text{tangential direction}} \equiv \rho\dot{\gamma} + r\,\dot{\phi} + r\,\dot{\psi}\, c\theta = 0, \tag{f1}$$

$$v_{C,\,\text{axial (vertical) direction}} \equiv \dot{z} - r\,\dot{\theta}\, s(\phi - \gamma) - r\,\dot{\psi}\, s\theta\, c(\phi - \gamma) = 0. \tag{f2}$$

Next, let us calculate the *kinetic and potential energies*:

(i) By König's theorem, we have

$$\begin{aligned} 2T &= m\,v_G^2 + (I_x\,\omega_x^2 + I_y\,\omega_y^2 + I_z\,\omega_z^2) \\ &= m\Big[(\dot{z})^2 + \rho^2(\dot{\gamma})^2\Big] + (m\,k^2)(\omega_x^2 + \omega_y^2 + \omega_z^2) \\ &= m\Big[(\dot{z})^2 + \rho^2(\dot{\gamma})^2\Big] + (m\,k^2)\Big[(\dot{\phi})^2 + (\dot{\theta})^2 + (\dot{\psi})^2 + 2\dot{\phi}\,\dot{\psi}\cos\theta)\Big] \end{aligned} \tag{g1}$$

[thanks to (b1–3), and recalling that $I_x = I_y = I_z = m\,k^2$]; and

(ii) $V = mgz \;\Rightarrow\; Q_z = -(\partial V/\partial z) = -mg$ (sole nonvanishing impressed force). (g2)

Tsenov Equations

Now we are ready to obtain the Tsenov equations of motion:

(i) Tsenov's function is

$$T \;\Rightarrow\; T_{(o)} = (m\,k^2)\underline{\dot\phi}\,\underline{\dot\psi}\,c\theta + constant = T_{(o)}(\theta)$$
$$\text{[underlined velocities behave as constants]}, \tag{h1}$$

and so

$$\dot T_{(o)} = -(m\,k^2)\underline{\dot\phi}\,\underline{\dot\psi}\,\dot\theta\,s\theta; \tag{h2}$$

(ii) By (g1),

$$\begin{aligned}\dot T = m\,\dot z\,\ddot z + m\,\rho^2\,\dot\gamma\,\ddot\gamma + m\,k^2\big[&\dot\phi\,\ddot\phi + \dot\theta\,\ddot\theta + \dot\psi\,\ddot\psi\\ &+ (\dot\phi\,\ddot\psi + \dot\psi\,\ddot\phi)c\theta - \dot\phi\,\dot\theta\,\dot\psi\,s\theta\big].\end{aligned} \tag{h3}$$

Therefore, choosing $\dot\phi$, $\dot\theta$, $\dot\psi$ as the *independent* velocities, in which case (f1, 2) yield for the *dependent ones*:

$$\dot z = r\big[\dot\theta\,s(\phi-\gamma) + \dot\psi\,s\theta\,c(\phi-\gamma)\big] = \dot z\big(\dot\theta,\,\dot\psi;\,\phi,\,\theta,\,\gamma\big), \tag{i1}$$

$$\dot\gamma = -(r/\rho)\big(\dot\phi + \dot\psi\,c\theta\big) = \dot\gamma\big(\dot\phi,\,\dot\psi;\,\theta\big), \tag{i2}$$

and with the familiar notation $(\ldots)_o \equiv$ *constrained* $(\ldots)$ we find

$$\begin{aligned}K_{(1)o} &\equiv (\dot T - 2\dot T_{(o)})_o - Q_z\,\dot z\\ &= m(\dot z\,\ddot z + \rho^2\dot\gamma\,\ddot\gamma)\\ &\quad + m\,k^2\big[\dot\phi\,\ddot\phi + \dot\theta\,\ddot\theta + \dot\psi\,\ddot\psi + (\dot\phi\,\ddot\psi + \dot\psi\,\ddot\phi) - \dot\phi\,\dot\theta\,\dot\psi\,s\theta\big]\\ &\quad + 2(m\,k^2)\underline{\dot\phi}\,\underline{\dot\psi}\,\dot\theta\,s\theta + m\,g\,\dot z\\ &= K_{(1)o}\big[\dot\gamma(\dot\phi,\,\dot\psi;\,\theta),\,\dot z(\dot\theta,\,\dot\psi;\,\gamma,\,\phi,\,\theta),\,\dot\phi,\,\dot\theta,\,\dot\psi;\,\gamma,\,\theta\big]\\ &= K_{(1)o}(\dot\phi,\,\dot\theta,\,\dot\psi;\,\gamma,\,\phi,\,\theta) \qquad \text{(i.e., } \textit{constrained} \text{ Tsenov function).}\end{aligned} \tag{i3}$$

Hence, the three kinetic Tsenov equations are

$$\partial K_{(1)o}/\partial\dot\phi = m\,\rho^2\,\ddot\gamma\,(\partial\dot\gamma/\partial\dot\phi) + m\,k^2(\ddot\phi + \ddot\psi\,c\theta - \dot\theta\,\dot\psi\,s\theta) = 0, \tag{j1}$$

$$\partial K_{(1)o}/\partial\dot\theta = m(\ddot z + g)(\partial\dot z/\partial\dot\theta) + m\,k^2(\ddot\theta - \dot\phi\,\dot\psi\,s\theta + 2\underline{\dot\phi}\,\underline{\dot\psi}\,s\theta) = 0, \tag{j2}$$

$$\begin{aligned}\partial K_{(1)o}/\partial\dot\psi = m(\ddot z + g)(\partial\dot z/\partial\dot\psi) + m\,\rho^2\,\ddot\gamma\,(\partial\dot\gamma/\partial\dot\phi)\\ + m\,k^2(\ddot\psi + \ddot\phi\,c\theta - \underline{\dot\phi}\,\underline{\dot\theta}\,s\theta) = 0;\end{aligned} \tag{j3}$$

or, since [by (i1, 2)]

$$\partial\dot\gamma/\partial\dot\phi = -(r/\rho), \qquad \partial\dot\gamma/\partial\dot\psi = -(r/\rho)c\theta, \tag{k1}$$

$$\partial\dot z/\partial\dot\theta = r\,s(\phi-\gamma), \qquad \partial\dot z/\partial\dot\psi = r\,s\theta\,c(\phi-\gamma), \tag{k2}$$

finally (and dropping the underlines),

$$-r\,\rho\,\ddot{\gamma} + k^2(\ddot{\phi} + \ddot{\psi}\,c\theta - \dot{\theta}\,\dot{\psi}\,s\theta) = 0, \tag{l1}$$

$$k^2(\ddot{\theta} + \dot{\phi}\,\dot{\psi}\,s\theta) + r(\ddot{z} + g)\,s(\phi - \gamma) = 0, \tag{l2}$$

$$k^2(\ddot{\psi} + \ddot{\phi}\,c\theta - \dot{\phi}\,\dot{\theta}\,s\theta) - r\,\rho\,\ddot{\gamma}\,c\theta + r(\ddot{z} + g)\,s\theta\,c(\phi - \gamma) = 0; \tag{l3}$$

which, along with (f1, 2) [or (i1, 2)], constitute a determinate system for γ, z, ϕ, θ, ψ. For its solution, and so on, see, for example, Neimark and Fufaev (1972, pp. 95–98) and Ramsey (1937, pp. 157–158). It is not hard to realize that eqs. (l1–3) are none other than the Chaplygin–Voronets equations of the problem.

Had we not enforced the constraints (f1, 2) or (i1, 2) in the Tsenov function, the equations of motion would have the "Hadamard form":

$$\partial K_{(1)}/\partial \dot{q}_I + \sum b_{DI}(\partial K_{(1)}/\partial \dot{q}_I) = 0, \tag{m1}$$

$$\dot{q}_D = \sum b_{DI}\dot{q}_I + b_D \qquad \text{[eqs. (i1, 2)]}, \tag{m2}$$

where $K_{(1)} = K_{(1)}(\dot{\gamma}, \dot{z}, \dot{\phi}, \dot{\theta}, \dot{\psi}; \gamma, z, \phi, \theta, \psi)$: *unconstrained* Tsenov function, instead of (j1–3).

Nielsen Equations

Next, let us derive the Routh–Voss form of the Nielsen equations:

$$N_k(T) = Q_k + \sum \lambda_D\, a_{Dk} \qquad (D = 1, 2;\ k = 1, \ldots, 5).$$

[We recall (a), (g2), and read off the coefficients a_{Dk} from (f1, 2)]. (m3)

To calculate $N_k(T)$, we apply the earlier Schieldrop–Nielsen rule [(ex. 6.3.1)]. We have already seen [eq. (h3)] that

$$\begin{aligned}\dot{T} &= m\,\dot{z}\,\ddot{z} + m\,\rho^2\,\dot{\gamma}\,\ddot{\gamma} + m\,k^2\,\dot{\phi}\,\ddot{\phi} + m\,k^2\,\dot{\theta}\,\ddot{\theta} + m\,k^2\,\dot{\psi}\,\ddot{\psi}\\ &\quad + m\,k^2\,\dot{\phi}\,\ddot{\psi}\,c\theta + m\,k^2\,\dot{\psi}\,\ddot{\phi}\,c\theta - m\,k^2\,\dot{\phi}\,\dot{\psi}\,\underline{\dot{\theta}}\,s\theta,\end{aligned} \tag{n}$$

that is, only the last term is underlined.

From this, we build table 6.4. Hence, the $N_{\ldots}(T)$ totals are

$$N_\gamma(T) = m\,\rho^2\,\ddot{\gamma}, \tag{o1}$$

$$N_z(T) = m\,\ddot{z} \ \Rightarrow\ N_z(L) \equiv N_z(T - V) = N_z(T - m\,g\,z) = m(\ddot{z} + g), \tag{o2}$$

$$\begin{aligned}N_\phi(T) &= m\,k^2\,\ddot{\phi} + m\,k^2\,\ddot{\psi}\,c\theta - m\,k^2\,\dot{\theta}\,\dot{\psi}\,s\theta\\ &= m\,k^2(\dot{\phi} + \dot{\psi}\,c\theta)^{\cdot},\end{aligned} \tag{o3}$$

$$N_\theta(T) = m\,k^2\,\ddot{\theta} + m\,k^2\,\dot{\phi}\,\dot{\psi}\,s\theta = m\,k^2(\ddot{\theta} + \dot{\phi}\,\dot{\psi}\,s\theta), \tag{o4}$$

$$\begin{aligned}N_\psi(T) &= m\,k^2\,\ddot{\psi} + m\,k^2\,\ddot{\phi}\,c\theta - m\,k^2\,\dot{\phi}\,\dot{\theta}\,s\theta\\ &= m\,k^2(\dot{\psi} + \dot{\phi}\,c\theta)^{\cdot};\end{aligned} \tag{o5}$$

Table 6.4

$\dot{T}$-terms	$N_\gamma(T)$	$N_z(T)$	$N_\phi(T)$	$N_\theta(T)$	$N_\psi(T)$
$m\dot{z}\ddot{z}$	$k=0$ 0	$k=1$ $m\ddot{z}$	$k=0$ 0	0	0
$m\rho^2\dot{\gamma}\ddot{\gamma}$	$k=1$ $m\rho^2\ddot{\gamma}$	$k=0$ 0	$k=0$ 0	0	0
$mk^2\dot{\phi}\ddot{\phi}$	$k=0$ 0	$k=0$ 0	$k=1$ $mk^2\ddot{\phi}$	0	0
$mk^2\dot{\theta}\ddot{\theta}$	$k=0$ 0	$k=0$ 0	$k=0$ 0	$mk^2\ddot{\theta}$	0
$mk^2\dot{\psi}\ddot{\psi}$	$k=0$ 0	$k=0$ 0	$k=0$ 0	0	$mk^2\ddot{\psi}$
$mk^2\dot{\phi}\ddot{\psi}c\theta$	$k=0$ 0	$k=0$ 0	$k=1$ $mk^2\ddot{\psi}c\theta$	0	0
$mk^2\dot{\psi}\ddot{\phi}c\theta$	$k=0$ 0	$k=0$ 0	$k=0$ 0	0	$mk^2\ddot{\phi}c\theta$
$-mk^2\dot{\phi}\dot{\psi}\underline{\dot{\theta}}s\theta$	$k=0$ 0	$k=0$ 0	$k=1$ $-mk^2\dot{\psi}\dot{\theta}s\theta$	$1-2=-1$ $mk^2\dot{\phi}\dot{\psi}s\theta$	1 $-mk^2\dot{\phi}\dot{\theta}s\theta$

and, therefore, equations (m3) become

$$N_\gamma(L) = N_\gamma(T) = \rho\,\lambda_1, \tag{p1}$$
$$N_z(L) = N_z(T) + m\,g = \lambda_2, \tag{p2}$$
$$N_\phi(L) = N_\phi(T) = r\,\lambda_1, \tag{p3}$$
$$N_\theta(L) = N_\theta(T) = -r\,\lambda_2\,s(\phi-\gamma), \tag{p4}$$
$$N_\psi(L) = N_\psi(T) = (r\,c\theta)\lambda_1 - [r\,s\theta\,c(\phi-\gamma)]\lambda_2. \tag{p5}$$

Recalling the constraints (f1, 2), we see that the multipliers λ_D are proportional to the components of the force of rolling friction: along the tangential direction $\boldsymbol{u}_2$ (λ_1), and along the vertical direction $\boldsymbol{u}_3$ (λ_2).

Eliminating $\lambda_{1,2}$ among (p1–5), we obtain the following three kinetic equations (what might be called "Maggi form of the Nielsen equations," or "Nielsen form of the Maggi equations"):

$$r\,N_\gamma(T) - \rho\,N_\phi(T) = 0, \tag{q1}$$
$$N_\theta(T) + r\,N_z(L)\sin(\phi-\gamma) = 0, \tag{q2}$$
$$\rho\,N_\psi(T) - r\,N_\gamma(T)\cos\theta + r\,\rho\sin\theta\cos(\phi-\gamma)N_z(L) = 0. \tag{q3}$$

Finally, if we use the constraints (f1, 2), or (i1, 2), to eliminate $\dot{z}$, $\dot{\gamma}$ (and hence also $\ddot{z}$, $\ddot{\gamma}$) from the above, we should get the earlier equations (l1–3).

Example 6.5.3 Let us verify the identity $(T_o)^{\cdot} = (\dot{T})_o$, for a system with

$$2T = (\dot{x})^2 + (\dot{y})^2, \qquad y = y(x), \tag{a}$$

that is, $q_1 = y,\ q_2 = x;\ n = 2,\ m = 1$.

With the customary notations $(\ldots)^{\cdot} \equiv d(\ldots)/dt$, $(\ldots)' \equiv d(\ldots)/dx$, we have, successively,

(i)
$$\dot{T} = \dot{x}\,\ddot{x} + \dot{y}\,\ddot{y}$$
$$\Rightarrow (\dot{T})_o = \dot{x}\,\ddot{x} + (y'\dot{x})\,[y''\,(\dot{x})^2 + y'\ddot{x}]$$
$$= \dot{x}\,\ddot{x} + y'\,y''\,(\dot{x})^3 + (y')^2\dot{x}\,\ddot{x}. \tag{b}$$

(ii)
$$T_o = (1/2)\,[(\dot{x})^2 + (y'\,\dot{x})^2] = (1/2)\,[(\dot{x})^2 + (y')^2\,(\dot{x})^2]$$
$$\Rightarrow (T_o)^{\cdot} = \dot{x}\,\ddot{x} + y'\,(y')^{\cdot}\,(\dot{x})^2 + (y')^2\,\dot{x}\,\ddot{x}$$
$$= \dot{x}\,\ddot{x} + y'\,(y''\,\dot{x})\,(\dot{x})^2 + (y')^2\dot{x}\,\ddot{x} = (\dot{T})_o, \quad \text{Q.E.D.} \tag{c}$$

Problem 6.5.2 (Mei, 1983, pp. 628–630). Consider a system under constraints of the form

$$\dot{q}_D = \phi_D(t, q, \dot{q}_{\mathrm{I}}) \qquad (D = 1, \ldots, m;\ I = m+1, \ldots, n); \tag{a}$$

and let, for any sufficiently smooth function f,

$$f = f(t, q, \dot{q}) = f\,[t, q, \phi_D(t, q, \dot{q}_I),\ \dot{q}_I] = f_o\,(t, q, \dot{q}_I) \equiv f_o. \tag{b}$$

Show that

$$\partial/\partial\dot{q}_I(df_o/dt) - 2(\partial f_o/\partial q_I)$$
$$= d/dt(\partial f_o/\partial\dot{q}_I) - \partial f_o/\partial q_I + \sum(\partial f_o/\partial q_D)\,(\partial\phi_D/\partial\dot{q}_I), \tag{c}$$

or, compactly,

$$N_I(f_o) = E_I(f_o) + \sum(\partial f_o/\partial q_D)\,(\partial\phi_D/\partial\dot{q}_I). \tag{d}$$

The above can be considered as an application of the earlier identity $N_k{}^*(f\,^*) = E_k{}^*(f\,^*)$ to the special form of the constraints:

$$\omega_D \equiv \dot{q}_D - \phi_D(t, q, \dot{q}_I) = 0, \qquad \omega_I \equiv \dot{q}_I. \tag{e}$$

Problem 6.5.3 (Mei, 1983, pp. 632–633; 1985, pp. 208–211). Using the kinematico-inertial identity (c, d) of the preceding problem, show that the *Nielsen form of the special nonlinear Voronets equations*

$$(\partial T_o/\partial\dot{q}_I)^{\cdot} - \partial T_o/\partial q_I$$
$$- \sum(\partial\phi_D/\partial\dot{q}_I)\,(\partial T_o/\partial q_D) - \sum W^D{}_I\,(\partial T/\partial\dot{q}_D)_o = Q_{Io}, \tag{a}$$

where

$$Q_{Io} \equiv Q_I + \sum(\partial\phi_D/\partial\dot{q}_I)Q_D, \tag{a1}$$

$$W^D{}_I \equiv (\partial\phi_D/\partial\dot{q}_I)^{\cdot} - \partial\phi_D/\partial q_I - \sum(\partial\phi_D/\partial q_{D'})\,(\partial\phi_{D'}/\partial\dot{q}_I)$$
$$\equiv E_I(\phi_D) - \sum(\partial\phi_D/\partial q_{D'})\,(\partial\phi_{D'}/\partial\dot{q}_I), \tag{a2}$$

is

$$\partial \dot{T}_o/\partial \dot{q}_I - 2\,(\partial T_o/\partial q_I) - \sum (\partial T/\partial \dot{q}_D)_o\,[\partial \ddot{q}_D/\partial \dot{q}_I - 2\,(\partial \dot{q}_D/\partial q_I)] \\ - 2\sum (\partial T/\partial q_D)_o\,(\partial \phi_D/\partial \dot{q}_I) = Q_{Io}, \tag{b}$$

or, compactly,

$$N_I(T_o) - \sum (\partial T/\partial \dot{q}_D)_o\, N_I(\dot{q}_D) - 2\sum (\partial T/\partial \dot{q}_D)_o(\partial \phi_D/\partial \dot{q}_I) \;=\; Q_{Io}. \tag{c}$$

[If $\partial T/\partial q_D = 0$, then (b) reduces to what may be termed the *Nielsen form of the special nonlinear Chaplygin equations*:

$$\partial \dot{T}_o/\partial \dot{q}_I - 2(\partial T_o/\partial q_I) \\ - \sum (\partial T/\partial \dot{q}_D)_o\,\big[\partial \ddot{q}_D/\partial \dot{q}_I - 2\,(\partial \dot{q}_D/\partial q_I)\big] = Q_{Io}\big]. \tag{d}$$

HINTS

By the kinematico-inertial identity of the preceding problem:

$$N_I(T_o) = E_I(T_o) + \sum (\partial T_o/\partial q_D)\,(\partial \phi_D/\partial \dot{q}_I), \tag{e}$$

$$N_I(\dot{q}_D) = E_I(\dot{q}_D) + \sum (\partial \phi_D/\partial q_{D'})\,(\partial \phi_{D'}/\partial \dot{q}_I). \tag{f}$$

Problem 6.5.4 (Mei, 1985, pp. 196–203; 1987, pp. 397–402). Continuing from the preceding problem, show that:

(i) If the constraints have the special Pfaffian form

$$\dot{q}_D = \sum b_{DI}(t,q)\dot{q}_I + b_D(t,q), \tag{a}$$

then the preceding *Nielsen form of the special Voronets equations*, eqs. (b, c), reduces to

$$\partial \dot{T}_o/\partial \dot{q}_I - 2\,(\partial T_o/\partial q_I) \\ - \sum (\partial T/\partial \dot{q}_D)_o\Big\{\sum \big[b^D{}_{II'} - 2\,(\partial b_{DI'}/\partial q_I)\big]\dot{q}_{I'} + \big[b^D{}_I - 2(\partial b_D/\partial q_I)\big]\Big\} \\ - 2\sum (\partial T/\partial q_D)_o\, b_{DI} = Q_{Io}, \tag{b}$$

where

$$b^D{}_{II'} \equiv \sum \big[(\partial b_{DI}/\partial q_{D'})b_{D'I'} + (\partial b_{DI'}/\partial q_{D'})b_{D'I}\big] + (\partial b_{DI}/\partial q_{I'} + \partial b_{DI'}/\partial q_I), \tag{c1}$$

$$b^D{}_I \equiv \sum \big[(\partial b_D/\partial q_{D'})b_{D'I} + (\partial b_{DI}/\partial q_{D'})b_{D'}\big] + (\partial b_{DI}/\partial t + \partial b_D/\partial q_I); \tag{c2}$$

and, therefore,

(ii) If the constraints (a) have the Chaplygin form

$$\dot{q}_D = \sum b_{DI}(q_I)\dot{q}_I, \tag{d}$$

and $\partial T/\partial q_D = 0$ (recall discussion in §3.8), then (b) reduces to the *Nielsen form of the linear (i.e., Pfaffian) Chaplygin equations*:

$$\partial \dot{T}_o/\partial \dot{q}_I - 2(\partial T_o/\partial q_I) - \sum\sum (\partial T/\partial \dot{q}_D)_o (\partial b_{DI}/\partial q_{I'} - \partial b_{DI'}/\partial q_I)\dot{q}_{I'} = Q_{Io}, \tag{e}$$

since in this case

$$b_D = 0, \qquad b^D{}_I = 0, \qquad b^D{}_{II'} = \partial b_{DI}/\partial q_{I'} + \partial b_{DI'}/\partial q_I. \tag{f}$$

Problem 6.5.5 Show that, for $s = 1, 2, 3, \ldots,$

$$d/dt\left[\partial \overset{(s-1)}{T}_o/\partial \overset{(s)}{q}_I\right] - \partial T/\partial q_I = d/dt\,(\partial T/\partial \dot{q}_I) - \partial T/\partial q_I + \sum d/dt\left[(\partial T/\partial \dot{q}_D)\,(\partial \overset{(s)}{q}_D/\partial \overset{(s)}{q}_I)\right]. \tag{a}$$

HINTS

Recall that $\left(\overset{(s-1)}{T}\right)_o = (T_o)^{(s-1)}$, and show that

$$\partial \overset{(s-1)}{T_o}/\partial \overset{(s)}{q}_I = \partial \overset{(s-1)}{T}/\partial \overset{(s)}{q}_I + \sum (\partial \overset{(s-1)}{T}/\partial \overset{(s)}{q}_D)\,(\partial \overset{(s)}{q}_D/\partial \overset{(s)}{q}_I). \tag{b}$$

Problem 6.5.6 *Higher-Order Equations of Nielsen et al. in Holonomic and Quasi Variables; and their Relation with the Equations of Lagrange, Hamel, et al.*

(i) Let us define the *(s)th-order holonomic operators of Nielsen*:

$$N_k{}^{(s)}(\ldots) \equiv \partial(\overset{(s)}{\ldots})/\partial \overset{(s)}{q}_k - 2\,[\partial(\overset{(s-1)}{\ldots})/\partial \overset{(s-1)}{q}_k], \tag{a}$$

and *Euler–Lagrange*:

$$E_k{}^{(s)}(\ldots) \equiv d/dt\,[\partial(\overset{(s-1)}{\ldots})/\partial \overset{(s)}{q}_k] - [\partial(\overset{(s-1)}{\ldots})/\partial \overset{(s-1)}{q}_k]. \tag{b}$$

Show that, for any sufficiently differentiable function $f = f(t, q, \dot{q})$, and any $k = 1, 2, \ldots, n$; $s = 1, 2, 3, \ldots,$

$$N_k{}^{(s)}(f) = E_k{}^{(s)}(f). \tag{c}$$

(ii) Let us define the *(s)th-order nonholonomic operators of Nielsen*:

$$N_k{}^{*(s)}(\ldots) \equiv \partial(\overset{(s)}{\ldots})/\partial \overset{(s)}{\theta}_k - 2\left[\partial(\overset{(s-1)}{\ldots})/\partial \overset{(s-1)}{\theta}_k\right], \tag{d}$$

and *Euler–Lagrange*:

$$E_k{}^{*(s)}(\ldots) \equiv d/dt\left[\partial(\overset{(s-1)}{\ldots})/\partial \overset{(s)}{\theta}_k\right] - \left[\partial(\overset{(s-1)}{\ldots})\Big/\partial \overset{(s-1)}{\theta}_k\right], \tag{e}$$

where

$$\partial(\overset{(s-1)}{\ldots})/\partial\overset{(s-1)}{\theta}_k \equiv \sum\left[\partial(\overset{(s-1)}{\ldots})/\partial\overset{(s-1)}{q_l}\right]\left[\partial\overset{(s)}{q_l}/\partial\overset{(s)}{\theta_k}\right] \tag{e1}$$

[(s)*th-order quasi chain rule*].

Show that, for any sufficiently differentiable function $f^* = f^*(t, q, \omega)$, and any $k = 1, 2, \ldots, n$; $s = 1, 2, 3, \ldots,$

$$N_k{}^*\left[\overset{(s)}{f}{}^*\right] = E_k{}^*\left[\overset{(s)}{f}{}^*\right], \tag{f}$$

where

$$f(t, q, \dot{q}) \Rightarrow \dot{f} \Rightarrow \cdots \overset{(s-1)}{f} \Rightarrow \overset{(s)}{f}, \tag{g}$$

$$\begin{aligned}\overset{(s-1)}{f}{}^* &= \overset{(s-1)}{f}\,[t, q, \dot{q} \equiv \overset{(1)}{q}, \ldots, \overset{(s-1)}{q};\ \overset{(s)}{q}(t, q, \overset{(1)}{q}, \ldots, \overset{(s-1)}{q}, \overset{(s)}{\theta})]\\ &= \overset{(s-1)}{f}\left(t, q, \overset{(1)}{q}, \ldots, \overset{(s-1)}{q}, \overset{(s)}{\theta}\right),\end{aligned} \tag{h}$$

$$\begin{aligned}\overset{(s)}{f}{}^* = \overset{(s)}{f}\Bigg[&t, q, \overset{(1)}{q}, \ldots, \overset{(s-1)}{q};\\ &\overset{(s)}{q}\left(t, q, \overset{(1)}{q}, \ldots, \overset{(s-1)}{q}, \overset{(s)}{\theta}\right), \overset{(s+1)}{q}\left(t, q, \overset{(1)}{q}, \ldots, \overset{(s-1)}{q}, \overset{(s)}{\theta}, \overset{(s+1)}{\theta}\right)\Bigg]\\ = \overset{(s)}{f}&\left(t, q, \overset{(1)}{q}, \ldots, \overset{(s-1)}{q}, \overset{(s)}{\theta}, \overset{(s+1)}{\theta}\right).\end{aligned} \tag{i}$$

Applications: Mei (1985, several places, esp. pp. 299-315; 1987, several places, esp. pp. 60 ff., 126 ff.).

(a) Consider the earlier, say unconstrained, equations of Mangeron et al. (6.4.14e):

$$(1/s)\left[\partial\overset{(s)}{T}/\partial\overset{(s)}{q_k} - (s+1)\,(\partial T/\partial q_k)\right] = Q_k,$$
$$(k = 1, \ldots, n;\ s = 1, 2, 3, \ldots). \tag{j}$$

Substituting into it $s - 1$ for s yields

$$\partial T/\partial q_k = (1/s)\left(\partial\overset{(s-1)}{T}/\partial\overset{(s-1)}{q_k}\right) - [(s-1)/s]\,Q_k, \tag{k}$$

and then reinserting this expression into (j) results in the *Nielsen* form:

$$s\left(\partial\overset{(s)}{T}/\partial\overset{(s)}{q_k}\right) - (s+1)\left(\partial\overset{(s-1)}{T}/\partial\overset{(s-1)}{q}\right) = Q_k; \tag{l}$$

and, by (c): $N_k{}^{(s)}(T) = E_k{}^{(s)}(T)$, also in the *Lagrange* form:

$$(s)\left(\partial \overset{(s-1)}{T} / \partial \overset{(s)}{q}\right)^{\cdot} - \partial \overset{(s-1)}{T} / \partial \overset{(s-1)}{q_k} = Q_k. \tag{m}$$

(b) Next, if the system is subject to the $m(< n)$ constraints

$$\overset{(s)}{\theta_D} \equiv \overset{(s-1)}{\omega_D} \equiv f_D\left(t, q, \dot{q}, \ldots, \overset{(s-1)}{q}, \overset{(s)}{q}\right) = 0 \qquad (D = 1, \ldots, m) \tag{n1}$$

$$\left[\overset{(s)}{\theta_I} \equiv \overset{(s-1)}{\omega_I} = \overset{(s-1)}{\omega_I}\left(t, q, \dot{q}, \ldots, \overset{(s-1)}{q}, \overset{(s)}{q}\right) \neq 0 \qquad (I = m+1, \ldots, n)\right] \tag{n2}$$

$$\Rightarrow \overset{(s)}{q_k} = \overset{(s)}{q_k}\left(t, q, \dot{q}, \ldots, \overset{(s-1)}{q}, \overset{(s)}{\theta} \equiv \overset{(s-1)}{\omega}\right) \quad [k,\ l\ \text{(below)} = 1, \ldots, n;\ s = 1, 2, \ldots] \tag{n3}$$

$$\left[\Rightarrow \partial \overset{(s)}{q_k} \Big/ \partial \overset{(s-1)}{\omega_l} = \partial \overset{(s+1)}{q_k} \Big/ \partial \overset{(s)}{\omega_l} = \cdots, \partial \overset{(s-1)}{\omega_l} \Big/ \partial \overset{(s)}{q_k} = \partial \overset{(s)}{\omega_l} \Big/ \partial \overset{(s+1)}{q_k} = \cdots\right] \tag{o}$$

(for any given system (n1–n3))

$$\Rightarrow \delta \overset{(s)}{q_k} = \sum \left(\partial \overset{(s)}{q_k} \Big/ \partial \overset{(s-1)}{\omega_l}\right) \delta \overset{(s-1)}{\omega_l} \Leftrightarrow \delta \overset{(s)}{\theta_l} \equiv \delta \overset{(s-1)}{\omega_l} = \sum \left(\partial \overset{(s-1)}{\omega_l} \Big/ \partial \overset{(s)}{q_k}\right) \delta \overset{(s)}{q_k} \tag{p}$$

[i.e., recalling (5.2.20c, d) and Tables 6.2, 6.3], then we either (i) add to the right ("force") side of the preceding equations of motion the constraint reaction term $\sum \lambda_D \left(\partial f_D \Big/ \partial \overset{(s)}{q_k}\right)$, or (ii) utilize the above introduced quasivariables, in which case we readily obtain the following, say kinetic, equations of motion ($l \to I$):

Hamel-type:

$$\begin{aligned} &(s)\ d/dt\left[\partial \overset{(s-1)}{T}{}^* / \partial \overset{(s)}{\theta_I}\right] - \left[\partial \overset{(s-1)}{T}{}^* / \partial \overset{(s-1)}{\theta_I}\right] \\ &- \sum \left[s\left(\partial \overset{(s)}{q_k} / \partial \overset{(s)}{\theta_I}\right)^{\cdot} - \partial \overset{(s)}{q_k} / \partial \overset{(s-1)}{\theta_I}\right] \left(\partial \overset{(s-1)}{T} / \partial \overset{(s)}{q_k}\right)^* \\ &= \sum \left(\partial \overset{(s)}{q_k} / \partial \overset{(s)}{\theta_I}\right) Q_k \equiv \Theta_I, \end{aligned} \tag{q}$$

and

Nielsen-type :

$$\begin{aligned} &(s)\left(\partial \overset{(s)}{T}{}^* / \partial \overset{(s)}{\theta_I}\right) - (s+1)\left(\partial \overset{(s-1)}{T}{}^* / \partial \overset{(s-1)}{\theta_I}\right) \\ &- \sum \left[s\left(\partial \overset{(s+1)}{q_k} / \partial \overset{(s)}{\theta_I}\right) - (s+1)\left(\partial \overset{(s)}{q_k} / \partial \overset{s-1)}{\theta_I}\right)\right] \left(\partial \overset{(s-1)}{T} / \partial \overset{(s)}{q_k}\right)^* \\ &= \Theta_I. \end{aligned} \tag{r}$$

For $s = 1$, the above yield, respectively,

$$\begin{aligned} &(\partial T^* / \partial \dot{\theta}_I)^{\cdot} - \partial T^* / \partial \theta_I \\ &\qquad - \sum [(\partial \dot{q}_k / \partial \dot{\theta}_I)^{\cdot} - \partial \dot{q}_k / \partial \theta_I](\partial T / \partial \dot{q}_k)^* = \Theta_I, \end{aligned} \tag{q1}$$

$$\begin{aligned} &\partial \dot{T}^* / \partial \dot{\theta}_I - 2(\partial T^* / \partial \theta_I) \\ &\qquad - \sum \left[\partial \ddot{q}_k / \partial \dot{\theta}_I - 2(\partial \dot{q}_k / \partial \theta_I)\right] (\partial T / \partial \dot{q}_k)^* = \Theta_I; \end{aligned} \tag{r1}$$

and, for $s = 2$,

$$2[\partial \dot{T}^*/\partial \ddot{\theta}_I]^{\cdot} - \partial \dot{T}^*/\partial \dot{\theta}_I - \sum \left[2\,(\partial \ddot{q}_k/\partial \ddot{\theta}_I)^{\cdot} - \partial \ddot{q}_k/\partial \dot{\theta}_I\right](\partial \dot{T}/\partial \ddot{q}_k)^* = \Theta_I, \tag{q2}$$

$$2(\partial \ddot{T}^*/\partial \ddot{\theta}_I) - 3\,(\partial \dot{T}^*/\partial \dot{\theta}_I) - \sum \left[2\,(\partial \ddot{q}_k/\partial \ddot{\theta}_I) - 3\,(\partial \ddot{q}_k/\partial \dot{\theta}_I)\right](\partial \dot{T}/\partial \ddot{q}_k)^* = \Theta_I. \tag{r2}$$

6.6 THE PRINCIPLE OF GAUSS (EXTENSIVE TREATMENT)

> It is quite remarkable that Nature modifies free motions incompatible with the necessary constraints in the same way in which the calculating mathematician uses least squares to bring into agreement results which are based on quantities connected to each other by necessary relations.
>
> (C. F. Gauss, 1829, *On a New General Fundamental Principle of Mechanics)*

> Gauss was not only a very eminent mathematician, but also an astronomer and geodesist, and as such, a passionate calculator of numerical results. It was he who founded the method of least squares, which he evolved with successively greater depth in three extensive treatises. If, as happened now and then, he was asked (against his will) to deliver a lecture at the University of Göttingen, his preferred topic was always the method of least squares.
>
> [A. Sommerfeld, 1964 (1940s), §48]

For complementary reading on Gauss' principle, see (alphabetically): Brill (1909, pp. 45–51), Coe (1938, pp. 421–423), Dugas (1955, pp. 367–369), Lanczos (1970, pp. 106–108), Lindsay and Margenau (1936, pp. 112–115), Mach (1960, pp. 440–443), MacMillan (1927, pp. 419–421), Volkmann (1900, pp. 355–357).

The Fundamental Theory

As was realized early in the 20th century, by Appell, Chetaev, Hamel, et al., the equations of motion of systems subject to the m nonlinear first-order constraints

$$f_D(t, \boldsymbol{r}, \boldsymbol{v}) = 0 \quad \text{(particle form)} \qquad \text{or} \qquad f_D(t, q, \dot{q}) = 0 \quad \text{(system form)}, \tag{6.6.1}$$

let alone higher-order such constraints, *cannot* be derived from Lagrange's principle (LP); the reason being that (6.6.1) cannot be attached, or adjoined, to LP—*we need its virtual form*, and it is not clear how that should be done, so as to get the correct equations of motion. For this, we need either the principle of Jourdain or Gauss' *principle of least constraint*, or *least compulsion*, or *least constriction*. The compulsion

Z (from the German *Zwang*) of a generally constrained mechanical system, in actual or kinematically possible motion, is defined as

$$\begin{aligned} Z &\equiv (1/2) \mathsf{S}\, dm\, [\boldsymbol{a} - (d\boldsymbol{F}/dm)]^2 \equiv (1/2) \mathsf{S}\, (1/dm)\, (dm\, \boldsymbol{a} - d\boldsymbol{F})^2 \\ &\equiv (1/2) \mathsf{S}\, (d\boldsymbol{R})^2/dm = (1/2) \mathsf{S}\, (-d\boldsymbol{R})^2/dm; \end{aligned} \tag{6.6.2}$$

where, as usual (§3.2), for the actual motion

$$dm\, \boldsymbol{a} = d\boldsymbol{F} + d\boldsymbol{R} \qquad (d\boldsymbol{F}:\ \textit{impressed}\ \text{force},\ d\boldsymbol{R}:\ \textit{constraint reaction}). \tag{6.6.2a}$$

The above show clearly that $Z \geq 0$; with the equal sign holding for unconstrained motion; that is, $d\boldsymbol{R} = \boldsymbol{0}$. Further, expanding (6.6.2), we readily find

$$\begin{aligned} Z &= (1/2) \mathsf{S}\, dm\, \boldsymbol{a} \cdot \boldsymbol{a} - \mathsf{S}\, d\boldsymbol{F} \cdot \boldsymbol{a} + (1/2) \mathsf{S}\, dm\, (d\boldsymbol{F}/dm)^2 \\ &= S - \mathsf{S}\, d\boldsymbol{F} \cdot \boldsymbol{a} + \cdots, \end{aligned} \tag{6.6.3}$$

where

$$S = (1/2) \mathsf{S}\, dm\, \boldsymbol{a} \cdot \boldsymbol{a}:\ \textit{Appellian}\ \text{function (§3.3 ff.)}, \tag{6.6.3a}$$

and $\ldots \equiv$ *terms not containing accelerations*, like $\boldsymbol{a}$, $\ddot{q}$, $\dot{\omega}$; that is, a function of $t, q, \dot{q}$ or ω. Obviously, the factor 1/2 in (6.6.2) is unimportant, and is frequently omitted in the literature; but, as (6.6.3) shows, it makes the connection between Z and S clearer.

Now, the principle of Gauss (GP) states that the (first) *Gaussian* variation of Z, $\delta'' Z$, to be (re)defined below, vanishes, that is,

$$\delta'' Z = 0, \tag{6.6.4}$$

for all variations of the accelerations from the actual motion, $\delta \boldsymbol{a} \equiv \delta'' \boldsymbol{a}$, *that are compatible with all the constraints, at a given time and with given positions and velocities (and impressed forces)*; that is, *for*

$$\delta'' t = 0, \quad \delta'' \boldsymbol{r} = \boldsymbol{0}, \quad \delta'' \boldsymbol{v} = \boldsymbol{0}, \quad \delta''(d\boldsymbol{F}) = \boldsymbol{0}, \qquad \textit{but} \qquad \delta'' \boldsymbol{a} \neq \boldsymbol{0}. \tag{6.6.5}$$

Since in classical mechanics $d\boldsymbol{F} = d\boldsymbol{F}(t, \boldsymbol{r}, \boldsymbol{v})$ (see, for example, Pars, 1965, pp. 11–12), we will have

$$\delta''(d\boldsymbol{F}) = \boldsymbol{0} \quad (\textit{particle}\ \text{force variation}) \qquad \text{and} \qquad \delta'' Q_k = 0 \quad (\textit{system}\ \text{force variation}), \tag{6.6.6}$$

and so GP reads

$$\begin{aligned} \delta'' Z &= (1/2) \mathsf{S}\, dm\, (2)\, [\boldsymbol{a} - (d\boldsymbol{F}/dm)] \cdot \delta'' \boldsymbol{a} \\ &= \mathsf{S}\, (dm\, \boldsymbol{a} - d\boldsymbol{F}) \cdot \delta'' \boldsymbol{a} = 0, \end{aligned} \tag{6.6.7}$$

or, in terms of the reactions,

$$\begin{aligned} \delta'' Z &= \mathsf{S}\, (d\boldsymbol{R}/dm) \cdot \delta''(d\boldsymbol{R}) = \mathsf{S}\, (d\boldsymbol{R}/dm) \cdot \delta''(dm\, \boldsymbol{a} - d\boldsymbol{F}) \\ &= \mathsf{S}\, (d\boldsymbol{R}/dm) \cdot dm\, \delta'' \boldsymbol{a} = \mathsf{S}\, d\boldsymbol{R} \cdot \delta'' \boldsymbol{a} = 0. \end{aligned} \tag{6.6.8}$$

Principle of Gauss (GP) versus Principle of Lagrange (LP)

The relation between

$$\text{LP}: \qquad S\, dm\, \boldsymbol{a} \cdot \delta \boldsymbol{r} = S\, d\boldsymbol{F} \cdot \delta \boldsymbol{r} \tag{6.6.9a}$$

and

$$\text{GP}: \qquad S\, dm\, \boldsymbol{a} \cdot \delta'' \boldsymbol{a} = S\, d\boldsymbol{F} \cdot \delta'' \boldsymbol{a}, \tag{6.6.9b}$$

that is, *the question of their mutual consistency and equivalence*, is of cardinal importance to constrained system mechanics. Since there is only one mechanics, *both LP and GP must produce the same equations of motion*. Therefore, let us begin by examining the derivation of such equations from these principles.

LP: substituting into (6.6.9a) the representation

$$\delta \boldsymbol{r} = \sum \boldsymbol{e}_k\, \delta q_k = \sum \boldsymbol{\varepsilon}_I\, \delta\theta_I, \tag{6.6.10a}$$

and recalling the arguments expounded in chapters 3 and 5, we find the *raw* form of the kinetic equations:

$$S\, dm\, \boldsymbol{a} \cdot \boldsymbol{\varepsilon}_I = S\, d\boldsymbol{F} \cdot \boldsymbol{\varepsilon}_I. \tag{6.6.10b}$$

GP: We need $\delta'' \boldsymbol{a}$. We have successively

$$\boldsymbol{v} = d\boldsymbol{r}/dt = \sum \boldsymbol{e}_k \dot{q}_k + no\ \dot{q}\ terms = \sum \boldsymbol{\varepsilon}_I\, \omega_I + no\ \omega\ terms,$$

$$\Rightarrow \boldsymbol{a} = d\boldsymbol{v}/dt = \sum \boldsymbol{e}_k\, \ddot{q}_k + no\ \ddot{q}\ terms = \sum \boldsymbol{\varepsilon}_I\, \dot{\omega}_I + no\ \dot{\omega}\ terms,$$

$$\Rightarrow \delta'' \boldsymbol{a} = \sum \boldsymbol{e}_k\, \delta\ddot{q}_k = \sum \boldsymbol{\varepsilon}_I\, \delta\dot{\omega}_I \qquad \text{[Gaussian counterpart of (6.6.10a)]}, \tag{6.6.11}$$

and, substituting this into (6.6.9b), we reobtain (6.6.10b).

Next, let us move to general *system* quasi variables. As seen in §5.2, for nonlinear (possibly nonholonomic) velocity constraints

$$\omega_D \equiv f_D(t, q, \dot{q}) = 0, \qquad \omega_I \equiv f_I(t, q, \dot{q}) \neq 0; \tag{6.6.12a}$$

$$\dot{q}_k = \dot{q}_k(t, q, \omega) = \dot{q}_k(t, q, \omega_I) \equiv F_k(t, q, \omega_I), \tag{6.6.12b}$$

we must define $\delta\theta_k$; to replace in (6.6.12a, b) ω with $\delta\theta$ and $\dot{q}$ with δq [i.e., $\delta\theta = f(t, q, \delta q)$ and $\delta q = F(t, q, \delta\theta)$] would be meaningless (useless). Instead, we are seeking a definition in which:

(i) The nonholonomic system virtual displacements, $\delta\theta$, are *linear and homogeneous* combinations of their holonomic counterparts, δq; and vice versa:

$$\delta\theta_l = \sum (\ldots)_{lk}\, \delta q_k \Leftrightarrow \delta q_k = \sum (\ldots)_{kl}\, \delta\theta_l, \tag{6.6.13}$$

so that we can attach (or adjoin) the constraints to LP; and

(ii) In the linear (Pfaffian) case, it reduces to the earlier results (chap. 2). This is accomplished by requiring compatibility between LP and GP.

(a) Indeed substituting (6.6.11) into (6.6.9b), we obtain the Gaussian form:

$$\sum \left(S\, (dm\, \boldsymbol{a} - d\boldsymbol{F}) \cdot \boldsymbol{e}_k \right) \delta\ddot{q}_k = 0; \tag{6.6.14a}$$

or, since $[(\ldots)^{\cdot}$-differentiating (6.6.12b) and then varying it à la Gauss, and setting $\delta\dot{\omega}_D = 0]$

$$\delta''(\ddot{q}_k) = \delta''\Big(\sum (\partial\dot{q}_k/\partial\omega_l)\dot{\omega}_l + no\ \dot{\omega}\ terms\Big)$$
$$= \sum (\partial\dot{q}_k/\partial\omega_l)\,\delta\dot{\omega}_l = \sum (\partial\dot{q}_k/\partial\omega_I)\,\delta\dot{\omega}_I, \tag{6.6.14b}$$

finally,

$$\sum\sum\Big\{ S\,(dm\,\boldsymbol{a} - d\boldsymbol{F})\cdot[\boldsymbol{e}_k(\partial\dot{q}_k/\partial\omega_I)]\Big\}\,\delta\dot{\omega}_I$$
$$= \sum\Big(S\,(dm\,\boldsymbol{a} - d\boldsymbol{F})\cdot\boldsymbol{\varepsilon}_I\Big)\,\delta\dot{\omega}_I = 0; \tag{6.6.14c}$$

(b) On the other hand, substituting (6.6.10a) into (6.6.9a), we obtain the Lagrangean form:

$$\sum\Big(S\,(dm\,\boldsymbol{a} - d\boldsymbol{F})\cdot\boldsymbol{e}_k\Big)\delta q_k$$
$$= \sum\Big(S\,(dm\,\boldsymbol{a} - d\boldsymbol{F})\cdot\boldsymbol{\varepsilon}_I\Big)\delta\theta_I = 0. \tag{6.6.15}$$

Now, the Gaussian variational equation (6.6.14c) can be brought into agreement with the Lagrangean (6.6.15) via the following *fundamental definition*:

$$\delta q_k \equiv \sum (\partial\dot{q}_k/\partial\omega_l)\,\delta\theta_l, \tag{6.6.16}$$

from which, inverting, we find

$$\delta\theta_l \equiv \sum (\partial\omega_l/\partial\dot{q}_k)\,\delta q_k \tag{6.6.17}$$

$$\Rightarrow \delta\theta_D \equiv \sum (\partial\omega_D/\partial\dot{q}_k)\,\delta q_k \equiv \sum (\partial f_D/\partial\dot{q}_k)\,\delta q_k = 0, \tag{6.6.17a}$$

$$\delta\theta_I \equiv \sum (\partial\omega_I/\partial\dot{q}_k)\,\delta q_k \equiv \sum (\partial f_I/\partial\dot{q}_k)\,\delta q_k \neq 0. \tag{6.6.17b}$$

Then (recalling p. 825ff.)

$$(\delta\theta_D)^{\cdot} = \sum(\partial f_D/\partial\dot{q}_k)^{\cdot}\,\delta q_k + \sum(\partial f_D/\partial\dot{q}_k)(\delta q_k)^{\cdot}\,, \tag{6.6.18a}$$

$$\delta\omega_D \equiv \delta(\dot{\theta}_D) = \delta f_D = \sum(\partial f_D/\partial q_k)\delta q_k + \sum(\partial f_D/\partial\dot{q}_k)\delta(\dot{q}_k) \text{ etc.} \tag{6.6.18b}$$

Principle of Jourdain (JP) versus Principle of Lagrange (LP)

The same conclusion — namely, (6.6.17a) — can also be reached by requiring compatibility between LP and JP:

$$S\,(dm\,\boldsymbol{a} - d\boldsymbol{F})\cdot\delta'\boldsymbol{v} = 0, \qquad \text{under} \quad \delta t = 0 \qquad \text{and} \qquad \delta\boldsymbol{r} = \boldsymbol{0}. \tag{6.6.19}$$

Successively,

$$\begin{aligned}\delta' \boldsymbol{v} &= \delta'\Big(\sum \boldsymbol{e}_k \dot{q}_k + no\ \dot{q}\ terms\Big)\\ &= \sum \boldsymbol{e}_k\ \delta' \dot{q}_k\\ &= \sum \boldsymbol{e}_k \Big(\sum (\partial \dot{q}_k/\partial \omega_l)\delta\omega_l\Big)\\ &= \sum\sum \boldsymbol{e}_k (\partial \dot{q}_k/\partial \omega_I)\,\delta\omega_I, \end{aligned} \tag{6.6.19a}$$

since (by §6.2, §6.3):

$$\delta\dot{q}_k \to \delta'\dot{q}_k = \sum (\partial\dot{q}_k/\partial\omega_l)\delta\omega_l, \tag{6.6.19b}$$

$$\delta\omega_l \to \delta'\omega_l = \sum (\partial\omega_l/\partial\dot{q}_k)\delta\dot{q}_k, \tag{6.6.19c}$$

and, inserting this into (6.6.19), we find

$$\sum\sum \Big(S(dm\,\boldsymbol{a} - d\boldsymbol{F})\cdot \boldsymbol{e}_k(\partial\dot{q}_k/\partial\omega_I)\Big)\delta\omega_I = 0. \tag{6.6.19d}$$

Again, this can be brought to the Lagrangean form (6.6.15) with the definitions (6.6.16-17b).

Equations of Motion

We already have GP in its raw form; that is, eq. (6.6.9b). To obtain its system form, we must transform (6.6.14a). Indeed, recalling standard kinematico-inertial identities (chap. 3), we find

$$\begin{aligned}\delta'' Z &= \sum\Big(S\,(dm\,\boldsymbol{a} - d\boldsymbol{F})\cdot\boldsymbol{e}_k\Big)\delta\ddot{q}_k\\ &= \sum\Big(S\,dm\,\boldsymbol{a}\cdot\boldsymbol{e}_k - S\,d\boldsymbol{F}\cdot\boldsymbol{e}_k\Big)\delta\ddot{q}_k\\ &= \sum\,[E_k(T) - Q_k]\delta\ddot{q}_k = 0. \end{aligned} \tag{6.6.20}$$

Next, to bring velocity constraints like (6.6.1) to Gaussian form—that is, to make them exhibit accelerations explicitly—*first* we $(\ldots)^{\cdot}$-differentiate them and *then* we vary them à la Gauss: $\delta''[(\ldots)^{\cdot}]$. Thus, (6.6.1) yields

Particle form:
$$\begin{aligned}\delta''(\dot{f}_D) &= \delta''\Big\{\partial f_D/\partial t + S\,[(\partial f_D/\partial\boldsymbol{r})\cdot\boldsymbol{v} + (\partial f_D/\partial\boldsymbol{v})\cdot\boldsymbol{a}]\Big\}\\ &= S\,(\partial f_D/\partial\boldsymbol{v})\cdot\delta\boldsymbol{a} = 0, \end{aligned} \tag{6.6.21a}$$

System form:
$$\begin{aligned}\delta''(\dot{f}_D) &= \delta''\Big\{\partial f_D/\partial t + \sum\,[(\partial f_D/\partial q_k)\dot{q}_k + (\partial f_D/\partial\dot{q}_k)\ddot{q}_k]\Big\}\\ &= \sum\,(\partial f_D/\partial\dot{q}_k)\,\delta\ddot{q}_k = 0\,, \end{aligned} \tag{6.6.21b}$$

$$\Big[\text{also, } (\delta'' f_D)^{\bullet} = \Big(\sum(\partial f_D/\partial\ddot{q}_k)\delta\ddot{q}_k\Big)^{\bullet} = \Big(\sum(0)\,\delta\ddot{q}_k\Big)^{\bullet} = 0\Big];$$

and, finally, adjoining the above to (6.6.9b) or to its system counterpart (6.6.20), via Lagrangean multipliers, we obtain the *general variational equation* (unconstrained variations):

$$\delta'' Z + \sum \lambda_D\,\delta''(\dot{f}_D) = 0. \tag{6.6.22}$$

From the above, all kinds of equations of motion, in *holonomic* variables flow; while for kinetic equations in *nonholonomic* variables, they follow from (6.6.7) or (6.6.9b) in connection with (6.6.11) (and similarly for kinetostatic equations). For example:

(i) Combining (6.6.7, 9b) with (6.6.21a), we get Lagrange's equations of the *first* kind:

$$dm\,\boldsymbol{a} = d\boldsymbol{F} + \sum \lambda_D\,(\partial f_D/\partial \boldsymbol{v}); \tag{6.6.23}$$

(ii) While, combining (6.6.20) with (6.6.21b), we obtain Lagrange's equations of the *second* kind (Routh–Voss equations):

$$E_k(T) \equiv (\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k = Q_k + \sum \lambda_D(\partial f_D/\partial \dot{q}_k); \tag{6.6.24a}$$

or, since $E_k(T) = \partial S/\partial \ddot{q}_k$, in their Appellian form:

$$\partial S/\partial \ddot{q}_k = Q_k + \sum \lambda_D(\partial f_D/\partial \dot{q}_k). \tag{6.6.24b}$$

REMARK

If the constraints have the form $f_D(t, \boldsymbol{r}) = 0$ $[f_D(t, q) = 0]$, it does not mean that we should set, in the right side of (6.6.23) [(6.6.24a, b)] $\partial f_D/\partial \boldsymbol{v} = \boldsymbol{0}$ $[\partial f_D/\partial \dot{q}_k = 0]$. It means that, first, we bring these constraints to Gaussian form and then we $\delta''(\ldots)$-vary them; that is, for $f_D(t, \boldsymbol{r})$, we have, successively,

$$\begin{aligned} f_D = 0 &\Rightarrow df_D/dt = \partial f_D/\partial t + S\,(\partial f_D/\partial \boldsymbol{r})\cdot \boldsymbol{v} \\ &\Rightarrow d^2 f_D/dt^2 = (\partial f_D/\partial t)^{\cdot} + S\,\big[(\partial f_D/\partial \boldsymbol{r})^{\cdot}\cdot \boldsymbol{v} + (\partial f_D/\partial \boldsymbol{r})\cdot \boldsymbol{a}\big] \\ &\Rightarrow \delta''(\ddot{f}_D) = S\,(\partial f_D/\partial \boldsymbol{r})\cdot \delta''\boldsymbol{a} = 0; \end{aligned} \tag{6.6.25}$$

and similarly for $f_D(t, q) = 0$: $\delta''(\ddot{f}_D) = \sum (\partial f_D/\partial q_k)\,\delta''\ddot{q}_k = 0$. Also, it is worth noting that, since this constraint is holonomic, the right side of (6.6.25) would have resulted even if we had *reversed* the order of differentiations:

$$\begin{aligned} \delta f_D &= S\,(\partial f_D/\partial \boldsymbol{r})\cdot \delta \boldsymbol{r} = 0 \\ &\Rightarrow (\delta f_D)^{\cdot} = S\,\big[(\partial f_D/\partial \boldsymbol{r})^{\cdot}\cdot \delta\boldsymbol{r} + (\partial f_D/\partial \boldsymbol{r})\cdot(\delta \boldsymbol{r})^{\cdot}\big] = 0, \\ &\Rightarrow (\delta f_D)^{\cdot\cdot} = S\,\big[(\partial f_D/\partial \boldsymbol{r})^{\cdot\cdot}\cdot \delta\boldsymbol{r} + 2\,(\partial f_D/\partial \boldsymbol{r})^{\cdot}\cdot(\delta \boldsymbol{r})^{\cdot} + (\partial f_D/\partial \boldsymbol{r})\cdot(\delta \boldsymbol{r})^{\cdot\cdot}\big] = 0, \end{aligned}$$

or, [invoking commutativity $\delta(\dot{\boldsymbol{r}}) = (\delta \boldsymbol{r})^{\cdot}$, etc.]

$$(\delta f_D)^{\cdot\cdot} = S\,\big[(\partial f_D/\partial \boldsymbol{r})^{\cdot\cdot}\cdot \delta\boldsymbol{r} + 2\,(\partial f_D/\partial \boldsymbol{r})^{\cdot}\cdot \delta\boldsymbol{v} + (\partial f_D/\partial \boldsymbol{r})\cdot \delta\boldsymbol{a}\big] = 0, \tag{6.6.25a}$$

$$\delta(\ldots) \Rightarrow \delta''(\ldots): \qquad (\delta'' f_D)^{\cdot\cdot} = S\,(\partial f_D/\partial \boldsymbol{r})\cdot \delta\boldsymbol{a} = 0. \tag{6.6.25b}$$

As a result of the above, equations (6.6.23, 24a, b) are replaced, respectively, by the familiar (§3.5)

$$dm\,\boldsymbol{a} = d\boldsymbol{F} + \sum \lambda_D(\partial f_D/\partial \boldsymbol{r}), \tag{6.6.26a}$$

$$(\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k = \partial S/\partial \ddot{q}_k = Q_k + \sum \lambda_D(\partial f_D/\partial q_k). \tag{6.6.26b}$$

(iii) *Appell's equations in quasi variables via Gauss' principle*. By $\delta''(\ldots)$-varying (6.6.3), we obtain

$$\delta'' Z = \delta'' S - \mathsf{S}\, d\boldsymbol{F} \cdot \delta'' \boldsymbol{a} = 0. \tag{6.6.27a}$$

But, successively,

$$\begin{aligned}
\delta'' S &= \delta'' \Big(\mathsf{S}\, (1/2)\, dm\, \boldsymbol{a}^2 \Big) \\
&= \mathsf{S}\, dm\, \boldsymbol{a} \cdot \delta'' \boldsymbol{a} \\
&= \mathsf{S}\, dm\, \boldsymbol{a} \cdot \Big(\sum \boldsymbol{\varepsilon}_k\, \delta\dot{\omega}_k \Big) \\
&= \sum \Big(\mathsf{S}\, dm\, \boldsymbol{a} \cdot \boldsymbol{\varepsilon}_k \Big)\, \delta\dot{\omega}_k \\
&= \sum (\partial S^* / \partial \dot{\omega}_k)\, \delta\dot{\omega}_k,
\end{aligned} \tag{6.6.27b}$$

and

$$\begin{aligned}
\mathsf{S}\, d\boldsymbol{F} \cdot \delta'' \boldsymbol{a} &= \mathsf{S}\, d\boldsymbol{F} \cdot \Big(\sum \boldsymbol{\varepsilon}_k\, \delta\dot{\omega}_k \Big) \\
&= \sum \Big(\mathsf{S}\, d\boldsymbol{F} \cdot \boldsymbol{\varepsilon}_k \Big)\, \delta\dot{\omega}_k \\
&= \sum \Theta_k\, \delta\dot{\omega}_k \qquad \text{(Gaussian form of Appellian virtual work);}
\end{aligned} \tag{6.6.27c}$$

and so (6.6.27a) yields

$$\delta'' Z = \sum (\partial S^* / \partial \dot{\omega}_k - \Theta_k)\, \delta\dot{\omega}_k = 0; \tag{6.6.27d}$$

that is, among kinematically admissible accelerations, *the actual (kinetic) ones make the Gaussian compulsion Z*:

$$Z = S - \sum \Theta_k\, \dot{\omega}_k + no\ \dot{\omega}\text{-}terms = Z(\dot{\omega}), \tag{6.6.28}$$

stationary (actually a *minimum*—see below).

Next, if the variations $\delta\dot{\omega}$ are *independent*, then (6.6.27d) yields the familiar Appellian equations

$$\partial S^* / \partial \dot{\omega}_k = \Theta_k. \tag{6.6.29}$$

Similarly, in holonomic variables: there, eqs. (6.6.28, 27d, 29) read, respectively,

$$Z = S - \sum Q_k\, \ddot{q}_k + no\ \ddot{q}\text{-}terms = Z(\ddot{q}), \tag{6.6.30a}$$

$$\delta'' Z = \sum (\partial S / \partial \ddot{q}_k - Q_k)\, \delta\ddot{q}_k = 0, \tag{6.6.30b}$$

$$\partial S / \partial \ddot{q}_k = Q_k. \tag{6.6.30c}$$

If, on the other hand, the variations $\delta\ddot{q}$, $\delta\dot{\omega}$ are not independent, then either we *adjoin* the constraints (in the proper form) via Lagrangean multipliers, or we *embed* them via quasi variables (see below).

Constraint Reactions (Kinetostatic Equations)

To calculate these reactions, we apply the relaxation principle (§3.7) to Z, just as in the Appellian and Lagrangean cases; that is, we calculate the *relaxed compulsion* Z as function of *all* n $\dot{\omega}$'s, then differentiate it appropriately, and, finally, enforce in it the constraints $\dot{\omega}_D = 0$ (and, of course, $\omega_D = 0$). We note that here, too,

$$(\partial Z/\partial \dot{\omega}_I)_o = \partial Z_o/\partial \dot{\omega}_I \qquad (= 0;\ I = m+1, \ldots, n), \tag{6.6.31a}$$

where

$$Z = Z(\dot{\omega}_D,\ \dot{\omega}_I):\quad \textit{relaxed compulsion}, \qquad Z_o = Z(0, \dot{\omega}_I):\quad \textit{constrained compulsion}, \tag{6.6.31b}$$

and, as usual, $(\ldots)_o \equiv (\ldots)$ *evaluated for* $\dot{\omega}_D = 0$. Hence, with the usual notations (chaps. 3 and 5), the equations of motion are

$$\textit{Kinetostatic}: \qquad (\partial Z/\partial \dot{\omega}_D)_o = (\partial S^*/\partial \dot{\omega}_D)_o - \Theta_D = \Lambda_D, \tag{6.6.32a}$$

$$\begin{aligned} \textit{Kinetic}: \qquad (\partial Z/\partial \dot{\omega}_I)_o &= \partial Z_o/\partial \dot{\omega}_I \\ &= (\partial S^*/\partial \dot{\omega}_I)_o - \Theta_I = \partial S^*{}_o/\partial \dot{\omega}_I - \Theta_I = 0; \end{aligned} \tag{6.6.32b}$$

and, in view of (6.6.31a), if no reactions are sought, we can enforce the constraints into Z right from the start, just like with S^*.

The Minimality of the Compulsion

Here, we show that for the actual constrained motion, Z is not just stationary but actually an *extremum*; specifically a *minimum*. (This can also be foreseen easily from the mathematical structure of Z: *a sum of essentially positive terms must have at least one minimum, somewhere*.)

From (6.6.2), we find

$$\begin{aligned} \Delta'' Z &\equiv Z(\boldsymbol{a} + \delta''\boldsymbol{a}) - Z(\boldsymbol{a}) \\ &= (1/2) \int dm\, [(\boldsymbol{a} + \delta''\boldsymbol{a}) - (d\boldsymbol{F}/dm)]^2 - (1/2) \int dm\, [\boldsymbol{a} - (d\boldsymbol{F}/dm)]^2 \\ &= \delta'' Z + (1/2)\, \delta''^{\,2} Z \geq 0, \end{aligned} \tag{6.6.33}$$

where

$$\delta'' Z = \int (dm\, \boldsymbol{a} - d\boldsymbol{F}) \cdot \delta''\boldsymbol{a} \quad (= 0), \tag{6.6.33a}$$

$$\delta''^{\,2} Z = \int (dm\, \delta''\boldsymbol{a} \cdot \delta''\boldsymbol{a}) \quad (\geq 0). \tag{6.6.33b}$$

No particular physical significance is to be attached to this *second-order* property of Z (as with other energetic functions of mechanics); it simply flows out of its mathematical structure.

Least Compulsion and Theory of Errors

Equation (6.6.2) can be rewritten as

$$Z = \mathcal{S}\,(-d\boldsymbol{R})^2/2\,dm = \mathcal{S}\,(\textit{Lost force})^2/2\,dm. \tag{6.6.34}$$

In the theory of *errors* (also founded by Gauss), the dm's are the "weights" of the observations, and the lost forces are their "errors."

On this matter, let us quote in detail the well-known expert Lanczos:

> Gauss was much attached to this principle because it represented a perfect physical analogy to the "method of least squares" (discovered by him and independently by Legendre), in the adjustment of errors. If a functional relation involves certain parameters which have to be determined by observations, the calculation is straightforward so long as the number of observations agrees with the number of unknown parameters. But if the number of observations exceeds the number of parameters, the equations become contradictory on account of the errors of observation. The hypothetical value of the function minus the observed value is the "error". The sum of the squares of all the individual errors is now formed, and the parameters of the problem are determined by the principle that this sum shall be a minimum. The principle of minimizing the quantity Z is completely analogous to the procedure sketched above. The $3N$ terms of the sum [the discretized (and rearranged but equivalent) version of our (6.6.2)]
>
> $$Z = \sum (m_k/2)\,(\boldsymbol{a}_k - \boldsymbol{F}_k/m_k)^2 = \sum (1/2m_k)\,(m_k\boldsymbol{a}_k - \boldsymbol{F}_k)^2 \qquad (k = 1, \ldots, N),$$
>
> correspond to $3N$ observations. This number is in excess of the number of unknowns $\ddot{q}$ on account of the m given kinematical conditions. The "error" is represented by the deviation of the impressed force $\boldsymbol{F}_k$ from the (negative of the) force of inertia "*mass times acceleration*". Even the factor $1/m_k$ in the expression for Z can be interpreted as a "weight factor", in analogy with the case of observations of different quality which are weighted according to their estimated reliability. (1970, p. 108) [A similar property holds for the center of mass G of N particles of masses m_k with Cartesian coordinates (x_k, y_k, z_k): *the coordinates of* $G\,(x, y, z)$ *minimize the expression*
>
> $$\sum m_k\left[(x_k - x)^2 + (y_k - y)^2 + (z_k - z)^2\right].]$$

Motivation for and Geometrical–Physical Meaning of Gauss' Principle

(i) Unconstrained versus Actual Constrained Motion

Let us consider a particle P of mass dm, possibly part of a larger system S, in actual *constrained* motion along a curve c, under a total impressed force $d\boldsymbol{F}$ and a total constraint reaction $d\boldsymbol{R}$. Let P, at the generic neighboring instants t and $t + \tau$, be at the neighboring c-points M and C, respectively (fig. 6.2). Then, by Taylor's theorem, to the second τ-order,

$$\begin{aligned}\Delta\boldsymbol{r} \equiv \boldsymbol{OC} - \boldsymbol{OM} &= (\boldsymbol{OM} + \boldsymbol{MA} + \boldsymbol{AC}) - \boldsymbol{OM} = \boldsymbol{MC}\\ &= \boldsymbol{r}(t + \tau) - \boldsymbol{r}(t) = \boldsymbol{v}\,\tau + (1/2)\boldsymbol{a}\,\tau^2.\end{aligned} \tag{6.6.35a}$$

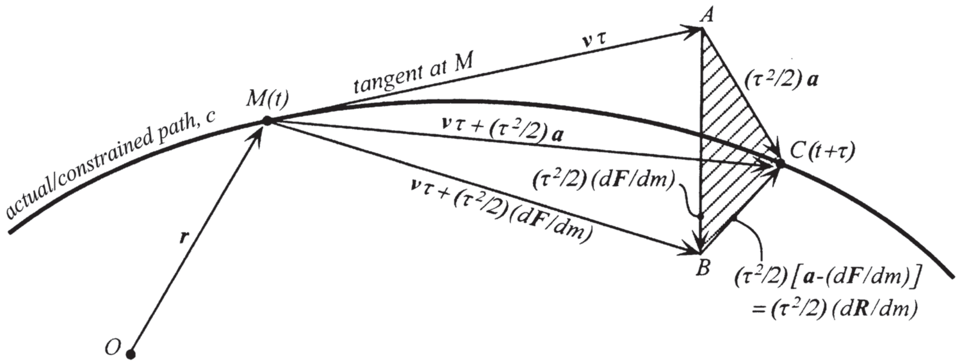

Figure 6.2 Geometrical interpretation of Gauss' constraint-compulsion:
$\boldsymbol{MA} = \boldsymbol{v}\,\tau$, $\quad \boldsymbol{MC} = \boldsymbol{v}\,\tau + (1/2)\boldsymbol{a}\,\tau^2$, $\quad \boldsymbol{MB} = \boldsymbol{v}\,\tau + (1/2)(d\boldsymbol{F}/dm)\tau^2$
$\Rightarrow\ \boldsymbol{BC} = \boldsymbol{MC} - \boldsymbol{MB} = (1/2)[\boldsymbol{a} - (d\boldsymbol{F}/dm)]\tau^2 = (1/2)[(d\boldsymbol{R}/dm)]\tau^2$.

On the other hand, if P was *unconstrained* or *free*—that is, if $d\boldsymbol{R} = \boldsymbol{0}$—then, even if it started with the *same initial conditions at M as in the actual constrained motion*—that is, $\boldsymbol{r}(t) = \boldsymbol{r}$ and $\dot{\boldsymbol{r}}(t) = \boldsymbol{v}$—since, then, $\boldsymbol{a} = d\boldsymbol{F}/dm$, at time $t + \tau$ the particle would end up somewhere *outside* c, say at B, where

$$\boldsymbol{OB} = \boldsymbol{OM} + \boldsymbol{MA} + \boldsymbol{AB} = \boldsymbol{r} + \boldsymbol{v}\,\tau + (1/2)\,(d\boldsymbol{F}/dm)\tau^2. \tag{6.6.35b}$$

Therefore, the *deviation* vector, *between the unconstrained and constrained motions*, during τ, is

$$\begin{aligned}\boldsymbol{OC} - \boldsymbol{OB} &= \boldsymbol{MC} - \boldsymbol{MB} = \boldsymbol{AC} - \boldsymbol{AB} = \boldsymbol{BC}\\ &= (1/2)[\boldsymbol{a} - (d\boldsymbol{F}/dm)]\tau^2 = (1/2)\,(d\boldsymbol{R}/dm)\tau^2;\end{aligned} \tag{6.6.35c}$$

and so [recalling (6.6.2)], the (elementary) *compulsion* of P, dZ, is

$$dZ \equiv (dm/2)\,[\boldsymbol{a} - (d\boldsymbol{F}/dm)]^2 = (dm/2)\,(d\boldsymbol{R}/dm)^2 = (2\,dm/\tau^4)\,(\boldsymbol{BC})^2; \tag{6.6.35d}$$

and from this it follows that the (total) compulsion of S, Z, is

$$\begin{aligned}Z &= \textstyle S\, dZ\\ &= \textstyle S\,(dm/2)\,[\boldsymbol{a} - (d\boldsymbol{F}/dm)]^2 = S\,(dm/2)\,(d\boldsymbol{R}/dm)^2\\ &= (2/\tau^4)\,\textstyle S\, dm\,(\boldsymbol{BC})^2\end{aligned} \tag{6.6.35e}$$

[= *Sum of* (*mass*) *weighted deviations between unconstrained and constrained motions* (to within an unimportant, "Gaussianly constant," factor)].

Why up to the second order, in (6.6.35d, e)? To the *first* order, clearly, $A = C = B$; that is, the deviation vanishes; while *higher than second* τ-orders would have introduced *variations in the forces* $d\boldsymbol{F}$ *and* $d\boldsymbol{R}$—something undesirable in the derivation of equations of motion at t, M.

(ii) Kinematically Admissible Constrained versus Actual Constrained Motion

Under a Gaussianly kinematically admissible acceleration $\boldsymbol{a} + \Delta''\boldsymbol{a} = \boldsymbol{a} + \delta''\boldsymbol{a} \equiv \boldsymbol{a}'$, the particle P, starting again from A [with the same initial conditions $\boldsymbol{r}(t) = \boldsymbol{r}$ and $\dot{\boldsymbol{r}}(t) = \boldsymbol{v}$], would have ended at $t + \tau$, say at C' (fig. 6.3).
Gauss' principle states that, *for the kinetically correct acceleration*, $C' \to C$. Let us examine the geometry of the "compulsion triangle" BCC'. From fig. 6.3, we readily obtain

$$\begin{aligned} &\boldsymbol{BC}' = \boldsymbol{BC} + \boldsymbol{CC}' \\ &\Rightarrow (\boldsymbol{BC}')^2 = (\boldsymbol{BC})^2 + (\boldsymbol{CC}')^2 + 2\,\boldsymbol{BC}\cdot\boldsymbol{CC}', \end{aligned} \tag{6.6.36a}$$

($2\boldsymbol{BC}\cdot\boldsymbol{CC}' = 2|\boldsymbol{BC}|\,|\boldsymbol{CC}'|\cos(\boldsymbol{BC}, \boldsymbol{CC}') = -2|\boldsymbol{BC}|\,|\boldsymbol{CC}'|\cos\theta$) and, therefore, recalling the interpretations (6.6.35d, e),

$$\begin{aligned} Z' &\equiv \mathsf{S}\,(dm/2)\,[\boldsymbol{a}' - (d\boldsymbol{F}/dm)]^2 \quad \left\{= \mathsf{S}\,(dm/2)\,[(\boldsymbol{a} + \delta''\boldsymbol{a}) - (d\boldsymbol{F}/dm)]^2\right\} \\ &= (2/\tau^4)\,\mathsf{S}\,dm\,(\boldsymbol{BC}')^2 \\ &= (2/\tau^4)\,\mathsf{S}\,dm\left[(\boldsymbol{BC})^2 + (\boldsymbol{CC}')^2 + 2\,\boldsymbol{BC}\cdot\boldsymbol{CC}'\right] \\ &= (2/\tau^4)\,\mathsf{S}\,dm\Big\{\left[(\tau^2/2)\,(\boldsymbol{a} - d\boldsymbol{F}/dm)\right]^2 + \left[(\tau^2/2)\,\delta''\boldsymbol{a}\right]^2 \\ &\qquad\qquad + 2\left[(\tau^2/2)\,(\boldsymbol{a} - d\boldsymbol{F}/dm)\right]\cdot\left[(\tau^2/2)\,\delta''\boldsymbol{a}\right]\Big\} \\ &= \mathsf{S}\,(dm/2)\,(\boldsymbol{a} - d\boldsymbol{F}/dm)^2 + \mathsf{S}\,dm\,(\boldsymbol{a} - d\boldsymbol{F}/dm)\cdot\delta''\boldsymbol{a} \\ &\qquad\qquad + \mathsf{S}\,(dm/2)\,(\delta''\boldsymbol{a})^2 \\ &= Z + \Delta Z \\ &= Z + \delta''Z + (1/2)\,\delta''^{\,2}Z \;=\; Z + 0 + (1/2)\,\delta''^{\,2}Z, \end{aligned} \tag{6.6.36b}$$

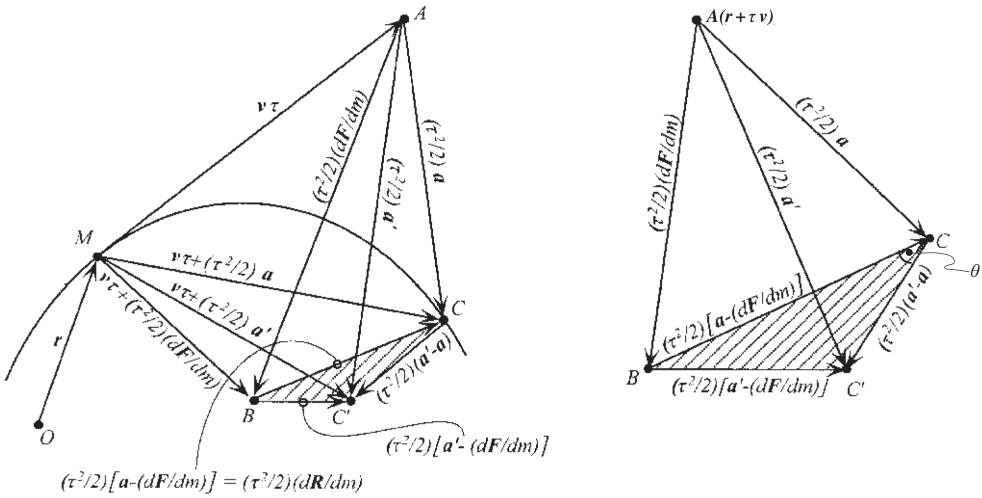

Figure 6.3 Constrained compulsion: kinematically admissible (C') versus actual (C); and detail of "compulsion triangle" BCC'.

from which, since

$$\Delta Z \equiv Z' - Z = (1/2)\,\delta''^{\,2} Z = (1/2) \mathsf{S}\, dm\,(\delta'' \boldsymbol{a})^2 \geq 0 \qquad [= 0,\ \text{for } \delta''\boldsymbol{a} = \boldsymbol{0}]$$

we conclude that

$$Z' \sim \mathsf{S}\, dm\,(\boldsymbol{BC}')^2 \ > \ Z \sim \mathsf{S}\, dm\,(\boldsymbol{BC})^2; \tag{6.6.36c}$$

that is, the actual acceleration minimizes the compulsion.

An additional, "minimum norm" interpretation of the above is known in the largely self-explanatory fig. 6.4 [see texts on applied/numerical linear algebra: least squares fitting of data; also, least squares derivation of Fourier series coefficients].

On the Uniqueness of the GP Solutions

The question of the uniqueness, or lack thereof, of the equations of motion obtained from the minimization, or *stationarization*, of Z is, obviously, of practical and physical importance. This is answered by the following considerations: *as long as rank* $(\partial f_D/\partial \dot{q}_k) = m$ (*regular* case), eliminating the *m dependent* $\ddot{q}_D$'s via the constraints, we will be able to express the *particle accelerations* $\boldsymbol{a}$ *as linear combinations of the* $n - m$ *independent* $\ddot{q}_I$'s *or* $\dot{\omega}_I$'s; and therefore Z will be a *quadratic* function in these variables. Hence, differentiating Z with respect to the independent system accelerations will result in a system of $n - m$ *linear* equations in them, and that system will have a *unique* solution. The dependent accelerations can then be determined uniquely from the constraint conditions, properly differentiated.

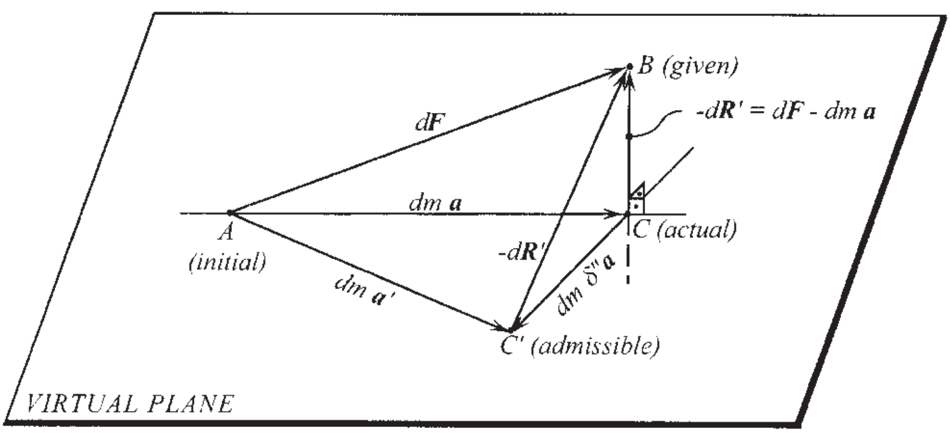

Figure 6.4 Minimum norm interpretation of minimality of Gaussian compulsion.
$dm\,\boldsymbol{a} = d\boldsymbol{F} + d\boldsymbol{R}$,
$A(t, \boldsymbol{r}, \boldsymbol{v})$: initial state, à la Gauss; $\boldsymbol{AB} = d\boldsymbol{F}$ (i.e., B: given);
Locus of C': virtual plane through $A(t, \boldsymbol{r}, \boldsymbol{v})$;
$\boldsymbol{AC}' = dm\,(\boldsymbol{a} + \delta''\boldsymbol{a}) \equiv dm\,\boldsymbol{a}'$: kinematically admissible accelerations à la Gauss;
$\boldsymbol{C}'\boldsymbol{B} = d\boldsymbol{F} - dm\,\boldsymbol{a}' \equiv -d\boldsymbol{R}'$ (C': admissible position);
$\boldsymbol{CB} = -d\boldsymbol{R} = d\boldsymbol{F} - dm\,\boldsymbol{a}$ (C: actual position)
$\Rightarrow\ \boldsymbol{CC}' = dm\,\delta''\boldsymbol{a}$, $\boldsymbol{AC} = dm\,\boldsymbol{a}$;
$|\boldsymbol{C}'\boldsymbol{B}| = |-d\boldsymbol{R}'|$: absolute value (norm) of admissible constraint reaction;
Gauss' principle: $|\boldsymbol{BC}'| = |d\boldsymbol{R}'| = minimum \Rightarrow C' = C$ (BC normal to virtual plane).

In sum, *excluding singular cases*, the positive definite function Z will have a minimum at only one "point."

[The singular case, with its important consequence, seems to have been noticed first by the distinguished German mathematician P. Stäckel (in 1919). As he put it: in singular configurations, it is not possible to deduce the principle of Gauss from that of d'Alembert. Rather, for singular configurations one must *postulate* Gauss' principle. Then, the argument presented in (6.2.2 ff.) no longer holds! For examples of the violation of this uniqueness of the minimum of Z in singular cases — that is, where LP and Lagrange's equations fail to determine the accelerations uniquely, but GP does — see, for example, Nordheim (1927, pp. 65–66, and references therein), Golomb (1961, pp. 69–72); and, for a comprehensive contemporary treatment, Pfister (1995).]

On the History of GP

Gauss himself never gave a precise mathematical formulation of his principle; that is, our equations (6.6.2–9). Instead, he stated it as follows:

> The motion of a system of material points, connected with each other in an arbitrary way and subjected to arbitrary influences takes place at every instant, in the most perfect accordance possible with the motion that they would have if they became completely free, that is to say, with the smallest possible constraint, taking as measure of the constraint [that the system goes through] during an infinitesimally small instant, the sum of the products of the mass of each point with the square of the quantity by which it deviates from the position that it would have taken, if it had been free. [*J. für Mathematik (Crelle)*, 1829, vol. 4, p. 232]

Perhaps this lack of quantitative formulation of the principle may explain its relative obscurity, compared with LP, throughout the 19th century and a fair part of the early 20th—one imagines the fate of the original, highly qualitative and primitive, principle of d'Alembert (of 1743) without Lagrange's formulation (of 1764). The first analytical expression for Z, in rectangular Cartesian coordinates, seems to have been given by Jacobi [1847–1848, lecture notes on Analytical Mechanics (publ. 1996, pp. 96–100); see also Appell, 1953, pp. 497–498] and Scheffler (in 1858). They wrote (with some obvious notations and without the factor 1/2)

$$Z = \sum m_k \left[(\ddot{x}_k - X_k/m_k)^2 + (\ddot{y}_k - Y_k/m_k)^2 + (\ddot{z}_k - Z_k/m_k)^2\right]. \qquad (6.6.37)$$

However, the first precise formulation of GP as a *minimum* condition, with Z expressed in general system coordinates q_k, and with the explicit realization that for this to happen only the accelerations should be varied, while the positions, velocities, and time must be treated as constant, is due to Lipschitz (*Crelle's J.*, 1877, vol. 82, p. 323); and, over the next 35 years or so (1877–1913), he and a few other distinguished mechanicians/physicists/mathematicians (including Schering, Gibbs, Mayer, Hertz, Voss, Brell, Schenkl, Wassmuth, Brill, and Mach) did for GP what Lagrange did for d'Alembert's principle. In particular, Gibbs (1879) extended the principle to *inequality* (or *unilateral*) constraints:

$$\delta\Big(\mathsf{S}\, dm\, \boldsymbol{a}^2/2\Big) - \mathsf{S}\, d\boldsymbol{F}\cdot\delta\boldsymbol{a} \geq 0 \qquad \text{or} \qquad \delta'' Z \;\geq\; 0; \qquad (6.6.38)$$

while Appell (in the late 1890s) applied it successfully to the formulation of his nonholonomic system equations. In most of the 20th century English language literature, GP has been barely tolerated as a clever but essentially useless academic curiosity, when it was mentioned at all. The only applications of it have appeared in problems of *impulsive motion* (with accelerations replaced by velocities), in British texts (§ 4.6).

However, this short-sighted situation seems to be changing for the better: in recent decades, GP has been experiencing a vigorous revival, in connection with *analytical/computational approximate* methods in such diverse areas of mechanics as nonlinear oscillations, multibody dynamics, heat transfer, structural analysis, elastic/plastic buckling, shell theory, and so on. [See, for example, Girtler (1928), Lilov and Lorer (1982), Lilov (1984), Vujanovic and Jones (1989, chap 7; this also contains a "complementary" formulation of GP where *the accelerations are kept fixed and the impressed forces are varied*), and Udwadia and Kalaba (1996). For the *continuum* formulation of GP, see, for example, Brill (1909), Hellinger (1914, pp. 633–635), and Truesdell and Toupin (1960, pp. 605–606).] Along with other DVP, GP has the big advantage over *time-integral* variational principles that — for discrete systems, at least — its application involves only ordinary differential calculus on a quadratic function of the acceleration components, and not variational calculus.

Example 6.6.1 *An ad hoc but Instructive Derivation of GP from LP (Nonsingular Cases).* Applying LP for $t + dt \equiv t + \tau$, where τ is an arbitrarily small time interval, we have

$$S\, dm\, \boldsymbol{a}(t+\tau) \cdot \delta \boldsymbol{r}(t+\tau) = S\, d\boldsymbol{F}\,(t+\tau) \cdot \delta \boldsymbol{r}(t+\tau). \tag{a}$$

Then, substituting into (a) the *special variation* (neglecting higher than τ^2-order terms), we get

$$\begin{aligned}\delta \boldsymbol{r}(t+\tau) &= \delta'' \boldsymbol{r}(t+\tau)\\ &= \delta''\big[\boldsymbol{r}(t) + \boldsymbol{v}(t)\tau + (\tau^2/2)\boldsymbol{a}(t) + \cdots\big] = (\tau^2/2)\,\delta'' \boldsymbol{a}(t),\end{aligned} \tag{b}$$

and simplifying, and renaming $\delta'' \boldsymbol{a}(t) = \delta \boldsymbol{a}(t)$, we obtain (the differential form of) GP:

$$S\, dm\, \boldsymbol{a}(t) \cdot \delta \boldsymbol{a}(t) = S\, d\boldsymbol{F}(t) \cdot \delta \boldsymbol{a}(t), \qquad \text{Q.E.D.} \tag{c}$$

Example 6.6.2 Using Gauss' principle, let us obtain the equations of motion of the system shown in fig. 6.5. (All pulleys and cables are assumed massless.)

Here, $n = 3$, $m = 1$: $q_{1,2,3} = x_A,\ x_B,\ x_C$; and, clearly, the sole constraint among them is

$$2\,x_A + x_B + x_C = constant, \tag{a}$$

or, in Gaussian form,

$$[eq.\ (a)]^{\cdot\cdot} = 0: \qquad 2\,\ddot{x}_A + \ddot{x}_B + \ddot{x}_C = 0. \tag{b}$$

Gauss' principle requires that we minimize the system compulsion (with easily understood notations, and $k = 1, 2, 3 \Rightarrow A, B, C$; i.e. $Q_k \to Q_{1,2,3} = 3W, 2W, W$):

$$Z = \sum (1/2m_k)\,(X_k - m_k \ddot{x}_k)^2, \qquad \text{under} \quad (a)^{\cdot\cdot} = (b) = 0. \tag{c}$$

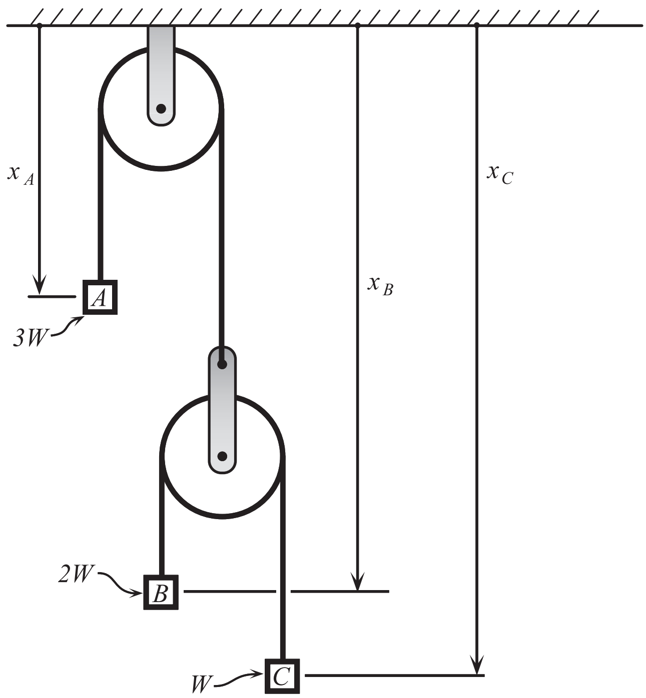

Figure 6.5 Motion of a system of three constrained particles *A*, *B*, *C* in a vertical plane [*gravity*: *g* (downward)].

This leads us readily to the constrained Gaussian variational equation

$$\delta Z = 0: \qquad [3W - (3W/g)\ddot{x}_A]\,\delta\ddot{x}_A + [2W - (2W/g)\ddot{x}_B]\,\delta\ddot{x}_B + [W - (W/g)\ddot{x}_C]\,\delta\ddot{x}_C = 0, \tag{d}$$

under

$$\delta''[eq.\ (a)^{\cdot\cdot}] = \delta''[eq.\ (b)] = \delta[eq.\ (b)]: \qquad 2\,\delta\ddot{x}_A + \delta\ddot{x}_B + \delta\ddot{x}_C = 0. \tag{e}$$

Application of the multiplier rule to the above leads at once to the three Routh–Voss equations of motion

$$(3W/g)\ddot{x}_A = 3W - 2\lambda, \tag{f1}$$

$$(2W/g)\ddot{x}_B = 2W - \lambda, \tag{f2}$$

$$(3W/g)\ddot{x}_C = W - \lambda; \tag{f3}$$

which, along with (a) constitute a determinate system for the four unknowns $x_{A,B,C}(t)$, $\lambda(t)$. [Since $-S_A\,\delta x_A = -2\,\lambda\,\delta x_A$, and $-S_B\,\delta x_B = -\lambda\,\delta x_B$, $-S_C\,\delta x_C = -\lambda\,\delta x_C$, λ equals either of the cable tensions S_B or S_C.]

Indeed, solving (f1–3) for $\ddot{x}_{A,B,C}$ in terms of λ and substituting the results into $[eq.\ (a)]^{\cdot\cdot} = eq.\ (b)$, we readily find $\lambda = (24/17)\ W$. Then, (f1–3) yield immediately

$$\ddot{x}_A = (1/17)\,g, \qquad \ddot{x}_B = (5/17)\,g, \qquad \ddot{x}_C = (7/17)\,g. \tag{g}$$

The solution of this problem via Jourdain's principle should be obvious.

Example 6.6.3 Using Gauss' principle and the method of relaxation of the constraints (§3.7), let us find the motion and reaction of a (plane) mathematical pendulum, of mass m and length l.

In polar coordinates r, ϕ (angle of pendulum's thread with vertical), the (physical) components of the acceleration of the pendulum's bob P are

$$\textit{radial}: \quad a_r = \ddot{r} - r\,(\dot{\phi})^2, \qquad \textit{tangential}: \quad a_\phi = 2\,\dot{r}\,\dot{\phi} + r\,\ddot{\phi}. \tag{a}$$

Therefore (and since these are orthogonal curvilinear coordinates), the *relaxed* system compulsion is [recalling (6.6.3), with S = Appellian function and T = thread tension]

$$\begin{aligned} Z &= S - [(Q_r + R_r)a_r + (Q_\phi + R_\phi)a_\phi] \\ &= (m/2)\Big\{[\ddot{r} - r\,(\dot{\phi})^2]^2 + (2\,\dot{r}\,\dot{\phi} + r\,\ddot{\phi})^2\Big\} \\ &\quad - \Big\{(m\,g\cos\phi - T)\,[\ddot{r} - r\,(\dot{\phi})^2] + (-m\,g\,r\sin\phi + 0)\,(2\,\dot{r}\,\dot{\phi} + r\,\ddot{\phi})\Big\}, \end{aligned}$$

and so, to within *Gauss-important terms*,

$$\begin{aligned} Z &= Z(\ddot{r},\ \ddot{\phi}) \\ &= (m/2)\,\Big[(\ddot{r})^2 - 2\,r\,(\dot{\phi})^2\ddot{r} + r^2\,(\ddot{\phi})^2 + 4\,r\,\dot{r}\,\dot{\phi}\,\ddot{\phi}\Big] \\ &\quad - m\,g\cos\phi\,\ddot{r} + m\,g\,r\sin\phi\,\ddot{\phi} + T\,\ddot{r}. \end{aligned} \tag{b}$$

Hence, the equations of motion are

$$\textit{Kinetostatic}: \quad (\partial Z/\partial\ddot{r})_{r=l} = 0: \quad [m\,\ddot{r} - m\,r\,(\dot{\phi})^2 - m\,g\cos\phi]_{r=l} = -T,$$
$$\Rightarrow m\,l\,(\dot{\phi})^2 = -m\,g\cos\phi + T, \tag{c1}$$

$$\textit{Kinetic}: \quad (\partial Z/\partial\ddot{\phi})_{r=l} = 0: \quad (m\,r^2\,\ddot{\phi} + 2\,m\,r\,\dot{r}\,\dot{\phi} + m\,g\,r\sin\phi)_{r=l} = 0,$$
$$\Rightarrow \ddot{\phi} + (g/l)\sin\phi = 0. \tag{c2}$$

We notice that (c2) can also be obtained from

$$\partial Z_o/\partial\ddot{\phi} = 0, \tag{d}$$

where Z_o is the *constrained* system compulsion:

$$Z_o = Z\big|_{r=l} = (m\,l^2/2)\,(\ddot{\phi})^2 + m\,g\,r\sin\phi\,\ddot{\phi}. \tag{e}$$

Example 6.6.4 (Hamel, 1949, pp. 787–789). Using Gauss' principle (GP), let us find the equations of motion of a rigid body that rotates about a fixed point O, under a total impressed moment $\boldsymbol{M}_O$ and, also, constrained by

$$f(t, \boldsymbol{\omega}, \boldsymbol{\alpha}) = 0; \qquad \boldsymbol{\omega}, \boldsymbol{\alpha}\text{: angular velocity and acceleration of the body.} \tag{a}$$

Substituting into GP, (6.6.9b), the well-known kinematical relation (§1.7)

$$\boldsymbol{a} = d\boldsymbol{v}/dt = d/dt(\boldsymbol{\omega}\times\boldsymbol{r}) = \boldsymbol{\alpha}\times\boldsymbol{r} + \boldsymbol{\omega}\times(\boldsymbol{\omega}\times\boldsymbol{r}), \tag{b}$$

and its Gaussian variation

$$\delta'' \boldsymbol{a} = \delta\boldsymbol{\alpha} \times \boldsymbol{r}, \tag{c}$$

we get

$$\mathbf{S}\, dm\, \boldsymbol{a} \cdot (\delta\boldsymbol{\alpha} \times \boldsymbol{r}) = \mathbf{S}\, d\boldsymbol{F} \cdot (\delta\boldsymbol{\alpha} \times \boldsymbol{r}), \tag{d}$$

or, rearranging,

$$\left(\mathbf{S}\, \boldsymbol{r} \times dm\, \boldsymbol{a}\right) \cdot \delta\boldsymbol{\alpha} = \left(\mathbf{S}\, \boldsymbol{r} \times d\boldsymbol{F}\right) \cdot \delta\boldsymbol{\alpha}, \tag{e}$$

or, finally (with the usual notations),

$$(d\boldsymbol{H}_O/dt) \cdot \delta\boldsymbol{\alpha} = \boldsymbol{M}_O \cdot \delta\boldsymbol{\alpha}. \tag{f}$$

The above must hold for any variation $\delta\boldsymbol{\alpha}$ satisfying (a):

$$\delta'' f = 0: \qquad (\partial f/\partial\boldsymbol{\alpha}) \cdot \delta\boldsymbol{\alpha} = 0. \tag{g}$$

Adjoining (g) to (f) via the Lagrangean multiplier λ and then setting the (total) coefficient of $\delta\boldsymbol{\alpha}$ equal to zero, we find

$$d\boldsymbol{H}_O/dt = \boldsymbol{M}_O + \lambda(\partial f/\partial\boldsymbol{\alpha}). \tag{h}$$

For example, if

$$f = \boldsymbol{\alpha} \cdot (\boldsymbol{\omega} \times \boldsymbol{H}_O) = 0 \qquad \text{(i.e., if } \boldsymbol{\alpha},\ \boldsymbol{\omega}, \text{ and } \boldsymbol{H}_O \text{ are coplanar)}, \tag{i}$$

then (h) yields

$$d\boldsymbol{H}_O/dt = \boldsymbol{M}_O + \lambda(\boldsymbol{\omega} \times \boldsymbol{H}_O); \tag{j}$$

or, in components along *body-fixed* principal axes at O [with $d\boldsymbol{H}_O/dt = d'\boldsymbol{H}_O/dt + \boldsymbol{\omega} \times \boldsymbol{H}_O$, and easily understood notations (§1.17)],

$$A\,(d\omega_x/dt) + (C - B)\,(1 - \lambda)\,\omega_y\,\omega_z = M_{O,x}, \tag{k1}$$

$$B\,(d\omega_y/dt) + (A - C)\,(1 - \lambda)\,\omega_x\,\omega_z = M_{O,y}, \tag{k2}$$

$$C\,(d\omega_z/dt) + (B - A)\,(1 - \lambda)\,\omega_x\,\omega_y = M_{O,z}; \tag{k3}$$

while the constraint reads, since then $\boldsymbol{H}_O = (A\,\omega_x,\ B\,\omega_y,\ C\,\omega_z)$,

$$\begin{vmatrix} d\omega_x/dt & d\omega_y/dt & d\omega_z/dt \\ \omega_x & \omega_y & \omega_z \\ A\,\omega_x & B\,\omega_y & C\,\omega_z \end{vmatrix} = 0, \tag{l}$$

or, in extenso,

$$(d\omega_x/dt)\,(C - B)\,\omega_y\,\omega_z + (d\omega_y/dt)\,(A - C)\,\omega_z\,\omega_x + (d\omega_z/dt)\,(B - A)\,\omega_x\,\omega_y = 0. \tag{m}$$

Equations (k1–3) and (l or m) constitute a system of four equations for $\omega_{x,\,y,\,z}(t),\ \lambda(t)$.

For additional details on special cases, see Hamel (1949, pp. 788–789).

Example 6.6.5 *Förster's Principle* (Förster, 1903; Whittaker, 1937, p. 262). Let T and V denote the kinetic and potential energies of a dynamical system. Show that

$$2(\ddot{V} + S) \equiv 2\ddot{V} + \mathsf{S}\, dm\ [(\ddot{x})^2 + (\ddot{y})^2 + (\ddot{z})^2] \tag{a}$$

differs from

$$\mathsf{S}\,(1/dm)\ \big[(dm\ \ddot{x} + \partial V/\partial x)^2 + (dm\ \ddot{y} + \partial V/\partial y)^2 + (dm\ \ddot{z} + \partial V/\partial z)^2\big] \tag{b}$$

by a quantity that does *not* involve accelerations. Hence, deduce that

$$\begin{aligned}\Theta &\equiv \ddot{T} - S\\ &\equiv \ddot{T} - \mathsf{S}\,(dm/2)\ [(\ddot{x})^2 + (\ddot{y})^2 + (\ddot{z})^2]\end{aligned} \tag{c}$$

is a maximum when the accelerations have the values corresponding to the actual motion, as compared with all motions that are consistent with the constraints and satisfy the same integral of energy, and that have the same values of the coordinates and velocities at the instant considered, provided the constraints do no work.

Let us show that

$$2\,Z - (2\,\ddot{V} + 2\,S) = 2\,(Z - S - \ddot{V}) \equiv \phi(t,\,q,\,\dot{q}). \tag{d}$$

This follows immediately from (6.6.3), if we note that, since $V = V(q)$,

$$\begin{aligned}\dot{V} &= \sum (\partial V/\partial q_k)\dot{q}_k = -\sum Q_k \dot{q}_k\\ \Rightarrow \ddot{V} &= -\sum \dot{Q}_k \dot{q}_k - \sum Q_k \ddot{q}_k\\ &= -\sum Q_k \ddot{q}_k + no\ \ddot{q}\ terms\end{aligned} \tag{e}$$

$$[Q_k = Q_k(q) \Rightarrow \dot{Q}_k = \dot{Q}_k(q,\,\dot{q})].$$

Next, let us show that Θ is a maximum, under the above-stated (Gaussian) restrictions. By $(\ldots)^{\cdot}$-differentiating the energy conservation equation: $T + V = constant$, yields $\ddot{T} = -\ddot{V}$, and therefore $\Theta = -\ddot{V} - S$, or explicitly, since $V = V(\mathbf{r})$,

$$\begin{aligned}-\Theta &= \mathsf{S}\,[(\partial V/\partial \mathbf{r})\cdot \boldsymbol{a} + no\ \boldsymbol{a}\text{-}terms] + \mathsf{S}\,(1/2)\ dm\ \boldsymbol{a}\cdot\boldsymbol{a}\\ &= \mathsf{S}\,(1/2\ dm)\ [dm\ \boldsymbol{a} + \partial V/\partial \mathbf{r}]^2 + no\ \boldsymbol{a}\text{-}terms\\ &= \mathsf{S}\,(dm/2)\ [\boldsymbol{a} + (\partial V/\partial \mathbf{r})/dm]^2 + no\ \boldsymbol{a}\text{-}terms\\ &= Z + no\ \boldsymbol{a}\text{-}terms,\end{aligned} \tag{f}$$

and, therefore, since Z is a *minimum* [eqs. (6.6.33–33b)], Θ will be a *maximum*, Q.E.D.

If, in Förster's terminology, we call $\ddot{T}$ *acceleration of kinetic energy*, and S *kinetic energy of accelerations*, then we can formulate his principle as follows: among all motions that (i) are admissible in a Gaussian sense and (ii) preserve the total energy of the system, the actual one maximizes the function "acceleration of the kinetic energy minus kinetic energy of the accelerations."

HISTORICAL REMARK

This "principle" was formulated in 1903, in order to reduce to mechanical principles (e.g., that of Gauss) another qualitative and ad hoc "principle" by the famous physical chemist W. Ostwald. As such, Förster's result, although today it may appear as an academic curiosity, at its time represented another victory of the *molecular/atomistic* viewpoint (of Boltzmann) over the *phenomenological/energetic* viewpoint of Ostwald, Helm, Mach, et al.

Example 6.6.6 *Explicit Form of the Gaussian Compulsion of a Scleronomic System, in Lagrangean Coordinates.* (This example requires some familiarity with general tensors.) Substituting into (6.6.3) the acceleration expression

$$\begin{aligned}\boldsymbol{a} &\equiv d\boldsymbol{v}/dt = d/dt\Big(\sum \dot{q}_k \boldsymbol{e}_k\Big)\\ &= \sum\Big(\ddot{q}_k + \sum\sum c^k{}_{rs}\,\dot{q}_r\dot{q}_s\Big)\boldsymbol{e}_k \equiv \sum a_k\boldsymbol{e}_k, \qquad \text{(a)}\end{aligned}$$

where

$$\Big[\partial\boldsymbol{e}_r/\partial q_s = \partial\boldsymbol{e}_s/\partial q_r \equiv \sum c^k{}_{rs}\,\boldsymbol{e}_k = \sum c^k{}_{sr}\,\boldsymbol{e}_k \Rightarrow \text{(and here is where tensors are needed)}\Big]:$$

$$(\partial\boldsymbol{e}_r/\partial q_s)\cdot\boldsymbol{e}_k \equiv c_{k,rs} = c_{k,sr}\text{: particle Christoffel symbols of the 1}st\text{ kind},$$

and recalling that (§3.10)

$$\mathcal{S}\, dm\ (\partial\boldsymbol{e}_r/\partial q_s)\cdot\boldsymbol{e}_k \equiv \mathcal{S}\, dm\ c_{k,rs} = \Gamma_{k,rs} = \Gamma_{k,sr} \qquad \text{and} \qquad \Gamma_{l,rs} \equiv \sum M_{lk}\Gamma^k{}_{rs}, \qquad \text{(b)}$$

we find, successively (recall derivation in §3.11),

$$\begin{aligned}Z &= (1/2)\,\mathcal{S}\, dm\Big(\sum a_k\boldsymbol{e}_k\Big)\cdot\Big(\sum a_l\boldsymbol{e}_l\Big) - \mathcal{S}\, d\boldsymbol{F}\cdot\Big(\sum a_k\boldsymbol{e}_k\Big)\\ &\quad + (1/2)\,\mathcal{S}\, dm\,(d\boldsymbol{F}/dm)^2\\ &= \cdots = (1/2)\sum\sum M_{kl}\,\ddot{q}_k\,\ddot{q}_l\\ &\qquad + \sum\sum\sum \Gamma_{k,rs}\,\ddot{q}_k\,\dot{q}_r\,\dot{q}_s - \sum Q_k\,\ddot{q}_k + no\ \ddot{q}\ terms, \qquad \text{(c)}\end{aligned}$$

[the second (triple) sum can also be written as

$$\begin{aligned}&(1/2)\sum\sum\sum(\Gamma_{k,rs}\,\ddot{q}_k + \Gamma_{l,rs}\,\ddot{q}_l)\dot{q}_r\,\dot{q}_s\\ &= (1/2)\sum\sum\sum\sum M_{kl}(\Gamma^l{}_{rs}\ddot{q}_k + \Gamma^k{}_{rs}\,\ddot{q}_l)\dot{q}_r\,\dot{q}_s\Big]\end{aligned}$$

and, therefore, varying this expression à la Gauss, we obtain

$$\delta'' Z = \sum (\partial Z/\partial \ddot{q}_k)\, \delta\ddot{q}_k = \sum [E_k(T) - Q_k]\, \delta\ddot{q}_k = 0, \tag{d}$$

where

$$\begin{aligned} E_k(T) = (\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k &= \sum M_{kl}\ddot{q}_l + \sum\sum\sum M_{kl}\Gamma^l{}_{rs}\,\dot{q}_r\,\dot{q}_s \\ &= \sum M_{kl}\Big(\ddot{q}_l + \sum\sum \Gamma^l{}_{rs}\,\dot{q}_r\,\dot{q}_s\Big) \\ &= \sum M_{kl}\,\ddot{q}_l + \sum\sum \Gamma_{k,rs}\,\dot{q}_r\,\dot{q}_s, \end{aligned} \tag{e}$$

as expected.

REMARKS

(i) With the help of the definitions

$$\mu_{rs} \equiv \sum\sum M_{kl}\Gamma^{(kl)}{}_{rs}, \tag{f1}$$

$$2\Gamma^{(kl)}{}_{rs} \equiv \Gamma^l{}_{rs}\,\ddot{q}_k + \Gamma^k{}_{rs}\,\ddot{q}_l : 2\,(\textit{symmetric}\text{ part of } \Gamma^k{}_{rs}\,\ddot{q}_l), \tag{f2}$$

we can rewrite Z as follows:

$$Z = (1/2)\sum\sum M_{kl}\,\ddot{q}_k\,\ddot{q}_l + \sum\sum \mu_{kl}\,\dot{q}_k\,\dot{q}_l - \sum Q_k\,\ddot{q}_k + \textit{no } \ddot{q} \textit{ terms}$$
$$[\textit{quadratic in } \ddot{q} + \textit{linear in } \ddot{q} + \textit{constant in } \ddot{q}\,]. \tag{g}$$

(ii) For a *rheonomic* system, the summations over the repeated Latin indices run from 1 to $n+1$ (with $q_{n+1} \equiv t \;\Rightarrow\; \dot{q}_{n+1} = 1 \;\Rightarrow\; \ddot{q}_{n+1} = 0$).

(iii) With the help of the above, the quantity Θ of the preceding example becomes

$$\Theta = \ddot{T} - (1/2)\sum\sum m_{kl}\,E_k(T)\,E_l(T), \tag{h}$$

where the m_{kl} ["conjugate" of M_{kl} (3.10.4); and denoted in tensor calculus as M^{kl}] are defined by

$$\sum m_{kl}M_{lr} = \delta_{kr.} \tag{i}$$

6.7 THE PRINCIPLE OF HERTZ

If the impressed forces, though not necessarily the constraint reactions, vanish—that is, in forceless but constrained motion, GP becomes *Hertz's principle (HZP) of the straightest path*, or *least curvature*:

$$Z \Rightarrow S = (1/2) \mathop{S} dm\, \boldsymbol{a}\cdot\boldsymbol{a} \rightarrow \textit{minimum}; \tag{6.7.1}$$

which is an actual minimum, since here $Z = S$ is a positive definite quadratic form. Let us see the consequences of this; in particular, its connection with the concept of *curvature*.

We consider a *scleronomic* system, moving in a (Riemannian) configuration space with the following *kinetic energy-based metric* [i.e., arc element formula — recall (3.9.4o)] formulae

$$ds \equiv \left(\sum\sum M_{kl}\, dq_k\, dq_l\right)^{1/2} = (2T)^{1/2} dt, \qquad M_{kl} \equiv \mathsf{S}\, dm\, \boldsymbol{e}_k \cdot \boldsymbol{e}_l, \tag{6.7.2a}$$

$$\Rightarrow 2T \equiv \mathsf{S}\, dm\, \boldsymbol{v} \cdot \boldsymbol{v} = \sum\sum M_{kl} \dot{q}_k \dot{q}_l \equiv (ds/dt)^2. \tag{6.7.2b}$$

[Other equivalent choices of system arc-parameter and metric are possible — see "Remarks" (i) below]. Then, since

$$\boldsymbol{v} \equiv d\boldsymbol{r}/dt = (d\boldsymbol{r}/ds)\,(ds/dt), \tag{6.7.3a}$$

$$\boldsymbol{a} \equiv d\boldsymbol{v}/dt = (d^2\boldsymbol{r}/ds^2)\,(ds/dt)^2 + (d\boldsymbol{r}/ds)\,(d^2 s/dt^2), \tag{6.7.3b}$$

the compulsion ⇒ Appellian becomes

$$\begin{aligned} S &= (1/2)\,\mathsf{S}\, dm\, \boldsymbol{a} \cdot \boldsymbol{a} \\ &= (1/2)\,(ds/dt)^4\, \mathsf{S}\, dm\, (d^2\boldsymbol{r}/ds^2)^2 + (1/2)\,(d^2 s/dt^2)^2\, \mathsf{S}\, dm\, (d\boldsymbol{r}/ds)^2 \\ &\quad + (d^2 s/dt^2)\,(ds/dt)^2\, \mathsf{S}\, dm\, (d\boldsymbol{r}/ds) \cdot (d^2\boldsymbol{r}/ds^2). \end{aligned} \tag{6.7.4}$$

But since then (6.7.2b) becomes

$$\begin{aligned} T &= (1/2)\,(ds/dt)^2 = \mathsf{S}\,(dm/2)\,(d\boldsymbol{r}/dt)^2 = \mathsf{S}\,(dm/2)\,[(ds/dt)\,(d\boldsymbol{r}/ds)]^2 \\ &= (1/2)\,(ds/dt)^2\, \mathsf{S}\, dm\, (d\boldsymbol{r}/ds)^2, \end{aligned} \tag{6.7.5}$$

it follows that, for this particular parametrization,

$$\mathsf{S}\, dm\, (d\boldsymbol{r}/ds)^2 = 1; \tag{6.7.6a}$$

and from the latter, by $d(\ldots)/ds$-differentiation,

$$\mathsf{S}\, dm\, (d\boldsymbol{r}/ds) \cdot (d^2\boldsymbol{r}/ds^2) = 0; \tag{6.7.6b}$$

so that S, eq. (6.7.4), reduces to a *sum of two positive terms*:

$$S = (1/2)\,(ds/dt)^4\, \mathsf{S}\, dm\, (d^2\boldsymbol{r}/ds^2)^2 + (1/2)\,(d^2 s/dt^2)^2. \tag{6.7.7}$$

Finally, with the help of the following definition of the *system curvature* K [guided by the Frenet–Serret formulae (§1.2): At a generic point $\boldsymbol{r}$ of a curve with arc-length s, we have $d^2\boldsymbol{r}/ds^2 = \boldsymbol{n}/\rho$, where $\boldsymbol{n}$ = (first) local unit normal, and ρ = (first) local radius of curvature]:

$$\mathsf{S}\, dm\, (d^2\boldsymbol{r}/ds^2)^2 \equiv 1/R^2 \equiv K^2 \tag{6.7.8a}$$

(R = *system radius of curvature*), the Appellian (6.7.7), assumes the form

$$S = (1/2)\,[(d^2 s/dt^2)^2 + (ds/dt)^4/R^2] = (1/2)\,[(d^2 s/dt^2)^2 + K^2 (ds/dt)^4]. \tag{6.7.8b}$$

[We remark that, since both s and K depend only on the system trajectories, and not on the time needed to traverse them, the above expression exhibits a *decoupling of the spatial and temporal aspects of the motion*.]

In view of (6.7.8b), HZP, eq. (6.7.1), becomes: *In the impressed force-free motion of a scleronomic* ($\Rightarrow$ *conservative*) *system, with momentarily given positions and velocities, the acceleration is such that the system Appellian is a minimum*; or, equivalently, since then

$$\begin{aligned} T &= (1/2)\,(ds/dt)^2 = constant \\ &\Rightarrow ds/dt = constant \Rightarrow d^2s/dt^2 = 0, \\ &\Rightarrow S = (1/2)\,K^2 (ds/dt)^4, \quad \text{i.e., } S \sim K^2, \end{aligned} \tag{6.7.9}$$

the system curvature is a minimum:

$$K^2 \equiv \mathsf{S}\, dm\,(d^2\mathbf{r}/ds^2)^2 \rightarrow minimum. \tag{6.7.10}$$

[Simply, S being the sum of two squares, it will be a minimum when each of these terms becomes least; which, since ds/dt is a given constant, leads to $d^2s/dt^2 = 0$ and $K \rightarrow minimum$.]

In words: *The inertial path of a system in configuration space is the "straightest" curve compatible with the given holonomic and/or nonholonomic, but stationary, constraints; and it is traced at a uniform rate.*

For example, in the case of a particle constrained to move on a smooth surface, under no impressed forces, HZP states that its path curvature is the least among all surface curvatures. We notice that HZP, like GP, holds for holonomic and nonholonomic systems alike [unlike the *integral* variational principles (in both their *time* or *geodesic* forms, like Jacobi's) which, for nonholonomic systems, do not hold without modifications (§7.7 ff.)].

REMARKS

(i) Had we defined the system arc-length s by

$$2T = m\,(ds/dt)^2, \qquad m \equiv \mathsf{S}\, dm, \tag{6.7.11}$$

$$\begin{aligned} &\Rightarrow m\,(ds)^2 = \mathsf{S}\, dm\,(d\mathbf{r}\cdot d\mathbf{r}) = \mathsf{S}\,(\sqrt{dm}\; d\mathbf{r})\cdot(\sqrt{dm}\; d\mathbf{r}) \equiv \mathsf{S}\, d\mathbf{r}'\cdot d\mathbf{r}' \\ &\Rightarrow (ds)^2 = \mathsf{S}\,(d\mathbf{r}'/\sqrt{dm})\cdot(d\mathbf{r}'/\sqrt{dm}) \equiv \mathsf{S}\, d\mathbf{r}''\cdot d\mathbf{r}''; \end{aligned} \tag{6.7.11a}$$

$$d\mathbf{r}'' \equiv d\mathbf{r}'/\sqrt{dm} \equiv (dm/m)^{1/2}\; d\mathbf{r}, \tag{6.7.11b}$$

it is not hard to see that, then, we would have

$$\mathsf{S}\, dm\,(d\mathbf{r}/ds)^2 = m, \qquad \mathsf{S}\,(d\mathbf{r}''/ds)^2 = 1, \tag{6.7.12}$$

and with the new definition [instead of (6.7.8a)]

$$\mathsf{S}\, dm\,(d^2\mathbf{r}/ds^2)^2 = \mathsf{S}\,(d^2\mathbf{r}'/ds^2)^2 = m/R^2 \equiv m\,K^2, \tag{6.7.13}$$

S would reduce to [instead of (6.7.8b)]

$$S = (m/2)\left[(d^2s/dt^2)^2 + (ds/dt)^4\big/R^2\right] = (m/2)\ \left[(d^2s/dt^2)^2 + K^2(ds/dt)^4\right]; \quad (6.7.14)$$

and, further [instead of (6.7.9)]

$$T = constant \ \Rightarrow\ (ds/dt)^2 = 2T/m = constant, \qquad (6.7.15a)$$

$$2S\big/m\,(ds/dt)^4 = K^2 = \mathcal{S}\,(d^2\mathbf{r}''/ds^2)^2. \qquad (6.7.15b)$$

(ii) It is worth pointing out the formal similarity between HZP and the principle of *minimum strain energy* of a thin linearly elastic, unloaded but constrained, beam in plane bending.

HISTORICAL REMARKS

Hertz's principle represents one of the highest, and admittedly quite elegant, pre-relativistic (late 19th century) efforts to *formulate a forceless/geometrical description of motion, within classical mechanics*; similar to the earlier attempts, by Kelvin et al. to explain forces by the motion of concealed built-in spinning bodies [gyrostats (§8.4 ff.)]. As is well known, the solution to that problem of *geometrization of mechanics* came about 20 years later with Einstein's *general theory of relativity* (mid-1910s).

The restriction of HZP to vanishing impressed forces (though not to holonomic constraints), makes it practically useless for applications; and this is in very sharp contrast to GP, which seems to be free of any kind of limitations.

The best single reference on HZP is, probably, Brill (1909, pp. 5–55); also, Heun [1902(c)], the thesis of Boltzmann's famous student Ehrenfest (1904), and the modern historical study by Lützen [1995(a), (b)]; and, of course, Hertz (1894, in German; 1899, English transl.; 1956, English transl., paperback edition).

7

Time-Integral Theorems and Variational Principles

As long as physical science exists, the highest goal to which it aspires is the solution of the problem of embracing all natural phenomena, observed and still to be observed, in one simple principle which will allow all past and, especially, future occurrences to be calculated. It follows from the nature of things, that this object neither has been, nor ever will be, completely attained. It is, however, possible to approach it nearer and nearer, and the history of theoretical physics shows that already an extensive series of important results can be obtained, which indicates clearly that the ideal problem is not purely Utopian, but that it is eminently practicable. Therefore, from a practical point of view, the ultimate object of research must be borne in mind. (Planck, 1960, p. 69; also, in German, in Wiechert, 1925, p. 772)

The variational principles of mechanics are firmly rooted in the soil of that great century of Liberalism which starts with Descartes and ends with the French Revolution and which has witnessed the lives of Leibniz, Spinoza, Goethe, and Johann Sebastian Bach. *It is the only period of cosmic thinking in the entire history of Europe since the time of the Greeks.*

(Lanczos, 1970, p. x; emphasis added)

The germ of the idea of a minimum principle, coming when it did, found a congenial environment. Both Euler and Lagrange were infected with the virus early in life, and though they both sloughed it in later years its effect can be seen on Gauss, through to Hamilton and right down to Willard Gibbs and Castigliano. Thus we find Euler saying (in Latin), ''Since the plan of the universe is the most perfect possible and the work of the wisest possible creator, nothing happens which has not some maximal or minimal property.'' Nowadays this mental attitude is démodé and we think more of the ''uncertainty principle,'' according to which (if the quantum theorists are to be believed) Nature cannot make up her mind which it is that is going to do what.

(Kilmister, 1964, pp. 50–51)

7.1 INTRODUCTION

Time-integral theorems and the *integral variational principles* (IVP) derived from them, as well as those of weighted residuals, occupy a central position in analytical mechanics (AM), and applied mechanics in general. This is not only due to the fact that they provide powerful analytical tools (for the derivation of global energetic results, existence and uniqueness theorems, upper and lower bound estimates for system eigenvalues and/or solutions, etc.) but also, primarily, because they constitute the foundation of the so-called *direct* variational methods. These latter bypass the equations of motion and proceed directly to the construction of *approximate* solutions of the problem; whether initial and/or boundary value, linear or nonlinear, conservative or not, holonomic or not.

The *first* part of this chapter (§7.2–5) derives all the important time-integral propositions of AM; variational, energetic, and virial-like, for linearly and/or nonlinearly constrained holonomic and/or nonholonomic systems, in both holonomic and nonholonomic coordinates, all from a simple unifying viewpoint: a general *time-integral identity* based on a few straightforward algebraic manipulations of the corresponding equations of motion. This unambiguous "from first principles (i.e., equations of motion) approach" will, hopefully, contribute to a more rational, or perhaps demythologized, attitude toward IVP, because, historically (since mid-18th century) these "principles" have been surrounded with superstition, mysticism, and ignorance (of the fine points of variational calculus and mechanics).

[We remark that in *continuum* mechanics, where even the simplest kinetic variational problem leads to a *partial* differential equation (e.g., string: one-dimensional wave equation), IVP have the additional and unique advantage that they supply *both* the equations of motion of the problem and its *boundary* conditions. Also, such *infinite* number of DOF systems may be *discretized*; that is, be approximated by systems with a *finite* number of DOF; and then, some of the (single) integral principles of this chapter may be applied to these systems to find their temporal evolution.]

The *second*, larger, part of this chapter (§7.6–9, Appendices) examines these IVP in some detail, especially in view of the fundamental (and yet frequently overlooked and/or misunderstood) *differences* between the *mathematically* correct and (generally different from it) *mechanically* correct variational formulations for nonholonomic systems.

Finally, most IVP are *first-order/stationarity requirements,* that is, of the kind that supplies only the equations of motion (the "laws of nature"). For certain systems, however, second-order/*extremality conditions* (not laws of nature) may be established, which constitute alternative tests for the stability/instability of certain of their motions. A summary of the relevant sufficiency variational theory and some applications is contained in an appendix, at the end of the chapter.

For complementary reading, we recommend the following general references (alphabetically): Boltzmann (1904a, vol. 2, chaps. 1, 3, 4), Finzi (1949), Gelfand and Fomin (1963), Lanczos (1970), Langhaar (1962), Logan (1977), Lovelock and Rund (1975), Lur'e (1968, chap. 12), Neimark and Fufaev (1972, chap. 3, section 10), Novoselov (1966; 1967), Papastavridis [1987(b)], Pars (1965, chaps. 26, 27), Polak (1959; 1960 — a unique and delightful reference), Prange (1935), Rund (1966), Tabarrok and Rimrott (1994, chap. 3, app. A), Vujanovic and Jones (1989, chaps. 1–6).

Chapter notations (see also Introduction, §4, and chap. 8):

- IVP: Time-*integral* variational principles;
- All *Latin* indices run from 1 to n (= number of "original" positional coordinates); except
  $D, D', D'', \ldots,$ (*dependent*) which run from 1 to m
  (= number of additional constraints, holonomic or not),
  and
  $I, I', I'', \ldots,$ (*independent*) which run from $m+1$ to n.
- $\int \equiv \int_{t_1}^{t_2}$: The integration extends from t_1 to t_2 ($t_{1,2}$: arbitrary time instants), unless specified otherwise.
- $\{\ldots\}_1^2 \equiv \{\ldots\}_{t_1}^{t_2} \equiv \{\ldots\}_{t_2} - \{\ldots\}_{t_1} \equiv BT$ (1, 2 stand for $t_{1,2}$, respectively): Boundary terms, where $\ldots$ = integrated out part(s).

Time-Integral Theorems

7.2 TIME-INTEGRAL THEOREMS: PFAFFIAN CONSTRAINTS, HOLONOMIC VARIABLES

Here, the starting point is the fundamental Routh–Voss equations (§3.5)

$$(\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k = Q_k + \sum \lambda_D a_{Dk} \qquad [T = T(t, q, \dot{q})\text{: unconstrained}]. \quad (7.2.1)$$

Multiplying each of (7.2.1) with z_k, where the $\{z_k = z_k(t); k = 1, \ldots, n\}$ are arbitrary functions but as well behaved as needed, and summing them over k, we obtain

$$\sum \left[(\partial T/\partial \dot{q}_k)^{\cdot} z_k - (\partial T/\partial q_k) z_k\right] = \sum \Big(Q_k + \sum \lambda_D a_{Dk}\Big) z_k,$$

or, rearranging with the help of the chain rule, and then integrating between the two arbitrary time instants t_1 and t_2, we obtain the following *generalized holonomic time-integral (or virial-like) identity*:

$$\int \Big[\sum (\partial T/\partial \dot{q}_k)\dot{z}_k + \sum \Big(\partial T/\partial q_k + Q_k + \sum \lambda_D a_{Dk}\Big) z_k\Big]\, dt$$
$$= \Big\{\sum (\partial T/\partial \dot{q}_k) z_k\Big\}_1^2. \quad (7.2.2)$$

As shown below, *special choices* of the z_k's in (7.2.2) yield all the important time integral theorems and variational "principles" of mechanics.

Let us examine them in detail:

(i) $z_k \to \delta q_k$: *Virtual displacement of* q_k (fig. 7.1). Then,

$$\sum \sum \lambda_D a_{Dk} z_k \;\to\; \sum \lambda_D \Big(\sum a_{Dk}\, \delta q_k\Big) = 0, \qquad (7.2.3a)$$

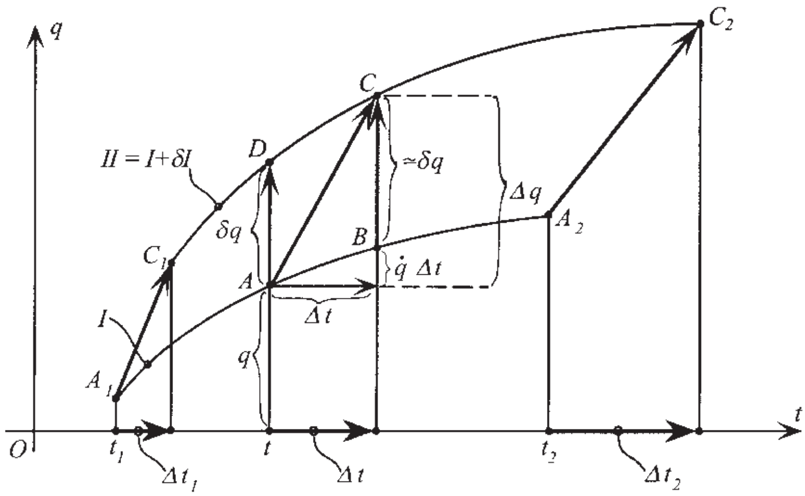

Figure 7.1 Variations of q in $(n+1)$-dimensional extended configuration space: *vertical* (δq) and *skew* (Δq).
Difference in velocity space (slope) between D and A: $\delta(\dot{q}) = (q+\delta q)^{\cdot} - \dot{q} = (\delta q)^{\cdot}$.
Point coordinates: $A(t, q)$, $B(t+\Delta t, q+\dot{q}\Delta t)$, $C(t+\Delta t, q+\Delta q)$, $D(t, q+\delta q)$.
Mappings: $A \to A+\delta A = D$ (vertical); $A \to A+\Delta A = C$ (skew);
$t \to t'(t) = t+\Delta t(t) \Rightarrow dt'/dt = 1+(\Delta t)^{\cdot}$.

by the virtual form of the Pfaffian constraints, and so (7.2.2) yields *Hamilton's law of vertically* (*virtually*) *varying action*:

$$\int (\delta T + \delta' W)\, dt = \Big\{\sum p_k\, \delta q_k\Big\}_1^2, \tag{7.2.3b}$$

where

$$\delta T = \sum \big[(\partial T/\partial \dot{q}_k)\, \delta\dot{q}_k + (\partial T/\partial q_k)\, \delta q_k\big], \qquad p_k \equiv \partial T/\partial \dot{q}_k, \tag{7.2.3c}$$

and

$$\delta\dot{q}_k \equiv \delta(\dot{q}_k) = (\delta q_k)^{\cdot}. \tag{7.2.3d}$$

As will be detailed in the *second* part (§7.6 ff.): (a) in general, no stationarity of a functional is implied by the integral equation (7.2.3b); and (b) *the commutation rule* (7.2.3d) *is a key assumption, or choice*, without which it would have been impossible to go from (7.2.2) to (7.2.3b).

(ii) $z_k \to \Delta q_k = \delta q_k + \dot{q}_k\, \Delta t$: *Noncontemporaneous, or skew, or oblique, variation of* q_k (fig. 7.1). Then,

$$\begin{aligned} 0 = \sum a_{Dk}\, \delta q_k &= \sum a_{Dk}(\Delta q_k - \dot{q}_k\, \Delta t) = \sum a_{Dk}\, \Delta q_k - \Big(\sum a_{Dk}\dot{q}_k\Big)\, \Delta t \\ &= \sum a_{Dk}\, \Delta q_k - (-a_D)\, \Delta t \;\Rightarrow\; \sum a_{Dk}\, \Delta q_k + a_D\, \Delta t = 0, \end{aligned} \tag{7.2.4a}$$

that is, the Δq_k and Δt are *kinematically admissible;* and so (7.2.2) yields *Hamilton's law of skew-varying action*:

$$\int \left[\sum (\partial T/\partial \dot{q}_k)(\Delta q_k)^{\cdot} + \sum (\partial T/\partial q_k + Q_k)\, \Delta q_k - \sum \lambda_D a_D\, \Delta t\right] dt = \left\{\sum p_k\, \Delta q_k\right\}_1^2. \qquad (7.2.4b)$$

For $a_D = 0$ (i.e., catastatic constraints), the left sides of (7.2.3b) and (7.2.4b) look similar, although in the latter $\Delta t \neq 0$. We also notice that, again assuming (7.2.3d), since

$$(\Delta q_k)^{\cdot} = (\delta q_k + \dot{q}_k\, \Delta t)^{\cdot} = (\delta q_k)^{\cdot} + \ddot{q}_k\, \Delta t + \dot{q}_k (\Delta t)^{\cdot}, \qquad (7.2.4c)$$

$$\Delta(\dot{q}_k) = \delta(\dot{q}_k) + (\dot{q}_k)^{\cdot}\, \Delta t = \delta \dot{q}_k + \ddot{q}_k\, \Delta t, \qquad (7.2.4d)$$

$$\Rightarrow (\Delta q_k)^{\cdot} - \Delta(\dot{q}_k) = \dot{q}_k (\Delta t)^{\cdot} \qquad (7.2.4e)$$

[i.e., $\Delta(\ldots)$ and $(\ldots)^{\cdot}$ do *not* commute, even when $\delta(\ldots)$ and $(\ldots)^{\cdot}$ do!], we can replace in (7.2.4b) $(\Delta q_k)^{\cdot}$ with $\Delta(\dot{q}_k) + \dot{q}_k (\Delta t)^{\cdot}$. (Integral equations/principles based on such noncontemporaneous variations are detailed in §7.9.)

(iii) $z_k \to q_k$: *Actual system coordinate*. Then (7.2.2) yields the *nonvariational/actual virial theorem* [of Clausius, Szily, et al. (mid- to late 19th century)]:

$$\int \left[\sum (\partial T/\partial \dot{q}_k)\dot{q}_k + \sum \left(\partial T/\partial q_k + Q_k + \sum \lambda_D a_{Dk}\right) q_k\right] dt = \left\{\sum p_k q_k\right\}_1^2. \qquad (7.2.5)$$

Specialization

If, in the above, $\{\sum p_k q_k\}_1^2 = 0$, for example, as a result of *periodicity* ($t_2 = t_1 + \tau$, τ: period of oscillatory motion); $\partial T/\partial q_k = 0$, for instance, in rectilinear coordinates; and the "original" holonomic constraints are *stationary*, in which case

$$\sum (\partial T/\partial \dot{q}_k)\dot{q}_k = 2T \qquad \text{[by the homogeneous function theorem]}; \qquad (7.2.5a)$$

then (7.2.5) specializes to the time-integral energetic theorem:

$$\int 2T\, dt = -\int \left[\sum \left(Q_k + \sum \lambda_D a_{Dk}\right) q_k\right] dt, \qquad (7.2.5b)$$

where the integrals extend from t_1 to $t_2 = t_1 + \tau$.

Additional special theorems result if, in (7.2.5b), $Q_k = -\partial V(t, q)/\partial q_k$, $V(t, q)$: potential function = sum of homogeneous functions of the q's of various degrees.

(iv) $z_k \to \dot{q}_k$: *Actual system velocity*. Then, since

$$\sum \left(\sum \lambda_D a_{Dk}\right) \dot{q}_k = \sum \left(\sum a_{Dk} \dot{q}_k\right) \lambda_D = \sum (-a_D)\lambda_D, \qquad (7.2.6a)$$

eq. (7.2.2) transforms to

$$\int \Big[\sum (\partial T/\partial \dot{q}_k)\ddot{q}_k + \sum (\partial T/\partial q_k + Q_k)\dot{q}_k - \sum a_D \lambda_D\Big]\, dt = \Big\{\sum p_k \dot{q}_k\Big\}_1^2, \tag{7.2.6b}$$

or, further, to

$$\int \Big[(dT/dt - \partial T/\partial t) + \sum Q_k \dot{q}_k - \sum a_D \lambda_D\Big]\, dt = \int \Big[\sum (\partial T/\partial \dot{q}_k)\dot{q}_k\Big]^{\cdot}\, dt, \tag{7.2.6c}$$

or, finally, to

$$\int \Big\{\Big[\sum (\partial T/\partial \dot{q}_k)\dot{q}_k - T\Big]^{\cdot} - \Big(-\partial T/\partial t + \sum Q_k \dot{q}_k - \sum \lambda_D a_D\Big)\Big\}\, dt = 0, \tag{7.2.6d}$$

from which, since the limits t_1 and t_2 are arbitrary, we conclude that the integrand must vanish identically; that is

$$d/dt\Big[\sum (\partial T/\partial \dot{q}_k)\dot{q}_k - T\Big] \;=\; -\partial T/\partial t + \sum Q_k \dot{q}_k - \sum \lambda_D a_D; \tag{7.2.6e}$$

and this is nothing but the earlier-found (§3.9) most general (nonpotential) form of the generalized power theorem, for systems under Pfaffian constraints and in holonomic variables.

Specialization

If, in (7.2.6e), some of the forces, or part of each Q_k, derive from a potential function $V = V(t, q)$, then we simply replace in there T with $L \equiv T - V$: Lagrangean of the system; and now Q_k stands for all the *nonpotential* forces or parts of them. If, further, $\partial L/\partial t = 0$ (e.g., stationary original constraints) and $a_D = 0$ (i.e., additional Pfaffian constraints catastatic), then, since $[\sum (\partial L/\partial \dot{q}_k)\dot{q}_k - L]^{\cdot} = [2T - (T - V)]^{\cdot} = (T + V)^{\cdot}$, and so eq. (7.2.6e) reduces to the more familiar (multiplierless) power equation

$$(T + V)^{\cdot} \equiv \dot{E} = \sum Q_k \dot{q}_k. \tag{7.2.6f}$$

We should point out that $\partial T/\partial t$ can vanish even for rheonomic holonomic constraints; that is, even if the position vectors of the system particles depend explicitly on time.

Example 7.2.1 *The Virial Theorem* [of Clausius (1870) et al.]. Let us consider a holonomic and conservative system with kinetic and potential energies $T(q, \dot{q})$ and $V(q)$, respectively. We are going to relate their time averages for various system motions; using both particle and system variables.

Let us define the (moment of inertia reminiscent) "second moment of the system"

$$\Phi \equiv S\,(1/2)\, dm\, \boldsymbol{r}\cdot\boldsymbol{r} = S\,(1/2)\, r^2\, dm. \tag{a}$$

By $(\ldots)^{\cdot}$-differentiating Φ twice, while noting that, by the Newton–Euler law of motion (with the usual notations, chap. 1),

$$dm\, \boldsymbol{a} = d\boldsymbol{f} = -\partial V/\partial \boldsymbol{r} \equiv -\boldsymbol{grad}\, V, \tag{b}$$

we find

$$d\Phi/dt \quad = \cdots = \mathsf{S}\, dm\, \boldsymbol{v} \cdot \boldsymbol{r} \equiv \Psi, \tag{c}$$

$$\begin{aligned} d^2\Phi/dt^2 &= \cdots = \mathsf{S}\, dm\, \boldsymbol{v} \cdot \boldsymbol{v} + \mathsf{S}\, dm\, \boldsymbol{a} \cdot \boldsymbol{r} \\ &= 2T + \mathsf{S}\, d\boldsymbol{f} \cdot \boldsymbol{r} \;=\; 2T - \mathsf{S}\, (\partial V/\partial \boldsymbol{r}) \cdot \boldsymbol{r} \;=\; d\Psi/dt; \end{aligned} \tag{d}$$

[$= 2T + V$, if V: homogeneous function of degree -1 in the components/coordinates of $\boldsymbol{r}$ (case of gravitational attraction)].

Equation (d) is known in celestial mechanics as Lagrange's identity.

Now, let us average the above; with the customary notation

$$\langle f \rangle \equiv (1/\tau) \int_0^\tau f(t)\, dt:$$

Time average of a function $f(t)$, between $t_1 = 0$ and $t_2 = \tau$, (e)

and noting that

$$\langle d\Psi/dt \rangle = (1/\tau) \int_0^\tau [d\Psi(t)/dt]\, dt = (1/\tau)[\Psi(\tau) - \Psi(0)], \tag{f}$$

the averaged eq. (d) becomes

$$(1/\tau)[\dot{\Phi}(\tau) - \dot{\Phi}(0)] = 2\langle T \rangle - \left\langle \mathsf{S}\, d\boldsymbol{f} \cdot \boldsymbol{r} \right\rangle,$$

or

$$(1/\tau)[\Psi(\tau) - \Psi(0)] = 2\langle T \rangle + \left\langle \mathsf{S}\, (\partial V/\partial \boldsymbol{r}) \cdot \boldsymbol{r} \right\rangle. \tag{g}$$

Specializations

(i) If the system is *periodic* with period τ, then $\Psi(\tau) = \Psi(0)$, and (g) results in

$$2\langle T \rangle = \left\langle \mathsf{S}\, (\partial V/\partial \boldsymbol{r}) \cdot \boldsymbol{r} \right\rangle$$

$$\left[= -\left\langle \mathsf{S}\, d\boldsymbol{f} \cdot \boldsymbol{r} \right\rangle : \text{General definition of } \textit{virial} \text{ of a system} \right]. \tag{h}$$

(ii) If the system is *nonperiodic*, but moves in a finite spatial region with finite velocities, then, as (c) shows, there is an *upper* bound to $d\Phi/dt \equiv \Psi$, and eq. (h) still holds, *provided the averages are taken over a very long time* (i.e., $\tau \to \infty$); or, by choosing τ sufficiently large, we can make $\langle d\Psi/dt \rangle$ as small as possible:

$$\begin{aligned} \langle d\Psi/dt \rangle &= \lim \left\{ (1/\tau) \int_0^\tau [d\Psi(t)/dt]\, dt \right\}_{\tau \to \infty} \\ &= \lim \left\{ (1/\tau)[\Psi(\tau) - \Psi(0)] \right\}_{\tau \to \infty} \;=\; 0. \end{aligned} \tag{i}$$

If, further, $V =$ *homogeneous* of degree f in the $\boldsymbol{r}$'s, then (by Euler's theorem) eq. (h) yields

$$2\langle T \rangle = f \langle V \rangle, \tag{j}$$

or, since $\langle T + V\rangle = \langle T\rangle + \langle V\rangle = \langle E\rangle = E$,

$$\langle T\rangle = fE/(f+2), \qquad \langle V\rangle = 2E(f+2). \tag{k}$$

In particular, if $f = 2$—that is, V is *quadratic* (linear vibrations)—then (j, k) yield the *equipartition* theorem:

$$\langle T\rangle = \langle V\rangle = E/2. \tag{l}$$

Let the reader verify that in a *central* force field with $V \sim r^{\varepsilon}$ (r = distance of dm from attracting origin)—that is, $f \to \varepsilon$—the virial theorem results in

$$2\langle T\rangle = \varepsilon\langle V\rangle; \tag{m}$$

from which it follows that in the *gravitational* case—that is, $\varepsilon = -1$, then,

$$\langle T\rangle = -E\ (>0), \qquad \langle V\rangle = 2E\ (<0) \Rightarrow 2\langle T\rangle = -\langle V\rangle; \tag{n}$$

which is in agreement with the general result that in such a Newtonian interaction "*the motion takes place in a finite region of space only if the total energy is negative*."

These and other similar virial theorems have interesting applications in the mechanics of the *very small* (classical statistical mechanics) and of the *very large* (astronomy). For example, with their help, we can derive the well-known gas law: $p\,v = n\,k\,\theta$ (p, v, n, k, θ: *pressure, volume, number of molecules, Boltzmann's constant, absolute temperature,* respectively).

[For further details and applications, see, for example: Corben and Stehle (1960, pp. 164–166), Goldstein (1980, pp. 82–85, 96–97, 121, 477), Kurth (1960, pp. 64–74, 149–153), Pollard (1976, pp. 60–71); and books on the kinetic theory of gases; also, for the Newtonian interaction/gravitational case, see Landau and Lifshitz (1960, pp. 35–39). For engineering applications (nonlinear oscillations and their stability), see, for example, Papastavridis [1986(a)] and problems and example below.]

Problem 7.2.1 *Virial Theorem* (*Jacobi "Instability Criterion"*). Consider a system of N mutually attracted (gravitating) particles. As is well known, its potential energy is a *negative* and homogeneous function of degree -1 in the $3N$ rectangular Cartesian coordinates of the position vectors of these particles. By applying the virial theorem for the case where the total energy $E \equiv T + V$ is a *positive* constant, show that

$$d^2\Phi/dt^2 = E + T = 2E - V \qquad \text{(Theorem of Lagrange–Jacobi)}. \tag{a}$$

[Recalling the definition of Φ from the preceding example: $2\Phi \equiv \mathsf{S}\, dm\, \boldsymbol{r}\cdot\boldsymbol{r} = \mathsf{S}\, r^2 dm$, where $\boldsymbol{r}$ is the position vector of a typical particle relative to the system's (uniformly moving) mass center.]

Then deduce that

$$\Phi > (1/2)E\,t^2 + (d\Phi/dt)_o\, t + \Phi_o, \tag{b}$$

where $(d\Phi/dt)_o$, Φ_o: $d\Phi/dt$, Φ evaluated at some initial instant $t = 0$; and from this, in turn, since $E > 0$, Φ becomes *infinite*, as $t \to \infty$.

[A word of *caution*: from the above, however, it does not necessarily follow that at least one of the nonnegative functions $r^2\, dm$, making up the sum Φ, becomes infinite; although it does follow that not every such term remains bounded, otherwise Φ would stay bounded. For example, consider the function $q(t) = t\cos^2 t + t\sin^2 t = t$ (sum of nonnegative functions, for $t \geq 0$). As $t \to \infty$, the sum q becomes infinite, but neither of its "components" $t\cos^2 t$, $t\sin^2 t$ does; instead, they become large *and* small; that is, they become *unbounded* but do not tend to infinity! Hence, the commonly stated conclusion: *"if the total energy is positive, at least one particle must escape from the system* (i.e., if $E > 0$, then $r \to \infty$ for at least one particle; and, hence, the system is *unstable*)" is mathematically unproved; although, physically, such reasoning may look like academic hair-splitting.]

For a generalization of (a, b) and applications to stellar systems, see Kurth (1957, pp. 63–69).

Problem 7.2.2 *Virial Theorem* (*Linear Undamped Oscillator*). Consider the *linear* (or harmonic), *free* (or unforced, or undriven), and *undamped* oscillator with equation of motion: $\ddot{q} + \omega_o{}^2 q = 0$, where $\omega_o{}^2 \equiv$ *linear elasticity/mass* $\equiv k/m$ and, therefore, solution $q = a\cos(\omega_o t + \phi)$, where a is a constant amplitude and ϕ is the initial phase.

(i) Show that

$$\langle T\rangle = \langle V\rangle \qquad \text{or} \qquad m\,\omega_o{}^2 a^2/4 = ka^2/4; \tag{a}$$

where $\langle\ldots\rangle$ is time average of $(\ldots)$ over a period $\tau = 2\pi/\omega_o$; and, consequently,

$$E = \langle E\rangle = \langle T + V\rangle = \langle T\rangle + \langle V\rangle = m\,\omega_o{}^2 a^2/2. \tag{b}$$

(ii) Let the *variance* of a periodic function $f(t)$, of period τ, Δf, be defined by $(\Delta f)^2 \equiv \langle (f - \langle f\rangle)^2\rangle$ (measure of *mean deviation of f from its average*). It is not too hard to see that $(\Delta f)^2 \equiv \langle f^2\rangle - \langle f\rangle^2$. Show that, for the harmonic oscillator discussed here,

$$(\Delta q)^2 = \langle q^2\rangle \qquad [\Delta(dq/dt)]^2 = \langle (dq/dt)^2\rangle. \tag{c}$$

Then, verify that $(\Delta q)(\Delta p) = E/\omega_o$, where $p \equiv m(dq/dt)$ is the linear momentum of the oscillator. (This constitutes a "constraint" between the root mean square deviations of a pair of measurable quantities, q and p, from their average values; and that is why it is called an *uncertainty* relation. Such conditions are important in quantum mechanics.)

(iii) Show that $\langle T\rangle = \langle V\rangle$ over *any time interval τ^* that is large relative to τ*; that is, even if τ^* is not an integral multiple of τ.

HINTS

With $\psi \equiv \omega_o t$, $\psi_1 \equiv \omega_1 t$, $\psi_2 \equiv \omega_2 t$, show that

$$\text{(i)}\ (1/\tau^*)\int_0^{\tau^*} \sin^2\psi\, dt = 1/2 + (1/4\tau^*\omega_o)[1 - \sin(2\omega_o\tau^*)] \quad [\to 1/2,\ \text{as}\ \tau^* \to \infty], \tag{d}$$

and the same for the integral of $\cos^2\psi$;

(ii) $$(1/\tau^*)\int_0^{\tau^*}(\sin\psi_1)(\cos\psi_2)\,dt = \{1-\cos[(\omega_1-\omega_2)\tau^*]\}/2(\omega_1-\omega_2)\tau^* + \{1-\cos[(\omega_1+\omega_2)\tau^*]\}/2(\omega_1+\omega_2)\tau^* \quad [\to 0, \text{as } \tau^*\to\infty]; \tag{e}$$

(iii) $$(1/\tau)\int_0^{\tau}\sin^2(\omega_o t+\phi)\,dt = 1/2, \tag{f}$$

and the same for the integral of $\cos^2(\omega_o t+\phi)$;

(iv) $$(1/\tau)\int_0^{\tau}\sin(\omega_o t+\phi)\cos(\omega_o t+\phi)\,dt = 0. \tag{g}$$

Problem 7.2.3 *Virial Theorem* (*Linear and Damped Oscillator*). Consider the linear, free, and damped oscillator with equation of motion (with the usual notations)

$$m\ddot{q}+f\dot{q}+kq=0 \qquad \text{or} \qquad \ddot{q}+(1/r)\dot{q}+{\omega_o}^2 q=0, \tag{a}$$

where $1/r \equiv f/m$ [with dimensions $(time)^{-1}$; and occasionally referred to as $(relaxation\ time)^{-1}$].

(i) Show that for *small damping*, the latter defined precisely by

$$\omega_o r \gg 1 \qquad [\Rightarrow \omega_o \gg f/m; \text{i.e., roughly, } \textit{elasticity} \gg \textit{friction}], \tag{b}$$

an approximate solution of (a) is

$$q_o = a_o\exp(-t/2r)\sin(\omega_o t), \qquad \text{where } a_o \sim \text{initial velocity (a constant)}. \tag{c}$$

(ii) Then, show that in this case

$$\langle T\rangle \approx (m/4)[{\omega_o}^2+(f/2m)^2]{a_o}^2\exp(-t/r) \approx (m/4){\omega_o}^2{a_o}^2\exp(-t/r), \tag{d}$$

$$\langle V\rangle \approx (m/4)\,{\omega_o}^2{a_o}^2\exp(-t/r). \tag{e}$$

(iii) If $\langle D\rangle$ is the average *rate of dissipation* of the oscillation—that is, of $(f\dot{q})\dot{q}$—over a single (undamped) period $\tau_o = 2\pi/\omega_o$, then show that (again for small damping)

$$-\langle D\rangle = d\langle E\rangle/dt = d\langle T\rangle/dt + d\langle V\rangle/dt \approx -(1/r)\big[(m/2){\omega_o}^2{a_o}^2\exp(-t/r)\big] = -E(t)/r. \tag{f}$$

HINT

If $\omega_o r \gg 1$, then, to a good approximation, we can take the factor $\exp(-t/r)$ outside the averaging integrals; that is, our energetic averages are to be understood as *taken over a period* (*or cycle*) τ_o *at, approximately,* t (in the sense of the averaging method—see examples/problems of §7.9); and that is why they are functions of t.

Problem 7.2.4 *Virial Theorem* (*Linear, Damped, and Forced Oscillator*). Consider the linear, damped, and harmonically forced oscillator with equation of motion

$$m\ddot{q} + f\dot{q} + kq = Q_o \cos(\omega t), \tag{a}$$

where Q_o, ω: forcing amplitude and frequency (both specified constants).

(i) Show that the time *average* of the rate of energy dissipation by the oscillator (i.e., of $(f\dot{q})\dot{q}$), over a *long* period of time $\tau^*(\gg 2\pi/\omega)$ equals

$$\langle D \rangle = ({Q_o}^2/2f)\cos^2\psi \qquad \cos\psi \equiv f[f^2 + (m\omega - k/\omega)^2]^{-1/2}. \tag{b}$$

HINT

Use the *steady-state* (particular, periodic) solution: $q = a_o \cos(\omega t - \phi)$, where a_o is a function of Q_o, ω, ω_o, f, m; $\tan\phi = \omega f/(k - m\omega^2)$, ϕ: phase difference between force and displacement; and $\phi - \psi = \pi/2$, where ψ: phase difference between force and velocity.

(ii) Then, conclude that

(a) If $\psi = 0$ (resonance), then $\langle D \rangle \to \langle D \rangle_{\text{maximum}} = {Q_o}^2/2f$; and
(b) If force and displacement are either in phase or differ by π (i.e., $\phi = 0 \Rightarrow \psi = -\pi/2$, or $\phi = \pi \Rightarrow \psi = \pi/2$), then $\langle D \rangle = 0$.

(iii) Show that, *in steady-state motion*, the time average of the rate of working (power) of the driving force, that is, of $[Q_o\cos(\omega t)](dq/dt)_{\text{steady-state}}$, $\langle W \rangle$, *equals* $\langle D \rangle$.

In words: Mean energy externally *supplied* to system, per unit time = Mean energy *absorbed* or *dissipated* by system (*friction*), per unit time; and, hence, in such a forced motion, the energy of the system remains unchanged.

(iv) From (ii) and (iii) conclude that *at resonance* (*with the external force*), *both* $\langle W \rangle$ *and its equal* $\langle D \rangle$ *are maxima.*

Problem 7.2.5 *Virial Theorem* (*Linear Damped and Forced Oscillator*). Continuing from the preceding problem,

(i) Show that

$$\langle W \rangle \equiv P(x; f) = {Q_o}^2 f/2\ (f^2 + m^2{\omega_o}^2 x^2), \tag{a}$$

where $x \equiv (\omega/\omega_o) - (\omega_o/\omega)$: roughly, *deviation* of ω from ω_o; and, therefore, if $x = 0$ (i.e., $\omega = \omega_o$), then $P(0; f) =$ *maximum*. (It is not hard to see that the graph of $\langle W \rangle$ vs. x, with f as parameter, looks like a *resonance* curve; i.e., $|a_o|$ vs. ω.)

(ii) Show that

$$\partial P/\partial x = -{Q_o}^2 f\ m^2{\omega_o}^2 x/(f^2 + m^2{\omega_o}^2 x^2)^2, \tag{b}$$

and, therefore:

(a) If $x > 0$ (i.e., $\omega > \omega_o$), then $\partial P/\partial x < 0$, and the smaller the f the larger $|\partial P/\partial x|$; and similarly for $x < 0$; whereas
(b) If $x = 0$ (i.e., $\omega = \omega_o$) and f is small, then P is large.

In words: *the smaller* (*larger*) *the damping, the higher* (*lower*) *and sharper or peaked* (*flatter*) *the resonance maximum:* $P(0; f) = (1/2)({Q_o}^2/f)$ (*say, like a Dirac delta function*).

For further details on such *dispersion* relations (very important in several areas of physics), see, for example, Falk (1966, pp. 37–43); also Landau and Lifshitz (1960, p. 79).

Problem 7.2.6 *Virial Theorem* (*Linear, Damped, and Forced Oscillator*). Continuing from the last two problems:

(i) Calculate and compare $\langle T \rangle$ and $\langle V \rangle$; and

(ii) Find the forcing frequencies at which each of them becomes maximum. Explain why these two maxima occur at different frequencies.

Example 7.2.2 *Nonlinear Oscillations via the Virial Theorem.*

1. *Duffing oscillator*. Let us find the amplitude versus frequency ("resonance curve") of the steady-state response of

$$m\ddot{q} + kq + hq^3 = Q_o \sin\chi, \qquad \chi \equiv \omega\, t, \tag{a}$$

where m is the mass of the oscillator (> 0), k is its linear stiffness (> 0), ω is the forcing frequency (given), Q_o is the forcing amplitude (given), and h is the nonlinearity constant.

Here, clearly,

$$2T = m(\dot{q})^2; \qquad V = V_2 + V_4, \quad 2V_2 \equiv kq^2, \quad 4V_4 \equiv hq^4; \qquad Q = Q_o \sin\chi, \tag{b}$$

and therefore for the trial steady-state solution of (a)

$$q = a \sin\chi, \qquad \text{where } a = a(\omega) \text{ (to be determined)}, \tag{c}$$

the virial equation (7.2.5), for this holonomic one-DOF system, with

$$\partial T/\partial q = 0, \qquad a_{Dk} = 0, \qquad \text{and} \qquad \left\{\sum p_k q_k\right\}_1^2 \to \{(\partial T/\partial \dot{q})q\}_0^{2\pi/\omega} \tag{d}$$

(and application of the homogeneous function theorem) gives

$$\begin{aligned}
\int_0^{2\pi/\omega} \big[2T - (\partial V/\partial q)q + Qq\big]\, dt &= \int_0^{2\pi/\omega} \big[2T - (2V_2 + 4V_4) + Qq\big]\, dt \\
&= \int_0^{2\pi/\omega} (m\, a^2\omega^2 \cos^2\chi - ka^2 \sin^2\chi - h\, a^4 \sin^4\chi + Q_o a \sin^2\chi)\, dt \\
&= (\pi/\omega)(m\, a^2\omega^2 - ka^2 - 3h\, a^4/4 + Q_o a) = 0,
\end{aligned} \tag{e}$$

from which we obtain the well-known *resonance* equation (with ${\omega_o}^2 \equiv k/m$)

$$\omega^2 = {\omega_o}^2 + (3/4)(h/m)a^2 - (Q_o/m)a^{-1}. \tag{f}$$

[For stability considerations of (a), via frequency derivatives of the virial equation, see Papastavridis (1986(b)).]

2. *Van der Pol oscillator*. Let us find the asymptotic ("limit cycle") amplitude of

$$\ddot{q} + \varepsilon(q^2 - 1)\dot{q} + q = 0, \tag{g}$$

where $\varepsilon(> 0)$ is such that the nonlinear damping term $\varepsilon(q^2 - 1)\dot{q}$ remains absolutely small relative to both inertia ($\ddot{q}$) and linear elasticity (q); that is, ε is a very small positive constant.

In the linear case—that is, for $\varepsilon = 0$—the solution of (g) is harmonic with frequency $\omega = 1$ and amplitude and phase depending on the initial conditions. Therefore, for $\varepsilon \neq 0$, we try the (asymptotically) harmonic solution

$$q = a \sin\chi, \qquad \chi = \omega t, \tag{h}$$

but with *both frequency* ω *and amplitude* a *unknown*. Here,

$$2T = (\dot{q})^2, \qquad 2V = q^2, \qquad Q = Q(q, \dot{q}) = -\varepsilon(q^2 - 1)\dot{q}, \tag{i}$$

and so the earlier virial equation yields

$$\begin{aligned} &\int_0^{2\pi/\omega} [2T - (\partial V/\partial q)q + Qq]\, dt \\ &\quad = \int_0^{2\pi/\omega} \left[(\dot{q})^2 - q^2 - \varepsilon(q^2 - 1)q\dot{q}\right] dt \\ &\quad = \cdots = (\pi/\omega)a^2(\omega^2 - 1) = 0 \;\Rightarrow\; \omega = 1; \end{aligned} \tag{j}$$

that is, if we insist on a harmonic solution, then the latter must have the undamped frequency.

Problem 7.2.7 *Virial Theorem* (*Nonlinear Oscillator*) (Killingbeck, 1970). Consider the unforced and undamped nonlinear (generalized Duffing) oscillator with Lagrangean

$$L = (1/2)(dq/dt)^2 - (1/2)\,\omega_o{}^2 q^2 - \varepsilon\, q^k \qquad [k\text{: } \textit{even} \text{ integer}], \tag{a}$$

and, accordingly, equation of motion

$$\ddot{q} + \omega_o{}^2 q + \varepsilon\, k\, q^{k-1} = 0. \tag{b}$$

For small amplitudes q (to ensure stability; i.e., $|\varepsilon| \ll 1$) the solution will be a symmetric anharmonic oscillation about the equilibrium position $q = 0$. By applying the virial theorem, and with $\langle \ldots \rangle \equiv$ *time average of* $(\ldots)$ *over the* (*unknown*) *period* $\tau = 2\pi/\omega$, show that

$$2\langle T \rangle = 2\langle \omega_o{}^2 q^2/2 \rangle + \varepsilon\, k \langle q^k \rangle. \tag{c}$$

Then show that, for the trial solution $q_o(t) = a\sin(\omega t)$ $[q_o(0) = q_o(2\pi/\omega) = 0$, $\dot{q}_o(0) = a\,\omega]$, the above yields the approximate frequency

$$\omega^2 = \omega_o{}^2 + 2\varepsilon\, k\, a^{k-2} \langle \sin^k q \rangle, \tag{d}$$

where the average of the last term is over 2π.

Problem 7.2.8 *Virial Theorem* (*Nonlinear Oscillator*) (Killingbeck, 1970). Continuing from the preceding problem, and applying energy conservation to it, show that the period of that oscillator has the following ε-power representation:

$$\tau = 2\int_{-a}^{+a} \left[{\omega_o}^2(a^2 - q^2) + 2\varepsilon(a^k - q^k)\right]^{-1/2} dq \qquad \text{[exact expression]}$$

$$= 2\pi/\omega_o - (2\varepsilon\, a^{k-2}/{\omega_o}^3)I + O(\varepsilon^2), \tag{a}$$

where k is an *even* integer, and

$$I \equiv \int_{-1}^{+1} (1 - y^2)^{-3/2}(1 - y^k)\, dy \tag{b1}$$

$$= \int_0^{\pi} (1 - \cos^k x)(1 - \cos^2 x)^{-1}\, dx \tag{b2}$$

$$= \int_0^{\pi} (1 + \cos^2 x + \cdots + \cos^{k-2} x)\, dx \tag{b3}$$

$$= \pi\, k\langle \sin^k x\rangle \qquad \text{[average over } 2\pi]. \tag{b4}$$

Problem 7.2.9 *Virial Theorem* (*Nonlinear Oscillator*) (Killingbeck, 1970). Referring to the exact expression for τ of the preceding problem, eq. (a), show that

$$\partial\tau/\partial\varepsilon < 0 \qquad \text{and} \qquad \partial^2\tau/\partial\varepsilon^2 > 0, \tag{a}$$

from which it follows that, *for large* ε, the virially obtained value of ω, to within $O(\varepsilon)$ terms, *overestimates* ω, *and therefore underestimates* τ.

Problem 7.2.10 *Variational and Virial Theorems for Linear Gyroscopic Systems*. Consider the linear, free, and undamped motions of a gyroscopic system (or the small such motions of a general system about *steady motion* or *relative equilibrium*). They are governed by the following equations (§3.10, §3.16):

$$E_k \equiv E_k(L_G) \equiv (\partial L_G/\partial \dot{q}_k)^{\cdot} - \partial L_G/\partial q_k = \sum (M_{kr}\ddot{q}_r + G_{kr}\dot{q}_r + V_{kr}q_r) = 0, \tag{a}$$

where

$$2T = \sum\sum M_{kr}\dot{q}_k\dot{q}_r \quad \text{(positive definite)}, \quad M_{kr} = M_{rk}\text{: constant}, \tag{b1}$$

$$2V = \sum\sum V_{kr}q_k q_r \quad \text{(assumed positive definite)}, \quad V_{kr} = V_{rk}\text{: constant}, \tag{b2}$$

$$2G = \sum\sum G_{kr}q_k\dot{q}_r \quad \text{(no sign properties)}, \quad G_{kr} = -G_{rk}\text{: constant}, \tag{b3}$$

and

$$L_G \equiv T - V - G\text{: } \textit{gyroscopic Lagrangean}. \tag{b4}$$

It can be shown that eqs. (a) can be brought to the *partially decoupled* form, in terms of the following "quasi-principal" (or "normal") coordinates x_r:

$$E_r \to m_r\ddot{x}_r + \sum g_{rs}\dot{x}_s + k_r x_r = 0, \tag{c}$$

where

$$2T = \sum m_r(\dot{x}_r)^2 \qquad \text{(positive definite and diagonal)}, \tag{d1}$$

$$2V = \sum k_r {x_r}^2 \qquad \text{(positive definite and diagonal)}, \tag{d2}$$

$$2G = \sum \sum g_{rs} x_r \dot{x}_s \qquad \text{(no sign properties)}, \qquad g_{rs} = -g_{rs} \text{ (constant)}. \tag{d3}$$

(i) With the help of the "gyroscopic action" $A_G \equiv \int L_G\, dt$, show that the above equations of motion can be derived from the following Hamilton-type variational principle:

$$\delta A_G = \textit{Boundary Terms} \qquad [= 0, \text{if, e.g.}, \delta q(t_1) = \delta q(t_2) = 0]. \tag{e}$$

(ii) Choosing in eq. (e) $\delta q = q$ (or $\delta x = x$), show that the following *virial gyroscopic theorem* results:

$$A_G \equiv \int L_G\, dt \equiv \int (T - V - G)\, dt = \Big\{(1/2) \sum (\partial T/\partial \dot{q}_r) q_r\Big\}_1^2. \tag{f}$$

(iii) Assuming the periodic free mode

$$x_r = a_r \cos(\omega t) + b_r \sin(\omega t), \tag{g}$$

and choosing $t_2 - t_1 = \tau \equiv 2\pi/\omega$: period, show that (f) yields the *gyroscopic generalization of the* (*virial* $\rightarrow$) *equipartition theorem*:

$$J \equiv \omega^2 T_x + \omega\, G_x - V_x = 0 \qquad (\Rightarrow \omega = \cdots), \tag{h}$$

where

$$2T_x \equiv \sum m_r({a_r}^2 + {b_r}^2), \qquad 2V_x \equiv \sum k_r({a_r}^2 + {b_r}^2), \qquad G_x \equiv \sum \sum g_{rs} a_r b_s. \tag{h1}$$

(iv) Assuming the mode (g) in (e), show that, for *fixed-frequency variations*,

$$\delta J \equiv \omega^2\, \delta T_x + \omega\, \delta G_x - \delta V_x = 0, \tag{i}$$

where

$$\delta x_r = \delta a_r \cos(\omega t) + \delta b_r \sin(\omega t). \tag{i1}$$

(v) In eq. (h), assume that the a_r and b_r are functions of ω, then form

$$\Delta J = \sum [(\ldots)\, \delta a_r + (\ldots)\, \delta b_r] + (\ldots)\, \delta\omega = 0, \tag{j}$$

and, combining it with (i), conclude that for that mode $\delta\omega = 0$.

For applications of this interesting "gyroscopic Rayleigh-like theorem," see, for example, Lamb (1932, pp. 313–315, 328–330, 337–338).

7.3 TIME-INTEGRAL THEOREMS: PFAFFIAN CONSTRAINTS, LINEAR NONHOLONOMIC VARIABLES

Here, the starting point is Hamel's equations (§3.5)

$$d/dt(\partial T^*/\partial \omega_k) - \partial T^*/\partial \theta_k - \Gamma_k = \Theta_k + \Lambda_k, \tag{7.3.1}$$

where, we are reminded,

$$T^* = T[t, q, \dot{q}(t, q, \omega)] \equiv T^*(t, q, \omega), \tag{7.3.1a}$$

$$\partial \ldots / \partial\theta_k \equiv \sum (\partial \ldots / \partial q_r)(\partial \dot{q}_r / \partial\omega_k) = \sum A_{rk}(\partial \ldots / \partial q_r) \qquad \text{[in Pfaffian case]}, \tag{7.3.1b}$$

$$\begin{aligned} -\Gamma_k &\equiv \sum\sum \gamma^b{}_{ks}(\partial T^*/\partial\omega_b)\omega_s + \sum \gamma^b{}_{k,n+1}(\partial T^*/\partial\omega_b)\omega_{n+1} \\ &\equiv \sum\sum \gamma^b{}_{ks}(\partial T^*/\partial\omega_b)\omega_s + \sum \gamma^b{}_k(\partial T^*/\partial\omega_b) \\ &\equiv \sum\sum \gamma^b{}_{ks}P_b\omega_s + \sum \gamma^b{}_k P_b \equiv \sum h^b{}_k P_b, \end{aligned} \tag{7.3.1c}$$

the Hamel coefficients $\gamma^b{}_{ks}$, $\gamma^b{}_{k,n+1} \equiv \gamma^b{}_k$, $h^b{}_k$ are defined by the *transitivity* relations [§2.10; and, again, assuming that $(\delta q_k)^{\cdot} = \delta(\dot{q}_k)$]

$$\begin{aligned} (\delta\theta_b)^{\cdot} - \delta\omega_b &= \sum\sum \gamma^b{}_{ks}\,\omega_s\,\delta\theta_k + \sum \gamma^b{}_k\,\delta\theta_k \\ &= \sum \Big(\sum \gamma^b{}_{ks}\,\omega_s + \gamma^b{}_k\Big)\,\delta\theta_k \equiv \sum h^b{}_k\,\delta\theta_k, \end{aligned} \tag{7.3.1d}$$

and the $\Theta_k(\Lambda_k)$ are the nonholonomic *impressed forces and constraint reactions*; and, of course, $\Lambda_D \neq 0$, $\Lambda_I = 0$. Multiplying each of (7.3.1) with the earlier arbitrary z_k's, and then summing over k, invoking chain rule, rearranging, and finally integrating between t_1 and t_2, we obtain the *generalized nonholonomic time-integral (or virial-like) identity*:

$$\begin{aligned} \int \Big[\sum (\partial T^*/\partial\omega_k)\dot{z}_k + \sum (\partial T^*/\partial\theta_k)z_k - \sum\sum h^b{}_k(\partial T^*/\partial\omega_b)z_k \\ + \sum (\Theta_k + \Lambda_k)z_k\Big]\,dt \;=\; \Big\{\sum (\partial T^*/\partial\omega_k)z_k\Big\}_1^2. \end{aligned} \tag{7.3.2}$$

Again, let us examine the following special z_k-choices:

(i) $z_k \to \delta\theta_k$ [recalling that now the constraints are simply $\delta\theta_D = 0$ (and $\delta\theta_{n+1} \equiv \delta t = 0$); while $\delta\theta_I \neq 0$]. Then (7.3.2) gives

$$\begin{aligned} \int \Big[\sum (\partial T^*/\partial\omega_k)(\delta\theta_k)^{\cdot} + \sum (\partial T^*/\partial\theta_k)\,\delta\theta_k - \sum\sum h^b{}_k(\partial T^*/\partial\omega_b)\,\delta\theta_k \\ + \sum (\Theta_k + \Lambda_k)\,\delta\theta_k\Big]\,dt = \Big\{\sum (\partial T^*/\partial\omega_k)\,\delta\theta_k\Big\}_1^2. \end{aligned} \tag{7.3.3}$$

However, due to the transitivity equations (7.3.1d), the *first* and *third* integrand terms combine to yield

$$\begin{aligned} \sum \Big[(\partial T^*/\partial\omega_k)\,\delta\omega_k + \sum h^b{}_k(\partial T^*/\partial\omega_b)\,\delta\theta_k\Big] - \sum\sum h^b{}_k(\partial T^*/\partial\omega_b)\,\delta\theta_k \\ = \sum (\partial T^*/\partial\omega_k)\,\delta\omega_k, \end{aligned} \tag{7.3.3a}$$

and, successively,

$$\begin{aligned} \sum (\partial T^*/\partial\theta_k)\,\delta\theta_k &= \sum \Big(\sum A_{sk}(\partial T^*/\partial q_s)\Big)\Big(\sum a_{kb}\,\delta q_b\Big) \\ &= \sum\sum (\partial T^*/\partial q_s)(\delta_{sb})\,\delta q_b = \sum (\partial T^*/\partial q_s)\,\delta q_s \end{aligned} \tag{7.3.3b}$$

[recalling that, since (a_{kr}) and (A_{sk}) are *inverse* matrices, $\sum A_{sk}a_{kb} = \delta_{sb}$: Kronecker delta], while, due to Lagrange's principle (§3.2),

$$\sum (\Theta_k + \Lambda_k)\,\delta\theta_k = \sum \Theta_k\,\delta\theta_k = \sum \Theta_I\,\delta\theta_I \equiv \delta' W^*; \tag{7.3.3c}$$

and so, finally, (7.3.3) reduces to *Hamilton's law of virtual and nonholonomic action*:

$$\int \Big(\delta T^* + \sum \Theta_I\,\delta\theta_I\Big)\,dt = \Big\{\sum P_I\,\delta\theta_I\Big\}_1^2, \tag{7.3.4}$$

where

$$\begin{aligned}\delta T^* = \delta T^*(t, q, \omega) &= \sum \big[(\partial T^*/\partial\omega_k)\,\delta\omega_k + (\partial T^*/\partial q_k)\,\delta q_k\big]\\ &= \sum \big[(\partial T^*/\partial\omega_k)\,\delta\omega_k + (\partial T^*/\partial\theta_k)\,\delta\theta_k\big].\end{aligned} \tag{7.3.4a}$$

Clearly, since (7.3.4) involves only the independent $\delta\theta_I$'s it can supply only the $n - m$ *kinetic* equations of motion. If we want *all* n equations—that is, $n - m$ *kinetic* + m *kinetostatic*—then can we replace (7.3.4) with one or the other of the following two equivalent formulations: either

$$\int \Big(\delta T^* + \sum \Theta_D\,\delta\theta_D + \sum \Theta_I\,\delta\theta_I\Big)\,dt = \Big\{\sum P_I\,\delta\theta_I\Big\}_1^2, \tag{7.3.5}$$

under the constraints

$$1\,\delta\theta_1 = 1\,\delta\theta_2 = \cdots = 1\,\delta\theta_m = 0 \qquad (\text{and}\ \ 0\,\delta\theta_{m+1} = 0\,\delta\theta_{m+2} = \cdots = 0\,\delta\theta_n = 0), \tag{7.3.5a}$$

or

$$\int \Big[\delta T^* + \sum (\Theta_D + \Lambda_D)\,\delta\theta_D + \sum \Theta_I\,\delta\theta_I\Big]\,dt = \Big\{\sum P_I\,\delta\theta_I\Big\}_1^2, \tag{7.3.6}$$

under the constraints

$$0\,\delta\theta_1 = 0\,\delta\theta_2 = \cdots = 0\,\delta\theta_n = 0 \qquad (\text{i.e., with } all\ \delta\theta_k \text{ unconstrained}). \tag{7.3.6a}$$

(ii) $z_k \to \dot\theta_k \equiv \omega_k$ (recalling that now the constraints are simply $\omega_D = 0$). Then (7.3.2) gives

$$\begin{aligned}\int \Big[\sum (\partial T^*/\partial\omega_I)\dot\omega_I + \sum (\partial T^*/\partial\theta_I)\omega_I - \sum\sum h^b{}_I(\partial T^*/\partial\omega_b)\omega_I + \sum \Theta_I\omega_I\Big]\,dt&\\ = \Big\{\sum (\partial T^*/\partial\omega_I)\omega_I\Big\}_1^2.&\end{aligned} \tag{7.3.7}$$

However:

(a) recalling the $\partial\ldots/\partial\theta_k$ definition (7.3.1b) and that $\dot q_k = \sum A_{kI}\omega_I + A_k$, we see that the *second* integrand sum equals $\sum (\partial T^*/\partial q_k)(\dot q_k - A_k)$;

(b) recalling the h-definition (7.3.1d) and the antisymmetry of the γ's in their subscripts—that is, $\gamma^b{}_{kl} = -\gamma^b{}_{lk}$ [and (3.9.12 ff.)]—we see that the *third* integrand (double) sum reduces to

$$-\sum\sum \gamma^b{}_I P_b\,\omega_I, \tag{7.3.7a}$$

and

(c) rewriting the *right*-hand side as $\int [\sum (\partial T^*/\partial\omega_I)\omega_I]^{\cdot}\, dt$, all these partial results allow us to convert (7.3.7) to

$$\int \Big\{ \Big[\sum (\partial T^*/\partial\omega_I)\omega_I - T \Big]^{\cdot} \\ - \Big[-\partial T^*/\partial t - \sum (\partial T^*/\partial q_k) A_k - \sum\sum \gamma^b{}_I P_b\, \omega_I + \sum \Theta_I \omega_I \Big] \Big\}\, dt = 0, \tag{7.3.7b}$$

from which, since the limits t_1 and t_2 are arbitrary, we finally obtain the most general (nonpotential) form of the generalized power theorem, for systems under Pfaffian constraints and in nonholonomic variables:

$$\Big[\sum (\partial T^*/\partial\omega_I)\omega_I - T \Big]^{\cdot} \\ = -\partial T^*/\partial t - \sum (\partial T^*/\partial q_k) A_k - \sum\sum \gamma^b{}_I P_b\, \omega_I + \sum \Theta_I\, \omega_I \\ \equiv -\partial T^*/\partial\theta_{n+1} + R + \sum \Theta_I\, \omega_I, \tag{7.3.7c}$$

where, in the last line, we invoked the earlier helpful notations (3.9.12f ff.)

$$\partial T^*/\partial\theta_{n+1} \equiv \partial T^*/\partial t + \sum (\partial T^*/\partial q_k) A_k, \qquad R \equiv -\sum\sum \gamma^b{}_I P_b\, \omega_I. \tag{7.3.7d}$$

(iii) $z_k \to \theta_k$: This case is meaningless because there is no such thing as θ_k.
(iv) $z_k \to \omega_k$: This choice does not seem to lead to any recognizably useful result.
(v) $z_k \to \Delta\theta_k$: Here, we must define $\Delta\theta_k$. We have, successively,

$$\Delta q_k = \delta q_k + \dot{q}_k\, \Delta t = \sum A_{kb}\, \delta\theta_b + \Big(\sum A_{kb}\omega_b + A_k \Big) \Delta t \\ = \sum A_{kb}(\delta\theta_b + \omega_b\, \Delta t) + A_k\, \Delta t \equiv \sum A_{kb}\, \Delta\theta_b + A_k\, \Delta t; \tag{7.3.8a}$$

that is, we can define consistently

$$\Delta\theta_b \equiv \delta\theta_b + \dot{\theta}_b\, \Delta t \equiv \delta\theta_b + \omega_b\, \Delta t. \tag{7.3.8b}$$

Inverting (7.3.8a), we find

$$\Delta\theta_b = \sum a_{bk}\, \Delta q_k + a_b\, \Delta t; \qquad \Delta\theta_D = 0, \qquad \Delta\,\theta_I \neq 0. \tag{7.3.8c}$$

We also need *commutation* relations between $(\Delta\theta)^{\cdot}$ and $\Delta(\dot{\theta})$; that is, the nonholonomic counterpart of (7.2.4e). Indeed, $(\ldots)^{\cdot}$-differentiating (7.3.8b) leads to

$$(\Delta\theta_b)^{\cdot} \equiv (\delta\theta_b)^{\cdot} + \dot{\omega}_b\, \Delta t + \omega_b(\Delta t)^{\cdot}, \tag{7.3.8d}$$

while applying the definition (7.3.8d) to $\dot{\theta}_k \equiv \omega_k$ yields

$$\Delta(\dot{\theta}_b) = \delta(\dot{\theta}_b) + \ddot{\theta}_b\, \Delta t, \qquad \text{or} \qquad \Delta\omega_b = \delta\omega_b + \dot{\omega}_b\, \Delta t. \tag{7.3.8e}$$

Therefore, subtracting (7.3.8e) from (7.3.8d) side by side, while invoking the transitivity relations (7.3.1d), we find

$$(\Delta\theta_b)^{\cdot} - \Delta\omega_b = (\delta\theta_b)^{\cdot} - \delta(\dot{\theta}_b) + \omega_b(\Delta t)^{\cdot} = \sum h^b{}_k\, \delta\theta_k + \omega_b(\Delta t)^{\cdot}. \tag{7.3.8f}$$

Now, under $z_k \to \Delta\theta_k$ eq. (7.3.2) becomes

$$\int \Big[\sum (\partial T^*/\partial\omega_k)(\Delta\theta_k)^{\cdot} + \sum (\partial T^*/\partial\theta_k)\,\Delta\theta_k - \sum\sum h^b{}_k(\partial T^*/\partial\omega_b)\,\Delta\theta_k + \sum (\Theta_k + \Lambda_k)\,\Delta\theta_k)\Big]\,dt = \Big\{\sum (\partial T^*/\partial\omega_k)\,\Delta\theta_k\Big\}_1^2, \quad (7.3.9a)$$

or, invoking (7.3.8f) for the *first* integrand sum, recalling that $\gamma^b{}_{kl} = -\gamma^b{}_{lk}$, and renaming some dummy indices, we finally obtain *Hamilton's law of skew-varying action in nonholonomic variables*:

$$\int \Big\{\sum (\partial T^*/\partial\theta_k)\,\Delta\theta_k + \sum (\partial T^*/\partial\omega_k)\,\Delta\omega_k + \sum (\partial T^*/\partial\omega_k)\Big[\omega_k(\Delta t)^{\cdot} - \sum \gamma^k{}_b\,\omega_b\,\Delta t\Big] + \sum (\Theta_k + \Lambda_k)\,\Delta\theta_k\Big\}\,dt = \Big\{\sum (\partial T^*/\partial\omega_k)\,\Delta\theta_k\Big\}_1^2. \quad (7.3.9b)$$

Here, too, we remember to set $\omega_D = 0$, $\omega_k \to \omega_I$; and, regarding the works $\sum (\Theta_k + \Lambda_k)\,\Delta\theta_k$, recalling the arguments leading to (7.3.4–6a):

(a) If we need only the kinetic equations from (7.3.9b), then we set in there

$$\Delta' W^* \equiv \sum \Theta_k\,\Delta\theta_k \equiv \sum \Theta_k\,\delta\theta_k + \Big(\sum \Theta_k\,\omega_k\Big)\,\Delta t = \sum \Theta_I\,\delta\theta_I + \Big(\sum \Theta_I\,\omega_I\Big)\,\Delta t = \sum \Theta_I\,\Delta\theta_I, \quad (7.3.9c)$$

$$\Delta' W_R{}^* \equiv \sum \Lambda_k\,\Delta\theta_k = \cdots = 0; \quad (7.3.9d)$$

whereas

(b) If we want to obtain both the kinetic and kinetostatic equations from (7.3.9b), then, either we set

$$\Delta' W^* = \sum \Theta_D\,\Delta\theta_D + \sum \Theta_I\,\Delta\theta_I \qquad \text{and} \qquad \Delta' W_R{}^* = 0, \quad (7.3.9e)$$

under the constraints

$$1\,\delta\theta_D = 0, \quad 1\,\omega_D = 0 \;\Rightarrow\; 1\,\Delta\theta_D = 0; \quad (7.3.9f)$$

or

$$\Delta' W^* = \sum \Theta_D\,\Delta\theta_D + \sum \Theta_I\,\Delta\theta_I \qquad \text{and} \qquad \Delta' W_R{}^* = \sum \Lambda_D\,\Delta\theta_D, \quad (7.3.9g)$$

with *all* $\delta\theta_k$ unconstrained. The details are left to the reader.

Finally, we notice that if we set in (7.3.9a,b) $\Delta t = 0$, we recover the virtual equations (7.3.3) $\to$ (7.3.4), as expected.

This completes the discussion of time-integral theorems and variational principles under Pfaffian constraints. In the next section, §7.4, these results are extended to *nonlinear* (holonomic and/or nonholonomic) velocity constraints (chap. 5):

$$f_D(t, q, \dot{q}) = 0 \qquad [D = 1, \ldots, m(< n)]. \quad (7.3.10)$$

Example 7.3.1 *The Maggi → Chaplygin–Hadamard Form of Hamilton's Principle*; that is, Hamilton's principle for systems subject to the special Pfaffian constraints (in virtual form)

$$\delta q_D = \sum b_{DI}\,\delta q_I, \qquad b_{DI} = b_{DI}(t, q); \tag{a}$$

with nonlinear counterpart $b_{DI} \to \partial\phi_D(t, q, \dot{q}_I)/\partial\dot{q}_I$ (see also §7.8).

Adopting the *Hölder–Voronets–Hamel* viewpoint—that is, $\delta(\dot{q}_k) = (\delta q_k)^{\cdot}$ for *all* holonomic coordinates—with the convenient notation $\{\sum(\partial T/\partial\dot{q}_k)\,\delta q_k\}_1^2 \equiv B_{\text{Boundary,}}\, T_{\text{Terms}} \equiv BT$, and (a), we find, successively,

$$\begin{aligned}
\int \delta T\,dt &= \int \sum \left[(\partial T/\partial q_k)\,\delta q_k + (\partial T/\partial\dot{q}_k)\,\delta(\dot{q}_k)\right] dt \\
&= \cdots = BT - \int \sum E_k(T)\,\delta q_k\,dt \\
&= BT - \int \left[\sum E_D(T)\,\delta q_D + \sum E_I(T)\,\delta q_I\right] dt \\
&= BT - \int \sum \left[E_I(T) + \sum b_{DI} E_D(T)\right] \delta q_I\,dt;
\end{aligned} \tag{b}$$

and, similarly,

$$\begin{aligned}
\int \delta' W\,dt \equiv \int \sum Q_k\,\delta q_k = \cdots &= \int \sum \left(Q_I + \sum b_{DI} Q_D\right) \delta q_I\,dt \\
&\equiv \int \left(\sum Q_{Io}\,\delta q_I\right) dt \equiv \int \delta' W_o\,dt.
\end{aligned} \tag{c}$$

Therefore,

$$\int (\delta T + \delta' W)\,dt \;=\; BT - \int \sum \left[E_I(T) + \sum b_{DI} E_D(T) - Q_{Io}\right] \delta q_I\,dt, \tag{d}$$

from which, since the δq_I are unconstrained, we obtain the $n - m$ kinetic (multiplierless) Chaplygin–Hadamard equations (not to be confused with the nonholonomic Chaplygin equations)

$$E_I(T) + \sum b_{DI} E_D(T) = Q_I + \sum b_{DI} Q_D. \tag{e}$$

As already explained in §3.8, here all constraint enforcement occurs at the final level; that is, in (e), *not* in T.

If we had used in (b, c) the general representations (§2.6)

$$\delta q_k = \sum A_{kI}\,\delta\theta_I; \qquad \delta\theta_D = \sum a_{Dk}\,\delta q_k = 0, \quad \delta\theta_I = 0, \tag{f}$$

where the (a_{kl}) and (A_{kl}) are inverse matrices, then Hamilton's principle would have led us to

$$\int (\delta T + \delta' W)\, dt = BT - \int \left\{ \sum \sum [E_k(T) - Q_k] A_{kD}\, \delta\theta_D \right\} dt$$
$$- \int \left\{ \sum \sum [E_k(T) - Q_k] A_{kI}\, \delta\theta_I \right\} dt; \qquad \text{(g)}$$

and this, with the help of the m multipliers λ_D, would have led us to the familiar Maggi equations (§3.5)

$$\textit{Kinetostatic:} \qquad \sum E_k(T) A_{kD} = \sum Q_k A_{kD} + \lambda_D, \qquad \text{(h)}$$

$$\textit{Kinetic:} \qquad \sum E_k(T) A_{kI} = \sum Q_k A_{kI}. \qquad \text{(i)}$$

Example 7.3.2 *The Torque-Free Case of the Sled Problem, via the preceding Hamiltonian formulation of the Chaplygin–Hadamard Equations.* (Recalling exs. 2.13.1, 2.13.2, and 3.18.1; also see Hamel, 1949, pp. 614–615.) We have seen there that the constraint is

$$\dot{x} \sin\phi - \dot{y}\cos\phi = 0 \;\Rightarrow\; \delta y = (\tan\phi)\, \delta x \qquad \text{(a)}$$

(i.e., $\delta q_D \equiv \delta y, \delta q_I \equiv \delta x, \delta\phi; n = 3, m = 1$), while the unconstrained kinetic energy of the sled is [with $I_{\text{Contact point}} \equiv I_C \equiv I$]

$$\begin{aligned} 2T &= m[(\dot{x}_G)^2 + (\dot{y}_G)^2] + I(\dot{\phi})^2 \\ &= m[(\dot{x} - b\dot{\phi}\sin\phi)^2 + (\dot{y} + b\dot{\phi}\cos\phi)^2] + I(\dot{\phi})^2 \\ &= m[(\dot{x})^2 + (\dot{y})^2] + I(\dot{\phi})^2 + 2m\, b\, \dot{\phi}(\dot{y}\cos\phi - \dot{x}\sin\phi). \end{aligned} \qquad \text{(b)}$$

Applying Hamilton's principle directly, with all impressed forces zero (i.e., $\delta' W^* = 0$), and the δq's chosen so that $BT \to 0$, we obtain

$$0 = \int \delta T\, dt = \int \left[(\partial T/\partial \dot{x})\, \delta(\dot{x}) + (\partial T/\partial \dot{y})\, \delta(\dot{y}) + (\partial T/\partial \phi)\, \delta\phi + (\partial T/\partial \dot{\phi})\, \delta(\dot{\phi}) \right] dt$$
$$= \left\{ (\partial T/\partial \dot{x})\, \delta x + (\partial T/\partial \dot{y})\, \delta y + (\partial T/\partial \dot{\phi})\, \delta\phi \right\}_1^2$$
$$- \int \left\{ (\partial T/\partial \dot{x})^{\cdot}\, \delta x + (\partial T/\partial \dot{y})^{\cdot}\, \delta y + [(\partial T/\partial \dot{\phi})^{\cdot} - (\partial T/\partial \phi]\, \delta\phi \right\} dt$$

[and enforcing the second constraint of (a) on the integrand variations, not on T]

$$= - \int \left\{ [(\partial T/\partial \dot{x})^{\cdot} + \tan\phi (\partial T/\partial \dot{y})^{\cdot}]\, \delta x + [(\partial T/\partial \dot{\phi})^{\cdot} - \partial T/\partial \phi]\, \delta\phi \right\} dt, \qquad \text{(c)}$$

from which, since δx and $\delta\phi$ can now be viewed as unconstrained, we obtain the *two* kinetic Chaplygin–Hadamard equations

$$(\partial T/\partial \dot{x})^{\cdot} + \tan\phi (\partial T/\partial \dot{y})^{\cdot} = 0: \quad (\dot{x} - b\, \dot{\phi}\sin\phi)^{\cdot} + \tan\phi\, (\dot{y} + b\, \dot{\phi}\cos\phi)^{\cdot} = 0, \qquad \text{(d)}$$

and

$$(\partial T/\partial\dot{\phi})^{\cdot} - \partial T/\partial\phi = 0:$$

$$[I\dot{\phi} + m\,b(\dot{y}\cos\phi - \dot{x}\sin\phi)]^{\cdot} + m\,b\,\dot{\phi}(\dot{x}\cos\phi + \dot{y}\sin\phi) = 0. \tag{e}$$

Since $\dot{y} = \dot{x}\tan\phi \equiv v\sin\phi$, $\dot{x} = v\cos\phi$ (v: velocity of C), eqs. (d, e) can be rewritten, respectively, in the quasi-velocity (Hamel) form:

$$(v\cos\phi - b\,\dot{\phi}\sin\phi)^{\cdot} + \tan\phi(v\sin\phi + b\,\dot{\phi}\cos\phi)^{\cdot} = 0 \Rightarrow \dot{v} - b(\dot{\phi})^2 = 0, \tag{f}$$

$$I\ddot{\phi} + m\,b\,\dot{\phi}\,v = 0. \tag{g}$$

Let the reader repeat this procedure with the constraints in the form $\delta x = (\cot\phi)\,\delta y$; that is, with $\delta q_D = \delta x$, $\delta q_I = \delta y$, $\delta\phi$.

Example 7.3.3 *The Sled via Hamel's Form of Hamilton's Principle.* We have already established the following kinematical results (recall ex. 2.13.2):

$$q_{1,2,3} = x, y, \phi; \tag{a}$$

$$\omega_I \equiv (-\sin\phi)\dot{x} + (\cos\phi)\dot{y} + (0)\dot{\phi}$$
$$(= \text{velocity of contact point } C \text{ normal to sled} = 0), \tag{b1}$$

$$\omega_2 \equiv (\cos\phi)\dot{x} + (\sin\phi)\dot{y} + (0)\dot{\phi}$$
$$(= \text{velocity of } C \text{ along sled} = v \neq 0), \tag{b2}$$

$$\omega_3 \equiv (0)\dot{x} + (0)\dot{y} + (1)\dot{\phi} = \dot{\phi} \quad (\neq 0); \tag{b3}$$

$$\dot{q}_1 \equiv \dot{x} = (-\sin\phi)\omega_1 + (\cos\phi)\omega_2 + (0)\omega_3, \tag{c1}$$

$$\dot{q}_2 \equiv \dot{y} = (\cos\phi)\omega_1 + (\sin\phi)\omega_2 + (0)\omega_3, \tag{c2}$$

$$\dot{q}_3 \equiv \dot{\phi} = (0)\omega_1 + (0)\omega_2 + (1)\omega_3; \tag{c3}$$

$$\delta\omega_1 = (\delta\theta_1)^{\cdot} + (0)\,\delta\theta_1 + (\omega_3)\,\delta\theta_2 + (-\omega_2)\,\delta\theta_3, \tag{d1}$$

$$\delta\omega_2 = (\delta\theta_2)^{\cdot} + (-\omega_3)\,\delta\theta_1 + (0)\,\delta\theta_2 + (\omega_1)\,\delta\theta_3, \tag{d2}$$

$$\delta\omega_3 = (\delta\theta_3)^{\cdot} + (0)\,\delta\theta_1 + (0)\,\delta\theta_2 + (0)\,\delta\theta_3; \tag{d3}$$

and so, recalling the results of the preceding example, the unconstrained kinetic energy of the sled becomes

$$2T \to 2T^* = m\,\omega_2{}^2 + I\omega_2{}^3 + m\,b\,\omega_1\omega_3. \tag{e}$$

Hence, varying the above *and then enforcing the constraint* $\omega_1 = 0$ (but *not* $\delta\theta_1 = 0$), we find

$$\begin{aligned}\delta T^* &= \sum (\partial T^*/\partial\omega_k)_o\,\delta\omega_k \equiv \sum P_{ko}\,\delta\omega_k \qquad [\text{invoking (d1–3) with } \omega_1 = 0] \\ &= P_1(\delta\theta_1)^{\cdot} + (-P_2\omega_3)\,\delta\theta_1 \\ &\quad + P_2(\delta\theta_2)^{\cdot} + (P_1\omega_3)\,\delta\theta_2 \\ &\quad + P_3(\delta\theta_3)^{\cdot} + (-P_1\omega_2)\,\delta\theta_3 \qquad [\neq \delta(T^*{}_o), \text{see also §7.7}],\end{aligned} \tag{f}$$

where

$$P_1 = m\,b\,\omega_3, \qquad P_2 = m\,\omega_2, \qquad P_3 = (m\,b\,\omega_1 + I\,\omega_3)_o = I\,\omega_3; \tag{g}$$

and

$$\delta' W^* \equiv \sum \Theta_k\,\delta\theta_k \quad (\equiv \delta' W). \tag{h}$$

Applying now Hamilton's principle directly [integrating by parts, grouping terms appropriately, and choosing the $\delta\theta$'s so that $BT \to 0$ (something that does no affect the equations of motion)], we obtain

$$\begin{aligned} 0 &= \int (\delta T^* + \delta' W^*)\,dt \\ &= \cdots = -\int \big[(\dot{P}_1 + P_2\,\omega_3 - \Theta_1)\,\delta\theta_1 + (\dot{P}_2 - P_1\,\omega_3 - \Theta_2)\,\delta\theta_2 \\ &\qquad\qquad + (\dot{P}_3 + P_1\,\omega_2 - \Theta_3)\,\delta\theta_3\big]\,dt; \end{aligned} \tag{i}$$

and from this, invoking the familiar multiplier arguments [$\delta\theta_1 = (1)\,\delta\theta_1 = 0$, $\delta\theta_{2,3}$: unconstrained], we finally get all three Hamel equations of the problem (recall ex. 3.18.1):

Kinetostatic:

$$\dot{P}_1 + P_2\,\omega_3 = \Theta_1 + \lambda_1: \qquad m(b\,\dot{\omega}_3 + \omega_2\,\omega_3) = \Theta_1 + \lambda_1; \tag{j1}$$

Kinetic:

$$\dot{P}_2 - P_1\,\omega_3 = \Theta_2: \qquad m(\dot{\omega}_2 - b\,{\omega_3}^2) = \Theta_2, \tag{j2}$$

$$\dot{P}_3 + P_1\,\omega_2 = \Theta_3: \qquad I\dot{\omega}_3 + m\,b\,\omega_2\,\omega_3 = \Theta_3, \tag{j3}$$

where

$\Theta_1 = -X\sin\phi + Y\cos\phi$: total impressed force *perpendicular* to sled, (k1)

$\Theta_2 = X\cos\phi + Y\sin\phi$: total impressed force *along* sled, (k2)

$\Theta_3 = M$: total impressed couple along z-axis; (k3)

(X, Y): rectangular Cartesian coordinates of total impressed force on sled; (k4)

obtained from the invariant equation (as if no constraint $\delta\theta_1 = 0$ existed):

$$\begin{aligned} \delta' W &\equiv X\,\delta x + Y\,\delta y + M\,\delta\phi \\ &= X(-\sin\phi\,\delta\theta_1 + \cos\phi\,\delta\theta_2) + Y(\cos\phi\,\delta\theta_1 + \sin\phi\,\delta\theta_2) + M\,\delta\theta_3 \\ &= \Theta_1\,\delta\theta_1 + \Theta_2\,\delta\theta_2 + \Theta_3\,\delta\theta_3 \equiv \delta' W^*. \end{aligned} \tag{k5}$$

Finally, since here all constraints are scleronomic, the power equation is

Holonomic variables: $\quad dT/dt = X\dot{x} + Y\dot{y} + M\dot{\phi},$ (l1)

Nonholonomic variables: $\quad dT^*/dt = \Theta_2\omega_2 + \Theta_3\omega_3;$ (l2) from which we conclude that if $\Theta_{2,3} = 0$, then $T^* = constant$

$$\Rightarrow \ (2T^*)_o = m\,\omega_2{}^2 + I\,\omega_3{}^2 = m\,v^2 + I(\dot{\phi})^2 = constant. \tag{13}$$

7.4 TIME-INTEGRAL THEOREMS: NONLINEAR VELOCITY CONSTRAINTS, HOLONOMIC VARIABLES

We recall (§5.1, §5.2) that the virtual displacements compatible with the constraints (§7.3.10) must satisfy, not the formal $\delta(\ldots)$-variation of $f_D(t, q, \dot{q}) = 0$ — that is,

$$\sum \left[(\partial f_D/\partial q_k)\,\delta q_k + (\partial f_D/\partial \dot{q}_k)\,\delta(\dot{q}_k)\right] = 0, \tag{7.4.1a}$$

but, instead, the *Maurer–Appell–Chetaev–Johnson–Hamel* conditions

$$\delta\theta_D \equiv \sum (\partial f_D/\partial \dot{q}_k)\,\delta q_k = 0; \tag{7.4.1b}$$

and, again,

$$d(\delta q_k) = \delta(dq_k). \tag{7.4.1c}$$

Here, the starting point is the *nonlinear Routh–Voss* equations (5.3.11c)

$$E_k(T) \equiv (\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k = Q_k + \sum \lambda_D(\partial f_D/\partial \dot{q}_k); \tag{7.4.2}$$

that is, equations (7.2.1) with a_{Dk} replaced by $\partial f_D/\partial \dot{q}_k$.

Performing similar operations on (7.4.2) as on (7.2.1), we readily find the following *generalized nonlinear holonomic time integral (or virial-like) identity*:

$$\int \left\{ \sum (\partial T/\partial \dot{q}_k)\dot{z}_k + \sum \left[\partial T/\partial q_k + Q_k + \sum \lambda_D\,(\partial f_D/\partial \dot{q}_k)\right] z_k \right\} dt = \left\{ \sum (\partial T/\partial \dot{q}_k) z_k \right\}_1^2. \tag{7.4.3}$$

Next, from (7.4.3) we obtain the following group of special integral formulae:

(i) The choice $z_k \to q_k$ yields the virial theorem

$$\int \left\{ \sum (\partial T/\partial \dot{q}_k)\dot{q}_k + \sum \left[\partial T/\partial q_k + Q_k + \sum \lambda_D\,(\partial f_D/\partial \dot{q}_k)\right] q_k \right\} dt = \left\{ \sum (\partial T/\partial \dot{q}_k) q_k \right\}_1^2. \tag{7.4.4}$$

If $\partial T/\partial q_k = 0$ and $\sum (\partial T/\partial \dot{q}_k)\dot{q}_k = 2T$, and the q-motion is *periodic* with period τ, then (7.4.4) reduces to:

$$\int 2T\,dt = -\int \sum \left[Q_k + \sum \lambda_D\,(\partial f_D/\partial \dot{q}_k)\right] q_k\,dt, \tag{7.4.4a}$$

where the integrals extend from t_1 to $t_2 = t_1 + \tau$.

(ii) The choice $z_k \to \dot{q}_k$ yields

$$\int \Big\{ \sum (\partial T/\partial \dot{q}_k)\ddot{q}_k + \sum \Big[\partial T/\partial q_k + Q_k + \sum \lambda_D\,(\partial f_D/\partial \dot{q}_k)\Big]\dot{q}_k \Big\}\,dt$$
$$= \Big\{ \sum (\partial T/\partial \dot{q}_k)\dot{q}_k \Big\}_1^2 = \int \sum [(\partial T/\partial \dot{q}_k)\dot{q}_k]^{\cdot}\,dt, \qquad (7.4.5a)$$

from which, using earlier described arguments, we obtain the *nonlinear (nonpotential) generalized power equation*:

$$\Big[\sum (\partial T/\partial \dot{q}_k)\dot{q}_k - T\Big]^{\cdot} = -\partial T/\partial t + \sum Q_k\dot{q}_k + \sum\sum \lambda_D\,(\partial f_D/\partial \dot{q}_k)\dot{q}_k. \quad (7.4.5b)$$

Specialization

If $\partial T/\partial t = 0$ and $\sum (\partial T/\partial \dot{q}_k)\dot{q}_k = 2T$, the above reduces to

$$dT/dt = \sum Q_k\dot{q}_k + \sum\sum \lambda_D(\partial f_D/\partial \dot{q}_k)\dot{q}_k; \qquad (7.4.5c)$$

a "kinetostatic" form which shows that, even if $Q_k = -\partial V(q)/\partial q_k$ and $\partial f_D/\partial t = 0$, in general, nonlinear velocity constraints are *nonconservative*. However, it is not hard to see that, if the constraints $f_D = 0$ are *homogeneous* (of any degree) in the $\dot{q}$'s, and the Q_k's derive from a potential $V(q)$, then the system is conservative.

(iii) The choice $z_k \to \delta q_k$ yields again Hamilton's law of varying action (7.2.3b): by (7.4.1b) we will have

$$\delta' W_R \equiv \sum\sum \lambda_D(\partial f_D/\partial \dot{q}_k)\,\delta q_k = 0 \qquad \text{(Lagrange's principle)}. \qquad (7.4.6)$$

(iv) The choice $z_k \to \Delta q_k = \delta q_k + \dot{q}_k\Delta t$, thanks to (7.4.6), yields *Hamilton's law of skew-varying action*:

$$\int \Big\{ \sum (\partial T/\partial \dot{q}_k)\,(\Delta q_k)^{\cdot} + \sum (\partial T/\partial q_k + Q_k)\,\Delta q_k + \Big[\sum\sum \lambda_D(\partial f_D/\partial \dot{q}_k)\dot{q}_k\Big]\Delta t \Big\}\,dt$$
$$= \Big\{ \sum (\partial T/\partial \dot{q}_k)\,\Delta q_k \Big\}_1^2. \quad (7.4.7)$$

Here, too, if the constraints are homogeneous in the $\dot{q}$'s, then the last integrand (double) sum vanishes; also, we may replace $(\Delta q)^{\cdot}$ with $\Delta(\dot{q}) + \dot{q}(\Delta t)^{\cdot}$.

7.5 TIME-INTEGRAL THEOREMS: NONLINEAR VELOCITY CONSTRAINTS, NONLINEAR NONHOLONOMIC VARIABLES

Here, the starting point is the Johnsen–Hamel equations of motion (§5.3)

$$d/dt(\partial T^*/\partial \omega_k) - \partial T^*/\partial \theta_k - \Gamma_k = \Theta_k + \Lambda_k, \qquad (7.5.1)$$

where, we are reminded (§5.2),

$$\Gamma_k = -\sum H^b{}_k(\partial T^*/\partial \omega_b) = \sum V^b{}_k(\partial T/\partial \dot{q}_b)^*, \qquad (7.5.1a)$$

and the nonlinear coefficients $H^b{}_k$ (Hamel) and $V^b{}_k$ (Voronets) can be defined by [*assuming again that* $(\delta q_k)^\cdot = \delta(\dot{q}_k)$]

$$(\delta\theta_b)^\cdot - \delta\omega_b = \sum E_s(\omega_b)\,\delta q_s = \sum\sum E_s(\omega_b)\,(\partial\dot{q}_s/\partial\omega_k)\,\delta\theta_k \equiv \sum H^b{}_k\,\delta\theta_k$$
$$= -\sum\sum E_k{}^*\,(\dot{q}_l)\,(\partial\omega_b/\partial\dot{q}_l)\,\delta\theta_k \equiv -\sum\sum V^l{}_k(\partial\omega_b/\partial\dot{q}_l)\,\delta\theta_k; \tag{7.5.1b}$$

also, the virtual variations are related by

$$\delta q_s = \sum (\partial\dot{q}_s/\partial\omega_k)\,\delta\theta_k \;\Leftrightarrow\; \delta\theta_k = \sum (\partial\omega_k/\partial\dot{q}_s)\,\delta q_s, \tag{7.5.1c}$$

and, of course, $\Lambda_D \neq 0, \Lambda_I = 0$.

Now, to build corresponding integral theorems, and so on, we, again, multiply (7.5.1) with the arbitrary set of functions $z_k(t)$, sum over k, apply chain rule, and so on, and, finally, integrate between t_1 and t_2. Below we show the details only for the important case $z_k \to \delta\theta_k$; that is; for *Hamilton's principle of vertically varying action*; those of the other cases are left to the reader (see also §7.6–7.9). Invoking the transitivity equations (7.5.1b) we find, successively,

$$\delta T^* = \sum [(\partial T^*/\partial\theta_k)\,\delta\theta_k + (\partial T^*/\partial\omega_k)\,\delta\omega_k]$$
$$= \sum \Big\{(\partial T^*/\partial\theta_k)\,\delta\theta_k + (\partial T^*/\partial\omega_k)\,\Big[(\delta\theta_k)^\cdot - \sum H^k{}_b\,\delta\theta_b\Big]\Big\}$$
$$= \Big[\sum (\partial T^*/\partial\omega_k)\,\delta\theta_k\Big]^\cdot - \sum (\partial T^*/\partial\omega_k)^\cdot\,\delta\theta_k$$
$$- \sum\sum H^k{}_b(\partial T^*/\partial\omega_k)\,\delta\theta_b + \sum (\partial T^*/\partial\theta_k)\,\delta\theta_k, \tag{7.5.2a}$$

and, therefore, integrating, we obtain the general kinematico-inertial transformation

$$\int \delta T^*\,dt = -\int \sum \Big[(\partial T^*/\partial\omega_k)^\cdot - \partial T^*/\partial\theta_k + \sum H^b{}_k(\partial T^*/\partial\omega_b)\Big]\,\delta\theta_k\,dt$$
$$+ \Big\{\sum(\partial T^*/\partial\omega_k)\,\delta\theta_k\Big\}_1^2; \tag{7.5.2b}$$

a result that shows the equivalence between the equations of motion (7.5.1, 1a) [plus boundary conditions $\delta\theta(t_{1,2})$] and the nonlinear counterpart of equations (7.3.4–6):

$$\int (\delta T^* + \delta' W^*)\,dt = \Big\{\sum P_k\,\delta\theta_k\Big\}_1^2; \tag{7.5.2c}$$

that is, the Hamiltonian variational equation has the same form for both Pfaffian and nonlinear constraints.

Let us now proceed to a detailed study of these variational "principles."

Time-Integral Variational Principles (IVP)

7.6 HAMILTON'S PRINCIPLE VERSUS CALCULUS OF VARIATIONS

(i) Mechanical Variational Problem

Let us take, without loss in generality for our purposes here, a system described completely by the Lagrangean function $L = L(t, q, \dot{q}) \equiv T - V$, and subjected to the nonlinear and possibly nonholonomic constraints (7.3.10)

$$\omega_D \equiv f_D(t, q, \dot{q}) = 0 \qquad \text{(velocity form)}, \tag{7.6.1a}$$

$$\delta\theta_D \equiv \sum (\partial f_D / \partial \dot{q}_k)\, \delta q_k = 0 \qquad \text{(virtual form)}. \tag{7.6.1b}$$

Its equations of motion, (7.4.2),

$$E_k(L) = \sum \lambda_D (\partial f_D / \partial \dot{q}_k) \qquad \left[= \sum \lambda_D a_{Dk}, \text{ in the Pfaffian case}\right], \tag{7.6.2}$$

are obtained by combining Lagrange's differential variational principle (LP): $\sum E_k(L)\, \delta q_k = 0$, with (7.6.1b), in, by now, well-understood ways; and, along with the m constraints $f_D \equiv \omega_D = 0$, they form a determinate system of $n + m$ equations for the functions $q_k(t)$ and $\lambda_D(t)$. Next, assuming that $(\delta q_k)^{\cdot} = \delta(\dot{q}_k)$, we are readily led (applying chain rule to LP, etc.) to the central equation:

$$\delta L \equiv \sum \left[(\partial L/\partial q_k)\, \delta q_k + (\partial L/\partial \dot{q}_k)\, \delta(\dot{q}_k)\right] = d/dt \left[\sum (\partial L/\partial \dot{q}_k)\, \delta q_k\right]; \tag{7.6.3a}$$

then, integrating the above in time between $t_{1,2}$, while assuming that

$$BT \equiv \left\{\sum (\partial L/\partial \dot{q}_k)\, \delta q_k\right\}_1^2 = 0 \qquad \text{(of no effect on the equations of motion)}, \tag{7.6.3b}$$

we obtain the *constrained* integral variational equation

$$\int \delta L\, dt = 0, \tag{7.6.3c}$$

and, finally, attaching (or adjoining) (7.6.1b) to (7.6.3c) via the m Lagrangean multipliers λ_D, we obtain the following *unconstrained* integral variational equation:

$$\int \left[\delta L + \sum \sum \lambda_D (\partial f_D / \partial \dot{q}_k)\, \delta q_k\right] dt = 0. \tag{7.6.4}$$

Conversely, integrating (7.6.4) by parts [and then using (7.6.3b)], we are easily led back to (7.6.2); that is, (7.6.2) and (7.6.4) are completely equivalent. *Equation (7.6.3c) under (7.6.1b)*, or *(7.6.4)*, constitute the *mechanical* variational problem for our system. Next, let us see the corresponding mathematical variational problem, for the same system, and its relation with the above.

(ii) Mathematical Variational Problem

According to variational calculus [see any good text on this subject; for example, Fox (1950/1987, pp. 94–102), Funk (1962, p. 253 ff.), Gelfand and Fomin (1963, chap. 2)] this would be

$$\int L\,dt = \textit{stationary}, \qquad \text{under (7.6.1a)}, \tag{7.6.5a}$$

or, equivalently,

$$\delta \int L\,dt = 0, \qquad \text{under (7.6.1a)} \rightarrow \ \delta f_D = 0. \tag{7.6.5b}$$

Applying again the multiplier rule, but with the m Lagrangean multipliers μ_D (since here $f_D \equiv \omega_D = 0$; and $\delta\omega_D = 0$) we are led, in well-known ways, to the unconstrained variational equation

$$\begin{aligned} 0 &= \delta \int \Big(L + \sum \mu_D\, f_D\Big)\, dt = \int \delta\Big(L + \sum \mu_D\, f_D\Big)\, dt \qquad \text{(for fixed time-endpoints)} \\ &= \int \Big[\delta L + \sum (\delta\mu_D\, f_D + \mu_D\, \delta f_D)\Big]\, dt = \int \Big(\delta L + \sum \mu_D\, \delta f_D\Big)\, dt \\ &= \ldots = -\int \sum E_k(L + \textstyle\sum \mu_D f_D)\, \delta q_k\, dt + \Big\{\sum\sum \mu_D(\partial f_D/\partial \dot{q}_k)\, \delta q_k\Big\}_1^2, \end{aligned} \tag{7.6.5c}$$

which, since now the δq's *can* be viewed as *unconstrained*, with (7.6.3b), immediately yields the following n *Euler–Lagrange* equations [observing that $E_k(\ldots)$ is a *linear* operator]:

$$E_k(L + \textstyle\sum \mu_D f_D) = E_k(L) + E_k(\sum \mu_D f_D) = 0, \tag{7.6.5d}$$

or, in extenso,

$$(\partial L/\partial \dot{q}_k)^{\cdot} - \partial L/\partial q_k = -\sum \mu_D\big[(\partial f_D/\partial \dot{q}_k)^{\cdot} - \partial f_D/\partial q_k\big] - \sum (d\mu_D/dt)(\partial f_D/\partial \dot{q}_k), \tag{7.6.5e}$$

or, again in operator form (recalling that $f_D \equiv \omega_D$),

$$E_k(L) = -\sum \mu_D E_k(\omega_D) - \sum (d\mu_D/dt)(\partial \omega_D/\partial \dot{q}_k). \tag{7.6.5f}$$

Now, comparing (7.6.2) and (7.6.5d–f) we immediately see that, even if we identify the λ_D with the $-(d\mu_D/dt)$, since, in general, $E_k(\omega_D) \equiv E_k(f_D) \neq 0$ (nonholonomic constraints), still these two sets of equations are different; that is, *equations (5d–f) are mechanically/physically incorrect!* However, for holonomic problems—that is, $E_k(f_D) = 0$—these equations, and, hence, corresponding integral variational problems, *are* completely equivalent.

REMARKS

(i) As clarified below, this should not come as a surprise: The basic principle of mechanics is *not* the *integral* principle/rule (7.6.5a, b), but the *differential* principle of Lagrange (LP).

(ii) Note that, in the variational calculus literature, (7.6.5a, b) is also called *Lagrange's problem!*

Source and Meaning of the Discrepancy

We begin with a fundamental actual path of the system, or simply an *orbit*, in the physical or in configuration space. That is a *dynamically* or *kinetically* possible path from an initial configuration $P_1 \equiv P(t_1)$ to a final one $P_2 \equiv P(t_2)$, where $P_{1,2}$ and $t_{1,2}$ are fixed, or given (see next section for slight changes in these boundary data); that is, an orbit satisfies (a) the equations of motion (of Lagrange, Routh–Voss, etc.) and (b) the boundary conditions. Thus, for a holonomic system with no additional Pfaffian constraints (i.e., $m = 0$), the orbit is a curve

$$q_k = q_k(t); \qquad t_1 \leq t \leq t_2, \tag{7.6.6a}$$

of class C_2 (i.e., with continuous derivatives of up to the *second* order, in that t-region) satisfying Lagrange's equations

$$E_k(L) \equiv (\partial L/\partial \dot{q}_k)^{\cdot} - \partial L/\partial q_k = 0, \tag{7.6.6b}$$

and the boundary conditions

$$q_k(t_1) = q_{k1}, \qquad q_k(t_2) = q_{k2}; \qquad q_{k;\,1,2}\text{: } \textit{given} \text{ numbers.} \tag{7.6.6c}$$

Let us see what happens under the additional (possibly nonholonomic) constraints (7.6.1a, b).

(i) In the *mechanical* problem, (7.6.3c, 1b), we build, in accordance with Lagrange's principle, varied, or comparison, paths by *adding to each point of the fundamental orbit I*, $[t, q_k(t)]$, the *contemporaneous* (or vertical) and *constraint compatible*—that is, virtual, displacement $\delta q_k = \delta q_k(t)$, of class C_2—that vanishes at $t_{1,2}$. In short, the *mechanical variations* consist of *kinematically admissible (or possible) displacements*; that is, δq's that satisfy (7.6.1b): $\delta\theta_D = 0$.

(ii) In the *mathematical* problem, (7.6.5a, 1a), on the other hand, we consider, in accordance with the multiplier rule of variational calculus, the family, or class, of all constraint compatible paths K that are of class C_2 and coincide with I at $t_{1,2}$ (i.e., I belongs to K). In short, the *mathematical variations* consist of kinematically admissible (or possible) *neighboring paths*; that is, paths that satisfy (7.6.1a): $\omega_D = 0$.

We express these differences, compactly, by

$$\int \delta L\, dt \qquad \left[\text{under } \delta\theta_D \equiv \sum (\partial f_D/\partial \dot{q}_k)\, \delta q_k = 0\text{—mechanics}\right]$$

$$\neq \delta \int L\, dt \qquad [\text{under } \omega_D \equiv f_D(t, q, \dot{q}) = 0\text{—mathematics}]; \tag{7.6.7}$$

with the equality sign holding for holonomic systems.

{As Capon puts it: "Whereas in the generally accepted method of the calculus of variations [i.e., mathematics] the comparison *paths* are required to satisfy the conditional equations [our $\omega_D = 0$], the displacements being free, in Hölder's treatment [i.e., mechanics] this is reversed: the *displacements* [our δq_k] are to satisfy the conditional equations [our $\delta\theta_D = 0$], and it follows from the theory of Pfaff equations [i.e., Frobenius' theorem (§2.12)] that the *comparison paths* do not satisfy them]" (1952, p. 473, emphasis added).

As shown below (§7.7), this means that from $\delta\theta_D(t) = 0$ (admissible *displacements*—mechanics), it does not follow that $\delta\omega_D(t) = 0$ (admissible *paths*—mathematics), and vice versa, unless the constraints are *holonomic*.

For these reasons, certain authors have *modified the integrand* of the mechanical variational principle so as to produce a mathematical variational principle that yields the correct equations of motion: for example, Borri (1994).}

Sufficiency of Hamilton's Principle (HP)

Before discussing the quantitative consequences of the above, let us examine the following important point: so far, both (7.6.3c, 5b) and (7.6.5a, 1a) have been shown to be *necessary* conditions for an orbit. But the practical usefulness of HP (and the other IVP, and of variational methods in general) lies largely in their *sufficiency: the solution(s) of these variational equations should be the orbit(s) of the problem*. Let us examine the nonholonomic case in more detail: clearly, the numbers n and m (and, therefore, also $f \equiv n - m$: #*DOF*) are system *invariants*; that is, independent of the q's chosen. Further, as shown below, starting from a given point P_1, of the configuration space V_n, the points P accessible from it by kinematically admissible paths lie on an n-dimensional manifold M_n; that is, any point P in V_n is kinematically accessible. However, the points accessible from P_1 by kinematically admissible paths (i.e., orbits through it) lie on an $(n - m)$-dimensional submanifold M_{n-m} (= a subspace of V_n). Hence, the sufficient part of the mathematical variational problem *cannot* hold for nonholonomic systems: if both P_1 and P_2 are given, then P_2 may *not* lie on M_{n-m}; eqs. (7.6.5a, 1a) will yield a path through P_1 and P_2, but that path will *not* be a mechanically correct motion, it will not be an orbit. Still worse, even if P_2 were kinematically accessible from P_1, the orbit would exist but it would not satisfy (7.6.5a, 1a); that is, it would not render $\int L\,dt$ stationary among K-curves. In sum: whether P_2 lies on M_{n-m} or not, the variational equation $\delta \int L\,dt = 0$ under the multiplier rule does not produce the orbit through P_1 and P_2; and, conversely, that orbit does not make $\int L\,dt$ stationary among kinematically admissible paths—*the mathematical variational principle is not valid for nonholonomic systems*, and therefore it *cannot* be used as a foundation of (even conservative) analytical mechanics!

If one still wants such a "principle" (better, integral energetic equation), *uniformly* valid for both holonomic and nonholonomic systems, that *can* be done, but it must be based on *some time integral of Lagrange's principle or the central equation*; that is, *on mechanical principles* (as detailed below §7.6, §7.7); then its application will produce the orbits of the system.

Differential Equation Considerations

These differences can also be seen from the viewpoint of differential equations.

(i) Mechanical Problem

The *general* solution of the latter depends on $2n - m$ arbitrary constants, not on $2n$. Here is why: due to the constraint equations, we can express the $m\,\lambda_D$'s as $\lambda = \lambda(t, q, \dot{q})$ [no $d\lambda/dt$ occur in (7.6.2)] and then substitute them back into (7.6.2) [recalling the "equations of Jacobi–Synge": exs. 3.2.6, 3.5.5, 3.10.2, 5.3.5, and 5.3.6]; that is, we can replace the latter by n multiplierless (kinetic) *second-order* equations in the q's; a system whose general solution will depend on $2n$ constants. Finally, since these q's should also satisfy the m constraints (7.6.1a), the general solution of (7.6.2) would depend on $2n - m$ arbitrary constants; that is, the "path multiplicity" is

∞^{2n-m}. [Or, we could argue on the following mechanical grounds: the kinetic (reactionless) equations of the system — e.g., those of Maggi, Hamel, etc. — constitute a system of $n-m$ *second-order* equations for the q's and, therefore, they generate $2(n-m)$ constants. On the other hand, the system of the m *first-order* constraints generates m such constants. So the total number of arbitrary integration constants will be $2(n-m)+m = 2n-m$.]

These constants can be expressed, for example, in terms of the $2n-m$ *initial* conditions (say, for $t_1 = 0$):

$$q_k(0) = q_{ko}\text{: given } (n \text{ conditions}), \qquad \dot{q}_I(0) = \dot{q}_{Io}\text{: given } (n-m \text{ conditions}), \tag{7.6.8}$$

while the remaining m such conditions, $\dot{q}_D(0) = \dot{q}_{Do}$: given, can be found from (7.6.8) and the m constraints $f_D = 0$ evaluated at $t_1 = 0$; that is, even though the q_o can be specified arbitrarily, the $\dot{q}_o$ require consideration of the constraints.

In short: *Orbits through a given point* must be along *constraint-compatible directions*. If, further, the system is *holonomic*, these directions define an $(n-m)$-*dimensional submanifold*, inside the original n-dimensional manifold of the q's. Hence, in such systems, an orbit cannot pass through two arbitrarily specified points P_1 (initial) and P_2 (final) in configuration space; if we fix P_1, then, for the arc P_1P_2 to be an orbit, P_2 cannot be specified arbitrarily, but must lie on an $(n-m)$-dimensional manifold through P_1.

(ii) Mathematical Problem

The system (7.6.5d–f) is of the *second* order in the q's and *first* order in the μ's, and therefore (since the $f_D = 0$ are nonholonomic $\Rightarrow E_k(f_D) \neq 0$) its general solution depends on $2n$ arbitrary constants; whereas that of the mechanical system (7.6.2), as explained above, depends on only $2n-m$ such constants. [This can also be seen as follows: since the n q's appear up to the *second* order and the m μ's up to the *first* order, we have a maximum of $2n+m$ arbitrary constants; that is, initial conditions for the q's and μ's. But the q's and $\dot{q}$'s must also satisfy the constraints $f_D(t, q, \dot{q}) = 0$, and so the *maximum number of such constants of the mathematical problem* (the "*multiplicity of its solutions*") is $(2n+m)-m = 2n$.]

In conclusion:

- Through any given pair of points P_1 and P_2, these $2n$ constants define a path uniquely;
- Through any point P_1, and in any constraint-compatible direction, there is an ∞^m multiplicity of paths; the position and (compatible) direction absorb $2n-m$ of the constants, leaving m of them disposable $[(2n-m)+m = 2n]$.

[It has been shown by Capon (1952, p. 476), that: (a) In the *mechanical* problem, if the m constraints have $r(< m)$ integrals, then the maximum multiplicity of the mechanical paths is $\infty^{(2n-m)-r} = \infty^{2n-(m+r)}$; and if, in addition, there are M ignorable/cyclic coordinates—that is, $\partial L/\partial q = 0$ (§8.4 ff.)—then the multiplicity is $\infty^{(2n-m)-(r+M)} = \infty^{2n-(m+r+M)}$. (b) In the *mathematical* problem, if there are integrals of the constraints then for each such integral the number of independent constants is reduced by 2; that is, the corresponding multiplicities are, respectively, $\infty^{2(n-r)}$ and $\infty^{2(n-r)-M}$.

In other words, there are many paths in the mathematical problem that are not mechanical paths; or, *all mathematical solutions satisfy the stationarity condition; while, in general, the mechanical paths (orbits) do not*.]

Conditions under which the Mechanical and Mathematical Problems Coincide

This means where the general or some particular solution(s) of these problems coincide, for the same initial conditions. By comparing (7.6.2) and (7.6.5f), we see that for this to happen we must have

$$\sum [\lambda_D + (d\mu_D/\,dt)]\,(\partial\omega_D/\partial\dot{q}_k) = -\sum \mu_D[(\partial\omega_D/\partial\dot{q}_k)^{\cdot} - \partial\omega_D/\partial q_k]. \qquad (7.6.9a)$$

Multiplying each of these n equations by δq_k and summing over k, while observing the constraints $\delta\theta_D = 0$, we find the alternative, virtual work form, of the necessary condition:

$$\delta' W_{R'} \equiv -\sum\sum \mu_D\big[(\partial\omega_D/\partial\dot{q}_k)^{\cdot} - \partial\omega_D/\partial q_k\big]\,\delta q_k \equiv -\sum\sum \mu_D E_k(\omega_D)\,\delta q_k = 0. \qquad (7.6.9b)$$

The above is also sufficient: assuming that some solution of the mathematical problem satisfies (7.6.9b) for δq's restricted by $\delta\theta_D = 0$, then multiplying (7.6.9a) with δq_k, and $\delta\theta_D$ with λ_D, and summing, respectively, over k and D, while observing (7.6.9b) and (7.6.5f), we find

$$\sum \Big[E_k(L) - \sum \lambda_D(\partial f_D/\partial\dot{q}_k)\Big]\,\delta q_k = 0; \qquad (7.6.9c)$$

that is, that solution satisfies the mechanical problem and its constraints.

In terms of the following constraint reactions:

$$R_k \equiv \sum \lambda_D(\partial f_D/\partial\dot{q}_k), \qquad (7.6.9d)$$

$$R_k{}' \equiv -\sum \mu_D E_k(\omega_D), \qquad R_k{}'' \equiv -\sum (d\mu_D/dt)\,(\partial f_D/\partial\dot{q}_k), \qquad (7.6.9e)$$

the "coincidence conditions" (7.6.9a, b) can be rewritten, respectively, as

$$R_k = R_k{}' + R_k{}'', \qquad (7.6.9f)$$

$$\sum R_k\,\delta q_k = \sum R_k{}'\,\delta q_k + \sum R_k{}''\,\delta q_k: \qquad 0 = 0 + 0. \qquad (7.6.9g)$$

Additional forms of these coincidence conditions will be given later (§7.8).

We can summarize the developments of this section as follows: The differences between the time-integral variational "principles" of analytical mechanics and variational calculus result from different assumptions about variations; that is, comparison motions: in mechanics we assume admissible *instantaneous displacements* ($\delta\theta_D = 0$), while in mathematics we assume admissible *paths, as a whole* ($\delta\omega_D = 0$). And since these assumptions result in different forms of the *transitivity equations*, we must examine the precise effect of the latter both on the principles of mechanics (i.e., Lagrange's principle, or his central equation—which are variational but *differential*) and on the corresponding Hamiltonian principles (which are also variational but *integral*). This is detailed in the next section.

7.7 INTEGRAL VARIATIONAL EQUATIONS OF MECHANICS

Mechanical Admissibility

The constraints (7.6.1a, b) must hold for a generic instant t, as well as for its adjacent $t + dt$; that is,

$$\omega_D(t) = 0 \quad \textit{and} \quad \omega_D(t+dt) = 0, \qquad \text{or} \qquad \delta\theta_D(t) = 0 \quad \textit{and} \quad \delta\theta_D(t+dt) = 0. \tag{7.7.1}$$

Expanding the *second* and *fourth* of the above à la Taylor, and invoking the *first* and *third*, we get, to the first order (omitting, for simplicity, the explicit time dependence), the following requirements for the mechanical realizability of adjacent motions:

$$\omega_D + d\omega_D = 0 \quad \Rightarrow \quad d\omega_D = 0,$$

or

$$\delta\theta_D + d(\delta\theta_D) = 0 \quad \Rightarrow \quad d(\delta\theta_D) = 0,$$

or

$$(\delta\theta_D)^{\cdot} = 0 \qquad \text{(evolution of displacement admissibility in time).} \tag{7.7.2}$$

Then, the earlier general transitivity equations [§5.2, or (7.5.1b), but *without* the special assumption $(\delta q_k)^{\cdot} = \delta(\dot{q}_k)$] yield

$$\begin{aligned} -\delta\omega_D &= \sum (\partial\omega_D/\partial\dot{q}_k)\,[(\delta q_k)^{\cdot} - \delta(\dot{q}_k)] + \sum H^D{}_I\,\delta\theta_I \\ &= \sum (\partial\omega_D/\partial\dot{q}_k)\,[(\delta\dot{q}_k)^{\cdot} - \delta(\dot{q}_k)] - \sum\sum V^k{}_I\,(\partial\omega_D/\partial\dot{q}_k)\,\delta\theta_I \end{aligned} \tag{7.7.3}$$

$$\Big[= \sum (\partial\omega_D/\partial\dot{q}_k)\,[(\delta q_k)^{\cdot} - \delta(\dot{q}_k)] + \sum\sum (\gamma^D{}_{II'}\omega_{I'})\,\delta\theta_I, \quad \text{in stationary Pfaffian case}\Big] \neq 0, \text{in general.} \tag{7.7.3a}$$

From the above we conclude the following:

- We cannot assume that both $(\delta q_k)^{\cdot} = \delta(\dot{q}_k)$ and $\delta(d\theta_D) = 0$, or $\delta\omega_D = 0$, hold; it is either one or the other.
- If we assume that $(\delta q_k)^{\cdot} = \delta(\dot{q}_k)$, then $\delta(d\theta_D), \delta\omega_D \neq 0$; unless $H^D{}_I = 0$ [which, in the stationary Pfaffian case (chosen here just for algebraic simplicity), reduces to the Frobenius integrability conditions: $\gamma^D{}_{II'} = 0$. Hence, by analogy, $H^D{}_I = 0$ become the "Frobenius (necessary and sufficient) conditions" for the holonomicity of the first-order nonlinear system $\omega_D \equiv f_D(t, q, \dot{q}) = 0$].

These results, under $(\delta q_k)^{\cdot} = \delta(\dot{q}_k)$, are depicted in fig. 7.2(a).

Mathematical Admissibility

Here, the constraints (7.6.1a) hold for both the fundamental orbit, or arc, I, as well as for its kinematically admissible adjacent arc $II = I + \delta I$; that is,

$$\omega_D(I) = 0 \qquad \textit{and} \qquad \omega_D(II) = \omega_D(I + \delta I) = 0, \tag{7.7.4a}$$

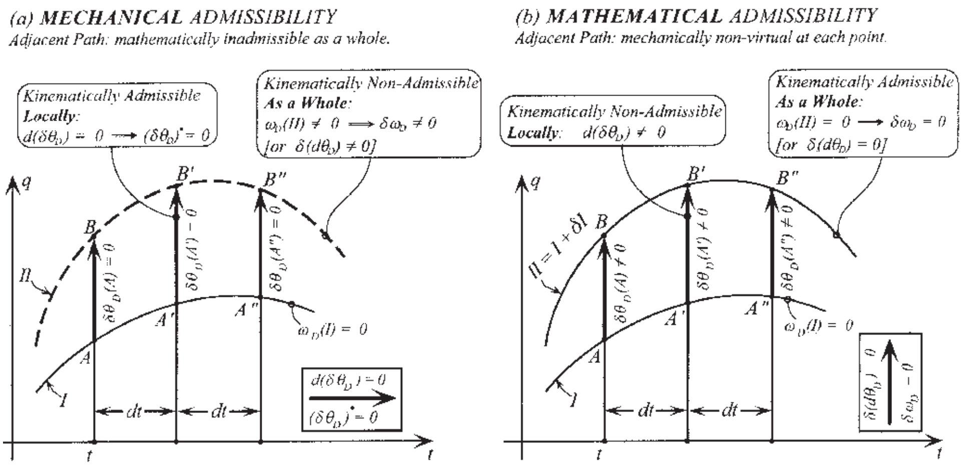

Figure 7.2 On the differences between (a) mechanical and (b) mathematical variations.

or

$$d\theta_D(I) = 0 \qquad \textit{and} \qquad d\theta_D(II) = d\theta_D(I + \delta I) = 0, \tag{7.7.4b}$$

from which, expanding as before, and so on, we obtain the following requirements for the mathematical realizability of adjacent motions:

$$\omega_D + \delta\omega_D = 0 \;\Rightarrow\; \delta\omega_D = 0,$$

or

$$d\theta_D + \delta(d\theta_D) = 0 \quad \Rightarrow \quad \delta(d\theta_D) = 0 \qquad \text{(virtual variation of path admissibility).} \tag{7.7.4c}$$

Then, the transitivity equations [again under $(\delta q_k)^{\cdot} \neq \delta(\dot{q}_k)$] yield

$$\begin{aligned}(\delta\theta_D)^{\cdot} &= \sum (\partial\omega_D/\partial\dot{q}_k)\,[(\delta\dot{q}_k)^{\cdot} - \delta(\dot{q}_k)] + \sum H^D{}_I\,\delta\theta_I \\ &= \sum (\partial\omega_D/\partial\dot{q}_k)\,[(\delta\dot{q}_k)^{\cdot} - \delta(\dot{q}_k)] - \sum\sum V^k{}_I(\partial\omega_D/\partial\dot{q}_k)\,\delta\theta_I; \qquad (7.7.5)\\ &\Big[= \sum (\partial\omega_D/\partial\dot{q}_k)\,[(\delta q_k)^{\cdot} - \delta(\dot{q}_k)] \\ &\quad + \sum\sum (\gamma^D{}_{II'}\omega_{I'})\,\delta\theta_I, \quad \text{in stationary Pfaffian case}\Big] \neq 0, \ \text{in general.} \qquad (7.7.5\text{a})\end{aligned}$$

From the above we conclude the following:

- We cannot assume that both $(\delta q_k)^{\cdot} = \delta(\dot{q}_k)$ and $d(\delta\theta_D) = 0$, or $(\delta\theta_D)^{\cdot} = 0$, hold; it is either one or the other.
- If we assume that $(\delta q_k)^{\cdot} = \delta(\dot{q}_k)$, then $d(\delta\theta_D), (\delta\theta_D)^{\cdot} \neq 0$; unless $H^D{}_I = 0$. These results, under $(\delta q_k)^{\cdot} = \delta(\dot{q}_k)$, are depicted in fig. 7.2(b).

In sum: even assuming that $(\delta q_k)^{\cdot} = \delta(\dot{q}_k)$, due to the purely analytical transitivity equations:

- We cannot assume that both $\delta(d\theta_D) = 0$ (or $\delta\omega_D = 0$) and $d(\delta\theta_D) = 0$ [or $(\delta\theta_D)^{\cdot} = 0$].

- In *mechanics* $[d(\ldots)]$, assuming $(\delta q_k)^\cdot = \delta(\dot{q}_k)$, we have

$$d(\delta\theta_D) = 0 \qquad \text{or} \qquad (\delta\theta_D)^\cdot = 0 \qquad (\text{and } d\omega_D = 0), \tag{7.7.6}$$

but $\delta(d\theta_D) \neq 0$ (or $\delta\omega_D \neq 0$), even though $d\theta_D = 0$ (or $\omega_D = 0$); in fact,

$$\begin{aligned} \delta\omega_D &= -\sum H^D{}_I\,\delta\theta_I = \sum\sum V^k{}_I(\partial\omega_D/\partial\dot{q}_k)\,\delta\theta_I \\ &= -\sum E_k(\omega_D)\,\delta q_k \equiv -\sum E_k(f_D)\,\delta q_k \equiv \delta f_D \qquad [\text{by (5.2.22a, b)}] \\ &\neq 0, \quad \text{for } nonholonomic \text{ constraints,} \\ &= 0, \quad \text{for } holonomic \text{ constraints.} \end{aligned} \tag{7.7.7}$$

$\Big\{$The reader may verify without much difficulty that in the Pfaffian case

$$\omega_D \equiv \sum a_{Dk}\dot{q}_k + a_D = 0,$$

the above specialize to

$$\begin{aligned} \delta\omega_D &\equiv \delta f_D \equiv \delta\left(\sum a_{Dk}\dot{q}_k + a_D\right) \\ &= \cdots = -\sum\left[\sum(\partial a_{Dk}/\partial q_b - \partial a_{Db}/\partial q_k)\dot{q}_b + (\partial a_{Dk}/\partial t - \partial a_D/\partial q_k)\right]\delta q_k \\ &\left[= -\sum\sum(\gamma^D{}_{II'}\omega_{I'})\,\delta\theta_I, \quad \text{in stationary Pfaffian case}\right]\Big\}. \end{aligned} \tag{7.7.7a}$$

Similarly, we obtain the corresponding *independent* transitivity equations:

$$\delta\omega_I = (\delta\theta_I)^\cdot - \sum H^I{}_{I'}\,\delta\theta_{I'} = (\delta\theta_I)^\cdot + \sum\sum V^k{}_{I'}(\partial\omega_I/\partial\dot{q}_k)\,\delta\theta_{I'} \tag{7.7.8}$$

$$\left[= (\delta\theta_I)^\cdot - \sum\sum(\gamma^I{}_{I'I''}\,\omega_{I''})\,\delta\theta_{I'}, \quad \text{in stationary Pfaffian case}\right]. \tag{7.7.8a}$$

[What happens in mechanics if we assume that $(\delta q_k)^\cdot \neq \delta(\dot{q}_k)$, for some or all values of k, is examined in §7.8. (Recall conclusions of prob. 2.12.5.)]

- In *mathematics* $[\delta(\ldots)]$, assuming $(\delta q_k)^\cdot = \delta(\dot{q}_k)$, we have

$$\delta(d\theta_D) = 0 \qquad \text{or} \qquad \delta\omega_D = 0,$$

but $d(\delta\theta_D) \neq 0$ (or $(\delta\theta_D)^\cdot \neq 0$) and $d\omega_D \neq 0$, even though $\delta\theta_D = 0$ (or $\omega_D = 0$).

In words: adjacent paths obtained by adding mechanically admissible variations to every point of an orbit $\left[d[\delta\theta_D(t)] = 0\right]$ are, in general, *mathematically inadmissible* $\left[\delta[d\theta_D(t)] \neq 0\right]$.

Next, to the various integral formulae of mechanics.

The Central Equation, its Integral Forms, and Corresponding Equations of Motion

(i) Holonomic Variables

Let us now extend the above to the IVPs of the most general systems [nonpotential, rheonomic, nonlinearly nonholonomic (chap. 5)] under *vertical* variations (i.e., $\Delta t = 0$); we consider a system with kinetic energy $T = T(t, q, \dot{q})$, impressed forces

$Q_k = Q_k(t, q, \dot{q})$ [some of which, or all, may be partially or completely potential; i.e., $Q_k = -\partial V(t, q)/\partial q_k$], subject to the $m(< n)$ independent and generally nonholonomic velocity constraints

$$f_D(t, q, \dot{q}) = 0, \qquad rank(\partial f_D/\partial \dot{q}_k) = m \qquad [D = 1, \ldots, m;\ I = m+1, \ldots, n], \tag{7.7.9a}$$

or, equivalently, solving for the m $\dot{q}_D$ in terms of the $n - m$ $\dot{q}_I$:

$$\dot{q}_D = \phi_D(t, q, \dot{q}_I) \qquad [\Rightarrow f_D \equiv \dot{q}_D - \phi_D(t, q, \dot{q}_I) = 0]; \tag{7.7.9b}$$

and whose virtual forms are, respectively,

$$\delta\theta_D \equiv \sum (\partial f_D/\partial \dot{q}_k)\, \delta q_k \ (= 0), \qquad \text{where } \dot{\theta}_D \equiv \omega_D \equiv f_D = 0, \tag{7.7.9c}$$

$$\delta q_D \equiv \sum (\partial \phi_D/\partial \dot{q}_I)\, \delta q_I \ (\neq 0). \tag{7.7.9d}$$

Here our discussion is based not on the equations of motion (§7.2–7.5), but on their equivalent principle of Lagrange (LP, §3.2):

$$\sum \left\{[(\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k] - Q_k\right\} \delta q_k \ \equiv \ \sum [E_k(T) - Q_k]\, \delta q_k = 0, \tag{7.7.10}$$

where the n δq's are restricted by the m conditions (7.7.9c).

Integrating (7.7.10) between the arbitrary times t_1 and t_2, then integrating by parts, and so on, and using the familiar notation $\delta' W \equiv \sum Q_k\, \delta q_k$, we obtain

$$\int \left\{\sum \left[(\partial T/\partial q_k)\, \delta q_k + (\partial T/\partial \dot{q}_k)\, (\delta q_k)^{\cdot}\right] + \delta' W\right\} dt \ = \ \left\{\sum (\partial T/\partial \dot{q}_k)\, \delta q_k\right\}_1^2; \tag{7.7.11}$$

or, further, since by standard δ-differential calculus,

$$\delta T = \sum [(\partial T/\partial q_k)\, \delta q_k + (\partial T/\partial \dot{q}_k)\, \delta(\dot{q}_k)], \tag{7.7.11a}$$

adding and subtracting to the integrand of (7.7.11) $\sum (\partial T/\partial \dot{q}_k)\, \delta(\dot{q}_k)$ (in order to create δT there), we finally transform it to

$$\int \left\{\delta T + \delta' W + \sum (\partial T/\partial \dot{q}_k)\, [(\delta q_k)^{\cdot} - \delta(\dot{q}_k)]\right\} dt \ = \ \left\{\sum (\partial T/\partial \dot{q}_k)\, \delta q_k\right\}_1^2. \tag{7.7.12}$$

$\Big\{$Equation (7.7.12) can also result, most simply, by integration of the general central equation, in holonomic variables, (3.6.8):

$$\delta T + \delta' W + \sum (\partial T/\partial \dot{q}_k)\, [(\delta q_k)^{\cdot} - \delta(\dot{q}_k)] = d/dt\Big[\sum (\partial T/\partial \dot{q}_k)\, \delta q_k\Big]\Big\}. \tag{7.7.13}$$

This general integral equation is fundamental to all subsequent IVP considerations.

Now, and this is the crux of the matter, (7.7.12) makes clear that we must relate the $(\delta q)^{\cdot}$'s, with the $\delta(\dot{q})$'s; that is, we must invoke some kind of *transitivity equations*. This can also be seen as follows: since the $\delta q(t)$'s are well-defined functions of time, so are the $(\delta q)^{\cdot}$'s; *but the* $\delta(\dot{q})$'s *need defining*, something which, again, is equivalent to a choice of transitivity equations. There is no unique way to do this, but, since there is only one mechanics, *we should always end up with the same (correct) equations of motion*. As the virtual constraints (7.7.9c, d) show, since not all δq's are specified uniquely, there is a certain freedom in defining $\delta(\dot{q}) \equiv \delta\dot{q}$; and this, historically, has given rise to various seemingly contradictory IVPs. We shall return to this topic in §7.8.

(ii) Nonholonomic Variables

To obtain the *nonholonomic* variable equivalent of this most general integral formula, we substitute into it the most general transitivity equations (5.2.23a ff.):

$$(\delta q_k)^{\cdot} - \delta(\dot{q}_k) = \sum (\partial\dot{q}_k/\partial\omega_b)\,[(\delta\theta_b)^{\cdot} - \delta\omega_b] + \sum V^k{}_b\,\delta\theta_b \tag{7.7.14a}$$

$$= \sum (\partial\dot{q}_k/\partial\omega_b)\,[(\delta\theta_b)^{\cdot} - \delta\omega_b] - \sum\sum (\partial\dot{q}_k/\partial\omega_l)\,H^l{}_b\,\delta\theta_b, \tag{7.7.14b}$$

while recalling that, since $T = T(t, q, \dot{q}) = T[t, q, \dot{q}(t, q, \omega)] \equiv T^*(t, q, \omega) \equiv T^*$,

$$\delta T = \delta T^* = \sum [(\partial T^*/\partial q_k)\,\delta q_k + (\partial T^*/\partial\omega_k)\,\delta\omega_k]$$
$$= \sum [(\partial T^*/\partial\theta_k)\,\delta\theta_k + (\partial T^*/\partial\omega_k)\,\delta\omega_k]; \tag{7.7.14c}$$

also

$$P_b \equiv \partial T^*/\partial\omega_b = \sum (\partial T/\partial\dot{q}_k)\,(\partial\dot{q}_k/\partial\omega_b) = \sum (\partial\dot{q}_k/\partial\omega_b)p_k, \tag{7.7.14d}$$

and

$$\delta' W = \delta' W^* \equiv \sum \Theta_k\,\delta\theta_k \qquad \text{(definition of } \Theta_k\text{'s)}. \tag{7.7.14e}$$

Thus, we transform (7.7.12) into its nonholonomic counterparts (no constraint enforcement yet!):

$$\int \Big\{\delta T^* + \delta' W^* + \sum P_k[(\delta\theta_k)^{\cdot} - \delta\omega_k] + \sum\sum V^k{}_b\,p_k\,\delta\theta_b\Big\}\,dt$$
$$= \Big\{\sum (\partial T^*/\partial\omega_k)\,\delta\theta_k\Big\}_1^2 \quad \Big[= \Big\{\sum (\partial T/\partial\dot{q}_k)\,\delta q_k\Big\}_1^2\Big], \tag{7.7.15a}$$

$$\int \Big\{\delta T^* + \delta' W^* + \sum P_k[(\delta\theta_k)^{\cdot} - \delta\omega_k] - \sum\sum H^k{}_b P_k\,\delta\theta_b\Big\}\,dt$$
$$= \Big\{\sum (\partial T^*/\partial\omega_k)\,\delta\theta_k\Big\}_1^2. \tag{7.7.15b}$$

As with (7.7.12), this can also be achieved (a) either by transforming (7.7.13) into quasi variables, via (7.7.14a–d), and then integrating, or (b) by integrating the earlier-found general central equation in quasi variables (3.6.9).

Next, to go from (7.7.15a, b) to the general nonlinear T^*-based equations of motion (§5.3), and thus establish the complete equivalence of the former with the latter, we employ the following general kinematico-inertial transformation of integral variational mechanics [obtained most easily by use of (7.7.14c, d) and integration by parts, and so on; also, recalling (7.5.2b)]:

$$\int \Big\{ \delta T^* + \sum P_k [(\delta\theta_k)^{\cdot} - \delta\omega_k] \Big\}\, dt$$
$$= \int \sum \big[(\partial T^*/\partial\omega_k)\,(\delta\theta_k)^{\cdot} + (\partial T^*/\partial\theta_k)\,\delta\theta_k \big]\, dt$$
$$= \cdots = \Big\{ \sum P_k\,\delta\theta_k \Big\}_1^2 - \int \sum \big[(\partial T^*/\partial\omega_k)^{\cdot} - \partial T^*/\partial\theta_k \big]\,\delta\theta_k\, dt. \qquad (7.7.15c)$$

As a result of this, (7.7.15a, b) are immediately transformed to the following *time-integral forms* of the nonlinear Johnsen–Hamel nonholonomic equations of motion (5.3.5a, b; 8a, b):

$$-\int \sum \big[(\partial T^*/\partial\omega_k)^{\cdot} - \partial T^*/\partial\theta_k - \sum\sum (\partial T/\partial \dot{q}_b)^* V^b{}_k - \Theta_k \big]\,\delta\theta_k\, dt \;=\; 0, \quad (7.7.16a)$$

$$-\int \sum \big[(\partial T^*/\partial\omega_k)^{\cdot} - \partial T^*/\partial\theta_k + \sum\sum (\partial T^*/\partial\omega_b) H^b{}_k - \Theta_k \big]\,\delta\theta_k\, dt \;=\; 0; \quad (7.7.16b)$$

from which (and the method of Lagrangean multipliers) both kinetic and kineto-static equations of mechanics follow at once.

REMARKS

(i) Had we assumed in (7.7.12, 13; 14a, b) that $(\delta q_k)^{\cdot} = \delta(\dot{q}_k)$, *whether the* δq_k *are further constrained or not* [what we shall, henceforth, call the viewpoint of *Hölder* (1896)–*Voronets* (1901)–*Hamel* (1904)], then eqs. (7.7.12; 15a, b) would have led us to the earlier form,

$$\int (\delta T + \delta' W)\, dt \;=\; \int (\delta T^* + \delta' W^*)\, dt \;=\; \Big\{ \sum (\partial T^*/\partial\omega_k)\,\delta\theta_k \Big\}_1^2, \qquad (7.7.17)$$

where now

$$\delta T^* = \sum [(\partial T^*/\partial\theta_k)\,\delta\theta_k + (\partial T^*/\partial\omega_k)\,\delta\omega_k] \qquad \text{[invoking (7.7.7–7.7.8a)]}$$
$$= \sum \Big\{ (\partial T^*/\partial\theta_k)\,\delta\theta_k + (\partial T^*/\partial\omega_k) \Big[(\delta\theta_k)^{\cdot} - \sum H^k{}_b\,\delta\theta_b \Big] \Big\}$$
$$= \sum (\partial T^*/\partial\theta_k)\,\delta\theta_k + \sum \{ [(\partial T^*/\partial\omega_k)\,\delta\theta_k]^{\cdot} - [(\partial T^*/\partial\omega_k)^{\cdot}\,\delta\theta_k] \}$$
$$- \sum\sum H^b{}_k (\partial T^*/\partial\omega_b)\,\delta\theta_k, \qquad (7.7.17a)$$

so that, upon time integration, and so on,

$$\int \delta T^*\, dt = -\int \sum \Big[(\partial T^*/\partial\omega_k)^{\cdot} - \partial T^*/\partial\theta_k + \sum H^b{}_k (\partial T^*/\partial\omega_b) \Big]\,\delta\theta_k\, dt$$
$$+ \Big\{ \sum P_k\,\delta\theta_k \Big\}_1^2, \quad (7.7.17b)$$

[which is none other than (7.5.2b)], and similarly in terms of the $V^b{}_k$; and these results would have, obviously, transformed (7.7.17) into the earlier (7.7.16a, b); that is, *whether we assume that* $(\delta q_k)^{\cdot} = \delta(\dot{q}_k)$ *or not, if we are internally consistent* *we will end up with the same equations of motion*, just like in the derivation of the equation of motion from the central equation (§3.6, §5.3).

In sum: To obtain the correct equations of motion of nonholonomic systems via a Hamiltonian IVP, we must stick with *mechanics* (i.e., Lagrange's principle) and *sacrifice mathematics* (i.e., calculus of variations)!

(ii) The earliest explicit realization of this fact — that is, that mechanical variational principles do not have to coincide with mathematical variational principles, and that *in all cases of discrepancy the former override the latter*, seems to be due to Voss (1885, second footnote, p. 266): "Aber das Hamilton'sche Princip [i.e., our mathematical variational principle] ist überhaupt kein eigentliches Princip der Mechanik, sondern hat—wenigstens zunächst—für dieselbe nur den Charakter einer analytischen Regel, welche *auch* die Differentialgleichungen der Bewegung liefert." Freely translated as "Hamilton's principle [as originally and commonly understood; i.e., as a mathematical variational principle] is not, generally, a proper principle of mechanics [i.e., like LP], but—at least for the moment—only a mathematical rule that also yields the equations of motion." See also Maurer (1905).

This point cannot be emphasized enough. Most mechanics texts we are aware of, including almost all contemporary ones in English, promote the *false* notion that the basic principle of (at least) potential but possibly nonholonomic systems is Hamilton's mathematical variational principle, eqs. (7.6.5a, b), or some variant of it (§7.9)! But even the few classy exceptions to this broad indictment, e.g., Rosenberg (1977, pp. x, 171 ff.) do *not pinpoint to the source of the discrepancy*, which is the transitivity equations (a topic absent from practically all English language texts on mechanics!).

Constrained Forms of the Integral "Principles"

Let us find the forms that (7.7.15a, b) (and hence, ultimately, the resulting equations of motion) assume if, in there, we enforce both $\delta\theta_D = 0$ (admissible displacements) and $\omega_D = 0$ (admissible paths); that is, let us express their integrands in terms of the *constrained* kinetic energy

$$T^* = T^*(t, q, \omega_D, \omega_I) \rightarrow T^*(t, q, \omega_D = 0, \omega_I) = T^*{}_o(t, q, \omega_I) = T^*{}_o; \qquad (7.7.18)$$

and its variations, and so on. Then, since $(\partial T^*/\partial\omega_I)_o = \partial T^*{}_o/\partial\omega_I$ [recalling (3.5.24a ff.)], $(\partial T^*/\partial q_k)_o = \partial T^*{}_o/\partial q_k \Rightarrow (\partial T^*/\partial\theta_k)_o = \partial T^*{}_o/\partial\theta_k$, and invoking (7.7.7) and (7.7.7a), we find, successively,

$$\begin{aligned}
\delta T^* &= \sum [(\partial T^*/\partial q_k)\,\delta q_k + (\partial T^*/\partial\omega_k)\,\delta\omega_k] \\
&= \Big[\sum (\partial T^*/\partial q_k)\,\delta q_k + \sum (\partial T^*/\partial\omega_I)\,\delta\omega_I\Big] + \sum (\partial T^*/\partial\omega_D)\,\delta\omega_D \\
&\equiv \delta T^*{}_o + \sum (\partial T^*/\partial\omega_D)_o\,\delta\omega_D && (7.7.18a) \\
&= \delta T^*{}_o + \sum (\partial T^*/\partial\omega_D)_o\Big(-\sum H^D{}_I\,\delta\theta_I\Big) && (7.7.18b) \\
&= \delta T^*{}_o + \sum (\partial T^*/\partial\omega_D)_o\Big[\sum\sum V^k{}_I(\partial\omega_D/\partial\dot{q}_k)\,\delta\theta_I\Big] \\
&= \delta T^*{}_o + \sum\sum (\partial T/\partial\dot{q}_k)_o V^k{}_I\,\delta\theta_I && (7.7.18c)
\end{aligned}$$

$$= \delta T^*{}_o + \sum (\partial T^*/\partial \omega_D)_o \Big[-\sum E_k(\omega_D)\, \delta q_k \Big] \tag{7.7.18d}$$

$$\Big\{ = \delta T^*{}_o + \sum (\partial T^*/\partial \omega_D)_o \Big[-\sum\sum (\gamma^D{}_{II'}\, \omega_{I'})\, \delta\theta_I \Big], \quad \text{for stationary Pfaffian constraints} \Big\}, \tag{7.7.18e}$$

where, invoking (7.7.8) and (7.7.8a),

$$\begin{aligned}
\delta T^*{}_o \equiv \delta(T^*{}_o) &\equiv \sum (\partial T^*{}_o/\partial q_k)\, \delta q_k + \sum (\partial T^*{}_o/\partial \omega_I)\, \delta\omega_I \\
&\equiv \sum (\partial T^*{}_o/\partial \theta_I)\, \delta\theta_I + \sum (\partial T^*{}_o/\partial \omega_I)\, \delta\omega_I \qquad (7.7.18\text{f}) \\
&= \sum (\partial T^*{}_o/\partial \theta_I)\, \delta\theta_I + \sum (\partial T^*{}_o/\partial \omega_I) \Big[(\delta\theta_I)^{\cdot} - \sum H^I{}_{I'}\, \delta\theta_{I'} \Big] \qquad (7.7.18\text{g}) \\
&= \sum (\partial T^*{}_o/\partial \theta_I)\, \delta\theta_I + \sum (\partial T^*{}_o/\partial \omega_I) \Big[(\delta\theta_I)^{\cdot} + \sum\sum V^k{}_{I'} (\partial \omega_I/\partial \dot{q}_k)\, \delta\theta_{I'} \Big] \qquad (7.7.18\text{h})
\end{aligned}$$

$$\Big\{ = \sum (\partial T^*{}_o/\partial \theta_I)\, \delta\theta_I + \sum (\partial T^*{}_o/\partial \omega_I) \Big[(\delta\theta_I)^{\cdot} - \sum\sum (\gamma^I{}_{I'I''}\, \omega_{I''})\, \delta\theta_{I'} \Big], \quad \text{for stationary Pfaffian constraints} \Big\}; \tag{7.7.18i}$$

and so, inserting (7.7.18c) into (7.7.15a) and (7.7.18b, d) into (7.7.15b), we obtain, respectively, the following *general nonlinear/Pfaffian and constrained form of the Hamilton-type "principles":*

$$\int \Big[\delta T^*{}_o + \sum\sum (\partial T/\partial \dot{q}_k)^*{}_o V^k{}_I\, \delta\theta_I + \delta' W^*{}_o \Big]\, dt = \Big\{ \sum (\partial T/\partial \dot{q}_k)\, \delta q_k \Big\}_1^2; \tag{7.7.19a}$$

$$\int \Big[\delta T^*{}_o - \sum\sum (\partial T^*/\partial \omega_D)_o\, H^D{}_I\, \delta\theta_I + \delta' W^*{}_o \Big]\, dt = \Big\{ \sum (\partial T/\partial \dot{q}_k)\, \delta q_k \Big\}_1^2; \tag{7.7.19b}$$

$$\int \Big[\delta T^*{}_o - \sum\sum (\partial T^*/\partial \omega_D)_o \gamma^D{}_{II'}\, \omega_{I'}\, \delta\theta_I + \delta' W^*{}_o \Big]\, dt = \Big\{ \sum (\partial T/\partial \dot{q}_k)\, \delta q_k \Big\}_1^2; \tag{7.7.19c}$$

where

$$\delta' W = \delta' W^* = \sum \Theta_k\, \delta\theta_k = \sum \Theta_I\, \delta\theta_I \equiv \delta' W^*{}_o.$$

Let the reader verify that inserting (7.7.18g, h) into (7.7.19b, a) leads readily to the $n - m$ *kinetic* equations of motion (5.3.8d, 8c), respectively; and similarly for the Pfaffian case [(3.5.24a ff.)].

REMARKS

(i) Equation (7.7.19c) is due to Hamel (1949, pp. 494–495; and references cited therein).

(ii) The form (7.7.19b) can also be obtained directly from (7.7.15b) if, following Hamel (1949, p. 494—Pfaffian case], we choose, in the latter,

$$\text{(a)} \qquad \delta\theta_D = 0, \quad d(\delta\theta_D) = 0 \quad \Rightarrow \quad (\delta\theta_D)^{\cdot} = 0, \quad \textit{and} \quad (\delta\theta_I)^{\cdot} = \delta\omega_I, \tag{7.7.20a}$$

something that does not restrict the $\delta\theta_I$ but *constitutes a suitable/permissible definition of the* $\delta\omega_I$ (like a Suslov et al. *second* transitivity choice but in nonholonomic variables—see next section). Indeed, then we have, successively,

$$\begin{aligned}
\text{(b)} \qquad \delta T^* + \sum P_k[(\delta\theta_k)^{\cdot} - \delta\omega_k] &= \delta T^* + \sum P_D[(\delta\theta_D)^{\cdot} - \delta\omega_D] \\
&= \delta T^* + \sum P_D[0 - \delta\omega_D] \qquad \text{[invoking (7.7.18a)]} \\
&\equiv \delta T^*_o + \sum P_D\,\delta\omega_D + \Big(-\sum P_D\,\delta\omega_D\Big) = \delta T^*_o;
\end{aligned} \tag{7.7.20b}$$

and [recalling (7.7.8)]

$$\text{(c)} \qquad -\sum\sum H^{I'}{}_I P_{I'}\,\delta\theta_I = -\sum P_I[(\delta\theta_I)^{\cdot} - \delta\omega_I] = 0. \tag{7.7.20c}$$

As a result of the above, (7.7.15b) (with $b \to I, k \to D$), clearly, becomes (7.7.19b), Q.E.D. And, similarly, for the reduction of (7.7.15a) to (7.7.19a).

7.8 SPECIAL INTEGRAL VARIATIONAL PRINCIPLES (OF SUSLOV, VORONETS, et al.)

Occasionally, the constraints are given in the form

$$\dot{q}_D \equiv \phi_D(t, q, \dot{q}_I). \tag{7.8.1}$$

But this, as explained in §5.2, can be viewed as the following special case of (7.6.1a, b):

$$\omega_D \equiv f_D(t, q, \dot{q}) \equiv \dot{q}_D - \phi_D(t, q, \dot{q}_I) = 0, \qquad \omega_I \equiv f_D(t, q, \dot{q}) \equiv \dot{q}_I \neq 0; \tag{7.8.1a}$$

$$[\Rightarrow\ \dot{q}_D = \omega_D + \phi_D[t, q, \dot{q}_I(t, q, \omega_I)] = \omega_D + \phi_D(t, q, \omega_I)] \tag{7.8.1b}$$

$$\delta\theta_D = \sum (\partial\omega_D/\partial\dot{q}_k)\,\delta q_k = \cdots = \delta q_D - \sum (\partial\phi_D/\partial\dot{q}_I)\,\delta q_I = 0, \tag{7.8.1c}$$

$$\delta\theta_I = \sum (\partial\omega_I/\partial\dot{q}_k)\,\delta q_k = \cdots = \delta q_I \neq 0; \tag{7.8.1d}$$

and, therefore,

$$\delta\omega_D \equiv \delta[\dot{q}_D - \phi_D(t, q, \dot{q})] = \,? \tag{7.8.2}$$

The above shows that to make further progress (and as mentioned at the end of §7.6), *we must define the* $\delta(\dot{q}_D)$. From the many conceivable such transitivity choices, the following two have dominated the literature:

(i) First transitivity choice of Hölder (1896)–Voronets (1901)–Hamel (1904). As already seen, this is

$$(\delta q_k)^{\cdot} = \delta(\dot{q}_k), \qquad \text{for } \textit{all } \delta q\text{'s, constrained or not;} \tag{7.8.3a}$$

(ii) Second transitivity choice of Suslov (1901) – Levi-Civita/Amaldi (1920s) – Rumiantsev (1970s) – Greenwood (1990s). (See also Suslov, 1946, pp. 596–600; and Rumiantsev, 1978, 1979.) This stipulates that

$$(\delta q_I)^{\cdot} = \delta(\dot{q}_I), \qquad \text{but} \qquad (\delta q_D)^{\cdot} \neq \delta(\dot{q}_D). \tag{7.8.3b}$$

Let us find the corresponding transitivity equations and integral variational "principles."

First Transitivity Choice

With its help, and (7.8.1c), (7.8.2) yields, successively,

$$\begin{aligned}
0 \neq \delta\omega_D &\equiv \delta(\dot{q}_D) - \delta\phi_D = (\delta q_D)^{\cdot} - \delta\phi_D \\
&= \left[\sum (\partial\phi_D/\partial\dot{q}_I)\,\delta q_I\right]^{\cdot} - \left[\sum (\partial\phi_D/\partial q_k)\,\delta q_k + \sum (\partial\phi_D/\partial\dot{q}_I)\,\delta(\dot{q}_I)\right] \\
&= \sum\ \left[(\partial\phi_D/\partial\dot{q}_I)^{\cdot}\,\delta q_I + (\partial\phi_D/\partial\dot{q}_I)\,(\delta q_I)^{\cdot}\right] \\
&\qquad\quad - \left[\sum (\partial\phi_D/\partial q_I)\,\delta q_I + \sum (\partial\phi_D/\partial q_{D'})\,\delta q_{D'} + \sum (\partial\phi_D/\partial\dot{q}_I)\,\delta(\dot{q}_I)\right] \\
&= \sum \left[(\partial\phi_D/\partial\dot{q}_I)^{\cdot} - \partial\phi_D/\partial q_I - \sum (\partial\phi_D/\partial q_{D'})\,(\partial\phi_{D'}/\partial\dot{q}_I)\right]\delta q_I \\
&\equiv \sum \left[(\partial\phi_D/\partial\dot{q}_I)^{\cdot} - \partial\phi_D/\partial(q_I)\right]\delta q_I \\
&\equiv \sum \left[E_I(\phi_D) - \sum (\partial\phi_D/\partial q_{D'})\,(\partial\phi_{D'}/\partial\dot{q}_I)\right]\delta q_I \\
&\equiv \sum E_{(I)}(\phi_D)\,\delta q_I \qquad \text{[recalling the special notations of ex. 5.2.3)} \\
&\equiv \sum W^D{}_I\,\delta q_I
\end{aligned} \tag{7.8.4a}$$

$$\left[= \sum W^D{}_I\,\delta\theta_I, \quad W^D{}_I\text{: specialization of the } V^D{}_I, \text{ for (7.8.1a)}\right] \tag{7.8.4b}$$

$$\Rightarrow\ \delta(\dot{q}_D) = (\delta\dot{q}_D) = \delta\phi_D + \sum E_{(I)}(\phi_D)\,\delta q_I \equiv \delta\phi_D + \sum W^D{}_I\,\delta q_I. \tag{7.8.4c}$$

[In the Pfaffian specialization of (7.8.1):

$$\dot{q}_D = \sum b_{DI}(t,q)\dot{q}_I + b_D(t,q) \equiv \phi_D(t,q,\dot{q}_I), \tag{7.8.4d}$$

the $E_{(I)}(\phi_D) \equiv W^D{}_I$ reduce to [ex. 2.12.1, probs. 2.12.2, 2.12.5; (3.8.14g, 14h)]

$$\begin{aligned}
v^D{}_I &\equiv \sum w^D{}_{II'}\dot{q}_{I'} + w^D{}_I \\
&\equiv \sum \Big\{(\partial b_{DI}/\partial q_{I'} - \partial b_{DI'}/\partial q_I) + \sum \left[(\partial b_{DI}/\partial q_{D'})b_{D'I'} - (\partial b_{DI'}/\partial q_{D'})b_{D'I}\right]\Big\}\dot{q}_{I'} \\
&\quad + \Big\{(\partial b_{DI}/\partial t - \partial b_D/\partial q_I) + \sum \left[(\partial b_{DI}/\partial q_{D'})b_{D'} - (\partial b_D/\partial q_{D'})\,b_{D'I}\right]\Big\},
\end{aligned} \tag{7.8.4e}$$

where the $w^D{}_{II'}, w^D{}_I$ are the Pfaffian (linear) Voronets coefficients.]

We remark that (i) these are none other than the earlier transitivity equations (5.2.22a, b) (also, recall results of ex. 5.2.3); and (ii) as shown in prob. 2.12.5, the first choice implies that

$$0 = (\delta\theta_D)^{\cdot} \neq \delta\omega_D\,(\neq 0), \qquad \text{but} \qquad (\delta\theta_I)^{\cdot} = \delta\omega_I. \tag{7.8.4f}$$

Let the reader verify that, as a result of the second of (7.8.4f), we can replace in the earlier integral equations (7.7.19b, c), the index D (and corresponding summation from 1 to m) with k (with summation from 1 to n). [*Hint*: Invoke (7.7.8); also, recall remark (ii) at end of §7.7.]

Integral Variational Principle Corresponding to the First Transitivity Choice

In this case, (7.7.12) reduces to the familiar (unconstrained) Hamiltonian form:

$$\int (\delta T + \delta' W)\,dt = \left\{ \sum (\partial T/\partial \dot{q}_k)\,\delta q_k \right\}_1^2. \tag{7.8.5}$$

Let us find the constrained form of (7.8.5). Applying the chain rule to

$$T = T(t, q, \dot{q}) = T[t, q, \dot{q}_I, \phi_D(t, q, \dot{q}_I)] \equiv T_o(t, q, \dot{q}_I) \equiv T_o, \tag{7.8.5a}$$

we readily get

$$\partial T_o/\partial q_k = \partial T/\partial q_k + \sum (\partial T/\partial \dot{q}_D)\,(\partial \phi_D/\partial q_k), \tag{7.8.5b}$$

$$\partial T_o/\partial \dot{q}_I = \partial T/\partial \dot{q}_I + \sum (\partial T/\partial \dot{q}_D)\,(\partial \phi_D/\partial \dot{q}_I), \tag{7.8.5c}$$

and so we find, successively,

$$\begin{aligned}
\delta T &= \sum [(\partial T/\partial q_k)\,\delta q_k + (\partial T/\partial \dot{q}_k)\,\delta(\dot{q}_k)] \\
&= \sum \Big[\partial T_o/\partial q_k - \sum (\partial T/\partial \dot{q}_D)\,(\partial \phi_D/\partial q_k)\Big]\,\delta q_k \\
&\quad + \sum \Big[\partial T_o/\partial \dot{q}_I - \sum (\partial T/\partial \dot{q}_D)\,(\partial \phi_D/\partial \dot{q}_I)\Big]\,\delta(\dot{q}_I) + \sum (\partial T/\partial \dot{q}_D)\,\delta(\dot{q}_D) \\
&= \sum (\partial T_o/\partial q_k)\,\delta q_k + \sum (\partial T_o/\partial \dot{q}_I)\,\delta(\dot{q}_I) \\
&\quad + \sum (\partial T/\partial \dot{q}_D)\Big\{\delta(\dot{q}_D) - \Big[\sum (\partial \phi_D/\partial q_k)\,\delta q_k + \sum (\partial \phi_D/\partial \dot{q}_I)\,\delta(\dot{q}_I)\Big]\Big\} \\
&\equiv \delta T_o + \sum (\partial T/\partial \dot{q}_D)\,[\delta(\dot{q}_D) - \delta\phi_D] \qquad [\text{where } \delta T_o \equiv \delta(T_o)] \\
&= \delta T_o + \sum (\partial T/\partial \dot{q}_D)\,\delta(\dot{q}_D - \phi_D) \qquad [\text{invoking (7.8.4a)}] \\
&= \delta T_o + \sum (\partial T/\partial \dot{q}_D)\,\delta\omega_D \qquad (\text{where } \delta\omega_D \neq 0) \\
&= \delta T_o + \sum\sum (\partial T/\partial \dot{q}_D)_o\,W^D{}_I\,\delta q_I,
\end{aligned} \tag{7.8.5d}$$

and, similarly,

$$\delta' W \equiv \sum Q_k\,\delta q_k = \cdots = \sum \Big[Q_I + \sum (\partial \dot{q}_D/\partial \dot{q}_I) Q_D\Big]\,\delta q_I \equiv \sum Q_{Io}\,\delta q_I \equiv \delta' W_o; \tag{7.8.5e}$$

and, therefore, substituting these expressions into Hamilton's principle (7.8.5), we obtain *Voronets' (constrained form of Hamilton's) principle* [1901, for the special Pfaffian constraints (7.8.4d)]:

$$\int \Big\{ \delta T_o + \sum (\partial T/\partial \dot{q}_D)_o [\delta(\dot{q}_D) - \delta\phi_D] + \delta' W_o \Big\} \, dt$$

$$= \int \Big\{ \delta T_o + \sum\sum (\partial T/\partial \dot{q}_D)_o W^D{}_I \, \delta q_I + \delta' W_o \Big\} \, dt = \Big\{ \sum (\partial T/\partial \dot{q}_k) \, \delta q_k \Big\}_1^2; \quad (7.8.6)$$

that is, the *middle* term in the integrand equals the *correction* term: $\delta T_{\text{unconstrained}} - \delta T_{\text{constrained}} \equiv \delta T - \delta T_o$:

$$\int \delta T \, dt = \int \delta T_o \, dt + \int (\delta T - \delta T_o) \, dt = \cdots .$$

Let the reader verify that (7.8.6) also results as the (7.8.1a–2)-based specialization of the earlier general nonholonomic variational equations (7.7.19a, b).

Second Transitivity Choice

In this case, (7.8.2) becomes

$$\delta\omega_D = \delta(\dot{q}_D) - \delta\phi_D = 0 \;\Rightarrow\; \delta(\dot{q}_D) = \delta\phi_D \qquad [\text{definition of } \delta(\dot{q}_D)], \qquad (7.8.7\text{a})$$

and so we obtain, successively,

$$(\delta q_D)^{\cdot} - \delta(\dot{q}_D) = \Big[\sum (\partial\phi_D/\partial\dot{q}_I) \, \delta q_I \Big]^{\cdot} - \delta\phi_D \qquad [\text{as in (7.8.4a), and with first of (7.8.3b)}]$$

$$= \cdots = \sum W^D{}_I \, \delta q_I \quad (\neq 0, \text{ in general}); \qquad (7.8.7\text{b})$$

that is,

$$(\delta q_D)^{\cdot} = \delta(\dot{q}_D) + \sum W^D{}_I \, \delta q_I \; = \; \delta\phi_D + \sum W^D{}_I \, \delta q_I . \qquad (7.8.7\text{c})$$

Again: (a) these are none other than the earlier transitivity equations (5.2.22a, b) [also, recall results of ex. 5.2.3]; and (b) as shown in prob. 2.12.5, the second choice implies that

$$(\delta\theta_k)^{\cdot} = \delta\omega_k \; (= 0); \qquad (7.8.7\text{d})$$

that is, both mechanical admissibility $[(\delta\theta_D)^{\cdot} = 0]$ and mathematical admissibility $[\delta\omega_D = 0]$.

Alternative Derivations of (7.8.7b)

(i) Enforcing the constraints $\delta\theta_D = 0$ into the general transitivity equations (7.7.14a):

$$(\delta q_k)^{\cdot} - \delta(\dot{q}_k) = \sum (\partial\dot{q}_k/\partial\omega_b) \, [(\delta\theta_b)^{\cdot} - \delta\omega_b] + \sum V^k{}_b \, \delta\theta_b , \qquad (7.8.7\text{e})$$

we obtain

$$\begin{aligned}(\delta q_D)^{\cdot} - \delta(\dot{q}_D) &= \sum (\partial \dot{q}_D/\partial \omega_k)\,[(\delta\theta_k)^{\cdot} - \delta\omega_k] + \sum {V^D}_I\,\delta\theta_I \quad \text{[invoking (7.8.7d)]}\\ &= \sum {V^D}_I\,\delta\theta_I = \sum {W^D}_I\,\delta q_I \qquad \text{[recalling (7.8.1d); i.e., (7.8.7.b)].}\end{aligned} \tag{7.8.7f}$$

(ii) Varying $\omega_D \equiv f_D(t, q, \dot{q}) = 0$ formally, we obtain

$$\begin{aligned}\delta f_D &= \sum (\partial f_D/\partial q_k)\,\delta q_k + \sum (\partial f_D/\partial \dot{q}_k)\,\delta(\dot{q}_k)\\ &= \sum (\partial f_D/\partial q_k)\,\delta q_k + \sum (\partial f_D/\partial \dot{q}_I)\,\delta(\dot{q}_I) + \sum (\partial f_D/\partial \dot{q}_{D'})\,\delta(\dot{q}_{D'})\\ &= \sum (\partial f_D/\partial q_k)\,\delta q_k + \sum (\partial f_D/\partial \dot{q}_I)\,(\delta q_I)^{\cdot} + \sum (\partial f_D/\partial \dot{q}_{D'})\,[(\delta q_{D'})^{\cdot} + S_{D'}]\\ &\qquad\qquad \text{[where } \ \delta(\dot{q}_D) - (\delta q_D)^{\cdot} \equiv S_D \quad \text{(Suslov term)} \neq 0]\\ &= \sum (\partial f_D/\partial q_k)\,\delta q_k + \sum (\partial f_D/\partial \dot{q}_k)\,(\delta q_k)^{\cdot} + \sum (\partial f_D/\partial \dot{q}_{D'}) S_{D'}\\ &= \sum (\partial f_D/\partial q_k)\,\delta q_k + \Big\{\sum [(\partial f_D/\partial \dot{q}_k)\,\delta q_k]^{\cdot} - \sum (\partial f_D/\partial \dot{q}_k)^{\cdot}\,\delta q_k\Big\}\\ &\quad + \sum (\partial f_D/\partial \dot{q}_{D'}) S_{D'} \quad \text{[by first of (7.8.1c), (7.8.7d), the \textit{second} sum vanishes],}\end{aligned}$$

or

$$0 = \delta\omega_D \equiv \delta f_D = -\sum \big[(\partial f_D/\partial \dot{q}_k)^{\cdot} - \partial f_D/\partial q_k\big]\,\delta q_k + \sum (\partial f_D/\partial \dot{q}_{D'}) S_{D'};$$

that is, finally,

$$\sum (\partial f_D/\partial \dot{q}_{D'})\,[\delta(\dot{q}_{D'}) - (\delta q_{D'})^{\cdot}] = \sum E_k(f_D)\,\delta q_k. \tag{7.8.7g}$$

But, here, $f_D \equiv \dot{q}_D - \phi_D(t, q, \dot{q}_I)$, and so the left side of (7.8.7g) specializes to

$$\sum (\delta_{DD'})\,[\delta(\dot{q}_{D'}) - (\delta q_{D'})^{\cdot}] = \delta(\dot{q}_D) - (\delta q_D)^{\cdot}, \tag{7.8.7h}$$

while its right side reduces, successively, to (independently of any transitivity assumptions)

$$\begin{aligned}\sum E_k(f_D)\,\delta q_k &= \sum E_I(f_D)\,\delta q_I + \sum E_{D'}(f_D)\,\delta q_{D'}\\ &= \sum E_I(f_D)\,\delta q_I + \sum E_{D'}(f_D)\Big[\sum (\partial\phi_{D'}/\partial \dot{q}_I)\,\delta q_I\Big]\\ &= \sum \Big[E_I(f_D) + \sum E_{D'}(f_D)\,(\partial\phi_{D'}/\partial \dot{q}_I)\Big]\,\delta q_I\\ &= \sum \Big[-E_I(\phi_D) - \sum (\partial\phi_D/\partial q_{D'})\,(\partial\phi_{D'}/\partial \dot{q}_I)\Big]\,\delta q_I\\ &\equiv -\sum E_{(I)}(\phi_D)\,\delta q_I \equiv -\sum {W^D}_I\,\delta q_I,\end{aligned} \tag{7.8.7i}$$

recalling ex. 5.2.3; that is, eq. (7.8.7g) specializes to

$$(\delta q_D)^{\cdot} - \delta(\dot{q}_D) = \sum E_{(I)}(\phi_D)\,\delta q_I \equiv \sum {W^D}_I\,\delta q_I; \quad \text{i.e. (7.8.7b).} \tag{7.8.7j}$$

Integral Variational Principle Corresponding to the Second Transitivity Choice

In this case, due to the preceding results, (7.7.12) reduces to *Suslov's (unconstrained form of Hamilton's) principle* [1901, for the special Pfaffian constraints (7.8.4d)]:

$$\int \Big\{\delta T + \sum (\partial T/\partial \dot{q}_D)_o [(\delta q_D)^{\cdot} - \delta(\dot{q}_D)] + \delta' W\Big\}\, dt$$

$$= \int \Big\{\delta T + \sum\sum (\partial T/\partial \dot{q}_D)_o {W^D}_I \,\delta q_I + \delta' W\Big\}\, dt = \Big\{\sum (\partial T/\partial \dot{q}_k)\,\delta q_k\Big\}_1^2. \tag{7.8.8}$$

[Suslov called the above "the modification of the d'Alembert principle"; and added, correctly, that our eq. (7.8.8) "in no way represents Hamilton's principle" (i.e., a principle of stationary action, à la variational calculus).]

Let us find the constrained form of (7.8.8); the "Suslovian counterpart of the Voronetsian (7.8.6)." Invoking again (7.8.5a, b, c) and the second of (7.8.7a), consequence of the second transitivity choice, we find, successively,

$$\begin{aligned}
\delta T &= \sum (\partial T/\partial q_I)\,\delta q_I + \sum (\partial T/\partial q_D)\,\delta q_D + \sum (\partial T/\partial \dot{q}_I)\,\delta(\dot{q}_I) + \sum (\partial T/\partial \dot{q}_D)\,\delta(\dot{q}_D)\\
&= \sum \Big[\partial T_o/\partial q_I - \sum (\partial T/\partial \dot{q}_{D'})\,(\partial \phi_{D'}/\partial q_I)\Big]\,\delta q_I\\
&\quad + \sum \Big[\partial T_o/\partial q_D - \sum (\partial T/\partial \dot{q}_{D'})\,(\partial \phi_{D'}/\partial q_D)\Big]\,\delta q_D\\
&\quad + \sum \Big[\partial T_o/\partial \dot{q}_I - \sum (\partial T/\partial \dot{q}_{D'})\,(\partial \phi_{D'}/\partial \dot{q}_I)\Big]\,\delta(\dot{q}_I)\\
&\quad + \sum (\partial T/\partial \dot{q}_D)\,\delta(\dot{q}_D)\\
&= \sum (\partial T_o/\partial q_I)\,\delta q_I + \sum (\partial T_o/\partial q_D)\,\delta q_D\\
&\quad + \sum (\partial T_o/\partial \dot{q}_I)\,\delta(\dot{q}_I) + \sum (\partial T/\partial \dot{q}_D)\,\delta(\dot{q}_D)\\
&\quad - \sum (\partial T/\partial \dot{q}_{D'})\,\Big[\sum (\partial \phi_{D'}/\partial q_I)\,\delta q_I + \sum (\partial \phi_{D'}/\partial q_D)\,\delta q_D\\
&\qquad\qquad + \sum (\partial \phi_{D'}/\partial \dot{q}_I)\,\delta(\dot{q}_I)\Big]
\end{aligned}$$

[by (7.8.7a), the *fourth* and *last* sum, which equals $-\sum (\partial T/\partial \dot{q}_{D'})\,\delta\phi_{D'}$, cancel with each other]

$$\begin{aligned}
&= \sum (\partial T_o/\partial q_k)\,\delta q_k + \sum (\partial T_o/\partial \dot{q}_I)\,\delta(\dot{q}_I)\\
&= \delta T_o
\end{aligned} \tag{7.8.9}$$

[notice carefully the slightly different steps taken between the above and (7.8.5d), of the Voronetsian case]. As a result of (7.8.9), and (7.8.5e), and so on, again, Suslov's principle (7.8.8) can be rewritten, in the definitive *constrained form*:

$$\int \Big\{\delta T_o + \sum (\partial T/\partial \dot{q}_D)_o \big[(\delta q_D)^{\cdot} - \delta(\dot{q}_D)\big] + \delta' W_o\Big\}\, dt$$

$$= \int \Big\{\delta T_o + \sum\sum (\partial T/\partial \dot{q}_D)_o {W^D}_I \,\delta q_I + \delta' W_o\Big\}\, dt = \Big\{\sum (\partial T/\partial \dot{q}_k)_o\,\delta q_k\Big\}_1^2, \tag{7.8.10}$$

which coincides with (7.8.6), as it should.

REMARKS

(i) Thanks to (7.8.1c), δT_o can be transformed further as follows:

$$\begin{aligned}\delta T_o &= \sum\Big\{\Big[\partial T_o/\partial q_I + \sum (\partial T_o/\partial q_D)\,(\partial\phi_D/\partial\dot{q}_I)\Big]\,\delta q_I + \sum (\partial T_o/\partial\dot{q}_I)\,\delta(\dot{q}_I)\Big\}\\
&\quad \Big[\equiv \sum (\partial T_o/\partial q_{(I)})\,\delta q_I + \sum (\partial T_o/\partial\dot{q}_I)\,\delta(\dot{q}_I)\Big]\\
&\quad = \Big[\sum (\partial T_o/\partial\dot{q}_I)\,\delta q_I\Big]^{\cdot} - \sum\big[(\partial T_o/\partial\dot{q}_I)^{\cdot} - \partial T_o/\partial q_I - \sum (\partial T_o/\partial q_D)\,(\partial\phi_D/\partial\dot{q}_I)\big]\,\delta q_I\\
&\quad \equiv \Big[\sum (\partial T_o/\partial\dot{q}_I)\,\delta q_I\Big]^{\cdot} - \sum E_{(I)}(T_o)\,\delta q_I,\end{aligned} \tag{7.8.11}$$

and, substituting this expression in (7.8.10) or (7.8.6), we obtain at once the nonlinear equations of Voronets and Chaplygin (ex. 5.3.4).

(ii) The Suslov form (7.8.10) can also be derived directly from the fundamental form (7.7.11) as follows. Invoking (7.8.7b) we find, successively,

$$\begin{aligned}&\sum\big[(\partial T/\partial q_k)\,\delta q_k + (\partial T/\partial\dot{q}_k)\,(\delta q_k)^{\cdot}\big]\\
&\quad = \sum (\partial T/\partial q_k)\,\delta q_k + \sum (\partial T/\partial\dot{q}_I)\,\delta(\dot{q}_I)\\
&\qquad\qquad + \sum (\partial T/\partial\dot{q}_D)\,\Big[\delta(\dot{q}_D) + \sum W^D{}_I\,\delta q_I\Big]\\
&\quad = \sum (\partial T/\partial q_k)\,\delta q_k + \sum (\partial T/\partial\dot{q}_I)\,\delta(\dot{q}_I) + \sum (\partial T/\partial\dot{q}_D)\,\delta(\dot{q}_D)\\
&\qquad\qquad + \sum\sum (\partial T/\partial\dot{q}_D)\,W^D{}_I\,\delta q_I\\
&\quad = \delta T + \sum\sum (\partial T/\partial\dot{q}_D)_o W^D{}_I\,\delta q_I \qquad \text{[then invoking (7.8.9)]}\\
&\quad = \delta T_o + \sum\sum (\partial T/\partial\dot{q}_D)_o W^D{}_I\,\delta q_I, \quad \text{Q.E.D.;}\end{aligned} \tag{7.8.12}$$

and analogously for the Voronets case (7.8.6).

(iii) In both the Voronets and Suslov principles,

$$\begin{aligned}&T \to T_o(t, q, \dot{q}_I) \to \delta T_o,\\
&\partial T/\partial\dot{q}_D \to (\partial T/\partial\dot{q}_D)_o = p_D[t, q, \dot{q}_I, \phi_D(t, q, \dot{q}_I)] \equiv p_{D,o}(t, q, \dot{q}_I) \equiv p_{Do},\end{aligned}$$

and so the boundary term assumes the constrained form

$$\Big\{\sum (\partial T/\partial\dot{q}_k)\,\delta q_k\Big\}_1^2 = \cdots = \Big\{\sum (\ldots)_I\,\delta q_I\Big\}_1^2.$$

(iv) The result of the indicated operations in these integral formulae (integrations by parts, etc.) will have the form

$$\int \{(\ldots)\,\delta q_{m+1} + \cdots + (\ldots)\,\delta q_n\}\,dt = \Big\{\sum (\ldots)_I\,\delta q_I\Big\}_1^2 \equiv BT, \tag{7.8.13}$$

and setting each $(\ldots)_I$ term of its integrand equal to zero will yield the $n - m$ kinetic equations of Voronets–Chaplygin.

(v) From the special nonholonomic form (7.8.8), we can easily go to the general nonholonomic forms (7.7.15a $\Rightarrow$ 7.7.19a) by inserting into the former the following substitutions/transformations:

$$\dot{q}_k = \dot{q}_k(t, q, \omega), \qquad \delta q_k = \sum (\partial \dot{q}_k / \partial \omega_I)\, \delta\theta_I,$$

$$\Rightarrow\ (\delta q_D)^{\cdot} - \delta(\dot{q}_D) = \sum W^D{}_I\, \delta q_I = \sum\sum W^D{}_{I'} (\partial \dot{q}_{I'}/\partial \omega_I)\, \delta\theta_I$$

$$\equiv \sum B^D{}_I\, \delta\theta_I \text{ (definition of special nonlinear Voronets coefficients } B^D{}_I); \tag{7.8.14}$$

noticing that $\delta T = \delta T^*$, and so on. (Remember the similar generalization in the Pfaffian case: probs. 3.8.2 and 3.8.3.)

Summary

In nonholonomic systems, Hamilton's variational equation is *never* $\int (\delta T_o + \delta' W_o)\, dt = BT$, but it is $\int [\delta T_o + \delta' W_o + \textit{correction term involving } (\delta q)^{\cdot} - \delta(\dot{q})]\, dt = BT$; and similarly in quasi variables, otherwise we lose the term $-\Gamma_I$ in the kinetic equations of motion.

To transform the unavoidable expression [holonomic variable counterpart of (7.7.15c)]

$$\int \Big\{ \delta T + \sum (\partial T/\partial \dot{q}_k)_o [(\delta q_k)^{\cdot} - \delta(\dot{q}_k)] \Big\}\, dt, \tag{7.8.15a}$$

where

$$\delta T = \delta T_o + \sum (\partial T/\partial \dot{q}_D)_o\, \delta\omega_D = \delta T_o + \sum (\partial T/\partial \dot{q}_D)_o\, \delta(\dot{q}_D - \phi_D), \tag{7.8.15b}$$

which appears in the basic integral variational formula (7.7.12), and thus derive the correct equations of motion in the variables involved there, we have the following two viewpoints:

(i) *Voronets*, *Hölder*, *Hamel*, et al.

$$\delta T = \delta T_o + \sum\sum (\partial T/\partial \dot{q}_D)_o W^D{}_I \delta q_I \qquad [\Rightarrow\ (\delta T)_o \neq \delta T_o],$$

$$\sum (\partial T/\partial \dot{q}_k)\, [(\delta q_k)^{\cdot} - \delta(\dot{q}_k)] = 0,$$

that is,

$$0 \neq \delta\omega_D = \delta(\dot{q}_D - \phi_D) = \delta(\dot{q}_D) - \delta\phi_D \qquad [\textit{assumption}\text{: } \delta(\dot{q}_D) = (\delta q_D)^{\cdot}]$$

$$= (\delta q_D)^{\cdot} - \delta\phi_D = \Big[\sum (\partial \phi_D/\partial \dot{q}_I)\, \delta q_I\Big]^{\cdot} - \delta\phi_D = \cdots = \sum W^D{}_I\, \delta q_I; \tag{7.8.16a}$$

(ii) *Suslov* (also Levi-Civita/Amaldi, Rumiantsev, Greenwood, et al.)

$$\delta T = \delta T_o \qquad [\Rightarrow\ (\delta T)_o = \delta T_o],$$

$$\sum (\partial T/\partial \dot{q}_k)_o [(\delta q_k)^{\cdot} - \delta(\dot{q}_k)] = \sum (\partial T/\partial \dot{q}_D)_o [(\delta q_D)^{\cdot} - \delta(\dot{q}_D)]$$

$$= \sum\sum (\partial T/\partial \dot{q}_D)_o W^D{}_I\, \delta q_I,$$

where

$$0 = \delta\omega_D = \delta[\dot{q}_D - \phi_D(t, q, \dot{q}_I)] \qquad [\text{i.e., } \textit{assumption}\text{: } \delta(\dot{q}_D) = \delta\phi_D]$$
$$\Rightarrow\ (\delta q_D)^{\cdot} - \delta(\dot{q}_D) = \Big[\sum (\partial\phi_D/\partial\dot{q}_I)\,\delta q_I\Big]^{\cdot} - \delta\phi_D = \cdots = \sum W^D{}_I\,\delta q_I. \quad (7.8.16\text{b})$$

Both these viewpoints are internally consistent, and completely equivalent to each other; that is, if applied correctly they yield the same equations of motion.

Resuming, next, our discussion from the last part of §7.6, let us present some additional forms.

Additional Forms of the Coincidence Conditions

(i) First Transitivity Assumption (Hölder–Voronets–Hamel)

Comparing the integral forms (7.6.4) and (7.6.5c), we see that they coincide, provided that

$$\int \sum \mu_D\,\delta f_D\,dt = \int \sum \lambda_D\,\delta\theta_D\,dt = 0, \tag{7.8.17a}$$

where

$$\delta\theta_D = \sum (\partial f_D/\partial\dot{q}_k)\,\delta q_k = 0 \qquad \text{(virtual variations)}. \tag{7.8.17b}$$

Since here $(\delta q_k)^{\cdot} = \delta(\dot{q}_k)$, and, therefore [recalling (7.7.7)],

$$\delta f_D = -\sum E_k(f_D)\,\delta q_k \equiv -\sum E_k(\omega_D)\,\delta q_k = \delta(\dot{\theta}_D) \equiv \delta\omega_D \neq 0$$
$$\text{(mathematically nonadmissible variations)}, \tag{7.8.17c}$$

sufficient conditions for (7.8.17a) to hold are $\delta f_D = 0$; that is, the system be holonomic.

{Condition (7.8.17a) [which, in view of (7.8.17c), is the same as (7.6.9b)], seems to be due to Jeffreys [1954, eqs. (10, 11)].}

(ii) Second Transitivity Assumption
(Suslov–Levi-Civita–Rumiantsev–Greenwood)

In this case, as (7.8.6, 10) with $\delta' W = \delta' W_o = 0$ readily show, the coincidence condition becomes

$$\int \Big[\sum\sum (\partial L/\partial\dot{q}_D)_o W^D{}_I\,\delta q_I\Big]\,dt = 0\ \Rightarrow\ \sum (\partial L/\partial\dot{q}_D)_o W^D{}_I = 0. \tag{7.8.17d}$$

[Further, if the constraints have the special form (7.8.1), then, invoking (7.8.4a), (7.8.7i), (7.8.17c) we deduce from (7.6.9b) $\Rightarrow$ (7.8.17a) the following (multiplier-containing) conditions:

$$\sum \Big(\sum \mu_D W^D{}_I\Big)\,\delta q_I = 0\ \Rightarrow\ \sum \mu_D W^D{}_I = 0. \tag{7.8.17e}$$

Conditions (7.8.17d) and (7.8.17e) seem to be due to Rumiantsev [1978, eqs. (3.5.6)]. Clearly, (7.8.7d), are easier to apply, since they do not involve (generally unknown) multipliers.]

Then, the nonlinear Voronets equations (ex. 5.3.4) reduce to the "holonomic form":

$$\begin{aligned} E_{(I)}(L_o) &\equiv (\partial L_o/\partial \dot{q}_I)^{\cdot} - \Big[\partial L_o/\partial q_I + \sum (\partial \phi_D/\partial \dot{q}_I)\,(\partial L_o/\partial q_D)\Big] \\ &\equiv (\partial L_o/\partial \dot{q}_I)^{\cdot} - \partial L_o/\partial (q_I) \\ &\equiv E_I(L_o) - \sum (\partial \phi_D/\partial \dot{q}_I)\,(\partial L_o/\partial q_D) = 0. \qquad (7.8.17\text{f}) \end{aligned}$$

As expected, the "potentialness" conditions (7.6.9b) and (7.8.17d, e) are very rarely satisfied, even for Pfaffian nonholonomic constraints. For the particular (or classes of) motions where that happens, Hamilton's principle becomes a stationarity principle.

In closing, we urge the reader to ponder carefully over the similarities, differences, internal consistency, and ultimate equivalence of these, and conceivably many more (admittedly slippery and sometimes confusing), IVPs.

Example 7.8.1 *Motion of a Particle of Mass $m = 1$, on a Fixed Plane O–xy in a Potential Field $V = V(x, y)$ and Under the Pfaffian Constraint*

$$t\,\dot{x} - \dot{y} = 0 \;\Rightarrow\; t\,\delta x - \delta y = 0, \qquad \text{(a)}$$

under the Suslov and Hölder–Voronets–Hamel Variational Principles (Mei, 1985, pp. 70–72; also Rosenberg, 1977, pp. 172–173).

(i) *Suslov approach.* With the choice $q_{I\,(\text{Independent})} = q_1 = x$ and $q_{D\,(\text{Dependent})} = q_2 = y$, we shall have

$$\dot{q}_D = \phi_D(t, q, \dot{q}_I): \qquad \dot{y} = \phi(t, \dot{x}) = t\,\dot{x}, \qquad \text{(b)}$$

and

$$(\delta x)^{\cdot} - \delta(\dot{x}) = 0, \qquad \text{(c1)}$$

$$(\delta y)^{\cdot} - \delta(\dot{y}) = (t\,\delta x)^{\cdot} - \delta(t\,\dot{x}) = \delta x + t(\delta x)^{\cdot} - t\,\delta(\dot{x}) = \delta x; \qquad \text{(c2)}$$

that is,

$$W^D{}_I \rightarrow\; W^y{}_x\,(\equiv v^y{}_x) = 1; \qquad \text{(c3)}$$

or, applying the general theory,

$$\begin{aligned} \delta(\dot{y}) &= (\delta y)^{\cdot} - \big[(\partial\phi/\partial\dot{x})^{\cdot} - \partial\phi/\partial x - (\partial\phi/\partial y)\,(\partial\phi/\partial\dot{x})\big]\,\delta x \\ &= (t\,\delta x)^{\cdot} - [(t)^{\cdot} - 0 - 0]\,\delta x = t\,\delta(\dot{x}) \equiv t(\delta x)^{\cdot}. \qquad \text{(c4)} \end{aligned}$$

Therefore, the Suslov variation of the unconstrained Lagrangean of the system

$$L = (1/2)\,[(\dot{x})^2 + (\dot{y})^2] - V(x, y), \qquad \text{(d1)}$$

is, successively,

$$
\begin{aligned}
\delta L &= \dot{x}\,\delta(\dot{x}) + \dot{y}\,\delta(\dot{y}) - (\partial V/\partial x)\,\delta x - (\partial V/\partial y)\,\delta y \qquad [\textit{then} \text{ enforcing } (\mathrm{a, b, c1–4})] \\
\delta L \to\ (\delta L)_o &= \dot{x}\,\delta(\dot{x}) + (t\,\dot{x})\,\delta(t\,\dot{x}) - [\partial V/\partial x + t(\partial V/\partial y)]\,\delta x \\
&= (1+t^2)\dot{x}\,\delta(\dot{x}) - [\partial V/\partial x + t(\partial V/\partial y)]\,\delta x \\
&= (1+t^2)\dot{x}(\delta x)^{\cdot} - [\partial V/\partial x + t(\partial V/\partial y)]\,\delta x, \qquad \text{(d2)}
\end{aligned}
$$

and so the unconstrained Suslov principle (7.8.8), with

$$(\partial L/\partial \dot{y})_o\,[(\delta y)^{\cdot} - \delta(\dot{y})] = (t\,\dot{x})\,\delta x, \qquad \textit{Boundary terms} \equiv BT \to\ 0, \text{ and } \delta' W_{np} = 0,$$

yields

$$
\begin{aligned}
0 &= \int \big\{(\delta L)_o + (\partial L/\partial \dot{y})_o[(\delta y)^{\cdot} - \delta(\dot{y})]\big\}\,dt \\
&= \int \big\{(1+t^2)\dot{x}(\delta x)^{\cdot} - [-(t\,\dot{x}) + \partial V/\partial x + t(\partial V/\partial y)]\big\}\,dt. \qquad \text{(d3)}
\end{aligned}
$$

Had we enforced the constraint (a) into L right from the start [i.e., before $\delta(\ldots)$-varying], then

$$L \to\ L_o = (1/2)[(\dot{x})^2 + (t\,\dot{x})^2] - V(x, y), \qquad \text{(e1)}$$

and, accordingly,

$$
\begin{aligned}
\delta L_o &= \dot{x}\,\delta(\dot{x}) + t^2\dot{x}\,\delta(\dot{x}) - (\partial V/\partial x)\,\delta x - (\partial V/\partial y)\,(\delta y)_o \\
&= (1+t^2)\dot{x}\,\delta(\dot{x}) - \big[\partial V/\partial x + t\,(\partial V/\partial y)\big]\,\delta x; \qquad \text{(e2)}
\end{aligned}
$$

that is, $\delta L = \delta L_o$, as expected by (7.8.9); and, hence, (d3) is the same as that obtained by applying (7.8.10). Integrating (d3) by parts, and so on, we readily find

$$0 = \int \big\{ -[(1+t^2)\dot{x}]^{\cdot} - [-t\,\dot{x} + (\partial V/\partial x + t\,(\partial V/\partial y))]\big\}\,\delta x\,dt, \qquad \text{(f1)}$$

and from this we get the following single (kinetic) Chaplygin–Voronets equation:

$$[(1+t^2)\dot{x}]^{\cdot} + t\,\dot{x} = -\big[\partial V/\partial x + t\,(\partial V/\partial y)\big]; \qquad \text{(f2)}$$

which, along with the constraint (a), constitute a determinate system for $x(t)$ and $y(t)$.

(ii) *Hölder–Voronets–Hamel approach*. Here

$$\delta(\dot{x}) = (\delta x)^{\cdot} \qquad \text{and} \qquad \delta(\dot{y}) = (\delta y)^{\cdot}, \qquad \text{(g1)}$$

or, due to (a),

$$
\begin{aligned}
&(\delta y)^{\cdot} = (t\,\delta x)^{\cdot} = \delta x + t(\delta x)^{\cdot} = \delta x + t\,\delta(\dot{x}) = \delta(\dot{y}) \quad (= \delta x + \delta\phi, \quad \phi = t\,\dot{x}) \\
&\Rightarrow \delta(\dot{y}) - \delta\phi = \delta x. \qquad \text{(g2)}
\end{aligned}
$$

Therefore, varying L accordingly we find

$$
\begin{aligned}
\delta L &= \dot{x}\,\delta(\dot{x}) + \dot{y}\,\delta(\dot{y}) - \delta V \qquad [\textit{then} \text{ enforcing } (\mathrm{a, b, g1\text{–}2})]\\
\delta L \to \ (\delta L)_o &= \dot{x}\,\delta(\dot{x}) + (t\,\dot{x})\,[\delta x + t\,\delta(\dot{x})] - (\partial V/\partial x)\,\delta x - (\partial V/\partial y)\,\delta y\\
&= (1+t^2)\dot{x}\,\delta(\dot{x}) - [\partial V/\partial x + t\,(\partial V/\partial y)]\,\delta x + (t\,\dot{x})\,\delta x\\
&= (1+t^2)\dot{x}(\delta x)^{\cdot} - [-(t\,\dot{x}) + \partial V/\partial x + t\,(\partial V/\partial y)]\,\delta x\\
&= \delta L_o + (t\,\dot{x})\,\delta x\\
\{ &= \delta L_o + (\partial L/\partial \dot{y})_o\,[\delta(\dot{y}) - \delta\phi], \quad \text{in accordance with (7.8.5d)},\\
&\neq \delta L_o = (1+t^2)\dot{x}\,\delta(\dot{x}) - \delta V; \text{ we notice difference from (d2, e2)}\}, \qquad \text{(h1)}
\end{aligned}
$$

and so the Hölder–Voronets principle (7.8.6), with $BT \to 0$ and $\delta' W_{np} = 0$, yields

$$
\begin{aligned}
0 &= \int \delta L\,dt = \int (\delta L)_o\,dt = \int \big\{\delta L_o + (\partial L/\partial \dot{y})_o\,[\delta(\dot{y}) - \delta\phi)]\big\}\,dt\\
&= \int \big\{(1+t^2)\dot{x}(\delta x)^{\cdot} + [t\,\dot{x} - \partial V/\partial x - t\,(\partial V/\partial y)]\,\delta x\big\}\,dt, \qquad \text{(h2)}
\end{aligned}
$$

which, as an integration by parts of the first integrand term shows, coincides with the Suslov results (f1, 2).

Generally, we have:

- *Suslov–Rumiantsev–Greenwood approach*:

$$
\begin{aligned}
(\delta q_D)^{\cdot} - \delta(\dot{q}_D) &= \Big(\sum b_{DI}\,\delta q_I\Big)^{\cdot} - \delta\Big(\sum b_{DI}\dot{q}_I + b_D\Big) = \cdots \equiv \sum W^D{}_I\,\delta q_I\\
&\Rightarrow\ \delta(\dot{q}_D) = (\delta q_D)^{\cdot} - \sum W^D{}_I\,\delta q_I. \qquad \text{(i1)}
\end{aligned}
$$

- *Hölder–Voronets–Hamel approach*:

$$
\begin{aligned}
\delta f_D &= \delta(\dot{q}_D) - \delta\phi_D = (\delta q_D)^{\cdot} - \delta\phi_D\\
&= \Big(\sum b_{DI}\,\delta q_I\Big)^{\cdot} - \delta\Big(\sum b_{DI}\dot{q}_I + b_D\Big) = \cdots \equiv \sum W^D{}_I\,\delta q_I \neq 0\\
&\Rightarrow\ \delta(\dot{q}_D) = (\delta q_D)^{\cdot} = \delta\phi_D + \sum W^D{}_I\,\delta q_I. \qquad \text{(i2)}
\end{aligned}
$$

Appendix: elementary solution. The Newton–Euler equation in the *tangential* direction is

$$
\begin{aligned}
dv/dt &= -\partial V/\partial s = -[(\partial V/\partial x)\,(dx/ds) + (\partial V/\partial y)\,(dy/ds)] \qquad (\text{where } v \equiv ds/dt)\\
&= -[(\partial V/\partial x)\,(dx/ds) + (\partial V/\partial y)\,(dy/dx)\,(dx/ds)]\\
&= -(dx/ds)\,[(\partial V/\partial x) + (\partial V/\partial y)\,(dy/dx)], \qquad \text{(j)}
\end{aligned}
$$

and, since (with ϕ: angle between Ox and path tangent),

$$dx/ds = \cos\phi, \qquad \cos^2\phi = (1 + \tan^2\phi)^{-1},$$

$$\tan\phi = \dot{y}/\dot{x} = t \;\Rightarrow\; dx/\,ds = (1 + t^2)^{-1/2},$$

and $$ds = dx/\cos\phi \;\Rightarrow\; v = \dot{x}(1 + t^2)^{1/2};$$

(j) is easily seen to coincide with the earlier (f2).

Example 7.8.2 *Rolling Disk via the Suslov and Voronets Principles.* Let us describe the application of the Suslov and Voronets forms of Hamilton's principle to the derivation of the equations of the rolling of a thin homogeneous circular disk of mass m and radius r on a rough horizontal and fixed plane O–XY.

The kinematics and kinetics of this well-known problem have already been detailed in §1.17, eqs. (1.17.17a) ff. (Eulerian treatment), ex. 2.13.7 (Lagrangean kinematics), and ex. 3.18.5 (Lagrangean kinetics). It was found there that the constraints are [in terms of the *coordinates of its contact point* C $(X, Y, Z = 0)$ along space-fixed axes O–XYZ and with $q_D \equiv q_{1,2}$: X, Y, and $q_I \equiv q_{3,4,5}$: ϕ, θ, ψ: Eulerian angles of body-fixed axes at G relative to O–XYZ]

$$\boldsymbol{v}_{C,\text{tangent}} \equiv f_1 = \dot{X} + (r\cos\phi)\dot{\psi} = 0, \qquad \boldsymbol{v}_{C,\text{normal}} \equiv f_2 = \dot{Y} + (r\sin\phi)\dot{\psi} = 0. \tag{a}$$

The unconstrained Lagrangean of the system (under gravity) is

$$\begin{aligned} L &\equiv T - V \\ &= (m/2)\left\{[(X - r\cos\theta\sin\phi)^{\cdot}]^2 + [(Y + r\cos\theta\cos\phi)^{\cdot}]^2 + [(r\sin\theta)^{\cdot}]^2\right\} \\ &\quad + (1/2)\,[I_x(\dot{\theta})^2 + I_y(\dot{\phi}\sin\theta)^2 + I_z(\dot{\psi} + \dot{\phi}\cos\theta)^2] - mgr\sin\theta, \end{aligned} \tag{b}$$

and the principal moments of inertia of the disk at G are $I_{x,y} = mr^2/4, I_z = mr^2/2$.

(i) *Hölder–Voronets–Hamel approach*. From (a) we find, successively,

$$\begin{aligned} \delta f_1 \equiv \delta\omega_1 &= \delta(\dot{X}) + (-r\sin\phi\,\delta\phi)\dot{\psi} + r\cos\phi\,\delta(\dot{\psi}) \\ &= (\delta X)^{\cdot} - r\,\dot{\psi}\sin\phi\,\delta\phi + r\cos\phi(\delta\psi)^{\cdot} \\ &= (-r\cos\phi\,\delta\psi)^{\cdot} - r\,\dot{\psi}\sin\phi\,\delta\phi + r\cos\phi(\delta\psi)^{\cdot} \qquad [\text{by first of (a)}] \\ &= \cdots = (-r\sin\phi\,\dot{\psi})\,\delta\phi + (r\sin\phi\,\dot{\phi})\,\delta\psi \neq 0, \end{aligned} \tag{c1}$$

$$\delta f_2 \equiv \delta\omega_2 = \cdots = (r\cos\phi\,\dot{\psi})\,\delta\phi + (-r\cos\phi\,\dot{\phi})\,\delta\psi \neq 0; \tag{c2}$$

that is,

$$W^Z{}_\phi = -r\sin\phi\,\dot{\psi}, \qquad W^Z{}_\theta = 0, \qquad W^Z{}_\psi = r\sin\phi\,\dot{\phi}, \tag{c3}$$

$$W^Y{}_\phi = r\cos\phi\,\dot{\psi}, \qquad W^Y{}_\theta = 0, \qquad W^Y{}_\psi = -r\cos\phi\,\dot{\phi}; \tag{c4}$$

and, accordingly [with $\dot{X} = \phi_X(\dot{\phi}, \dot{\theta}, \dot{\psi};\ \phi, \theta, \psi)$, $\dot{Y} = \phi_Y(\dot{\phi}, \dot{\theta}, \dot{\psi};\ \phi, \theta, \psi)$, from (a)],

$$\delta(\dot{X}) = (\delta X)^{\cdot} = \delta\phi_X + W^X{}_\phi\,\delta\phi + W^X{}_\theta\,\delta\theta + W^X{}_\psi\,\delta\psi,$$

that is,

$$(-r\cos\phi\,\delta\psi)^{\cdot} = \delta(-r\cos\phi\,\dot{\psi}) + (-r\sin\phi\,\dot{\psi})\,\delta\phi + (0)\,\delta\theta + (r\sin\phi\,\dot{\phi})\,\delta\psi$$
$$\Rightarrow\ \delta(\dot{X}) = (r\,\dot{\phi}\,\sin\phi)\,\delta\psi + (-r\cos\phi)\,\delta(\dot{\psi}); \tag{c5}$$
$$\delta(\dot{Y}) = (\delta Y)^{\cdot} = \delta\phi_Y + W^Y{}_\phi\,\delta\phi + W^Y{}_\theta\,\delta\theta + W^Z{}_\psi\,\delta\psi,$$

that is,

$$(-r\sin\phi\,\delta\psi)^{\cdot} = \delta(-r\sin\phi\,\dot{\psi}) + (r\cos\phi\,\dot{\psi})\,\delta\phi + (0)\,\delta\theta + (-r\cos\phi\,\dot{\phi})\,\delta\psi$$
$$\Rightarrow\ \delta(\dot{Y}) = (-r\,\dot{\phi}\cos\phi)\,\delta\psi + (-r\sin\phi)\,\delta(\dot{\psi}). \tag{c6}$$

Then, Voronets' principle yields

$$\begin{aligned}0 = \int \delta L\,dt = \int \big[&(\partial L/\partial\dot{X})\,\delta(\dot{X}) + (\partial L/\partial\dot{Y})\,\delta(\dot{Y})\\ &+ (\partial L/\partial\dot{\phi})\,\delta(\dot{\phi}) + (\partial L/\partial\dot{\theta})\,\delta(\dot{\theta}) + (\partial L/\partial\dot{\psi})\,\delta(\dot{\psi})\\ &+ (\partial L/\partial\phi)\,\delta\phi + (\partial L/\partial\theta)\,\delta\theta\big]\,dt\end{aligned}$$

[integrating by parts, and using (b), and (c5, 6) for $\delta(\dot{X}), \delta(\dot{Y})$]

$$= \int [(\ldots)\,\delta\phi + (\ldots)\,\delta\theta + (\ldots)\,\delta\psi]\,dt; \tag{c7}$$

and the corresponding equations of motion will result by setting the coefficients of $\delta\phi/\delta\theta/\delta\psi$, in the above, equal to zero. These will be the kinetic equations of Maggi $\Rightarrow$ Voronets of the problem [the latter resulting by eliminating $\dot{X}$, $\dot{Y}$, from L via (a)]. The details are left to the reader.

(ii) *Suslov approach*. In this case,

$$\delta f_1 = 0,\ \delta f_2 = 0; \qquad (\delta\phi)^{\cdot} = \delta(\dot{\phi}), \quad (\delta\theta)^{\cdot} = \delta(\dot{\theta}), \quad (\delta\psi)^{\cdot} = \delta(\dot{\psi}), \tag{d1}$$

and therefore, invoking (c3, 4),

$$\begin{aligned}(\delta X)^{\cdot} - \delta(\dot{X}) &= (-r\cos\phi\,\delta\psi)^{\cdot} - \delta(-r\cos\phi\,\dot{\psi})\\ &= W^X{}_\phi\,\delta\phi + W^X{}_\theta\,\delta\theta + W^X{}_\psi\,\delta\psi\\ &= (-r\sin\phi\,\dot{\psi})\,\delta\phi + (0)\,\delta\theta + (r\sin\phi\,\dot{\phi})\,\delta\psi\\ \Rightarrow\ \delta(\dot{X}) &= (\delta X)^{\cdot} - (W^X{}_\phi\,\delta\phi + W^X{}_\theta\,\delta\theta + W^X{}_\psi\,\delta\psi)\\ &= (r\sin\phi\,\dot{\psi})\,\delta\phi - r\cos\phi\,\delta(\dot{\psi}) \qquad \text{[compare with (c5)]};\end{aligned} \tag{d2}$$

$$\begin{aligned}(\delta Y)^{\cdot} - \delta(\dot{Y}) &= (-r\sin\phi\,\delta\psi)^{\cdot} - \delta(-r\sin\phi\,\dot{\psi})\\ &= W^Y{}_\phi\,\delta\phi + W^Y{}_\theta\,\delta\theta + W^Y{}_\psi\,\delta\psi\\ &= (r\cos\phi\,\dot{\psi})\,\delta\phi + (0)\,\delta\theta + (-r\cos\phi\,\dot{\phi})\,\delta\psi\\ \Rightarrow\ \delta(\dot{Y}) &= (\delta Y)^{\cdot} - (W^Y{}_\phi\,\delta\phi + W^Y{}_\theta\,\delta\theta + W^Y{}_\psi\,\delta\psi)\\ &= (-r\cos\phi\,\dot{\psi})\,\delta\phi + (-r\sin\phi)\,\delta(\dot{\psi}) \quad \text{[compare with (c6)]}.\end{aligned} \tag{d3}$$

Then, the constrained Suslov principle (7.8.10) yields

$$0 = \int \{\delta L_o + (\partial T/\partial \dot{X})_o[(\delta X)^{\cdot} - \delta(\dot{X})] + (\partial T/\partial \dot{Y})_o[(\delta Y)^{\cdot} - \delta(\dot{Y})]\}\,dt$$
$$= \cdots = \int [(\ldots)\,\delta\phi + (\ldots)\,\delta\theta + (\ldots)\,\delta\psi]\,dt, \tag{d4}$$

which results in Voronets-type equations, as explained earlier.

(iii) *Stationarity (or coincidence) conditions*. Let us, finally, examine whether the above Hamilton-like variational expressions of Voronets and Suslov are genuine stationarity conditions. Invoking the constraints (a) and (b) provides the constrained momenta

$$(\partial L/\partial \dot{X})_o = (\partial T/\partial \dot{X})_o$$
$$= m(\dot{X} + r\,\dot{\theta}\sin\phi\sin\theta - r\,\dot{\phi}\cos\phi\cos\theta)_o$$
$$= m[(-r\cos\phi\cos\theta)\dot{\phi} + (r\sin\phi\sin\theta)\dot{\theta} + (-r\cos\phi)\dot{\psi}], \tag{e1}$$
$$(\partial L/\partial \dot{Y})_o = (\partial T/\partial \dot{Y})_o$$
$$= m(\dot{Y} - r\,\dot{\theta}\cos\phi\sin\theta - r\,\dot{\phi}\sin\phi\cos\theta)_o$$
$$= m[(-r\sin\phi\cos\theta)\dot{\phi} + (-r\cos\phi\sin\theta)\dot{\theta} + (-r\sin\phi)\dot{\psi}]; \tag{e2}$$

and so, invoking (c3, 4), the coincidence conditions (7.8.17d) give

$$\phi: \quad (\partial L/\partial \dot{X})_o W^X{}_\phi + (\partial L/\partial \dot{Y})_o W^Y{}_\phi = \cdots = -mr^2\dot{\theta}\,\dot{\psi}\sin\theta = 0, \tag{e3}$$
$$\theta: \quad (\partial L/\partial \dot{X})_o W^X{}_\theta + (\partial L/\partial \dot{Y})_o W^Y{}_\theta = m(\ldots)\,(0) + m(\ldots)\,(0) = 0, \tag{e4}$$
$$\psi: \quad (\partial L/\partial \dot{X})_o W^X{}_\psi + (\partial L/\partial \dot{Y})_o W^Y{}_\psi = \cdots = mr^2\dot{\phi}\,\dot{\theta}\sin\theta = 0. \tag{e5}$$

Since, on physically nontrivial grounds $\sin\theta \neq 0$, eqs. (e3–5) are satisfied either when $\dot{\theta} = 0 \Rightarrow \theta = constant\ (\neq 0)$, or when $\dot{\phi} = 0 \Rightarrow \phi = constant$ and $\dot{\psi} = 0 \Rightarrow \psi = constant$. The first possibility indicates *rolling of the disk at a constant nutation angle* (to the vertical GZ or OZ); while the second indicates absence of proper spin, in which case (a) yields $\dot{X} = 0$, $\dot{Y} = 0$; that is, a motion of no further physical interest. See also Capon (1952) and Rumiantsev (1978).

Example 7.8.3 *Rolling Sphere via the Suslov Principle*. Using Suslov's principle, let us derive the equations of motion of a homogeneous sphere of mass m and radius r rolling on a rough horizontal and fixed plane O–XY.

The kinematics and kinetics of this classical problem have already been discussed in exs. 2.13.5 and 2.13.6 (Lagrangean kinematics) and exs. 3.18.2 and 3.18.3 (Lagrangean kinetics). It was found there that the constraints are (in terms of $q_D \equiv q_{1,2,3}$: X, Y, Z: inertial coordinates of center/center-of-mass of sphere G, and $q_I \equiv q_{4,5,6}$: ϕ, θ, ψ: Eulerian angles of body-fixed axes at G relative to fixed axes O–xyz)

$$\dot{X} - r\,\omega_Y = 0, \qquad \dot{Y} + r\,\omega_X = 0 \qquad \text{(nonholonomic constraints)}, \tag{a1}$$
$$\Rightarrow \delta X - r\,\delta\theta_Y = 0, \qquad \delta Y + r\,\delta\theta_X = 0, \tag{a2}$$
$$Z = r \;\Rightarrow\; \dot{Z} = 0 \qquad \text{(holonomic constraint)} \;\Rightarrow\; \delta Z = 0; \tag{a3}$$

where (§1.12) (with $d\theta_{X,Y,Z} \equiv \omega_{X,Y,Z}\, dt$)

$$\omega_X = (\cos\phi)\dot{\theta} + (\sin\phi\sin\theta)\dot{\psi} \;\Rightarrow\; \delta\theta_X = (\cos\phi)\,\delta\theta + (\sin\phi\sin\theta)\,\delta\psi, \tag{b1}$$

$$\omega_Y = (\sin\phi)\dot{\theta} + (-\cos\phi\sin\theta)\dot{\psi} \;\Rightarrow\; \delta\theta_Y = (\sin\phi)\,\delta\theta + (-\cos\phi\sin\theta)\,\delta\psi, \tag{b2}$$

$$\omega_Z = \dot{\phi} + (\cos\theta)\dot{\psi} \;\Rightarrow\; \delta\theta_Z = \delta\phi + (\cos\theta)\,\delta\psi, \tag{b3}$$

with corresponding transitivity equations

$$(\delta\theta_X)^{\cdot} - \delta\omega_X = \omega_Y\,\delta\theta_Z - \omega_Z\,\delta\theta_Y, \tag{c1}$$

$$(\delta\theta_Y)^{\cdot} - \delta\omega_Y = \omega_Z\,\delta\theta_X - \omega_X\,\delta\theta_Z, \tag{c2}$$

$$(\delta\theta_Z)^{\cdot} - \delta\omega_Z = \omega_X\,\delta\theta_Y - \omega_Y\,\delta\theta_X. \tag{c3}$$

Hence, following the Suslov viewpoint, we find

$$\delta s_X \equiv (\delta X)^{\cdot} - \delta(\dot{X}) = (r\,\delta\theta_Y)^{\cdot} - \delta(r\,\dot{\theta}_Y) = \cdots = r(\omega_Z\,\delta\theta_X - \omega_X\,\delta\theta_Z), \tag{d1}$$

$$\delta s_Y \equiv (\delta Y)^{\cdot} - \delta(\dot{Y}) = (-r\,\delta\theta_X)^{\cdot} - \delta(-r\,\dot{\theta}_X) = \cdots = -r(\omega_Y\,\delta\theta_Z - \omega_Z\,\delta\theta_Y), \tag{d2}$$

$$\delta s_Z \equiv (\delta Z)^{\cdot} - \delta(\dot{Z}) = 0. \tag{d3}$$

The kinetic energy of the sphere is [with $I_{G;\,X,Y,Z} = 2mr^2/5 \equiv I$]

$$T = (m/2)\,[(\dot{X})^2 + (\dot{Y})^2 + (\dot{Z})^2] + (I/2)\,({\omega_X}^2 + {\omega_Y}^2 + {\omega_Z}^2) \tag{e1}$$

$$\begin{aligned}\Rightarrow\; T_o &= (m/2)\,[(r\,\omega_Y)^2 + (-r\,\omega_X)^2 + (0)^2] + (1/2)\,(2m\,r^2/5)\,({\omega_X}^2 + {\omega_Y}^2 + {\omega_Z}^2)\\ &= (1/2)\,(7m\,r^2/5)\,({\omega_X}^2 + {\omega_Y}^2) + (1/2)\,(2m\,r^2/5)\,({\omega_Z}^2),\end{aligned} \tag{e2}$$

and so its Suslovian variation equals

$$\delta T_o = (7mr^2/5)\,(\omega_X\,\delta\omega_X + \omega_Y\,\delta\omega_Y) + (2mr^2/5)\,(\omega_Z\,\delta\omega_Z). \tag{e3}$$

Therefore, invoking the transitivity relations (c1–3) and integrating by parts, and so on, we obtain

$$\begin{aligned}\int \omega_X\,\delta\omega_X\,dt &= \int \omega_X[(\delta\theta_X)^{\cdot} + (\omega_Z\,\delta\theta_Y - \omega_Y\,\delta\theta_Z)]\,dt\\ &= \int [(-\dot{\omega}_X)\,\delta\theta_X + \omega_X(\omega_Z\,\delta\theta_Y - \omega_Y\,\delta\theta_Z)]\,dt,\end{aligned} \tag{f1}$$

and, similarly,

$$\int \omega_Y\,\delta\omega_Y\,dt = \int [(-\dot{\omega}_Y)\,\delta\theta_Y + \omega_Y(\omega_X\,\delta\theta_Z - \omega_Z\,\delta\theta_X)]\,dt, \tag{f2}$$

$$\int \omega_Z\,\delta\omega_Z\,dt = \int [(-\dot{\omega}_Z)\,\delta\theta_Z + \omega_Z(\omega_Y\,\delta\theta_X - \omega_X\,\delta\theta_Y)]\,dt. \tag{f3}$$

Next, with the help of (a, d, e), the Suslov integrand term $s \equiv \sum (\partial T/\partial \dot{q}_D)_o \,\delta s_D$ becomes

$$
\begin{aligned}
s &\equiv (\partial T/\partial \dot{X})_o \,\delta s_X + (\partial T/\partial \dot{Y})_o \,\delta s_Y + (\partial T/\partial \dot{Z})_o \,\delta s_Z \\
&= (m\dot{X})_o[r(\omega_Z \,\delta\theta_X - \omega_X \,\delta\theta_Z)] + (m\dot{Y})_o[r(\omega_Z \,\delta\theta_Y - \omega_Y \,\delta\theta_Z)] + 0 \\
&= \cdots = (m r^2 \omega_Y \omega_Z)\,\delta\theta_X + (-m r^2 \omega_X \omega_Z)\,\delta\theta_Y; \qquad \text{(g1)}
\end{aligned}
$$

while the total impressed virtual work is [with $Q_{X,Y,Z;\,\phi,\theta,\psi} \equiv Q_X, Q_Y, Q_Z;$ Q_ϕ, Q_θ, Q_ψ]

$$
\begin{aligned}
\delta' W &= Q_X \,\delta X + Q_Y \,\delta Y + Q_Z \,\delta Z + Q_\phi \,\delta\phi + Q_\theta \,\delta\theta + Q_\psi \,\delta\psi \\
&\qquad \text{[by (a2) and the inverse of (b1–3) \quad see §1.12]} \\
&= \cdots \equiv M_X \,\delta\theta_X + M_Y \,\delta\theta_Y + M_Z \,\delta\theta_Z \quad (= \delta' W^*{}_o), \qquad \text{(g2)}
\end{aligned}
$$

where [recalling (3.15.2a ff.)]

$$M_X = (-r)Q_Y + (-\cot\theta \sin\phi)Q_\phi + (\cos\phi)Q_\theta + (\sin\phi/\sin\theta)Q_\psi, \qquad \text{(g3)}$$

$$M_Y = (r)Q_X + (-\cot\theta \cos\phi)Q_\phi + (\sin\phi)Q_\theta + (-\cos\phi/\sin\theta)Q_\psi, \qquad \text{(g4)}$$

$$M_Z = Q_\phi. \qquad \text{(g5)}$$

Substituting all these results into Suslov's variational formula (7.8.10), we obtain

$$
\begin{aligned}
\int \big\{ &[-(7mr^2/5)\dot{\omega}_X + M_X]\,\delta\theta_X + [-(7mr^2/5)\dot{\omega}_Y + M_Y]\,\delta\theta_Y \\
&+ [-(2mr^2/5)\dot{\omega}_Z + M_Z]\,\delta\theta_Z \big\}\, dt = 0, \qquad \text{(h1)}
\end{aligned}
$$

and this, since the $\delta\theta_{X,Y,Z}$ are independent (free), leads immediately to the following three kinetic equations:

$$(7mr^2/5)\,\dot{\omega}_X = M_X, \qquad (7mr^2/5)\,\dot{\omega}_Y = M_Y, \qquad (2mr^2/5)\,\dot{\omega}_Z = M_Z; \qquad \text{(h2)}$$

which, along with the two constraints (a1) and the three kinematical relations (b1–3), constitute a determinate system for $X(t), Y(t);\ \phi(t), \theta(t), \psi(t);\ \omega_X(t),$ $\omega_Y(t), \omega_Z(t)$.

Let the reader formulate this problem via Voronets' principle (7.8.6); or even via those of § 7.7.

7.9 NONCONTEMPORANEOUS VARIATIONS; ADDITIONAL IVP FORMS

The General Formulae

We begin with the following slightly modified version of the fundamental integral variational equation (7.2.3b):

$$\int (\delta L + \delta' W_{np})\, dt = \Big\{ \sum p_k \,\delta q_k \Big\}_1^2, \qquad (7.9.1)$$

where

$L = L(t, q, \dot{q}) \equiv T(t, q, \dot{q}) - V(t, q)$: Lagrangean of the system,

$\delta' W_{np} \equiv \delta' W - (-\delta V)$: Total (first-order) virtual work of *nonpotential* impressed forces,

$$p_k \equiv \partial T/\partial \dot{q}_k = \partial L/\partial \dot{q}_k\text{: Holonomic system (“generalized”) momentum.} \qquad (7.9.1a)$$

Now, if in (7.9.1), $\delta' W_{np} = 0$, the q's and δq's are chosen so that $\{\sum p_k\, \delta q_k\}_1^2 \equiv BT = 0$ [e.g., by taking $\delta q(t_1) = \delta q(t_2) = 0$], and *if no additional constraints are imposed on the system* (unless explicitly specified otherwise), then (7.9.1) yields the customary form of *Hamilton*'s *principle* of stationarity:

$$\delta A_H = 0, \qquad (7.9.2)$$

where

$$A_H \equiv \int (T - V)\, dt \equiv \int L\, dt\text{: Hamiltonian action (functional).} \qquad (7.9.2a)$$

Let us express the above in terms of the earlier-introduced *noncontemporaneous*, or *skew*, or *oblique*, or *asynchronous*, or *nontautochronous*, or *nonsimultaneous* variations (§7.2, fig.7.1):

$$\Delta q_k = \delta q_k + \dot{q}_k \Delta t; \qquad (7.9.3)$$

where, generally,

$$\Delta(\ldots) \equiv \delta(\ldots) + [d(\ldots)/dt]\Delta t\text{: } \textit{noncontemporaneous variation operator}; \qquad (7.9.3a)$$

for example, $\Delta t = \delta t + (dt/dt)\Delta t = 0 + (1)\Delta t = \Delta t$.

Our discussion is based on the following fundamental, purely analytical and interrelated, formulae, obtained by applying $\Delta(\ldots)$ to $\int (\ldots)\, dt$ and its integrand (which is nothing but an application of the well-known theorem of differentiation of a definite integral with respect to a general parameter that may appear in both its limits of integration $t_{1,2}$ and in its integrand, or “Leibniz' rule”):

- $$\begin{aligned}\Delta \int (\ldots)\, dt &= \int \delta(\ldots)\, dt + \{(\ldots)\Delta t\}_1^2 \\ &= \int \{\Delta(\ldots) + (\ldots)[d(\Delta t)/dt]\}\, dt \\ &= \int [\Delta(\ldots)\, dt + (\ldots)\, d(\Delta t)], \end{aligned} \qquad (7.9.3b)$$

- $$\begin{aligned}\int \Delta(\ldots)\, dt &= \int \{\delta(\ldots) - (\ldots)[d(\Delta t)/dt]\}\, dt + \{(\ldots)\Delta t\}_1^2 \\ &= \int [\delta(\ldots)\, dt - (\ldots)\, d(\Delta t)] + \{(\ldots)\Delta t\}_1^2; \end{aligned} \qquad (7.9.3c)$$

from which the (intuitively “obvious”) $\Delta - \int$ noncommutativity formula results:

- $$\Delta \int (\ldots)\, dt - \int \Delta(\ldots)\, dt = \int (\ldots)\, d(\Delta t) = \int \{(\ldots)\, [d(\Delta t)/dt]\}\, dt. \qquad (7.9.3d)$$

With the help of the above, *Hamilton's principle* (7.9.1–2a) can be easily brought to its following *two equivalent noncontemporaneous forms*:

- $$\Delta \int T\,dt + \int \delta' W\,dt = \Big\{\sum p_k \Delta q_k + \Big(T - \sum p_k \dot{q}_k\Big)\Delta t\Big\}_1^2$$
$$= \Big\{\sum p_k\,\delta q_k + T\,\Delta t\Big\}_1^2, \qquad (7.9.4a)$$

- $$\Delta A_H + \int \delta' W_{np}\,dt = \Big\{\sum p_k \Delta q_k - h\Delta t\Big\}_1^2 = \Big\{\sum p_k\,\delta q_k + L\Delta t\Big\}_1^2, \qquad (7.9.4b)$$

where (recalling §3.9)

$$h \equiv \sum p_k \dot{q}_k - L = h(t, q, \dot{q})\text{: Generalized energy}$$
$$\text{[or Hamiltonian, when expressed in terms of } t, q, p \text{ (chap. 8)].} \qquad (7.9.4c)$$

Further, with the definitions

$$A_L \equiv \int 2T\,dt\text{: Lagrangean action (functional),} \qquad (7.9.4d)$$

$$E \equiv T + V\text{: Total } \textit{energy} \text{ of the system,} \qquad (7.9.4e)$$

it is not hard to see that we can rewrite (7.9.4a, b) as the following general *principle of noncontemporaneously varying, or varied, Lagrangean action*:

- $$\Delta A_L - \int (\delta E - \delta' W_{np})\,dt = \Big\{\sum p_k \Delta q_k - \Big(\sum p_k \dot{q}_k - 2T\Big)\Delta t\Big\}_1^2$$
$$= \Big\{\sum p_k\,\delta q_k + 2T\Delta t\Big\}_1^2; \qquad (7.9.4f)$$

and, finally, adding and subtracting (7.9.4a, b) with the purely mathematical equation

$$\Delta \int E\,dt = \int \delta E\,dt + \{E\Delta t\}_1^2, \qquad (7.9.4g)$$

side by side, produces the additional "symmetrical principles":

- $$\Delta \int 2T\,dt = \int (\delta E - \delta' W_{np})\,dt + \Big\{\sum p_k \Delta q_k + \Big(2T - \sum p_k \dot{q}_k\Big)\Delta t\Big\}_1^2, \qquad (7.9.4h)$$
- $$\Delta \int 2V\,dt = \int (\delta E + \delta' W_{np})\,dt + \Big\{-\sum p_k \Delta q_k + \Big(2V + \sum p_k \dot{q}_k\Big)\Delta t\Big\}_1^2. \qquad (7.9.4i)$$

An additional IVP can be obtained if we *express the integrands of the above in terms of* $\Delta(\ldots)$-variations: adding side by side (i) eqs. (7.9.4a, b), but with

$$\Delta \int T\,dt \qquad \text{replaced by} \qquad \int [\Delta T + T(\Delta t)^{\cdot}]\,dt \qquad \text{[applying (7.9.3b)],} \qquad (7.9.5a)$$

and (ii) the obvious identity

$$\{T\varDelta t\}_1^2 = \int (T\varDelta t)^{\cdot}\, dt = \int [T(\varDelta t)^{\cdot} + \dot{T}\varDelta t]\, dt \tag{7.9.5b}$$

produces the alternative forms:

$$\begin{aligned}
&\int [\varDelta T + 2T(\varDelta t)^{\cdot} + \dot{T}\varDelta t]\, dt + \int \delta' W\, dt \\
&\qquad = \int \left[\varDelta T\, dt + 2T\, d(\varDelta t) + dT\varDelta t + \delta' W\, dt\right] \\
&\qquad = \left\{\sum p_k\, \delta q_k + (2T)\varDelta t\right\}_1^2 \\
&\qquad = \left\{\sum p_k \varDelta q_k - \left(\sum p_k \dot{q}_k - 2T\right)\varDelta t\right\}_1^2 .
\end{aligned} \tag{7.9.5c}$$

The above are usually associated with the names of O. Hölder, Voss, et al., and a time when the differences between $\varDelta(\ldots)$ and $\delta(\ldots)$ were not clearly understood (late 19th to early 20th century). Unless one distinguishes carefully between these two kinds of variation, notices the resulting integral noncommutativity formula (7.9.3d), and states carefully the system properties and boundary conditions, the results are very likely to be erroneous and extremely difficult to compare with those of other authors. This is a tricky area (like §7.8) that has caused considerable confusion and frustration; see, for example, Papastavridis [1987(d)].

Specializations

(i) If the following hold:

the (holonomic) constraints are *stationary*, in which case $\sum p_k \dot{q}_k = 2T$,

$\delta' W_{np} = 0$,

$\varDelta q_k(t_1) = \varDelta q_k(t_2) = 0$,

and

$$\delta E = \delta h = 0, \tag{7.9.6a}$$

then (7.9.4f) reduces to the original *principle of "least" action* of *Maupertuis* $\rightarrow$ *Euler* $\rightarrow$ *Lagrange* (MEL):

$$\varDelta A_L \equiv \varDelta \int 2T\, dt = \varDelta \int \left(\sum (\partial L/\partial \dot{q}_k)\dot{q}_k\right) dt = 0. \tag{7.9.6b}$$

Of course, other combinations of boundary conditions and system assumptions may produce the same result. [An alternative derivation of (7.9.6b) is given below.]

(ii) For stationary constraints, the power equation (7.2.6e, f) reduces to $dT/dt = \sum Q_k \dot{q}_k$ (where Q_k is the *total* impressed force), so that

$$\dot{T}\varDelta t + \delta' W = \left(\sum Q_k \dot{q}_k\right)\varDelta t + \sum Q_k\, \delta q_k = \sum Q_k \varDelta q_k \equiv \varDelta' W,$$

and therefore the left side of (7.9.5c) simplifies to

$$\int \left[\Delta T + 2T(\Delta t)^{\cdot} + \Delta' W\right] dt = \int \left[\Delta T\, dt + 2T\, d(\Delta t) + \Delta' W\, dt\right], \tag{7.9.7a}$$

whereas the right reduces to

$$\left\{\sum p_k \Delta q_k\right\}_1^2 = \left\{\sum p_k\, \delta q_k + (2T)\Delta t\right\}_1^2. \tag{7.9.7b}$$

REMARKS ON MEL'S ACTION

(i) The A_L-definition (7.9.4d) is not arbitrary. It constitutes the earliest of all such action definitions (early 1740s); that is, of energetic functions/functionals of dimensions

$$(energy) \times (time) = (momentum) \times (length).$$

(Originally, it was given by Euler for a special case, then generalized by Lagrange for arbitrary holonomic and scleronomic systems, and fully justified later by modern variational calculus.)

For a single, say unconstrained, particle of mass m, moving along a path of arc length s with velocity $\boldsymbol{v} = d\boldsymbol{r}/dt$ [$\Rightarrow$ velocity component along path tangent $\equiv v = ds/dt$], (7.9.4d) gives

$$A_L = \int m\, v^2\, dt = \int (m\, \boldsymbol{v}) \cdot \boldsymbol{v}\, dt = \int (m\, \boldsymbol{v}) \cdot d\boldsymbol{r} = \int m\, v\, ds \tag{7.9.8a}$$

[= sum of elementary "works of the (linear) momentum" along the particle's path];

and, for a material system (with the usual notations):

$$A_L = \int \left[\boldsymbol{S}\,(dm\, \boldsymbol{v}) \cdot d\boldsymbol{r}\right] = \int \sum p_k\, dq_k. \tag{7.9.8b}$$

(ii) It is frequently claimed, in the variational mechanics literature, that starting with (7.9.2, 2a) and substituting in there the energy conservation relation $\delta E = 0 \Rightarrow \delta T = -\delta V$, between the orbit(s) and other kinematically admissible paths, one obtains the (*contemporaneous* variation $\Rightarrow$ fixed time-endpoints) MEL principle (7.9.6b):

$$0 = \int [\delta T - (-\delta T)]\, dt = \int \delta(2T)\, dt = \delta \int (2T)\, dt; \qquad \text{i.e.,}\ \ \delta A_L = 0. \tag{7.9.9}$$

However, such a reasoning would be incorrect for the following reasons: eq. (7.9.2) yields the n Lagrangean equations $E_k(L) = 0$, the general solution of which contains $2n$ integration constants, to be determined from $2n$ boundary conditions such as $q_k(t_{1,2}) = given$, where $t_{1,2}$ are also given. Hence, it will be impossible for the resulting particular solution(s) to satisfy the *additional* energy constraint: $T(q, \dot{q}) + V(q) = E = given\ constant$ (the same for all competing trajectories).

That the reasoning leading to (7.9.9) is incorrect can also be seen as follows: The last condition implies that $\delta E = 0$ (virtual form of constraint), and this, for given q's and δq's, imposes restrictions on the corresponding velocities; that is, on the $\delta(\dot{q})$'s; and this, in particular, makes it impossible for the system to go from an initial position to a final one along the actual (kinetic) path and along a typical comparison (adjacent) path, with the *same energy* and in the *same time* for *both paths*; hence, in MEL's principle, the energy constraint necessitates *noncontemporaneous variations* (i.e., $\delta q \to \Delta q$, $\delta t = 0 \to \Delta q \neq 0$, and results in variable time limits). This can be illustrated with the following simple example of a free particle in rectilinear motion. Here (with q: rectilinear coordinate, and other notations standard),

$$V = 0, \qquad 2T = m\,v^2 \equiv m(dq/dt)^2 = 2E = constant \quad (> 0), \tag{7.9.10a}$$

and, therefore, along its orbit

$$v \equiv \dot{q} = (2E/m)^{1/2} \Rightarrow \delta[\dot{q}(t)] = \delta[(2E/m)^{1/2}] = 0 \qquad (\text{since } \delta E = 0), \tag{7.9.10b}$$

from which, integrating and using the convenient initial conditions $q_1 = q(t_1) \equiv q(0) = 0$, we get

$$q(t) = (2E/m)^{1/2} t, \tag{7.9.10c}$$

a straight line in rectangular Cartesian q versus t axes; and, therefore, any other continuous comparison path *with the same spatio-temporal endpoints as the orbit* (7.9.10c), $(t_1 = 0, q_1 = 0)$ and $[t_2, q_2 = q(t_2)]$, so that $\delta q_1 = \delta q_2 = 0$ [as required by (7.9.9)], would have to be *nonrectilinear* somewhere between t_1, t_2; that is, in there, $\delta[\dot{q}(t)] \neq 0$, in clear contradiction to (7.9.10b); or, trivially, the actual path and its comparison paths coincide. Hence, it is impossible to reach, *by a (smooth) neighboring path of the same constant energy as the orbit*, the endpoint $q_2 = q(t_2)$, as demanded by the boundary condition, in the same time $t_2 - t_1 = t_2 - 0 = t_2$; or, if we insist on isoenergeticity, $\Delta E = \delta E + \dot{E}\Delta t = \delta E = 0$, we cannot have $\delta q_2 = 0$ (and vice versa), but we can have $\Delta q_2 = \delta q_2 + \dot{q}(t_2)\Delta t_2 = 0 \Rightarrow \delta q_2 = -\dot{q}(t_2)\Delta t_2 \neq 0$ $\Rightarrow \Delta t_2 \neq 0$, since (here, and in general) $\dot{q}(t_2) \neq 0$. (As a way out of these difficulties, some have suggested using virtual paths with discontinuous velocity reversals—that is, $\dot{q} \to -\dot{q}$—but this seems artificial and impractical.)

The preceding discussion leads us to the following correct formulation of MEL's principle: Among all sufficiently smooth kinematically admissible trajectories $q(t)$, in configuration space, passing through the given *initial* point $P_1[q_k(t_1) = q_{k1}$: *given*; t_1: *given*] and given *final* point $P_2[q_k(t_2) = q_{k2}$: *given*; but t_2: *unknown*, to be determined from the stationarity condition] and satisfying the total energy constraint $T + V = E$: *given constant*, the actual (kinetic) motion(s), or orbit(s), satisfies (satisfy) (7.9.6b); that is, contrary to the *fixed* time-endpoints Hamilton's principle (7.9.2), MEL's principle (7.9.6b) is a *variable upper time endpoint variational problem*: $\Delta t_1 = 0$ *but* $\Delta t_2 \neq 0$, and as such is fundamentally different from it; although, in both principles, the *total number of given data is* $(n + 1) + (n + 1) = 2n + 2$.

General Kinematico-Inertial Identities

The preceding results (7.9.1a, 2; 4a, b, f, h, i; 6b, etc.) hold for *variations* $\Delta(\ldots)$, $\delta(\ldots)$ *from an orbit*; in fact, they were obtained from the equations of motion, or LP, or the central equation. Let us now see the converse; that is, derive those IVP by direct variations of, say, A_H from a kinematically admissible path, and then specialize to an orbit.

Invoking (7.2.4c, d) and (7.9.3, 3b–d), and with the already familiar notations

$$E_k(\ldots) \equiv [\partial(\ldots)/\partial \dot{q}_k]^{\cdot} - \partial(\ldots)/\partial q_k\text{: } \textit{Euler–Lagrange operator}, \tag{7.9.11a}$$

$$h(\ldots) \equiv \sum [\partial(\ldots)/\partial \dot{q}_k]\dot{q}_k - (\ldots)\text{: } \textit{Generalized energy operator}, \tag{7.9.11b}$$

$$\Delta(\ldots) \equiv \sum \{[\partial(\ldots)/\partial q_k]\Delta q_k + [\partial(\ldots)/\partial \dot{q}_k]\Delta(\dot{q}_k)\} + [\partial(\ldots)/\partial t]\Delta t\text{:}$$
$$\textit{Noncontemporaneous (first-order) variation operator}, \tag{7.9.11c}$$

we find, successively (recalling fig. 7.1),

$$\begin{aligned}
\Delta A_H &\equiv \Delta \int L\, dt \equiv \int L[II;\ \mathrm{arc}(C_1 C_2)]\, dt - \int L[I;\ \mathrm{arc}(A_1 A_2)]\, dt \\
&= \int L[t + \Delta t, q + \Delta q, \dot{q} + \Delta(\dot{q})]\, d(t + \Delta t) \ - \ \int L(t, q, \dot{q})\, dt \\
&\approx \int [L\, dt + L\, d(\Delta t) + \Delta L\, dt + \Delta L\, d(\Delta t) - L\, dt] \\
&\approx \int [\Delta L\, dt + L\, d(\Delta t)] \qquad [\text{to the } \textit{first} \text{ order, and with } L(t, q, \dot{q}) \equiv L] \\
&= \int [\Delta L + L(\Delta t)^{\cdot}]\, dt \\
&= \int \Big\{\sum \big[(\partial L/\partial q_k)\Delta q_k + (\partial L/\partial \dot{q}_k)\Delta(\dot{q}_k)\big] + (\partial L/\partial t)\Delta t + L(\Delta t)^{\cdot}\Big\}\, dt \\
&\quad [\text{replacing } \Delta(\dot{q}) \text{ with } (\Delta q)^{\cdot} - \dot{q}(\Delta t)^{\cdot}] \\
&= \int \Big\{\sum \big[(\partial L/\partial q_k)\Delta q_k + (\partial L/\partial \dot{q}_k)\,(\Delta q_k)^{\cdot}\big] + (\partial L/\partial t)\Delta t \\
&\qquad\qquad - \Big[\sum (\partial L/\partial \dot{q}_k)\dot{q}_k - L\Big]\,(\Delta t)^{\cdot}\Big\}\, dt \\
&= -\int \sum E_k(L)\Delta q_k\, dt \\
&\qquad + \int \Big\{(\partial L/\partial t)\Delta t - \Big[\sum (\partial L/\partial \dot{q}_k)\dot{q}_k - L\Big]\,(\Delta t)^{\cdot}\Big\}\, dt \\
&\qquad + \int d/dt\Big[\sum (\partial L/\partial \dot{q}_k)\Delta q_k\Big]\, dt \\
&= \cdots = -\int \sum E_k(L)\Delta q_k\, dt + \int \Big[\sum (\partial L/\partial \dot{q}_k)\Delta q_k - h(L)\Delta t\Big]^{\cdot}\, dt \\
&\qquad\qquad + \int [dh(L)/\,dt + \partial L/\partial t]\Delta t\, dt;
\end{aligned} \tag{7.9.11d}$$

that is,

$$\begin{aligned}
&\Delta A_H + \int \delta' W_{np}\, dt = \\
&\quad -\int \sum [E_k(L) - Q_k]\Delta q_k\, dt + \int \Big[dh(L)/dt + \partial L/\partial t - \sum Q_k \dot{q}_k\Big]\Delta t\, dt, \\
&\quad + \Big\{\sum p_k \Delta q_k - h(L)\Delta t\Big\}_1^2
\end{aligned}$$

$$= -\int \sum [E_k(L) - Q_k]\,\delta q_k\,dt - \int \Big(\sum E_k(L)\dot{q}_k - dh(L)/dt - \partial L/\partial t\Big)\Delta t\,dt$$
$$+ \Big\{\sum p_k \Delta q_k - h(L)\Delta t\Big\}_1^2; \tag{7.9.11e}$$

or, due to the analytical identity (3.9.3b; with T replaced by L),

$$dh(L)/dt \;+\; \partial L/\partial t = \sum E_k(L)\dot{q}_k, \tag{7.9.11f}$$

finally [with $h(L)$ renamed simply h],

$$\Delta \int L\,dt = -\int \Big[\sum E_k(L)\,(\Delta q_k - \dot{q}_k \Delta t)\Big]\,dt$$
$$+ \Big\{\sum (\partial L/\partial \dot{q}_k)\Delta q_k - h\Delta t\Big\}_1^2; \tag{7.9.11g}$$

that is,

$$\Delta A_H = -\int \sum E_k(L)\,\delta q_k\,dt + \Big\{\sum p_k \Delta q_k - h\Delta t\Big\}_1^2. \tag{7.9.11h}$$

Kinetic Specializations

(i) For variations from an orbit, $\sum E_k(L)\,\delta q_k = \delta' W_{np}$, by LP, and so (7.9.11h) reduces to (7.9.4a, b).

(ii) If, further, we assume that $\delta' W_{np} = 0$, and choose "*cotermini variations*" in space and time:

$$\Delta q_k(t_1) = \Delta q_k(t_2) = 0 \qquad \text{and} \qquad \Delta t(t_1) = \Delta t(t_2) = 0, \tag{7.9.12a}$$

then (7.9.11h) yields "Voss' principle," $\Delta A_H = 0$.

(iii) If, again for variations from an orbit and $Q_{k,np} = 0 \;\Rightarrow\; \delta' W_{np} = 0$,

$$L = L(q, \dot{q}) \;\Rightarrow\; \partial L/\partial t = 0 \;\Rightarrow\; h \equiv \sum (\partial L/\partial \dot{q}_k)\dot{q}_k - L = constant, \tag{7.9.12b}$$

we choose *spatially* cotermini variations:

$$\Delta q_k(t_1) = \Delta q_k(t_2) = 0 \qquad \text{but} \qquad \Delta t(t_1) = \Delta t(t_2) \neq 0, \tag{7.9.12c}$$

then (7.9.11h) also yields $\Delta A_H = 0$.

If, instead of (7.9.12c), $\Delta t(t_1) = 0$, but $\Delta t(t_2) \equiv \Delta t$, then (7.9.11h) reduces to

$$\Delta A_H + h\,\Delta t = 0, \tag{7.9.12d}$$

a form that has applications in nonlinear oscillations (ex. 7.9.13; see also § 8.11).

(iv) Again, for variations from an orbit and $Q_{k,np} = 0 \Rightarrow \delta' W_{np} = 0$, and $L = L(q, \dot{q}) \Rightarrow h = constant$, we find, successively,

$$\Delta \int \left[\sum (\partial L/\partial \dot{q}_k)\dot{q}_k\right] dt \qquad \left[= \Delta \int 2T\, dt \equiv \Delta A_L\right]$$

$$\equiv \int \left[\sum (\partial L/\partial \dot{q}_k)\dot{q}_k\right]_{II} dt \;-\; \int \left[\sum (\partial L/\partial \dot{q}_k)\dot{q}_k\right]_I dt$$

$$= \Delta \int (L + h)\, dt$$

$$= \Delta \int L\, dt + \Delta[h(t_2 - t_1)]$$

$$= \Delta A_H + \Delta[h(t_2 - t_1)]$$

$$= \cdots = \left\{\sum p_k \Delta q_k\right\}_1^2 + \Delta h(t_2 - t_1) \qquad \text{[invoking (7.9.11h)]}$$

$$= \left\{\sum p_k \Delta q_k + (t)\; \Delta h\right\}_1^2 \tag{7.9.12e}$$

[we notice that, here, $\Delta h \equiv \delta h + \dot{h}\; \Delta t = \delta h$ ($= \delta E$, for stationary constraints)], and so, if in addition, we choose the *spatially* cotermini and *isoenergetic* variations

$$\Delta q_k(t_1) = \Delta q_k(t_2) = 0 \qquad \text{and} \qquad \Delta h = 0, \tag{7.9.12f}$$

(7.9.12d) yields

$$\Delta \int \left[\sum (\partial L/\partial \dot{q}_k)\dot{q}_k\right] dt \;\to\; \Delta A_L \;=\; 0; \tag{7.9.12g}$$

which coincides with the earlier MEL principle (7.9.6b).

ANALYTICAL REMARK

(See also ex. 7.9.1 and prob. 7.9.1.) Clearly, (7.9.11d) is a general result holding for *any* (well-behaved) function $F = F(t, q, \dot{q})$; that is,

$$\Delta \int F\, dt = \cdots = -\int \sum E_k(F)\; \Delta q_k\, dt$$

$$+ \int \left\{(\partial F/\partial t)\Delta t - \left[\sum (\partial F/\partial \dot{q}_k)\dot{q}_k - F\right] (\Delta t)^{\cdot}\right\} dt$$

$$+ \int d/dt\left[\sum (\partial F/\partial \dot{q}_k)\Delta q_k\right] dt$$

$$= \cdots = -\int \sum E_k(F)\Delta q_k\, dt + \int [dh(F)/dt + \partial F/\partial t]\Delta t\, dt$$

$$+ \left\{\sum (\partial F/\partial \dot{q}_k)\Delta q_k - h(F)\Delta t\right\}_1^2,$$

$$= \cdots = -\int \sum E_k(F)\; \delta q_k\, dt + \left\{\sum (\partial F/\partial \dot{q}_k)\Delta q_k - h(F)\Delta t\right\}_1^2$$

$$= -\int \sum E_k(F)\; \delta q_k\, dt + \left\{\sum (\partial F/\partial \dot{q}_k)\delta q_k + F\Delta t\right\}_1^2 . \tag{7.9.12h}$$

A Generalization of MEL's Principle; Jacobi's Form

Let us consider a *conservative* system; that is, recalling (7.2.6e) and §3.9, one in which $\partial L/\partial t = 0$, all forces are either potential (included in L) or gyroscopic, and all additional Pfaffian constraints are, at most, catastatic. Then, the power equation reduces to the *Jacobi–Painlevé integral*

$$h = L_2 - L_0 \equiv T_2 + (V - T_0) = constant \;\Rightarrow\; (L_2)^{1/2} = (L_0 + h)^{1/2}. \qquad (7.9.13a)$$

It is then possible to replace the variable time-endpoint principle (7.9.6b, 12e) with a simpler one with *fixed* time-endpoints. To this end, we first define the Jacobi action-like functional:

$$\begin{aligned} A_J{}' &\equiv \int L\,dt - \int \left[(L_2)^{1/2} - (L_0 + h)^{1/2}\right]^2 dt \\ &\equiv A_H - \int [\ldots]^2\,dt \\ &\left[= \cdots = \int \left\{2[L_2(L_0 + h)]^{1/2} + L_1 - h\right\} dt\right]. \end{aligned} \qquad (7.9.13b)$$

For general contemporaneous variations around an admissible path, clearly, we will have

$$\delta A_J{}' = \delta A_H - \int 2[\ldots]\,\delta[\ldots]\,dt, \qquad (7.9.13c)$$

and, therefore, for variations from an orbit — that is, an actual motion satisfying (7.9.13a) (with the same h-value for both $A_J{}'$ and A_H) — we shall have

$$\delta A_J{}' = \delta A_H \quad (\to 0,\ \text{for vanishing endpoint variations}); \qquad (7.9.13d)$$

or, neglecting the constant last h-term in (7.9.13b), $A_J{}' \to A_J$:

$$A_J \equiv \int \left\{2[L_2(L_0 + h)]^{1/2} + L_1\right\} dt \equiv \int J(q, \dot{q})\,dt, \qquad (7.9.13e)$$

we arrive at the "least action"-like (better, *stationarity*) condition

$$\delta A_J = 0, \qquad (7.9.13f)$$

Since the integrand of the above, $J = J(q, \dot{q})$, is positively homogeneous of the *first* degree in the $\dot{q}$'s (which means that, for *any positive* number λ, $\lambda J(q, \dot{q}) = J(q, \lambda\dot{q})$; i.e., J is not really a function of time t), we can write

$$A_J = \int J(q, \dot{q})\,dt = \int J(q, dq) = \int J(q, q')\,d\sigma, \qquad (7.9.13g)$$

where $t = t(\sigma) \Leftrightarrow \sigma = \sigma(t)$ are arbitrary (increasing) functions (and, therefore, the integration limits are changed accordingly) and

$$(\ldots)^{\cdot} \equiv d(\ldots)/dt = [d(\ldots)/d\sigma]\,\dot{\sigma} \equiv (\ldots)'\,\dot{\sigma}, \qquad (\ldots)' \equiv d(\ldots)/d\sigma; \qquad (7.9.13h)$$

for example, $\dot{q}_k \equiv q_k{}'\dot{\sigma}$. Then, the stationarity condition (7.9.13e) leads to the following n Euler–Lagrange equations:

$$(\partial J/\partial q_k{}')' - \partial J/\partial q_k = 0; \tag{7.9.13i}$$

and, conversely, the parameter t can be chosen so that

$$\begin{aligned} &[L_2(q,\dot{q})]^{1/2} = [L_0(q) + h]^{1/2} \\ &\Rightarrow\ t = \int \{L_2(q,\dot{q})/[L_0(q)+h]\}^{1/2}\, d\sigma, \end{aligned} \tag{7.9.13j}$$

where the $q(\sigma)$'s verify (7.9.13i). Then, from $\delta A_J = 0$, it also follows that $\delta A_H = 0$.

Next, from (7.9.13i), and since $J = \sum (\partial J/\partial q_k{}')q_k{}'$, we readily find the additional equation,

$$\begin{aligned} &\sum\ [(\partial J/\partial q_k{}')' - \partial J/\partial q_k]q_k{}' \\ &\quad = \Big[\sum (\partial J/\partial q_k{}')q_k{}'\Big]' - \sum\ [(\partial J/\partial q_k{}')q_k{}'' + (\partial J/\partial q_k)q_k{}'] \\ &\quad = J' - J' = 0; \end{aligned} \tag{7.9.13k}$$

that is, *only* $n-1$ *of the* n *equations (7.9.13i) are independent* (something to be expected, due to the σ arbitrariness). Hence if, following Jacobi, we choose as σ one of the q's, say, q_1, the orbit(s) of the system will be given by the following $n-1$ Lagrangean equations in $q_2(q_1), \ldots, q_n(q_1)$:

$$d/dq_1\big[\partial J/\partial(dq_k/dq_1)\big] - \partial J/\partial q_k = 0 \qquad (k = 2, \ldots, n), \tag{7.9.13l}$$

whose general solution will depend on $2(n-1)+1 = 2n-1$ integration constants [one of them could be the h constant in (7.9.13a)].

Jacobi's Form (early 1840s)

If, in addition to being conservative and holonomic, our system is also *scleronomic* (and these restrictions severely limit the usefulness of the principle to engineering dynamics problems) then, since in this case

$$L_2 = T_2 = T = \sum\sum (1/2)M_{kl}\dot{q}_k\dot{q}_l, \qquad M_{kl} = M_{kl}(q), \tag{7.9.14a}$$

$$L_1 = T_1 = 0, \quad L_0 = T_0 - V = -V, \qquad V = V(q), \tag{7.9.14b}$$

$$h\ = T + V = E \qquad \text{(a positive constant)}, \tag{7.9.14c}$$

the action A_J, (7.9.13f), reduces to

$$A_J = \int 2[T(E-V)]^{1/2}\, dt. \tag{7.9.14d}$$

But, recalling (3.9.4o) or (6.7.2a), we have

$$2T(dt)^2 = \sum\sum M_{kl}\, dq_k\, dq_l = 2(E - V)\,(dt)^2 \equiv ds^2, \tag{7.9.14e}$$

ds: elementary arc-length along orbit of figurative particle representing the system in configuration space, (7.9.14f)

and therefore we can rewrite (7.9.14d) as

$$\begin{aligned} A_J &= \int [2(E - V)]^{1/2}[2T(dt)^2]^{1/2} \\ &= \int \Big[2(E - V)\Big(\sum\sum M_{kl}\, dq_k\, dq_l\Big)\Big]^{1/2} \\ &= \int [2(E - V)]^{1/2}\, ds, \end{aligned} \tag{7.9.14g}$$

or, in terms of the new function R (and the earlier parameter σ) defined by

$$\begin{aligned} &2(E - V)\Big(\sum\sum M_{kl}\, dq_k\, dq_l\Big) \equiv R(d\sigma)^2 \\ &\Rightarrow\ R = R(q, q') = 2(E - V)\Big(\sum\sum M_{kl} q_k{}' q_l{}'\Big), \end{aligned} \tag{7.9.14h}$$

or, equivalently,

$$2T\, dt = \sqrt{R}\, d\sigma = J(q, q')\, d\sigma, \tag{7.9.14i}$$

we can, finally, bring A_J to the *Jacobi form* (fixed time-endpoints):

$$A_J = \int \sqrt{R}\, d\sigma \quad \Big[= A_L \equiv \int 2T\, dt\Big] \tag{7.9.14j}$$

with limits σ_1 and σ_2 corresponding to the initial and final system positions, respectively.

Again, with the choice $\sigma = q_1$ (and since $M_{kl} = M_{lk}$), and with *upper*-case subscripts running from 2 to n, we find, successively,

$$\begin{aligned} ds^2 &\equiv \sum\sum M_{kl}\, dq_k\, dq_l = \sum\sum M_{kl}\,(dq_k/dq_1)\,(dq_l/dq_1)\,(dq_1)^2 \\ &= \Big[M_{11} + \sum M_{K1}\,(dq_K/dq_1) \\ &\qquad + \sum M_{1L}\,(dq_L/dq_1) + \sum\sum M_{KL}\,(dq_K/dq_1)(dq_L/dq_1)\Big](dq_1)^2 \\ &= \Big[M_{11} + 2\sum M_{K1}\,(dq_K/dq_1) + \sum\sum M_{KL}\,(dq_K/dq_1)\,(dq_L/dq_1)\Big](dq_1)^2, \end{aligned}$$

and, therefore,

$$R = \cdots = 2(E - V)\Big(M_{11} + 2\sum M_{1L}\, q_L{}' + \sum\sum M_{KL}\, q_K{}' q_L{}'\Big), \tag{7.9.14k}$$

and

$$A_J = A_L = \int \sqrt{R}\, dq_1; \tag{7.9.14l}$$

and, of course, the orbits are defined by the Euler–Lagrange equations of $\delta A_J = 0$ [(7.9.13l) with $J \to \sqrt{R}$]:

$$d/dq_1\,(\partial\sqrt{R}/\partial q_K{}') - \partial\sqrt{R}/\partial q_K = 0 \qquad (K = 2, \ldots, n). \tag{7.9.14m}$$

Also, since by (7.9.14e, f) and (7.9.14h)

$$dt = \left(\sum\sum M_{kl}\,dq_k\,dq_l\Big/2(E - V)\right)^{1/2} = [\sqrt{R}/2(E - V)]\,d\sigma, \tag{7.9.14n}$$

we can find time by the quadrature:

$$t - t_1 = \int \big[\sqrt{R}/2(E - V)\big]\,dq_1. \tag{7.9.14o}$$

Here, the general solution involves a total of $2n$ constants: $2(n - 1)$ from the integration of the $n - 1$ equations (7.9.14m), plus E and t_1.

In closing, we should point out that if the initial and final orbit points, P_1 and P_2 respectively, are *close* to each other, then that orbit is *unique*; and, further, for that orbit, A_L is a *minimum* or least; in Hertz's terminology, arc(P_1P_2) = *shortest* or *straightest path*, in configuration space (and, for holonomic systems, coincides with the *geodesic* through these points). The quantification of these ideas constitutes the *extremum* theory of variational calculus, and is summarized in this chapter's appendix.

Example 7.9.1 *Alternative Derivations of* $\Delta\int L\,dt$ [recall (7.9.3b ff.)]. To avoid variable time-endpoints variations, we may introduce the "arc parameter" σ via $t = t(\sigma)$ [similar to that of the Jacobi form of MEL's principle (7.9.13g ff.)] *for both the fundamental (kinetic) path and its* Δ*-variation*, so that

$$t(\sigma_1) = t_1, \qquad t(\sigma_2) = t_2, \quad \text{and} \quad dt = (dt/d\sigma)\,d\sigma \equiv t'\,d\sigma \qquad [(\ldots)' \equiv d(\ldots)/d\sigma]. \tag{a}$$

Then, and since $\dot{q}_k \equiv dq_k/dt = (dq_k/d\sigma)\,(d\sigma/dt) = q_k{}'/t'$,

$$A_H \equiv \int L\,dt = \int L_\sigma\,d\sigma, \tag{b1}$$

$$L_\sigma \equiv L(dt/d\sigma) = L(t, q, \dot{q})t' = L(t, q, q'/t')t' \equiv L_\sigma(t, t', q, q')$$
$$\text{[function of the } 2n + 2 \text{ functions of } \sigma\text{: } t, q, t', q'\text{]}. \tag{b2}$$

By Δ-varying A_H, we obtain, successively (since now $\Delta\sigma = 0$),

$$\Delta A_H = \int \Delta L_\sigma \, d\sigma$$

$$= \int \Big\{ \sum \big[(\partial L_\sigma/\partial q_k)\Delta q_k + (\partial L_\sigma/\partial q_k{}')\,\Delta(q_k{}')\big] + (\partial L_\sigma/\partial t)\Delta t + (\partial L_\sigma/\partial t')\Delta t' \Big\}\, d\sigma$$

[integrating the $\Delta q'$ and $\Delta t'$-proportional terms by parts, while noting that, since $\Delta\sigma = 0$, the path points $P(t, q)$ and $P + \Delta P(t + \Delta t, q + \Delta q)$ *correspond to the same value of* σ, and, therefore, $\Delta[d(\ldots)/d\sigma] = d\Delta(\ldots)/d\sigma$ — see Remark below.]

$$= -\int \sum \big[d/d\sigma\,(\partial L_\sigma/\partial q_k{}') - (\partial L_\sigma/\partial q_k)\big]\Delta q_k\, d\sigma$$

$$- \int \big[d/d\sigma\,(\partial L_\sigma/\partial t') - (\partial L_\sigma/\partial t)\big]\Delta t\, d\sigma$$

$$+ \Big\{\sum (\partial L_\sigma/\partial q_k{}')\Delta q_k\Big\}_1^2 + \{(\partial L_\sigma/\partial t')\Delta t\}_1^2. \tag{c}$$

But, by chain rule:

$$\text{(i)}\quad \partial L_\sigma/\partial q_k{}' = t'\,\big[(\partial L/\partial \dot q_k)\,(\partial \dot q_k/\partial q_k{}')\big]$$
$$= t'\,(\partial L/\partial \dot q_k)\,[(\partial (q_k{}'/t')/\partial q_k{}')]$$
$$= t'\,(\partial L/\partial \dot q_k)\,(1/t') = \partial L/\partial \dot q_k \equiv p_k, \tag{c1}$$

$$\text{(ii)}\quad \partial L_\sigma/\partial t' = L + t'\,\Big[\sum (\partial L/\partial \dot q_k)\,(\partial \dot q_k/\partial t')\Big]$$
$$= L + t'\,\Big\{\sum (\partial L/\partial \dot q_k)\,\big[\partial (q_k{}'/t')/\partial t'\big]\Big\}$$
$$= L + t'\,\Big\{\sum (\partial L/\partial \dot q_k)\,\big[(-q_k{}')\,(t')^{-2}\big]\Big\}$$
$$= L - \sum (\partial L/\partial \dot q_k)\,(q_k{}'/t')$$
$$= L - \sum (\partial L/\partial \dot q_k)\dot q_k \;=\; -h \text{ (generalized energy/Hamiltonian);} \tag{c2}$$

and so (c) reduces to

$$\Delta A_H = -\int \Big\{\sum \big[d/d\sigma\,(\partial L_\sigma/\partial q_k{}') - \partial L_\sigma/\partial q_k\big]\Delta q_k$$
$$+ \big[d/d\sigma\,(\partial L_\sigma/\partial t') - \partial L_\sigma/\partial t\big]\Delta t\Big\}\, d\sigma$$
$$+ \Big\{\sum p_k \Delta q_k - h\Delta t\Big\}_1^2. \tag{d}$$

If, at σ_1, σ_2, the Δq_k and Δt vanish (generally, if the boundary term vanishes, say, by periodicity), then the single variational equation $\Delta A_H = 0$ leads to the following $n + 1$ differential equations:

$$d/d\sigma\,(\partial L_\sigma/\partial q_k{}') - \partial L_\sigma/\partial q_k = 0 \qquad (k = 1, \ldots, n), \tag{d1}$$

$$d/d\sigma\,(\partial L_\sigma/\partial t') - \partial L_\sigma/\partial t = 0. \tag{d2}$$

Let us find the power (energy rate) equation associated with eqs. (d1): multiplying each one of them with ${q_k}'$ and summing over k yields, successively,

$$\begin{aligned}
0 &= \sum \left[({q_k}')\, d/d\sigma(\partial L_\sigma/\partial {q_k}') - (\partial L_\sigma/\partial q_k){q_k}'\right] \\
&= d/d\sigma\left[\sum (\partial L/\partial {q_k}'){q_k}'\right] - \sum \left[(\partial L_\sigma/\partial {q_k}'){q_k}'' + (\partial L_\sigma/\partial q_k)\, {q_k}'\right] \\
&= d/d\sigma\left[\sum (\partial L_\sigma/\partial {q_k}'){q_k}'\right] - [dL_\sigma/\, d\sigma - (\partial L_\sigma/\partial t')t'' - (\partial L_\sigma/\partial t)t'],
\end{aligned}$$

from which, rearranging, and invoking (b2, c2), we obtain the "parametric power equation":

$$dh_\sigma/d\sigma = -(\partial L_\sigma/\partial t')t'' - (\partial L_\sigma/\partial t)t' = h\, t'' - (\partial L/\partial t)\, (t')^2, \tag{e}$$

where the *parametric generalized energy* h_σ is defined as

$$\begin{aligned}
h_\sigma &\equiv \sum (\partial L_\sigma/\partial {q_k}'){q_k}' - L_\sigma \\
&= \sum p_k(\dot{q}_k t') - (L\, t') = \left(\sum p_k \dot{q}_k - L\right) t' = h\, t'.
\end{aligned} \tag{e1}$$

On the other hand, by (b2, c2) again, eq. (d2) is rewritten as

$$\begin{aligned}
&- dh/d\sigma - t'\, (\partial L/\partial t) = 0 \\
&\Rightarrow\ dh/d\sigma = (dh/dt)t' = -t'\, (\partial L/\partial t)\ \Rightarrow\ dh/dt = -\partial L/\partial t,
\end{aligned} \tag{e2}$$

as expected; and, hence, $d(\ldots)/\, d\sigma$-differentiating (e1), we obtain

$$dh_\sigma/d\sigma = (dh/d\sigma)t' + h\, t'' = -(\partial L/\partial t)\, (t')^2 + h\, t''; \tag{e3}$$

that is, eq. (e).

In sum: eq. (d2) is not independent from eqs. (d1), but results from them as their *power equation*. [For further related results, see Frank (1927, pp. 13–16, 23–24) and Nevzgliadov (1959, pp. 371–375).]

REMARK

In view of the earlier "σ-commutativity": $\Delta[d(\ldots)/d\sigma] = d\Delta(\ldots)/d\sigma$, the former noncommutativity relation (7.2.4e) for a typical coordinate $q_k(t)$, or simply $q(t)$, generalizes as follows:

$$\begin{aligned}
\Delta(\dot{q}) = \Delta\left[(dq/d\sigma)\big/(dt/d\sigma)\right] &= \frac{(dt/d\sigma)\Delta(dq/d\sigma) - (dq/d\sigma)\Delta(dt/d\sigma)}{(dt/d\sigma)^2} \\
&= \frac{(dt/d\sigma)[d(\Delta q)/d\sigma] - (dq/d\sigma)[d(\Delta t)/d\sigma]}{(dt/d\sigma)^2} \\
&= (\Delta q)'/t' - \dot{q}[(\Delta t)'/t'] \qquad [\text{since } \ q'/t' = \dot{q}] \\
&= (\Delta q)^{\cdot} - \dot{q}(\Delta t)^{\cdot}.
\end{aligned} \tag{f}$$

The above can be viewed as a general definition of $\Delta(dq/dt)$.

Problem 7.9.1 Continuing from the preceding example, show that for an arbitrary (but as well behaved as needed) function $F = F(t, q, \dot{q})$:

$$F \to F_\sigma \equiv F\,(dt/d\sigma) = F(t, q, \dot{q})\,t' = F(t, q, q'/t')\,t' \equiv F_\sigma(t, t', q, q'), \qquad \text{(a)}$$

the following integral variational identities hold:

$$\begin{aligned}
\Delta \int F\,dt &= \int \Delta F_\sigma\,d\sigma \\
&= \int \Big\{ \sum \big[(\partial F_\sigma/\partial q_k)\Delta q_k + (\partial F_\sigma/\partial q_k{}')\Delta(q_k{}') \big] + (\partial F_\sigma/\partial t)\Delta t + (\partial F_\sigma/\partial t')\Delta t' \Big\}\,d\sigma \\
&= \int \Big\{ \sum \big[(\partial F/\partial q_k)\Delta q_k + (\partial F/\partial \dot{q}_k)\big(\partial(q_k{}'/t')/\partial q_k{}'\big)(\Delta q_k)^{\cdot}\,t' \big]\,t' \\
&\qquad + (\partial F/\partial t)t'\Delta t + \sum \big[(\partial F/\partial \dot{q}_k)\big(\partial(q_k{}'/t')/\partial t'\big)t' + F \big]\,(\Delta t)^{\cdot}\,t' \Big\}\,d\sigma \\
&= \int \Big\{ \sum \big[(\partial F/\partial q_k)\Delta q_k + (\partial F/\partial \dot{q}_k)\,(\Delta q_k)^{\cdot} \big] \\
&\qquad + (\partial F/\partial t)\Delta t - \sum (\partial F/\partial \dot{q}_k)\dot{q}_k(\Delta t)^{\cdot} + F(\Delta t)^{\cdot} \Big\}\,t'\,d\sigma \\
&= \int \Big\{ \sum \big[(\partial F/\partial q_k)\Delta q_k + (\partial F/\partial \dot{q}_k)\big((\Delta q_k)^{\cdot} - \dot{q}_k(\Delta t)^{\cdot}\big) \big] \\
&\qquad + (\partial F/\partial t)\Delta t + F(\Delta t)^{\cdot} \Big\}\,dt; \qquad \text{(b)}
\end{aligned}$$

that is,

$$\Delta \int F\,dt = \int \Delta F_\sigma\,d\sigma = \int [\Delta F + F(\Delta t)^{\cdot}]\,dt. \qquad \text{(c)}$$

Problem 7.9.2 Consider the following four possible definitions of the *total noncontemporaneous variation of the Hamiltonian action* $A_H \equiv A$:

$$\Delta^T A \equiv \int_{t_1+\Delta t_1}^{t_2+\Delta t_2} (L + \delta L)\,dt - \int_{t_1}^{t_2} L\,dt, \qquad \text{(a)}$$

$$\Delta^T A \equiv \int_{t_1}^{t_2} (L + \Delta L)\,d(t + \Delta t) - \int_{t_1}^{t_2} L\,dt, \qquad \text{(b)}$$

$$\Delta^T A \equiv \int_{t_1+\Delta t_1}^{t_2+\Delta t_2} (L + \Delta L)\,d(t + \Delta t) - \int_{t_1}^{t_2} L\,dt, \qquad \text{(c)}$$

$$\Delta^T A \equiv \int_{t_1+\Delta t_1}^{t_2+\Delta t_2} (L + \delta L)\,d(t + \Delta t) - \int_{t_1}^{t_2} L\,dt. \qquad \text{(d)}$$

Examine them carefully, and determine which ones of them, *to the first order* (i.e., $\Delta^1 A \equiv \Delta A$), lead to the correct expression; that is,

$$\Delta A = \Delta \int L\,dt = \int \delta L\,dt + \{L\Delta t\}_1^2$$
$$= \int \{\Delta L + L[d(\Delta t)/dt]\}\,dt = \int [\Delta(\ldots)\,dt + (\ldots)\,d(\Delta t)]. \tag{e}$$

ANSWERS

Yes: a, b; No: c, d.

Problem 7.9.3 *O. Hölder* and *Voss* forms of the action principle (may be omitted in a first reading).

(i) By invoking the noncommutativity equation (7.2.4e): $(\Delta q_k)^{\cdot} - \Delta(\dot{q}_k) = \dot{q}_k(\Delta t)^{\cdot}$, show that

$$\int \Delta L\,dt = \int \Big[(\partial L/\partial t)\Delta t + \sum (\partial L/\partial q_k)\Delta q_k + \sum (\partial L/\partial \dot{q}_k)\Delta(\dot{q}_k)\Big]\,dt$$
$$= \int \Big\{(\partial L/\partial t)\Delta t - \Big[\sum (\partial L/\partial \dot{q}_k)\dot{q}_k\Big](\Delta t)^{\cdot}\Big\}\,dt - \int \sum E_k(L)\,\Delta q_k\,dt$$
$$+ \Big\{\sum (\partial L/\partial \dot{q}_k)\Delta q_k\Big\}_1^2. \tag{a}$$

Next, consider the special case where Δq, *although still noncontemporaneous (i.e., $\Delta t \neq 0$), equals numerically the virtual displacement at time t*, δq [fig. 7.3(a)]:

$$\Delta q(t + \Delta t) = \delta q(t); \tag{b}$$

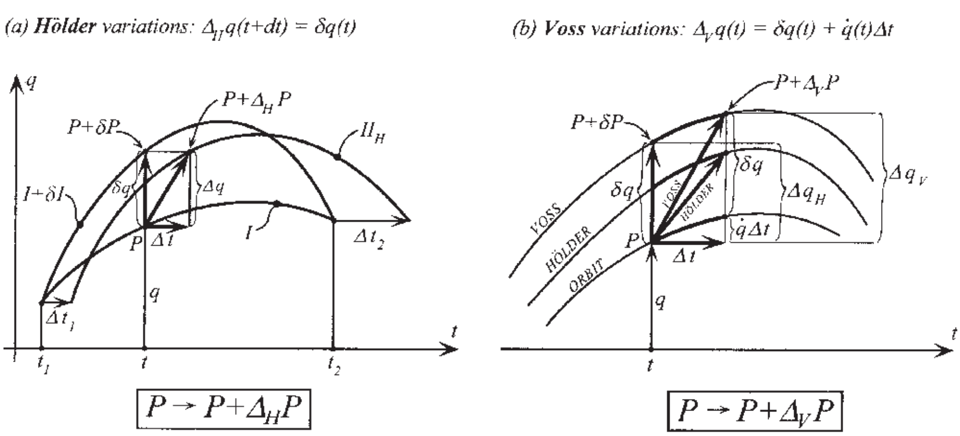

Figure 7.3 On the meaning of the *Hölder* and *Voss* variations.

and, accordingly, the point (t, q) of the fundamental path $\rightarrow$ orbit I is mapped to the neighboring point $(t + \Delta t, q + \Delta q = q + \delta q)$, and the totality of the latter constitutes the *varied path in the sense of O. Hölder* $II_H = I + \Delta_H I$ (symbolically). It follows that, in this case, Δt is not necessarily zero at the path endpoints $t_{1,2}$, even if the δq are.

Then, and assuming $\delta' W_{\text{nonpotential}} = 0$, the *second* integral vanishes, and so (a) reduces to *O. Hölder*'s variational "principle" (1896):

$$\int \left\{ \Delta L + \left(\sum (\partial L/\partial \dot{q}_k) \dot{q}_k \right) (\Delta t)^{\cdot} - (\partial L/\partial t) \Delta t \right\} dt = \left\{ \sum (\partial L/\partial \dot{q}_k) \Delta q_k \right\}_1^2$$

$$[= 0; \quad \text{e.g., if } \Delta q_k(t_{1,2}) = 0]. \tag{c}$$

(ii) For nonholonomic systems, the so-varied path will *not* satisfy the constraints; that is, *the Hölder-varied path is not kinematically possible*, unless the constraints are holonomic. For this reason, *Voss* (in 1990) chose:

$$q + \Delta q\text{: kinematically possible at } t + \Delta t, \qquad \dot{q}\text{: kinematically possible at } t$$

$$\Rightarrow \Delta q - \dot{q}\Delta t = \delta q \qquad (\textit{virtual};\ \text{recalling §2.5 ff.}); \tag{d}$$

that is, the I-point (t, q) is mapped to the neighboring point $(t + \Delta t, q + \Delta q = q + \delta q + \dot{q}\Delta t)$, and the totality of the latter constitutes the *varied path in the sense of Voss* $II_V = I + \Delta_V I$ [symbolically, fig. 7.3(b)]. This is how the variation $\Delta(\ldots) = \delta(\ldots) + (\ldots)^{\cdot}\Delta t$ was created; and, of course, it yields the integral Δ-theorems already detailed in §7.9.

[See also Pars, 1965, p. 533 ff.; with a slightly different (confusion-prone) notation; and Lützen, 1995(b), p. 55 ff., for the history of these variations, etc.]

Example 7.9.2 *Least Action as a Constrained Variational Problem.* Let us formulate MEL's principle (7.9.6b) as a variable (second) endpoint variational problem under the energy constraint

$$E \equiv T(q, \dot{q}) + V(q) = h = \textit{constant} \equiv C, \tag{a}$$

and then deduce from it the correct Lagrangean equations of motion; that is, $E_k(L) = 0$.

We recall that, for a holonomic, scleronomic, and potential system, MEL's principle of "least" action (or Lagrange's problem of variational calculus) states that $A_L \equiv \int 2T\, dt$ is stationary for the orbit in the class of admissible paths that satisfy (i) the constraint (a), where C is a *given constant* along the orbit; the same for all admissible paths (i.e., $\Delta h = \delta h + \dot{h}\Delta t = 0 + 0 = 0$), and (ii) the $2n + 1$ boundary conditions: $t_1, q_k(t_1) = q_{k1}, q_k(t_2) = q_{k2}$, *given*; but t_2 *not given*. Due to constraint (a), we will not work with A_L, but with the *unconstrained* variation functional

$$F = \int f\, dt, \qquad \text{where } f = f(t, q, \dot{q};\ \lambda) \equiv 2T + \lambda(T + V - C). \tag{b}$$

Then, by (7.9.12g) applied to (b), we see that the stationarity condition

$$0 = \Delta F = \Delta \int f\,dt$$
$$= -\int \sum E_k(f)\,\delta q_k\,dt + \Big\{\sum (\partial f/\partial \dot{q}_k)\Delta q_k - h(f)\Delta t\Big\}_1^2 \tag{c}$$

leads to: (i) the differential equations

$$E_k(f) = 0$$
$$\Rightarrow\ (2+\lambda)\,[d/dt\,(\partial T/\partial \dot{q}_k) - \partial(T-V)/\partial q_k]$$
$$-\,2(1+\lambda)\,(\partial V/\partial q_k) + (d\lambda/dt)\,(\partial T/\partial \dot{q}_k) = 0, \tag{d}$$

and (ii) the boundary or *transversality* condition

$$\Big\{\sum (\partial f/\partial \dot{q}_k)\Delta q_k - h(f)\Delta t\Big\}_1^2 = 0, \tag{e}$$

from which, since $t_1, q_k(t_1), q_k(t_2)$ are given, we conclude that

$$\Delta t_1 = 0, \qquad \Delta q_k(t_1) = \delta q_k(t_1) = 0,$$
$$\Delta q_k(t_2) = \delta q_k(t_2) + \dot{q}_k(t_2)\Delta t_2 = 0\ \Rightarrow\ \delta q_k(t_2) = -\dot{q}_k(t_2)\Delta t_2 \neq 0, \tag{e1}$$

and, since $\Delta t_2 \neq 0$,

$$h(f, evaluated\ at\ t_2) \equiv \Big\{\sum (\partial f/\partial \dot{q}_k)\dot{q}_k - f\Big\}_2 \equiv h(f_2) = 0 \tag{e2}$$
$$\Rightarrow\ \{2T(1+\lambda)\}_2 = 0\ \Rightarrow\ \lambda(t_2) \equiv \lambda_2 = -1. \tag{e3}$$

On the other hand, applying the purely analytical result (7.9.11f, with L replaced by f) to (b), while recalling (a), we find

$$dh(f)/dt + \partial f/\partial t = \sum E_k(f)\dot{q}_k = 0 \qquad \text{[by (d)]} \tag{f1}$$
$$\Rightarrow\ dh(f)/dt = -\partial f/\partial t = -(d\lambda/dt)\,(T+V-C) = 0$$
$$\Rightarrow\ h(f) = 2T(1+\lambda) = constant\ along\ the\ orbit, \tag{f2}$$

and, combining this with (e3), we conclude that

$$\lambda = \lambda(t) = -1, \textit{everywhere}\ \text{on the orbit.} \tag{g}$$

Then, (b) yields

$$f = 2T - (T+V-C) = L + C\ \Rightarrow\ E_k(f) = E_k(L) = 0. \tag{h}$$

In sum: the stationarity condition $\Delta F = 0$ yields the correct Lagrangean equations of motion. The unknown (not necessarily unique) t_2, corresponding to the given data of our orbit, is determined from the $n+1$ equations

$$q_k(t_1;\ c_1, \ldots, c_{2n}) = q_{k1}, \qquad q_k(t_2;\ c_1, \ldots, c_{2n}) = q_{k2}, \tag{i1}$$
$$T(q, \dot{q}) + V(q) = C, \tag{i2}$$

where $q_k = q_k(t;\ c_1, \ldots, c_{2n})$ is the general solution of (h).

See also Papastavridis [1986(c)], which also contains a study of the extremality of F via the study of its second variation $\Delta^2 F$.

Example 7.9.3 *Whittaker's Variational Principle*: "Show that the principle of Least Action can be extended to systems for which the integral of energy does not exist, in the following form. Let the expression $\sum (\partial L/\partial \dot{q}_k)\dot{q}_k - L$ be denoted by h; then the integral [our terminology]

$$A_{\text{Whittaker}} \equiv A_W \equiv \int \Big(\sum (\partial L/\partial \dot{q}_k)\dot{q}_k + t(dh/dt)\Big)\, dt, \tag{a}$$

has a stationary value for any part of an actual trajectory (i.e., an orbit) as compared with other paths between the same terminal points for which h has the same terminal values" (Whittaker, 1937, p. 248).

This constitutes the extension of MEL's "least action," (7.9.6b), to potential but nonconservative systems (i.e., $\partial L/\partial t \neq 0$), where, as a result, no Jacobi–Painlevé integral exists. The most general such Lagrangean is

$$L(t, q, \dot{q}) = L_1(t, q, \dot{q}) + \sum Q_k(t) q_k \tag{b}$$

(e.g., forced autonomous vibrations), in which case the power theorem reduces to

$$dh/dt = -\partial L/\partial t = -\partial L_1/\partial t - \sum (dQ_k/dt) q_k \neq 0. \tag{c}$$

Whittaker's theorem states that

$$\Delta A_W = 0, \tag{d}$$

under

$$\Delta q_k(t_1) = \Delta q_k(t_2) = 0 \qquad \text{and} \qquad \Delta h(t_1) = \Delta h(t_2) = 0. \tag{d1}$$

To prove (d, d1), first, invoking the h-definition, we transform A_W to

$$\begin{aligned} A_W &= \int \big[L + h + t(dh/dt)\big]\, dt \\ &= \int L\, dt + \{t\, h\}_1^2 \\ &= A_H + \{t\, h\}_1^2\text{: Hamilton's } \textit{characteristic function} \text{ (see also §8.11).} \end{aligned} \tag{e}$$

Then, operating on (e) with $\Delta(\ldots)$, while recalling (7.9.3b, c; 11f, g, h), we obtain

$$\begin{aligned} \Delta A_W &= \Delta A_H + \Delta\{t\, h\}_1^2 \\ &= -\int \sum E_k(L)\, \delta q_k\, dt + \Big\{\sum p_k \Delta q_k - h\Delta t\Big\}_1^2 + \Delta\{t\, h\}_1^2 \\ &= -\int \sum E_k(L)\, \delta q_k\, dt + \Big\{\sum p_k \Delta q_k + t\Delta h\Big\}_1^2 = 0, \end{aligned} \tag{f}$$

by (d1) and LP for the orbit, Q.E.D. Of course, other boundary conditions (e.g., periodic ones) could have nullified the boundary term. For an investigation of the *extremality* of A_W via the study of the sign of $\Delta^2 A_W$, see Papastavridis [1985(b)].

Example 7.9.4 *Projectile Motion via Jacobi's Form of Least Action.* Let us study the motion of a particle of mass m in the vertical plane under constant gravity, and neglecting air resistance, via the geodesic form of Jacobi's principle, (7.9.14a ff.).

Here, with $q_1 = x$ (horizontal), $q_2 = y$ (positive upward; $y = 0$: ground), and

$$2T = m(\dot{x}^2 + \dot{y}^2), \qquad V = m\,g\,y, \tag{a}$$

the energy equation is

$$(m/2)\,(\dot{x}^2 + \dot{y}^2) + m\,g\,y = E\text{: } \textit{total energy}, \text{ a positive constant.} \tag{b}$$

As a result, the integrand of the Jacobi functional, (7.9.14h), becomes

$$\begin{aligned} R &= 2(E - m\,g\,y)\,[m + 0 + m\,(dy/dx)^2] \\ &= 2m(E - m\,g\,y)\,[1 + (y')^2] = R(y, y'), \end{aligned} \tag{c}$$

from which we obtain

$$\partial\sqrt{R}/\partial y' = [2m\,(E - m\,g\,y)]^{1/2}[1 + (y')^2]^{-1/2} y', \tag{d1}$$

$$\partial\sqrt{R}/\partial y = -\{m^2 g\,[1 + (y')^2]\}\,\{2m(E - m\,g\,y)\,[1 + (y')^2]\}^{-1/2}, \tag{d2}$$

and so the Euler–Lagrange equations of the Jacobi functional A_J, eqs. (7.9.14m), are

$$E_y(\sqrt{R}) = 0\text{:} \qquad 2(E - m\,g\,y)y'' + m\,g[1 + (y')^2] = 0. \tag{d3}$$

To integrate (d3), we $(\ldots)'$-differentiate it once more, thus obtaining

$$2(E - m\,g\,y)y''' = 0, \tag{e1}$$

from which, since $E \neq m\,g\,y$, it follows that

$$y''' = 0 \;\Rightarrow\; y = c_1 x^2 + c_2 x + c_3 \qquad (c_{1,2,3}\text{: constants of integration}). \tag{e2}$$

To find the three constants of this *parabolic* orbit, we apply the two boundary conditions

$$y(x_1) = y_1 \text{ (given)} \qquad \text{and} \qquad y(x_2) = y_2 \text{ (given)}, \tag{f1}$$

and the equation of motion (d3). Choosing, for simplicity, $x(0) = x_1 = 0$ and $y(0) = y_1 = 0$, we immediately find $c_3 = 0$. Then, substituting the resulting $y = c_1 x^2 + c_2 x$ into (d3) and setting $x = 0$, we obtain, after some simple algebra,

$$c_1 = -mg(1 + c_2{}^2)/4E < 0; \tag{f2}$$

that is, the parabolic orbit opens downward. Finally, substituting (f2) into the second of (f1): $y_2 = c_1 x_2{}^2 + c_2 x_2$, yields the second-degree equation for c_2:

$$c_2{}^2 - (4E/mgx_2)c_2 + [(4Ey_2/mgx_2{}^2) + 1] = 0. \tag{f3}$$

Since, on physical grounds, c_2 must be real, the discriminant of (f3) must be nonnegative; and this leads directly to the condition $4E(E - m g y_2) \geq (m g x_2)^2$ (> 0), from which we get the upper bound:

$$y_2 < E/mg, \qquad \text{or} \qquad E > mgy_2 = V(P_2). \tag{f4}$$

The two (real) values of c_2 obtained from (f3) yield the *two* parabolic orbits reaching $P_2(x_2, y_2)$ from $P_1(= O$: origin of coordinates); one *high* and one *low*.

REMARK

Between P_1 and P_2, both these orbits satisfy the same equations of motion and boundary conditions; that is, both satisfy the first-order (stationarity) condition $\delta A_J = 0$: namely, Jacobi's principle. Their differences appear in the *second-order* (extremality) conditions: the sign of $\delta^2 A_J$. It can be shown that, for motion between P_1 and P_2, *only the low orbit minimizes* A_J: $\delta^2 A_J > 0$, whereas the high orbit does not; and for motion beyond P_2, even the low orbit does not minimize A_J. [For further details, see (alphabetically): Koschmieder (1962, pp. 45–46), Lur'e (1968, pp. 752–754), Papastavridis [1986(a)], Peisakh (1966, and references cited therein).]

GENERALIZATION

We leave it to the reader to show, using again $\delta A_J = 0 \Rightarrow E_y(\sqrt{R}) = 0$, that if our particle moves freely in a plane O–xy under a general potential $V = V(x, y)$, its orbits are given by

$$2(E - V)y'' + [1 + (y')^2]\,(V_y - y' V_x) = 0, \tag{g}$$

where subscripts denote partial derivatives. (See, e.g., Kauderer, 1958, p. 599 ff.)

Example 7.9.5 *Uniqueness of a Lagrangean.* Let us examine the variations of the Hamiltonian action functionals of two (holonomic) systems, A_H and $A_H{}'$, whose corresponding Lagrangeans, L and L', differ by the total time derivative of an arbitrary "gauge" function of the coordinates and time $F = F(t, q)$; that is,

$$L'(t, q, \dot{q}) - L(t, q, \dot{q}) = dF(t, q)/dt. \tag{a}$$

Since $\delta(\dot{F}) = (\delta F)^{\cdot}$, we find, successively,

$$\begin{aligned}\delta A_H{}' &= \delta \int L'\, dt = \int \delta L'\, dt = \int [\delta L + \delta(\dot{F})]\, dt \\ &= \delta A_H + \left\{ \sum (\partial F/\partial q_k)\, \delta q_k \right\}_1^2;\end{aligned} \tag{b}$$

and, therefore, if $\delta q_k(t_1) = \delta q_k(t_2) = 0$, the conditions $\delta A_H{}' = 0$ and $\delta A_H = 0$ are *equivalent*; that is, both yield the same equations of motion:

$$\delta A_H = 0 \;\Rightarrow\; E_k(L) = 0, \qquad \delta A_H{}' = 0 \;\Rightarrow\; E_k(L') = E_k(L) = 0. \tag{c}$$

This simple variational argument shows that L is *nonunique*; *it is defined only to within the total time derivative of an arbitrary function of the coordinates and time, at most*. Accordingly, constant terms, or pure functions of time terms, may be safely omitted from a Lagrangean. Finally, we point out that we *always* have

$$E_k(L') = E_k(L + F) = E_k(L) + E_k(F) = E_k(L), \tag{d}$$

even if $\{\sum (\partial F/\partial q_k)\, \delta q_k\}_1^2 = \{\delta F\}_1^2 \neq 0$ (recalling ex. 3.5.13); but then the arrows in (c) cannot be reversed.

Example 7.9.6 *Routh's Problem I:* "If the period of complete recurrence of a dynamical system is not altered by the addition of energy, prove that this additional energy is equally distributed into potential and kinetic energies" [Routh, 1905(b), p. 315; also Papastavridis, 1985(a)].

Choosing in the fundamental equations (7.9.4h, i): $t_1 = 0, \Delta t_1 = 0, t_2 = \tau$ (period of "complete recurrence"), $\Delta q_k(t_1) = \Delta q_k(t_2)$ (say, 0) and assuming that the system is potential ($\delta' W_{np} = 0$) and scleronomic ($\sum p_k \dot{q}_k = 2T$), we get, respectively,

$$\Delta \int_0^\tau 2T\, dt = \int_0^\tau \delta E\, dt, \tag{a}$$

$$\Delta \int_0^\tau 2V\, dt = \int_0^\tau \delta E\, dt + 2E(\tau)\Delta\tau. \tag{b}$$

If, further, the addition of energy δE does *not* alter the period of oscillation (i.e., if $\Delta\tau = 0$), the above yield immediately the *equipartition* theorem:

$$\Delta \int_0^\tau T\, dt = \Delta \int_0^\tau V\, dt = \int_0^\tau (\delta E/2)\, dt, \quad \text{Q.E.D.} \tag{c}$$

Example 7.9.7 *Routh's Problem II*: "A dynamical system passes freely from one configuration to another in time i [our τ] with constant energy E; with energy $E + \delta E$ its time of free passage between the same configurations is $i + \delta i$, verify that on a time average the increment of the mean kinetic energy T_m [our $\langle T \rangle$] of the system throughout its path is less than half of δE by the amount $T_m(\delta i/i)$. Show that in case there are two adjacent paths that take the same time, their mean potential and kinetic energies differ by equal amounts" [Routh, 1905(b), p. 315; also Papastavridis, 1985(a)].

Here, as in the preceding example, let us choose $t_1 = 0, \Delta t_1 = 0, t_2 = \tau \equiv i$ (period of oscillation), $\Delta t_2 = \Delta\tau \equiv \Delta i$, and assume that the system is potential $[\langle \delta' W_{np} \rangle = 0]$ and scleronomic $[\sum p_k \dot{q}_k = 2T]$. Then, since

$$\Delta \int_0^\tau T\, dt = \Delta(\langle T \rangle \tau) = (\Delta\langle T \rangle)\tau + \langle T \rangle \Delta\tau, \tag{a1}$$

$$\Delta \int_0^\tau V\, dt = \Delta(\langle V \rangle \tau) = (\Delta\langle V \rangle)\tau + \langle V \rangle \Delta\tau, \tag{a2}$$

eqs. (7.9.4h, i) specialize to

$$\Delta\langle T \rangle = \delta E/2 - \langle T \rangle(\Delta\tau/\tau), \tag{b1}$$

$$\Delta\langle V \rangle = \delta E/2 - \big[\langle V \rangle - E\big]\,(\Delta\tau/\tau) = \delta E/2 + \langle T \rangle\,(\Delta\tau/\tau), \quad \text{Q.E.D.} \tag{b2}$$

Theorems like this and the one of the preceding example arose during the late 19th century in connection with the (partially successful) attempts of Clausius, Szily, Boltzmann, et al. to supply *analytical mechanics–based explanations of thermomechanical phenomena*; see, for example, the papers by Bierhalter [1981(a), (b), 1982, 1983, 1992], and the monograph and original papers by Polak (1959, 1960)].

Problem 7.9.4 *Time Integral Theorems for Periodic Systems* (Williamson and Tarleton, 1900, pp. 457–458). For the system described in the preceding examples, show that "When the entire state of a moving system recurs at the end of equal intervals of time whose common magnitude is τ, if the total energy E receive a small change, the corresponding variation of the mean Lagrangean function, L_m [our $\langle L\rangle$], is given by the equation

$$\Delta L_m = -2T_m(\Delta\tau/\tau).\text{''} \tag{a}$$

Problem 7.9.5 *Time Integral Theorems for Periodic Systems (continued)* [Routh, 1905(b), pp. 314–315; Williamson and Tarleton, 1900, p. 458]. Continuing from the preceding examples and problem, show that "If the total energy of a recurring system, ..., receive a series of variations at intervals of time which are large compared with the period of recurrence of the system, and if finally the system return to its original state, show that $\int (dE/T_m)$ taken from the beginning to the end of the cycle is zero."

HINT

$E + L = 2T \;\Rightarrow\; dE + dL_m = 2\,dT_m \;\Rightarrow\; dE/T_m = \textit{perfect (or exact) differential}$ (by the preceding problem).

These two problems are important in connection with the (late 19th century) attempts at a mechanical explanation of the *second* law of thermodynamics (entropy).

Example 7.9.8 *Pendulum of Slowly Varying Length; Adiabatic Invariance*. We consider a mathematical pendulum, consisting of a bob (particle) of mass m and a constraining light thread of length l, performing small (linear), free and undamped oscillations under gravity (fig. 7.4). If ϕ is the instantaneous inclination of the thread to the vertical, then

$$2T = m\,l^2(\dot\phi)^2, \qquad V = -m\,g\,l\cos\phi + C \approx (1/2)m\,g\,l\phi^2 + C'$$
$$\text{(for small angular motions; } C, C'\text{: constants)}, \tag{a}$$

$$L \equiv T - V = (1/2)m\,l^2(\dot\phi)^2 + m\,g\,l\cos\phi - C$$
$$\approx (1/2)m\,l^2(\dot\phi)^2 - (1/2)m\,g\,l\phi^2 - C' \qquad \text{("small Lagrangean")}, \tag{b}$$

and, accordingly, Lagrangean equation of (small) motion:

$$E_\phi(L) \equiv (\partial L/\partial\dot\phi)^{\cdot} - \partial L/\partial\phi = 0:$$
$$\ddot\phi + (g/l)\sin\phi = 0 \;\Rightarrow\; \ddot\phi + (g/l)\phi = 0, \tag{c}$$

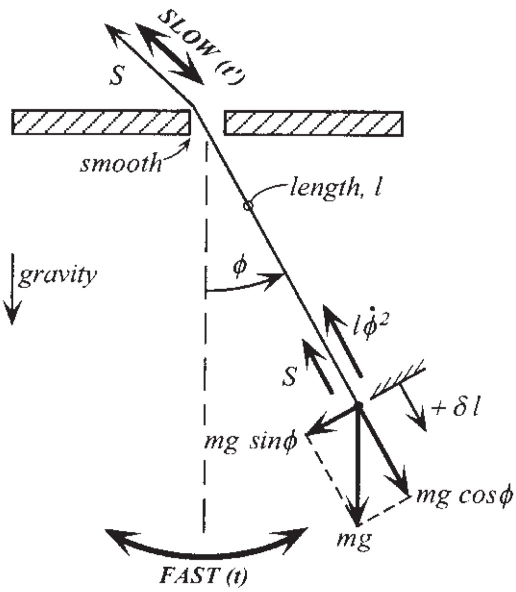

Figure 7.4 Adiabatic pendulum, of length l and mass m.
Thread tension: $S = ml(\dot{\phi})^2 + mg\cos\phi \approx ml(\dot{\phi})^2 - (\frac{1}{2})mg\phi^2 + mg$.

and total energy

$$E \equiv T + V = h \equiv (\partial L/\partial\dot{\phi})\dot{\phi} - L\text{:}\quad (1/2)m\,l^2(\dot{\phi})^2 - m\,g\,l\cos\phi = \textit{constant},$$

$$\Rightarrow\ (1/2)m\,l^2(\dot{\phi})^2 + (1/2)m\,g\,l\phi^2 = \textit{constant} \qquad (\text{"small energy equation"}). \qquad \text{(d)}$$

Equation (d) shows that as long as the pendulum parameters, m and l, remain constant in time so does $E = h$. Now, let us assume that some external (energy-supplying) agency acts to change these parameters, say, the length l; for example, we can imagine the thread held between the fingers of one hand and shortened/lengthened by drawing it up/down with the fingers of the other; or, the bob picks up dust and, thus, its mass changes. Then, the power equation yields

$$dE/dt = dh/dt = -\partial L/\partial t = -(\partial L/\partial l)\,(dl/dt) \neq 0; \qquad \text{(e)}$$

that is, the system is no longer conservative.

Let us now examine the special case where the above length change, from l to $l + dl$, is spread over several (to and fro) oscillations; that is, let us assume that *dl takes a very large number of periods*, and, therefore, within any one of them, l can be considered constant. Since the pendulum still oscillates under these very slow, or *adiabatic*, variations, henceforth denoted by δl (like the virtual variations), both its new frequency and period,

$$\omega + \delta\omega \qquad \text{and} \qquad \tau + \delta\tau = (2\pi/\omega) + (-2\pi/\omega^2)\,\delta\omega, \qquad \text{(f)}$$

will be functions of δl. Mathematically, we are dealing here with a differential equation, (c), whose coefficients (parameters) are explicit functions, not of the ordinary (or "fast") time t, but of an adiabatic (or "slow") time $t' \equiv \varepsilon t$, ε: small number; that is, $l = l(t')$.

Now we ask the following fundamental question: Are there any energetic quantities that, in spite of these adiabatic (nonconservative) changes of l, remain constant, not in t but in t'; that is, to the first ε-order?

As we explain below, one such constant, or *adiabatic invariant*, is the *time average of twice the kinetic energy of the system, divided by its frequency*, $2\langle T \rangle/\omega$; which, to within a constant factor, equals the Lagrangean action A_L. If, further, V is homogeneous *quadratic* in the coordinates (i.e., linear oscillations) then, since by the virial theorem (ex. 7.2.1 ff.) $\langle T \rangle = \langle V \rangle$, that invariant becomes $2\langle T \rangle/\omega = E/\omega$. [This is a famous problem: It was posed at the Solvay Congress (Brussels, 1911) by the great physicist H. A. Lorentz, and was answered (for the small motion case) by the ... greater physicist A. Einstein!] Other special variations of the system parameters produce other special invariants ("integrals"); see, for example, Kronauer and Musa (1966), Kronauer (1983), Papastavridis [1982(b)].

Let us establish this adiabatic invariant directly, by elementary considerations. As (c) shows, the small motion frequency (squared) equals $\omega^2 = g/l$, and so, for small variations,

$$(2\omega\,\delta\omega)l + \omega^2\,\delta l = 0 \;\Rightarrow\; (\delta\omega/\omega) = -(\delta l/2l). \tag{g}$$

Next, by kinetics (equation of motion of bob along the thread direction), the tension of the thread S equals

$$\begin{aligned} S &= m\,l(\dot\phi)^2 + m\,g\cos\phi \\ &\approx m\,g + m\,l(\dot\phi)^2 - m\,g\,\phi^2/2 \qquad \text{(for small motions)}, \end{aligned} \tag{h}$$

where, as (c) shows [under the initial conditions, say, $\phi(0) = \phi_o$ and $\dot\phi(0) = 0$], $\phi(t) = \phi_o\cos(\omega t)$. Therefore, the elementary work of S during a δl change, $\delta' W_{\text{external}} \equiv \delta' W$, *averaged over several oscillation periods*, will be

$$\begin{aligned} \langle \delta' W \rangle &= -\langle S\,\delta l \rangle = -\delta l[\langle m\,g \rangle + \langle m\,l(\dot\phi)^2 \rangle - \langle m\,g\,\phi^2/2 \rangle] \\ &= -\delta l[\langle m\,g \rangle + \langle m\,l\,{\phi_o}^2\omega^2\sin^2(\omega t) \rangle - \langle m\,g\,{\phi_o}^2\cos^2(\omega t)/2 \rangle] \\ &= \cdots = -\delta l[m\,g + m\,l\,{\phi_o}^2\omega^2(1/2) - m\,g\,{\phi_o}^2(1/4)] \\ &= -m\,g(1 + {\phi_o}^2/4)\,\delta l = -\langle S \rangle\,\delta l \qquad [\text{since } \omega^2 l = g]. \end{aligned} \tag{i}$$

Further, recalling (a),

$$\begin{aligned} \langle T \rangle &= \langle (1/2)m\,l^2(\dot\phi)^2 \rangle = \langle (1/2)m\,l^2\omega^2{\phi_o}^2\sin^2(\omega t) \rangle \\ &= (1/4)m\,l^2\omega^2{\phi_o}^2 = m\,g\,l{\phi_o}^2/4, \end{aligned} \tag{j}$$

$$\begin{aligned} \langle V \rangle &= \langle C - m\,g\,l[1 - (\phi^2/2)] \rangle \\ &= C - m\,g\,l\big[1 - ({\phi_o}^2/2)\langle\cos^2(\omega t)\rangle\big] \\ &= C - m\,g\,l(1 - {\phi_o}^2/4). \end{aligned} \tag{k}$$

With the help of the above results, the averaged energy equation

$$\langle \delta' W \rangle = \langle \delta E \rangle = \delta \langle E \rangle = \delta(\langle T + V \rangle) = \delta \langle T \rangle + \delta \langle V \rangle \tag{l}$$

yields

$$-m g(1 + {\phi_o}^2/4)\,\delta l = \delta(m g\, l {\phi_o}^2/4) + \delta\big[C - m g\, l(1 - {\phi_o}^2/4)\big]$$
$$\Rightarrow\ 3\phi_o\,\delta l + 4l\,\delta\phi_o = 0, \tag{m}$$

from which, integrating adiabatically, we find

$$l^3 {\phi_o}^4 = constant \qquad \text{or} \qquad l\sqrt{l}\,{\phi_o}^2 = constant. \tag{n}$$

Hence,

$$2\langle T \rangle/\omega = (mgl{\phi_o}^2/2)/(g/l)^{1/2} = (m\sqrt{g}/2)\,(l\sqrt{l}\,{\phi_o}^2) = constant, \tag{o}$$

and

$$A_L \equiv \int_0^{\tau} 2T\,dt = 2\langle T \rangle \tau = 2\pi\big(2\langle T \rangle/\omega\big) = constant, \quad \text{Q.E.D.} \tag{p}$$

For further details see Papastavridis [1985(a)] and §8.15.

Problem 7.9.6 *Adiabatic Invariance (Linear Pendulum).* In connection with the adiabatic pendulum of the preceding example, ex. 7.9.8 (i.e., particle P of mass m, suspended by a light and inextensible thread of slowly and randomly varying length l, and instantaneous tension S) under gravity, show that

$$S = \partial L/\partial l \qquad [= m\, l(\dot{\phi})^2 + m g \cos\phi,\ \text{exactly}]; \tag{a}$$

and therefore its averaged energy equation is

$$\langle \delta' W \rangle = \delta \langle h \rangle = -\langle S \rangle\,\delta l = -\langle \partial L/\partial l \rangle\,\delta l$$
$$\equiv -(\omega/2\pi) \int_0^{2\pi/\omega} (\partial L/\partial l)\,\delta l\,dt$$
$$= \cdots = -m g(1 + {\phi_o}^2/4)\delta l \qquad \text{(linear pendulum case).} \tag{b}$$

[Equation (b) is, essentially, the adiabatic and averaged version of the holonomic and potential power equation: $dh/dt = -\partial L/\partial t$.]

Problem 7.9.7 *Adiabatic Invariance (The Rayleigh Pendulum).* Continuing from the preceding problem of the adiabatic mathematical pendulum under gravity, let us examine the case where, at the suspension point, there is a small ring R constrained to slide up and down the smooth, vertical, and fixed line AB (otherwise the pendulum would be a nonconservative system).

(i) Show that *if R is kept fixed*, in which case RP is an ordinary (i.e., constant parameter) pendulum, *the vertical force tending to push R upward, F*, equals

$$F = S(1 - \cos\phi) \approx m g \cos\phi\,(1 - \cos\phi)\text{: “}vibration\ pressure\text{”} \tag{a}$$

(disregarding an unessential centripetal force contribution to S—explain); and since $V = mgl\,(1 - \cos\phi)$, deduce that, for small vibrations (recall virial theorem),

$$2F \approx mg\phi^2 \Rightarrow \langle F \rangle = \langle V/l \rangle = \cdots = (1/2)\,(E/l), \tag{b}$$

where E is the total energy of the pendulum (a constant); that is, *the average force on the ring is proportional to the pendulum's energy density* (= energy per unit length) [a result which, as Rayleigh has pointed out (1902), has a close analog in electromagnetism (vibration pressure → "radiation pressure"]. Also, verify that the *horizontal* force on R is $S \sin\phi = m\,g \cos\phi \sin\phi$, and its average vanishes.

(ii) Next, assume that while P oscillates with frequency $\omega = (g/l)^{1/2}$, R is let slide adiabatically upward; that is, $\delta l > 0$. Then, clearly, the (positive) work done on R by F comes at the expense of the oscillatory energy of the pendulum. Show that, in such a case,

$$\delta E = -\langle F \rangle\, \delta l = -(E/2)\,(\delta l/l), \tag{c}$$

from which, by "adiabatic integration," it follows that

$$E\sqrt{l} = constant, \tag{d}$$

and from this we conclude that as $l \to \infty$, $E \to 0$; that is, the entire energy of P is then expended as work done on R.

Problem 7.9.8 *Adiabatic Invariance (The Rayleigh Pendulum)*. Continuing from the preceding problem,

(i) By averaging Lagrange's equation of motion for a typical positional coordinate l:

$$Q_l = (\partial T/\partial \dot{l})^{\cdot} - \partial T/\partial l + \partial V/\partial l, \tag{a}$$

over a very long time interval τ, show that, since $p_l \equiv \partial T/\partial \dot{l}$ is finite,

$$\begin{aligned}\langle Q_l \rangle &\equiv (l/\tau) \int_0^\tau Q_l\, dt = (1/\tau) \int_0^\tau (\partial V/\partial l - \partial T/\partial l)\, dt \\ &= -(1/\tau) \int_0^\tau (\partial L/\partial l)\, dt \equiv -\langle \partial L/\partial l \rangle.\end{aligned} \tag{b}$$

(ii) Show that, in the case of our ringed pendulum (i.e., $\dot{l} = 0$),

$$\partial V/\partial l = m\,g(1 - \cos\phi) = V/l, \qquad \partial T/\partial l = m\,l(\dot{\phi})^2 = 2T/l, \tag{c}$$

and, therefore, since $\langle V \rangle = \langle T \rangle = E/2$ (by the virial theorem, for small vibrations), eq. (b) yields

$$\langle Q_l \rangle = (1/\tau) \int_0^\tau \big[(V - 2T)/l\big]\, dt = \cdots = -(1/2)\,(E/l) = -\langle F \rangle; \tag{d}$$

that is, the average force necessary to hold the ring must be directed *downward* (so as to tend to diminish l).

This "ringed pendulum" problem seems to be the earliest simple and concrete example of adiabatic invariance. For additional examples and insights, see Rayleigh

(1902); also Bakay and Stepanovskii (1981, pp. 100–107), Tomonaga (1962, pp. 290–294), and Thomson (1888, chaps. 4, 9).

Example 7.9.9 *Rayleigh's Principle via the Principle of Least Action.* Let us consider a holonomic and scleronomic system with n *DOF* undergoing small (linear) free and undamped vibrations about a configuration of stable equilibrium defined by $q_k = 0$. Then, to within our approximations, its kinetic and potential energies are, respectively,

$$2T = \sum\sum M_{kl}\dot{q}_k\dot{q}_l, \qquad 2V = \sum\sum V_{kl}q_k q_l, \tag{a}$$

where (M_{kl}) and (V_{kl}) are constant, symmetric, and positive definite matrices of *inertia* (*mass*) and *total potential* (*stiffness*), respectively, and the q's give the small motion from equilibrium. Next, let us assume that *the system oscillates in its (M)th mode* $(M = 1, \ldots, n)$; that is, each q_k varies as

$$q_k{}^{(M)} \equiv q_{k,M} \equiv A_{kM}(C_M \sin\psi_M), \qquad \psi_M \equiv \omega_M t + \phi_M, \tag{b}$$

where C_M, ϕ_M, and ω_M are, respectively, the *amplitude*, *phase*, and *frequency* of that mode (the first two to be determined from the initial conditions of that mode); and the A_{kM} are the "normal mode coefficients" or "direction cosines" of the modal vector $C_M \sin\psi_M$, in q-space, and depend on M_{kl}, V_{kl}, and $\omega_M{}^2$ [they are the minors of the *characteristic* or *secular* determinant $|V_{kl} - \omega_M{}^2 M_{kl}|$; assuming that all ω_M's are different. The practically much rarer case of multiple or *degenerate* frequencies introduces some very minor modifications; see, e.g., Greenwood (1988, pp. 497–498), Lamb (1929, pp. 230–232).]

From (b) we immediately find

$$dq_{k,M}/\,dt = A_{kM}C_M\,\omega_M \cos\psi_M, \tag{c}$$

and so the (double) kinetic and potential energies of that mode are, respectively,

$$2T_M = (C_M\omega_M \cos\psi_M)^2 K_M, \qquad 2V_M = (C_M \sin\psi_M)^2 \Pi_M, \tag{d}$$

where

$$K_M \equiv \sum\sum M_{kl}A_{kM}A_{lM}, \qquad \Pi_M \equiv \sum\sum V_{kl}A_{kM}A_{lM}. \tag{d1}$$

[Had we included $C_M{}^2/2$ in K_M, Π_M, the latter would be, respectively, the *maximum* kinetic and potential energies of the system, at the (M)th mode.]

Below, using the general "least" action equation (7.9.4f), we derive *Rayleigh's principle*; that is,

$$\omega_M{}^2\,\delta K_M - \delta\Pi_M = 0 \qquad \text{or} \qquad \delta(\Pi_M/K_M) = 0, \tag{e}$$

where

$$\delta K_M \equiv 2\sum\sum M_{kl}A_{kM}\,\delta A_{lM}, \qquad \delta\Pi_M \equiv 2\sum\sum V_{kl}A_{kM}\,\delta A_{lM}, \tag{e1}$$

and the δA_{kM} are small variations about the (M)th mode. The qualitative and physical interpretation of (e) is given later.

By $\delta(\ldots)$-varying the $q_{k,M}$, eqs. (b), around the (M)th mode, we find

$$\delta q_{k,M} = (C_M \sin\psi_M)\,\delta A_M + (A_{kM}\sin\psi_M)\,\delta C_M + (A_{kM} C_M \cos\psi_M)\,\delta\psi_M, \quad \text{(f1)}$$

$$\delta\psi_M = t\,\delta\omega_M + \delta\phi_M, \quad \text{(f2)}$$

and so the corresponding boundary terms of (7.9.4f) become

$$\begin{aligned}\Big\{\sum p_{kM}\,\delta q_{kM}\Big\}_1^2 &= \Big\{\sum\sum M_{kl}(dq_{lM}/dt)\,\delta q_{kM}\Big\}_1^2\\ &= \big\{\big[\big({C_M}^2\omega_M/2\big)\,\delta K_M + (C_M\,\omega_M K_M)\,\delta C_M\big]\sin\psi_M\cos\psi_M\\ &\quad + \big({C_M}^2\omega_M K_M\big)\cos^2\psi_M\,\delta\psi_M\big\}_1^2, \quad \text{(g1)}\end{aligned}$$

$$\{2T_M \Delta t_M\}_1^2 = \big\{\big({C_M}^2\omega_M K_M\big)\cos^2\psi_M \Delta t_M\big\}_1^2. \quad \text{(g2)}$$

To eliminate both (g1) and (g2) we make the following (clearly nonunique) choices:

$$\begin{aligned}&(\psi_M)_1 = \pi/2 \;\Rightarrow\; \omega_M t_1 + \phi_M = \pi/2,\\ &(\psi_M)_2 = (\psi_M)_1 + 2\pi \;\Rightarrow\; \omega_M t_2 + \phi_M = 5\pi/2,\\ &\Rightarrow\; \tau_M = t_2 - t_1 = 2\pi/\omega_M\text{: } (M)\text{th } \textit{principal period}. \quad \text{(g3)}\end{aligned}$$

With these time limits, and since here $\delta' W_{np} = 0$, equation (7.9.4f) reduces to

$$\Delta A_{L,M} - \int \delta E_M\,dt = \Delta\int 2T_M\,dt - \int(\delta T_M + \delta V_M)\,dt = 0. \quad \text{(h)}$$

Let us implement (h): a series of straightforward trigonometric integrations, with use of (a–d, f1, 2) and $t_2 = t_1 + \tau_M$, yields

$$\begin{aligned}A_{L,M} &\equiv \int 2T_M\,dt\\ &= \int \big({C_M}^2{\omega_M}^2 K_M\big)\cos^2\psi_M\,dt = (\pi/\omega_M)\big({C_M}^2{\omega_M}^2 K_M\big), \quad \text{(i1)}\end{aligned}$$

$$\Rightarrow\; \Delta A_{L,M} = (\pi/\omega_M)\big[\big(2C_M{\omega_M}^2 K_M\big)\,\delta C_M + \big({C_M}^2\omega_M K_M\big)\,\delta\omega_M + \big({C_M}^2{\omega_M}^2\big)\,\delta K_M\big], \quad \text{(i2)}$$

$$\begin{aligned}\int \delta T_M\,dt = \int \big[&\big(C_M{\omega_M}^2 K_M\,\delta C_M\big)\cos^2\psi_M + \big({C_M}^2\omega_M K_M\,\delta\omega_M\big)\cos^2\psi_M\\ &- \big({C_M}^2{\omega_M}^2 K_M\,\delta\psi_M\big)\sin\psi_M\cos\psi_M + \big({C_M}^2{\omega_M}^2\delta K_M/2\big)\cos^2\psi_M\big]\,dt, \quad \text{(i3)}\end{aligned}$$

$$\begin{aligned}\int \delta V_M\,dt = \int \big[&(C_M \Pi_M\,\delta C_M)\sin^2\psi_M + \big({C_M}^2\Pi_M\,\delta\psi_M\big)\sin\psi_M\cos\psi_M\\ &+ \big({C_M}^2\,\delta\Pi_M/2\big)\sin^2\psi_M\big]\,dt, \quad \text{(i4)}\end{aligned}$$

$$\begin{aligned}\Rightarrow\; \int(\delta T_M + \delta V_M)\,dt &= \int \delta E_M\,dt\\ &= \cdots = (\pi/\omega_M)\big[\big({\omega_M}^2 K_M + \Pi_M\big)C_M\,\delta C_M\\ &\quad + \big({C_M}^2\omega_M K_M\big)\,\delta\omega_M\\ &\quad + (1/2)\big({\omega_M}^2\,\delta K_M + \delta\Pi_M\big){C_M}^2\big]. \quad \text{(i5)}\end{aligned}$$

Hence, substituting (i2) and (i5) into (h), while noting that due to the *linearity* of the system (in the equations of motion), we have *equipartition of its kinetic and potential energies* over τ_M; that is,

$$\int T_M\,dt = \int V_M\,dt, \tag{j}$$

or, since

$$\begin{aligned}\int T_M\,dt &= (\pi/\omega_M){\omega_M}^2\Big[\sum\sum (1/2)M_{kl}(A_{kM}C_M)\,(A_{lM}C_M)\Big]\\ &= (\pi/\omega_M){\omega_M}^2{C_M}^2K_M/2 \equiv (\pi/\omega_M){\omega_M}^2T_{M,\max},\end{aligned} \tag{j1}$$

$$\begin{aligned}\int V_M\,dt &= (\pi/\omega_M)\Big[\sum\sum (1/2)V_{kl}(A_{kM}C_M)\,(A_{lM}C_M)\Big]\\ &= (\pi/\omega_M){C_M}^2\Pi_M/2 \equiv (\pi/\omega_M)V_{M,\max},\end{aligned} \tag{j2}$$

$$\text{Equation (j)} \Rightarrow\ {\omega_M}^2 = \Pi_M/K_M = V_{M,\max}/T_{M,\max} \tag{j3}$$

[and this is a key step in the proof of Rayleigh's theorem, which shows why (j3) and the theorem do *not* hold for nonlinear oscillations], we finally find

$$\begin{aligned}&(\pi/\omega_M)\,(1/2)\,({C_M}^2{\omega_M}^2\,\delta K_M - {C_M}^2\,\delta\Pi_M) = 0\\ &\Rightarrow\ {\omega_M}^2\,\delta K_M - \delta\Pi_M = 0\ \Rightarrow\ {\omega_M}^2 = \delta\Pi_M/\delta K_M = \delta V_{M,\max}/\delta T_{M,\max},\quad \text{Q.E.D.}\end{aligned} \tag{k}$$

This can also be written as

$$\delta R_M = 0, \qquad \text{where}\ \ R_M \equiv {\omega_M}^2T_{M,\max} - V_{M,\max} \qquad (\text{or}\ \ V_{M,\max} - {\omega_M}^2T_{M,\max}), \tag{k1}$$

and that variation *does not affect* ω_M; or, due to (j3), as

$$\begin{aligned}0 = \delta{\omega_M}^2 &= \delta(V_{M,\max}/T_{M,\max})\\ &= (1/{T_{M,\max}}^2)\,(T_{M,\max}\,\delta V_{M,\max} - V_{M,\max}\,\delta T_{M,\max})\\ &= (1/T_{M,\max})\,\big[\delta V_{M,\max} - (V_{M,\max}/T_{M,\max})\,\delta T_{M,\max}\big]\\ &= (1/T_{M,\max})\,(\delta V_{M,\max} - {\omega_M}^2\,\delta T_{M,\max}).\end{aligned} \tag{k2}$$

REMARKS

(i) A Hamilton principle-based derivation of (k–k3) would utilize expressions (i3–5) with $\delta\omega_M = 0$ [i.e., fixed endpoints, since

$$\delta\omega_M = \delta(2\pi/\tau_M) = -(2\pi/{\tau_M}^2)\,\delta\tau_M = -(2\pi/{\tau_M}^2)\Delta(t_2 - t_1)]. \tag{l}$$

Then,

$$\begin{aligned}0 = \delta\int (T_M - V_M)\,dt &= \int (\delta T_M - \delta V_M)\,dt\\ &= (\pi/\omega_M)\,\big[({\omega_M}^2K_M - \Pi_M)\,C_M\,\delta C_M + (1/2)\,({\omega_M}^2\,\delta K_M - \delta\Pi_M){C_M}^2\big],\end{aligned} \tag{m}$$

from which, again thanks to (j3), eq. (k) follows.

Such a derivation does not exactly coincide with those found in the literature; there, one sets

$$q_{k,M} = B_{kM} \sin \psi_M, \qquad B_{kM} \equiv A_{kM} C_M, \tag{m1}$$

from which

$$\delta q_{k,M} = \delta B_{kM} \sin \psi_M, \tag{m2}$$

and so Hamilton's principle yields

$$\begin{aligned} 0 &= \delta \int (T_M - V_M)\, dt = \delta\big[(\pi/\omega_M)({\omega_M}^2 T_{M,\max} - V_{M,\max})\big] \\ &= (\pi/\omega_M)\delta({\omega_M}^2 T_{M,\max} - V_{M,\max}) = (\pi/\omega_M)({\omega_M}^2 \delta T_{M,\max} - \delta V_{M,\max}), \end{aligned} \tag{m3}$$

because, here, $\delta(\ldots)$ implies $\omega_M = constant$. Again, we notice the indispensability of (j3).

(ii) As eqs. (h) and (i5) show, even if $\delta A_{L,M} = 0$ and $\delta\omega_M = 0$, still

$$\int \delta E_M \, dt \neq 0, \tag{n}$$

whereas the customary formulation of "least" action, eq. (7.9.6b), requires that $\delta E_M = 0$ for the admissible varied paths.

For a derivation of Rayleigh's principle based on the Hamiltonian action, eq. (7.9.4b), see Lur'e (1968, pp. 689–694).

More on Rayleigh's Principle (RP)

The *stationary* property (k) had already been noticed by Lagrange; and is indeed referred to by some authors as *Lagrange's theorem*. But Rayleigh (1870s) revealed the following, additional, *extremum* property: If we imagine the system reduced to one with a *single degree of freedom,* say, by the imposition of $n-1$ frictionless (ideal) constraints so that the ratios $q_1 : q_2 : \ldots : q_n$ have any given values, then the (square of the) frequency of the so-constrained system ω^2 will lie between the (squares of the) least and greatest natural frequencies of the unconstrained system:

$$\omega^2_{\min} \equiv {\omega_1}^2 \leq \omega^2 \leq \omega^2_{\max} \equiv {\omega_n}^2. \tag{o}$$

To understand these results better we need some "normal mode theory". [See any good vibrations text; or Gantmacher (1970, pp. 202–222), Synge and Griffith (1959, pp. 483–505).]

As shown there, *the most general q_k-variation is a superposition of n simple harmonic, or principal, independent oscillations,*

$$x_M = C_M \sin \psi_M\!: \qquad (M)\text{th } \textit{principal mode}, \qquad \psi_M = \omega_M t + \phi_M, \tag{p1}$$

where the amplitudes C_M and phases ϕ_M are to be determined from the $2n$ initial conditions $x_M(0)$ and $dx_M(0)/dt$ [or from the $q_k(0)$ and $dq_k(0)/dt$], each of which contributes to q_k proportionately to the coefficient A_{kM}; that is, recalling (b),

$$q_k = \sum q_{k,M} = \sum A_{kM} x_M = \sum A_{kM} C_M \sin \psi_M. \tag{p2}$$

This expresses D. Bernoulli's *principle of the superposition of linear vibrations* (1753). The great advantage of such Lagrangean coordinates is that *in them the equations of motion decouple* to the n independent equations

$$d^2x_M/dt^2 + \omega_M{}^2 x_M = 0 \ \Rightarrow \ \text{eq. (p1)}. \tag{p3}$$

Next, it is physically (though not mathematically) clear, that

$$T = \sum T_M = \sum (1/2)m_M(dx_M/dt)^2, \qquad V = \sum V_M = \sum (1/2)k_M x_M{}^2, \tag{p4}$$

$$m_M\text{: } \textit{principal coefficients of inertia} \quad (>0),$$

$$k_M\text{: } \textit{principal coefficients of stability} \quad (>0;\ \text{since } V>0); \tag{p5}$$

that is, in such coordinates, T and V can be expressed in *sum of squares*, or *diagonal*, forms; and, when comparing them with (p3), we easily conclude that

$$\omega_M{}^2 = k_M/m_M \quad (>0). \tag{p6}$$

[Some authors define *normal*(*ized*) coordinates, as opposed to principal coordinates, so that the *inertia matrix* (M_{kl}) is the *unit matrix,* while the *stiffness* $\rightarrow$ *stability matrix* (V_{kl}) is the *diagonal matrix of the* $\omega_M{}^2$; that is, such coordinates are principal and inertially normalized.]

In terms of these principal coordinates, any $n-1$ geometrical constraints imposed on our system, (which in effect reduce it to a *one-DOF* system) will be given by the linear relations

$$x_1 = X_1\,\xi, \qquad x_2 = X_2\,\xi, \ldots, \qquad x_n = X_n\,\xi, \tag{q1}$$

where the $X_{1,\ldots,n}$ are constants and $\xi = \xi(t)$ is any of the x_M's or q_k's. Then T and V, eqs. (p4, 5) take the constrained values

$$T_\xi = (1/2)(m_1X_1{}^2 + \cdots + m_nX_n{}^2)(d\xi/dt)^2 \equiv T_{\xi,o}(d\xi/dt)^2, \tag{q2}$$

$$V_\xi = (1/2)(k_1X_1{}^2 + \cdots + k_nX_n{}^2)\,\xi^2 \equiv V_{\xi,o}\,\xi^2; \tag{q3}$$

and, due to equipartition over the period of ξ, $\tau_\xi = 2\pi/\omega_\xi$ — that is,

$$\int (T_\xi - V_\xi)\,dt = 0 \ \Rightarrow \ (\pi/\omega_\xi)(\omega_\xi{}^2 T_{\xi,\max} - V_{\xi,\max}) = 0, \tag{q4}$$

we find that the so-constrained frequency is given by *Rayleigh's quotient*:

$$\begin{aligned}\omega_\xi{}^2 &= V_{\xi,\max}/T_{\xi,\max}\\ &= (k_1X_1{}^2 + \cdots + k_nX_n{}^2)/(m_1X_1^2 + \cdots + m_nX_n{}^2) = V_{\xi,o}/T_{\xi,o};\end{aligned} \tag{q5}$$

and since we have numbered our frequencies so that

$$\min(k_M/m_M) = k_1/m_1 \equiv \omega_1{}^2 \qquad \text{and} \qquad \max(k_M/m_M) = k_n/m_n \equiv \omega_n{}^2, \tag{q6}$$

the (extremal) RP states that

$$\omega_1{}^2 \le \omega_\xi{}^2 \le \omega_n{}^2, \quad \text{for arbitrary sets of real numbers } X_{1,\ldots,n};\ \text{that is, eq. (o);} \tag{r}$$

in words: the approximate (constrained) value of Rayleigh's quotient is never lower than the actual ${\omega_1}^2$, and thus furnishes an *upper bound* for it.

[For an algebraic derivation of RP, based on the solutions of the corresponding (constrained) Routh–Voss equations, see, for example, Chirgwin and Plumpton (1966, pp. 376–379), Ramsey (1937, pp. 267–269), Smart (1951, pp. 399–401); while for extensions to the *higher frequencies*, see any good book on linear algebra (eigenvalue problem), or Gantmacher (1970, pp. 216–222).]

As for the earlier-proved stationary property of Rayleigh's quotient (Lagrange's theorem), the above results allow us to reformulate it as follows: If $n - 1$ of the X's, eqs. (q1), are very small (of the *first* order) relative to any particular X_M — that is, *if the constraints (q1) force the system to oscillate very closely to the* (M)*th mode — then* $\omega_\xi \approx \omega_M$ (*to the second* order); or, if all X's, except X_M, become very small (first order), then ${\omega_\xi}^2$ will differ from ${\omega_M}^2$ by second-order quantities; and, of course, if all X's, except X_M, vanish, then ${\omega_\xi}^2 = {\omega_M}^2$.

In sum: The frequency (squared) of the constrained system is stationary for those constraints that make the oscillation a normal one of the natural (i.e., unconstrained) system; and these stationary values are the (squares of the) system's natural frequencies.

Finally, we point out that in concrete applications of RP there is no need to employ normal coordinates; if there was, in view of the work needed to find the latter, RP would be practically useless. Both stationarity and extremality of Rayleigh's quotient are *intrinsic* system properties, and, as such, are independent of any particular q's used. Thus, if, in general coordinates, the constraints are $q_k = B_k\,\xi(t)$, or $q_k = B_k \sin(\omega_\xi t)$, where the B_k's are constants and ξ is any one of the q_k's or x_M's, then (r) is replaced by

$$ {\omega_1}^2 \le {\omega_\xi}^2 = \sum V_{kl} B_k B_l \Big/ \sum M_{kl} B_k B_l \le {\omega_n}^2, $$

$$ \text{for an arbitrary set of real numbers } B_{1,\dots,n}. \tag{s} $$

In particular, for a *two*-DOF system, equations (q5, s) yield, respectively [fig. 7.5(a, b)],

$$ {\omega_\xi}^2 = (k_1 {X_1}^2 + k_2 {X_2}^2)/(m_1 {X_1}^2 + m_2 {X_2}^2), $$

or

$$ \omega^2(\lambda) = (k_1 + k_2\lambda^2)/(m_1 + m_2\lambda^2), \tag{s1} $$

where

$$ \lambda \equiv X_2/X_1; \tag{s2} $$

$$ {\omega_\xi}^2 = (V_{11}{B_1}^2 + 2V_{12}B_1B_2 + V_{22}{B_2}^2)/(M_{11}{B_1}^2 + 2M_{12}B_1B_2 + M_{22}{B_2}^2) $$

or

$$ \omega^2(\mu) = (V_{11} + 2V_{12}\mu + V_{22}\mu^2)/(M_{11} + 2M_{12}\mu + M_{22}\mu^2), \tag{s3} $$

where

$$ \mu \equiv B_2/B_1. \tag{s4} $$

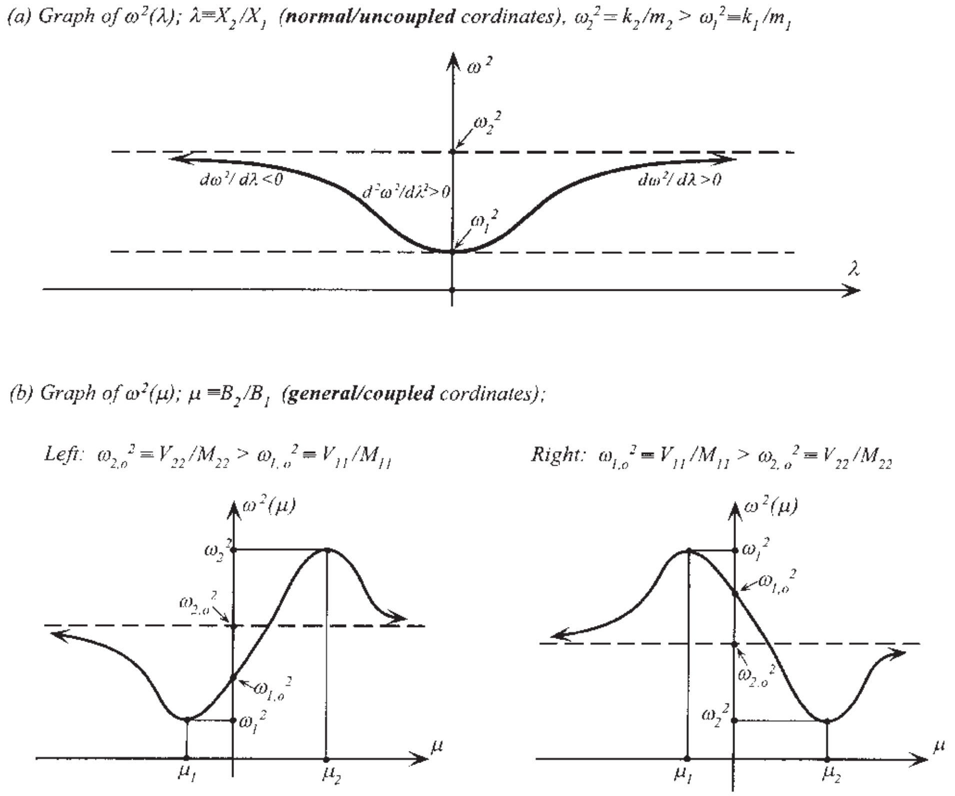

Figure 7.5 Rayleigh quotient for a two-DOF system.

An Illustration

Let us consider three particles of equal masses m attached at equal intervals l to a light and flexible string fixed at its ends, and stretched with a tension S (practically unaffected by the small deflections of the particles) (fig. 7.6). Here, to within *quadratic* terms in the q's,

$$2T = m[(\dot{q}_1)^2 + (\dot{q}_2)^2 + (\dot{q}_3)^2], \tag{t1}$$

$$V = S[(l_1 - l)^2 + (l_2 - l)^2 + (l_3 - l)^2 + (l_4 - l)^2] \equiv S(\Delta l_1 + \Delta l_2 + \Delta l_3 + \Delta l_4)$$

[no factor 1/2 needed, due to the assumed constancy of S]

$$\approx (S/2l)[q_1{}^2 + (q_2 - q_1)^2 + (q_3 - q_2)^2 + q_3{}^2]$$

$$= (S/l)[q_1{}^2 + q_2{}^2 + q_3{}^2 - q_1 q_2 - q_2 q_3]. \tag{t2}$$

Let us now assume the $3 - 1 = 2$ *symmetric* mode constraints: $q_1 = q_2 = \mu\, q_3$. Then,

$$2T = m(2\mu^2 + 1)(\dot{q}_2)^2, \qquad 2V = (S/l)(4\mu^2 - 4\mu + 2)q_2{}^2, \tag{u1}$$

and so [with $q_2 \sim \sin(\omega t)$, or $\sim \cos(\omega t)$] Rayleigh's quotient becomes

$$\omega^2 = \omega^2(\mu) = \sigma[(4\mu^2 - 4\mu + 2)/(2\mu^2 + 1)], \quad \text{where } \sigma \equiv S/ml. \tag{u2}$$

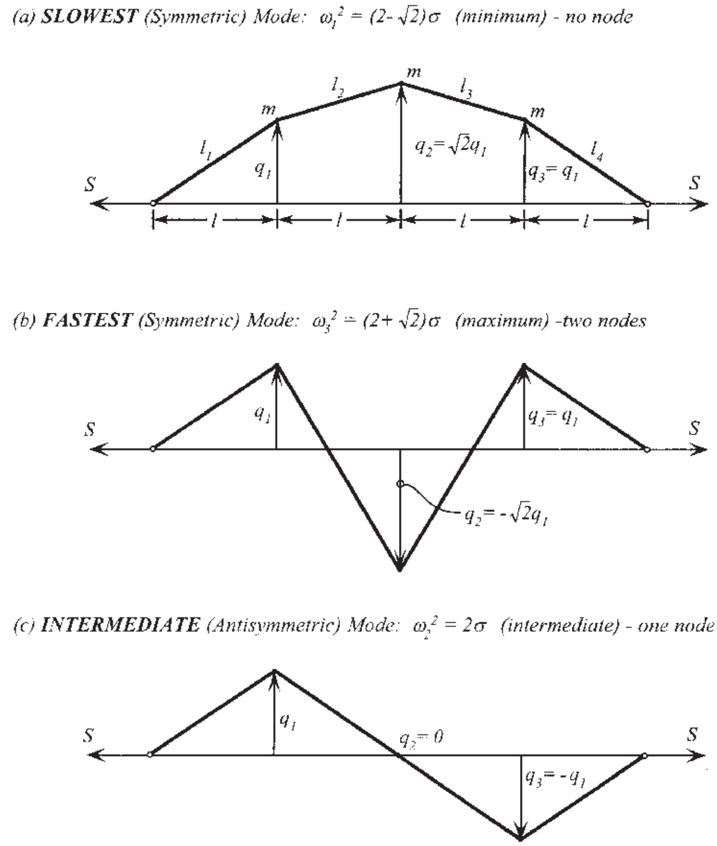

Figure 7.6 Symmetric and antisymmetric modes of three equal masses on a taut string.
(a) $\Delta l_1 \equiv l_1 - l = ({q_1}^2 + l^2)^{1/2} - l = l\{[1 + (q_1/l)^2]^{1/2} - 1\} \approx (1/2l){q_1}^2$,
$\Delta l_2 \equiv l_2 - l \approx (1/2l)(q_2 - q_1)^2$, $\Delta l_3 \equiv l_3 - l \approx (1/2l)(q_2 - q_3)^2$, $\Delta l_4 \equiv l_4 - l \approx (1/2l){q_3}^2$.

By the *stationarity* part of RP, the roots of $d\omega^2/d\mu = 0$, for μ to produce a *principal symmetric mode*, are $\mu_1 = -1/\sqrt{2}$, and $\mu_3 = +1/\sqrt{2}$, and the corresponding (exact) values of the frequencies squared are [fig. 7.6(a, b)]

$$\omega_1{}^2 \equiv \omega_{\min}{}^2 = (2 - \sqrt{2})\sigma \approx 0.5858\,\sigma \quad \text{(signs of } q_1, q_2, q_3 \text{ the same)}, \tag{u3}$$

$$\omega_3{}^2 \equiv \omega_{\max}{}^2 = (2 + \sqrt{2})\sigma \approx 3.4142\,\sigma \quad \text{(sign of } q_2 \text{ opposite to those of } q_1, q_3); \tag{u4}$$

while by the *extremality* part of RP

$$\omega_{\min}{}^2 \approx 0.5858\,\sigma \leq \omega^2 \leq \omega_{\max}{}^2 \approx 3.4142\,\sigma; \tag{v1}$$

for example, assuming $q_1 = q_3 = (3/4)q_2$ (parabolic shape), we find

$$\omega^2 = 0.5882\,\sigma > 0.5858\,\sigma = \omega_{\min}{}^2; \tag{v2}$$

and assuming $q_1 = q_3 = (\sqrt{2}/2)q_2$ (sine curve of "period" $8l$), we find

$$\omega^2 = 0.5970\,\sigma > 0.5858\,\sigma = \omega_{\min}{}^2. \tag{v3}$$

Let the reader show that the *antisymmetric* mode $q_1 = -q_3$, $q_2 = 0$, or $q_1 = -q_3 = \mu q_2$, has the (intermediate) frequency: ${\omega_2}^2 = 2\sigma$; that is, $\mu \to \mu_2 = 0$.

Problem 7.9.9 *Rayleigh's Principle.* By using the *stationarity* property of Rayleigh's quotient, find (exactly) the two natural frequencies and corresponding mode ratios of the small (linear) oscillations of a double pendulum, consisting of two identical homogeneous bars, AB and BC, each of mass m and length l, under gravity [A: hinge of AB with fixed point ("ceiling"), B: hinge connecting AB and BC].

ANSWER

$\omega^2 = (3g/l)(1 \pm 2/\sqrt{7})$. With θ: angle of AB (*upper* bar) with vertical, and ϕ: angle of BC (*lower* bar) with vertical, we have $\phi/\theta = (1/3)(-1 \pm \sqrt{28})$:

for ω^2_-: $(\phi/\theta)_+ \approx +1.43$ (*lower* mode); for ω^2_+: $(\phi/\theta)_- \approx -2.10$ (*higher* mode).

Problem 7.9.10 *Rayleigh's Principle.* Consider a system consisting of a small bead B of mass m sliding on a smooth circular hoop H, also of mass m, and radius r. The hoop can turn freely about a fixed point O in its circumference, on a vertical plane. By using the stationarity property of Rayleigh's quotient, find (exactly) the two natural frequencies and corresponding mode ratios of its small oscillations, under gravity.

ANSWER

Let C be the center of the hoop. With θ: angle of OC with vertical, and ϕ: angle of CB with vertical, we have

Lower mode: ${\omega_{\min}}^2 = (1/2)(g/r)$, $\phi/\theta = +1$; *Higher* mode: ${\omega_{\max}}^2 = 2(g/r)$, $\phi/\theta = -2$.

Problem 7.9.11 *Lagrangean Action.* Show that the Lagrangean action functional A_L [(7.9.4d)] can also be expressed as

$$\int \left(\sum p_k \dot{q}_k - h + E\right) dt, \tag{a}$$

where, as usual, $p_k \equiv \partial L/\partial \dot{q}_k$, $h \equiv \sum (\partial L/\partial \dot{q}_k)\dot{q}_k - L$.

Example 7.9.10 *Hamiltonian Action in Nonlinear Oscillations; Van der Pol and Rayleigh Oscillators.* Here, the starting point is the general Hamiltonian variational equation (7.9.4b)

$$\Delta \int L\, dt + \int \delta' W_{np}\, dt = \left\{\sum p_k\, \delta q_k + L \Delta t\right\}_1^2. \tag{a}$$

We will specialize (a) to *periodic* motions: choosing $\delta q_k(t_1) = \delta q_k(t_2)$ (not necessarily zero), where $t_2 - t_1 = \tau$ (common) period of oscillation, and since, in such a case,

$$\left\{\sum p_k\, \delta q_k\right\}_1^2 = 0, \qquad L(t_1) = L(t_2) \equiv L_o, \tag{b}$$

and $\Delta t = \Delta\tau = \Delta(2\pi/\omega) = -(2\pi/\omega^2)\,\delta\omega$, eq. (a) reduces to

$$\Delta \int_0^{2\pi/\omega} L\,dt + \int_0^{2\pi/\omega} \delta' W_{np}\,dt + (2\pi/\omega^2)L_o\,\delta\omega = 0. \tag{c}$$

1. Van der Pol Oscillator

Let us apply (c) to [recalling ex. 7.2.2: (g) ff.]

$$\ddot{q} + \varepsilon(q^2 - 1)\dot{q} + q = 0. \tag{d}$$

For the reasons given earlier, we try the (asymptotically) harmonic "limit cycle" solution:

$$q = a\sin\chi, \qquad \chi = \omega\,t. \tag{e}$$

Varying both a and ω (since they are both unknown), we obtain

$$\delta q = \delta a \sin\chi + (a\,t)\cos\chi\,\delta\omega, \tag{f}$$

and so the periodicity condition

$$\{p\,\delta q\}_1^2 = \{\dot{q}\,\delta q\}_1^2 = \{(a\,\delta a)\sin\chi\cos\chi + (a^2\,\delta\omega)t\cos^2\chi\}_1^2 = 0$$

supplies the time endpoints $t_1 = \pi/2\omega$, $t_2 = 3\pi/2\omega$ or $5\pi/2\omega \Rightarrow \tau = 2\pi/\omega$ or π/ω; which, in turn, yield

$$\begin{aligned} \delta q(\pi/2\omega) &= \delta q(5\pi/2\omega) = \delta a \quad (\neq 0),\\ L(\pi/2\omega) &= L(5\pi/2\omega) \equiv L_o = -(a^2/2). \end{aligned} \tag{g}$$

From the above, we find, successively,

$$\begin{aligned} A_H &= \int (T - V)\,dt = \int (1/2)[(\dot{q})^2 - q^2]\,dt\\ &= \int [(1/2)a^2\omega^2\cos^2\chi - (1/2)a^2\sin^2\chi]\,dt\\ &= (\pi/\omega)[a^2(\omega^2 - 1)/2] = A_H(a, \omega), \end{aligned} \tag{h1}$$

$$\begin{aligned} \Rightarrow \Delta A_H &= (\partial A_H/\partial a)\,\delta a + (\partial A_H/\partial\omega)\,\delta\omega\\ &= (\pi/\omega)\big[a(\omega^2 - 1)\,\delta a + (a^2/2)(\omega + \omega^{-1})\,\delta\omega\big]; \end{aligned} \tag{h2}$$

$$L(t_1)\,\Delta(t_2 - t_1) = L_o\,\Delta(2\pi/\omega) = -(a^2/2)[-(2\pi/\omega^2)\,\delta\omega] = (\pi/\omega^2)a^2\,\delta\omega; \tag{h3}$$

$$\begin{aligned} \int \delta' W_{np}\,dt &= \int Q\,\delta q\,dt = -\int \varepsilon(q^2 - 1)\dot{q}\,\delta q\,dt\\ &= \int (-\varepsilon\,a^3\omega\sin^2\chi\cos\chi + \varepsilon\,a\,\omega\cos\chi)[\delta a\sin\chi + (a\,t)\cos\chi\,\delta\omega]\,dt\\ &= \cdots = (\pi/\omega)^2(3\varepsilon\,a^2\omega/2)(1 - a^2/4). \end{aligned} \tag{h4}$$

Substituting (h2–4) into (c), and simplifying, yields

$$[a(\omega^2 - 1)]\,\delta a + \left[(a^2/2)(\omega + \omega^{-1}) - (a^2/\omega) + (3\pi/2)\varepsilon a^2(1 - a^2/4)\right]\delta\omega = 0, \quad \text{(i)}$$

from which, since δa and $\delta\omega$ are *independent*, we find $\omega^2 = 1$, and thanks to it, $1 - a^2/4 = 0 \Rightarrow |a| = 2$; values that agree with those found by other means in the oscillations literature; for example, Kauderer (1958, p. 343 ff.).

Also, we note that for $|a| = 2$, eq. (h4) yields

$$\int \delta' W_{np}\,dt = \int Q\,\delta q\,dt\text{: } \textit{virtual nonpotential work} \text{ (damping)} = 0. \quad \text{(j)}$$

For better approximations to (d), than (e), see Papastavridis [1986(b)].

2. Generalizations

Let us now extend the above to the periodic solutions of the general *quasi-linear* equation

$$\ddot{q} + q = \varepsilon f(q, \dot{q}), \quad \text{(k)}$$

where, again, $f(\ldots)$: nonlinear in q, $\dot{q}$, and $\varepsilon f(q, \dot{q})$ is very small compared with $\ddot{q}$ and q (all taken absolutely).

With the periodic solution (e) [viewed as the first term of the Fourier series representation of the assumed periodic solution of (k)], eqs. (h2, 3), and the notation

$$f(a \sin\chi, a\,\omega\cos\chi) \equiv F(a, \chi) \equiv F, \quad \text{(l)}$$

we find

$$\int_0^{2\pi/\omega} \delta' W_{np}\,dt = \int_0^{2\pi/\omega} Q\,\delta q\,dt = \varepsilon \int_0^{2\pi/\omega} F(a, \chi)\,\delta q\,dt$$
$$= \varepsilon \left[\delta a \int_0^{2\pi/\omega} F \sin\chi\,dt + (a\,\delta\omega) \int_0^{2\pi/\omega} F\,t\cos\chi\,dt\right]. \quad \text{(m)}$$

Substituting (h2, 3, m) into (c) yields

$$\left[(\pi/\omega)(\omega^2 - 1)a + \varepsilon \int_0^{2\pi/\omega} F \sin\chi\,dt\right]\delta a$$
$$+ a\left[(\pi/2)(1 - \omega^{-2})a + \varepsilon \int_0^{2\pi/\omega} F\,t\cos\chi\,dt\right]\delta\omega = 0, \quad \text{(n)}$$

from which, since δa and $\delta\omega$ are independent, we obtain the following system for a and ω:

$$(\pi/\omega)(\omega^2 - 1)a + \varepsilon \int_0^{2\pi/\omega} F(a, \chi) \sin\chi\,dt = 0, \quad \text{(o1)}$$

$$(\pi/2)(1 - \omega^{-2})a + \varepsilon \int_0^{2\pi/\omega} F(a, \chi)t\cos\chi\,dt = 0. \quad \text{(o2)}$$

The earlier Van der Pol case (d) corresponds to $f = -(q^2 - 1)\dot{q}$. Then, since

$$\int_0^{2\pi/\omega} F \sin\chi \, dt = (-a^3\omega) \int_0^{2\pi/\omega} \sin^3\chi \cos\chi \, dt + (a\,\omega) \int_0^{2\pi/\omega} \sin\chi \cos\chi \, dt = 0, \quad \text{(p1)}$$

eq. (o1) yields $\omega^2 = 1$ and this, in turn, simplifies (o2) to

$$\begin{aligned} &\int_0^{2\pi/\omega} F(a, \chi)\, t \cos\chi \, dt = 0 \\ &\Rightarrow a^2 = \left(\int_0^{2\pi/\omega} t\cos^2\chi \, dt\right) \Big/ \left(\int_0^{2\pi/\omega} t\sin^2\chi \ \cos^2\chi \, dt\right) \\ &\qquad = [(3/2)(\pi/\omega)^2]/[(3/8)(\pi/\omega)^2] = 4, \end{aligned} \quad \text{(p2)}$$

as before.

Next, let us consider the *Rayleigh equation*

$$\ddot{q} + q = \varepsilon[\dot{q} - (\dot{q})^3], \qquad \varepsilon\text{: very small positive constant.} \quad \text{(q)}$$

With q, δq, τ as before, and $F = a\,\omega\cos\chi - a^3\omega^3\cos^3\chi$, we find (with $t_1 = \pi/2\omega$, $t_2 = 5\pi/2\omega$)

$$\begin{aligned} \varepsilon \int F \sin\chi \, dt = \varepsilon \int [(a\,\omega)\sin\chi\cos\chi - (a^3\omega^3)\cos^3\chi\sin\chi] dt = 0 \\ \Rightarrow \omega^2 = 1 \qquad \text{[by (o1)]}, \end{aligned} \quad \text{(q1)}$$

and so (o2) reduces to

$$\begin{aligned} \varepsilon \int F\, t\cos\chi \, dt = \varepsilon \int \left[(a\,\omega) t\cos^2\chi - (a^3\omega^3) t\cos^4\chi\right] dt = 0 \\ \Rightarrow (3\pi^2\varepsilon a/2)(1 - 3a^2\omega^2/4) = 0 \ \Rightarrow \ |a| = 2/\sqrt{3}. \end{aligned} \quad \text{(q2)}$$

Pars (1965, pp. 388–389) shows that by an appropriate change of variables, (q) can be transformed back to the Van der Pol equation (d); see also Panovko (1971, pp. 209–213) for a small-parameter (perturbation) treatment.

Also, the above extend to the case where

$$f(\ldots) = f(t, q, \dot{q}) = f(\Omega\, t, q, \dot{q})\text{: } (2\pi/\Omega)\text{-periodic in time, } \Omega\text{: given.}$$

Finally, on the connection between the above results, $\int Q\,\delta q \, dt = 0$ and eqs. (o1, 2), and the method of *slowly varying parameters*, see ex. 7.9.14 and Bogoliubov and Mitropolskii (1974, §21).

Example 7.9.11 *Lagrangean "least" action in Nonlinear Oscillations; Nonlinear Pendulum and Van der Pol Oscillators*. Here, the basic variational equation (7.9.4a, or 4h)

$$\Delta \int 2T \, dt = \int (\delta T + \delta V - \delta' W_{np}) \, dt + BT, \quad \text{(a)}$$

where

$$\begin{aligned} BT &\equiv \left\{\sum p_k \,\Delta q_k + \left(2T - \sum p_k \dot{q}_k\right) \Delta t\right\}_1^2 \\ &= \left\{\sum p_k \,\Delta q_k + (T_1 + 2T_o)\, \Delta t\right\}_1^2 \\ &= \left\{\sum p_k \,\delta q_k + 2T\, \Delta t\right\}_1^2 \\ &\left[= \left\{\sum p_k \,\Delta q_k\right\}_1^2 \equiv (BT)_{scl}, \text{for scleronomic systems}\right], \end{aligned} \tag{b}$$

will be applied to the approximate solution of one-DOF (hence, holonomic) nonlinear and/or nonconservative oscillations.

For periodic motions and variations, with period $\tau = t_2 - t_1 = 2\pi/\omega$:

(i) If periodicity means $\delta q_k(t_1) = \delta q_k(t_2)$, $p_k(t_1) = p_k(t_2)$, then

$$BT = 2T(t_1)\, \Delta(2\pi/\omega) = -2T(t_1)(2\pi/\omega^2)\, \delta\omega; \tag{c1}$$

whereas (ii) If periodicity means $\Delta q_k(t_1) = \Delta q_k(t_2)$, $p_k(t_1) = p_k(t_2)$, then

$$(BT)_{scl} = 0. \tag{c2}$$

In sum: whenever $BT = 0$, the fundamental equation (a) becomes

$$\Delta \int 2T\, dt - \int (\delta T + \delta V - \delta' W_{np})\, dt = 0. \tag{d}$$

The *single but variational* equation (d) [or (a), if needed] can produce as many independent algebraic equations as the number of the unknown parameters (amplitudes and/or frequencies) entering the assumed trial solution(s).

Illustrations

1. Free and Undamped Nonlinear (Plane) Pendulum Oscillations

Here, to within a constant factor and with dimensionless time $(g/l)^{1/2} t$ substituted for t (g: constant acceleration of gravity, l: length of pendulum), the kinetic and potential energies and Lagrangean equation of its (free and undamped) motion are, respectively,

$$2T = (\dot{\phi})^2, \qquad V = 1 - \cos\phi \approx \phi^2/2 - \phi^4/24, \tag{e1}$$

$$E_\phi(T - V) = 0: \qquad \ddot{\phi} + \phi - \phi^3/6 = 0, \tag{e2}$$

where ϕ is the angle of the pendulum with the vertical. [Equation (e2) is referred to as a *soft* Duffing oscillator, because its frequency *decreases* when the amplitude increases (absolutely).] Following Lur'e (1968, pp. 702–703), we will calculate the approximate oscillatory solution of (e2) for the *initial* conditions

$$\phi(0) = \phi_o \text{ (given)}, \qquad \dot{\phi}(0) = 0, \tag{f1}$$

and trial solution

$$\phi = \phi(t) = (\phi_o + \alpha)\cos\chi - \alpha\cos(3\chi), \qquad \chi = \omega\, t, \tag{f2}$$

where α and ω are unknown. We notice that (f2) satisfies (f1), just like the solution of the linearized version of (e2): $\phi = \phi_o \cos t$ (i.e. $\alpha = 0$, $\omega = 1$).

Varying (f2) in its unknowns gives

$$\begin{aligned}\delta\phi &= (\partial\phi/\partial\alpha)\,\delta\alpha + (\partial\phi/\partial\omega)\,\delta\omega \\ &= [\cos\chi - \cos(3\chi)]\,\delta\alpha + t\,[-(\phi_o + \alpha)\sin\chi + 3\alpha\sin(3\chi)]\,\delta\omega;\end{aligned} \tag{g1}$$

also

$$\dot{\phi} = p_\phi \equiv \partial T/\partial\dot{\phi} = -\omega(\phi_o + \alpha)\sin\chi + 3\omega\,\alpha\sin(3\chi). \tag{g2}$$

Then, the periodicity condition $\{p_\phi\,\delta\phi\}_1^2 = 0$ yields $t_1 = 0$, $t_2 = \pi/\omega = \tau/2$. With this choice, $T(t_1) = T(t_2) = 0$, and so $\{2T\,\Delta t\}_0^{2\pi/\omega} = 0$.

From the above, we readily find

$$A_L \equiv \int_0^{\pi/\omega} 2T\,dt = \int_0^{\pi/\omega} (\dot{\phi})^2\,dt = (\pi/2)\omega({\phi_o}^2 + 2\phi_o\alpha + 10\alpha^2), \tag{h1}$$

$$\begin{aligned}\Rightarrow \Delta A_L &= (\partial A_L/\partial\alpha)\,\delta\alpha + (\partial A_L/\partial\omega)\,\delta\omega \\ &= (\pi/2)[2\omega(\phi_o + 10\alpha)\,\delta\alpha + ({\phi_o}^2 + 2\phi_o\alpha + 10\alpha^2)\,\delta\omega],\end{aligned} \tag{h2}$$

$$E \equiv T + V = (\dot{\phi})^2/2 + \phi^2/2 - \phi^4/24, \tag{h3}$$

$$\delta E = \dot{\phi}\,\delta(\dot{\phi}) + \phi\,\delta\phi - (\phi^3/6)\,\delta\phi; \tag{h4}$$

and, therefore, after several straightforward integrations [and noting that $\delta(\dot{\phi}) = (\delta\phi)^{\cdot}$]

$$\begin{aligned}\int_0^{\pi/\omega} \delta E\,dt &= (\pi/4)\{2\omega(\phi_o + 10\alpha) + \omega^{-1}[(2\phi_o - {\phi_o}^3/6) + (4 - 3{\phi_o}^2/4)\alpha - 3\phi_o\alpha^2/2]\}\,\delta\alpha \\ &\quad + (\pi/4)\{({\phi_o}^2 + 2\phi_o\alpha + 10\alpha^2) + \omega^{-2}[({\phi_o}^2 - 5{\phi_o}^4/48) \\ &\qquad + (-2\phi_o + {\phi_o}^3/6)\alpha + (-2 + 3{\phi_o}^2/8)\alpha^2]\}\,\delta\omega.\end{aligned} \tag{h5}$$

Substituting (h2) and (h5) into (d) [with $\int \delta' W_{np}\,dt = 0$], and regrouping terms, we obtain

$$I\,\delta\alpha + II\,\delta\omega = 0, \tag{i}$$

where

$$\begin{aligned}I &\equiv (\pi/4)\{2\omega(\phi_o + 10\alpha) \\ &\qquad - \omega^{-1}[2\phi_o + 4\alpha - {\phi_o}^3/6 - 3{\phi_o}^2\alpha/4 - 3\phi_o\alpha^2/2]\},\end{aligned} \tag{i1}$$

$$\begin{aligned}II &\equiv (\pi/4)\{({\phi_o}^2 + 2\phi_o\alpha + 10\alpha^2) \\ &\qquad - \omega^{-2}[{\phi_o}^2 - 2\phi_o\alpha - 5{\phi_o}^4/48 + {\phi_o}^3\alpha/6 + (-2 + 3{\phi_0}^2/8)\alpha^2]\}.\end{aligned} \tag{i2}$$

Setting I and II equal to zero, since $\delta\alpha$ and $\delta\omega$ are independent, and neglecting terms proportional to α^2 and $\alpha\,\phi_o{}^2$ (last two terms in I, and third and last three terms in II) yields the following two algebraic equations:

$$\phi_o + 10\alpha - \omega^{-2}(\phi_o + 2\alpha - \phi_o{}^3/12) = 0, \tag{j1}$$

$$\phi_o{}^2 + 2\phi_o\,\alpha - \omega^{-2}(\phi_o{}^2 - 2\phi_o\,\alpha - 5\phi_o{}^4/48) = 0. \tag{j2}$$

To the required degree of approximation, the above give

$$\alpha = \phi_o{}^3/192, \qquad \omega = 1 - \phi_o{}^2/16, \tag{k}$$

which agree with the values of Lur'e.

2. Free van der Pol Oscillator with Nonlinear Elastic Term

(i.e., van der Pol + Duffing). Here, the equation of motion is

$$\ddot{q} + \varepsilon(q^2 - 1)\dot{q} + q + \varepsilon\,\kappa\,q^3 = 0, \tag{l}$$

where $\varepsilon\kappa$ is the nonlinear stiffness constant [like h/m in ex. 7.2.2: (a)]; and from it we easily deduce that

$$2T = (\dot{q})^2, \qquad 2V = q^2 + \varepsilon\,\kappa\,q^4/2, \qquad Q = \varepsilon(1 - q^2)\dot{q}. \tag{l1}$$

Guided by our knowledge of the "linear elasticity Van der Pol equation", that is, (l) with $\kappa = 0$ [ex. 7.2.2: (g) ff.; ex. 7.9.10: (d) ff.] we assume the following trial function, independent of the initial conditions (see, e.g., Kauderer, 1958, pp. 343–347),

$$q = 2\sin\chi + \varepsilon\big[\alpha\cos(3\chi) + \beta\,\kappa\sin(3\chi)\big], \qquad \chi \equiv \omega\,t, \qquad \omega = 1 + \gamma(\varepsilon\kappa), \tag{m}$$

where α, β, γ are first-order *correction constants,* to be determined.

From (m) we readily find

$$\dot{q} = p = 2\,\omega\cos\chi + \varepsilon[-3\alpha\,\omega\sin(3\chi) + 3\beta\,\kappa\,\omega\cos(3\chi)], \tag{n1}$$

$$\delta q = [\varepsilon\cos(3\chi)]\,\delta\alpha + [\varepsilon\,\kappa\sin(3\chi)]\,\delta\beta$$
$$+ [2\cos\chi - 3\alpha\,\varepsilon\sin(3\chi) + 3\beta\,\varepsilon\,\kappa\cos(3\chi)]t\,\delta\omega, \tag{n2}$$

$$\delta\omega = (\varepsilon\kappa)\,\delta\gamma; \tag{n3}$$

and so

$$p\,\delta q = \dot{q}\,\delta q = \cdots = (\ldots)\,\delta\alpha + (\ldots)\,\delta\beta + (\ldots)\,\delta\gamma,$$

$$\Rightarrow \{p\,\delta q\}_0^{\pi/\omega} = (2 + 3\beta\,\varepsilon\,\kappa)^2\pi\,\delta\omega,$$

and since

$$T(t_1 = 0) = T(t_2 = \pi/\omega) \equiv T_0$$

$$\Rightarrow \{2T\,\Delta t\}_0^{\pi/\omega} = -2T_0(\pi/\omega^2)\,\delta\omega = -(2 + 3\beta\,\varepsilon\,\kappa)^2\pi\,\delta\omega,$$

finally,

$$\{p\,\delta q\}_0^{\pi/\omega} + \{2T\,\Delta t\}_0^{\pi/\omega} = \{p\,\Delta q\}_0^{\pi/\omega} = 0. \tag{n4}$$

With the help of the above we find, after a long series of elementary integrations,

$$A_L \equiv \int_0^{\pi/\omega} 2T\,dt = \cdots = (\pi/2)\omega\,(4 + 9\alpha^2\varepsilon^2 + 9\beta^2\varepsilon^2\kappa^2),$$

from which we obtain, by variation,

$$\begin{aligned} \Delta A_L = \pi[&(9\alpha\,\varepsilon^2\omega)\,\delta\alpha + (9\beta\,\varepsilon^2\kappa^2\omega)\,\delta\beta \\ &+ (2 + 9\alpha^2\varepsilon^2/2 + 9\beta^2\varepsilon^2\kappa^2\omega/2)\,\delta\omega], \end{aligned} \tag{o1}$$

and, upon neglecting all terms proportional to α^2, β^2, $\alpha\beta$,

$$\begin{aligned} \int_0^{\pi/\omega} \delta T\,dt &= \int_0^{\pi/\omega} \dot{q}\,\delta(\dot{q})\,dt \\ &= (9\pi\alpha\,\varepsilon^2\omega/2)\,\delta\alpha + (9\pi\beta\,\varepsilon^2\kappa^2\omega/2)\,\delta\beta + (3\pi + 6\pi\beta\,\varepsilon\kappa)\,\delta\omega, \end{aligned} \tag{o2}$$

$$\begin{aligned} \int_0^{\pi/\omega} \delta V\,dt &= \int_0^{\pi/\omega} (q + \varepsilon\,\kappa\,q^3)\,\delta q\,dt \\ &= \pi(\varepsilon^2/2 + 3\varepsilon^3\kappa)\alpha\,\omega^{-1}\,\delta\alpha \\ &\quad + \pi(\beta/2 - 1 + 3\beta\,\varepsilon\kappa)\varepsilon^2\kappa^2\omega^{-1}\,\delta\beta \\ &\quad + \pi(-1 - 3\varepsilon\,\kappa/2 + \beta\,\varepsilon^2\kappa^2)\omega^{-2}\,\delta\omega, \end{aligned} \tag{o3}$$

$$\begin{aligned} \int_0^{\pi/\omega} Q\,\delta q\,dt &= \varepsilon \int_0^{\pi/\omega} (1 - q^2)\dot{q}\,\delta q\,dt \\ &= \pi(1 - 3\beta\,\varepsilon\,\kappa/2)\varepsilon^2\,\delta\alpha + \pi(3\alpha\,\varepsilon^3\kappa/2)\,\delta\beta \\ &\quad + \pi(5\alpha/6 + 2\pi\beta\,\kappa)\omega^{-1}\varepsilon^2\,\delta\omega. \end{aligned} \tag{o4}$$

Inserting all these results into eq. (d) and regrouping terms [while recalling (n3)], yields

$$A\,\delta\alpha + B\,\delta\beta + \Gamma\,\delta\gamma = 0, \tag{p}$$

where

$$A \equiv \pi[9\alpha\,\varepsilon^2\omega - 9\alpha\,\varepsilon^2\omega/2 - (\varepsilon^2/2 + 3\varepsilon^3\kappa)\alpha\,\omega^{-1} + \varepsilon^2(1 - 3\beta\,\varepsilon\,\kappa/2)], \tag{p1}$$

$$B \equiv \pi[9\beta\,\varepsilon^2\kappa^2\omega - 9\beta\,\varepsilon^2\kappa^2\omega/2 - (\beta/2 - 1 + 3\beta\,\varepsilon\,\kappa)\varepsilon^2\kappa^2\omega^{-1} + 3\alpha\,\varepsilon^3\kappa/2], \tag{p2}$$

$$\begin{aligned} \Gamma \equiv \pi[&2 + 9\alpha^2\varepsilon^2/2 + 9\beta^2\varepsilon^2\kappa^2/2 - (3 + 6\beta\,\varepsilon\,\kappa) \\ &- (-1 - 3\varepsilon\,\kappa/2 + \beta\,\varepsilon^2\kappa^2)\omega^{-2} + (5\alpha/6 + 2\pi\beta\,\kappa)\omega^{-1}\varepsilon^2]. \end{aligned} \tag{p3}$$

To the lowest order, the three independent equations A, B, $\Gamma = 0$ yield, successively:

(i) $A = 0$: $9\alpha\,\omega/2 - (1/2 + 3\varepsilon\,\kappa)\alpha\,\omega^{-1} + 1 - 3\beta\,\varepsilon\kappa/2 = 0$, or, substituting into it the third of (m), $\omega = 1 + \gamma\varepsilon\kappa$, and omitting all higher order terms in ε, we obtain

$$9\alpha/2 - \alpha/2 + 1 = 0 \;\Rightarrow\; \alpha = -1/4; \tag{q1}$$

(ii) $B = 0$: $9\beta\omega/2 - \beta\omega^{-1}/2 + \omega^{-1} = 0$, or, setting $\omega = 1 + \gamma\varepsilon\kappa$, and so on,

$$9\beta/2 - \beta/2 + 1 = 0 \;\Rightarrow\; \beta = -1/4; \tag{q2}$$

(iii) $\Gamma = 0$: with $\omega^{-2} \approx 1 - 2\gamma\varepsilon\kappa$, we find

$$\begin{aligned} &-1 - 6\beta\varepsilon\kappa + (1 - 2\gamma\varepsilon\kappa)(1 + 3\varepsilon\kappa/2) = 0 \\ &\Rightarrow -6\beta\varepsilon\kappa - 2\gamma\varepsilon\kappa + 3\varepsilon\kappa/2 = 0 \;\Rightarrow\; \gamma = 3/2. \end{aligned} \tag{q3}$$

Hence, the trial solution (m), *correct to the first order in* κ (and in agreement with Kauderer) is

$$q = 2\sin\chi - (\varepsilon/4)[\cos(3\chi) + \kappa\sin(3\chi)], \qquad \chi \equiv \omega t, \qquad \omega = 1 + 3\varepsilon\kappa/2. \tag{r}$$

For additional related examples, see Papastavridis and Chen (1986).

Example 7.9.12 *The "Direct" Variational Methods of Galerkin and Ritz in Nonlinear Oscillations.*

1. Galerkin (1915)

Let us consider a one-DOF (hence, holonomic) system described by the, generally, nonlinear differential equation of motion

$$E = E(t, q, \dot q, \ddot q) \equiv E(t, q) \equiv \ddot q - F(t, q, \dot q) = 0. \tag{a}$$

Here, of particular interest is the case where $F(\ldots)$ is a *periodic* function of given period $\tau \equiv 2\pi/\omega$ (ω = frequency). Suppose then that we are seeking periodic solutions to (a), of period τ, that satisfy the initial conditions

$$q(t_1) = q(t_1 + \tau), \qquad \dot q(t_1) = \dot q(t_1 + \tau), \qquad \text{for } any\ t_1. \tag{b}$$

Let us assume the approximate solution to $q(t)$:

$$q(t) \approx q_o(t) = \sum a_k \psi_k(t) \qquad [k = 1, \ldots, N;\ \text{or, sometimes}, k = 0, \ldots, N], \tag{c}$$

where the a_k are unknown *constant* parameters (to be determined by a "Galerkin criterion" — see below), and the $\psi_k(t)$ are known and preferably orthogonal (or, better, orthonormal) "coordinate functions" that satisfy (b):

$$\psi(t_1) = \psi(t_1 + \tau), \qquad \dot\psi(t_1) = \dot\psi(t_1 + \tau), \qquad \text{for } any\ t_1. \tag{c1}$$

For example, we may choose as q_o a Fourier series defined in the interval $(t_1, t_1 + \tau)$ and having period τ outside it:

$$q_o = a_0/2 + \sum \left[a_k \cos(2\pi k t/\tau) + b_k \sin(2\pi k t/\tau)\right] \qquad (k = 1, \ldots, n), \tag{d1}$$

where, as is (hopefully) well known,

$$a_k = (2/\tau)\int_{t_1}^{t_1+\tau} q_o(t)\cos(2\pi k t/\tau)\,dt, \qquad b_k = (2/\tau)\int_{t_1}^{t_1+\tau} q_o(t)\sin(2\pi k t/\tau)\,dt, \tag{d2}$$

$$(k = 0, \ldots, N;\ \text{frequently } t_1 = 0 \text{ or } -\tau/2).$$

Then the a_k are selected so that $E_o \equiv E(t, q_o) = 0$ holds, if not identically, at least, *in a weighted average over a period*, sense; that is,

$$\int_{t_1}^{t_1+\tau} E_o\, w(t)\, dt = 0, \qquad \text{where } w(t) \text{ is some } \textit{weighting function}. \tag{e}$$

If we choose N *different* such functions, $w_1(t), \ldots, w_N(t)$, then we can obtain from (e) N algebraic equations for the N a_k's, contained in E_o. As such, we usually pick the $\psi_k(t)$'s appearing in (c); then (e) yields the N *weighted residual* or *Galerkin* equations:

$$\int_{t_1}^{t_1+\tau} E\Big[t, \sum a_s \psi_s(t)\Big]\psi_k(t)\, dt = 0 \qquad [k, s = 1, \ldots, N]. \tag{f}$$

If $F(\ldots)$ is *non-periodic*, we may choose as q_o the following power series

$$q_o = a_0 + a_1 t + a_2 t^2 + \cdots + a_N t^N. \tag{d3}$$

Interpretations of Equations (e, f)

(i) In the theory of ordinary differential equations, (f) appear as the conditions for the vanishing of the coefficients of the generalized Fourier series expansion of $E(t, q_o) = 0$. (ii) With $w \to \delta q_o = \sum \delta a_k \psi_k(t)$, eq. (e) and then eq. (f), essentially, constitute the time integral of Lagrange's principle; and thus can be viewed as requiring that the error, or "residual force," $e \equiv E_o - E = E_o (\neq 0)$ do zero virtual work on $w \to \delta q_o$ over τ. Other "error residual" versions of (e) exist in the literature.

In view of these interpretations, it should be clear that *Galerkin's method holds for any mechanical system*; that is, with *several DOF*, or *continuous* (such as beams, plates, shells) undergoing any type of motion and not just a periodic one; although for periodic motions the algebra is manageable.

2. Ritz (1908, 1909)

Let us consider a one-DOF (hence, holonomic) system, that is completely described by Hamilton's principle; that is, with $L = L(t, q, \dot{q})$ and $\delta q(t_1) = \delta q(t_2) = 0$,

$$\delta A_H = \delta \int L\, dt = \cdots = -\int E\, \delta q\, dt = 0, \qquad E = E(L) \equiv (\partial L/\partial \dot{q})^{\cdot} - \partial L/\partial q = 0; \tag{g}$$

where the last (Lagrangean) equation coincides with the earlier equation (a), whenever both refer to the same problem.

In view of the approximation (c), we will have

$$A_H = A_H[q(t)] \;\Rightarrow\; A_H[q_o(t)] = A_H(a_1, \ldots, a_N) \equiv A_{H,o}, \tag{h}$$

and so the variational equation (g) is replaced by one of ordinary differential calculus:

$$\delta A_{H,o} = \sum (\partial A_{H,o}/\partial a_k)\, \delta a_k = 0, \tag{i}$$

from which, since the N a_k are independent (otherwise we introduce Lagrangean multipliers), we obtain the N *Ritz* equations:

$$\partial A_{H,o}/\partial a_k = 0 \qquad [k = 1, \ldots, N]. \tag{j}$$

In the presence of *nonpotential* forces $Q = Q(t, q, \dot{q})$, in which case the second equation of (g) is replaced by $E(L) = Q$, eqs. (j) are replaced by

$$P_k(a_1, \ldots, a_N) \equiv \partial A_{H,o}/\partial a_k + \int_{t_1}^{t_1+\tau} Q\ (\partial q_o/\partial a_k)\, dt = 0. \tag{k}$$

In particular, if Q is *very small*, and the exact solution of the *unperturbed* problem—that is, of $E(L) = 0$—is $q_{(o)}(t; a_1, \ldots, a_N)$, we may reasonably assume that $q_o = q_{(o)}$. Then,

$$\partial A_{H,o}/\partial a_k = 0, \text{independently, and (k) reduces to } \int_{t_1}^{t_1+\tau} Q(\partial q_{(o)}/\partial a_k)\, dt = 0.$$

Let us calculate (j) explicitly: recalling (b, c), and since now $L(t, q, \dot{q}) \to L(t, q_o, \dot{q}_o)$, we find

$$\begin{aligned}
\partial A_{H,o}/\partial a_k &= \int_{t_1}^{t_1+\tau} \big[(\partial L/\partial \dot{q}_o)(\partial \dot{q}_o/\partial a_k) + (\partial L/\partial q_o)(\partial q_o/\partial a_k)\big]\, dt \\
&= \int_{t_1}^{t_1+\tau} \big[(\partial L/\partial \dot{q}_o)\dot{\psi}_k + (\partial L/\partial q_o)\psi_k\big]\, dt \\
&= -\int_{t_1}^{t_1+\tau} E_o \psi_k\, dt + \psi_k(t_1)\big[(\partial L/\partial \dot{q}_o)_{t_1+\tau} - (\partial L/\partial \dot{q}_o)_{t_1}\big] = 0,
\end{aligned} \tag{l}$$

where

$$\begin{aligned}
E(t, q, \dot{q}) \to E(t, q_o, \dot{q}_o) &= E\Big[t, \sum a_s \psi_s(t)\Big] \\
&\equiv (\partial L/\partial \dot{q}_o)^{\cdot} - \partial L/\partial q_o \equiv E_o.
\end{aligned} \tag{l1}$$

If the integrated out (boundary) term in (l) vanishes — for example, if $\partial L/\partial \dot{q}$ is periodic with period τ—(l) reduces to the *first, or minimizing, Ritz* ($\to$ *Galerkin*) equation:

$$\partial A_{H,o}/\partial a_k \;=\; -\int_{t_1}^{t_1+\tau} E_o \psi_k\, dt \;=\; 0, \tag{m1}$$

However, if the ψ_k are *not* periodic, then (j) leads to the *second, or minimizing, Ritz* ($\to$ *Galerkin*) equation (t_1, t_2: arbitrary time limits):

$$\partial A_{H,o}/\partial a_k = -\int_{t_1}^{t_2} E_o \psi_k\, dt + \big\{(\partial L/\partial \dot{q}_o)\psi_k\big\}_1^2 = 0; \tag{m2}$$

and if, instead of (c), we use the more general trial function

$$q_o(t) = \sum q_k(a_{k1}, \ldots, a_{kN}; t), \tag{m3}$$

then (m2) are replaced by the $N \times N$ equations:

$$-\int_{t_1}^{t_2} E_o(\partial q_o/\partial a_{ks})\,dt + \{(\partial L/\partial \dot{q}_o)(\partial q_o/\partial a_{ks})\}_1^2 = 0 \quad (k, s = 1, \ldots, N). \tag{m4}$$

3. Galerkin versus Ritz

Let us, next, compare the methods of Galerkin and Ritz. These two, although theoretically equivalent for periodic systems—that is eq. (f) = eqs. (m1)—differ in fundamental ways; and the principles of analytical mechanics help us to understand that:

(i) Not every problem's equations of motion derive from a Lagrangean and therefore from a stationarity variational principle (in the sense of variational calculus); and even if they happen to do that, finding the corresponding Lagrangean may be quite a mathematical task in itself. Thus, Galerkin's method, since it does not depend on Lagrangeans, is more general than Ritz's. [On how to find the Lagrangean of a given equation of motion (which is known as the *inverse* problem of variational calculus), there exists an extensive literature; see, for example, Santilli (1978, 1980).]

(ii) On the other hand, wherever both methods apply, the method of Ritz requires *less* accuracy in the trial function q_o—that is, the $\psi_k(t)$—than that of Galerkin. The reason for this is that *Ritz's method involves energetic functions that entail lower-order derivatives than the force/acceleration functions of Galerkin's method.*

(iii) Finally, in both methods, the accuracy of the solution depends on the number of terms taken in eq. (c) and the judicious choice of the ψ_k's.

Sometimes, advance qualitative knowledge of the behavior of the solution can restrict q_o to a *single* term and still provide a good approximation.

For *nonperiodic* initial value problems, eqs. (m2, 4), with *nonhomogeneous* conditions [e.g., $q(t_1) = q_1$ (given), $q(t_2) = q_2$ (given), with at least one of them nonzero], we can choose the following trial function:

$$q_o = \psi_0(t) + \sum a_k \psi_k(t), \tag{n1}$$

where $\psi_0(t_1) = q_1$, $\psi_0(t_2) = q_2$, and $\psi_k(t_1) = 0$, $\psi_k(t_2) = 0$; for example, for ψ_0 we can try the linear function

$$\psi_0(t) = [(q_2 - q_1)/(t_2 - t_1)](t - t_1) + q_1. \tag{n2}$$

4. An Illustration

Let us apply these methods to the earlier-discussed (ex. 7.2.2), undamped but periodically forced, Duffing's oscillator:

$$m\ddot{q} + kq + hq^3 - Q_o \sin\chi = 0, \qquad \chi \equiv \omega t, \tag{o}$$

or, with ${\omega_o}^2 \equiv k/m$: natural frequency of corresponding linear oscillator [i.e., (o) for $h = 0$], (o1)

$\varepsilon \equiv h/m$: measure of elastic nonlinearity

(if > 0: *hard* or *overlinear* spring; if < 0: *soft* or *underlinear* spring), (o2)

ω: given forcing frequency, (o3)

$f_o \equiv Q_o/m$: forcing amplitude per unit mass, (o4)

$$\ddot{q} + {\omega_o}^2 q + \varepsilon\, q^3 - f_o \sin\chi = 0, \qquad \chi \equiv \omega\, t. \tag{p}$$

Let us investigate the forced response of (p) of the same frequency ω. Since eqs. (o, p) are "symmetric" about $t = 0$, we try the *single* parameter solution

$$q_o = a \sin\chi, \qquad a = a(\omega). \tag{p1}$$

Then, Galerkin's equation (f) yields

$$\int_0^{2\pi/\omega} (\ddot{q}_o + {\omega_o}^2 q_o + \varepsilon {q_o}^3 - f_o \sin\chi) \sin\chi\, dt = 0; \tag{p2}$$

and from this, after some simple integrations, we obtain the earlier equation [ex. 7.2.2: (f)]

$$\begin{aligned} &(3\varepsilon/4)a^3 + ({\omega_o}^2 - \omega^2)a - f_o = 0 \\ &\Rightarrow \omega^2 = \omega^2(a, f_o) = {\omega_o}^2 + 3\varepsilon\, a^2/4 - f_o/a. \end{aligned} \tag{p3}$$

This equation constitutes the *resonance curve*; that is, it gives the response amplitude $|a|$ as function of ω and the specified system parameters h and f_o (fig. 7.7). For $f_o = 0$ (free vibration) (p3) reduces to

$$\omega^2 = {\omega_o}^2 + (3/4)\varepsilon a^2 \;\Rightarrow\; \omega = \omega_o(1 + 3\varepsilon a^2/4{\omega_o}^2)^{1/2}. \tag{p4}$$

As for the Ritz method, since here

$$2T = m(\dot{q})^2; \quad V = V_2 + V_4, \quad 2V_2 \equiv k\, q^2, \quad 4V_4 \equiv h\, q^4; \quad Q = Q_o \sin\chi, \tag{q1}$$

and $q_o = a \sin\chi \;\Rightarrow\; \delta q_o = \delta a \sin\chi$, eqs. (g, j) give, with $t_1 = 0$ and $t_2 = 2\pi/\omega$,

$$\begin{aligned} \delta A_H &= \delta \int_0^{2\pi/\omega} \left[(m/2)(dq_o/dt)^2 - (k\, {q_o}^2/2 + h\, {q_o}^4/4) + Q(t)\, q_o\right] dt \\ &= \left\{(m\, \dot{q}_o)\, \delta q_o\right\}_0^{2\pi/\omega} - \int_0^{2\pi/\omega} \left[(m(d^2 q_o/dt^2) + k\, q_o + h\, {q_o}^3 - Q(t)\right] \delta q_o\, dt \\ &= 0 - \left[(-m\, a\, \omega^2 + k\, a - Q_o) \int_0^{2\pi/\omega} \sin^2\chi\, dt + (h\, a^3) \int_0^{2\pi/\omega} \sin^4\chi\, dt\right] \delta a \\ &= (\pi/\omega)(-m\, a\, \omega^2 + k\, a + 3h\, a^3/4 - Q_o)\, \delta a, \end{aligned} \tag{q2}$$

from which (p3) follows.

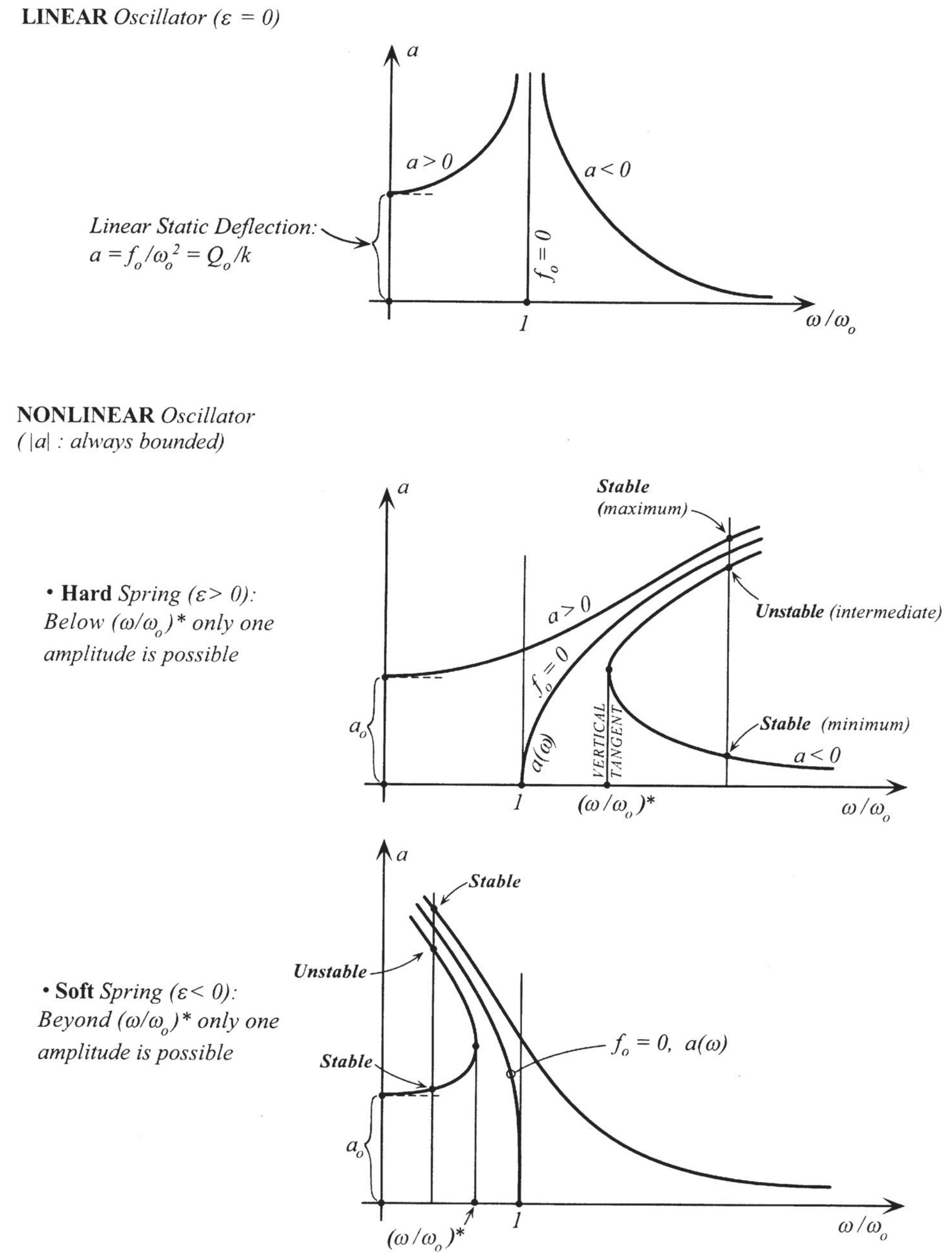

Figure 7.7 Resonance curves; that is, $a = a(\omega)$, for linear and (cubically) nonlinear oscillators.

[For a treatment of the *stability* of this oscillator via the *second* variation of A_H, $\delta^2 A_H \equiv \delta(\delta A_H)$, see Papastavridis [1983(a)].

5. A Generalization of Galerkin's Method

(See Chen, 1987.) The conventional Galerkin's method, presented above, assumes that the frequency ω is given, and so there is no need to vary it. Indeed, as already pointed out, with

$$\delta q_o = \sum (\partial q_o/\partial a_k)\,\delta a_k = \sum \psi_k(t)\,\delta a_k, \tag{r1}$$

the variational equation $\int E_o\,\delta q_o\,dt = 0$ (time integral of Lagrange's principle) leads to the Galerkin equations (f). However, in some problems, ω *is unknown and also unrelated to the amplitude*; for example, limit cycle oscillations (van der Pol equation); then δq_o *must be augmented by* $\delta\omega$*-proportional terms*. Indeed, let the trial solution be (only periodic solutions are of interest here)

$$q_o = \sum a_k\psi_k(t,\omega) = \sum a_k\psi_k(\omega t),\quad \psi_k(\omega t + 2\pi) = \psi_k(\omega t), \tag{r2}$$

and its variation

$$\delta q_o = \sum (\partial q_o/\partial a_k)\,\delta a_k + (\partial q_o/\partial\omega)\,\delta\omega = \sum \psi_k\,\delta a_k + \Omega\,\delta\omega, \tag{r3}$$

where

$$\Omega \equiv \Omega(t,\omega t, a_k) \equiv \partial q_o/\partial\omega = \sum a_k(\partial\psi_k/\partial\omega)$$
$$= \sum a_k t\,\left[d\psi_k/d(\omega t)\right]:\ \textit{secular coordinate function}. \tag{r4}$$

Substituting (r2–4) into $\int E_o\,\delta q_o\,dt = 0$ (with $t_1 = 0$, $t_2 = t_1 + 2\pi/\omega = 2\pi/\omega$, or $t_1 + \pi/\omega = \pi/\omega$) and setting, in the resulting variational equation, the coefficients of both δa_k and $\delta\omega$ equal to zero, we obtain the $N+1$ *generalized Galerkin equations*, for the $N+1$ unknowns a_k, ω:

$$\int E_o(\partial q_o/\partial a_k)\,dt = \int E_o\psi_k\,dt = 0 \qquad (k = 1,\ldots,N), \tag{r5}$$

$$\int E_o(\partial q_o/\partial\omega)\,dt = \int E_o\,\Omega\,dt = 0. \tag{r6}$$

[Equation (r6) is the Galerkin equivalent of *secular term suppression* of, say, the perturbation method.]

An Illustration

Let us apply the above to determine both the (limit cycle) amplitude and frequency of the earlier van der Pol equation (exs. 7.2.2, 7.9.10, and 7.9.11):

$$E = E(q,\dot q,\ddot q) = \ddot q + \varepsilon(q^2 - 1)\dot q + q = 0. \tag{s1}$$

With the trial solution

$$q_o = a\cos\chi, \qquad \chi \equiv \omega\,t, \tag{s2}$$

we find

$$\delta q_o = (\cos\chi)\,\delta a + (-a\,t\sin\chi)\,\delta\omega, \tag{s3}$$

and

$$E \to E_o = (1-\omega^2)a\cos\chi + a\,\varepsilon\,\omega(1 - a^2\cos^2\chi)\sin\chi \neq 0, \tag{s4}$$

and therefore (r5, 6) yield the two Galerkin equations

$$\int_0^{2\pi/\omega} E_o(\partial q_o/\partial a)\,dt = \int_0^{2\pi/\omega} E_o \cos\chi\,dt = 0:$$
$$a(1-\omega^2)(\pi/2\omega) = 0 \;\Rightarrow\; \omega = 1, \tag{s5}$$
$$\int_0^{2\pi/\omega} E_o(\partial q_o/\partial\omega)\,dt = \int_0^{2\pi/\omega} E_o(-a\,t\sin\chi)\,dt = 0:$$
$$a(1-\omega^2)(-\pi/4\omega^2) + a\,\varepsilon\,\omega(\pi^2/4\omega^2) - a^3\varepsilon\,\omega(\pi^2/16\omega^2) = 0$$
$$\Rightarrow\; a^2 = 4 \;\Rightarrow\; |a| = 2, \tag{s6}$$

in agreement with the values found by the earlier methods.

In a several-DOF system, eqs. (r2–6) are replaced, respectively, by

$$q_{k,o} = \sum a_{kk'}\psi_{k'}(\omega t)$$
$$\Rightarrow \delta q_{k,o} = \sum \psi_{k'}\,\delta a_{kk'} + \Omega_k\,\delta\omega, \qquad \Omega_k \equiv \sum a_{kk'}t\,[d\psi_{k'}/d(\omega t)], \tag{t1, 2}$$
$$\int E_{k,o}\psi_{k'}\,dt = 0 \qquad (n\times N \text{ eqs.}), \qquad \int\Big(\sum E_{k,o}\,\Omega_k\Big)\,dt = 0 \quad (1 \text{ eq.}); \tag{t3}$$

where

$k = 1,\ldots,n$ is the number of independent coordinates; $k' = 1,\ldots,N$ is the number of independent coordinate functions, and coefficients; ω is the assumed common frequency to all q's. (t4)

If each q_k is known to have a frequency ω_k, then the first of (t3) are replaced by the $n\times N$ equations

$$\int_0^{2\pi/\omega_k} E_{k,o}\psi_{k'}\,dt = 0, \tag{t5}$$

where $\psi_{k'}(t + 2\pi/\omega_k) = \psi_{k'}(t)$.

For further insights and examples, see, for example, Chen (1987), Fischer and Stephan [1972, pp. 150–151; good compact discussion of one and *several* DOF systems, both "autonomous" (no explicit time dependence) and "heteronomous" (explicit time dependence; e.g., forced vibrations); pp. 217–229: fully solved example; also 1984, pp. 267–268], Kosenko (1995).

Problem 7.9.12 *Lagrange–Ritz Method (General Considerations).* Consider a *one*-DOF conservative oscillatory system of period τ. Let q_o be an approximate periodic trial solution to its exact motion $q: q \approx q_o = q_o(t;\ \omega \equiv 2\pi/\tau, a_1, \ldots a_N)$, where both its frequency ω and "amplitude parameters" a_k are unknown.

Show that the latter can be determined from the following $N+1$ "Lagrange–Ritz" stationarity (of A_L) equations:

$$\partial A_{L,o}/\partial a_k = 0, \qquad \partial A_{L,o}/\partial\omega = 0 \qquad (k = 1,\ldots,N), \tag{a}$$

where

$$A_L(q) = \int 2T\,dt = \int (L+E)\,dt \to A_L(q_o) \equiv A_{L,o}, \tag{b}$$

$$L = L(q,\dot{q}) \to L_o\text{: Lagrangean,} \qquad E \equiv T + V \to E_o\text{: total energy.} \tag{c}$$

HINT

Set $\omega t \equiv x$. Then, $q_o = q_o(\omega t) = q_o(x)$, and with $(\ldots)' \equiv d(\ldots)/dx$,

$$A_{L,o} = \omega^{-1} \int_0^{2\pi} \left\{ L[q_o(x), \omega\, q_o{}'(x)] + E_o \right\} dt. \tag{d}$$

Problem 7.9.13 *Lagrange–Ritz Method.* Continuing from the preceding problem, show that if V is an *even* function of $q = q(\omega t)$ (symmetric potential), and $q(0) = 0$, then the most general harmonic trial function q_o becomes a linear combination of *sines* with arguments *odd* multiples of ωt; that is,

$$q_o = a_1 \sin(\omega t) + a_3 \sin(3\omega t) + \cdots = \sum a_k \sin(k\omega t) \qquad (k = 1, 3, 5, \ldots). \tag{a}$$

HINT

Here, $\dot{q}(\omega t = \pi/2) = 0$.

Problem 7.9.14 *Lagrange–Ritz Method (A Theoretical Result).* Continuing from the preceding two problems, show that for a trial function

$$q_o = q_o(\omega t; a_1, \ldots, a_N), \tag{a}$$

the following stationarity condition results:

$$dA_{L,o}/dE = \cdots = \partial A_{L,o}/\partial E = \cdots = 2\pi/\omega = \tau, \tag{b}$$

where $A_L \to A_{L,o}(a_1, \ldots, a_N; \omega, E)$.

Problem 7.9.15 *Lagrange–Ritz Method.* Consider the harmonic oscillator with equation of motion $\ddot{q} + q = 0$ (i.e., of unit mass and frequency), and corresponding (double) Lagrangean $2L = (\dot{q})^2 - q^2$, and assume the trial solution $q_o = a\sin(\omega t)$. Show that, then,

$$A_{L,o} = (\pi/2)a^2(\omega - \omega^{-1}) + 2\pi E/\omega, \tag{a}$$

and thus the earlier stationarity conditions yield

$$\partial A_{L,o}/\partial a = 0 \;\Rightarrow\; \omega = 1, \qquad \partial A_{L,o}/\partial \omega = 0 \;\Rightarrow\; E = a^2/2. \tag{b}$$

Problem 7.9.16 *Lagrange–Ritz Method (Linear Oscillator).* In the oscillator of the preceding problem, assume the quadratic trial function

$$q_o = a(x - x^2/\pi), \qquad x \equiv \omega\, t. \tag{a}$$

Show that, then,

$$A_{L,o} = \pi\omega a^2/3 + 2\pi E/\omega - \pi^3 a^2/30\omega, \tag{b}$$

and thus the earlier stationarity conditions yield

$$\partial A_{L,o}/\partial a = 0 \;\Rightarrow\; \omega^2 = \pi^2/10 \approx 0.987,$$
$$\partial A_{L,o}/\partial \omega = 0 \;\Rightarrow\; E = (\pi^2/30)a^2 \approx 0.33a^2. \tag{c}$$

Problem 7.9.17 *Lagrange–Ritz Method.* Consider the nonlinear Duffing oscillator with equation of motion $\ddot{q} + \omega_o{}^2 q + 2c\,q^3 = 0$ ($\omega_o{}^2, c > 0$; c: small) and corresponding (double) Lagrangean $2L = (\dot{q})^2 - (\omega_o{}^2 q^2 + c\,q^4)$. Show that for the trial solution $q_o = a\sin(\omega t)$,

$$A_{L,o} = \pi\omega a^2/2 + 2\pi E/\omega - \pi\omega_o{}^2 a^2/2\omega - 3\pi c\,a^4/16\,\omega. \tag{a}$$

Then, set $\partial A_{L,o}/\partial a = 0$ and $\partial A_{L,o}/\partial \omega = 0$, and find the relations among ω, a, E.

ANSWER

$$\omega^2 = (\omega_o{}^2/3)\{1 + 2[1 + (9cE/\omega_o{}^2)]^{1/2}\}. \tag{b}$$

Problem 7.9.18 *Lagrange–Ritz Method.* Consider a mathematical pendulum of mass $m = 1$ and length l in general plane motion, under gravity. Here, with the usual notations,

$$2T = l(\dot{\phi})^2 \qquad \text{and} \qquad V = g\,l(1 - \cos\phi). \tag{a}$$

Show that

(i) In the new variable $x \equiv \sin(\phi/2)$, the Lagrangean of the pendulum becomes

$$L = \left[2l^2/(1 - x^2)\right](dx/dt)^2 - 2g\,l\,x^2 = L(x, \dot{x}), \tag{b}$$

and then

(ii) The trial solution $x_o = a\sin(\omega t)$ yields

$$A_{L,o} = 2\pi E/\omega + 4\pi\omega\,l^2[1 - (1 - a^2)^{1/2}] - 2\pi g\,l\,a^2/\omega. \tag{c}$$

Then, set $\partial A_{L,o}/\partial a = 0$ and $\partial A_{L,o}/\partial \omega = 0$, and find the relations among ω, a, E.

For further details, see Luttinger and Thomas (1960); and for a generalization to systems with Lagrangeans $L = L(t, q, \dot{q})$, see Buch and Denman (1976).

Problem 7.9.19 *Hamilton–Ritz Method.* Consider the earlier Duffing oscillator with equation of motion $\ddot{q} + \omega_o{}^2 q + c\,q^3 = 0$, and boundary conditions $q(0) = q(\pi/\omega) = 0$. Show that the method of "Hamilton–Ritz," applied here for the trial solution $q_o = a\sin(\omega t)$, yields either $a = 0$ or $\omega^2 = \omega_o{}^2 + (3/4)a^2 c$; that is, given a we find ω, and vice versa; while applied for the trial solution

$q_o = a\sin(\omega t) + b\sin(3\omega t)$, the method yields

$$a^2 - a\,b + 2b^2 - (4/3)(\omega^2 - \omega_o{}^2)/c = 0, \tag{a}$$

$$3b^3 - a^3 + 6a^2 b + 4b(\omega_o{}^2 - 9\omega^2)/c = 0; \tag{b}$$

that is, given a (or b) we find b (or a), and ω.

Further, with the help of the dimensionless quantities $x \equiv b/a$, $y \equiv a^2 c/\omega_o$, and $z \equiv (\omega/\omega_o)^2 - 1$, eqs. (a, b) can be rewritten, respectively, as

$$y(6x^2 - 3x + 3) - 4z = 0, \qquad y(3x^3 + 6x - 1) - x(36z + 32) = 0; \tag{c}$$

and, finally, eliminating z between them, we obtain

$$y = -32x(51x^3 - 27x^2 + 21x + 1)^{-1}. \tag{d}$$

Plot and discuss this curve [i.e., given a we find y and, via (d), we find x].

For a *two*-DOF example, see Schräpel (1988).

Problem 7.9.20 *Galerkin Method.* Consider the forced and nonlinearly damped oscillator

$$\ddot{q} + \omega_o{}^2 q + f_1\,\dot{q} + f_3\,(\dot{q})^3 = Q_o\,\sin(\omega t), \tag{a}$$

where $\omega_o{}^2, f_1, f_3, Q_o, \omega$ are specified positive constants (with the usual and/or easily understood meanings). Show that the Galerkin method applied to (a) for the trial steady-state solution

$$q = a\,\sin(\omega\,t) + b\,\cos(\omega\,t), \tag{b}$$

yields the following algebraic system for the unknown amplitudes a, b:

$$a\,(\omega_o{}^2 - \omega^2) - b f_1\omega - (3/4) f_3\,\omega^3 b\,(a^2 + b^2) - Q_o = 0, \tag{c}$$

$$a f_1\omega + b\,(\omega_o{}^2 - \omega^2) + (3/4) f_3\,\omega^3\,a\,(a^2 + b^2) = 0. \tag{d}$$

Discuss these results for various limiting cases.

Example 7.9.13 *The Variational Principles of Gray–Karl–Novikov (GKN, 1996).* Quite generally, we obviously have

$$\int (T - V)\,dt = \int (2T)\,dt - \int (T + V)\,dt;$$

or, recalling earlier definitions (§7.9), and with the still general but convenient time-integration limits $t_1 = 0$, $t_2 = t \;\Rightarrow\; t_2 - t_1 = t$,

$$A_H = A_L - A_E \equiv A_L - t\langle E\rangle, \tag{a}$$

where

$$A_E \equiv \int_0^t (T + V)\,dt \equiv \int_0^t (E)\,dt \equiv t\,\langle E\rangle. \tag{a1}$$

Therefore, Δ-varying the above, we obtain the following basic relation:

$$\Delta A_H = \Delta A_L - \Delta t \langle E\rangle - t\,\Delta\langle E\rangle \;\Rightarrow\; \Delta A_H + \langle E\rangle \Delta t = \Delta A_L - t\,\Delta\langle E\rangle. \qquad \text{(b)}$$

Now, and recalling, again, the general results of (3.9.11b ff.; 7.2.6e, f; and 7.9.4a ff.), let us see how (b) specializes for a holonomic, scleronomic, and potential system; that is, one completely describable by the Lagrangean: $L = L(q, \dot q) \Rightarrow \partial L/\partial t = 0 \Rightarrow dh/dt = -\partial L/\partial t = 0 \Rightarrow h \equiv \sum (\partial L/\partial \dot q_k)\dot q_k - L = 2T - (T - V) = T + V \equiv E$ (i.e., generalized energy = ordinary energy) = *constant* $\Rightarrow h(t_2) = h(t_1) = \langle h\rangle = \langle E\rangle$ [recalling (7.9.12b)], and for fixed endpoint variations (i.e., $\Delta q_{1,2} = 0$, and with no loss in generality, $\Delta t_1 = 0$, $\Delta t_2 = \Delta t$) from an actual trajectory (orbit; i.e., $E_k(L) = 0$). We easily see that, then, (7.9.4b, 11h) reduce to (7.9.12d):

$$\Delta A_H = -\{h\,\Delta t\}_1^2 = -h\,\Delta t = -\langle E\rangle\,\Delta t \;\Rightarrow\; \Delta A_H + \langle E\rangle\,\Delta t = 0 \quad \text{(Hamiltonian)} \qquad \text{(c1)}$$

$$\Rightarrow \Delta A_L - t\,\Delta\langle E\rangle = 0 \quad \text{(Lagrangean)}, \qquad \text{(c2)}$$

that is, for such systems and variations, *both the left and right sides of (b) vanish independently*.

Next, a little reflection (with invocation of the reasoning of the theory of constrained stationarity conditions and method of Lagrangean multipliers) will convince us that the *two unconstrained* variational equations (c) lead to the following *four constrained GKN* variational principles:

(i) $(\Delta A_H)_{t=\text{constant}} = 0$ (Hamilton), (d1)

(ii) $(\Delta t)_{\textit{Hamiltonian}\ \text{action}=\text{constant}} = 0$ ("Reciprocal Hamilton"), (d2)

(iii) $(\Delta A_L)_{\langle E\rangle=\text{constant}} = 0$ ("Reformulated MEL"), (d3)

(iv) $(\Delta\langle E\rangle)_{\textit{Lagrangean}\ \text{action}=\text{constant}} = 0$ ("Reciprocal MEL"). (d4)

[We notice that (a) eq. (d1) is a specialization of the method presented in the earlier probs. 7.9.12 and 7.9.13; and that (b) eq. (d3), with $\langle E\rangle = constant$, is slightly more general than the ordinary MEL principle ($E = constant$).] The following applications to simple problems of nonlinear oscillations illustrate the use of the above, especially (d3) and (d4) [one of the main contributions of GKN (1996)]:

(i) *One-dimensional quartic oscillator*, with $2T = m\,(\dot q)^2$ (m: mass), $4V = c\,q^4$ (c: positive constant). With trial trajectory solution, $q = a\,\sin(\omega t) \;\Rightarrow\; \dot q = a\,\omega\cos(\omega t)$, where ω (frequency, and $\tau \equiv 2\pi/\omega$: period) and a (amplitude) are the hitherto unknown parameters to be determined by the above variational principles, and with the simpler notation $A_L \equiv W$ (from the German *Wirkung* = *action*), and integration limits $t_1 = 0$, $t_2 = 2\pi/\omega$, we find

$$W \equiv \int_0^\tau 2T\,dt = \int_0^{2\pi/\omega} [m\,(\dot q)^2]\,dt = \int_0^{2\pi/\omega} [m\,a^2\,\omega^2\cos^2(\omega t)]\,dt = m\,a^2\,\pi\omega, \qquad \text{(e1)}$$

$$\Rightarrow a^2 = W/m\,\pi\,\omega; \qquad \text{(e2)}$$

$$\langle E\rangle \equiv (1/\tau)\int_0^\tau (T + V)\,dt = (1/\tau)\int_0^{2\pi/\omega} \left[(1/2)\,m\,(\dot q)^2 + (1/4)\,c\,q^4\right] dt$$

$$= \cdots \text{[and utilizing (e2)]} = W\,\omega/4\pi + (3/32)(c\,W^2/\pi^2 m^2\omega^2). \qquad \text{(e3)}$$

Then, applying (d4) [which, in view of the above results, is the easiest among (d1–4) to implement], we obtain the frequency that makes (e3) stationary (and, here, a minimum):

$$0 = (\partial\langle E\rangle/\partial\omega)_{W=\text{constant}} = (W/4\pi)\left[1 - (3/4)\left(c\,W/\pi m^2\omega^3\right)\right], \tag{e4}$$

$$\Rightarrow \omega = (3\,c\,W/4\,\pi\,m^2)^{1/3}, \tag{e5}$$

$$\Rightarrow \langle E\rangle = (1/2)(c/m^2)^{1/3}\,(3A_L/4\pi)^{4/3} = (1/2)(m^2/c)\omega^4, \tag{e6}$$

$$\Rightarrow \tau = 2\pi/\omega = 2\pi\,(m^2/2c\langle E\rangle)^{1/4}. \tag{e7}$$

Since the exact value of τ is {see Gray et al. [1996(a)], or books on nonlinear oscillations}:

$$\tau_{\text{exact}} = \left[\Gamma(1/2)\,\Gamma(1/4)/\Gamma(3/4)\right]\,(m^2/c\,\langle E\rangle)^{1/4} \qquad [\Gamma(\ldots)\text{: Gamma function}], \tag{e8}$$

$$\Rightarrow \tau/\tau_{\text{exact}} = (2\pi/2^{1/4})\,\left[\Gamma(3/4)/\Gamma(1/2)\,\Gamma(1/4)\right] = 1.0075, \tag{e9}$$

the error committed is less than 1%.

The reader is urged to verify that these results can also be obtained by applying (d1)—in which case, the constraint $t = constant$ implies $\tau = constant \Rightarrow \omega = constant$, in our trial solution; that is, $A_H = A_H(a;\,\omega)$, and so (d1) translates to $dA_H/da = 0$. (Compare with the more general method discussed in probs. 7.9.12 and 7.9.13.)

(ii) *Anharmonic oscillator*, with $2T = m\,(\dot{q})^2$, $V = (1/2)\,m\,\omega_o{}^2\,q^2 + (1/4)\lambda\,q^4$ [which can be viewed as the *quartic* approximation to the potential energy of a plane mathematical pendulum, $V_{\text{exact}} = m\,l^2\,\omega_o{}^2\,(1 - \cos\theta)$, where, as usual, m, l, θ are the mass, length, and angle with vertical, of the pendulum; $\omega_o \equiv (g/l)^{1/2}$ (frequency in *quadratic* approximation of $\cos\theta$ to V_{exact}), $q \equiv l\,\theta$, and $\lambda \equiv -m\,\omega_o{}^2/6l^2$]. Again, with trial solution, $q = a\,\sin(\omega t) \Rightarrow \dot{q} = a\,\omega\cos(\omega t)$, where ω (frequency) and a (amplitude) are the hitherto unknown parameters to be determined by the GKN variational principles, and integration limits $t_1 = 0$, $t_2 = 2\pi/\omega$, we find

$$W = \int_0^{2\pi/\omega} [m\,(\dot{q})^2]\,dt = \int_0^{2\pi/\omega} [m\,a^2\omega^2\cos^2(\omega t)]\,dt = m\,a^2\pi\,\omega \tag{f1}$$

$$\Rightarrow a^2 = W/m\,\pi\,\omega; \tag{f2}$$

$$\begin{aligned}\langle E\rangle &\equiv (1/\tau)\int_0^{\tau}(T + V)\,dt\\ &= (1/\tau)\int_0^{2\pi/\omega}\left[(1/2)\,m\,(\dot{q})^2 + (1/2)\,m\,\omega_o{}^2\,q^2 + (1/4)\lambda\,q^4\right]\,dt\\ &= \cdots\,[\text{and utilizing (f2)}] = (A_L/4\pi)\,\left[\omega + \omega_o{}^2/\omega + (3\lambda W/8\pi m^2\omega^2)\right].\end{aligned} \tag{f3}$$

Here, too, applying (d4) with ω as variational parameter, we get

$$0 = (\partial\langle E\rangle/\partial\omega)_{W=\text{constant}}$$

$$\Rightarrow \omega^2 = \omega_o{}^2 + (3\lambda W/4\pi\,m^2\omega) = \omega_o{}^2 + (3\lambda/4m)\,a^2, \tag{f4}$$

which agrees with earlier-found approximate values (exs. 7.9.11, probs. 7.9.17 and 7.9.18; also exs. 8.16. and 8.16.2). For the pendulum, (f4), with $\lambda \equiv -m\,\omega_o{}^2/6l^2$ and $a/l \equiv \theta_{\max}$, gives

$$\omega = \omega_o\,(1 - \theta_{\max}{}^2/8)^{1/2} = \omega_o\,(1 - \theta_{\max}{}^2/16 - \theta_{\max}{}^4/512 + \cdots), \tag{f5}$$

and, hence, corresponding period $\tau(\theta_{\max}) \equiv \tau$ (with $\tau_o \equiv 2\pi/\omega_o$):

$$\tau = 2\pi/\omega = \tau_o\,(1 - \theta_{\max}{}^2/8)^{-1/2} = \tau_o(1 + \theta_{\max}{}^2/16 + 3\theta_{\max}{}^4/512 + \cdots), \tag{f6}$$

which is correct to $\theta_{\max}{}^2$ (since the trial solution is correct to the zeroth order in λ, and our variational principle makes sure that first-order such errors vanish). A better approximation to the exact expansion (the latter obtained through integration of the well-known nonlinear equation of motion, via an elliptic integral)

$$\tau_{\text{exact}} = \tau_o\big[1 + \theta_{\max}{}^2/16 + (11/18)(3\theta_{\max}{}^4/512) + \cdots\big], \tag{f7}$$

is obtained by keeping the $\theta^6/6!$ term in the $\cos\theta$ expansion, in $V_{\text{exact}} \to V$; also by adding to the trial solution higher harmonics: for example, $b\,\sin(3\omega t)$ (b: corresponding amplitude) (recall ex. 7.9.11, prob. 7.9.19). For further examples and insights, see Gray et al. [1996(a),(b)].

Example 7.9.14 *Method of Slowly Varying Parameters (Amplitude and Phase) in Weakly Nonlinear (Quasi-linear) Oscillators.* Let us consider the general equation [recalling ex. 7.9.10: k ff.)]

$$\ddot{q} + \omega_o{}^2\,q = \varepsilon\,f(q,\,\dot{q}), \tag{a}$$

where

- ω_o: natural (constant) frequency of (a) when $\varepsilon\,f(q,\,\dot{q}) = 0$;
- $f(\ldots)$: arbitrary *nonlinear* (but integrable) function of its arguments; and
- ε: very small positive constant, so that (a) differs by very little from a linear equation (hence the name *quasilinear*).

Due to the presence of damping—namely, $\dot{q}$-proportional terms—the solutions of (a) are, in general, no longer periodic and, accordingly, the earlier-described methods of Hamilton/least action and Ritz/Galerkin do not apply, except asymptotically, as in the limit cycle case (e.g., van der Pol oscillator)—that is, *they need modification to account for the generally nonvanishing boundary terms* (see also the remarks at end of this example).

Below, we describe an approximate *averaging* method for the solution of (a), originated by van der Pol (in the early 1920s) and thoroughly extended and perfected by a host of distinguished Soviet scientists: Krylov, Bogoliubov, Mitropolskii, Andronov, Vitt, Mandelstam, Papaleksi, Malkin et al. (between the two World Wars), in connection with problems of electrical and mechanical engineering. In fact, this area of *asymptotic methods in nonlinear oscillations* was fairly considered as a Soviet (→Russian) specialty.

[That eq. (a) may, under certain conditions, have some periodic solutions (e.g., limit cycles) is far from obvious—in fact, it took a giant of mathematics, H. J.

Poincaré (late 19th century), to show that. A small change in the *form* of a (linear or nonlinear) differential equation may change radically the qualitative nature of its solutions; for example, the equation $\ddot{q} + \omega_o{}^2 q = 0$ possesses only periodic solutions, but the equation $\ddot{q} + \mu\,\dot{q} + \omega_o{}^2 q = 0$ *does not possess any such solutions, no matter how small (but nonzero) the friction/damping coefficient* μ *is!*]

As is well known, the solution of the *undamped* problem—that is, (a) with $\varepsilon = 0$—is

$$q = a \cos\chi, \qquad \chi \equiv \omega_o t + \phi, \tag{b}$$

where, a is the constant amplitude, ϕ is the constant phase, (both determined from the initial conditions), ω_o is the natural linear frequency (a given constant), and χ is the total phase.

For the damped nonlinear equation (a), we apply the Lagrangean *method of variation of constants* or *parameters* (for a general discussion of this, in terms of both Lagrangean and Hamiltonian variables, see §8.7): we try a solution *of the same form as the "generating solution"* (b) but with a and ϕ replaced by unknown functions of time; that is,

$$q = a(t) \cos\chi(t), \qquad \chi(t) = \omega_o t + \phi(t). \tag{c}$$

By $(\ldots)^{\cdot}$-differentiating eqs. (b) and (c) we find, respectively,

$$(\mathrm{b})^{\cdot}: \qquad \dot{q} = -a\,\omega_o \sin\chi, \tag{d}$$

$$(\mathrm{c})^{\cdot}: \qquad \dot{q} = -a\,\omega_o \sin\chi + (\dot{a}\cos\chi - a\,\dot{\phi}\sin\chi). \tag{e}$$

Now, to determine $a(t)$ and $\phi(t)$, we impose the *first* ("arbitrary") requirement: the "nonlinear" velocity $\dot{q}$, eq. (e), should have the same form as the "linear" velocity, eq. (d); that is,

$$\dot{a}\cos\chi - a\,\dot{\phi}\sin\chi = 0, \qquad \chi(t) = \omega_o t + \phi(t). \tag{f}$$

The *second* equation for $a(t)$, $\phi(t)$ is obtained by inserting (c) and (e) [under (f)] back into (a): since

$$\begin{aligned}(\mathrm{e})^{\cdot}: \qquad \ddot{q} &= -\dot{a}\,\omega_o \sin\chi - a\,\omega_o{}^2 \cos\chi - a\,\omega_o\,\dot{\phi}\sin\chi \\ &= -\dot{a}\,\omega_o \sin\chi - a\,\omega_o{}^2 \cos\chi - \dot{a}\,\omega_o \cos\chi \qquad \text{[by the first of (f)]},\end{aligned}$$

we obtain

$$\dot{a}\sin\chi + a\,\dot{\phi}\cos\chi = -(\varepsilon/\omega_o) f(a\cos\chi, -a\,\omega_o\sin\chi) \equiv -(\varepsilon/\omega_o)F(a,\ \chi). \tag{g}$$

Solving the system of the first of (f) and (g) for $\dot{a}$ and $\dot{\phi}$ yields the *first-order* coupled nonlinear equations

$$\dot{a} = -(\varepsilon/\omega_o)F(a,\ \chi)\sin\chi, \qquad \dot{\phi} = -(\varepsilon/a\,\omega_o)F(a,\ \chi)\cos\chi \quad (= \dot{\chi} - \omega_o). \tag{h}$$

So far, *no approximations have been involved*: the exact solution of the system (h), if available, would be the exact solution of its equivalent original equation (a) for any value of ε; *conditions (f) and (g) may be arbitrary but they are consistent*.

[A geometrical interpretation: In terms of the "canonical" variables q and $p \equiv \dot{q}$, the original equation (a) becomes the *first-order* system

$$\dot{p} = -\omega_o{}^2 q + \varepsilon f(q,\ p) \equiv P(q,\ p) \qquad \text{(equation of motion)}, \tag{h1}$$

$$\dot{q} = p \equiv Q(q,\ p) \qquad \text{(kinematical equation)}. \tag{h2}$$

Then, eqs. (c) are simply a *transformation among dependent* variables — from the old q, p to the new $a,\ \phi$ or $a,\ \chi$ — and (h1, 2) transforms to (h). Geometrically, if (q, p) are viewed as the rectangular Cartesian coordinates of a point in a (fixed) q, p-plane (called "phase space"; see chap. 8) then, as eqs. (c) show, for $\omega_o = 1$ (which can always be accomplished by an independent variable change) $(a,\ \chi)$ become its polar coordinates in that plane, and $(a,\ \phi)$ become its polar coordinates in the (rotating) "van der Pol plane."]

Equations (h) are, usually, quite complicated and *cannot* be solved exactly. To make some headway toward their solution we now introduce the *smallness* assumption: if the nonlinear term $\varepsilon f(\ldots)$ remains small, absolutely, relative to both $\ddot{q}$ (inertia) and $\omega_o{}^2 q$ (linear elasticity), then $\dot{a}$ and $\dot{\phi}$ are also small; that is, a and ϕ *change very slowly during a (linear) period* $\tau_o = 2\pi/\omega_o$; χ will increase, approximately, by 2π. Mathematically, we assume that ε is small enough that

$$|da/dt| \ll |a|/\tau_o \ \Rightarrow\ (2\pi/\omega_o)|\dot{a}/a| \ll 1, \tag{i1}$$

$$|d\phi/dt| \ll 2\pi/\tau_o \ \Rightarrow\ |\dot{\phi}|/\omega_o \ll 1; \tag{i2}$$

and analogously for the higher derivatives:

$$|d^2a/dt^2| \ll |\dot{a}|/\tau_o \equiv |\dot{a}|(\omega_o/2\pi)$$
$$\Rightarrow |d^2a/dt^2| \ll |a|(\omega_o/2\pi)^2. \tag{i3}$$

This key assumption allows us to proceed from (h) as follows:

(i) First, and since the nonlinear right sides of (h) are periodic in χ with period 2π, we expand them into Fourier series in χ:

$$F(a,\ \chi)\sin\chi = A_o(a) + \sum \left[A_k(a)\cos(k\chi) + B_k(a)\sin(k\chi)\right], \tag{j1}$$

$$F(a,\ \chi)\cos\chi = \Phi_o(a) + \sum \left[\Phi_k(a)\cos(k\chi) + \Psi_k(a)\sin(k\chi)\right], \tag{j2}$$

where $k = 1, 2, 3, \ldots$, and the expansion coefficients ("amplitudes") A_o, Φ_o; A_k, B_k; Φ_k, Ψ_k are determined in well-known ways [recall ex. 7.9.12: (d2), (d3)]. In particular, it is known that the first terms (constant in χ) equal the *average* (mean value) of the corresponding expanded functions, over 2π:

$$A_o(a) = (1/2\pi)\int_0^{2\pi} F(a,\ \chi)\sin\chi\, d\chi, \qquad \Phi_o(a) = (1/2\pi)\int_0^{2\pi} F(a,\ \chi)\cos\chi\, d\chi. \tag{j3}$$

(ii) Next, substituting the series (j1, 2) back into (h) and integrating both sides between 0 and 2π, while invoking (j3) and noting that all integrals containing trigonometric terms vanish, we obtain the (still exact) system

$$\int_0^{2\pi} \dot{a}\, d\chi = -(\varepsilon/\omega_o)\, 2\pi A_o(a), \qquad \int_0^{2\pi} \dot{\phi}\, d\chi = -(\varepsilon/a\,\omega_o)\, 2\pi \Phi_o(a). \tag{j4}$$

(iii) Last, we use the smallness (slowness) assumption to transform the left sides of (j4). We have, successively (since $2\pi = \omega_o\, \tau_o = \omega\,\tau \ \Rightarrow\ d\chi = \omega\, dt = (2\pi/\tau)\, dt$, $\omega \equiv \dot{\chi} = \omega_o + \dot{\phi}$),

$$\int_0^{2\pi} \dot{a}\, d\chi = (2\pi/\tau)\int_0^{\tau} \dot{a}\, dt = 2\pi\big\{[a(t+\tau) - a(t)]/\tau\big\}$$
$$= 2\pi\big\{[a(t+\tau_o) - a(t)]/\tau_o\big\}, \tag{j5}$$

and similarly for the integral of $\dot{\phi}$. But, since a and ϕ do not change appreciably during τ or τ_o, $\Delta a \equiv a(t+\tau) - a(t)$ and $\Delta\phi \equiv \phi(t+\tau) - \phi(t)$ are small, and also τ and τ_o are small relative to the total process duration, which involves several periods (i.e., $\tau \to \Delta\tau$), and so (j4, 5) are replaced by the (finite difference) equations

$$\Delta a/\Delta\tau = -(\varepsilon/\omega_o)A_o(a), \qquad \Delta\phi/\Delta\tau = -(\varepsilon/a\omega_o)\Phi_o(a), \tag{j6}$$

which, in the limit, produce the first approximation (differential) equations

$$da/dt = -(\varepsilon/\omega_o)A_o(a), \qquad d\phi/dt = -(\varepsilon/a\omega_o)\Phi_o(a). \tag{j7}$$

Comparing the above with the exact equations (h), we see that the former result from the latter by averaging over a period, and while doing that regard a as a constant; that is, eqs. (j6, 7) do *not* describe the *instantaneous physical behavior of the system*, but, rather, its *evolution over the several cycles of the duration of the process*; what the distinguished nonlinear mechanics expert N. Minorsky calls "the behavior of the *envelope of modulation*."

Substituting (j3) into (j7), we finally obtain the famous *van der Pol/Krylov/Bogoliubov* equations, or *slowly varying equations* (SVE):

$$da/dt = -(\varepsilon/2\pi\,\omega_o)\int_0^{2\pi} F(a,\ \chi)\sin\chi\ d\chi \equiv \varepsilon A(a), \tag{k1}$$

$$d\phi/dt = -(\varepsilon/2\pi a\,\omega_o)\int_0^{2\pi} F(a,\ \chi)\cos\chi\ d\chi \equiv \varepsilon\Phi(a). \tag{k2}$$

The *first* of these equations gives the variation of a in time [also, the solutions of $\dot{a} = 0 \Rightarrow A(a) = 0$ yield the *stationary amplitude* oscillations (possible limit cycles)]; while the *second* of them yields the corresponding frequency correction: then,

$$\chi = \omega_o t + \phi(t):\ \textit{total phase angle}$$
$$\Rightarrow \dot{\chi} \equiv \omega = \omega_o + \dot{\phi}:\ \textit{instantaneous}\ \text{frequency}. \tag{k3}$$

Finally, and this is quite useful, we note that if $f(q,\ \dot{q}) = f_1(q) + f_2(\dot{q})$ [*nonlinear* in their corresponding arguments; e.g., f_1 contains powers of q like $q^2,\ q^3, \ldots,$ and f_2 contains powers of $\dot{q}$ like $(\dot{q})^2,\ (\dot{q})^3, \ldots$], then, due to the identities

$$\int_0^{2\pi} f_1(a\ \cos\chi)\sin\chi\ d\chi = 0, \qquad \int_0^{2\pi} f_2(-a\,\omega_o\sin\chi)\cos\chi\ d\chi = 0, \tag{k4}$$

- da/dt is unaffected by the nonlinear additions to the linear elastic force, $f_1(q)$, but $d\phi/dt$ is affected:
- $d\phi/dt$ is unaffected by the nonlinear additions to the linear damping force, $f_2(\dot{q})$, but da/dt is affected. For example, if $f_1 = 0$, then $\dot{\phi} = 0 \;\Rightarrow\; \dot{\chi} \equiv \omega = \omega_o$ for any small but nonzero nonlinear damping $f_2(\dot{q})$.

In sum, for small ε (first approximation), *nonlinear restoring (spring) terms* affect the *frequency but not the amplitude*; while *nonlinear damping terms* affect the *amplitude but not the frequency*. [For larger ε, however, this is no longer true: either type of terms affects *both* amplitude and frequency.]

REMARK

The above-described method constitutes the *first* approximation of a general asymptotic scheme due to Bogoliubov and Mitropolsky. For extensions to periodically forced oscillators [i.e., $\varepsilon f(\ldots) = \varepsilon f(t, q, \dot{q}) = \varepsilon f(\Omega t, q, \dot{q}) = (2\pi/\Omega)$—periodic function of time, Ω: specified] and to *several degrees of freedom*, see Bogoliubov and Mitropolsky (1974), which is the undisputable "bible" on the subject; also Fischer and Stephan (1972, pp. 144–150, 217–229). For combinations of the method of slowly varying parameters, and averaging in general, (a) with the method of Galerkin, see, for example, Chen and Hsieh (1981), and (b) with the various Δ-forms of Hamilton's principle (this section), as well as the methods of perturbations, strained coordinates, and multiple time scales, see Rajan and Junkins (1983). The combinations among these methods seem endless, but as Rajan and Junkins aptly remark "On the average, it appears algebraic misery may be conserved; we do not claim that the above processes (for a given problem) will result in less algebraic effort. On the other hand, the developments offer numerous insights and exceptional latitude in solution procedures (through the infinity of possible choices for the generators of the variations)" (1983, p. 350). See also "Closing General Remarks," below.

Illustrations

1. Nonlinearly Damped Duffing Oscillator

Let us solve, approximately,

$$\ddot{q} + \varepsilon\,\nu\,\dot{q}|\dot{q}| + \omega_o{}^2\,q + \varepsilon\,\kappa\,q^3 = 0, \tag{11}$$

where $-\nu\,\dot{q}|\dot{q}|$ is a small damping force, proportional to the square of $\dot{q}$, and oppositely directed to $\dot{q}$ (hence the use of $|\dot{q}|$); and ν is a damping coefficient; this is frequently called "turbulence damping." Here,

$$\begin{aligned} &f(q,\ \dot{q}) = -\kappa\,q^3 - \nu\,\dot{q}|\dot{q}| \\ &\Rightarrow\ F(a,\chi) = -\kappa\,a^3\cos^3\chi + \nu\,a^2\omega_o{}^2\sin\chi\,|\sin\chi|, \end{aligned} \tag{12}$$

and so (k1, 2) yield the averaged system

$$da/dt = -(4/3\pi)\varepsilon\,\nu\,\omega_o\,a^2 \quad \text{(i.e., } da/dt \text{ is affected by the nonlinear damping)}, \quad \text{(m1)}$$
$$d\phi/dt = (3/8)\varepsilon\,\kappa(a^2/\omega_o) \quad \text{(i.e., } d\phi/dt \text{ is affected by the nonlinear elasticity)}. \quad \text{(m2)}$$

The first of these equations integrates readily to

$$a = a_o\{1 + [(4\varepsilon\nu/3\pi)\omega_o a_o]t\}^{-1}, \qquad a_0: \text{ initial displacement,} \tag{m3}$$

and so the second becomes (to the first ε-order)

$$d\phi/dt = (3/8)\varepsilon\kappa(a_o{}^2/\omega_o), \tag{m4}$$

and integrates easily to

$$\phi = \left[(3/8)\varepsilon\kappa(a_o{}^2/\omega_o)\right] t + \phi_o, \qquad \phi_0: \text{ initial phase;} \tag{m5}$$

and, therefore,

$$q(0) = a(0)\cos\phi(0) = a_o\cos\phi_o = a_o \;\Rightarrow\; \phi_o = 0. \tag{m6}$$

The above show that *the bigger the* a_o, *the faster the amplitude decreases*; also, for $\nu = 0$ (undamped oscillator), $a = a_o$ and $\omega^2 = (\dot{\chi})^2 = (\omega_o + \dot{\phi})^2 = \omega_o{}^2 + (3/4)\varepsilon\kappa a^2 + (\dot{\phi})^2$, or, to the first ε-order, $\omega^2 \approx \omega_o{}^2 + (3/4)\varepsilon\kappa a^2$.

For a generalization of (l1) that includes *linear* and *cubic* damping (problem of rolling of a ship equipped with a gyrostabilizer), see, for example, McLachlan (1956/1958, pp. 92–94).

2. Van der Pol Equation

Here, the equation of motion is

$$\ddot{q} + \varepsilon(q^2 - 1)\dot{q} + \omega_o^2 q = 0, \tag{n1}$$

that is,

$$\begin{aligned} f(q, \dot{q}) &= (1 - q^2)\dot{q} \\ \Rightarrow F(a,\ \chi) &= -a\omega_o\sin\chi - (-a\omega_o\sin\chi)(a^2\cos^2\chi) \\ &= (1 - a^2\cos^2\chi)(-a\omega_o\sin\chi), \end{aligned} \tag{n2}$$

and so eqs. (k1, 2) yield

$$\begin{aligned} da/dt &= -(\varepsilon/2\pi\omega_o)\int_0^{2\pi}(1 - a^2\cos^2\chi)(-a\omega_o\sin\chi)\sin\chi\, d\chi \\ &= (\varepsilon a/2)(1 - a^2/4), \end{aligned} \tag{o1}$$

$$\begin{aligned} d\phi/dt &= -(\varepsilon/2\pi a\omega_o)\int_0^{2\pi}(1 - a^2\cos^2\chi)(-a\omega_o\sin\chi)\cos\chi\, d\chi \;=\; 0 \\ &\Rightarrow \chi = \omega_o t + \phi_o; \end{aligned} \tag{o2}$$

that is, to the first ε-order, the nonlinearity does not change the frequency: $\omega = \omega_o$.

With the arbitrary initial conditions $a(0) = a_o$, $\phi(0) = \phi_o = \chi(0)$, and the well-known "energy identity" $2a\dot{a} = d(a^2)/dt$, eq. (o1) transforms to

$$d(a^2)/dt = \varepsilon a^2(1 - a^2/4) \qquad [\text{i.e., } \dot{b} = \varepsilon b\,(1 - b/4), \text{ with } b \equiv a^2], \tag{o3}$$

and integrates readily to

$$a = a_o \exp(\varepsilon t/2)\{1 + (a_o{}^2/4)\,[\exp(\varepsilon t) - 1]\}^{-1/2}$$
$$\Rightarrow q(t) = a(t)\cos(\omega_o t + \phi_o). \qquad \text{(p)}$$

The stationary, or steady-state, amplitude solutions of the problem, obtained from (o1) for $\dot{a} = 0$, are (i) $a = 0$ (equilibrium), and (ii) $a = 2$ (limit cycle).

This can also be seen from the transient amplitude equation (p): by rewriting it as

$$a = a(t) = 2\left[1 - \exp(-\varepsilon t)(1 - 4/a_o{}^2)\right]^{-1/2}, \qquad \text{(q)}$$

we can readily see that for $t \to \infty$, $a \to 2$ *always*; that is, this is so, no matter how small (but nonzero) or large a_o may be, even if $a_o > 2$. If $a_o = 0$, then $a(t) = 0$ (no oscillation) — the oscillation must be initiated by *external* means. [For additional examples and questions on (limit cycle) stability, see standard texts on nonlinear mechanics, for example, Kauderer (1958, pp. 295–304), Stoker (1950); also Butenin et al. (1985, pp. 485–491).]

Problem 7.9.21 *Method of Slowly Varying Parameters (SVP).* By applying SVP to the linear damped oscillator:

$$\ddot{q} + 2f\,\dot{q} + \omega_o{}^2\,q = 0 \qquad (f\text{: small friction constant}), \qquad \text{(a)}$$

with initial conditions $q(0) = A$, $\dot{q}(0) = 0$, show that the "slowly varying equations" (SVE) [ex. 7.9.14: (k1), (k2)], yield

$$\dot{a} = -f\,a \;\Rightarrow\; a = a_o\,\exp(-f\,t), \qquad \dot{\phi} = 0 \Rightarrow \phi = constant; \qquad \text{(b)}$$

from which, and the small friction requirement $f/\omega_o \ll 1$, we find

$$q = A\,\exp(-f\,t)\,\cos(\omega_o t - f/\omega_o); \qquad \text{(c)}$$

that is, here, damping causes a change in the amplitude, not in the frequency.

Then show that, here, the smallness requirement [ex. 7.9.14: (i1)], $|\dot{a}/a|$ $(2\pi/\omega_o) \ll 1$, leads to the sharper restriction

$$2f \ll \omega_o/\pi = 2/\tau_o \qquad \text{(physical meaning and dimensions of "small friction").} \qquad \text{(d)}$$

Finally, compare the approximate solution (c) with the well-known exact solution of this problem,

$$q = \left[A\omega_o/(\omega_o{}^2 - f^2)^{1/2}\right]\exp(-f\,t)\cos\left[(\omega_o{}^2 - f^2)^{1/2}t - \tan^{-1}(f/\omega_o)\right], \qquad \text{(e)}$$

and show that under $f/\omega_o \ll 1$ the above solution reduces to the approximate one.

Problem 7.9.22 *Method of Slowly Varying Parameters.* By applying SVP to the quadratically damped and unforced oscillator

$$\ddot{q} + \omega_o{}^2\,q + 2f(\dot{q})^2 = 0, \qquad \text{(a)}$$

with (the usual notations, and) initial conditions $q(0) = A$, $\dot{q}(0) = 0$, show that the SVE yield

$$da/dt = -(8/3) f\, \omega_o\, a^2 \;\Rightarrow\; a = a_o[1 + (8/3) f\, \omega_o\, a_o\, t]^{-1}, \qquad a(0) = a_o = A, \tag{b}$$

$$d\phi/dt = 0 \;\Rightarrow\; \phi = constant. \tag{c}$$

Compare this result with the preceding case of *linear* damping: $2 f\, \dot{q}$.

Problem 7.9.23 *Method of Slowly Varying Parameters.* By applying SVP to the undamped and unforced Duffing oscillator

$$\ddot{q} + \omega_o{}^2\, q + c\, q^3 = 0, \tag{a}$$

with initial conditions $q(0) = A$, $\dot{q}(0) = 0$, show that the SVE yield

$$da/dt = 0 \;\Rightarrow\; a = constant \equiv a_o = A, \tag{b}$$

$$d\phi/dt = 3\, c\, a^2/8\omega_o \;\Rightarrow\; \phi = (3\, c\, a^2/8\omega_o)\, t + constant \;\Rightarrow\; \omega = \omega_o + \dot{\phi}. \tag{c}$$

Then show that, here, the smallness requirement $|\dot{\phi}| \ll \omega_o$ leads to $c \ll 8\omega_o{}^2/3a_o{}^2$.

Problem 7.9.24 *Method of Slowly Varying Parameters.* By applying SVP to the nonlinearly damped and unforced Rayleigh oscillator (e.g., electrically driven tuning fork)

$$\ddot{q} - 2 f\, \dot{q} + g\, (\dot{q})^3 + \omega_o{}^2\, q = 0, \tag{a}$$

where f, g are small positive constants, and $-2 f\, \dot{q}$ is *effective negative damping* (equivalent to a driving force), show that the SVE yield

$$da/dt = a\, [f - (3/8)\, g\, \omega_o{}^2\, a^2], \qquad d\phi/dt = 0. \tag{b}$$

and, therefore, (i) for a *stationary* (or steady-state) amplitude,

$$da/dt = 0 \;\Rightarrow\; a = (2/\omega_o)(2f/3\, g)^{1/2} \equiv a_{st}, \tag{c}$$

while (ii) for a *transient* one,

$$a\,(t) = a_o\, \exp(f\, t)\Big\{1 + R^2\, a_o{}^2[\exp(2f\, t) - 1]\Big\}^{-1/2}, \tag{d}$$

where $R^2 \equiv 3\, g\, \omega_o{}^2/8f$, $a(0) = a_o$.

Hence, if $a_o = 0$, then $a(t) = 0$; and if $a_o \neq 0$, then $a \to a_{st}$, as $t \to \infty$. Compare with the van der Pol oscillator. For further details, see, for example, McLachlan (1956/1958, pp. 90–91).

Problem 7.9.25 *Method of Slowly Varying Parameters.* By applying SVP to the linearly damped Duffing oscillator (with the usual notations and smallness assumptions, and $\omega_o{}^2 > f^2$)

$$\ddot{q} + 2f\, \dot{q} + \omega_o{}^2\, q + c\, q^3 = 0, \tag{a}$$

with initial conditions $q(0) = A$, $\dot{q}(0) = 0$, show that the SVE yield

$$da/dt = -f\,a, \qquad d\phi/dt = 3\,c\,a^2/8\,\omega_o. \tag{b}$$

Integrate these equations and discuss their results.

Closing General Remarks on Time-Integral and Variational Methods in Nonlinear Oscillations

1. All these methods assume that the degree of the nonlinearity is not too large.
2. The accuracy (error) of the so-obtained approximate solutions is, often, difficult to assess.
3. As mentioned earlier, the method of "Hamilton–Ritz" works best for *periodic* solutions; for example, steady states in forced systems — otherwise, we must include the boundary terms, and this increases the computational difficulty of the problem. The method of Galerkin, in general, does not have that drawback, but both methods (i.e., Ritz and Galerkin) require a good knowledge of the physical meaning of the equations and the qualitative behavior of their solutions so as to make a successful ("optimal") choice in the trial functions.
4. For *slowly varying* (*nonperiodic*) solutions — for example, transients in self-excited or damped systems, and limit cycles/points (if they exist) — the methods of van der Pol, Bogoliubov and Mitropolskii, work best. However, as the reader will have noticed, their mathematical operations are less simple than those of Ritz and Galerkin (and, worse, for *higher-order* approximations, these methods are, in general, *cost-ineffective*; that is, additional small corrections require disproportionately long and arduous calculations).

The moral of the above is that, as in most other areas of science, no single approach is uniformly best: in view of the (unknown) approximations involved, it is wiser, in dealing with a particular equation, to *use several complementary strategies/techniques*: those described here and the many more available in the enormous nonlinear mechanics literature, such as perturbations, harmonic balance (or equivalent linearization), and so on. For comprehensive and readable overviews of these classical methods, we refer the reader to (alphabetically): Blekhman (1979), Bogoliubov and Mitropolskii (1974), Klotter (1955), Magnus (1957).

APPENDIX 7.A

EXTREMAL PROPERTIES OF THE HAMILTONIAN ACTION (IS THE ACTION REALLY A MINIMUM; NAMELY, LEAST?)

7.A1 Introduction

The following is restricted to holonomic systems that can be completely described by a Lagrangean $L = L(t, q, \dot{q})$. Therefore, the discussion can be safely limited, for algebraic simplicity, to a *one*-DOF system S. Let

$$A_H = A_H(q) = A_H(I)$$
$$\equiv \int L\,dt: \quad \text{Hamiltonian action of } S, \text{ evaluated along an orbit } I,\ q(t)(\text{from } t_1 \text{ to } t_2). \tag{7.A1.1}$$

Then, as we have seen in this chapter, Hamilton's principle states that A_H *is stationary (or critical) for small (or first-order) variations around* I, $\delta q = \delta q(t)$, *that nullify the boundary terms*; that is, with $p \equiv \partial T/\partial \dot{q} = \partial L/\partial \dot{q}$ and boundary conditions, say, $\delta q_1 \equiv \delta q(t_1) = 0$ and $\delta q_2 \equiv \delta q(t_2) = 0$, this "principle" states that

$$\delta A_H = \int \delta L\,dt = \cdots = \{p\,\delta q\}_1^2 - \int E(L)\,\delta q\,dt$$
$$= 0 - \int E(L)\,\delta q\,dt = 0, \tag{7.A1.2}$$

from which we find

$$E(L) \equiv (\partial L/\partial \dot{q})^{\cdot} - \partial L/\partial q$$
$$= (\partial^2 L/\partial \dot{q}^2)\ddot{q} + (\partial^2 L/\partial q \partial \dot{q})\dot{q} + \partial^2 L/\partial t\,\partial \dot{q} - \partial L/\partial q = 0. \tag{7.A1.3}$$

As in the ordinary calculus (of functions), the *first-order* equation $\delta A_H = 0$, in δq and $\delta(\dot{q}) = (\delta q)^{\cdot}$, is only a *stationarity* condition — not an *extremality* one. That is, it does not tell us whether $A_H(q)$ is a maximum: $A_H(q + \delta q) > A_H(q)$, or a minimum: $A_H(q + \delta q) < A_H(q)$, or neither. Again, as in calculus, the answer to that comes (usually) from the study of the *second variation* of A_H, $\delta^2 A_H \equiv \delta(\delta A_H)$: *quadratic and homogeneous* functional in δq and $\delta(\dot{q}) = (\delta q)^{\cdot}$ (defined precisely below).

Now, the study of $\delta^2 A_H$, and corresponding extremal — namely, maximum/minimum — properties of A_H, has received little attention in the literature (it is conspicuously absent from most texts on advanced dynamics), primarily for the following reason: the laws of nature for S — namely, its *ever valid* equations of motion (7.A1.3) — result from (7.A1.2), or from the vanishing of some other equivalent first-order functional equation. On the other hand, the (possible) extremum properties of its A_H are *not* laws of mechanics, but only particular *conditions* that may hold for some orbits of S and not for others, or hold only along a certain part(s) of an orbit and not for all of it. Such *second (and possibly higher)-order* properties of A_H have been associated with *kinetic stability/instability* of S in some sense; that is, both stable and unstable orbits satisfy $\delta A_H = 0$, but the stable ones among them, if such exist, give $\delta^2 A_H$ one sign, and the unstable ones the opposite — pretty much like the theorems of the minimum of the total potential energy in static stability/buckling, and so on [Dirichlet (1846) → Bryan (1890s) → *Trefftz* (1930s) → Koiter (1940s)].

For detailed and readable treatments of the relevant *sufficiency variational theory*, see, for example (alphabetically): Elsgolts (1970), Fox (1950/1963), Funk (1962), Gelfand and Fomin (1963); also Hussein et al. (1980), Levit and Smilansky (1977); and for the connection with *kinetic stability (stability of motion)*, see the works of some of the older masters of mechanics, for example, Joukovsky (1937, pp. 110–208), Thomson and Tait (1912, pp. 416–439), Routh (1877, pp. 103–108); also Lur'e (1968, pp. 651–667, 749–754), Routh [1898, pp. 399–405; 1905(b), pp. 308–310], Watson and Burbury (1879, pp. 72–99), Whittaker (1937, pp. 250–253).

For the second variation of A_H of *nonholonomic* systems, see Novoselov (1966, pp. 26–49, and references cited therein).

7.A2 The Fundamental Minimum Theory (of Jacobi and A. Mayer)

Let us summarize the problem of the extremality, say, minimality of A_H. The *necessary* conditions for this are eqs. (7.A1.1) and (7.A1.2). The *sufficient* conditions come from the study of the sign of $\delta^2 A_H$. The latter is defined, equivalently, either as:

(i) The *quadratic and homogeneous* part in δq and $\delta(\dot{q})$ in the Taylor-like expansion of the *total contemporaneous* variation of A_H around I, $\delta^T A_H$,

$$\delta^T A_H \equiv A_H(q + \delta q) - A_H(q) = \delta A_H + (1/2)\,\delta^2 A_H + \cdots, \tag{7.A2.1a}$$

i.e., $\delta^2 A_H$; or by

(ii) The δ-variation of δA_H:

$$\begin{aligned}\delta^2 A_H \equiv \delta(\delta A_H) &= \int \delta^2 L\, dt\\ &= \cdots = -\int J(\delta q)\,\delta q\, dt + \{\delta p\,\delta q\}_1^2,\end{aligned} \tag{7.A2.1b}$$

where

$$\begin{aligned}\delta^2 L \equiv \delta(\delta L) &= \left[(\partial/\partial q)\,\delta q + (\partial/\partial \dot{q})\,\delta(\dot{q})\right]^2 L\\ &= \cdots = (\partial^2 L/\partial \dot{q}^2)(\delta\dot{q})^2 + 2(\partial^2 L/\partial q\,\partial\dot{q})\,\delta q\,\delta(\dot{q}) + (\partial^2 L/\partial q^2)(\delta q)^2:\\ &\qquad \textit{Second variation}\text{ of the Lagrangean,}\end{aligned} \tag{7.A2.1c}$$

and [invoking $\delta(\dot{q}) = (\delta q)^{\cdot}$]

$$\begin{aligned}J(\delta q) &= \left\{d/dt\,[\partial\ldots/\partial(\delta\dot{q})] - [\partial\ldots/\partial(\delta q)]\right\}(1/2)\,\delta^2 L\\ &= (\partial^2 L/\partial\dot{q}^2)\,\delta(\ddot{q}) + (\partial^2 L/\partial\dot{q}^2)^{\cdot}\,\delta(\dot{q}) + \left[(\partial^2 L/\partial q\partial\dot{q})^{\cdot} - (\partial^2 L/\partial q^2)\right]\delta q = 0:\\ &\qquad \textit{Jacobi's variational equation}\text{ (a \textit{linear} and \textit{homogeneous} but, generally,}\\ &\qquad \textit{variable coefficient differential equation}).\end{aligned} \tag{7.A2.1d}$$

REMARKS

(i) $\delta^T A_H$ is frequently denoted as ΔA_H; but here (§7.9) $\Delta(\ldots)$ has been reserved for the first *noncontemporaneous* variation. For the total such variation, we could use $\Delta^T(\ldots)$; that is,

$$\Delta^T A_H = \Delta A_H + (1/2)\,\Delta^2 A_H + \cdots, \tag{7.A2.2}$$

in variable time-endpoints problems (see, e.g., Santilli, 1978, pp. 41–43).

(ii) $J(\delta q)$ equals the *first*-order virtual variation of $E(L) = E[L(t,\ q,\ \dot{q})]$; or, $J(\delta q) = 0$ *is the Euler–Lagrange equation for* δq *of* $\delta^2 A_H$:

$$\begin{aligned}
&E[L(t,\ q + \delta q,\ \dot{q} + \delta(\dot{q}))] - E[L(t,\ q,\ \dot{q})]\\
&\qquad \approx \delta E(q,\ \delta q,\ \delta(\dot{q})) \qquad [\text{to first order in } \delta(\ldots)]\\
&\qquad = J(\delta q;\ q) \equiv J(\delta q),
\end{aligned} \tag{7.A2.3a}$$

where, successively,

$$\begin{aligned}
J(\delta q) &= \delta[(\partial L/\partial \dot{q})^{\cdot} - \partial L/\partial q]\\
&= [\delta(\partial L/\partial \dot{q})]^{\cdot} - \delta(\partial L/\partial q)\\
&= [(\partial^2 L/\partial q \partial \dot{q})\ \delta q + (\partial^2 L/\partial \dot{q}^2)\ \delta(\dot{q})]^{\cdot}\\
&\quad - [(\partial^2 L/\partial q^2)\ \delta q + (\partial^2 L/\partial q \partial \dot{q})\ \delta(\dot{q})]\\
&\qquad\qquad [\text{invoking}\ \ \delta(\dot{q}) = (\delta q)^{\cdot}]\\
&= (\partial^2 L/\partial \dot{q}^2)\ (\delta q)^{\cdot\cdot} + (\partial^2 L/\partial \dot{q}^2)^{\cdot}(\delta q)^{\cdot}\\
&\quad + \big[(\partial^2 L/\partial q \partial \dot{q})^{\cdot} - (\partial^2 L/\partial q^2)\big]\ \delta q\\
&= \big[(\partial^2 L/\partial \dot{q}^2)\ (\delta q)^{\cdot}\big]^{\cdot} - \big[(\partial^2 L/\partial q^2) - (\partial^2 L/\partial q \partial \dot{q})^{\cdot}\big]\ \delta q\\
&\qquad (\text{Sturm–Liouville form}),
\end{aligned} \tag{7.A2.3b}$$

and all partial derivatives are evaluated along the solution(s) of (7.A1.2, 3), Q.E.D.

Now, the relevant extremum results are contained in the following fundamental theorem.

THEOREM

For the action functional A_H to attain a *minimum* in the class of piecewise smooth functions $q(t)$ that join the points $[t_1,\ q(t_1) \equiv q_1]$ and $[t_2,\ q(t_2) \equiv q_2]$, and for nearby variations such that both $|\delta q|$ *and* $|\delta(\dot{q})| = |(\delta q)^{\cdot}|$ are small (i.e., for a *relative* and *strong* minimum), it is sufficient that:

(i) $q(t)$ satisfies the Euler–Lagrange equations (7.A1.3), $\delta A_H = 0 \Rightarrow E(q) = 0$; that is, $q(t)$ be an orbit, say I; (7.A2.4a)

(ii) The strengthened *Legendre–Weierstrass* condition holds: along I, for $t_1 \leq t \leq t_2$ and for *any* $\dot{q}$ in its neighborhood:

$$\partial^2 L/\partial \dot{q}^2 > 0; \tag{7.A2.4b}$$

(iii) The strengthened *Jacobi* condition holds: let $t_1{}^*$ be the *first* root, to the right of t_1, of the solution $\delta q = \delta q(t)$ to the following *initial-value* problem:

$$J(\delta q) = 0; \qquad \delta q(t_1) = 0, \quad \delta \dot{q}(t_1{}^*) = \text{arbitrary } nonzero \text{ constant} \equiv \alpha; \tag{7.A2.4c}$$

that is, $\delta q(t_1) = 0$ and $\delta q(t_1{}^*) = 0,\ t_1{}^* > t_1$. The root $t_1{}^*$ is called *conjugate* to t_1; and q_1 and $q(t_1{}^*) \equiv q_1{}^*$, along I, are known [after Thomson and Tait (1860s)] as *mutually conjugate kinetic foci*. Jacobi's criterion states that, for a minimum of A_H,

$$t_1{}^* > t_2 \qquad \text{or} \qquad \Delta t \equiv t_2 - t_1 < t_1{}^* - t_1 \equiv \Delta t^*; \tag{7.A2.4d}$$

that is, *the interval* $(t_1,\ t_2)$ *should not contain any roots conjugate to* t_1. [For a *maximum*, the inequality signs in (7.A2.4d) must be reversed.]

It can be shown that $t_1{}^*$ is independent of the value of α, eq. (4c), but does depend on the partial derivatives/coefficients of the δq's in $J(\delta q)$, eqs. (7.A2.1d, 3b); that is, on the orbit I.

If $t_1{}^* = t_2$, then $\delta^2 A_H$ is positive *semidefinite* — that is, it may vanish for a $\delta q(t) \neq 0$ — in which case, we have to resort to higher-order variations. If $t_1{}^* < t_2$, then $\delta^2 A_H$ is *sign-indefinite* — that is, it is negative for one class of variations and positive for another — $A_H(q)$ has a *minimax* (or *saddle-point*); that is, there is no extremum.

REMARKS

(i) The Euler–Lagrange test supplies the orbit equation; its solution(s) require(s) integration of the equation of motion and then utilization of the given boundary conditions.

(ii) The Legendre–Weierstrass test means that *locally* — that is, for *very small* $t_2 - t_1$ — A_H *is always a minimum*; that is, for any potential force field.

Let us show this for *stationary* constraints. Since $\delta q(t_1) = 0$, we have

$$|\delta q(t)| = \left| \int_{t_1}^{t} \delta(\dot{q})\, dt \right| \leq \varepsilon(t - t_1), \tag{7.A2.5a}$$

where $\varepsilon \equiv \max |\delta(\dot{q})|$ in $(t_1,\ t_2)$; and, therefore, *for very small* $t_2 - t_1$, *the* $\delta(\dot{q})$*-terms always dominate over the* δq*-terms*. Hence, for such constraints,

$$\begin{aligned}\delta^2 L &= (1/2)(\partial^2 L/\partial q^2)(\delta q)^2 + (\partial^2 T/\partial q\,\partial\dot{q})\ \delta q\ \delta(\dot{q}) + (1/2)(\partial^2 T/\partial\dot{q}^2)(\delta(\dot{q}))^2\\ &= (1/2)(\partial^2 L/\partial q^2)(\delta q)^2 + (\partial^2 T/\partial q\,\partial\dot{q})\ \delta q\ \delta(\dot{q}) + T[\delta(\dot{q})]\\ &\approx T[\delta(\dot{q})] > 0\end{aligned} \tag{7.A2.5b}$$

[where $T(\delta\dot{q})$ signifies what becomes of $T(\dot{q})$, which is positive definite in $\dot{q}$, if we replace in it $\dot{q}$ with $\delta(\dot{q})$], and, accordingly,

$$\delta^2 A_H = \int \delta^2 L\, dt \approx \int T[\delta(\dot{q})]\, dt > 0 \ \Rightarrow\ A_H(q):\ \textit{minimum},\ \text{Q.E.D.} \tag{7.A2.5c}$$

(iii) The Jacobi test imposes a *limit on the length of the orbit*; that is, on the $t_2 - t_1$ range (as long as $t_1{}^*$ is finite). [The sum of two minimal orbits will be a minimal orbit if the "sum orbit" does not exceed its Jacobi limit.]

Ideally, and very rarely, the conjugate root(s) to t_1 are found as follows: the general solution of the *second-order* Lagrangean equation $E(q) = 0$ has the form:

$$q = q(t;\ c_1,\ c_2), \qquad c_1,\ c_2:\ \text{integration constants.} \tag{7.A2.6a}$$

Now, the orbit I corresponds to fixed values of c_1 and c_2 [to be determined from the boundary conditions: $q(t_1;\ c_1,\ c_2) = q_1$ (given), $q(t_2;\ c_1,\ c_2) = q_2$ (given)], whereas typical neighboring paths $II = I + \delta I$ correspond to the values $c_1 + \delta c_1$ and $c_2 + \delta c_2$. On such adjacent paths,

$$\delta q = (\partial q/\partial c_1)\ \delta c_1 + (\partial q/\partial c_2)\ \delta c_2, \tag{7.A2.6b}$$

and therefore the boundary conditions for $t_1,\ t_1{}^*$ become [with the notation $(\ldots)_* \equiv$ $(\ldots)$ evaluated at $*$]

$$\delta q(t_1) = (\partial q/\partial c_1)_1\, \delta c_1 + (\partial q/\partial c_2)_1\, \delta c_2 = 0, \tag{7.A2.6c}$$

$$\delta q(t_1{}^*) = (\partial q/\partial c_1)_*\, \delta c_1 + (\partial q/\partial c_2)_*\, \delta c_2 = 0. \tag{7.A2.6d}$$

This linear and homogeneous system, in the δq's, expresses the fact that *the slightly differing paths I and II cross at t_1 and then again at $t_1{}^*$*; or, *they are traversed in the same time $t_1{}^* - t_1$*; q_1 and q_{1*} are (mutually) conjugate kinetic foci on I.

For nontrivial solutions (i.e., $\delta c_1,\ \delta c_2 \neq 0$), the system of equations (7.A2.6c, d) leads, in well-known ways, to the determinantal equation

$$\Delta(t_1,\ t_1{}^*) \equiv \begin{vmatrix} (\partial q/\partial c_1)_1 & (\partial q/\partial c_2)_1 \\ (\partial q/\partial c_1)_* & (\partial q/\partial c_2)_* \end{vmatrix} = 0. \tag{7.A2.7}$$

The *first*, or *smallest*, of its (real) roots to the right of t_1 is what enters the Jacobi condition (7.A2.4d).

Example 7.A2.1 As an illustration, let us consider the linear harmonic oscillator:

$$m\,\ddot{q} + k\,q = 0 \Rightarrow \ddot{q} + \omega^2 q = 0,\ \omega \equiv (k/m)^{1/2}:\ \text{frequency (a positive constant).} \tag{a}$$

Here, as is well known,

$$2T = m\,(\dot{q})^2 \quad (m:\ \text{mass}), \qquad 2V = k\,q^2 \quad (k:\ \text{positive constant}) \tag{b}$$

$$\Rightarrow Q = -dV/dq = -k\,q \ \Rightarrow\ dQ/dq = -d^2V/dq^2 = -k < 0, \tag{c}$$

and so the general solution of (a) and its variation are, respectively,

$$q = c_1 \sin(\omega\, t) + c_2 \cos(\omega\, t), \qquad \delta q = [\sin(\omega\, t)]\, \delta c_1 + [\cos(\omega\, t)]\, \delta c_2. \tag{d}$$

Therefore, with $t_1 = 0$, eq. (7.A2.7) gives

$$\Delta(0,\ t_1{}^*) \equiv \begin{vmatrix} 0 & 1 \\ \sin(\omega\, t_1{}^*) & \cos(\omega\, t_1{}^*) \end{vmatrix} = -\sin(\omega\, t_1{}^*) = 0, \tag{e}$$

and, clearly, its first root to the right of $t_1 = 0$ is

$$t_1{}^* = \pi/\omega = \tau/2:\ \text{half period of oscillation.} \tag{f}$$

Since $\partial^2 L/\partial \dot{q}^2 = \partial^2 T/\partial \dot{q}^2 = m > 0$, always, the corresponding action

$$A_H = \int_0^{t_2} (1/2)\ [m\,(\dot{q})^2 - k\,q^2]\ dt, \tag{g}$$

is a minimum as long as $t_2 < \tau/2$ (generally, for $t_2 - t_1 < \tau/2$).

For an n DOF linear oscillatory system (expressing its T and V in principal coordinates, and noting that its n characteristic frequencies $\omega_1 \leq \omega_2 \leq \cdots \leq \omega_n$ are intrinsic system properties), it is not hard to show that the corresponding Jacobi minimum action condition is

$$t_2 < t_1{}^* = \tau_{\min}/2 = \tau_n/2 \equiv \pi/\omega_n: \textit{smallest} \text{ half period of oscillation.} \tag{h}$$

(See also Aizerman, 1974, pp. 276–279.) From the above, we conclude that:

(i) For $n \to \infty$ (i.e., *continuum*; e.g., oscillating string), $\omega_n \to \infty$ and, therefore, $t_1{}^* \to 0$, A_H is *never* a minimum.

(ii) Under *constant* or *repulsive* (nonoscillatory) forces — that is, $dQ/dq = -d^2V/dq^2 \geq 0$, $t_1{}^* \to \infty$ — such forces *always* minimize A_H.

---

n DOF

Finally, the entire argument for the determination of kinetic foci, namely eqs. (7.A2.6a–7), carries over to the n DOF case. There, eqs. (7.A2.6a, b) are replaced, respectively, by

$$q_k = q_k(t;\ c_1, \ldots, c_{2n}) \ \Rightarrow\ \delta q_k = \sum (\partial q_k/\partial c_\alpha)\, \delta c_\alpha$$

$$(k = 1, \ldots, n; \quad \alpha = 1, \ldots, 2n) \tag{7.A2.8a}$$

and eqs. (7.A2.6c, d) and (7.A2.7) by

$$\sum (\partial q_k/\partial c_\alpha)_1\, \delta c_\alpha = 0, \qquad \sum (\partial q_k/\partial c_\alpha)_*\, \delta c_\alpha = 0, \tag{7.A2.8b}$$

and the $2n \times 2n$ determinantal equation

$$\Delta(t_1,\ t_1{}^*) = \begin{vmatrix} (\partial q_1/\partial c_1)_1 & \ldots & (\partial q_1/\partial c_{2n})_1 \\ \cdots & \cdots & \cdots \\ (\partial q_n/\partial c_1)_1 & \ldots & (\partial q_n/\partial c_{2n})_1 \\ \hline (\partial q_1/\partial c_1)_* & \ldots & (\partial q_1/\partial c_{2n})_* \\ \cdots & \cdots & \cdots \\ (\partial q_n/\partial c_1)_* & \ldots & (\partial q_n/\partial c_{2n})_* \end{vmatrix} = 0. \tag{7.A2.8c}$$

Here too, the smallest root of (7.A2.8c) to the right of t_1, $t_1{}^*$, is what enters Jacobi's minimum condition: $t_2 < t_1{}^*$.

[This argument and equations are due to the noted German mathematician A. Mayer (1866 and subsequently); one of the founders of the sufficiency variational theory, for both fixed and variable endpoint problems.]

The problem of the extremum of the Hamiltonian action can be summarized as follows:

- A_H, along an orbit I, is *never* a maximum; it is either a *minimum* (from an initial configuration C_1 up to any other configuration C_2 located *before* the first kinetic focus of C_1, $C_1{}^*$; all on I), or a *minimax (saddle-point)* (from C_1 to a C_2 beyond $C_1{}^*$).
- Limiting cases: If $C_1{}^* \to C_1$, then A_H is a minimax for any $t_2 > t_1 = t_1{}^*$; if $C_1{}^* \to \infty$, then A_H is a minimum for any t_2.

Such tests have also been obtained for the Lagrangean action A_L; see Papastavridis [1985(b), 1986(a), 1986(c): general variable endpoints form], Peisakh [1966: Jacobi's geodesic (fixed endpoints) form].

7.A3 Averaged Action

As we have just seen, the stationary (or critical) "points" of A_H are, in general (i.e., for extended periods of time), saddle-points. Therefore, if we are to develop reliable A_H-based extremum criteria, similar to those of static stability, we must introduce some other energetic functions or functionals. Following the valuable lessons of the method of *averaging* of nonlinear oscillations (ex. 7.9.7), we choose as such function the *time average* of the system's Lagrangean. Indeed, with $t_2 - t_1 \equiv \tau$, we have, for a general motion,

$$\langle L \rangle \equiv \lim[A_H(\tau)/\tau]_{\tau\to\infty} = \lim\left[(1/\tau)\int L\, dt\right]_{\tau\to\infty} \tag{7.A3.1}$$

(for periodic motions, no limiting process is needed). $\langle L \rangle$ is no longer a function of time, and its stationarity/extremality becomes a problem of ordinary differential calculus. For example, and again guided by nonlinear oscillations, we may try in A_H the Fourier series expansion of the trial solution (say, in complex form, for compactness; see also §8.14):

$$q(t) \approx q_o(t) = \sum c_s \exp(i\,\omega_s\, t), \qquad c_s = (1/\tau)\int_{-\tau/2}^{+\tau/2} q_o(t)\exp(-i\,\omega_s\, t)\, dt, \tag{7.A3.2}$$

$$s = -\infty, \ldots, +\infty; \qquad \omega_s \equiv s\,\omega = (2\pi/\tau)s. \tag{7.A3.2a}$$

Then $\langle L \rangle$ becomes a function of the Fourier coefficients (amplitudes), and "Hamilton's averaged principle" takes the discrete form

$$\delta\langle L \rangle = 0 \;\Rightarrow\; \partial\langle L \rangle/\partial c_s = 0 \qquad (s = 0,\ \pm1,\ \pm2, \ldots); \tag{7.A3.3}$$

while the type of the stationarity of $\langle L \rangle$ is determined from the study of the sign properties of its "Hessian matrix" $(\partial^2\langle L \rangle/\partial c_r \partial c_s)$, every element of which is an algebraic function of the Fourier coefficients. For the use of $\langle L \rangle$ in general nonlinear dynamics, see the earlier-mentioned (ex. 7.9.13) highly readable and informative papers by Gray et al. [1996(a), (b); and references cited therein]; also Helleman (1978); and for applications to the stability of nonlinear oscillations, see Baumgarte (1987).

Problem 7.A3.1 Show that the averaged Lagrangean of the undamped and forced linear oscillator $\ddot{q} + \omega_o{}^2 q = Q_o \cos(\omega\, t)$, where Q_o, ω are, respectively, the forcing amplitude and frequency, and

$$A_H(\tau) = \int_0^\tau \left[(1/2)(\dot{q})^2 - (1/2)\,\omega_o{}^2\, q^2 + Q_o \cos(\omega\, t)\, q\right] dt \tag{a}$$

has a minimum for $\omega_o < \omega$, and a maximum for $\omega_o > \omega$ (both for all time).

7.A4 The Integral Stability Criterion [of Blekhman–Lavrov and Valeev-Ganiev (1960s)]

To dispel any possible impressions that the extrema of the averaged Lagrangean are somehow only of "academic" interest, we sketch below their application to the theory of *synchronization* of oscillating mechanical objects. For a complete treatment of this theoretically and practically important subject (that is conspicuously absent from almost all Western references), see the fundamental and extensive works of its key exponent, Blekhman (1971, 1979, 1981/1988; and Blekhman and Malakhova, 1990).

Following Valeev and Ganiev (1969), we consider the oscillations of an n DOF *weakly nonlinear, or quasi-linear*, potential system with Lagrangean [say, in the principal coordinates of the corresponding linear (i.e., unperturbed), constant coefficient system; that is, for $\varepsilon = 0$]:

$$\begin{aligned} L &= L(\omega t,\ q,\ \dot{q};\ \varepsilon) \equiv T - V \\ &= \sum (1/2)\ [(\dot{q}_k)^2 - {\omega_k}^2 {q_k}^2] + \varepsilon L_1(\omega t,\ q,\ \dot{q};\ \varepsilon), \end{aligned} \tag{7.A4.1}$$

where ω_k are the natural frequencies of the system (given constants), $0 < \varepsilon \ll 1$ (hence the name quasi-linear), and $L_1(\ldots)$ is periodic in the forcing (external) frequency ω; that is,

$$L_1(\omega t + 2\pi,\ q,\ \dot{q};\ \varepsilon) = L_1(\omega\, t,\ q,\ \dot{q};\ \varepsilon). \tag{7.A4.1a}$$

Below we examine the case where ω is, approximately, in rational ratios to the ω_k's (frequently referred to as *near-resonance* case):

$$\omega_k/\omega \approx i_k/N \quad \text{or} \quad i_k\, \omega \approx \omega_k N, \qquad \text{and} \qquad \nu_k/\omega = i_k/N \quad \text{or} \quad i_k\, \omega = \nu_k N, \tag{7.A4.2}$$

where

$${\omega_k}^2 - {\nu_k}^2 = O(\varepsilon), \tag{7.A4.2a}$$

$$i_k:\ \text{nonnegative integer}, \qquad N:\ \text{sufficiently large positive integer}, \tag{7.A4.2b}$$

[and $O(\ldots) \equiv$ *Of order* $(\ldots)$ has its usual meaning: $f(\varepsilon) = O[g(\varepsilon)]$, for two general functions $f(\ldots)$ and $g(\ldots)$, means that for $\varepsilon \to 0$: $\lim |f(\varepsilon)/g(\varepsilon)| < \infty$; e.g., $\sin(6\varepsilon) = O(\varepsilon)$, $\cos(3\varepsilon) = O(\varepsilon^0) = O(1)$]. Then (7.A4.1) can be re-expressed as

$$\begin{aligned} L &= \sum (1/2)\ \left[(\dot{q}_k)^2 - {\nu_k}^2 {q_k}^2\right] \\ &\quad + \varepsilon\left[L_1(\omega t,\ q,\ \dot{q};\ \varepsilon) + (1/\varepsilon) \sum ({q_k}^2/2)({\nu_k}^2 - {\omega_k}^2)\right] \\ &\equiv \sum (1/2)\ \left[(\dot{q}_k)^2 - {\nu_k}^2 {q_k}^2\right] + \varepsilon L^{(1)}(\omega t,\ q,\ \dot{q};\ \varepsilon). \end{aligned} \tag{7.A4.3}$$

The above show that the *unperturbed* system [i.e., (7.A4.3) for $\varepsilon = 0$: $q_k \to q_{ko}$: *generating function*] has equations of motion $d^2 q_{ko}/dt^2 + {\nu_k}^2 q_{ko} = 0$, and, therefore, general solutions

$$\begin{aligned} &q_{ko} = q_{ko}(t) = a_k \cos(\nu_k t) + (b_k/\nu_k) \sin(\nu_k t), \\ &a_k = q_{ko}(0) \quad \text{and} \quad b_k = \dot{q}_{ko}(0):\ \ \text{initial conditions}. \end{aligned} \tag{7.A4.4}$$

We notice that since the ν_k are *rationally commensurate* to ω — that is, $\nu_k = (i_k/N)\omega$ — the q_{ko} have the *common* period

$$\tau \equiv (2\pi/\omega)N = 2\pi(N/\omega) = 2\pi(i_k/\nu_k) = (2\pi/\nu_k) i_k \equiv \tau_k i_k. \tag{7.A4.5}$$

Let us now examine the *perturbed* system ($\varepsilon \neq 0$). Its equations of motion are

$$E_k(L) \equiv (\partial L/\partial \dot{q}_k)^{\cdot} - \partial L/\partial q_k = 0:$$
$$\ddot{q}_k + {\nu_k}^2 q_k = -\varepsilon\big[(\partial L^{(1)}/\partial \dot{q}_k)^{\cdot} - \partial L^{(1)}/\partial q_k\big] \equiv \varepsilon F_k(\omega t,\ q,\ \dot{q};\ \varepsilon), \tag{7.A4.6}$$

where $F_k(\omega t,\ q,\ \dot{q};\ \varepsilon) = F_k(2\pi + \omega t,\ q,\ \dot{q};\ \varepsilon)$.

Applying, next, the well-known method of *variation of constants* (ex. 7.9.14 and §8.7) to these *perturbed* (nonhomogeneous) equations, based on the general solutions of the corresponding *unperturbed* (homogeneous) equations (7.A4.4), we find

$$q_k(t) = q_{ko}(t) + (\varepsilon/\nu_k)\bigg[\sin(\nu_k t)\int_0^t F_k(\omega x,\ q_{ko},\ \dot{q}_{ko};\ 0)\cos(\nu_k x)\,dx$$
$$- \cos(\nu_k t)\int_0^t F_k(\omega x,\ q_{ko},\ \dot{q}_{ko};\ 0)\sin(\nu_k x)\,dx\bigg] + O(\varepsilon^2), \tag{7.A4.7}$$

(a result reminiscent of the well-known "Duhamel's superposition integral" formula of forced linear vibrations); or, further, with some standard manipulations and recalling eqs. (7.A4.4–6),

$$q_k(t) = a_k\cos(\nu_k t) + (b_k/\nu_k)\sin(\nu_k t)$$
$$- (\varepsilon/\nu_k)\bigg\{\int_0^t \big[(\partial L^{(1)}/\partial \dot{q}_k)^{\cdot} - \partial L^{(1)}/\partial q_k\big]_o \sin[\nu_k(t-x)]\,dx\bigg\} + O(\varepsilon^2), \tag{7.A4.8}$$

where $[\ldots]_o \equiv [\ldots]$ evaluated for the *generating solution* $q_{ko}(x)$, where x is a dummy variable of integration. This allows us to calculate the *new initial values* a_{k1} and b_{k1} after the period τ: from (7.A4.8) [or, more easily, (7.A4.7)] with $t \to \tau$, we find

$$q_k(\tau) = q_{ko}(\tau) + (\varepsilon/\nu_k)\int_0^\tau [\ldots]_o \sin(\nu_k x)\,dx + O(\varepsilon^2) \qquad (\text{with } t_1 = 0,\ t_2 = \tau), \tag{7.A4.9}$$

or

$$a_{k1} = a_k + \varepsilon\tau P_k + O(\varepsilon^2), \tag{7.A4.9a}$$

$$P_k = P_k(a_l,\ b_l) \equiv (1/\nu_k\tau)\int_0^\tau \big[(\partial L^{(1)}/\partial \dot{q}_k)^{\cdot} - \partial L^{(1)}/\partial q_k\big]_o \sin(\nu_k x)\,dx. \tag{7.A4.9b}$$

Similarly, $(\ldots)^{\cdot}$-differentiating (7.A4.8), or (7.A4.7), and so on, we find

$$\dot{q}_k\,(\tau) = \dot{q}_{ko}\,(\tau) - \varepsilon\int_0^\tau [\ldots]_o \cos(\nu_k x)\,dx + O(\varepsilon^2), \tag{7.A4.10}$$

or

$$b_{k1} = b_k + \varepsilon\tau Q_k + O(\varepsilon^2), \tag{7.A4.10a}$$

$$Q_k = Q_k(a_l,\ b_l) \equiv -(1/\tau)\int_0^\tau \big[(\partial L^{(1)}/\partial \dot{q}_k)^{\cdot} - \partial L^{(1)}/\partial q_k\big]_o \cos(\nu_k x)\,dx. \tag{7.A4.10b}$$

Next, integrating the $d/dx(\ldots)$-term of the integrand of both P_k and Q_k by parts, and noting that the integrated-out terms vanish (due to *periodicity*), we find

$$P_k = -(1/\tau)\int_0^\tau \left\{(\partial L^{(1)}/\partial \dot{q}_k)\cos(\nu_k x) + (\partial L^{(1)}/\partial q_k)\,[\sin(\nu_k x)/\nu_k]\right\}_o dx$$
$$= -(1/\tau)\int_0^\tau (\partial L^{(1)}/\partial b_k)_o\, dx, \tag{7.A4.11a}$$

$$Q_k = -(1/\tau)\int_0^\tau \left\{(\partial L^{(1)}/\partial \dot{q}_k)\,[\nu_k \sin(\nu_k x)] + (\partial L^{(1)}/\partial q_k)\cos(\nu_k x)\right\}_o dx$$
$$= (1/\tau)\int_0^\tau (\partial L^{(1)}/\partial a_k)_o\, dx. \tag{7.A4.11b}$$

A final simplification of the above occurs with the help of the following function:

$$\Lambda = \Lambda(a_k,\ b_k) \equiv (1/\tau)\int_0^\tau L\big[\omega x,\ q_{ko}(x),\ dq_{ko}(x)/dx;\ \varepsilon\big]\, dx:$$

Average of *perturbed* Lagrangean, but evaluated along the (known) *unperturbed* solution ($\neq \langle L\rangle$), (7.A4.12)

or, recalling (7.A4.3), and noting that due to (7.A4.4)

$$\int_0^\tau (1/2)\big\{[dq_{ko}(x)/dx]^2 - {\nu_k}^2 q_{ko}(x)^2\big\}\, dx = 0 \qquad \text{(Virial theorem for } q_{ko}), \tag{7.A4.12a}$$

finally,

$$\Lambda = (\varepsilon/\tau)\int_0^\tau [L^{(1)}]_o\, dx = O(\varepsilon). \tag{7.A4.12b}$$

Then, and recalling (7.A4.11a, b), eqs. (7.A4.9a, 10a) reduce, respectively, to

$$\Delta a_k \equiv a_{k1} - a_k = -\tau(\partial\Lambda/\partial b_k) + O(\varepsilon^2)$$
$$= -\varepsilon\left\{\partial/\partial b_k \int_0^\tau [L^{(1)}]_o\, dx\right\} + O(\varepsilon^2), \tag{7.A4.13a}$$
$$\Delta b_k \equiv b_{k1} - b_k = +\,\tau(\partial\Lambda/\partial a_k) + O(\varepsilon^2)$$
$$= +\,\varepsilon\left\{\partial/\partial a_k \int_0^\tau [L^{(1)}]_o\, dx\right\} + O(\varepsilon^2). \tag{7.A4.13b}$$

Now Valeev and Ganiev (1969), reasoning as in the method of slowly varying parameters, have demonstrated that this *finite difference* system can be replaced by the following Hamiltonian, or *canonical*, differential system (§8.2):

$$da_k/dt = -\partial\Lambda/\partial b_k + O(\varepsilon^2), \qquad db_k/dt = +\,\partial\Lambda/\partial a_k + O(\varepsilon^2). \tag{7.A4.14}$$

These equations readily show that the *periodic* solutions of (7.A4.3, 6)—that is, $\Delta a_k = 0$, $\Delta b_k = 0$, or $da_k/dt = 0$, $db_k/dt = 0$—to the first ε-order, are determined from the following $2n$ conditions of stationarity, or "equilibrium," of Λ:

$$\partial\Lambda/\partial a_k = 0, \qquad \partial\Lambda/\partial b_k = 0 \qquad (k = 1,\ldots,n); \tag{7.A4.15}$$

and also provide the "energy" integral

$$dA/dt = \sum \left[(\partial A/\partial a_k)\dot{a}_k + (\partial A/\partial b_k)\,\dot{b}_k\right] = O(\varepsilon^2),$$
$$\Rightarrow A(a_k,\ b_k) = constant + O(\varepsilon^2). \qquad (7.A4.16)$$

Next, let $(a_{ko},\ b_{ko})$ be a solution of (7.A4.15); that is, a stationary point of A. To examine its *stability* in the first ε-approximation, we expand eqs. (7.A4.14) around that equilibrium solution, and linearize them in the deviations from it, $A_k \equiv a_k - a_{ko}$ and $B_k \equiv b_k - b_{ko}$, while invoking (7.A4.15). In this way, we obtain the following linear *variational* equations (Poincaré's "équations aux variations"):

$$dA_k/dt = -\sum \left[(\partial^2 A/\partial b_k\ \partial a_l)\ A_l + (\partial^2 A/\partial b_k\ \partial b_l)\ B_l\right], \qquad (7.A4.17a)$$

$$dB_k/dt = +\sum \left[(\partial^2 A/\partial a_k\ \partial a_l)\ A_l + (\partial^2 A/\partial a_k\ \partial b_l)\ B_l\right], \qquad (7.A4.17b)$$

where all partial derivatives are calculated at $(a_{ko},\ b_{ko})$.

Assuming, as usual, time-exponential solutions for A_k and B_k [i.e., $\sim \exp(\lambda t)$], and substituting them into the (7.A4.17a, b), we are readily led at the following $2n$-degree characteristic equation for λ:

$$\Delta = \Delta(\lambda) \equiv \begin{vmatrix} -(\partial^2 A/\partial b_k\ \partial a_l) - \lambda\ \delta_{kl} & -(\partial^2 A/\partial b_k\ \partial b_l) \\ \partial^2 A/\partial a_k\ \partial a_l & (\partial^2 A/\partial a_k\ \partial b_l) - \lambda\ \delta_{kl} \end{vmatrix} = 0. \qquad (7.A4.18)$$

For (asymptotic) stability of the point $(a_{ko},\ b_{ko})$: All λ-roots of $\Delta = 0$ must have *negative real parts (*§3.10); if the real part of even one such root is positive, that point is unstable; while if it is zero, that point is stable in the first ε-approximation.

Therefore, the conditions for a "coarse" extremum of $A(a_k,\ b_k)$ [i.e., a strict extremum detected by analysis of the second-order terms in the expansion $A(a_{ko} + A_k,\ b_{ko} + B_k) - A(a_{ko},\ b_{ko})$—the term is due to Blekhman] at $(a_{ko},\ b_{ko})$ also represent the sufficient conditions for a stable periodic solution, to the first ε-order; and for $\varepsilon = 0$ reducing to the generating solution (7.A4.4). Hence, A plays the role that the *total potential energy* plays, in the static stability analysis of potential systems. Let us examine (7.A4.17a, b, 18) further. With the help of the notations

$$\partial^2 A/\partial a_k\,\partial a_l \equiv \alpha_{kl} = \alpha_{lk}, \qquad \partial^2 A/\partial b_k\,\partial b_l \equiv \beta_{kl} = \beta_{lk},$$
$$\partial^2 A/\partial b_k\,\partial a_l = \partial^2 A/\partial a_l\,\partial b_k \equiv \gamma_{kl} \neq \gamma_{lk} \equiv \partial^2 A/\partial b_l\,\partial a_k = \partial^2 A/\partial a_k\,\partial b_l, \qquad (7.A4.19)$$

equations (7.A4.17a, b) can be written, respectively,

$$dA_k/dt = -\sum (\beta_{kl}\ B_l + \gamma_{kl}\ A_l), \qquad (7.A4.20a)$$
$$dB_k/dt = +\sum (\gamma_{lk}\ B_l + \alpha_{kl}\ A_l); \qquad (7.A4.20b)$$

while in terms of the Lagrange-like function K [see also (8.3.12 ff.)]

$$2K = \sum\sum (\beta_{kl}\ B_k\ B_l + 2\gamma_{kl}\ B_k\ A_l + \alpha_{kl}\ A_k\ A_l), \qquad (7.A4.21)$$

they can be brought to the Hamiltonian form (§8.2)

$$dA_k/dt = -\,\partial K/\partial B_k, \qquad dB_k/dt = +\,\partial K/\partial A_k. \qquad (7.A4.22)$$

In view of the above, the characteristic equation (7.A4.18) can also be rewritten, successively, as follows (partitioned in subdeterminants):

$$\Delta(\lambda) = \begin{vmatrix} |\gamma_{lk} - \lambda\, \delta_{lk}| & |\alpha_{kl}| \\ |-\beta_{kl}| & |-\gamma_{kl} - \lambda\, \delta_{kl}| \end{vmatrix}$$

$$= (-1)^n \begin{vmatrix} |\gamma_{lk} - \lambda\, \delta_{lk}| & |\alpha_{kl}| \\ |\beta_{kl}| & |\gamma_{kl} + \lambda\, \delta_{kl}| \end{vmatrix}$$

$$= (-1)^n \begin{vmatrix} |\beta_{kl}| & |\gamma_{kl} + \lambda\, \delta_{kl}| \\ |\gamma_{lk} - \lambda\, \delta_{lk}| & |\alpha_{kl}| \end{vmatrix}$$

[after swapping the first n *rows* with the last n rows]

$$= (-1)^n \begin{vmatrix} |\gamma_{kl} + \lambda\, \delta_{kl}| & |\beta_{kl}| \\ |\alpha_{kl}| & |\gamma_{lk} - \lambda\, \delta_{lk}| \end{vmatrix}$$

[after swapping the first n *columns* with the last n columns]

$$= (-1)^n \begin{vmatrix} |\gamma_{kl} + \lambda\, \delta_{kl}| & |\alpha_{kl}| \\ |\beta_{kl}| & |\gamma_{lk} - \lambda\, \delta_{lk}| \end{vmatrix}$$

[after *transposing* the determinant about its main diagonal], (7.A4.23)

and comparing the *second* and *last* of these forms of $\Delta(\lambda)$, we readily see that

$$\Delta(\lambda) = \Delta(-\lambda). \tag{7.A4.24}$$

In words: if λ is a root of the characteristic equation (and hence an eigenvalue of the variational equations), then so is $-\lambda$; that is, $\Delta(\lambda) = 0$ can contain only *even* powers of λ. Therefore, if such a root is complex with negative real part, or a negative real number ($\Rightarrow$ asymptotic stability), its negative will also be a root with *positive* real part, or a positive real number ($\Rightarrow$ exponential, or flutteral, instability). Hence (and since asymptotic stability cannot occur in our conservative system), *for stability, all* λ's *must be purely imaginary*, and then they appear in mutually conjugate pairs: $\pm ia$ (a: real). In this case [recall discussion following eq. (3.10.18a)] we say that the system possesses *critical* or *nonsignificant* behavior, i.e., its stability cannot be safely concluded from its linear perturbation equations (7.A4.17a, b; 20a, b); in such cases, we must consider the *nonlinear* A and B terms of $O(\varepsilon^2)$. However, if no such higher-order terms are present, which is the quasi-linear (first ε-approximation) case discussed here, then *purely imaginary roots of* $\Delta(\lambda) = 0$ *do signify stability*.

[For detailed discussions of this very important problem of the stability of motion, including the fundamental contributions of Liapunov on it, see, for example (alphabetically): Chetayev (1955), Hughes (1986, pp. 480–521), Kuzmin (1973), Meirovitch (1970, chap. 6), Pars (1965, chap. 23), Pollard (1976, pp. 117–131).]

Our discussion of the *integral stability criterion* can be summarized as follows: Let Λ be the time average of the Lagrangean of the original quasi-linearly *perturbed* system, eqs. (7.A4.6), but calculated along the periodic solutions of the *unperturbed* linear system, eqs. (7.A4.4), as a function of the initial values of the *generating solution* $(a_k,\ b_k)$. Next, consider the *stationary* points of Λ, $(a_{ko},\ b_{ko})$: if these points are also *extrema* (maxima or minima) of Λ, then, to the first ε-approximation, they constitute *stable* (periodic) solutions of the original system. *Nonextremum* stationary points require special consideration.

Example 7.A4.1 Let us consider a system with (exact) Lagrangean

$$L = (\dot{q})^2/2 - q^2/2 + \varepsilon[-\kappa\, q^2 + q\,\dot{q}\sin(2t)] \qquad (0 < \varepsilon \ll 1), \tag{a}$$

and, therefore, equation of motion, the linear *Mathieu* equation

$$\ddot{q} + q = -\varepsilon[\kappa + 2\cos(2t)]\, q,$$

or

$$\ddot{q} + [1 + \varepsilon\kappa + 2\varepsilon\cos(2t)]\, q = 0. \tag{b}$$

Here, clearly, $n = 1$, $\nu_k = 1$, $\omega = 2\ \Rightarrow\ \tau = \pi N$, $\tau_k = 2\pi$, and the unperturbed system $(\varepsilon = 0)$: $\ddot{q} + q = 0$ has generating solution

$$q_o = q_o(t) = a\ \cos t + b\ \sin t \qquad (a,\ b\text{: initial values of } q_o,\ \dot{q}_o). \tag{c}$$

The average of L evaluated along (c) (i.e., between $t_1 = 0$ and $t_2 = 2\pi$) equals, after (7.A4.12, 12b),

$$\begin{aligned}\Lambda &= (1/2\pi)\int_0^{2\pi} L\big[q_o(x),\ dq_o(x)/dx,\ x\big]\, dx\\ &= \cdots = -(\varepsilon/4)\ \big[(\kappa+1)\, a^2 + (\kappa-1)\, b^2\big] \equiv \Lambda(a,\ b).\end{aligned} \tag{d}$$

Using subscripts to denote partial derivatives relative to $a,\ b$, we readily see that the sole root of $\Lambda_a = 0,\ \Lambda_b = 0$ is $(a_o = 0,\ b_o = 0)$; that is, the equilibrium state $q_o(t) = 0$. At that point, since

$$\Lambda_{aa} = -(\varepsilon/2)(\kappa+1): \quad \begin{cases} > 0 & \text{for } \kappa < -1,\\ < 0 & \text{for } \kappa > -1,\end{cases} \tag{e1}$$

$$\Lambda_{bb} = -(\varepsilon/2)(\kappa-1): \quad \begin{cases} > 0 & \text{for } \kappa < 1,\\ < 0 & \text{for } \kappa > 1,\end{cases} \tag{e2}$$

$$\Lambda_{ab} = \Lambda_{ba} = 0, \tag{e3}$$

$$\begin{aligned}&\Rightarrow D \equiv \Lambda_{aa}\Lambda_{bb} - \Lambda_{ab} = \varepsilon^2(\kappa^2 - 1)/4:\\ &\qquad > 0, \quad \text{for } \kappa > 1 \ \text{ or } \ \kappa < -1, \quad \text{i.e., for } |\kappa| > 1,\\ &\qquad < 0, \quad \text{for } -1 < \kappa < 1, \quad \text{i.e., for } |\kappa| < 1\end{aligned} \tag{e4}$$

(using ordinary theory of extrema of a function of two variables), we easily conclude that

$$D > 0 \quad \textit{and} \quad \Lambda_{aa}\ (\text{or } \Lambda_{bb}) > 0: \quad \kappa < -1 \Rightarrow \Lambda:\ \textit{minimum},$$

$$D > 0 \quad \textit{and} \quad \Lambda_{aa}\ (\text{or } \Lambda_{bb}) < 0: \quad \kappa > 1 \Rightarrow \Lambda:\ \textit{maximum};$$

$$D < 0: \quad |\kappa| < 1 \Rightarrow \Lambda:\ \textit{min/max}\ (\textit{saddle}\text{-point}). \tag{e5}$$

Therefore, the equilibrium solution of (b) is stable for $|\kappa| > 1$, and unstable for $|\kappa| < 1$; while for $\kappa = \pm 1 \Rightarrow D = 0$, the equilibrium point is defined ambiguously, and this implies the existence of periodic solutions — we are exactly on top of the famous stability/instability boundaries of Mathieu's equation, which emanate from the (usually) horizontal axis of the "Strutt chart" at 1; that is, for $\varepsilon = 0$. These results coincide with those found by other methods; see, for example, Cunningham (1958, pp. 270–273), Papastavridis [1981, 1982(b)].

Finally, let us examine the equivalence between the above, extremum of Λ-based approach, with that based on the study of the eigenvalues of the variational equations (7.A4.17a, b; 20a, b). We have

$$\dot{a} = -\Lambda_b \;\Rightarrow\; \dot{A} = -\Lambda_{ba} A - \Lambda_{bb} B, \tag{f1}$$

$$\dot{b} = \Lambda_b \;\Rightarrow\; \dot{B} = \Lambda_{aa} A + \Lambda_{ab} B; \tag{f2}$$

and so the corresponding characteristic equation is

$$\Delta(\lambda) = \begin{vmatrix} -(\Lambda_{ab} + \lambda) & -\Lambda_{bb} \\ \Lambda_{aa} & \Lambda_{ab} - \lambda \end{vmatrix} = 0, \tag{g1}$$

from which we readily get

$$\lambda^2 = \Lambda_{ab}{}^2 - \Lambda_{aa}\Lambda_{bb} \;\Rightarrow\; \lambda^2 = -D. \tag{g2}$$

For stability, clearly, $\lambda^2 < 0 \;\Rightarrow\; D > 0$; as in the first two of eqs. (e5). Then λ is purely imaginary, and therefore, A, B are harmonically oscillatory.

If $\lambda^2 > 0 \;\Rightarrow\; D < 0$, as in the third of eqs. (e5), then λ is real, and therefore, A, B increase exponentially; that is, instability. If $\lambda^2 = -D = 0$, the linear stability criterion fails.

Thus, we have affirmed the equivalence between the extremum of (d) and the stability of (f1, 2).

Introduction to Hamiltonian/Canonical Methods

Equations of Hamilton and Routh; Canonical Formalism

This is the celebrated ''canonical form'' of the equations of motion of a system, though why it has been so called it would be hard to say.

(Thomson and Tait, 1912, no. 319, p. 307)

We recognize two purposes in the study of general methods in dynamics. First, the practical purpose, to increase our power in solving specific problems by developing standard techniques with a wide range of applicability. Secondly, the intellectual purpose, to understand the mathematical structure of dynamics. . . . Historically [general dynamical theory] has been suggested by, and developed in terms of, the Newtonian dynamics of particles and rigid bodies. But we feel an urgent need to give it a wider scope, presenting it as a consistent mathematical theory applicable to any physical system the behaviour of which can be expressed in Lagrangian or Hamiltonian form.

(Synge, 1960, pp. 99–100)

Hamiltonian mechanics is the description of a mechanical system in terms of generalized coordinates q_i and generalized momenta $p_i, \ldots$ the Hamiltonian formulation . . . is far better suited for the formulation of quantum mechanics, statistical mechanics, and perturbation theory. In particular, the use of Hamiltonian phase space provides the ideal framework for a discussion of the concepts of integrability and nonintegrability and the description of the chaotic phenomena that can be exhibited by nonintegrable systems.

(Tabor, 1989, p. 48)

8.1 INTRODUCTION

The independent variables of Lagrangean mechanics (holonomic and/or nonholonomic) are t, q, and $\dot{q}$ (or ω). In this chapter, we introduce the reader to a very important alternative formulation of analytical mechanics, known as Hamiltonian mechanics (HM), where the independent dynamical variables are t, q, and

$p \equiv \partial T/\partial \dot{q}$ = *system (or generalized) momenta* (or, sometimes, $p \equiv \partial L/\partial \dot{q}$). Hamiltonian mechanics and its associated equations of motion constitute a powerful and fertile version of theoretical mechanics. It represents the last and most abstract/mathematical stage of classical mechanics, and is the one that played a crucial role in the latter's eventual replacement by quantum mechanics (1920s) as a fundamental physical theory. Although, historically, of primary interest to physicists and astronomers/celestial mechanicians, over the past few decades HM has been becoming increasingly relevant, if not indispensable, to engineers; for example, in optimization, robotics, and, most importantly, for the understanding of modern nonlinear dynamics [which includes prominently (deterministic) chaos].

HISTORICAL

Hamiltonian mechanics was originated by Lagrange himself (1810–1811), and also Poisson (1809), in connection with perturbation methods for celestial mechanics problems; was duly noted and generally formulated by Cauchy (1819); but was brought to prominence by Hamilton (1834–1835); and was extended to nonstationary constraints by Ostrogradskii (1848–1850), and Donkin (1854).

Briefly, in HM, the n system positions q and associated n system momenta p become the system coordinates in a $2n$-dimensional *phase*, or *state*, space; and the corresponding n Lagrangean equations of motion of the system (in the q's) are replaced by $2n$ *first-order* symmetrical, or *canonical*, Hamiltonian equations of motion (in the q's and p's).

That a $\dot{q} \Leftrightarrow p$ transformation is "always" possible, is easily seen as follows: by $(\partial/\partial \dot{q})$-differentiating the kinetic energy (recalling expressions in §3.9),

$$\begin{aligned} 2T &= \sum\sum M_{kl}\dot{q}_k\dot{q}_l + 2\sum M_k\dot{q}_k + M_0 \\ &= 2T(t, q, \dot{q}) \qquad (= 2T_2 + 2T_1 + 2T_0), \end{aligned} \tag{8.1.1}$$

$$(M_{kl}, M_k, M_0\text{: functions of the } q\text{'s and } t;\ k,\ l = 1, \ldots, n), \tag{8.1.1a}$$

we obtain the p's as linear and independent functions in the $\dot{q}$'s (and t, q's):

$$p_k \equiv \partial T/\partial \dot{q}_k = \sum M_{kl}\, \dot{q}_l + M_k \equiv p_k(t, q, \dot{q}); \tag{8.1.2}$$

while inverting (8.1.2) [assuming that $Det\,(M_{kl}) \equiv Det\,(\partial^2 T/\partial \dot{q}_k\, \partial \dot{q}_l) \neq 0$; that is, assuming that the Hessian of T (or L) does not vanish identically; and viewing t and the q's as parameters; see also MacMillan (1936, pp. 358–360)], we obtain the $\dot{q}$'s as linear functions of the p's:

$$\dot{q}_l = \sum M'_{lk}\, p_k + M'_l \equiv \dot{q}_l(t, q, p); \tag{8.1.3}$$

$$(M'_{lk}, M'_l\text{: functions of the } q\text{'s and } t;\ k,\ l = 1, \ldots, n). \tag{8.1.3a}$$

Thus, Lagrange's equations, say,

$$(\partial T/\partial \dot{q}_l)^{\cdot} - \partial T/\partial q_l = Q_l, \tag{8.1.4}$$

(§3.5) have been transformed into the completely equivalent system of $2n$ *first-order* equations:

$$dp_l/dt = (\partial T/\partial q_l)|_{\dot{q}=\dot{q}(t,q,p)} + Q_l(t,\ q) \equiv dp_l(t,q,p)/dt, \tag{8.1.5}$$

$$dq_l/dt = \sum M'_{lk} p_k + M'_l \equiv dq_l(t,q,p)/dt \qquad (\textit{linear} \text{ in the } p\text{'s}); \tag{8.1.5a}$$

and this is the essence of the Hamiltonian formalism.

In general, any function of the Lagrangean variables $f = f(t,q,\dot{q})$, becomes, upon substitution of (8.1.5a) in it, a certain "associated" function of the Hamiltonian variables:

$$f = f(t,q,\dot{q}) \equiv f_{(q\dot{q})} = f[t,q,\dot{q}(t,q,p)] \equiv f(t,q,p) \equiv f_{(qp)}; \tag{8.1.6}$$

and conversely, any $f(t,q,p)$ becomes, upon substitution of (8.1.2) in it, an associated $f(t,q,\dot{q})$. [The elaborate notations $f_{(q\dot{q})}$ and $f_{(qp)}$ will be used only in potentially ambiguous situations.] A detailed treatment of HM, comparable to that of Lagrangean mechanics presented so far, is beyond the scope and limits of this book. Instead, in this chapter, *we concentrate on topics of more or less engineering significance*; for example, (i) equations of Routh [a *mixed* formulation that uses as independent variables some of the p's and the remaining $\dot{q}$'s (and, of course, t and the q's); and as such is "halfway" between the methods of Lagrange and Hamilton], and their application to the study of steady motion and its stability; and (ii) applications of the canonical formalism to the approximate analytical solution of the equations of motion (canonical perturbation theory).

The literature on Hamiltonian mechanics is, expectedly, very extensive and varied. For concurrent (and further) reading we recommend (alphabetically):

Born (1927): Masterful and readable exposition by a very famous and wise theoretical physicist.

Chertkov (1960): Applications of Jacobi's method to rigid-body dynamics.

Frank (1935, pp. 59–65, 72–136, 191–239): Encyclopedic classical treatment.

Fues (1927, pp. 131–177): Classical Hamiltonian perturbation theory.

Gantmacher (1970, pp. 71–87, 98–165, 242–258): Compact classical treatment; excellent.

Hagihara (1970): Advanced and comprehensive treatise, primarily for celestial mechanicians.

Hamel (1949, pp. 281–312, 317–361, 653–709): Insightful and masterful presentation, as usual.

Lanczos (1970, pp. 125–130, 161–290): Extensive classical coverage; highly recommended.

Lichtenberg and Lieberman (1992): Warmly recommended for further study of nonlinear/chaotic dynamics.

McCauley (1997): Modern, mature, insightful treatment; most highly recommended.

Nordheim and Fues (1927, pp. 91–130): General and compact encyclopedic treatment.

Prange (1935, pp. 570–785): Extensive and authoritative classical coverage; highly recommended.

Tabor (1989): One of the most readable modern accounts of nonlinear dynamics; very highly recommended for further study.

Whittaker (1937, pp. 54–57, 193–208, 263–338): Mature and insightful classical treatment.

Winkelmann and Grammel (1927, pp. 469–483): Outstanding engineering reference.

Additional special references will be given in later sections.

8.2 THE HAMILTONIAN, OR CANONICAL, CENTRAL EQUATION AND HAMILTON'S CANONICAL EQUATIONS OF MOTION

To obtain equations in the canonical variables t, q, p, we proceed, as in the Lagrangean case, from the invariant differential principle of Lagrange (LP), but in the central equation form (§3.6):

$$\delta I = \delta' W: \qquad \Big(\sum p_k\, \delta q_k\Big)^{\cdot} - \delta T = \sum Q_k\, \delta q_k, \tag{8.2.1}$$

or, after carrying out the differentiations indicated [and assuming that, as in (8.2.1), $(\delta q)^{\cdot} = \delta(\dot{q})$],

$$\sum (dp_k/dt)\, \delta q_k + \sum p_k\, \delta(\dot{q}_k) - \delta T = \delta' W. \tag{8.2.1a}$$

Now, combining the *second* and *third* terms of the left side of the above, so as to create a total $\delta(\ldots)$-variation:

$$\sum p_k\, \delta(\dot{q}_k) - \delta T = \delta\Big(\sum p_k\, \dot{q}_k - T\Big) - \sum \dot{q}_k\, \delta p_k, \tag{8.2.1b}$$

and introducing the new function (and this is the key step!)

$$\begin{aligned} T' &\equiv \Big(\sum p_k\, \dot{q}_k - T\Big)_{\dot{q}=\dot{q}(t,q,p)} \\ &= \sum p_k\, \dot{q}_k(t,q,p) - T[t,q,\dot{q}(t,q,p)] \equiv \sum p_k\, \dot{q}_k(t,q,p) - T_{(qp)} \\ &\equiv T'(t,q,p)\text{: } \textit{Conjugate (to T) kinetic energy} \\ &\Big[= \sum (\partial T/\partial \dot{q}_k)\dot{q}_k - T = (2T_2 + T_1) - (T_2 + T_1 + T_0) = T_2 - T_0, \\ &\quad \text{i.e., if } T = T_2 \text{ (e.g., stationary "initial" constraints), then } T' = T\Big], \end{aligned} \tag{8.2.2}$$

we can rewrite (8.2.1a) as

$$\sum (dp_k/dt)\, \delta q_k + \sum \big[(\partial T'/\partial q_k)\, \delta q_k + (\partial T'/\partial p_k)\, \delta p_k\big] - \sum (dq_k/dt)\, \delta p_k = \delta' W,$$

or, collecting $(\ldots)\,\delta q$ and $(\ldots)\,\delta p$ terms, finally,

$$\sum (dp_k/dt + \partial T'/\partial q_k - Q_k)\, \delta q_k + \sum (-dq_k/dt + \partial T'/\partial p_k)\, \delta p_k = 0. \tag{8.2.3}$$

This (differential) variational equation, holding for *all* virtual δq's and δp's—that is, constrained or not—and known (after Winkelmann, 1909, 1930, p. 39 ff.; also Hamel, 1949, p. 286 ff.) as the *canonical, or Hamiltonian, central equation*, is fundamental to all subsequent considerations.

1. δq and δp Unconstrained

Now, if the δq and δp are *unconstrained*, then (8.2.3) leads immediately to the famous *canonical*, or Hamiltonian, equations of motion:

$$dp_k/dt = -\partial T'/\partial q_k + Q_k, \tag{8.2.4}$$

$$dq_k/dt = \partial T'/\partial p_k \qquad [= \textit{linear} \text{ in the } p\text{'s; recall (8.2.2)}]. \tag{8.2.4a}$$

• Clearly, the *second* set, eqs. (8.2.4a), must coincide with the earlier, purely kinematico-inertial equations (8.1.5a); it is the canonical counterpart of the Lagrangean $p_k = \partial T/\partial \dot{q}_k$.

• It is the *first* set, eqs. (8.2.4), that expresses the *equations of motion*, in a manner almost identical to that of the Lagrangean method; but, unlike the latter, eqs. (8.2.4, 4a) are already expressed directly and linearly in the $(\ldots)^{\cdot}$-derivatives of the $2n$ "coordinates" q and p involved.

The $2n$ *first-order* equations (8.2.4, 4a) allow us to determine the values of the q's and p's at any time, once their values at some initial time are known. They constitute the equations of motion of the representative system "particle" in the (symbolical/mathematical) $2n$-dimensional *phase space* of q's and p's; and, through each (admissible) point of that space, there passes only one such mechanical trajectory (orbit), if the system is scleronomic; or more if the system is rheonomic. In *extended* phase space (t, q, p), however, only one orbit can pass through a point. Comparing the Hamiltonian equations (8.2.4) with their Lagrangean counterparts: $dp_k/dt = \partial T/\partial q_k + Q_k$, we readily obtain the additional kinematico-inertial result

$$\partial T/\partial q_k = -\partial T'/\partial q_k. \tag{8.2.5}$$

If $Q_k = -\partial V(t,\ q)/\partial q_k$, then (8.2.4, 4a) assume the purely *antisymmetrical* form

$$dp_k/dt = -\partial H/\partial q_k, \qquad dq_k/dt = \partial H/\partial p_k, \tag{8.2.6}$$

where

$$\begin{aligned}
H \equiv T' + V &= \left(\sum p_k\, \dot{q}_k - T + V\right)_{\dot{q}=\dot{q}(t,q,p)} \\
&= \sum p_k \dot{q}_k(t,q,p) - (T_{(qp)} - V) \\
&= \left(\sum p_k\, \dot{q}_k - L\right)_{\dot{q}=\dot{q}(t,q,p)} \\
&= \sum p_k\, \dot{q}_k(t,q,p) - L[t,q,\dot{q}(t,q,p)] \equiv \sum p_k\, \dot{q}_k(t,q,p) - L_{(qp)} \\
&= \left(\sum (\partial L/\partial \dot{q}_k)\dot{q}_k - L\right)_{\dot{q}=\dot{q}(t,q,p)} \\
&\equiv H(t,q,p) \qquad \text{(function of } 2n+1 \text{ arguments)},
\end{aligned} \tag{8.2.7}$$

is the *Hamiltonian* function of the system, or, simply, its Hamiltonian; and, similarly,

$$\begin{aligned}
L(t,q,\dot{q}) &= \sum p_k(t,q,\dot{q})\dot{q}_k - H[t,q,p(t,q,\dot{q})] \\
&\equiv \sum p_k(t,q,\dot{q})\dot{q}_k - H_{(q\dot{q})} \\
&= \left(\sum (\partial L/\partial \dot{q}_k)\dot{q}_k - H\right)_{p=p(t,q,\dot{q})}.
\end{aligned} \tag{8.2.7a}$$

• If both potential *and* nonpotential forces (Q_k) are present, eqs. (8.2.6) are replaced by

$$dp_k/dt = -\partial H/\partial q_k + Q_k, \qquad dq_k/dt = \partial H/\partial p_k; \tag{8.2.8}$$

while (8.2.5) becomes

$$\partial H/\partial q_k = -\partial L/\partial q_k. \tag{8.2.9}$$

• Also if we view *time* t, and/or any other number of system *parameters* $(c_1, \ldots, c_{n'})$, on which T, T' and L, H might depend, as *additional* system coordinates (i.e., $q_{n+1} \equiv t$, $q_{n+2} \equiv c_1, \ldots, q_{n+n'} \equiv c_{n'}$), then from the above we easily deduce the following two sets of kinematico-inertial identities (with $* = n+1, \ldots, n'$):

$$\partial T/\partial t = -\partial T'/\partial t, \qquad \partial T/\partial c_* = -\partial T'/\partial c_*; \tag{8.2.10a}$$

and

$$\partial L/\partial t = -\partial H/\partial t, \qquad \partial L/\partial c_* = -\partial H/\partial c_*. \tag{8.2.10b}$$

(See also Landau and Lifshitz, 1960, pp. 132–133.)

• In the presence of a *generalized* potential (3.9.8c)

$$V = V(t, q, \dot{q}) = V_1(t, q, \dot{q}) + V_0(t,\ q) = \sum \gamma_k(t,\ q)\dot{q}_k + V_0(t,\ q), \tag{8.2.11}$$

the momenta p_k are redefined by the [slightly more general than (8.1.2)] relation

$$p_k \equiv \partial L/\partial \dot{q}_k = \partial(T - V)/\partial \dot{q}_k = \partial T/\partial \dot{q}_k - \gamma_k = \sum\sum M_{kl}\dot{q}_l + (M_k - \gamma_k), \tag{8.2.11a}$$

and the Hamiltonian takes the explicit form (recalling that $L = L_2 + L_1 + L_0$),

$$\begin{aligned} H &= \Big(\sum p_k\ \dot{q}_k - L\Big)_{\dot{q}=\dot{q}(t,q,p)} \qquad (\equiv L') \\ &= \Big(\sum (\partial L/\partial \dot{q}_k)\dot{q}_k - L\Big)_{\dot{q}=\dot{q}(t,q,p)} \\ &= \big[(2L_2 + L_1) - (L_2 + L_1 + L_0)\big]_{\dot{q}=\dot{q}(t,q,p)} = (L_2 - L_0)_{\dot{q}=\dot{q}(t,q,p)} \\ &= [T_2 + (V_0 - T_0)]_{\dot{q}=\dot{q}(t,q,p)} \\ &= T' + V_0 \quad [= h(t, q, \dot{q}),\ \text{when expressed in Lagrangean variables}]; \end{aligned} \tag{8.2.11b}$$

that is, just like (8.2.7), but with $V = V_0$; while the canonical equations of motion retain their forms (8.2.6, 8). For *stationary* (holonomic) constraints, clearly, $T = T_2 (\Rightarrow T_0 = 0)$ and so the above reduces to

$$H = T(t, q, p) + V_0(t,\ q) \equiv E(t, q, p) = \textit{total energy},\ \text{in Hamiltonian variables.} \tag{8.2.11c}$$

Henceforth, only ordinary potentials $V = V(t,\ q)$ will be considered; then $p_k = \partial L/\partial \dot{q}_k = \partial T/\partial \dot{q}_k$. In sum, in *all* cases, the following kinematico-inertial identities hold:

$$\partial T'/\partial t = -\partial T/\partial t, \qquad \partial T'/\partial q_k = -\partial T/\partial q_k, \qquad \partial T'/\partial p_k = dq_k/dt; \tag{8.2.12a}$$

and

$$\partial H/\partial t = -\partial L/\partial t, \qquad \partial H/\partial q_k = -\partial L/\partial q_k, \qquad \partial H/\partial p_k = dq_k/dt. \tag{8.2.12b}$$

In both (8.2.12a, b):

(i) The *last* (*third*) group is essentially the Hamiltonian counterpart of the Lagrangean definition $\partial T/\partial \dot{q}_k = p_k$.

(ii) The *first two* groups are mathematically equivalent, if we think of time as an $(n+1)$th system coordinate (i.e., $q_{n+1} \equiv t$), but the *first* group is useful in energy rate/power theorems (see below); it states that if L does not involve the time explicitly, neither does H.

(iii) The key group is the *second*: combining it with a(ny) Lagrangean kinetic equation(s), we obtain the corresponding Hamiltonian equation(s) of motion; for example, combining it with the Lagrangean equation $(\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k = Q_k$, we obtain the Hamiltonian equation $dp_k/dt = -\partial T'/\partial q_k + Q_k$.

• Finally, the common derivations of the canonical equations found in the literature are based on *Legendre's transformation* (see below) and *Donkin's theorem* (see, e.g., Crandall et al., 1968, pp. 13–22, 402–406; Gantmacher, 1970, pp. 73–76; Rosenberg, 1977, pp. 279–285). However, the *central equation–based derivation* presented here, due to *Winkelmann* and *Hamel*, is *far simpler and motivated*; it clearly separates the *kinematico-inertial* from the *kinetical aspects* of the *Lagrangean →Hamiltonian transition*, and thus makes its extensions to more general coordinates and/or constraints easier; some expositions falsely imply that the canonical formalism applies only to potential systems!

Legendre's Transformation (LT)

In general, a LT transforms a function $Y(y;x)$ (assumed *convex*; i.e., $\partial^2 Y/\partial y^2 > 0$, like T in the $\dot{q}$'s) into its "conjugate" function

$$Z(z;x)\colon Z + Y = yz$$
$$\Rightarrow y = \partial Z/\partial z = y(z;x), \qquad z = \partial Y/\partial y = z(y;x),$$

that is, $Z(z;x) \equiv zy - Y(y;x) = zy(z;x) - Y[y(z;x);x]$, and similarly for $Y(y;x)$ [(fig. 8.1)].

Here, in dynamics, we have the following identifications:

$$x \to q,\ t, \qquad y \to \dot{q}, \qquad z \to p, \qquad Y(\ldots) \to L, \qquad Z(\ldots) \to H, \tag{8.2.13a}$$
$$z = \partial Y/\partial y \to p = \partial L/\partial \dot{q}, \qquad y = \partial Z/\partial z \to \dot{q} = \partial H/\partial p. \tag{8.2.13b}$$

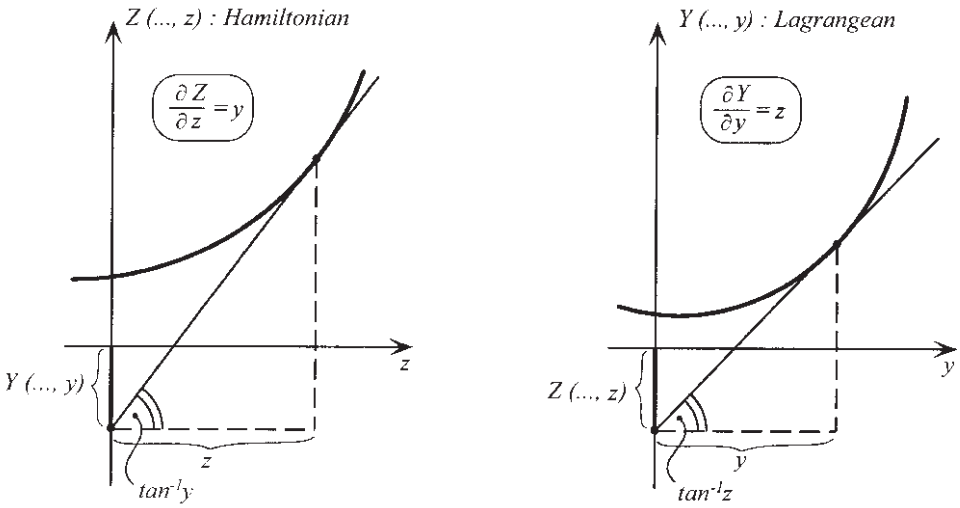

Figure 8.1 Geometrical interpretation of the Legendre transformation.

REMARKS ON LT

(i) For an alternative geometrical interpretation, see Tabor (1989, pp. 79–80).

(ii) Such transformations also appear in other areas of engineering/physics; for instance,

$$\text{Thermodynamics:} \qquad (Y,\ Z) \to (\textit{energy},\ \textit{free energy}),$$
$$\text{Elasticity:} \qquad (Y,\ Z) \to (\textit{strain energy},\ \textit{complementary energy});$$

see, for example, Langhaar (1962, pp. 119–121, 133–136, 244–245); also Hamel (1949, pp. 368–375).

To understand the *connection of H to the power theorems* of §3.9, let us calculate dH/dt and then invoke the earlier canonical equations. Thus, we obtain, successively,

$$\begin{aligned} dH/dt &= \sum \big[(\partial H/\partial q_k)(dq_k/dt) + (\partial H/\partial p_k)(dp_k/dt)\big] + \partial H/\partial t \\ &= \sum \big[(\partial H/\partial q_k)(\partial H/\partial p_k) + (\partial H/\partial p_k)(Q_k - \partial H/\partial q_k)\big] + \partial H/\partial t \\ &= \sum (\partial H/\partial p_k)\, Q_k + \partial H/\partial t = \partial H/\partial t + \sum Q_k\, \dot{q}_k; \end{aligned} \tag{8.2.14}$$

and, therefore, if $\partial H/\partial t = 0$ (e.g., stationary constraints) and $Q_k = 0$ (e.g., wholly potential forces), then the Hamiltonian energy of the system is conserved:

$$H = H(q,\ p) = \textit{constant}. \tag{8.2.14a}$$

2. δq Constrained, δp Unconstrained

If the δq's are restricted by the (additional) m Pfaffian constraints

$$\delta\theta_D \equiv \sum a_{Dk}\, \delta q_k = 0 \qquad [\textit{rank}(a_{Dk}) = m;\ D = 1, \ldots, m(< n)], \tag{8.2.15a}$$

while, in spite of (8.1.2, 3, 5a), the δp's are still viewed as free, then application of the method of Lagrangean multipliers to the canonical central equation (8.2.3) readily yields the $2n$ *canonical Routh–Voss equations*:

$$\begin{aligned} dp_k/dt &= -\partial T'/\partial q_k + Q_k + \sum \lambda_D\, a_{Dk} \quad (\text{where } Q_k = \textit{total impressed} \text{ force}) \\ &= -\partial H/\partial q_k + Q_k + \sum \lambda_D\, a_{Dk} \quad (\text{where } Q_k = \textit{nonpotential impressed} \text{ force}), \end{aligned} \tag{8.2.15b}$$

$$dq_k/dt = \partial T'/\partial p_k \quad (= \partial H/\partial p_k); \tag{8.2.15c}$$

which, along with the m constraints (8.2.15a) (in velocity form)

$$\omega_D \equiv \sum a_{Dk}\, \dot{q}_k + a_D = 0 \tag{8.2.15d}$$

constitute a determinate system for the $2n + m$ functions $\{q_k(t),\ p_k(t),\ \lambda_D(t)\}$.

To uncouple the first set of (8.2.15b) into kinetic and kinetostatic equations, we proceed as in the Lagrangean variable case (§4.5); that is, we introduce the $n - m$ additional ω_I's by

$$\omega_I \equiv \sum a_{Ik}\,\dot{q}_k + a_I \quad (\neq 0,\ \text{velocity form}) \quad \text{or} \quad \delta\theta_I \equiv \sum a_{Ik}\,\delta q_k \quad (\neq 0,\ \text{virtual form}), \tag{8.2.15e}$$

then invert the system (8.2.15d, e), thus obtaining

$$\dot{q}_k = \sum A_{kI}\,\omega_I + A_k \quad \text{(velocity form)} \qquad \text{or} \qquad \delta q_k \equiv \sum A_{kI}\,\delta\theta_I \quad \text{(virtual form)}; \tag{8.2.15f}$$

and inserting this δq-representation into the central equation (8.2.3), we finally obtain the *canonical Maggi equations*:

Kinetostatic equations:
$$\sum A_{kD}\,(dp_k/dt + \partial T'/\partial q_k) = \sum A_{kD}\,Q_k + \lambda_D, \tag{8.2.15g}$$

Kinetic equations:
$$\sum A_{kI}(dp_k/dt + \partial T'/\partial q_k) = \sum A_{kI}\,Q_k; \tag{8.2.15h}$$

while (8.2.15c) remain unchanged.

Similarly, if the Pfaffian constraints have the special form

$$\delta q_D = \sum b_{DI}\,\delta q_I, \tag{8.2.15i}$$

then (8.2.3) easily yields the *canonical Hadamard equations* [special case of (8.2.15g, h)]:

Kinetostatic equations:
$$dp_D/dt + \partial T'/\partial q_D = Q_D + \lambda_D, \tag{8.2.15j}$$

Kinetic equations:
$$dp_I/dt + \partial T'/\partial q_I + \sum b_{DI}(dp_D/dt + \partial T'/\partial q_D) = Q_I + \sum b_{DI}\,Q_D. \tag{8.2.15k}$$

[The multipliers in (8.2.15b) and (8.2.15g) are the same, but they are different in value from those in (8.2.15j).]

3. Nonholonomic Variables

The canonical formalism can be easily extended to quasi variables. We set

$$P_k \equiv \partial T^*/\partial\omega_k = \textit{Nonholonomic system momentum},$$

where

$$T^* = T^*(t, q, \omega) \equiv T^*_{(q\omega)} = T^*[t,\ q,\ \omega(t, q, P)] = T^*(t, q, P) \equiv T^*_{(qP)}, \tag{8.2.16a}$$

and build the nonholonomic counterpart of T':

$$T^{*\prime} \equiv \sum P_k\, \omega_k(t, q, P) - T^*(t, q, P) \equiv T^{*\prime}(t, q, P):$$

$$\textit{Nonholonomic conjugate to } T^* \textit{ kinetic energy.} \tag{8.2.16b}$$

It is not hard to show that:

(i) the nonholonomic counterparts of the Legendre–Donkin identities are

$$\partial T^{*\prime}/\partial\theta_k \equiv \sum (\partial T^{*\prime}/\partial q_l)(\partial \dot{q}_l/\partial\omega_k) = \sum A_{lk}(\partial T^{*\prime}/\partial q_l) = -\partial T^*/\partial\theta_k, \tag{8.2.16c}$$

$$\partial T^{*\prime}/\partial P_k = \omega_k \quad \text{(canonical counterpart of the Lagrange–Hamel: } \partial T^*/\partial\omega_k = P_k), \tag{8.2.16d}$$

and with

$$H^* \equiv T^{*\prime} + V(t,\ q) = \sum P_k\, \omega_k(t, q, P) - L^*(t, q, P)$$
$$\equiv H^*(t, q, P) \equiv H^*{}_{(qP)} = \textit{Nonholonomic Hamiltonian.} \tag{8.2.16e}$$

(ii) The *nonholonomic canonical equations* (most likely due to Pöschl, 1913) are [assuming no further constraints; and for algebraic simplicity *stationary* $\omega \Leftrightarrow \dot{q}$ relationships: $dq_l/dt = \sum A_{lk}\, \omega_k = \sum A_{lk}(\partial H^*/\partial P_k)$]

$$dP_k/dt = -\partial T^{*\prime}/\partial\theta_k - \sum\sum \gamma^s{}_{kl}\ P_s(\partial T^{*\prime}/\partial P_l) + \Theta_k$$
$$\text{(where } \Theta_k = \textit{total impressed} \text{ force),} \tag{8.2.16f}$$
$$= -\partial H^*/\partial\theta_k - \sum\sum \gamma^s{}_{kl}\ P_s(\partial H^*/\partial P_l) + \Theta_k$$
$$\text{(where } \Theta_k = \textit{nonpotential impressed} \text{ force).} \tag{8.2.16g}$$

In the case of m Pfaffian constraints $\omega_D = 0$, the indices in (8.2.16f, g), for the *kinetic* equations, are $s,\ k = m+1, \ldots, n$; $l = m+1, \ldots, n,\ n+1$; and analogously for the *kinetostatic* equations. These equations will not be pursued any further here. For additional details, see, for example, Chetaev (1989, pp. 340–341), Corben and Stehle (1960, pp. 256–257); and for a multibody dynamics application, see Maißer (1982).

Example 8.2.1 *Direct Derivation of the Hamiltonian Kinematico-inertial Identities.* By $d(\ldots)$-differentiating $T' \equiv \sum p_k \dot{q}_k - T(t, q, \dot{q})$, and with $p_k \equiv \partial T/\partial \dot{q}_k$, we find

$$dT' = \sum [p_k d(\dot{q}_k) + \dot{q}_k\, dp_k] - \Big\{(\partial T/\partial t)\, dt + \sum [(\partial T/\partial q_k)\, dq_k + (\partial T/\partial \dot{q}_k)\, d(\dot{q}_k)]\Big\}$$

[the *first* and *last* (fourth) sums cancel each other]

$$= -(\partial T/\partial t)\, dt - \sum (\partial T/\partial q_k)\, dq_k + \sum \dot{q}_k\, dp_k. \tag{a}$$

But also, since $T' = T'(t, q, p)$, we have

$$dT' = (\partial T'/\partial t)\, dt + \sum \big[(\partial T'/\partial q_k)\, dq_k + (\partial T'/\partial p_k)\, dp_k\big]. \tag{b}$$

Equating these two general dT' expressions, (a) and (b), we immediately obtain the $1 + n + n = 1 + 2n$ Hamiltonian *kinematico-inertial* identities (8.2.12a):

$$\partial T'/\partial t = -\partial T/\partial t, \qquad \partial T'/\partial q_k = -\partial T/\partial q_k, \qquad \partial T'/\partial p_k = dq_k/dt. \tag{c}$$

[This is another opportunity to show the advantages of (total) differentials over derivatives!] Repeating the above argument for $H \equiv \sum p_k\, \dot{q}_k - L(t, q, \dot{q})$, and with $p_k \equiv \partial L/\partial \dot{q}_k$, we obtain the earlier identities (8.2.12b):

$$\partial H/\partial t = -\partial L/\partial t, \qquad \partial H/\partial q_k = -\partial L/\partial q_k, \qquad \partial H/\partial p_k = dq_k/dt. \tag{d}$$

Example 8.2.2 *Another Direct Derivation of the Hamiltonian Kinematico-inertial Identities.*

(i) Applying chain rule to $H \equiv \sum p_k\, \dot{q}_k - L(t, q, \dot{q})$, we find

$$\begin{aligned}\partial H/\partial p_k &= dq_k/dt + \sum p_l(\partial \dot{q}_l/\partial p_k) - \sum (\partial L/\partial \dot{q}_l)(\partial \dot{q}_l/\partial p_k)\\ &= dq_k/dt + \sum (p_l - \partial L/\partial \dot{q}_l)(\partial \dot{q}_l/\partial p_k) = dq_k/dt + 0 = dq_k/dt.\end{aligned}$$

Hence, we obtained the "reciprocal" relationships

$$\partial L/\partial \dot{q}_k = p_k \qquad \text{and} \qquad \partial H/\partial p_k = dq_k/dt. \tag{a}$$

(ii) By $d(\ldots)$-varying $L + H - \sum p_k\, \dot{q}_k = 0$ (= *function of* $t, q, \dot{q}, p$), we find

$$\begin{aligned}0 = dL + dH - \sum d(p_k\, \dot{q}_k) = \sum [(\partial L/\partial q_k + \partial H/\partial q_k)\, dq_k + (\partial L/\partial \dot{q}_k - p_k)\, d(\dot{q}_k)\\ + (\partial H/\partial p_k - dq_k/dt)\, dp_k] + (\partial L/\partial t + \partial H/\partial t)\, dt,\end{aligned}$$

and from this, due to (a) and the arbitrariness of the dq's and dt, we obtain the remaining Hamiltonian identities:

$$\partial L/\partial q_k = -\partial H/\partial q_k \qquad \text{and} \qquad \partial L/\partial t = -\partial H/\partial t. \tag{b}$$

Example 8.2.3 *Still Another Direct Derivation of Hamilton's Equations.* By $(\partial/\partial q_k)$- and $(\partial/\partial p_k)$-differentiating the invariant equation

$$L_{(qp)} \equiv L(t, q, p) = L(t, q, \dot{q}) \equiv L_{(q\dot{q})}, \tag{a}$$

we obtain, respectively,

$$\begin{aligned}\partial L_{(qp)}/\partial q_k &= \partial L_{(q\dot{q})}/\partial q_k + \sum (\partial L_{(q\dot{q})}/\partial \dot{q}_l)(\partial \dot{q}_l/\partial q_k)\\ &= \partial L_{(q\dot{q})}/\partial q_k + \sum p_l(\partial \dot{q}_l/\partial q_k) = \partial L_{(q\dot{q})}/\partial q_k + \partial/\partial q_k\Big(\sum p_l\, \dot{q}_l\Big),\end{aligned} \tag{b}$$

(since q and p are treated as independent)

$$\begin{aligned}\partial L_{(qp)}/\partial p_k &= \sum (\partial L_{(q\dot{q})}/\partial \dot{q}_l)(\partial \dot{q}_l/\partial p_k) = \sum p_l(\partial \dot{q}_l/\partial p_k)\\ &= \partial/\partial p_k\Big(\sum p_l\, \dot{q}_l\Big) - \dot{q}_k,\end{aligned} \tag{c}$$

from which, rearranging (collecting the q, p functions on the left sides and the rest on the right), we obtain the kinematico-inertial identities:

$$\partial/\partial q_k\Big(L_{(qp)} - \sum p_l\,\dot{q}_l\Big) = \partial L_{(q\dot{q})}/\partial q_k, \tag{d}$$

$$\partial/\partial p_k\Big(L_{(qp)} - \sum p_l\,\dot{q}_l\Big) = -dq_k/dt. \tag{e}$$

Finally, (i) introducing the Hamiltonian $H(t,q,p) \equiv \sum p_l\,\dot{q}_l(t,q,p) - L(t,q,p)$, and (ii) expressing in (d) $\partial L_{(q\dot{q})}/\partial q_k$ via Lagrange's equations, say $dp_k/dt = \partial L_{(q\dot{q})}/\partial q_k$, we readily obtain the corresponding canonical equations: $dp_k/dt = -\partial H/\partial q_k$ and $dq_k/dt = \partial H/\partial p_k$.

Example 8.2.4 *A Lagrangean Derivation of Hamilton's Equations.* We consider an additional (fictitious) system with $2n$ Lagrangean *coordinates*: $q \equiv (q_1, \ldots, q_n)$ *and* $p \equiv (p_1, \ldots, p_n)$, and Lagrangean function

$$L(t,q,p;\dot{q},\dot{p}) \equiv \sum p_k\dot{q}_k - H(t,q,p); \tag{a}$$

that is, we solve the Hamiltonian definition for the Lagrangean. Now:

(i) The Lagrangean equations for the n coordinates q are, say,

$$0 = (\partial L/\partial\dot{q}_k)^{\cdot} - \partial L/\partial q_k = dp_k/dt - (-\partial H/\partial q_k), \qquad \text{or} \qquad dp_k/dt = -\partial H/\partial q_k; \tag{b}$$

while

(ii) The Lagrangean equations for the n "coordinates" p are

$$0 = (\partial L/\partial\dot{p}_k)^{\cdot} - \partial L/\partial p_k = (0)^{\cdot} - (dq_k/dt - \partial H/\partial p_k), \qquad \text{or} \qquad dq_k/dt = \partial H/\partial p_k. \tag{c}$$

And similarly for systems with more general Lagrangean equations.

Problem 8.2.1 Let $2T = \sum\sum M_{kl}\dot{q}_k\dot{q}_l$ (= *homogeneous* quadratic in the n $\dot{q}$), in which case

$$p_k \equiv \partial T/\partial\dot{q}_k = \sum M_{kl}\dot{q}_l \qquad [\text{assume that: } M_n \equiv Det\ (M_{kl}) \neq 0], \tag{a}$$

and, therefore, by inversion,

$\dot{q}_l = \sum M'_{lk}\,p_k$ (= velocities due to given impulses applied to system, when at rest in a given configuration; hence the name *coefficients of mobility* for the M'_{lk}),

where

$$\begin{aligned} M'_{lk} &\equiv (\text{minor of element } M_{kl} \text{ in determinant } M_n)/M_n \\ &= (1/M_n)(\partial M_n/\partial M_{kl}). \end{aligned} \tag{b}$$

Show that, then,

$$2T' = \sum p_k \dot{q}_k = \sum\sum M'_{kl}\, p_k\, p_l = \sum\sum \left[(1/M_n)(\partial M_n/\partial M_{lk})\right] p_k\, p_l$$
$$\Big[= \sum (\partial T/\partial \dot{q}_k)\, \dot{q}_k = 2T \;\Rightarrow\; T' + T = \sum p_k \dot{q}_k,$$
$$\text{i.e., } T \text{ in the } \dot{q}\text{'s} = T' \text{ in the } p\text{'s: } T(t, q, \dot{q}) = T'(t, q, p)\Big]; \tag{c}$$

and, conjugately to (a),

$$dq_k/dt = \partial T'/\partial p_k. \tag{d}$$

Also, show that:

(i) $$\partial p_k/\partial \dot{q}_l = \partial p_l/\partial \dot{q}_k = \cdots \quad \text{and} \quad \partial \dot{q}_k/\partial p_l = \partial \dot{q}_l/\partial p_k = \cdots. \tag{e}$$

(ii) $$M_n M'_n = 1, \qquad \text{where} \;\; M'_n \equiv Det(M'_{kl}) \quad (\neq 0). \tag{f}$$

Problem 8.2.2 Continuing from prob. 8.2.1, let

$$2T = M_{11}(\dot{q}_1)^2 + 2M_{12}\dot{q}_1\dot{q}_2 + M_{22}(\dot{q}_2)^2; \tag{a}$$

that is, $n = 2$. Show that, then,

$$2T' = M'_{11}\, p_1{}^2 + 2M'_{12}\, p_1\, p_2 + M'_{22}\, p_2{}^2, \tag{b}$$

where

$$M'_{11} = M_{22}/M, \qquad M'_{22} = M_{11}/M, \qquad M'_{12} = -M_{12}/M,$$
$$M \equiv M_2 \equiv Det\,(M_{kl}) = M_{11}M_{22} - M_{12}{}^2; \tag{c}$$

and thus verify directly the Hamiltonian identities

$$dq_1/dt = \partial T'/\partial p_1, \quad dq_2/dt = \partial T'/\partial p_2,$$

and

$$\partial T/\partial q_1 = -\partial T'/\partial q_1, \quad \partial T/\partial q_2 = -\partial T'/\partial q_2. \tag{d}$$

Problem 8.2.3 *Reciprocal Theorem.* Consider the following *two* states of motion of a scleronomic mechanical system through the *same configuration*:

$$\textit{State } 1\ (q_k)\text{: } \dot{q}_k,\ p_k = \sum M_{kl}\,\dot{q}_l, \qquad \textit{State } 2\ (q_k)\text{: } \dot{q}'_k,\ p'_k = \sum M_{kl}\,\dot{q}'_l. \tag{a}$$

Show that

$$\sum p_k \dot{q}'_k = \sum p'_k \dot{q}_k. \tag{b}$$

For further details and applications to impulsive motion, see, for example, Lamb (1929, pp. 184–187, 206); also, the discussion in ex. 4.6.8, and Rayleigh (1894, pp. 91 ff.).

Example 8.2.5 Let us derive the Hamiltonian equations of a spherical pendulum, of mass m and length l. With the $+Oz$ axis taken vertically downward (recall prob. 3.5.16, fig. 3.8), and since $x = (l\sin\theta)\cos\phi$, $y = (l\sin\theta)\sin\phi$, $z = l\cos\theta$, we readily find

$$2T = m[(\dot{x})^2 + (\dot{y})^2 + (\dot{z})^2] = \cdots = ml^2[(\dot{\theta})^2 + \sin^2\theta(\dot{\phi})^2] \quad (= 2T_2), \tag{a}$$

$$V = -mgl\cos\theta \quad (= V_0,\ V = 0 \text{ on plane } z = 0), \tag{b}$$

and, therefore,

$$p_\phi \equiv \partial T/\partial\dot{\phi} = (ml^2\sin^2\theta)\dot{\phi}$$

$(=$ *angular momentum about the vertical axis through the origin*$)$,

$$p_\theta \equiv \partial T/\partial\dot{\theta} = (ml^2)\dot{\theta}$$

$(=$ *angular momentum about horizontal, and perpendicular to instantaneous meridian plane axis through the origin*$)$. (c)

Inverting (c) we immediately obtain the *second* set of the canonical equations:

$$d\phi/dt = p_\phi/ml^2\sin^2\theta \quad (= \partial H/\partial p_\phi), \qquad d\theta/dt = p_\theta/ml^2 \quad (= \partial H/\partial p_\theta). \tag{d}$$

Hence, the Hamiltonian of the system is

$$\begin{aligned} H &= p_\phi\dot{\phi} + p_\theta\dot{\theta} - (T - V) = 2T - (T - V) = T + V = T(t, q, p) + V \\ &= (1/2\,ml^2)\,[(p_\phi{}^2/\sin^2\theta) + p_\theta{}^2] - mgl\cos\theta = H(\phi, \theta, p_\phi,\ p_\theta), \end{aligned} \tag{e}$$

and accordingly the *first* set of its canonical equations (of motion) are

$$dp_\phi/dt = -\partial H/\partial\phi: \qquad dp_\phi/dt = 0 \ \Rightarrow\ p_\phi = constant \equiv c, \tag{f}$$

or, thanks to the first of (d),

$$d\phi/dt = c/ml^2\sin^2\theta, \tag{g}$$

$$dp_\theta/dt = -\partial H/\partial\theta\text{:}\ \ dp_\theta/dt = (\cos\theta/ml^2\sin^3\theta)p_\phi{}^2 - mgl\sin\theta; \tag{h}$$

or, thanks to (f, g),

$$dp_\theta/dt = \cos\theta\, c^2/ml^2\sin^3\theta - mgl\sin\theta \quad [= (ml^2)\ddot{\theta}]. \tag{i}$$

To integrate (i), we multiply both its sides with $p_\theta/\dot{\theta} = (dt/d\theta)p_\theta = (dt/d\theta)(ml^2\dot{\theta}) = ml^2$:

$$p_\theta(dp_\theta/d\theta) = (\cos\theta/\sin^3\theta)\,c^2 - m^2gl^3\sin\theta,$$

and from this, by a θ-integration, we obtain the energy integral $[H = T(t, q, p) + V = constant]$:

$$p_\theta{}^2/2 \ =\ (-1/\sin^2\theta)(c^2/2) + m^2gl^3\cos\theta + constant. \tag{j}$$

Of course, since here $Q_{\phi,\theta} = 0$ and $\partial H/\partial t = 0$, by (8.2.14, 14a) the integral (j) could have been written down immediately.

Problem 8.2.4 Show that the conjugate kinetic energy T' of a particle of mass m moving in space equals

$$2mT' = p_x{}^2 + p_y{}^2 + p_z{}^2 \qquad \text{(rectangular Cartesian coordinates)} \tag{a}$$

$$= p_r{}^2 + (p_\phi/r)^2 + p_z{}^2 \qquad \text{(cylindrical coordinates)} \tag{b}$$

$$= p_r{}^2 + (p_\theta/r)^2 + (p_\phi/r\sin\theta)^2 \qquad \text{(spherical coordinates).} \tag{c}$$

HINT

Recall that (prob. 3.5.15)

$$2T/m = (\dot{x})^2 + (\dot{y})^2 + (\dot{z})^2 = (\dot{r})^2 + (r\dot{\phi})^2 + (\dot{z})^2 = (\dot{r})^2 + (r\dot{\theta})^2 + (r\sin\theta\,\dot{\phi})^2.$$

[Caution: $r_{\text{cylindrical coordinates}}$ (*2nd expression*) $\neq r_{\text{spherical coordinates}}$ (*3rd expression*).]

Problem 8.2.5 Show that the Hamiltonian of a particle of mass m moving on a uniformly rotating frame of reference (of constant inertial angular velocity $\boldsymbol{\Omega}$ is, with the usual notations,

$$\begin{aligned} H &= p^2/2m - \boldsymbol{p}\cdot(\boldsymbol{\Omega}\times\boldsymbol{r}) + V(\boldsymbol{r}) = H(t,\ \boldsymbol{r},\ \boldsymbol{p}) \\ &= v_{\text{relative}}{}^2/2m - m(\boldsymbol{\Omega}\times\boldsymbol{r})^2/2 + V(\boldsymbol{r}) = H(t,\ \boldsymbol{r},\ \boldsymbol{v}_{\text{relative}}). \end{aligned} \tag{a}$$

HINT

$$L = v_{\text{relative}}{}^2/2m + m\,\boldsymbol{v}_{\text{relative}}\cdot(\boldsymbol{\Omega}\times\boldsymbol{r}) + m(\boldsymbol{\Omega}\times\boldsymbol{r})^2/2 - V(\boldsymbol{r}), \tag{b}$$

$$H \equiv (\partial L/\partial \boldsymbol{v}_{\text{relative}})\cdot\boldsymbol{v}_{\text{relative}} - L = \cdots, \qquad \boldsymbol{p} = \partial L/\partial \boldsymbol{v}_{\text{relative}} \Rightarrow \boldsymbol{v}_{\text{relative}} = \cdots.$$

[Recall problems of Lagrangean treatment of particles in uniformly rotating turntables (§3.16).]

Problem 8.2.6 *Unified Treatment of Auxiliary Forms of Lagrange's Inertia Terms.* Let

$$\begin{aligned} 2T &= \sum\sum M_{kl}(q)\dot{q}_k\dot{q}_l = 2T(q,\dot{q}) \equiv 2T_{\dot{q}\dot{q}} \\ &= \sum p_k\dot{q}_k = 2T(\dot{q},p) \equiv 2T_{\dot{q}p} \equiv 2T_{p\dot{q}} \\ &= \sum\sum M'_{kl}(q)p_k p_l = 2T(q,p) \equiv 2T_{pp} \quad (= 2T_{(qp)} \equiv 2T'), \end{aligned} \tag{a}$$

with all Latin indices ranging from 1 to n, and where, as we have seen,

$$p_k = \partial T_{\dot{q}\dot{q}}/\partial\dot{q}_k \qquad \text{and} \qquad \dot{q}_k = \partial T_{pp}/\partial p_k. \tag{b}$$

Show that:

(i)
$$2T_{\dot{q}\dot{q}} = \sum (\partial T_{\dot{q}\dot{q}}/\partial \dot{q}_k)\dot{q}_k, \tag{c}$$

$$2T_{p\dot{q}} = \sum (\partial T_{\dot{q}\dot{q}}/\partial \dot{q}_k)(\partial T_{pp}/\partial p_k), \tag{d}$$

$$2T_{pp} = \sum (\partial T_{pp}/\partial p_k)p_k; \tag{e}$$

and

(ii)
$$\partial T_{pp}/\partial q_k = -\partial T_{\dot{q}\dot{q}}/\partial q_k, \tag{f}$$

$$\partial T_{\dot{q}p}/\partial \dot{q}_k = (1/2)(\partial T_{\dot{q}\dot{q}}/\partial \dot{q}_k) = (1/2)p_k, \tag{g}$$

$$\partial T_{\dot{q}p}/\partial p_k = (1/2)(\partial T_{pp}/\partial p_k) = (1/2)\dot{q}_k; \tag{h}$$

and, therefore,

$$\begin{aligned}
E_k(T) &\equiv (\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k \equiv (\partial T_{\dot{q}\dot{q}}/\partial \dot{q}_k)^{\cdot} - \partial T_{\dot{q}\dot{q}}/\partial q_k \\
&\equiv dp_k/dt - \partial T_{\dot{q}\dot{q}}/\partial q_k && (\textit{Lagrange}) \\
&= (\partial T_{\dot{q}\dot{q}}/\partial \dot{q}_k)^{\cdot} + \partial T_{pp}/\partial q_k \equiv dp_k/dt + \partial T_{pp}/\partial q_k && (\textit{Hamilton}) \\
&= 2(\partial T_{\dot{q}p}/\partial \dot{q}_k)^{\cdot} - \partial T_{\dot{q}\dot{q}}/\partial q_k \\
&= 2(\partial T_{\dot{q}p}/\partial \dot{q}_k)^{\cdot} + \partial T_{pp}/\partial q_k. && \text{(i)}
\end{aligned}$$

HINT

First, using (a–e), verify that

$$T_{pp} = -T_{\dot{q}\dot{q}} + 2T_{\dot{q}p} = -T_{\dot{q}\dot{q}} + \sum p_k\,\dot{q}_k \;\Rightarrow\; T_{pp} + T_{\dot{q}\dot{q}} - 2T_{\dot{q}p} = 0, \tag{j}$$

then differentiate the above totally, and then equate the coefficients of its differentials to zero.

[See Weinstein (1901, pp. 95–97, 186–189) (earliest publication: 1882); also Budde (1890, Vol. 1, pp. 397–401), and Watson and Burbury (1879, pp. 14–22). Such "mixed" equations have been used by Maxwell et al. in electromechanical investigations; see, for example, Maxwell (1877 and 1920, pp. 127–136, 158–161).]

Problem 8.2.7 As a simple application of the preceding problem, consider a particle of mass m described by spherical polar coordinates. In this case, and with the usual notations,

$$2T = m[(\dot{r})^2 + (r\dot{\theta})^2 + (r\sin\theta\,\dot{\phi})^2] = 2T_{\dot{q}\dot{q}}. \tag{a}$$

Show that:

(i)
$$p_r = m\,\dot{r}, \qquad p_\theta = m\,r^2\dot{\theta}, \qquad p_\phi = m\,r^2\sin^2\theta\dot{\phi}; \tag{b}$$

(ii)
$$2T_{\dot{q}p} = \dot{r}\,p_r + \dot{\theta}\,p_\theta + \dot{\phi}\,p_\phi; \tag{c}$$

(iii)
$$2T_{pp} = (1/m)\,[{p_r}^2 + (p_\theta/r)^2 + (p_\phi/r\sin\theta)^2]. \tag{d}$$

Hence, verify that, for example,

$$\partial T_{\dot{q}\dot{q}}/\partial\dot{\theta} = 2(\partial T_{\dot{q}p}/\partial\dot{\theta}) = \cdots, \tag{e}$$

$$\partial T_{\dot{q}\dot{q}}/\partial\theta = -\partial T_{pp}/\partial\theta = \cdots, \tag{f}$$

$$\partial T_{pp}/\partial p_\theta = 2(\partial T_{\dot{q}p}/\partial p_\theta) = \cdots. \tag{g}$$

Problem 8.2.8 Let the general solution of Hamilton's equations be

$$q_k = q_k(t;\ c_1, \ldots, c_{2n}) \equiv q_k(t;\ c), \qquad p_k = p_k(t;\ c_1, \ldots, c_{2n}) \equiv p_k(t;\ c), \tag{a}$$

where $c \equiv (c_1, \ldots, c_{2n}) = 2n$ constants of integration; and we assume that the Jacobian of the q's and p's relative to the c's nowhere vanishes. Then,

$$H = H(t, q, p) = H[t,\ q(t;\ c),\ p(t;\ c)] \equiv H(t,\ c). \tag{b}$$

(i) Show that

$$\partial H/\partial c_\alpha = d/dt\Big[\sum (\partial p_k/\partial c_\alpha) q_k\Big] - \partial/\partial c_\alpha\Big(\sum \dot{p}_k\, q_k\Big) \qquad (\alpha = 1, \ldots, 2n). \tag{c}$$

(ii) Show that eqs. (c) are equivalent to the Hamiltonian equations:

$$dq_k/dt = \partial H/\partial p_k, \qquad dp_k/dt = -\partial H/\partial q_k; \tag{d}$$

that is, if (d) hold, so do (c); and vice versa.

HINT

Note the identity

$$d/dt\Big[\sum (\partial p_k/\partial c_\alpha) q_k\Big] - \partial/\partial c_\alpha\Big(\sum \dot{p}_k\, q_k\Big) = \sum\ \big[(\partial p_k/\partial c_\alpha)\dot{q}_k - (\partial q_k/\partial c_\alpha)\dot{p}_k\big].$$

Problem 8.2.9 Consider the linear differential form (Pfaffian form) in the variables $x = (x_1, \ldots, x_n)$:

$$df \equiv \sum X_k\,(x)\, dx_k. \tag{a}$$

By definition, its *bilinear covariant* is (recall §2.8)

$$\begin{aligned} d_2(d_1 f) - d_1(d_2 f\,) &\equiv \sum (d_2 X_k\, d_1 x_k - d_1 X_k\, d_2 x_k) \\ &= \cdots = \sum\sum (\partial X_k/\partial x_l - \partial X_l/\partial x_k)\, d_2 x_l\, d_1 x_k. \end{aligned} \tag{b}$$

Show that *Hamilton's equations, as well as the power theorem (for* $Q_k = 0$), result from the vanishing of the bilinear covariant of

$$\begin{aligned} dA &\equiv \sum p_k\, dq_k - H\, dt \\ &\Big[= \sum p_\alpha dq_\alpha \quad (\alpha = 1, \ldots, n+1);\ \text{with}\ \ p_{n+1} \equiv -H\ \ \text{and}\ \ q_{n+1} \equiv t\Big], \end{aligned} \tag{c}$$

under arbitrary variations $d_1(\ldots)$ and $d_2(\ldots)$; that is, from

$$\begin{aligned}0 &= d_2(d_1 A) - d_1(d_2 A)\\ &= d_2\Big(\sum p_k\, d_1 q_k - H\, d_1 t\Big) - d_1\Big(\sum p_k\, d_2 q_k - H\, d_2 t\Big)\\ &= \sum (d_2 p_k\, d_1 q_k - d_1 p_k\, d_2 q_k) - (d_2 H\, d_1 t - d_1 H\, d_2 t).\end{aligned} \tag{d}$$

Problem 8.2.10 Consider a potential (but possibly rheonomic) system described by n Lagrangean coordinates.

(i) Define the Hamiltonian-like function

$$H' \equiv \sum (p_k q_k)^{\boldsymbol{\cdot}} - L = \cdots = \sum \dot{p}_k q_k + H = H'(t, p, \dot{p}). \tag{a}$$

Show that the corresponding equations of motion are

$$q_k = \partial H'/\partial \dot{p}_k \quad \text{and} \quad dq_k/dt = \partial H'/\partial p_k \quad [\Rightarrow (\partial H'/\partial \dot{p}_k)^{\cdot} - \partial H'/\partial p_k = 0]. \tag{b}$$

(ii) Similarly, define the Hamiltonian-like function

$$H'' \equiv \sum \dot{p}_k q_k - L = \cdots = \sum (\dot{p}_k q_k - p_k \dot{q}_k) + H = H''(t, \dot{q}, \dot{p}). \tag{c}$$

Show that the corresponding equations of motion are

$$q_k = \partial H''/\partial \dot{p}_k \quad \text{and} \quad p_k = -\partial H''/\partial \dot{q}_k. \tag{d}$$

(iii) Discuss possible theoretical and practical advantages/disadvantages of (b) and (d) over the equations of Hamilton; and verify that $L + H - H' + H'' = 0$.

Problem 8.2.11 Show, by means of general considerations and/or concrete examples, that *the 2n first-order Hamiltonian equations of a problem*, *in general*, *do not coincide with the first-order equations (or state-space) version of its n second-order Lagrangean equations*.

REMARK

This has important consequences in nonlinear dynamics (including chaos): The Hamiltonian first-order version of a Lagrangean (second-order) problem may be *divergenceless* $\Rightarrow$ "volume/area preserving" or *incompressible* (by analogy with continuum fluid mechanics), in the phase space (p, q), i.e. for a one degree-of-freedom system for simplicity,

$$div(\dot{q}, \dot{p}) = \partial\dot{q}/\partial q + \partial\dot{p}/\partial p = \partial/\partial q(\partial H/\partial p) + \partial/\partial p(-\partial H/\partial q) = 0, \tag{a}$$

a fundamental property of conservative/non-dissipative Hamiltonian systems, known as *Liouville's theorem* (§8.9, p. 1183; §8.12, p. 1236); BUT, the first-order version of the same problem in the "Lagrangean phase/state space" $(q, dq/dt \equiv v)$ [§3.12], may *not* be, i.e. (with some simple self-explanatory notations):

$$div(\dot{q}, \dot{v}) \equiv \partial\dot{q}/\partial q + \partial\dot{v}/\partial v = \cdots \neq 0, \qquad v \equiv \dot{q}, \tag{b}$$

in general. See e.g. Tabor (1989, pp. 49–52); also, McCauley (1993, pp. 9–12).

8.3 THE ROUTHIAN CENTRAL EQUATION AND ROUTH'S EQUATIONS OF MOTION

The method of Routh (1877) constitutes an ingenious combination of the methods of Hamilton and Lagrange that results in two sets of equations of motion:

(i) One *Hamiltonian-like* for t and, say the first M q's and corresponding p's, to be henceforth denoted for notational clarity by ψ's and Ψ's, respectively; that is,

$$(q_1, \ldots, q_M) \equiv (\psi_1, \ldots, \psi_M) \equiv (\psi_i) \equiv \psi, \tag{8.3.1a}$$

and

$$(p_1, \ldots, p_M) \equiv (\Psi_1, \ldots, \Psi_M) \equiv (\Psi_i) \equiv \Psi; \tag{8.3.1b}$$

and

(ii) One *Lagrange-like* for t and the remaining $n - M$ q's and corresponding $\dot{q}$'s, to be henceforth denoted by q's and $\dot{q}$'s, respectively; that is,

$$(q_{M+1}, \ldots, q_n) \equiv (q_p) \equiv q \qquad \text{and} \qquad (\dot{q}_{M+1}, \ldots, \dot{q}_n) \equiv (\dot{q}_p) \equiv \dot{q}, \tag{8.3.2a, b}$$

where the subscripts $\boldsymbol{i}$ and $\boldsymbol{p}$ stand for *ignorable* (or *cyclic*) and *palpable* (or *positional*, or *essential*), respectively. Such a *mixed* approach combines the best of both Hamilton and Lagrange, and proves particularly useful in problems of *latent* (or *cyclic*) and *steady* motions. (All these terms/concepts are detailed in the following sections.) With this idea in mind, we begin by rewriting the most general Lagrangean expression for the kinetic energy of a system as follows:

$$\begin{aligned} T &= T(t,\ q_1, \ldots, q_n;\ \dot{q}_1, \ldots, \dot{q}_n) \\ &= T(t;\ q_1, \ldots, q_M;\ q_{M+1}, \ldots, q_n;\ \dot{q}_1, \ldots, \dot{q}_M;\ \dot{q}_{M+1}, \ldots, \dot{q}_n) \\ &\equiv T(t;\ \psi_1, \ldots, \psi_M;\ q_{M+1}, \ldots, q_n;\ \dot{\psi}_1, \ldots, \dot{\psi}_M;\ \dot{q}_{M+1}, \ldots, \dot{q}_n) \\ &\equiv T(t,\ \psi,\ q;\ \dot{\psi},\ \dot{q}), \end{aligned} \tag{8.3.3a}$$

and, in there, replace $\dot{\psi} \equiv (\dot{\psi}_1, \ldots, \dot{\psi}_M)$ in terms of their momenta $\boldsymbol{\Psi} \equiv (\boldsymbol{\Psi}_1, \ldots, \boldsymbol{\Psi}_M)$, and so on, à la Hamilton; that is, $\dot{\psi}_i = \dot{\psi}_i(t,\ \psi,\ q;\ \boldsymbol{\Psi}, \dot{q})$. The result is

$$\begin{aligned} T &= T[t,\ \psi,\ q;\ \dot{\psi}(t,\ \psi,\ q;\ \boldsymbol{\Psi},\ \dot{q}),\ \dot{q}] \\ &= T(t;\ \psi_1, \ldots, \psi_M;\ q_{M+1}, \ldots, q_n;\ \boldsymbol{\Psi}_1, \ldots, \boldsymbol{\Psi}_M;\ \dot{q}_{M+1}, \ldots, \dot{q}_n) \\ &= T(t,\ \psi,\ q;\ \boldsymbol{\Psi},\ \dot{q}) \equiv T_{\psi\boldsymbol{\Psi}}. \end{aligned} \tag{8.3.3b}$$

Next, with the help of the new (conjugate-like, to within a minus sign) function

$$\begin{aligned} T'' &\equiv T - \sum \boldsymbol{\Psi}_i \dot{\psi}_i = \left(T - \sum \boldsymbol{\Psi}_i \dot{\psi}_i\right)_{\dot{\psi} = \dot{\psi}(t;\psi,q;\boldsymbol{\Psi},\dot{q})} \\ &= T''(t,\ \psi,\ q;\ \boldsymbol{\Psi},\ \dot{q}), \end{aligned} \tag{8.3.3c}$$

we transform the fundamental central equation (8.2.1; with $k = 1, \ldots, n$)

$$\delta I = \delta' W: \qquad d/dt\left(\sum p_k\ \delta q_k\right) - \delta T = \sum Q_k\ \delta q_k, \tag{8.3.4a}$$

or, [assuming that $(\delta q_k)^{\cdot} = \delta(\dot{q}_k)$]

$$\sum \left[\dot{p}_k\ \delta q_k + p_k\ \delta(\dot{q}_k)\right] - \delta T = \sum Q_k\ \delta q_k, \tag{8.3.4b}$$

and since $\delta T = \delta T_{\psi\boldsymbol{\Psi}}$, to

$$\sum \left[\dot{p}_k\ \delta q_k + p_k\ \delta(\dot{q}_k)\right] - \delta T'' - \sum \left[\delta\boldsymbol{\Psi}_i\ \dot{\psi}_i + \boldsymbol{\Psi}_i\ \delta(\dot{\psi}_i)\right] = \sum Q_k\ \delta q_k; \tag{8.3.4c}$$

or, carrying out the $\delta T''$-variation (with $i = 1, \ldots, M;\ p = M + 1, \ldots, n$):

$$\begin{aligned} &\sum \left[\dot{p}_k\ \delta q_k + p_k\ \delta(\dot{q}_k)\right] - \sum \left[(\partial T''/\partial \psi_i)\ \delta\psi_i + (\partial T''/\partial \boldsymbol{\Psi}_i)\ \delta\boldsymbol{\Psi}_i\right] \\ &\quad - \sum \left[(\partial T''/\partial q_p)\ \delta q_p + (\partial T''/\partial \dot{q}_p)\ \delta(\dot{q}_p)\right] - \sum \left[\dot{\psi}_i\ \delta\boldsymbol{\Psi}_i + \boldsymbol{\Psi}_i\ \delta(\dot{\psi}_i)\right] = \sum Q_k\ \delta q_k, \end{aligned} \tag{8.3.4d}$$

or, collecting δq, $\delta\psi$, $\delta(\dot{q})$, and $\delta\Psi$-proportional terms [while recalling that $q_i \equiv \psi_i \Rightarrow \delta q_i \equiv \delta\psi_i$, $\delta(\dot{q}_i) \equiv \delta(\dot{\psi}_i)$, and $p_i \equiv \Psi_i$], we finally obtain the *Routhian central equation*:

$$\sum (dp_k/dt - \partial T''/\partial q_k - Q_k)\,\delta q_k + \sum (p_p - \partial T''/\partial \dot{q}_p)\,\delta(\dot{q}_p) - \sum (d\psi_i/dt + \partial T''/\partial \Psi_i)\,\delta\Psi_i = 0, \tag{8.3.4e}$$

which holds for *all* δq_k, $\delta(\dot{q}_p)$, and $\delta\Psi_i$ (again, with $k = 1, \ldots, n$; $p = M+1, \ldots, n$; $i = 1, \ldots, M$) and, as expected, is fundamental to all subsequent developments.

Now, as with (8.2.3):

1. If the δq_k, $\delta(\dot{q}_p)$, and $\delta\Psi_i$ are mutually *independent*, then (8.3.4e) leads immediately to *the equations of Routh* [1877 — not to be confused with the earlier Routh–Voss equations (§3.5)!]:

(i) $dp_k/dt = \partial T''/\partial q_k + Q_k$: $\quad d\Psi_i/dt = \partial T''/\partial \psi_i + Q_i \quad (i = 1, \ldots, M)$, (8.3.5a)

$$dp_p/dt = \partial T''/\partial q_p + Q_p \quad (p = M+1, \ldots, n); \tag{8.3.5b}$$

(ii) $$d\psi_i/dt = -\partial T''/\partial \Psi_i \qquad (i = 1, \ldots, M), \tag{8.3.5c}$$

(iii) $$p_p = \partial T''/\partial \dot{q}_p \qquad (p = M+1, \ldots, n). \tag{8.3.5d}$$

Of these equations, (8.3.5a, b) are *kinetic* (i.e., equations of motion), whereas (8.3.5c, d) are *kinematico-inertial identities*. The Hamilton-like equations (8.3.5a, c) (with $-T''$ playing the role of our earlier T'), are Routh's equations for ψ and Ψ; while the Lagrange-like equations (8.3.5b, d) (with T'' playing the role of T) are Routh's equations for q and $\dot{q}$; that is, rearranging:

Hamilton-like Routh equations:

$$d\Psi_i/dt = -\partial(-T'')/\partial\psi_i + Q_i, \qquad d\psi_i/dt = \partial(-T'')/\partial\Psi_i; \tag{8.3.6a}$$

Lagrange-like Routh equations:

$$dp_p/dt = \partial T''/\partial q_p + Q_p, \qquad p_p = \partial T''/\partial \dot{q}_p \quad (= \partial T/\partial \dot{q}_p)$$
$$\Rightarrow (\partial T''/\partial \dot{q}_p)^{\cdot} - \partial T''/\partial q_p = Q_p. \tag{8.3.6b}$$

- If $M = 0$ — that is, if no velocities $\dot{\psi}_i$ are eliminated through $\dot{\psi}_i(t,\ \psi,\ q;\ \Psi,\ \dot{q})$ — then the group of equations (8.3.6a) drops; while the group (8.3.6b) coincide with Lagrange's equations for T (since then $T'' = T$).
- If, on the other hand, $M = n$ — that is, if all $\dot{\psi}_i$ are eliminated through $\dot{\psi}_i(t,\ \psi,\ q;\ \Psi,\ \dot{q})$ — then the situation is reversed: group (8.3.6b) drops (since then $T'' = -T'$), while group (8.3.6a) coincides with Hamilton's equations. Schematically,

$$M: \qquad 0\ (\textit{Lagrange}) \leftarrow \cdots \text{————} \cdots \rightarrow n\ (\textit{Hamilton}).$$

Finally, comparing the above with the corresponding Lagrangean equations $dp_k/dt = \partial T/\partial q_k + Q_k$, we immediately obtain the additional Routhian *kinematico-inertial identities*

$\partial T/\partial q_k = \partial T''/\partial q_k$: $\quad \partial T/\partial \psi_i = \partial T''/\partial \psi_i \qquad (i = 1, \ldots, M)$, (8.3.7a)

$$\partial T/\partial q_p = \partial T''/\partial q_p \qquad (p = M+1, \ldots, n); \tag{8.3.7b}$$

which can be utilized in any set of Hamiltonian- or Lagrangean-type equations of motion.

In sum, we have the following *two groups* of such kinematico-inertial identities:

$$\partial T''/\partial\psi_i = \partial T/\partial\psi_i \qquad \text{and} \qquad \partial T''/\partial\Psi_i = -d\psi_i/dt; \tag{8.3.8a}$$

$$\partial T''/\partial q_p = \partial T/\partial q_p \qquad \text{and} \qquad \partial T''/\partial\dot{q}_p = \partial T/\partial\dot{q}_p \quad (= p_p); \tag{8.3.8b}$$

see also examples on direct derivations, below.

If $p_k \equiv \partial L/\partial\dot{q}_k$, then (8.3.6a, b) are replaced, respectively, by the Routhian equations:

Hamilton-like Routh equations:

$$d\Psi_i/dt = \partial R/\partial\psi_i + Q_i, \qquad d\psi_i/dt = -\partial R/\partial\Psi_i; \tag{8.3.9a}$$

Lagrange-like Routh equations:

$$\begin{gathered} dp_p/dt = \partial R/\partial q_p + Q_p, \qquad p_p = \partial R/\partial\dot{q}_p \quad (= \partial L/\partial\dot{q}_p) \\ \Rightarrow E_p(R) \equiv (\partial R/\partial\dot{q}_p)^{\cdot} - \partial R/\partial q_p = Q_p; \end{gathered} \tag{8.3.9b}$$

where

$$\begin{gathered} R \equiv \Big(L - \sum \Psi_i\dot{\psi}_i\Big)_{\dot{\psi}=\dot{\psi}(t;\psi,q;\Psi,\dot{q})} = R(t;\ \psi,\ q;\ \Psi,\ \dot{q}): \\ \textit{Routhian function}, \text{ or } \textit{Modified Lagrangean}, \end{gathered} \tag{8.3.9c}$$

and

$$\begin{gathered} L = L(t;\ \psi,\ q;\ \Psi,\ \dot{q}) \equiv T_{\psi\Psi} - V \equiv L_{\psi\Psi}: \\ \textit{Lagrangean expressed in Routhian variables}; \end{gathered} \tag{8.3.9d}$$

and the *nonpotential* forces Q_k have also been expressed in the Routhian variables t, ψ, q, Ψ, $\dot{q}$; while (8.3.7a, b) and (8.3.8a, b) are replaced, respectively, by

$$\partial L/\partial\psi_i = \partial R/\partial\psi_i \qquad \text{and} \qquad \partial L/\partial q_p = \partial R/\partial q_p; \tag{8.3.9e}$$

and

$$\partial R/\partial\psi_i = \partial L/\partial\psi_i \qquad \text{and} \qquad \partial R/\partial\Psi_i = -d\psi_i/dt; \tag{8.3.9f}$$

$$\partial R/\partial q_p = \partial L/\partial q_p \qquad \text{and} \qquad \partial R/\partial\dot{q}_p = \partial L/\partial\dot{q}_p \quad (= p_p); \tag{8.3.9g}$$

that is, *the Routhian is a Hamiltonian [times* (-1)*] for the* ψ_i*, and a Lagrangean for the* q_p.

HISTORICAL

The Routhian was also introduced, independently, by Helmholtz (in 1884), who called it "new kinetic potential"; that is, (negative of) new Lagrangean = (negative of) Routhian. See, for example, Helmholtz [1898, pp. 361–369, eq. (200a)], Webster (1912, pp. 176–179).

To find the relation between the Routhian and the Hamiltonian (or generalized energy), we proceed as follows:

$$
\begin{aligned}
H &\equiv \sum p_k \dot{q}_k - L \\
&= \sum \dot{\psi}_i(\partial L/\partial\dot{\psi}_i) + \sum \dot{q}_p(\partial L/\partial\dot{q}_p) - L \qquad &&\text{[invoking (8.3.9g)]} \\
&= \sum \dot{q}_p(\partial R/\partial\dot{q}_p) - \left(L - \sum \dot{\psi}_i \Psi_i\right) &&\text{[invoking (8.3.9c)]} \\
&= \sum \dot{q}_p(\partial R/\partial\dot{q}_p) - R,
\end{aligned}
$$

from which we immediately conclude that

$$
\begin{aligned}
&R = \sum \dot{q}_p(\partial R/\partial\dot{q}_p) - H = \sum p_p\dot{q}_p - H \\
&\left[-\left(H - \sum p_p\dot{q}_p\right) = L - \sum \Psi_i\,\dot{\psi}_i\text{: equivalent definitions of the Routhian}\right].
\end{aligned}
\tag{8.3.10}
$$

REMARK

Some authors define the Routhian as the *negative* of ours; that is, as

$$R \equiv \sum \dot{\psi}_i(\partial L/\partial\dot{\psi}_i) - L \equiv \sum \Psi_i\,\dot{\psi}_i - L.$$

In such a case, all the above results hold intact, but with R replaced with $-R$; then (8.3.9a) look exactly like Hamiltonian equations for the ψ's, Ψ's. That definition would be "Hamiltonian" in spirit—that is, *Routhian* $=$ *Hamiltonian* $- \sum p_p\,\dot{q}_p$; ours, being closer to engineering, is "Lagrangean"—that is, *Routhian* $=$ *Lagrangean* $- \sum \Psi_i\dot{\psi}_i$.

2. If the n δq_k are restricted by the m Pfaffian constraints

$$\delta\theta_D \equiv \sum a_{Dk}\,\delta q_k = 0 \qquad [rank(a_{Dk}) = m;\ D = 1, \ldots, m(< n)], \tag{8.3.11a}$$

while the $n - M$ $\delta(\dot{q}_p)$ and M $\delta\Psi_i$ are still viewed as independent, then application of the method of Lagrangean multipliers to the Routhian central equation (8.3.4e) readily yields the *constrained Routhian equations*:

$$dp_k/dt = \partial T''/\partial q_k + Q_k + \sum \lambda_D\,a_{Dk},$$

or, split in two groups (assuming that $m < M$ and $m < n - M$):

$$d\Psi_i/dt = \partial T''/\partial\psi_i + Q_i + \sum \lambda_D\,a_{Di}, \qquad dp_p/dt = \partial T''/\partial q_p + Q_p + \sum \lambda_D\,a_{Dp}, \tag{8.3.11b}$$

and the earlier kinematico-inertial identities

$$d\psi_i/dt = -\partial T''/\partial\Psi_i, \qquad p_p = \partial T''/\partial\dot{q}_p. \tag{8.3.11c}$$

The formulation of the above in terms of the Routhian, whenever the impressed forces are partly or wholly potential, does not offer any difficulties and will be left to the reader.

3. For an extension of these results to *quasi variables*, see, for example, Chetaev (1989, pp. 339–346).

Example 8.3.1 *Direct Derivation of the Routhian Kinematico-inertial Identities.* By $d(\ldots)$-differentiating $T'' \equiv (T - \sum \Psi_i \dot{\psi}_i) = T''(t, \psi, q; \Psi, \dot{q})$, we find

$$\begin{aligned} dT'' &= (\partial T/\partial t)\, dt + \sum \left[(\partial T/\partial q_k)\, dq_k + (\partial T/\partial \dot{q}_k)\, d\dot{q}_k\right] \\ &\quad - \sum \left[d\Psi_i\, \dot{\psi}_i + \Psi_i\, d\dot{\psi}_i\right] \\ &= \cdots = (\partial T/\partial t)\, dt + \sum \left[(\partial T/\partial \psi_i)\, d\psi_i - \dot{\psi}_i\, d\Psi_i\right] \\ &\qquad + \sum \left[(\partial T/\partial q_p)\, dq_p + (\partial T/\partial \dot{q}_p)\, d\dot{q}_p\right]. \end{aligned} \tag{a}$$

But also, since $T'' = T''(t, \psi, q; \Psi, \dot{q})$, we will have

$$\begin{aligned} dT'' &= (\partial T''/\partial t)\, dt + \sum \left[(\partial T''/\partial \psi_i)\, d\psi_i + (\partial T''/\partial \Psi_i)\, d\Psi_i\right] \\ &\qquad + \sum \left[(\partial T''/\partial q_p)\, dq_p + (\partial T''/\partial \dot{q}_p)\, d\dot{q}_p\right]. \end{aligned} \tag{b}$$

Therefore, equating the coefficients of these two general dT'' expressions, (a) and (b), since the differentials involved are arbitrary, we immediately obtain the following $1 + 2M + 2(n - M) = 2n + 1$ Routhian kinematico-inertial identities:

$$\partial T''/\partial t = \partial T/\partial t, \tag{c}$$

$$\partial T''/\partial \psi_i = \partial T/\partial \psi_i, \qquad \partial T''/\partial \Psi_i = -\dot{\psi}_i; \tag{d}$$

$$\partial T''/\partial q_p = \partial T/\partial q_p, \qquad \partial T''/\partial \dot{q}_p = \partial T/\partial \dot{q}_p \quad (= p_p). \tag{e}$$

Let us resummarize our findings:

(i) Equations (c), first of (d), and first of (e) are fundamentally equivalent, if we think of time as the $(n+1)$th Lagrangean coordinate: $q_{n+1} \equiv t$;
(ii) The first of eqs. (d) are, essentially, Hamiltonian in nature, while the first of eqs. (e) are Lagrangean; and both sets are used in the corresponding kinetic equations;
(iii) The second of eqs. (d) are the Hamiltonian counterpart of the Lagrangean identity $\partial T/\partial \dot{\psi}_i = \Psi_i$ (with T'' replaced with $-T''$); while
(iv) The second of eqs. (e) are purely Lagrangean.

Repeating this procedure for the Routhian $R = L - \sum \Psi_i \dot{\psi}_i$, with $p_k = \partial L/\partial \dot{q}_k$, we similarly obtain the following identities:

$$\partial R/\partial t = \partial L/\partial t, \tag{f}$$

$$\partial R/\partial \psi_i = \partial L/\partial \psi_i, \qquad \partial R/\partial \Psi_i = -d\psi_i/dt; \tag{g}$$

$$\partial R/\partial q_p = \partial L/\partial q_p, \qquad \partial R/\partial \dot{q}_p = \partial L/\partial \dot{q}_p \quad (= p_p); \tag{h}$$

or, compactly,

$$\partial R/\partial q_k = \partial L/\partial q_k \qquad (k = 1, \ldots, n \ \ \textit{and} \ \ n+1), \tag{i}$$

$$\partial R/\partial \dot{q}_p = \partial L/\partial \dot{q}_p \qquad (p = M+1, \ldots, n), \tag{j}$$

$$\partial R/\partial \Psi_i = -d\psi_i/dt \qquad (i = 1, \ldots, M). \tag{k}$$

Last, since by (8.2.10b), $\partial H/\partial t = -\partial L/\partial t$, eq. (f) shows that if a Lagrangean is explicitly independent of time, then so are the corresponding Routhian and Hamiltonian; and for potential systems [since, then, $dH/dt = \partial H/\partial t$, by (8.2.14)], the latter is also a constant.

Example 8.3.2 *Another Direct Derivation of the Routhian Kinematico-inertial Identities.* Applying chain rule, carefully, to the Routhian definition $R = L - \sum \Psi_i \dot{\psi}_i$, where

$$R = R(t, \psi, q; \Psi, \dot{q}), \qquad L = L(t, \psi, q; \dot{\psi}, \dot{q}), \qquad \text{and} \qquad \dot{\psi}_i = \dot{\psi}_i(t, \psi, q; \Psi, \dot{q}), \quad \text{(a)}$$

we obtain (with $i, j = 1, \ldots, M;\ p = M + 1, \ldots, n$):

$$\text{(i)}\quad \partial R/\partial t = \left[\partial L/\partial t + \sum (\partial L/\partial \dot{\psi}_i)(\partial \dot{\psi}_i/\partial t)\right] - \sum \Psi_i(\partial \dot{\psi}_i/\partial t) = \partial L/\partial t; \qquad \text{(b)}$$

$$\text{(ii)}\quad \partial R/\partial q_p = \left[\partial L/\partial q_p + \sum (\partial L/\partial \dot{\psi}_i)(\partial \dot{\psi}_i/\partial q_p)\right] - \sum \Psi_i(\partial \dot{\psi}_i/\partial q_p) = \partial L/\partial q_p; \qquad \text{(c)}$$

$$\text{(iii)}\quad \partial R/\partial \dot{q}_p = \left[\partial L/\partial \dot{q}_p + \sum (\partial L/\partial \dot{\psi}_i)(\partial \dot{\psi}_i/\partial \dot{q}_p)\right] - \sum \Psi_i(\partial \dot{\psi}_i/\partial \dot{q}_p) = \partial L/\partial \dot{q}_p; \qquad \text{(d)}$$

$$\text{(iv)}\quad \partial R/\partial \psi_i = \left[\partial L/\partial \psi_i + \sum (\partial L/\partial \dot{\psi}_j)(\partial \dot{\psi}_j/\partial \psi_i)\right] - \sum \Psi_j(\partial \dot{\psi}_j/\partial \psi_i) = \partial L/\partial \psi_i; \qquad \text{(e)}$$

$$\text{(v)}\quad \partial R/\partial \Psi_i = \sum (\partial L/\partial \dot{\psi}_j)(\partial \dot{\psi}_j/\partial \Psi_i) - \left[\dot{\psi}_i + \sum \Psi_j(\partial \dot{\psi}_j/\partial \Psi_i)\right] = -\dot{\psi}_i; \qquad \text{(f)}$$

which are indeed the earlier Routhian identities.

Clearly, the method of the preceding example (*total differentials*) seems simpler and safer than this one (*derivatives*), as in the earlier derivations of the Hamiltonian equations (exs. 8.2.1–3).

Analytical Structure of the Routhian

Let us consider (with no loss of generality, just algebraic simplicity) a *scleronomic* system whose kinetic energy T is, therefore, a *homogeneous* quadratic function in its chosen n Lagrangean velocities $\dot{q}_k$'s ($k = 1, \ldots, n$). First, we decompose T into the following *three* parts:

$$T = T_{\dot{q}\dot{q}} + T_{\dot{q}\dot{\psi}} + T_{\dot{\psi}\dot{\psi}} = T(\psi, q; \dot{\psi}, \dot{q}), \qquad (8.3.12)$$

where

$$2T_{\dot{q}\dot{q}} \equiv \sum\sum a_{pq}\dot{q}_p\dot{q}_q = \textit{homogeneous quadratic in the } \dot{q}\text{'s} \quad (a_{pq} = a_{qp};\ \textit{positive definite}),$$

$$T_{\dot{q}\dot{\psi}} \equiv \sum\sum b_{pi}\dot{q}_p\dot{\psi}_i = \textit{homogeneous bilinear in the } \dot{q}\text{'s } \textit{and } \dot{\psi}\text{'s}$$
$$(\textit{in general},\ b_{pi} \neq b_{ip};\ \textit{sign indefinite}), \tag{8.3.12b}$$

$$2T_{\dot{\psi}\dot{\psi}} \equiv \sum\sum c_{ij}\dot{\psi}_i\dot{\psi}_j = \textit{homogeneous quadratic in the } \dot{\psi}\text{'s}$$
$$(c_{ij} = c_{ji};\ \textit{positive definite},\ \text{otherwise the } \textit{cyclic kinetic energy } T_{\dot{\psi}\dot{\psi}} \text{ would not be positive definite}); \tag{8.3.12c}$$

with $i, j = 1, \ldots, M$; $p, q = M + 1, \ldots, n$; and the coefficients are functions of all n q_k's. [It is not hard to see that, in the most general case, $T_{\dot{\psi}\dot{\psi}}$, $T_{\dot{q}\dot{\psi}}$, and $T_{\dot{q}\dot{q}}$ contain, respectively (with $g \equiv n - m$), $M + (\frac{1}{2})M(M - 1)$, Mg, and $g + (\frac{1}{2})g(g - 1)$ terms; that is, a total of $(\frac{1}{2})(M + g)(M + g + 1) = (\frac{1}{2})n(n + 1)$ terms, as expected.]

Now, solving the linear system

$$\Psi_i \equiv \partial T/\partial\dot{\psi}_i = \sum c_{ji}\dot{\psi}_j + \sum b_{pi}\dot{q}_p \ \Rightarrow\ \sum c_{ji}\dot{\psi}_j = \Psi_i - \sum b_{pi}\dot{q}_p, \tag{8.3.12d}$$

for the $\dot{\psi}_j$, via Cramer's rule [i.e., inverting (8.3.12d), which, since (c_{ji}) is *nonsingular*, is possible], we obtain

$$\dot{\psi}_j = \sum C_{ji}\Big(\Psi_i - \sum b_{pi}\dot{q}_p\Big), \tag{8.3.12e}$$

where

$$C_{ji} = [\textit{cofactor of element } c_{ji} \textit{ in } Det(c_{ji})]/Det(c_{ji}) = C_{ij}$$
$$(= \textit{known function of the } q\text{'s } \textit{and } \psi\text{'s});$$

and then substituting these expressions for the $\dot{\psi}_j$ into (8.3.12–8.3.12c), and using well-known properties of inverse matrices, we obtain

$$T = T_{2,0} + T_{0,2} = T(\psi, q; \Psi, \dot{q}) \quad (\equiv T_{\dot{q}\Psi}), \tag{8.3.12f}$$

where

$$2T_{2,0} \equiv \sum\sum\Big(a_{pq} - \sum\sum C_{ji}b_{pj}b_{qi}\Big)\dot{q}_p\dot{q}_q, \tag{8.3.12g}$$

$$2T_{0,2} \equiv \sum\sum C_{ji}\Psi_j\Psi_i; \tag{8.3.12h}$$

that is, $T = T(\psi, q; \Psi, \dot{q})$ does *not* contain any bilinear terms in the $\dot{q}$'s and Ψ's!

With the help of the above, the *modified kinetic energy* T'' becomes, successively,

$$\begin{aligned} T'' &\equiv T - \sum \Psi_i\dot{\psi}_i = T - \sum \Psi_i\Big[\sum C_{ij}\Big(\Psi_j - \sum b_{pj}\dot{q}_p\Big)\Big] \\ &= T_{2,0} + T''_{1,1} - T_{0,2} \equiv T''_{2,0} + T''_{1,1} + T''_{0,2} \\ &= T''(\psi, q; \Psi, \dot{q}), \end{aligned} \tag{8.3.12i}$$

where

$$\begin{aligned} 2T''_{2,0} &\equiv \sum\sum\Big(a_{pq} - \sum\sum C_{ji}b_{pj}b_{qi}\Big)\dot{q}_p\dot{q}_q \equiv \sum\sum r_{pq}(q)\dot{q}_p\dot{q}_q \\ &= 2T_{2,0} \quad (= \textit{positive definite in the } \dot{q}\text{'s}), \end{aligned} \tag{8.3.12j}$$

$$T''_{1,1} \equiv \sum\sum\left(\sum C_{ji}b_{pi}\right)\Psi_j\dot{q}_p \equiv \sum r_p(q,\Psi)\dot{q}_p,$$
$$[\textit{No counterpart in } T = T(\psi, q; \Psi, \dot{q});\ \text{i.e., } T_{1,1} = 0;\ \textit{sign indefinite}], \quad (8.3.12\text{k})$$

$$2T''_{0,2} \equiv -\sum\sum C_{ji}\Psi_j\Psi_i = 2T''_{0,2}(q,\Psi)$$
$$= -2T_{0,2} \quad (= \textit{negative definite in the } \Psi\text{'s}). \quad (8.3.12\text{l})$$

Conversely, if $T'' = T''_{2,0} + T''_{1,1} + T''_{0,2}$, then (by Routh's identities and the homogeneous function theorem),

$$T \equiv T'' + \sum \Psi_i\dot{\psi}_i = T'' - \sum \Psi_i(\partial T''/\partial\Psi_i)$$
$$= (T''_{2,0} + T''_{1,1} + T''_{0,2}) - (T''_{1,1} + 2T''_{0,2})$$
$$= T''_{2,0} - T''_{0,2} = T(\psi, q; \Psi, \dot{q}) \qquad [\text{Compare this with (8.3.12f) and (8.3.12)}]. \quad (8.3.12\text{m})$$

In view of these results, the Lagrangean and Routhian assume, respectively, the following forms:

$$L = T - V = (T_{2,0} + T_{0,2}) - V = T_{2,0} - (V - T_{0,2})$$
$$= (T''_{2,0} - T''_{0,2}) - V = T''_{2,0} - (V + T''_{0,2}) = L(\psi, q; \Psi, \dot{q}), \quad (8.3.13)$$
$$R = L - \sum \Psi_i\dot{\psi}_i = L + \sum(\partial T''/\partial\Psi_i)\Psi_i$$
$$= (T''_{2,0} - T''_{0,2} - V) + (2T''_{0,2} + T''_{1,1})$$
$$\equiv R_2 + R_1 + R_0 = R(\psi, q; \Psi, \dot{q}), \quad (8.3.14)$$

where

$$R_2 \equiv T''_{2,0} = T_{2,0}, \qquad R_1 \equiv T''_{1,1}, \qquad R_0 \equiv T''_{0,2} - V = -T_{0,2} - V. \quad (8.3.14\text{a})$$

These remarkable identities seem to be due to Routh (also, Kelvin and Helmholtz), and are very useful in the theory of *cyclic* systems (§8.4).

[For additional explicit expressions of the Routhian, and so on, see, for example: Gantmacher [1970, pp. 242–252 (§48)], Lur'e [1968, pp. 340–351 (§7.15–7.17); also contains the *decomposition into Routhian variables in the general nonstationary/rheonomic T case*], Merkin (1974, pp. 24–36), Routh [1877 and 1975, pp. 63–64, 93–94; 1905(b), pp. 341–342], Winkelmann and Grammel (1927, pp. 470–474); also Easthope (1964, pp. 382–383), Grammel (1950, Vol. 1, pp. 255–258), Heun (1914, pp. 454–457).]

Problem 8.3.1 Continuing from the above, let

$$T = T_{\dot{q}\dot{q}} + T_{\dot{q}\dot{\psi}} + T_{\dot{\psi}\dot{\psi}} = T(\psi, q; \dot{\psi}, \dot{q}). \quad (\text{a})$$

Using the homogeneous function theorem, show that its modified kinetic energy

$$T'' = T - \sum \Psi_i\dot{\psi}_i = T - \sum(\partial T/\partial\dot{\psi}_i)\dot{\psi}_i, \quad (\text{b})$$

equals

$$T'' = T_{\dot{q}\dot{q}} - T_{\dot{\psi}\dot{\psi}} = T''(\psi, q; \dot{\psi}, \dot{q}); \quad (\text{c})$$

that is, $T'' = T''(\psi, q; \dot{\psi}, \dot{q})$ does *not* contain any bilinear terms in the variables $\dot{q}$ and $\dot{\psi}$!

Problem 8.3.2 Continuing from the above, show that Routh's nonkinetic equations (i.e., his kinematico-inertial identities) transform further to

$$d\psi_i/dt = -\partial T''/\partial \Psi_i = \cdots = \partial T_{0,2}/\partial \Psi_i - \partial K_{2,2}/\partial \pi_i, \tag{a}$$

where

$$2T_{0,2} = -2T''_{0,2} \equiv \sum\sum C_{ji} \Psi_j \Psi_i, \tag{b}$$

and

$$2K_{2,2} \equiv \sum\sum C_{ji}\Big(\sum b_{pj}\dot{q}_p\Big)\Big(\sum b_{qi}\dot{q}_q\Big) \equiv \sum\sum C_{ji}\pi_j\pi_i. \tag{c}$$

Example 8.3.3 (May be omitted in a first reading). Here, we carry out a *matrix derivation* of the above results on the structure of the Routhian, for the benefit of those more comfortable with that currently popular notation.

With the notations $(\ldots)^{\mathrm{T}} \equiv$ *transpose* of matrix $(\ldots)$, $(\ldots)^{-1} \equiv$ *inverse* of matrix $(\ldots)$, and

$$\dot{\mathbf{q}}^{\mathrm{T}} = (\dot{q}_{M+1}, \ldots, \dot{q}_n), \qquad \dot{\boldsymbol{\psi}}^{\mathrm{T}} = (\dot{\psi}_1, \ldots, \dot{\psi}_M), \qquad \boldsymbol{\Psi}^{\mathrm{T}} = (\Psi_1, \ldots, \Psi_M), \tag{a}$$

$$\mathbf{a} = (a_{pq}) = (a_{qp}) = \mathbf{a}^{\mathrm{T}}, \qquad \mathbf{b} = (b_{ip}) \neq (b_{pi}) = \mathbf{b}^{\mathrm{T}}, \qquad \mathbf{c} = (c_{ij}) = (c_{ji}) = \mathbf{c}^{\mathrm{T}}, \tag{b}$$

we have the following correspondences with the earlier indicial equations:

(8.3.12–8.3.12c): $$2T = \dot{\mathbf{q}}^{\mathrm{T}}\mathbf{a}\dot{\mathbf{q}} + 2\dot{\boldsymbol{\psi}}^{\mathrm{T}}\mathbf{b}^{\mathrm{T}}\dot{\mathbf{q}} + \dot{\boldsymbol{\psi}}^{\mathrm{T}}\mathbf{c}\dot{\boldsymbol{\psi}}, \tag{c}$$

(8.3.12d): $$\partial T/\partial\dot{\boldsymbol{\psi}} = \mathbf{b}^{\mathrm{T}}\dot{\mathbf{q}} + \mathbf{c}\dot{\boldsymbol{\psi}} = \boldsymbol{\Psi}, \tag{d}$$

(8.3.12e): $$\dot{\boldsymbol{\psi}} = \mathbf{c}^{-1}(\boldsymbol{\Psi} - \mathbf{b}^{\mathrm{T}}\dot{\mathbf{q}}) \equiv \mathbf{C}(\boldsymbol{\Psi} - \mathbf{b}^{\mathrm{T}}\dot{\mathbf{q}}) \;\Rightarrow\; \dot{\boldsymbol{\psi}}^{\mathrm{T}} = (\boldsymbol{\Psi}^{\mathrm{T}} - \dot{\mathbf{q}}^{\mathrm{T}}\mathbf{b})\mathbf{C}, \tag{e}$$

$$[\text{since } \mathbf{c} \text{ is symmetric, so is its inverse } \mathbf{C} \equiv (C_{ji})\text{: } \mathbf{C} \equiv \mathbf{c}^{-1} = (\mathbf{c}^{-1})^{\mathrm{T}} \equiv \mathbf{C}^{\mathrm{T}}]$$

(8.3.12f–h): $$\begin{aligned} T &= \ldots [\text{since } \boldsymbol{\Psi}^{\mathrm{T}}\,\mathbf{C}\,\mathbf{b}^{\mathrm{T}}\dot{\mathbf{q}} = \dot{\mathbf{q}}^{\mathrm{T}}\mathbf{b}\mathbf{C}\boldsymbol{\Psi} \\ &\qquad\qquad (\text{easily proved by indicial notation})] \\ &= (1/2)\dot{\mathbf{q}}^{\mathrm{T}}(\mathbf{a} - \mathbf{b}\,\mathbf{C}\,\mathbf{b}^{\mathrm{T}})\dot{\mathbf{q}} + (1/2)\boldsymbol{\Psi}^{\mathrm{T}}\mathbf{C}\boldsymbol{\Psi} \\ &\equiv T_{2,0} + T_{0,2} = T''_{2,0} - T''_{0,2}, \end{aligned} \tag{f}$$

(8.3.12i–8.3.14a): $$\boldsymbol{\Psi}^{\mathrm{T}}\dot{\boldsymbol{\psi}} = \cdots = \boldsymbol{\Psi}^{\mathrm{T}}\mathbf{C}\boldsymbol{\Psi} - \boldsymbol{\Psi}^{\mathrm{T}}\mathbf{C}\,\mathbf{b}^{\mathrm{T}}\dot{\mathbf{q}} = -2T''_{0,2} - \boldsymbol{\Psi}^{\mathrm{T}}\mathbf{C}\,\mathbf{b}^{\mathrm{T}}\dot{\mathbf{q}}, \tag{g}$$

$$R = (T - V) - \boldsymbol{\Psi}^{\mathrm{T}}\dot{\boldsymbol{\psi}} = \cdots = R_2 + R_1 + R_0, \tag{h}$$

$$R_2 \equiv T''_{2,0} = T_{2,0} = (1/2)\dot{\mathbf{q}}^{\mathrm{T}}(\mathbf{a} - \mathbf{b}\,\mathbf{C}\,\mathbf{b}^{\mathrm{T}})\dot{\mathbf{q}}, \tag{h1}$$

$$R_1 \equiv T''_{1,1} = \boldsymbol{\Psi}^{\mathrm{T}}\mathbf{C}\,\mathbf{b}^{\mathrm{T}}\dot{\mathbf{q}}, \tag{h2}$$

$$R_0 \equiv T''_{0,2} - V = -(V + T_{0,2}) = -(1/2)\boldsymbol{\Psi}^{\mathrm{T}}\mathbf{C}\boldsymbol{\Psi} - V. \tag{h3}$$

If $\mathbf{b} = \mathbf{0}$ — that is, if the $\dot{q}$'s and $\dot{\psi}$'s are *uncoupled* in the original T, eq. (c) — then R reduces to

$$R = (1/2)\dot{\mathbf{q}}^{\mathrm{T}}\mathbf{a}\dot{\mathbf{q}} - (1/2)\boldsymbol{\Psi}^{\mathrm{T}}\mathbf{C}\boldsymbol{\Psi} - V. \tag{h4}$$

For an extension of the above to general *nonstationary* systems, see, for example, Otterbein (1981, pp. 31–35).

8.4 CYCLIC SYSTEMS; EQUATIONS OF KELVIN–TAIT

Let us begin with the holonomic, possibly rheonomic, system whose configurations are determined by the n Lagrangean coordinates $q_1, \ldots, q_n$. The system will be called *cyclic*, or *gyrostatic*, if the following conditions apply:

(i) A number of these coordinates, say (as in §8.3) the *first* M ($\leq n$):

$$(q_1, \ldots, q_M) \equiv (\psi_1, \ldots, \psi_M) \equiv (\psi_i) \equiv \psi, \tag{8.4.1a}$$

do *not* appear explicitly in either its kinetic energy or its impressed forces; only the corresponding Lagrangean velocities

$$(\dot{q}_1, \ldots, \dot{q}_M) \equiv (\dot{\psi}_1, \ldots, \dot{\psi}_M) \equiv (\dot{\psi}_i) \equiv \dot{\psi} \tag{8.4.1b}$$

appear there, and, of course time t and the remaining coordinates and/or velocities

$$(q_{M+1}, \ldots, q_n) \equiv (q_p) \equiv q \qquad \text{and} \qquad (\dot{q}_{M+1}, \ldots, \dot{q}_n) \equiv (\dot{q}_p) \equiv \dot{q}, \tag{8.4.1c}$$

respectively; that is,

$$\partial T/\partial\psi_i = 0 \quad \text{but, in general,} \quad \partial T/\partial\dot{\psi}_i \neq 0 \;\Rightarrow\; T = T(t; q, \dot{\psi}, \dot{q}). \tag{8.4.2a}$$

(ii) The corresponding impressed forces vanish; that is,

$$Q_i = 0, \qquad \text{but} \qquad Q_p = Q_p(q) \neq 0. \tag{8.4.2b}$$

If *all* impressed forces are wholly *potential*, then the above requirements are replaced, respectively by

$$\partial L/\partial\psi_i = 0 \quad \text{and} \quad \partial L/\partial\dot{\psi}_i \neq 0 \;\Rightarrow\; L = L(t; q, \dot{\psi}, \dot{q}) \tag{8.4.2c}$$

$\big[\Rightarrow$ the ψ do not appear *explicitly* in the corresponding Lagrangean equations of motion $E_q(L) = 0, E_\psi(L) = 0$ $\big(\Rightarrow \partial L/\partial\dot{\psi}_i = \textit{constant}$ — recall (3.12.12c) and see below$\big)\big]$

The coordinates ψ, and corresponding velocities $\dot{\psi}$, are called *cyclic* (Helmholtz), or *absent* (Routh), or *kinosthenic*, or *speed* (J. J. Thomson), or *ignorable* (Whittaker); for example, the angular coordinates of flywheels of frictionless gyrostats, included in a system of bodies ("housings"), relative to their housings, are such cyclic coordinates. [The term *ignorable* seems, in general, more appropriate since such coordinates may occur in *nonspinning* systems; e.g., the kinetic energy of a translating rigid body contains only the $(\ldots)^{\cdot}$-derivatives of the coordinates of its center of mass, but not these coordinates themselves.]

The remaining coordinates q, and corresponding velocities $\dot{q}$, are called *palpable*, or *positional*, since in many problems they are the only ones directly visible, or manifest; for example, the angle of nutation of a spinning gyroscope.

Below, we apply Routh's method and relations (§8.3) to obtain equations of motion for such cyclic systems, in terms of their positional coordinates alone. Thanks to (8.4.2a–b), the Lagrangean equations corresponding to the cyclic coordinates/variables, become

$$(\partial T/\partial \dot{\psi}_i)^{\cdot} - \partial T/\partial \psi_i = Q_i\colon \qquad (\partial T/\partial \dot{\psi}_i)^{\cdot} = 0 \;\Rightarrow\; \partial T/\partial \dot{\psi}_i \equiv \Psi_i = constant \equiv C_i; \tag{8.4.3}$$

that is, the momenta Ψ_i corresponding to the cyclic coordinates ψ_i are *constants of the motion*. [Conversely, however, if $\partial T/\partial \dot{\psi}_i = 0$, then $\partial T/\partial \psi_i = 0$, and as a result $T = T(t; q, \dot{q})$; that is, the evolution of the ψ's does not affect that of the q's at all!] Therefore, by §8.3, the Routhian of a cyclic system is a function of $t, q, \dot{q}$ and $\Psi \equiv (\Psi_i)$; indeed, by (8.3.9c) and with $C \equiv (C_i)$,

$$\begin{aligned}
R &\equiv \Big(L - \sum \Psi_i \dot{\psi}_i\Big)_{\dot{\psi}=\dot{\psi}(t;q;\dot{q};C)} \\
&\qquad \text{[after solving the linear equations (8.4.3) for the } \dot{\psi} \text{ in terms of } t, q, \dot{q}, C] \\
&= L[t, q, \dot{q}, \dot{\psi}(t; q, \dot{q}; C); C] - \sum \Psi_i \dot{\psi}_i(t; q, \dot{q}; C) \\
&= R(t; q, \dot{q}; C) \\
&\Big[\Rightarrow L = \sum C_i \dot{\psi}_i(t; q, \dot{q}; C) + R(t; q, \dot{q}; C)\Big];
\end{aligned} \tag{8.4.4}$$

which shows that, since the ψ have been completely eliminated (or ignored), our system has been reduced to one with only $n - M$ Lagrangean coordinates, new reduced Lagrangean R, and therefore, Lagrange-type Routhian equations for the positional coordinates (8.3.9b):

$$(\partial R/\partial \dot{q}_p)^{\cdot} - \partial R/\partial q_p = Q_p, \tag{8.4.5}$$

where the Q_p are *nonpotential impressed positional forces*. [As Kilmister and Reeve aptly put it (our notation): "we may *in R* put $\Psi_i = C_i$ before differentiation and thus consider the motion of the subsystem (q_p) *conjugate* to the ignorable system (ψ_i)" (1966, p. 294).]

Solving these equations, we obtain the palpable motion $q_p(t)$. Then, as (8.4.4) shows,

$$\begin{aligned}
R &= \textit{known function of time} \\
&\Rightarrow \partial R/\partial C_i = \textit{known function of time} \equiv -f_i(t; C),
\end{aligned} \tag{8.4.6}$$

from which, since $d\psi_i/dt = -(\partial R/\partial \Psi_i)$,

$$\begin{aligned}
\psi_i &= -\int (\partial R/\partial \Psi_i)\, dt + constant = \int f_i\,(t; C)\, dt + constant \\
&= \psi_i(t, C) + constant;
\end{aligned} \tag{8.4.6a}$$

that is, the problem has been reduced to the $n - M$ *equations* (8.4.5) and the M *quadratures* (8.4.6a); or, equivalently [since every ignorable coordinate generates two integrals (§3.12)], the order of the system has been reduced by $2M$. [Since $d\psi_i/dt = \partial H/\partial \Psi_i$, similar results hold in terms of the Hamiltonian of cyclic systems; see, for example, McCuskey (1959, p. 208 ff.).]

REMARK

Kilmister (1964, pp. 43, 46) and others have suggested an alternative handling of cyclic systems via Hamel's method of quasi variables and equations (chaps. 2 and 3). According to this method, we choose the following quasi velocities:

$$\omega_i \equiv \partial L/\partial \dot{\psi}_i - C_i \quad (= 0) \qquad (i = 1, \ldots, M), \tag{8.4.7a}$$

$$\omega_p \equiv \dot{q}_p \quad (\neq 0) \qquad (p = M+1, \ldots, n). \tag{8.4.7b}$$

The resulting $n - M$ *kinetic* equations (Hamel $\to$ *noncyclic* Routhian) plus the M "cyclicity" constraints (8.4.7a) constitute a determinate system of n equations for the n velocities $(\dot{\psi}_i, \dot{q}_p)$. After solving these equations, we can then proceed to the M *kinetostatic* equations (Hamel $\to$ *cyclic* Routhian) and determine the reaction forces associated with these constraints. For a rare implementation of these ideas, see, for example, Vujanovic (1970); also, ex. 8.4.2, below.

Example 8.4.1 *Routhian Method in Problem of Central Motion.* Let us consider a particle P, of mass m, in plane motion under a *radial* force. Here,

$$2T = m[(\dot{r})^2 + (r\,\dot{\phi})^2] \qquad (r,\ \phi\text{: inertial plane polar coordinates}), \tag{a}$$

$$Q_r = Q_r(r) \qquad \text{and} \qquad Q_\phi = 0. \tag{b}$$

From the obvious ignorability of ϕ, we obtain the (area) integral

$$p_\phi \equiv \partial T/\partial \dot{\phi} = m\,r^2\,\dot{\phi} \equiv \Psi_\phi = constant \equiv m\,C$$
$$\Rightarrow\ \dot{\phi} = C/r^2 \quad (\neq constant). \tag{c}$$

Hence, the modified kinetic energy equals

$$T'' = \left[T - \dot{\phi}(\partial T/\partial \dot{\phi})\right]_{\dot{\phi}=\dot{\phi}(r;\,C)} = (m/2)\ [(\dot{r})^2 + C^2/r^2] - m(C^2/r^2)$$
$$= (m/2)\ [(\dot{r})^2 - C^2/r^2] = T''(r, \dot{r}; C), \tag{d}$$

and so the Lagrangean equation of motion of the nonignorable coordinate r is

$$(\partial T''/\partial \dot{r})^{\cdot} - \partial T''/\partial r = Q_r: \qquad m(\ddot{r} - C^2/r^3) = Q_r. \tag{e}$$

Multiplying (e) with $\dot{r}$, and then integrating, we easily obtain the *energy integral*

$$(m/2)\ \left[(\dot{r})^2 + C^2/r^2\right] = \int Q_r\,dr + constant. \tag{f}$$

Example 8.4.2 *Direct Elimination of Ignorable Coordinates from the Lagrangean Equations of Motion; and Some General Theoretical Conclusions.* Let us consider, with no loss of generality, a holonomic, scleronomic, and potential system with M *ignorable* coordinates $\psi \equiv (\psi_1, \ldots, \psi_M)$, and $n - M$ *nonignorable*, or *positional*, coordinates $q \equiv (q_{M+1}, \ldots, q_n)$, so that $L = L(q, \dot{q}, \dot{\psi})$. Below, we show, quite generally and with no recourse to Routh's method, that the ψ's can be *eliminated* from the $n - M$ Lagrangean equations for the q's. For concreteness, let us take *two* ignorable coordinates, ψ_1, ψ_2, and *two* positional coordinates, q_3, q_4; that is, $M = 2$, $n - M = 4 - 2 = 2$. Then we will have, with the usual notations,

$$\begin{aligned} T = {} & (1/2)(M_{33}\dot{q}_3\dot{q}_3 + M_{44}\dot{q}_4\dot{q}_4 + 2M_{34}\dot{q}_3\dot{q}_4) \\ & + (M_{13}\dot{q}_3 + M_{14}\dot{q}_4)\dot{\psi}_1 + (M_{23}\dot{q}_3 + M_{24}\dot{q}_4)\dot{\psi}_2 \\ & + (1/2)(M_{11}\dot{\psi}_1\dot{\psi}_1 + M_{22}\dot{\psi}_2\dot{\psi}_2 + 2M_{12}\dot{\psi}_1\dot{\psi}_2), \end{aligned} \tag{a}$$

where the inertia coefficients $M_{kl} = M_{lk}(k, l = 1, \ldots, 4)$ and the potential energy V are functions of $q_{3,4}$ only. From the above it follows easily that:

(i) Lagrange's equations for the q's are (with $p = 3$, 4):

$$\begin{aligned} & (M_{p3}\ddot{q}_3 + M_{p4}\ddot{q}_4 + M_{p1}\ddot{\psi}_1 + M_{p2}\ddot{\psi}_2) \\ & \quad + [(\partial M_{p3}/\partial q_3)\,\dot{q}_3 + (\partial M_{p3}/\partial q_4)\,\dot{q}_4]\,\dot{q}_3 \\ & \quad + [(\partial M_{p4}/\partial q_3)\,\dot{q}_3 + (\partial M_{p4}/\partial q_4)\,\dot{q}_4]\,\dot{q}_4 \\ & \quad + [(\partial M_{p1}/\partial q_3)\,\dot{q}_3 + (\partial M_{p1}/\partial q_4)\,\dot{q}_4]\,\dot{\psi}_1 \\ & \quad + [(\partial M_{p2}/\partial q_3)\,\dot{q}_3 + (\partial M_{p2}/\partial q_4)\,\dot{q}_4]\,\dot{\psi}_2 = -\,\partial V/\partial q_p; \end{aligned} \tag{b}$$

(ii) Lagrange's equations for the ψ's are (with $i = 1$, 2)

$$(\partial L/\partial\dot{\psi}_i)^{\cdot} = 0 \;\Rightarrow\; \Psi_i \equiv \partial L/\partial\dot{\psi}_i = \mathit{constant} \equiv C_i, \tag{c}$$

or, using (a) and rearranging,

$$M_{11}\dot{\psi}_1 + M_{12}\dot{\psi}_2 = C_1 - (M_{13}\dot{q}_3 + M_{14}\dot{q}_4), \tag{c1}$$

$$M_{21}\dot{\psi}_1 + M_{22}\dot{\psi}_2 = C_2 - (M_{23}\dot{q}_3 + M_{24}\dot{q}_4). \tag{c2}$$

Now, solving the system (c1, 2), we obtain $\dot{\psi}_1$ and $\dot{\psi}_2$ in terms of C_1, C_2; q_3, q_4; $\dot{q}_3$, $\dot{q}_4$; and, then, $(\ldots)^{\cdot}$-differentiating these expressions we obtain $\ddot{\psi}_1$ and $\ddot{\psi}_2$ in terms of the same variables and their $(\ldots)^{\cdot}$-derivatives. [Here, $\dot{C}_i = 0$, but this procedure applies, in principle, to noncyclic systems too.]

Next, substituting the so-found expressions for $\dot{\psi}_1$, $\dot{\psi}_2$; $\ddot{\psi}_1$, $\ddot{\psi}_2$ into eqs. (b), we obtain, finally, two Lagrangean equations containing only q_3 and q_4 and their $(\ldots)^{\cdot}$-derivatives; that is, as far as the equations of motion are concerned, ψ_1 and ψ_2 have been "ignored"—the system has been reduced to one with only $n - M = 2$ Lagrangean coordinates. Solving these two nonignorable equations, we find the *palpable motion* $q_3(t)$ and $q_4(t)$; and, then, substituting these solutions back into (c1, 2), and integrating, we obtain the *cyclic motion* $\psi_1(t)$ and $\psi_2(t)$. As one might expect, finding $q_{3,4}(t)$ is, in general, considerably harder than finding $\psi_{1,2}(t)$.

General Conclusions

(i) The difference between this approach and the earlier general Routhian methodology is that here we eliminated the $\dot{\psi}$ and $\ddot{\psi}$ from each of the q-equations of motion; whereas there (§8.3) this elimination was done in one step, right at the beginning—that is, by replacing the Lagrangean with the Routhian. For few-degree-of-freedom systems, the two approaches are practically equivalent, but for larger systems, as well as for theoretical arguments and insights, the general Routhian approach is much preferable.

This is analytically identical with the difference between the following:

(a) Enforcing Pfaffian (and generally nonholonomic) constraints, like (c, c1, 2), not in L but in each Lagrangean equation of motion; and
(b) Enforcing such constraints directly in L; that is, replacing the "relaxed" Lagrangean L with the "constrained" one L_o or L^* (chap. 3), and then applying it to "modified" equations of motion.

Actually, *Routh's method modifies the Lagrangean (replaces it with the Routhian, which incorporates the constraints), and then applies it to ordinary Lagrangean equations of motion*. In sum, in such approaches: *Either we still operate with the Lagrangean ($L \to L_o$ or L^*), and modify the form of the equations of motion (Lagrange $\to$ Voronets or Hamel)*; or *we modify the Lagrangean ($\to$ Routhian), and leave the form of the equations of motion unchanged.*

(ii) The simple example below shows why if we enforce (c)-like constraints into the Lagrangean, then, in general, the ordinary Lagrangean equations for the independent coordinates (here the q's), *do not hold*. Let us consider, for algebraic simplicity, a potential system with the *single* ignorable coordinate ψ (i.e., $M = 1$) and, hence, Lagrangean $L = L(t, q, \dot{q}, \dot{\psi})$. Enforcing the Pfaffian cyclicity constraint

$$\partial L/\partial\dot{\psi} = constant \equiv C \ \Rightarrow\ \dot{\psi} = \dot{\psi}(t, q, \dot{q}; C) \equiv f(t, q, \dot{q}; C) \tag{d}$$

into L, we obtain the "constrained" Lagrangean L_o:

$$L = L(t, q, \dot{q}, \dot{\psi}) = L[t, q, \dot{q}, \dot{\psi}(t, q, \dot{q}; C)] \equiv L_o(t, q, \dot{q}; C) = L_o. \tag{e}$$

Applying chain rule to this equality, carefully, we find (with $p = 2, \ldots, n$)

$$\partial L_o/\partial q_p = \partial L/\partial q_p + (\partial L/\partial\dot{\psi})(\partial f/\partial q_p) = \partial L/\partial q_p + C(\partial f/\partial q_p), \tag{f1}$$

$$\partial L_o/\partial \dot{q}_p = \partial L/\partial \dot{q}_p + (\partial L/\partial\dot{\psi})(\partial f/\partial \dot{q}_p) = \partial L/\partial \dot{q}_p + C(\partial f/\partial \dot{q}_p), \tag{f2}$$

and therefore the Lagrangean expression for L_o becomes

$$\begin{aligned}(\partial L_o/\partial\dot{q}_p)^{\cdot} - \partial L_o/\partial q_p &= [(\partial L/\partial\dot{q}_p)^{\cdot} - \partial L/\partial q_p] + C[(\partial f/\partial\dot{q}_p)^{\cdot} - \partial f/\partial q_p]\\ &= 0 + C\,E_p(f) \neq 0;\end{aligned} \tag{g}$$

that is, in general, $E_p(L_o) \neq 0$, even though $E_p(L) = 0$! However, using the above results, it is not hard to verify that

$$\left[\partial(L_o - C\,\dot{\psi})/\partial\dot{q}_p\right]^{\cdot} - \partial(L_o - C\,\dot{\psi})/\partial q_p = 0; \tag{h}$$

or $E_p(L_o - C\,\dot{\psi}) \equiv E_p(R) = 0$; that is, if we want to keep the form of the Lagrangean equations of motion (for the independent coordinates) *unchanged*, we must take as new Lagrangean not the *constrained* Lagrangean L_o, but the *modified* Lagrangean $L_o - C\,\dot{\psi} \equiv R(outhian)$.

Example 8.4.3 *Routhian of a Three-DOF Cyclic System; Effects of Cyclicity on the Visible Motions.* Let us examine a scleronomic and cyclic system with *one* ignorable coordinate, $q_1 \equiv \psi_1$, and *two* positional coordinates, q_2, q_3; that is,

$M = 1,\ n - M = 3 - 1 = 2$. This is the simplest system that shows clearly the *gyroscopic*, and other, effects of ignorable coordinates. Its kinetic energy is

$$2T = M_{11}(\dot{\psi}_1)^2 + M_{22}(\dot{q}_2)^2 + M_{33}(\dot{q}_3)^2 + 2(M_{12}\,\dot{\psi}_1\,\dot{q}_2 + M_{13}\,\dot{\psi}_1\,\dot{q}_3 + M_{23}\,\dot{q}_2\,\dot{q}_3), \tag{a}$$

where all the inertia coefficients $M_{kl}\ (k, l = 1, 2, 3)$ are independent of ψ_1, and $Q_1 \equiv Q_\psi = 0$. Then, the cyclicity constraint is

$$p_1 \equiv \Psi_1 \equiv \partial T/\partial\dot{\psi}_1 = M_{11}\,\dot{\psi}_1 + M_{12}\,\dot{q}_2 + M_{13}\,\dot{q}_3 = constant \equiv C_1. \tag{b}$$

Solving it, we obtain

$$\dot{\psi}_1 = (C_1 - M_{12}\,\dot{q}_2 - M_{13}\,\dot{q}_3)/M_{11} \quad (\neq constant) \tag{c}$$
$$[= \text{function of } q, \dot{q}, C_1, \text{ and the } coupling \text{ inertia coefficients } M_{12},\ M_{13}];$$

and, inserting this expression back into (a), we obtain

$$T = T''_{2,0} - T''_{0,2} = T(q, \dot{q}, C_1)$$

where

$$\begin{aligned} 2T''_{2,0} &= [(M_{11}\,M_{22} - M_{12}{}^2)/M_{11}]\,(\dot{q}_2)^2 \\ &\quad + [(M_{11}\,M_{33} - M_{13}{}^2)/M_{11}]\,(\dot{q}_3)^2 \\ &\quad + 2[(M_{11}\,M_{23} - M_{12}\,M_{13})/M_{11}]\,\dot{q}_2\,\dot{q}_3 \\ &\equiv M''_{22}(\dot{q}_2)^2 + M''_{33}(\dot{q}_3)^2 + 2M''_{23}\dot{q}_2\,\dot{q}_3 \qquad \text{(positive definite in the } \dot{q}\text{'s)}, \end{aligned} \tag{d1}$$

$$-2T''_{0,2} = C_1{}^2/M_{11} \qquad \text{(positive definite in } C_1\text{)}; \tag{d2}$$

the bilinear terms in the $\dot{q}$'s and C_1 having canceled, as expected by the general theory [(8.3.12m)]. As a result of the above, the modified kinetic energy T'' (to be used as kinetic energy in the Routhian–Lagrangean equations for the q's), becomes

$$T'' \equiv T - \dot{\psi}_1 C_1 = \cdots = T''_{2,0} + T''_{1,1} + T''_{0,2} = T''(q, \dot{q}, C_1), \tag{e}$$

where

$$T''_{2,0} = T''_{2,0}(q, \dot{q}): \qquad \text{given by (d1)}, \tag{e1}$$

$$T''_{0,2} = T''_{0,2}(q, C_1): \qquad \text{given by (d2)}, \tag{e2}$$

$$\begin{aligned} T''_{1,1} &= (C_1 M_{12}/M_{11})\dot{q}_2 + (C_1 M_{13}/M_{11})\dot{q}_3 \\ &= r_2\dot{q}_2 + r_3\dot{q}_3 = T''_{1,1}(q, \dot{q}; C_1), \end{aligned} \tag{e3}$$

and

$$r_2 \equiv (M_{12}/M_{11})C_1 \equiv \rho_{21}C_1, \qquad r_3 \equiv (M_{13}/M_{11})C_1 \equiv \rho_{31}C_1. \tag{e4}$$

The equations of motion for the q's (i.e., the equations of the *reduced*, or *apparent*, or *visible*, or *palpable* system) are

$$(\partial T''/\partial\dot{q}_p)^{\cdot} - \partial T''/\partial q_p = Q_p \qquad (p = 2,\ 3). \tag{f}$$

Upon carrying out the operations indicated in (f), with the expressions (e–e4), we notice that the cyclic coordinate(s) ψ_1 (through its constant momentum C_1), and the *coupling* coefficients M_{12} and M_{13}, have the following *triple* effect on the palpable motion:

(i) $T''_{2,0}$: The original coefficients of inertia M_{kl} have been replaced by the "reduced coefficients of inertia" M''_{kl}, unless M_{12} and M_{13} vanish.

(ii) $T''_{1,1}$: The effect of C_1 and M_{12}, M_{13}, appears in the coefficients of $\dot{q}_2$ and $\dot{q}_3$; and their contribution to (f) is

$$(\partial T''_{1,1}/\partial \dot{q}_2)^{\cdot} - \partial T''_{1,1}/\partial q_2 = C_1\left[\partial/\partial q_3(M_{12}/M_{11}) - \partial/\partial q_2(M_{13}/M_{11})\right]\dot{q}_3, \tag{g1}$$

$$(\partial T''_{1,1}/\partial \dot{q}_2)^{\cdot} - \partial T''_{1,1}/\partial q_2 = C_1\left[\partial/\partial q_2(M_{13}/M_{11}) - \partial/\partial q_3(M_{12}/M_{11})\right]\dot{q}_2; \tag{g2}$$

that is, a coupling of the *nonignorable (visible) motions*, generated by the *ignorable (invisible) ones*, through C_1 and M_{12}, M_{13}.

(iii) $T''_{0,2} = -C_1{}^2/2M_{11} = T''_{0,2}(q, C_1)$: this term behaves like an *additional negative potential energy*; and since

$$E_p(T''_{0,2}) \equiv (\partial T''_{0,2}/\partial \dot{q}_p)^{\cdot} - \partial T''_{0,2}/\partial q_p \;=\; 0 - (1/2)(C_1/M_{11})^2(\partial M_{11}/\partial q_p),$$

it gives rise to an *additional inertial "force"*

$$-E_p(T''_{0,2}) = \partial T''_{0,2}/\partial q_p = (C_1{}^2/2M_{11}{}^2)(\partial M_{11}/\partial q_p), \tag{h}$$

which is indistinguishable, in its mechanical effects, from the ordinary potential force $-\partial V/\partial q_p$. [During the late 19th century, this remarkable situation prompted several famous scientists (notably Hertz), to try to do the *reverse*; that is, explain V as a $T''_{0,2}$-like term of some *concealed*, or *latent*, motions! Such a "forceless" approach did not go very far in classical mechanics, but its conceptual implications proved helpful, a little later (in the 1910s), in the development of the (also forceless) general theory of relativity.]

These results are systematized and extended to the general case below, which may also include, with slight modifications, systems with no ignorable coordinates.

The Kelvin–Tait Equations

(Thomson and Tait, 1912, art. 319, ex. G.) Continuing from the preceding example, let us now find the *explicit* form of Routh's equations for the palpable motion of a general holonomic, scleronomic (no real loss in generality), and cyclic system with M ignorable coordinates $\psi \equiv (\psi_i;\ i = 1, \ldots, M)$ and $n - M$ nonignorable coordinates $q \equiv (\dot{q}_p;\ q = M + 1, \ldots, n)$—what is referred to as the *Kelvin–Tait equations*. Here,

$$T = T(q, \dot{q}, \dot{\psi}) = \textit{homogeneous quadratic in the } \dot{\psi}\text{'s } \textit{and } \dot{q}\text{'s}, \tag{8.4.8}$$

and, therefore, as shown in (8.3.12 ff.) and the preceding example, the Routhian will equal

$$R = R_2 + R_1 + R_0, \tag{8.4.9}$$

where

$$R_2 \equiv T''_{2,0} = (1/2)\sum\sum r_{pq}(q)\dot{q}_p\,\dot{q}_q \quad (= T_{2,0}) = R_2(q, \dot{q}):$$

homogeneous quadratic in the nonignorable velocities $\dot{q}$, (8.4.9a)

$$R_1 \equiv T''_{1,1} = \sum r_p(q, C)\dot{q}_p = R_1(q, \dot{q}, C):$$

homogeneous linear in the nonignorable velocities $\dot{q}$,

with $\quad r_p = \sum \rho_{pi} C_i \qquad \left[\rho_{pi} \equiv \sum C_{ij} b_{pj} = \rho_{pi}(q), \text{ by } (8.3.12\text{k})\right],$ (8.4.9b)

$$R_0 \equiv T''_{0,2} - V = -(V - T''_{0,2}) \equiv -(1/2)\sum\sum C_{ji} C_j\, C_i - V \quad [= -(V + T_{0,2})]$$

$= R_0(q; C)$: *homogeneous quadratic in the constant ignorable momenta* $\Psi = C$. (8.4.9c)

The above indicate that *even in an originally scleronomic system*, the Routhian elimination of the ignorable velocities, in favor of their constant momenta, produces an additional *apparent potential energy* $T''_{0,2} = -T_{0,2} (< 0)$, and (possibly) an additional *apparent kinetic energy* $T''_{1,1}$; and, therefore, the situation is *mathematically identical to that of relative motion* (§3.16). Hence, utilizing the expressions (8.4.9–9c) in the Lagrangean equation of the palpable motion (8.4.5):

$$(\partial R/\partial \dot{q}_p)^{\cdot} - \partial R/\partial q_p = Q_p, \tag{8.4.5}$$

where Q_p = *nonpotential impressed positional forces*, and proceeding as in §3.16, we obtain the *Kelvin–Tait equations* (with $p, p' = M+1, \ldots, n$):

$$E_p(R) \equiv E_p(R_2 + R_1 + R_0) = E_p(R_2) + E_p(R_1) + E_p(R_0) = Q_p,$$

or

$$E_p(R_2) = Q_p - E_p(R_1) - E_p(R_0),$$

or

$$\begin{aligned}(\partial R_2/\partial \dot{q}_p)^{\cdot} - \partial R_2/\partial q_p &= Q_p + \partial R_0/\partial q_p - \left[(\partial R_1/\partial \dot{q}_p)^{\cdot} - \partial R_1/\partial q_p\right] \\ &= Q_p - \partial(V - T''_{0,2})/\partial q_p + \sum (\partial r_{p'}/\partial q_p - \partial r_p/\partial q_{p'})\dot{q}_{p'} \\ &= Q_p - \partial(V - T''_{0,2})/\partial q_p + G_p,\end{aligned} \tag{8.4.10}$$

where

$$G_p \equiv \sum (\partial r_{p'}/\partial q_p - \partial r_p/\partial q_{p'})\dot{q}_{p'} \equiv \sum G_{pp'}\dot{q}_{p'}:$$

Gyroscopic Routhian "force," since $G_{pp'} = -G_{p'p}\ [= G_{pp'}(q; C)]$. (8.4.10a)

These are the equations of motion of a *fictitious* scleronomic system (sometimes referred to as "conjugate" to the original system, or *reduced* system) with $n - M$ positional coordinates q, and subject, in addition to the impressed forces Q_p (nonpotential) and $-\partial V/\partial q_p$ (potential), to two *special constraint forces*: a *centrifugal-like* one, $\partial T''_{0,2}/\partial q_p$, and a *gyroscopic* one, G_p. Once the palpable motion $q_p(t)$ has been determined by solving (8.4.10), then substituting it into the Routhian equations for the ignorable motion, eqs. (8.3.6a, 9a):

$$d\psi_i/dt = -\partial R/\partial C_i = -\partial R_1/\partial C_i - \partial R_0/\partial C_i = -\partial T''_{0,2}/\partial C_i - \sum \rho_{pi}\dot{q}_p; \quad (8.4.11)$$

and carrying out a quadrature, we find the $\psi_i(t)$.

Gyroscopic Uncoupling

If *all* the $G_{pp'}$'s vanish, then the gyroscopic forces disappear, and so the equations of the reduced system take the *gyroscopically uncoupled* form:

$$E_p(R_2) \equiv (\partial R_2/\partial\dot{q}_p)^{\cdot} - \partial R_2/\partial q_p = Q_p + \partial R_0/\partial q_p; \qquad (8.4.12)$$

that is, the centrifugal forces express the entire effect of cyclicity on that system.

Since $G_p \equiv -[(\partial R_1/\partial\dot{q}_p)^{\cdot} - \partial R_1/\partial q_p]$, and reasoning as in the case of integrability of Pfaffian constraints (chap. 2, also chap. 5), we may state with Pars (1965, p. 172) that: a system is *gyroscopically uncoupled* if, and only if,

$$R_1\,dt \equiv \sum r_p(q; C)\,dq_p$$

is an *exact, or total*, differential. Obviously, this holds always if there is only *one* nonignorable coordinate [recall (prob. 3.16.3)]. A similar uncoupling occurs, of course, if all C_i's vanish [$\Rightarrow r_p = 0 \Rightarrow R_1 = 0;$ *and* $R_0 = -V(q)$].

REMARKS

(i) It should be pointed out that the nonignorable coordinates do not fix the position of every system particle: in general, to one set of values of the q's there correspond *more than one set of values of the* ψ's; or, if the system, by suitable forces, is brought back to its original q's, after an arbitrary type of motion, its cyclic ψ will not, in general, return to their original values.

(ii) Also, the *gyroscopic* ($\sim \dot{q}_p$) terms in (8.4.10) are *irreversible* (i.e., they change sign under $dt \rightarrow -dt$); while in the absence of friction (i.e., only configuration-dependent forces), the other terms are not. This means that in order to reverse the motion of a cyclic system, we must reverse both the $\dot{q}$'s and the $\dot{\psi}$'s; reversing only the $\dot{q}$'s will not suffice! For example, the precessional motion of a top (gyroscope) is not reversed unless we also reverse its (cyclic) intrinsic spin $\dot{\psi}$.

A Cyclic Power Theorem

Multiplying each of (8.4.10) with $\dot{q}_p$ and then adding them together, while noting that $\sum r_{pp'}\,\dot{q}_{p'}\,\dot{q}_p = 0$ (gyroscopicity), we readily obtain the *cyclic energy rate/power theorem*:

$$dh_R/dt = \sum Q_p\dot{q}_p, \qquad (8.4.13)$$

where [recalling (8.3.13–14a)]

$$\begin{aligned} h_R &\equiv R_2 - R_0 = T''_{2,0} + (V - T''_{0,2}) \\ &= T_{2,0} + (V + T_{0,2}) \equiv h_R(q, \dot{q}, C) \\ &= \textit{modified (or cyclic) generalized energy}; \end{aligned} \qquad (8.4.13a)$$

from which, if $\sum Q_p \dot{q}_p = 0$, we are immediately led to the (Routhian counterpart of the Jacobi–Painlevé) *conservation theorem*:

$$h_R \equiv T''_{2,0} + (V - T''_{0,2}) = constant. \tag{8.4.14}$$

Alternatively, we may transform the energy equation of the *original* system as follows:

$$\begin{aligned} H &\equiv \sum (\partial L/\partial \dot{q}_k)\dot{q}_k - L \qquad (= constant, \text{ if } Q_p = 0 \text{ and } \partial L/\partial t = \partial R/\partial t = 0) \\ &= -R + \sum (\partial R/\partial \dot{q}_p)\dot{q}_p \qquad [\text{recalling (8.3.10)}] \\ &= -(R_2 + R_1 + R_0) + (2R_2 + R_1) \\ &= R_2 - R_0 = h_R(q, \dot{q}, C). \end{aligned} \tag{8.4.13b}$$

Extensions of the above to *rheonomic* cyclic systems — that is, to the case where

$$\begin{aligned} &L = L(t, q, \dot{q}, C) \\ &\Rightarrow R = L(t, q, \dot{q}, C) - \sum C_i \dot{\psi}_i(t, q, \dot{q}, C) = R(t, q, \dot{q}, C), \end{aligned} \tag{8.4.14a}$$

can be easily obtained; see, for example, Kil'chevskii (1977, pp. 350–352), Merkin (1974, chap. 1).

Example 8.4.4 *Energetics of a Simple Cyclic System.* Let us consider a potential system with Lagrangean

$$L = (1/2)(a\dot{\psi}^2 + 2e\,\dot{\psi}\,\dot{q} + b\,\dot{q}^2) - V(q), \tag{a}$$

where $a, e, b = constant$ inertial coefficients; $\psi/q = ignorable/nonignorable$ coordinates (i.e., $n = 2$, $M = 1$); and initial conditions at $t = 0$: $\psi = q = 1$, $\dot{\psi} = \dot{q} = 0$. Since ψ is ignorable,

$$\partial L/\partial\dot{\psi} = a\,\dot{\psi} + e\,\dot{q} = constant \equiv C, \tag{b}$$

from which, applying the initial conditions, we find $e = C$. Hence, solving (b) for $\dot{\psi}$, we obtain $\dot{\psi} = (C - e\,\dot{q})/a = (e/a)(1 - \dot{q})$, and so the Routhian becomes

$$\begin{aligned} R &= L(q, \dot{q}, C = e, a, b) - C\,\dot{\psi} = \cdots \\ &= (1/2)\,[b - (e^2/a)]\,(\dot{q})^2 + (e^2/a)\,\dot{q} - (e^2/2a) - V(q) \\ &= R_2(\dot{q}, a, b, e) + R_1(\dot{q}, a, e) + R_0(q, a, e). \end{aligned} \tag{c}$$

This yields the following Routhian equation of motion for q:

$$(\partial R/\partial\dot{q})^{\cdot} - \partial R/\partial q = 0\!: \ \left\{(e^2/a) + [b - (e^2/a)]\dot{q}\right\}^{\cdot} + dV/dq = 0, \tag{d}$$

or, solved for $\ddot{q}$:

$$\ddot{q} = -\left[a/(b\,a - e^2)\right](dV/dq). \tag{e}$$

Clearly, if $e = 0$, the motions of ψ and q decouple.

Now, if $V(q) = known$, then (e) supplies $q(t)$; its two integration constants are determined from the earlier initial conditions for q.

On the other hand, the Routhian form of the energy theorem for this system is [by (8.4.13b)]

$$h_R = H = R_2 - R_0 = (1/2)[b - (e^2/a)](\dot{q})^2 + (e^2/2a) + V(q)$$
$$= H(\dot{q}, a, b, e) = constant \equiv h. \tag{f}$$

Solving (f) for $\dot{q}$, we get

$$\dot{q} = [A - B\,V(q)]^{1/2}, \tag{g1}$$

where

$$A \equiv (2h\,a - e^2)\big/(b\,a - e^2), \qquad B \equiv 2a\big/(b\,a - e^2), \tag{g2}$$

and then separating variables and integrating, while using the initial conditions for q, we finally obtain $q(t)$:

$$t = \int [A - B\,V(q)]^{-1/2}\,dq, \tag{g3}$$

where the integral extends from 1 to q. Then, $\psi(t)$ can be found by the following quadrature:

$$\psi = \int -(\partial R/\partial C)\;dt + 1 = 1 + \int (e/a)(1 - \dot{q})\;dt, \tag{h}$$

where both integrals extend from 0 to t.

Example 8.4.5 *Hamiltonian and Routhian Treatments of the Top.* Let us consider a top (i.e., an axially symmetrical, or uniaxial, body) moving about a fixed point of its axis O under gravity (fig. 8.2). Using *intermediate* axes $O{-}xyz$, we find (with principal inertias there: $I_x = I_y \equiv A$, $I_z \equiv C$)

$$\boldsymbol{\omega} = (\dot{\theta},\ \dot{\phi}\sin\theta,\ \dot{\psi} + \dot{\phi}\cos\theta) = \textit{inertial angular velocity of top}, \tag{a1}$$

$$L = T - V,$$
$$2T = I_x\,{\omega_x}^2 + I_y\,{\omega_y}^2 + I_z{\omega_z}^2 = A\big[(\dot{\theta})^2 + (\dot{\phi})^2\sin^2\theta\big] + C(\dot{\psi} + \dot{\phi}\cos\theta)^2,$$
$$V = m\,g\,l\cos\theta \qquad (l \equiv OG,\ G = \textit{center of mass of top}), \tag{a2}$$

and, therefore, the system momenta are

$$p_\phi \equiv \partial T/\partial\dot{\phi} = \partial L/\partial\dot{\phi} = A\,\dot{\phi}\,\sin^2\theta + C(\dot{\psi} + \dot{\phi}\cos\theta)\cos\theta$$
$$\equiv A\,\dot{\phi}\,\sin^2\theta + C\,n\,\cos\theta = constant \equiv C_\phi$$

[since, clearly, ϕ is an ignorable coordinate]

$=$ component of angular momentum of top about the vertical axis through O (i.e., OZ), (b1)

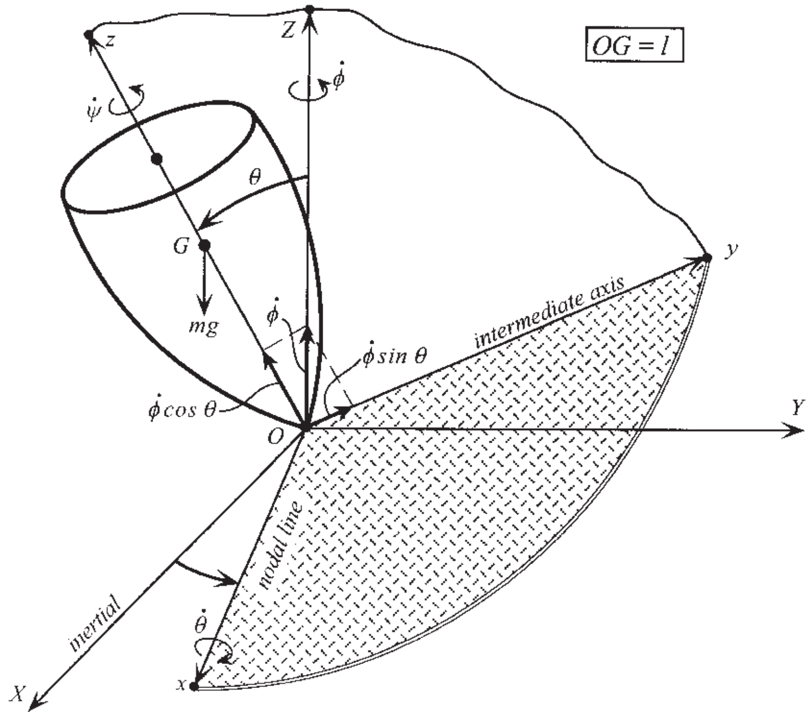

Figure 8.2 Geometry and kinematics of a top moving about a fixed point O.

$$p_\theta \equiv \partial T/\partial\dot{\theta} = \partial L/\partial\dot{\theta} = A\,\dot{\theta}$$

$=$ component of angular momentum of top about axis through O perpendicular to plane of θ, (b2)

$$p_\psi \equiv \partial T/\partial\dot{\psi} = \partial L/\partial\dot{\psi} = C(\dot{\psi} + \dot{\phi}\,\cos\theta) \equiv C\,n = constant \equiv C_\psi$$

[since, clearly, ψ is an ignorable coordinate]

$=$ component of angular momentum of top about the symmetry axis Oz (i.e., the fixed line with which the top axis instantaneously coincides). (b3)

(i) From the above, it follows easily that the *Lagrangean equations* of the top are

$$(\partial L/\partial\dot{\phi})^{\cdot} - \partial L/\partial\phi = 0: \qquad [A\,\dot{\phi}\,\sin^2\theta + C(\dot{\psi} + \dot{\phi}\,\cos\theta)\cos\theta]^{\cdot} = 0, \tag{c1}$$

$$(\partial L/\partial\dot{\theta})^{\cdot} - \partial L/\partial\theta = 0: \qquad (A\,\dot{\theta})^{\cdot} - [A(\dot{\phi})^2\,\sin\theta\,\cos\theta - C(\dot{\psi} + \dot{\phi}\,\cos\theta)\dot{\phi}\,\sin\theta + m\,g\,l\,\sin\theta] = 0, \tag{c2}$$

$$(\partial L/\partial\dot{\psi})^{\cdot} - \partial L/\partial\psi = 0: \qquad [C(\dot{\psi} + \dot{\phi}\,\cos\theta)]^{\cdot} = 0. \tag{c3}$$

The first and last of these equations express the constancy of p_ϕ and p_ψ, respectively; and so we can rewrite the first and second, as follows:

$$\phi: \qquad A\,\dot{\phi}\,\sin^2\theta + C_\psi\,\cos\theta = C_\phi, \tag{d1}$$

$$\theta: \qquad A\,\ddot{\theta} - A(\dot{\phi})^2\sin\theta\,\cos\theta + C_\psi\,\dot{\phi}\,\sin\theta = m\,g\,l\,\sin\theta. \tag{d2}$$

These two equations allow us, among other things, to study the small (linearized) motion of the top about its *vertical* axis OZ—that is, $\theta = 0$—and its stability/instability. Indeed, setting in (d1, 2), approximately, $\sin\theta \approx \theta$ and $\cos\theta \approx 1 - \theta^2/2$, we obtain

$$\phi: \qquad \theta^2\dot{\zeta} = constant, \tag{e1}$$

$$\theta: \qquad \ddot{\theta} - (\dot{\zeta})^2\theta = -[(C_\psi - 4A\,m\,g\,l)/4A^2]\theta, \tag{e2}$$

where

$$\zeta \equiv \phi - (C_\psi/2A)t \;\Rightarrow\; \dot{\zeta} = \dot{\phi} - (C_\psi/2A). \tag{e3}$$

Now, due to the *form* of equations (e1, 2) we may view θ and ζ as the *polar coordinates* of the horizontal projection of a point on the top axis Oz, relative to a line that revolves around OZ with (constant) angular velocity $\dot{\phi} - \dot{\zeta} = C_\psi/2A$. It follows that the *relative* motion of such a point will be elliptic harmonic with period $4\pi A({C_\psi}^2 - 4A\,m\,g\,l)^{-1/2}$, as long as ${C_\psi}^2 > 4A\,m\,g\,l$ (stability condition; see also stability of *sleeping top*, ex. 8.4.6 below).

(ii) *Hamiltonian equations*. Solving (b1–3) for the velocities in terms of the momenta, we get

$$\dot{\phi} = (p_\phi - p_\psi\cos\theta)/A\,\sin^2\theta, \tag{f1}$$

$$\dot{\theta} = p_\theta/A, \tag{f2}$$

$$\dot{\psi} = p_\psi/C - (p_\phi - p_\psi\cos\theta)\cos\theta/A\,\sin^2\theta. \tag{f3}$$

Accordingly, the Hamiltonian becomes

$$\begin{aligned} H &= (1/2)(p_\phi\,\dot{\phi} + p_\theta\,\dot{\theta} + p_\psi\,\dot{\psi}) + V \\ &= (1/2A)\left[{p_\theta}^2 + (p_\phi - p_\psi\cos\theta)^2/\sin^2\theta\right] + (1/2C)\,{p_\psi}^2 + m\,g\,l\cos\theta, \end{aligned} \tag{g}$$

and leads easily to the following pairs of Hamilton's equations:

$$\phi: \qquad \dot{p}_\phi = -\partial H/\partial\phi = 0 \qquad (\phi = \text{ignorable coordinate}) \tag{h1}$$

$$\dot{\phi} = \partial H/\partial p_\phi = (p_\phi - p_\psi\cos\theta)/A\,\sin^2\theta, \tag{h2}$$

$$\theta: \qquad \dot{p}_\theta = -\partial H/\partial\theta = -(p_\phi - p_\psi\cos\theta)(p_\psi - p_\phi\cos\theta)/A\,\sin^3\theta + m\,g\,l\sin\theta, \tag{h3}$$

$$\dot{\theta} = \partial H/\partial p_\theta = p_\theta/A, \tag{h4}$$

$$\psi: \qquad \dot{p}_\psi = -\partial H/\partial\psi = 0 \qquad (\psi = \text{ignorable coordinate}) \tag{h5}$$

$$\dot{\psi} = \partial H/\partial p_\psi = -(p_\phi - p_\psi\cos\theta)\cos\theta/A\,\sin^2\theta + p_\psi/C. \tag{h6}$$

Equations (h2, 4, 6) are kinematico-inertial, and coincide with the earlier (f1–3); while (h1, 3, 5) are the kinetic equations.

(iii) *Routhian equations*. Since, here, the ignorable coordinates are $\psi_1 = \phi$ and $\psi_2 = \psi$, and corresponding constant momenta $\Psi_1 = p_\phi = C_\phi$ and $\Psi_2 = p_\psi = C_\psi$ (i.e., $n = 3$, $M = 2$), the Routhian is

$$R = L - p_\phi\dot{\phi} - p_\psi\dot{\psi} = \cdots = R_2 + R_1 + R_0, \tag{i}$$

where

$$R_2 = T''_{2,0} = (1/2)\,A\,(\dot{\theta})^2, \tag{i1}$$

$$R_1 = 0 \qquad \text{(we need at least } \textit{two} \text{ nonignorable } q\text{'s to have gyroscopicity!)}, \tag{i2}$$

$$\begin{aligned} R_0 &= T''_{0,2} - V \\ &= -[(C_\phi - C_\psi \cos\theta)^2/2A\,\sin^2\theta + (1/2C)\,{C_\psi}^2] - m\,g\,l\cos\theta, \end{aligned} \tag{i3}$$

and therefore Routh's equation for the nonignorable coordinate θ is

$$A(d^2\theta/dt^2) + [(C_\phi - C_\psi\cos\theta)(C_\psi - C_\phi\cos\theta)]/A\,\sin^3\theta = m\,g\,l\sin\theta. \tag{j}$$

The *second* left-side (centrifugal-like) terms, equal to $E_\theta(T''_{0,2}) = -\partial T''_{0,2}/\partial\theta$, represents the contribution of the *apparent potential energy* $T''_{0,2}(<0)$; there are no gyroscopic terms.

Equation (j) can also be rewritten as

$$A(d^2\theta/dt^2) + (1/2A)\,d/d\theta\big[(C_\phi - C_\psi\cos\theta)^2/\sin^2\theta\big] = m\,g\,l\sin\theta; \tag{j1}$$

The nonlinear equations (j, j1) can be used, just like the earlier Lagrangean equations (d1, 2), to study the small motion of the top about a given precessional motion, say one with constant nutation $\theta(t) = \theta_o$ [i.e., set in, say (j), $\theta = \theta_o + \Delta\theta(t)$, keep *up to linear terms* in $\Delta\theta$ and its $(\ldots)^{\cdot}$-derivatives; and then find conditions so that the resulting *linear second-order $\Delta\theta$ equation* has *harmonic* solutions. The details are left to the reader.]

Finally, either from the general theory, or directly from (j1) (i.e., multiply it with $2\dot{\theta}$, etc.), we can easily show that the system has the following cyclic generalized integral:

$$\begin{aligned} R_2 - R_0 \equiv T''_{2,0} - (T''_{0,2} - V) &= \textit{constant}: \\ (1/2)A(\dot{\theta})^2 + \big[(C_\phi - C_\psi\cos\theta)^2/2A\sin^2\theta &+ (1/2C)\,{C_\psi}^2\big] \\ + m\,g\,l\cos\theta &= \textit{constant}, \end{aligned} \tag{k1}$$

or

$$A(\dot{\theta})^2 + (C_\phi - C_\psi\cos\theta)^2/A\sin^2\theta + 2m\,g\,l\cos\theta = \textit{constant} \equiv h; \tag{k2}$$

or, setting $x \equiv \cos\theta \;\Rightarrow\; \dot{x} = -\dot{\theta}\sin\theta \;\Rightarrow\; (\dot{x})^2 = (1 - x^2)(\dot{\theta})^2$, finally,

$$A(dx/dt)^2 + (C_\phi - C_\psi\,x)^2/A + (2\,mgl\,x - h)(1 - x^2) = 0, \tag{k3}$$

which has the form $(\dot{x})^2 = \textit{known function of } x \equiv f(x) \;\Rightarrow\; dx/[f(x)]^{1/2} = dt$, and upon integration yields $x \equiv \cos\theta$ as an elliptic function of t. The cyclic motions $\phi(t)$ and $\psi(t)$ can then be found from the corresponding Routhian equations (8.4.11), or (b1, 3), by quadratures.

A Generalization

If $Q_\phi \neq 0$, then only ψ is cyclic. Solving (b3) for $\dot{\psi}$, we obtain

$$\dot{\psi} = p_\psi/C - \dot{\phi}\cos\theta \equiv n - \dot{\phi}\cos\theta, \tag{l}$$

and so, in this case, the Lagrangean and Routhian of the top become, respectively,

$$\begin{aligned} L \equiv T - V &= (A/2)\ [(\dot\theta)^2 + (\dot\phi)^2 \sin^2\theta] + (C/2)\ [(n - \dot\phi\cos\theta) + \dot\phi\cos\theta]^2 - mgl\cos\theta \\ &= (A/2)\ [(\dot\theta)^2 + (\dot\phi)^2 \sin^2\theta] + (C/2)n^2 - m\,g\,l\cos\theta \\ &= T''_{2,0} - T''_{0,2} - V = L(\theta; \dot\phi, \dot\theta; C_\psi = C\,n), \end{aligned} \tag{m1}$$

$$R = L - p_\psi\dot\psi = (T - p_\psi\dot\psi) - V = R_2 + R_1 + R_0, \tag{m2}$$

where

$R_2 = T''_{2,0} = (A/2)\ [(\dot\theta)^2 + (\dot\phi)^2 \sin^2\theta]$:

Kinetic energy of a thin homogeneous bar, of transverse moment of inertia A about O, moving about that point, (m3)

$$\begin{aligned} R_1 &= T''_{1,1} = (C\,n\ \cos\theta)\dot\phi \\ &[\equiv r_\phi\dot\phi \equiv (\rho_{\phi\psi}C_\psi)\dot\phi \ \Rightarrow\ r_\phi = (\cos\theta)C\,n,\ \rho_{\phi\psi} = \cos\theta], \end{aligned} \tag{m4}$$

$R_0 = T''_{0,2} - V = -[(C/2)\,n^2 + m\,g\,l\cos\theta]$

[the constant term $T''_{0,2} = -(C/2)n^2$ does not enter the Routhian equations of motion; but it does enter the corresponding energy rate equation]; (m5)

and therefore Routh's equations for the nonignorable coordinates ϕ and θ are

$$(\partial R/\partial\dot\phi)^{\cdot} - \partial R/\partial\phi = Q_\phi:$$

$$(\partial R_2/\partial\dot\phi)^{\cdot} - \partial R_2/\partial\phi = Q_\phi - [(\partial R_1/\partial\dot\phi)^{\cdot} - \partial R_1/\partial\phi],$$

or

$$A\,\ddot\phi\sin^2\theta + 2A\,\dot\phi\,\dot\theta\sin\theta\cos\theta = Q_\phi + (C\,n\ \sin\theta)\,\dot\theta, \tag{n1}$$

$$(\partial R/\partial\dot\theta)^{\cdot} - \partial R/\partial\theta = Q_\theta:$$

$$(\partial R_2/\partial\dot\theta)^{\cdot} - \partial R_2/\partial\theta = -(-\partial R_0/\partial\theta) + Q_\theta - [(\partial R_1/\partial\dot\theta)^{\cdot} - \partial R_1/\partial\theta],$$

or

$$A\,\ddot\theta - A(\dot\phi)^2\sin\theta\cos\theta = m\,g\,l\ \sin\theta + Q_\theta - (C\,n\ \sin\theta)\dot\phi. \tag{n2}$$

Notice that (i) the impressed forces Q_ϕ, Q_θ do not include gravity; (ii) the terms $\pm(C\,n\ \sin\theta)\dot\phi$ are the gyroscopic "forces"; and (iii) these are the Lagrangean equations of the earlier-mentioned fictitious bar rotating about O under the action of (a) gravity, (b) Q_ϕ, Q_θ, and (c) the *gyroscopic couple* $\boldsymbol{M}'_G \equiv \boldsymbol{M}_G\ \sin\theta$, where (with some standard notations)

$$\begin{aligned} \boldsymbol{M}_G &= -d/dt\ (\textit{angular momentum about } Oz) \\ &= -d/dt(C\,n\,\boldsymbol{k}) = -C\,n(\boldsymbol{\omega}_{O-xyz} \times \boldsymbol{k}) \quad [= -C\,n(\boldsymbol{\omega} \times \boldsymbol{k})] \\ &= -C\,n[(\dot\phi\,\boldsymbol{K} + \dot\theta\,\boldsymbol{i}) \times \boldsymbol{k}] = -C\,n\,[\dot\phi(+\boldsymbol{i}) + \dot\theta(-\boldsymbol{j})] \\ &= (-C\,n\,\dot\phi)\boldsymbol{i} + (C\,n\,\dot\theta)\boldsymbol{j} = \big(M_{G,x},\ M_{G,y}\big). \end{aligned} \tag{n3}$$

Finally, if Q_ϕ, $Q_\theta = 0$, the system has the modified generalized energy integral

$$h_R \equiv R_2 - R_0 \equiv T''_{2,0} + (V - T''_{2,0})$$
$$= (A/2)\,\left[(\dot\theta)^2 + (\dot\phi)^2 \sin^2\theta\right] + \left[(C/2)n^2 + m\,g\,l\cos\theta\right] = constant,$$

or, simply,

$$(A/2)\,\left[(\dot\theta)^2 + (\dot\phi)^2 \sin^2\theta\right] + m\,g\,l\cos\theta = constant. \tag{n4}$$

Example 8.4.6 *Sleeping Top.* Continuing from the preceding example, let us study the motion (and linear stability) of the top under gravity, when its spin axis OG is nearly vertical; that is, in the vicinity of OZ [fig. 8.3(a)]. The inertial coordinates X, Y of the projection of G on the horizontal plane O–XY are [fig. 8.3(b)]

$$X = (l\sin\theta)\sin\phi \qquad \text{and} \qquad Y = -(l\sin\theta)\cos\phi. \tag{a}$$

Below, using these coordinate transformations, we express the Lagrangean and Routhian of the top in terms of X, Y and their $(\ldots)^{\cdot}$-derivatives (instead of the earlier ϕ, θ), and keep only up to *quadratic* terms in these variables, so that the corresponding equations of motion be *linear* in them; which is the mathematical meaning of near verticalness, or "sleepingness" of the top. Then, we study the stability/instability of these small motions.

Indeed, $(\ldots)^{\cdot}$-differentiating (a), and then solving for $\dot\phi$ and $\dot\theta$, while noting that $X^2 + Y^2 = l^2\sin^2\theta$, we obtain

$$\dot\phi = (\dot X\,\cos\phi + \dot Y\,\sin\phi)/l\sin\theta, \qquad \dot\theta = (\dot X\,\sin\phi - \dot Y\,\cos\phi)/l\cos\theta; \tag{b}$$

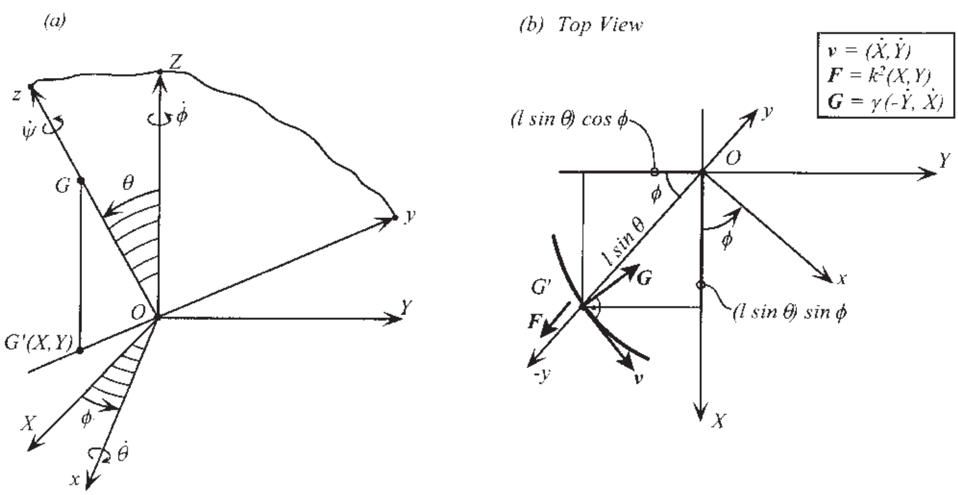

Figure 8.3 (a) Geometry and kinematics of sleeping on top (see also fig. 8.2). (b) Motion of projection of center of mass G of (sleeping) top, G', on horizontal plane O–XY.

and so, to the second order,

$$(\dot{\theta})^2 + (\dot{\phi})^2 \sin^2\theta = \left[(\dot{X})^2 + (\dot{Y})^2\right]/l^2,$$
$$\dot{\phi}\cos\theta = (X\,\dot{Y} - Y\,\dot{X})\left[(X^2 + Y^2)^{-1} - (2l^2)^{-1}\right] = (X\,\dot{Y} - Y\,\dot{X})/2l^2,$$
$$\cos\theta = 1 - (X^2 + Y^2)/2l^2. \tag{c}$$

Hence, recalling the relevant expressions of the preceding example [and that $C(\dot{\psi} + \dot{\phi}\cos\theta) \equiv C\,n = constant \equiv C_\psi$], we find

$$\begin{aligned} L &= (A/2)\ \left[(\dot{\theta})^2 + (\dot{\phi})^2 \sin^2\theta\right] + (C/2)(\dot{\psi} + \dot{\phi}\cos\theta)^2 - m\,g\,l\cos\theta \\ &= (1/2)\ \left\{A[(\dot{X})^2 + (\dot{Y})^2]/l^2 + C_\psi(X\,\dot{Y} - Y\,\dot{X})[(X^2 + Y^2)^{-1} - (2l^2)^{-1}] + C_\psi\dot{\psi}\right\} \\ &\qquad - m\,g\,l[1 - (X^2 + Y^2)/2l^2] = L(X,\ Y,\ \dot{X},\ \dot{Y},\ \dot{\psi};\ C_\psi), \end{aligned} \tag{d1}$$

and (since we are seeking the X, Y equations, we will ignore only ψ; *not* both ϕ and ψ!)

$$\begin{aligned} R &= L - p_\psi\,\dot{\psi} = R_2 + R_1 + R_0 \\ &= (A/2)[(\dot{\theta})^2 + (\dot{\phi})^2\sin^2\theta] + C_\psi\,\dot{\phi}\cos\theta - [({C_\psi}^2/2C) + m\,g\,l\cos\theta] \\ &= A[(\dot{X})^2 + (\dot{Y})^2]/2l^2 - (C_\psi/2l^2)(X\,\dot{Y} - Y\,\dot{X}) \\ &\qquad\qquad + (m\,g\,l/2l^2)(X^2 + Y^2) + constant\ terms \\ &= R(X,\ Y,\ \dot{X},\ \dot{Y};\ C_\psi). \end{aligned} \tag{d2}$$

From these expressions, we obtain the following Routhian equations:

$$(\partial R/\partial\dot{X})^{\cdot} - \partial R/\partial X = 0: \qquad \ddot{X} = k^2 X - \gamma\dot{Y}, \tag{e1}$$

$$(\partial R/\partial\dot{Y})^{\cdot} - \partial R/\partial Y = 0: \qquad \ddot{Y} = k^2 Y + \gamma\dot{X}, \tag{e2}$$

where

$$k^2 \equiv m\,g\,l/A, \qquad \gamma \equiv C_\psi/A \equiv (C/A)\,n. \tag{e3}$$

These coupled equations are the equations of motion of a fictitious particle of unit mass moving on the inertial plane $O\text{–}XY$ under (i) a (centrifugal-like) radial *repulsive* force $\boldsymbol{F} = k^2(X,\ Y)$ (i.e., along OP, from O toward P, proportional to the distance from the origin); and (ii) a *gyroscopic* (Coriolis-like) force $\boldsymbol{G} = \gamma(-\dot{Y},\ \dot{X})$ [fig. 8.3(b)].

Energy Integral

Multiplying (e1) by $\dot{X}$ and (e2) by $\dot{Y}$, and then adding them together, while noting that $\boldsymbol{G}\cdot\boldsymbol{v} = \gamma(-\dot{Y}\,\dot{X} + \dot{X}\,\dot{Y}) = 0$, we readily obtain the generalized energy integral:

$$(1/2)\ [(\dot{X})^2 + (\dot{Y})^2] - (k^2/2)(X^2 + Y^2) = constant, \tag{f}$$

as also expected from the general theory.

Stability

Equations (e) describe the evolution of small deviations (and their rates) of the axis of the top OG from a fundamental state of vertical spinning ($\theta = 0$). They show that the projection of G, G', on the one hand tends to get away from O [$\sim k^2$ terms (gravity)], and on the other turns around the origin [$\sim \gamma$ terms (spinning)], clockwise or counterclockwise, depending on the sign of γ.

As an introduction to §8.6, let us examine the *stability of that motion*; that is, investigate whether G' (OG) remains in the neighborhood of O (OZ), under arbitrary initial conditions of disturbance from these fundamental states. To this end, we set in (e) (since it is a constant coefficient system)

$$X = X_o \exp(\lambda t) \qquad \text{and} \qquad Y = Y_o \exp(\lambda t), \tag{g1}$$

where X_o, Y_o = constant amplitudes and $-\lambda^2 = \omega^2$ = square of frequency of motion (if stable), and thus obtain the following homogeneous system for these amplitudes:

$$(\lambda^2 - k^2)X_o + (\lambda\gamma)Y_o = 0, \qquad (-\lambda\gamma)X_o + (\lambda^2 - k^2)Y_o = 0. \tag{g2}$$

The requirement for nontrivial solutions of the above leads us, in well-known ways, to the determinantal (or secular) equation

$$\Delta(\lambda) = \begin{vmatrix} \lambda^2 - k^2 & \lambda\gamma \\ -\lambda\gamma & \lambda^2 - k^2 \end{vmatrix} = 0, \tag{g3}$$

whose solutions are readily found to be

$$\lambda = \pm(1/2)\,[i\gamma \pm (4k^2 - \gamma^2)^{1/2}]. \tag{g4}$$

From this, we conclude that:

(i) If $\qquad \gamma^2 > 4k^2 \qquad$ [i.e., recalling (e1), if $n^2 > 4\,A\,m\,g\,l/C^2$], $\qquad$ (g5)

then λ will be *purely imaginary*, and therefore X, Y will be *harmonic* (bounded); that is, the vertically spinning state will be *stable*; but

(ii) If $\qquad \gamma^2 < 4k^2 \qquad$ [i.e., if $n^2 < 4\,A\,m\,g\,l/C^2$], $\qquad$ (g6)

then there will be *two pairs of conjugate complex roots*, one with *positive* real part, and one with *negative*. As a result, in general, a part of X, Y will be exponentially *unbounded*; that is, the vertically spinning state will be *unstable*. [Since for *small* θ and *very high* $\dot{\psi}$:

$$n^2 = (\dot{\psi} + \dot{\phi}\cos\theta)^2 = (\dot{\psi})^2 + (\dot{\phi}\cos\theta)^2 + 2\dot{\phi}\,\dot{\psi}\cos\theta \approx (\dot{\psi})^2,$$

the condition (g5) can then be replaced by $(\dot{\psi})^2 > (4A/C^2)m\,g\,l$; and analogously for (g6).]

For additional details of the stable case, see, for example, McCuskey (1959, p. 181); also Routh (1877, pp. 64–66, 94–96), Smart (1951, vol. 2, pp. 409–412), and Whittaker (1937, pp. 206–207). For a general discussion of the sleeping top, including a method for the *uncoupling* of (e) and associated conservation laws/integrals, see Bahar (1992).

Problem 8.4.1 Show that the linearized equations of the sleeping top, in terms of the angular variables ϕ and θ, are:

$$A(\ddot{\theta} - \dot{\phi}^2\theta) + C\,n\,\theta\,\dot{\phi} = m\,g\,l\theta, \quad A(\theta\ddot{\phi} + 2\dot{\theta}\dot{\phi}) - C\,n\,\dot{\theta} = 0. \tag{a}$$

Then show that (a) also lead to the earlier stability condition $\dot{\psi}^2 > (4A/C^2)m\,g\,l$.

HINT

Assume steady precession around the vertical, i.e., $\theta = \text{constant}$ ($\neq 0$). Then require that the resulting quadratic equation in $\dot{\phi}$ ($= \text{constant}$) have real roots. (This argument also works for stability of steady precession about any nutation angle.)

REMARK

Since for small θ the angles ϕ and ψ are not necessarily small (and for $\theta = 0$, $\dot{\phi}$, $\dot{\psi}$ become indeterminate, §1.12), other angles, free of this drawback, have been used; e.g., the Eulerian sequence $1 \to 2 \to 3$. For a treatment of the sleeping top via such singularity-free parameters, see e.g., Beghin (1967, pp. 503–504) and Berezkin (1968, pp. 261–262).

8.5 STEADY MOTION (OF CYCLIC SYSTEMS)

Continuing from §3.10, we define as *steady motion of a general* (not necessarily *cyclic*) *system, relative to a given set of Lagrangean coordinates*, (q_k), one in which *all* corresponding velocities are constant; that is, $(\dot{q}_k) = \textit{constant}$. Hence, if that system is also cyclic, *relative to a particular set of ignorable coordinates*, saying that it is in a state of *steady* (or *isocyclic*) motion means that, during the latter, *the velocities corresponding to both its ignorable and nonignorable coordinates remain constant*; that is, and in the notation of §8.3 and §8.4 (with $i = 1, \ldots, M$; $p = M + 1, \ldots, n$), a motion of that system is steady if during it

$$\dot{\psi}_i = \textit{constant} \equiv c_i \qquad (\text{in } \textit{addition} \text{ to } \Psi_i = \textit{constant} \equiv C_i), \tag{8.5.1a}$$

and

$$q_p = \textit{constant} \equiv s_p \qquad (\Rightarrow \dot{q}_p = 0); \tag{8.5.1b}$$

that is, *all* system velocities are *constant* (and, hence, all corresponding accelerations vanish); and, for scleronomic such systems, the Lagrangean has the form $L = L(c_i, s_p)$. Conditions (8.5.1b) state that (these special motions of the original system called) *steady motions relative to the ignorable coordinates* (ψ_i) are equilibrium states of the conjugate subsystem (q_p). [Recall "bracketed comment" following (8.4.5).]

Clearly, *steadiness is a coordinate-dependent property*, like cyclicity; and outside of uniform translation and rotation about a fixed axis, constitutes one of the simplest kinds of motion. Thus, the spinning top of the preceding examples is in a state of steady motion if its ignorable velocities $\dot{\phi}$ (precession rate) and $\dot{\psi}$ (intrinsic, or proper, spin), and its nonignorable coordinate θ (nutation) remain constant.

To find the conditions for such a state of motion, of, say, a *scleronomic* and holonomic system (extensions to more general systems, even quasi variables and noncyclic systems, do not offer any theoretical difficulties), we take the earlier Kelvin–Tait equations (8.4.10; with p, $p' = M+1, \ldots, n$):

$$\begin{aligned}(\partial R_2/\partial \dot{q}_p)^{\cdot} - \partial R_2/\partial q_p &= Q_p + \partial R_0/\partial q_p + G_p \\ &= Q_p + (\partial T''_{0,2}/\partial q_p - \partial V/\partial q_p) + G_p, \end{aligned} \tag{8.5.2}$$

where

$$G_p \equiv \sum (\partial r_{p'}/\partial q_p - \partial r_p/\partial q_{p'})\dot{q}_{p'} \equiv \sum G_{pp'}\dot{q}_{p'}, \tag{8.5.2a}$$

$$R_1 \equiv T''_{1,1} = \sum r_p\,\dot{q}_p, \tag{8.5.2b}$$

and in there apply the (equilibrium-like) equations (8.5.1a, b). We, thus, obtain the following conditions of steady motion:

$$Q_p + \partial R_0/\partial q_p \equiv Q_p + (\partial T''_{0,2}/\partial q_p - \partial V/\partial q_p) = 0, \tag{8.5.3a}$$

or, if the system is *wholly potential*,

$$\partial R_0/\partial q_p = 0, \qquad \text{or} \qquad \partial T''_{0,2}/\partial q_p = \partial V/\partial q_p. \tag{8.5.3b}$$

Equivalently, since [recalling (8.3.12 ff.)]

$$\begin{aligned}R = R_2\ &(\textit{homogeneous quadratic} \text{ in the } \dot{q}\text{'s}) + R_1\ (\textit{homogeneous bilinear} \text{ in the } \Psi\text{'s } \textit{and } \dot{q}\text{'s}) \\ &+ R_0\ (\textit{homogeneous quadratic} \text{ in the } \Psi\text{'s}),\end{aligned} \tag{8.5.3c}$$

and by Routh's kinematico-inertial identities

$$\partial R/\partial q_p = \partial L/\partial q_p, \tag{8.5.3d}$$

the above "equilibrium" conditions can be rewritten as

$$(\partial R/\partial q_p)_o = (\partial L/\partial q_p)_o = 0 \qquad [(\ldots)_o \equiv (\ldots)_{\dot{\psi}=c,\, q=s,\, \dot{q}=0}]. \tag{8.5.3e}$$

These $n - M$ equations, expressing the hitherto unknown q's $\equiv s$'s in terms of the arbitrarily chosen Ψ's $\equiv C$'s, are the necessary and sufficient conditions for the steady motion of the original system; or, equivalently, for the equilibrium of the reduced system. The $\dot{\psi}$'s can then be found from the *second* (Hamiltonian) group of Routh's equations:

$$\begin{aligned}d\psi_i/dt &= -(\partial R/\partial \Psi_i)_o = -(\partial R_0/\partial \Psi_i)_o = -(\partial T''_{0,2}/\partial \Psi_i)_o \\ &= \sum C_{ij}C_j = \textit{constant} \equiv c_i \qquad [\text{by (8.3.12d, e), with } \dot{q}_p = 0] \\ &= \text{Function of the } s\text{'s [roots of (8.5.3b), (8.5.3e)] and the (arbitrarily} \\ &\qquad \text{chosen) } C_j\text{'s [as (8.3.12l) show, once (8.5.3a, b) have been solved, the} \\ &\qquad C_{ji} \text{ change, from known functions of the } q\text{'s, to known functions} \\ &\qquad \text{of the } \Psi\text{'s],}\end{aligned} \tag{8.5.4a}$$

which, upon integration, yields the ψ's:

$$\psi_i(t) = -c_i(t - t_{\text{initial}}) + \psi_{i,\text{initial}}:$$

Function of the s's and the (now) arbitrarily chosen c_i's and ψ_{initial}'s; (8.5.4b)

that is, *in steady motion, the cyclic coordinates vary linearly with time.*

As stated above, if we initially choose arbitrarily the Ψ's, then eqs. (8.5.3b) relate them to the q's. If, on the other hand, we initially choose arbitrarily the $\dot{\psi}$'s $\equiv c$'s, then, to relate them directly to the q's, we must modify (8.5.3b) somewhat. To this end, we take, first, $T''_{0,2}$, which is homogeneous quadratic in the Ψ's, and, using $\Psi_i = \sum c_{ji}\,\dot{\psi}_j$, we change it to a *homogeneous quadratic* function in the $\dot{\psi}$'s. Indeed, we have, successively (with i, j, j', j'': $1, \ldots, M$),

$$\begin{aligned}
2T''_{0,2} &\equiv 2T''_{\Psi\Psi} \equiv -\sum\sum C_{ji}\Psi_j\Psi_i && \text{[recalling (8.3.12l)]}\\
&= -\sum\sum C_{ji}\Big(\sum c_{j'j}\,\dot{\psi}_{j'}\Big)\Big(\sum c_{j''i}\,\dot{\psi}_{j''}\Big) && \Big[\text{recalling that} \sum C_{ji}\,c_{j'j} = \delta_{ij'}, \text{ etc.}\Big]\\
&= \cdots = -\sum\sum c_{ij}\,\dot{\psi}_i\,\dot{\psi}_j \equiv 2T''_{\dot{\psi}\dot{\psi}} = -2T_{\dot{\psi}\dot{\psi}} && \text{[recalling (8.3.12c, l)].}
\end{aligned} \tag{8.5.5a}$$

Next, applying the results of (probs. 8.2.1 and 8.2.6) to the *conjugate* functions $T''_{\Psi\Psi}$ and $T''_{\dot{\psi}\dot{\psi}}$, we find that

$$\partial T''_{\Psi\Psi}/\partial q_p \;=\; -\partial T''_{\dot{\psi}\dot{\psi}}/\partial q_p \;=\; \partial T_{\dot{\psi}\dot{\psi}}/\partial q_p, \tag{8.5.5b}$$

and so, finally, we can replace the steady motion conditions (8.5.3b) by

$$-\partial T''_{\dot{\psi}\dot{\psi}}/\partial q_p \;=\; \partial V/\partial q_p \qquad \text{or} \qquad \partial T_{\dot{\psi}\dot{\psi}}/\partial q_p \;=\; \partial V/\partial q_p, \tag{8.5.5c}$$

which relate the unknown q's to the arbitrarily chosen $\dot{\psi}$'s; and using $\Psi_i = \sum c_{ji}\,\dot{\psi}_j$ we can relate both sets to the Ψ's.

Example 8.5.1 Let us apply eqs. (8.5.5b, c) to the spinning top described earlier. Here, $\Psi_1 \equiv C_\phi$ and $\Psi_2 \equiv C_\psi$, and

$$2T = A[(\dot{\theta})^2 + (\dot{\phi})^2\sin^2\theta] + C(\dot{\psi} + \dot{\phi}\cos\theta)^2, \qquad V = m\,g\,l\cos\theta, \tag{a1}$$

$$R_2 \equiv T''_{2,0} = (1/2)A(\dot{\theta})^2, \tag{a2}$$

$$R_1 \equiv T''_{1,1} = 0, \tag{a3}$$

$$\begin{aligned}
R_0 &\equiv T''_{0,2} - V \equiv T''_{\Psi\Psi} - V\\
&= -[(C_\phi - C_\psi\cos\theta)^2/2A\sin^2\theta + (1/2C)\,C_\psi{}^2] - m\,g\,l\cos\theta.
\end{aligned} \tag{a4}$$

Therefore, (8.5.4a) yield

$$\dot{\phi} = -(\partial T''_{\Psi\Psi}/\partial C_\phi)_o = (C_\phi - C_\psi\cos\theta)/A\sin^2\theta, \tag{b1}$$

$$\dot{\psi} = -(\partial T''_{\Psi\Psi}/\partial C_\psi)_o = -(C_\phi - C_\psi\cos\theta)\cos\theta/A\sin^2\theta + C_\psi/C. \tag{b2}$$

Solving these two equations for C_ϕ and C_ψ, we obtain

$$C_\phi = (A\sin^2\theta + C\cos^2\theta)\dot{\phi} + (C\cos\theta)\dot{\psi} = constant, \tag{c1}$$

$$C_\psi = (C\cos\theta)\dot{\phi} + (C)\dot{\psi} = constant; \tag{c2}$$

and, inserting these representations in $T''_{\Psi\Psi}$, (a4), we find

$$-2T''_{\dot{\psi}\dot{\psi}} = 2T_{\dot{\psi}\dot{\psi}} = A(\dot{\phi})^2\sin^2\theta + C(\dot{\psi} + \dot{\phi}\cos\theta)^2, \tag{c3}$$

something that could have also been written down immediately from (a1) and the general result (8.5.5a)! With these expressions, we readily confirm that

$$\begin{aligned}\partial T''_{\Psi\Psi}/\partial\theta &= -(\partial T''_{\dot{\psi}\dot{\psi}}/\partial\theta) = \partial T_{\dot{\psi}\dot{\psi}}/\partial\theta \\ &= A(\dot{\phi})^2\sin\theta\cos\theta - C(\dot{\psi} + \dot{\phi}\cos\theta)\dot{\phi}\sin\theta,\end{aligned} \tag{c4}$$

and so the condition of steady motion (here, steady precession) (8.5.5c) becomes [assuming that $\sin\theta \neq 0$ and recalling that $C(\dot{\psi} + \dot{\phi}\cos\theta) \equiv C_\psi$]

$$\partial T''_{\dot{\psi}\dot{\psi}}/\partial\theta \equiv -(\partial T_{\dot{\psi}\dot{\psi}}/\partial\theta) = -(\partial V/\partial\theta): \qquad A(\dot{\phi})^2\cos\theta - C_\psi\,\dot{\phi} + m\,g\,l = 0, \tag{d1}$$

which is an equation relating the noncyclic *coordinate* θ with the cyclic *velocities* $\dot{\phi}$ and $\dot{\theta}$, at that state. Solving this quadratic algebraic equation for $\dot{\phi}$, we find

$$d\phi/dt = \left[C_\psi \pm (C_\psi{}^2 - 4A\,m\,g\,l\cos\theta)^{1/2}\right]/2A\cos\theta, \tag{d2}$$

from which it follows that if $C_\psi{}^2 > 4A\,m\,g\,l\cos\theta$, there will be *two* distinct values of $\dot{\phi}$ for which $\theta = constant$. (The reader can compare this approach with those of the preceding examples.) Of course, the same equations and conditions would result by implementation of (8.5.3b), (8.5.3e); their details are left to the reader.

Problem 8.5.1 Consider the *steady precession* of the spinning top; that is, the special motion where $\dot{\phi} = constant$, $\dot{\psi} = constant$, and $\theta = constant$. Using the results of ex. 8.4.5:

(i) Show that, in this case,

$$\begin{aligned}m\,g\,l\sin\theta &= [(C_\phi - C_\psi\cos\theta)/A\sin\theta]\{[C_\psi\sin^2\theta - (C_\phi - C_\psi\cos\theta)\cos\theta]/\sin^2\theta\} \\ &= (1/A)(A\dot{\phi}\sin\theta)(C_\psi - A\dot{\phi}\cos\theta).\end{aligned} \tag{a}$$

(ii) Further, and since $C_\psi = C\,n \equiv C(\dot{\psi} + \dot{\phi}\cos\theta)$, show that

$$m\,g\,l = \dot{\phi}(C\,n - A\dot{\phi}\cos\theta), \tag{b}$$

which is a functional relation of the form

$$F[\theta(nutation),\ n(total\ spin),\ \dot{\phi}(rate\ of\ precession)] = 0 \Rightarrow \theta = \theta(n,\ \dot{\phi}).$$

(iii) Finally, show that *for high total spins* condition (b) can be approximated by

$$m\,g\,l = C\dot{\phi}\,n; \tag{c}$$

that is, roughly, in the case of "equilibrium" known as *steady precession*, the destabilizing effect of gravity is balanced by the stabilizing (= restoring) effect of spinning.

Problem 8.5.2 Consider the cyclic system of our general theory; that is, $\partial L/\partial\psi_i = 0$.

(i) Show that under the (local and time-independent) coordinate transformation

$$\psi \to \psi' = \psi \qquad \text{and} \qquad q \to q' = f(q), \tag{a}$$

the ψ' remain ignorable.

(ii) Show that the steady motion conditions remain *invariant* under (a); that is,

$$\text{if } \dot\psi = constant \text{ and } q = constant, \text{ then also } \dot\psi' = constant \text{ and } q' = constant. \tag{b}$$

HINT

Apply chain rule to $L(\dot\psi;\, q,\, \dot q) = L(\dot\psi';\, q',\, \dot q')$.

Example 8.5.2 Let us examine the total energy of our original (holonomic, stationary, potential, and cyclic) system at steady motions. Varying $H = T + V = H(q, p)$ *around such a state*, we find, successively [with $\Delta(\ldots)$ denoting generic variations of $(\ldots)$],

$$\begin{aligned}
\Delta H &= \sum [(\partial H/\partial q_k)\Delta q_k + (\partial H/\partial p_k)\Delta p_k] \qquad \text{[invoking the Hamiltonian identities]}\\
&= \sum [(-\partial L/\partial q_k)\Delta q_k + (\dot q_k)\Delta(\partial L/\partial \dot q_k)] \qquad [\text{recalling that } \partial L/\partial\psi_i = 0]\\
&= \sum [(-\partial L/\partial q_p)\Delta q_p + (\dot q_p)\Delta(\partial L/\partial \dot q_p)] + \sum \dot\psi_i\, \Delta\Psi_i\\
&\qquad \text{[invoking (8.5.1b), (8.5.3e)]}\\
&= \sum [(0)\Delta q_p + (0)\Delta(\partial L/\partial \dot q_p)] + \sum \dot\psi_i \Delta\Psi_i\\
&= 0, \qquad \text{if } \Delta\Psi_i = 0.
\end{aligned} \tag{a}$$

Hence, the following theorem.

THEOREM

At a state of steady motion, the energy of the original system is stationary, for vanishing variations of the cyclic momenta around that state.

Since, here, the Δq's and Δp's are viewed as independent, it is not hard to show that the *converse* is also true; that is, if $\Delta H = 0$, for $\Delta\Psi_i = 0$, then the state considered is one of steady motion—namely, there, $\dot q_p = 0$ and $\partial L/\partial q_p = 0$.

[This theorem is important in the Hamiltonian treatment of the stability of steady motion, along lines similar to the study of the stability of equilibrium via the stationarity/extremality of the total potential energy; see §8.6.]

8.6 STABILITY OF STEADY MOTION (OF CYCLIC SYSTEMS)

Continuing from the preceding section, we consider, again, a holonomic, scleronomic (no real loss in generality), potential, and cyclic system S in a so-called *fundamental state* of steady motion I, described by

$$\dot{\psi}_i = constant \equiv c_i \qquad \text{and} \qquad q_p = constant \equiv s_p$$
$$\Rightarrow \Psi_i = constant \equiv C_i \qquad \text{and} \qquad p_p \equiv \partial T/\partial \dot{q}_p = constant \equiv S_p.$$
$$[i = 1, \ldots, M \text{ (number of ignorable coordinates)},\ p = M + 1, \ldots, n \quad (n - M = g\text{: number of nonignorable coordinates})]. \tag{8.6.1}$$

Next, we also consider S in an *adjacent* state of (generally, nonsteady) motion $II = I + \Delta(I)$, caused by *arbitrary* disturbances, and, hence, specified by the following general variations:

$$q_p \to q_p + \Delta q_p \equiv s_p + \Delta s_p \equiv s_p + z_p(t) \ (z_p\text{: } relative \text{ coordinates})$$
$$[\Rightarrow\ p_p \to p_p + \Delta p_p \equiv S_p + \Delta S_p \equiv S_p + Z_p(t)],$$
$$\Psi_i \to \Psi_i + \Delta\Psi_i \equiv C_i + \Delta C_i = constant \text{ (since } S \text{ is cyclic in both } I \text{ and } II)$$
$$[\Rightarrow\ \dot{\psi}_i \to \dot{\psi}_i + \Delta\dot{\psi}_i \equiv c_i + \Delta c_i(t) \equiv c_i + \eta_i(t)]. \tag{8.6.2}$$

Here is why: since our system S remains cyclic, the kinematico-inertial equations (8.3.12d, e; 8.5.4a)

$$\dot{\psi}_i = \sum C_{ij}(q)\Big[\Psi_j - \sum b_{pj}(q)\dot{q}_p\Big],$$

will hold in both states I and II. Therefore,

$$I\text{:} \qquad c_i = \sum C_{ij}(s)\Big[C_j - \sum b_{pj}(s)\dot{s}_p\Big] = \sum C_{ij}(s)C_j \equiv \sum C_{ij}C_j \qquad \text{(since } s_p\text{: } constant\text{);}$$

$$\begin{aligned} II\text{:} \qquad c_i + \eta_i(t) &= \sum C_{ij}[s + z(t)]\Big\{(C_j + \Delta C_j) - \sum b_{pj}[s + z(t)]\dot{z}_p\Big\} \\ &\equiv \sum \big[C_{ij}(s) + \Delta C_{ij}(z; s)\big]\Big\{(C_j + \Delta C_j) - \sum \big[b_{pj}(s) + \Delta b_{pj}(z; s)\big]\dot{z}_p\Big\} \\ &\equiv \sum (C_{ij} + \Delta C_{ij})\Big[(C_j + \Delta C_j) - \sum (b_{pj} + \Delta b_{pj})\dot{z}_p\Big] \\ &\approx \sum C_{ij}C_j + \sum \Big[C_{ij}\ \Delta C_j + \Delta C_{ij}C_j - \sum (C_{ij}b_{pj})\dot{z}_p\Big] \end{aligned} \tag{8.6.2a}$$

[to the *first order* in the $\Delta(I)$-deviations: z_p, $\dot{z}_p$, ΔC_i; $\Delta C_{ji} \approx \sum (\partial C_{ji}/\partial q_p)_I z_p$]

$$\Rightarrow\ \eta_i(t) = \sum \Big[C_{ij}\ \Delta C_j + C_j\ \Delta C_{ij}(t) - \sum C_{ij}b_{pj}\dot{z}_p(t)\Big]; \tag{8.6.2b}$$

that is,

$$\Delta\dot{\psi}(t) = Function\ of\ \ \Delta\Psi,\ \Delta q(t);\ \ \Psi,\ q. \tag{8.6.2c}$$

From the above, it follows that: (a) The specification of $\Delta(I)$, or II, requires n quantities: $M\ \ \Delta\Psi_i$'s, and $n - M\ \ \Delta q_p(t)$'s.

(b) $\Delta\dot{\psi}_i \equiv \eta_i(t) \neq 0$, even if we assume that $\Delta\Psi_j \equiv \Delta C_j = 0$.

(c) After finding the palpable/noncyclic perturbations $z_p(t) \to \dot{z}_p(t) \to \Delta C_{ij}(t)$, we can calculate those of the cyclic velocities $\eta_i(t)$, from (8.6.2b), without any difficulty.

Important Clarifications

(i) Usually, but not always, we consider perturbations $\Delta(I)$ that preserve the values of the ignorable momenta; that is, $\Delta\Psi_i \equiv \Psi_i(II) - \Psi_i(I) = \Delta C_i = 0$. [As shown in ex. 8.5.2, such *equimomental* deviations are also *isoenergetic*; that is, the total energy is also preserved: $H(I) = H(II)$.]

(ii) By adjacent state, we mean one that can be adequately described by *linear*(*ized*) equations in the above nonignorable deviations $q_p(t)$ [and $p_p(t)$] and their $(\ldots)^\cdot$-derivatives.

Now, if, as $t \to \infty$, these perturbations remain bounded—for example, if they vary harmonically about the steady state I, or if they approach it asymptotically—then we say that I is *stable*; if not, then it is *unstable*. [As (8.5.4a) and (8.5.2b) show, a small change in the I-values $q(I)$, $p(I)$, $\Psi(I)$ produces a small change in the $\dot{\psi}(I)$'s: $\dot{\psi}_i \to \dot{\psi}_i + \Delta\dot{\psi}_i(t)$. But in view of the *linear variation of the ignorable coordinates with time,* eq. (8.5.4b), a small change in the $\dot{\psi}(I)$'s produces, after sufficient time, an arbitrarily large change in the $\psi(I)$'s. Therefore, *steady motions cannot be stable relative to their ignorable coordinates*.]

To study such perturbed motions, either:

• We substitute $q_p \to s_p + \Delta s_p \equiv s_p + z_p(t)$ [and $\dot{\psi}_i \to c_i + \Delta c_i(t) \equiv c_i + \dot{\psi}_i(t)$] in the Lagrangean equations of motion of the original system, or (8.6.2) (with $\Psi_i \to C_i + \Delta C_i \equiv C_i$, since we assumed that $\Delta C_i = 0$) in the Routhian equations of motion [i.e., the Lagrangean equations of the reduced, or conjugate, (sub)system]; and then keep only up to *first-order*/*linear* terms in the $\Delta s_p \equiv z_p(t)$, $\Delta c_i \equiv \eta_i(t)$ and their $(\ldots)^\cdot$-derivatives. Since the fundamental state is assumed steady, the so-resulting linear perturbation equations will have coefficients that will be known functions of the (assumed known) constant I-values C_i, s_p (or c_i, s_p), and so will be themselves known constants; or

• We substitute (2) in the exact Routhian $R(q_p, \dot{q}_p; \Psi_i)$ expand it à la Taylor around I [i.e., in powers of the $\Delta q_p(t) \equiv z_p(t)$ and their $(\ldots)^\cdot$-derivatives], keep only up to *second-order*/*quadratic* terms in them, while evaluating all derivatives at I, and then form Routh's equations for the nonignorable perturbations $z_p(t)$. Indeed, with $p, p' = M+1, \ldots, n$ and $(\ldots)_o \equiv (\ldots)_{\text{evaluated at } I}$ (to be used now and then for extra clarity), we obtain, successively,

$$R \equiv R(II) \equiv R[I + \Delta(I)] \equiv R(I) + \Delta R$$

or

$$\begin{aligned} R(q, \dot{q}; \Psi) &= R[s + z(t), \dot{s} + \dot{z}(t); C + \Delta C] = R[s + z(t), \dot{z}(t); C] \\ &\equiv R_{(0)} + R_{(1)} + R_{(2)}, \end{aligned} \tag{8.6.3}$$

where

$$R_{(0)} \equiv R(I) = R(s; C) = \textit{constant}, \tag{8.6.3a}$$

$$\begin{aligned} R_{(1)} &\equiv \sum \left[(\partial R/\partial q_p)_o z_p + (\partial R/\partial \dot{q}_p)_o \dot{z}_p\right]: \textit{linear homogeneous} \text{ in } z, \dot{z} \\ &= \sum \left[(0) z_p + (\partial R/\partial \dot{q}_p)_o \dot{z}_p\right] \qquad \text{[invoking (8.5.3e)]} \end{aligned} \tag{8.6.3b}$$

$$2R_{(2)} \equiv \sum\sum \left[(\partial^2 R/\partial q_p\, \partial q_{p'})_o\, z_p\, z_{p'} + 2(\partial^2 R/\partial q_p\, \partial \dot{q}_{p'})_o\, z_p\, \dot{z}_{p'} + (\partial^2 R/\partial \dot{q}_p\, \partial \dot{q}_{p'})_o\, \dot{z}_p\, \dot{z}_{p'}\right]: \quad \textit{quadratic homogeneous} \text{ in } z, \dot{z}, \tag{8.6.3c}$$

and, therefore {assuming $Q_p(I) = Q_p(II) = 0$, and since $(\partial R/\partial \dot{q}_p)_o = constant \Rightarrow [(\partial R/\partial \dot{q}_p)^{\cdot}]_o = 0$}, the linearized equations of state *II*

$$\big(\partial(\Delta R)/\partial \dot{z}_p\big)^{\cdot} - \partial(\Delta R)/\partial z_p = (\partial R_{(2)}/\partial \dot{z}_p)^{\cdot} - \partial R_{(2)}/\partial z_p = 0, \tag{8.6.3d}$$

become

$$\sum \big(\mu_{pp'}\, \ddot{z}_{p'} + \gamma_{pp'}\, \dot{z}_{p'} + \kappa_{pp'}\, z_{p'}\big) = 0, \tag{8.6.4}$$

where the *constant* coefficients μ, γ, κ are

$$\mu_{pp'} \equiv (\partial^2 R/\partial \dot{q}_p\, \partial \dot{q}_{p'})_o \qquad (= \mu_{p'p}\text{: \textit{positive definite}}), \tag{8.6.4a}$$

$$\kappa_{pp'} \equiv -(\partial^2 R/\partial q_p\, \partial q_{p'})_o \qquad (= \kappa_{p'p},\ \textit{note minus sign}), \tag{8.6.4b}$$

$$\gamma_{pp'} \equiv (\partial^2 R/\partial q_{p'}\, \partial \dot{q}_p - \partial^2 R/\partial q_p\, \partial \dot{q}_{p'})_o = \big[\partial/\partial \dot{q}_p(\partial R/\partial q_{p'}) - \partial/\partial \dot{q}_{p'}(\partial R/\partial q_p)\big]_o \qquad (= -\gamma_{p'p}\text{: \textit{sign indefinite}}). \tag{8.6.4c}$$

REMARKS

(i) The μ- and κ-terms represent, respectively, *inertia* and "*elasticity*," as in ordinary linear vibration theory; the γ-terms, however, do not represent dissipation, but *gyroscopicity*; that is, they are powerless (§3.9):

$$\sum \Big(\sum \gamma_{pp'}\, \dot{z}_{p'}\Big) \dot{z}_p = 0. \tag{8.6.4d}$$

For example, for $n - M = 2$ (= minimum number of nonignorable coordinates for appearance of gyroscopicity; then p, $p' = 1, 2$), eqs. (8.6.4) read, in extenso,

$$\mu_{11}\ddot{z}_1 + \mu_{12}\ddot{z}_2 + \gamma_{12}\dot{z}_2 + \kappa_{11}z_1 + \kappa_{12}z_2 = 0, \tag{8.6.4e}$$

$$\mu_{21}\ddot{z}_1 + \mu_{22}\ddot{z}_2 + \gamma_{21}\dot{z}_1 + \kappa_{21}z_1 + \kappa_{22}z_2 = 0; \tag{8.6.4f}$$

that is, they involve *seven* distinct coefficients [*three inertial* (μ_{11}, $\mu_{12} = \mu_{21}$, μ_{22}) + *one gyroscopic* ($\gamma_{12} = -\gamma_{21}$) + *three elastic* ($\kappa_{11}$, $\kappa_{12} = \kappa_{21}$, κ_{22})].

(ii) Neither $R_{(0)}$ nor $R_{(1)}$ enter the equations of adjacent motion [recall mathematically similar situation in derivation of (3.10.12)].

(iii) The constancy of all coefficients in the expansions (8.6.3–8.6.3c), and therefore also in the perturbation equations (8.6.4–8.6.4c), has been used by Routh as the *mathematical* definition of steady motion. The *physical* characteristic of such a motion is, in his words, "that ... the same oscillations follow from the same disturbance of the same [nonignorable] coordinate at whatever instant the disturbance may be applied to the motion" [Routh (1905(b), p. 77].

To study the nature of the solutions of (8.6.4) with an eye toward their stability, and so on, and guided by the linear and unforced vibration case (i.e., linear homogeneous systems with constant coefficients), we substitute in (8.6.4)

$$z_p = z_{po} \exp(\lambda t), \qquad z_{po} = \text{constant amplitude}, \tag{8.6.5a}$$

and, proceeding in well-known ways, we find that, for nontrivial z_{po}'s, the (constant) λ's must be roots of the following determinantal (or *secular*, or *characteristic*) equation:

$$\Delta(\lambda) \equiv \begin{vmatrix} \mu_{11}\lambda^2 + \kappa_{11} & \mu_{12}\lambda^2 + \gamma_{12}\lambda + \kappa_{12} & \cdots & \mu_{1g}\lambda^2 + \gamma_{1g}\lambda + \kappa_{1g} \\ \mu_{21}\lambda^2 + \gamma_{21}\lambda + \kappa_{21} & \mu_{22}\lambda^2 + \kappa_{22} & \cdots & \mu_{2g}\lambda^2 + \gamma_{2g}\lambda + \kappa_{2g} \\ \cdots & \cdots & \cdots & \cdots \\ \mu_{g1}\lambda^2 + \gamma_{g1}\lambda + \kappa_{g1} & \mu_{g2}\lambda^2 + \gamma_{g2}\lambda + \kappa_{g2} & \cdots & \mu_{gg}\lambda^2 + \kappa_{gg} \end{vmatrix} = 0, \tag{8.6.5b}$$

$$= 2g\text{-degree polynomial in } \lambda \ (g \equiv n - M = \# \textit{ nonignorable coordinates}).$$

The complete (or general) solution of (8.6.4) will equal the linear superposition of the $2g$ (8.6.5a)-like solutions; one for each of the $2g$ roots of (8.6.5b).

The stability/instability of the fundamental state I is determined by the nature (and/or sign) of these roots; which, in turn, are determined by the coefficients μ, γ, κ, whose values depend on that state. In general (recall summary in §3.10), roots that are:

- *real* and *positive*, or *complex with positive real parts* signal *instability* (i.e., solutions increase exponentially with time);
- *real* and *negative*, or *complex with negative real parts* signal (asymptotic) *stability* (i.e., solutions decrease exponentially with time);
- *purely imaginary* signal *stability* (i.e., constant amplitude oscillations. This case is called *critical*: actually, our linearized stability analysis is inconclusive; we need *nonlinear* perturbation equations for $\Delta(I)$ to safely ascertain the stability/instability of I).

Hence, to test stability: either

(i) We find all roots of (8.6.5b) and then check to see if their real parts are negative; or
(ii) We apply any one of a number of existing criteria that does not actually find the roots, but checks the sign of their real parts; for example, Routh–Hurwitz test (§3.10, Method of Small Oscillations).

As in ordinary linear vibration theory, the reason that (8.6.5b) is not so easy to study is because equations (8.6.4) are coupled. An important simplification occurs if we choose new $\Delta(I)$-coordinates $z_p \to x \equiv (x_1, \ldots, x_g)$, via an ever-existing linear, real, and nonsingular transformation that diagonalizes (i.e., uncouples) simultaneously both matrices ($\mu_{pp'}$: positive definite) and ($\kappa_{pp'}$), and thus reduces the "perturbation kinetic and potential energies"

$$2R_{(2)T} \equiv \sum\sum (\partial^2 R/\partial\dot{q}_p\, \partial\dot{q}_{p'})_o\, \dot{z}_p\, \dot{z}_{p'} \equiv \sum\sum \mu_{pp'}\, \dot{z}_p\, \dot{z}_{p'}, \tag{8.6.6a}$$

$$2R_{(2)V} \equiv -\sum\sum (\partial^2 R/\partial q_p\, \partial q_{p'})_o\, z_p\, z_{p'} \equiv \sum\sum \kappa_{pp'}\, z_p\, z_{p'}, \tag{8.6.6b}$$

respectively, to *sums of squares*:

$$2R_{(2)T} = \sum \mu_p(\dot{x}_p)^2 \qquad \text{and} \qquad 2R_{(2)V} = \sum \kappa_p\, x_p{}^2. \tag{8.6.6c}$$

[Note minus sign in $R_{(2)V}$, to give $R_{(2)}$ the form of a Lagrangean; see also (8.6.10b).] However, then, the "gyroscopic energy"

$$R_{(2)G} \equiv \sum\sum (\partial^2 R/\partial q_p\, \partial \dot{q}_{p'})_o\, z_p\, \dot{z}_{p'} \equiv \sum\sum E_{p'p}\, z_p\, \dot{z}_{p'} \qquad (E_{p'p} \neq E_{pp'}) \tag{8.6.6d}$$

(which does not exist in linear, unforced, and undamped vibrations about *equilibrium*) transforms, in general, to another *nondiagonal* form,

$$R_{(2)G} = \sum\sum \varepsilon_{p'p}\, x_p\, \dot{x}_{p'} \qquad \left[\equiv \sum \left(\sum \varepsilon_{p'p}\, x_p\right) \dot{x}_{p'}\right]. \tag{8.6.6e}$$

As mentioned above, since $R_{(2)T}$ (but not necessarily $R_{(2)V}$) is positive definite, such a *partially decoupling transformation* is always possible; but it must be borne in mind that because the "elastic" coefficients $\kappa_{pp'}$, in general, depend on the $\dot{\psi}$, Ψ's, [or, in the mathematically equivalent case of small motion around *relative* equilibrium (recall §3.16), they depend on the constant angular velocity of the rotating frame] the x's may also depend on them as parameters. [The x's are sometimes called principal coordinates, just like the (*completely decoupling*) principal/normal coordinates of ordinary (i.e., nongyroscopic) vibration theory.]

In these coordinates, the Lagrange-type equations of perturbed motion

$$(\partial R_{(2)}/\partial \dot{x}_p)^{\cdot} - \partial R_{(2)}/\partial x_p = 0, \tag{8.6.7a}$$

where $R_{(2)} = R_{(2)T} + R_{(2)G} - R_{(2)V}$, assume the simpler form

$$\mu_p \ddot{x}_p + \sum g_{pp'} \dot{x}_{p'} + \kappa_p x_p = 0, \tag{8.6.7b}$$

where $g_{pp'} \equiv \varepsilon_{pp'} - \varepsilon_{p'p} = -g_{p'p}$; and upon substituting $x_p = x_{po} \exp(\lambda t)$ into them, and so on, we are led to the simpler characteristic equation

$$\Delta(\lambda) \equiv \begin{vmatrix} \mu_1 \lambda^2 + \kappa_1 & g_{12}\lambda & \cdots & g_{1g}\lambda \\ g_{21}\lambda & \mu_2\lambda^2 + \kappa_2 & \cdots & g_{2g}\lambda \\ \cdots & \cdots & \cdots & \cdots \\ g_{g1}\lambda & g_{g2}\lambda & \cdots & \mu_g \lambda^2 + \kappa_g \end{vmatrix} = 0. \tag{8.6.8}$$

Now, the determinant $\Delta(\lambda)$ is *nonsymmetric* [unlike the corresponding determinant of the nongyroscopic case (undamped vibration around *absolute* equilibrium) which, as is well known, is symmetric], but its off-diagonal elements are antisymmetric: $g_{pp'} = -g_{p'p}$. Hence, reversing the sign of λ in $\Delta(\lambda)$ simply interchanges its rows and columns [or, the rows (columns) of $\Delta(\lambda)$ equal the columns (rows) of $\Delta(-\lambda)$] and so, by determinant theory,

$$\Delta(\lambda) = \Delta(-\lambda); \tag{8.6.8a}$$

in words, eq. (8.6.8) [as well as its completely uncoupled version (8.6.5b), and the nongyroscopic case] *is independent of the sign of* λ. Therefore *all odd λ-powers are absent* from it:

$$0 = \Delta(\lambda) \equiv A_g(\lambda^2)^g + A_{g-1}(\lambda^2)^{g-1} + \cdots + A_1(\lambda^2) + A_0$$

$$[(g)\text{th degree polynomial in } \lambda^2]. \tag{8.6.8b}$$

Next, as algebra teaches, since the coefficients μ, κ, g are real, the g λ^2-roots of (8.6.8b) will, in general, be either *real* or *complex conjugate pairs*, like

$$\lambda^2 = \alpha \pm i\beta \qquad (\alpha, \beta\text{: real} \ \Rightarrow \ \lambda = \pm(\varepsilon \pm i\sigma) \qquad (\varepsilon, \sigma\text{: real}). \tag{8.6.8c}$$

and such λ's will produce x's of the following general (real) form:

$$C \exp(\varepsilon t) \cos(\sigma t + c) + D \exp(-\varepsilon t) \cos(\sigma t + d), \tag{8.6.8d}$$

where C, c; D, d are real constants, and, therefore, unless $\varepsilon = 0$, the amplitudes $C \exp(\varepsilon t)$, $D \exp(-\varepsilon t)$ will increase indefinitely, that is, the state I will be unstable. Hence the rule.

RULE

For the fundamental state of steady motion I to be stable, in the above sense, all λ^2-roots of the characteristic equation (8.6.8–8.6.8b) must be *real* and *negative*, that is,

$$\lambda^2\text{-roots} = -\lambda_p{}^2 \ \Rightarrow \ \lambda\text{-roots} = \pm i\,\lambda_p \qquad (\lambda_p\text{: real, } p = 1, \ldots, g). \tag{8.6.8e}$$

Algebraic Detour

The theory of algebraic (polynomial) equations allows us to relate the roots of (8.6.8b) with its coefficients A_g, $A_{g-1}, \ldots, A_1$, A_0. According to the fundamental theorem of algebra (see books on algebra, or handbooks of engineering, mathematics, etc.), if $\Lambda_1, \ldots, \Lambda_{2g}$ are the $2g$ roots of (8.6.8b) (i.e., $\Lambda_1 = +i\lambda_1$, $\Lambda_2 = -i\lambda_1$, etc.), then

$$\Delta(\lambda) = A_g(\lambda - \Lambda_1)(\lambda - \Lambda_2) \cdots (\lambda - \Lambda_{2g}) \qquad \text{(always);} \tag{8.6.9a}$$

and, therefore,

$$\begin{aligned} \Delta(0) &= A_g(-1)^{2g} \Lambda_1 \Lambda_2 \cdots \Lambda_{2g} = +A_g \Lambda_1 \Lambda_2 \cdots \Lambda_{2g} \\ &= \kappa_1 \kappa_2 \cdots \kappa_g = A_0 \quad \text{[by (8.6.8)],} \qquad \text{(always);} \end{aligned} \tag{8.6.9b}$$

and

$$[\lim \Delta(\lambda)]_{\lambda \to \infty} \equiv \Delta(\infty) > 0 \qquad \text{(always).} \tag{8.6.9c}$$

Hence *in the case of stability*—namely (8.6.8e)—and since then to each stable pair of λ-roots, $\pm i\,\lambda_p$, there corresponds in $\Delta(\lambda)$ a factor $[\lambda - (+i\lambda_p)][\lambda - (-i\,\lambda_p)] = \lambda^2 - (-\lambda_p{}^2) = \lambda^2 + \lambda_p{}^2$, eq. (8.6.9a) must have the following form ($A_g > 0$, with no loss in generality):

$$\Delta(\lambda) = A_g(\lambda^2 + \lambda_1{}^2) \ldots (\lambda^2 + \lambda_g{}^2) \qquad \text{(stability case),} \tag{8.6.9d}$$

that is, be a *polynomial with all its coefficients positive*; and so in this case

$$\Delta(0) = A_g(\lambda_1{}^2 \lambda_2{}^2 \ldots \lambda_g{}^2) > 0 \qquad \text{(stability case).} \tag{8.6.9e}$$

Further, according to *Viète's rules* (and counting k-ple roots k times),

$$\Lambda \equiv \Lambda_1 \Lambda_2 \cdots \Lambda_{2g} = (-1)^{2g}(A_0/A_g) = A_0/A_g \qquad \text{(always)} \tag{8.6.9f}$$

and so *in the case of stability* we must have

$$\Lambda = [(-i\lambda_1)(+i\lambda_1)]\ldots[(-i\lambda_g)(+i\lambda_g)] = \lambda_1{}^2\lambda_2{}^2\ldots\lambda_g{}^2$$

$$[\text{also: } (-\lambda_1{}^2)(-\lambda_2{}^2)\ldots(-\lambda_g{}^2) = (-1)^g(\lambda_1{}^2\lambda_2{}^2\ldots\lambda_g{}^2) = (-1)^g(A_0/A_g)]$$

$$\Rightarrow \lambda_1{}^2\lambda_2{}^2\ldots\lambda_g{}^2 = A_0/A_g > 0 \qquad \text{(stability case)}. \tag{8.6.9g}$$

Last, to express this necessary condition for gyroscopic stability in terms of the nongyroscopic parameters of our system in state I (i.e., in terms of the κ_p's and the μ_p's), we expand the determinant (8.6.8) and compare it with (8.6.8b) [or use mathematical *induction*, i.e., confirm it for $g \to 2$, then assume it holds for $g \to g$, and finally prove it for $g \to g+1$]. Thus we get

$A_0 \equiv \kappa_1\kappa_2\ldots\kappa_g = Det\,(\kappa_{pp'}) = Det\,(\kappa_p)\ \ [\neq 0,\ \text{if all}\ \kappa_p \neq 0]$:

Product of coefficients of (nongyroscopic, or irrotational) stability of $R_{(2)V}$,

(always), (8.6.9h)

$A_g \equiv \mu_1\mu_2\ldots\mu_g = Det\,(\mu_{pp'}) = Det\,(\mu_p) \neq 0$:

Product of coefficients of inertia ($\sim$ *masses*) *of positive definite* $R_{(2)T}$,

(always). (8.6.9i)

In view of the above, the essential stability condition (8.6.9g) translates to

$$\lambda_1{}^2\lambda_2{}^2\ldots\lambda_g{}^2 = (\kappa_1\kappa_2\ldots\kappa_g)/(\mu_1\mu_2\ldots\mu_g) > 0 \qquad \text{(stability case)}; \tag{8.6.9j}$$

or, equivalent, since $A_g \equiv \mu_1\mu_2\ldots\mu_g > 0$, to

$$\Delta(0) = A_0 = \kappa_1\kappa_2\ldots\kappa_g > 0 \qquad \text{(stability case)}. \tag{8.6.9k}$$

These results lead us to the following stability criteria [Kelvin and Tait (1860s)]:

Criteria of Gyroscopic Stabilization

Consider a fundamental state of steady motion (ignored coordinates) I, of a cyclic system [or a state of relative equilibrium (rheonomic constraints—§3.16) of a general system], and let (8.6.7b) be the equations of linearized perturbations from I (i.e., no friction taken into account). Then

- If all κ_p's are positive [$\Rightarrow$ $R_{(2)V}$: positive definite $\Rightarrow$ $R_{(2)V}(I)$: minimum, and all λ^2-roots are negative $= -\lambda_p{}^2 < 0$], then I is stable, both nongyroscopically (i.e., with all $g_{pp'}$'s absent) and gyroscopically (i.e., with at least one pair of $g_{pp'}$'s present). If even one κ_p vanishes while the rest remain positive [$R_{(2)V}$: positive semidefinite], then I is unstable both nongyroscopically and gyroscopically. [For alternative proofs including the well-known stability arguments of Dirichlet and Kelvin, see, e.g., Lamb (1943, pp. 245–248; 1932, pp. 310–313), also discussion following (8.6.10).]
- If all κ_p's are negative [$\Rightarrow$ $R_{(2)V}$: negative definite $\Rightarrow$ $R_{(2)V}(I)$: maximum], then I is nongyroscopically unstable. However, if the number of these negative κ_p's is *even* [$\Rightarrow \Delta(0) = A_0 > 0$ and $\Delta(\infty) > 0$], then I can always be stabilized gyroscopically—at least temporarily (see destabilizing effect of ever-present friction, below); but if their number is *odd* [$\Rightarrow \Delta(0) = A_0 < 0$ and $\Delta(\infty) > 0$, i.e., at least one λ-root is positive], then gyroscopic stabilization of I is impossible—in this case, gyroscopic

effects cannot save I from instability. If even one κ_p vanishes while the rest remain negative [$\Rightarrow$ $R_{(2)V}$: negative semidefinite], then I is unstable both nongyroscopically and gyroscopically.

• If some κ_p's are positive, some are negative, and some are zero [$\Rightarrow$ $R_{(2)V}$: indefinite $\Rightarrow$ $R_{(2)V}(I)$: min/max ("saddle point")], then state I can, sometimes, be stabilized gyroscopically; specifically, if no vanishing κ_p's are present, and if the number of negative κ_p's is even.

[The case of equal, or multiple, roots in $\Delta(\lambda) = 0$, as in the nongyroscopic case, is due to accidental properties of the system's physical and geometrical parameters, and, therefore, does not create any real complications; see, e.g., Routh (1905(b), p. 82); also Frank (1935, pp. 136–138).] These conclusions can, of course, also be reached by application of the Routh–Hurwitz theorem to (8.6.8b); see references given in §3.10, and Bellet (1988, pp. 311–327), Grammel (1950, vol. 1, pp. 258–262), Winkelmann and Grammel (1927, pp. 481–483), Merkin (1987, pp. 168–184).

In sum:

- Gyroscopic effects cannot destabilize a state of steady motion, but sometimes they can stabilize it.
- If the number of nonignorable freedoms is even (and no κ_p vanishes), then either I is stable or it can always be stabilized; or, if g is even, gyroscopic stabilization is always possible.

In view of these results, it has become necessary to distinguish stability/instability, in the context of cyclic systems and relative equilibrium, into one based on the ${\lambda_p}^2$'s and one based only on the κ_p's [equivalently, on the extremum–min/max properties of $R_{(2)V}$. We have just seen that (a) if $R_{(2)V}$ is *positive definite*, then I is *stable*, *both nongyroscopically and gyroscopically;* (b) if it is *nonpositive definite,* then I is *nongyroscopically unstable*; and (c) if it is *semidefinite, whether positive or negative* (e.g., $R_{(2)V} \equiv 0$), then I is *gyroscopically unstabilizable*.] Let us elaborate on these concepts.

• Stability ascertained on the basis of the above-presented method of *small oscillations* (i.e., of conditions for the roots of the associated characteristic equation, which includes gyroscopic effects, to be either *purely imaginary* or have *negative real parts*) is called *ordinary*, or *temporary* (due to the eventual destabilization by damping — see below), or *dynamical* (since it is based on equations of motion), and is associated with Lagrange and Routh.

• A second stability method, for holonomic and potential systems, called *practical*, or *permanent*, or *secular* (due to its application to problems of celestial mechanics; e.g., stability of rotating liquid masses), and associated with the names of Kelvin, Poincaré, et al., is based on the *extremum* properties of the system's total potential energy at the fundamental state I, here the negative of R_0; that is,

$$\begin{aligned} -R_0 &\equiv -(T''_{0,2} - V) = V - T''_{0,2} = V + T_{0,2} \\ &\equiv \Big[(1/2)\sum\sum C_{ji}(q)\Psi_j\Psi_i + V(q)\Big]_I \equiv \textit{reduced (total) potential}, \end{aligned} \tag{8.6.10}$$

and this, in turn, is based on the earlier (Jacobi–Painlevé) energy integral (8.4.13a, b, 14):

$$h_R \equiv R_2 - R_0 = T''_{2,0} + (V - T''_{0,2}) = \textit{constant} \qquad (R_2 = \textit{positive definite}), \tag{8.6.10a}$$

(i.e., it takes into account the rotation (κ) but not its gyroscopic effects (g)!) and a reasoning identical to that used in the stability of ordinary (i.e., inertial) equilibrium via the well-known equation $T + V \equiv E = constant$ [what is, generally, referred to as theorem of Dirichlet (1846); see e.g., Lamb (1943, pp. 214–215)]. Equivalently, since the earlier linear perturbation equations (8.6.3d, 4) can be rewritten, with the help of the general quadratic/bilinear forms (8.6.6a–d), as

$$\left[(\partial R_{(2)T}/\partial \dot{z}_p)^{\cdot} - \partial R_{(2)T}/\partial z_p\right] + \left[(\partial R_{(2)G}/\partial \dot{z}_p)^{\cdot} - \partial R_{(2)G}/\partial z_p\right] \\ - \left[(\partial R_{(2)V}/\partial \dot{z}_p)^{\cdot} - \partial R_{(2)V}/\partial z_p\right] = 0,$$

or

$$(\partial R_{(2)T}/\partial \dot{z}_p)^{\cdot} + \left[(\partial R_{(2)G}/\partial \dot{z}_p)^{\cdot} - \partial R_{(2)G}/\partial z_p\right] + \partial R_{(2)V}/\partial z_p = 0, \qquad (8.6.10b)$$

and [by multiplication of each with $\dot{z}_p$, summation over $p = M+1, \ldots, n$, and then invocation of (8.6.4)] readily yield the *perturbational energy* integral:

$$R_{(2)T} + R_{(2)V} = constant$$

$$(R_{(2)T} = positive\ definite;\ \text{no}\ R_{(2)G}\ \text{present, as in relative motion}), \qquad (8.6.10c)$$

for these reasons, *we may, in our practical stability investigation, replace* $-R_0$ *with its quadratic approximation* $R_{(2)V}$ *:*

$$2R_{(2)V} \equiv -\sum\sum (\partial^2 R/\partial q_p\, \partial q_{p'})_o\, z_p\, z_{p'} \equiv \sum\sum \kappa_{pp'}\, z_p\, z_{p'} = \sum \kappa_p {x_p}^2. \qquad (8.6.10d)$$

According to this criterion, the *fundamental state I* is called *practically stable* if

$$-R_0 > 0 \ \Rightarrow\ R_0 < 0, \qquad \text{or} \qquad R_{(2)V} > 0. \qquad (8.6.10e)$$

Since, by (8.5.3b), $(\partial R_0/\partial q_p)_o = 0$, or $(\partial R_{(2)}/\partial q_p)_o = -(\partial R_{(2)V}/\partial z_p)_o = 0$, the above mean that I is stable, in that sense, *if* $R_0(R_{(2)V})$ is a *strict maximum (minimum) there*.

For then, arguing à la Dirichlet, the integral (8.6.10c) will yield

$$R_{(2)T} + (1/2)\sum \kappa_p {x_p}^2 = small\ positive\ constant \equiv c, \qquad (8.6.11a)$$

from which, since $R_{(2)T}$ is positive definite, we conclude that no x_p can ever exceed a certain small value; for example, $|x_1| \leq (2c/\kappa_1)^{1/2}$. Hence, in the *absence of friction*, the *system oscillates around I*, as in stability about ordinary equilibrium. This is the *sufficiency* part of the theorem. The *necessity* part is most easily established by taking into account the always present *friction* during every motion from I. Then (8.6.10c, 11a) are replaced by the power equation

$$d/dt(R_{(2)T} + R_{(2)V}) = negative\ quantity, \qquad (8.6.11b)$$

which implies that, as long as even one $\dot{x}_p$ is nonzero, the perturbational energy $R_{(2)T} + R_{(2)V}$ decreases monotonically until, eventually, *both* $R_{(2)T}$ and $R_{(2)V}$ vanish; that is, all x's and $\dot{x}$'s vanish simultaneously. [It can be shown that this stability criterion also holds if we vary the cyclic momenta; that is, even for $\Psi_i(I) \equiv C_i$, $\Psi_i(II) \equiv C_i + \Delta C_i$; see, for example, Gantmacher (1970, pp. 255–256).]

Since the criteria of practical stability (being *energetic* and not involving the gyroscopic terms) are easier to apply than those of ordinary stability (which are *algebraic* and do involve the gyroscopic terms), it is important to know when these two approaches are completely equivalent.

The foregoing discussion allows us to summarize this comparison in the following complementary statements:

(i) *If state I is practically stable* (*PS*; i.e., *all* $\kappa_p > 0 \Rightarrow R_{(2)V} =$ *positive definite*), *it is also ordinarily stable* (OS; i.e., *all* λ^2 roots *real and negative*); that is, a nongyroscopically stable state remains stable upon addition of gyroscopic effects to it. Accordingly, *if I is ordinarily unstable, it is also practically unstable.*

(ii) *If state I is practically unstable* (say, at least one $\kappa_p < 0 \Rightarrow R_{(2)V} \neq$ *positive definite*), *it may or may not be ordinarily unstable*, depending on whether the number of negative κ_p's is odd (instability) or even (stability); that is, a nongyroscopically unstable state may become stable upon addition of gyroscopic effects to it (Kelvin's stabilization theorem); and *if it is OS, it may or may not be PS*, depending on whether no κ_p is negative or zero (stable) or at least one of them is (unstable). In sum: *PS is sufficient but not necessary for OS*. [For additional details, see, for example (alphabetically): Greenwood (1977, pp. 125–128), Lamb (1943, chap. 11), Langhaar (1962, chap. 1), Thomson and Tait (1912), Ziegler (1968, chaps. 1, 2, 4); for *Hamiltonian* treatments, see, for example, Gantmacher (1970, pp. 252–256), Frank (1935, pp. 129–133), Synge (1960, pp. 191–195).]

Finally, let us examine the effect of (light) *damping* on the nature of these instabilities. We will restrict ourselves to the common case where, say, the Rayleigh dissipation function of the system, *in the* $n - M \equiv g$ *nonignored coordinate* perturbations z or x, *is positive definite* [i.e., if $z, x \neq 0$, then $(R_{(2)T} + R_{(2)V})^{\cdot} < 0$, also known as *complete* damping — to be distinguished from the, more general, *pervasive* damping where Rayleigh's dissipation function is positive but *semidefinite* in z, x]; while the M ignored coordinates ψ will be assumed to remain undamped.

(i) Let state I be *ordinarily stable but practically unstable*. In the absence of friction, as already stated, any small disturbance will simply result in oscillations about I. In the presence of friction, on the other hand, due to (8.6.11b), and since then $R_{(2)T}(I) = 0$ while $R_{(2)V}(I) =$ *maximum*, we will have, *initially*,

$$R_{(2)T} + R_{(2)V} = -(\textit{small positive constant}) \equiv -c, \tag{8.6.12a}$$

and so, later, either $R_{(2)T}$ or $R_{(2)V}$, or both, will be nonzero; that is, the system *will* move away from I, regardless of any gyroscopic effects. But then $R_{(2)T} + R_{(2)V}$ will decrease further, so that, *after a short time t*,

$$R_{(2)T} + R_{(2)V} = -c - kt \qquad (k > 0); \tag{8.6.12b}$$

which means that, since $R_{(2)T}$ is positive definite, $R_{(2)V}$ will keep decreasing further. As a result, the system will move further away from I; that is, the deviation amplitude(s) will increase indefinitely with time, but at a rate depending on the friction present: the larger the friction, the faster the deviation, and vice versa. Such unavoidable destabilization can be slowed down either by decreasing friction or by countering its effect with some other, external, influences.

For example, a spinning gyroscope stabilized against gravity by its spinning, but destabilized by the friction at its support (vertex) and aerodynamic forces, slows down (i.e., its nutation angle gets larger and larger, and its spin decreases) and eventually hits the ground and comes to rest.

(ii) Let state I be *ordinarily unstable*; that is,

$$x \sim \exp(\pm\,\varepsilon t), \qquad \varepsilon = real. \tag{8.6.13}$$

In the *absence* of friction, the system moves quickly away from I. In the *presence* of friction, the system still moves away from I, but *less quickly*, until it reaches another state of steady motion or relative equilibrium. In sum: (complete) damping changes stability ($R_{(2)V}$: positive definite) to the slightly stronger *asymptotic* stability, but it does not change instability ($R_{(2)V}$: nonpositive definite); that is, such damping does not alter the nature of a state of motion in any significant/critical way. Last, we should always remember that our perturbation equations (8.6.4), (8.6.7b) only show the nature of the *initial* motion away from I; to find other such states we need the exact, and generally *nonlinear*, perturbation equations. (See, e.g., articles in Mikhailov and Parton, 1990, and references cited therein.)

In the light of the above, the practical conclusions of Kelvin's theorem can be summed up as follows:

(i) Only systems with an *even* number of unstable nonignorable coordinates can be stabilized gyroscopically.
(ii) In the *absence* of friction, such a stabilization can always be achieved via appropriately oriented and sufficiently fast-spinning gyroscopes (*one* fixed point, relative to the housing) and/or gyrostats (*two* fixed points, relative to the housing) built into the system.
(iii) In the presence of *damped* nonignorable coordinates, to counter the destabilizing frictional losses and thus stabilize our system, we must supply it with external energy.

For extensive and authoritative treatments of the effects of friction on gyroscopic systems, see the earlier-mentioned texts of Merkin (1987) and Ziegler (1968); also Klotter (1960/1981, pp. 186–199, 241–253).

Example 8.6.1 Let us consider a system with kinetic and potential energies

$$2T = A\,\dot{x}^2 + 2\Gamma\,\dot{x}\,\dot{y} + B\,\dot{y}^2, \qquad V = V(x), \tag{a}$$

where A, B, Γ are functions of x only (and such that T remains positive definite); and examine the possible existence of steady motions: $x = constant \equiv s$, $\dot{y} = constant \equiv c_y \equiv c$, and their stability.

(i) *Steady motion*: since y is ignorable, we will have

$$\begin{aligned} &\partial T/\partial \dot{y} = \Gamma \dot{x} + B\dot{y} = constant \equiv C_y \equiv C \\ &\Rightarrow\ \dot{y} = (C - \Gamma\,\dot{x})/B, \text{ and so, for a steady motion, } c = C/B, \end{aligned} \tag{b}$$

and therefore the Routhian function becomes, successively,

$$\begin{aligned} R &= (T - V) - (\partial T/\partial \dot{y})\dot{y} \\ &= (A/2)(\dot{x})^2 + \Gamma\,\dot{x}[(C - \Gamma\,\dot{x})/B] + (B/2)[(C - \Gamma\,\dot{x})/B]^2 \\ &\qquad\qquad - C[(C - \Gamma\,\dot{x})/B] - V(x) \\ &= \cdots = T''_{2,0} + T''_{1,1} + T''_{0,2} - V(x) = R(x, \dot{x}; C), \end{aligned} \tag{c}$$

where

$$T''_{2,0} = (1/2)\{[A - (\Gamma^2/B)]\}(\dot{x})^2,$$
$$T''_{1,1} = (\Gamma/B)C\,\dot{x},$$
$$T''_{0,2} = -(1/2B)C^2. \tag{c1}$$

For steady motion, and with the notation $(\ldots)_o \equiv (\ldots)_{x=s,\,\dot{y}=c}$, the above yield

$$(\partial R/\partial x)_o = [\partial(T''_{0,2} - V)/\partial x]_o = [(C^2/2B^2)(dB/dx) - (dV/dx)]_o = 0,$$

or, due to (b),

$$(c^2/2)(dB/dx)_o = (dV/dx)_o. \tag{d}$$

This algebraic (equilibrium-like) equation connects the values of the palpable coordinate (s) and ignorable velocity (c) at steady motion(s), and allows us to find one in terms of the other.

(ii) *Stability*. Substituting into R: $x = s + z(t)$, expanding à la Taylor, and keeping only *up to quadratic* q-powers, since we are seeking *linear* perturbation equations, we obtain

$$\begin{aligned} R = (1/2)\{&[A - (\Gamma^2/B)]_o(\dot{z})^2 + 2C(\Gamma/B)_o\,\dot{z} - C^2/B_o \\ &+ C^2[B^{-2}(dB/dx)]_o\,z + (C^2/2)[d/dx(B^{-2}(dB/dx))]_o\,z^2\} \\ &- [V_o + (dV/dx)_o\,z + (1/2)(d^2V/dx^2)_o\,z^2] \\ = R(z, \dot{z}; C, s) \qquad &[\text{by (d), the } (\ldots)\ z\text{-terms cancel each other}], \end{aligned} \tag{e}$$

and therefore the z-equation of motion $(\partial R/\partial \dot{z})^{\cdot} - \partial R/\partial z = 0$ becomes

$$[A - (\Gamma^2/B)]_o\,\ddot{z} + \{(d^2V/dx^2)_o - (C^2/2)[d/dx(B^{-2}(dB/dx))]_o\}z = 0. \tag{f}$$

Since, here, $n - M = 2 - 1 = 1$, no $\sim \dot{z}$ (gyroscopic) terms appear in (f). Clearly, the z-motion is harmonic ($\Rightarrow$stable) if

$$\{(d^2V/dx^2)_o - (C^2/2)[d/dx(B^{-2}(dB/dx))]_o\}\big/[A - (\Gamma^2/B)]_o > 0, \tag{g}$$

or, equivalently, since $A - (\Gamma^2/B) > 0$ (due to the positive definiteness of T in $\dot{x}$, $\dot{y}$) and by (b) $cB = C$,

$$B(d^2V/dx^2)_o + c^2[(dB/dx)_o]^2 - (c^2/2)[B(d^2B/dx^2)]_o > 0. \tag{h}$$

Problem 8.6.1 Continuing with the system described by (a) of the preceding example, *but with* $\Gamma = 0$, consider its fundamental steady state I: $x = s$ and $\dot{y} = c$, and the adjacent to it $I + \Delta(I)$: $x = s + z(t)$ and $\dot{y} = c + \eta(t)$.

(i) Show that the (linearized) equations of $\Delta(I)$ are

$$A_o\,\ddot{z} - (c^2/2)(d^2B/dx^2)_o\,z - c(dB/dx)_o\,\eta + (d^2V/dx^2)_o\,z = 0, \tag{a}$$

$$B_o\dot{\eta} + c(dB/dx)_o\,\dot{z} = 0. \tag{b}$$

(ii) Verify that by eliminating η between (a, b) we recover (f), with $\Gamma = 0$.
(iii) Show that state I of that system (e.g., rotation at the rate c), is stable if

$$\{(d^2V/dx^2)/(dV/dx)\}_o > \{[B(d^2B/dx^2) - 2(dB/dx)^2]/[B(dB/dx)]\}_o. \qquad \text{(c)}$$

Example 8.6.2 *General Solution of the Frictionless Gyroscopic Equations.* Assuming $x_p = x_{po}\exp(\lambda t)$ for the solutions of the characteristic equation (8.6.8), $\Delta(\lambda) = 0$, then, for a particular root λ_* $(* = 1, \ldots, 2g)$, we will have

$$x^*_{1o}/\Delta^*_1 = \cdots = x^*_{go}/\Delta^*_g = constant \equiv C_*, \qquad \text{(a)}$$

where

$$\Delta^*_p = \text{minors of any row of } \Delta(\lambda_*) = M^*_p + i\,N^*_p, \qquad \text{(a1)}$$

since, in general, these minors contain both *odd* and *even* powers of λ_*. Therefore, the $(*)$th "natural mode" of oscillation, around the fundamental state I, can be written as

$$x^*_p = x^*_{po}\exp(\lambda_* t) = C_*(M^*_p + i\,N^*_p)\exp(\lambda_* t), \qquad \text{(b)}$$

or, setting $C_* = X_*\exp(i\,\delta_*)$, where X_*, δ_* = real constants, and taking real parts,

$$x^*_p = X_*\big[M^*_p\cos(\omega_*\,t + \delta_*) - N^*_p\sin(\omega_*\,t + \delta_*)\big]. \qquad \text{(b1)}$$

Hence, in the stable case, the oscillations corresponding to a particular (negative) ${\lambda_*}^2$ *have the same frequency but do not move in phase*; that is, the latter varies with the coordinates. Such a natural mode is referred to as "elliptic harmonic" to distinguish it from the "circular harmonic" of the nongyroscopic oscillations.

In the case of *distinct* roots, the general solution is found by superposition of the various modes:

$$x_p = \sum x^*_p = \sum \Delta^*_p\big[C_*\exp(\lambda_*\,t)\big] \qquad (p = 1, \ldots, g;\ * = 1, \ldots, 2g), \qquad \text{(c)}$$

where the $2g$ (real or complex conjugate) C_* are determined from the $2g$ initial conditions.

Example 8.6.3 *Ordinary versus Practical Stability for a Two-DOF System—No Friction.* For such a system (i.e., p, $p' = 1, 2$), the fundamental perturbational equations (8.6.7b) become

$$\mu_1\ddot{x}_1 - \gamma\,\dot{x}_2 + \kappa_1 x_1 = 0, \qquad \mu_2\ddot{x}_2 + \gamma\,\dot{x}_1 + \kappa_2 x_2 = 0, \qquad \text{(a1, 2)}$$

where

$$g_{12} = -g_{21} \equiv -\gamma, \quad \text{and} \quad \mu_1, \mu_2 > 0.$$

Setting in there

$$x_1 = x_{1o}\exp(\lambda t), \qquad x_2 = x_{2o}\exp(\lambda t), \qquad \text{(b)}$$

and eliminating the amplitude ratio x_{1o}/x_{2o}, we are readily led to the characteristic equation

$$(\mu_1\mu_2)\lambda^4 + (\mu_1\kappa_2 + \mu_2\kappa_1 + \gamma^2)\lambda^2 + \kappa_1\kappa_2 = 0. \qquad \text{(c)}$$

By elementary algebra, the two λ^2-roots of (c) will be *real* if

$$(\mu_1\kappa_2 + \mu_2\kappa_1 + \gamma^2)^2 - 4(\mu_1\mu_2)(\kappa_1\kappa_2) > 0, \tag{d}$$

or, expanding and rearranging in γ-powers,

$$\gamma^4 + 2(\mu_1\kappa_2 + \mu_2\kappa_1)\gamma^2 + (\mu_2\kappa_1 - \mu_1\kappa_2)^2 > 0. \tag{d1}$$

Now we have to consider the following three cases:

(i) κ_1 and κ_2 are both *positive*. Then, clearly, (d1), all three of its left-side terms being positive, is fulfilled for *any* γ; and since, from algebra,

$$\lambda_1{}^2\lambda_2{}^2 = (-1)^2(\kappa_1\kappa_2)/(\mu_1\mu_2) \;\Rightarrow\; \lambda_1{}^2\lambda_2{}^2 > 0, \tag{e1}$$

$$\lambda_1{}^2 + \lambda_2{}^2 = -(\mu_1\kappa_2 + \mu_2\kappa_1 + \gamma^2)/(\mu_1\mu_2) \;\Rightarrow\; \lambda_1{}^2 + \lambda_2{}^2 < 0, \tag{e2}$$

we conclude that, then, both $\lambda_1{}^2$ and $\lambda_2{}^2$ are *negative*; that is,

$$\lambda_1 = \pm i\,\sigma_1 \qquad \text{and} \qquad \lambda_2 = \pm i\,\sigma_2\,. \tag{e3}$$

where $\sigma_1{}^2$ and $\sigma_2{}^2$ are the roots of

$$(\mu_1\mu_2)\sigma^4 - (\mu_1\kappa_2 + \mu_2\kappa_1 + \gamma^2)\sigma^2 + \kappa_1\kappa_2 = 0. \tag{e4}$$

In this case, the solutions of (a1, 2) are simple harmonic oscillations, and so *the fundamental state I is stable, both ordinarily (negative λ^2-roots) and practically* $(\kappa_1, \kappa_2 > 0)$.

(ii) κ_1 and κ_2 have *opposite* signs. Then, clearly, (d), both its left-side terms being positive, still holds for *any* γ; but, by the first part of (e1), the roots $\lambda_1{}^2$, $\lambda_2{}^2$ now have opposite signs; that is,

$$\lambda_1{}^2\lambda_2{}^2 < 0; \tag{f}$$

and the positive of them leads to $\exp(\pm\varepsilon t)$-proportional factors in the perturbations $x_p(t)$, and hence *ordinary instability* (and, of course, practical instability).

(iii) κ_1 and κ_2 are both *negative*. If $\lambda_1{}^2$ and $\lambda_2{}^2$ are real, *which, by (d), can happen if γ^2 is large enough*; that is, if, successively,

$$\begin{aligned}
\mu_1\kappa_2 + \mu_2\kappa_1 + \gamma^2 &\geq [4(\mu_1\mu_2)(\kappa_1\kappa_2)]^{1/2} \qquad (= \textit{positive})\\
\Rightarrow \gamma^2 &\geq -(\mu_1\kappa_2 + \mu_2\kappa_1) + 2[(\mu_1\mu_2)(\kappa_1\kappa_2)]^{1/2}\\
&= [(-\mu_1\kappa_2)^{1/2} + (-\mu_2\kappa_1)^{1/2}]^2\\
\Rightarrow \gamma &\geq (-\mu_1\kappa_2)^{1/2} + (-\mu_2\kappa_1)^{1/2},
\end{aligned} \tag{g1}$$

then, as in (e1, 2),

$$\lambda_1{}^2\lambda_2{}^2 = (-1)^2(\kappa_1\kappa_2)/(\mu_1\mu_2) \;\Rightarrow\; \lambda_1{}^2\lambda_2{}^2 > 0, \tag{g2}$$

$$\lambda_1{}^2 + \lambda_2{}^2 = -(\mu_1\kappa_2 + \mu_2\kappa_1 + \gamma^2)/(\mu_1\mu_2) \;\Rightarrow\; \lambda_1{}^2 + \lambda_2{}^2 < 0; \tag{g3}$$

that is, as in (i), both $\lambda_1{}^2$ and $\lambda_2{}^2$ are *negative*, and hence the system is *ordinarily stable*, although *practically unstable* ($R_{(2)V}$ = *negative definite* $\Rightarrow$ *maximum, or*

$R_0 = minimum$)! But, as explained earlier, such a gyroscopic stabilization is gradually lost due to friction. (See next example; also Thomson and Tait, 1912, pp. 395–396, Gray, 1918, pp. 439–440.)

Example 8.6.4 *Ordinary versus Practical Stability for a Two-DOF System—Friction.* Continuing from the preceding example, let us now examine the effect of small $\dot{x}$-proportional friction terms in case (iii) (i.e., both κ_1 and κ_2 *negative* $\Rightarrow$ ordinary stability but practical instability). Here, the perturbation equations are

$$\mu_1 \ddot{x}_1 + f_{11}\dot{x}_1 + (f_{12} - \gamma)\dot{x}_2 + \kappa_1 x_1 = 0, \tag{a1}$$

$$\mu_2 \ddot{x}_2 + f_{22}\dot{x}_2 + (f_{21} + \gamma)\dot{x}_1 + \kappa_2 x_2 = 0, \tag{a2}$$

where

$f_{11}, f_{12} = f_{21}, f_{22}$ are the small constant coefficients of the *dissipation function* (§3.9)

$2F = f_{11}(\dot{x}_1)^2 + 2 f_{12}\dot{x}_1\dot{x}_2 + f_{22}(\dot{x}_2)^2$

[assumed *positive definite*; i.e., during every motion from *I*, *F* does *negative* work and hence reduces the perturbational energy $R_{(2)T} + R_{(2)V}$], (b1)

$$\Rightarrow \quad f_{11} > 0, \qquad f_{22} > 0, \qquad Det(f_{pp'}) = f_{11} f_{22} - f_{12}{}^2 > 0. \tag{b2}$$

In this case, the characteristic equation, the counterpart of (c) of the preceding example, becomes

$$(\mu_1\mu_2)\lambda^4 + (\mu_2 f_{11} + \mu_1 f_{22})\lambda^3 + (\mu_1\kappa_2 + \mu_2\kappa_1 + \gamma^2 + f_{11} f_{22} - f_{12}{}^2)\lambda^2 + (\kappa_2 f_{11} + \kappa_1 f_{22})\lambda + \kappa_1\kappa_2 = 0. \tag{c}$$

Assuming that the roots of the previous frictionless case are $\pm i\,\sigma_1$ and $\pm i\,\sigma_2$ (ordinary stability; from which, as explained earlier, it follows that κ_1 and κ_2 have the *same sign*), we try for the roots of (c) the modified forms

$$\lambda_{1,2} = \varepsilon_1 \pm i\,\sigma_1 \qquad \text{and} \qquad \lambda_{3,4} = \varepsilon_2 \pm i\,\sigma_2, \tag{c1}$$

where ε_1, ε_2 are first-order (i.e., $\sim f_{pp'}$) corrections to σ_1, σ_2; and the latter are, of course, determined from (e4) of ex. 8.6.3. Now, from algebra (see texts on algebra, or handbooks of mathematics, etc.) we know that

- $$\lambda_1 + \lambda_2 + \lambda_3 + \lambda_4 = -(\mu_2 f_{11} + \mu_1 f_{22})/(\mu_1\mu_2) < 0, \tag{c2}$$

and this, thanks to (c1), yields, to the first order,

$$2(\varepsilon_1 + \varepsilon_2) = -[(f_{11}/\mu_1) + (f_{22}/\mu_2)] < 0, \tag{c3}$$

- $$\begin{aligned} &\lambda_1{}^{-1} + \lambda_2{}^{-1} + \lambda_3{}^{-1} + \lambda_4{}^{-1} \\ &\quad = (\lambda_2\lambda_3\lambda_4 + \lambda_1\lambda_3\lambda_4 + \lambda_1\lambda_2\lambda_4 + \lambda_1\lambda_2\lambda_3)/(\lambda_1\lambda_2\lambda_3\lambda_4) \\ &\quad = -(\kappa_2 f_{11} + \kappa_1 f_{22})/(-1)^4(\kappa_1\kappa_2), \end{aligned} \tag{c4}$$

from which, and (c1), and noting further that

$$\lambda_1{}^{-1} + \lambda_2{}^{-1} + \lambda_3{}^{-1} + \lambda_4{}^{-1} = (\lambda_1{}^{-1} + \lambda_2{}^{-1}) + (\lambda_3{}^{-1} + \lambda_4{}^{-1})$$
$$= 2[\varepsilon_1(\varepsilon_1{}^2 + \sigma_1{}^2)^{-1} + \varepsilon_2(\varepsilon_2{}^2 + \sigma_2{}^2)^{-1}], \qquad \text{(c5)}$$

we obtain, again to the first order,

$$2\big[(\varepsilon_1/\sigma_1{}^2) + (\varepsilon_2/\sigma_2{}^2)\big] = -[(f_{11}/\kappa_1) + (f_{22}/\kappa_2)]. \qquad \text{(c6)}$$

Hence:

(i) If both κ_1 and κ_2 are *positive* (practical stability), then both ε_1 and ε_2 are *negative* $\Rightarrow$ $\exp(\varepsilon t)$-terms; that is, we also have ordinary damped stability.

(ii) If both κ_1 and κ_2 are *negative* (practical instability), then ε_1 and ε_2 must have *opposite signs*; which means that, then, one of the two oscillations dies away, while the other increases exponentially at an $f_{pp'}$-proportional rate; that is, we have ordinary damped instability. To find what happens where, we solve (c3, 6) for, say ε_1, and thus obtain

$$\varepsilon_1(\sigma_2{}^{-2} - \sigma_1{}^{-2}) = -(1/2\sigma_2{}^2)[(f_{11}/\mu_1) + (f_{22}/\mu_2)] + (1/2)[(f_{11}/\kappa_1) + (f_{22}/\kappa_2)] < 0,$$
$$\Rightarrow \ \varepsilon_1(\sigma_1{}^2 - \sigma_2{}^2) < 0, \qquad \text{(c7)}$$

from which we conclude that if $\sigma_1 < \sigma_2$, then $\varepsilon_1 > 0$; and, of course, $\varepsilon_2 < 0$; and analogously if $\sigma_1 > \sigma_2$. In words: the *exponentially increasing oscillation* (say $\varepsilon_1 > 0$) corresponds to the *smaller of the two frictionless frequencies* (here, σ_1) $\Rightarrow$ *longer period*; while the *damped oscillation* (here, $\varepsilon_2 < 0$) corresponds to the *larger frequency* (here, σ_2) $\Rightarrow$ *smaller period*.

Example 8.6.5 *The Monorail.* Let us consider a car (or wagon) K of mass M supported by one (or more, but aligned) wheels W rolling on a *single* fixed horizontal rail OY (+away from the reader—fig. 8.4). Inside K there is a gimbal G' of negligible mass that can rotate freely about a K-fixed axis $G_1'G_2'$; and inside G' there is a heavy gyroscope G of mass m that can rotate about a G'-fixed axis G_1G_2—that is, on the car's plane of symmetry $O\text{–}yz$ ($Oy \equiv OY$), at a constant rate ω_0. In addition, G' carries at its top, above and around G_1, a heavy particle P of mass μ, so that (in accordance with Kelvin's theorem of stabilization of an *even* number of nongyroscopically unstable freedoms) *both* such freedoms θ and χ (see below) are *unstable*; or, equivalently, we may skip P but make sure that the center of mass of G, C' is *above* the axis $G_1{}'O'G_2{}'$. The rotation of G' about its housing K (axis $G_1'G_2'$) is measured by the "precession" angle χ between the gyro axis G_1G_2 and Oz ($O\text{–}yz$ = plane of symmetry of K), while the rotation ("nutation") of the entire K about $OY \equiv Oy$ is measured by the angle θ between $O\text{–}yz$ and the vertical OZ. All other kinematico-inertial parameters of the system are shown in the figure, and will be identified below as needed. Let us find the equations of small motion of this *two*-DOF system around the "normal attitude" $\chi,\ \theta = 0$, when K travels at a *uniform* rate along OY; and examine their stability.

Let T_K/V_K, T_G/V_G, and T_P/V_P, be the (inertial) kinetic/potential energies of the car (K), gyro (G), and particle (P), respectively. Then, to the *second order* in θ and χ and their rates (since we are only interested in *linear* equations of motion in them),

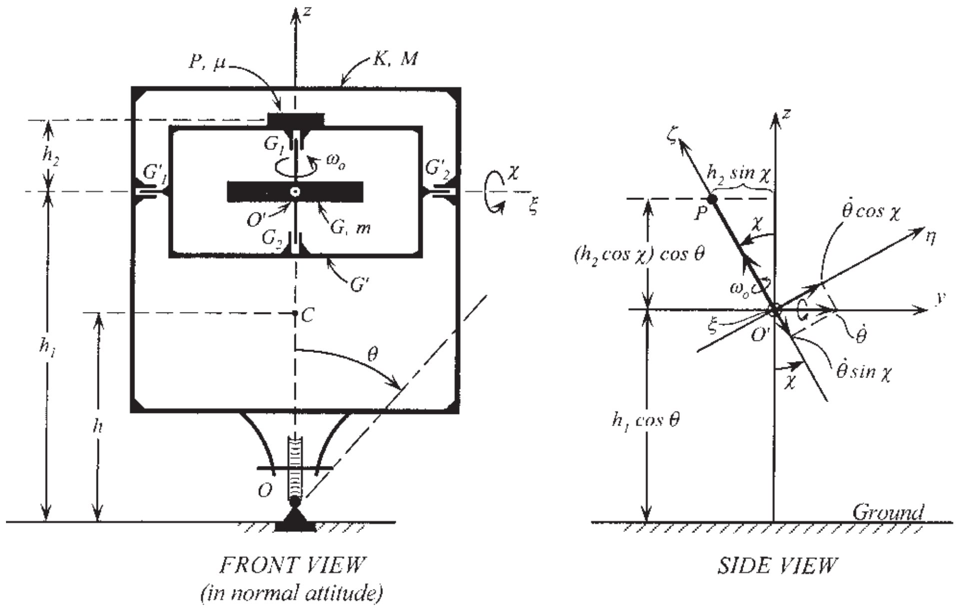

Figure 8.4 Kinematico-inertial parameters of the monorail. C, $C' \equiv O'$: centers of mass of K and G, respectively; both along Oz. [In some treatments, C' is *above* O'; e.g., Cabannes (1968, pp. 276–277). Here, we achieve the same result with P]; $h_2 = G_1 O$, $h_1 = O'O$, $h = CO$; O–xyz: *car–fixed* axes, O–yz: car *plane of symmetry*, O–XYZ: *inertial* axes with which O–xyz coincide in the normal attitude configuration.

and to within inconsequential constant terms, we have

(i) $$T_K = (1/2)I(\dot{\theta})^2 \qquad (I = \text{moment of inertia of } K \text{ about } Oy \equiv OY), \quad \text{(a1)}$$

$$V_K = M\,g\,h\cos\theta \;\approx\; -M\,g\,h\,\theta^2/2 + \textit{constant}; \quad \text{(a2)}$$

(ii) $$T_G = (1/2)m\,{v_G}^2 + (1/2)\left[A({\omega_\xi}^2 + {\omega_\eta}^2) + C\,{\omega_\zeta}^2\right]$$

$[O'$–$\xi\eta\zeta$: G'-fixed axes;

A/C: transverse/axial principal moments of inertia of G at $O']$

$$= (1/2)m(h_1\dot{\theta})^2 + (1/2)\left\{A[(\dot{\chi})^2 + (\dot{\theta}\cos\chi)^2] + C(\omega_o - \dot{\theta}\sin\chi)^2\right\}$$

$$\approx (1/2)m\,{h_1}^2(\dot{\theta})^2 + (1/2)\left\{A[(\dot{\chi})^2 + (\dot{\theta})^2] + C(\omega_o - \dot{\theta}\chi)^2\right\}$$

$$\approx (1/2)m\,{h_1}^2(\dot{\theta})^2 + (1/2)\left\{A[(\dot{\theta})^2 + (\dot{\chi})^2] + C({\omega_o}^2 - 2\omega_0\chi\dot{\theta})\right\},$$

$$V_G = m\,g\,h_1\cos\theta \;\approx\; -M\,g\,h_1\theta^2/2 + \textit{constant}. \quad \text{(a3, 4)}$$

(iii) The inertial coordinates and velocities of P (X_P, Y_P, Z_P) equal

$$X_P = (h_1 + h_2\cos\chi)\sin\theta \;\approx\; (h_1 + h_2)\theta \;\Rightarrow\; \dot{X}_P \approx (h_1 + h_2)\dot{\theta}, \quad \text{(a5)}$$

$$Y_P = -h_2\sin\chi \;\approx\; -h_2\chi \;\Rightarrow\; \dot{Y}_P \approx -h_2\dot{\chi}, \quad \text{(a6)}$$

$$Z_P = (h_1 + h_2\cos\chi)\cos\theta \approx (-1/2)\left[(h_1 + h_2)\theta^2 + h_2\chi^2\right]$$

$$\Rightarrow\; \dot{Z}_P \approx -(h_1 + h_2)\theta\,\dot{\theta} + h_2\chi\,\dot{\chi} \;\Rightarrow\; (\dot{Z}_P)^2 \approx 0; \quad \text{(a7)}$$

and therefore, to the second order,

$$2T_P = \mu[(\dot{X}_P)^2 + (\dot{Y}_P)^2 + (\dot{Z}_P)^2] = \cdots \approx \mu[(h_1 + h_2)^2(\dot{\theta})^2 + h_2{}^2(\dot{\chi})^2], \tag{a8}$$

$$V_P = \mu\, g\, Z_P \approx -(\mu\, g/2)[(h_1 + h_2)\theta^2 + h_2\chi^2] + constant. \tag{a9}$$

In view of the above results, the "quadratisized" system Lagrangean equals

$$L = (T_K + T_G + T_P) - (V_K + V_G + V_P) \equiv L_2 + L_1 + L_0, \tag{b1}$$

where

$$2L_2 \equiv M_{11}(\dot{\theta})^2 + M_{22}(\dot{\chi})^2 \qquad \text{(Inertial part)},$$
$$M_{11} \equiv I + m\, h_1{}^2 + A + \mu(h_1 + h_2)^2, \qquad M_{22} \equiv A + \mu h_2{}^2; \tag{b2}$$

$$L_1 \equiv M_1\chi\dot{\theta} \qquad \text{(Gyroscopic part)},$$
$$M_1 \equiv C\omega_o; \tag{b3}$$

$$2L_0 \equiv k_{11}\theta^2 + k_{22}\,\chi^2 \qquad \text{(Potential part)},$$
$$k_{11} = M\, h + m\, h_1 + \mu(h_1 + h_2) \quad (> 0), \qquad k_{22} = \mu\, h_2 \quad (> 0); \tag{b4}$$

or, in the new *normalized* Lagrangean coordinates $x_1 \equiv (M_{11})^{1/2}\theta$ and $x_2 \equiv (M_{22})^{1/2}\chi$:

$$2L = [(\dot{x}_1)^2 + (\dot{x}_2)^2] - 2\gamma x_2\dot{x}_1 - (\kappa_1 x_1{}^2 + \kappa_2 x_2{}^2),$$

where

$$\kappa_1 \equiv -(k_{11}/M_{11}) \quad (< 0), \qquad \kappa_2 \equiv -(k_{22}/M_{22}) \quad (< 0),$$
$$\gamma \equiv M_1/(M_{11}M_{22})^{1/2} \equiv C\,\omega_o/(M_{11}M_{22})^{1/2}. \tag{c}$$

Hence, the linear(ized) Lagrangean equations of motion for $x_1(\theta)$ and $x_2(\chi)$ are

$$\ddot{x}_1 - \gamma\dot{x}_2 + \kappa_1 x_1 = 0, \qquad \ddot{x}_2 + \gamma\dot{x}_1 + \kappa_2 x_2 = 0; \tag{d}$$

and, by (ex. 8.6.3: g1), for ordinary (= asymptotic) stability their coefficients must satisfy

$$\gamma \geq (-\kappa_1)^{1/2} + (-\kappa_2)^{1/2}; \tag{e}$$

that is, recalling (c), *the spin ω_o must be sufficiently high to counter the destabilizing effect of gravity.*

Problem 8.6.2 Continuing from the preceding example, in the presence of small $\dot{x}$-proportional *damping*, the normalized monorail equations of motion (ex. 8.6.5: d) are, generally, replaced by (recall ex. 8.6.4):

$$\ddot{x}_1 + f_{11}\dot{x}_1 + (f_{12} - \gamma)\dot{x}_2 + \kappa_1 x_1 = 0, \tag{a1}$$
$$\ddot{x}_2 + f_{22}\dot{x}_2 + (f_{21} + \gamma)\dot{x}_1 + \kappa_2 x_2 = 0. \tag{a2}$$

(i) Show that the characteristic equation of this system is

$$\Delta(\lambda) = \lambda^4 + a_1\lambda^3 + a_2\lambda^2 + a_3\lambda + a_4 = 0 \qquad (a_0 = 1), \tag{a3}$$

where

$$a_1 \equiv f_{11} + f_{22}, \tag{a4}$$

$$a_2 \equiv \kappa_1 + \kappa_2 + \gamma^2 + f_{11} f_{22} - f_{12}{}^2, \tag{a5}$$

$$a_3 \equiv \kappa_1 f_{22} + \kappa_2 f_{11}, \tag{a6}$$

$$a_4 \equiv \kappa_1 \kappa_2. \tag{a7}$$

(ii) By applying the Routh–Hurwitz stability criterion (§3.10, and its examples/problems), investigate the possibility/impossibility of gyroscopic stabilization of the damped monorail. [For practical insights, see, e.g., Grammel (1950, Vol. 2, pp. 230–247); also Merkin (1987, pp. 182–184; 1974, pp. 232–234).]

Problem 8.6.3 Consider a cyclic system with *one* nonignorable coordinate, q, whose Routhian equation of motion is

$$(\partial R/\partial \dot{q})^{\cdot} - \partial R/\partial q = 0, \tag{a}$$

or, explicitly, since $R = R(q, \dot{q};\ \textit{constant cyclic momenta} \equiv C)$,

$$(\partial^2 R/\partial \dot{q}^2)\ddot{q} + (\partial^2 R/\partial q\, \partial \dot{q})\dot{q} - \partial R/\partial q = 0. \tag{b}$$

Let the small motion of the system around a *steady* state I: $q = \textit{constant} \equiv s$, be $s + z(t)$. By expanding (b) à la Taylor around I, and keeping up to *linear* terms in the perturbation $z(t)$ and its $(\ldots)^{\cdot}$-derivatives, show that the latter satisfies the following equation:

$$(\partial^2 R/\partial \dot{q}^2)_o \ddot{x} - (\partial^2 R/\partial q^2)_o x = 0, \tag{c}$$

where $(\ldots)_o \equiv (\ldots)$ evaluated at I; and hence for *stability* of that state [i.e., harmonic $z(t)$], and since $(\partial^2 R/\partial \dot{q}^2)_o > 0$, we must have

$$(\partial^2 R/\partial q^2)_o < 0. \tag{d}$$

HINT

The value(s) of state I satisfy the equation $(\partial R/\partial q)_o = 0$; and hence, by (d), $R_0 = \textit{maximum}$.

Problem 8.6.4 Consider a particle P of mass m that can slide on a smooth circular hoop H of radius r and moment of inertia about any diameter I (fig. 8.5). H spins about a fixed vertical axis with constant angular velocity $\omega \equiv \dot{\phi}$.

(i) Show that, since ϕ is ignorable $[\Rightarrow p_\phi \equiv \partial T/\partial \dot{\phi} = (I + m r^2 \sin^2\theta)\dot{\phi} = \textit{constant} \equiv C$, with solution(s) $\theta = \theta']$, the Routhian equals

$$R \equiv L - p_\phi \dot{\phi} = L - C\omega = R_2 + R_1 + R_0 = R(\theta, \dot{\theta}; C), \tag{a}$$

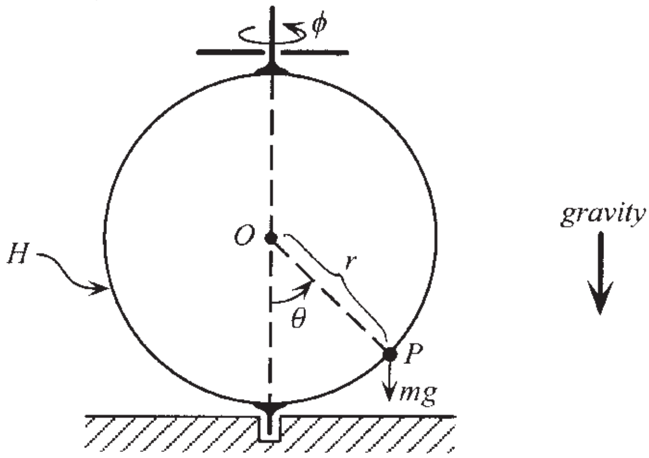

Figure 8.5 Particle moving on a smooth and uniformly spinning circular ring.

where

$$R_2 = (m r^2/2)(\dot{\theta})^2 \quad (\equiv T''_{2,0}), \tag{b}$$

$$R_1 = 0 \quad (\equiv T''_{1,1}), \tag{c}$$

$$R_0 = m g r \cos\theta - \left[C^2/2(I + m r^2 \sin^2\theta)\right] \quad (\equiv -V + T''_{2,0}). \tag{d}$$

(ii) Show that the steady motion condition:

$$\partial R_0/\partial\theta = -m g r \sin\theta + (C^2 m r^2 \sin\theta\cos\theta)(I + m r^2 \sin^2\theta)^{-2} = 0, \tag{e}$$

leads, further, to the following *two* algebraic equations (with corresponding roots θ' and θ''):

$$-m g r(I + m r^2 \sin^2\theta')^2 + C^2 m r^2 \cos\theta' = 0, \qquad \sin\theta'' = 0\ (\Rightarrow \theta'' = 0,\ \text{etc.}). \tag{e1, 2}$$

(iii) Show that

$$\begin{aligned}(\partial^2 R_0/\partial\theta^2)|_{\theta=\theta'} &= -m g r\cos\theta' + m r^2\omega^2[\cos(2\theta') - m r^2(I + m r^2\sin^2\theta')^{-1}\sin^2(2\theta')] \\ &= \cdots = -[(mr^2\omega^2\sin^2\theta')/(I + mr^2\sin^2\theta')][I + mr^2(1 + 3\cos^2\theta')] < 0;\end{aligned} \tag{f}$$

namely, θ' is *stable*: and that

$$\begin{aligned}(\partial^2 R_0/\partial\theta^2)|_{\theta=\theta''=0} &= m g r[(C^2 r/I^2 g) - 1] \qquad \text{[or, eliminating } C \text{ via the first of (e)]} \\ &= m g r\{[(\omega^2 r/g) - 1] \\ &\qquad + (\omega^2 r/I^2 g)(2m r^2 I\sin^2\theta' + m^2 r^4\sin^4\theta')\} > 0,\end{aligned} \tag{g}$$

since $\omega^2 r > g$ (explain); namely, $\theta'' = 0$ is *unstable*.

HINT

Since $(I + m\,r^2 \sin^2\theta)\omega \equiv C \neq 0$, the first of (e) yields

$$-m\,g\,r + m\,r^2\omega^2\cos\theta' = 0 \qquad (\Rightarrow \cos\theta' = g/\omega^2 r < 1). \tag{h}$$

Problem 8.6.5 Continuing from the preceding problem, show that the equation of small (linearized) oscillations of P around the steady state θ'—that is, $\theta = \theta' + z(t)$—is

$$\ddot{z} + \Omega\,z = 0, \tag{a}$$

where

$$\Omega \equiv \omega\sin\theta'\big\{[I + m\,r^2(1 + 3\cos^2\theta')]/(I + m\,r^2\sin^2\theta')\big\}^{1/2}. \tag{b}$$

Show that the stability condition obtained from (a, b) coincides with prob. 8.6.4: (f).

Problem 8.6.6 *Stability of Steady Precession of Top. Method of Perturbations.* As seen in exs. 8.4.5 and 8.5.1, in this case the exact Routhian of the top equals

$$R \;= R_2 + R_1 + R_0 = R(\theta, \dot{\theta}; C_\phi, C_\psi), \tag{a}$$

$$R_2 \equiv T''_{2,0} = (1/2)A(\dot{\theta})^2, \tag{a1}$$

$$R_1 \equiv T''_{1,1} = 0, \tag{a2}$$

$$R_0 \equiv T''_{0,2} - V$$
$$= -\big\{[(C_\phi - C_\psi\cos\theta)^2/2A\sin^2\theta] + (1/2C){C_\psi}^2\big\} - m\,g\,l\cos\theta. \tag{a3}$$

Therefore, the Routhian equation for the sole nonignorable coordinate θ becomes

$$(\partial R/\partial\dot{\theta})^{\cdot} - \partial R/\partial\theta = 0:$$
$$A\,\ddot{\theta} + \big[(C_\phi - C_\psi\cos\theta)(C_\psi - C_\phi\cos\theta)/A\sin^3\theta\big] = m\,g\,l\sin\theta. \tag{b}$$

(i) Setting in (b) $\theta = \theta_o + z(t)$, where θ_o is the (constant) root(s) of the steady motion condition $(\partial R/\partial\theta)_o = 0$, expanding in powers of z and its $(\ldots)^{\cdot}$-derivatives, and keeping only up to *linear* such terms, show that we eventually [after using ex. 8.5.1: (d1), or (c) of prob. 8.6.7 to eliminate C_ϕ and C_ψ] obtain the perturbation equation,

$$\ddot{z} + \Omega\,z = 0, \tag{c}$$

where

$$\Omega \equiv {c_\phi}^2 + (m\,g\,l/A\,c_\phi)^2 - 2m\,g\,l\cos\theta_o. \tag{d}$$

This equation determines $z(t)$ (a harmonic oscillation, if $\Omega > 0$) in terms of the steady-state values θ_o and $\dot{\phi} = constant \equiv c_\phi$; or, equivalently, θ_o and C_ϕ, C_ψ.

(ii) Show that the same equation results if we set into the Routhian (a–a3) $\theta = \theta_o + z(t)$, expand it in powers of z and its $(\ldots)^{\cdot}$-derivatives, keep only up to *quadratic* such terms, and then write down the equation for z:

$$(\partial R/\partial\dot{z})^{\cdot} - \partial R/\partial z = 0.$$

Problem 8.6.7 *Stability of Steady Precession of Top. Method of Extremum of Reduced Potential Energy.* Continuing from the preceding problem, we saw there that

$$-R_0 \equiv V - T''_{0,2} = (C_\phi - C_\psi \cos\theta)^2/2A\sin^2\theta + (1/2C){C_\psi}^2 + m\,g\,l\cos\theta$$
$$\equiv f(\theta; C_\phi, C_\psi) \equiv -(\textit{Routhian, or reduced, potential}), \tag{a}$$

where [recall results of (ex. 8.5.1)]

$$C_\phi = (A\sin^2\theta + C\cos^2\theta)\dot{\phi} + (C\cos\theta)\dot{\psi}$$
$$\equiv A\sin^2\theta\,\dot{\phi} + C\,n\cos\theta \equiv \textit{constant}, \tag{a1}$$
$$C_\psi = (C\cos\theta)\dot{\phi} + (C)\dot{\psi} \equiv C\,n = \textit{constant}; \tag{a2}$$

and, therefore, inversely,

$$\dot{\phi} = (C_\phi - C_\psi\cos\theta)/A\sin^2\theta \qquad (= \textit{constant} \equiv c_\phi, \text{ in steady precession}), \tag{b1}$$
$$\dot{\psi} = -\big[(C_\phi - C_\psi\cos\theta)\cos\theta/A\sin^2\theta\big] + (C_\psi/C)$$
$$(= \textit{constant} \equiv c_\psi, \text{ in steady precession}). \tag{b2}$$

Setting $df(\theta)/d\theta = 0$, and assuming $\theta \neq 0$, we obtain the steady motion condition [(ex. 8.5.1: d1), with $\dot{\phi} = \textit{constant} \equiv c_\phi$]:

$$A{c_\phi}^2\cos\theta_o - C_\psi\,c_\phi + m\,g\,l = 0,$$

or

$$A{c_\phi}^2\cos\theta_o + m\,g\,l = C(c_\phi\cos\theta_o + c_\psi)c_\phi. \tag{c}$$

(i) Calculate $d^2f(\theta)/d\theta^2$ and show that the condition for the *minimum* of $-R_0$, or the *maximum* of R_0, for small changes of the nonignorable coordinate θ from the steady state (c): θ_o, c_ϕ, C_ψ, is

$$\big[C_\psi(C_\psi - C_\phi\cos\theta_o) + C_\phi(C_\phi - C_\psi\cos\theta_o)\big]\big/A\sin^2\theta_o > 4m\,g\,l\cos\theta_o. \tag{d}$$

(ii) For $\theta_o = 0$, the cyclicity conditions (a1, 2) reduce to $C_\phi = C_\psi = C\,n = C(c_\phi + c_\psi) \equiv \textit{constant} \equiv D$. Show that for *small* θ_o, the stability condition (d) approximates to

$$2D^2(1 - \cos\theta_o)/\sin^2\theta_o > 4A\,m\,g\,l\cos\theta_o; \tag{e}$$

or, in the limit of vanishingly small θ_o's,

$$D^2 > 4A\,m\,g\,l \qquad (\text{“sleeping top” stability}). \tag{f}$$

These results have been obtained earlier by other means. For additional examples and details, see, for example, Merkin (1987, pp. 88–95; 1974, pp. 318–321, 323–324), Gantmacher (1970, pp. 256–258).

Problem 8.6.8 *Stability of Steady Precession of Top. Relations among the Perturbations.* Continuing from the preceding problem, show that the three (time-dependent!) perturbations

$$\theta = \theta_o + z(t), \qquad \dot{\phi} = c_\phi + \eta(t), \qquad \dot{\psi} = c_\psi + \xi(t), \tag{a}$$

are related by

$$(A \sin\theta_o)\eta = \left[C(c_\phi \cos\theta_o + c_\psi) - 2Ac_\phi \cos\theta_o\right]z, \tag{b}$$

$$(\cos\theta_o)\eta + \xi = (c_\phi \sin\theta_o)z. \tag{c}$$

These equations, assuming $\sin\theta_o \neq 0$ (i.e., no sleeping top), yield the hitherto unknown functions η and ξ in terms of z and the steady precession values; that is, in terms of quantities already determined in previous problems:

$$\eta = \eta\left[z(t); \theta_o, c_\phi, c_\psi, C_\phi, C_\psi\right], \qquad \xi = \xi\left[z(t); \theta_o, c_\phi, c_\psi, C_\phi, C_\psi\right]. \tag{d}$$

A final integration of these known functions of time, right-sides of (d), yields the time behavior of ϕ and ψ, if desired.

Problem 8.6.9 *Stability of Steady Precession of Top. Relations among the Perturbations (continued).* Continuing from the preceding problem, show that $\eta(t)$ and $\xi(t)$ can be obtained by inserting (a) in the earlier steady precession relations (prob. 8.6.7: b1, 2)

$$\dot{\phi} = (C_\phi - C_\psi \cos\theta)/A \sin^2\theta, \tag{a1}$$

$$\dot{\psi} = -\left[(C_\phi - C_\psi \cos\theta)\cos\theta/A\sin^2\theta\right] + (C_\psi/C), \tag{a2}$$

(which hold for both the fundamental state and the disturbed one), expanding à la Taylor, and keeping up to *linear* terms in the (equimomental) perturbations.

REMARKS

(i) Also, one could calculate the Routhian, expand and keep up to *quadratic* terms, and then apply Routh's "Hamiltonian" equations $\partial R/\partial \Psi_i = -d\psi_i/dt$.

(ii) As pointed out in the explanatory remarks following (8.6.2), the above are special cases of application of the general kinematico-inertial relations (8.3.12d, e):

$$\Psi_i \equiv \partial T/\partial\dot{\psi}_i = \sum c_{ji}\dot{\psi}_j + \sum b_{pi}\dot{q}_p \;\Leftrightarrow\; \dot{\psi}_j = \sum C_{ji}\Big(\Psi_i - \sum b_{pi}\dot{q}_p\Big), \tag{b}$$

to both states I and $II = I + \Delta(I)$, with subsequent expansion and equation of their first-order terms in $\Delta\dot{\psi}$, Δq, $\Delta\dot{q}$, $\Delta\Psi$, $\Delta C_{ji} \approx \sum(\ldots)_{jip}\,\Delta q_p$. For given Ψ's and $\dot{q}(t)$'s it supplies the $\dot{\psi}(t)$'s.

Problem 8.6.10 *Stability of Steady Precession of Top. Relations among the Perturbations (continued).* Show that the results of the preceding problems can be obtained by substituting (prob. 8.6.6: a) in the Lagrangean equations of the top, then linearizing, and so on.

For additional similar problems, see, for example, Chirgwin and Plumpton (1966, pp. 282–305) and Wells (1967, pp. 239–255).

This concludes the treatment of Routh's method of the "modified Lagrangean." The rest of this chapter deals with the applications and ramifications of the method of Hamilton.

8.7 VARIATION OF CONSTANTS (OR PARAMETERS)

> In order to solve the exact problem approximately, we first solve an approximate problem exactly.
>
> (T. E. Sterne, quoted in Garfinkel, 1966, p. 67)

Since the equations of motion, in either Lagrangean or Hamiltonian variables, are intrinsically nonlinear (§3.10), *general* methods for obtaining their exact solutions are out of the question, and being able to solve exactly the equations of an actual physical system is the rare exception rather than the rule (§3.12). For these reasons, some kind of approximation (analytical, numerical/computational, graphical, or combination thereof) is needed. In this section we develop one of the most important, general and systematic such approximation methods (originated by Lagrange himself in connection with problems of celestial mechanics, which, although unconstrained, lead to complicated equations of motion), known as the method of *variation of "constants"*, and associated calculus of *perturbations*. Either Lagrangean $(q, \dot{q})$ or Hamiltonian (q, p) variables can be used; but the latter, since they lead to *first-order* equations, are the preferred ones.

Theorem of Lagrange–Poisson

Let us consider a general system S, in Hamiltonian variables, with *equations of motion*

$$dp_k/dt = f_k(t, q, p) \qquad \text{and} \qquad dq_k/dt = g_k(t, q, p); \tag{8.7.1}$$

and corresponding *general solution*

$$p_k = p_k(t; c) \qquad \text{and} \qquad q_k = q_k(t; c), \tag{8.7.2}$$

where

$$c \equiv (c_1, \ldots, c_{2n}) \equiv (c_\nu;\ \nu = 1, \ldots, 2n)\text{: } \textit{constants of integration}; \tag{8.7.3}$$

and, unless specified otherwise Greek (Latin) *indices* run from 1 to $2n$ (n). Each particular set of c_ν's defines a particular dynamical trajectory, or *orbit*, say I, in phase space. Therefore, varying these constants slightly—that is, $c \to c + \delta c$—we obtain an *adjacent* such trajectory, say $II = I + \delta(I)$, given by the first-order (virtual-like; i.e., contemporaneous) changes of (8.7.2):

$$\delta p_k = \sum (\partial p_k/\partial c_\nu)\, \delta c_\nu \qquad \text{and} \qquad \delta q_k = \sum (\partial q_k/\partial c_\nu)\, \delta c_\nu, \tag{8.7.4}$$

where the derivatives are evaluated at I. As a result, II is governed by the following linear *variational*, or perturbational, equatons:

$$(\delta p_k)^{\cdot} = \delta(\dot{p}_k) = \sum [(\partial f_k/\partial p_l)\, \delta p_l + (\partial f_k/\partial q_l)\, \delta q_l], \tag{8.7.5a}$$

$$(\delta q_k)^{\cdot} = \delta(\dot{q}_k) = \sum [(\partial g_k/\partial p_l)\, \delta p_l + (\partial g_k/\partial q_l)\, \delta q_l]. \tag{8.7.5b}$$

Now, let us carry out *two* distinct c-variations from I, $\delta_1 c$ and $\delta_2 c$:

$$c \to c + \delta_1 c, \text{ resulting in the adjacent orbit } II_1 = I + \delta_1(I), \tag{8.7.6a}$$

$$c \to c + \delta_2 c, \text{ resulting in the adjacent orbit } II_2 = I + \delta_2(I). \tag{8.7.6b}$$

Then, in view of the above, we obtain, successively,

$$\begin{aligned}
(\delta_1 p_k\, \delta_2 q_k - \delta_2 p_k\, \delta_1 q_k)^{\cdot} &= (\delta_1 p_k)^{\cdot}\, \delta_2 q_k - (\delta_2 p_k)^{\cdot}\, \delta_1 q_k + \delta_1 p_k (\delta_2 q_k)^{\cdot} - \delta_2 p_k (\delta_1 q_k)^{\cdot} \\
&= \sum [(\partial f_k/\partial p_l)\, \delta_1 p_l + (\partial f_k/\partial q_l)\, \delta_1 q_l]\, \delta_2 q_k \\
&\quad - \sum [(\partial f_k/\partial p_l)\, \delta_2 p_l + (\partial f_k/\partial q_l)\, \delta_2 q_l]\, \delta_1 q_k \\
&\quad + \sum [(\partial g_k/\partial p_l)\, \delta_2 p_l + (\partial g_k/\partial q_l)\, \delta_2 q_l]\, \delta_1 p_k \\
&\quad - \sum [(\partial g_k/\partial p_l)\, \delta_1 p_l + (\partial g_k/\partial q_l)\, \delta_1 q_l]\, \delta_2 p_k \\
&= \sum (\partial f_k/\partial p_l)(\delta_1 p_l\, \delta_2 q_k - \delta_2 p_l\, \delta_1 q_k) + \sum (\partial f_k/\partial q_l)(\delta_1 q_l\, \delta_2 q_k - \delta_2 q_l\, \delta_1 q_k) \\
&\quad + \sum (\partial g_k/\partial p_l)(\delta_1 p_k\, \delta_2 p_l - \delta_1 p_l\, \delta_2 p_k) + \sum (\partial g_k/\partial q_l)(\delta_1 p_k\, \delta_2 q_l - \delta_1 q_l\, \delta_2 p_k);
\end{aligned}$$

and, therefore, summing these $(\ldots)^{\cdot}$-derivatives of *bilinear covariants* over k, and ofter some "dummy"-index changes, we finally obtain the fundamental result:

$$\begin{aligned}
d/dt\Big[\sum (\delta_1 p_k\, \delta_2 q_k - \delta_2 p_k\, \delta_1 q_k)\Big]
&= \sum\sum (\partial f_k/\partial p_l + \partial g_l/\partial q_k)(\delta_1 p_l\, \delta_2 q_k - \delta_2 p_l\, \delta_1 q_k) \\
&\quad + (1/2) \sum\sum (\partial f_k/\partial q_l - \partial f_l/\partial q_k)(\delta_1 q_l\, \delta_2 q_k - \delta_2 q_l\, \delta_1 q_k) \\
&\quad + (1/2) \sum\sum (\partial g_k/\partial p_l - \partial g_l/\partial p_k)(\delta_1 p_k\, \delta_2 p_l - \delta_2 p_k\, \delta_1 p_l).
\end{aligned} \tag{8.7.7}$$

Specializations

(i) If the original equations (8.7.1) are *Hamilton's canonical equations*—that is, if (§8.2)

$$f_k = -\partial H/\partial q_k + Q_k \qquad \text{and} \qquad g_k = \partial H/\partial p_k, \tag{8.7.8}$$

then, since,

(a) $$\begin{aligned} \partial f_k/\partial p_l + \partial g_l/\partial q_k &= (-\partial^2 H/\partial p_l\, \partial q_k + \partial Q_k/\partial p_l) + (-\partial^2 H/\partial q_k\, \partial p_l) \\ &= \partial Q_k/\partial p_l \quad [= 0, \text{ assuming } Q_k = Q_k(t, q)], \end{aligned} \tag{8.7.8a}$$

(b) $$\begin{aligned} \partial f_k/\partial q_l - \partial f_l/\partial q_k &= (-\partial^2 H/\partial q_l\, \partial q_k + \partial Q_k/\partial q_l) \\ &\quad - (-\partial^2 H/\partial q_k\, \partial q_l + \partial Q_l/\partial q_k) \\ &= \partial Q_k/\partial q_l - \partial Q_l/\partial q_k \quad (\neq 0, \text{ in general}), \end{aligned} \tag{8.7.8b}$$

(c) $$\partial g_k/\partial p_l - \partial g_l/\partial p_k = \partial^2 H/\partial p_l\, \partial p_k - \partial^2 H/\partial p_k\, \partial p_l = 0, \tag{8.7.8c}$$

equation (8.7.7) reduces to

$$\begin{aligned} d/dt\Big[\sum(\delta_1 p_k\,\delta_2 q_k - \delta_2 p_k\,\delta_1 q_k)\Big] &= (1/2)\sum\sum(\partial Q_k/\partial q_l - \partial Q_l/\partial q_k)(\delta_1 q_l\,\delta_2 q_k - \delta_2 q_l\,\delta_1 q_k)\\ &= \sum(\delta_1 Q_k\,\delta_2 q_k - \delta_2 Q_k\,\delta_1 q_k), \end{aligned} \tag{8.7.9}$$

where

$$\delta_* Q_k = \sum(\partial Q_k/\partial q_l)\,\delta_* q_l \quad (* = 1, 2).$$

(ii) If all forces are *potential*—that is, if $Q_k = 0$, or $\partial Q_k/\partial q_l = \partial Q_l/\partial q_k$, for all k, $l = 1, \ldots, n$—then (8.7.9) immediately yields the *Theorem of Lagrange–Poisson*: in a holonomic and potential (but possibly rheonomic) system, the expression

$$I \equiv \sum(\delta_1 p_k\,\delta_2 q_k - \delta_2 p_k\,\delta_1 q_k) \tag{8.7.10}$$

is *time-independent*; that is, it is a constant of the motion.

[For applications of (8.7.10) to the "reciprocal theorems" of mechanics and optics, see, for example, Lamb (1910, p. 763; 1943, pp. 227–281).]

Lagrange Brackets

With the help of (8.7.4), this important quantity can be rewritten as follows:

$$\begin{aligned} I &= \sum\Big\{\Big[\sum(\partial p_k/\partial c_\mu)\,\delta_1 c_\mu\Big]\Big[\sum(\partial q_k/\partial c_\nu)\,\delta_2 c_\nu\Big]\\ &\qquad - \Big[\sum(\partial p_k/\partial c_\nu)\,\delta_2 c_\nu\Big]\Big[\sum(\partial q_k/\partial c_\mu)\,\delta_1 c_\mu\Big]\Big\}\\ &= \sum\sum\Big\{\sum\big[(\partial p_k/\partial c_\mu)(\partial q_k/\partial c_\nu) - (\partial p_k/\partial c_\nu)(\partial q_k/\partial c_\mu)\big]\Big\}\,\delta_1 c_\mu\,\delta_2 c_\nu, \end{aligned} \tag{8.7.11}$$

or, finally,

$$I = \sum\sum\big[c_\mu, c_\nu\big]\,\delta_1 c_\mu\,\delta_2 c_\nu, \tag{8.7.12}$$

where

$$\begin{aligned} [c_\mu, c_\nu] &\equiv \sum\big[(\partial p_k/\partial c_\mu)(\partial q_k/\partial c_\nu) - (\partial p_k/\partial c_\nu)(\partial q_k/\partial c_\mu)\big]:\\ &= -[c_\nu, c_\mu] \text{ (prob. 8.7.1, below):}\\ &\qquad \textit{Lagrange bracket} \text{ of } c_\mu, c_\nu \text{ (1808).} \end{aligned} \tag{8.7.13}$$

The above show that if $I = constant$, for all $\delta_1 c$ and $\delta_2 c$, then *all Lagrange brackets must be constant*. (For an alternative proof, see ex. 8.11.3.)

Example 8.7.1 *Second, Lagrangean, Proof of the Lagrange–Poisson Theorem*. By $\delta_1(\ldots)$-varying (i) the definition $p_k = \partial L/\partial \dot{q}_k$ and then (ii) Lagrange's equations, say $dp_k/dt = \partial L/\partial q_k + Q_k$, we get

$$\delta_1 p_k = \delta_1(\partial L/\partial \dot{q}_k) = \sum \big[(\partial^2 L/\partial q_l\, \partial \dot{q}_k)\, \delta_1 q_l + (\partial^2 L/\partial \dot{q}_l\, \partial \dot{q}_k)\, \delta_1(\dot{q}_l)\big], \tag{a}$$

$$\begin{aligned} \delta_1(\dot{p}_k) &= (\delta_1 p_k)^{\cdot} = \delta_1(\partial L/\partial q_k + Q_k) \\ &= \sum \big[(\partial^2 L/\partial q_l\, \partial q_k)\, \delta_1 q_l + (\partial^2 L/\partial \dot{q}_l\, \partial q_k)\, \delta_1(\dot{q}_l)\big] + \delta_1 Q_k, \end{aligned} \tag{b}$$

respectively, and therefore [assuming $\delta[d(\ldots)] = d[\delta(\ldots)]$ for both q's and p's], we obtain, successively,

$$\begin{aligned} &\sum (\delta_1 p_k\, \delta_2 q_k)^{\cdot} \\ &\quad = \sum (\delta_1 p_k)^{\cdot}\, \delta_2 q_k + \sum \delta_1 p_k (\delta_2 q_k)^{\cdot} \\ &\quad = \sum\sum \big[(\partial^2 L/\partial q_l\, \partial q_k)\, \delta_1 q_l\, \delta_2 q_k + (\partial^2 L/\partial \dot{q}_l\, \partial q_k)\, \delta_1(\dot{q}_l)\, \delta_2 q_k\big] + \sum \delta_1 Q_k\, \delta_2 q_k \\ &\qquad + \sum\sum \big[(\partial^2 L/\partial q_l\, \partial \dot{q}_k)\, \delta_1 q_l\, \delta_2(\dot{q}_k) + (\partial^2 L/\partial \dot{q}_l\, \partial \dot{q}_k)\, \delta_1(\dot{q}_l)\, \delta_2(\dot{q}_k)\big]. \end{aligned} \tag{c}$$

Now, in (c), we interchange the variation subscripts 1 and 2, thus creating $\sum (\delta_2 p_k\, \delta_1 q_k)^{\cdot} = \cdots$, and then subtract it from (c), while renaming some summation ("dummy") indices. It is not hard to see that, then,

$$d/dt\Big(\sum (\delta_1 p_k\, \delta_2 q_k - \delta_2 p_k\, \delta_1 q_k)\Big) = \sum (\delta_1 Q_k\, \delta_2 q_k - \delta_2 Q_k\, \delta_1 q_k), \quad \text{Q.E.D.} \tag{d}$$

More general Lagrangean equations lead, naturally, to more general forms of (d).

Example 8.7.2 *Third, Hamiltonian, Proof of the Lagrange–Poisson Theorem.* Since $H = H(t, q, p)$, we have

$$\begin{aligned} \delta_1 H &= \sum \big[(\partial H/\partial q_k)\, \delta_1 q_k + (\partial H/\partial p_k)\, \delta_1 p_k\big] \\ &= \sum \big[(-\dot{p}_k + Q_k)\, \delta_1 q_k + (\dot{q}_k)\, \delta_1 p_k\big] \qquad \text{[by Hamilton's equations]} \\ &= \sum \big[(\dot{q}_k)\, \delta_1 p_k - (\dot{p}_k - Q_k)\, \delta_1 q_k\big], \end{aligned} \tag{a}$$

and, therefore, $\delta_2(\ldots)$-varying the above, we obtain

$$\begin{aligned} \delta_2(\delta_1 H) &= \sum \big\{\delta_2(\dot{q}_k)\, \delta_1 p_k - [\delta_2(\dot{p}_k) - \delta_2 Q_k]\, \delta_1 q_k\big\} \\ &\quad + \sum \big[\dot{q}_k\, \delta_2(\delta_1 p_k) - (\dot{p}_k - Q_k)\, \delta_2(\delta_1 q_k)\big]. \end{aligned} \tag{b}$$

Similarly, reversing the order of $\delta_1(\ldots)$ and $\delta_2(\ldots)$, we obtain

$$\begin{aligned} \delta_1(\delta_2 H) &= \sum \big\{\delta_1(\dot{q}_k)\, \delta_2 p_k - [\delta_1(\dot{p}_k) - \delta_1 Q_k]\, \delta_2 q_k\big\} \\ &\quad + \sum [\dot{q}_k\, \delta_1(\delta_2 p_k) - (\dot{p}_k - Q_k)\, \delta_1(\delta_2 q_k)]. \end{aligned} \tag{c}$$

Subtracting (c) from (b), while noting that for all genuine functions/variables $(\ldots)$, $\delta_1[\delta_2(\ldots)] = \delta_2[\delta_1(\ldots)]$, we obtain

$$
\begin{aligned}
0 &= \delta_2(\delta_1 H) - \delta_1(\delta_2 H) \\
&= \sum \{[\delta_2(\dot{q}_k)\,\delta_1 p_k - \delta_1(\dot{q}_k)\,\delta_2 p_k] - [\delta_2(\dot{p}_k) - \delta_2 Q_k]\,\delta_1 q_k + [\delta_1(\dot{p}_k) - \delta_1 Q_k]\,\delta_2 q_k\} \\
&= \left[\sum (\delta_1 p_k\,\delta_2 q_k - \delta_2 p_k\,\delta_1 q_k)\right]^{\cdot} - \sum (\delta_1 Q_k\,\delta_2 q_k - \delta_2 Q_k\,\delta_1 q_k), \quad \text{Q.E.D.} \qquad \text{(d)}
\end{aligned}
$$

Here, too, more general Hamiltonian equations lead to more general forms of (d).

Example 8.7.3 Let us consider a system with Hamiltonian

$$H = (1/2)(p^2 + \lambda^2 q^2), \qquad \text{(a)}$$

and general solution of its equations of motion, as can be easily verified by the reader,

$$q = c_1 \cos(\lambda t) + (c_2/\lambda)\sin(\lambda t), \qquad p = -c_1\lambda \sin(\lambda t) + c_2 \cos(\lambda t) \qquad \text{(b)}$$

(i.e., free vibration of a linear harmonic and undamped oscillator of unit mass and frequency equal to λ). Hence, the (sole) Lagrange bracket of the system equals

$$
\begin{aligned}
[c_1, c_2] = -[c_2, c_1] &= (\partial p/\partial c_1)(\partial q/\partial c_2) - (\partial p/\partial c_2)(\partial q/\partial c_1) \\
&= [-\lambda \sin(\lambda t)][\lambda^{-1} \sin(\lambda t)] - [\cos(\lambda t)][\cos(\lambda t)] \\
&= -[\sin^2(\lambda t) + \cos^2(\lambda t)] = -1, \qquad \textit{a constant}; \qquad \text{(c)}
\end{aligned}
$$

which, in the language of §8.9, means that (b) is a canonical transformation.

Problem 8.7.1 Show that Lagrange's brackets satisfy the following identities:

(i) $$[c_\mu, c_\mu] = 0; \qquad \text{(a)}$$

(ii) $$[c_\mu, c_\nu] = -[c_\nu, c_\mu]; \qquad \text{(b)}$$

(iii) $$\partial[c_\mu, c_\nu]/\partial c_\lambda + \partial[c_\nu, c_\lambda]/\partial c_\mu + \partial[c_\lambda, c_\mu]/\partial c_\nu = 0. \qquad \text{(c)}$$

HINT

[For (iii)]: Notice that

$$[c_\mu, c_\nu] = \partial/\partial c_\nu\left[\sum q_k(\partial p_k/\partial c_\mu)\right] - \partial/\partial c_\mu\left[\sum q_k(\partial p_k/\partial c_\nu)\right]. \qquad \text{(d)}$$

Perturbation Equations

Next, we apply the above formalism to the theory of perturbations. Let the canonical equations and corresponding general solution of the *unperturbed* problem be

$$dp_k/dt = -\partial H/\partial q_k \qquad \text{and} \qquad dq_k/dt = \partial H/\partial p_k, \qquad \text{(8.7.14a)}$$

$$p_k = p_k(t; c) \qquad \text{and} \qquad q_k = q_k(t; c), \qquad \text{(8.7.14b)}$$

respectively, and let the equations of the *slightly perturbed* problem be

$$dp_k/dt = -\partial H/\partial q_k + X_k \qquad \text{and} \qquad dq_k/dt = \partial H/\partial p_k, \tag{8.7.15a}$$

where

$$\begin{aligned} X_k = X_k(t, q, p) &= \textit{given function of its arguments} \\ \approx X_k{}^{(1)}(t; c) &\quad \text{[first-order approximation, upon substitution of } \textit{unperturbed} \\ &\quad \text{solution (8.7.14b) in it].} \end{aligned} \tag{8.7.15b}$$

Let us solve (8.7.15a) by treating the c's as *variable*; that is, $c_\mu = c_\mu(t)$. Indeed, $(\ldots)^{\cdot}$-differentiating (8.7.14b), we obtain

$$\begin{aligned} dp_k/dt &= \partial p_k/\partial t + \sum (\partial p_k/\partial c_\mu)(dc_\mu/dt), \\ dq_k/dt &= \partial q_k/\partial t + \sum (\partial q_k/\partial c_\mu)(dc_\mu/dt). \end{aligned} \tag{8.7.16a}$$

But since $\partial q_k/\partial t$ $(\partial p_k/\partial t)$ = *unperturbed velocities* (*accelerations*), while $\dot{q}_k$ $(\dot{p}_k)$ = *perturbed velocities* (*accelerations*), we can rewrite (8.7.14a) and (8.7.15a) as follows:

$$\partial p_k/\partial t = -\partial H/\partial q_k \qquad \text{and} \qquad \partial q_k/\partial t = \partial H/\partial p_k, \tag{8.7.16b}$$

$$dp_k/dt = -\partial H/\partial q_k + X_k \qquad \text{and} \qquad dq_k/dt = \partial H/\partial p_k; \tag{8.7.16c}$$

and, comparing these with (8.7.16a), we are readily led to the $2n$ *first-order* differential equations for the $c_\mu(t)$:

$$\sum (\partial p_k/\partial c_\mu)(dc_\mu/dt) = X_k{}^{(1)}, \qquad \sum (\partial q_k/\partial c_\mu)(dc_\mu/dt) = 0. \tag{8.7.17}$$

To understand the motivation behind these key arguments, let us pause to examine briefly the physical problem that led Lagrange et al. to the method of variation of constants: finding the orbit of Earth (E) around the Sun (S). As is well known: in this case, the solution to the *unperturbed*, or *two-body*, problem (i.e., when only the gravitational pull of S on E is included, whereas the small such influences of the other solar system planets on the orbit of E are neglected) are Keplerian elliptical orbits, I, with S at one of their foci, defined at every generic instant by the constants, or "*orbit elements*" c_μ. Here, the *perturbed* problem consists in calculating the small time-dependent deviations of E's orbit from ellipticity; that is, the dc_μ/dt, due to the gravitational pull of the other planets. Our conditions (8.7.17) amount to stating that, at every instant, *E has the same coordinates and velocity (→ momentum) in both the unperturbed (two-body) and perturbed (many-body) orbits* (fig. 8.6).

As the famous Victorian mechanician Tait puts it (see also Lagrange's summary in ex. 8.7.4):

> [T]he disturbing forces are, at any instant, small in comparison with the forces regulating the motion; so that, during any brief period, the motion is practically the same as if no disturbing cause had been at work. But in time, the effects of the disturbance may become so great as entirely to change the dimensions and form of the orbit described. The *character* of the path is not, at any particular instant, affected by the disturbance; but its form and dimensions are in a state of slow, and usually progressive change. Hence, as the first depends upon the *form* of the equations which represent it, while the latter depend upon the actual and relative magnitudes of the constants involved in the

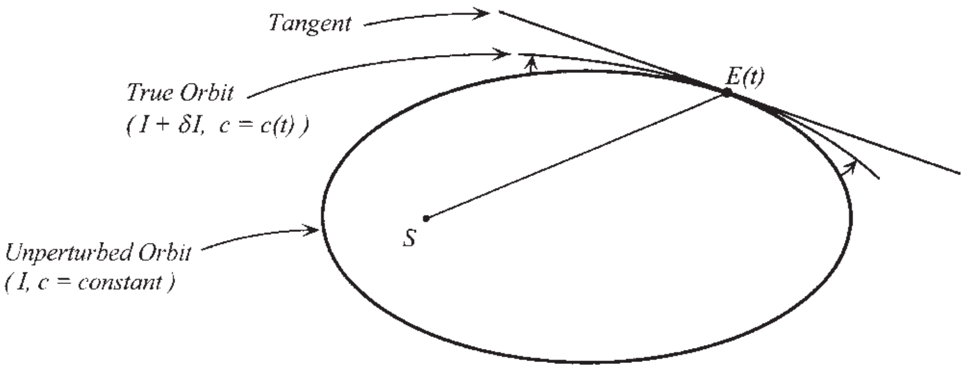

Figure 8.6 Geometry of unperturbed and perturbed orbits of Earth around the Sun.

> integrals, we settle, once for all, the *form* of the equation as if no disturbing cause had acted. But we are thus entitled to assume that the constants which the solution involves are quantities which vary with the time in consequence of the slight, but persistent, effects of the disturbance. And, . . . , if at any moment the disturbance were to cease, the motion would forthwith go on for ever in the orbit *then being described*, it follows that in the expressions for the components of the velocity no terms occur depending on the rate of alteration of the values of the constants. (1895, p. 174)

The above help us to understand the differences between partial and total time derivatives:

- *Partial* derivatives refer to the *unperturbed* (or osculating) orbit; that is, constant orbit elements.
- *Total* derivatives refer to the *perturbed* (or true) orbit; that is, variable orbit elements.

Two additional forms of the perturbation equations are obtained as follows:

(i) Multiplying the *first* of (8.7.17) with $\delta_2 q_k = \sum (\partial q_k/\partial c_\nu)\,\delta_2 c_\nu$ and summing over k, and multiplying the *second* of (8.7.17) with $\delta_2 p_k = \sum (\partial p_k/\partial c_\nu)\,\delta_2 c_\nu$ and summing over k, and then subtracting the so-resulting expressions, we obtain

$$\sum\sum\sum \left[(\partial p_k/\partial c_\mu)(dc_\mu/dt)\right]\left[(\partial q_k/\partial c_\nu)\,\delta_2 c_\nu\right] \\ -\sum\sum\sum \left[(\partial q_k/\partial c_\mu)(dc_\mu/dt)\right]\left[(\partial p_k/\partial c_\nu)\,\delta_2 c_\nu\right] \\ =\sum\sum X_k{}^{(1)}\left[(\partial q_k/\partial c_\nu)\,\delta_2 c_\nu\right], \tag{8.7.18a}$$

or, recalling the Lagrange bracket definition (8.7.13),

$$\sum\sum [c_\mu, c_\nu](dc_\mu/dt)\,\delta_2 c_\nu = \sum\sum X_k{}^{(1)}\left[(\partial q_k/\partial c_\nu)\,\delta_2 c_\nu\right], \tag{8.7.18b}$$

and from this, since the $\delta_2 c_\nu$ are arbitrary, we finally obtain the *Lagrangean form of the perturbation equations*:

$$\sum [c_\nu, c_\mu](dc_\nu/dt) = \sum X_k{}^{(1)}(\partial q_k/\partial c_\mu). \tag{8.7.19}$$

In particular, if the perturbations are *potential*—that is, if $X_k = -\partial\Omega/\partial q_k$—then, since $q_k = q_k(t; c)$, (8.7.19) specializes to

$$\sum [c_\nu, c_\mu](dc_\nu/dt) = -\partial\Omega/\partial c_\mu. \tag{8.7.20}$$

Also, since, here, the fundamental state I is *time-independent*, the brackets depend only on the c's.

(ii) Inverting the general solution (8.7.2), or (8.7.14b), we obtain

$$c_\mu = h_\mu(t, q, p) = \textit{first integral (constant) of the unperturbed problem}, \tag{8.7.21a}$$

and, therefore, treating them as variable, we get

$$dc_\mu/dt = \partial h_\mu/\partial t + \sum \big[(\partial h_\mu/\partial q_k)(dq_k/dt) + (\partial h_\mu/\partial p_k)(dp_k/dt)\big]. \tag{8.7.21b}$$

But invoking the perturbation conditions (8.7.17), we find

$$dp_k/dt = \partial p_k/\partial t + \sum (\partial p_k/\partial c_\mu)(dc_\mu/dt) = \partial p_k/\partial t + X_k{}^{(1)}, \tag{8.7.21c}$$

$$dq_k/dt = \partial q_k/\partial t + \sum (\partial q_k/\partial c_\mu)(dc_\mu/dt) = \partial q_k/\partial t; \tag{8.7.21d}$$

and so, inserting these expressions back into (8.7.21b), we have

$$\begin{aligned} dc_\mu/dt = \partial h_\mu/\partial t + \sum \big[(\partial h_\mu/\partial q_k)(\partial q_k/\partial t) + (\partial h_\mu/\partial p_k)(\partial p_k/\partial t)\big] \\ + \sum (\partial h_\mu/\partial p_k) X_k, \end{aligned}$$

or, since the first two summands vanish, because they represent the $(\ldots)^{\cdot}$-derivative of the unperturbed constant c_μ, we obtain, finally,

$$dc_\mu/dt = \sum (\partial h_\mu/\partial p_k) X_k = \sum (\partial c_\mu/\partial p_k) X_k{}^{(1)}. \tag{8.7.22}$$

Poisson Brackets

In particular, if the perturbations are *potential*—that is, if

$$X_k = -\partial\Omega/\partial q_k = -\sum (\partial\Omega/\partial c_\nu)(\partial c_\nu/\partial q_k), \tag{8.7.22a}$$

(8.7.22) becomes

$$dc_\mu/dt = -\sum \Big[\sum (\partial\Omega/\partial c_\nu)(\partial c_\nu/\partial q_k)\Big](\partial c_\mu/\partial p_k); \tag{8.7.22b}$$

or, if (as is commonly the case)

$$\begin{aligned} 0 = \partial\Omega/\partial p_k &= \sum (\partial\Omega/\partial c_\nu)(\partial c_\nu/\partial p_k) \\ &\Rightarrow \sum \Big(\sum (\partial\Omega/\partial c_\nu)(\partial c_\nu/\partial p_k)\Big)(\partial c_\mu/\partial q_k) = 0, \end{aligned} \tag{8.7.22c}$$

adding a zero [i.e., (8.7.22c)] to the right side of (8.7.22b) we finally obtain the *potential perturbation equations* in the following convenient form:

$$dc_\mu/dt = -\sum (\partial\Omega/\partial c_\nu)(c_\mu, c_\nu), \tag{8.7.23}$$

where

$$(c_\mu, c_\nu) \equiv \sum \big[(\partial c_\mu/\partial p_k)(\partial c_\nu/\partial q_k) - (\partial c_\mu/\partial q_k)(\partial c_\nu/\partial p_k)\big]:$$
$$\textit{Poisson bracket of } c_\mu, c_\nu \quad [= -(c_\nu, c_\mu)]. \tag{8.7.24}$$

[See also §8.9. On the history of Poisson's brackets, and so on, see Dugas (1955, p. 384 ff.)].

Equations (8.7.23) have the advantage over (8.7.20) that they are already solved for the dc/dt; but, in return, eqs. (8.7.20) contain Lagrange's brackets, which do not require solving the p's and q's for the c's, as Poisson's brackets do.

Now, since these two perturbation forms, (8.7.20) and (8.7.23), are equivalent, the brackets of Lagrange and Poisson must satisfy certain consistency requirements. Indeed, substituting $dc_\mu/dt \to dc_\nu/dt$ from (8.7.23) into (8.7.20), we get

$$\sum\sum [c_\nu, c_\mu](c_\nu, c_\lambda)(\partial\Omega/\partial c_\lambda) = -\partial\Omega/\partial c_\mu,$$

from which, since the $\partial\Omega/\partial c_\lambda$ are arbitrary, we obtain the inverse matrix-like relations:

$$\sum [c_\nu, c_\mu](c_\nu, c_\lambda) = \delta_{\mu\lambda} = \delta_{\lambda\mu}\text{: } \textit{Kronecker delta}$$
$$[= 1 \text{ or } 0, \text{ according as } \mu = \lambda \text{ or } \mu \neq \lambda]. \tag{8.7.25}$$

These compatibility conditions readily show that:

- If Lagrange's brackets are constant, then so are Poisson's brackets, and vice versa.
- If we know Lagrange's brackets, then using (8.7.25) we can find Poisson's brackets, and vice versa; that is, these two behave as if they were elements of two inverse $2n \times 2n$ matrices.

REMARK

Equations (8.7.23) are *exact*, but they are expressed in terms of *perturbed* quantities. Let us formulate them in terms of the known *unperturbed* quantities and their *first-order* corrections. Setting in (8.7.23): $c_\mu = c_{\mu o} + c_{\mu 1}$, where $c_{\mu o}$ = unperturbed values and $c_{\mu 1}$ = corresponding first-order corrections, we readily find that the differential equations of the latter are

$$dc_{\mu 1}/dt = -\sum (\partial\Omega_o/\partial c_{\nu o})(c_{\mu o}, c_{\nu o}), \qquad \text{where} \qquad \Omega_o \equiv \Omega(c_o). \tag{8.7.23a}$$

Example 8.7.4 *Canonical Form of Lagrange's Perturbation Equations* [1810; see Lagrange, 1965, Vol. 1, pp. 299–320].

HISTORICAL

In the second edition of his *Mécanique Analytique*, Lagrange summarizes the gist of his method as follows:

> Dans les problèmes de Mécanique qu'on ne peut résoudre que par approximation, on trouve ordinairement la première solution en n'ayant égard qu'aux forces principales qui agissent sur les corps; et pour étendre cette solution aux autres forces qu'on peut appeler *perturbatrices*, ce qu'il y a de plus simple, c'est de conserver la forme de la

> première solution, mais en rendant variables les constantes arbitraires qu'elle renferme; car, si les quantités qu'on avait négligées, et dont on veut tenir compte, sont très-petites, les nouvelles variables seront à peu près constantes, et l'on pourra y appliquer les méthodes ordinaires d'approximation. Ainsi la difficulté se reduit à trouver les équations entre ces variables. [1965, p. 299]

Let $q_k = q_k(t)$ and $p_k = p_k(t)$ be represented by the following power series in time t:

$$q_k = q_{k0} + q_{k1}\,t + q_{k2}\,t^2 + \cdots, \qquad p_k = p_{k0} + p_{k1}\,t + p_{k2}\,t^2 + \cdots. \tag{a}$$

Let us find the form of the Lagrangean perturbational equations, say the potential case (8.7.20), when we *choose as constants the initial conditions*; that is,

$$c_k = q_{k0} \qquad \text{and} \qquad c_{n+s} = p_{s0} \qquad (k,\, s = 1, \ldots, n). \tag{b}$$

Then, since

$$[c_\mu,\, c_\nu] = [c_\mu,\, c_\nu]_{t=0} = constant, \tag{c}$$

we obtain:
(i) For $\mu,\, \nu = 1, \ldots, n$:

$$\begin{aligned}[c_\mu,\, c_\nu] &= \sum [(\partial p_{k0}/\partial c_\mu)(\partial q_{k0}/\partial c_\nu) - (\partial p_{k0}/\partial c_\nu)(\partial q_{k0}/\partial c_\mu)] \\ &= \sum [(0)(\delta_{k\nu}) - (0)(\delta_{k\mu})] = 0.\end{aligned} \tag{d}$$

(ii) For $\mu \to n+s,\ s = 1, \ldots, n;\ \nu = 1, \ldots, n$:

$$\begin{aligned}[c_{n+s},\, c_\nu] &= \sum [(\partial p_{k0}/\partial c_{n+s})(\partial q_{k0}/\partial c_\nu) - (\partial p_{k0}/\partial c_\nu)(\partial q_{k0}/\partial c_{n+s})] \\ &= \sum [(\delta_{ks})(\delta_{k\nu}) - (0)(0)] = \sum (\delta_{ks})(\delta_{k\nu}) = \delta_{s\nu};\end{aligned} \tag{e}$$

from which we also get

$$[c_\nu,\, c_{n+s}] = -[c_{n+s},\, c_\nu] = -\delta_{s\nu} = -\delta_{\nu s}. \tag{f}$$

(iii) For $\mu \to n+r,\ \nu \to n+b;\ r,\, b = 1, \ldots, n$:

$$\begin{aligned}[c_{n+r},\, c_{n+b}] &= \sum \big[(\partial p_{k0}/\partial c_{n+r})(\partial q_{k0}/\partial c_{n+b}) - (\partial p_{k0}/\partial c_{n+b})(\partial q_{k0}/\partial c_{n+r})\big] \\ &= \sum \big[(\delta_{kr})(0) - (\delta_{kb})(0)\big] = 0.\end{aligned} \tag{g}$$

Therefore, the perturbation equations (8.7.20):

$$\sum [c_\nu,\, c_\mu](dc_\nu/dt) = -\partial\Omega/\partial c_\mu, \tag{h}$$

become
(i) $\mu = 1, \ldots, n$:

$$\sum [c_{n+s},\, c_\mu](dc_{n+s}/dt) = \sum \delta_{s\mu}(dc_{n+s}/dt) = -\partial\Omega/\partial c_\mu, \tag{i}$$

or (renaming μ as k)

$$dc_{n+k}/dt = -\partial\Omega/\partial c_k \qquad (k = 1, \ldots, n). \tag{j}$$

(ii) $\mu = n+1, \ldots, 2n$; or $\mu = n+s,\ s = 1, \ldots, n$:

$$\sum [c_k,\, c_{n+s}](dc_k/dt) = \sum (-\delta_{sk})(dc_k/dt) = -\partial\Omega/\partial c_k, \tag{k}$$

or (renaming s to k)

$$dc_k/dt = \partial\Omega/\partial c_{n+k} \qquad (k = 1, \ldots, n). \tag{l}$$

Hence Lagrange's result: If we choose as our constants the initial values of q and p, then (provided the *perturbative forces are potential*) the *perturbation equations are canonical*; with Ω as the *perturbation Hamiltonian* (see also §8.10).

Example 8.7.5 *Variation of Constants: The Forced Linear Oscillator.* Let us consider a system with Lagrangean equation of motion

$$\ddot{q} + \omega^2 q = f(t); \tag{a}$$

that is, a linear and undamped oscillator of (constant) natural frequency ω acted upon by the disturbing external force $f(t)$. As is well known, the general solution of the unperturbed problem [i.e., (a) with $f(t) = 0$] is

$$q = c_1 \sin(\omega t) + c_2 \cos(\omega t); \qquad c_1,\, c_2 = \text{arbitrary constants}. \tag{b}$$

Elementary Method

To solve the perturbed problem (a), and following the well-known method of variation of constants (see any text on ordinary differential equations), we try a solution of the *same form* as (b) but with c_1 and c_2 unknown functions of time:

$$q = c_1(t) \sin(\omega t) + c_2(t) \cos(\omega t), \tag{c}$$

where $c_1(t)$ and $c_2(t)$ are the coefficients of the *instantaneous simple harmonic motion* (i.e., the arbitrary constants of the motion that would result, at a generic instant, if $f(t)$ suddenly vanished) and they will be determined by the following *two* requirements:

(i) Both unperturbed and perturbed velocities $\dot{q}$, obtained by $(\ldots)^{\cdot}$-differentiation of (b) and (c), respectively, will have the *same form*;
(ii) The so-perturbed motion (c) will satisfy the perturbed equation (a).

Indeed:
(i) By $(\ldots)^{\cdot}$-differentiating (c), we obtain

$$\dot{q} = \dot{c}_1 \sin(\omega t) + \dot{c}_2 \cos(\omega t) + \omega[c_1 \cos(\omega t) - c_2 \sin(\omega t)], \tag{d}$$

and so the *first* requirement leads to the condition

$$\dot{c}_1 \sin(\omega t) + \dot{c}_2 \cos(\omega t) = 0; \tag{e}$$

and
(ii) By $(\ldots)^{\cdot}$-differentiating (d), invoking (e), and then inserting the result in (a), we find the *second* condition:

$$\ddot{q} + \omega^2 q = \cdots = \omega[\dot{c}_1 \cos(\omega t) - \dot{c}_2 \sin(\omega t)] = f(t). \tag{f}$$

Solving the system (e, f) for $\dot{c}_1,\ \dot{c}_2$, we readily obtain

$$\dot{c}_1 = \omega^{-1} f(t)\cos(\omega t), \qquad \dot{c}_2 = -\,\omega^{-1} f(t)\sin(\omega t). \tag{g}$$

Integrating (g) for a given $f(t)$, we obtain a particular solution of (a). The reader should compare this method with that of the *slowly varying parameters*, in (weakly) nonlinear oscillations (see next example, and also examples in § 7.9).

Generalization. In the *variable coefficient* case

$$\ddot{q} + a(t)\dot{q} + b(t)q = f(t) \qquad [a(t),\ b(t) = \text{known functions of time}], \tag{h}$$

(b) and (c) are replaced, respectively, by

$$q = c_1\, q_1(t) + c_2\, q_2(t):\quad \text{general solution of (h) when } f(t) = 0, \tag{i1}$$

$$q = c_1(t)\, q_1(t) + c_2(t)\, q_2(t), \qquad q_1(t) = \sin(\omega t),\ q_2(t) = \cos(\omega t); \tag{i2}$$

while the conditions (e, f) are replaced, respectively, by

$$\dot{c}_1\, q_1(t) + \dot{c}_2\, q_2(t) = 0, \tag{j1}$$

$$\dot{c}_1\, \dot{q}_1(t) + \dot{c}_2\, \dot{q}_2(t) = f(t). \tag{j2}$$

Solving (j1, 2) for $\dot{c}_1,\ \dot{c}_2$, we obtain the generalization of (g):

$$\dot{c}_1 = -[\,f(t)\, q_2(t)]/W \qquad \text{and} \qquad \dot{c}_2 = [\,f(t)\, q_1(t)]/W, \tag{k}$$

where

$$W = W[q_1(t),\ q_2(t)] \equiv [q_1(t)\,\dot{q}_2(t) - q_2(t)\dot{q}_1(t)] \equiv W(t):$$
Wronskian determinant of $q_1(t),\ q_2(t)$
$[\neq 0,$ since $q_1(t),\ q_2(t)$ are *linearly independent*; i.e., $(q_2/q_1)^{\cdot} \neq 0]$; (k1)

and, integrating the above and inserting the result in (c)/(i2), we obtain a particular solution of (h).

Via Lagrange's Brackets

We begin with (c):

$$q = c_1(t)\sin(\omega t) + c_2(t)\cos(\omega t) = q[t; c_1,\ c_2]. \tag{l}$$

Equations (d, e) can be rewritten, respectively, as

$$\begin{aligned} dq/dt &= [c_1\omega\cos(\omega t) - c_2\,\omega\sin(\omega t)] + [\sin(\omega t)\dot{c}_1 + \cos(\omega t)\dot{c}_2] \\ &= \partial q/\partial t + [(\partial q/\partial c_1)\dot{c}_1 + (\partial q/\partial c_2)\,\dot{c}_2], \end{aligned} \tag{m1}$$

$$\sum (\partial q/\partial c_\mu)(dc_\mu/dt) = [\sin(\omega t)]\,\dot{c}_1 + [\cos(\omega t)]\,\dot{c}_2 = 0; \tag{m2}$$

while, since

$$\begin{aligned} d^2q/dt^2 &= [-c_1\omega^2\sin(\omega t) - c_2\,\omega^2\cos(\omega t)] + [\dot{c}_1\,\omega\cos(\omega t) - \dot{c}_2\,\omega\sin(\omega t)] \\ &= \partial^2 q/\partial t^2 + \left[(\partial^2 q/\partial t\,\partial c_1)\dot{c}_1 + (\partial^2 q/\partial t\,\partial c_2)\dot{c}_2\right], \end{aligned} \tag{m3}$$

condition (f) becomes

$$(\partial^2 q/\partial t\,\partial c_1)\,\dot{c}_1 + (\partial^2 q/\partial t\,\partial c_2)\dot{c}_2 = f(t). \tag{m4}$$

But, and this is a general result,

$$\partial/\partial c_1(\partial q/\partial t) = \partial/\partial c_1(\dot{q}) = \omega\cos(\omega t) = \partial/\partial t(\partial q/\partial c_1) = \partial/\partial t[\sin(\omega t)], \tag{n1}$$

$$\partial/\partial c_2(\partial q/\partial t) = \partial/\partial c_2(\dot{q}) = -\omega\sin(\omega t) = \partial/\partial t(\partial q/\partial c_2) = \partial/\partial t[\cos(\omega t)]; \tag{n2}$$

and, therefore, the system (e, f) can be rewritten as

$$(\partial p/\partial c_1)\dot{c}_1 + (\partial q/\partial c_2)\dot{c}_2 = 0, \qquad (\partial\dot{q}/\partial c_1)\dot{c}_1 + (\partial q/\partial c_2)\dot{c}_2 = f(t). \tag{o1, 2}$$

To solve this system for $\dot{c}_1,\ \dot{c}_2$, we multiply (o2) with $\partial q/\partial c_\mu$ (where $\mu = 1, 2$) and (o1) with $\partial\dot{q}/\partial c_\mu$, and then subtract from each other, thus obtaining

$$\begin{aligned}&\big[(\partial q/\partial c_\mu)(\partial\dot{q}/\partial c_1) - (\partial q/\partial c_1)(\partial\dot{q}/\partial c_\mu)\big]\dot{c}_1\\ &\quad + \big[(\partial q/\partial c_\mu)(\partial\dot{q}/\partial c_2) - (\partial q/\partial c_2)(\partial\dot{q}/\partial c_\mu)\big]\dot{c}_2 = (\partial q/\partial c_\mu)f(t);\end{aligned}$$

that is, in the Lagrangean form (8.7.19) (recalling that here $p = \dot{q}$):

$$[c_1,\ c_\mu]\dot{c}_1 + [c_2,\ c_\mu]\dot{c}_2 = (\partial q/\partial c_\mu)f(t); \tag{p}$$

from which, due to the antisymmetry of the Lagrangean brackets (problem 8.7.1)—that is,

$$[c_1,\ c_1] = [c_2,\ c_2] = 0, \qquad [c_1,\ c_2] = \omega\ \Rightarrow\ [c_2,\ c_1] = -\omega, \tag{q}$$

we finally obtain (g) in the following general form:

$$dc_1/dt = \big((\partial q/\partial c_2)f(t)\big)/[c_1,\ c_2] \qquad dc_2/dt = \big((\partial q/\partial c_1)f(t)\big)/[c_2,\ c_1]. \tag{r}$$

Comparing (g, k) with (r) we immediately conclude that

$$[c_2,\ c_1] = (f\,W)\big((\partial q/\partial c_1)/W_2\big), \qquad [c_1,\ c_2] = (f\,W)\big((\partial q/\partial c_2)/W_1\big), \tag{r1, 2}$$

where

$$W_1 \equiv -f\,q_2, \qquad W_2 \equiv f\,q_1. \tag{r3}$$

Let the reader express the solution of the more general equation (h) via Lagrangean brackets.

This completes the fundamentals of classical canonical perturbation theory. We shall return to such approximation methods in §8.14. Now, using the insights gained in Hamiltonian variables, let us make a small detour to discuss the following.

Perturbation Equations in Lagrangean Variables

The most general Lagrangean-type *perturbed* equations of motion in these variables have the form (§3.10 and §3.11):

$$\sum M_{kl}\ddot{q}_l + f_k(t, q, \dot{q}) = Q_k + X_k, \tag{8.7.26}$$

where

$$f_k(t, q, \dot{q}): \quad \text{known function of its arguments,}$$
$$X_k = X_k(t, q, \dot{q}): \quad \text{small (total impressed) perturbative force.} \tag{8.7.26a}$$

Let the general solution of the corresponding *unperturbed* problem be

$$q_k = q_k(t;\, c). \tag{8.7.27a}$$

We have seen earlier (8.7.16a, 21d) that by demanding equality between the *unperturbed* and *perturbed* velocities, $\partial q_k/\partial t$ and

$$dq_k/dt = \partial q_k/\partial t + \sum (\partial q_k/\partial c_\mu)(dc_\mu/dt),$$

respectively, we arrive at the n conditions (8.7.17) for the dc/dt's:

$$\sum (\partial q_k/\partial c_\mu)(dc_\mu/dt) = 0. \tag{8.7.27b}$$

The additional n conditions will result by substituting the *perturbed accelerations*

$$d^2 q_k/dt^2 = \partial^2 q_k/\partial t^2 + \sum (\partial^2 q_k/\partial t\,\partial c_\mu)(dc_\mu/dt) \qquad \text{[after invoking (8.7.27b)]}, \tag{8.7.27c}$$

in (8.7.26), and then subtracting from it the unperturbed equation; that is, eq. (8.7.26) with $X_k = 0$ and $d^2 q_k/dt^2 = \partial^2 q_k/\partial t^2$: *unperturbed accelerations*. Thus, we obtain the following *Lagrangean perturbational equations of motion*:

$$\sum\sum M_{kl}(\partial^2 q_l/\partial t\,\partial c_\mu)(dc_\mu/dt) = X_k{}^{(1)}, \tag{8.7.28}$$

or, in extenso,

$$\sum \left[M_{k1}(\partial^2 q_1/\partial t\,\partial c_\mu) + \cdots + M_{kn}(\partial^2 q_n/\partial t\,\partial c_\mu)\right] (dc_\mu/dt) = X_k{}^{(1)}. \tag{8.7.28a}$$

These are the Lagrangean counterpart of the first of (8.7.17), and together with (8.7.27b) they constitute a system of $2n$ linear equations for the $2n$ dc/dt's. Indeed, with the abbreviations

$$\Lambda_{k\mu} \equiv \sum M_{kl}(\partial^2 q_l/\partial t\,\partial c_\mu) = \sum M_{kl}(\partial^2 q_l/\partial c_\mu\,\partial t), \qquad \Pi_{k\mu} \equiv \partial q_k/\partial c_\mu, \tag{8.7.29a}$$

the system (8.7.27b, 28) can be rewritten as

$$\sum \Lambda_{k\mu}\dot{c}_\mu = X_k{}^{(1)}, \qquad \sum \Pi_{k\mu}\dot{c}_\mu = 0, \tag{8.7.29b}$$

and, by Cramer's rule, its solution is

$$\dot{c}_\mu = \sum (-1)^{k+\mu} \Delta_{k\mu} X_k{}^{(1)}/\Delta \qquad (\text{summation on } k = 1, \ldots, n), \tag{8.7.29c}$$

$$\Delta \equiv \begin{vmatrix} \Lambda_{11} & \ldots & \Lambda_{1,2n} \\ \cdots & \cdots & \cdots \\ \Lambda_{n1} & \ldots & \Lambda_{n,2n} \\ \Pi_{11} & \ldots & \Pi_{1,2n} \\ \cdots & \cdots & \cdots \\ \Pi_{n1} & \ldots & \Pi_{n,2n} \end{vmatrix} \equiv Det(\Lambda_{k\mu},\, \Pi_{l\nu}) \quad (\neq 0, \text{ assumed}), \tag{8.7.29d}$$

and $(-1)^{k+\mu}\Delta_{k\mu} = \textit{cofactor (i.e., signed minor) of } \Lambda_{k\mu} \textit{ in } \Delta$. Integrating (8.7.29c), we obtain the $2n$ $c_\mu(t)$, and afterwards the *perturbed* solution $q_k = q_k[t;\, c(t)]$.

Example 8.7.6 *Variation of Constants: Quasi-Linear Oscillator.* Let us consider a system with equation of motion

$$m\,\ddot{q} + k\,q = \varepsilon\, f(q, \dot{q}), \tag{a}$$

where the generally nonlinear force $\varepsilon\, f(q, \dot{q})$ [ε: *constant, such that* $\varepsilon\, f(\ldots)$ has the dimensions of force] is assumed *small* compared with inertia ($m\ddot{q}$; m: constant mass) and elasticity ($-k\dot{q}$; k: constant modulus); this is the meaning of the adjective *quasi-linear*.

Lagrangean Variables

Here,

$$2T = m(\dot{q})^2 \;\Rightarrow\; M_{11} = m. \tag{b}$$

The general solution of the unperturbed equation [i.e., (a) with $\varepsilon f(q, \dot{q}) = 0$] is

$$q = c_1 \sin(\omega_o t) + c_2 \cos(\omega_o t), \qquad {\omega_o}^2 \equiv k/m. \tag{c}$$

Therefore, since $n = 1 \;\Rightarrow\; \nu = 1, 2$, we obtain, successively,

$$\begin{aligned} &\Pi_{11} \equiv \partial q/\partial c_1 = \sin(\omega_o t), \qquad \Pi_{12} \equiv \partial q/\partial c_2 = \cos(\omega_o t), \\ &\Lambda_{11} = M_{11}(\partial^2 q/\partial t\,\partial c_1) = m[\omega_o \cos(\omega_o t)], \\ &\Lambda_{12} = M_{11}(\partial^2 q/\partial t\,\partial c_2) = m[-\omega_o \sin(\omega_o t)], \\ &\Delta = \Lambda_{11}\Pi_{12} - \Lambda_{12}\Pi_{11} = \cdots = m\,\omega_o[\cos^2(\omega_o t) + \sin^2(\omega_o t)] = m\,\omega_o; \end{aligned} \tag{d}$$

$$\dot{c}_1 = (-1)^{1+1}\Delta_{11}X_1/\Delta = \Pi_{12}X_1/\Delta = (m\,\omega_o)^{-1}\varepsilon\, f(q, \dot{q})\cos(\omega_o t), \tag{e1}$$

$$\dot{c}_2 = (-1)^{1+2}\Delta_{12}X_1/\Delta = \Pi_{11}X_1/\Delta = -(m\,\omega_o)^{-1}\varepsilon\, f(q, \dot{q})\sin(\omega_o t). \tag{e2}$$

In the theory of nonlinear oscillations, it is customary and convenient to work, not with c_1 and c_2, but with the following variables:

$$c_1 = q_o \sin\phi \qquad \text{and} \qquad c_2 = q_o \cos\phi. \tag{f}$$

By $(\ldots)^{\cdot}$-differentiating the above, we obtain

$$\dot{c}_1 = \dot{q}_o \sin\phi + q_o\dot{\phi}\cos\phi \qquad \text{and} \qquad \dot{c}_2 = \dot{q}_o \cos\phi - q_o\dot{\phi}\sin\phi, \tag{g}$$

$$\begin{aligned} \Rightarrow f(q,\dot{q})\big|_{\text{unperturbed } q,\dot{q}} &\\ &= f\,[c_1 \sin(\omega_o t) + c_2 \cos(\omega_o t),\ c_1\omega_o \cos(\omega_o t) - c_2\omega_o \sin(\omega_o t)] \\ &= f\,[q_o \cos(\omega_o t - \phi),\ -q_o\,\omega_o \sin(\omega_o t - \phi)] \equiv f\,[\ldots,\ldots], \end{aligned} \tag{h}$$

and so (e1, e2) translate, respectively, to

$$\dot{q}_o \sin\phi + q_o\dot{\phi}\cos\phi = (\varepsilon/m\,\omega_o) f\,[\ldots,\ldots]\cos(\omega_o t), \tag{i1}$$

$$\dot{q}_o \cos\phi - q_o\dot{\phi}\sin\phi = -(\varepsilon/m\,\omega_o) f\,[\ldots,\ldots]\sin(\omega_o t). \tag{i2}$$

Solving this system for $\dot{q}_o$ and $q_o\dot{\phi}$, we get

$$\dot{q}_o = -(\varepsilon/m\,\omega_o) f\,[\ldots,\ldots]\sin\chi, \qquad q_o\dot{\phi} = (\varepsilon/m\,\omega_o) f\,[\ldots,\ldots]\cos\chi, \tag{i3}$$

where $\chi \equiv \omega_o t - \phi(t) \equiv \chi(t)$.

These equations for q_o and ϕ are *exact*; but since they are still nonlinear, they are not very useful. They become useful when q_o and ϕ *change very little* during the unperturbed period $\tau_o \equiv 2\pi/\omega_o$. Then, we can replace the exact equations (i3) with a new set whose right sides are the *averages* of the right sides of (i3) over τ_o:

$$\begin{aligned} dq_o/dt &= -(\varepsilon/2\pi m)\int f\,[\ldots,\ldots]\sin\chi\, dt \\ &= -(\varepsilon/2\pi\omega_o m)\int f\,[q_o\cos\chi,\ -q_o\,\omega_o\sin\chi]\sin\chi\, d\chi, \end{aligned} \tag{j1}$$

$$\begin{aligned} q_o(d\phi/dt) &= (\varepsilon/2\pi m)\int f\,[\ldots,\ldots]\cos\chi\, dt \\ &= +(\varepsilon/2\pi\omega_o m)\int f\,(q_o\cos\chi,\ -q_o\,\omega_o\sin\chi)\cos\chi\, d\chi; \end{aligned} \tag{j2}$$

where the dt-integrals extend from 0 to $2\pi/\omega_o$, while the $d\chi$-integrals extend from 0 to 2π.

For a general and masterful treatment of such *averaging* techniques, see, for example, Bogoliubov and Mitropolskii (1974, chap. 5, pp. 355–429); also ex. 7.9.14 ff.

Hamiltonian Variables

Here,

$$p = \partial T/\partial\dot{q} = m\dot{q} \ \Rightarrow\ \dot{q} = p/m, \tag{k1}$$

$$\begin{aligned} \Rightarrow\ H &= p\dot{q} - (T - V) = p(p/m) - (m/2)(p/m)^2 + (k/2)p^2 \\ &= p^2/2m + kq^2/2 = H(q,p)\text{: } \textit{unperturbed Hamiltonian}. \end{aligned} \tag{k2}$$

(a) The *unperturbed* canonical equations and their general solution are, respectively,

$$\dot{p} = -\partial H/\partial q: \qquad \dot{p} = -kq, \tag{l1}$$

$$\dot{q} = \partial H/\partial p: \qquad \dot{q} = p/m; \tag{l2}$$

$$p = p(t, c) = m\,\omega_o[c_1 \cos(\omega_o t) - c_2 \sin(\omega_o t)], \tag{m1}$$

$$q = q(t, c) = c_1 \sin(\omega_o t) + c_2 \cos(\omega_o t). \tag{m2}$$

(b) The *perturbed* canonical equations are

$$\begin{aligned}\dot{p} &= -\partial H/\partial q + X = -kq + X\\ &= -kq + \varepsilon f(q, p/m) \equiv -kq + \varepsilon F(q, p),\end{aligned} \tag{n1}$$

$$\dot{q} = \partial H/\partial p: \qquad \dot{q} = p/m. \tag{n2}$$

(i) Let us, first, apply the Lagrangean form (8.7.19):

$$\sum [c_\nu, c_\mu](dc_\nu/dt) = X(\partial q/\partial c_\mu) \qquad (\mu = 1, 2). \tag{o1}$$

We have

$$\partial q/\partial c_1 = \sin(\omega_o t), \qquad \partial q/\partial c_2 = \cos(\omega_o t), \tag{o2}$$

$$\begin{aligned}&[c_1,\, c_1] = 0, \qquad [c_2,\, c_2] = 0 \qquad \text{(since these brackets are antisymmetric)},\\ &[c_1,\, c_2] = (\partial p/\partial c_1)(\partial q/\partial c_2) - (\partial p/\partial c_2)(\partial q/\partial c_1)\\ &\qquad = [m\,\omega_o \cos(\omega_o t)][\cos(\omega_o t)] - [-m\,\omega_o \sin(\omega_o t)][\sin(\omega_o t)] = m\,\omega_o,\\ &[c_2,\, c_1] = -[c_1,\, c_2] = -m\,\omega_o;\end{aligned} \tag{o3}$$

and hence (o1) reduce to

$$[c_2, c_1]\dot{c}_2 = X(\partial q/\partial c_1): \qquad (-m\,\omega_o)\dot{c}_2 = \varepsilon F(q, p) \sin(\omega_o t), \tag{o4}$$

$$[c_1,\, c_2]\dot{c}_1 = X(\partial q/\partial c_2): \qquad (m\,\omega_o)\dot{c}_1 = \varepsilon F(q, p) \cos(\omega_o t); \tag{o5}$$

that is, the earlier (e1), (e2).

(ii) Finally, let us apply the form (8.7.22):

$$dc_\mu/dt = \sum (\partial c_\mu/\partial p)X. \tag{p1}$$

Solving (m1), (m2) for c_1 and c_2, we obtain

$$c_1 = [\sin(\omega_o t)]q + [\cos(\omega_o t)/m\,\omega_o]p, \tag{p2}$$

$$c_2 = [\cos(\omega_o t)]q + [-\sin(\omega_o t)/m\,\omega_o]p, \tag{p3}$$

and so (p1) yield

$$dc_1/dt = (\partial c_1/\partial p)X = [\cos(\omega_o t)/m\,\omega_o]\varepsilon F(q, p); \qquad \text{i.e., (e1)/(o5);} \tag{p4}$$

$$dc_2/dt = (\partial c_2/\partial p)X = [-\sin(\omega_o t)/m\,\omega_o]\varepsilon F(q, p); \qquad \text{i.e., (e2)/(o4).} \tag{p5}$$

Example 8.7.7 *Variation of Constants: Effect of Small Air Resistance (Drag) on Projectiles.* Let us consider a particle P of mass m in free motion on a fixed vertical plane O–xy (Ox: horizontal, $+Oy$: upward) under the action of constant gravity g and small air resistance (perturbation) equal to

$$\boldsymbol{D} = -\varepsilon(\boldsymbol{v}/v)f(v), \tag{a}$$

where $\boldsymbol{v}$ = velocity of $P = (\dot{x}, \dot{y})$, ε = small parameter (> 0), $f(v)$ = experimentally determined function of $|\boldsymbol{v}| \equiv v = [(\dot{x})^2 + (\dot{y})^2]^{1/2}$ (> 0). Here, $n = 2$, and so, with $q_1 = x$ and $q_2 = y$, we have

$$2T = m[(\dot{x})^2 + (\dot{y})^2], \qquad V = m\,g\,y + constant, \qquad Q_k = 0, \tag{b}$$

$$X_1 \equiv X = \boldsymbol{D}\cdot\boldsymbol{i} = -\varepsilon(\dot{x}/v)f(v), \qquad X_2 \equiv Y = \boldsymbol{D}\cdot\boldsymbol{j} = -\varepsilon(\dot{y}/v)f(v), \tag{c}$$

and so the *perturbed* equations of motion are

$$\text{Horizontal:} \qquad m\ddot{x} = -\varepsilon(\dot{x}/v)f(v), \tag{d1}$$

$$\text{Vertical:} \qquad m\ddot{y} = -m\,g - \varepsilon(\dot{y}/v)f(v). \tag{d2}$$

Since the general solution of the *unperturbed* problem [i.e., (d1, d2) with $\varepsilon = 0$] is

$$x = c_1 t + c_2, \qquad y = -(g/2)t^2 + c_3\,t + c_4, \tag{e1, 2}$$

we readily find

$$\Pi_{11} = \partial x/\partial c_1 = t, \quad \Pi_{12} = \partial x/\partial c_2 = 1, \quad \Pi_{13} = \partial x/\partial c_3 = 0, \quad \Pi_{14} = \partial x/\partial c_4 = 0,$$
$$\partial^2 x/\partial t\,\partial c_1 = 1, \quad \partial^2 x/\partial t\,\partial c_2 = 0, \quad \partial^2 x/\partial t\,\partial c_3 = 0, \quad \partial^2 x/\partial t\,\partial c_4 = 0; \tag{f1}$$

$$\Pi_{21} = \partial y/\partial c_1 = 0, \quad \Pi_{22} = \partial y/\partial c_2 = 0, \quad \Pi_{23} = \partial y/\partial c_3 = t, \quad \Pi_{24} = \partial y/\partial c_4 = 1,$$
$$\partial^2 y/\partial t\,\partial c_1 = 0, \quad \partial^2 y/\partial t\,\partial c_2 = 0, \quad \partial^2 y/\partial t\,\partial c_3 = 1, \quad \partial^2 y/\partial t\,\partial c_4 = 0; \tag{f2}$$

$$\begin{aligned}
\Lambda_{11} &= M_{11}(\partial^2 x/\partial t\,\partial c_1) + M_{12}(\partial^2 y/\partial t\,\partial c_1) = (m)(1) + (0)(0) = m\\
\Lambda_{12} &= M_{11}(\partial^2 x/\partial t\,\partial c_2) + M_{12}(\partial^2 y/\partial t\,\partial c_2) = (m)(0) + (0)(0) = 0,\\
\Lambda_{13} &= M_{11}(\partial^2 x/\partial t\,\partial c_3) + M_{12}(\partial^2 y/\partial t\,\partial c_3) = (m)(0) + (0)(1) = 0,\\
\Lambda_{14} &= M_{11}(\partial^2 x/\partial t\,\partial c_4) + M_{12}(\partial^2 y/\partial t\,\partial c_4) = (m)(0) + (0)(0) = 0;
\end{aligned} \tag{g1}$$

$$\begin{aligned}
\Lambda_{21} &= M_{21}(\partial^2 x/\partial t\,\partial c_1) + M_{22}(\partial^2 y/\partial t\,\partial c_1) = (0)(1) + (m)(0) = 0,\\
\Lambda_{22} &= M_{21}(\partial^2 x/\partial t\,\partial c_2) + M_{22}(\partial^2 y/\partial t\,\partial c_2) = (0)(0) + (m)(0) = 0,\\
\Lambda_{23} &= M_{21}(\partial^2 x/\partial t\,\partial c_3) + M_{22}(\partial^2 y/\partial t\,\partial c_3) = (0)(0) + (m)(1) = m,\\
\Lambda_{24} &= M_{21}(\partial^2 x/\partial t\,\partial c_4) + M_{22}(\partial^2 y/\partial t\,\partial c_4) = (0)(0) + (m)(0) = 0;
\end{aligned} \tag{g2}$$

$$\begin{aligned}
&\Delta \equiv Det(\Lambda_{k\mu}/\Pi_{l\nu}) = \cdots = -m^2 \qquad (k, l = 1, 2;\ \mu, \nu = 1, 2, 3, 4),\\
&\Delta_{11} = -m, \quad \Delta_{12} = -m\,t, \quad \Delta_{13} = 0, \quad \Delta_{14} = 0;\\
&\Delta_{21} = 0, \quad \Delta_{22} = 0, \quad \Delta_{23} = m, \quad \Delta_{24} = m\,t.
\end{aligned} \tag{g3}$$

Hence, the perturbation equations (8.7.29c) yield

$$\begin{aligned}
dc_1/dt &= \sum (-1)^{k+1} \Delta_{k1} X_k{}^{(1)}/\Delta \qquad (k = 1, 2) \\
&= [(-1)^{1+1}\Delta_{11} X_1{}^{(1)} + (-1)^{2+1}\Delta_{21} X_2{}^{(1)}]/\Delta \\
&= [(-1)^2 \Delta_{11} X^{(1)} + (-1)^3 \Delta_{21} Y^{(1)}]/\Delta \\
&= \{(-1)^2(-m)[-\varepsilon(\dot{x}/v)f(v)] + (-1)^3(0)[-\varepsilon(\dot{y}/v)f(v)]\}/(-m^2) \\
&= -(\varepsilon/m)(\dot{x}/v)f(v)|_{\text{unperturbed}} \\
&= -(\varepsilon/m)(c_1/v_{\text{unperturbed}})f(v_{\text{unperturbed}}) \equiv -(\varepsilon/m)(c_1/v_o)f(v_o), \\
dc_2/dt &= \cdots = (\varepsilon/m)(c_1/v_o)f(v_o)\,t, \\
dc_3/dt &= \cdots = -(\varepsilon/m)[(c_3 - g\,t)/v_o]f(v_o), \\
dc_4/dt &= \cdots = (\varepsilon/m)[(c_3 - g\,t)/v_o]f(v_o)\,t,
\end{aligned} \tag{h}$$

where

$$v_{\text{unperturbed}} = [(\dot{x})^2 + (\dot{y})^2]^{1/2}\Big|_{\text{unperturbed}} = [(c_1)^2 + (c_3 - g\,t)^2]^{1/2} \equiv v_o. \tag{h1}$$

Integrating the four expressions (h), while (since the drag is small) replacing in their right sides $c_{1,2,3,4}$ with the corresponding integration constants $c_{1o,2o,3o,4o}$ using $*$ as (dummy) variable of integration, and the notation $f(v_{\text{unperturbed}}) \equiv f(v_o) \equiv f_o$, we obtain, finally,

$$\begin{aligned}
c_1 &= c_{1o} - (\varepsilon/m)\int_0^t (c_1/v_o)f_o\,d* \;\approx\; c_{1o} - (\varepsilon/m)c_{1o}\int_0^t (f_o/v_o)\,d*, \\
c_2 &= c_{2o} + (\varepsilon/m)\int_0^t (c_1/v_o)f_o * d* \;\approx\; c_{2o} + (\varepsilon/m)c_{1o}\int_0^t (f_o/v_o) * d*, \\
c_3 &= c_{3o} - (\varepsilon/m)\int_0^t [(c_3 - g*)/v_o]f_o\,d* \;\approx\; c_{3o} - (\varepsilon/m)\int_0^t (c_{3o} - g*)(f_o/v_o)\,d*, \\
c_4 &= c_{4o} + (\varepsilon/m)\int_0^t [(c_3 - g*)/v_o]f_o * d* \;\approx\; c_{4o} + (\varepsilon/m)\int_0^t (c_{3o} - g*)(f_o/v_o) * d*,
\end{aligned} \tag{i1, 2, 3, 4}$$

where $v_o \approx [(c_{1o})^2 + (c_{3o} - g*)^2]^{1/2} \Rightarrow f_o$: known function of $*$, c_{1o}, c_{3o}.

Last, substituting (i1–4) into (e1, 2), we obtain a particular solution of the perturbed problem (d1, 2) in terms of t and $c_{1o,2o,3o,4o}$, correct to the first-order in ε.

For the *Hamiltonian* perturbation treatment—that is, via (8.7.19) or (8.7.22), including special $f(v)$ cases, see, for example, Hamel (1949, pp. 309–311; and pp. 689–691 for the plane linear elastic and isotropic oscillator under small air resistance); also Lur'e (1968, pp. 569–571).

8.8 CANONICAL TRANSFORMATIONS (CT)

We have already seen (ex. 3.5.11) that a key advantage of the Lagrangean-type equations, say

$$E_k \equiv E_k(L) \equiv (\partial L/\partial \dot{q}_k)^{\cdot} - \partial L/\partial q_k = Q_k, \tag{8.8.1}$$

over those of Newton–Euler, is their *form invariance* under the group of frame-of-reference transformations, or *point transformations*, defined by

$$G: \qquad q_k = q_k(t, q_{k'}) \leftrightarrow q_{k'} = q_{k'}(t, q_k) \qquad (k, k' = 1, \ldots, n), \tag{8.8.2}$$

$$q_k(\ldots)\text{: twice differentiable,} \qquad \text{and} \qquad J \equiv |\partial q/\partial q'| \neq 0; \tag{8.8.2a}$$

that is, under G,

$$E_k \to E_{k'}(L') \equiv (\partial L'/\partial \dot{q}_{k'})^{\cdot} - \partial L'/\partial q_{k'} = Q_{k'}, \tag{8.8.3}$$

where

$$L \to L[t, q(t, q'), \dot{q}(t, q, \dot{q}')] \equiv L'(t, q', \dot{q}') = L', \tag{8.8.3a}$$

$$E_{k'} = \sum (\partial q_k/\partial q_{k'}) E_k \;\Leftrightarrow\; E_k = \sum (\partial q_{k'}/\partial q_k)\, E_{k'}, \tag{8.8.3b}$$

$$Q_{k'} = \sum (\partial q_k/\partial q_{k'})\, Q_k \;\Leftrightarrow\; Q_k = \sum (\partial q_{k'}/\partial q_k)\, Q_{k'}. \tag{8.8.3c}$$

When it comes to Hamiltonian type of equations, since they are mathematically equivalent to the Lagrangean ones, we expect similar form invariance under G. However, if we define

$$\begin{aligned} p_{k'} \equiv \partial L'/\partial \dot{q}_{k'} &= \sum (\partial L/\partial \dot{q}_k)(\partial \dot{q}_k/\partial \dot{q}_{k'}) = \sum (\partial L/\partial \dot{q}_k)(\partial q_k/\partial q_{k'}) \\ &= \sum (\partial \dot{q}_k/\partial \dot{q}_{k'}) p_k = \sum (\partial q_k/\partial q_{k'})\, p_k \\ &= p_{k'}(t, q', p) = p_{k'}[t, q'(t, q), p] = p_{k'}(t, q, p) \end{aligned} \tag{8.8.4}$$

(i.e., the new momenta depend on both the old momenta *and* the old coordinates and time), and the Hamiltonian equations corresponding to (8.8.1)

$$dq_k/dt = \partial H/\partial p_k, \qquad dp_k/dt = -\partial H/\partial q_k + Q_k, \tag{8.8.5}$$

are transformed to

$$dq_{k'}/dt = \partial H'/\partial p_{k'}, \qquad dp_{k'}/dt = -\partial H'/\partial q_{k'} + Q_{k'}, \tag{8.8.6}$$

the *new Hamiltonian* $H' = H'(t, q', p')$, unlike $L = L'$, *may no longer equal the old one* H; that is, in general,

$$H' = H'(t, q', p') \neq H(t, q, p) = H. \tag{8.8.6a}$$

Indeed, assuming (8.8.5) to hold, we have, successively,

$$\begin{aligned} H' &\equiv \sum p_{k'} \dot{q}_{k'} - L' \\ &= \sum p_{k'} \dot{q}_{k'} - L = \sum p_{k'} \dot{q}_{k'} - \Big(\sum p_k \dot{q}_k - H\Big) \\ &= \sum \Big(\sum (\partial q_k/\partial q_{k'})\, p_k\Big) \dot{q}_{k'} - \Big(\sum p_k \dot{q}_k - H\Big) \\ &= \sum \Big(\sum (\partial q_k/\partial q_{k'}) \dot{q}_{k'} - \dot{q}_k\Big) p_k + H \\ &= -\sum (\partial q_k/\partial t) p_k + H; \end{aligned} \tag{8.8.7}$$

that is, in general, H' defined as above, or equivalently by

$$L = L': \qquad \sum p_{k'}\,\dot{q}_{k'} - H' = \sum p_k\,\dot{q}_k - H, \tag{8.8.7a}$$

does *not* equal H (recalling probs. 3.16.11 and 3.16.12); but it does if $\partial q_k/\partial t = 0$, that is whenever (8.8.2) specializes to the geometrical (non–frame-of-reference transformations)

$$q_k = q_k(q_{k'}) \Leftrightarrow q_{k'} = q_{k'}(q_k). \tag{8.8.7b}$$

Hence, in the Hamiltonian case, it is necessary to widen the meaning of invariance. Specifically, and since here the independent variables are the q's and p's, we are seeking the *most general transformations in (the phase space of) these variables*; that is,

$$q = q(t, q', p') \Leftrightarrow q' = q'(t, q, p), \tag{8.8.8a}$$

$$p = p(t, q', p') \Leftrightarrow p' = p'(t, q, p) \tag{8.8.8b}$$

[with nonvanishing Jacobian $|\partial(q', p')/\partial(q, p)|$] that leave Hamilton's equations *form invariant*, as in (8.8.5). Such transformations are called *canonical*.

REMARK ON NOTATION

A number of authors denote our $(q_{k'}, p_{k'})$ as (Q_k, P_k). Our notation was chosen to avoid confusion with the holonomic components of Lagrangean impressed forces and nonholonomic momenta, respectively (chap. 3); also, it is in line with the more precise tensorial notations.

Problem 8.8.1 Show that under point transformations:

(i) $$\partial H'/\partial p_{k'} - dq_{k'}/dt = \sum (\partial p_k/\partial p_{k'})(\partial H/\partial p_k - dq_k/dt) \quad (= 0), \tag{a}$$

(ii) $$\partial H'/\partial q_{k'} + dp_{k'}/dt = \sum (\partial q_k/\partial q_{k'})(\partial H/\partial q_k + dp_k/dt) \quad (= 0). \tag{b}$$

Problem 8.8.2 Show that

$$\partial p_k/\partial p_{k'} = \partial q_k/\partial q_{k'}, \qquad \partial p_{k'}/\partial p_k = \partial q_{k'}/\partial q_k. \tag{a}$$

Whence the Significance of Canonical Transformations (CT)

The reason that such transformations are important in theoretical mechanics is their ability to transform an original set of Hamiltonian equations, in (unprimed) q's and p's, into a *simpler* set of Hamiltonian equations in the new (primed) variables q''s and p''s.

In particular, we are seeking *transformations in which one or more (or even all) of the coordinates are ignorable*. In such q''s $\to \psi'$'s (and with $L'/R'/H' \equiv$ *New Lagrangean/Routhian/Hamiltonian*)

$$\partial L'/\partial\psi_{i'} = \partial R'/\partial\psi_{i'} = -\partial H'/\partial\psi_{i'} = 0 \qquad (i' = 1, \ldots, M \leq n), \tag{8.8.9a}$$

that is, these three mutually equal partial derivatives vanish simultaneously (which is the definition of these coordinates, §8.2–8.4); and, as a result, assuming, as in §8.4 ff., that $Q_{i'} = 0$,

$$d\Psi_{i'}/dt = \partial L'/\partial\psi_{i'} = -\partial H'/\partial\psi_{i'} = 0 \;\Rightarrow\; \Psi_{i'} = constant \equiv C_{i'}, \tag{8.8.9b}$$

$$\Rightarrow\; H' = H'(t, q', p'; C), \tag{8.8.9c}$$

where the $2(n - M)$ q''s and p''s are the remaining nonignorable coordinates and momenta. {In order to benefit from the new ignorable coordinates [as in §8.4 and §8.10 (Hamilton–Jacobi's method)], a number of authors set $Q_k = 0$ from the outset. Then, clearly, $Q_{k'} = 0$.}

Solving the Hamiltonian equations of such a system — that is,

$$dq_{p'}/dt = \partial H'/\partial p_{p'}, \qquad dp_{p'}/dt = -\partial H'/\partial q_{p'} \qquad (p' = M+1, \ldots, n), \tag{8.8.9d}$$

we find

$$q_{p'} = q_{p'}(t;\, C_{i'}, \alpha_{p'}, \beta_{p'}), \qquad p_{p'} = p_{p'}(t; C_{i'}, \alpha_{p'}, \beta_{p'}),$$
$$(\alpha_{p'}, \beta_{p'}) = 2(n - M): \quad \text{constants of integration of (8.8.9d)}; \tag{8.8.9e}$$

then, substituting (8.8.9e) into (8.8.9c), we obtain

$$H' = H'(t;\, C_{i'}, \alpha_{p'}, \beta_{p'}), \tag{8.8.9f}$$

and so, finally, we can calculate the ψ''s from their equations of motion via a quadrature:

$$d\psi_{i'}/dt = \partial H'/\partial C_{i'} \;\Rightarrow\; \psi_{i'} = \int (\partial H'/\partial C_{i'})\, dt + \psi_{i',o}, \tag{8.8.9g}$$

where $\psi_{i',o}$ = integration constants, to be determined from the initial conditions, as in the Routhian case (§8.3, 8.4). In particular, if *all* new coordinates are ignorable, *and* $\partial H'/\partial t = 0$, then

$$H' = H'(C_{k'};\, \alpha_{l'}, \beta_{m'}) \;\Rightarrow\; d\psi_{i'}/dt = \partial H'/\partial C_{i'} = constant \equiv c_{i'}, \text{ etc.} \tag{8.8.9h}$$

Hence, CT can simplify the equations of motion considerably, and supply integrals of motion, as in (8.8.9b). Of course, other, *noncanonical* transformations may achieve additional simplifications.

Definition of, and Conditions for, Canonicity; Generating Function

In view of (8.8.3a) and the fact that a Lagrangean is defined only to within the total derivative of an arbitrary function of the coordinates and time (ex. 3.5.13) — that is, two such Lagrangeans yield the same equations of motion — we, following (the eminent Norwegian mathematician) S. Lie, introduce the following general definition: an (8.8.8a, b)-like transformation $(q, p) \to (q', p')$ is called canonical (CT) if

$$L\,dt = L'\,dt + dF$$

$$\Rightarrow \sum p_k\,dq_k - H\,dt = \sum p_{k'}\,dq_{k'} - H'\,dt + dF, \qquad (8.8.10)$$

$$\Rightarrow \sum p_k\,dq_k - \sum p_{k'}\,dq_{k'} = (H - H')\,dt + dF, \qquad (8.8.11)$$

where F called (after Jacobi) the *generating*, or *substitution, function* of the transformation, is an arbitrary differentiable function of the coordinates, momenta, and time; and H' satisfies the Hamiltonian equations in the new variables. Equivalently, we may call an (8.8.8a, b)-like transformation canonical if

$$\left(\sum p_k\,dq_k - H\,dt\right) - \left(\sum p_{k'}\,dq_{k'} - H'\,dt\right)$$
$$= \left(\sum p_k\,dq_k - \sum p_{k'}\,dq_{k'}\right) - (H - H')\,dt = dF \qquad \text{(i.e., integrable);} \quad (8.8.11\text{a})$$

even though $\sum p_k\,dq_k$: *nonintegrable*, and $\sum p_{k'}\,dq_{k'}$: *nonintegrable*. For $dt \to \delta t = 0$ and $dq,\ dp \to \delta q,\ \delta p$, the above yield the *virtual form* of a canonical transformation:

$$\sum p_k\,\delta q_k - \sum p_{k'}\,\delta q_{k'} = \delta F, \qquad (8.8.12)$$

a form that is, sometimes, taken as the primitive CT definition.

In view of its so-revealed importance, F deserves a detailed examination. Although, due to (8.8.8a, b), $F = F(t, q, p) = F(t, q', p')$, yet it turns out that the resulting equations are *simpler* if F (and the corresponding phase space points) *is expressed as a combination of old* (q, p) *and new* (q', p') "*coordinates*"; that is, if F has one of the following *four* forms:

$$F_1(t, q, q'), \qquad F_2(t, q, p'), \qquad F_3(t, p, q'), \qquad F_4(t, p, p'), \qquad (8.8.13)$$

depending on the problem at hand, and our choice of which $2n(+\textit{time})$ of these $4n(+\textit{time})$ variables to consider as *independent*. Let us examine the consequences of these four choices:

(i) If $F = F(t, q, q') \equiv F_1$, then

$$dF_1/dt = \partial F_1/\partial t + \sum (\partial F_1/\partial q_k)(dq_k/dt) + \sum (\partial F_1/\partial q_{k'})(dq_{k'}/dt). \qquad (8.8.14)$$

Substituting (8.8.14) in (8.8.10) and equating the coefficients of the $2n + 1$ independent $dq/dq'/dt$, we obtain

$$p_k = \partial F_1/\partial q_k, \qquad p_{k'} = -\partial F_1/\partial q_{k'}, \qquad H' = H + \partial F_1/\partial t, \qquad (8.8.15)$$

from which it follows that if $\partial F_1/\partial t = 0$, then $H = H'$. Solving the first of (8.8.15) for the q's we obtain

$$q_{k'} = q_{k'}(t, q, p), \qquad (8.8.15\text{a})$$

and substituting this into the second of (8.8.15) we get

$$p_{k'} = p_{k'}(t, q, p). \qquad (8.8.15\text{b})$$

Equations (8.8.15a, b) express the transformations among the old and new canonical variables. These operations require that $|\partial^2 F_1/\partial q_k\,\partial q_{k'}| \neq 0$, and so we will henceforth assume this to hold; and similarly for the corresponding Hessian determinants of F_2, F_3, F_4.

(ii) Let $F = F(t, q, p') \equiv F_2$. Here, as well as in the cases of F_3, F_4 (see below), we *cannot* proceed as in the case of F_1 [i.e., via (8.8.10, 11)], because we do *not* have $\dot{q}_k$ and $\dot{q}_{k'}$. However, in view of the second of (8.8.15), the transition from the (t, q, q') of F_1 to the (t, q, p') of F_2 can be effected by the following Hamilton (Legendre)-type of transformation (§8.2):

$$F_2(\ldots p' \ldots) = \sum p_{k'}\, q_{k'} - [-F_1(\ldots q' \ldots)]; \tag{8.8.16}$$

where F_2, $p_{k'}$, $q_{k'}$, $-F_1$ play, respectively, the roles of Hamiltonian, momenta, "velocities," and Lagrangean. Substituting from (8.8.16)

$$F_1(t, q, q') = F_2(t, q, p') - \sum p_{k'}\, q_{k'} \tag{8.8.16a}$$

into (8.8.10), we find

$$\begin{aligned}
\sum p_k\, dq_k - H\, dt
&= \sum p_{k'}\, dq_{k'} - H'\, dt + dF_1 \\
&= \sum p_{k'}\, dq_{k'} - H'\, dt + dF_2(t, q, p') - d\Big(\sum p_{k'}\, q_{k'}\Big) \\
&= -\sum q_{k'}\, dp_{k'} - H'\, dt + dF_2(t, q, p') \\
&= (-H' + \partial F_2/\partial t)\, dt + \sum (\partial F_2/\partial q_k)\, dq_k + \sum (\partial F_2/\partial p_{k'} - q_{k'})\, dq_{k'},
\end{aligned}$$

and, comparing coefficients, we immediately conclude that

$$p_k = \partial F_2/\partial q_k, \qquad q_{k'} = \partial F_2/\partial p_{k'}, \qquad H' = H + \partial F_2/\partial t. \tag{8.8.17}$$

To obtain the old/new variable transformation equations, we solve the first of (8.8.17) for the p', thus obtaining

$$p_{k'} = p_{k'}(t, q, p), \tag{8.8.17a}$$

and then substitute the result in the second of (8.8.17), thus getting

$$q_{k'} = q_{k'}(t, q, p). \tag{8.8.17b}$$

(iii) Let $F = F(t, p, q') \equiv F_3$. In view of the first of (8.8.15), or $-p_k = \partial(-F_1)/\partial q_k$, the transition from the (t, q, q') of F_1 to the (t, p, q') of F_3 can be effected by the following Hamilton-type transformation:

$$F_3(\ldots - p \ldots) = \sum (-p_k)(q_k) - [-F_1(\ldots q \ldots)]; \tag{8.8.18}$$

where F_3, $-p_k$, $q_k, -F_1$ play, respectively, the roles of Hamiltonian, momenta, "velocities," and Lagrangean. Substituting from (8.8.18)

$$F_1(t, q, q') = F_3(t, p, q') + \sum p_k q_k \tag{8.8.18a}$$

into (8.8.10), we find

$$\sum p_k\, dq_k - H\, dt = \sum p_{k'}\, dq_{k'} - H'\, dt + dF_1$$
$$= \sum p_{k'}\, dq_{k'} - H'\, dt + dF_3(t, p, q') + d\Big(\sum p_k q_k\Big),$$

or

$$-\sum q_k\, dp_k - H\, dt = \sum p_{k'}\, dq_{k'} - H'\, dt + dF_3(t, p, q'),$$

or, expanding dF_3 and collecting $dt/dp/dp'$ terms,

$$(-H' + H + \partial F_3/\partial t)\, dt + \sum (\partial F_3/\partial p_k + q_k)\, dp_k + \sum (\partial F_3/\partial q_{k'} + p_{k'})\, dq_{k'} = 0,$$

and setting the differential coefficients equal to zero, we immediately obtain

$$q_k = -\partial F_3/\partial p_k, \qquad p_{k'} = -\partial F_3/\partial q_{k'}, \qquad H' = H + \partial F_3/\partial t. \tag{8.8.19}$$

To obtain the old/new variable transformation equations, we solve the first of (8.8.19) for the q', thus obtaining

$$q_{k'} = q_{k'}(t, q, p), \tag{8.8.19a}$$

and then substitute the results in the second of (8.8.19), thus getting

$$p_{k'} = p_{k'}(t, q, p). \tag{8.8.19b}$$

(iv) Finally, let $F = F(t, p, p') \equiv F_4$. By repeating the above arguments *twice*, we can show that the transition from the (t, q, q') of F_1 to the (t, p, p') of F_4 can be effected by the following *double* Hamilton-type transformation:

$$F_4(\ldots - p, p' \ldots) = \sum (-p_k)(q_k) + \sum p_{k'} q_{k'} - [-F_1(\ldots q, q' \ldots)]; \tag{8.8.20}$$

where $F_4, -p_k, p_{k'}, q_k, q_{k'}, -F_1$ play, respectively, the roles of Hamiltonian, old momenta, new momenta, old "velocities," new "velocities," and Lagrangean. Repeating similar steps as in the previous cases [i.e., from (8.8.20) to (8.8.10) etc.] and setting the coefficients of $dt/dp/dp'$ equal to zero, we find

$$q_k = -\partial F_4/\partial p_k, \qquad q_{k'} = \partial F_4/\partial p_{k'}, \qquad H' = H + \partial F_4/\partial t. \tag{8.8.21}$$

Finally, to obtain the old/new variable transformation equations, we solve the first of (8.8.21) for the p''s, and thus acquire

$$p_{k'} = p_{k'}(t, q, p), \tag{8.8.21a}$$

and then substitute (8.8.21a) into the second of (8.8.21), thus getting

$$q_{k'} = q_{k'}(t, q, p). \tag{8.8.21b}$$

All these interrelated formulae are summarized, for convenience, in table 8.1.

In Sum

A canonical transformation can be created from a generating function. As such, we can choose *any* differentiable function of *half* of the *old* variables (either the q_k's or

Table 8.1 Types of Generating Functions

$F = F_1(t, q, q')$:	$p_k = \partial F_1/\partial q_k$,	$p_{k'} = -\partial F_1/\partial q_{k'}$;	$H' = H + \partial F_1/\partial t$
$F = F_2(t, q, p')$:	$p_k = \partial F_2/\partial q_k$,	$q_{k'} = \partial F_2/\partial p_{k'}$;	$H' = H + \partial F_2/\partial t$
$F = F_3(t, p, q')$:	$q_k = -\partial F_3/\partial p_k$,	$p_{k'} = -\partial F_3/\partial q_{k'}$;	$H' = H + \partial F_3/\partial t$
$F = F_4(t, p, p')$:	$q_k = -\partial F_4/\partial p_k$,	$q_{k'} = \partial F_4/\partial p_{k'}$;	$H' = H + \partial F_4/\partial t$

$F_2 = F_1 + \sum p_{k'} q_{k'}$,
$F_3 = F_1 - \sum p_k q_k$,
$F_4 = F_1 + \sum p_{k'} q_{k'} - \sum p_k q_k = F_2 - \sum p_k q_k = F_3 + \sum p_{k'} q_{k'}$

the p_k's) and *half* of the *new* (either the $q_{k'}$'s or the $p_{k'}$'s), and time; a total of $2n + 1$ independent variables. Once a generating function has been selected, table 8.1 gives the transformation relations between the (remaining half of the chosen) old and new variables.

REMARKS

(i) In *all* four cases, we have $H' - H = \partial F/\partial t$; and therefore if $\partial F/\partial t = 0$, the new Hamiltonian results by simply substituting, in the old Hamiltonian, the old variables in terms of the new variables:

$$H = H(t, q, p) = H[t, q(t, q', p'), p(t, q', p')] = H'(t, q', p') = H'.$$

(ii) From the above derivations and results we are gradually led to the realization that, in the rarified atmosphere of Hamiltonian mechanics, the terms coordinate (q) and momentum (p) have lost a lot of their original physical meaning; as (8.8.8a, b) show, each q' and each p' may relate to all the q's and the p's. In view of this blurring of the nomenclature (in both Hamiltonian mechanics and, especially, in its famous heir quantum mechanics) we call the q's and p's *canonically conjugate* variables. For example, the CT: $q_k = -p_{k'}$ and $p_k = q_{k'}$, with generating functions $F = q_1 q_{1'} + \cdots + q_n q_{n'} = F_1$ (or $F = p_1 p_{1'} + \cdots + p_n p_{n'} = F_4$) swaps coordinates and momenta, to within a sign. (Strictly speaking, these should have been written as $q_k = -\sum \delta_{kk'} p_k$ and $p_k = \sum \delta_{kk'} q_{k'}$, respectively.)

Example 8.8.1 Let us show that *all point transformations* (8.8.2)

$$q_k = q_k(t, q_{k'}) \Leftrightarrow q_{k'} = q_{k'}(t, q_k) \qquad (k, k' = 1, \ldots, n) \tag{a}$$

are canonical.

Choosing as generating function

$$F = \sum q_{k'} p_{k'} = \sum q_{k'}(t, q) p_{k'} = F(t, q, p') \equiv F_2, \tag{b}$$

and, therefore, applying (8.8.17), we obtain

$$p_k = \partial F_2/\partial q_k = \sum (\partial q_{k'}/\partial q_k) p_{k'} \qquad \text{[i.e., (8.8.4) with } k \text{ and } k' \text{ swapped]}, \tag{c}$$

$$q_{k'} = \partial F_2/\partial p_{k'} = q_{k'}(t, q) \qquad \text{[i.e., (8.8.2)]}, \tag{d}$$

$$\begin{aligned} H' &= H + \partial F_2/\partial t = H + \sum (\partial q_{k'}/\partial t) p_{k'} \\ &= -\sum (\partial q_k/\partial t) p_k + H \qquad \text{[i.e., (8.8.7); prove the last step]}, \quad \text{Q.E.D.} \end{aligned} \tag{e}$$

For example, if $F_2 = \sum q_{k'}(q) p_{k'} + f(q) =$ *linear* in the p', the above reduce to the general point transformation

$$p_k = \sum (\partial q_{k'}/\partial q_k) p_{k'} + \partial f/\partial q_k, \qquad q_{k'} = q_{k'}(q). \tag{f}$$

Similarly, choosing

$$F = -\sum p_k \, q_k(t, q') = F(t, p, q') \equiv F_3, \tag{g}$$

and, therefore, applying (8.8.19), we obtain

$$q_k = -\partial F_3/\partial p_k = q_k(t, q'), \tag{h}$$

$$p_{k'} = -\partial F_3/\partial q_{k'} = \sum (\partial q_k/\partial q_{k'}) p_k, \tag{i}$$

$$H' = H + \partial F_3/\partial t = H - \sum (\partial q_k/\partial t) p_k, \quad \text{Q.E.D.} \tag{j}$$

In particular, if, in (g), $q_k(t, q') = q_{k'}$, we obtain the *identity* transformation.

Example 8.8.2 Let us check the following transformations for canonicity:

(i) $$q' = -p, \qquad p' = q. \tag{a}$$

We have, successively,

$$p\,\delta q - p'\,\delta q' = p\,\delta q - (q)(-\delta p) = \delta(p\,q) = \delta F, \tag{b}$$

and, therefore, by (8.8.12), (a) is canonical. Similarly, we can show that

$$q_{k'} = -p_k, \quad p_{k'} = q_k \qquad \text{and} \qquad q_{k'} = p_k, \quad p_{k'} = -q_k, \tag{c}$$

are canonical. This example makes clear that the Hamiltonian form of the equations of motion is *unaffected even if we take as new coordinates the old momenta, and vice versa*!

(ii) $$q' = (q)^{1/2} \cos(2p), \qquad p' = (q)^{1/2} \sin(2p) \qquad \text{(due to H. Poincaré)}. \tag{d}$$

Inverting (d), we find

$$q = (q')^2 + (p')^2, \qquad \tan(2p) = p'/q'; \tag{e}$$

and, therefore, successively,

$$\begin{aligned} p\,\delta q - p'\,\delta q' &= p\,\delta q \\ &\quad - [(q)^{1/2}\sin(2p)]\{[\cos(2p)/2(q)^{1/2}]\,\delta q - [2(q)^{1/2}\sin(2p)]\,\delta p\} \\ &= [p - (\sin(2p)\cos(2p)/2)]\,\delta q + [2q\sin^2(2p)]\,\delta p \\ &= \delta\{q[p - (\sin(4p)/4)]\} = \delta F; \end{aligned} \tag{f}$$

that is, by (8.8.12), (d) is canonical.

(iii)
$$q' = \ln[\sin(p)/q], \qquad p' = q\cot(p). \tag{g}$$

We have, successively,

$$q' = -\ln(q) + \ln[\sin(p)] \;\Rightarrow\; \delta q' = -(\delta q/q) + [\cot(p)]\,\delta p, \tag{h}$$

and, therefore,

$$\begin{aligned} p\,\delta q - p'\,\delta q' &= p\,\delta q - [q\cot(p)]\{-(\delta q/q) + [\cot(p)]\,\delta p\} \\ &= [p + \cot(p)]\,\delta q - [q\cot^2(p)]\,\delta p \equiv Q\,\delta q + P\,\delta p. \end{aligned} \tag{i}$$

The necessary and sufficient conditions for the integrability (i.e., canonicity) of (i) are $\partial Q/\partial p = \partial P/\partial q$:

$$\begin{aligned} &\partial/\partial p[p + \cot(p)] = 1 - [1/\sin^2(p)] = -\cot^2(p), \\ &\partial/\partial q[-q\cot^2(p)] = -\cot^2(p); \end{aligned}$$

that is, (g) is indeed canonical.

Example 8.8.3 Let us determine the values of α and β so that the transformation

$$q' = q^\alpha\cos(\beta p), \qquad p' = q^\alpha\sin(\beta p) \tag{a}$$

is canonical. From the first of them, we obtain

$$\delta q' = [-\beta\,q^\alpha\sin(\beta p)]\,\delta p + [\alpha\,q^{\alpha-1}\cos(\beta p)]\,\delta q, \tag{b}$$

and, therefore,

$$p\,\delta q - p'\,\delta q' = \left[p - (1/2)\alpha\,q^{2\alpha-1}\sin(2\beta p)\right]\delta q + \left[\beta\,q^{2\alpha}\sin^2(\beta p)\right]\delta p \equiv Q\,\delta q + P\,\delta p.$$

Again, for integrability, we must have $\partial Q/\partial p = \partial P/\partial q$:

$$\partial/\partial p\left[p - (1/2)\alpha\,q^{2\alpha-1}\sin(2\beta p)\right] = \partial/\partial q\left[\beta\,q^{2\alpha}\sin^2(\beta p)\right], \tag{c}$$

from which we obtain the condition

$$\alpha\,\beta\,q^{2\alpha-1} = 1; \tag{d}$$

and since this equation must hold for all values of q, we are led to the system

$$2\alpha - 1 = 0 \qquad \text{and} \qquad \alpha\beta = 1, \tag{e}$$

whose roots are $\alpha = 1/2$ and $\beta = 2$. Hence, (a) becomes

$$q' = (q)^{1/2}\cos(2p), \qquad p' = (q)^{1/2}\sin(2p); \tag{f}$$

that is, the Poincaré transformation of the preceding example.

Example 8.8.4 *Canonicity via the Central Equation*:

$$\delta T + \delta' W = \left(\sum p_k\,\delta q_k\right)^{\cdot} \;\Rightarrow\; \left(\sum p_k\,\delta q_k\right)^{\cdot} - \delta T = \delta' W. \tag{a}$$

If the impressed forces are wholly *potential* forces—that is, $\delta' W = -\delta V \;\Rightarrow\; \delta(T - V) = \delta L$—then, in view of the fundamental definition (8.8.12), we can transform (a) to

$$\left(\sum p_{k'}\,\delta q_{k'}\right)^{\cdot} - [\delta L - (\delta F)^{\cdot}] = 0. \tag{b}$$

But since $(\delta F)^{\cdot} = \delta(\dot{F})$, this new central equation has the old form (a) *if we define as new Lagrangean*:

$$L' = L - dF/dt, \qquad L' = L'(q', p'). \tag{c}$$

Then, standard transformations, as in the old variables (§8.2) lead us to the new Hamiltonian equations:

$$dq_{k'}/dt = \partial H'/\partial p_{k'}, \qquad dp_{k'}/dt = -\,\partial H'/\partial q_{k'}, \tag{d}$$

where

$$\begin{aligned} H' &\equiv \sum p_{k'}\dot{q}_{k'} - L' \qquad \text{[invoking (8.8.12)]} \\ &= \left[\sum p_k\dot{q}_k - (dF/dt - \partial F/\partial t)\right] - (L - dF/dt) \\ &= \left(\sum p_k\dot{q}_k - L\right) + \partial F/\partial t = H + \partial F/\partial t, \end{aligned} \tag{e}$$

as before. Hence, the fundamental result: *under a canonical transformation, the canonical equations preserve their form.*

Example 8.8.5 *Canonical Transformation: The Harmonic Oscillator*. Let us consider a linear harmonic oscillator of mass m and stiffness constant k, and, therefore,

Lagrangean: $\quad L = (1/2)[m(\dot{q})^2 - kq^2] \;\Rightarrow\; p \equiv \partial L/\partial\dot{q} = m\dot{q} \;\Rightarrow\; \dot{q} = p/m,$ (a)

Hamiltonian: $\quad H = p\dot{q} - L = \cdots = p^2/2m + kq^2/2;$ (b)

and, therefore, Hamiltonian equations of (free and undamped) motion:

$$\dot{q} = \partial H/\partial p = p/m, \qquad \dot{p} = -\partial H/\partial q = -kq, \tag{c}$$

whose solution is well known [eliminating p between (c) we obtain the Lagrangean equation $m\ddot{q} + kq = 0$]. Instead, let us here consider the canonical transformation with generating function

$$F = F_1(q, q') = c\,q^2\cot(q') \qquad (c = \text{a constant}), \tag{d}$$

and, therefore, by (8.8.15), transformation equations

$$p = \partial F_1/\partial q = 2c\,q\cot(q'), \qquad p' = -\partial F_1/\partial q' = c\,q^2\,\mathrm{cosec}^2(q'),$$
$$H' = H + \partial F_1/\partial t = H; \tag{e}$$

or, solving them for the old variables in terms of the new variables,

$$p = (4c\,p')^{1/2}\cos(q'), \qquad q = (p'/c)^{1/2}\sin(q'), \tag{f}$$

$$H' = (1/2)(p^2/m + kq^2) = \cdots = (1/2)\big[(4cp'/m)\cos^2(q') + (kp'/c)\sin^2(q')\big]$$
$$= (kp'/2c)\big[\sin^2(q') + (4c^2/mk)\cos^2(q')\big] \qquad [\text{choosing } 4c^2 = mk]$$
$$= kp'/2c = (k/m)^{1/2}p' \equiv \omega\,p' \qquad [\omega^2 \equiv k/m\text{: oscillation frequency}]. \tag{g}$$

Hence, the Hamiltonian equations in these new variables are

$$dp'/dt = -\partial H'/\partial q' = 0 \;\Rightarrow\; p' = constant \equiv c' \qquad (q' \text{ is ignorable}), \tag{h}$$
$$dq'/dt = +\partial H'/\partial p' = \omega \;\Rightarrow\; q' = \omega\,t + c'' \qquad (c''\text{: integration constant}). \tag{i}$$

Substituting (h, i) back in (f) we, naturally, obtain the (well-known) old variable solution.

Geometrical Interpretation of these Solutions in Phase Space

(i) in the *old* variables (q, p) the representative point describes an *ellipse* whose dimensions and sense of traverse are determined by the system constants and initial conditions ($\Rightarrow$ *energy* $\equiv E = H = \omega\,p' =$ *constant*; fig. 8.7).

(ii) In the *new* variables (q', p') the corresponding system point moves on the straight line

$$p' = E/\omega = constant. \tag{j}$$

The ellipse points $(1, 2, 3, 4)$ are mapped into the straight line points $(1', 2', 3', 4')$.

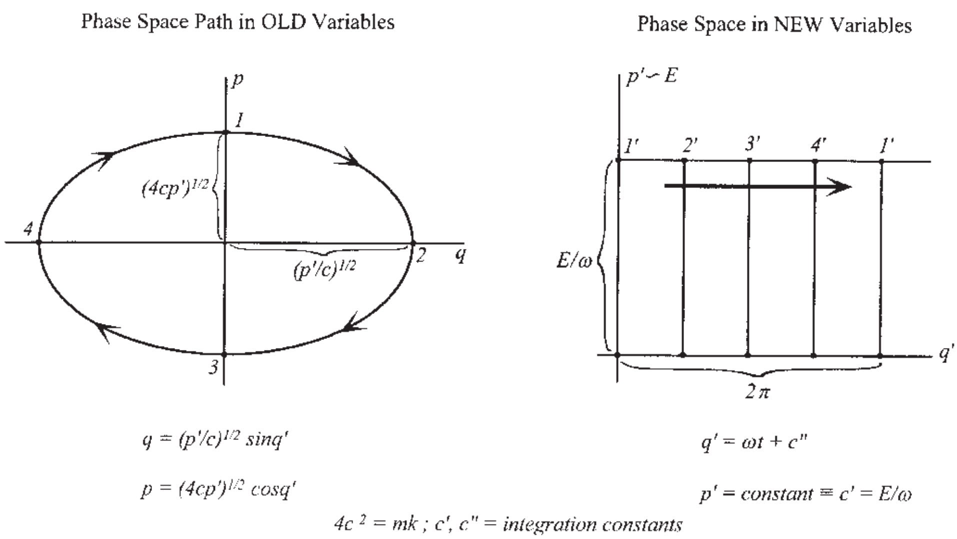

Figure 8.7 Paths of harmonic oscillator in phase space, in old and new variables.

This procedure—that is, the search for new canonical variables in which one or more (or all!) of the coordinates are ignorable—is systematized in §8.10. These investigations show that *every holonomic, scleronomic, and potential system with n DOF can be transformed by a canonical transformation into one with Hamiltonian* $2H = \sum (p_{k'})^2$*; and, therefore, equations of motion:* $p_{k'} = constant \equiv \Psi_{k'}$, $q_{k'} = \Psi_{k'} t + constant$; a fundamental result that is behind such important concepts as action–angle variables and complete separability/integrability (§8.14).

Example 8.8.6

(i) *Generalized Canonical Transformations* (GCT) are CT that, in addition to the fundamental definition (8.8.12):

$$\delta F = \sum p_k \,\delta q_k - \sum p_{k'} \,\delta q_{k'}, \tag{a}$$

also satisfy, say, holonomic constraints like

$$C_D(q, q') = 0 \qquad [D = 1, \ldots, m\text{: rank of corresponding Jacobian} = m(\leq n)] \tag{b}$$

or, in virtual form,

$$\delta C_D = \sum (\partial C_D/\partial q_k)\,\delta q_k + \sum (\partial C_D/\partial q_{k'})\,\delta q_{k'} = 0. \tag{c}$$

Applying the Lagrangean multiplier method, we readily see that, in this case, $(F \to F_1)$, eqs. (8.8.15) must now be replaced by

$$p_k = \partial F_1/\partial q_k + \sum \lambda_D(\partial C_D/\partial q_k), \qquad p_{k'} = -\partial F_1/\partial q_{k'} - \sum \lambda_D(\partial C_D/\partial q_{k'}), \tag{d}$$

which, along with (b), constitute a system of $2n + m$ equations for the $2n + m$ q's, p's, λ's (multipliers), in terms of the q's, p's.

(ii) For the *point transformation*, for which [recalling (8.8.2) and (8.8.4)]

$$q_k = q_k(q_{k'}), \qquad p_{k'} = \sum (\partial q_k/\partial q_{k'}) p_k, \tag{e}$$

the definition (8.8.12), (a) gives

$$\begin{aligned} &\sum p_k \,\delta q_k - \sum p_{k'} \,\delta q_{k'} \\ &\quad = \sum p_k \Big(\sum (\partial q_k/\partial q_{k'})\,\delta q_{k'} \Big) - \sum p_{k'} \,\delta q_{k'} \\ &\quad = \sum \Big[\sum (\partial q_k/\partial q_{k'}) p_k - p_{k'} \Big] \,\delta q_{k'} = 0; \end{aligned} \tag{f}$$

that is, for such a transformation, $F \to F_1(q, q') \equiv 0$ (however, $F \to F_2, F_3, \ldots \neq 0$). Such transformations can be viewed as the following choices of the earlier GCT case (b):

$$C_D \equiv q_D - \phi_D(q_{k'}) = 0, \qquad \lambda_D = p_D. \tag{g}$$

For additional related results, see, for example, Whittaker (1937, pp. 294–296), Hamel (1949, pp. 292, 666).

Example 8.8.7 *Time Transformation.* The general transformation $(t, q, p) \to (t', q', p')$:

$$q_k = q_k(t', q', p'), \qquad p_k = p_k(t', q', p'), \qquad t = t(t', q', p') \tag{a}$$

is called *canonical* if:

(i) *Jacobian*: $\partial(t, q, p)/\partial(t', q', p') \neq 0$, and
(ii) There exist three functions $H(t, q, p)$, $H'(t', q', p')$, $F'(t, q, p)$, such that

$$\sum p_k \, dq_k - H \, dt = \sum p_{k'} \, dq_{k'} - H' \, dt' + dF', \tag{b}$$

identically, upon utilization of (a) in it.

It is not hard to show that such a generalized CT also leaves the form of the Hamiltonian equations unaltered. Here, we have treated only the special case $t' = t$; for a fuller discussion, see books on partial differential equations, for example, Carathéodory (1935).

Problem 8.8.3 *Point Transformation: Polar Cylindrical Coordinates.* With the help of (8.8.4), show that under a (point) transformation from rectangular Cartesian coordinates q_k: (x, y, z) to polar cylindrical ones $q_{k'}$: (r, ϕ, z), the corresponding momenta transform from the rectangular Cartesian p_k: $p_{x,y,z}$ to the following polar $p_{k'}$: $p_{r,\phi,z}$:

$$p_r = [x/(x^2 + y^2)^{1/2}]p_x + [y/(x^2 + y^2)^{1/2}]p_y, \tag{a}$$

$$p_\phi = (-y)p_x + (x)p_y, \tag{b}$$

$$p_z = p_z. \tag{c}$$

Problem 8.8.4 Show that the transformation

$$q = p' \sin(q'), \qquad p = p' \cos(q') \tag{a}$$

is *not* canonical, but that the following, is:

$$q = (2p')^{1/2} \sin(q'), \qquad p = (2p')^{1/2} \cos(q'). \tag{b}$$

Problem 8.8.5 Show that the following generating functions produce the canonical transformations indicated:

(i) $$F = \sum q_k q_{k'}: \qquad p_k = q_{k'}, \qquad p_{k'} = -q_k, \tag{a}$$

(ii) $$F = \sum q_k p_{k'}: \qquad p_k = p_{k'}, \qquad q_{k'} = q_k. \tag{b}$$

[This *identity* transformation can also be achieved with $F = -\sum p_k q_{k'}$.]

(iii) $$F = \sum p_k q_{k'}: \qquad q_k = -q_{k'}, \qquad p_{k'} = -p_k. \tag{c}$$

[This *spatial inversion*, or *reflection*, transformation can also be achieved with $F = -\sum q_k p_{k'}$.]

(iv) $$F = \sum p_k p_{k'}: \qquad q_k = -p_{k'}, \qquad q_{k'} = p_k. \tag{d}$$

HINTS

(i) All these F's have the form $\sum x_k y_{k'}$, where x_k, $y_{k'}$ are any of the four possible pairs of $(q, p; q', p')$. (ii) The first and fourth cases coincide. (iii) In all cases, $H' = H$.

Problem 8.8.6 We have already seen (ex. 3.5.11) that the two Lagrangeans

$$L \qquad \text{and} \qquad L' = L + df(t, q)/dt \tag{a}$$

[where $f(t, q) =$ arbitrary differentiable function] produce the same Lagrangean equations of motion, that is, $E_k(L) = E_k(L')$. Show that under such a "gauge" transformation, the corresponding Hamiltonians

$$H \equiv \sum (\partial L/\partial \dot{q}_k)\dot{q}_k - L \qquad \text{and} \qquad H' \equiv \sum (\partial L'/\partial \dot{q}_k)\dot{q}_k - L' \tag{b}$$

are related by

$$H' = H - \partial f/\partial t. \tag{c}$$

Problem 8.8.7 (Butenin, 1971, pp. 149–150). Consider a particle P of mass m whose kinetic and potential energies, in polar cylindrical coordinates $r, \phi, z = q_{1,2,3}$, are, respectively,

$$2T = m[(\dot{q}_1)^2 + {q_1}^2(\dot{q}_2)^2 + (\dot{q}_3)^2], \quad V = m\,g\,q_3 \quad (g = \text{gravitational constant}). \tag{a}$$

Show that:

(i) Its Hamiltonian in these variables (i.e., q's, plus corresponding momenta p's) is

$$H = H(q, p) = (1/2m)\left[{p_1}^2 + (1/{q_1}^2){p_2}^2 + {p_3}^2\right] + m\,g\,q_3. \tag{b}$$

(ii) Under a canonical transformation with generating function

$$F = p_{1'}\,q_1 \cos(q_2) + p_{2'}\,q_1 \sin(q_2) + p_{3'}\,q_3 = F(q, p') \equiv F_2, \tag{c}$$

the *new* Hamiltonian $H'(= H)$ is

$$H' = H'(q', p') = (1/2m)\left[(p_{1'})^2 + (p_{2'})^2 + (p_{3'})^2\right] + m\,g\,q_{3'}. \tag{d}$$

Interpret the q's and p's geometrically.

Problem 8.8.8 We have already seen that the transformation

$$q_{k'} = q_{k'}(q, p), \qquad p_{k'} = p_{k'}(q, p) \tag{a}$$

is canonical if, and only if, the differential form

$$\delta F_1 = \sum p_k\,\delta q_k - \sum p_{k'}\,\delta q_{k'}, \tag{b}$$

after replacement of p_k and δq_k from (the inverse of) (a), is *exact* in the q' and p'; or similarly, if, after replacement of p' and $\delta q'$ from (a), it is exact in the q, p.

Show that, instead of δF_1, we may choose—to test for exactness—any of the following three interrelated differential forms:

$$\delta F_2 = \sum p_k\,\delta q_k + \sum q_{k'}\,\delta p_{k'} \qquad \Big[= \delta F_1 + \delta\Big(\sum p_{k'}q_{k'}\Big)\Big], \tag{c}$$

$$\delta F_3 = -\sum q_k\,\delta p_k - \sum p_{k'}\,\delta q_{k'} \qquad \Big[= \delta F_1 - \delta\Big(\sum p_k q_k\Big)\Big], \tag{d}$$

$$\delta F_4 = -\sum q_k\,\delta p_k + \sum q_{k'}\,\delta p_{k'} \qquad \Big[= \delta F_1 - \delta\Big(\sum p_k q_k - \sum p_{k'}q_{k'}\Big)\Big], \tag{e}$$

that is, (a) is canonical if, and only if, any one of (b–e) is exact in the new (old) variables after replacement of the old (new) variables and their variations, from (a), in terms of the new (old) variables and their variations.

HINT

Recall table 8.1.

8.9 CANONICITY CONDITIONS VIA POISSON'S BRACKETS (PB)

Here, we show that these brackets, already introduced in §8.7 in connection with the method of variations of constants, appear naturally in the formulation of alternative conditions for canonicity. Let us, therefore, summarize their relevant theory.

Poisson Brackets; Theorem of Poisson–Jacobi

Let $f = f(t, q, p)$ be an arbitrary differentiable dynamical quantity. Then, we have, successively,

$$\begin{aligned} df/dt &= \partial f/\partial t + \sum \big[(\partial f/\partial q_k)(dq_k/dt) + (\partial f/\partial p_k)(dp_k/dt)\big] \\ &\qquad\qquad\qquad\qquad [\text{invoking Hamilton's equations}] \\ &= \partial f/\partial t + \sum \big[(\partial f/\partial q_k)(\partial H/\partial p_k) + (\partial f/\partial p_k)(-\partial H/\partial q_k + Q_k)\big] \\ &= \partial f/\partial t + (H, f) + \sum (\partial f/\partial p_k)Q_k, \end{aligned} \tag{8.9.1}$$

where

$$(H, f) \equiv \sum \big[(\partial H/\partial p_k)(\partial f/\partial q_k) - (\partial H/\partial q_k)(\partial f/\partial p_k)\big]: \quad \textit{Poisson bracket of } H \text{ and } f. \tag{8.9.2}$$

Hence, for f to be an *integral of the motion* (i.e., $df/dt = 0$), we must have

$$\partial f/\partial t + \sum (\partial f/\partial p_k)Q_k + (H, f) = 0,$$

or, assuming that $f = f(q, p)$ and $Q_k = 0$,

$$(H, f) = 0; \tag{8.9.3}$$

that is, its PB with the Hamiltonian of its variables must be *zero* (in this case, df/dt can be expressed without explicit reference to time).

The PB of any two variables, f and g, defined in complete analogy to (8.9.2) by

$$(f, g) \equiv \sum \left[(\partial f/\partial p_k)(\partial g/\partial q_k) - (\partial f/\partial q_k)(\partial g/\partial p_k)\right]$$
$$\equiv \sum \left[\partial(f, g)/\partial(p_k, q_k)\right], \tag{8.9.4}$$

has the following, easily verifiable, properties:

- $(f, g) = -(g, f) = (-g, f)$ (antisymmetry), (8.9.5a)

  $\Rightarrow (f, f) = 0,$ (8.9.5b)

- $(f, c) = 0$ (c = a constant), (8.9.5c)

- $(f_1 + f_2, g) = (f_1, g) + (f_2, g)$ (distributivity), (8.9.5d)

- $(f_1 f_2, g) = f_1(f_2, g) + f_2(f_1, g)$ (8.9.5e)

  $\Rightarrow (cf, g) = c(f, g)$ (c = a constant),

  $\Rightarrow$ if $f = \sum c_k f_k$, then $(f, g) = \sum c_k(f_k, g)$ (c_k = constants),

- $\partial/\partial t(f, g) = (\partial f/\partial t, g) + (f, \partial g/\partial t)$ ("Leibniz rule"). (8.9.5f)

  [Actually, $\partial/\partial x(f, g) = (\partial f/\partial x, g) + (f, \partial g/\partial x)$, x = any variable.] (8.9.5g)

REMARKS ON NOTATION

(i) Unfortunately, here too, no uniformity of notation for these brackets exists. A number of famous authors, such as (alphabetically): Appell, Gantmacher, Hagihara, Lanczos, Lur'e, Synge, Whittaker, et al. define PB as the *opposite* of ours, that is, as

$$(f, g) \equiv \sum \left[(\partial f/\partial q_k)(\partial g/\partial p_k) - (\partial f/\partial p_k)(\partial g/\partial q_k)\right]. \tag{8.9.6}$$

Our choice (8.9.4) follows the practices of such (equally famous) authors as: S. Flügge, Hamel, Landau/Lifshitz, Lindsay/Margenau, Prange, Schaefer/Päsler, Routh, Scheck, Spiegel, Tabor, et al., including Poisson himself (1809)! Therefore, a certain caution should be exercised when comparing various references.

(ii) Also, certain authors (especially those in quantum mechanics; e.g., Dirac) denote our Lagrangean brackets, [...], by {...}; and our Poisson brackets, (...), by [...].

With the help of the above properties, we can easily prove the following useful theorems (by taking as f/g one of the *coordinates/momenta*):

- $(f, q_k) = \partial f/\partial p_k,$ (8.9.7a)

- $(f, p_k) = -\partial f/\partial q_k,$ (8.9.7b)

- $(q_k, q_l) = 0,$ (8.9.7c)

- $(p_k, p_l) = 0,$ (8.9.7d)

- $(p_k, q_l) = \delta_{kl}$ (= *Kronecker delta*). (8.9.7e)

The last three types of brackets are called *fundamental*, or *basic*, PB.

Identity of Poisson–Jacobi

Below we prove that, for any three variables f, g, h (at least twice continuously differentiable), the following important identity holds:

$$\big(f, (g, h)\big) + \big(g, (h, f)\big) + \big(h, (f, g)\big) = 0; \tag{8.9.8a}$$

or, equivalently [invoking (8.9.5a)],

$$\big((f, g), h\big) + \big((g, h), f\big) + \big((h, f), g\big) = 0. \tag{8.9.8b}$$

(i) First Proof

Using the earlier definitions, we have, successively (with $k, l = 1, \ldots, n$),

$$\begin{aligned}
\big((f, g), h\big) &= \sum \big[(\partial(f, g)/\partial p_k)(\partial h/\partial q_k) - (\partial(f, g)/\partial q_k)(\partial h/\partial p_k)\big] \\
&= \sum\sum \big\{\partial/\partial p_k\big[(\partial f/\partial p_l)(\partial g/\partial q_l) - (\partial f/\partial q_l)(\partial g/\partial p_l)\big](\partial h/\partial q_k) \\
&\qquad - \partial/\partial q_k[(\partial f/\partial p_l)(\partial g/\partial q_l) - (\partial f/\partial q_l)(\partial g/\partial p_l)](\partial h/\partial p_k)\big\} \\
&= \sum\sum \big[(\partial^2 f/\partial q_k \partial q_l)(\partial g/\partial p_l)(\partial h/\partial p_k) + (\partial f/\partial q_l)(\partial^2 g/\partial q_k \partial p_l)(\partial h/\partial p_k) \\
&\qquad - (\partial^2 f/\partial q_k \partial p_l)(\partial g/\partial q_l)(\partial h/\partial p_k) - (\partial f/\partial p_l)(\partial^2 g/\partial q_k \partial q_l)(\partial h/\partial p_k) \\
&\qquad - (\partial^2 f/\partial p_k \partial q_l)(\partial g/\partial p_l)(\partial h/\partial q_k) - (\partial f/\partial q_l)(\partial^2 g/\partial p_k \partial p_l)(\partial h/\partial q_k) \\
&\qquad + (\partial^2 f/\partial p_k \partial p_l)(\partial g/\partial q_l)(\partial h/\partial q_k) + (\partial f/\partial p_l)(\partial^2 g/\partial p_k \partial q_l)(\partial h/\partial q_k)\big];
\end{aligned} \tag{8.9.8c}$$

and cyclically for the other 2×8 terms of $\big((g, h), f\big)$ and $\big((h, f), g\big)$. Then, it is not hard to see that *all 24 terms cancel in pairs*. This is a straightforward proof, but since it is long and visually tedious, we present below a shorter alternative.

(ii) Second Proof

We have, successively,

$$\begin{aligned}
&\big(f, (g, h)\big) - \big(g, (f, h)\big) \\
&\quad = \Big(f, \sum \big[(\partial g/\partial p_k)(\partial h/\partial q_k) - (\partial g/\partial q_k)(\partial h/\partial p_k)\big]\Big) \\
&\qquad - \Big(g, \sum \big[(\partial f/\partial p_k)(\partial h/\partial q_k) - (\partial f/\partial q_k)(\partial h/\partial p_k)\big]\Big) \\
&\qquad\qquad \text{[invoking properties (8.9.5) and then regrouping terms]} \\
&\quad = \sum \big\{ - (\partial h/\partial p_k)[(\partial f/\partial q_k, g) + (f, \partial g/\partial q_k)] \\
&\qquad\qquad + (\partial h/\partial q_k)[(\partial f/\partial p_k, g) + (f, \partial g/\partial p_k)]\big\} \\
&\qquad\qquad + \sum \big[(\partial g/\partial p_k)(f, \partial h/\partial q_k) - (\partial g/\partial q_k)(f, \partial h/\partial p_k) \\
&\qquad\qquad - (\partial f/\partial p_k)(g, \partial h/\partial q_k) + (\partial f/\partial q_k)(g, \partial h/\partial p_k)\big].
\end{aligned} \tag{8.9.8d}$$

Now: (a) by (8.9.5g) the *first* sum transforms to

$$\sum \big[-(\partial h/\partial p_k)\,\partial/\partial q_k(f,g) + (\partial h/\partial q_k)\,\partial/\partial p_k(f,g)\big] = -\big(h,(f,g)\big),$$

while (b) the *second* sum can be shown (by direct expansion) to vanish. Therefore,

$$\big(f,(g,h)\big) - \big(g,(f,h)\big) = -\big(h,(f,g)\big),$$

or, rearranging, while using (8.9.5a, c, e),

$$\big(f,(g,h)\big) + \big(g,(h,f)\big) + \big(h,(f,g)\big) = 0, \quad \text{Q.E.D.} \tag{8.9.8e}$$

[For alternative, indirect proofs, see, for example, Appell (1953, pp. 445–447; and references cited therein), Landau and Lifshitz (1960, pp. 136–137).]

The above Poisson–Jacobi identity allows us to prove the following fundamental theorem.

Theorem of Poisson–Jacobi

If f and g are any two integrals of the motion, so is their PB; that is, if $f = c_1$ and $g = c_2$, then $(f,g) = c_3$ ($c_{1,2,3}$ = constants).

We distinguish *two* cases:

(i) $\partial f/\partial t = 0$ and $\partial g/\partial t = 0$. Then, by (8.9.1–3),

$$(f,H) = 0, \qquad (g,H) = 0 \qquad \text{(identically)}, \tag{8.9.9a}$$

and, therefore, also

$$\big((f,H),h\big) = 0, \qquad \big((g,H),f\big) = 0 \qquad \text{(identically)}; \tag{8.9.9b}$$

and substituting the above in the Poisson–Jacobi identity (8.9.8b), with $h \to H$, we immediately obtain

$$\big((f,g),H\big) = 0 \;\Rightarrow\; (f,g) = \textit{constant} \qquad \text{[invoking (8.9.5c)]}, \quad \text{Q.E.D.} \tag{8.9.9c}$$

(ii) $\partial f/\partial t \neq 0$ and $\partial g/\partial t \neq 0$. Then, by (8.9.1),

$$df/dt = \partial f/\partial t + (H,f) \equiv 0, \qquad dg/dt = \partial g/\partial t + (H,g) \equiv 0, \tag{8.9.9d}$$

and as a result the Poisson–Jacobi identity (8.9.8a), with $h \to H$, yields, successively,

$$\begin{aligned} 0 &= \big(H,(f,g)\big) + \big(f,(g,H)\big) + \big(g,(H,f)\big) \\ &= \big(H,(f,g)\big) + (f, \partial g/\partial t) - (g, \partial f/\partial t) \\ &= \big(H,(f,g)\big) + (f, \partial g/\partial t) + (\partial f/\partial t, g) \\ &= \big(H,(f,g)\big) + \partial/\partial t(f,g), \end{aligned} \tag{8.9.9e}$$

that is, by (8.9.3), (f,g) is also an integral. This presents us with *two* possibilities: (a) either $(f,g) =$ *function of* $f = c_1$ *and* $g = c_2$, and therefore does not constitute a new integral; or (b) $(f,g) =$ *new function, not depending on* c_1 *and* c_2, and does constitute a new, third, integral.

However, frequently, such new integrals are trivial; for example, using $f, g = \textit{constant}$, $p_k, p_l = \textit{constant}$, we simply obtain $0 = \textit{constant}$. As MacMillan puts it: "Notwithstanding the fact that Poisson's theorem gives an interesting relation among integrals, it cannot be said that it has led to integrals that were not already known. As a matter of fact it has been singularly sterile" (1936, p. 383).

COROLLARY

Let $\partial H/\partial t = 0$, then $H = c_1$ (energy integral). If $f(t, q, p) = c_2$ is a second integral, then, by the Poisson–Jacobi theorem, $(f, H) = c_3$ is also an integral. But, in this case,

$$df/dt = \partial f/\partial t + (H, f) \;\Rightarrow\; dc_2/dt = \partial f/\partial t - c_3 = 0; \tag{8.9.9f}$$

that is, if $f = c_2$ is a time-containing integral, so is $\partial f/\partial t = c_3$; and, similarly, $\partial^2 f/\partial t^2 = c_4$, and so on; however, if $\partial f/\partial t = 0$, then $c_3 = 0$ and $(f, H) = 0$.

For *group-theoretic* aspects of this theorem (Lie) and its relation to the famous *Theorema Gravissimum* of Jacobi (1842–1843, publ. 1866), see, for example, Hamel (1949, pp. 297–299, 301–302); also Frank (1935, p. 61 ff.).

Poisson Brackets (PB) and Canonical Transformations (CT)

Here, with the help of PB, we (i) show that *these brackets are invariant under CT*, and then (ii) obtain *conditions for the transformation* (8.8.8a,b) *to be canonical* [alternative to (8.8.10–12)].

(i) Let us prove that

$$(f, g)_{q,p} = (f, g)_{q',p'} = \cdots, \tag{8.9.10}$$

where f and g keep their *value* but not necessarily their *form* in the various canonical coordinates involved.

We begin by proving it for the fundamental PB (8.9.7e):

$$(p_{k'}, q_{l'})_{q,p} = (p_{k'}, q_{l'})_{q',p'} = \cdots = \delta_{k'l'}. \tag{8.9.10a}$$

Using the generating function $F = F_1 = F_1(t, q, q')$ and corresponding equations (8.8.15), we readily find

$$\partial p_k/\partial q_{k'} = \partial/\partial q_{k'}(\partial F_1/\partial q_k) = \partial/\partial q_k(\partial F_1/\partial q_{k'}) = -\partial p_{k'}/\partial q_k; \tag{8.9.10b}$$

and, similarly, using F_2, F_3, F_4 and (8.8.17, 19, 21), we obtain

$$\partial q_k/\partial q_{k'} = \partial p_{k'}/\partial p_k, \qquad \partial q_k/\partial p_{k'} = -\partial q_{k'}/\partial p_k, \qquad \partial p_k/\partial p_{k'} = \partial q_{k'}/\partial q_k. \tag{8.9.10c}$$

With the help of these results, we find

$$\begin{aligned}(p_{k'}, q_{l'})_{q,p} &\equiv \sum \left[(\partial p_{k'}/\partial q_k)(\partial q_{l'}/\partial q_k) - (\partial p_{k'}/\partial q_k)(\partial q_{l'}/\partial p_k)\right] \\ &= \sum \left[(\partial p_{k'}/\partial p_k)(\partial p_k/\partial p_{l'}) - (\partial p_{k'}/\partial q_k)(-\partial q_k/\partial p_{l'})\right] \\ &= \partial p_{k'}/\partial p_{l'} = \delta_{k'l'};\end{aligned} \tag{8.9.10d}$$

and

$$(p_{k'}, q_{l'})_{q',p'} \equiv \sum \left[(\partial p_{k'}/\partial p_{r'})(\partial q_{l'}/\partial q_{r'}) - (\partial p_{k'}/\partial q_{r'})(\partial q_{l'}/\partial p_{r'})\right]$$
$$= \sum \left[(\delta_{k'r'})(\delta_{l'r'}) - (0)(0)\right] = \delta_{k'l'}; \quad \text{Q.E.D.} \qquad (8.9.10e)$$

Similarly, we show that

$$(q_{k'}, q_{l'})_{q,p} = (q_{k'}, q_{l'})_{q',p'} = 0, \qquad (8.9.10f)$$
$$(p_{k'}, p_{l'})_{q,p} = (p_{k'}, p_{l'})_{q',p'} = 0. \qquad (8.9.10g)$$

Now to the demonstration of (8.9.10). We have, successively,

$$(f, g)_{q',p'} \equiv \sum \left[(\partial f/\partial p_{r'})(\partial g/\partial q_{r'}) - (\partial f/\partial q_{r'})(\partial g/\partial p_{r'})\right]$$
$$= \sum \sum \left\{(\partial f/\partial p_{r'})\left[(\partial g/\partial q_r)(\partial q_r/\partial q_{r'}) + (\partial g/\partial p_r)(\partial p_r/\partial q_{r'})\right]\right.$$
$$\left. - (\partial f/\partial q_{r'})\left[(\partial g/\partial q_r)(\partial q_r/\partial p_{r'}) + (\partial g/\partial p_r)(\partial p_r/\partial q_{r'})\right]\right\}$$
$$= \sum \left[(\partial g/\partial q_r)(f, q_r)_{q',p'} + (\partial g/\partial p_r)(f, p_r)_{q',p'}\right]. \qquad (8.9.10h)$$

Applying the above, first for $f \to q_r$ and $g \to f$, and then for $f \to q_r$ and $g \to f$, while invoking (8.9.10e–g), we get, respectively,

$$(q_r, f)_{q',p'} = \sum \left[(\partial f/\partial q_l)(q_r, q_l)_{q',p'} + (\partial f/\partial p_l)(q_r, p_l)_{q',p'}\right]$$
$$= \sum \left[(\partial f/\partial q_l)(0) + (\partial f/\partial p_l)(-\delta_{lr})\right] = -(\partial f/\partial p_r), \qquad (8.9.10i)$$
$$(p_r, f)_{q',p'} = \sum \left[(\partial f/\partial q_l)(p_r, q_l)_{q',p'} + (\partial f/\partial p_l)(p_r, p_l)_{q',p'}\right]$$
$$= \sum \left[(\partial f/\partial q_l)(\delta_{rl}) + (\partial f/\partial p_l)(0)\right] = \partial f/\partial q_r. \qquad (8.9.10j)$$

Finally, substituting (8.9.10i, j) back in (8.9.10h), while invoking the antisymmetry of PB, we find

$$(f, g)_{q',p'} = \sum \left[(\partial f/\partial p_r)(\partial g/\partial q_r) - (\partial f/\partial q_r)(\partial g/\partial p_r)\right] \equiv (f, g)_{q,p} \quad \text{Q.E.D.} \qquad (8.9.10k)$$

[For an alternative derivation, see also Landau and Lifshitz (1960, p. 145); and ex. 8.9.1 below, with direct proof.]

In view of this fundamental theorem, *the PB subscripts become unnecessary, and will, henceforth, be omitted.*

(ii) Let us now express the conditions for the canonicity of the transformations (8.8.8a, b)

$$q' = q'(t, q, p), \qquad p' = p(t, q, p), \qquad (8.9.11a)$$

via PB. The fundamental relevant definition/requirement (8.8.12) yields, successively,

$$\begin{aligned}
&\sum p_k\,\delta q_k - \sum p_{k'}\,\delta q_{k'} \\
&\quad = \sum p_k\,\delta q_k - \sum p_{k'}\Big\{\sum\,[(\partial q_{k'}/\partial q_k)\,\delta q_k + (\partial q_{k'}/\partial p_k)\,\delta p_k]\Big\} \\
&\quad = \sum \Big\{\Big[p_k - \sum p_{k'}(\partial q_{k'}/\partial q_k)\Big]\,\delta q_k - \sum p_{k'}(\partial q_{k'}/\partial p_k)\,\delta p_k\Big\} \\
&\quad = \sum\,[(\ldots)_k\,\delta q_k + (\ldots)_k\,\delta p_k]. \qquad (8.9.11\text{b})
\end{aligned}$$

As is well-known (§2.3 ff.), for this differential expression to be an exact (virtual) differential, the following *three* groups of necessary and sufficient conditions must hold [identically, and for all values of their free (= unsummed) indices]:

(a) $\delta p'$s: $$\partial/\partial p_l\Big[-\sum p_{k'}(\partial q_{k'}/\partial p_k)\Big] = \partial/\partial p_k\Big[-\sum p_{k'}(\partial q_{k'}/\partial p_l)\Big], \qquad (8.9.11\text{c})$$

or, carrying out the differentiations and recalling the earlier definitions of Lagrangean brackets (8.7.13),

$$\sum\,[(\partial p_{k'}/\partial p_l)(\partial q_{k'}/\partial p_k) - (\partial p_{k'}/\partial p_k)(\partial q_{k'}/\partial p_l)] \equiv [p_l, p_k] = 0; \qquad (8.9.11\text{d})$$

and

(b) $\delta q'$s: $$\partial/\partial q_l\Big[p_k - \sum p_{k'}(\partial q_{k'}/\partial q_k)\Big] = \partial/\partial q_k\Big[p_l - \sum p_{k'}(\partial q_{k'}/\partial q_l)\Big], \qquad (8.9.11\text{e})$$

or, carrying out the differentiations and noting that the q's and p's are mutually *independent*,

$$\sum\,[(\partial p_{k'}/\partial q_l)(\partial q_{k'}/\partial q_k) - (\partial p_{k'}/\partial q_k)(\partial q_{k'}/\partial q_l)] \equiv [q_l, q_k] = 0; \qquad (8.9.11\text{f})$$

and

(c) $\delta q'$s and $\delta p'$s: $$\partial/\partial q_l\Big[-\sum p_{k'}(\partial q_{k'}/\partial p_k)\Big] = \partial/\partial p_k\Big[p_l - \sum p_{k'}(\partial q_{k'}/\partial q_l)\Big], \qquad (8.9.11\text{g})$$

or

$$\begin{aligned}
&\sum\,[(\partial p_{k'}/\partial q_l)(\partial q_{k'}/\partial p_k) - (\partial p_{k'}/\partial p_k)(\partial q_{k'}/\partial q_l)] = [q_l, p_k] = -(\partial p_l/\partial p_k) = -\delta_{kl} \\
&\qquad\qquad \Rightarrow [p_k, q_l] = \delta_{kl}. \qquad (8.9.11\text{h})
\end{aligned}$$

Similarly, the exactness conditions of

$$\sum p_k\,\delta q_k - \sum p_{k'}\,\delta q_{k'} = \sum\,[(\ldots)_{k'}\,\delta q_{k'} + (\ldots)_{k'}\,\delta p_{k'}], \qquad (8.9.11\text{i})$$

lead to

$$[p_{l'}, p_{k'}] = 0, \qquad [q_{l'}, q_{k'}] = 0, \qquad [p_{l'}, q_{k'}] = \delta_{l'k'}. \qquad (8.9.11\text{j})$$

Although these canonicity conditions are in terms of the *Lagrangean* brackets, yet noting that in there the roles of q's, p's and q''s, p''s can be exchanged, and that [due to (8.9.10) and (8.7.25)] *both Poisson and Lagrange brackets are canonically invariant,* we easily deduce the earlier PB conditions (8.9.10a, f, g):

$$(p_{l'}, p_{k'}) = 0, \qquad (q_{l'}, q_{k'}) = 0, \qquad (p_{l'}, q_{k'}) = \delta_{l'k'}. \tag{8.9.11k}$$

Equations (8.9.11j, k) have the following interesting geometrical interpretation. Let us consider, for simplicity, a one-DOF system. Under the canonical transformation $(q, p) \to (q', p')$, the region of allowable values of q and p—namely, R—is transformed into a region R' for the corresponding values of q' and p'. If all these coordinates are assumed rectangular Cartesian, the areas of R and R' are, respectively (for a *fixed time*, if the transformation is explicitly time-dependent),

$$A_R \equiv A = \iint dq\, dp \qquad \text{and} \qquad A_{R'} \equiv A' = \iint dq'\, dp'. \tag{8.9.12a}$$

But, by well-known theorems of advanced (or vector) calculus, we have, successively,

$$\begin{aligned} A' &= \iint dq'\, dp' = \iint \big[\partial(q', p')/\partial(q, p)\big]\, dq\, dp \\ &= \iint \big[(\partial q'/\partial q)(\partial p'/\partial p) - (\partial q'/\partial p)(\partial p'/\partial q)\big]\, dq\, dp \\ &= \iint (p', q')_{q,p}\, dq\, dp = \iint (1)\, dq\, dp \qquad (\text{since } \delta_{11} = 1) \\ &= \iint [p, q]\, dq\, dp = \iint (1)\, dq\, dp = A; \end{aligned} \tag{8.9.12b}$$

and, similarly,

$$\begin{aligned} A &= \iint dq\, dp = \iint \big[\partial(q, p)/\partial(q', p')\big]\, dq'\, dp' \\ &= \iint (p, q)_{q',p'}\, dq'\, dp' = \iint (1)\, dq'\, dp' \\ &= \iint [p', q']\, dq'\, dp' = \iint (1)\, dq'\, dp' = A'. \end{aligned} \tag{8.9.12c}$$

In words: *canonical transformations are area-preserving*, among their various representations. Similarly, for the *n-DOF* case, but with areas replaced by *volumes* (*Liouville's theorem*); see also "Integral Invariants" (§8.12).

Example 8.9.1 *Direct Proof of the Canonical Invariance of PB.* Under a canonical transformation $(q, p) \to (q', p')$, an arbitrary (differentiable) function $f = f(q, p)$ becomes another function of q', p':

$$f = f(q, p) = f[q(q', p'), p(q', p')] \equiv f'(q', p') = f'; \tag{a}$$

and similarly for the function $g = g(q,p) = \cdots = g'$. Hence, by chain rule we find, successively,

$$
\begin{aligned}
(f,g)_{q,p} &= \sum \left[(\partial f/\partial p_r)(\partial g/\partial q_r) - (\partial f/\partial q_r)(\partial g/\partial p_r)\right] \\
&= \sum\sum\sum \big\{\left[(\partial f'/\partial p_{k'})(\partial p_{k'}/\partial p_r) + (\partial f'/\partial q_{k'})(\partial q_{k'}/\partial p_r)\right]\left[(\partial g'/\partial p_{l'})(\partial p_{l'}/\partial q_r)\right. \\
&\qquad\qquad \left. + (\partial g'/\partial q_{l'})(\partial q_{l'}/\partial q_r)\right] \\
&\qquad\qquad - [(\partial f'/\partial p_{k'})(\partial p_{k'}/\partial q_r) + (\partial f'/\partial q_{k'})(\partial q_{k'}/\partial q_r)][(\partial g'/\partial p_{l'})(\partial p_{l'}/\partial p_r) \\
&\qquad\qquad + (\partial g'/\partial q_{l'})(\partial q_{l'}/\partial p_r)]\big\} \\
&= \sum\sum\sum \big\{(\partial f'/\partial p_{k'})(\partial g'/\partial p_{l'})[(\partial p_{k'}/\partial p_r)(\partial p_{l'}/\partial q_r) - (\partial p_{k'}/\partial q_r)(\partial p_{l'}/\partial p_r)] \\
&\qquad\qquad + (\partial f'/\partial q_{k'})(\partial g'/\partial q_{l'})[(\partial q_{k'}/\partial p_r)(\partial q_{l'}/\partial q_r) - (\partial q_{k'}/\partial q_r)(\partial q_{l'}/\partial p_r)] \\
&\qquad\qquad + (\partial f'/\partial p_{k'})(\partial g'/\partial q_{l'})[(\partial p_{k'}/\partial p_r)(\partial q_{l'}/\partial q_r) - (\partial p_{k'}/\partial q_r)(\partial q_{l'}/\partial p_r)] \\
&\qquad\qquad + (\partial f'/\partial q_{k'})(\partial g'/\partial p_{l'})[(\partial q_{k'}/\partial p_r)(\partial p_{l'}/\partial q_r) - (\partial q_{k'}/\partial q_r)(\partial p_{l'}/\partial p_r)]\big\}
\end{aligned}
$$

[recalling the PB definition, $(\ldots)_{q,\,p}$, and then invoking (8.9.10a f, g)/(8.9.11k)]

$$
\begin{aligned}
&= \sum\sum \big\{[(\partial f'/\partial p_{k'})(\partial g'/\partial p_{l'})](p_{k'}, p_{l'}) + [(\partial f'/\partial q_{k'})(\partial g'/\partial q_{l'})](q_{k'}, q_{l'}) \\
&\qquad + [(\partial f'/\partial p_{k'})(\partial g'/\partial q_{l'}) - (\partial f'/\partial q_{k'})(\partial g'/\partial p_{l'})](p_{k'}, q_{l'})\big\} \\
&= \sum\sum \big\{[(\partial f'/\partial p_{k'})(\partial g'/\partial p_{l'})](0) + [(\partial f'/\partial q_{k'})(\partial g'/\partial q_{l'})](0) \\
&\qquad + [(\partial f'/\partial p_{k'})(\partial g'/\partial q_{l'}) - (\partial f'/\partial q_{k'})(\partial g'/\partial p_{l'})](\delta_{k'l'})\big\} \\
&= \sum\sum \left[(\partial f'/\partial p_{k'})(\partial g'/\partial q_{l'}) - (\partial f'/\partial q_{k'})(\partial g'/\partial p_{l'})\right](\delta_{k'l'}) \\
&= \sum \left[(\partial f'/\partial p_{k'})(\partial g'/\partial q_{k'}) - (\partial f'/\partial q_{k'})(\partial g'/\partial p_{k'})\right] \equiv (f,g)_{q',p'}, \quad \text{Q.E.D.} \qquad \text{(b)}
\end{aligned}
$$

Example 8.9.2 *Relations among the Fundamental Brackets of Poisson and Lagrange.* Let the transformation

$$q_{k'} = q_{k'}(t,q,p), \quad p_{k'} = p_{k'}(t,q,p) \qquad \text{(a)}$$

be canonical. Then,

$$[p_{k'}, p_{l'}] = 0, \qquad [q_{k'}, q_{l'}] = 0, \qquad [p_{k'}, q_{l'}] = \delta_{k'l'}. \qquad \text{(b)}$$

Now, if in the earlier-found compatibility conditions (8.7.25, with $\mu \to k'$, $\lambda \to l'$)

$$\sum [c_\nu, c_{k'}](c_\nu, c_{l'}) = \delta_{k'l'} \qquad (\nu = 1, \ldots, 2n), \qquad \text{(c)}$$

we substitute $c_{k'} \to p_{k'}$, $c_{l'} \to p_{l'}$; $c_1 = p_{1'}, \ldots, c_n = p_{n'}; c_{n+1} = q_{1'}, \ldots, c_{2n} = q_{n'}$, we obtain

$$\sum [p_{r'}, p_{k'}](p_{r'}, p_{l'}) + \sum [q_{r'}, p_{k'}](q_{r'}, p_{l'}) = \delta_{k'l'},$$

or, due to (b),

$$\sum (0)(p_{r'}, p_{l'}) + \sum (-\delta_{r'k'})(q_{r'}, p_{l'}) = \delta_{k'l'} \;\Rightarrow\; -(q_{r'}, p_{l'}) = \delta_{k'l'}. \qquad \text{(d1)}$$

Similarly:

(i) Substituting $c_{k'} \to p_{k'}$, $c_{l'} \to q_{l'}$ we obtain

$$(q_{k'}, q_{l'}) = 0; \tag{d2}$$

(ii) Substituting $c_{k'} \to q_{k'}$, $c_{l'} \to p_{l'}$ we obtain

$$(p_{k'}, p_{l'}) = 0; \tag{d3}$$

(iii) Substituting $c_{k'} \to q_{k'}$, $c_{l'} \to q_{l'}$ we obtain

$$(p_{k'}, q_{l'}) = \delta_{k'l'}. \tag{d4}$$

Hence, starting with (b), and using (c), we proved (d1–4). Let the reader verify the converse; that is, use (c) to show that if (d1–4) hold, so do (b).

Example 8.9.3 *Area Preservation in Phase Space under Canonical Transformations.* Under the two distinct virtual variations $\delta_1(\ldots)$ and $\delta_2(\ldots)$, the fundamental canonical transformation definition (8.8.12),

$$\delta F = \sum p_k\, \delta q_k - \sum p_{k'}\, \delta q_{k'},$$

yields

$$\delta_1 F = \sum p_k\, \delta_1 q_k - \sum p_{k'}\, \delta_1 q_{k'}, \qquad \delta_2 F = \sum p_k\, \delta_2 q_k - \sum p_{k'}\, \delta_2 q_{k'}. \tag{a}$$

Now, $\delta_2(\ldots)$-varying $\delta_1 F$ and $\delta_1(\ldots)$-varying $\delta_2 F$, and then subtracting side by side, while noting that $\delta_2(\delta_1 q_k) = \delta_1(\delta_2 q_k)$ and $\delta_2(\delta_1 q_{k'}) = \delta_1(\delta_2 q_{k'})$, we obtain

$$\begin{aligned} 0 &= \delta_1(\delta_2 F) - \delta_2(\delta_1 F) \\ &= \sum (\delta_1 p_k\, \delta_2 q_k - \delta_2 p_k\, \delta_1 q_k) - \sum (\delta_1 p_{k'}\, \delta_2 q_{k'} - \delta_2 p_{k'}\, \delta_1 q_{k'}), \end{aligned} \tag{b}$$

that is,

$$I \equiv \sum (\delta_1 p_k\, \delta_2 q_k - \delta_2 p_k\, \delta_1 q_k) = \sum (\delta_1 p_{k'}\, \delta_2 q_{k'} - \delta_2 p_{k'}\, \delta_1 q_{k'}) \equiv I' \tag{c}$$

[recall (8.7.10)]. Geometrically, and for a one-DOF system, the Lagrangean invariant (bilinear covariant) I, a generalization of the Wronskian determinant, equals the area of the elementary parallelepiped with (rectangular Cartesian) sides $\delta \boldsymbol{s}_1 = (\delta_1 q, \delta_1 p)$ and $\delta \boldsymbol{s}_2 = (\delta_2 q, \delta_2 p)$, emanating from (q, p) in phase space:

$$Area = (\delta \boldsymbol{s}_2 \times \delta \boldsymbol{s}_1)_z = \delta_1 p\, \delta_2 q - \delta_2 p\, \delta_1 q = \delta_1 p'\, \delta_2 q' - \delta_2 p'\, \delta_1 q' = constant. \tag{d}$$

Example 8.9.4 *Angular Momentum and Poisson's Brackets.*

(i) The components of the angular momentum of a particle P of mass m relative to the origin of rectangular Cartesian axes O–$xyz \equiv O$–123 are (with $p_x \equiv m\dot{x} \;\to\; p_1 = m\dot{x}_1$, etc.)

$$
\begin{aligned}
h_x &= yp_z - zp_y \;\rightarrow\; h_1 = x_2p_3 - x_3p_2, \\
h_y &= zp_x - xp_z \;\rightarrow\; h_2 = x_3p_1 - x_1p_3, \\
h_z &= xp_y - yp_x \;\rightarrow\; h_3 = x_1p_2 - x_2p_1.
\end{aligned} \tag{a}
$$

Hence, their PB are

$$
\begin{aligned}
(h_1, h_2) &\equiv \sum \big[(\partial h_1/\partial p_r)(\partial h_2/\partial x_r) - (\partial h_1/\partial x_r)(\partial h_2/\partial p_r)\big] \\
&= \cdots = -(x_1p_2 - x_2p_1) = -h_3,
\end{aligned} \tag{b}
$$

and, similarly,

$$
(h_1, h_3) = h_2, \qquad (h_2, h_3) = -h_1; \tag{c}
$$

or, compactly, with the help of the well-known Levi–Civita *permutation* symbol ε_{krs} $[= +1/-1/0$, according as $k,\ r,\ s$ are an *even/odd/no* permutation of 1, 2, 3 (§1.1)]:

$$
(h_k, h_l) = -\sum \varepsilon_{klr} h_r = \sum \varepsilon_{krl} h_r. \tag{d}
$$

(ii) With the help of the above [and (8.9.5d) → (8.9.5e) → (8.95a)], we find, successively (with $h \equiv |\boldsymbol{h}|$),

$$
\begin{aligned}
(h_k, h^2) &= \Big(h_k, \sum {h_r}^2\Big) \\
&= \sum (h_k, {h_r}^2) \\
&= \sum \big[h_r(h_k, h_r) + h_r(h_k, h_r)\big] = \sum 2h_r(h_k, h_r) \\
&= \sum 2h_r\Big(-\sum \varepsilon_{krl} h_l\Big) = -2\sum\sum \varepsilon_{krl} h_r h_l = 0,
\end{aligned} \tag{e}
$$

since $\varepsilon_{krl} = -\varepsilon_{klr}$ (as in the case of gyroscopicity!).

These results are important in the extension of the Hamiltonian formalism to quantum mechanics.

Example 8.9.5 *Canonicity via Symplectic (or Simplicial) Matrices.* (May be omitted in a first reading.) Here, we summarize a more algebraic approach to canonicity. Let $\mathbf{J}$, or $\mathbf{J}_{2n}$, be the following block matrix

$$
\mathbf{J} \equiv \mathbf{J}_{2n} \equiv \begin{pmatrix} \mathbf{0}_n & \mathbf{1}_n \\ -\mathbf{1}_n & \mathbf{0}_n \end{pmatrix} \tag{a}
$$

where $\mathbf{0}_n = n \times n$ *zero* matrix, and $\mathbf{1}_n = n \times n$ (diagonal) *unit*, or *identity*, matrix.

We can readily confirm that

$$
\mathbf{J}^2 = -\mathbf{1}_{2n} \qquad \text{and} \qquad \mathbf{J} = -\mathbf{J}^{-1}, \tag{b}
$$

and, therefore,

$$
\mathrm{Det}(\mathbf{J}^2) = (\mathrm{Det}\,\mathbf{J})^2 = \mathrm{Det}\,\mathbf{1}_{2n} = 1 \;\Rightarrow\; \mathrm{Det}\,\mathbf{J} \neq 0. \tag{c}
$$

Next, a $2n \times 2n$ matrix $\mathbf{M}_{2n}$, or simply $\mathbf{M}$, is called *symplectic* if

$$\mathbf{M}^{\mathrm{T}}\mathbf{J}\mathbf{M} = \mathbf{J} \qquad [(\ldots)^{\mathrm{T}}: \textit{Transpose} \text{ of } (\ldots)]. \tag{d}$$

Since $\mathrm{Det}\,(\mathbf{M}^{\mathrm{T}}\mathbf{J}\mathbf{M}) = (\mathrm{Det}\,\mathbf{M}^{\mathrm{T}})\,(\mathrm{Det}\,\mathbf{J})\,(\mathrm{Det}\,\mathbf{M}) = \mathrm{Det}\,\mathbf{J}$, then due to $\mathrm{Det}\,\mathbf{M}^{\mathrm{T}} = \mathrm{Det}\,\mathbf{M}$ and (c), we readily conclude that $(\mathrm{Det}\,\mathbf{M})^2 = 1 \;\Rightarrow\; \mathrm{Det}\,\mathbf{M} = \pm 1$ (it can be shown that $\mathrm{Det}\,\mathbf{M} = 1$). Hence, $\mathbf{M}$ is invertible. Indeed, from (d), we find that

$$\mathbf{M}^{-1} = -\mathbf{J}\mathbf{M}^{\mathrm{T}}\mathbf{J}. \tag{e}$$

Now, we introduce the following fundamental definition.

DEFINITION

The one-to-one (invertible) transformation $(p, q) \to (p', q')$, *in the* $2n$*-dimensional phase space, is called canonical if the corresponding* $2n \times 2n$ *Jacobian matrix*

$$\begin{pmatrix} \partial p_k/\partial p_{l'} & \partial p_k/\partial q_{l'} \\ \partial q_k/\partial p_{l'} & \partial q_k/\partial q_{l'} \end{pmatrix} \tag{f}$$

is symplectic. The equivalence of this definition with those based on the Poisson brackets is established as follows:

(i) Using the fact that the transpose of the block matrix

$$\begin{pmatrix} \mathbf{A} & \mathbf{B} \\ \mathbf{C} & \mathbf{D} \end{pmatrix} \tag{g}$$

equals

$$\begin{pmatrix} \mathbf{A}^{\mathrm{T}} & \mathbf{C}^{\mathrm{T}} \\ \mathbf{B}^{\mathrm{T}} & \mathbf{D}^{\mathrm{T}} \end{pmatrix} \tag{h}$$

where $\mathbf{A}$, $\mathbf{B}$, $\mathbf{C}$, $\mathbf{D}$ are arbitrary $n \times n$ matrices, we can show that

$$\mathbf{M} \equiv \begin{pmatrix} \mathbf{A} & \mathbf{B} \\ \mathbf{C} & \mathbf{D} \end{pmatrix} \tag{i}$$

is symplectic if, and only if

- $\mathbf{A}^{\mathrm{T}}\mathbf{C}$ and $\mathbf{B}^{\mathrm{T}}\mathbf{D}$ are *symmetric* (i.e., equal to their transposes),
- $\mathbf{D}^{\mathrm{T}}\mathbf{A} - \mathbf{B}^{\mathrm{T}}\mathbf{C} = \mathbf{1}$.

(ii) Applying these results to the Jacobian (f); that is

$$\mathbf{A} = (\partial p_k/\partial p_{l'}), \qquad \mathbf{B} = (\partial p_k/\partial q_{l'}), \qquad \mathbf{C} = (\partial q_k/\partial p_{l'}), \qquad \mathbf{D} = (\partial q_k/\partial q_{l'}), \tag{j}$$

we see that it is symplectic, and hence the transformation $(p, q) \to (p', q')$ is canonical, if, and only if,

$$[p_{k'}, p_{l'}] = 0, \qquad [q_{k'}, q_{l'}] = 0, \qquad [p_{k'}, q_{l'}] = \delta_{k'l'}; \tag{k}$$

which are, of course, the earlier-found Lagrangean bracket conditions.

Example 8.9.6 *Evolution of a Mechanical System via PB.* Let $f = f(q,p)$ and $H = H(q,p)$. Then, by (8.9.1), and assuming only potential forces,

$$df/dt = (H, f); \tag{a}$$

and again by (8.9.1), with $f \to df/dt$:

$$d^2f/dt^2 = (H, df/dt) = \big(H, (H, f)\big); \tag{b}$$

and similarly for $d^3f/dt^3, \ldots$. As a result, the MacLaurin expansion,

$$f[q(t), p(t)] \equiv f(t) = f(0) + (df/dt)_o\, t + (1/2)(d^2f/dt^2)_o\, t^2 + \cdots, \tag{c}$$

becomes

$$\begin{aligned} f(t) &= f(0) + t\big(H, f(0)\big) + (t^2/2)\Big(H, \big(H, f(0)\big)\Big) \\ &\quad + (t^3/6)\Big(H, \big(H, (H, f(0))\big)\Big) + \cdots \\ &\equiv f(0)\exp[t(H, \ldots)] \qquad \text{[symbolically]} \end{aligned} \tag{d}$$

This expresses the earlier-described (§3.12) *doctrine of determinism*: if all q's and p's, and hence all system functions, like $f(q,p)$, are known at an "initial" instant $t = 0$, then the state of the system at any later time t can be determined with the help of its known (constant) Hamiltonian $H(q,p)$, from (d), to any degree of accuracy.

Example 8.9.7 *Infinitesimal Canonical Transformations.* A general transformation

$$q_k \to q_{k'} = q_k + \varepsilon\, f_k(q,p), \qquad p_k \to p_{k'} = p_k + \varepsilon\, g_k(q,p) \tag{a}$$

is called *infinitesimal* (IT) if ε can be viewed as an infinitesimal parameter, independent of the q's and p's, whose higher powers can, therefore, be neglected. Under such a transformation, a general function $F(q', p')$ becomes

$$\begin{aligned} F(q', p') &= F(q + \varepsilon f,\, p + \varepsilon g) \\ &= F(q,p) + \varepsilon \sum \big[(\partial F/\partial q_k) f_k + (\partial F/\partial p_k) g_k\big]. \end{aligned} \tag{b}$$

Examples of such IT are (i) the *infinitesimal rotations* of a rigid body about a fixed point (§ 1.9ff.); and, of course, (ii) the general (first-order) *virtual displacement* (§2.5) $\delta \mathbf{r} = \sum (\partial \mathbf{r}/\partial q_k)\, \delta q_k$.

If the transformation (a) is also canonical (infinitesimal canonical transformation, ICT) then, by the definition (8.8.12), we must have

$$\begin{aligned} \delta F &= \sum p_k\, \delta q_k - \sum p_{k'}\, \delta q_{k'} \\ &= \sum p_k\, \delta q_k - \sum (p_k + \varepsilon\, g_k)(\delta q_k + \varepsilon\, \delta f_k) \\ &= -\varepsilon \sum (p_k\, \delta f_k + g_k\, \delta q_k) \qquad \text{[to the } \textit{first} \text{ order in } \varepsilon] \\ &= -\varepsilon \sum \Big\{ p_k \Big(\sum \big[(\partial f_k/\partial p_l)\, \delta p_l + (\partial f_k/\partial q_l)\, \delta q_l \big] \Big) + g_k\, \delta q_k \Big\} \\ &= -\varepsilon \sum \Big\{ \Big[g_l + \sum p_k (\partial f_k/\partial q_l) \Big] \delta q_l + \Big(\sum p_k (\partial f_k/\partial p_l) \Big) \delta p_l \Big\}, \end{aligned} \tag{c}$$

and from this, setting $F \equiv \varepsilon W(q,p)$ and equating virtual differential coefficients, we obtain

$$g_l + \sum p_k(\partial f_k/\partial q_l) = -\partial W/\partial q_l, \qquad \sum p_k(\partial f_k/\partial p_l) = -\partial W/\partial p_l, \tag{d}$$

or, since here the q's and p's are considered independent,

$$g_l + \partial/\partial q_l\Big(\sum p_k\, f_k\Big) = -\partial W/\partial q_l, \qquad \partial/\partial p_l\Big(\sum p_k\, f_k\Big) - f_l = -\partial W/\partial p_l,$$

or, finally, with the help of the new generating function: $G \equiv W + \sum p_k\, f_k$,

$$f_l = \partial G/\partial p_l, \qquad g_l = -\partial G/\partial q_l. \tag{e}$$

Hence, the original transformations (a) become

$$q_{k'} - q_k \equiv \xi_k = \varepsilon(\partial G/\partial p_k), \qquad p_{k'} - p_k \equiv \eta_k = -\varepsilon(\partial G/\partial q_k); \tag{f}$$

that is, Hamilton's equations can be viewed as an *ICT with generating function the system Hamiltonian*:

$$\varepsilon \to dt, \qquad G \to H: \qquad dq_k = (\partial H/\partial p_k)\, dt, \qquad dp_k = -(\partial H/\partial q_k)\, dt; \tag{g}$$

a result admirably summed up by Whittaker in the following words: "*The whole course of a dynamical system can thus be regarded as the gradual self-unfolding of a contact transformation*" (1937, p. 304), with time merely as a *parameter* of that transformation.

[Some authors, *including Whittaker*, by contact transformations mean our canonical transformations — see next example. Others, however, use that term to signify *homogeneous canonical (or Mathieu) transformations*; see, for example, Rund (1966).]

Finally, substituting (e, f) in (b), we obtain

$$\begin{aligned} \Delta F &= \sum \big[(\partial F/\partial q_k)\xi_k + (\partial F/\partial p_k)\eta_k\big] \\ &= \varepsilon \sum \big[(\partial F/\partial q_k)(\partial G/\partial p_k) - (\partial F/\partial p_k)(\partial G/\partial q_k)\big] \\ &= \varepsilon(G, F), \end{aligned} \tag{h}$$

thus providing another interpretation of Poisson's brackets.

REMARKS

(i) Equations (f) can also be obtained by adding the infinitesimal $\varepsilon G(q, p')$ to the *identity* transformation [generated by $\sum q_k p_{k'}$, or by $-\sum p_k q_{k'}$ (§8.8)]; that is, if we take as generating function

$$F = \sum q_k p_{k'} + \varepsilon G(q, p') \equiv F_2(q, p'), \tag{i}$$

then, recalling (8.8.17),

$$q_{k'} = \partial F_2/\partial p_{k'} = q_k + \varepsilon(\partial G/\partial p_{k'}), \tag{j1}$$

$$p_k = \partial F_2/\partial q_k = p_{k'} + \varepsilon(\partial G/\partial q_k); \tag{j2}$$

that is, to the first order,

$$\xi_k = \varepsilon(\partial G/\partial p_{k'}) \approx \varepsilon(\partial G/\partial p_k), \tag{k1}$$

$$\eta_k = -\varepsilon(\partial G/\partial q_k); \qquad G(q, p') \approx G(q, p). \tag{k2}$$

(ii) That the transformation of the q's and p's from their initial values to their values at any later time is canonical can also be seen from the *group* property of these transformations; that is, from that, (a) *the result of two successive canonical transformations is also canonical, and* (b) *the inverse of a canonical transformation, from the new variables to the old ones, is also canonical.*

Example 8.9.8 *Contact Transformation.* If $\sum p_k\,\delta q_k = total$ virtual differential $\equiv \delta f$, then, by the fundamental definition (8.8.12),

$$\sum p_{k'}\,\delta q_{k'} = \sum p_k\,\delta q_k - \delta F = \delta(f - F); \tag{a}$$

that is, $\sum p_{k'}\,\delta q_{k'}$ is also a *total* virtual differential.

Let us see if the converse is also true. For $\sum p_{k'}\,\delta q_{k'} = \delta f'$ to follow from $\sum p_k\,\delta q_k = \delta f$, we must have

$$\sum p_{k'}\,\delta q_{k'} - \delta f' = \mu\Big(\sum p_k\,\delta q_k - \delta f\Big). \tag{b}$$

Now:

(i) If $\mu \equiv 1$, then, clearly, we are dealing with a canonical transformation with generating function $F = f - f'$;

(ii) If $\mu \neq 1$, then (b) represents a so-called general *contact transformation* (Lie). We will not pursue such transformations any further here, but the reader should be aware that, in a number of expositions, the terms canonical and contact transformations are used synonymously.

Problem 8.9.1 *Canonicity Conditions.*

(i) Show that the linear homogeneous transformation

$$q_{k'} = \sum Q_{k'k}\, q_k, \qquad p_{k'} = \sum P_{k'k}\, p_k, \tag{a}$$

where $Q_{k'k}$, $P_{k'k}$ are *constant* coefficients, is canonical if, and only if,

$$\sum Q_{k'k} P_{k'l} = \delta_{kl}; \tag{b}$$

that is, $P_{k'k}$: cofactor of $Q_{k'k}$ in $Det(Q_{k'k}) \equiv Q$, divided by $Q(\neq 0)$.

(ii) Then show that, as a result of (b), we have

$$\sum p_{k'} q_{k'} = \sum p_k q_k. \tag{c}$$

HINT

For canonicity, we must have $(p_{k'}, q_{l'}) = \delta_{k'l'}$.

Problem 8.9.2 *Properties of Poisson's Brackets.* Show that, for a general function $f = f(t, q, p)$, and with t, q, p regarded as independent variables,

$$(f, q_k) = \partial f/\partial p_k, \qquad (f, p_k) = -\partial f/\partial q_k, \qquad (f, t) = 0. \tag{a}$$

Problem 8.9.3 *Properties of Poisson's Brackets.* Using the results of the preceding problem, show that

$$\partial^2 f/\partial q_k\, \partial q_l = \big(p_l, (p_k, f)\big). \tag{a}$$

Obtain similar expressions for $\partial^2 f/\partial q_k\, \partial p_l$ and $\partial^2 f/\partial p_k\, \partial p_l$.

Problem 8.9.4 *Equations of Motion via Poisson's Brackets.*
(i) Show that Hamilton's equations

$$dq_k/dt = \partial H/\partial p_k, \qquad dp_k/dt = -\partial H/\partial q_k + Q_k \tag{a}$$

can be rewritten, with the help of PB, as

$$dq_k/dt = (H, q_k), \qquad dp_k/dt + (H, p_k) + Q_k. \tag{b}$$

(ii) Then show that, if $\partial H/\partial t = 0$ and $Q_k = 0$,

$$d^2 p_k/dt^2 = \big(H, (H, p_k)\big). \tag{c}$$

Problem 8.9.5 *Power Theorem via Poisson's Brackets.* Consider a system whose motion is governed by the Hamiltonian equations

$$dq_k/dt = \partial H/\partial p_k, \qquad dp_k/dt = -\partial H/\partial q_k + Q_k. \tag{a}$$

Using the dynamical identity (8.9.1), show that its power equation is

$$dH/dt = \partial H/\partial t + \sum Q_k (dq_k/dt). \tag{b}$$

HINT

In (8.9.1), set $f \to H$.

Problem 8.9.6 *Angular Momentum and Poisson's Brackets.* Continuing from ex. 8.9.3, show that:

(i) $$(x_k, h_l) = -\sum \varepsilon_{klr} x_r = \sum \varepsilon_{krl}\, x_r; \tag{a}$$

(ii) $$(p_k, h_l) = -\sum \varepsilon_{klr} p_r = \sum \varepsilon_{krl}\, p_r. \tag{b}$$

Problem 8.9.7 *Infinitesimal Canonical Transformations (ICT).* Show that if $G = constant$ is an integral of the canonical equations of motion of a system $dq_k/dt = \partial H/\partial p_k$ and $dp_k/dt = -\partial H/\partial q_k$, then all trajectories created by the ICT with G as generating function satisfy its *canonical variational equations* of Jacobi (or Poincaré's *équations aux variations*):

$$d\xi_k/dt = \sum \left[(\partial^2 H/\partial p_k\,\partial q_l)\xi_l + (\partial^2 H/\partial p_k\,\partial p_l)\eta_l\right], \tag{a}$$

$$d\eta_k/dt = \sum \left[(\partial^2 H/\partial q_k\,\partial q_l)\xi_l + (\partial^2 H/\partial q_k\,\partial p_l)\eta_l\right], \tag{b}$$

where all partial derivatives are evaluated at the system's *fundamental trajectory* (i.e., for $\varepsilon = 0$).

HINT

Show that (a, b) are satisfied by the G-generated perturbations

$$\xi_k = \varepsilon(\partial G/\partial p_k), \qquad \eta_k = -\varepsilon(\partial G/\partial q_k), \tag{c}$$

where $dG/dt = \partial G/\partial t + (H, G) = 0$.

For additional related results, see, for example, Hamel (1949, pp. 301–303).

8.10 THE HAMILTON–JACOBI THEORY

In this section we are carrying out the ultimate objective of canonical transformation (CT) theory: to provide a systematic way of finding CT that simplify the Hamiltonian equations of motion as much as possible, by which we mean *CT that render: (i) all new coordinates q', or (ii) all new momenta p', or (iii) both (q', p'), constant in time.*

Then, and assuming $Q_{k'} = 0$, the new Hamiltonian equations

$$dq_{k'}/dt = \partial H'/\partial p_{k'}, \qquad dp_{k'}/dt = -\partial H'/\partial q_{k'}, \tag{8.10.1}$$

yield, successively:

(i)

$$dq_{k'}/dt = 0 \;\Rightarrow\; q_{k'} = constant \equiv \alpha_k, \tag{8.10.2a}$$

$$\partial H'/\partial p_{k'} = 0 \qquad \text{(i.e., } \textit{all } p' \textit{ ignorable}\text{)}, \tag{8.10.2b}$$

$$\Rightarrow H' = H'(t, q') = H'(t, \alpha_1, \ldots, \alpha_n) \equiv H'(t, \alpha). \tag{8.10.2c}$$

[We hope no confusion will arise from the (tensorially nonrigorous) fact that in this, and similar equations, quantities with accented indices are equated to quantities with nonaccented indices!]

If, further, $\partial H'/\partial t = 0 \Rightarrow H' = H'(q') = H'(\alpha)$: constant total energy $\equiv E$, then, by the second of (8.10.1),

$$dp_{k'}/dt = -\partial H'/\partial \alpha_k = constant \;\Rightarrow\; p_{k'} = \textit{linear function of time}. \tag{8.10.2d}$$

(ii)

$$dp_{k'}/dt = 0 \;\Rightarrow\; p_{k'} = constant \equiv \beta_k, \tag{8.10.3a}$$

$$\partial H'/\partial q_{k'} = 0 \text{ (i.e., } \textit{all } q' \textit{ ignorable}\text{)}, \tag{8.10.3b}$$

$$\Rightarrow H' = H'(t, p') = H'(t, \beta_1, \ldots, \beta_n) \equiv H'(t, \beta). \tag{8.10.3c}$$

If, further, $\partial H'/\partial t = 0 \Rightarrow H' = H'(p') = H'(\beta)$: constant total energy $\equiv E$, then, by the first of (8.10.1),

$$dq_{k'}/dt = \partial H'/\partial \beta_k = constant \equiv \omega_k$$
$$\Rightarrow q_{k'} = linear\ function\ of\ time \equiv \omega_k t + \alpha_k = (\partial E/\partial \beta_k)t + \alpha_k. \tag{8.10.3d}$$

Cases (ii) and (i) can be summed up, respectively, in the following theorem.

THEOREM

If all coordinates (momenta) are ignorable, then the conjugate momenta (coordinates) are constant and the coordinates (momenta) vary linearly with time.

(iii) $$dq_{k'}/dt = \partial H'/\partial p_{k'} = 0 \Rightarrow q_{k'} = constant \equiv \alpha_k, \tag{8.10.4a}$$
$$dp_{k'}/dt = -\partial H'/\partial q_{k'} = 0 \Rightarrow p_{k'} = constant \equiv \beta_k; \qquad H' = H'(t). \tag{8.10.4b}$$

Theorem of Jacobi

The simplest (of course, arbitrary) choice satisfying (8.10.4a, b) is $H' \equiv 0$. The particular generating function accomplishing this we shall call (Hamiltonian) *action*: A_H, or, simply, A. [This function is frequently denoted by S (also W, usually for the Lagrangean action; from the German *Wirkung* = *action* $\equiv$ *work* $\times$ *time*; not as in action/reaction of Newton's "third law"); but here that letter has been appropriated for the Appellian function; see also §8.11. Such action *functions* $\rightarrow$ *functionals* play a prominent role in chapter 7.]

It is expedient to assume that A has the following functional representation:

$$A = A(t, q, p') \qquad (= F_2, \text{recall §8.8}). \tag{8.10.5a}$$

Then, by (8.8.17) and the earlier requirement $H' \equiv 0$,

$$p_k = \partial A/\partial q_k, \qquad q_{k'} = \partial A/\partial p_{k'}; \tag{8.10.5b}$$
$$H' = H(t, q, p) + \partial A/\partial t = 0 \Rightarrow H(t, q, \partial A/\partial q) + \partial A/\partial t = 0, \tag{8.10.5c}$$

or, since (prob. 8.2.1)

$$\begin{aligned} H &\equiv T'(t, q, p) + V(t, q) \\ &= (1/2)(M'_{11} {p_1}^2 + M'_{22} {p_2}^2 + \cdots + 2M'_{12} p_1 p_2 + \cdots) + V \equiv H(t, q, p), \\ &\{M'_{lk} = M'_{kl} \equiv [minor\ of\ element\ M_{kl}(= M_{lk})\ in\ determinant\ M_n \equiv (M_{kl})]/M_n\}, \end{aligned}$$

explicitly;

$$\begin{aligned} &\partial A/\partial t + (1/2)\big[M'_{11}(\partial A/\partial q_1)^2 + M'_{22}(\partial A/\partial q_2)^2 \\ &\qquad + \cdots + 2M'_{12}(\partial A/\partial q_1)(\partial A/\partial q_2) + \cdots\big] + V = 0. \end{aligned} \tag{8.10.6}$$

This first-order *nonlinear* partial differential equation for A is the famous *Hamilton–Jacobi (HJ) equation*. Hence, the problem of bringing the Hamiltonian equations of motion to their simplest (integrable) form, by an appropriate canonical transformation, has been reduced to that of the integration of (8.10.6).

On this equation we can state the following: Since it depends on the $n+1$ *independent variables* t (time), q (space/coordinates), and the n constants $p' = \beta$, *a(ny) complete integral (CI) of it must contain an equal number of independent arbitrary constants*; say, $\beta_1, \ldots, \beta_n; \beta_{n+1}$. [A CI of a first-order PDE is to be distinguished from its *general integral* (GI), which depends on an *arbitrary function,* and is not as important to dynamics as are the CIs. On how to obtain the GI from CIs, see ex. 2, below.] However, since (8.10.6) does not contain A explicitly, but only its derivatives (and, therefore, if A is a solution of it, so is $A + \beta'$), identifying β_{n+1} with the additive (and dynamically inconsequential) constant β', we can finally state that a(ny) complete integral of the HJ equation of an n-DOF system contains n nontrivial, or essential, constants; that is, any such A has the form:

$$A = A(t, q, \beta), \qquad \beta \equiv (\beta_1, \ldots, \beta_n). \tag{8.10.7}$$

Thus, for this special generating function, the new momenta p', by (8.10.4b), can be identified with the constants β:

$$p_{k'} = \beta_k; \tag{8.10.8a}$$

while, by (8.10.4a) and the second of (8.10.5b),

$$q_{k'} = \partial A/\partial p_{k'} = \partial A(t, q, \beta)/\partial \beta_k = \alpha_k \qquad \text{(arbitrary constants)}. \tag{8.10.8b}$$

From these algebraic equations, we can express the q's in terms of t and the $2n$ essential arbitrary constants (α, β):

$$\begin{aligned} q_k &= q_k(t; \alpha_1, \ldots, \alpha_n; \beta_1, \ldots, \beta_n) \equiv q_k(t; \alpha, \beta) \\ &= \textit{general integral of original problem}. \end{aligned} \tag{8.10.9a}$$

The old momenta can then be found from the first of (8.10.5b):

$$\begin{aligned} p_k &= \partial A/\partial q_k = \left(\partial A(t, q, \beta)/\partial q_k\right)_{q=q(t,\alpha,\beta)} = \cdots = p_k(t; \alpha, \beta) \\ &= \textit{general integral of original problem}. \end{aligned} \tag{8.10.9b}$$

Finally, evaluating (8.10.9a, b) for an *initial* time t_o, we can express α, β in terms of the $2n$ (arbitrary) *initial* values of the old coordinates and momenta, q_o, p_o [assuming that the corresponding Jacobian, $\partial(q,p)/\partial(\alpha,\beta)$, does not vanish; otherwise, since the α, β would not be independent, the solution $q(t; \alpha, \beta)$, $p(t; \alpha, \beta)$, would not be general]; and then, reinserting these expressions back into (8.10.9a, b), we can have q, p as functions of time t and the q_o's, p_o's. This completes, in principle, the HJ procedure for solving/simplifying canonical equations of motion. [For a proof that (8.10.8b), (8.10.9b) satisfy the canonical equations (8.10.10a), see ex. 8.10.1, below.]

REMARK

Incomplete HJ integrals—that is, expressions satisfying (8.10.6) but depending on fewer than n constants—cannot furnish the general integral (8.10.9a, b); but it can help us find it. Thus, from the known "incomplete integral" $A = A(t; q, \beta_1, \ldots, \beta_m)$ $(m < n)$, we obtain the m (8.10.8b)-like equations: $\partial A/\partial \beta_D = (constant)_D$ $(D = 1, \ldots, m)$.

The general integral (8.10.9a, b), thanks to the preceding theory, constitutes a canonical transformation from the α, β to the q, p with generating function

$A(t, q, \beta)$. However, every other general integral, say $q_k(t; \gamma, \delta)$, $p_k = p_k(t; \gamma, \delta)$, where $\gamma \equiv (\gamma_1, \ldots, \gamma_n)$, $\delta \equiv (\delta_1, \ldots, \delta_n)$ are arbitrary constants, is *not* a canonical transformation; and therefore knowledge of such an integral does not allow the construction of the complete integral of the HJ equation. That can happen only if the γ's and δ's equal, respectively, the initial positions and momenta.

The above results constitute the famous *theorem of Jacobi* (1842–1843). Let us restate it compactly:

(i) The integration of the canonical equations

$$dq_k/dt = \partial H/\partial p_k, \qquad dp_k/dt = -\partial H/\partial q_k, \tag{8.10.10a}$$

is reduced to the integration of the Hamilton–Jacobi equation:

$$H(t, q, \partial A/\partial q) + \partial A/\partial t = 0. \tag{8.10.10b}$$

(ii) If we have a complete solution of (8.10.10b)—that is, a solution of the form

$$A = A(t; q_1, \ldots, q_n; \beta_1, \ldots, \beta_n) \equiv A(t; q, \beta), \tag{8.10.10c}$$

where $\beta \equiv (\beta_1, \ldots, \beta_n) = n$ *essential arbitrary constants,* and $|\partial^2 A/\partial q \partial \beta| \neq 0$ (*non-vanishing Jacobian*), then the solution of the algebraic system:

$\partial A/\partial \beta_k = \alpha_k$

[*Finite equations of motion,* α*: new arbitrary constants* $\Rightarrow$ $q_k = q_k(t, \alpha, \beta)$], (8.10.10d)

$\partial A/\partial q_k = p_k$

[$\Rightarrow p_k = p_k(t, \alpha, \beta)$*: canonically conjugate (finite) equations of motion*], (8.10.10e)

constitutes a complete solution of (8.10.10a). For a proof, see ex. 8.10.1.

Schematically:

Hamilton: Differential equations of motion: $dq/dt = \partial H/\partial p$, $dp/dt = -\partial H/\partial q$

(*If these equations can be integrated, an Action function can be obtained*),

Hamilton–Jacobi: $H(t, q, \partial A/\partial q) + \partial A/\partial t = 0 \;\Rightarrow\; A = A(t, q, \beta)$,

Jacobi: Finite equations of motion: $\partial A/\partial \beta = \alpha \;\Rightarrow\; q = q(t, \alpha, \beta)$,

$\partial A/\partial q = p \;\Rightarrow\; p = p(t, \alpha, \beta)$

(*If an Action function can be obtained, then Hamilton's equations can be integrated*).

Special Cases

Obtaining the complete integral of the HJ equation is, in general, quite complicated; but, frequently, simpler than solving the corresponding Hamiltonian equations; and if that can be done, either exactly (e.g., via quadratures) or approximately (e.g., via perturbations), it constitutes one of the most straightforward methods of solution of mechanical problems.

1. Conservative Systems

In this case, the Hamiltonian form of the power theorem yields

$$dH/dt = \partial H/\partial t + \sum Q_k(dq_k/dt) = 0$$
$$\Rightarrow \ \partial H/\partial t = 0 \qquad \text{(since we have assumed } Q_k = 0)$$
$$\Rightarrow \ H = H(q,p) = H(q, \partial A/\partial q) = E \equiv \textit{constant (total energy)}; \quad (8.10.11a)$$

and so, from (8.10.10b), we conclude that, for such systems, A must be (to within an additive constant) a *linear* function of time:

$$A(t;q,p') = -E\,t + A_o(q,p'), \tag{8.10.11b}$$

where A_o is the *abbreviated*, or *reduced*, action. As a result of (8.10.11a, b), the HJ equation (8.10.10b) assumes the abbreviated, or reduced, form:

$$H(q, \partial A_o/\partial q) = E. \tag{8.10.11c}$$

or, explicitly,

$$(1/2)\big[M'_{11}(\partial A_o/\partial q_1)^2 + M'_{22}(\partial A_o/\partial q_2)^2 + \cdots + 2M'_{12}(\partial A_o/\partial q_1)(\partial A_o/\partial q_2) + \cdots\big] + V = E. \tag{8.10.11d}$$

Now, the complete integral of the above must contain E as an essential constant. On the other hand, the action

$$A = A(t;q,p') = A(t;q,\beta) = A_o(q,\beta) - E\,t \tag{8.10.11e}$$

can contain only n essential independent constants. Hence, it follows that E and the $n\,\beta$'s must be connected functionally:

$$E = E(\beta_1, \ldots, \beta_n) \equiv E(\beta); \tag{8.10.11f}$$

that is, we can identify E with any one of the β's, say $E = \beta_1$ (or, we need a A_o that contains only $n-1$ essential constants). Then, (8.10.11e) becomes

$$A(t,q,\beta) = A_o(q;\beta) - E(\beta)t = A_o(q;\beta_1,\ldots,\beta_n) - \beta_1 t = A_o(q;E,\beta_2,\ldots,\beta_n) - E\,t, \tag{8.10.11g}$$

and, provided that

$$\begin{vmatrix} \partial^2 A/\partial E\partial q_1 \cdots \partial^2 A/\partial E\partial q_n \\ \cdots\cdots\cdots\cdots\cdots \\ \cdots\cdots\cdots\cdots\cdots \\ \partial^2 A/\partial\beta_n\partial q_1 \cdots \partial^2 A/\partial\beta_n\partial q_n \end{vmatrix} \neq 0, \tag{8.10.11h}$$

the finite equations of motion (8.10.8b, 10d) yield:

(i) For $k', k = 1$: $\quad q_{1'} = \partial A/\partial\beta_1 = \partial A/\partial E = \partial A_o/\partial E - t = \alpha_1$, or

$$\partial A_o/\partial E = t + \alpha_1 \equiv f(q,\beta) \Rightarrow \alpha_1 = -t + \partial A_o/\partial E; \tag{8.10.11i}$$

(ii) For

$$k', k = 2, \ldots, n: \quad q_{k'} = \partial A/\partial\beta_k = \partial A_o/\partial\beta_k = \alpha_k \equiv g(q, \beta) \quad (k > 1); \tag{8.10.11j}$$

also

$$\partial A/\partial t = -E; \text{ and, of course, } p_k = \partial A_o/\partial q_k. \tag{8.10.11k}$$

The $n-1$ equations (8.10.11j), $\partial A_o/\partial\beta_k = \alpha_k$, connect the q's with the constants $\beta_1, \ldots, \beta_n; \alpha_2, \ldots, \alpha_n$, and thus specify the form of the sequence of configurations the system goes through during its motion — that is, the shape of its trajectory (orbit); while the remaining equation (8.10.11i), $\partial A_o/\partial\beta_1 = t + \alpha_1$, yields the time it takes the system to arrive at each of these configurations. Since this implies that α_1 must have temporal dimensions, setting $\alpha_1 = -t_o$ (some "initial" instant) in (8.10.11i), we find

$$\partial A_o/\partial E = t - t_o \equiv f(q, \beta), \tag{8.10.11l}$$

again a total of $2n$ arbitrary constants: $\beta_1 = E$; $\beta_2, \ldots, \beta_n$ and $\alpha_1 = -t_o$, $\alpha_2, \ldots, \alpha_n$. From these equations we can have the n q's in terms of $t - t_o$ and either the n α's or the n β's.

[If the total energy is a function of a certain variable, say u: $u = u(E) \Leftrightarrow E = E(u)$, then

$$A_o = A_o[q; E(u), \beta_2, \ldots, \beta_n] \equiv A'_o(q; u; \beta_2, \ldots, \beta_n),$$

and, accordingly, (8.10.11i, l) is replaced by

$$\partial A_o/\partial E = (\partial A'_o/\partial u)(du/dE) = t + \alpha_1 \;\Rightarrow\; \partial A'_o/\partial u = (dE/du)(t + \alpha_1).] \tag{8.10.11m}$$

In sum, for a conservative system:

$$q_k = q_k(t - t_o; c_1, \ldots, c_{2n-1}), \qquad p_k = p_k(t - t_o; c_1, \ldots, c_{2n-1}), \tag{8.10.11n}$$

where $c' = (c_1, \ldots, c_{2n-1})$: $2n - 1$ *constants of integration.*

2. Separation of Variables

This is a method of finding complete integrals of the HJ equation in the special but important case where a particular coordinate, say q_1, and corresponding derivative $\partial A/\partial q_1$ do not appear in the Hamilton–Jacobi equation (8.10.10b), except in the separable combination $f_1(q_1, \partial A/\partial q_1)$, so that the latter takes the form

$$F\big[t, q_R, \partial A/\partial q_R, \partial A/\partial t; f_1(q_1, \partial A/\partial q_1)\big] = 0, \tag{8.10.12a}$$

where q_R denotes the *remaining* coordinates, here $q_2, \ldots, q_n$. In this case, we seek a complete integral in the following separable, or sum, form:

$$A = A_R(t, q_R) + A_1(q_1). \tag{8.10.12b}$$

Substituting (8.10.12b) in (8.10.12a), we obtain

$$F\big[t, q_R, \partial A_R/\partial q_R, \partial A_R/\partial t; f_1(q_1, dA_1/dq_1)\big] = 0, \tag{8.10.12c}$$

which, since *it must be an identity in* q_1 [and the latter affects only $f_1(\ldots)$], leads us to the following: (i) *ordinary* differential equation,

$$f_1(q_1, dA_1/dq_1) = \textit{arbitrary constant} \equiv \beta_1, \tag{8.10.12d}$$

from which, by a simple quadrature, we obtain A_1; and (ii) the *partial* differential equation,

$$F(t, q_R, \partial A_R/\partial q_R, \partial A_R/\partial t; \beta_1) = 0, \tag{8.10.12e}$$

which contain *fewer* independent variables than the original equation (8.10.12a).

If it is possible to carry out this separation process for *all n q's and t,* then the complete integral of the HJ equation will have been reduced to quadratures. In particular, for a *conservative* system, *complete separation* of its variables allows us to express its action integral (8.10.11e–g) as

$$A = A_o - E\,t \equiv \sum A_k(q_k; \beta_1, \ldots, \beta_n) - E(\beta_1, \ldots, \beta_n)t; \tag{8.10.12f}$$

that is, A_k = function of q_k only, and all the β's; and the constant energy $E = E(\beta)$ is found from (8.10.11c) with $A_o = \sum A_k(q_k; \beta)$. Then, $p_k = \partial A_o/\partial q_k = \partial A_k/\partial q_k$ and the HJ equation for A_o separates to n equations of the form (8.10.12d)

$$f_k(q_k, \partial A_k/\partial q_k; \beta) = \beta_k, \qquad \text{or} \qquad f_k(q_k, \partial A_k/\partial q_k) = E_k(\beta_1, \ldots, \beta_n), \tag{8.10.12g}$$

from which the sought $A_k(q_k, \beta)$ can be obtained by quadratures.

Hence, it is very important to know whether a given Hamiltonian $H(q, p)$ is (completely or partially) separable or not. It has been shown that the necessary and sufficient conditions for such separability are the following $n(n-1)/2$ equations:

$$\begin{vmatrix} 0 & \partial H/\partial q_k & \partial H/\partial p_k \\ \partial H/\partial q_l & \partial^2 H/\partial q_k \partial q_l & \partial^2 H/\partial p_k \partial q_l \\ \partial H/\partial p_l & \partial^2 H/\partial q_k \partial p_l & \partial^2 H/\partial p_k \partial q_l \end{vmatrix} = 0, \tag{8.10.12h}$$

for $k,\ l = 1, \ldots, n$ $(k \neq n)$. [See, for example, Hagihara (1970, p. 77 ff.); who also "translates" (8.10.12h) into conditions in terms of the kinetic and potential energies.]

Alternatively, it can be shown that (8.10.12f)-type of separability occurs if (i) the HJ equation does *not* contain mixed products of $(\partial A_o/\partial q_k)(\partial A_o/\partial q_l)$, $k \neq l$, but only pure squares $(\partial A_o/\partial q_k)^2$, that is, if the Hamiltonian has the so-called *Stäckel* (or *orthogonal*) form:

$$H = (1/2) \sum v_k(q) {p_k}^2 + V(q), \ \ v_k(q)\text{: functions of the } q\text{'s (as in ex. 3.12.4)}, \tag{8.10.12i}$$

and (ii) if, in addition, H satisfies certain necessary and sufficient "Stäckel conditions."

[For detailed treatments of separability, see, for example (alphabetically): Dobronravov (1976, pp. 117–129), Frank (1935, pp. 83–90), Goldstein (1980, pp. 449–457, 613–615), Lur'e (1968, pp. 538–548), Nordheim and Fues (1927, pp. 122), Pars (1965, pp. 320–348), Prange (1935, pp. 644–657); and books on celestial mechanics: for example, Hagihara (1970, p. 77 ff.). For a readable discussion of the Stäckel theorem/conditions, including proof and examples, see, for example, Greenwood (1977, pp. 206–211).]

3. Ignorable Coordinates

Finally, in the case of an *ignorable* coordinate, say $q_1 \equiv \psi_1$, since the latter does not appear explicitly in either the Hamiltonian or the HJ equation, eqs. (8.10.12d) and (8.10.12b), with the slight indicial change $R \to P$, $p = 2, \ldots, n$ (in conformity with §8.3 ff.), reduce, respectively, to

$$dA_1/dq_1 = \beta_1 \equiv \Psi_1 \;\Rightarrow\; A_1 = \Psi_1\psi_1 + (additive)\ constant, \tag{8.10.13a}$$

$$A = A_R(t, q_R) + \Psi_1\psi_1 \equiv A_P(t, q_p) + \Psi_1\psi_1, \tag{8.10.13b}$$

where $\Psi_1 = \partial A/\partial\psi_1 =$ constant momentum, corresponding to ψ_1. Then, the HJ equation

$$H\big(t; q_2, \ldots, q_n;\ \partial A/\partial q_1 = \Psi_1, \partial A/\partial q_2, \ldots, \partial A/\partial q_n\big) + \partial A/\partial t = 0, \tag{8.10.13c}$$

simplifies to

$$H\big(t; q_2, \ldots, q_n; \Psi_1, \partial A_P/\partial q_2, \ldots, \partial A_P/\partial q_n\big) + \partial A_P/\partial t = 0, \tag{8.10.13d}$$

and has as complete solution

$$A_P = A_P(t; q_2, \ldots, q_n; \Psi_1, \beta_2, \ldots, \beta_n) \equiv A_P(t; q_p; \beta_1 = \Psi_1, \beta_p); \tag{8.10.13e}$$

$$\Rightarrow A = \Psi_1\psi_1 + A_P(t, q_p, \Psi_1, \beta_p). \tag{8.10.13f}$$

Hence, the finite equations of motion become

$$\partial A/\partial\Psi_1 = \psi_1 + \partial A_P/\partial\Psi_1 = \alpha_1, \qquad \partial A/\partial\beta_k = \partial A_P/\partial\beta_k = \alpha_k \qquad (k = 2, \ldots, n). \tag{8.10.13g}$$

In a conservative system, $q_1 \to t$ (time as an ignorable and separable "coordinate"), and $\beta_1 q_1 \to -E\,t(-E$ as corresponding constant "momentum"). For extensions of the above special cases to more than one variable, see ex. 8.10.5, below.

The inclusion of both ignorable and nonignorable coordinates under the general roof of separation of variables makes the HJ method one of the most powerful tools for integrating the Hamiltonian equations of motion. [The most prominent applications of this method are to be found not so much in earthly engineering as in celestial mechanics and modern nonlinear dynamics (and its transition to quantum mechanics); see, for example, Born (1927), Hagihara (1970), Tabor (1989). For extensive applications to rigid-body dynamics, see, for example, Chertkov (1960).]

Example 8.10.1 *Proof of Theorem of Jacobi.* Here, we show that the following equations

$$\partial A/\partial\beta_k = \alpha_k, \qquad \partial A/\partial q_k = p_k, \tag{a}$$

where $A = A[t, q(t), \beta_1, \ldots, \beta_n] \equiv A[t, q(t), \beta]$, constitute a complete integral of the HJ equation

$$H(t, q, \partial A/\partial q) + \partial A/\partial t = 0, \tag{b}$$

or, explicitly,

$$\partial A/\partial t + (1/2)\big[M'_{11}(\partial A/\partial q_1)^2 + M'_{22}(\partial A/\partial q_2)^2 + \cdots + 2M'_{12}(\partial A/\partial q_1)(\partial A/\partial q_2) + \cdots\big] + V = 0; \qquad \text{(b1)}$$

and $|\partial^2 A/\partial\beta_k \partial q_l| \neq 0$ [so that eqs. (a) are independent], satisfy the canonical equations

$$dq_k/dt = \partial H/\partial p_k, \qquad dp_k/dt = -\partial H/\partial q_k, \qquad \text{(c)}$$

identically.

PROOF

Since the α_k are constant, $(\ldots)^{\cdot}$-differentiating the first of (a), we obtain

$$0 = d\alpha_k/dt = (\partial A/\partial\beta_k)^{\cdot} = \partial^2 A/\partial t\,\partial\beta_k + \sum (\partial^2 A/\partial q_l\,\partial\beta_k)(dq_l/dt). \qquad \text{(d)}$$

Now we can either (i) solve the system (d) for the $\dot{q}_l$ and show that the solution satisfies the first of (c) identically; or, conversely, (ii) insert the $\dot{q}_k$ from the first of (c) into (d) and show that they satisfy it identically. Indeed:

(i) Equations (b, b1) hold identically in the β's. Therefore, comparing their $\partial(\ldots)/\partial\beta_k$-derivative

$$\partial^2 A/\partial\beta_k\,\partial t + \sum \big[M'_{1l}(\partial A/\partial q_1) + \cdots + M'_{1n}(\partial A/\partial q_n)\big](\partial^2 A/\partial\beta_k\,\partial q_l) = 0 \qquad \text{(e1)}$$

with (d), we conclude that

$$dq_l/dt = M'_{1l}(\partial A/\partial q_1) + \cdots + M'_{nl}(\partial A/\partial q_n). \qquad \text{(e2)}$$

[Equations (d) determine the $\dot{q}_l$ uniquely as linear functions of the $\partial^2 A/\partial\beta_k\,\partial t$; and, similarly, (e1) determine the right sides of (e2) as the same functions of them.] Hence, by prob. 8.2.1, $p_k = \partial A/\partial q_k$; and, accordingly, the Hamiltonian first of (c) hold; also, from (b), we conclude that $H = -\partial A/\partial t$. To prove the second of (c), we $\partial(\ldots)/\partial q_k$-differentiate (b), since the latter is an identity in the q's thus obtaining, successively,

$$\begin{aligned}\partial^2 A/\partial q_k\,\partial t &= -\partial H/\partial q_k - \sum (\partial H/\partial p_l)(\partial p_l/\partial q_k)\\ &= -\partial H/\partial q_k - \sum (\partial H/\partial p_l)(\partial^2 A/\partial q_k\,\partial q_l)\\ &= -\partial H/\partial q_k - \sum (\partial^2 A/\partial q_k\,\partial q_l)(dq_l/dt) \quad \text{[by first of (c)]}, \qquad \text{(f1)}\end{aligned}$$

or, rearranging,

$$\partial^2 A/\partial q_k\,\partial t + \sum (\partial^2 A/\partial q_k\,\partial q_l)(dq_l/dt) = -\partial H/\partial q_k, \qquad \text{(f2)}$$

or, finally,

$$(\partial A/\partial q_k)^{\cdot} = dp_k/dt = -\partial H/\partial q_k, \quad \text{Q.E.D.} \qquad \text{(f3)}$$

Hence, in the assumed motion, both Hamiltonian equations hold.

(ii) Due to the first of (c), (d) becomes

$$\partial^2 A/\partial t\,\partial\beta_k + \sum (\partial^2 A/\partial q_l\,\partial\beta_k)(\partial H/\partial p_l) = 0. \tag{g}$$

We will show that (g) holds identically. By $\partial(\ldots)/\partial\beta_k$-differentiating (b), since the latter is satisfied for arbitrary β's (i.e., identically), we obtain

$$\partial H/\partial\beta_k + \partial^2 A/\partial\beta_k\,\partial t = 0. \tag{h1}$$

But, since H depends on the β_k through the $\partial A/\partial q_k$ and these, in turn, depend on the β_k through $A = A[t, q(t), \beta]$,

$$\partial H/\partial\beta_k = \sum \big[\partial H/\partial(\partial A/\partial q_l)\big](\partial^2 A/\partial q_l\,\partial\beta_k), \tag{h2}$$

and so, comparing (h1) with (h2), we find

$$\partial^2 A/\partial\beta_k\,\partial t + \sum \big[\partial H/\partial(\partial A/\partial q_l)\big](\partial^2 A/\partial q_l\,\partial\beta_k) = 0,$$

or, thanks to the second of (a),

$$\partial^2 A/\partial\beta_k\,\partial t + \sum (\partial H/\partial p_l)(\partial^2 A/\partial q_l\,\partial\beta_k) = 0; \tag{h3}$$

that is, eqs. (g). Therefore, the first of (a) is indeed a solution of the first of (c).

Similarly, we can show that the second of (a) is a solution of the second of (c): $(\ldots)^{\cdot}$-differentiating the second of (a) and combining the so-resulting (d)-like system for the p_k with the second of (c), we are led to a (g)-like equation, and so on. (See also MacMillan, 1936, pp. 371–375.)

Example 8.10.2 *HJ Equation: From a Complete Integral (CI) to the General Integral (GI)* (Landau and Lifshitz, 1960, p. 148, footnote). Even though the GI is not needed in dynamics, it can be obtained from a CI as follows: we begin with the CI

$$A = A'(t; q_1, \ldots, q_n; \beta_1, \ldots, \beta_n) + \beta_{n+1} \equiv A'(t, q, \beta) + \beta', \tag{a}$$

but now we view its $(n+1)$th additive constant β' as an arbitrary function of the n β's:

$$\beta' = \beta'(\beta_1, \ldots, \beta_n) \equiv \beta'(\beta) \;\Rightarrow\; A = A(t, q, \beta). \tag{b}$$

Then, the GI of the HJ equation (8.10.10b) is found by replacing the β_k in (b) by their functional expressions obtained from the following n conditions

$$\partial A/\partial\beta_k = 0 \;\Rightarrow\; \beta_k = \beta_k(t, q) \;\Rightarrow\; \beta' = \beta'(t, q). \tag{c}$$

Indeed, applying chain rule to

$$A = A[t, q, \beta(t, q)] = W'[t; q, \beta(t, q)] + \beta'[\beta(t, q)] \equiv a(t, q), \tag{d}$$

and then invoking (d), we find

$$\partial a/\partial q_k = \partial A/\partial q_k + \sum (\partial A/\partial\beta_l)(\partial\beta_l/\partial q_k) = \partial A/\partial q_k; \tag{e}$$

that is, since the $\partial A/\partial q_k$ satisfy the HJ equation (A being a CI), so do the $\partial a/\partial q_k$, Q.E.D.

Example 8.10.3 *Particle in a Conservative Force Field; Harmonic Oscillator.* Let us consider the free motion of a particle P of mass m in a potential field $V = V(x, y, z)$, where (x, y, z) = rectangular Cartesian and inertial coordinates of P. Then, since

$$\begin{aligned} H = E \equiv T + V = mv^2/2 + V = p^2/2m + V& \\ = (1/2m)({p_x}^2 + {p_y}^2 + {p_z}^2) + V,& \end{aligned} \tag{a}$$

where $v^2 = \dot{x}^2 + \dot{y}^2 + \dot{z}^2$, and recalling (8.10.10e), $p_x = \partial A/\partial x = \partial A_o/\partial x = x$-component of linear momentum of P, and so on, cyclically, the "abbreviated" HJ equation of the system (8.10.11c) becomes

$$(\partial A_o/\partial x)^2 + (\partial A_o/\partial y)^2 + (\partial A_o/\partial z)^2 = 2m[E - V(x, y, z)]. \tag{b}$$

If P undergoes *one*-dimensional motion, say $V = V(q)$, where q = single Lagrangean coordinate, then (b) reduces to the *ordinary* differential equation

$$(dA_o/dq)^2 = 2m[E - V(q)], \tag{c}$$

and this leads readily to the quadrature

$$A_o(q; E) - A_o(q_o; E) = \int_{q_o}^{q} \{2m[E - V(q)]\}^{1/2} dq, \tag{d}$$

from some initial value q_o to q. From this, by (8.10.11l), we obtain

$$\partial A_o/\partial E = (m/2)^{1/2} \int_{q_o}^{q} [E - V(q)]^{-1/2} dq \equiv f(q, E) = t - t_o, \tag{e}$$

$$\Rightarrow \; q = q(t - t_o; E). \tag{e1}$$

Specialization

One-Dimensional Linear Harmonic Oscillator. Here,

$$2T = m(\dot{q})^2, \qquad 2V = kq^2 \qquad (k = \text{constant coefficient of elasticity}), \tag{f}$$

from which

$$\begin{aligned} &p = \partial L/\partial \dot{q} \;\Rightarrow\; \dot{q} = p/m \\ &\quad \Rightarrow\; T = p^2/2m \;\Rightarrow\; H = p^2/2m + kq^2/2 \\ &\quad \Rightarrow\; dq/dt = \partial H/\partial p = p/m, \quad dp/dt = -\partial H/\partial q = -kq. \end{aligned} \tag{g}$$

Accordingly, the HJ equation (8.10.10b) and its conservative specialization (8.10.11c) become

$$(1/2m)(\partial A/\partial q)^2 + kq^2/2 + \partial A/\partial t = 0, \tag{h}$$

$$(1/2m)(\partial A_o/\partial q)^2 + kq^2/2 = E, \tag{i}$$

respectively, where

$$A = A(t, q, \beta) = A(t, q, E) = A_o(q, E) - Et. \tag{j}$$

The solution of (i) is, to within an inessential additive constant, the quadrature

$$A_o(q, E) = (km)^{1/2} \int \left[(2E/k) - q^2\right]^{1/2} dq, \tag{k}$$

and, consequently,

$$A(t, q, E) = (km)^{1/2} \int \left[(2E/k) - q^2\right]^{1/2} dq - E\,t. \tag{l}$$

As a result, (8.10.10e) becomes (there is no need to evaluate the above integral yet)

$$\begin{aligned} \alpha = \partial A/\partial\beta = \partial A/\partial E &= (m/k)^{1/2} \int \left[(2E/k) - q^2\right]^{-1/2} dq - t \\ &= (m/k)^{1/2} \arccos[(k/2E)^{1/2} q] - t \qquad \text{(to within an arbitrary constant)}, \end{aligned} \tag{m}$$

and solving for q

$$q = (2E/k)^{1/2} \cos\left[(k/m)^{1/2}(t + \alpha)\right] = q(t; E, \alpha). \tag{n}$$

To express q in terms of t and the initial values q_o, p_o, we apply (8.10.10e):

$$\begin{aligned} p_o &= (\partial A/\partial q)_{\text{initial values}} = (km)^{1/2}\left[(2E/k) - {q_o}^2\right]^{1/2} \\ &= (2m)^{1/2}(E - k{q_o}^2/2)^{1/2} = (2m)^{1/2}(E - V_o)^{1/2} = \cdots = mv_o; \end{aligned} \tag{o}$$

from which, solving for E, we get

$${p_o}^2/2m + k{q_o}^2/2 = E = H. \tag{p}$$

Next, evaluating (m), or (n), at the initial instant t_o:

$$q_o = (2E/k)^{1/2} \cos[(k/m)^{1/2}(t_o + \alpha)] \qquad [\Rightarrow\ \alpha = \alpha(q_o, E; t_o)], \tag{q}$$

then, solving (p) and (q) for E and α in terms of q_o and p_o, and inserting these values in (n), we obtain $q = q(t; q_o, p_o)$.

For example, choosing $t_o = 0$, $q_o = 0$, $p_o \neq 0$ (i.e., impact), and with ${\omega_o}^2 \equiv k/m = (\textit{frequency})^2$, we obtain from (p, q)

$$E = {p_o}^2/2m, \qquad 0 = (2E/k)^{1/2} \cos(\omega_o \alpha) \ \Rightarrow\ \alpha = \pm(\pi/2\omega_o), \tag{r}$$

and so (n) becomes

$$q = ({p_o}^2/km)^{1/2} \cos(\omega_o t \pm \pi/2) = (-/+)({p_o}^2/k\,m)^{1/2} \sin(\omega_o t). \tag{s}$$

This yields, further,

$$p = m\,\dot{q} = \cdots = (-/+)\,m({p_o}^2/km)^{1/2}(k/m)^{1/2} \cos(\omega_o t), \tag{t}$$

and since for $t = 0$: $p = p_o$, only the $+$ sign applies in (s); that is, finally,

$$q = (p_o{}^2/km)^{1/2} \sin(\omega_o t) \qquad (\Rightarrow q_o = 0). \tag{u}$$

Geometrical Interpretation

(i) In the phase space of the *old* variables (i.e., the retangular Cartesian *qp*-plane), the representative system point describes an *ellipse* (with center at the origin *O–qp*, and *Oq*, *Op* as its principal axes) whose dimensions are determined from the initial conditions $q_o, p_o \to E$.

(ii) In the phase space of the *new* variables $q' = \alpha$, $p' = \beta = E$; however, *the representative point does not vary with time — that is, it is fixed on that plane* (compare with ex. 8.8.5). The properties of A_o, for this *periodic* system, are detailed in ex. 8.14.1.

Example 8.10.4 *HJ Equation of a Heavy Axisymmetric Gyroscope, Moving about a Fixed Point O.* For this well-known problem, we have already seen that (ex. 8.4.5; with the transverse moment of inertia denoted by B, instead of A, to avoid confusion with the action)

$$2T = B[(\dot{\theta})^2 + (\dot{\phi})^2 \sin^2\theta] + C(\dot{\psi} + \dot{\phi}\cos\theta)^2,$$

$$V = mgl\cos\theta \qquad (l \equiv OG, G = center\ of\ mass\ of\ gyroscope); \tag{a1}$$

$$\Rightarrow p_\phi \equiv \partial T/\partial\dot{\phi} = B\dot{\phi}\sin^2\theta + C(\dot{\psi} + \dot{\phi}\cos\theta)\cos\theta$$

$$\equiv B\dot{\phi}\sin^2\theta + Cn\cos\theta = constant \equiv C_\phi, \tag{a2}$$

$$p_\theta \equiv \partial T/\partial\dot{\theta} = B\,\dot{\theta}, \tag{a3}$$

$$p_\psi \equiv \partial T/\partial\dot{\psi} = C(\dot{\psi} + \dot{\phi}\cos\theta) \equiv C\,n = constant \equiv C_\psi; \tag{a4}$$

$$\dot{\phi} = (p_\phi - p_\psi\cos\theta)/B\sin^2\theta, \tag{a5}$$

$$\dot{\theta} = p_\theta/B, \tag{a6}$$

$$\dot{\psi} = p_\psi/C - (p_\phi - p_\psi\cos\theta)\cos\theta/B\sin^2\theta; \tag{a7}$$

$$\Rightarrow\ H = (1/2B)[p_\theta{}^2 + (p_\phi - p_\psi\cos\theta)^2/\sin^2\theta] + (1/2C)p_\psi{}^2 + m\,g\,l\cos\theta. \tag{a8}$$

Accordingly, the HJ equation of this conservative system becomes

$$(1/2)\{B^{-1}(\partial A_o/\partial\theta)^2 + C^{-1}(\partial A_o/\partial\psi)^2$$
$$+ (B\sin^2\theta)^{-1}[\partial A_o/\partial\phi - \cos\theta(\partial A_o/\partial\psi)]^2\} + mgl\cos\theta = E \quad (= \beta_1). \tag{b}$$

But, since ϕ and ψ are *ignorable* coordinates, we also have the two integrals

$$p_\phi = \partial A_o/\partial\phi = constant \equiv C_\phi \equiv B\beta_2, \tag{c1}$$

$$p_\psi = \partial A_o/\partial\psi = constant \equiv C_\psi \equiv B\beta_3; \tag{c2}$$

and, accordingly, (b) simplifies to

$$(1/2)\big[B^{-1}(\partial A_o/\partial\theta)^2 + C^{-1}(B\beta_3)^2 + (A/\sin^2\theta)(\beta_2 - \beta_3\cos\theta)^2\big] + m\,g\,l\cos\theta = E; \qquad \text{(d)}$$

from which, solving for $\partial A_o/\partial\theta$, we find

$$\begin{aligned} B^{-1}(\partial A_o/\partial\theta)^2 &= 2E - B^2\beta_3{}^2/C - 2m\,g\,l\cos\theta - (B/\sin^2\theta)(\beta_2 - \beta_3\cos\theta)^2 \\ &\equiv B f(\theta; \beta_1 = E, \beta_2, \beta_3) \equiv B f(\theta). \end{aligned} \qquad \text{(e)}$$

Therefore, it follows from the general results (8.10.11b, e) that (to within an additive constant)

$$A = A_o - E\,t = B\int [f(\theta)]^{1/2}\,d\theta + B(\beta_2\phi + \beta_3\psi) - E\,t. \qquad \text{(f)}$$

Hence, the three finite equations of motions of the gyroscope are

$$\partial A/\partial E = -t + \int [f(\theta)]^{-1/2}\,d\theta = -t_o \quad (= \alpha_1), \qquad \text{(g1)}$$

$$\partial A/\partial\beta_2 = B\Big\{\phi - \int [(\beta_2 - \beta_3\cos\theta)/\sin^2\theta][f(\theta)]^{-1/2}\,d\theta\Big\} = B\,\phi_o \quad (= \alpha_2), \qquad \text{(g2)}$$

$$\begin{aligned} \partial A/\partial\beta_3 &= B\Big\{\psi + \int [-(B\beta_3/C) + (\beta_2 - \beta_3\cos\theta)\cos\theta/\sin^2\theta][f(\theta)]^{-1/2}\,d\theta\Big\} \\ &= B\psi_o \quad (= \alpha_3), \end{aligned} \qquad \text{(g3)}$$

where t_o, ϕ_o, ψ_o are three new constants. Equation (g1) yields θ as a function of time, while (g2, 3) yield, respectively, ϕ and ψ as functions of θ. These results, of course, coincide with those found by other means. See also MacMillan (1936, pp. 378–380).

Example 8.10.5 *Separation of Variables, Ignorable Coordinates, Conservative Systems.*

(i) Separation of Variables

Let the system Hamiltonian have the form

$$H = H\big[f_1(q_1, p_1), \ldots, f_M(q_M, p_M); q_{M+1}, \ldots, q_n; \partial A/\partial q_{M+1}, \ldots, \partial A/\partial q_n; t\big]; \qquad \text{(a)}$$

that is, the first $M(< n)$ variables are separable. Then, the HJ equation becomes

$$H\big[f_1(q_1, \partial A/\partial q_1), \ldots, f_M(q_M, \partial A/\partial q_M); q_{M+1}, \ldots, q_n;\ \partial A/\partial q_{M+1}, \ldots, \partial A/\partial q_n; t\big] + \partial A/\partial t = 0. \qquad \text{(b)}$$

Assuming the following partially *separable* action:

$$A = A_1(q_1) + \cdots + A_M(q_M) + A_R(q_R, t), \qquad \text{(c)}$$

where $q_R \equiv (q_{M+1}, \ldots, q_n) =$ *remaining* (nonseparable) coordinates, reduces (b) to

$$H\big[f_1(q_1, dA_1/dq_1), \ldots, f_M(q_M, dA_M/dq_M); q_{M+1}, \ldots, q_n; \partial A_R/\partial q_{M+1}, \ldots, \partial A_R/\partial q_n; t\big] + \partial A_R/\partial t = 0, \qquad \text{(d)}$$

and from this, reasoning as in the derivation of (8.10.12d, e) from (8.10.12c), we are readily led to the M uncoupled ordinary differential equations:

$$f_1(q_1, dA_1/dq_1) = \beta_1, \ldots, f_M(q_M, dA_M/dq_M) = \beta_M, \qquad \text{(e)}$$

from which we can determine $A_1, \ldots, A_M$ by quadrature; and the partial differential equation

$$H\big[\beta_1, \ldots, \beta_M; q_{M+1}, \ldots, q_n; \partial A_R/\partial q_{M+1}, \ldots, \partial A_R/\partial q_n; t\big] + \partial A_R/\partial t = 0, \qquad \text{(f)}$$

which is still coupled, but in *fewer* variables than the original (b).

(ii) Ignorable Coordinates

Next, let $q_1 \equiv \psi_1, \ldots, q_M \equiv \psi_M$ be *ignorable* (recall §8.4). Then, the corresponding momenta are constant:

$$p_1 = \partial A/\partial \psi_1 = \beta_1 \equiv \Psi_1, \ldots, p_M = \partial A/\partial \psi_M = \beta_M \equiv \Psi_M, \qquad \text{(g)}$$

Setting in the corresponding HJ equation

$$H(q_p;\ \Psi;\ \partial A/\partial q_p, t) + \partial A/\partial t = 0 \qquad \text{(h)}$$

the action

$$A = \sum \Psi_i \psi_i + A_P(q_p, t) \qquad (i = 1, \ldots, M), \qquad \text{(i)}$$

where $q_p \equiv (q_{M+1}, \ldots, q_n)$, $\Psi \equiv (\Psi_1, \ldots, \Psi_M) \equiv (\Psi_i)$, reduces (h) to the simpler form:

$$H(q_p; \Psi; \partial A_P/\partial q_{M+1}, \ldots, \partial A_P/\partial q_n;\ t) + \partial A_P/\partial t = 0; \qquad \text{(j)}$$

A_P depends on fewer independent variables than A: the $M - n$ q_p and t.

(iii) Conservative Systems

Continuing, we consider a conservative system with *completely separable* Hamiltonian

$$H = H\big[f_1(q_1, p_1), \ldots, f_n(q_n, p_n)\big], \qquad \text{(k)}$$

and, therefore, by (8.10.11c), HJ equation

$$H\big[f_1(q_1, \partial A_o/\partial q_1), \ldots, f_n(q_n, \partial A_o/\partial q_n)\big] = E\ (\textit{constant}). \qquad \text{(l)}$$

Substituting in it the completely separable reduced action

$$A_o = \sum A_k(q_k) \qquad \text{(m)}$$

transforms it to

$$H\big[f_1(q_1, dA_1/dq_1), \ldots, f_n(q_n, dA_n/dq_n)\big] = E; \tag{n}$$

and this, reasoning as in the derivation of (8.10.12d), leads us to the n ordinary differential equations:

$$f_1(q_1, dA_1/dq_1) = \beta_1, \ldots, f_n(q_n, dA_n/dq_n) = \beta_n, \tag{o}$$

which can be solved by quadratures.

In view of these results, the fundamental HJ relations (8.10.11e ff., 10d) reduce to

$$E = H(\beta_1, \ldots, \beta_n) \equiv H(\beta), \tag{p}$$

$$A = A_o - E\,t = \sum A_k(q_k; \beta_k) - E\,t, \tag{q}$$

$$\alpha_k = \partial A/\partial\beta_k = \partial A_k/\partial\beta_k - (\partial E/\partial\beta_k)t \;\Rightarrow\; \partial A_k/\partial\beta_k = \alpha_k + (\partial E/\partial\beta_k)t. \tag{r}$$

(iv) Conservative Systems with Ignorable Coordinates

Finally, for a conservative system with $M(< n)$ ignorable coordinates $\psi \equiv (\psi_1, \ldots, \psi_M) \equiv (\psi_i)$, the reduced HJ equation (8.10.11c) becomes (with the earlier notations)

$$H(q_p;\ \Psi;\ \partial A_o/\partial q_p) = E. \tag{s}$$

Substituting into it, as in (h),

$$A_o = \sum \Psi_i\,\psi_i + A_P(q_p, \partial A_P/\partial q_{M+1}, \ldots, \partial A_P/\partial q_n), \tag{t}$$

we are led to the simpler than (s) HJ equation

$$H(q_p;\ \Psi;\ \partial A_P/\partial q_{M+1}, \ldots, \partial A_P/\partial q_n) = E \tag{u}$$

(since A_P is a function of only $n - M$ independent variables, the q_p), whose solution is, to within an inessential additive constant,

$$A_P = A_P(q_{M+1}, \ldots, q_n;\ \beta_{M+1}, \ldots, \beta_n;\ \Psi_i = \beta_i) \equiv A_P(q_p;\ \beta_p;\ \Psi), \tag{v}$$

$$\Rightarrow\;\; A = A_o - E\,t = \sum \Psi_i\,\psi_i + A_P(q_p, \beta_p, \Psi) - E\,t. \tag{w}$$

Hence, the fundamental HJ relations (8.10.11i, j, l) reduce to

$$\alpha_i = \partial A/\partial\beta_i \equiv \partial A/\partial\Psi_i = \partial A_o/\partial\Psi_i = \psi_i + \partial A_P/\partial\Psi_i \qquad (\text{here}, \beta_i = \Psi_i),$$

$$\Rightarrow\;\; \partial A_P/\partial\Psi_i = \alpha_i - \psi_i \qquad (i = 1, \ldots, M), \tag{x}$$

$$\alpha_{M+1} = \partial A/\partial\beta_{M+1} \equiv \partial A/\partial E = \partial A_o/\partial E - (\partial E/\partial E)t = \partial A_P/\partial E - (1)t = -t_o,$$

$$\Rightarrow \partial A_P/\partial E = t - t_o \qquad (\text{here}, \beta_{M+1} = E), \tag{y}$$

$$\alpha_{p'} = \partial A/\partial\beta_{p'} = \partial A_o/\partial\beta_{p'} = \partial A_P/\partial\beta_{p'} \qquad (p' = M+1, \ldots, n). \tag{z}$$

Below, we discuss a few elementary applications of the foregoing theory.

Example 8.10.6 *Two-Dimensional Linear and Isotropic Oscillator* (Butenin, 1971, pp. 163–165). Here, the kinetic and potential energies of this conservative system are (using standard notations)

$$2T = m[(\dot{q}_1)^2 + (\dot{q}_2)^2], \qquad 2V = k({q_1}^2 + {q_2}^2), \tag{a}$$

respectively, and therefore the Hamiltonian and reduced HJ equations are

$$H = (1/2m)({p_1}^2 + {p_2}^2) + (k/2)({q_1}^2 + {q_2}^2), \tag{b}$$

$$\left[(1/2m)(\partial A_o/\partial q_1)^2 + (k/2){q_1}^2\right] + \left[(1/2m)(\partial A_o/\partial q_2)^2 + (k/2){q_2}^2\right] = E. \tag{c}$$

Substituting into the completely separable equation (c) the equally separable reduced action

$$A_o = A_1(q_1) + A_2(q_2), \tag{d}$$

we are immediately led to the two uncoupled ordinary differential equations

$$(1/2m)(dA_1/dq_1)^2 + (k/2){q_1}^2 = \beta_1, \qquad (1/2m)(dA_2/dq_2)^2 + (k/2){q_2}^2 = \beta_2, \tag{e}$$

where

$$\beta_1 + \beta_2 = E. \tag{f}$$

The above readily lead to the quadratures (omitting inessential additive constants)

$$A_r = \int \left[m(2\beta_r - k{q_r}^2)\right]^{1/2} dq_r \qquad (r = 1, 2), \tag{g}$$

and from these we obtain, by differentiation and elementary integrations,

$$dA_r/d\beta_r = (m/k)^{1/2} \arcsin\left[q_r/(2\beta_r/k)^{1/2}\right]; \tag{h}$$

and when these results are compared with the corresponding finite equations of motion [equations (r) of preceding example, and (8.10.10e)]:

$$dA_r/d\beta_r = \alpha_r + (\partial E/\partial\beta_r)t = \alpha_r + t, \tag{i}$$

$$dA_r/dq_r = p_r \quad (= m\dot{q}_r), \tag{j}$$

they yield, respectively,

$$\arcsin\left[q_r/(2\beta_r/k)^{1/2}\right] = (k/m)^{1/2}(t + \alpha_r) \ \Rightarrow\ q_r = (2\beta_r/k)^{1/2} \sin\left[(k/m)^{1/2}(t + \alpha_r)\right], \tag{k}$$

$$p_r = \left[m(2\beta_r - k{q_r}^2)\right]^{1/2}. \tag{l}$$

For the initial conditions at $t = 0$: $q_1 = a$, $\dot{q}_1 = 0$, $q_2 = 0$, $\dot{q}_2 = v_o$, (k, l) give

$$a = (2\beta_1/k)^{1/2} \sin[(k/m)^{1/2}\alpha_1], \qquad 0 = (2\beta_2/k)^{1/2} \sin[(k/m)^{1/2}\alpha_2],$$
$$\left[m(2\beta_1 - ka^2)\right]^{1/2} = 0, \qquad [m(2\beta_2)]^{1/2} = mv_o, \tag{m}$$

or, upon solving for the β's and α's,

$$\beta_1 = ka^2/2, \quad \beta_2 = mv_o{}^2/2; \qquad \alpha_1 = (\pi/2)(m/k)^{1/2}, \quad \alpha_2 = 0; \tag{n}$$

and so, finally, the motion (k, l) specializes to

$$q_1 = a\cos[(k/m)^{1/2}t], \qquad q_2 = v_o(m/k)^{1/2}\sin[(k/m)^{1/2}t]. \tag{o}$$

Example 8.10.7 *Plane Motion of a Particle in a Uniform Gravitational Field.* Here, the kinetic and potential energies of this system are (using standard notations)

$$2T = m[(\dot{q}_1)^2 + (\dot{q}_2)^2], \qquad V = m\,g\,q_2, \tag{a}$$

respectively [$O - q_1q_2$: inertial rectangular Cartesian coordinates of particle, q_1: *horizontal*, q_2: *vertical* (positive upward)], and therefore the Hamiltonian and HJ equations are

$$H = (1/2m)(p_1{}^2 + p_2{}^2) + m\,g\,q_2, \tag{b}$$

$$(1/2m)\left[(\partial A/\partial q_1)^2 + (\partial A/\partial q_2)^2\right] + m\,g\,q_2 + \partial A/\partial t = 0. \tag{c}$$

Since q_1 is also *ignorable*, in addition to the system being conservative, following the theory of (8.10.13a ff.) and the preceding example, we try the Action function (with $q_1 \equiv \psi_1, p_1 \equiv \Psi_1 = \beta_1$):

$$A = \beta_1\psi_1 + A_2(q_2) - Et \equiv A_o - E\,t. \tag{d}$$

First Solution

Substituting (d) into (c), we readily find

$$\beta_1{}^2/2m + (1/2m)(dA_2/dq_2)^2 + m\,g\,q_2 = E, \tag{e}$$

and this leads us, easily, to the following *two* equations:

$$(1/2m)(dA_2/dq_2)^2 + m\,g\,q_2 = \beta_2, \qquad \beta_2 + \beta_1{}^2/2m = E. \tag{f}$$

Hence, the finite equations of motion are

$$\begin{aligned}\partial A/\partial\beta_1 &= q_1 - (\partial E/\partial\beta_1)t = q_1 - (\beta_1/m)t = \alpha_1\\ &\Rightarrow\ q_1 = (\beta_1/m)t + \alpha_1,\end{aligned} \tag{g}$$

$$\begin{aligned}\partial A/\partial\beta_2 &= dA_2/d\beta_2 - (\partial E/\partial\beta_2)t = dA_2/d\beta_2 - (1)t = \alpha_2\\ &\Rightarrow\ dA_2/d\beta_2 = t + \alpha_2.\end{aligned} \tag{h}$$

But, from the first of (f), we find

$$dA_2/dq_2 = [2m(\beta_2 - m\,g\,q_2)]^{1/2}, \tag{i}$$

$$\Rightarrow\ A_2 = \int [2m(\beta_2 - m\,g\,q_2)]^{1/2}\,dq_2 + constant; \tag{j}$$

and, therefore

$$dA_2/d\beta_2 = \int m\big[2m(\beta_2 - m\,g\,q_2)\big]^{-1/2}\,dq_2 = -(1/mg)\big[2m(\beta_2 - m\,g\,q_2)\big]^{1/2}. \qquad \text{(k)}$$

Equating the right sides of (h) and (k), and then solving for q_2, we get

$$q_2 = -(g/2)(t + \alpha_2)^2 + \beta_2/mg. \qquad \text{(l)}$$

Finally, applying the remaining finite equations

$$\partial A/\partial q_1 = \beta_1 = p_1 = m\,\dot{q}_1, \qquad \partial A/\partial q_2 = dA_2/dq_2 = t + \beta_2 = p_2 = m\,\dot{q}_2, \qquad \text{(m)}$$

for the common initial conditions at $t = 0$: $q_1 = 0$, $\dot{q}_1 = v_o$, $q_2 = h$, $\dot{q}_2 = 0$, we find

$$\beta_1 = m\,v_o, \quad \beta_2 = mgh; \qquad \alpha_1 = 0, \quad \alpha_2 = 0; \qquad \text{(n)}$$

and so, finally, the motion (g, l) specializes to the well-known solution

$$q_1 = v_o t, \qquad q_2 = h - (1/2)gt^2. \qquad \text{(o)}$$

Second Solution

The reduced HJ equation is

$$(1/2m)\big[(\partial A_o/\partial q_1)^2 + (\partial A_o/\partial q_2)^2\big] + m\,g\,q_2 = \beta_2, \qquad \text{(p)}$$

or

$$(\partial A_o/\partial q_1)^2 + (\partial A_o/\partial q_2)^2 + 2m^2 g q_2 = 2m\beta_2. \qquad \text{(q)}$$

By Hamilton's equations: $\partial H/\partial q_1 = dp_1/dt = 0 \;\Rightarrow\; p_1 = constant \equiv \beta_1 = \partial A_o/\partial q_1$, and so (q) gives

$$(\partial A_o/\partial q_2)^2 = 2m\beta_2 - 2m^2 g\,q_2 - (\partial A_o/\partial q_1)^2 = 2m\beta_2 - {\beta_1}^2 - 2m^2 g\,q_2.$$

Hence, q_1, q_2 are *separable* and

$$\begin{aligned} A_o &= \int (\partial A_o/\partial q_1)\,dq_1 + \int (\partial A_o/\partial q_2)\,dq_2 \\ &= \beta_1 q_1 + \int (2m\beta_2 - {\beta_1}^2 - 2m^2 g q_2)^{1/2}\,dq_2. \end{aligned} \qquad \text{(r)}$$

The particle trajectory is given by $\partial A_o/\partial \beta_1 = \alpha_1$:

$$\begin{aligned} & q_1 - \int \beta_1 (2m\beta_2 - {\beta_1}^2 - 2m^2 g\,q_2)^{-1/2}\,dq_2 = \alpha_1 \\ & \Rightarrow\; q_1 + (\beta_1/g\,m^2)(2m\beta_2 - {\beta_1}^2 - 2m^2 g q_2)^{1/2} = \alpha_1 \qquad \text{(a parabola);} \end{aligned} \qquad \text{(s)}$$

and the corresponding time by $\partial A_o/\partial\beta_2 = t + \alpha_2$:

$$\int m(2m\beta_2 - \beta_1{}^2 - 2m^2 g q_2)^{-1/2}\, dq_2 = t + \alpha_2$$

$$\Rightarrow\ -(1/mg)(2m\beta_2 - \beta_1{}^2 - 2m^2 g\, q_2)^{1/2} = t + \alpha_2 \qquad \text{(time at which height is } q_2\text{).} \tag{t}$$

Example 8.10.8 *Theorem of Liouville* (Recall ex. 3.12.4). This generalizes the results of the preceding examples, 8.10.6 and 8.10.7. Let us consider a *Liouville* system; that is, one whose kinetic and potential energies have the following forms:

$$2T = u\big[v_1(q_1)(\dot q_1)^2 + \cdots + v_n(q_n)(\dot q_n)^2\big] \equiv u\big[v_1(\dot q_1)^2 + \cdots + v_n(\dot q_n)^2\big], \tag{a}$$

$$V = \big[w_1(q_1) + \cdots + w_n(q_n)\big]/u \equiv (w_1 + \cdots + w_n)/u, \tag{b}$$

respectively, where $u \equiv u_1(q_1) + \cdots + u_n(q_n) \equiv u_1 + \cdots + u_n\ (> 0)$.

Since $p_k \equiv \partial T/\partial \dot q_k = u\, v_k\, \dot q_k$, it is not hard to see that the corresponding Hamiltonian function and reduced HJ equation of this conservative system are

$$H = T + V = (1/2)\, u \sum v_k(\dot q_k)^2 + u^{-1} \sum w_k = u^{-1} \sum (p_k{}^2/2v_k + w_k) \quad (\equiv E),$$

$$\sum \big[(1/2v_k)(\partial A_o/\partial q_k)^2 + w_k - E\, u_k\big] = 0. \tag{c}$$

Setting in this *completely separable* equation the following similarly separable reduced action:

$$A_o = A_1(q_1) + \cdots + A_n(q_n), \tag{d}$$

yields

$$\sum \big[(1/2v_k)(dA_k/dq_k)^2 + w_k - E\, u_k\big] = 0, \qquad p_k = dA_k/dq_k, \tag{e}$$

and from this, reasoning as in the derivation of (8.10.12d), we obtain the following n ordinary differential equations:

$$(1/2v_k)(dA_k/dq_k)^2 + w_k - E\, u_k = \beta_k, \tag{f}$$

where the n constants β_k are subject to the condition

$$\beta_1 + \beta_2 + \cdots + \beta_n = 0 \ \Rightarrow\ \beta_1 = -(\beta_2 + \cdots + \beta_n) = \beta_1(\beta_2, \ldots, \beta_n). \tag{g}$$

[Recall equivalent condition (j4) of ex. 3.12.4.]

From (f), we are readily led to the quadratures (to within inessential additive constants)

$$A_k = \int \big[2v_k(\beta_k + E\, u_k - w_k)\big]^{1/2}\, dq_k \quad \left[= \int p_k\, dq_k = A_k(q_k; \beta, E)\right]. \tag{h}$$

Due to the constraint (g), only n of the constants $E, \beta_1, \beta_2, \ldots, \beta_n$ appearing in the integrals (h) are independent; and therefore the reduced action built from the latter via (d), as containing n independent essential constants, will indeed be a complete integral; that is,

$$A_0 = \sum A_k(q, E, \beta_1, \beta_2, \ldots, \beta_n) = \sum A_k\big[q, E, \beta_1(\beta_2, \ldots, \beta_n), \beta_2, \ldots, \beta_n\big]$$
$$\equiv A_{oo}(q, E, \beta_2, \ldots, \beta_n) = A_{oo}. \tag{i}$$

In view of these results, the finite equations of motion reduce to the following quadratures:

(i) $\partial A_{oo}/\partial E = \partial A_o/\partial E = t - t_o$:

$$\sum \int (v_k)^{1/2}\big[2(\beta_k + E\,u_k - w_k)\big]^{-1/2} u_k\, dq_k = t - t_o, \tag{j}$$

(ii) $\partial A_{oo}/\partial \beta_r = \partial A_o/\partial \beta_r + (\partial A_o/\partial \beta_1)(\partial \beta_1/\partial \beta_r)$

$$= \partial A_o/\partial \beta_r + (\partial A_o/\partial \beta_1)(-1) = \partial A_o/\partial \beta_r - \partial A_o/\partial \beta_1 = \alpha_r \ (r = 2, \ldots, 2n):$$

$$\int (v_r)^{1/2}[2(\beta_r + E\,u_r - w_r)]^{-1/2}\, dq_r - \int (v_1)^{1/2}[2(\beta_1 + E\,u_1 - w_1)]^{-1/2}\, dq_1 = \alpha_r. \tag{k}$$

[Compare with their equivalent equations (k1, 2) of ex. 3.12.4.] Equation (j) and the $n-1$ equations (k) supply the n independent constants $\alpha_1 = -t_o, \ldots, \alpha_n$, which, along with the earlier $n-1$ independent β's and the energy (i.e., $E, \beta_2, \ldots, \beta_n$), constitute the $2n$ constants of integration of our system (a, b).

For additional details on these systems [including generalizations originally studied by Goursat, Di Pirro, Stäckel et al. (late 19th century)] see, for example (alphabetically): Appell (1953, vol. 2, pp. 439–440), Hamel (1949, pp. 302–303, 358–361), Lur'e (1968, pp. 538–548), Whittaker (1937, pp. 335–336); and, especially, texts on celestial mechanics, for example, Hagihara (1970).

Example 8.10.9 *Hamiltonian Form of Lagrangean Method of Variation of Constants/Parameters.* Let us consider a system with canonical equations of motion

$$dq_k/dt = \partial H/\partial p_k, \qquad dp_k/dt = -\partial H/\partial q_k \qquad (k = 1, \ldots, n) \tag{a}$$

and such that

$$H = H_o + H_1, \qquad H_1\text{: } \textit{small} \text{ relative to } H_o. \tag{b}$$

For example, in a planetary motion problem, H_o would be the Sun–Earth (two-body problem) Hamiltonian, while H_1 would be the Hamiltonian of the perturbative action of the remaining planets of our solar system on Earth [recall discussion following eq. (8.7.17)]. Let us assume that the solution of the *unperturbed* problem

$$dq_k/dt = \partial H_o/\partial p_k, \qquad dp_k/dt = -\partial H_o/\partial q_k \tag{c}$$

is known — that is, an action function

$$A = A(t, q, \beta), \qquad \beta \equiv (\beta_1, \ldots, \beta_n), \tag{d}$$

has been (or can be) found that satisfies the unperturbed Hamilton–Jacobi (HJ) equation

$$\partial A/\partial t + H_o(t, q, \partial A/\partial t) = 0, \tag{e}$$

and can, therefore, supply the integrals of (c) via the finite equations

$$p_k = \partial A/\partial q_k, \qquad \alpha_k = \partial A/\partial \beta_k; \tag{f}$$

that is, the solutions of (f):

$$q_k = q_k(t, \alpha, \beta), \qquad p_k = p_k(t, \alpha, \beta), \qquad \alpha \equiv (\alpha_1, \ldots, \alpha_n) \tag{g}$$

when substituted back into (c), satisfy them identically.

Here, however, we will view (g) not as solutions of (c) but as *equations of a canonical transformation from the old variables* (q, p) *to the new "variables"* $(\alpha, \beta) \equiv (q', p')$, with generating function $A = A(t, q, \beta) \equiv A(t, q, \beta = p') = F_2(t, q, p')$ (§8.8). In this interpretation, the (no longer constant) $\alpha = q'$ and $\beta = p'$, satisfy the *perturbation* canonical equations

$$\begin{aligned} d\alpha_k/dt &= \partial H'/\partial \beta_k = \partial/\partial \beta_k(H + \partial A/\partial t) \\ &= \partial/\partial \beta_k(H_o + H_1 + \partial A/\partial t) = \partial H_1/\partial \beta_k \qquad \text{[invoking (e)]}, \end{aligned} \tag{h}$$

$$d\beta_k/dt = -\partial H'/\partial \alpha_k = \cdots = -\partial H_1/\partial \alpha_k; \tag{i}$$

where we have used the unperturbed solutions (g) in H_1 to express it in terms of the α and β, and t. Substituting the solutions of (h, i) in the unperturbed solutions for q, p, we obtain the solutions of the perturbed problem.

We notice that equations (h, i) coincide with the earlier (j, l) of ex. 8.7.4, with the following identifications: $c_k \to \alpha_k$, $c_{n+l} \to \beta_l$, $\Omega \to H_1$.

An Application

Let the unperturbed Hamiltonian be

$$H_o = (1/2)p^2; \qquad \text{e.g., free rectilinear motion of particle of unit mass.} \tag{j}$$

The corresponding HJ equations is

$$(1/2)\,(\partial A_o/\partial q)^2 = \alpha \quad (= \text{total energy}), \tag{k}$$

and its solution is

$$A_o = (2\alpha)^{1/2} q \qquad [A = A_o - \alpha t = F_1(t, q, q')]. \tag{l}$$

Hence, the complete unperturbed solution is

$$p = \partial F_1/\partial q = \partial A_o/\partial q = (2\alpha)^{1/2}, \tag{m}$$

$$\begin{aligned} &\beta = -\partial A/\partial \alpha = -\partial A_o/\partial \alpha + t \;\Rightarrow\; t - \beta = \partial A_o/\partial \alpha = (2\alpha)^{-1/2} q \\ &\quad \Rightarrow\; q = (2\alpha)^{1/2}(t - \beta); \quad \text{i.e., rectilinear motion with uniform velocity } (2\alpha)^{1/2}. \end{aligned} \tag{n}$$

Next, let us add to the system the perturbative (linear elastic) force $-q$, so that its complete perturbed Hamiltonian is

$$H = (1/2)p^2 + (1/2)q^2 \equiv H_o + H_1, \tag{o}$$

and view the perturbed solution as having the same *form* as the unperturbed solution (m, n), but with α and β as variables satisfying the perturbation equations (h, i), with $k = 1$ and

$$H_1 = (1/2)q^2|_{\text{unperturbed solution }(n)} = \alpha(t-\beta)^2 = H_1(t, \alpha, \beta), \tag{p}$$

$$d\alpha/dt = \partial H_1/\partial\beta = -2\alpha(t-\beta), \qquad d\beta/dt = -\partial H_1/\partial\alpha = -(t-\beta)^2. \tag{q}$$

Integrating (p, q) we readily find

$$\alpha = \alpha_o \cos^2(t-\beta_o), \quad \beta = t - \tan(t-\beta_o); \qquad \alpha_o, \beta_o\text{: integration constants,} \tag{r}$$

and hence the perturbed solution is

$$q = (2\alpha_o)^{1/2}\sin(t-\beta_o), \qquad p = (2\alpha_o)^{1/2}\cos(t-\beta_o); \tag{s}$$

that is, a simple harmonic motion of amplitude: $(2\alpha_o)^{1/2}$, frequency: 1 (period: 2π), and phase (or "epoch of origin passage"): β_o. It is not hard to verify that (s) does indeed satisfy the canonical perturbed [(o)-based] equations:

$$dq/dt = \partial H/\partial p = p, \qquad dp/dt = -\partial H/\partial q = -q. \tag{t}$$

Example 8.10.10 *A Simplification of the Perturbation Equations.* Continuing from the preceding example, *let α_{ko}, β_{ko} denote the parts of α_k, β_k that are constant in the perturbed motion.* Then we can write

$$\alpha_k = \alpha_{ko} + x_k(t), \qquad \beta_k = \beta_{ko} + y_k(t), \tag{a}$$

and, therefore, to the *same degree* of accuracy [since the Hamiltonian equations, unlike the Lagrangean equations (§3.10), are of the *first order*], and with some easily understood notations,

$$\begin{aligned} H_1 &= H_1(\alpha, \beta) = H_1(\alpha_o + x, \beta_o + y) \\ &= H_1(\alpha_o, \beta_o) + \sum \left[(\partial H_1/\partial\alpha_k)_o x_k + (\partial H_1/\partial\beta_k)_o y_k\right] \\ &\equiv H_{1o} + \sum \left[(\partial H_{1o}/\partial\alpha_{ko})x_k + (\partial H_{1o}/\partial\beta_{ko})y_k\right]. \end{aligned} \tag{b}$$

Substituting the above into eqs. (h, i) of the preceding example, we obtain

$$dx_k/dt = \partial H_1/\partial\beta_{ko}, \qquad dy_k/dt = -\partial H_1/\partial\alpha_{ko}; \tag{c}$$

or, *again, to the first order*,

$$dx_k/dt = \partial H_{1o}/\partial\beta_{ko}, \qquad dy_k/dt = -\partial H_{1o}/\partial\alpha_{ko}. \tag{d}$$

An Application

Let us apply these results to the (weakly) *quadratically* nonlinear oscillator:

$$\ddot{q} + \omega_o{}^2 q + \varepsilon\, q^2 = 0 \qquad [\omega_o = \text{frequency for } \varepsilon = 0, \text{a constant}]. \tag{e}$$

Here, clearly,

$$H_o = (1/2)\,(p^2 + \omega_o{}^2 q^2), \qquad H_1 = (1/3)\varepsilon q^3, \tag{f}$$

and since the solution of the *unperturbed* problem (i.e., $\varepsilon = 0,\ H_1 = 0$) is

$$q = q_o \cos(\omega_o t) + (p_o/\omega_o)\sin(\omega_o t), \qquad p = \dot{q} = \ldots, \tag{g}$$

where $q_o/p_o =$ initial *position/momentum* of *unperturbed* problem (i.e., $\alpha_o = q_o$, $\beta_o = p_o$), we will have

$$H_1 \to H_{1o} = (\varepsilon/3)[q_o \cos(\omega_o t) + (p_o/\omega_o)\sin(\omega_o t)]^3 \equiv (\varepsilon/3)[\ldots]^3. \tag{h}$$

As a result, the perturbation equations (d) yield

$$dx/dt = \partial H_{1o}/\partial p_o = \varepsilon[\ldots]^2\,[\sin(\omega_o t)/\omega_o], \tag{i}$$

$$dy/dt = -\partial H_{1o}/\partial q_o = -\varepsilon[\ldots]^2 \cos(\omega_o t). \tag{j}$$

Integrating (i, j), and then adding the results to (g), we obtain the solution of (e), correct to ε-proportional terms. The details are left to the reader (see, e.g., Kilmister, 1967, p. 118).

Example 8.10.11 *Hamiltonian Form of Variation of Constants/Parameters (continued): Combination with Method of Averaging.* Continuing from the last two examples, if the solution of the unperturbed equations is τ-*periodic*, then we still solve the approximate perturbation equations (h, i) of ex. 8.10.9, but *with* $H' = H_1$ *replaced with its average over* τ, that is, by

$$\langle H_1 \rangle \equiv (1/\tau)\int_0^\tau H_1(\alpha, \beta, t)\,dt, \tag{a}$$

and α, β treated as constants. Let us apply this "*averaged method of variation of parameters*" to the well-known Duffing's oscillator:

$$\ddot{q} + \omega_o{}^2 q + \varepsilon q^3 = 0 \qquad [\omega_o = \text{frequency for } \varepsilon = 0, \text{a constant}]. \tag{b}$$

Its Hamiltonian is easily found to be

$$H = H_o + H_1,$$

$$H_o = (1/2)(p^2 + \omega_o{}^2 q^2), \qquad H_1 = (1/4)\varepsilon\, q^4 = \textit{small perturbation}. \tag{c}$$

The corresponding reduced and unperturbed HJ equation ($\varepsilon = 0$) is

$$(dA_o/dq)^2 + \omega_o{}^2 q^2 = 2\beta \qquad [\text{where } A = A_o(q) - \beta\, t], \tag{d}$$

and so its solution is

$$A_o = \int (2\beta - \omega_o{}^2 q^2)^{1/2}\,dq \;\Rightarrow\; A = \int (2\beta - \omega_o{}^2 q^2)^{1/2} - \beta\, t. \tag{e}$$

As a result, the equation of finite unperturbed motion becomes

$$\alpha = \partial A/\partial\beta = \int (2\beta - \omega_o{}^2 q^2)^{-1/2}\, dq - t = (1/\omega_o)\arcsin\left[\omega_o q/(2\beta)^{1/2}\right] - t,$$

$$\Rightarrow\ q = [(2\beta)^{1/2}/\omega_o]\sin[\omega_o(t+\alpha)]\text{: unperturbed solution; } \tau = 2\pi/\omega_o. \tag{f}$$

Therefore, the perturbation Hamiltonian equals

$$\begin{aligned} H_1 &= (1/4)\varepsilon q^4 = (\varepsilon\beta^2/\omega_o{}^4)\sin^4[\omega_o(t+\alpha)] = H_1(t,\alpha,\beta) \\ &= \cdots = (\varepsilon\beta^2/\omega_o{}^4)\{(3/8) - (1/2)\cos[2\omega_o(t+\alpha)] + (1/8)\cos[4\omega_o(t+\alpha)]\}, \end{aligned}$$

and so its average over τ is

$$\langle H_1\rangle \equiv (\omega_o/2\pi)\int_0^{2\pi/\omega_o} H_1\, dt = \cdots = 3\varepsilon\beta^2/8\omega_o{}^4. \tag{g}$$

Hence, the averaged perturbation equations give

$$d\beta/dt = -\partial\langle H_1\rangle/\partial\alpha = 0\ \Rightarrow\ \beta = constant, \tag{h}$$

$$d\alpha/dt = \partial\langle H_1\rangle/\partial\beta = 3\varepsilon\beta/4\omega_o{}^4\ \Rightarrow\ \alpha = (3\varepsilon\beta/4\omega_o{}^4)t + \alpha_o, \tag{i}$$

where α_o is the integration constant. Finally, substituting (h, i) back into (f), we obtain the first ε-order correction:

$$q = [(2\beta)^{1/2}/\omega_o]\sin\{\omega_o[1 + (3\varepsilon\beta/4\omega_o{}^4)]t + \omega_o\alpha_o\}, \tag{j}$$

and the constants β, α_o are to be determined from the initial conditions. This agrees with the expressions obtained by other asymptotic methods (e.g., Krylov, Bogoliubov, Mitropolskii; see also chap. 7). For additional problems, see, for example, Nayfeh (1973, pp. 183–189).

Problem 8.10.1 Show that the HJ equation of a particle of mass m in a potential field $V = V(particle\ position, time)$ in the following common systems of coordinates (with standard notations) is:

(i) *rectangular Cartesian*:

$$\partial A/\partial t + (1/2m)\left[(\partial A/\partial x)^2 + (\partial A/\partial y)^2 + (\partial A/\partial z)^2\right] + V(x,y,z;\ t) = 0, \tag{a}$$

(ii) *polar cylindrical*:

$$\partial A/\partial t + (1/2m)\left[(\partial A/\partial r)^2 + r^{-2}(\partial A/\partial\phi)^2 + (\partial A/\partial z)^2\right] + V(r,\phi,z;\ t) = 0, \tag{b}$$

(iii) *spherical coordinates*:

$$\partial A/\partial t + (1/2m)\left[(\partial A/\partial r)^2 + r^{-2}(\partial A/\partial\theta)^2 + (r\sin\theta)^{-2}(\partial A/\partial\phi)^2\right] + V(r,\phi,\theta;\ t) = 0. \tag{c}$$

Recall that r has different meanings in (b) and (c).

Problem 8.10.2 Consider the following action function, $A = A(t, q, q')$, that satisfies the HJ equation

$$H(t, q, \partial A/\partial q) + \partial A/\partial t = 0. \tag{a}$$

Show that any solution of (a) of the form

$$A = A(t, q, \alpha), \qquad \alpha \equiv (\alpha_1, \ldots, \alpha_n){:}\ n \ \text{ arbitrary and independent constants,} \tag{b}$$

solves the dynamical problem through the $2n$ finite equations

$$p_k = \partial A/\partial q_k, \qquad -\beta_k = \partial A/\partial \alpha_k, \tag{c}$$

where

$$q' \to \alpha \ \text{ and } \ p' \to \beta \ \ [\equiv (\beta_1, \ldots, \beta_n){:}\ n \ \text{ new arbitrary and independent constants}]$$

are, respectively, the new *constant* canonical coordinates and momenta.

HINT

Recall (8.8.15), with $A(t, q, \alpha) \to F_1(t, q, q')$.

Problem 8.10.3 Continuing from the preceding problem, show that if $\partial H/\partial t = 0$, then the HJ equation assumes the special form

$$H(q, \partial A_o/\partial q) = E, \tag{a}$$

where $A = A_o(q, \alpha) - E\,t$, and the solution of the dynamical problem is given by the following $2n$ finite equations:

$$\partial A_o/\partial q_k = p_k; \tag{b}$$

$$\partial A_o/\partial E = t - \beta_1, \tag{c}$$

$$\partial A_o/\partial \alpha_r = -\beta_r \qquad (r = 2, \ldots, n), \tag{d}$$

where $\alpha_1 = E$ and $(\alpha_2, \ldots, \alpha_n)$: $n - 1$ constants of integration of (a).

HINT

$$\beta_1 = -\partial A/\partial \alpha_1 = -\big[\partial A_o/\partial \alpha_1 - (\partial E/\partial \alpha_1)t\big] = \cdots .$$

Problem 8.10.4 *Hamiltonian Form of Variation of Constants/Parameters: Nonpotential Forces.*

(i) By applying (8.7.22 ff.) with

$$X_k \to X_k{}^{(1)} = -\partial H_1/\partial q_k + Q_k, \qquad (k = 1, \ldots, n) \tag{a}$$

$$Q_k = \text{small } \textit{nonpotential} \text{ perturbative forces,} \tag{b}$$

$$c_k \to \alpha_k, \quad c_{n+l} \to \beta_l \qquad (k, l = 1, \ldots, n), \tag{c}$$

and (8.9.10 ff.), show that, in the presence of forces — that is, for perturbed Hamiltonian equations: $dq_k/dt = \partial H/\partial p_k$, $dp_k/dt = -\partial H/\partial q_k + Q_k$, $H = H_o + H_1$ — the fundamental perturbation equations (ex. 8.10.9: h, i) generalize to

$$d\alpha_k/dt = \partial H_1/\partial \beta_k + \sum (\partial \alpha_k/\partial p_l) Q_l = \partial H_1/\partial \beta_k - \sum (\partial q_l/\partial \beta_k) Q_l, \tag{d}$$

$$d\beta_k/dt = -\partial H_1/\partial \alpha_k + \sum (\partial \beta_k/\partial p_l) Q_l = -\partial H_1/\partial \alpha_k + \sum (\partial q_l/\partial \alpha_k) Q_l. \tag{e}$$

The advantage of the *second* forms of (d, e) over their corresponding *first* forms lies in that *the former do not require inversion of the general solution of the unperturbed problem:* $q = q(t, \alpha, \beta)$, $p = p(t, \alpha, \beta)$.

(ii) Verify that if $Q_k = Q_k(t)$ — for example, if the perturbative forces are constant — then (d, e) can be rewritten, respectively, in the canonical form:

$$d\alpha_k/dt = \partial \eta_1/\partial \beta_k, \qquad d\beta_k/dt = -\partial \eta_1/\partial \alpha_k, \tag{f}$$

where

$$\eta_1 \equiv H_1 - \sum Q_k q_k = \textit{generalized Hamiltonian perturbation}. \tag{g}$$

[Under such forces, the perturbed Hamiltonian equations can, similarly, be written as

$$dq_k/dt = \partial \eta/\partial p_k, \qquad dp_k/dt = -\partial \eta/\partial q_k, \tag{h}$$

where

$$\eta \equiv H - \sum Q_k q_k = \textit{generalized Hamiltonian}.] \tag{i}$$

HINTS

To prove the *second* forms of (d, e), we proceed as follows: from the table of the various types of generating functions of §8.8 (table 8.1) by equating the second mixed partial $F_{1,2,3,4}$-derivatives, we readily find the following equalities:

$$\partial^2 F_1/\partial q_k \partial q_{k'} = \partial p_k/\partial q_{k'} = -\partial p_{k'}/\partial q_k, \tag{j}$$

$$\partial^2 F_2/\partial q_k \partial p_{k'} = \partial p_k/\partial p_{k'} = \partial q_{k'}/\partial q_k, \tag{k}$$

$$\partial^2 F_3/\partial p_k \partial q_{k'} = -\partial q_k/\partial q_{k'} = -\partial p_{k'}/\partial p_k, \tag{l}$$

$$\partial^2 F_4/\partial p_k \partial p_{k'} = -\partial q_k/\partial p_{k'} = \partial q_{k'}/\partial p_k; \tag{m}$$

and then, as described in ex. 8.10.9, we view [in (l, m)] the q', p' as α, β.

For an alternative derivation of (d, e) along with several advanced and detailed applications of them, see Lur'e (1968, pp. 560–562, ff.].

8.11 HAMILTON'S PRINCIPAL AND CHARACTERISTIC FUNCTIONS, AND ASSOCIATED VARIATIONAL PRINCIPLES/ DIFFERENTIAL EQUATIONS

In this section, we examine the connection between the Hamilton–Jacobi (HJ) equation and Hamilton's integral variational principle (chap. 7). Let us assume that, somehow, we have obtained the general solution of the canonical equations

$$dq_k/dt = \partial H/\partial p_k, \qquad dp_k/dt = -\partial H/\partial q_k \qquad (k = 1, \ldots, n); \tag{8.11.1}$$

that is, we have found the expressions

$$q_k = q_k(t; c), \qquad p_k = p_k(t; c), \qquad c \equiv (c_1, \ldots, c_{2n}) = \text{constants of integration.} \tag{8.11.1a}$$

Substituting (8.11.1a) in the system Hamiltonian $H = H(t, q, p)$, we obtain

$$H = H(t, q, p) = H[t, q(t;\ c), p(t;\ c)] \equiv H(t, c), \tag{8.11.2}$$

and, therefore, applying chain rule to the above, we find, successively (with $\mu = 1, \ldots, 2n$),

$$\begin{aligned}\partial H/\partial c_\mu &= \sum \left[(\partial H/\partial q_k)(\partial q_k/\partial c_\mu) + (\partial H/\partial p_k)(\partial p_k/\partial c_\mu)\right]\\ &= \sum \left[(\partial p_k/\partial c_\mu)(dq_k/dt) - (\partial q_k/\partial c_\mu)(dp_k/dt)\right] \qquad \text{[by (8.11.1)]}\\ &= \partial/\partial c_\mu\Big(\sum p_k \dot{q}_k\Big) - d/dt\Big(\sum p_k(\partial q_k/\partial c_\mu)\Big)\end{aligned} \tag{8.11.2a}$$

[due to the identity: $\partial \dot{q}_k/\partial c_\mu = \partial/\partial c_\mu(\partial q_k/\partial t) = \partial/\partial t(\partial q_k/\partial c_\mu) = (\partial q_k/\partial c_\mu)^{\cdot}$];

or, since

$$\partial/\partial c_\mu\Big(\sum p_k \dot{q}_k\Big) - \partial H/\partial c_\mu = \partial L/\partial c_\mu = \partial(T - V)/\partial c_\mu, \tag{8.11.3}$$

we finally obtain the following [special form of the *central equation* (§3.6)]:

$$\partial L/\partial c_\mu = d/dt\Big(\sum p_k(\partial q_k/\partial c_\mu)\Big). \tag{8.11.4}$$

Integrating the above, from an initial instant t_o to a current one t [and noting that $\partial(\ldots)/\partial c_k$ and $\int(\ldots)\,dt$ commute], we get

$$\partial/\partial c_\mu \int_{t_o}^{t} L\,dt \;=\; \sum \left[p_k(\partial q_k/\partial c_\mu) - p_{ko}(\partial q_{ko}/\partial c_\mu\right], \tag{8.11.5}$$

where $q_{ko}(p_{ko})$ are the values of $q_k(p_k)$ at $t = t_o$. The function (§7.9)

$$A_H \equiv \int_{t_o}^{t} L\,dt = \int_{t_o}^{t} (T - V)\,dt \equiv A \tag{8.11.6}$$

is called, after Hamilton (1834–1835), the *principal function* of the motion of the system, because, in his words, "The variation of this definite integral S [our A] has therefore the double property, of giving the differential equations of motion for any transformed coordinates when the extreme positions are regarded as fixed, and of giving the integrals of those differential equations when the extreme positions are treated as varying." (Quoted in MacMillan, 1936, p. 367.) To understand these statements better, we need to examine A more closely. In view of (8.11.1a) and (8.11.6), we will have

$$q_k = q_k(t;\ c) \ \Rightarrow\ q_{ko} = q_k(t_o;\ c) \tag{8.11.7a}$$

$$\Rightarrow\ A = A(t, t_o;\ c), \tag{8.11.7b}$$

and, therefore, arbitrary variations of the $2n$ integration constants, $c \to c + \delta c$, cause the following (first-order in the δc, and fixed-time) variations in the q's and A:

$$\delta q_k = \sum (\partial q_k/\partial c_\mu)\,\delta c_\mu, \qquad \delta A = \sum (\partial A/\partial c_\mu)\,\delta c_\mu. \tag{8.11.8}$$

Hence, multiplying (8.11.5) with δc_μ and summing over $\mu = 1, \ldots, 2n$, we arrive at the fundamental variational equation

$$\delta A = \sum (p_k\,\delta q_k - p_{ko}\,\delta q_{ko}). \tag{8.11.9}$$

To obtain differential equations from the above, we, first, solve the $2n$ equations (8.11.7a) for the $2n$ constants c in terms of the $2n$ q's and q_o's (and time): $c_\mu = c_\mu(t;\ q, q_o)$, and then substitute this result in (8.11.7b)

$$A = A(t, t_o;\ q, q_o). \tag{8.11.10}$$

This expresses the action *functional* along the actual path (or orbit) as a *function* of the coordinates of its lower (initial) and upper (final) limits of integration. More important: (i) from the *mathematical* point of view, the transition from (8.11.7b) to (8.11.10) is one from an *initial*-value problem [c given, or equivalently, due to (8.11.1a), q_o and p_o given] to a *boundary*-value problem (q_o and q given); while (ii) *physically,* it signifies a transition from motion determined by the initial positions and velocities (or momenta) to motion determined by the initial and final positions (provided, of course, that the latter are achievable from the former).

Varying (8.11.10), for fixed t, we obtain

$$\delta A = \sum \big[(\partial A/\partial q_k)\,\delta q_k + (\partial A/\partial q_{ko})\,\delta q_{ko}\big], \tag{8.11.11}$$

and, therefore, comparing this with (8.11.9), *while recalling that the δq and δq_o are arbitrary,* we obtain the equations

$$\partial A/\partial q_k = p_k, \qquad \partial A/\partial q_{ko} = -p_{ko}. \tag{8.11.12}$$

Solving the *second* group of (8.11.12) for the q's in terms of t and q_o's, p_o's, and then substituting these expressions into the *first* group, we obtain the p's as functions of t, q_o's, p_o's:

$$q_k = q_k(t;\ q_o, p_o), \qquad p_k = p_k(t;\ q_o, p_o); \tag{8.11.13}$$

that is, *eqs. (8.11.12) constitute a complete set of integrals of the equations of motion (8.11.1)*: knowledge of A provides a complete solution to the problem. Indeed, A satisfies the Hamilton–Jacobi equation (HJ, §8.10), and, hence, can be identified with the there-introduced action function A. Here is why: $(\ldots)^{\cdot}$-differentiating (8.11.10), we find, successively,

$$dA/dt = \partial A/\partial t + \sum (\partial A/\partial q_k)(dq_k/dt) = \partial A/\partial t + \sum p_k \dot{q}_k$$
$$\text{[by the first of (8.11.12)]},$$

and from this, since $dA/dt = L\ (= T - V)$ [by (8.11.6)] and $\sum p_k \dot{q}_k = L + H$ [by the Hamiltonian definition], we readily conclude that

$$\partial A/\partial t + H(t;\ q, p) = \partial A/\partial t + H(t;\ q, \partial A/\partial q) = 0, \quad \text{Q.E.D.} \tag{8.11.14}$$

Hamilton's Principle

Substituting $L = \sum p_k \dot{q}_k - H$ in (8.11.6), and then taking its (first and fixed-end-point) variation δA, we find, successively,

$$\begin{aligned}
\delta A &= \delta \int L\,dt = \delta \int \Big(\sum p_k \dot{q}_k - H\Big)\,dt \\
&= \int \Big\{\sum \big[p_k\,\delta(\dot{q}_k) + \dot{q}_k\,\delta p_k\big] - \delta H\Big\}\,dt \\
&= \int \Big\{\Big[\Big(\sum p_k\,\delta q_k\Big)^{\cdot} - \sum \dot{p}_k\,\delta q_k + \sum \dot{q}_k\,\delta p_k\Big] \\
&\qquad - \sum \big[(\partial H/\partial q_k)\,\delta q_k + (\partial H/\partial p_k)\,\delta p_k\big]\Big\}\,dt \\
&\qquad \text{[assuming that } \delta(dq) = d(\delta q), \text{or } \delta(\dot{q}) = (\delta q)^{\cdot}],
\end{aligned}$$

or, after integrating out the $(\ldots)^{\cdot}$ term:

$$\begin{aligned}
\delta A = \int \sum \big[(dq_k/dt - \partial H/\partial p_k)\,\delta p_k - \sum (dp_k/dt + \partial H/\partial q_k)\,\delta q_k\big] \\
+ \sum (p_k\,\delta q_k - p_{ko}\,\delta q_{ko}).
\end{aligned} \tag{8.11.15}$$

Now, if

$$dq_k/dt = \partial H/\partial p_k, \qquad dp_k/dt = -\partial H/\partial q_k, \tag{8.11.16}$$

and $\delta q_k = \delta q_{ko} = 0$ (or some other combination that nullifies the last ("boundary") terms, then $\delta A = 0$; and, conversely, if $\delta A = 0$, for all variations of the q's and p's that vanish at the temporal endpoints, then (8.11.16) follow. This is Hamilton's principle in canonical variables (and for contemporaneous variations).

In sum:

(i) Given the function $H = H(t, q, p)$ and the differential equations $dq_k/dt = \partial H/\partial p_k$, $dp_k/dt = -\partial H/\partial q_k$, the principal function $A \equiv \int L\,dt = \int (\sum p_k \dot{q}_k - H)\,dt = \int (\sum p_k\,dq_k - H\,dt)$ satisfies the partial differential equation $\partial A/\partial t + H(t;\ q, \partial A/\partial q) = 0$.

(ii) *Hamilton*: if $A = A(t, t_o;\ q, q_o)$, then a complete integral of the equations of motion can be obtained from $p_k = \partial A/\partial q_k$, $p_{ko} = \partial A/\partial q_{ko}$.

(iii) *Jacobi*: If $A = A(t, q, \beta)$ is a complete solution of $\partial A/\partial t + H(t, q, \partial A/\partial q) = 0$, then a complete integral of the equations of motion can be obtained from $p_k = \partial A/\partial q_k$, $\alpha_k = \partial A/\partial \beta_k$.

Action as a Function of the Coordinates and Time

Comparing the earlier $dA/dt = L$ with $dA/dt = \partial A/\partial t + \sum (\partial A/\partial q_k)(dq_k/dt) = \partial A/\partial t + \sum p_k \dot{q}_k$, we immediately obtain

$$\partial A/\partial t = L - \sum p_k \dot{q}_k = -H; \tag{8.11.17}$$

which also follows from the HJ equation (8.11.14). Hence, *if A is considered as a function of the current coordinates and upper (current) time limit in (8.11.6)*, its total differential equals

$$dA = (\partial A/\partial t)\, dt + \sum (\partial A/\partial q_k)\, dq_k = \sum p_k\, dq_k - H\, dt. \tag{8.11.18}$$

Generally, if A is considered as a function of both initial and final coordinates and time, then

$$dA = \left(\sum p_k\, dq_k - H\, dt\right) - \left(\sum p_{ko}\, dq_{ko} - H_o\, dt_o\right); \tag{8.11.19}$$

which can be rewritten in terms of variational calculus notation as

$$\begin{aligned} \Delta A &= \left(\sum p_k \Delta q_k - H \Delta t\right) - \left(\sum p_{ko}\, \Delta q_{ko} - H_o\, \Delta t_o\right) \\ &= \sum p_k \Delta q_k - \sum p_{ko} \Delta q_{ko} - H \Delta(t - t_o) \qquad [\text{if } H = constant] \end{aligned} \tag{8.11.20}$$

[where $\Delta(\ldots) = \delta(\ldots) + (\ldots)^{\cdot} \Delta t =$ *noncontemporaneous variation* (§7.2, §7.9)], from which (8.11.12) and (8.11.17) follow. If $(\partial L/\partial t = 0 \;\Rightarrow)$ $H = constant$, then the latter can be rewritten as

$$\partial A/\partial \tau = -H, \qquad \tau \equiv t - t_o = time\ of\ transit; \tag{8.11.21}$$

whereas if $H \neq constant$, then we have $\partial A/\partial t_o = H_o$, $\partial A/\partial t = -H$. Equation (8.11.20) is referred to as *Hamilton's principle of varying, or varied, action*.

The above show that the final (or current) state of the system cannot be an arbitrary function of its initial state; the right side of (8.11.19) must be an exact differential, no matter what the impressed (potential) forces are. These results are of interest in *geometrical optics*.

Specializations

(i) If $\partial L/\partial t = -\partial H/\partial t = 0$, then $H(q, p) = constant \equiv E$ (*total energy*). Then we can write

$$A = \int \left(\sum p_k\, dq_k - H\, dt\right) = A_o - E(t - t_o), \tag{8.11.22}$$

where

$$A_o \equiv \int \sum p_k\, dq_k = \int \Big(\sum p_k \dot{q}_k\Big)\, dt = \int 2T\, dt$$
$$= \textit{Abbreviated action (or characteristic function} — A_o \text{ of §8.10; and the } \textit{Lagrangean action } A_L \textit{ of §7.9}; \text{ also, frequently denoted by } W). \tag{8.11.23}$$

In this case, and for variations satisfying $(\Delta t_o \to)\, dt_o = 0, (\Delta q_{ko} \to)\, dq_{ko} = 0$, and $(\Delta q_k \to)\, dq_k = 0$ but $(\Delta t \to)\, dt \neq 0$ (i.e., given initial coordinates and time, and given final coordinates but not time) eqs. (8.11.19), (8.11.20) reduce, respectively, to

$$dA = -H\, dt = -E\, dt, \qquad \Delta A = -E\Delta t; \tag{8.11.24}$$

and, therefore, comparing with (8.11.22), we conclude that, for such *isoenergetic* variations,

$$\Delta A_o = 0. \tag{8.11.25}$$

This is the "principle" of *Maupertuis → Euler → Lagrange* (MEL; recalling discussion in §7.9): The abbreviated, or Lagrangean, action has a stationary value for the actual path of the system, among all comparison paths that satisfy conservation of energy (and all have the same energy constant as the actual path), pass from the given initial configuration at a given time, and from the given final configuration at an unspecified time.

Generally, and in variational calculus notation,

$$\Delta A_o = \Big(\sum p_k \Delta q_k - \sum p_{ko} \Delta q_{ko}\Big) + \Delta H(t - t_o), \tag{8.11.26}$$

from which, if we regard A_o as a *function of the initial and final coordinates and the energy*—that is, $A_o = A_o(q_o, q, E)$—we obtain the differential relations

$$p_k = \partial A_o/\partial q_k, \qquad p_{ko} = -\partial A_o/\partial q_{ko}, \qquad \tau \equiv t - t_o = \partial A_o/\partial E. \tag{8.11.27}$$

Here, too, knowledge of A_o determines the motion: the $n + 1$ equations, second and third of (8.11.27), plus q_o, p_o determine the energy H and the q's; then the first of (8.11.27) gives the p's.

If the system Lagrangean has the common form

$$L = (1/2) \sum\sum M_{kl}(q)\dot{q}_k \dot{q}_l - V(q), \tag{8.11.28}$$

then, since $p_k = \partial L/\partial \dot{q}_k = \sum M_{kl}(q)\dot{q}_l$, and by energy conservation:

$$E = (1/2) \sum\sum M_{kl}\dot{q}_k \dot{q}_l + V \;\Rightarrow\; (dt)^2 = \Big(\sum\sum M_{kl}\, dq_k\, dq_l\Big)\Big/ 2(E - V), \tag{8.11.29}$$

the corresponding A_o is expressed in terms of the coordinates q and their differentials dq, and with the energy as a constant parameter, in the *generalized*

Jacobi form (§7.9):

$$A_o \equiv \int \sum p_k \, dq_k = \int \sum \sum \left[M_{kl}(dq_l/dt) \right] dq_k \qquad \text{[by (8.11.29): } dt = \cdots]$$
$$= \int \left[2(E - V) \sum \sum M_{kl} \, dq_k \, dq_l \right]^{1/2}. \tag{8.11.30}$$

Clearly, since $p_k = \partial L(q, \dot{q})/\partial \dot{q}_k$ and $E = H(q, \dot{q}) = E(q, \dot{q})$, this method can be extended to systems with more general Lagrangeans than (8.11.28).

(ii) If, in (8.11.22), we vary both E and t, we obtain (again in variational notation, and recalling (8.11.24)]

$$\Delta A = \Delta A_o - (t - t_o) \, \Delta E - E \Delta t = -E \Delta t, \tag{8.11.31}$$

from which we easily conclude that

$$\partial A_o / \partial E = t - t_o. \tag{8.11.32}$$

(a) If, further, A_o has the form (8.11.30), then (8.11.32) leads to the integral [of (8.11.29)]:

$$t - t_o = \int \left(\sum \sum M_{kl} \, dq_k \, dq_l / 2(E - V) \right)^{1/2}, \tag{8.11.33}$$

which, along with the path equation, determines the motion.

(b) If the system undergoes *periodic* motion with the (single) period $\tau = t - t_o = 2\pi/\omega$, then its frequency ω is found from

$$\omega = 2\pi (\partial A_o / \partial E)^{-1}. \tag{8.11.34}$$

Additional related results are given in the examples and problems of §7.9.

Extension to Cyclic/Ignorable Systems (Larmor, 1884)

In such a case, A and A_o are replaced, respectively, by (recalling eq. (8.3.3c)):

$$A_R \equiv \int (T'' - V) \, dt \equiv \int \left[\left(T - \sum \Psi_i \dot{\psi}_i \right) - V \right] dt \equiv \int \left(L - \sum \Psi_i \dot{\psi}_i \right) dt$$
$$\equiv \int R(t, q, \dot{q}; \Psi \equiv C) \, dt \equiv \int R \, dt:$$

Function of the initial and final values of the nonignorable (or positional) coordinates q and time of transit $\tau \equiv t - t_o$*; with the cyclic momenta* Ψ *as constant parameters,* (8.11.35)

$$A_{o,R} \equiv \int \left(2T - \sum \Psi_i \dot{\psi}_i \right) dt:$$

Function of the initial and final values of the nonignorable coordinates q, and the total energy H under constant cyclic momenta. (8.11.36)

All previous variations and differential equations hold for A_R and $A_{o,R}$, *provided only the nonignorable coordinates and velocities are varied.* Indeed:

(i) Varying A_R, we obtain, successively,

$$\begin{aligned}\Delta A_R &= \delta\int R\,dt + (R\,\Delta t - R_o\,\Delta t_o)\\ &= \cdots = -\int\sum E_p(R)\,\delta q_p\,dt + \sum(p_p\,\delta q_p - p_{po}\,\delta q_{po}) + (R\,\Delta t - R_o\,\Delta t_o)\\ &= -(0) + \sum\left[p_p(\Delta q_p - \dot{q}_p\,\Delta t) - p_{po}(\Delta q_{po} - \dot{q}_{po}\,\Delta t_o)\right] + (R\,\Delta t - R_o\,\Delta t_o),\end{aligned}$$

or, since $R = T'' - V,\ T + V = H = constant$; and

$$\begin{aligned}&2T = \sum p_p\dot{q}_p + \sum \Psi_i\,\dot{\psi}_i\\ &\Rightarrow \sum p_p\dot{q}_p = 2T - \sum \Psi_i\,\dot{\psi}_i = T + \Big(T - \sum \Psi_i\,\dot{\psi}_i\Big) = T + T'',\end{aligned}$$

finally,

$$\Delta A_R = \sum(p_p\,\Delta q_p - p_{po}\,\Delta q_{po}) - H\,\Delta(t - t_o). \tag{8.11.37}$$

- If $\Delta q_p = 0, \Delta q_{po} = 0, \Delta(t - t_o) \equiv \Delta\tau = 0$, then the above yields $\Delta A_R = 0$; which is the Routhian generalization of Hamilton's principle.
- If both initial and final configurations as well as time of transit are variable, then (8.11.37) leads us to

$$p_p = \partial A_R/\partial q_p, \qquad p_{po} = -\partial A_R/\partial q_{po}, \qquad H = -\partial A_R/\partial\tau \qquad (p = M + 1, \ldots, n), \tag{8.11.38}$$

  which are the Routhian versions of (8.11.12) and (8.11.17).

(ii) For $A_{o,R}$, we find, similarly,

$$\begin{aligned}A_{o,R} &= \int\Big(\sum p_p\,\dot{q}_p\Big)\,dt = \cdots = \int(T + T'')\,dt\\ &= A_R + \int(T + V)\,dt = A_R + H\tau;\end{aligned} \tag{8.11.39}$$

that is, here, the independent variable is the total energy, not the transit time. Hence, varying this generally, we obtain

$$\begin{aligned}\Delta A_{o,R} &= \Delta A_R + \tau\,\Delta H + H\,\Delta\tau \qquad \text{[invoking (8.11.37)]}\\ &= \sum(p_p\,\Delta q_p - p_{po}\,\Delta q_{po}) + \tau\,\Delta H,\end{aligned} \tag{8.11.40}$$

and from this we get the equations

$$p_p = \partial A_{o,R}/\partial q_p, \qquad p_{po} = -\partial A_{o,R}/\partial q_{po}, \qquad \tau = \partial A_{o,R}/\partial H \qquad (p = M + 1, \ldots, n), \tag{8.11.41}$$

which constitute the Routhian versions of (8.11.27).

Example 8.11.1 *The Characteristic Function, or Abbreviated Action, of a One-DOF System.* Application of the energy equation to such a system yields

$$p = p(q, E) \qquad (\beta = E,\ n = 1), \tag{a}$$

and therefore its characteristic function becomes

$$A_o = \int p(q, E)\, dq, \tag{b}$$

with the integral extending from an initial configuration, q_o, to a current one, q. Hence, by (8.10.11l):

$$t - t_o = \partial A_o/\partial E = \partial/\partial E\left[\int p(q, E)\, dq\right] = \int [\partial p(q, E)/\partial E]\, dq. \tag{c}$$

Specialization

For a *single particle* of mass m, the energy equation

$$H = p^2/2m + V(q) = E, \tag{d}$$

yields the (a)-like representation

$$p = \{2m[E - V(q)]\}^{1/2} = p(q;\, E), \tag{e}$$

and hence the (b)-like action

$$A_o = (2m)^{1/2}\int [E - V(q)]^{1/2}\, dq. \tag{f}$$

From (e), we obtain

$$\partial p/\partial E = (m/2)^{1/2}[E - V(q)]^{-1/2}, \tag{g}$$

and, from this, the (c)-like equation of motion

$$t = (m/2)^{1/2}\int [E - V(q)]^{-1/2}\, dq + t_o. \tag{h}$$

In particular, if $V = mgq$ (i.e., vertical motion of particle in constant field of gravity), then (h) gives

$$t = (m/2)^{1/2}\int (E - mgq)^{-1/2}\, dq + t_o = t_o - (1/g)\,[2(E - mgq)/m]^{1/2};$$

and if we choose the q-origin so that $mgq_o = E$, the above reduces to the well-known $q = q_o - (g/2)\,(t - t_o)^2$.

It is not hard to see that the above also apply to *an n-DOF system with only one nonignorable coordinate:* $q_n = q$. Then, since all momenta except $p_n = p$ are constant, the energy equation and characteristic function reduce, respectively, to

$$H(q, p;\, \beta_1, \ldots, \beta_{n-1}) = E, \qquad A_o = \int p(q;\, \beta_1, \ldots, \beta_{n-1}, \beta_n = E)\, dq. \tag{i}$$

Example 8.11.2 *On Hamilton's Principal Function and Associated Differential Equations.*

(i) Let

$$L = T - V = (m/2)\,[(\dot{x})^2 + (\dot{y})^2 + (\dot{z})^2]; \tag{a}$$

that is, free motion of particle P of mass m. Then, as is well known,

$$x = x_o + \dot{x}_o\,t, \qquad y = y_o + \dot{y}_o\,t, \qquad z = z_o + \dot{z}_o\,t \qquad \text{(law of inertia)}, \tag{b}$$

where $x_o, y_o, z_o/\dot{x}_o, \dot{y}_o, \dot{z}_o =$ rectangular Cartesian components of initial position/velocity of P, at time $t_o = 0$. As a result of (b), the corresponding action (principal function) becomes, successively,

$$\begin{aligned}
A &= \int L\,dt = \int (m/2)\,[(\dot{x})^2 + (\dot{y})^2 + (\dot{z})^2]\,dt \\
&= \cdots = (m/2)\left[(\dot{x}_o)^2 + (\dot{y}_o)^2 + (\dot{z}_o)^2\right](t - t_o) \equiv (m{v_o}^2/2)t
\end{aligned}$$

[by (b): $\quad \dot{x}_o = (x - x_o)/t = \dot{x}, \qquad \dot{y}_o = (y - y_o)/t = \dot{y}, \qquad \dot{z}_o = (z - z_o)/t = \dot{z}$]

$$\begin{aligned}
&= (m/2t)\left[(x - x_o)^2 + (y - y_o)^2 + (z - z_o)^2\right] \\
&= A(t, t_o;\ x, y, z;\ x_o, y_o, z_o),
\end{aligned} \tag{c}$$

and from this expression we readily find

$$\partial A/\partial x = (m/2t)\,[2(x - x_o)] = m(x - x_o)/t = m\,\dot{x} \equiv p_x, \quad \text{etc., cyclically,} \tag{d}$$

$$\partial A/\partial x_o = -(m/2t)\,[2(x - x_o)] = \cdots = -m\,\dot{x}_o \equiv -p_{xo}, \quad \text{etc., cyclically,} \tag{e}$$

$$\begin{aligned}
\partial A/\partial t &= -(m/2t^2)\,[(x - x_o)^2 + \cdots] = -(m/2)\left\{[(x - x_o)/t]^2 + \cdots\right\} \\
&= -(m{v_o}^2/2) = -(\mathit{energy}) \equiv -E, \qquad \text{as expected.}
\end{aligned} \tag{f}$$

(ii) Let the equations of motion of a particle P be

$$\ddot{x} = -\omega^2 x, \qquad \ddot{y} = -\omega^2 y; \tag{g}$$

that is, isotropic harmonic oscillator of (constant) frequency ω; $x, y =$ rectangular Cartesian coordinates. The general solution of (g) is

$$x = a\sin(\omega t + \phi_o), \qquad y = b\sin(\omega t + \psi_o), \tag{h}$$

where $a, b;\ \phi_o, \psi_o =$ four constants of integration. From the above, we readily obtain the system Lagrangean:

$$\begin{aligned}
L = T - V &= (m/2)\,[(\dot{x})^2 + (\dot{y})^2] - (m\,\omega^2/2)\,(x^2 + y^2) \\
&= \cdots = (m\omega^2/2)\left\{a^2\cos[2(\omega\,t + \phi_o)] + b^2\cos[2(\omega t + \psi_o)]\right\},
\end{aligned} \tag{i}$$

and, from the latter, the following system action:

$$A = \int L\,dt = (m\omega/4)\left\{a^2 \sin[2(\omega t + \phi_o)] + b^2 \sin[2(\omega t + \psi_o)] - a^2 \sin(2\phi_o) - b^2 \sin(2\psi_o)\right\}$$

$$\text{[introducing the initial positions: } x(0) \equiv x_o = a \sin\phi_o,\ y(0) \equiv y_o = b \sin\psi_o]$$

$$= (m\omega/2)\left\{[a\,x \cos(\omega t + \phi_o) + b\,y \cos(\omega t + \psi_o)] - a\,x_o \cos\phi_o - b\,y_o \cos\psi_o\right\}$$

$$\left[\text{since by (h)}, a\cos\phi_o = [x - x_o \cos(\omega t)]/\sin(\omega t),\ b\cos\psi_o = [y - y_o \cos(\omega t)]/\sin(\omega t)\right]$$

$$= (m\omega/2)\left\{a\,x[\cos(\omega t)\cos\phi_o - \sin(\omega t)\sin\phi_o] + b\,y[\cos(\omega t)\cos\psi_o - \sin(\omega t)\sin\psi_o] - ax_o\cos\phi_o - by_o\cos\psi_o\right\}$$

$$= [m\omega/2\sin(\omega t)]\,[(x^2 + y^2 + x_o{}^2 + y_o{}^2)\cos(\omega t) - 2(xx_o + yy_o)]$$

$$= [m\omega/2\sin(\omega t)]\left\{[(x - x_o)^2 + (y - y_o)^2]\cos(\omega t) - 2[1 - \cos(\omega t)]\,(xx_o + yy_o)\right\}. \quad \text{(j)}$$

From this expression, we readily obtain

$$\partial A/\partial x = [m\omega/2\sin(\omega t)]\,[2x\cos(\omega t) - 2x_o]$$

$$[x = a\sin(\omega t + \phi_o) \ \Rightarrow\ x_o = a\ \sin\phi_o]$$

$$= a\,m\,\omega\cos(\omega t + \phi_o) = m\,\dot{x} = p_x, \quad \text{etc., cyclically,} \quad \text{(k)}$$

$$\partial A/\partial x_o = [m\,\omega/2\sin(\omega t)]\,[2x_o\cos(\omega t) - 2x]$$

$$= -[a\,m\,\omega/\sin(\omega t)]\sin(\omega t)\cos\phi_o = -m\,\dot{x}_o = -p_{xo}, \quad \text{etc., cyclically.} \quad \text{(l)}$$

Let the reader verify that $\partial A/\partial t = -(T + V) = -E$.

Example 8.11.3 *Second Proof of the Constancy of Lagrange's Brackets (8.7.11 ff.).* The expression following eq. (8.11.2) can be successively rewritten as follows:

$$\partial H/\partial c_\mu = \partial/\partial c_\mu\Big(\sum p_k\,\dot{q}_k\Big) - d/dt\Big(\sum p_k(\partial q_k/\partial c_\mu)\Big)$$

(expanding and simplifying)

$$= \sum \dot{q}_k(\partial p_k/\partial c_\mu) - \sum \dot{p}_k(\partial q_k/\partial c_\mu)$$

(adding and subtracting the *second* and *fourth* summands below)

$$= \sum\,[\dot{q}_k(\partial p_k/\partial c_\mu) + q_k(\partial\dot{p}_k/\partial c_\mu)] - \sum\,[\dot{p}_k(\partial q_k/\partial c_\mu) + q_k(\partial\dot{p}_k/\partial c_\mu)]$$

$$= d/dt\Big[\sum q_k(\partial p_k/\partial c_\mu)\Big] - \partial/\partial c_\mu\Big(\sum q_k\,\dot{p}_k\Big), \quad \text{(a)}$$

or, after slight rearrangement and use of $dp_k/dt = -\partial H/\partial q_k$,

$$d/dt\Big(\sum q_k(\partial p_k/\partial c_\mu)\Big) = \partial/\partial c_\mu\Big(H - \sum q_k(\partial H/\partial q_k)\Big) \equiv \partial H'/\partial c_\mu; \quad \text{(b)}$$

and, similarly, with $c_\mu \to c_\nu$, we obtain

$$d/dt\,\Big(\sum q_k(\partial q_k/\partial c_\nu)\Big) = \partial/\partial c_\nu\Big(H - \sum q_k(\partial H/\partial q_k)\Big) \equiv \partial H'/\partial c_\nu. \quad \text{(c)}$$

Now, differentiating (b) relative to c_ν and (c) relative to c_μ, and then subtracting side by side, we readily obtain

$$d/dt\Big[\partial/\partial c_\nu \sum q_k(\partial p_k/\partial c_\mu) - \partial/\partial c_\mu \sum q_k(\partial p_k/\partial c_\nu)\Big]$$
$$= \partial^2 H'/\partial c_\nu \partial c_\mu - \partial^2 H'/\partial c_\mu \partial c_\nu = 0; \tag{d}$$

that is,

$$d/dt\Big(\sum (\partial q_k/\partial c_\nu)(\partial p_k/\partial c_\mu) - \sum (\partial q_k/\partial c_\mu)(\partial p_k/\partial c_\nu)\Big) \equiv [c_\mu, c_\nu]^{\boldsymbol{\cdot}} = 0 \tag{e}$$
$$\Rightarrow\ [c_\mu, c_\nu] = constant, \quad \text{Q.E.D.} \tag{f}$$

Problem 8.11.1 By carrying out the two distinct (fixed time) variations $\delta_1(\ldots)$ and $\delta_2(\ldots)$ on the Hamiltonian equations

$$p_{ko} = -\partial A/\partial q_{ko}, \qquad p_k = \partial A/\partial q_k, \text{where } \ A = A(t, t_o; q, q_o), \tag{a}$$

prove the earlier Lagrange–Poisson theorem (8.7.10):

$$I \equiv \sum (\delta_1 p_k\, \delta_2 q_k - \delta_2 p_k\, \delta_1 q_k) = \sum (\delta_1 p_{ko}\, \delta_2 q_{ko} - \delta_2 p_{ko}\, \delta_1 q_{ko}) \equiv I_o; \tag{b}$$

that is, I = constant in time, namely, $dI/dt = 0$. (For relevant applications, see, e.g., Lamb, 1943, pp. 277–281.)

Problem 8.11.2 Assume that after the action-like integral (functional)

$$A' \equiv \int \Big(T + V + \sum q_k \dot{p}_k\Big)\, dt \tag{a}$$

is evaluated along an actual path, it becomes a *function* of the initial and final *momenta* and time of transit $\tau \equiv t - t_o$: $A' = A'(p, p_o, \tau)$. Show that

$$\Delta A' = (\partial A'/\partial \tau)\Delta\tau + \sum \big[(\partial A'/\partial p_k)\, \Delta p_k + (\partial A'/\partial p_{ko})\, \Delta p_{ko}\big]$$
$$= H\Delta\tau + \sum (q_k\, \Delta p_k - q_{ko}\, \Delta p_{ko}); \tag{b}$$

that is,

$$\partial A'/\partial\tau = H, \qquad \partial A'/\partial p_k = q_k, \qquad \partial A'/\partial p_{ko} = -q_{ko}.$$

Problem 8.11.3 *Alternative Variational Formulation of the Routhian Formalism.* Show that the variational problem (say, with vanishing endpoint variations, and the usual notations)

$$\delta \int \Lambda\, dt = 0, \tag{a}$$

where

$$\Lambda \equiv R(t, q, \dot{q};\ \psi, \Psi) + \sum \dot{\psi}_i\, \Psi_i = \Lambda(t, q, \dot{q}, \psi, \dot{\psi}, \Psi, \dot{\Psi}), \tag{b}$$

yields Routh's equations for the system described by the "Lagrangean" Λ; that is, verify that

$(\partial\Lambda/\partial\dot{q}_p)^{\cdot} - \partial\Lambda/\partial q_p = 0$ gives Routh's equations of motion (i.e., R: Lagrangean for the q's),

$(\partial\Lambda/\partial\dot{\psi}_i)^{\cdot} - \partial\Lambda/\partial\psi_i = 0$ gives $d\Psi_i/dt = \partial R/\partial\psi_i$ $(\Rightarrow\ \Psi_i = constant$, if $\partial R/\partial\psi_i = \partial L/\partial\psi_i = 0)$,

$(\partial\Lambda/\partial\dot{\Psi}_i)^{\cdot} - \partial\Lambda/\partial\Psi_i = 0$ gives $d\psi_i/dt = \partial R/\partial\Psi_i$.

8.12 INTEGRAL INVARIANTS

We have already seen (§8.8) that canonical transformations leave the Hamiltonian equations form invariant, and they also have the same effect on Hamilton's principle; that is, if

$$\int\Big(\sum p_k\dot{q}_k - H(t,q,p)\Big)\,dt \to stationary, \tag{8.12.1a}$$

and the transformation $(q,p)\to(q',p')$ is canonical, then

$$\int\Big(\sum p_{k'}\dot{q}_{k'} - H'(t,q',p')\Big)\,dt \to stationary. \tag{8.12.1b}$$

[In this case, the difference of the integrands of (8.12.1a, b) equals the $(\ldots)^{\cdot}$-derivative of a function of $2n$ of the old and new variables, and time (i.e., the generating function F); and so, under *fixed endpoint* (q,p) *variations*, that difference vanishes.]

Now, Poincaré, E. Cartan, et al. have shown that not only differential, but also certain *integral* forms exist that remain invariant under canonical transformations. Such quantities, named by them *integral invariants*, are the object of study of this section.

We begin by considering the fundamental equation of varied action (8.11.20), rewritten as

$$\Delta A = \Big(\sum p_k\,\Delta q_k - H\,\Delta t\Big)\Big|_{\mathit{Final}\ \text{time}} - \Big(\sum p_k\,\Delta q_k - H\Delta t\Big)\Big|_{\mathit{Initial}\ \text{time}}, \tag{8.12.2}$$

where (fig. 8.8), and to the first order in $\Delta q, \Delta t$:

$$\Delta A = A\,(from\ a_1{}'\ to\ a_2{}', along\ C')\ —A\,(from\ a_1\ to\ a_2, along\ C). \tag{8.12.3}$$

Let us assume that not only the *fundamental path* C, but also its adjacent C' are actual mechanical trajectories (or integral curves) of the system; that is, *both are solutions of its equations of motion but have different initial conditions* (*positions and momenta*) *and initial times* (a total of $2n+1$ initial parameters); and, as a result, A, A' and ΔA are *functions* (not functionals) of these initial conditions.

To study these changes analytically, we begin with the following, easy to understand, parametric representation of the Hamiltonian variables:

$$q_k = q_k(s;\,c), \qquad p_k = p_k(s;\,c), \qquad t = t(s;\,c), \tag{8.12.4a}$$

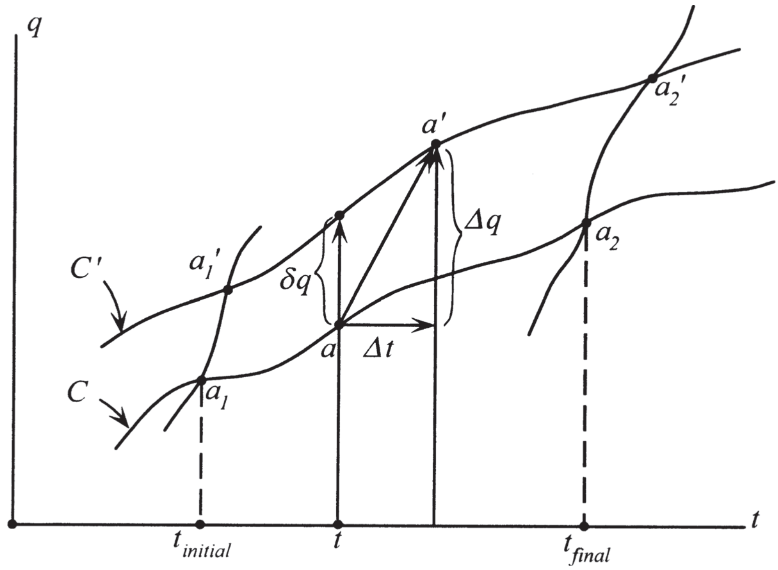

Figure 8.8 Trajectories C and C' satisfy the same equations of motion, but have different initial conditions and times (only q vs. t shown here; see also Fig. 8.9).

Coordinates of points involved: $a_1(t_1, q_1) \to a_1{}'(t_1 + \Delta t_1, q_1 + \Delta q_1)$,
$a_2(t_2, q_2) \to a_2{}'(t_2 + \Delta t_2, q_2 + \Delta q_2)$.

or, equivalently,

$$q_k = q_k[s; t_1, q^{(1)}, p^{(1)}], \qquad p_k = p_k[s; t_1, q^{(1)}, p^{(1)}], \qquad t = t[s; t_1, q^{(1)}, p^{(1)}], \tag{8.12.4b}$$

where s is an "arc-length" parameter in the $(2n+1)$-dimensional *extended phase space* of (t, q, p), and $c \equiv (c_1, \ldots, c_{2n+1})$ are $2n+1$ constants of integration; while $t_1, q^{(1)} \equiv (q_1{}^{(1)}, \ldots, q_n{}^{(1)}), p^{(1)} \equiv (p_1{}^{(1)}, \ldots, p_n{}^{(1)})$ are the initial values of t, q, p, respectively.

Now, let us assume that these $2n+1$ *initial values* (corresponding to the initial value s_1 of s) *are all functions of a single parameter* α, *independent of* s:

$$q_k{}^{(1)} = q_k{}^{(1)}(\alpha), \qquad p_k{}^{(1)} = p_k{}^{(1)}(\alpha), \qquad t^{(1)} = t^{(1)}(\alpha), \tag{8.12.5}$$

so that as α varies between the finite values α_1(*initial*) and α_2(*final*) $(\alpha_1 \le \alpha \le \alpha_2)$, the initial (left) endpoint of the system trajectories goes around the simple closed curve γ_1 in (t, q, p)-space:

$$a_1(\alpha_1) \to a_1{}' \to a_1{}'' \to \cdots \to a_1(\alpha_2). \tag{8.12.6}$$

Then, substituting (8.12.5) into (8.12.4b), we obtain the following parametric representation of the system trajectories:

$$q_k = q_k[s; t_1(\alpha), q^{(1)}(\alpha), p^{(1)}(\alpha)] = q_k(s; \alpha),$$
$$p_k = p_k[s; t_1(\alpha), q^{(1)}(\alpha), p^{(1)}(\alpha)] = p_k(s; \alpha),$$
$$t = t[s; t_1(\alpha), q^{(1)}(\alpha), p^{(1)}(\alpha)] = t(s; \alpha). \tag{8.12.7}$$

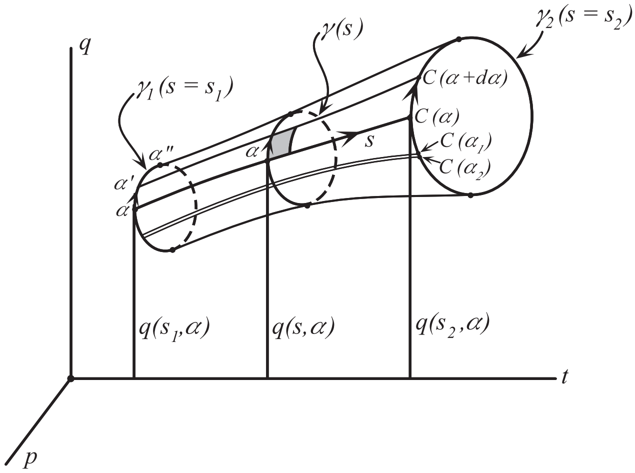

Figure 8.9 As the parameter α varies from α_1 to α_2, a closed tube of trajectories is created.

These equations show that as the left endpoint traces γ_1, the right (final) endpoint traces a similar closed curve γ_2, and a generic in-between point traces a closed curve γ (fig. 8.9); that is, as α varies from α_1 to α_2, a closed *tube of trajectories* (as its generatrices) is created in (t, q, p)-space. We assume that the closed curves $\gamma_1, \ldots, \gamma, \ldots, \gamma_2$ are nowhere tangent to the trajectories $C, C', C'', \ldots, C$, and are intersected only once by them. The above translate to the following α-*periodicity* relations:

$$\begin{aligned} \gamma_1: \quad & q_k{}^{(1)}(\alpha_1) = q_k{}^{(1)}(\alpha_2) \qquad && [\text{or } q_k(s_1;\, \alpha_1) = q_k(s_1; \alpha_2)], \\ & p_k{}^{(1)}(\alpha_1) = p_k{}^{(1)}(\alpha_2) && [\text{or } p_k(s_1;\, \alpha_1) = p_k(s_1; \alpha_2)], \\ & t_1(\alpha_1) = t_1(\alpha_2) && [\text{or } t(s_1;\, \alpha_1) = t(s_1; \alpha_2)]; \end{aligned} \tag{8.12.8}$$

and similarly for γ_2 and γ.

From (8.12.7) we immediately see that the most general variations/differentials of t, q, p along $\gamma_1, \gamma_2, \gamma$—that is, from trajectory to trajectory by varying the initial conditions (with a slight, easily understood, notational change to conform with calculus and the integrations below)—are

$$\begin{aligned} \Delta q_k \to dq_k = \Big\{ & (\partial q_k/\partial t_1)(dt_1/d\alpha) \\ & + \sum \big[(\partial q_k/\partial q_l{}^{(1)})(dq_l{}^{(1)}/d\alpha) + (\partial q_k/\partial p_l{}^{(1)})(dp_l{}^{(1)}/d\alpha)\big] \Big\}\, d\alpha, \\ \Delta p_k \to dp_k = \Big\{ & (\partial p_k/\partial t_1)(dt_1/d\alpha) \\ & + \sum \big[(\partial p_k/\partial q_l{}^{(1)})(dq_l{}^{(1)}/d\alpha) + (\partial p_k/\partial p_l{}^{(1)})(dp_l{}^{(1)}/d\alpha)\big] \Big\}\, d\alpha, \\ \Delta t \to dt = \Big\{ & (\partial t/\partial t_1)(dt_1/d\alpha) \\ & + \sum \big[(\partial t/\partial q_l{}^{(1)})(dq_l{}^{(1)}/d\alpha) + (\partial t/\partial p_l{}^{(1)})(dp_l{}^{(1)}/d\alpha)\big] \Big\}\, d\alpha. \end{aligned} \tag{8.12.9}$$

With these analytical preliminaries, let us now *integrate the fundamental equation (8.12.2) for a complete variation of* α; that is, $\alpha_1 \to \alpha_2$. Since, here,

$$A = \int L(t, q, \dot{q})\, dt$$
$$= \int_{t_1(\alpha)}^{t_2(\alpha)} L[t(s;\alpha), q(s;\alpha), p(s;\alpha)]\,[(\partial t/\partial s)\, ds] = A(\alpha), \qquad (8.12.10)$$

[where the integrand is taken along a trajectory; i.e., for a *fixed* α],

the total change of A *equals zero:*

$$\oint dA \equiv \int_{\alpha_1}^{\alpha_2} dA \equiv \int_{\alpha_1}^{\alpha_2} A'(\alpha)\, d\alpha = A(\alpha_2) - A(\alpha_1) = 0; \qquad (8.12.11)$$

and therefore the integral of (8.12.2) (slightly rewritten in simplified standard calculus notation, now that we understand the situation better) becomes

$$0 = \oint dA = \oint_{\gamma_2} \Big(\sum p_k{}^{(2)}(\alpha)\, dq_k{}^{(2)}(\alpha) - H^{(2)}(\alpha)\, dt_2(\alpha)\Big)$$
$$- \oint_{\gamma_1} \Big(\sum p_k{}^{(1)}(\alpha)\, dq_k{}^{(1)}(\alpha) - H^{(1)}(\alpha)\, dt_1(\alpha)\Big), \qquad (8.12.12a)$$

where

$$H^{(*)}(\alpha) \equiv H[t_*(\alpha), q^{(*)}(\alpha), p^{(*)}(\alpha)], \qquad q^{(*)}(\alpha) \equiv q(s_*;\alpha), \qquad p^{(*)}(\alpha) \equiv p(s_*;\,\alpha),$$
$$dq^{(*)}(\alpha),\ dt_*(\alpha)\text{: as given by (8.12.9), at } s_*\ (* = 1, 2);$$

or, after another easily understood notational simplification,

$$\oint_{\gamma_1} \Big(\sum p_k\, dq_k - H\, dt\Big) = \oint_{\gamma_2} \Big(\sum p_k\, dq_k - H\, dt\Big) = \oint_{\gamma} \Big(\sum p_k\, dq_k - H\, dt\Big), \qquad (8.12.12b)$$

that is,

$$I \equiv \oint \Big(\sum p_k\, dq_k - H\, dt\Big) = constant. \qquad (8.12.13)$$

In words: The integral I (around an arbitrary closed curve that encircles the tube of system trajectories and intersects them only once) is constant along these trajectories; as we say, I is a (Poincaré–Cartan) *relative integral invariant*. [If the domain of integration is *closed (open)*, like γ, the integral invariant is called *relative (absolute)*.]

For $t = constant$ ($\Rightarrow dt = 0$; i.e., γ consists of *simultaneous* system states), I reduces to the *first-order (Poincaré) relative integral invariant*:

$$I \to I_1 \equiv \oint \sum p_k\, dq_k = constant. \qquad (8.12.14)$$

I_1 is also called *circulation integral*, due to its formal similarity with the integrals that appear in the Helmholtz–Thomson theorems of continuum kinematics.

REMARK

If we, formally, set $q_{n+1} \equiv t$, then, since $\partial A/\partial t = -H$, the corresponding canonical "momentum" equals $-H$; that is, $p_{n+1} = \partial A/\partial q_{n+1} = \partial A/\partial t = -H$, and therefore (8.12.13) can be rewritten in the following (i)-form for $n+1$ q's:

$$I \equiv \oint \sum p_\mu \, dq_\mu = constant \qquad (\mu = 1, \ldots, n+1). \tag{8.12.13a}$$

Now, the simple closed curve γ [a one-dimensional manifold in either the $(n+1)$-dimensional extended configuration space, or the $(2n+1)$-dimensional extended phase space] can be viewed as the *boundary of a two-dimensional (simply connected) surface there*, σ, *described by the two Gaussian (curvilinear) coordinates u, v*. Hence, when the system point varies over σ, we can write

$$q_k = q_k(u, v) \to \; dq_k = (\partial q_k/\partial u)\, du + (\partial q_k/\partial v)\, dv, \tag{8.12.15a}$$

and similarly for p_k, dp_k. Then, say (8.12.14) becomes

$$I_1 = \oint \Big\{ \Big[\sum p_k(\partial q_k/\partial u) \Big] \, du + \Big[\sum p_k(\partial q_k/\partial v) \Big] \, dv \Big\}, \tag{8.12.15b}$$

or, applying the (two-dimensional) Kelvin–Stokes theorem to it:

$$\oint_\gamma [(*)\, du + (**)\, dv] = \iint_\sigma \{ [\partial(*)/\partial v] - [\partial(**)/\partial u] \} \, du\, dv, \tag{8.12.15c}$$

$$I_1 = \iint_\sigma \Big\{ \partial/\partial v \Big[\sum p_k(\partial q_k/\partial u) \Big] - \partial/\partial u \Big[\sum p_k(\partial q_k/\partial v) \Big] \Big\} \, du\, dv,$$

[where $\sigma =$ region in uv-plane bounded by image of γ there]

$$= \iint_\sigma \Big\{ \sum \big[(\partial p_k/\partial v)\, (\partial q_k/\partial u) - (\partial p_k/\partial u)\, (\partial q_k/\partial v) \big] \Big\} \, du\, dv$$

$$\equiv \iint_\sigma \sum \big[\partial(q_k, p_k)/\partial(u, v) \big] \, du\, dv, \tag{8.12.15d}$$

or, finally, recalling that $\partial(q_k, p_k)/\partial(u, v)$ is none other than the Jacobian of the transformation $(q_k, p_k) \to (u, v)$, where the q's and p's are rectangular Cartesian coordinates in phase space, and the earlier definition of Lagrangean brackets (8.7.9), we can rewrite $I_1 = constant$ as

$$I_1 = I_2 = \iint_{S_2} \sum dq_k \, dp_k = \iint_{\sigma_2} [u, v] \, du\, dv = constant, \tag{8.12.16}$$

where $S_2 =$ two-dimensional subspace in phase space corresponding to σ_2 via (8.12.16). Alternatively, invariance of I_2 under a canonical transformation

$(q, p) \to (q', p')$ requires that (here, for *constant* time, but the argument can be extended to variable time):

$$I_2{}' \equiv \iint_{S_2} \sum dq_{k'}\, dp_{k'} = \iint_{\sigma_2} \sum \left[\partial(q_{k'}, p_{k'})/\partial(u, v)\right] du\, dv$$
$$= I_2 = \iint \sum dq_k\, dp_k = \iint \sum \left[\partial(q_k, p_k)/\partial(u, v)\right] du\, dv,$$
$$\Rightarrow \sum \left[\partial(q_{k'}, p_{k'})/\partial(u, v)\right] = \sum \left[\partial(q_k, p_k)/\partial(u, v)\right]$$

or

$$[u, v]_{q', p'} = [u, v]_{q, p}, \qquad (8.12.17)$$

which is the earlier-proved canonical invariance property of the Lagrange's (and Poisson's) brackets (§8.9).

Similarly, we can prove the integral invariance of

$$I_4 \equiv \iiiint \sum\sum dq_k\, dq_l\, dp_k\, dp_l, \qquad (8.12.18a)$$

$$I_6 \equiv \iiiint\!\!\iint \sum\sum\sum dq_k\, dq_l\, dq_r\, dp_k\, dp_l\, dp_r, \qquad (8.12.18b)$$

and, generally, of

$$I_{2n} \equiv \int \cdots (2n \text{ times}) \cdots \int \sum \cdots (n \text{ sums}) \cdots \sum dq_k\, dq_{k'} \cdots dp_k\, dp_{k'}. \qquad (8.12.18c)$$

The last integral of this series:

$$\int \cdots (2n \text{ times}) \cdots \int dq_1 \cdots dq_n\, dp_1 \cdots dp_n, \qquad (8.12.19a)$$

represents the volume of the corresponding region in (q, p) phase space. Hence, *such volumes are invariant under canonical transformations*; that is,

$$\int \cdots (2n \text{ times}) \cdots \int dq_1 \cdots dq_n\, dp_1 \cdots dp_n$$
$$= \int \cdots (2n \text{ times}) \cdots \int dq_{1'} \cdots dq_{n'}\, dp_{1'} \cdots dp_{n'}; \qquad (8.12.19b)$$

and this (by the earlier-mentioned theorem of multiple integral calculus) shows that *the corresponding Jacobian* $\partial(q, p)/\partial(q', p')$ *equals* $+1$.

This theorem leads to an important conclusion in phase space: we have already seen (ex. 8.9.6) that $(\dot{q}_k, \dot{p}_k)$, or (dq_k, dp_k), can be viewed as an infinitesimal canonical transformation with the Hamiltonian as generating function. Therefore, *all invariants of canonical transformations are also invariants of the motion*. This means, geometrically, that the corresponding $2n$-dimensional phase space points can be viewed as representative points of a corresponding manifold of identical mechanical systems with differing initial state conditions. As a result of the motion of these systems, the initial domain of integration of (q, p) is carried over to another one of equal volume.

In the extended phase space of (t, q, p), the world lines of such systems build a tube of constant cross-section. This constitutes the celebrated *theorem of Liouville* of statistical mechanics. As mentioned earlier, the above integral invariants are called *absolute*, because no special assumptions were made about their region of integration. However, with the help of the multidimensional generalization of Stokes' theorem, they can be transformed to *relative* invariants; that is, invariants over closed areas of lower order (= fewer integrations). For example, the absolute integral invariant I_1 can be transformed into the following relative integral invariant:

$$I_1 = \oint \sum p_k\, dq_k, \quad \text{over a } \textit{closed curve} \text{ in } (q, p)\text{-space, which lies on the plane } t = \textit{constant}, \text{ in } (t, q, p)\text{-space.}$$

As an application of the above, it follows that if we choose as range of integration the elementary parallelogram spanned by the two infinitesimal (q, p)-space vectors;

$$\big(d_1 q_k = (\partial q_k/\partial u)\, du, \quad d_1 p_k = (\partial p_k/\partial u)\, du\big),$$

and

$$\big(d_2 q_k = (\partial q_k/\partial v)\, dv, \quad d_2 p_k = (\partial p_k/\partial v)\, dv\big),$$

for a *constant* time t, then

$$\begin{aligned} I_2 &= \iint \Big\{\sum \big[(\partial p_k/\partial u)\, du\big]\big[(\partial q_k/\partial v)\, dv - (\partial p_k/\partial v)\, dv\big]\big[(\partial q_k/\partial u)\, du\big]\Big\} \\ &= \iint \sum (d_1 p_k\, d_2 q_k - d_2 p_k\, d_1 q_k) = \textit{integral invariant}, \end{aligned} \tag{8.12.20}$$

from which it follows that the *Lagrangean bilinear covariant* (8.7.10 ff.)

$$\sum (d_1 p_k\, d_2 q_k - d_2 p_k\, d_1 q_k) = \sum\sum [c_\mu, c_\nu]\, \delta_1 c_\mu\, \delta_2 c_\nu, \tag{8.12.21}$$

of the *differential form* $\sum p_k\, dq_k$, is invariant; and, conversely, *its invariance is sufficient for the corresponding transformation to be canonical* (with no recourse to generating functions, as in §8.8). [For alternative proofs see examples below, and Whittaker (1937, pp. 272–274).]

In sum:

- *Direct*: The quantity $\oint p\, dq$ is a relative integral invariant of any Hamiltonian system of differential equations ("the circulation in any circuit moving with the fluid does not change with time").
- *Converse*: If a system of equations $dq/dt = Q$, $dp/dt = -P$ possesses the relative integral invariant $\oint p\, dq$, then its equations of motion have the Hamiltonian form: $Q = \partial H/\partial p$, $P = -\partial H/\partial q$.

REMARKS

(i) The invariance of the *circulation*

$$\oint \sum p_k\, dq_k = \iint \Big\{\sum \big[(\partial p_k/\partial v)\,(\partial q_k/\partial u) - (\partial p_k/\partial u)\,(\partial q_k/\partial v)\big]\Big\}\, du\, dv \tag{8.12.22}$$

should not come as a complete surprise; after all, the fundamental definition of canonical transformations (8.8.12):

$$\sum p_k\,\delta q_k - \sum p_{k'}\,\delta q_{k'} = \delta F, \tag{8.12.22a}$$

looks like a requirement that "the work" of the left side of the above be potential; or, equivalently, that, for any closed path in phase space, $\oint dF = 0$; and this leads immediately to

$$\oint \sum p_k\,dq_k = \oint \sum p_{k'}\,dq_{k'}. \tag{8.12.22b}$$

(ii) If we also vary the time, then it is not (8.12.21) that is invariant, but the *extended bilinear covariant* of the extended differential form $\sum p_k\,dq_k - H\,dt$:

$$\sum (d_1 p_k\,d_2 q_k - d_2 p_k\,d_1 q_k) - (d_1 H\,d_2 t - d_2 H\,d_1 t). \tag{8.12.23}$$

(See also Routh, 1905(b), §479, pp. 325–326.)

Incidentally, this theorem of Lagrange signals a basic difference between Lagrangean and Hamiltonian mechanics. Restricting ourselves to the common *scleronomic* case, we may remark that:

(a) In the former (Lagrangean), due to the geometrical structure of its *configuration* space, the fundamental invariant under point transformations $q \to q'$ is the Riemannian *line element ds* (§3.9):

$$(ds)^2 \equiv 2T(dt)^2 = \sum\sum M_{kl}\,dq_k\,dq_l = \sum\sum M_{k'l'}\,dq_{k'}\,dq_{l'} = \cdots; \tag{8.12.24}$$

whereas

(b) In the latter (Hamiltonian), due to the geometrical structure of its *phase space*, the fundamental invariant under canonical transformations $(q,p) \to (q',p')$ is the also quadratic and homogeneous form in the dq's and dp's expression (8.12.21); but since it is associated with *two*, rather than one, infinitesimal displacements, $d_1(\ldots)$ and $d_2(\ldots)$, it is a *bilinear* form in them and hence represents an *area*, rather than a line, element $d_{12}A$:

$$I \equiv d_{12}A \equiv \sum (d_1 p_k\,d_2 q_k - d_2 p_k\,d_1 q_k) = \sum (d_1 p_{k'}\,d_2 q_{k'} - d_2 p_{k'}\,d_1 q_{k'}) = \cdots. \tag{8.12.25}$$

These remarks can be extended, with some precautions, to the *rheonomic* case.

[The literature on integral invariants is quite extensive and varied. For further details and insights, we recommend (alphabetically): Aizerman (1974, pp. 289–308), Cartan (1922: a classic in the field), Gantmacher (1970, pp. 119–127), Kilmister (1964, pp. 128–140), Lovelock and Rund (1975, pp. 207–213), Prange (1935, pp. 657–689).]

Example 8.12.1 Let us calculate the Poincaré–Cartan invariant

$$I \equiv \oint \Big(\sum p_k\;dq_k - H\,dt\Big), \tag{a}$$

for a system with Hamiltonian

$$H = (1/2)\,(p^2 + q^2); \tag{b}$$

that is, a one-DOF linear oscillator (of unit mass and stiffness).

We will evaluate (a) along (i) the *initial* closed curve $\gamma_1 \equiv OABO$ $(s = s_1)$, which has the following parametric representation [(fig. 8.10); since there is only one DOF, we use subscripts throughout: 1 for initial values and 2 for final values]:

$$\begin{aligned} \gamma_1: \quad & OA(s_1): && t_1 = \alpha, \quad q_1 = 0, \quad p_1 = 0, \\ & AB(s_1): && t_1 = \alpha_2, \quad q_1 = 0, \quad p_1 = 0, \\ & BO(s_1): && t_1 = \alpha, \quad q_1 = 0, \quad p_1 = \alpha; \\ & && [\alpha_1 = 0 \le \alpha \le \alpha_2]; \end{aligned} \tag{c}$$

and (ii) along the *intermediate* closed curve $\gamma\,(s = s)$. Since the solution of the Hamiltonian equations of motion of (b), with initial conditions: t_1, q_1, p_1, is

$$t = t_1 + f, \qquad q = q_1 \cos f + p_1 \sin f, \qquad p = \dot{q} = -q_1 \sin f + p_1 \cos f,$$
$$f \equiv f(s; q_1, p_1) = \text{monotonic function in } s, \text{and such that } \ f(s_1; q_1, p_1) = 0, \tag{d}$$

the parametric representation of γ will be

$$\begin{aligned} \gamma: \quad & OA(s): && t = \alpha + f(s,0,0), && q = 0, \quad p = 0, \\ & AB(s): && t = \alpha_2 + f(s,0,\alpha), && q = \alpha \sin f(s,0,\alpha), \ \ p = \alpha \cos f(s,0,\alpha), \\ & BO(s): && t = \alpha + f(s,0,\alpha), && q = \alpha \sin f(s,0,\alpha), \ \ p = \alpha \cos f(s,0,\alpha); \\ & && [\alpha_1 = 0 \le \alpha \le \alpha_2]. \end{aligned} \tag{e}$$

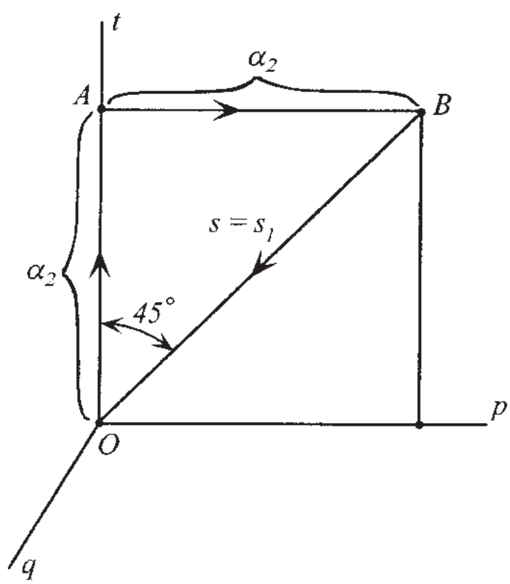

Figure 8.10 Initial closed path of harmonic oscillator conditions, in three-dimensional phase space.

Hence, we find, successively:

(i) Along γ_1 $(s = s_1)$:

$$\begin{aligned}
I(\gamma_1) &= \oint_{\gamma_1} (p_1\, dq_1 - H_1\, dt_1) \\
&= \int [along\ OA(s_1)] + \int [along\ AB(s_1)] + \int [along\ BO(s_1)] \\
&= 0 + 0 + \int [along\ BO(s_1)] \\
&= \int_{\alpha_2}^{0} -({p_1}^2/2)\, dt_1 = +(1/2) \int_0^{\alpha_2} \alpha^2\, d\alpha = {\alpha_2}^3/6.
\end{aligned} \tag{f}$$

(ii) Along γ $(s = s)$:

$$\begin{aligned}
I(\gamma) &= \oint (p\, dq - H\, dt) = \int [along\ OA(s)] + \int [along\ AB(s)] + \int [along\ BO(s)] \\
&= 0 + \int_0^{\alpha_2} \big\{(\alpha \cos f)\,(d\alpha \sin f) - (1/2)\,(\alpha^2 \sin^2 f + \alpha^2 \cos^2 f)\,[(\partial f/\partial\alpha)\, d\alpha]\big\} \\
&\quad + \int_{\alpha_2}^{0} \big\{(\alpha \cos f)\,(d\alpha \sin f) - (1/2)\,(\alpha^2 \sin^2 f + \alpha^2 \cos^2 f)\,[d\alpha + (\partial f/\partial\alpha)\, d\alpha]\big\} \\
&= \int_0^{\alpha_2} \big[\alpha \sin f \cos f - (\alpha^2/2)\,(\partial f/\partial\alpha)\big]\, d\alpha \\
&\qquad - \int_0^{\alpha_2} \big\{\alpha \sin f \cos f - (\alpha^2/2)\,[1 + (\partial f/\partial\alpha)]\big\}\, d\alpha \\
&= - \int_0^{\alpha_2} [-(\alpha^2/2)]\, d\alpha = {\alpha_2}^3/6;
\end{aligned} \tag{g}$$

that is, $I(s_1) = I(s)$, Q.E.D.; I is indeed constant along the trajectories of (b).

Example 8.12.2 *Integral Variants for Nonpotential* ($\rightarrow$ *Nonconservative*) *Holonomic Systems*. Starting with Hamilton's principle of varying action for systems under *nonpotential* forces $(Q_k; k = 1, \ldots, n)$ (chap. 7), and proceeding as in the potential case discussed earlier, it is not hard to show that, here, the Poincaré–Cartan and Poincaré invariant equations must be replaced, respectively, by the following integral *variant* relations:

$$dI/dt \equiv d/dt \left[\oint_\gamma \left(\sum p_k\, dq_k - H\, dt\right)\right] = \oint_\gamma \sum Q_k\, dq_k, \tag{a1}$$

$$dI_1/dt \equiv d/dt \left[\oint_\gamma \left(\sum p_k\, dq_k\right)\right] = \oint_\gamma \sum Q_k\, dq_k. \tag{a2}$$

For these variants to become *invariants*—namely, in order that $I = constant$, $I_1 = constant$—we must have

$$\oint_\gamma \sum Q_k \, dq_k = 0. \tag{b}$$

Application of the *generalized theorem of Stokes:*

$$\oint_\gamma \sum A_s \, dx_s = \iint_\sigma \sum\sum (\partial A_s/\partial x_r - \partial A_r/\partial x_s) \, dx_s \, dx_r \tag{c}$$

[where $s, r =, \ldots$; on the right side (double) summation $r < s$; and γ is the boundary of the diaphragm-like surface σ, locus at time t of points that were initially located on another surface bounded by the initial position of γ] to eq. (b), with the identifications

$$A_k = Q_k, \quad A_{n+k} = 0; \quad x_k = q_k, \ x_{n+k} = p_k \ (s, r = 1, \ldots, n, \ldots, 2n; \ k = 1, \ldots, n), \tag{d}$$

shows that the necessary and sufficient conditions for it to occur (for arbitrary σ and independent dx_s, dx_r) are

$$\partial A_s/\partial x_r - \partial A_r/\partial x_s = 0 \qquad (s, r = 1, \ldots, 2n; \ r < s):$$
$$\partial Q_k/\partial q_l = \partial Q_l/\partial q_k \qquad \text{and} \qquad \partial Q_k/\partial p_l = 0 \qquad (k, l = 1, \ldots, n); \tag{e}$$

that is, the Q_k must be derivable from a *potential* function, say $V = V(t, q)$: $Q_k = -\partial V/\partial q_k$. Hence, *no Poincaré–Cartan/Poincaré invariants exist for nonpotential forces.*

An Application of Equation (a2) to the Method of Slowly Varying Parameters

However, equations (a1, 2) can become useful in approximate calculations. Let us apply (a2) to such a solution of the quasi-linear oscillator equation

$$\ddot{q} + \omega_o{}^2 q = \varepsilon f(q, \dot{q}), \tag{f}$$

where $\varepsilon f(\ldots) =$ small relative to $\ddot{q}$ (inertia) and $\omega_o{}^2 q$ (elasticity). Here, clearly,

$$L = (1/2)\,(\dot{q})^2 - (1/2)\omega_o{}^2 q^2, \qquad Q = \varepsilon f(q, \dot{q}) \equiv \varepsilon f(\ldots), \tag{g}$$

and therefore the corresponding canonical equations are

$$\dot{q} = p, \qquad \dot{p} = -\omega_o{}^2 q + \varepsilon f(\ldots). \tag{h}$$

Let us seek a solution of the above in the form

$$q = a(t) \sin \chi(t) \ \Rightarrow \ p = \dot{q} = a(t)\omega_o \cos \chi(t), \tag{i}$$

where $\chi(t) = \omega_o t + \phi(t)$ and $a(t), \phi(t) =$ unknown functions to be determined.

By δ-varying the first of (i), we obtain

$$\delta q = (\partial q/\partial a)\,\delta a + (\partial q/\partial \phi)\,\delta\phi = \sin\chi\,\delta a + a\cos\chi\,\delta\phi, \tag{j}$$

and, therefore $\{$returning to the δ-notation, $\delta(\ldots) \equiv [\partial(\ldots)/\partial\alpha]\,\delta\alpha$, to avoid possible confusion with $d(\ldots) \equiv [\partial(\ldots)/\partial s]\,ds\}$,

$$I_1 \equiv \oint_\gamma p\,\delta q = \oint_\gamma [a\,\omega_o \cos\chi\,(\sin\chi\,\delta a + a\cos\chi\,\delta\phi)], \tag{k}$$

$$\oint_\gamma Q\,\delta q = \oint_\gamma \varepsilon\, f\,\delta q = \oint_\gamma [\varepsilon\, f(\ldots)\,(\sin\chi\,\delta a + a\cos\chi\,\delta\phi)], \tag{l}$$

where $\gamma =$ arbitrary closed curve encircling simultaneously ($dt = 0$) the closed tube of trajectories.

Now, proceeding as in the method of slowly varying parameters (ex. 7.9.14 ff.), we *average* equations (k, l) over χ, from 0 to 2π, thus obtaining (skipping the factor $1/2$ in both equations)

$$\langle I_1\rangle = \int_0^{2\pi} d\chi\left(\oint_\gamma p\,\delta q\right) = \oint_\gamma\left(\int_0^{2\pi} a\,\omega_o\cos\chi(\sin\chi\,\delta a + a\cos\chi\,\delta\phi)\right)d\chi$$

$$= \oint_\gamma\left[a\,\omega_o\,\delta a\left(\int_0^{2\pi}\sin\chi\cos\chi\,d\chi\right) + a^2\omega_o\,\delta\phi\left(\int_0^{2\pi}\cos^2\chi\,d\chi\right)\right]d\phi$$

[the *second* (inner) integral vanishes, while the *second* equals π]

$$= \oint_\gamma \pi a^2\omega_o\,\delta\phi, \tag{m}$$

$$\langle Q\rangle = \int_0^{2n} d\chi\left(\oint_\gamma Q\,\delta q\right) = \oint_\gamma\left[\int_0^{2\pi}\varepsilon\, f(\ldots)\,(\sin\chi\,\delta a + a\cos\chi\,\delta\phi)\right]d\chi, \tag{n}$$

and then apply to them the integral variant equation (a2); or, equivalently, we average (a2) over χ from 0 to 2π; that is,

$$\langle dI_1/dt\rangle = \langle Q\rangle \;\Rightarrow\; d\langle I_1\rangle/dt = \langle Q\rangle. \tag{o}$$

In this way, we find

$$d/dt\left(\oint_\gamma \pi a^2\omega_o\,\delta\phi\right) = \pi\,\omega_o\left\{\oint_\gamma\left[(a^2)^{\cdot}\,\delta\phi + (a^2)(\delta\phi)^{\cdot}\right]\right\}$$

[in the *second* term, we assume that $(\delta\phi)^{\cdot} = \delta(\dot\phi)$, then integrate it by parts (for $t = constant$)]

$$= \pi\omega_o\left[\oint_\gamma (2a\,\dot a)\,\delta\phi + (a^2\dot\phi)\Big|_\gamma - \int\dot\phi\,\delta(a^2)\right]$$

[by periodicity, the integrated out boundary/endpoints term vanishes]

$$= \oint_\gamma\left[(2\pi\omega_o a\,\dot a)\,\delta\phi - (2\pi\omega_o a\,\dot\phi)\,\delta a\right]$$

$$= \langle Q\rangle = \oint_\gamma\left\{\left(\int_0^{2\pi}\varepsilon\, f(\ldots)\sin\chi\,d\chi\right)\delta a + \left(\int_0^{2\pi}\varepsilon\, f(\ldots)a\cos\chi\,d\chi\right)\delta\phi\right\}; \tag{p}$$

and, from this, since γ is arbitrary and the $\delta a, \delta\phi$ are independent (and $a \neq 0$), we obtain the well-known *van der Pol/Krylov/Bogoliubov equations:*

$$da/dt = (\varepsilon/2\pi\omega_o)\int_0^{2\pi} f(\ldots)\cos\chi\, d\chi, \tag{q}$$

$$d\phi/dt = -(\varepsilon/2\pi a\omega_o)\int_0^{2\pi} f(\ldots)\sin\chi\, d\chi. \tag{r}$$

Example 8.12.3 *Alternative Proof of Relation between Integral Invariance and Canonicity of Equations of Motion.* Here, we show, by direct calculation, that if

$$I \equiv \oint_\gamma \left(\sum p_k\, dq_k - H\, dt\right) = constant, \tag{a}$$

then

$$dp_k/dt = -\partial H/\partial q_k, \qquad dq_k/dt = \partial H/\partial p_k, \qquad dH/dt = \partial H/\partial t. \tag{b}$$

For extra clarity, we introduce the following special notations:

$$d_1(\ldots) = [\partial(\ldots)/\partial s]\, ds = \text{differential along an integral curve}, \tag{c1}$$

$$d_2(\ldots) = [\partial(\ldots)/\partial\alpha]\, d\alpha = \text{differential along closed curve } \gamma \text{ encircling tube of integral curves}. \tag{c2}$$

Clearly, since the parameters s and α are independent, $d_1[d_2(\ldots)] = d_2[d_1(\ldots)]$; and so (a) can be rewritten as

$$I \equiv I(s) \equiv \oint_\gamma \left(\sum p_k\, d_2 q_k - H\, d_2 t\right) = constant. \tag{d}$$

We have, successively,

$$\begin{aligned}
d_1 I \equiv d_1 I(s) = d_1 \oint_\gamma (\ldots)&\\
&= \oint_\gamma \left\{\sum \left[d_1 p_k\, d_2 q_k + p_k\, d_1(d_2 q_k)\right] - \left[d_1 H\, d_2 t - H\, d_1(d_2 t)\right]\right\}\\
&= \oint_\gamma \left\{\sum \left[d_1 p_k\, d_2 q_k + p_k\, d_2(d_1 q_k)\right] - \left[d_1 H\, d_2 t - H\, d_2(d_1 t)\right]\right\}\\
&\quad \text{[integrating the } \textit{second} \text{ and } \textit{fourth} \text{ terms by parts relative to } d_2(\ldots)\text{; i.e., along } \gamma]\\
&= \oint_\gamma \sum d_1 p_k\, d_2 q_k + \left(\sum p_k\, d_1 q_k\right)\Big|_\gamma - \oint_\gamma \sum d_2 p_k\, d_1 q_k\\
&\qquad - \oint_\gamma d_1 H\, d_2 t - \left(\sum H\, d_1 t\right)\Big|_\gamma + \oint_\gamma d_2 H\, d_1 t
\end{aligned}$$

[due to the α-periodicity, the integrated out (second and fifth sums) vanish]

$$= \oint_\gamma \Big[\Big(\sum d_1 p_k\, d_2 q_k - \sum d_2 p_k\, d_1 q_k\Big) - (d_1 H\, d_2 t - d_2 H\, d_1 t)\Big]$$

$$\Big[\text{setting}\quad d_2 H = \sum[(\partial H/\partial q_k) d_2 q_k + (\partial H/\partial p_k) d_2 p_k] + (\partial H/\partial t) d_2 t, \text{ and regrouping terms}\Big]$$

$$= \oint_\gamma \Big(\sum\{[d_1 p_k + (\partial H/\partial q_k) d_1 t] d_2 q_k + [-d_1 q_k + (\partial H/\partial p_k) d_1 t] d_2 p_k\} + [-d_1 H + (\partial H/\partial t) d_1 t] d_2 t\Big). \qquad \text{(e)}$$

Therefore, if $d_1 I(s) = 0$, since γ is arbitrary and the α-differentials $d_2 q, d_2 p, d_2 t$ are independent, it follows that, *along each trajectory* [with $s = t \Rightarrow d_1(\ldots) = (\ldots)^{\boldsymbol{\cdot}} dt = dt$]

$$d_1 p_k + (\partial H/\partial q_k) d_1 t = 0 \;\Rightarrow\; dp_k/dt = -\partial H/\partial q_k, \qquad \text{(f1)}$$

$$-d_1 q_k + (\partial H/\partial p_k) d_1 t = 0 \;\Rightarrow\; dq_k/dt = \partial H/\partial p_k, \qquad \text{(f2)}$$

$$-d_1 H + (\partial H/\partial t) d_1 t = 0 \;\Rightarrow\; dH/dt = \partial H/\partial t; \qquad \text{(f3)}$$

that is, the Hamiltonian equations of *motion* and *energy* (b) hold. Hence, the importance of the integral invariant $I = I(s)$ to mechanics. The converse theorem can be shown similarly.

In sum:
- If $I = constant$, then the system satisfies Hamilton's equations.
- If the system satisfies Hamilton's equations, then $I = constant$.

---

§8.13 NOETHER'S THEOREM (E. Noether, 1918)

This famous and conceptually elegant theorem — much more useful to physicists (classical and quantum field theory) than to engineers — uncovers the consequences of the invariance of the, say, Lagrangean action functional of a system S

$$A = \int L(t, q, \dot{q}) dt \quad \text{(with arbitrary time limits, say from } t_1 \text{ to } t_2) \qquad (8.13.1)$$

not under the customary, and hitherto examined (ch.7) (first-order *special kinematically* admissible changes known as) *virtual* variations δq, from a "fundamental" kinetic trajectory q (i.e. a solution of S's Lagrangean equations of motion), BUT under the special, "narrower", *finite continuous/Lie group* of transformations

$t \to t' = t'(t; \varepsilon)$ [or even $t' = t'(t, q; \varepsilon)$] and $q_k \to q_{k'}$ or $q'_k = q'_k(t, q; \varepsilon)$:

> *coordinate system*, or "*extended point*, transformations" (or, simply, "point transformations" if $t' = t$), in configuration space (or collection of system *trajectories*, i.e. solutions of the system's Lagrangean equations of motion) *generated/evolved from t, q by the continuous variation of the parameter* ε, and assumed: (a) as many times continuously differentiable in ε as needed, and uniquely invertible $t, q \Leftrightarrow t', q'$ (i.e. each ε-value defines a different coordinate system q'), *AND* with (b) the group parameter ε chosen so that

$$t'(t; 0) = t \;[\text{or } t'(t, q; 0) = t],\; q'_k(t, q; 0) = q_k\text{: } \textit{identity} \text{ transformation.} \qquad (8.13.2, 2a)$$

In other words, under such "Lie-Noether changes" *both* $q = q'(0)$ and $q' = q'(\varepsilon)$ *are different coordinate descriptions of the same dynamics!* [Remark: As with orthogonal matrices/tensors (§1.11), both *active* and *passive* interpretations of q and q' are available: either our physical system stays fixed in space while the coordinate system ("laboratory") is transformed, i.e. the same system configuration viewed from two different coordinate systems (passive interpretation); or our system is transformed (moved) while the coordinate system stays fixed in space (active i.)]

Now: that the *finite* transformation (8.13.2) $t'(\varepsilon)$, $q'(\varepsilon)$ results, or can be generated, by a continuous *sequence* of "infinitesimal/elementary" transformations, i.e. by a *continuous variation* of ε, from the identity transformation $t = t'(0)$, $q = q'(0)$, allows us to replace A-invariance under the *finite* ε coordinate change (8.13.2) with invariance under the *first-order* ε-change, that is, with $(\partial \ldots/\partial\varepsilon)_{\varepsilon=0} \equiv (\partial \ldots/\partial\varepsilon)_o$, under:

$$t \to t' = t'(t; \varepsilon) \approx t'(t; 0) + (\partial t'/\partial\varepsilon)_o\, \varepsilon \equiv t + \Delta t, \qquad (8.13.3a)$$

$$q_k \to q'_k = q'_k(t, q; \varepsilon) \approx q'_k(t, q; 0) + (\partial q'_k/\partial\varepsilon)_o\, \varepsilon \equiv q_k + \Delta q_k, \qquad (8.13.3b)$$

[$\Rightarrow q'_k - q_k \approx \Delta q_k$: a *kinetic* variation, i.e. from one system trajectory to another, *not* a kinematic one];

also, $$(\partial q'_k/\partial q_l)_o = \delta_{kl} \text{ (Kronecker delta)},\; (\partial q'_k/\partial t)_o = 0;\; (\partial t'/\partial q_k)_o = 0,\; (\partial t'/\partial t)_o = 1, \qquad (8.13.3c)$$

and $$(\partial^2 \ldots/\partial\varepsilon\, \partial q_l)_o = \partial/\partial q_l[(\partial \ldots/\partial\varepsilon)_o]; \qquad (8.13.3d)$$

As a result of these, ε-induced, transformations the system Lagrangean becomes:

$$L(t, q, dq/dt) = L\{t(t', q'; \varepsilon), q(t', q'; \varepsilon), d/dt\,[q(t', q'; \varepsilon)]\} \equiv L'(t', q', dq'/dt'; \varepsilon) \qquad (8.13.4)$$

(left side independent of ε). The above expresses the *numerical* invariance of the scalar function L; no surprises here: such invariance holds not only under the smaller/restricted Lie-Noether transformations (8.13.2, 2a), but under *arbitrary* (differentiable) point transformations $q = q(t', q') \Leftrightarrow q' = q'(t, q)$ (ex. 3.5.12, and §8.8); however, in the latter L' is, generally, a different *function* of $t', q', dq'/dt'$ than L is of $t, q, dq/dt$! For example, the kinetic energy of a particle of mass m, T, in plane rectangular Cartesian and polar coordinates, (x, y) and (r, ϕ): $x = r\cos\phi$, $y = r\sin\phi$, is:

$$2T(\dot{x}, \dot{y})/m = (dx/dt)^2 + (dy/dt)^2 = (dr/dt)^2 + r^2(d\phi/dt)^2 = 2T'(\dot{r}, \dot{\phi})/m, \tag{8.13.4a}$$

i.e. $T(\dot{x}, \dot{y}) = T'(\dot{r}, \dot{\phi})$: *same numerical value*, BUT $T(\dots)$ is a *different function* (-al form) *of* $\dot{x}, \dot{y}$ *than* $T'(\dots)$ *is of* $\dot{r}$, $\dot{\phi}$, i.e. $T'(\dot{r}, \dot{\phi}) \neq T(\dot{r}, \dot{\phi})$ and $T'(\dot{x}, \dot{y}) \neq T(\dot{x}, \dot{y})$! Here, since we are interested in discovering the consequences of the *symmetry*(-ies) of L ($\Rightarrow$ *invariance of* A), we require, *in addition* to the "same number" invariance (8.13.4), that:

$$L(t, q, dq/dt) = L(t', q', dq'/dt'), \quad \text{or simply } \; L(q) = L(q'), \tag{8.13.5}$$

$$[\text{briefly: } \; L(q) = L'(q') = L(q') \text{ — need for precise notation here!}]; \tag{8.13.5a}$$

in words, that, under (8.13.2), the Lagrangean be also *form* invariant, i.e. that it *retains its original functional form* in both the original and the Noetherianly transformed variables; or, that the new Lagrangean be the same function in the new variables as the old one was in the old. In the above example, such narrower transformation $\rightarrow$ Noetherian invariance occurs, for instance, under

$$q = (x, y) \rightarrow q' = (x' = x'(x, y; \varepsilon) = x\cos\varepsilon + y\sin\varepsilon, y' = y'(x, y; \varepsilon) = -x\sin\varepsilon + y\cos\varepsilon):$$

i.e., say, a rigid rotation of "old" rectangular Cartesian axes x, y by an angle ε to "new/transformed", also rectangular Cartesian, axes x', y'(*passive* interpretation); (8.13.4b)

then

$$\begin{aligned} 2T(dx/dt, dy/dt)/m &= (dx/dt)^2 + (dy/dt)^2 = \cdots = (dx'/dt)^2 + (dy'/dt)^2 \\ &= 2T'(dx'/dt, dy'/dt)/m \quad (\text{same } \textit{number}, \text{ i.e. } \textit{numerical invariance/equality}) \\ &= 2T(dx'/dt, dy'/dt)/m \quad (\text{same } \textit{function}, \text{ i.e. } \textit{form invariance}). \end{aligned} \tag{8.13.4c}$$

Hence, under Noetherian transformations, not just the *general* form of the system's Lagrangean equations of motion is preserved, i.e.

$$E_k(L) \equiv (\partial L/\partial \dot{q}_k)^{\cdot} - \partial L/\partial q_k = 0, \;\; E_{k'}(L') \text{ or } E'_k(L') \equiv (\partial L'/\partial \dot{q}'_k)^{\cdot} - \partial L'/\partial q'_k = 0,$$

but so is their *explicit* form, i.e. these equations are the same in the q s and q's. Now we are ready to find the consequences of our initial A-invariance assumption, under (8.13.2), for *any* ε, and arbitrary integration limits $t'_{1,2}$, $t_{1,2}$, respectively, i.e.

$$A(\varepsilon) - A(0) \equiv \int L'(t', q', dq'/dt')dt' - \int L(t, q, dq/dt)dt = \int L(t', q', dq'/dt')dt' - \int L(t, q, dq/dt)dt = 0 \tag{8.13.6a}$$

$$[\Rightarrow \; L(t', q', dq'/dt')(dt'/dt) = L(t, q, dq/dt) \quad (\text{necessary and sufficient})]; \tag{8.13.6b}$$

indeed, utilizing the preceding in the earlier general integral identities (7.9.11a-h)ff., we find successively,

$$\Delta A = \cdots = \int \Big\{ d/dt \Big[L\,\Delta t + \sum (\partial L/\partial \dot{q}_k)(\Delta q_k - \dot{q}_k\,\Delta t) \Big] - \sum E_k(L)(\Delta q_k - \dot{q}_k\,\Delta t) \Big\} dt = 0, \tag{8.13.6c}$$

[or, equivalently, ε-differentiating (8.13.6b), while noting that its right side is independent of ε], (8.13.6d)

from which, since $E_k(L) = 0$, and the integration limits (and ε) are arbitrary, Noether's theorem follows:

$$N \equiv L\Delta t + \sum (\partial L/\partial \dot{q}_k)(\Delta q_k - \dot{q}_k\,\Delta t) = \sum (\partial L/\partial \dot{q}_k)\Delta q_k - \Big(\sum (\partial L/\partial \dot{q}_k)\,\dot{q}_k - L \Big)\Delta t = \textit{constant},$$

or, in common "Noetherian notation",

$$\begin{aligned} N &= L(\partial t'/\partial\varepsilon)_o + \sum (\partial L/\partial \dot{q}_k)\,[(\partial q'_k/\partial\varepsilon)_o - \dot{q}_k(\partial t'/\partial\varepsilon)_o] = \textit{constant} \text{ (along any system trajectory/orbit)} \\ &= \sum (\partial L/\partial \dot{q}_k)(\partial q'_k/\partial\varepsilon)_o - \Big(\sum (\partial L/\partial \dot{q}_k)\,\dot{q}_k - L \Big)(\partial t'/\partial\varepsilon)_o \qquad (\textit{Lagrangean} \text{ form}) \\ &\equiv \sum p_k(\partial q'_k/\partial\varepsilon)_o - h(L)(\partial t'/\partial\varepsilon)_o \qquad (\textit{Hamiltonian} \text{ form}); \end{aligned} \tag{8.13.6e}$$

in words: *If A is invariant under the one-parameter* (*finite*) *continuous/Lie group of transformations* [8.13.2 (finite) $\rightarrow$ 8.13.3 (first-order)], the *n equations* $E_k(L) = 0$ *imply the single conservation equation* $N = constant$; or, *every family of such transformations that leaves the action functional invariant leads to a first integral of the equations of motion*; and inversely, *given the equation* $N = constant$, the *n equations* $E_k(L) = 0$ *ensure the existence of a one-parameter continuous transformation* (8.13.3) *that leaves A invariant*.

Noether's theorem (NT): (i) Can be generalized in the following ways: (i.a) From first to higher derivatives of the q s (of minor physical interest); (i.b) From one to several, say m, group parameters (in which case we obtain m distinct constants/integrals, along any system trajectory — of great physical interest; see examples below); and (i.c) From one to several independent variables (of great interest in field theory). These, and "Invariance under Gauge Transformations" (below), lead to additional invariance theorems (see references at this section's end); and (ii) Along with the concepts of closed/open systems and Routh's method for "ignorable coordinates" {§3.12 (esp. pp. 573-574), §8.3, §8.4}, the latter seen now as a specialization of NT [i.e. (8.13.6e) with $(\partial t'/\partial\varepsilon)_o = 0$, $(\partial q'_k/\partial\varepsilon)_o = 1$ (explain)], reveal the following fundamental idea of theoretical dynamics (and physics):

SYMMETRIES (of Lagrangean, Hamiltonian etc; invariance under a ***transformation group***, a ***geometrical*** idea)
$\rightarrow$ ***INVARIANCE*** *properties* (of Action, Langrangean; an ***algebraic/analytical*** idea expressing these symmetries)
$\rightarrow$ ***CONSERVATION*** *quantities*, or ***integrals/constants of motion*** (of momentum, energy, etc).

Example 8.13.1

(i) The action functional

$$A = \int_{t_1}^{t_2} L(q, \dot{q})\, dt \qquad [\text{i.e., } \partial L/\partial t = 0] \tag{a}$$

is, clearly, invariant under the one-parameter group of transformations:

$$t' = t + \varepsilon, \qquad q_{k'} = q_k \qquad [\textit{temporal} \text{ translation}]. \tag{b}$$

Since, in this case, $(\partial t'/\partial\varepsilon)_o = 1$ and $(\partial q_{k'}/\partial\varepsilon)_o = 0$, the Noetherian expressions (8.13.4, 5) yield the generalized energy integral

$$N = \sum p_k(0) - h(1) = -h = \textit{constant}, \tag{c}$$

an already well-known result. Hence, *invariance under time-translation leads to energy conservation.*

(ii) The action functional [with x, y, z: rectangular Cartesian coordinates; and $K, L = 1, \ldots, N$ (# of particles)]

$$A = \int \left\{ \sum (1/2) m_K [(\dot{x}_K)^2 + (\dot{y}_K)^2 + (\dot{z}_K)^2] - \sum\sum V_{KL}(|\boldsymbol{r}_K - \boldsymbol{r}_L|) \right\} dt, \tag{d}$$

where $K \neq L$ (or $K < L$) and $\boldsymbol{r}_K = (x_K, y_K, z_K)$, is, clearly, invariant under the one-parameter rigid *spatial translations* in the x-direction:

$$x_{K'} = x_K + \varepsilon, \qquad y_{K'} = y_K, \qquad z_{K'} = z_K, \quad (\text{and } \; t' = t). \tag{e}$$

Therefore, by (8.13.4, 5), the system possesses the integral $(K = 1, \ldots, 3N)$

$$\begin{aligned} N &= \sum (\partial L/\partial \dot{x}_K)(\partial x_{K'}/\partial\varepsilon)_o - \left[\sum (\partial L/\partial \dot{q}_k)\dot{q}_k - L\right](\partial t'/\partial\varepsilon)_o \\ &= \sum (\partial L/\partial \dot{x}_K)(1) - \left[\sum (\partial L/\partial \dot{q}_k)\dot{q}_k - L\right](0) \\ &= \sum \partial L/\partial \dot{x}_K = \sum m_K \dot{x}_K \equiv p_X \\ &= x\text{-component of total } \textit{linear} \text{ momentum} = \textit{constant}; \end{aligned} \tag{f}$$

and similarly for the y- and z-directions.

Hence, *invariance under rigid translations leads to conservation of the linear momentum vector.*

(iii) If the above action (d) is invariant under the one-parameter rigid rotations of the system about, say the z-axis, through an angle ε (say, under the *active* interpretation, §1.11):

$$\begin{aligned} x_{K'} &= x_{K'}(x_K, y_K; \varepsilon) = x_K \cos\varepsilon - y_K \sin\varepsilon \approx x_K - \varepsilon y_K, \\ y_{K'} &= y_{K'}(x_K, y_K; \varepsilon) = x_K \sin\varepsilon + y_K \cos\varepsilon \approx y_K + \varepsilon x_K, \\ z_{K'} &= z_K \qquad (\text{and } \; t' = t), \end{aligned} \tag{g}$$

then, again by (8.13.4, 5), the system has the integral

$$
\begin{aligned}
N &= \sum \big[(\partial L/\partial \dot{x}_K)\,(\partial x_{K'}/\partial \varepsilon)_o + (\partial L/\partial \dot{y}_K)\,(\partial y_{K'}/\partial \varepsilon)_o \\
&\qquad\qquad + (\partial L/\partial \dot{z}_K)\,(\partial z_{K'}/\partial \varepsilon)_o\big] - h(\partial t'/\partial \varepsilon)_o \\
&= \sum \big[(\partial L/\partial \dot{x}_K)\,(-y_K) + (\partial L/\partial \dot{y}_K)\,(+x_K) + (\partial L/\partial \dot{z}_K)\,(0)\big] - h(0) \\
&= \sum \big[(x_K)\,(\partial L/\partial \dot{y}_K) - (y_K)\,(\partial L/\partial \dot{x}_K)\big] \\
&= \sum \big[(x_K)(m_K \dot{y}_K) - (y_K)\,(m_K \dot{x}_K)\big] \equiv H_z \\
&= z\text{-component of total } \textit{angular} \text{ momentum about origin } O = \textit{constant}; \quad \text{(h)}
\end{aligned}
$$

and similarly for its x- and y-components.

Hence, *invariance under rigid rotations, about a point, leads to conservation of the angular momentum vector about that point*.

[The reader may verify that the *passive* interpretation of rotation (as well as of the earlier translation) leads to the same result!]

Extension of Noether's Theorem to *m*-Parameter Family of Transformations

If the action A is invariant under the m-parameter continuous group of transformations

$$t \to t' = t'(t, q; \varepsilon), \qquad q_k \to q_{k'} = q_{k'}(t, q; \varepsilon), \tag{8.13.7}$$

where $\varepsilon \equiv (\varepsilon_1, \ldots, \varepsilon_m) =$ *group parameters*, and, again, such that

$$t'(t, q; 0) = t, \qquad q_{k'}(t, q; 0) = q_k \qquad \text{[identity transformations]}; \tag{8.13.7a}$$

then, along each system trajectory, the following m distinct quantities ($\bullet$: $1, \ldots, m$):

$$
\begin{aligned}
N_\bullet &\equiv \sum (\partial L/\partial \dot{q}_k)(\partial q_{k'}/\partial \varepsilon_\bullet)_o - \Big(\sum (\partial L/\partial \dot{q}_k)\dot{q}_k - L\Big)(\partial t'/\partial \varepsilon_\bullet)_o \\
&= L(\partial t'/\partial \varepsilon_\bullet)_o + \sum (\partial L/\partial \dot{q}_k)\big[(\partial q_{k'}/\partial \varepsilon_\bullet)_o - \dot{q}_k(\partial t'/\partial \varepsilon_\bullet)_o\big] \\
&\qquad\qquad \text{[Lagrangean form]}, \qquad (8.13.8) \\
&= \sum p_k(\partial q_{k'}/\partial \varepsilon_\bullet)_o - h(\partial t'/\partial \varepsilon_\bullet)_o \qquad \text{[Hamiltonian form]}, \qquad (8.13.9)
\end{aligned}
$$

are constant. In words: *every m-parameter family of transformations that leaves the action functional invariant leads to m distinct first integrals of the equations of motion*.

[For readable proofs, see, for example, Lovelock and Rund (1975, pp. 201–207), Mittelstaedt (1970, pp. 138–160); or, one could extend the previous one-parameter proof to the m-parameter case.]

Invariance under Gauge Transformations

Recalling the nonuniqueness of the Lagrangean (ex's. 3.5.13 and 7.9.5)—namely, that $L = L(t, q, \dot{q})$ and $L' = L + df(t, q)/dt$ [$f(\ldots) =$ arbitrary function of t and the

q's] yield the same equations of motion — we, now, generalize Noether's theorem as follows: If the invariance equation (8.13.6a), under (8.13.2), is replaced by

$$\int_{t'_1}^{t'_2} L(t', q', dq'/dt')\, dt' = \int_{t_1}^{t_2} \left[L(t, q, \dot{q}) + df(t, q; \varepsilon)/dt\right] dt, \tag{8.13.10a}$$

or, equivalently, by

$$L[t', q', dq'(t')/dt'](dt'/dt) = L[t, q,\, dq(t)/dt] + df(t, q; \varepsilon)/dt \tag{8.13.10b}$$

(again, from action *integrals* to their Lagrangean *integrands*), then the Noetherian integrals (8.13.6a, b) are replaced by

$$\begin{aligned} N' &= N - (\partial f/\partial\varepsilon)_o \\ &= \sum (\partial L/\partial\dot{q}_k)(\partial q_{k'}/\partial\varepsilon)_o - \left[\sum (\partial L/\partial\dot{q}_k)\dot{q}_k - L\right](\partial t'/\partial\varepsilon)_o - (\partial f/\partial\varepsilon)_o \\ &= L(\partial t'/\partial\varepsilon)_o + \sum (\partial L/\partial\dot{q}_k)\left[(\partial q_{k'}/\partial\varepsilon)_o - \dot{q}_k(\partial t'/\partial\varepsilon)_o\right] - (\partial f/\partial\varepsilon)_o \\ &= \textit{constant}, \qquad \text{[Lagrangean form]}, \qquad (8.13.11) \\ &= \sum p_k(\partial q_{k'}/\partial\varepsilon)_o - h(\partial t'/\partial\varepsilon)_o - (\partial f/\partial\varepsilon)_o \\ &= \textit{constant}, \qquad \text{[Hamiltonian form]}. \qquad (8.13.12) \end{aligned}$$

This follows easily if we notice that, in this case, the first ε-order action variation (8.13.6c) must be replaced by

$$\begin{aligned} \Delta A &= \varepsilon\left[\sum p_k(\partial q_{k'}/\partial\varepsilon)_o - \left(\sum p_k\dot{q}_k - L\right)(\partial t'/\partial\varepsilon)_o\right] \\ &= \Delta\int (df/dt)\, dt = \Delta[f] = \left[(\partial f/\partial\varepsilon)_o\right]\varepsilon. \end{aligned} \tag{8.13.13}$$

The rest of the details are left to the reader.

Example 8.13.2 Continuing from the conservation theorems of the preceding example, let us consider the motion of our system in two inertial frames, (O, F) and (O', F'), in relative motion with constant velocity $\boldsymbol{v}_o \equiv \boldsymbol{v}_{F/F'}$, and let us assume, for simplicity but no loss in generality, that $V = 0$ and $Q_k = 0$ (inertial motion).

The system Lagrangean in F' is (with $P = 1, \ldots, N = \#$ system particles):

$$\begin{aligned} L' &= \sum (1/2)m_P(d\boldsymbol{r}'_P/dt)\cdot(d\boldsymbol{r}'_P/dt) \\ &= \sum (1/2)m_P\left[(d\boldsymbol{r}_P/dt) + \boldsymbol{v}_o\right]\cdot\left[(d\boldsymbol{r}_P/dt) + \boldsymbol{v}_o\right] \\ &= L + df/dt, \end{aligned} \tag{a}$$

where

$$L = \sum (1/2)m_P(d\boldsymbol{r}_P/dt)\cdot(d\boldsymbol{r}_P/dt) = \text{system Lagrangean in } F, \tag{b}$$

$$f = \sum m_P\,\boldsymbol{r}_P\cdot\boldsymbol{v}_o + \left[\sum (1/2)m_P(\boldsymbol{v}_o\cdot\boldsymbol{v}_o)\right]t:$$

Galilean gauge; function of time, coordinates, and group parameter $\varepsilon \to \boldsymbol{v}_o$,

$$\Rightarrow\ df/dt = \sum m_P(d\boldsymbol{r}_P/dt)\cdot\boldsymbol{v}_o + \sum (1/2)m_P(\boldsymbol{v}_o\cdot\boldsymbol{v}_o). \tag{c}$$

Choosing, for mathematical convenience, in these two frames, rectangular Cartesian coordinates F: $(O; x, y, z)$ and F': $(O'; x', y', z')$, such that

$$x' = x + v_o t \quad (\Rightarrow \dot{x}' = \dot{x} + v_o), \qquad y' = y, \qquad z' = z, \qquad t' = t, \tag{d}$$

reduces (b, c) to

$$L = \sum (1/2)m_P\,\dot{x}_P\,\dot{x}_P, \qquad f = \sum m_P\,x_P\,v_o + \left[\sum (1/2)m_P\,{v_o}^2\right]t; \tag{e}$$

and, therefore, with parameter ε the relative frame velocity v_o, the Noetherian expressions (8.13.10, 11) yield the integral

$$\begin{aligned} N' &= N - (\partial f/\partial\varepsilon)_o \\ &= \sum p_P(\partial x'_P/\partial\varepsilon)_o - h(\partial t'/\partial\varepsilon)_o - (\partial f/\partial\varepsilon)_o \\ &= \sum p_P(\partial x'_P/\partial v_o)_o - h(\partial t'/\partial v_o)_o - (\partial f/\partial v_o)_o \\ &= \sum (m_P\dot{x}_P)(t) - h(0) - \sum m_P x_P = \mathit{constant} = c, \end{aligned} \tag{f}$$

or, since $\sum m_P\,\dot{x}_P \equiv p_x = \mathit{constant} \equiv c_x$ (by ex. 8.13.1) and $\sum m_P\,x_P = (\mathit{total\ mass})\,(x - \mathit{coordinate\ of\ mass\ center}) \equiv m\,x$,

$$N' = c_x t - m\,x = c \ \Rightarrow\ m\,x = c_x t - c,$$

$$\Rightarrow\ \dot{x} = c_x/m \qquad \text{(mass center moves with constant velocity)}; \tag{g1}$$

$$\text{or,}\quad \text{if } c_x = 0, \quad x = -c/m \quad \text{(mass center at rest)}; \tag{g2}$$

and similarly for the y- and z-directions (recall ex. 3.12.3).

These results can be summed up in the following theorem.

THEOREM

Let us consider a system of N particles moving under their mutual (Newtonian) gravitational attractions ["*N-body problem*" of classical (celestial) mechanics], and therefore having equations of motion

$$m_P\,\ddot{\boldsymbol{r}}_P = \sum \Delta_{PP'}G(m_P\,m_{P'}/{r_{PP'}}^3)\boldsymbol{r}_{PP'}, \tag{h}$$

where $\Delta_{PP'} \equiv 1 - \delta_{PP'} = \mathit{complementary\ Kronecker\ delta}, G = \mathit{gravitational\ constant}$ (not gauge function!), $r_{PP'} \equiv |\boldsymbol{r}_{PP'}| \equiv |\boldsymbol{r}_{P'} - \boldsymbol{r}_P| = |-\boldsymbol{r}_{P'P}| = r_{P'P} \neq 0$, and P, $P' = 1, \ldots, N =$ number of particles.

From the Noetherian invariance of its action under the *ten*-parameter Galilean group [between two inertial frames $\big(x_k(t), t\big)$, $\big(x_{k'}(t'), t'\big)$, in arbitrary mutual orientation]

$$x_{k'}(t') = \sum a_{k'k}(\varepsilon_1, \varepsilon_2, \varepsilon_3)x_k + b_k(\varepsilon_4, \varepsilon_5, \varepsilon_6)t + c_k(\varepsilon_7, \varepsilon_8, \varepsilon_9),$$

$$\big[(a_{k'k}) = (a_{k'k}(\varepsilon_1, \varepsilon_2, \varepsilon_3))\text{: proper orthogonal matrix [eqs. (1.1.19a ff.) and(1.5.1a, b)]; with } k, l = 1, 2, 3\big], \tag{i}$$

$$t' = t + \varepsilon_{10}, \tag{j}$$

we obtain the following *ten integrals*:

(i) *Temporal* translation (1) $\rightarrow$ *energy* conservation:

$$T + V \equiv \sum (1/2)m_P(\dot{\boldsymbol{r}}_P \cdot \dot{\boldsymbol{r}}_P) - \sum\sum (1/2)\varDelta_{PP'}G(m_P m_{P'}/r_{PP'}) = constant, \tag{k}$$

(ii) *Spatial* translation (3) $\rightarrow$ *linear momentum* conservation:

$$\sum m_P \dot{\boldsymbol{r}}_P = m\,\boldsymbol{v}_{\text{mass center}} = constant \equiv \boldsymbol{b} = (b_1, b_2, b_3), \tag{l}$$

(iii) *Spatial* rotation (3) $\rightarrow$ *angular momentum* conservation:

$$\sum \boldsymbol{r}_P \times (m_P \dot{\boldsymbol{r}}_P) = constant. \tag{m}$$

(iv) *Galilean transformation* (3) $\rightarrow$ *center of mass* theorem [integral of (l)]:

$$\sum m_P \boldsymbol{r}_P = m\,\boldsymbol{r}_{\text{mass center}} = \boldsymbol{b}t + \boldsymbol{c} \qquad [\boldsymbol{c} = (c_1, c_2, c_3)]. \tag{n}$$

For a detailed Noetherian treatment, see, for example, Funk [1962, pp. 442–445; after the original derivation of Bessel–Hagen (1921)]. For an alternative derivation (via symmetrical infinitesimal canonical transformations), see Schmutzer (1989, pp. 438–445); also Meirovitch (1970, pp. 413–416).

Closing Remarks

Noether's theorem, in spite of its conceptual beauty and simplicity, has not been very successful in producing new and nontrivial integrals of the equations of motion. The systematic search for infinitesimal transformations that leave the Hamiltonian action functional invariant leads to a system of first-order partial differential equations (Killing's equations), the solution of which is a taxing problem in itself. The theorem seems to have fared better in *field theory* (i.e., invariance of *multiple* integrals under continuous groups of transformations).

For detailed treatments of these topics, and applications to the search for system symmetries/conservation theorems, we recommend (alphabetically):

(a) *Mathematics* oriented: Funk (1962, pp. 437–452 — best overall treatment), Logan (1977), Lovelock and Rund (1975, pp. 201–207, 226–231), Rund (1966, pp. 208–322); and, of course, Noether's original paper (1918).

(b) *Mechanics–physics* oriented: Bahar and Kwatny (1987), Dobronravov (1976, pp. 139–163), Hill (1951 — primarily for physicists), Kuypers (1993, pp. 281–295), Saletan and Cromer (1971, pp. 60–87, 219–226, 345–348), Sudarshan and Mukunda (1974), Vujanovic and Jones (1989, pp. 74–151; and references given therein).

8.14 PERIODIC MOTIONS; ACTION–ANGLE VARIABLES

Outside of equilibrium, *periodic* motion is one of the most important and interesting physical states; for example, planets revolving around the Sun; penduli; parts of engines; the building blocks of molecular and atomic systems; and so on. Also, the close connection between periodicity (aperiodicity) and stability (instability) of motion is well known. Hence, such a state deserves a closer examination. This section constitutes a modest introduction to this vast and fascinating topic, using the earlier-developed concepts and theorems of Hamiltonian mechanics.

One DOF

Such a system undergoes *periodic* motion with period τ, if, after a time interval τ, it always returns to where it was before; that is, analytically, its Lagrangean coordinate $q = q(t)$ satisfies the condition

$$q = q(t) = q(t + \tau), \tag{8.14.1}$$

and can, therefore, under mild continuity conditions, be represented by the Fourier series (in complex form, for algebraic compactness):

$$q(t) = \sum c_s \exp(is\,\omega\, t) = \sum c_s \exp(2\pi i s\,\nu t), \tag{8.14.2}$$

where $\exp(\ldots) \equiv e^{\cdots}$,

$s = -\infty, \ldots, +\infty,$

$\omega \equiv 2\pi/\tau =$ fundamental *angular*, *or circular*, *frequency*;
i.e., *number of oscillations or rotations* (*see below*) *in* 2π *seconds*,

$\nu \equiv 1/\tau = \omega/2\pi =$ fundamental (*true*) *frequency*; i.e., *number of oscillations or rotations in* 1 *second*, (8.14.2a)

and the *amplitudes* c_s, which depend on the motion during a single period, are given by the well-known formula (which also makes it clear how it was obtained)

$$c_s = (1/\tau)\int_0^\tau q(t)\exp(-is\,\omega t)\,dt \qquad (c_{-s} \equiv c_s{}^* = \text{complex } \textit{conjugate} \text{ of } c_s). \tag{8.14.3}$$

From the above, it follows that $\dot{q}$ and any function of q and $\dot{q}$ is also a Fourier series with the same fundamental frequency (period) $\nu(\tau)$. Other system properties, or variables, may also be periodic; for example, periodic system momentum $p \equiv \partial T/\partial \dot{q}$ means that $p(t) = p(t + \tau)$. However, this natural and simple concept can be obscured by the use of the wrong, that is, nonperiodic coordinates. For example, the uniform circular motion of a particle (or, of a rigid body about a fixed axis) is, clearly, periodic; but its description in terms of its angle of rotation ϕ (from a fixed radius):

$$\phi = c_1 t + c_2 \qquad (c_{1,2}\text{: constants}), \tag{8.14.4}$$

is a monotonically increasing (nonperiodic!) function of time; also, the corresponding angular momentum $p \sim \dot{\phi}$ is constant; that is, trivially periodic.

In view of these possibilities, we classify periodic motions (according to their trajectories) in *phase space* into *two* kinds:

(i) *Libration* [from Latin verb *librare* = to balance (libra = scales), to sway]

This is the case where the coordinate q is a *single-valued* function of the system's position (i.e., it is not an angle that can have different values for the same configuration), and it remains between fixed limits; say, q_1, q_2, q_3, q_4, q_1 (fig. 8.11).

Both q and p are bounded, continuous and periodic in time, with the same period; say, τ. As a result, the corresponding (q, p)-curve, in phase space, is *closed*, and repeats itself after every time interval τ. Since the system integral $H(q, p) = constant \equiv C$ (usually equal to the total energy of the system E) is single-valued, different values of C produce a family of closed and *nonintersecting* phase space trajectories; in fact, by decreasing C appropriately, we may reduce the trajectory to the fixed *libration center* q_o, so that the motion degenerates to small oscillations about the stable equilibrium position q_o. The *libration limits* are the roots of $dq/dt = \partial H/\partial p = 0$ and they appear always *in pairs* (e.g., q_3 and q_4); the point where they coincide (or, coalesce; e.g., $q_\bullet$) signifies an *unstable* equilibrium configuration. In particular, *if p appears quadratically in the Hamiltonian* $H = H(q, p)$, *the system path in phase space* $p = p(q;\, E)$, obtained from its *energy surface* $H(q, p) = E$, is *symmetric about the q-axis* (fig. 8.11).

For example, if $H = p^2/2m + V(q) = E$, then, to within a sign,

$$
\begin{aligned}
&p = (2m)^{1/2}[E - V(q)]^{1/2} \\
&\Rightarrow\; dp/dq = -(m/2)^{1/2}[E - V(q)]^{-1/2}\,(dV/dq).
\end{aligned}
\tag{8.14.5}
$$

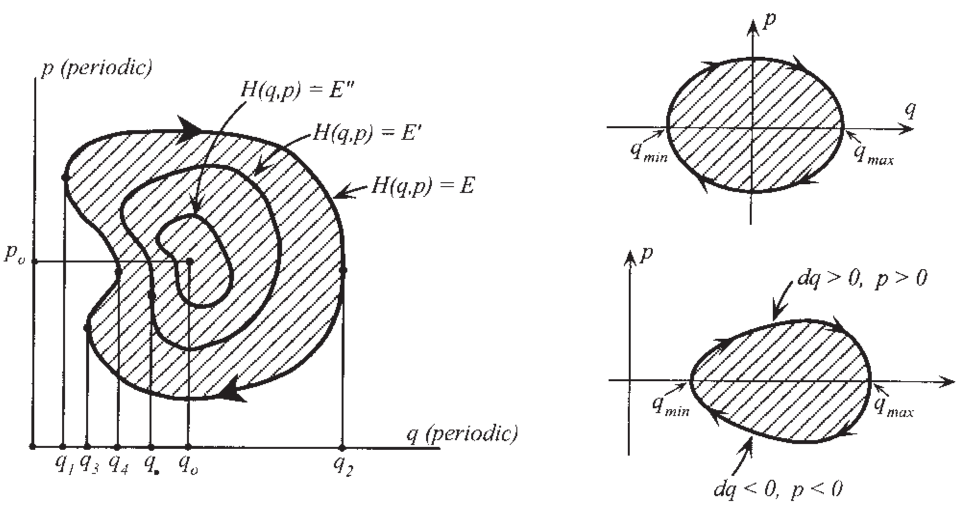

Figure 8.11 Phase plane trajectory of *libratory* periodic motion (*1 DOF*), and example of harmonic oscillator. [The energy curve $H(q, p) = E$ (outer contour, left figure, for general q, p *is not necessarily quadratic in* p; that is why there are *four* possible values of p for $q_3 < q < q_4$. If $H(q, p)$ was *quadratic* in p, there would be only *two*.]

Therefore, for libration, the equation $E - V(q) = 0$ must have *two* simple zeros: $q_{\min}, q_{\max}$; *and between them be positive*; at $q_{\min/\max}$, $dp/dq \to \infty$. Then, the curve is traversed *completely* and in the same sense. [Since $p\dot{q} = 2T \Rightarrow p\,dq > 0$, the curve is traveled *outward* $(dq > 0)$ in its *upper* branch $(p > 0)$, and in its *lower* branch $(p < 0)$ on its *return* $(dq < 0)$.]

(ii) *Rotation* (or *circulation*, or *revolution*)

If, however, the coordinate q is *angle-like*, then since q and $q + kq_o$ ($k =$ arbitrary integer — fig. 8.12) describe the same system configuration, the unique determination of the integral constant C by the system's state of motion requires either that the curve $H(q, p) = C$ is closed, or that $p = p(q)$ is a periodic function of q, with minimum period q_o (frequently, $q_o = 2\pi$). In the second case, q takes the full range of values; that is, it is neither bounded nor periodic (timewise) — this kind of motion is called *rotation*. In particular, the uniform rectilinear motion can be viewed as the limiting case of a periodic motion, indeed as a rotation on a circle of infinite radius.

REMARK

In HM, we always seek coordinates in which the motion appears as rotation; then (as with ignorable coordinates) $q =$ linear in time, $p =$ constant (see "action-angle" variables, below).

The libration–rotation difference can be summed up, mathematically, as follows:

(i) In a libration, $q \to q_L$ can be represented by a Fourier series;
(ii) In a rotation, $q \to q_R$ cannot be so represented. But for periodic motion, the new function: $q_R - 2\pi\nu t \equiv q_R - \omega t$, *can* be represented by a Fourier series with fundamental frequency ν. For example, if $q_R \to \phi = 2\pi\nu t$ (i.e., uniform rotation) $\to \phi - 2\pi\nu t = 0$; and the latter can be represented by a Fourier series with all its coefficients zero. Thus, whether a periodic motion will be classified as libration or as rotation depends on the chosen positional coordinates. Also, one and the same physical system may, under different initial conditions ($\Rightarrow$ different initial energy constant) exhibit both libration and rotation. (The limiting case separating libration

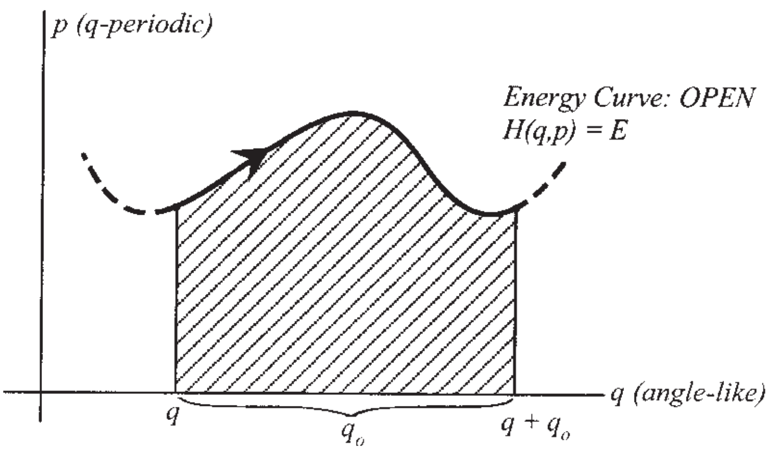

Figure 8.12 Phase plane trajectory of *rotatory* periodic motion (*1 DOF*).

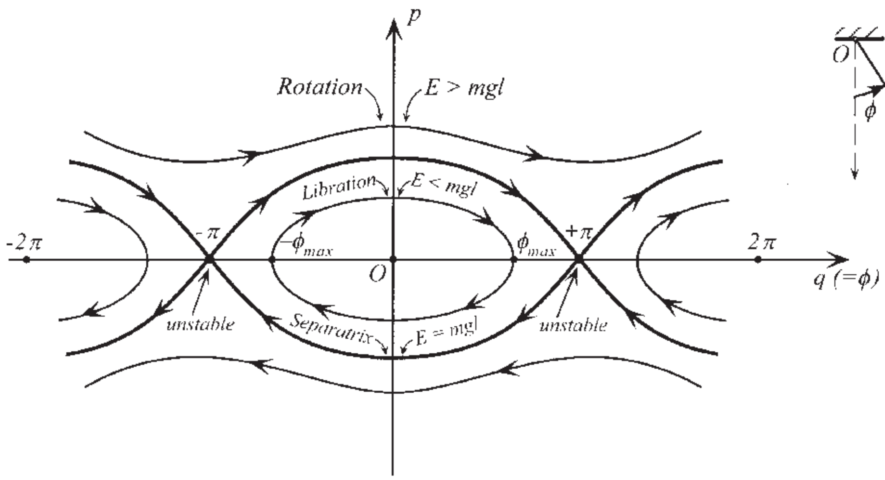

Figure 8.13 Phase plane trajectories of a planar mathematical pendulum.

from rotation is sometimes called *limitation*; that is, one where the points of motion reversal are reached in infinite time.)

The classic example here is the *planar mathematical pendulum with fixed support O* (fig. 8.13):

(i) Its to and fro oscillatory motion is a libration; whereas
(ii) Its full rotation around O, if its energy is sufficient, is a rotation.

Here,

$$2T = m\,l^2(\dot{\phi})^2, \qquad V = m\,g\,l(1 - \cos\phi), \tag{8.14.6a}$$

$$\Rightarrow\ T + V = T_{\text{initial}} + V_{\text{initial}} = m\,g\,l(1 - \cos\phi_o) \equiv E \qquad (\phi_o \equiv \phi_{\text{maximum}}), \tag{8.14.6b}$$

$$H \equiv (1/2A)p^2 - D\cos\phi = C \equiv E \qquad \text{(energy equation)}, \tag{8.14.6c}$$

$$\Rightarrow\ p = \pm(2A)^{1/2}(E + D\cos\phi)^{1/2} = \pm(m\,l)\,(2g\,l)^{1/2}(\cos\phi - \cos\phi_o) \tag{8.14.6d}$$

$$[A \equiv m\,l^2, \quad D \equiv m\,g\,l].$$

We distinguish the following *four* cases:

(a) If $E = -m\,g\,l \equiv -D(< 0)$, the (q, p)-trajectory contracts to the *libration center* q_o.
(b) If $-D < E < D$, then we have *libration* only for $|\phi| < \phi_{\max}$. [The libration limits are given by $dq/dt = \partial H/\partial p = 0 \ \Rightarrow\ p = 0$: $\cos\phi_o = -(E/m\,g\,l) \equiv -(E/D)$; there, $p = 0$. Hence oscillation/libration will occur between $-\phi_{\max} \equiv -\arccos(-D/E)$ and $\phi_{\max} \equiv \arccos(-D/E)$.]
(c) If $E > D$, we have *rotation* (always in the same direction).
(d) If $E = D$, we move on a *stability/instability boundary*, or *asymptotic orbit*; and approach the highest point $q = \pi$ very slowly ("in infinite time"). (See also Born, 1927, pp. 48–52.)

However, in general, and for reasons that will appear gradually below (also, recalling rationale for canonical transformations, §8.8), we seek new ignorable *coordinates* q'

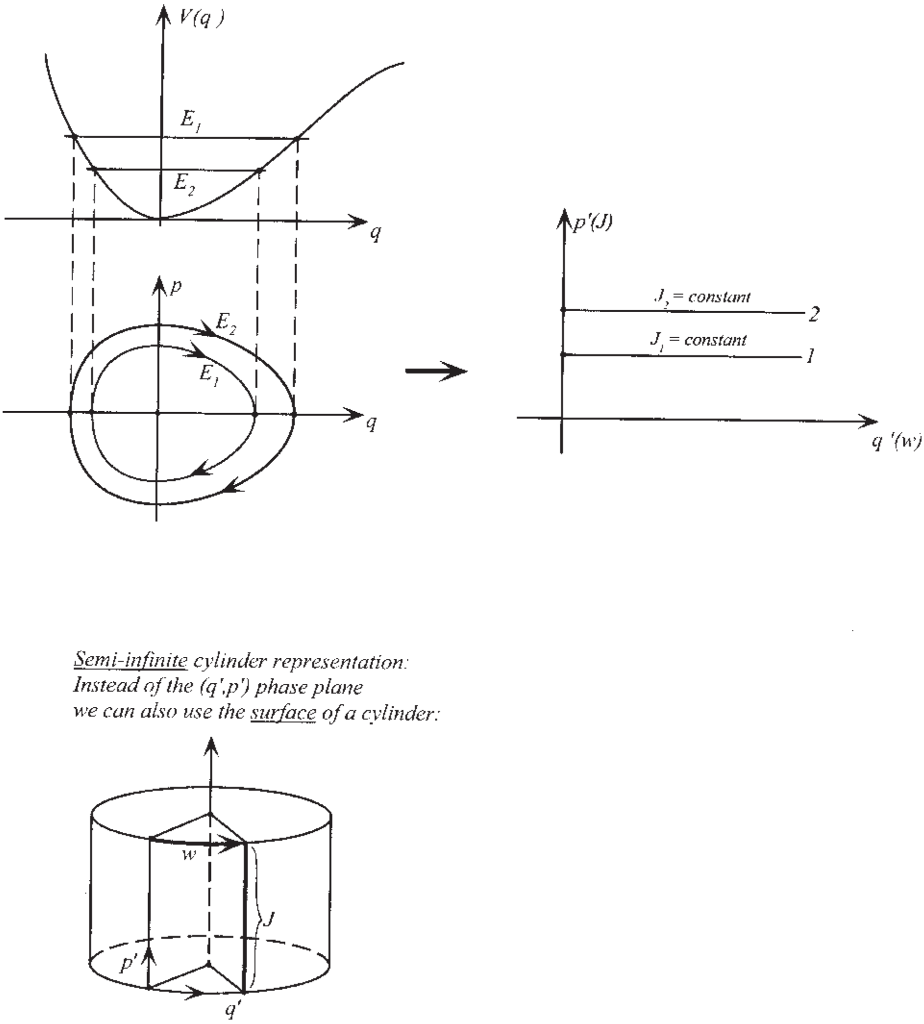

Figure 8.14 Canonical transformation to action–angle variables: $(q, p) \to (q' = w, p' = J)$.

in which our periodic motion appears as a rotation (*angle* variables, $q' \equiv w$), and new constant *momenta* p' (*action* variables $p' \equiv J$) which are the sole "variables" of the system Hamiltonian (which, here, equals the total energy); that is, recalling §8.10 (fig. 8.14),

$$(q, p) \to (q', p'):$$

$$dq'/dt = \partial H'(p')/\partial p' = constant \equiv c_1$$

$$\Rightarrow q' = c_1 t + c_2 \qquad (c_2\text{: integration constant}), \tag{8.14.7a}$$

$$dp'/dt = -\partial H'(p')/\partial q' = 0 \;\Rightarrow\; p' = constant \equiv c_3. \tag{8.14.7b}$$

Let us quantify these concepts:

(i) The *phase integral* [with physical dimensions of (*mass* × *velocity*) × (*length*); that is, *angular momentum*, or action]:

$$J \equiv \oint p(q, \beta)\, dq \;\left[\text{or, equivalently, } \oint p(q, E)\, dq\right]:$$

Libration: the integration extends over the *closed* path;
and thus takes care of the multiple-valuedness of the momentum,
due to its *quadratic* appearance in (8.14.5, 6d): $p = \pm \ldots$
(integral equal to the *shaded* area in fig. 8.11);

Rotation: the integration extends over a single period q_o of q
(integral equal to the *shaded* area in fig. 8.12), (8.14.8)

is called *action variable*.

In a constant parameter (closed) system, J is independent of time. Therefore (recalling the Hamilton–Jacobi method, §8.10), for such systems, J can be taken as one of the *two* integration constants of motion (here, $n = 1$); or, in the action function of our problem, $A(t, q, \beta) = A_o(q, \beta) - E(\beta)t$, we can take J as the new momentum $p' = \beta$ (with a constant value for each particular periodic motion); that is, $\beta = J$, and consider the total energy E as a function of it:

$$J \equiv \oint p\, dq = \oint (\partial A_o/\partial q)\, dq = J(E) \;\Rightarrow\; E = E(J)$$
$$\Rightarrow\; A(t, q, J) = A_o(q, J) - E(J)t. \tag{8.14.9a}$$

From the foregoing, it follows that the *first* of the Hamilton–Jacobi (HJ) transformation equations, and corresponding HJ equation are

$$(\partial A_o/\partial q)_{E=\text{constant}} = (\partial A_o/\partial q)_{J=\text{constant}} = p, \tag{8.14.9b}$$
$$H(q, \partial A_o/\partial q) = \mathit{constant} = E. \tag{8.14.9c}$$

(ii) The corresponding new coordinate $q' \equiv w$, of the canonical transformation $(q, p) \to (q' = w, p' = J)$ with generating function $F = F_2(q, p') = A_o(q, J)$, is

$$q' = \partial F_2/\partial p': \qquad w = \partial A_o(q, J)/\partial J. \tag{8.14.10}$$

To find its properties, we need the Hamiltonian equations of motion in these variables. Since $H' = H + \partial A_o/\partial t = H = E(J) = \mathit{constant}$ (i.e., w is *ignorable*, and therefore J is a constant) these equations are

$$dq'/dt = \partial H'(p')/\partial p': \qquad dw/dt = \partial H(J)/\partial J = \mathit{constant} \equiv \nu(J) \equiv \nu$$
$$\Rightarrow\; w = \nu t + \gamma, \tag{8.14.11}$$

(ν is to be identified later with the fundamental frequency of the system and γ with a *phase* constant)

$$dp'/dt = -\partial H'(p')/\partial q': \qquad dJ/dt = -\partial H(J)/\partial w = 0$$
$$\Rightarrow\; J = \mathit{constant}. \tag{8.14.12}$$

From the above, it follows that w *increases linearly with time*; and during a period τ it increases by

$$\Delta w \equiv w(t + \tau) - w(t) = \cdots = [\partial H(J)/\partial J]\tau \equiv \nu\tau. \tag{8.14.13a}$$

But also, from the earlier definitions, as q goes through a complete cycle of libration or rotation, we have, successively,

$$\Delta w = \oint (\partial w/\partial q)\, dq = \oint (\partial^2 A_o/\partial J\ \partial q)\, dq = \partial/\partial J \left(\oint (\partial A_o/\partial q)\, dq\right)$$

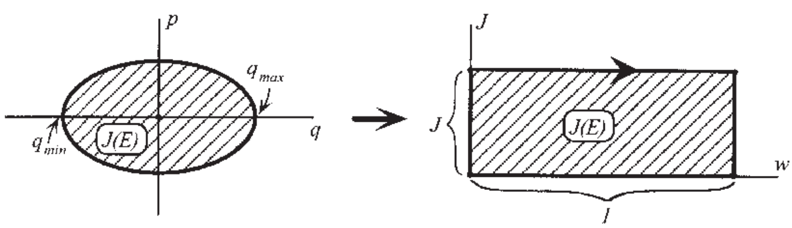
$$= \partial/\partial J\left(\oint p\, dq\right) = \partial J/\partial J = 1; \tag{8.14.13b}$$

that is, *the state of the system is periodic in w with period 1*. (For a full justification of the commutation rule employed here, see ex. 8.14.13.) Comparing (8.14.13a, b), we immediately conclude that

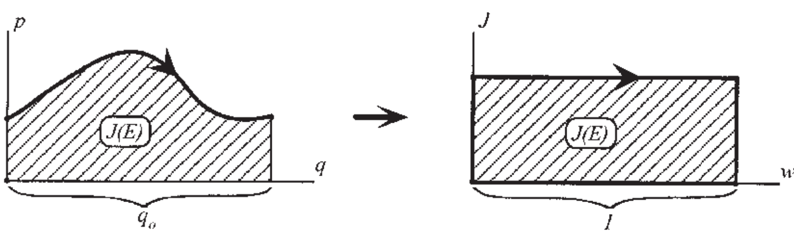
$$\nu \equiv 1/\tau \equiv \omega/2\pi = \partial H(J)/\partial J = \partial E(J)/\partial J; \tag{8.14.14}$$

that is, *by differentiating the (constant) total energy with respect to the (constant) action variable, as soon as it becomes available in that form [without finding $q(t)$ from the equations of motion!], we obtain the fundamental frequency of the periodic motion.* Thus, the difficulty of solving the equations of motion has been transferred to that of calculating the action integrals $J \equiv \oint p\, dq$; and in this lies the importance of action and angle variables.

The geometrical meaning of these transformations, and resulting advantage of action–angle variables, for systems with Hamiltonian $H = p^2/2m + V(q)$ are shown in fig. 8.15.



Libration: $J(E) = \oint p(q, E)\, dq = 2\int_{q_{\min}}^{q_{\max}} (2m)^{1/2}[E - V(q)]^{1/2}\, dq = (J)(1) = J;$



Rotation: $J(E) = \int_0^{q_o} p(q, E)\, dq$; where $H(q, p) = E \ \Rightarrow\ p = p(q, E)$.

[Two solutions in opposite directions; from two actions corresponding to each direction of motion.]

Figure 8.15 Libration and rotation in general and in angle–action variables, in phase space (1 DOF system).

REMARK

Some authors define J as $(1/2\pi)\oint p\,dq$. Then,

$$w = [\partial H(J)/\partial J]t + constant = \omega\, t + constant \;\Rightarrow\; \Delta w = \omega\,\tau = 2\pi;$$

that is,

$$\omega \equiv 2\pi\nu = \partial H(J)/\partial J = \textit{fundamental circular frequency}. \tag{8.14.15a}$$

Others define J as $\oint p\,dq$, but w as $2\pi(\partial A_o/\partial J)$. Then,

$$w = 2\pi\big\{[\partial H(J)/\partial J]t + \gamma\big\} \equiv 2\pi(\nu t + \gamma) \;\Rightarrow\; \Delta w = 2\pi\nu\,\tau = 2\pi;$$

that is, again,

$$\nu = \partial H(J)/\partial J = \textit{fundamental frequency}. \tag{8.14.15b}$$

(And similarly for the general n-DOF case.)

In view of the w-periodicity, eq. (8.14.13b), and recalling (8.14.2–3), we can write (again, with $s = -\infty, \ldots, +\infty$)

(i) *Libration*:

$$q = q(w) = \sum c_s \exp(2\pi i s w) = \sum c_s \exp[2\pi i s(\nu t + \gamma)]$$
$$\equiv \sum d_s \exp(2\pi i s t),$$
$$c_s = \int_0^1 q(w)\exp(-2\pi i s w)\,dw = c_s(J); \tag{8.14.16a}$$

(ii) *Rotation*:

$$q = q_o w + \sum c_s \exp(2\pi i s w) = q_o(\nu t + \gamma) + \sum c_s \exp[2\pi i s(\nu t + \gamma)]$$
$$\equiv \sum d_s \exp(2\pi i s t),$$
$$c_s = \int_0^1 (q - q_o w)\exp(-2\pi i s w)\,dw = c_s(J). \tag{8.14.16b}$$

It is not hard to see, from the above, that any single-valued function $f(q,p)$ when expressed in terms of the corresponding action (J) and angle (w) variables, becomes a periodic function of w with period 1.

THEOREM

The reduced action $A_o(q,J)$ is a multiple-valued function of the coordinate q. Every time q varies over a cycle once — that is, during each period τ — the reduced action $A_o = A_o(q,J)$ increases by

$$\Delta A_o \equiv A_o(t+\tau) - A_o(t) = \oint (\partial A_o/\partial q)\,dq = \oint p\,dq = J, \tag{8.14.17a}$$

and hence the name *modulus of periodicity of* A_o for J. From the above, it follows that

$$\Delta(A_o - wJ) = \Delta A_o - \Delta w\,J = J - J = 0; \tag{8.14.17b}$$

that is, the new action function

$$A_{oo} \equiv A_o - wJ = A_{oo}(q, w), \tag{8.14.17c}$$

is periodic in w, while $A_o(q, J)$ is not. Also, for two distinct but neighboring motions, with corresponding action variable values J and $J + \Delta J$, eq. (8.14.14) yields

$$\Delta E = \nu \, \Delta J \tag{8.14.17d}$$

(an equation that constituted the starting point of the famous *correspondence* principle of the older quantum theory of N. Bohr, late 1910s–early 1920s).

REMARK

Instead of the canonical transformation $(q, p) \to (w, J)$, with generating function $A_o(q, J)$ and new Hamiltonian $H' = H(J) = E(J)$, we can, equivalently, consider the canonical transformation $(q, p) \to (\gamma, J)$ with generating function $A(t, q, J)$ and, hence, new Hamiltonian $H' = H + \partial A/\partial t = 0$, so that

$$\begin{aligned} p &= \partial A/\partial q, \\ \gamma = \partial A/\partial J &= \partial A_o/\partial J - t(\partial E/\partial J) = w - (\partial E/\partial J)t = \textit{phase constant} \\ &\Rightarrow \; w = (\partial E/\partial J)t + \gamma = \nu t + \gamma; \end{aligned} \tag{8.14.18a}$$

and new Hamiltonian equations

$$d\gamma/dt = \partial H'/\partial J = 0 \;\Rightarrow\; \gamma = \textit{constant}, \tag{8.14.18b}$$

$$dJ/dt = -\partial H'/\partial \gamma = 0 \;\Rightarrow\; J = \textit{constant}. \tag{8.14.18c}$$

Hence, in the new phase space $(q' = \gamma,\ p' = J)$, the system motion is specified by the *point* $(\gamma = \textit{constant}, J = \textit{constant})$.

[Strictly speaking, it is *not* $w \equiv \partial A_o/\partial J$ that is canonically conjugate to J, but $(q' \to)\gamma \equiv \partial A/\partial J = \partial A_o/\partial J - (\partial E/\partial J)t = w - \nu t \;\Rightarrow\; w = \nu t + \gamma$.]

HISTORICAL

Action–angle variables were introduced to dynamics by the French engineering scientist C. Delaunay, in connection with astronomical perturbation problems (1846: *Sur une nouvelle théorie analytique du mouvement de la lune*; 1860: *Théorie du mouvement de la Lune*) and were also used by the German mathematician P. Stäckel (1891) and the Swedish astronomer C. L. Charlier (1907: *Die Mechanik des Himmels*); although the term "action–angle variables" seems to have been introduced by the German (astro)physicist K. Schwarzschild (1916; in German: *Wirkungs–Winkel Variable*). They became very important again in both the old and new quantum mechanics (1910s, early 1920s), where they proved indispensable in several key theoretical developments and analytical tools; for example, *quantum conditions* (Sommerfeld, Bohr), *adiabatic invariants* (Ehrenfest, Burgers; see §8.15), *canonical perturbation theory* (Born, Heisenberg, Jordan, Pauli, Epstein, Brody, Fues, et al.; see §8.16).

Example 8.14.1 *Action–Angle Variables for the Harmonic Oscillator* (Recall ex. 8.10.3). From the energy conservation equation

$$H(q, p) = p^2/2m + kq^2/2 = E, \tag{a}$$

where $m =$ mass, $q =$ amplitude, $k =$ stiffness, so that $\omega^2 = k/m \Rightarrow k = m\omega^2 = m(2\pi\nu)^2$, we obtain the momentum:

$$p = \partial A_o/\partial q = \pm(2mE - m\,k\,q^2)^{1/2} = p(q; E, k, m), \tag{b}$$

and therefore the corresponding action variable becomes

$$J = \oint p\,dq = \oint (\partial A_o/\partial q)\,dq = \oint (2mE - m\,kq^2)^{1/2}\,dq$$

[In this case of libration, q extends (oscillates) between the roots of $dq/dt = \partial H/\partial p = 0$ $\Rightarrow p = 0$: $\quad q_{\min} \equiv -(2E/k)^{1/2} \quad$ and $\quad q_{\max} \equiv +(2E/k)^{1/2}$; this also guarantees that $p = (2mE - m\,k\,q^2)^{1/2}$ remains *real*]

$$= 4\int_0^{q_{\max}} [2m(E - kq^2/2)]^{1/2}\,dq = \text{area of ellipse in } (q,p)\text{-space}$$

[utilizing the standard trigonometric substitution $q = (2E/k)^{1/2}\sin x$, etc.]

$$= (2E)\,(m/k)^{1/2}\left(\int_0^{2\pi} \cos^2 x\,dx\right) = (2\pi E)\,(m/k)^{1/2}. \tag{c}$$

From (c), we obtain

$$E = (J/2\pi)\,(k/m)^{1/2} = E(J) = H'$$

$$\Rightarrow \nu = \partial E/\partial J = (1/2\pi)\,(k/m)^{1/2} = \omega/2\pi. \tag{d}$$

Next, by calculating how A_o changes during a *complete period of oscillation*—that is, as q varies from $q_{\min}$ to $q_{\max}$ and then back to $q_{\min}$—we will verify that $A_o(q, E)$, or $A_o(q, J)$, is indeed a multiple-valued function of q. Integrating (b) [or ex. 8.10.3: (k)], while suppressing the resulting inessential constant, we obtain (fig. 8.16):

$$A_o = A_o(q, E) = E(m/k)^{1/2}\{\arcsin[(k/2E)^{1/2}q] + (k/2E)^{1/2}q[1 - (k/2E)q^2]^{1/2}\}. \tag{e}$$

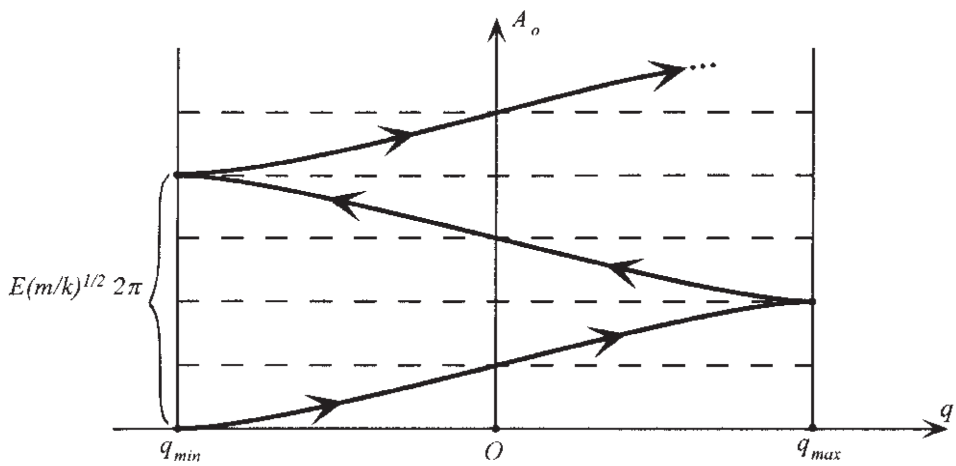


Figure 8.16 Graph of $A_o(q; E)$, eq. (e). Its slope is the momentum of the particle: $p = \partial A_o/\partial q$.

Now, clearly, the *second* term of (e) is *single-valued*, and so, during one such period, contributes nothing to A_o (in fact, at its beginning and ending, $q_{\min}$, it vanishes); but its *first* term is *multiple-valued*, and since, during $q_{\min} \to q_{\max} \to q_{\min}$, the argument of $\arcsin(\ldots)$ changes from $-1 \to +1 \to -1, \arcsin(\ldots)$ itself changes by 2π. Hence,

$$\begin{aligned} \Delta A_o &= E(m/k)^{1/2}(2\pi) = E/\nu \equiv E\tau \quad [\equiv (2\pi)E/\omega] \\ &= J \ (\textit{modulus of periodicity} \text{ of } A_o); \end{aligned} \tag{f}$$

and, further, replacing in (e) E with $J\nu$, we obtain

$$\begin{aligned} A_o &= A_o(q, J) \\ &= (J/2\pi)\left\{ \arcsin[(k/2\nu J)^{1/2}q] + (k/2\nu J)^{1/2}q[1 - (k/2\nu J)q^2]^{1/2} \right\} \\ &\left[= \int p(q, J)\, dq = (1/2\pi\nu) \int (2k\nu J - k^2q^2)^{1/2}\, dq \right]. \end{aligned} \tag{g}$$

The above shows that in one complete period of q, the new coordinate w (canonically conjugate to J) changes by $+1$:

$$w \equiv \partial A_o/\partial J = (1/2\pi) \arcsin\left[(k/2\nu J)^{1/2}q\right] = \nu t + \gamma, \tag{h}$$

$$\Rightarrow \ \Delta w = (1/2\pi)\,(2\pi) = +1;$$

like an angle $\phi \equiv 2\pi w$, hence the name *angle* variable. Finally, inverting (h), we obtain

$$q = (2\nu J/k)^{1/2} \sin(2\pi w) = (J/2\pi^2\nu m)^{1/2} \sin[2\pi(\nu t + \gamma)], \tag{i}$$

$$\Rightarrow \ p = m\dot{q} = (kJ/2\pi^2\nu)^{1/2} \cos(2\pi w); \tag{j}$$

that is, both q and p are periodic in w, with period 1. Incidentally, eqs. (i, j) are the equations of canonical transformation from (w, J) to (q, p).

This simple example may, hopefully, begin to show the advantages of the action–angle variables: in the (q, p)-space, the system trajectory for a given constant energy E is the *two-valued* function (b); whereas in (w, J)-space, the system trajectory is characterized *uniquely* by the *constant* J, $J = J(E)$, and each such curve is characterized by a *single-valued* function of w.

Finally, we note the close relation of the above results to those of ex. 8.10.8. Each of the latter's equations (h) is of the harmonic oscillator type (b) $\to$ (g): $A_o = \int (2mE - mkq^2)^{1/2}\, dq$; that is, each q_k varies between a $q_{k,\min}$ to $q_{k,\max}$ and then back to $q_{k,\min}$, with frequency ν_k. However, even though these q_k's are uncoupled (Liouville system), this does not guarantee that the system is *periodic as a whole*; namely, that it *returns to its original configuration*. Such questions of periodicity in several DOF systems are treated below.

Several DOF, Multiply Periodic Motion

Here, we shall restrict ourselves to systems that are *completely separable* in all their $n + 1$ variables $(q_1, \ldots, q_n; t) \equiv (q;\ t)$ (which, for all practical purposes is the only case where the Hamilton–Jacobi equation *can* be solved), and *periodic* in at least one set of canonical variables. This (recalling §8.10) means that

$$\begin{aligned} A &= A_o(q_1, \ldots, q_n; \beta_1, \ldots, \beta_n) - E(\beta_1, \ldots, \beta_n)t \\ &\equiv A_o(q;\, \beta) - E(\beta)t \\ &= \sum A_{ok}(q_k, \beta) - E(\beta)t, \qquad (k = 1, \ldots, n) \end{aligned} \tag{8.14.19a}$$

from which it follows that

$$dA_o = \sum (\partial A_o/\partial q_k)\, dq_k = \sum (\partial A_{ok}/\partial q_k)\, dq_k = \sum p_k\, dq_k, \tag{8.14.19b}$$

or, by (indefinite) q_k-integration,

$$\begin{aligned} A_o &= \int \sum (\partial A_o/\partial q_k)\, dq_k = \int \sum (\partial A_{ok}/\partial q_k)\, dq_k = \sum \left(\int (\partial A_{ok}/\partial q_k)\, dq_k \right) \\ &= \sum \left(\int p_k(q_k, \beta)\, dq_k \right) \equiv \sum \int [\, f_k(q_k, \beta)]^{1/2}\, dq_k \end{aligned} \tag{8.14.19c}$$

[where the $A_{ok} = A_{ok}(q, J)$ are multiple-valued functions of the q's]; and the projection of the system trajectory in phase space on every (q_k, p_k)-subplane, $p_k = p_k\,(q_k, \beta)$ (since now *each* p_k *depends only on* q_k, and the β's) is also periodic (libration or rotation).

However this does *not* necessarily mean that all such projected (q_k, p_k)-subtrajectories have the same fundamental frequency — that is, *periodicity in the sense that, after the passage of a certain finite time interval, all q's and p's return to their initial values, in general, does not exist* — due to coordinate coupling; after the passage of a time interval τ_k, only the pair (q_k, p_k) returns to its initial values, but not the other pairs (The reader, probably, recalls a similar situation in linear multi-DOF vibrations: each normal mode is periodic in time but their superposition, in general, is not.)

Such a motion (and system), is *n-ply*, or *multiply, periodic*. It can become truly periodic, in the earlier sense of the *system as a whole*, when certain special conditions of proportionality, or *commensurability*, exist among its partial frequencies $\nu_k = 1/\tau_k$ $(k = 1, \ldots, n)$. According to this definition, a two-dimensional oscillator *is* a periodic system even when its xy-plane trajectory (Lissajous' figure) is an *open* curve. These fundamental concepts are examined in detail below. [For an excellent summary of the basic underlying theory of multiply periodic *functions*, see Born (1927, pp. 71–76).]

As a result of the complete separability of the system: (i) once $A(t, q, \beta)$ has been found (as explained in §8.10), the individual $q_k(t)$ and $p_k(t)$ are determined by the finite Hamilton–Jacobi equations

$$\partial A/\partial \beta_k = \alpha_k, \qquad \partial A/\partial q_k = \partial A_o/\partial q_k = \partial A_{ok}/\partial q_k = p_k \tag{8.14.20a}$$

[provided that $Det(\partial^2 A_o/\partial q_k \partial \beta_l) \neq 0$]; that is, the motion has been reduced to one-variable integrations; and (ii) the constant energy equation

$$\begin{aligned} H(q_1, \ldots, q_n;\, p_1, \ldots, p_n) &\equiv H(q, p) = H(q, \partial A_o/\partial q) \\ &= E = E(\beta_1, \ldots, \beta_n) \equiv E(\beta) = constant \end{aligned} \tag{8.14.20b}$$

[a $(2n-1)$-dimensional *energy hypersurface* in (q,p)-phase space] separates to the n one-to-one first integrals

$$H_k(q_k, p_k) = E_k(\beta) \equiv E_k, \tag{8.14.20c}$$

where $E_1 + \cdots + E_n = E$ is the value of the new Hamiltonian H', so that the projections of the phase-space trajectory of the system on the individual (q_k, p_k)-planes look just like the previous 1-DOF trajectories; that is, each individual q_k either librates between two fixed limits ($q_{\min}$ and $q_{\max}$); or increases boundlessly, but its corresponding p_k periodically returns to its original value (rotation).

Now, *for such a completely separable system, with individually periodic* (libratory or rotatory) q_k's, we define the *action variable* J_k corresponding to q_k by the phase integral

$$\begin{aligned} J_k &\equiv \oint p_k\, dq_k = \oint p_k(q_k, \beta)\, dq_k = J_k(\beta_1, \ldots, \beta_n) \equiv J_k(\beta) \\ &= \oint (\partial A_o/\partial q_k)\, dq_k = \oint \left[\partial A_{ok}(q_k, \beta)/\partial q_k\right] dq_k, \end{aligned} \tag{8.14.21}$$

where the integrations extend over the complete periods on the (q_k, p_k)-plane, for fixed β_k's $\Rightarrow$ fixed E_k's $\Rightarrow$ fixed E. In the case of libration, this means integration over the closed (q_k, p_k) paths — something that takes care of the multiple-valuedness of the momenta, due to their *quadratic* appearance in (8.14.20c): $p_k = \pm \ldots$; while in the case of rotation, the integration extends over a single period q_{ko} of q_k. Hence, each J_k equals the corresponding *shaded area* of its trajectory in its (q_k, p_k)-plane (figs. 8.11, 8.12); that is, the area contained *within* the closed trajectory (libration), or *under* a single q_k-cycle (rotation).

REMARK

Comparison of (8.14.19c) with (8.14.21) shows that the former is an indefinite integral, while the latter is the closed line integral of the partial derivative $\partial A_{ok}/\partial q_k$ in the (q_k, p_k)-plane, as explained above. Since $J_k \neq 0$, we conclude that A_{ok} is a *multiple-valued* function of its coordinate. In general, the calculation of the numbers J_k via (8.14.21) is very laborious; but since these are two-dimensional *contour integrals*, the application of complex variables (Cauchy integration) can be utilized to great advantage; see, for example, Born (1927; appendix II), Sommerfeld (1931, vol. 1); also Goldstein (1980, p. 472 ff.), Pars (1965, pp. 344–346).

In the case where neither the motion as a whole, nor each q_k, have a periodic variation in time, the integrals in (8.14.21) are understood as extending over the entire range of q_k values. See equations (8.14.24i, j) and subsequent discussion; and *conditional periodicity* and *degeneracy* below.

Solving the n independent functions (8.14.21), $J_k = J_k(\beta)$, for the β's, we obtain

$$\beta_k = \beta_k(J_1, \ldots, J_n) \equiv \beta_k(J); \tag{8.14.21a}$$

that is, the n J_k's can replace the n β_k's as the new constant momenta. Then A_o takes the following functional form:

$$A_o = A_o(q, \beta) = A_o[q, \beta(J)] = A_o(q, J) = \sum A_{ok}(q, J) \tag{8.14.21b}$$

[= generating function of the *old coordinates* (q) and the *new momenta* (J); i.e., $F_2(q, p')$], and therefore the canonical transformation equations $(q,p) \to (q', p') = (w, J)$ become

$$p_k = \partial F_2/\partial q_k: \quad p_k = \partial A_{ok}(q_k, \beta)/\partial q_k = \partial A_{ok}(q_k, J)/\partial q_k = p_k(q_k, J), \qquad (8.14.21c)$$

$$q_{k'} = \partial F_2/\partial p_{k'}: \quad w_k = \partial A_o(q_k, J)/\partial J_k = \sum [\partial A_{ol}(q_l, J)/\partial J_k] = w_k(q, J); \quad (8.14.21d)$$

and show that each p_k depends only on the corresponding q_k (*separation*) and all the J_k's; and each w_k depends on all the q's (*coupling*) and all the J_k's.

The new *coordinates* $w \equiv (w_1, \ldots, w_n)$, canonically conjugate to the new momenta $J \equiv (J_1, \ldots, J_n)$, are called *angle variables*. Let us find the corresponding equations of motion. Since the new Hamiltonian $H' = H'(w, J)$ equals

$$H' = H + \partial A_o/\partial t = H = E(\beta) = E[\beta(J)] \equiv E(J) = H'(J) \qquad (8.14.22a)$$

(i.e., *all the* w's *are ignorable*), the canonical equations are

$$dw_k/dt = \partial E(J)/\partial J_k = constant \equiv \nu_k(J) = \nu_k \;\Rightarrow\; w_k = \nu_k t + \gamma_k, \qquad (8.14.22b)$$

$$dJ_k/dt = -\partial E(J)/\partial w_k = 0 \;\Rightarrow\; J_k = constant, \qquad (8.14.22c)$$

recalling (8.10.3a–d) and the discussion following them.

BRIEF REMARKS ON COMPLETE INTEGRABILITY IN HAMILTONIAN SYSTEMS

(i) (Cont'd from §3.12, but now in canonical variables) We will call a, say (for concreteness but no loss of generality) Hamiltonian n – degree-of-freedom (DOF) holonomic system S, i.e. one of total order $2n$, *completely integrable* (CI), or simply integrable, if it possesses $2n$ (functionally independent/distinct, analytic, global) *first integrals*:

$f_\alpha(t, q, p) = C_\alpha$: *constant/time invariant/conserved*, for all finite times, along any system trajectory/orbit/ "*streamline/flow*", i.e. evaluated along any solution of S's canonical equations of motion [with Greek (Latin) subsripts running from 1 to $2n(n)$].

Among a system's integrals, those that *isolate* $\to$ determine the $2n$ variables in terms of the $(2n+1)$th variable, say as $q_k = q_k(t; C_1, \ldots, C_{2n})$, $p_k = p_k(t; C_1, \ldots, C_{2n})$, known as *isolating integrals*, or *separation constants*, are the most useful; the preceding $2n$ constant *momenta/actions* J_k and *phase constants/shifts* γ_k [eq's (8.14.22b, c)] constitute an example of $2n$ such integrals. Physically: "As in the noncanonical case, *an integrable canonical Hamiltonian flow is one where the interactions can be transformed away*: there is a special system of generalized coordinates and canonical momenta where the motion consists of n independent global translations $w_k = \nu_k t + \gamma_k$ along n axes, with both the ν_k and J_k constant. Irrespective of the details of the interactions, all integrable canonical flows are geometrically equivalent by a change of coordinates to n hypothetical free particles moving one-dimensionally at constant velocity in the (w, J) coordinate system." McCauley (1997, pp. 158 ff., 192 ff; our notations, *his* italics).

(ii) However, Hamiltonian system integrability should not be confused with either *separability* (CI systems may exist that are *not* separable in any canonical coordinate system), or with "exact solubility (or solvability)" = closed algebraic form solution; the latter may be completely chaotic, i.e. *its phase space may be completely* ("densely") *filled with unstable* (*periodic or non-periodic*) *initial condition-sensitive orbits*, while CI systems are either *stable periodic* (= all frequency ratios *rational* – commensurability) or *stable-quasiperiodic* (= at least one *irrational* frequency ratio – incommensurability), on tori. The central point of this specialized (group-theory based) iuntegrability is the following fundamental:

Theorem of Liouville [1850, e.g. Whittaker (1937, pp. 307-308, 322-325) and its specialization known as theorem of *Liouville-Arnold*]: **(a)** A CI n-DOF Hamiltonian system S is one that possesses n (functionally independent, analytic, global) first integrals $f_1, \ldots, f_n$ in *involution*: $(f_k, f_l) = 0$, for all k, l (mutually *commuting* integrals); i.e. to integrate S we need only n (not $2n$) such integrals; **(b)** Once the latter have been found (e.g. the J_k), the remaining n integrals (e.g. the γ_k) follow automatically; **(c)** In such involutive systems, a canonical trsnsformation *can* be found such that, in the new (q, p) coordinates, the $n\, f_k$ yield constant system momenta, also in involution: $p \to J_k = constant$ (isolating integrals: each constant isolates one independent DOF), $(J_k, J_l) = 0$; and **(d)** S's motion in phase space is confined to a (smooth n-dimensional closed surface that is topologically equivalent to a) *torus*, and is *either stable-periodic* or *stable-quasiperiodic*; i.e. the ratios of the n independent frequencies determine the nature of the system's motion; or: *integrable motions in* q, p *space are*, *irrespective of the details of their Hamiltonians* (i.e. "*of their interactions*"), *not more complex than collections of independent translations or simple harmonic oscillators!*

IN SUM: Completely integrable (CI) systems cannot be (classically or deterministically) chaotic, i.e. such *chaos cannot occur in CI systems*, *only among non-CI ones*. CI systems exhibit stable, multiply periodic behavior: all their localized (bound) orbits are confined to an n-dimensional manifold (inside their $2n$ phase space) that is geometrically equivalent to an n-dimensional torus; *the conditions for the preservation of such tori under nontrivial perturbations* [although in disturbed form (-s)] constitute the famous KAM theorem (§8.16).

For details, including the basic question of CI, or lack thereof, of a system's equations of motion, and ways to ascertain this – topics well beyond the scope of this book – see (alphabetically): Gallavotti (1983, pp. 287-289, 361-362), Lichtenberg and Lieberman (1992), McCauley (1993), (1997, pp. 158 ff., 192 ff., 311 ff., 316 ff., 409 ff.), Tabor (1989, pp. 68-79), Wintner (1941, pp. 68, 144); also, encyclopaedic summary in our forthcoming *Elementary Mechanics* (Part I, "20th century").

Below, we show that *the constants* $\nu \equiv (\nu_1, \ldots, \nu_n)$ *are the fundamental frequencies of each DOF of this multiply periodic motion — the main advantage of the action–angle method — while the* $\gamma \equiv (\gamma_1, \ldots, \gamma_n)$ *are its phase constants.*

Let us consider a special, kinematically admissible or possible, motion in which each q_l $(l = 1, \ldots, n)$ goes through a *complete* (libratory or rotatory) cycle an integral number of times i_l $(= 0, 1, 2, \ldots)$. Then, recalling (8.14.21d), and that the J remain constant here, we find that w_k changes by the following amount;

$$\begin{aligned}
\Delta w_k &= \oint dw_k = \oint \sum \left[\partial w_k(q, J)/\partial q_l\right] dq_l = \oint \sum (\partial^2 A_o/\partial J_k \partial q_l)\, dq_l \\
&= \sum \partial/\partial J_k \left(\oint (\partial A_o/\partial q_l)\, dq_l \right) = \sum \partial/\partial J_k \left(\oint (\partial A_{ol}/\partial q_l)\, dq_l \right) \\
&\equiv \sum \partial/\partial J_k \left(\oint p_l(q_l, J)\, dq_l \right) = \sum \partial(i_l J_l)/\partial J_k \\
&= \sum i_l\, \delta_{kl} = i_k.
\end{aligned} \tag{8.14.23}$$

(For complete justification of the commutation step used in this derivation, see ex. 8.14.13 below.)

In words: the mapping (8.14.21d) from the q-space to the w-space has the following properties:

- If, starting from a certain configuration, a particular q_k is allowed to complete i_k cycles — that is, either vary "from here to there and back" (libration), or revolve (rotation), an integral number of times i_k — then only w_k changes by i_k, all other w's do not; in other words, $w_k(q, J)$ is a multiple-valued function of the q's, periodic in q_l $(l \neq k)$ and monotonically increasing in q_k; for each cycle of the latter, w_k increases by 1.
- Inverting (8.14.21d), we also conclude that *if w_k increases by i_k while the other w's do not change, only q_k goes through i_k complete cycles*. Any other q_l $(l \neq k)$ depending on w_k would have varied, but would have returned to its original value without completing its cycles; otherwise w_l would have increased by the number of those cycles. Hence, in general, *each q depends on all the w's and J's; and is periodic in each w with fundamental period unity*. (If a particular q does not depend on all the w's, then, of course, it will not be periodic in all of them; but the totality of q's depends on the totality of the w's.)

In addition, since:

(i) the $A_{ok}(q, J)$ are also multiple-valued functions of the q's, every time q_k varies over a cycle once (i_k times), while all other q's remain unchanged, the reduced action A_o increases by the amount J_k $(i_k J_k)$:

$$\begin{aligned}
\Delta A_o &\equiv A_o(t + \tau) - A_o(t) = \oint (\partial A_o/\partial q_k)\, dq_k \\
&= \Delta A_{ok} = \oint (\partial A_{ok}/\partial q_k)\, dq_k = \oint p_k\, dq_k = J_k;
\end{aligned} \tag{8.14.23a}$$

and since, then,

(ii) w_k increases by 1, while the other w's do not change, the sum $\sum w_k J_k$ also increases by J_k; therefore, it follows that the new function

$$A_{oo} \equiv A_o - \sum w_k J_k, \tag{8.14.23b}$$

remains *unchanged*; that is, A_{oo} *is multiply periodic in the* w's *with fundamental period 1 in each of them.*

[Recalling §8.8, we see that this is a Legendre transformation, from a $F_2(q, p')$-type generating function, $A_o(q, J)$, to a $F_1(q, q')$-type, $A_{oo} = A_{oo}(q, w)$. Indeed $(\ldots)^{\cdot}$-differentiating $A_o = A_o(q, J)$ and then invoking (8.14.21c, d) and (8.14.23b), we obtain

$$\begin{aligned} dA_o/dt &= \sum \big[(\partial A_o/\partial q_k)\,(dq_k/dt) + (\partial A_o/\partial J_k)\,(dJ_k/dt)\big] \\ &= \sum p_k(dq_k/dt) + \sum w_k(dJ_k/dt) \\ \Rightarrow \sum p_k(dq_k/dt) &= -\sum w_k(dJ_k/dt) + dA_o/dt \\ \Rightarrow \sum p_k(dq_k/dt) &- \sum J_k(dw_k/dt) = dA_{oo}/dt \\ \Rightarrow p_k = \partial A_{oo}(q, w)/\partial q_k, &\qquad J_k = -\partial A_{oo}(q, w)/\partial w_k.] \end{aligned} \tag{8.14.23c}$$

The foregoing analysis is summarized in the following rule.

Frequency Rule

To calculate the fundamental frequencies of a completely separable multiply periodic system, we proceed as follows:

- Using the Hamilton–Jacobi theory (§8.10), we first determine its reduced characteristic function

$$A_o = A_o(q, \beta) = \sum A_{ok}(q_k;\, \beta_1, \ldots, \beta_n).$$

- Then, using the definition (8.14.21) $J_k \equiv \oint p_k\, dq_k$, we calculate its action variables $J_k = J_k(\beta)$; and this is the *main difficulty of the method.*
- Next, we express its Hamiltonian as function of the J_k's: $H'(J) = H(q, p) = E(J)$.
- Finally, we calculate its fundamental frequencies from $\nu_k = \partial E(J)/\partial J_k$.

Analytically, the above are expressed as follows:

(i) *Libration*: The q's (and p's) are multiply periodic functions of the w's with fundamental period 1:

$$q_k(w_1 + i_1, \ldots, w_n + i_n;\, J) = q_k(w_1, \ldots, w_n;\, J) \equiv q_k(w, J). \tag{8.14.24a}$$

(ii) *Rotation*. If q_k has period q_{ko}, then

$$q_k(w_1 + i_1, \ldots, w_n + i_n;\, J) = q_k(w_1, \ldots, w_n;\, J) + i_k q_{ko}. \tag{8.14.24b}$$

The rotation case can be brought to the libration form in the new coordinates $q_{R,k}$ defined by

$$q_{R,k} \equiv q_k(w, J) - w_k q_{ko} \equiv q_{R,k}(w, J) \tag{8.14.24c}$$

$$\Rightarrow\; q_{R,k}(w_1 + i_1, \ldots, w_n + i_n;\, J) = q_{R,k}(w_1, \ldots, w_n;\, J) \equiv q_{R,k}(w, J). \tag{8.14.24d}$$

[Clearly, conditions (8.14.24a–d) still hold, trivially, even for the w's absent from a particular q_k.] Other (nonseparable) arbitrary coordinates related to our (separable

q's) by one-to-one and well-behaved transformations—for example, from the q's and/or q_R's to, say rectangular Cartesian coordinates

$$x_k = x_k(q) \;\Leftrightarrow\; q_k(x), \tag{8.14.24e}$$

will be representable by the following *multiple-frequency Fourier series* (for generality, we keep the *same notation* as for the hitherto separable q's):

$$\begin{aligned}\sum \cdots n\text{-ple sum} \cdots \sum c_{k,\boldsymbol{s}}(J)\, \exp(2\pi i\, \boldsymbol{s}\cdot\boldsymbol{w})& \\ &= q_k(w, J) \qquad\qquad\qquad (\textit{Libration}) \\ &= q_k(w, J) - w_k q_{ko} \equiv q_{R,k}(w, J) \qquad (\textit{Rotation}),\end{aligned} \tag{8.14.24f}$$

where

$$\begin{aligned}&\boldsymbol{s} \equiv (s_1, \ldots, s_n) = \text{positive or negative integers, or zero; ranging from } -\infty \text{ to } +\infty, \\ &\boldsymbol{w} \equiv (w_1, \ldots, w_n), \\ &\boldsymbol{s}\cdot\boldsymbol{w} \equiv s_1 w_1 + \cdots + s_n w_n \qquad (\text{"dot product" of "vectors" } \boldsymbol{s} \text{ and } \boldsymbol{w}),\end{aligned} \tag{8.14.24g}$$

and

$$c_{k,\boldsymbol{s}}(J) = \int_0^1 \cdots n\text{-ple} \cdots \int_0^1 q_k(w, J)\, \exp(-2\pi i\, \boldsymbol{s}\cdot\boldsymbol{w})\, dw_1, \ldots, dw_n. \tag{8.14.24h}$$

[For a simple proof of (8.14.24f–h) see ex. 8.14.2, below; and for a discussion of the significance of such series, in the context of general vibration theory, see the appendix at the end of this section.]

Since $w_k = \nu_k t + \gamma_k$, the above yield the following multiply periodic *temporal* variation of q_k:

$$\begin{aligned}\sum \cdots n\text{-ple sum} \cdots \sum c_{k,\boldsymbol{s}}(J) \exp[2\pi i\, (\boldsymbol{s}\cdot\boldsymbol{\nu}t + \boldsymbol{s}\cdot\boldsymbol{\gamma})]& \\ &= \sum \cdots n\text{-ple sum} \cdots \sum d_{k,\boldsymbol{s}}(J, \boldsymbol{\gamma}) \exp(2\pi i\, \boldsymbol{s}\cdot\boldsymbol{\nu}t) \\ &= q_k(t, J) \qquad\qquad\qquad (\textit{Libration}) \\ &= q_k(t, J) - w_k q_{ko} \equiv q_{R,k}(t, J) \qquad (\textit{Rotation}),\end{aligned} \tag{8.14.24i}$$

where

$$\begin{aligned}&\boldsymbol{\nu} \equiv (\nu_1, \ldots, \nu_n), \quad \boldsymbol{\gamma} \equiv (\gamma_1, \ldots, \gamma_n), \\ &\boldsymbol{s}\cdot\boldsymbol{\nu} \equiv s_1\nu_1 + \cdots + s_n\nu_n, \quad \boldsymbol{s}\cdot\boldsymbol{\gamma} \equiv s_1\gamma_1 + \cdots + s_n\gamma_n,\end{aligned}$$

and

$$d_{k,\boldsymbol{s}}(J, \gamma) \equiv c_{k,\boldsymbol{s}}(J) \exp(2\pi i\, \boldsymbol{s}\cdot\boldsymbol{\gamma}). \tag{8.14.24j}$$

Since in separable systems, by (8.14.21c), $p_k = p_k(q_k, J)$, we will have similar Fourier expansions for the momenta p_k; and, in fact, *any single-valued function $f(q, p)$ when expressed in terms of the corresponding action (J) and angle (w) variables, becomes a periodic function of the w's with period 1 in each of them*; for example, the earlier-mentioned rectangular Cartesian coordinates.

Now, the series (8.14.24i) decomposes the q_k-motion into a sum of periodic motions (harmonic vibrations), each with frequency $|\boldsymbol{s}\cdot\boldsymbol{\nu}| \equiv |s_1\nu_1 + \cdots + s_n\nu_n|$; but since, in general, these frequencies are *not in rational ratios to each other* (i.e., they are *not mutually commensurate*, or *commensurable* — see (8.14.27a) ff. below), *their sum is not periodic in time*; no common period τ exists that contains every "component period" an integral number of times; and similarly for the momenta, even though $p_k = p_k(q_k)$ is closed (libration) or periodic (rotation).

Hence, the system motion (as a whole) is *nonperiodic*, i.e. the system does not return to any of its initial states in finite time (although, given sufficient time, it passes arbitrarily close to those states); or geometrically, the system trajectory, in the $2n$-dimensional phase space, does not close on itself [in the n-dimensional configuration space, such orbits are called Lissajous figures (ex.8.14.4)] [Since *all irrational numbers can be approximated to any desired accuracy with rational ones*, we can approximate a nonperiodic function with a periodic one, for a given time. The latter is called *almost periodic function*. Also, recall discussion in §7.A4, and see "remark" below; and McCauley (1997, ch. 4: pp. 126–147).] For these reasons, such multiply, or quasi-periodic motions [since, for sufficiently short times and within finite accuracy, they may appear to be periodic ("mimic clockwork")] they have also been termed *conditionally periodic* (O. Staude, 1887); that is, they can become truly periodic (i.e., singly periodic) only under certain conditions among the system frequencies ν_k $(k = 1, \ldots, n)$. These conditions are summarized in the following theorem.

THEOREM

The motion of $q_k(t)$ and $p_k(t)$, given by (8.14.24f–j), is periodic in *time* with fundamental frequency ν_k in the first *three* of the following cases:

(i) The motion is *one*-dimensional; that is, only the pair (q_k, p_k) varies. Then, (8.14.24i, j) becomes

$$\sum d_{k,s}(J,\gamma)\exp(2\pi i\, s\nu_k t)$$
$$= q_k(t, J) \qquad \text{(Libration)}$$
$$= q_k(t, J) - w_k q_{ko} \equiv q_{R,k}(t, J) \qquad \text{(Rotation)}, \qquad (8.14.25a)$$

and from (8.14.22b–23) for one cycle (i.e., $i_k = 1$), we obtain

$$\Delta w_k \equiv w_k(t + \tau_k) - w_k(t) = \nu_k\tau_k = 1$$
$$\Rightarrow \nu_k = 1/\tau_k = \partial E(J)/\partial J_k = \text{fundamental frequency}. \qquad (8.14.25b)$$

(ii) The motion of q_k is not influenced by the other coordinates (separability of variables: generalization of the uncoupled *normal coordinates* of linear vibration theory): in (8.14.24i, j) only the coefficient $d_{k;0\ldots s(k)\ldots 0}(J,\gamma)$ survives; that is, the Fourier expansion looks like (8.14.25a). As a result, $q_k = q_k(w_k, J) \Leftrightarrow w_k = w_k(q_k, J)$; and also [recalling (8.14.21d)]

$$w_k = \partial A_o(q_k, J)/\partial J_k = \partial A_{ok}(q_k, J_k)/\partial J_k = w_k(q_k, J_k); \qquad (8.14.26)$$

that is, J_k occurs only in A_{ok}, not in A_{ol} $(l \neq k)$. Here, too, $\Delta w_k = \nu_k\tau_k = 1 \Rightarrow \nu_k = 1/\tau_k$. General functions of them, say $f(q_1, \ldots, q_n)$, will be *multiply periodic functions of the w*'s and, hence, *nonperiodic functions of time*, unless the ν_k are mutually commensurate [see (iii), (iv) below].

(iii) The other fundamental frequencies are *integral multiples* of ν_k:

$$\nu_l = i_l\,\nu_k: \qquad i_l = \text{positive integer } (l \neq k), \qquad (8.14.27a)$$
$$i_k = 1. \qquad (8.14.27b)$$

Then, (8.14.24i, j), with

$$\boldsymbol{i} \equiv (i_1, \ldots, i_n), \tag{8.14.27c}$$

$$\boldsymbol{s} \cdot \boldsymbol{i} = s_1 i_1 + \cdots + s_n i_n = \textit{integer}, \tag{8.14.27d}$$

becomes

$$\begin{aligned} q_k(t) &= \sum \cdots n\text{-ple sum} \cdots \sum d_{k,\boldsymbol{s}}(J, \gamma) \exp[2\pi i\, (\boldsymbol{s} \cdot \boldsymbol{i}) \nu_k t] \\ &= \text{periodic function of time, with fundamental frequency (period)} \\ &\quad\ \nu_k\ (\tau_k); \end{aligned} \tag{8.14.27e}$$

and, of course, after a time interval $\tau_k = 1/\nu_k = i_l/\nu_l$:

$$\Delta w_l = \nu_l \tau_l = i_l\, (\nu_k \tau_k) = i_l \qquad (l \neq k), \tag{8.14.27f}$$

$$\Delta w_k = \nu_k \tau_k = i_k = 1, \tag{8.14.27g}$$

and q_l returns to its initial value, after performing i_l complete cycles.

(iv) If none of the above three conditions hold, the motion of the system *as a whole* is periodic if all its *fundamental frequencies are commensurate (or commensurable); that is, they are in rational ratios to each other*—namely, for *all* $k, l = 1, \ldots, n$ $(k \neq l)$, and for arbitrary values of the J's, integers i_k, i_l exist such that

$$\nu_k/\nu_l = i_k/i_l\ (\equiv \omega_k/\omega_l) \ \Rightarrow\ \tau_l/\tau_k = i_k/i_l; \tag{8.14.28a}$$

or, equivalently ($n - 1$ relations),

$$\nu_k/i_k = \nu_l/i_l\colon \qquad \nu_1/i_1 = \nu_2/i_2 = \cdots = \nu_n/i_n \equiv \nu\ (\equiv 1/\tau); \tag{8.14.28b}$$

$$\tau_k i_k = \tau_l\, i_l\colon \qquad \tau_1 i_1 = \tau_2 i_2 = \cdots = \tau_n\, i_n \equiv \tau\ (\equiv 1/\nu); \tag{8.14.28c}$$

where ν = common/system *frequency*, τ = common/system *period*.

Then, the particular coordinate q_k $(k = 1, \ldots, n)$ becomes

$$\begin{aligned} &q_k(t) = \sum \cdots n\text{-ple sum} \cdots \sum d_{k,\boldsymbol{s}}(J, \gamma) \exp[2\pi i\, (\boldsymbol{s} \cdot \boldsymbol{i}) \nu t]\colon \\ &\quad \text{periodic function of time, with fundamental frequency} \\ &\qquad\qquad\qquad (\textit{not}\ \nu_k = i_k \nu, \text{but})\ \nu; \end{aligned} \tag{8.14.28d}$$

and

$$\Delta w_k \equiv w_k(t + \tau_k) - w_k(t) = \nu_k \tau = \nu_k/\nu = i_k; \tag{8.14.28e}$$

after a time $\tau = 1/\nu = i_k/\nu_k$, each q_k returns to its initial value (after performing i_k complete cycles).

REMARK

Let q_k be a general multiply periodic function of *all* the w's. Now, assume that *during a time interval* τ, q_k performs i_k complete cycles plus a fraction of a cycle. Then, it has been shown by Vinti (1961), via number-theoretic tools (Dirichlet's theorem), that

$$\text{as } \tau \to \infty\colon \qquad \lim(i_k/\tau) = \nu_k; \tag{8.14.29}$$

that is, *even when q_k is not a singly periodic function with frequency ν_k, still its "mean* *frequency" [as defined by the left side of (8.14.29)] equals* ν_k (see, e.g., Garfinkel, 1966, pp. 57–58).

Example 8.14.2 (Mathematical Appendix) *Fourier's Theorem for Multiply Periodic Functions.* Here, we prove (8.14.24f–h) for $n = 2$. The extension to the general case $n = n$ should then be obvious.

Let the function $f = f(w)$ be periodic in w with period 1 (a function with arbitrary period can easily be brought to this case — see any text on Fourier series). Then, by Fourier's theorem in complex form:

$$f(w) = \sum c_s \exp(2\pi i\, sw) \qquad (s = -\infty, \ldots, +\infty),$$

where

$$c_s = \int_0^1 f(w) \exp(-2\pi i\, sw)\, dw. \tag{a}$$

Next, let us consider the function $F = F(w, w')$, periodic in both w and w', with period 1 in each of them. Since F is periodic in w', by (a), we will have

$$F(w, w') = \sum c_{s'} \exp(2\pi i\, s'w') \qquad (s' = -\infty, \ldots, +\infty),$$

where

$$c_{s'} = \int_0^1 F(w, w') \exp(-2\pi i\, s'w')\, dw' \;=\; c_{s'}(w). \tag{b}$$

Now, it is not hard to see that $c_{s'}(w)$ is periodic in w with period 1. Therefore, again by (a), we can write

$$c_{s'} = \sum c_{s,s'} \exp(2\pi i\, sw) \qquad (s = -\infty, \ldots, +\infty),$$

where

$$c_{s,s'} = \int_0^1 c_{s'} \exp(-2\pi i\, sw)\, dw \qquad \text{(a constant)}. \tag{c}$$

From the above, it follows immediately that

$$F(w, w') = \sum\sum c_{s,s'} \exp[2\pi i\, (s\, w + s'w')] \qquad (s, s' = -\infty, \ldots, +\infty),$$

where

$$c_{s,s'} = \int_0^1 \int_0^1 F(w, w') \exp[-2\pi i\, (s\, w + s'w')]\, dw\, dw', \quad \text{Q.E.D.} \tag{d}$$

If the function $F(w, w')$ is real, as assumed here, the Fourier coefficients $c_{s,s'}$ and $c_{-s,-s'}$ are *complex conjugate* numbers; and similarly for the general n-variable case.

Geometrical Interpretation of Multiple Periodicity; Degeneracy

To understand the above results better, let us examine the system motion, neither in phase space (P_n) nor in configuration space (Q_n), but in the earlier-introduced, via (8.14.21d), $w_k = w_k(q;\, J)$, *space of the angle variables; or w-space* W_n.

Let us view the q's as rectangular Cartesian coordinates, spanning an n-dimensional Euclidean space Q_n. Then, since these coordinates have been assumed separable and periodic, the system motion in Q_n will be restricted to the interior of an n-dimensional finite rectangular prism, with sides parallel to the q-axes and size determined by the initial conditions on the q's. If we also assume that W_n is an n-dimensional Euclidean space spanned by the rectangular Cartesian coordinates $\{w_k;\ k = 1, \ldots, n\}$, then, due to (8.14.23) and its consequences, the earlier Q_n-prism will be mapped onto an infinity of *unit cubes*, in W_n, such that corresponding points in any two or more such cubes correspond to the same Q_n-space point. It follows that the entire system motion in W_n-space can be described by the motion of a figurative system point in a single representative fundamental unit cube C_n, one corner of which is taken at the origin of the w-axes ($t = 0$). Then partial motions in any other W_n-cube can be transferred to their corresponding segment in C_n. Indeed, eliminating the time t among the n equations $w_n = \nu_k t + \gamma_k$ ($k = 1, \ldots, n$), we see that the system motion in C_n is a uniformly traversed *straight line* whose direction cosines with the w-axes, l_k, satisfy the following $n - 1$ relations:

$$l_1 \colon l_2 \colon \ldots \colon l_n = dw_1 \colon dw_2 \colon \ldots \colon dw_n = \nu_1 \colon \nu_2 \colon \ldots \colon \nu_n. \tag{8.14.30}$$

In view of the w-periodicity, there is no need to examine that line in its entire length, only its portions inside C_n; every other part of it is transferred there by translation parallel to the w-axes. In conclusion, *the system path in W_n consists of well-defined parallel straight-line segments inside C_n*; and this is far simpler than the corresponding path in Q_n (or in real space) which, in general, is a complicated "Lissajous figure."

Let us examine, for concreteness, a *two-dimensional* such case (fig. 8.17(a)). Let the C_2-origin O coincide with the initial system position $w_k(t = 0) = \gamma_k = 0$. When the system path meets the right C_2-boundary at O_1 it is reflected horizontally back to the left boundary, which it meets at O_2, and with that as new origin continues again along a straight line segment parallel to OO_1. The reflection, or jump, at O_1, and so on, is the mathematical equivalent of transferring all w-motion inside C_2, and, as such, has no particular physical significance. The motion continues, similarly,

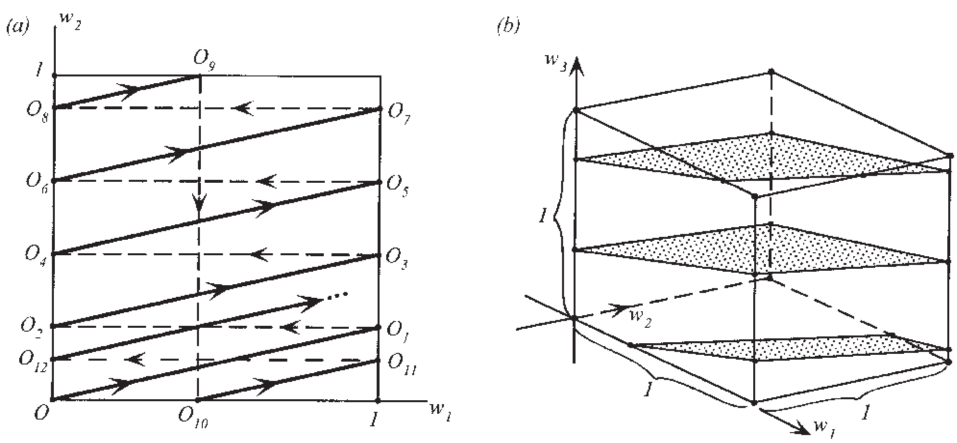

Figure 8.17 (a) Motion of separable and periodic systems in angle-space ($n = 2$) inside the fundamental unit cube $\rightarrow$ square C_2. (b) Case of degeneracy ($n = 3, m = 1$).

through $O_2 \to O_3 \to O_4 \to O_5 \to O_6 \to O_7$, where it is reflected vertically downwards to O_8, and from there on to $O_9 \to O_{10} \to \cdots$. That is why C_n has been aptly described by Lanczos (1970, p. 249) as a small cubic room with doorless reflecting walls; a "mirror-cabinet."

Here, the following fundamental questions arise: will the system path ever return to its initial position O, and from there on repeat itself ad infinitum (in which case, C_2 is laced by a finite number of parallel straight-line segments); or, will it keep going indefinitely, gradually filling C_2 completely?

The answer to these questions involves the key concept of *degeneracy*. Let us summarize it here. A system whose frequencies satisfy the m $(0 \le m \le n-1)$ linear, homogeneous, and independent *commensurability relations* (i.e., special "frequency constraints"):

$$\sum i_{dk}\nu_k = 0 \qquad (d = 1, \ldots, m), \tag{8.14.31}$$

where the i_{dk} are *integers*, or zero, but at least two of them (in each such equation) are nonzero, for arbitrary values of its actions, J_k is called m-ply (or m-fold) *degenerate*. Only an $(n-m)$-dimensional submanifold of the system's C_n cube is filled up densely; that is, only a finite number of equidistant and parallel planes [fig. 8.17(b): $n = 3, m = 1$]. The system point comes, infinitely often, arbitrarily close to any chosen point there. Similarly, its motion in Q_n-space is confined to an $(n-m)$-dimensional submanifold there, which it also fills up completely: straight lines $(C_n) \to$ curves (Q_n), plane subspace $(C_n) \to$ curved subspace (Q_n), and so on, but with the same number of dimensions. Due to (8.14.31), the Fourier series (8.14.24i, j), is reduced from an n-ply periodic function of time to an $(n-m)$-ply periodic function of time. (See pp. 1287–1289.)

In sum: *an m-ply degenerate n-DOF system is* $(n-m)$*-ply periodic*; compactly,

$$\#\,DOF - \text{degree of degeneracy} \;\equiv\; n - m \;=\; \#\,\text{periods}.$$

Special Cases

(i) If $m = 0$ $(\Rightarrow n - m = n)$, the system is called *nondegenerate*. Then, there exist n *independent fundamental frequencies*, and therefore the corresponding Fourier series is genuinely n-ply periodic. The system orbit, in Q_n or C_n, is *open*, but, in time, fills the entire n-dimensional q/w-region *densely*; that is, given sufficiently long time $(\tau \to \infty)$, the orbit will pass as near as we want ("arbitrarily close") to any arbitrarily chosen initial q/w-region point. In particular, C_n will, eventually, fill up completely by parallel, equally spaced (a nonobvious fact!) and uniformly traversed straight-line segments; and similarly for the Q_n-prism.

(ii) On the other extreme, if $m = n - 1$ $(\Rightarrow n - m = 1)$, for example, $\nu_1 = \nu_2 = \cdots = \nu_n$, *which is completely equivalent to the earlier case described by eqs. (8.14.28a–e) (since any* ν_k *can be expressed as a rational fraction of any other* ν_l), the system is called *completely, or fully, degenerate*. In this case, eqs. (8.14.24i, j) become a *purely* (or *singly*, or *genuinely*) *periodic function of time*; and, hence, the system motion is confined to a *one-dimensional* submanifold—that is, a straight line (C_n) or curve (Q_n). In the C_2-square of the earlier example, the line $O\ O_1 \ldots O_{10} \ldots$ returns to O after a *finite* time τ (fundamental period); and from there on it repeats itself; while, in the corresponding configuration plane Q_2, the system trajectory becomes a "Lissajous figure" that, depending on the values of the phase constants, either *closes* or *retraces itself between an initial and a final point*, again with fundamental period τ. Finally, such single-frequency motions have a single angle variable and corresponding action variable equal to $J = \oint \sum p_k\, dq_k$.

The situation is summarized in the following diagram:

Extreme cases of degeneracy

$$m = 0 \;\Rightarrow\; n - m = n \;\leftarrow \cdots \rightarrow\; m = n - 1 \;\Rightarrow\; n - m = 1$$

No degeneracy	*Complete degeneracy*
Motion manifold: n-dimensional	Motion manifold: one-dimensional
Orbit: *open* curve	Orbit: *closed* curve (or flattened curve)

Effects of Degeneracies

The latter, in addition to reducing the number of independent frequencies of a system, also:

(i) Reduce the number of its independent (and constant) action variables; and so restrict the forms in which the latter appear in the energy $E(J_1, \ldots, J_n) \equiv E(J)$. Thus, if ν_k and ν_l $(k, l = 1, 2, \ldots;\ k \neq l)$ are such that

$$i_k \tau_k = i_l \tau_l \Rightarrow\ i_k \nu_l = i_l\, \nu_k, \qquad \text{or} \qquad i_k(\partial E/\partial J_l) = i_l(\partial E/\partial J_k), \tag{8.14.32}$$

where $i_k, i_l =$ integers, then J_k, J_l may appear in E only in the form:

$$J \equiv i_k J_k + i_l J_l\ [\nu_k = \partial E/\partial J_k = (\partial E/\partial J)\,(\partial J/\partial J_k) = (\partial E/\partial J) i_k,$$
$$\nu_l = \cdots = (\partial E/\partial J) i_l \;\Rightarrow\; i_k \nu_l = i_l\, \nu_k];$$

or, equivalently, if they are such that

$$i_k \tau_l = i_l \tau_k \;\Rightarrow\; i_k \nu_k = i_l \nu_l, \qquad \text{or} \qquad i_k(\partial E/\partial J_k) = i_l(\partial E/\partial J_l), \tag{8.14.32a}$$

then J_k, J_l may appear in E only in the form $J' \equiv i_k J_l + i_l J_k$.

(ii) Increase the number of its single-valued integrals of motion over that number for the corresponding "same" but nondegenerate system. Indeed, a general *nondegenerate* conservative system has, outside of the energy integral, $2n - 1$ integrals of motion, of which only n are single-valued; for example, the n J's; the remaining $(2n - 1) - n = n - 1$ integrals can be written as

$$\begin{aligned} w_k(\partial E/\partial J_l) - w_l(\partial E/\partial J_k) &= w_k \nu_l - w_l \nu_k = (\nu_k t + \gamma_k)\nu_l - (\nu_l t + \gamma_l)\nu_k \\ &= \gamma_k \nu_l - \gamma_l \nu_k \quad [= \gamma_k(\partial E/\partial J_l) - \gamma_l(\partial E/\partial J_k)] \\ &= \textit{constant};\ \textit{but multiple-valued, since the angle variables are also} \\ &\quad\ \textit{multiple-valued}. \end{aligned} \tag{8.14.33a}$$

Now, in the case of degeneracy, as (8.14.32a) shows, the integral

$$\begin{aligned} w_k i_k - w_l i_l &= (\nu_k t + \gamma_k) i_k - (\nu_l t + \gamma_l) i_l \\ &= (i_k \nu_k - i_l \nu_l) t + (\gamma_k i_k - \gamma_l i_l) \\ &= \gamma_k i_k - \gamma_l i_l = \textit{constant}; \end{aligned} \tag{8.14.33b}$$

is multiple-valued, but to within an arbitrary multiple integral of 2π; and, therefore, by taking a *trigonometric function* of it, we obtain an *additional single-valued integral of motion*.

Also, this increase in the number of single-valued integrals allows for *complete separability for more than one choice of coordinates*: before the degeneracy, the n J_k's ($k = 1, \ldots, n$) are single-valued integrals of the corresponding separable coordinates. Upon imposition of a degeneracy, however, since then the number of single-valued integrals exceeds n, the choice of the new n J_k's among them becomes *nonunique*. [On the connection between degeneracy (nondegeneracy) of motion and nonuniqueness (uniqueness) of separation of variables in its Hamilton–Jacobi equation, see, for example, Born (1927, pp. 76–95), Goldstein (1980, pp. 469–470).]

Nonseparable Systems

Lastly, let us outline the properties of *finite* motion of a general *n-DOF* conservative but *nonseparable* system. Here, contrary to the separable case where the single-valued integrals are the n J_k's, the single-valued integrals are only those obtained from the homogeneity of space (linear momentum), isotropy of space (angular momentum), and isotropy of time (energy).

Now, generally, the representative system point in phase space can traverse regions defined by the specified constant values of its single-valued integrals.

(i) For *separable* systems with n single-valued integrals, these n constants define an n-dimensional *hypersurface* in phase space; given sufficient time, the system can pass arbitrarily close to every other chosen point on that hypersurface.
(ii) For *nonseparable* systems (*degenerate* systems), however, which possess fewer (more) than n single-valued integrals, the system point occupies, in phase space, a subspace with *more* (*less*) than n dimensions.

If the Hamiltonian of a nonseparable system differs by a very small amount from that of a separable (conditionally periodic) system, then we may reasonably suppose that the motion of the former will be *very close* to that of the latter; and that the difference between these two motions is *much smaller* than that of their Hamiltonians.

The systematic quantitative discussion of these topics belongs squarely to the frontier of contemporary nonlinear dynamics; and such Hamiltonian deep waters are, most definitely, beyond the scope of this introductory treatment (and the present state of knowledge of this writer!). For these advanced topics, and their connections to both classical chaotic/stochastic and quantum dynamics, we recommend the following readable and capable references (alphabetically): Dittrich and Reuter (1994), Hagihara (1970), Lichtenberg and Liebermann (1992), McCauley (1997), Pars (1965), Tabor (1989).

Action–Angle Variables and Atomic Physics

As mentioned earlier, action–angle variables have played a decisive part in the *older quantum theory* of Sommerfeld, Bohr, et al. (in the 1910s). According to this theory, the actual motions of an atomic system obey the quantization rule:

$$J_k = \oint p_k\, dq_k = n_k h \qquad (n_k\text{: integer}, h\text{: Planck's action constant}). \qquad (8.14.34a)$$

However, this theory led to the appearance of the harmonics $\nu_k, 2\nu_k, 3\nu_k, \ldots$, and so on, in the Fourier series expansion of its variables; and this contrasted sharply with experimental facts that indicated that the frequencies of the atomic spectra are not harmonics of some fundamental frequency but, instead, obey the "Ritz combination principle," according to which these frequencies result from a series of energy levels E_k, E_l satisfying

$$\nu_{kl} = (E_k - E_l)/h \qquad (k, l\text{: integers}). \tag{8.14.34b}$$

The resolution of these difficulties was carried out in the mid-1920s by *W. Heisenberg* (with some help from his teacher *M. Born* and his classmate *P. Jordan*, at Göttingen, Germany), and constitutes the *matrix form of quantum mechanics* — one of the greatest triumphs ("revolutions") of 20th century theoretical physics. Heisenberg (1925) replaced the Fourier series of, say q with the set

$$\{c_{ss'} \exp(2\pi i \nu_{ss'} t);\ s, s'\text{: } integers\}, \tag{8.14.34c}$$

that is, *he replaced the frequencies* ν_k, $2\nu_k$, $3\nu_k, \ldots,$ *(and amplitudes* c_s*) with the matrices*

$$\nu(s, s') \equiv \nu_{ss'} \qquad (\text{and } c_{ss'}), \tag{8.14.34d}$$

and introduced the algebra of these new "matrix coordinates" and functions of them. Born recognized that these were none other than the rules of matrix algebra, for the addition and multiplication of the q's, and formulated the following famous *noncommutative* (Poisson bracket-like, §8.9) rules, for pairs of canonically conjugate variables:

$$p_k\, q_l - q_l\, p_k = (h/2\pi\, i)\, \delta_{kl}, \qquad p_k p_l - p_l p_k = 0, \qquad q_k\, q_l - q_l\, q_k = 0. \tag{8.14.34e}$$

For readable accounts of those epoch-making developments, see, for example, Hund (1972), Simonyi (1986), and references cited therein; also Heisenberg (1930, p. 105 ff.).

Example 8.14.3 *Action for Cyclic Systems.* Let the coordinate q_i, of a separable group of q's, be ignorable. Then (§8.4) $p_i = constant \equiv \Psi_i$, and therefore the corresponding action variable equals:

$$J_i = \oint p_i\, dq_i = \Psi_i \left(\oint dq_i \right) = \Psi_i [q_i(2\pi) - q_i(0)]$$

$$= 0 \qquad (\text{Libration}), \tag{a}$$

$$= q_{io} \Psi_i \qquad (\text{Rotation};\, q_{io}\text{: fundamental period; e.g., } q_{io} = 2\pi). \tag{b}$$

Example 8.14.4 *Two-DOF Conditionally Periodic System.*

(i) *Equal frequencies*. Let us examine a particle P performing planar harmonic oscillations along the rectangular Cartesian axes O–x, O–y [fig. 8.18(a)]. Let us assume that the displacements $q_1 = x$, $q_2 = y$ are

$$x = a \cos(\omega t), \qquad y = b \cos(\omega t - \delta), \tag{a}$$

where a, b = constant amplitudes, $\omega = 2\pi\nu$ = common circular frequency, δ = phase difference.

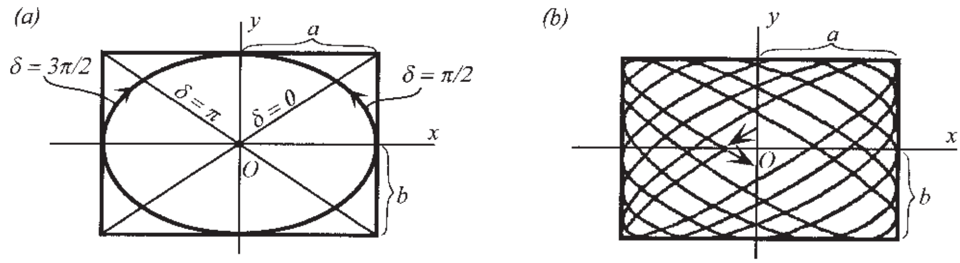

Figure 8.18 Path of a two-DOF system: (a) *equal* frequencies, (b) *unequal* (incommensurate case) frequencies (Lissajous figures).

Depending on the values of δ, the tip of the vector $\boldsymbol{OP} = (x, y)$ describes very different curves. Thus:

(a) If $\delta = 0$ $[= 0(\pi/2)]$, P describes the *straight line*

$$y/x = b/a \qquad \text{(diagonal of rectangle with sides } a \text{ and } b). \tag{b}$$

(b) If $\delta = \pi/2$ $[= 1(\pi/2)]$, eqs. (a) reduce to

$$x = a\cos(\omega t), \qquad y = b\cos(\omega t), \tag{c}$$

which are the parametric equations of an *ellipse* with semiaxes a, b:

$$(x/a)^2 + (y/b)^2 = 1, \tag{d}$$

traversed in a *counterclockwise* sense.

(c) If $\delta = \pi$ $[= 2(\pi/2)]$, P describes the *straight line*

$$y/x = -b/a, \tag{e}$$

which is the straight line of case (a), but reflected about the axis Oy.

(d) If $\delta = 3\pi/2$ $[= 3(\pi/2)]$, P describes the *ellipse* of eqs. (c, d), but traversed in a *clockwise* sense.

(e) If $\delta = 2\pi$ $[= 4(\pi/2)]$, P describes the *straight line* of eq. (b).

(f) If $a = b$, P traces a *circle* (clockwisely/counterclockwisely).

(ii) *Unequal frequencies*. Let us, next, assume that the displacements are

$$x = a\cos(\omega_x t), \qquad y = b\cos(\omega_y t). \tag{f}$$

Now we must distinguish the following two cases:

(a) If ω_x, ω_y are *commensurate* (*degenerate* case)—that is, if

$$\tau_x i_x = \tau_y i_y \equiv \tau \Rightarrow \omega_x/\omega_y = i_x/i_y = \textit{rational} \qquad (i_{x,y}\text{: integers}) \tag{g}$$

(e.g., the earlier $\omega_x = \omega_y = \omega$)—then eqs. (f) become

$$x = a\cos(\omega_x t), \qquad y = b\cos(\omega_y t) = b\cos\left[(i_y/i_x)\omega_x t\right]; \tag{h}$$

the motion has a *single* period — namely, it is periodic *as a whole* — and so the orbit of P is a *closed* curve.

(b) If ω_x, ω_y are *incommensurate* (*nondegenerate* case) — that is, if ω_x/ω_y = *irrational* — the orbit of P is a continuous Lissajous curve that *never closes* [fig. 8.18(b)] but forms a very dense web; that is, given sufficient time, it *practically* covers all points of the $2a \times 2b$ rectangle $ABCD$. Multiply periodic (or conditionally periodic) orbits are, in general, of that type: a certain space portion (the range of their q's) is densely filled, even though the orbit is *not* closed, and the motion is not singly periodic in time.

In sum:

- If $\omega_x = \omega_y$ (special commensurate/degenerate case), the orbit of P is a *straight line/ellipse/circle*, depending on the phase constant, and the relative size of the amplitudes.
- If ω_x/ω_y = *rational* (*degeneracy*), the orbit of P is a *closed* curve.
- If ω_x/ω_y = *irrational* (*nondegeneracy*), the orbit of P is an *open* curve that gradually fills up the whole rectangle (range of its variables).

Example 8.14.5 *Two-DOF Linear Anisotropic Oscillator; Degeneracy.* Here, using standard notation (x, y = rectangular Cartesian coordinates):

$$\begin{aligned} H &= (1/2m)({p_x}^2 + {p_y}^2) + (1/2)({k_x}^2 x^2 + {k_y}^2 y^2) \\ &= (1/2m)({p_x}^2 + {p_y}^2) + (m/2)({\omega_x}^2 x^2 + {\omega_y}^2 y^2), \end{aligned} \tag{a}$$

${\omega_x}^2 \equiv k_x/m$, and so on. Using the results of ex. 8.10.6 [slightly modified notationally, and also to take into account the anisotropy of (a)] we obtain, successively,

$$\begin{aligned} A_1 \to A_{ox} &= \int p_x\, dx = \int \left[m(2\beta_x - k_x x^2)\right]^{1/2} dx \\ &= (x/2)(2m\beta_x - k_x m x^2)^{1/2} + \beta_x (m/k_x)^{1/2} \arcsin[(k_x/2\beta_x)^{1/2} x] \\ &\qquad [\text{multiple-valued function of the } x\text{-coordinate}], \text{etc.} \end{aligned} \tag{b}$$

$$\begin{aligned} J_x &= \oint p_x\, dx = \int (\partial A_{ox}/\partial x)\, dx = A_{ox}(\tau_x) - A_{ox}(0) \\ &\qquad [\text{after a period } \tau_x, \text{the term } (2m\beta_x - k_x m x^2)^{1/2} \text{ returns to its} \\ &\qquad \text{original value, while } \arcsin(\ldots) \text{ increases by } 2\pi] \\ &= 2\pi\beta_x (m/k_x)^{1/2} \equiv (2\pi/\omega_x)\beta_x, \quad \text{etc.}; \end{aligned} \tag{c}$$

$$E = \beta_x + \beta_y = \text{total energy} \quad (= \text{sum of ``partial energies''}), \tag{d}$$

$$\Rightarrow E = (J_x/2\pi)(k_x/m)^{1/2} + (J_y/2\pi)(k_y/m)^{1/2} = E(J_x, J_y), \tag{e}$$

$$\Rightarrow \ \nu_x = \partial E/\partial J_x = (1/2\pi)(k_x/m)^{1/2},\ \nu_y = \partial E/\partial J_y = (1/2\pi)(k_y/m)^{1/2}; \tag{f}$$

$$\begin{aligned} \alpha_x &= \partial A/\partial \beta_x = \partial A_o/\partial \beta_x - t = \partial A_{ox}/\partial \beta_x - t \\ &= -t + (m/k_x)^{1/2} \arcsin[(k_x/2\beta_x)^{1/2} x], \qquad \text{etc.} \end{aligned} \tag{g}$$

$$\begin{aligned} \Rightarrow \ x &= (2\beta_x/k_x)^{1/2} \sin\left[(k_x/m)^{1/2}(t + \alpha_x)\right] \\ &= (J_x/\pi\omega_x m)^{1/2} \sin(2\pi w_x) = \left[J_x/\pi(k_x m)^{1/2}\right]^{1/2} \sin(2\pi w_x), \end{aligned} \tag{h}$$

$$\Rightarrow\ p_x = (\omega_x m J_x/\pi)^{1/2}\cos(2\pi w_x), \tag{i}$$

$$\Rightarrow\ y = (2\beta_y/k_y)^{1/2}\sin[(k_y/m)^{1/2}(t+\alpha_y)]$$
$$= (J_y/\pi\omega_y m)^{1/2}\sin(2\pi w_y) = [J_y/\pi(k_y\, m)^{1/2}]^{1/2}\sin(2\pi w_y), \tag{j}$$

$$\Rightarrow\ p_y = (\omega_y m J_y/\pi)^{1/2}\cos(2\pi w_y); \tag{k}$$

where

$$w_x = \nu_x t + \gamma_x$$
$$\Rightarrow\ 2\pi w_x = 2\pi(\nu_x t + \gamma_x) \equiv 2\pi\nu_x(t+\alpha_x) \equiv \omega_x t + \delta_x, \quad \text{etc.} \tag{l}$$

To represent the above graphically in their rectangular Cartesian $w_{x,y}$-axes, we eliminate t between w_x, w_y in (l), and thus obtain the curves (straight lines)

$$w_y = (\nu_y/\nu_x)w_x + [\gamma_y - (\nu_y/\nu_x)\gamma_x]. \tag{m}$$

As discussed in the preceding example, we must distinguish the following *two* general cases:

(i) $\nu_y/\nu_x =$ *rational* (*commensurability*, or *complete degeneracy*): the motion as a whole is (singly) periodic, which means that the representative system point traces a (n – *number of commensurability relations* $= 2 - 1 =$) *one*-dimensional manifold; that is, in our xy-axes, a *closed and always retraceable Lissajous curve*. [If that curve has an endpoint (e.g., flattened, open-*looking*, path), the motion reverses itself at that point (i.e., it does a very flat U-turn there) and proceeds in the opposite direction until it reaches the next endpoint; and then the whole process repeats itself periodically.] The corresponding w-curve, inside the system's "unit square" C_2, consists of straight-line segments, as explained earlier in this section.

Figures 8.19 and 8.20 show the following special such cases (in both figures, the *left* column shows the x, y (Lissajous) curves, while the *right* column shows the corresponding $w_{x,y}$ straight lines):

(α) Figure 8.19:

$$\textit{frequency ratio}\text{: } \nu_y/\nu_x = 1, 2, 3, 5/3,\ \ \textit{phase constants}\text{: } \gamma_x, \gamma_y = 0, \tag{n}$$

$$(\text{h, j}):\ \ x = [J_x/\pi(k_x m)^{1/2}]^{1/2}\sin(2\pi\nu_x t), \qquad y = [J_y/\pi(k_y m)^{1/2}]^{1/2}\sin(2\pi\nu_y t), \tag{o}$$

$$(\text{m}):\ \ w_y = (\nu_y/\nu_x)w_x\ \text{(straight lines through the } w_{x,y}\text{-origin)}; \tag{p}$$

(β) Figure 8.20 [*same frequency ratios as (a), but different phase constants*]:

$$\textit{frequency ratio}\text{: } \nu_y/\nu_x = 1, 2, 3, 5/3, \quad \textit{phase constants}\text{: } \gamma_x = 0, \gamma_y = 1/4, \tag{q}$$

$$(\text{h}):\ \ x = [J_x/\pi(k_x\, m)^{1/2}]^{1/2}\sin(2\pi\nu_x t), \tag{r}$$

$$(\text{j}):\ \ y = [J_y/\pi(k_y\, m)^{1/2}]^{1/2}\sin[(2\pi\nu_y + \pi/2)t] = [J_y/\pi(k_y\, m)^{1/2}]^{1/2}\cos(2\pi\nu_y\, t), \tag{s}$$

$$(\text{m}):\ \ w_y = (\nu_y/\nu_x)w_x + 1/4\ \text{(straight lines not through the } w_{x,y}\text{-origin)}. \tag{t}$$

(ii) $\nu_y/\nu_x \neq$ *rational* (*incommensurability*, or *nondegeneracy*): the motion as a whole is not periodic, which means that the representative system point traces a ($n - 0 = 2 - 0$) *two*-dimensional manifold; that is, in our xy-axes an *open and non-retraceable* curve, which eventually ($t \to \infty$) covers the entire finite area formed by

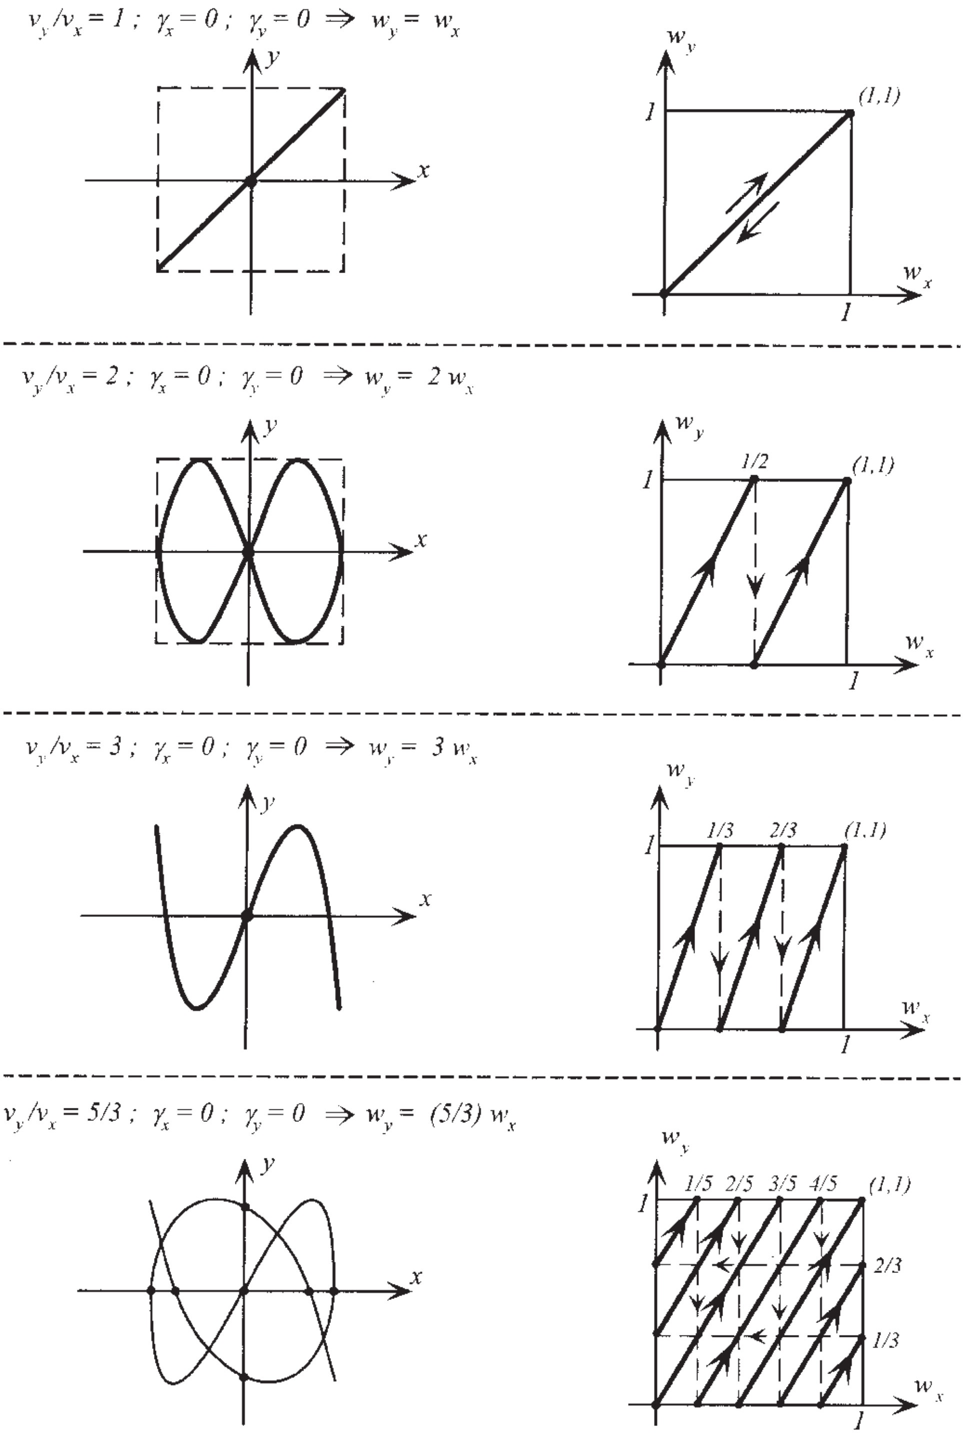

Figure 8.19 System paths in x, y-space (Lissajous curves) and in $w_{x,y}$-space; for $\nu_y/\nu_x = 1, 2, 3, 5/3$, and $\gamma_x = 0$, $\gamma_y = 0$.

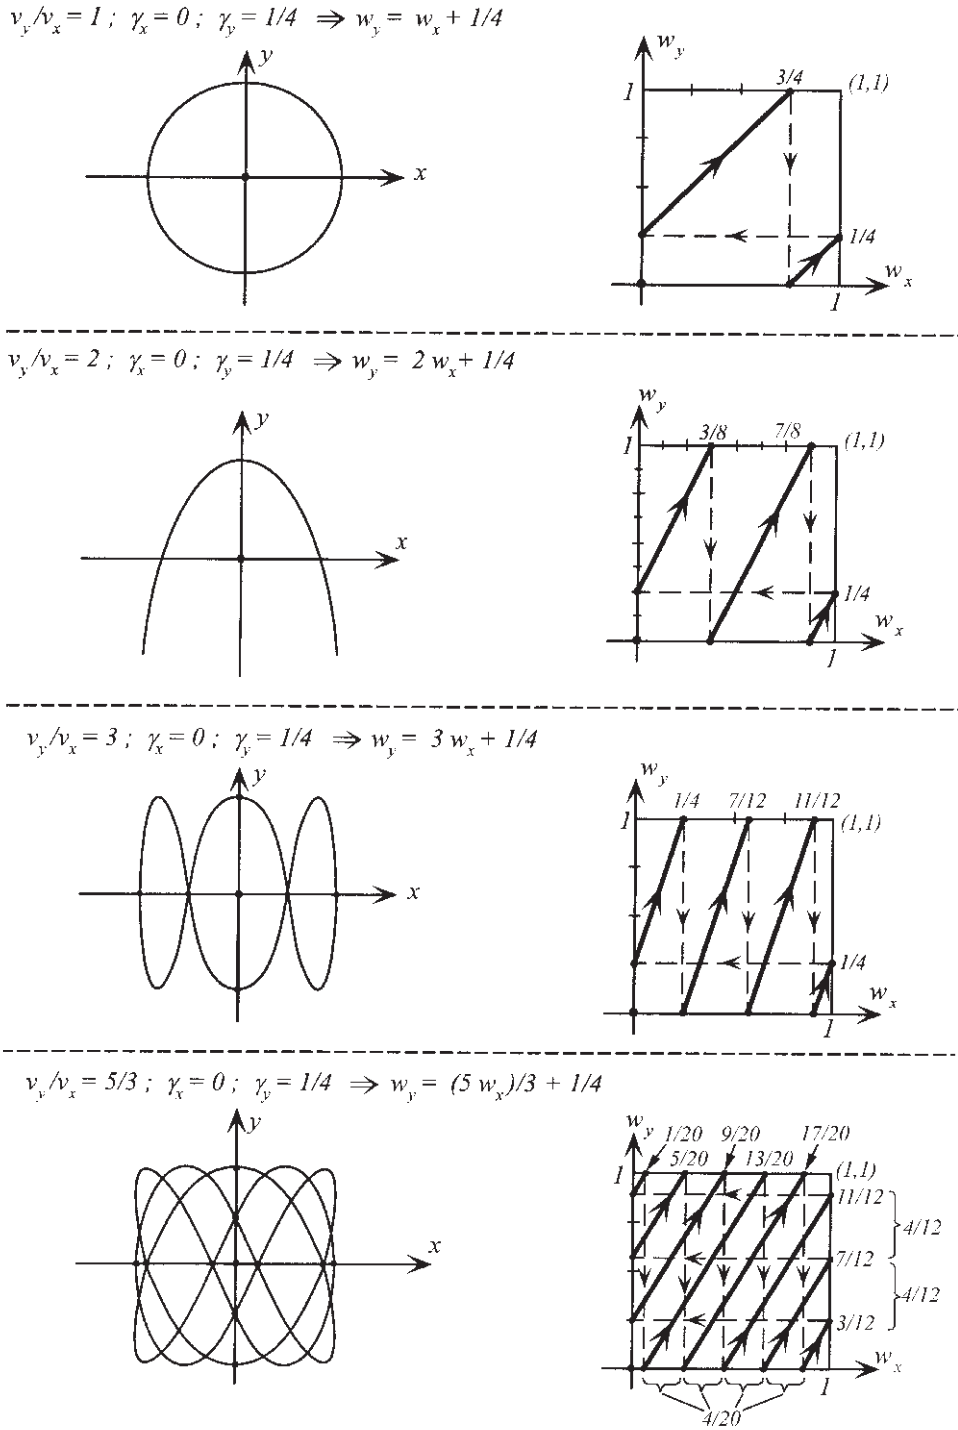

Figure 8.20 System paths in x, y-space (Lissajous curves) and in $w_{x,y}$-space; for $\nu_y/\nu_x = 1, 2, 3, 5/3$, and $\gamma_x = 0$, $\gamma_y = 1/4$.

the tangents bounding the motion (analogous to the rectangle $ABCD$ of the preceding example); and similarly for the unit square $w_{x,y}$

Finally, *for complicated but rational ratios* ν_y/ν_x, the system path comes close to covering the corresponding xy-plane region and unit square $w_{x,y}$ completely, that is, such ratios approximate the nonrational ratio case.

Example 8.14.6 *Coupled Penduli via Action–Angle Variables* (Butenin, 1971, pp. 173–176). Let us consider a system consisting of two thin homogeneous bars, O_1A_1 and O_2A_2 of masses/lengths/moments of inertia about their pivots O_1 and O_2: $m_1/l_1/I_1$ and $m_2/l_2/I_2$, respectively (fig. 8.21), oscillating about O_1 and O_2, and connected at C_1, C_2 ($O_1C_1 = O_2C_2 \equiv c$) by a light linear spring of constant stiffness k. Let us calculate the two natural frequencies of its free (small amplitude) oscillations under gravity, via the method of action–angle variables.

The kinetic and potential energies of the system are, respectively,

$$2T = I_1(\dot{\phi}_1)^2 + I_2(\dot{\phi}_2)^2, \tag{a}$$

$$V = m_1 g(l_1/2)(1 - \cos\phi_1) + m_2 g(l_2/2)(1 - \cos\phi_2) + (k/2)(e - e_o)^2$$

[using the second-order approximations: $\cos\phi_k \approx 1 - {\phi_k}^2/2 \qquad (k = 1, 2)$,

and

$e - e_o \approx c\phi_1 - c\phi_2$]

$$\approx (1/2)\{[m_1 g(l_1/2) + kc^2]{\phi_1}^2 - 2kc^2\phi_1\phi_2 + [m_2 g(l_2/2) + kc^2]{\phi_2}^2\}, \tag{b}$$

or, after choosing, for algebraic convenience, $l_1 = l_2 = l$, $m_1 = m_2 = m$, $I_1 = I_2 = I$:

$$2T = I[(\dot{\phi}_1)^2 + (\dot{\phi}_2)^2], \tag{c}$$

$$2V = [K({\phi_1}^2 + {\phi_2}^2) - 2kc^2\phi_1\phi_2], \qquad K \equiv mg(l/2) + kc^2; \tag{d}$$

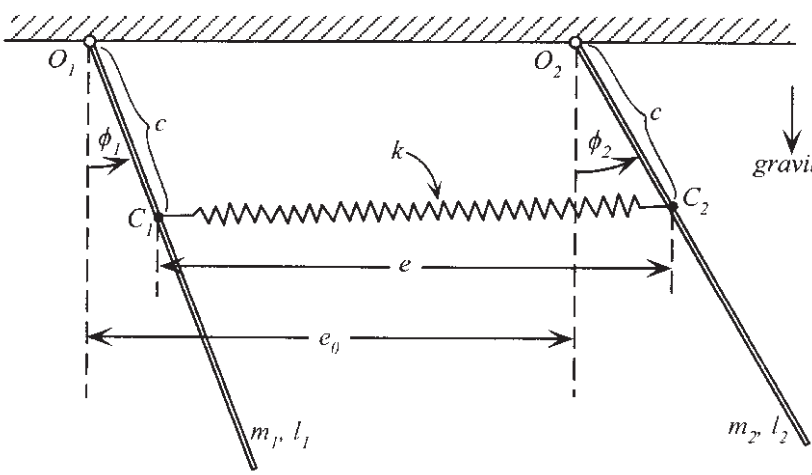

Figure 8.21 Coupled double penduli, oscillating under gravity.

or, in terms of the (easily noticeable) new uncoupling coordinates:

$$\phi_1 = q_1 + q_2, \qquad \phi_2 = q_1 - q_2 \;\Rightarrow\; 2q_1 = \phi_1 + \phi_2, \qquad 2q_2 = \phi_1 - \phi_2,$$

$$T = I[(\dot{q}_1)^2 + (\dot{q}_2)^2], \qquad V = K_1 {q_1}^2 + K_2 {q_2}^2, \tag{e}$$

where $K_1 \equiv mgl/2$, $K_2 \equiv K_1 + 2kc^2 \equiv K + kc^2$.

Since $p_1 = 2I\dot{q}_1$ and $p_2 = 2I\dot{q}_2$, the time-independent (reduced) Hamilton–Jacobi equation of the system is

$$\left[(1/4I)(\partial A_o/\partial q_1)^2 + K_1 {q_1}^2\right] + \left[(1/4I)(\partial A_o/\partial q_2)^2 + K_2 {q_2}^2\right] = E, \tag{f}$$

and separates, in by now well-understood ways, to the two HJ equations

$$(1/4I)(\partial A_{o1}/\partial q_1)^2 + K_1 {q_1}^2 = \beta_1, \qquad (1/4I)(\partial A_o/\partial q_2)^2 + K_2 {q_2}^2 = \beta_2, \tag{g}$$

where $A_o = A_{o1}(q_1) + A_{o2}(q_2)$, $\beta_1 + \beta_2 = E$. Hence, the finite HJ equations become

$$p_1 = \partial A_o/\partial q_1 = \partial A_{o1}/\partial q_1 = 2(IK_1)^{1/2}\left[(\beta_1/K_1) - {q_1}^2\right]^{1/2}, \tag{h}$$

$$p_2 = \partial A_o/\partial q_2 = \partial A_{o2}/\partial q_2 = 2(IK_2)^{1/2}\left[(\beta_2/K_2) - {q_2}^2\right]^{1/2}, \tag{i}$$

and, from these expressions, it follows that the corresponding action variables are

$$J_1 = 2(IK_1)^{1/2} \oint \left[(\beta_1/K_1) - {q_1}^2\right]^{1/2} dq_1, \tag{j}$$

$$J_2 = 2(IK_2)^{1/2} \oint \left[(\beta_2/K_2) - {q_2}^2\right]^{1/2} dq_2. \tag{k}$$

With the help of the convenient transformation of variables:

$$q_1 \equiv (\beta_1/K_1)^{1/2} \sin x, \qquad q_2 \equiv (\beta_2/K_2)^{1/2} \sin x, \tag{l}$$

(and, accordingly, x-limits of integration: 0, 2π) eqs. (j, k) integrate readily to

$$J_1 = 2\pi(I/K_1)^{1/2}\beta_1, \qquad J_2 = 2\pi(I/K_2)^{1/2}\beta_2, \tag{m}$$

and so the total energy assumes the following form, in terms of the action variables:

$$E = \beta_1 + \beta_2 = (J_1/2\pi)(K_1/I)^{1/2} + (J_2/2\pi)(K_2/I)^{1/2} = E(J_1, J_2). \tag{n}$$

From this expression (and recalling the definitions of K_1, K_2, and that $3I = ml^2$), we readily obtain the system frequencies:

$$\nu_1 = \partial E/\partial J_1 = (1/2\pi)(K_1/I)^{1/2} = (1/2\pi)(3g/2l)^{1/2}, \tag{o}$$

$$\nu_2 = \partial E/\partial J_2 = (1/2\pi)(K_2/I)^{1/2} = (1/2\pi)\left[(3g/2l) + (6kc^2/ml^2)\right]^{1/2}; \tag{p}$$

which, of course, coincide with the values found by ordinary linear vibration theory.

Example 8.14.7 *Action–Angle Formulation for Partially Separable Systems.* Let us consider a system in motion, and such that the projection of its orbit on the particular phase space subplane (q_k, p_k) is a *periodic* (libratory or rotatory) curve. This can occur if the system action has the *separable form in* q_1 (§8.10):

$$A = A_{oR}(q_2, \ldots, q_n;\ \beta_2, \ldots, \beta_n) + A_{o1}(q_1, \beta_1) - E\,t. \tag{a}$$

Here, as in the completely separable case, we replace throughout the constant β_1 with the constant *action* variable (with the usual notations):

$$J_1 \equiv \oint p_1\,dq_1 = \oint (\partial A_{o1}/\partial q_1)\,dq_1 = A_{o1}(\tau_1) - A_{o1}(0); \tag{b}$$

and similarly for $E = E(\beta_1) = E(J_1)$.

Then, the corresponding (ignorable) canonical *angle* variable w_1 equals

$$w_1 = \partial A_o/\partial J_1 = \partial A_{o1}(q_1, J_1)/\partial J_1 = (\partial E/\partial J_1)t + \partial A/\partial J_1, \tag{c}$$

and, from this, it follows that during a cycle with (fundamental) period τ_1, it changes by

$$\Rightarrow\ \Delta w_1 \equiv w_1(t+\tau_1) - w_1(t) = \tau_1(\partial E/\partial J_1). \tag{d}$$

Comparing (d) with the general result:

$$\begin{aligned}\Delta w_1 &= \oint (\partial w_1/\partial q_1)\,dq_1 = \oint (\partial^2 A_{o1}/\partial q_1\,\partial J_1)\,dq_1 \\ &= \partial/\partial J_1\left[\oint (\partial A_{o1}/\partial q_1)\,dq_1\right] = \partial/\partial J_1\left(\oint p_1\,dq_1\right) = \partial J_1/\partial J_1 = 1,\end{aligned} \tag{e}$$

we readily conclude that

$$\partial E/\partial J_1 = \textit{frequency of } (q_1, p_1)\textit{-motion} \equiv \nu_1 = 1/\tau_1. \tag{f}$$

Finally, q_1 is a periodic function in w_1 with period 1, and can therefore be represented by a single Fourier series à la (24f–j). The extension of the above to partially separable systems in two, three, ... , periodic coordinates should be obvious.

Example 8.14.8 *An Alternative Expression for the Frequencies.* Since $w_k = \partial A_o(q, J)/\partial J_k = w_k(q, J)$, and the J_k's remain constant during the motion, any changes in the w_k's can arise only from changes in the q's. Indeed, from the preceding, we find, successively,

$$\begin{aligned}dw_k &= \sum (\partial w_k/\partial q_l)\,dq_l = \sum\ [\partial/\partial q_l(\partial A_o/\partial J_k)]\,dq_l \\ &= \sum\ [\partial/\partial J_k(\partial A_o/\partial q_l)]\,dq_l \\ &= \sum\ (\partial p_l/\partial J_k)\,dq_l, \qquad \text{where } p_l = p_l(q_l, J);\end{aligned} \tag{a}$$

and, since $w_k = \nu_k t + \gamma_k \ \Rightarrow\ dw_k = \nu_k\,dt$ and $dq_l = \dot{q}_l\,dt$, we finally obtain the alternative frequency expression

$$\nu_k = \sum (\partial p_l/\partial J_k)(dq_l/dt). \tag{b}$$

Example 8.14.9 (Born, 1927, p. 82). Let

$$K \equiv \sum p_k \dot{q}_k \quad (= 2T, \text{ for stationary constraints}). \tag{a}$$

Below we show that

$$\langle K \rangle \equiv \sum \nu_k J_k; \tag{b}$$

where $\langle \ldots \rangle \equiv$ *time-average of* $(\ldots)$ *over a long period of time* τ, including a large number of w-periods. With the help of the earlier (8.14.23b, c):

$$A_{oo} \equiv A_o - \sum w_k J_k, \qquad \dot{A}_{oo} = \sum p_k \dot{q}_k - \sum J_k \dot{w}_k, \tag{c}$$

we obtain, successively,

$$\begin{aligned}
\langle K \rangle &\equiv \tau^{-1} \left(\int_0^\tau \sum p_k \dot{q}_k \right) dt \\
&= \tau^{-1} \left[\int_0^\tau \left(\sum J_k \dot{w}_k + \dot{A}_{oo} \right) dt \right] = \tau^{-1} \left[\int_0^\tau \left(\sum J_k \nu_k + \dot{A}_{oo} \right) dt \right] \\
&= \sum w_k J_k + \{A_{oo}/\tau\}_0^\tau \ \text{ (since both the } \nu_k\text{'s and } J_k\text{'s } \textit{are constant}\text{)},
\end{aligned} \tag{d}$$

from which, since A_{oo} is w-periodic and τ contains a large number of periods of the w's, and therefore $A_{oo}(0) = A_{oo}(\tau)$, the proposition (b) follows.

Example 8.14.10 (Bohr, 1918). Here, we show that for an *n-DOF* but completely degenerate (i.e., singly periodic) system

$$\Delta E = \nu \, \Delta J. \tag{a}$$

Let us consider the system in a fundamental oscillatory state I of period τ. Then, its (sole) action variable is

$$J = \int_0^\tau \left(\sum p_k \dot{q}_k \right) dt. \tag{b}$$

Now, let us consider a small noncontemporaneous variation from that state to the neighboring, also oscillatory and singly periodic, state $II = I + \Delta(I)$ with period $\tau + \Delta\tau$. Using the results of §7.9, we obtain, successively,

$$\begin{aligned}
\Delta J &= \int_0^\tau \delta \left(\sum p_k \dot{q}_k \right) dt + \left\{ \left(\sum p_k \dot{q}_k \right) \Delta t \right\}_0^\tau \\
&= \int_0^\tau \sum (\delta p_k \, \dot{q}_k + p_k \, \delta \dot{q}_k) \, dt + \left\{ \left(\sum p_k \dot{q}_k \right) \Delta t \right\}_0^\tau
\end{aligned}$$

[integrating the $p\,\delta(\dot{q})$ terms by parts, and using Hamilton's equations with $Q_k = 0$; while recalling that $\Delta q = \delta q + \dot{q}\,\Delta t$]

$$= \int_0^\tau \sum \left[(\partial H/\partial p_k)\, \delta p_k - (-\partial H/\partial q_k)\, \delta q_k\right] dt + \left\{\sum p_k\, \Delta q_k\right\}_0^\tau$$

$$= \int_0^\tau \delta H\, dt \qquad \text{[the integrated-out "boundary" term vanishes by periodicity]}$$

$$= \int_0^\tau \delta E\, dt. \tag{c}$$

If the adjacent motion *II* corresponds to slightly different initial conditions, then $\delta E = constant$ ($\Rightarrow \Delta E = \delta E + \dot{E}\, \Delta t = \delta E$), and so (b) yields immediately

$$\Delta J = (\Delta E)\tau \;\Rightarrow\; \Delta E = \Delta J/\tau = \nu\, \Delta J, \quad \text{Q.E.D.} \tag{d}$$

Example 8.14.11 Let us show that

$$\Delta E = \sum \nu_k\, \Delta J_k. \tag{a}$$

Since $H = H(J)$, we have

$$\Delta H = \sum (\partial H/\partial J_k)\, \Delta J_k = \sum \nu_k\, \Delta J_k = \Delta E, \quad \text{Q.E.D.} \tag{b}$$

Example 8.14.12 (Born, 1927, pp. 94–95). According to (8.14.23a) and (8.14.23b), the function

$$A_o = A_{oo} + \sum w_k J_k \tag{a}$$

increases by J_k whenever w_k increases by 1, while the remaining w's and J's *remain constant*. This is expressed mathematically by

$$\begin{aligned} J_k &= \int_0^1 \left[\partial A_o(w, J)/\partial w_k\right] dw_k \\ &= \int_0^1 \left\{\sum \left[\partial A_o(q, J)/\partial q_l\right](\partial q_l/\partial w_k)\right\} dw_k \\ &= \int_0^1 \left(\sum p_l(\partial q_l/\partial w_k)\right) dw_k; \end{aligned} \tag{b}$$

and its usefulness consists in yielding the action variables from a knowledge of the q's and p's in terms of the w's.

Example 8.14.13 *Proof of Commutativity of* $\partial/\partial J_k[\oint(\ldots)\, dq] = \oint(\partial\ldots/\partial J_k)\, dq$, eqs. (8.14.13b, 23) (Kuypers, 1993, pp. 345–346, 533–534). In the derivation of (8.14.13b, 23), we assumed that

$$\oint (\partial^2 A_o/\partial J_k \partial q_l)\, dq_l = \partial/\partial J_k\left[\oint (\partial A_o/\partial q_l)\, dq_l\right], \tag{a}$$

in spite of the fact that the integration limits do depend on J_k. Let us justify this point. The proof is based on the well-known "Leibniz formula" (using standard calculus notations):

$$\partial/\partial\alpha \int_{l_1(\alpha)}^{l_2(\alpha)} f(x;\alpha,\ldots)\,dx$$
$$= \int_{l_1(\alpha)}^{l_2(\alpha)} \big[\partial f(x;\alpha,\ldots)/\partial\alpha\big]\,dx$$
$$+ f(x, l_2,\ldots)[\partial l_2(\alpha)/\partial\alpha] - f(x, l_1,\ldots)[\partial l_1(\alpha)/\partial\alpha]. \tag{b}$$

With the identifications:

$$\alpha \to J_k, \qquad x \to q_l, \qquad f(x;\alpha,\ldots) \to \partial A_o(q,J)/\partial q_l, \tag{c}$$

eq. (b) yields

$$\partial/\partial J_k \int_{q_{l,1}(J)}^{q_{l,2}(J)} \big[\partial A_o(q,J)/\partial q_l\big]\,dq_l$$
$$= \int_{q_{l,1}(J)}^{q_{l,2}(J)} \big[\partial/\partial J_k(\partial A_o/\partial q_l)\big]\,dq_l$$
$$+ \big\{(\partial A_o/\partial q_l)_2[\partial q_{l,2}(J)/\partial J_k] - (\partial A_o/\partial q_l)_1[\partial q_{l,1}(J)/\partial J_k]\big\}, \tag{d}$$

where the subscripts 1, 2 refer to the limits of integration.

Now we apply (d) to our two periodic cases:

(i) Case of *libration*. Then,

$$\oint (\partial A_o/\partial q_l)\,dq_l \;=\; 2\int_{q_{l,\min}(J)}^{q_{l,\max}(J)} (\partial A_o/\partial q_l)\,dq_l, \tag{e}$$

where the integration limits $q_{\max/\min}$ are the *turning points* of the oscillation. But, there, we also have $p_l = \partial A_o/\partial q_l = 0$, and therefore the boundary terms in (d) vanish *individually*; that is, (a) holds for libration.

(ii) Case of *rotation*. Here,

$$\oint (\partial A_o/\partial q_l)\,dq_l = \int_{q_{l,i}(J)}^{q_{l,i}(J)+q_{lo}} (\partial A_o/\partial q_l)\,dq_l, \tag{f}$$

where $q_{l,i}$ = arbitrary *initial* position of q_l, q_{lo} = fundamental period of q_l. However, since $\partial A_o/\partial q_l = p_l =$ *periodic* function of q_l, and

$$\partial/\partial J_k\big[q_{l,i}(J) + q_{lo}\big] = \partial/\partial J_k\big[q_{l,i}(J)\big], \tag{g}$$

the boundary terms in (d) *taken together* vanish; that is, (a) also holds for rotation, and so it holds for periodic motions in general.

Example 8.14.14 *Independent Action–Angle Variables in the Case of Degeneracy*. Whenever the frequency constraints (8.14.31)

$$\sum i_{dk}\,\nu_k = 0 \qquad (d = 1,\ldots,m) \tag{a}$$

hold [and following the Lagrange–Hamel method of constrained coordinates/velocities (chaps. 2 and 3), with which this theory of degenerate systems bears some unmistakable mathematical similarities!], we may replace the old action–angle variables (w, J) with new action–angle variables (w', J'), defined through the following special equations:

$$w'_k: \qquad w'_d \equiv \sum i_{dk} w_k = 0 \qquad (d = 1, \ldots, m), \tag{b}$$

$$w'_i \equiv w_i \neq 0 \qquad (i = m+1, \ldots, n), \tag{c}$$

and generating function [recalling §8.8, with $F_1 = 0$, and the correspondences: $q \to w,\ p' \to J',\ F_2(q, p') \to F_2(w, J')$]

$$\begin{aligned} F_2(w, J') &= \sum w'_k\, J'_k \qquad \left(= \sum w_k J_k\right) \\ &= \sum w'_d\, J'_d + \sum w'_i\, J'_i \\ &= \sum\sum i_{dk} w_k\, J'_d + \sum w_i\, J'_i \qquad \left(= \sum w_i\, J'_i\right). \end{aligned} \tag{d}$$

Then, the old and new action variables will be related by [recalling (8.8.17)]

$$p_k = \partial F_2/\partial q_k: \quad J_k = \partial F_2/\partial w_k = \sum i_{dk}\, J'_d + \sum \delta_{ik}\, J'_i \quad (\delta_{ik}\text{: Kronecker delta}), \tag{e}$$

$$\Rightarrow\ J_{d'} = \sum i_{dd'} J'_d \qquad (d' = 1, \ldots, m), \tag{e1}$$

$$\Rightarrow\ J_{i'} = J'_{i'} + \sum i_{di'} J'_d \qquad (i' = m+1, \ldots, n); \tag{e2}$$

$$q_{k'} = \partial F_2/\partial p_{k'}: \qquad w'_k = \partial F_2/\partial J'_k \qquad [\text{i.e., eqs. (b, c)}]. \tag{f}$$

From the above, it follows that

(i) The *new* frequencies will be

$$\nu'_k = dw'_k/dt: \quad dw'_d/dt = \sum i_{dk}(dw_k/dt) = \sum i_{dk}\, \nu_k = 0; \quad \text{i.e.,}\ \nu'_d = 0; \tag{g1}$$

$$dw'_i/dt = dw_i/dt = \nu_i; \qquad \text{i.e.}\ \nu'_i = \nu_i; \tag{g2}$$

with the zeroes among them (ν'_d) yielding constant factors in the corresponding Fourier series expansions; while

(ii) Since the $H'(J') = H(J) = E(J) = E'(J')$, the Hamiltonian equations in the new variables will be

$$dw'_k/dt = \partial H'/\partial J'_k = \nu'_k:$$

$$\Rightarrow\ \partial H'/\partial J'_d = \nu'_d = 0\ \Rightarrow\ E\text{: } \textit{independent of the } J'_d, \tag{h1}$$

$$\Rightarrow\ \partial H'/\partial J'_i = \nu'_i = \nu_i \neq 0; \tag{h2}$$

$$dJ'_k/dt = -\partial H'/\partial w'_k = 0\ \Rightarrow\ J'_k = \textit{constant}. \tag{h3}$$

Hence, in a completely degenerate system $(m = n - 1)$ $H' = H'(J'_n)$; that is, the Hamiltonian can depend on only one new action variable.

We leave it to the reader to show that the new coordinates obtained by the generating function $A_o(q, \beta) = A_o(q, J) = A_o(q, J')$ are indeed the new angle variables w', that is, $w'_k = \partial A_o / \partial J'_k$. For further details and insights, see, for example, Frank (1935, pp. 97–99), Fues (1927, p. 142 ff.).

Problem 8.14.1 Show that equation (a) of the preceding example implies that

$$\nu_k = \sum i'_{ki} \nu'_i = 0 \qquad (i = M + 1, \ldots, n), \tag{a}$$

where i'_{ki} = integers; that is, the old frequencies are linear/homogeneous/integral combinations of the $n - m$ independent quantities ν'_i (the new frequencies).

REMARK

If we analogize the n old frequencies with n constrained virtual displacements (the δq's of chap. 2) and the $n - m$ new ones with $n - m$ independent virtual variations of quasi coordinates (the $\delta\theta_I$'s of chap. 2, or any other group of $n - m$ independent "parameters"), then (a) is the analog of none other than Maggi's projection idea (§ 3.5)!

Problem 8.14.2 Extend the results of ex. 8.14.13 for the case where its equations (b, c) are replaced by

$$w'_k: \;\; w'_d \equiv \sum i_{dk} w_k = 0 \qquad (d = 1, \ldots, m), \tag{a}$$

$$w'_i \equiv \sum i_{ik} w_k \neq 0 \qquad (i = m + 1, \ldots, n), \tag{b}$$

REMARK

This is the frequency analog of the general Hamel choice of quasi velocities (chap. 2).

Problem 8.14.3 Let $H' = H = E = E(J)$ have the special form

$$E(J) = F(f, J_4, J_5, \ldots, J_n), \tag{a}$$

where $f \equiv i_1 J_1 + i_2 J_2 + i_3 J_3$, $i_{1,2,3}$ are given integers. Show that the first three system frequencies are given by

$$\nu_r = i_r (\partial F / \partial f) \qquad (r = 1, 2, 3); \tag{b}$$

and then show that they also satisfy the *two* degeneracy conditions

$$i_2 \nu_1 - i_1 \nu_2 = 0, \qquad i_3 \nu_1 - i_1 \nu_3 = 0. \tag{c}$$

Appendix: On Multiply Periodic Functions/Motions

To help the reader to understand better the meaning of multiple Fourier series, like (8.14.24f–j), we point out the following facts from linear and nonlinear vibrations of discrete systems with constant coefficients (for extra clarity in real forms):

(i) The free vibrations of a *linear, 1-DOF* system [e.g., particle with kinetic and potential energies $m(\dot{q})^2/2$ and $kq^2/2$, respectively (m: mass, k: elasticity constant > 0)], have the following form:

$$q = a\sin(\omega t) + b\cos(\omega t) = c\cos(\omega t + \delta)$$

$$(\omega^2 = k/m;\ a, b, c\text{: constant amplitudes}, \delta = \text{“phase” constant}). \qquad (8.14.35)$$

Motion: *simply harmonic* and *singly periodic*.

(ii) The free vibrations of a *nonlinear, 1-DOF* system [e.g., elastic potential equal to $kq^2/2 + k'q^3 + k''q^4 + \cdots$ ($k, k', k'', \ldots$: constants)] have the single Fourier series form: $q = c_0 + c_1\cos(\omega t + \delta_1) + c_2\cos(2\omega t + \delta_2) + \cdots$

(*periodic* but *non-simply harmonic* due to the presence of *higher harmonics*, or *overtones*: $\omega, 2\omega, 3\omega, \ldots$; ω depends on both the physical constitution (parameters) of the system [as in (i) and (iii), below] and on the *initial conditions* of its motions [as in (iv), below]). (8.14.36)

Motion: *multiply harmonic* and *singly periodic*.

(iii) The free vibrations of a *linear, n-DOF* system [one with elastic potential equal to $(1/2)({k_{11}q_1}^2 + 2k_{12}q_1q_2 + {k_{22}q_2}^2 + \cdots + {k_{nn}q_n}^2)$: positive definite] have the form (assuming no degeneracies!):

$$q_k = \sum c_{kl}\cos(\omega_l t + \delta_l) \qquad [c_{kl} = \text{amplitudes},\ \delta_l = \text{phase constants};\ k,\ l = 1, \ldots, n]$$

(*simply harmonic* but with n intrinsic (natural) frequencies, or “modes of vibration” ω_l; i.e., no overtones). (8.14.37)

Motion: *simply harmonic* and *multiply periodic*; an n-dimensional Lissajous figure in q-space.

(iv) The free vibrations of a *nonlinear, n-DOF* system (one whose elastic potential contains terms of the *third* and *higher* order in the q_k's) have the following mutually equivalent forms of multiple Fourier series [infinite r-ple sums $\boldsymbol{s} \equiv (s_1, \ldots, s_r)$]:

$$q_k = \sum \ldots \sum c_{k,s}\cos\left[(s_1\omega_1 + \cdots + s_r\omega_r)t + \delta_s\right] \qquad (8.14.38a)$$

$$= \cdots$$

$$= \sum \ldots \sum \left\{A_{k,s}\cos\left[2\pi(s_1w_1 + \cdots + s_rw_r)\right] + B_{k,s}\sin\left[2\pi(s_1w_1 + \cdots + s_rw_r)\right]\right\} \qquad (8.14.38b)$$

$$= \sum \ldots \sum \left\{(1/2)(A_{k,s} - iB_{k,s})\exp\left[2\pi i(s_1w_1 + \cdots + s_rw_r)\right] + (1/2)(A_{k,s} + iB_{k,s})\exp\left[-2\pi i(s_1w_1 + \cdots + s_rw_r)\right]\right\} \qquad (8.14.38c)$$

$$= \sum \ldots \sum C_{k,s}\exp\left[2\pi i(s_1w_1 + \cdots + s_rw_r)\right] \qquad (8.14.38d)$$

$$= \sum \ldots \sum D_{k,s}\exp\left[2\pi i(s_1\nu_1 + \cdots + s_r\nu_r)t\right] \qquad (8.14.38e)$$

$$= \sum \ldots \sum D_{k,s}\exp\left[i(s_1\omega_1 + \cdots + s_r\omega_r)t\right]. \qquad (8.14.38f)$$

Here:

• In (8.14.38a–c), the summations extend over all possible positive and negative but integral values of the integers $\boldsymbol{s} \equiv (s_1, \ldots, s_r)$, from 0 to $+\infty$; while in

(8.14.38d–f) they extend from $-\infty$ to $+\infty$. [We may assume, with no loss of generality, that $f \equiv s_1\omega_1 + \cdots + s_r\omega_r > 0$; because a term in f, in (8.14.38), can be combined with one with $-f$, and therefore the number of terms for which $f < 0$ can be reduced by half.]

- $r \equiv n - m \leq n$ [m = number of degeneracies ($\leq n-1$), r = number of independent frequencies].
- The series of equations (8.14.38) combine the structures of both (8.14.36) (*nonlinearity* $\rightarrow$ *overtones*: $s_k\omega_k$) and (8.14.37) (*several DOFs* $\rightarrow$ *combination tones*: $s_1\omega_1 + \cdots + s_r\omega_r$); and that is why they consist of an (r) ple-infinity of terms.
- The ω's, known as "intrinsic vibration frequencies," are *constants* whose values depend on *both the physical constitution of the system and the initial conditions of its motions*; but they are not frequencies in the ordinary sense of the term, that is like ω in (8.14.35), (8.14.36): the system does not return to its original configuration after a time $\tau_k = 2\pi/\omega_k$ $(k = 1, \ldots, n)$.

Motion: *multiply harmonic* and *multiply* (or *conditionally*, or *occasionally*) *periodic*; that is, superposition of r periodic motions of different frequencies, each consisting of an infinite number of overtones; an n-dimensional Lissajous figure in q-space. If, for certain values of the constants of integration (initial conditions) and/or the coefficients (parameters) of the equations of motion, $m = n - 1 \Rightarrow r = 1$, the motion (8.14.38a–f) degenerates into the multiply harmonic and singly periodic case (ii), eq. (8.14.36); and that is the reason for the adjective "conditionally."

Finally, if, in eqs. (8.14.38), we replace $(s_1\omega_1 + \cdots + s_r\omega_r)\,t$ with $s_1x_1 + \cdots + s_rx_r$, we obtain the generalization of a Fourier series to a function $q_k = q_k(x_1, \ldots, x_r)$, where the x's range over a generalized unit cube in x-space.

In sum: (i) the adjective *Fourier* series refers to the presence of a, generally, infinite number of higher harmonics, originating from the same fundamental frequency; and it is the result of the nonlinearity; (ii) whereas the adjectives *singly/multiply* periodic series refer to the number of independent frequencies present, and are the result of the number of DOFs; that is

$$\begin{aligned}&\textit{linear (nonlinear)} \rightarrow \textit{harmonic (overtones)}\\ &\textit{one DOF (several DOF)} \rightarrow \textit{singly (multiply) periodic};\end{aligned}$$

and the corresponding frequencies are

$$\textit{fundamental frequency} \qquad \nu = \partial E/\partial J_k \tag{8.14.39a}$$

$$\textit{overtones} \qquad \nu = s_k(\partial E/\partial J_k) \tag{8.14.39b}$$

$$\textit{combination tones} \qquad \nu = \sum s_k(\partial E/\partial J_k). \tag{8.14.39c}$$

The systems encountered in celestial mechanics and the old quantum theory were both nonlinear and had several DOFs; that is why their periodic motions (orbits) were expressed as multiple Fourier series.

HISTORICAL

It was N. Bohr who, with his famous "principle of correspondence" (late 1910s – early 1920s), established the quantum counterparts of eqs. (8.14.39) for the frequencies of the spectra of atomic systems, and thus prepared the way for Heisenberg's invention of modern quantum mechanics that followed soon thereafter (1925–1927).

8.15 ADIABATIC INVARIANTS

Historical Background

Roughly, adiabatic invariants (AI), or parameter invariants, of a periodic system, are quantities that remain essentially constant, or invariant, when *the system parameters change very slowly* relative to its periods. These quantities have played a key role in both classical (Boltzmann) and older quantum (Ehrenfest, Burgers, et al.) mechanics {see, for example, Bierhalter [1981(a), (b), 1982, 1983, 1992], Papastavridis [1985(a)], Polak (1959, 1960); also, recall introductory examples/problems on this topic in §7.9 of this book.} But also, recently, AI have become important in problems of charged particles in magnetic fields, and modern nonlinear dynamics. [See, for example, Lichtenberg (1969), Lichtenberg and Lieberman (1992), Percival and Richards (1982). For a detailed treatment, see Bakay and Stepanovskii (1981).]

Let us consider, with no loss in generality, a mechanical system S that is completely describable by the Hamiltonian

$$H = H(q, p; c), \tag{8.15.1}$$

where, with the usual notations, $q \equiv (q_1, \ldots, q_n)$, $p \equiv (p_1, \ldots, p_n)$; and the additional special *parameters* $c = c(t) \equiv \big(c_1(t), \ldots, c_m(t)\big) \equiv (c_1, \ldots, c_m) \equiv (c_\alpha)$ characterize the external and/or internal kinematico-inertial structure of S (e.g., length or mass of bob of a mathematical pendulum), and/or strength of the *external* field(s) of force in which S may be immersed.

REMARK

From a mechanistic viewpoint of thermodynamics, system coordinates are divided into *two* distinct kinds: (i) *macroscopic*, or *controllable,* whose variations produce *visible* changes to the system and flows of *mechanical* energy ΔW_c in/out of it (see below); and (ii) *molecular*, or *uncontrollable*, whose unceasing changes become perceptible only as energy going in/out of the system in the form of *heat* ΔQ (see below). [See also Brillouin (1964, pp. 231–245) and Bryan (1891–2, 1903).]

The earlier m c's classify as controllable and are treated as additional Lagrangean coordinates, constrained to remain constant during certain motions and vary in certain ways in others. Now, since, in general [recalling (8.2.14); see also (8.15.5) below],

$$dH/dt = \partial H/\partial t = \sum (\partial H/\partial c_\alpha)(dc_\alpha/dt) \qquad (\alpha = 1, \ldots, m), \tag{8.15.2}$$

if the c_α are constant ("turned off"), the system is closed and its generalized energy H is conserved; whereas if they are variable ("turned on"), the system has become open and H is no longer constant. In the latter case [i.e., $H = H(t, q, p)$], no general and exact methods are available for the analysis of motion. However, for some special cases of variation of the c's it is possible to find other energetic quantities that are conserved, exactly or approximately. Among the most interesting such cases are the two extremes of *very slow* (*adiabatic*) and *very fast* (or *parametric*) variations of the c's, relative to some characteristic time interval of the unperturbed (here, conservative) system. Below, we examine in some detail the adiabatic case; for the rapid case, see, for example, Forbat (1966, pp. 189–193), Landau and Lifshitz (1960, pp. 93–95), Percival and Richards (1982, pp. 153–157, 161–162).

We assume that initially the c_α are turned off and the system oscillates with the single frequency $\nu(= 1/\tau,\ \tau = \text{period})$. Then, as a result of some external energy-supplying agency, the c_α are turned on and begin to vary (i) *erratically*, or randomly (i.e., their variations are not systematically correlated to the oscillation of the system; namely, they are not in phase with that motion—no resonances), and (ii) *very slowly relative to* τ:

$$dc/dt \ll c/\tau, \qquad \text{or} \qquad \tau(dc/dt) \ll c; \tag{8.15.3}$$

or

$$dc/dt = (dc/d\tau)(d\tau/dt) \equiv c'\varepsilon = (\textit{finite})\ (\textit{small}) = \textit{small}; \tag{8.15.3a}$$

that is, the parameter changes, being small fractions of their original constant values, are spread over a large number of oscillations; or, equivalently, *within a period* τ *these parameters may be considered constant*; for example, the mass of the bob of an oscillating mathematical pendulum varying slowly by picking up dust from its environment. [In the earlier-mentioned rapid case, the period (frequency) of the external disturbance is small (large) relative to the period (frequency) of the undisturbed system; or, generally, relative to a time interval during which the motion of the latter changes appreciably.] If the system can still oscillate (an example to the contrary is an axially loaded and transversely oscillating "beam–column" whose adiabatically varying axial load reaches the critical value for buckling, and hence reduces the fundamental frequency of the beam to zero; i.e., no motion), our task consists in:

(i) Calculating its new frequency (frequencies) $\nu + \Delta\nu$, or period(s):

$$\tau + \Delta\tau = 1/\nu + \Delta(1/\nu) = 1/\nu + (-1/\nu^2)\,\Delta\nu, \tag{8.15.4}$$

in terms of these $c \to c + \Delta c$ changes; and, since its energy is no longer constant,

(ii) Finding out if there exist new "adiabatic constants of motion," or *adiabatic invariants*. That such quantities occur can be argued as follows: by (8.15.2) we have $dH \sim dc$, and so there exists some combination(s) of H and the c's that *remains constant during the motion*, replacing the energy integral of the constant parameter system.

The classic example here is the oscillating mathematical pendulum whose length l (and/or mass m) is varied very slowly by some external agency. It turns out that, for small (linear) and undamped oscillations, the ratio of the pendulum's energy to its frequency is an *adiabatic invariant*; and this also allows us to relate the adiabatic change Δl to the amplitude and period changes $\Delta\tau$.

The Fundamental Theory

Let us quantify these ideas. Below, we present three treatments, in increasing order of difficulty: (i) *Energetic* (one DOF, single frequency), (ii) *integral variational* (n DOF; first singly periodic, then multiply/conditionally periodic motion), and (iii) *action–angle variables* (n DOF, multiply/conditionally periodic motion).

(i) Energetic Derivation

Let us assume here, for algebraic simplicity, that $m = 1$ (i.e., $c_1 \equiv c$), and that the kinetic energy is *homogeneous* quadratic in $\dot{q}$ (or p), so that $H = \textit{total energy} \equiv E$.

If $H = H[q(t), p(t); c(t)] \equiv H(q, p; c)$, then we obtain, successively,

$$\begin{aligned} dH/dt &= (\partial H/\partial q)(dq/dt) + (\partial H/\partial p)(dp/dt) + (\partial H/\partial c)(dc/dt) \\ &= (\partial H/\partial q)(\partial H/\partial p) + (\partial H/\partial p)(-\partial H/\partial q) + (\partial H/\partial c)(dc/dt) \end{aligned}$$

(by Hamilton's equations)

that is,

$$dE/dt = (\partial H/\partial c)(dc/dt) \quad (= \partial H/\partial t). \tag{8.15.5}$$

Averaging (8.15.5) over a complete cycle (of libration or rotation), while noting that, by (8.15.3), we can treat dc/dt as a constant, we obtain [with the customary notation $\langle \ldots \rangle \equiv$ *time average of* $(\ldots)$]

$$\langle dE/dt \rangle = \tau^{-1} \int_0^\tau (\partial H/\partial c)(dc/dt)\, dt, \tag{8.15.6}$$

or, since

$$dq/dt = \partial H/\partial p \;\Rightarrow\; dt = dq\big/(\partial H/\partial p) \;\Rightarrow\; \tau = \int_0^\tau dt = \oint dq\big/(\partial H/\partial p),$$

we obtain

$$\langle dE/dt \rangle = \left\{ \oint (\partial H/\partial c)/(\partial H/\partial p)\, dq \bigg/ \oint [1/(\partial H/\partial p)]\, dq \right\} (dc/dt). \tag{8.15.7}$$

Let us transform (8.15.7) further. Solving the energy equation

$$H(q, p; c) = E \quad (= \textit{constant}, \text{if } \; c = \textit{constant}), \tag{8.15.8}$$

for the momentum p, we obtain

$$p = p(q, E; c), \tag{8.15.8a}$$

and, inserting this back into (8.15.8), we can rewrite the latter in the convenient form

$$H\big[q, p(q, E; c); c\big] = E. \tag{8.15.8b}$$

Next, differentiating (8.15.8b) partially with respect to c and E, which for the integrations involved in (8.15.6, 7) must be considered as *two independent and constant parameters,* we obtain, respectively,

$$(\partial H/\partial p)(\partial p/\partial c) + \partial H/\partial c = \partial E/\partial c = 0 \;\Rightarrow\; \partial p/\partial c = -(\partial H/\partial c)\big/(\partial H/\partial p), \tag{8.15.8c}$$

$$(\partial H/\partial p)(\partial p/\partial E) = \partial E/\partial E = 1 \;\Rightarrow\; \partial p/\partial E = 1\big/(\partial H/\partial p). \tag{8.15.8d}$$

As a result of (8.15.8c, d), eq. (8.15.7) transforms to

$$\langle dE/dt \rangle = -\left[\oint (\partial p/\partial c)\, dq \bigg/ \oint (\partial p/\partial E)\, dq \right] (dc/dt), \tag{8.15.8e}$$

and, rearranging this, we obtain

$$\oint \left[(\partial p/\partial E)\langle dE/dt\rangle + (\partial p/\partial c)(dc/dt)\right] dq = 0; \tag{8.15.8f}$$

and this, recalling the action variable definition (§8.14), states simply that

$$dJ/dt = 0, \qquad J \equiv \oint p(q; E, c)\, dq\Big|_{\text{given } E,c} = J(E, c). \tag{8.15.9}$$

In words: If the oscillatory motion of a system is altered very slowly relative to its period, either by gradually varying the external field of force or by slowly modifying the system's physical constitution, then, *during such adiabatic changes, the action variable remains constant*; it is an adiabatic invariant. [Or, equivalently, *the ratio of twice its average kinetic energy divided by its frequency* remains constant — see (8.15.16–19) and ex. 8.15.1.] The preceding arguments indicate that for an adiabatic invariant to exist, the period (frequency) *must remain finite* (*nonzero*); *if* $\tau \to \infty$ ($\nu \to 0$), *the argument fails.*

One might have thought that, under such an external influence, J would depend on the precise moment at which c ceased to vary — that is, $dc/dt = 0$ (and the system became, again, truly periodic) — but, as shown below, the change of the action over a (possibly very long) time interval Δt, during which c changes adiabatically (but without causing a resonance), is $\Delta J \sim \langle dc/dt\rangle^2 \Delta t$.

From the above, it also follows that

$$\partial J/\partial E = \oint (\partial p/\partial E)\, dq = \oint dq\Big/(\partial H/\partial p) = \int_0^\tau dt = \tau = 1/\nu; \tag{8.15.10}$$

in complete agreement with §8.14.

Geometrical Interpretation. Let us assume, for concreteness, that the periodic motion of the system is a *libration*. Then, as explained in §8.14, the action variable *J equals the area enclosed by the closed curve representing that motion,* in (q, p) space (fig. 8.22).

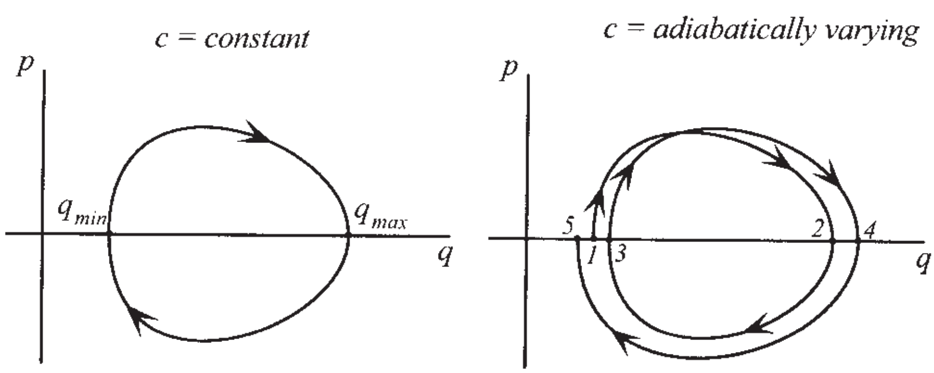

Figure 8.22 Geometrical interpretation of adiabatic invariance in phase space (1 DOF, libration): $p = \pm(2m)^{1/2}[E - V(q; c)]^{1/2} = p(q; E, c)$. In the adiabatic case, the area enclosed by the *open* path of each cycle (say, $1 \to 2 \to 3$) remains constant; although it changes shape. Then, J equals the area enclosed by a hypothetical closed trajectory obtained by fixing c at the beginning of each cycle.

Hence, by the well-known plane Green–Stokes theorem, also:

$$J = \oint p\,dq = -\oint q\,dp = \iint dq\,dp = \textit{adiabatic invariant}. \tag{8.15.11}$$

[Generally, if $I = f(q, p, c, t)$ is a first integral of the equations of motion, then its total change over the duration of the adiabatic variation process, say from t_1 to t_2, will be

$$\Delta I = \int_{t_1}^{t_2} (\partial f/\partial c)(dc/dt)\,dt \;=\; \langle \partial f/\partial c\rangle\,\Delta c, \tag{8.15.11a}$$

were, due to the adiabaticity, the time average can be taken over the *unvaried* motion. Hence, if the integral $I = f$ is independent of c, it is an adiabatic invariant. See also action–angle variable proof below.]

(ii) Integral Variational Derivation

[The following is due to Boltzmann (late 19th century, classical case) and his student Ehrenfest (1910s, classical $\to$ quantum case). We follow Schaefer (1937, pp. 58–66); see also Brillouin (1964, pp. 231–243), De Donder (1924, 1925), Jeans (1925, pp. 409–417), and Juvet (1926, pp. 134–144).] Let us reconsider the earlier system with Hamiltonian given by (8.15.1) and, hence, Lagrangean of the same form:

$$L = L(q, \dot q; c), \tag{8.15.12}$$

in the following two *continuous* and *finite* (but not yet assumed periodic) motions:

(a) A fundamental orbit I lasting from an *initial* time t_1 to a *final* t_2, and characterized by $q = q(t)$ and $c = \textit{constant along } I \equiv c(I)$; and
(b) A neighboring orbit $II = I + \Delta(I)$, lasting from $t_1 + \Delta t_1$ to $t_2 + \Delta t_2$, and characterized by $q + \Delta q$ and $c + \Delta c = \textit{constant along } II \equiv c(II)$.

Now, using the analytical results and notation of §7.9, and treating the parameters $c_\alpha(\alpha = 1, \ldots, m)$ as *additional* Lagrangean coordinates, it is not hard to show that, under such a $I \to II$ variation, and since, along both these orbits, Lagrange's equations of motion for the q's hold, to the first noncontemporaneous order,

$$\begin{aligned}\Delta A_H &\equiv \Delta \int_{t_1}^{t_2} L\,dt\\ &= \int_{t_1}^{t_2} \sum (\partial L/\partial c_\alpha)\,\Delta c_\alpha\,dt + \Big\{\sum p_k\,\Delta q_k - h\,\Delta t\Big\}_{t_1}^{t_2}\end{aligned} \tag{8.15.13}$$

(notice the *additional* Δc-sum) where (§3.9)

$$h \equiv \sum (\partial L/\partial \dot q_k)\dot q_k - L = \text{generalized energy (Hamiltonian) in Lagrangean variables}$$

$$= h(c) = h(I) = \textit{constant} \equiv h, \tag{8.15.13a}$$

$$= h(c + \Delta c) \equiv h(II) = \textit{constant} \equiv h + \Delta h. \tag{8.15.13b}$$

Next, let I be a completely degenerate periodic motion, with the single period τ and frequency ν, and let, in eq. (8.15.13), $t_1 = 0$, $t_2 = \tau$ (the multiply/conditionally periodic case is discussed later). With

$\partial L/\partial c_\alpha \equiv C_\alpha$: *Lagrangean force with which the system reacts to a change of its parameter* c_α, (8.15.14a)

and, hence,

$-C_\alpha \equiv -\partial L/\partial c_\alpha$: *External force that, at every instant, must be acting on the system to keep* c_α *constant*, (8.15.14b)

so that

$\sum (\partial L/\partial c_\alpha)\, \Delta c_\alpha = \sum C_\alpha\, \Delta c_\alpha \equiv \Delta W_c$: *First-order work done by the system to its environment, during a* $c \to c + \Delta c$ *change*, (8.15.14c)

and analogously for $-\Delta W_c$, and with the notation $\int_0^\tau \ldots \equiv \oint \ldots$, eq. (8.15.13) becomes

$$\Delta \oint L\, dt = \oint \Delta W_c\, dt + \Big\{\sum p_k\, \Delta q_k - h\, \Delta t\Big\}_0^\tau. \tag{8.15.14d}$$

If, further, the neighboring orbit II is also (singly) periodic with period

$$\tau + \Delta\tau = \tau + \Delta(1/\nu) = \tau + (-1/\nu^2)\, \Delta\nu \tag{8.15.14e}$$

(a fact that clearly indicates why we need a *variable time-endpoints* treatment), then choosing, with no loss in generality, $\Delta t_1 = 0$, and since, then, $\Delta t_2 = \Delta\tau$, $h(I) = constant \equiv h$, $\{\sum p_k\, \Delta q_k\}_0^\tau \equiv 0$ (due to periodicity), reduces (8.15.14d) to

$$\Delta \oint L\, dt = \oint \Delta W_c\, dt - h\, \Delta\tau, \tag{8.15.14f}$$

or, equivalently, in terms of mean/averaged values of their integrands,

$$\begin{aligned}
&\Delta(\langle L\rangle \tau) = \langle \Delta W_c\rangle \tau - h\, \Delta\tau \\
&\qquad \{\text{or, adding and subtracting } \tau\, \Delta h \equiv \tau[h(II) - h(I)] \equiv \tau[h(c + \Delta c) - h(c)]\} \\
&\qquad \equiv \langle \Delta W_c\rangle \tau - \Delta(h\, \tau) + \tau\, \Delta h,
\end{aligned} \tag{8.15.14g}$$

or, rearranging,

$$\Delta\big[(\langle L\rangle + h)\tau\big] = \big(\Delta h + \langle \Delta W_c\rangle\big)\tau. \tag{8.15.14h}$$

But, (i) $\langle L\rangle = \langle T - V\rangle = \langle T\rangle - \langle V\rangle$, and (assuming T: quadratic *homogeneous* in $\dot{q}$ or p)

$$h = T + V = \langle T + V\rangle = \langle T\rangle + \langle V\rangle = constant, \tag{8.15.14i}$$

so that

$$\langle L\rangle + h = 2\langle T\rangle; \tag{8.15.14j}$$

and (ii) by the *first law of thermodynamics*: if

$$\Delta Q = \textit{Heat added to the system during the transition } I \to II, \tag{8.15.14k}$$

then

$$\Delta Q + (-\Delta W_c) = \Delta h; \tag{8.15.14l}$$

that is,

Heat supplied to system + Work done to system to violate its constraint (c = constant) = Increase of energy of system.

As a result of (8.15.14j, l), eq. (8.15.14h) assumes the *Boltzmann–Clausius form*:

$$\Delta\big[2\langle T\rangle\tau\big] = \tau\,\Delta Q. \tag{8.15.15}$$

This result is exact. If we, now, assume that the transition $I \to II$ is adiabatic (i.e., $\Delta Q = 0$), then (8.15.15) immediately leads us to the famous *adiabatic theorem of Ehrenfest*:

$$\Delta\big[2\langle T\rangle\tau\big] = \Delta\big[2\langle T\rangle/\nu\big] = 0. \tag{8.15.16}$$

[Physically the process must be (i) *fast* enough so that our system cannot exchange heat with its environment (i.e., it remains thermally insulated); and (ii) *slow* compared with other processes that lead to thermal equilibrium. For example, in order that the expansion of a gas in a cylinder be adiabatic, the velocity of its outward moving piston must be slow only relative to the velocity of sound in the gas; that is, the piston may move quite fast!

For a precise definition of adiabaticity, see books on thermal physics, and so on: for example, Landau and Lifshitz (1980, pp. 38–41).]

Other, equivalent, forms of the theorem are

$$[2\langle T\rangle/\nu]_I = [2\langle T\rangle/\nu]_{II}\text{: } \textit{Adiabatic invariant}; \tag{8.15.17}$$

$$J \equiv 2\langle T\rangle/\nu = 2\oint T\,dt = \oint\Big(\sum p_k\dot{q}_k\Big)\,dt$$
$$= \sum\left(\int_0^{1/\nu}(p_k\dot{q}_k)\,dt\right)\text{: } \textit{Adiabatic invariant}. \tag{8.15.18}$$

Specialization. If $2\langle T\rangle = h = E$ (i.e., if $\langle T\rangle = \langle V\rangle$; e.g., linear harmonic oscillations), eqs. (8.15.16, 17) reduce to the "*Planck form*":

$$E/\nu\text{: } \textit{adiabatic invariant}. \tag{8.15.19}$$

Multiply/Conditionally Periodic System

So far, we have assumed that our *n-DOF* system is *completely separable and completely degenerate* (§8.14) and has the single period τ; that is, there exist $n-1$ independent equations of the form (8.14.31)

$$i'_1\nu_1 + i'_2\nu_2 + \cdots + i'_n\nu_n = 0, \tag{8.15.20}$$

where the i'_k are integers and the ν_k are the fundamental frequencies of its individual DOFs; or, equivalently,

$$i_1(1/\nu_1) = i_2(1/\nu_2) = \cdots = i_n(1/\nu_n) = 1/\nu \equiv \tau, \tag{8.15.21}$$

or, with $\tau_k = 1/\nu_k$,

$$i_1\tau_1 = i_2\tau_2 = \cdots = i_n\tau_n = \tau, \tag{8.15.21a}$$

where the i_k are positive integers (naturals). Then, (8.15.18) reduces further to

$$\begin{aligned}\sum\left(\int_0^{i_k/\nu_k}(p_k\dot{q}_k)\,dt\right) &= \sum\left(i_k\int_0^{1/\nu_k}(p_k\dot{q}_k)\,dt\right)\\ &= \sum i_k\,J_k\text{: } \textit{adiabatic invariant},\end{aligned} \tag{8.15.22}$$

or, since $i_k = \nu_k/\nu = \tau\,\nu_k$ $(\nu \neq 0)$, finally,

$$\sum \nu_k J_k\text{: } \textit{adiabatic invariant}, \tag{8.15.23}$$

in agreement with ex. 8.14.9.

If, however, our system is only *conditionally/multiply periodic*—that is, if at least one or more of (8.15.20, 21) do *not* hold, and, instead, are replaced with equations of the form

$$I_1\nu_1 + I_2\nu_2 + \cdots + I_n\nu_n = \varepsilon, \tag{8.15.24}$$

where the I_k are, generally, *large integers* and ε is arbitrarily small, then a "quasi period" τ can be defined by

$$\tau = 1/\nu = i_1/\nu_1 + \varepsilon_1 = i_2/\nu_2 + \varepsilon_2 = \cdots = i_n/\nu_n + \varepsilon_n, \tag{8.15.25a}$$

$$= i_1\tau_1 + \varepsilon_1 = i_2\tau_2 + \varepsilon_2 = \cdots = i_n\tau_n + \varepsilon_n, \tag{8.15.25b}$$

where the ε_k are arbitrarily small (in order to achieve any required degree of accuracy) and the boundary terms $\{\sum p_k\,\Delta q_k\}_0^\tau$ can be made as small as needed. Hence, *a conditionally periodic system can also be brought as close as desired to a purely (singly) periodic one,* so that (8.15.22, 23) still hold. [More precisely: $\sum(\int_{t_1}^{t_2}(p_k\dot{q}_k)\,dt) = \textit{adiabatic invariant}$, where $t_2 = i_k/\nu_k + \varepsilon_k$, $t_1 = 0$.]

• If the original system is completely separable, then it is reduced to n subsystems, each with one DOF and one frequency. If, further, these frequencies, $\nu_1, \ldots, \nu_n$, are incommensurate—that is, independent—then our *non-degenerate* system has n *independent* adiabatic invariants:

$$J_k \equiv \oint p_k\,dq_k = \textit{adiabatic invariant} \qquad (k = 1, \ldots, n). \tag{8.15.26a}$$

• But if our system is m-fold degenerate, or $(n-m)$-periodic, then it has only $n-m$ independent adiabatic invariants; namely, certain combinations of its n J_k's.

Hence the rule: There exist as many independent adiabatic invariants as there are independent (incommensurate) frequencies; that is, $n-m$ $(0 \leq m \leq n-1)$. For example, the spatial linear and isotropic oscillator has three mutually equal frequencies (i.e., $n = 3$, and since $\nu_x = \nu_y = \nu_z$, $m = 2$) and, therefore, only *one* adiabatic invariant:

$$J_x + J_y + J_z = \oint p_x\, dq_x + \oint p_y\, dq_y + \oint p_z\, dq_z = \textit{adiabatic invariant}. \tag{8.15.26b}$$

(iii) Action–Angle Variables Derivation

[The following is due to Burgers (1917) and Krutkow (1919); also Bohr (1918, who calls it *theorem of mechanical transformability*). Here, we follow the excellent summary of these proofs given by Birtwistle (1926, pp. 76–78). See also Born (1927, pp. 56–59, 95–98), Haar (1971, pp. 139–144), Saletan and Cromer (1971, pp. 259–263). It may be omitted in a first reading.]

To simplify the discussion, let us assume, with no loss in generality, that our n-DOF system contains only *one* adiabatically varying parameter, $c = c(t)$. As we have seen in §8.10, in the *constant* parameter case, the generating function of the canonical transformation $(q, p) \to (q' = w,\ p' = J)$ is $A_o(q, J)$ $[= F_2(q, p')]$. In the adiabatic case, we can think of c as an additional system coordinate unrelated to the motion; that is, unrelated to the q's. Hence, the reduced action A_o *becomes the explicitly time-dependent function* $A_o[q, J; c(t)]$, so that

$$w_k = \partial A_o(q, J, c)/\partial J_k, \qquad p_k = \partial A_o(q, J, c)/\partial q_k. \tag{8.15.27a}$$

Here, the Hamiltonian transformation $H \to H' (\neq H)$ is

$$H = H(J;\, c) = E(J;\, c) \ \to\ H' = H + \partial A_o/\partial t = E + (\partial A_o/\partial c)(dc/dt), \tag{8.15.27b}$$

and, therefore, with $A_o = A_o[q(w, J; c), J; c] \equiv A_o(w, J; c)$ $[\Rightarrow H' = H'(w, J; c)]$, the Hamiltonian equations of motion of the w_k's and J_k's are

$$\begin{aligned} dw_k/dt &= \partial H'/\partial J_k = \partial H/\partial J_k + \partial/\partial J_k(\partial A_o/\partial t) \\ &= \partial H/\partial J_k + \partial/\partial J_k\big[(\partial A_o/\partial c)(dc/dt)\big] \\ &= \nu_k + \big[\partial/\partial w_k(\partial A_o/\partial c)\big](dc/dt), \end{aligned} \tag{8.15.27c}$$

$$\begin{aligned} dJ_k/dt &= -\partial H'/\partial w_k = -\partial H/\partial w_k - \partial/\partial w_k(\partial A_o/\partial t) \\ &= 0 - \partial/\partial w_k\big[(\partial A_o/\partial c)(dc/dt)\big] = -\big[\partial/\partial w_k(\partial A_o/\partial c)\big](dc/dt). \end{aligned} \tag{8.15.27d}$$

Equivalently, instead of the above choice $A_o(q, J) \to A_o[q, J;\, c(t)]$ for generating function, we try the form $W(q, w, t) \equiv A(q, w, t)$ $[= F_1(t, q, q')]$. Indeed, recalling (8.14.23b, c), we have

$$\begin{aligned} \delta A_{oo} &\equiv \delta\Big(A_o - \sum w_k J_k\Big) \\ &= \sum \big[(\partial A_o/\partial q_k)\,\delta q_k + (\partial A_o/\partial J_k)\,\delta J_k\big] - \sum \delta(w_k\, J_k) \\ &= \sum (p_k\, \delta q_k + w_k\, \delta J_k) - \sum (\delta w_k J_k + w_k\, \delta J_k) \\ &= \sum (p_k\, \delta q_k - J_k\, \delta w_k) \\ &\Rightarrow\ p_k = \partial A_{oo}/\partial q_k, \qquad J_k = -\partial A_{oo}/\partial w_k, \end{aligned} \tag{8.15.28a}$$

and therefore (by the theory of §8.8 and §8.10) the Hamiltonian equations of w_k and J_k are

$$dw_k/dt = \partial H'/\partial J_k, \qquad dJ_k/dt = -\partial H'/\partial w_k, \qquad \text{where } H' = H + \partial A_{oo}/\partial t. \tag{8.15.28b}$$

But since $H = H(J;\, c)$ and $A_{oo} = A_{oo}[q, w;\, c(t)] \equiv A_{oo}(q, w;\, t)$, and therefore $\partial A_{oo}/\partial t = (\partial A_{oo}/\partial c)(dc/dt)$, the above yield, further,

$$dw_k\, dt = \partial H/\partial J_k + \partial/\partial J_k\big[(\partial A_o/\partial c)(dc/dt)\big] = \nu_k + \big[\partial/\partial w_k(\partial A_o/\partial c)\big](dc/dt), \tag{8.15.28c}$$

$$[\Rightarrow w_k = \nu_k(J, c)t + \gamma_k(J, c) = (\nu_{ko}t + \gamma_{ko}) + (\nu_{k1}t^2 + \gamma_{k1}t)(dc/dt) + \cdots]$$

$$\begin{aligned} dJ_k/dt &= -\partial H/\partial w_k - \partial/\partial w_k(\partial A_{oo}/\partial t) \\ &= 0 - \partial/\partial w_k\big[(\partial A_{oo}/\partial c)(dc/dt)\big] = -\big[\partial/\partial w_k(\partial A_{oo}/\partial c)\big](dc/dt), \end{aligned} \tag{8.15.28d}$$

or, finally, with the simplifying notation $\Phi \equiv \partial A_{oo}/\partial c = \Phi[q(w, J, c), J, c] = \Phi(w, J, c)$,

$$dJ_k/dt = -(\partial\Phi/\partial w_k)(dc/dt). \tag{8.15.28e}$$

Integrating, next, (8.15.28d, e) over a long time interval $\Delta t \equiv t_2 - t_1$, we obtain

$$\Delta J_k \equiv J_k(t_2) - J_k(t_1) = -\int_{t_1}^{t_2} (\partial\Phi/\partial w_k)(dc/dt)\, dt. \tag{8.15.29a}$$

Now, since A_{oo} *is periodic in each of the* w_k*'s with period 1* [(8.14.23b ff.)], so is $\partial A_{oo}/\partial c$; that is, $\Phi = \Phi(w, J, c)$ $[\rightarrow \Phi(w, J, t)]$. Therefore, we can represent it as the following multiply periodic Fourier series [(8.14.24f–j), with a *single* $\sum$ sign standing for all summations, for simplicity]:

$$\sum D_{k,\boldsymbol{s}}(J, c)\exp(2\pi i\boldsymbol{s}\cdot\boldsymbol{w}), \tag{8.15.29b}$$

where, as earlier, $\boldsymbol{s} \equiv (s_1, \ldots, s_n)$ are positive or negative integers, or zero; ranging from $-\infty$ to $+\infty$,

$$\boldsymbol{w} \equiv (w_1, \ldots, w_n), \qquad \boldsymbol{s}\cdot\boldsymbol{w} \equiv s_1w_1 + \cdots + s_nw_n; \tag{8.15.29c}$$

and from this we readily conclude that

$$\partial\Phi/\partial w_k = -{\sum}' E_{k,\boldsymbol{s}}\exp(2\pi i\,\boldsymbol{s}\cdot\boldsymbol{w}) = -{\sum}' F_{k,\boldsymbol{s}}\exp(2\pi i\,\boldsymbol{s}\cdot\boldsymbol{\nu}t) \tag{8.15.29d}$$

(= a multiply periodic Fourier series *but without the constant term*),

such terms having been removed, from each of these series, by the $\partial/\partial w_k$-differentiations. This key step in our proof is designated by the *accent (prime) on the summation sign*. We have also made the related assumption (see below) that

$$\boldsymbol{s}\cdot\boldsymbol{\nu} \equiv s_1\nu_1 + \cdots + s_n\nu_n \neq 0 \qquad \text{(i.e., no degeneracies!)}. \tag{8.15.29e}$$

As a result of the above, (8.15.29a) becomes, successively,

$$\begin{aligned}\Delta J_k &= -\int_{t_1}^{t_2} (dc/dt)\Big[-\sum{}' F_{k,\mathbf{s}} \exp(2\pi i\, \mathbf{s}\cdot\boldsymbol{\nu} t)\Big]\, dt \\ &= -\langle dc/dt\rangle \int_{t_1}^{t_2} \Big[-\sum{}' F_{k,\mathbf{s}} \exp(2\pi i\, \mathbf{s}\cdot\boldsymbol{\nu} t)\Big]\, dt \\ &\equiv -\langle dc/dt\rangle \int_{t_1}^{t_2} G(c,t)\, dt, \end{aligned} \tag{8.15.29f}$$

since both the $F_{k,s}$'s and ν_k's depend on c. [The condition of erratic or unsymmetric variation of $c(t)$ can be satisfied by taking, for example, $dc/dt = constant$.] Next, to study the precise dependence of the above integral on c, we expand its integrand à la Taylor around $c_1 \equiv c(t)$, and thus obtain

$$\int_{t_1}^{t_2} G(c,t)\, dt = \int_{t_1}^{t_2} \big[G(c_1,t) + (c - c_1)\, G'(c_1,t) + \cdots\big]\, dt. \tag{8.15.29g}$$

Now:

(i) The *first* term of the integrand is periodic in the *constant* ν_k's (i.e., the frequencies before c began to vary). Therefore, if Δt is long enough to contain a large number of the corresponding periods, since G is periodic in time (and does not contain a constant term),

$$\int_{t_1}^{t_2} G(c_1,t)\, dt = 0. \tag{8.15.29h}$$

(ii) The *second* term,

$$\int_{t_1}^{t_2} (c - c_1)\, G'(c_1,t)\, dt, \tag{8.15.29i}$$

is of the same order (of magnitude) as

$$\int_{t_1}^{t_2} \big[(dc/\,dt)t\big]\, G'(c_1,t)\, dt, \tag{8.15.29j}$$

and that, in turn, is of the order of

$$\langle dc/dt\rangle(t_2 - t_1) \equiv \langle dc/dt\rangle \Delta t \equiv \Delta c \quad (= \textit{finite}). \tag{8.15.29k}$$

From the above, we conclude that

$$\Delta J_k = -\langle dc/dt\rangle\ (\textit{Term of order } \Delta c)\ \sim\ \langle dc/dt\rangle\, \Delta c\ =\ \langle dc/dt\rangle^2 \Delta t,$$

or, equivalently, since $\Delta J_k = \langle dJ_k/dt\rangle \Delta t$,

$$\langle dJ_k/dt\rangle \sim \langle dc/dt\rangle^2; \tag{8.15.29l}$$

and hence even if Δc is finite (after a very long period of time), it is possible to make ΔJ_k as small as desired by decreasing dc/dt; that is, the J_k's are adiabatic invariants. [The extension of this proof to several c's does not offer any difficulties; (8.15.28d) is replaced by $dJ_k/dt = -\sum [(\partial^2 A_{oo}/\partial w_k \partial c_l)]\,(dc_l/dt)$, where $l = 1, 2, \ldots, m$, and so on.]

Effect of Degeneracies on Adiabatic Invariance. The no degeneracy requirement (8.15.29e) is crucial. If an (8.14.31)-like relation

$$\boldsymbol{i} \cdot \boldsymbol{\nu} \equiv i_1 \nu_1 + \cdots + i_n \nu_n = 0 \qquad [\boldsymbol{i} \equiv (i_1, \ldots, i_n)\text{: integers}], \tag{8.15.30a}$$

exists among the original frequencies (and/or occurs at some stage of the subsequent adiabatic variation), then, for $\boldsymbol{s} = \boldsymbol{i}$, the Fourier series

$$G(c_1, t) = \left[-\sum{}' F_{k,\boldsymbol{s}} \exp(2\pi i\, \boldsymbol{s} \cdot \boldsymbol{\nu} t) \right]\Big|_{c=c_1}, \tag{8.15.30b}$$

will contain a constant term, say C; and, accordingly, eq. (8.15.29h) will be replaced by

$$\int_{t_1}^{t_2} G(c_1, t)\, dt \;=\; C\,\Delta t. \tag{8.15.30c}$$

Then we will have, instead of (8.15.29l),

$$\begin{aligned} \Delta J_k &= -\langle dc/dt \rangle\, (C\Delta t + \textit{Term of order } \Delta c) \\ &= -C\Delta c - \langle dc/dt \rangle\, (\textit{Term of order } \Delta c) \\ &= -C\Delta c = \textit{finite change}, \qquad \text{as} \qquad \langle dc/\,dt \rangle^2 \to 0; \end{aligned} \tag{8.15.30d}$$

that is, the J_k will no longer be adiabatic invariants. In such degenerate cases, as stated earlier, the number of independent adiabatic invariants equals the number of independent frequencies $(n - m)$.

[If m (8.15.30a)-like relations hold *identically*—that is, for all J's, for a certain c, then, following the method of (ex. 8.14.14), we introduce new w's and J's such that the first $n - m$ of the new frequencies $(\nu'_d;\ d = 1, \ldots, m)$ are equal to zero, while the remaining m of them $(\nu'_i;\ i = n - m, \ldots, n)$ are independent (i.e., incommensurate). Then, the constant exponents appearing in the Fourier series for A_{oo} involve only the "dependent" angle variables (w'_d), and, upon differentiation with respect to the "independent" such variables (w'_i), they disappear. It follows that at such "places of degeneration" the "independent" actions (J'_i) remain invariant; while, in general, the "dependent" ones (J'_i) do not.

If, in addition to the above cases of identical degeneration, (8.15.30a)-like relations hold for particular values of the employed J's—a case known as *accidental degeneration*—these action variables need not be invariant; unless the amplitude corresponding to (8.15.30a) also vanishes from its (8.15.29g)-like series. On this delicate topic, see also Fues (1927, p. 150; and references given therein).]

Example 8.15.1 *Adiabatic Invariant of Linear 1-DOF Oscillator.* Here, with the customary notations,

$$H = p^2/2m + m\,\omega^2 q^2/2 = H(q, p), \tag{a}$$

and therefore the energy curve in phase space, $H(q, p) = E$ (libration), is

$$\left[p/(2mE)^{1/2} \right]^2 + \left[q/(2E/m\omega^2)^{1/2} \right]^2 = 1; \tag{b}$$

that is, an ellipse with semiaxes: $(2E/m\,\omega^2)^{1/2}$ along q, and $(2mE)^{1/2}$ along p. Hence,

$$\begin{aligned} J &= \textit{area of ellipse} = \pi\left[(2E/m\,\omega^2)^{1/2} \times (2mE)^{1/2}\right] \\ &= \pi(2E/\omega) = 2\pi(E/\omega) = E/\nu = \textit{adiabatic constant}; \qquad \text{(c)} \end{aligned}$$

that is, as long as $\nu \neq 0$, under adiabatic changes, *the oscillator energy is proportional to its frequency*; as predicted by the general theory.

Example 8.15.2 *Effect of Light Damping on the Adiabatic Invariant.* Let us consider the linear 1-DOF spring–mass–damper system with equation of motion

$$m\,\ddot{q} + d\dot{q} + k\,q = 0, \qquad \text{(a)}$$

where m, d, k = *mass*, *viscous damping coefficient (constant)*, *spring constant*, respectively. Since (a) has no periodic solutions, it has no adiabatic invariants. However, as is well known from second-order differential equations, the change of variables

$$q \to q' = q\exp[(d/2m)t] \;\Rightarrow\; q = q'\exp[-(d/2m)t], \qquad \text{(b)}$$

transforms (a) to the linear *dampingless* equation (for the fictitious system described by q'):

$$m'(q')^{\cdot\cdot} + k'q' = 0, \qquad \text{(c)}$$

where
$$\begin{aligned} & m' = m, \\ & (\omega')^2 \equiv k'/m' = k/m - (1/4)(d/m)^2 = \omega^2[1 - (d^2/4mk)], \\ & \omega^2 \equiv k/m. \qquad \text{(d)} \end{aligned}$$

Clearly, (c) has periodic solutions with the single frequency $\nu' \equiv \omega'/2\pi$, and therefore adiabatically invariant action {with a' = amplitude of (b, c) = a $\exp[(d/2m)t]$}:

$$\begin{aligned} J' &= E'/\nu' = V'_{\max}/\nu' \\ &= \left[(1/2)k'(a')^2\right] = \left[(1/2)m'(\omega')^2(a')^2\right]/(\omega'/2\pi) \\ &= \pi m'\omega'\left\{a\,\exp[(d/2m)t]\right\}^2 \\ &= \pi m\left\{\omega[1 - (d^2/4mk)]^{1/2}\right\}\left\{a^2\exp[(d/m)t]\right\} \\ &= \pi\left\{ma^2\omega[1 - (d^2/4mk)]^{1/2}\right\}\exp[(d/m)t] = \textit{constant} \\ &= \pi\left\{ma^2\omega[1 - (d^2/4mk)]^{1/2}\right\} \qquad (\text{i.e., } J'|_{t=0}). \qquad \text{(e)} \end{aligned}$$

Hence, for the adiabatically *noninvariant* action of (a), we will have the following *exponential decay* variation:

$$J(t') = J(0)\exp(-kt'/m), \qquad \text{(f)}$$

where

$$t' \equiv \varepsilon\,t = \textit{slow time} \equiv (d/k)t, \qquad -(d/m)t = -(k/m)(\varepsilon\,t) \equiv -(k/m)t'. \qquad \text{(g)}$$

For an alternative treatment of a more general case, see Kevorkian and Cole (1981, pp. 271–272).

Example 8.15.3 Let us consider a particle, of mass m, in rectilinear horizontal and perfectly elastic collisional motion between two perfectly elastic and infinitely massive walls of width l, one fixed (say, the left) and one movable (the right).

(i) If both walls are *fixed* (stationary), and the particle moves with velocity v, then, clearly, its energy (neglecting gravity) and "period of collision" are, respectively,

$$E = T = (1/2)mv^2, \qquad \tau = 2l/v. \tag{a}$$

(ii) If the right wall *moves* with velocity $\dot{l}$, assumed unaffected by the repeated particle collisions, (i.e., to the right, if $\dot{l} > 0$), then, after the particle has collided with *both* walls, once, its velocity has changed from v to $v - 2\dot{l}$ [recalling definition of restitution coefficient, (4.4.1), e; here $e = 1$]; i.e., $\Delta v = -2\dot{l}$. Assuming now that $\dot{l} \ll v$; that is, the right wall moves very slowly relative to the *particle*, let us calculate the adiabatic invariant of this periodic system.

From First Principles

Choosing a time interval Δt that is very large relative to the collision period of the fixed wall case, and very small relative to the $l/\dot{l}$—that is,

$$2l/v \ll \Delta t \ll l/\dot{l}, \tag{b}$$

it is not hard to see that if one pair of such collisions changes the velocity of the particle by $-2\dot{l}$, $(v/2l)\,\Delta t$ pairs will change it by

$$\Delta v = -(v\dot{l}/l)\,\Delta t \qquad \text{(a decrease if the right wall moves outward).} \tag{c}$$

Integrating (c), we readily obtain the adiabatic invariant

$$v\,l = constant, \tag{d}$$

or, due to (a),

$$E\,l^2 = constant. \tag{e}$$

From the General Adiabatic Theory

We readily find

$$J = \oint p\,dq = \int_0^\tau (mv)\,(v\,dt) = 2mvl = constant. \tag{f}$$

These results are shown graphically in fig. 8.23.

For alternative treatments of this popular example, see, for example, Kuypers (1993, pp. 346, 535–536), Matzner and Shepley (1991, pp. 198–199), Percival and Richards (1982, pp. 142–144).

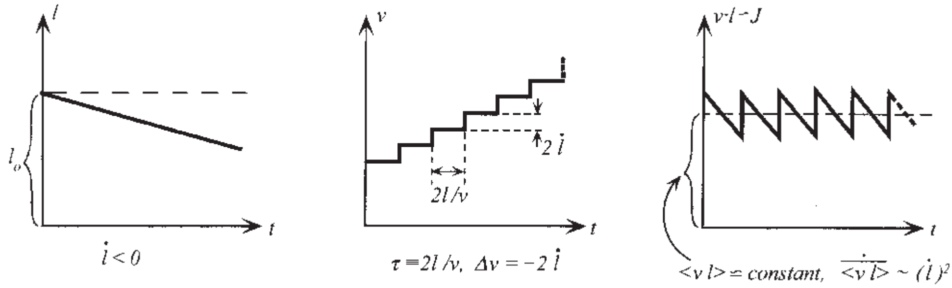

Figure 8.23 Temporal variation of wall distance $(l, \dot{l})$, particle velocity (v), and action variable $(J \sim lv)$.

Problem 8.15.1 *Adiabatic Motion of a Planar Mathematical Pendulum* (Ol'khovskii, 1970, p. 430 ff.). Consider the small angular amplitude adiabatic motions of a planar mathematical pendulum of mass m, length l, and angle with the vertical ϕ.

(i) Show that its reduced Hamilton–Jacobi equation is (with E = total energy of pendulum)

$$(dA_o/\,d\phi)^2 + m^2 g\, l^3 \phi^2 = 2m\, l^2 E. \tag{a}$$

(ii) Show that the complete solution of (a) is

$$A_o = (m^2 g\, l^3)^{1/2}\big\{(\phi/2)\,[(2E/m\,g\,l) - \phi^2]^{1/2} + (E/m\,g\,l)\arcsin\,\big[\phi/(2E/m\,g\,l)^{1/2}\big]\big\}, \tag{b}$$

and, therefore, during a complete libratory cycle of the pendulum,

$$\Delta A_o = E/\nu = J \;\Rightarrow\; E(t) = J\nu(t), \qquad \text{where } \omega^2 = g/l\,\big(= (2\pi\nu)^2\big). \tag{c}$$

(iii) Show that the average of the total energy of the pendulum, over a cycle, equals

$$\langle E\rangle = (m\,l^2/2)\langle(\dot{\phi})^2\rangle + (m\,g\,l/2)\langle\phi^2\rangle, \tag{d}$$

that is,

$$E = \langle T + V\rangle = \langle T\rangle + \langle V\rangle. \tag{e}$$

(iv) Show that

$$\langle\phi^2\rangle = {\phi_o}^2/2, \qquad \langle(\dot{\phi})^2\rangle = ({\phi_o}^2/2)\omega^2 \tag{f}$$

(ϕ_o = maximum angular amplitude), and, therefore,

$$\langle E\rangle = m\,g\,l{\phi_o}^2/2 \quad (= E). \tag{g}$$

(v) Show that

$$l^{3/4}\phi_o = \textit{adiabatic invariant}, \qquad \text{or} \qquad l^3{\phi_o}^4 = \textit{adiabatic invariant}; \tag{h}$$

or $\phi_o \sim l^{-3/4}$; that is, if l is *reduced* adiabatically by 50%, ϕ_o *increases* by 68%.

(vi) Show that under adiabatic variations,

$$dE = -(E/2l)\,dl. \tag{i}$$

Problem 8.15.2 Consider the linear oscillations of a mathematical pendulum of mass m and length l on a smooth inclined plane of angle with the horizontal χ. Show that under adiabatic changes of χ,

$$\phi_o \sim (\sin\chi)^{-1/4}, \tag{a}$$

where $\phi_o =$ angular amplitude.

HINT

In the equation of motion of the ordinary mathematical pendulum (i.e., when $\chi = \pi/2$), replace g with g sin χ. Then, the frequency becomes

$$\nu = (1/2\pi)(g/l)^{1/2}(\sin\chi)^{1/2},$$

and

$$E = \textit{maximum potential energy} \sim mgl\sin\chi{\phi_o}^2. \tag{b}$$

Problem 8.15.3 Consider a linear and undamped spring–mass oscillator of frequency

$$\nu = (1/2\pi)\,(k/m)^{1/2} \tag{a}$$

($k =$ spring "constant," $m =$ mass). Show that under adiabatic variations of k:

(i) $$E^2/k = \textit{adiabatic invariant} \quad (E = \text{total energy}); \tag{b}$$

(ii) $$ka^4 = \textit{adiabatic invariant} \quad (a = \text{oscillation amplitude}). \tag{c}$$

HINT

$$E = \textit{maximum potential energy} = ka^2/2.$$

For additional examples on adiabatic invariance, see, for example, Kotkin and Serbo [1971, chap. 13; too compact; to be read in conjunction with the mechanics volume of Landau and Lifshitz (1960)], Morton (1929), Pöschl (1949, pp. 161–163); and the examples/problems of §7.9 in this book.

8.16 CANONICAL PERTURBATION THEORY IN ACTION–ANGLE VARIABLES

[For the writing of this section, we owe a big debt to the following excellent references: Born (1927, pp. 107–110, 249–261), Dittrich and Reuter (1994, pp. 109–136), Saletan and Cromer (1971, pp. 241–247, 251–258), Tabor (1989, pp. 96–105).]

This section constitutes a concise introduction to *canonical* perturbation theory; that is, an asymptotic approximation technique based on canonical transformations and action–angle variables (§8.14). We have already treated perturbation problems via general canonical variables [variation of constants and associated averaging (§8.7, examples in §8.10)]. But, it turns out that action–angle variables, due to their special properties, are particularly well suited here; and this may explain why this topic has been so central to both the genesis of the new quantum mechanics (1920s) and modern (classical) nonlinear dynamics (1960s to the present).

One DOF

Let us begin with the first-order perturbation of a one-DOF *conservative* system; that is, $\partial H/\partial t = 0$ (*time-independent*, or *stationary state*, perturbation theory). We will assume that both its undisturbed and disturbed motions are *periodic*, and that the undisturbed one of them is known exactly; that is, after solving its unperturbed Hamilton–Jacobi (HJ) equation, say by separation of its (unperturbed) variables, we have expressed the latter (q_o, p_o) in terms of (unperturbed) action and angle variables (J_o, w_o). Its Hamiltonian H_o will, then, depend only on J_o: $H_o = H_o(q_o, p_o) = H_o(J_o)$; so that its (constant) frequency equals $\nu_o = \partial H_o/\partial J_o$ and, therefore, $w_o = \nu_o t + \gamma_o$.

Let the disturbed problem be described by the perturbed Hamiltonian $H = H_o + \varepsilon H_1 + \varepsilon^2 H_2 + \cdots$, or, more precisely, after substituting in it the unperturbed variables,

$$H = H(w_o, J_o; \varepsilon) = H_o(J_o) + \varepsilon H_1(w_o, J_o) + \varepsilon^2 H_2(w_o, J_o) + \cdots$$
$$(= \textit{unperturbed Hamiltonian} + \textit{first-order perturbation Hamiltonian}$$
$$+ \textit{second-order Hamiltonian} + \cdots), \quad (8.16.1a)$$

where

$$\varepsilon = \textit{parameter, or strength, of the perturbation}$$
$$\text{(of the order of the ratio of the disturbing agency to that already in action)} \ll 1; \quad (8.16.1b)$$

and $H(w_o, J_o; 0) = H_o(J_o)$. Since H is a known function of w_o and J_o, all the "perturbation components" H_p $(p = o \equiv 0, 1, 2, 3, \ldots)$ are known.

The series (8.16.1a) is assumed to converge for a sufficiently large domain of values of the coordinates and momenta used; and, the resulting motions are assumed to remain periodic for all values of ε in an interval of interest containing $\varepsilon = 0$.

By solution of the perturbed problem, we will understand the finding of a generating function $W_o \equiv A_o \equiv G$ [new notation is introduced in this section to avoid having too many subscripts (see below)] that transforms the original Hamiltonian coordinates into new angle–action variables

$$(q_o, p_o) \to (w, J): \qquad p_o = \partial G/\partial q_o, \qquad w = \partial G/\partial J, \quad (8.16.1c)$$

[recall §8.8, case: $F_2(q, p') \to G(q_o, J)$] or, if the original coordinate and momentum are w_o and J_o, respectively [i.e., $F_2(q, p') \to G(w_o, J) \ \Rightarrow\ \delta G = J_o\,\delta w_o + w\,\delta J$], then

$$(w_o, J_o) \to (w, J): \qquad J_o = \partial G/\partial w_o, \qquad w = \partial G/\partial J, \quad (8.16.1d)$$

and, also, is such that:

- For $\varepsilon = 0, (w, J)$ reduce to (w_o, J_o);

- The perturbed (new) coordinate q is periodic in the new angle variable w with period 1;
- The perturbed (new) Hamiltonian depends only on the *new action variable*: $H = H(J)$; that is,

$$H(q_o, p_o; 0) = H_o(J_o) = E(J_o; 0) \;\rightarrow\; H(q, p; \varepsilon) = H(J) = E(J; \varepsilon). \tag{8.16.1e}$$

Then,

$$\nu = \partial H(J)/\partial J = \partial E(J)/\partial J = \textit{new (constant) frequency}, \tag{8.16.1f}$$

$$\Rightarrow\; w = \nu t + \gamma = \textit{new angle variable}. \tag{8.16.1g}$$

Since $\partial G/\partial t = 0$, the corresponding (perturbed) HJ equation is

$$H(w_o, J_o) = H(w_o, \partial G/\partial w_o) = E(J). \tag{8.16.2a}$$

REMARK

The undisturbed motion variables w_o, J_o remain canonical in the *perturbed* motion; but without their usual angle–action behavior. Indeed, here, the corresponding equations of motion are

$$dJ_o/dt = -\partial H/\partial w_o = -\varepsilon(\partial H_1/\partial w_o) \neq 0, \tag{8.16.2b}$$

$$dw_o/dt = \partial H/\partial J_o = \partial H_o/\partial J_o + \varepsilon(\partial H_1/\partial J_o) \neq \textit{constant}; \tag{8.16.2c}$$

that is, J_o *is no longer constant*, and w_o *is no longer a linear function of time*.

Let us find the perturbational consequences of the basic equation (8.16.2a), or, more precisely,

$$H\big[w_o(w, J), J_o(w, J), \varepsilon\big] = E(J, \varepsilon). \tag{8.16.2d}$$

Expanding all functions involved there in ε-powers, we obtain

$$\begin{aligned} H(w_o, J_o) &= H_o(J_o) + \varepsilon\, H_1(w_o, J_o) + \cdots \\ &= H_o(\partial G/\partial w_o) + \varepsilon\, H_1(w_o, \partial G/\partial w_o) + \cdots, \end{aligned} \tag{8.16.3a}$$

$$E(J, \varepsilon) = E_o(J) + \varepsilon\, E_1(J) + \cdots, \tag{8.16.3b}$$

$$\begin{aligned} G(w_o, J) &= G_o(w_o, J) + \varepsilon\, G_1(w_o, J) + \cdots \\ &= w_o\, J + \varepsilon\, G_1(w_o, J) + \cdots, \end{aligned} \tag{8.16.3c}$$

since for $\varepsilon = 0$ the function G must reduce to the *identity* transformation $w_o\, J$ $(J_o = \partial G/\partial w_o = J,\; w = \partial G/\partial J = w_o)$; and where all its "perturbation components" $G_1, G_2, \ldots,$ are periodic in w_o with fundamental period 1.

[To prove this, it suffices to prove the w_o-periodicity of

$$G'(w_o, J) \equiv G(w_o, J) - w_o\, J = \varepsilon\, G_1(w_o, J) + \cdots.$$

Indeed, since (§8.12) after j cycles of q the action function increases by $j\,J$, we will have

$$\begin{aligned} G'(w_o + j, J) &= G(w_o + j, J) - (w_o + j)J = [G(w_o, J) + j\ J] - (w_o\, J + j\, J) \\ &= G(w_o, J) - w_o\, J = G'(w_o, J), \quad \text{Q.E.D.} \end{aligned}$$

Then, as eq. (8.16.3e) shows, $w = w_o +$ *periodic function of* w_o, *with fundamental period 1)*; and so q *is periodic in both* w *and* w_o.]

Next, to be able to compare the various ε-order terms of H and E [i.e., implement (8.16.2d)], we must express (8.16.3a) in terms of J, instead of J_o. To this end, first, we introduce (8.16.3c) in (8.16.1d) and expand in ε:

$$J_o = \partial G(w_o, J)/\partial w_o = J + \varepsilon\,[\partial G_1(w_o, J)/\partial w_o] + \cdots, \tag{8.16.3d}$$

$$w = \partial G(w_o, J)/\partial J = w_o + \varepsilon\,[\partial G_1(w_o, J)/\partial J] + \cdots; \tag{8.16.3e}$$

and then insert these series into (8.16.3a) and, again, expand in ε. Thus, we find, to the first order,

$$\begin{aligned} H(w_o, J_o) &= H_o\big[J + \varepsilon(\partial G_1/\partial w_o)\big] + \varepsilon\, H_1\big[w_o, J + \varepsilon\,(\partial G_1/\partial w_o)\big] \\ &= \big\{H_o(J) + \varepsilon(\partial G_1/\partial w_o)\,[\partial H_o(J)/\partial J]\big\} + \varepsilon\, H_1(w_o, J) \\ &= H_o(J) + \varepsilon\big\{H_1(w_o, J) + (\partial G_1/\partial w_o)\,[\partial H_o(J)/\partial J]\big\}, \end{aligned} \tag{8.16.3f}$$

where

$$H_o(J) = [H_o(J_o)]_{J_o=J}, \qquad H_1(w_o, J) = [H_1(w_o, J_o)]_{J_o=J}. \tag{8.16.3g}$$

Substituting the above results into (8.16.2a, d) we obtain, to the first order,

$$\begin{aligned} H_o(J) + \varepsilon\big\{H_1(w_o, J) + [\partial H_o(J)/\partial J][\partial G_1(w_o, J)/\partial w_o]\big\} \\ = E_o(J) + \varepsilon E_1(J), \end{aligned} \tag{8.16.4a}$$

and, equating the coefficients of like powers of ε, we get

$$\varepsilon^0: \qquad H_o(J) = E_o(J), \tag{8.16.4b}$$

$$\varepsilon^1: \qquad H_1(w_o, J) + [\partial H_o(J)/\partial J]\,[\partial G_1(w_o, J)/\partial w_o] = E_1(J). \tag{8.16.4c}$$

Now:

- Equation (8.16.4b) yields the *zeroth approximation* to the energy E_o: we find it by replacing J_o with J in the energy of the unperturbed motion.
- Equation (8.16.4c) is a differential equation that yields the *first approximation* to the energy E_1; and, at first sight, it gives the impression that to do this we need not only H_1, but also G_1, both functions of w_o, and the unknown but *constant* J.

However, things are not that complicated:

(i) Since [recalling (8.16.3g)]

$$\partial H_o(J)/\partial J = \big[\partial H_o(J_o)/\partial J_o\big]_{J_o=J} \;=\; \partial/\partial J\big\{[H_o(J_o)]_{J_o=J}\big\} = \nu_o(J) \tag{8.16.5a}$$

[i.e., $\nu_o(J)$ is obtained from the frequency of the unperturbed motion $\nu_o(J_o)$, by replacing in it J_o with J], (8.16.4c) can be rewritten as

$$H_1(w_o, J) + \nu_o\,\big[\partial G_1(w_o, J)/\partial w_o\big] = E_1(J); \tag{8.16.5b}$$

(ii) E_1 is constant, and H_1 is periodic in w_o *with constant term*; and

(iii) G_1 is periodic in w_o *with constant term*; that is, it is representable by the Fourier series:

$$G_1(w_o, J) = \sum g_s(J)\exp(2\pi i\, s\, w_o) \qquad (s = -\infty, \ldots, +\infty), \tag{8.16.5c}$$

and so its derivative $\partial G_1/\partial w_o$ is also periodic in w_o, *but contains no constant term*. Hence, averaging (8.16.5b) over one unperturbed period $\tau_o = 1$ (or over the unperturbed time variation), and noting that

$$\langle \partial G_1/\partial w_o \rangle = 0, \tag{8.16.5d}$$

a consequential result in our perturbation scheme, we obtain the first-order energy correction:

$$E_1(J) = \langle H_1(w_o, J)\rangle \quad \big(= \langle E_1(J)\rangle\big), \tag{8.16.5e}$$

where

$$\langle H_1(w_o, J)\rangle \equiv (1/1)\int_0^1 H_1(w_o, J)\, dw_o = \text{function of } J. \tag{8.16.5f}$$

Then, (8.16.3b) becomes

$$E(J) = E_o(J) + \varepsilon E_1(J) = H_o(J) + \varepsilon\, \langle H_1(w_o, J)\rangle; \tag{8.16.5g}$$

in words: *to a first approximation, the energy of the perturbed motion equals the energy of the unperturbed motion plus the average of the first-order part of the perturbation Hamiltonian taken over the unperturbed motion.*

The perturbed frequency is then given, to the first order, by

$$\nu = \partial E(J)/\partial J = \nu_o + \varepsilon\big[\partial E_1(J)/\partial J\big] = \nu_o + \varepsilon\big[\partial\langle H_1\rangle/\partial J\big]_{J=J_o}. \tag{8.16.5h}$$

Next, we turn to the calculation of the first-order correction of the motion. As (8.16.3d, e) show, this requires finding G_1: due to (8.16.5e), eq. (8.16.5b) can be written as the following (linear and constant coefficient partial differential) equation for G_1:

$$\nu_o[\partial G_1(w_o, J)/\partial w_o] = \textit{known function of } w_o \textit{ and } J = -\Delta H_1(w_o, J), \tag{8.16.5i}$$

where

$$\begin{aligned} H_1(w_o, J) - \langle H_1(w_o, J)\rangle &= H_1(w_o, J) - E_1(J) \equiv \Delta H_1(w_o, J) \\ &= \textit{oscillatory part, or periodic component, of } H_1 \text{ (of zero average/mean,} \\ &\quad \text{and a known function of } w_o \text{ and the constant } J), \end{aligned} \tag{8.16.5j}$$

and so it is expressible as a Fourier series *without constant term* (a fact denoted, as in §8.15, by a prime on the summation sign):

$$\Delta H_1(w_o, J) = {\sum}' h_s(J)\exp(2\pi i\, s\, w_o) \qquad (s = -\infty, \ldots, +\infty; \neq 0). \tag{8.16.5k}$$

Utilizing (8.16.5c) and (8.16.5k) in (8.16.5i) and then equating coefficients of like harmonics, we express the unknown amplitudes g_s in terms of the known ones h_s: $g_s = -[2\pi i(\nu_o s)]^{-1} h_s$, and so

$$\begin{aligned} G_1(w_o, J) &= -\sum{}' \, [2\pi i(\nu_o s)]^{-1} h_s \exp(2\pi i\, s\, w_o) \\ &= \sum{}' \, (\omega_o\, s)^{-1}\, (i\, h_s) \exp(2\pi i\, s\, w_o) \\ &[= \textit{Infinite sum of finite terms} \text{ (assuming, of course } \nu_o \neq 0, \\ &\qquad \text{and since } s \neq 0]. \end{aligned} \tag{8.16.5l}$$

[The general solution of (8.16.5i) is $G_1(w_o, J) + f(J)$, where $f(J)$ is an arbitrary function of J. But as (8.16.3d, e) show, $f(J)$ *does not affect the* $J - J_o$ *relation*, and simply adds a term $\varepsilon\,[df(J)/dJ]$ to $w - w_o$. However, since $J = constant$, this amounts to the *addition of an inconsequential constant to* $w - w_o$; w and w_o being angle variables, their difference at the "initial" angle w_o ($= 0$, for convenience) is arbitrary. In view of this freedom, we will henceforth set $f(J) = 0$.]

Then, using (8.16.3d, e), we obtain the new action–angle variables to the first order; that is, eq. (8.16.3e) yields the small oscillations, superimposed on the unperturbed motion, with amplitude of order ε, and analogously for (8.16.3d). Hence, in this perturbation scheme, *no secular perturbations occur*; that is, quantities that are constant in the unperturbed motion do not undergo changes of their own order of magnitude.

REMARK

A word of caution is needed here: if ν_o is *very small*, then, as (8.16.5k) shows, the effect of this first-order perturbation may be *pretty substantial*—the convergence of our perturbation series cannot be guaranteed for very long time intervals (i.e., for all time). (Similarly, it can be shown that the effect of the (p)th perturbation will be proportional to ${\nu_o}^{-p}$.) As a rule, "small ν_o" situations occur near a *separatrix*—that is, a boundary that separates phase space curves of very different properties; for example, a curve that separates libration from rotation (fig. 8.13). As shown below, such mathematical difficulties become *far greater* in n (≥ 2) DOF systems: there, not just small frequencies, but also *finite/large ones*, may combine among themselves (i.e., *in near-degeneracy conditions*) to produce very small denominators in the coefficients of the corresponding perturbational series; and, thus, may call into question its convergence. More on this famous problem of "*small divisors*" later.

Several DOF

Here, we extend our perturbation method in a twofold way: (i) to systems with n DOF, and (ii) to include up to *second-order* terms in ε. The basic assumptions of the one-DOF case are also made here:

- For $\varepsilon = 0$, the new (perturbed) angle–action variables

$$w \equiv (w_1, \ldots, w_n) \equiv (w_k;\ k = 1, \ldots, n), \tag{8.16.6a}$$

$$J \equiv (J_1, \ldots, J_n) \equiv (J_k;\ k = 1, \ldots, n), \tag{8.16.6b}$$

  reduce to the old (unperturbed) ones

$$w_o \equiv (w_{1o}, \ldots, w_{no}) \equiv (w_{ko};\ k = 1, \ldots, n), \tag{8.16.6c}$$

$$J_o \equiv (J_{1o}, \ldots, J_n) \equiv (J_{ko};\ k = 1, \ldots, n). \tag{8.16.6d}$$

- The solution of the unperturbed problem in the (w_o, J_o) is assumed *known and non-degenerate*.
- Both unperturbed and perturbed Hamiltonians depend only on the *corresponding action variables*: $H_o = H_o(J_o)$ and $H = H(J)$, and
- The perturbed coordinates are *periodic in both the w_{ko} and w_k, with fundamental period 1.*

As in the one-DOF case, we are seeking the perturbative solution of the new HJ equation

$$H(w_o, J_o) = H(w_o, \partial G/\partial w_o) = E(J), \tag{8.16.6e}$$

where $G = G(w_o, J)$ is the generating function of the canonical transformation

$$(w_o, J_o) \to (w, J): \qquad J_{ko} = \partial G(w_o, J)/\partial w_{ko}, \qquad w_k = \partial G(w_o, J)/\partial J_k. \tag{8.16.6f}$$

Expanding H, E, and G in ε-powers, we obtain

$$\begin{aligned} H(w_o, J_o) &= H_o(J_o) + \varepsilon H_1(w_o, J_o) + \varepsilon^2 H_2(w_o, J_o) + \cdots \\ &= H_o(\partial G/\partial w_o) + \varepsilon H_1(w_o, \partial G/\partial w_o) + \varepsilon^2 H_2(w_o, \partial G/\partial w_o) + \cdots, \end{aligned} \tag{8.16.7a}$$

$$E(J, \varepsilon) = E_o(J) + \varepsilon E_1(J) + \varepsilon^2 E_1(J) + \cdots, \tag{8.16.7b}$$

$$\begin{aligned} G(w_o, J) &= G_o(w_o, J) + \varepsilon G_1(w_o, J) + \varepsilon^2 G_2(w_o, J) + \cdots \\ &= \sum w_{ko} J_k + \varepsilon G_1(w_o, J) + \varepsilon^2 G_2(w_o, J) + \cdots. \end{aligned} \tag{8.16.7c}$$

Then, (8.16.6f) become

$$J_{ko} = J_k + \varepsilon(\partial G_1/\partial w_{ko}) + \varepsilon^2(\partial G_2/\partial w_{ko}) + \cdots, \tag{8.16.8a}$$

$$w_k = w_{ko} + \varepsilon(\partial G_1/\partial J_k) + \varepsilon^2(\partial G_2/\partial J_k) + \cdots; \tag{8.16.8b}$$

and this allows us to rewrite (8.16.7a) to the second order as follows:

$$\begin{aligned} H(w_o, J_o) &= H_o\big[J + \varepsilon(\partial G_1/\partial w_o) + \varepsilon^2(\partial G_2/\partial w_o)\big] \\ &\qquad + \varepsilon H_1(w_o, J + \cdots) + \varepsilon^2 H_2(w_o, J + \cdots) \\ &= H_o(J) + \sum \big[\varepsilon(\partial G_1/\partial w_{ko}) + \varepsilon^2(\partial G_2/\partial w_{ko})\big](\partial H_o/\partial J_k) \\ &\qquad + (1/2)\sum\sum (\partial^2 H_o/\partial J_k\, \partial J_l)\big[\varepsilon(\partial G_1/\partial w_{ko})\big]\big[\varepsilon(\partial G_1/\partial w_{lo})\big] \\ &\qquad + \varepsilon H_1(w_o, J) + \varepsilon^2 \sum (\partial G_1/\partial w_{ko})(\partial H_1/\partial J_k) + \varepsilon^2 H_2(w_o, J); \end{aligned} \tag{8.16.8c}$$

where, as in (8.16.5a),

$$\partial H_o/\partial J_k \equiv [\partial H_o(J_o)/\partial J_{ko}]_{J_o = J} = \partial/\partial J_k\,[H_o(J_o)|_{J_o = J}], \tag{8.16.8d}$$

and similarly for the other H-derivatives.

Next, inserting the power series (8.16.8c, 7b) into (8.16.6e), and equating coefficients of like powers of ε, while noting that [recall (8.16.5a)]

$$\partial H_o/\partial J_k = \nu_{ko}(J) \qquad [\Rightarrow\ \partial \nu_{ko}/\partial J_l = \partial \nu_{lo}/\partial J_k], \tag{8.16.9a}$$

we obtain the following group of differential equations:

$$\varepsilon^0: \qquad H_o(J) = E_o(J), \tag{8.16.9b}$$

$$\varepsilon^1 \equiv \varepsilon: \qquad H_1(w_o, J) + \sum \nu_{ko}(\partial G_1/\partial w_{ko}) = E_1(J), \tag{8.16.9c}$$

$$\varepsilon^2: \qquad K_2(w_o, J) + \sum \nu_{ko}(\partial G_2/\partial w_{ko}) = E_2(J), \tag{8.16.9d}$$

where

$$K_2(w_o, J) \equiv H_2(w_o, J) + \sum (\partial G_1/\partial w_{ko})(\partial H_1/\partial J_k) + (1/2)\sum\sum (\partial^2 H_o/\partial J_k \partial J_l)(\partial G_1/\partial w_{ko})(\partial G_1/\partial w_{lo}). \tag{8.16.9e}$$

Next, as in the 1-DOF case, it can be shown that all G_p's in (8.16.7c) are periodic in the w_{ko}'s; that is,

$$G_p(w_o, J) = \sum g_{p,\boldsymbol{s}}(J)\exp(2\pi i\, \boldsymbol{s} \cdot \boldsymbol{w_o}), \tag{8.16.10a}$$

where $p = 1, 2, \ldots, \boldsymbol{s} \equiv (s_1, \ldots, s_n) =$ *integers ranging from* $-\infty$ to $+\infty$, $\boldsymbol{w_o} \equiv (w_{1o}, \ldots, w_{no}) \equiv w_o$, and so their w_o-derivatives $\partial G_p/\partial w_{ko}$ *contain no constant terms*; that is, $\boldsymbol{s} \neq (0, \ldots, 0)$. Therefore, averaging (8.16.9b–e) over a complete unperturbed period w_o — that is, over the unit w_o-cube (§8.14), since $\langle \partial G_p/\partial w_{ko}\rangle = 0$ and the last/double sum group of terms in (8.16.9e) is periodic in the w_o's (the $\partial^2 H_o/\partial J_k \partial J_l$ depend only on the J's) — we obtain

$$H_o(J) = E_o(J), \tag{8.16.10b}$$

$$\langle H_1(w_o, J)\rangle = E_1(J), \tag{8.16.10c}$$

$$\langle K_2(w_o, J)\rangle = \left\langle H_2(w_o, J) + \sum (\partial G_1/\partial w_{ko})(\partial H_1/\partial J_k)\right\rangle = E_2(J); \tag{8.16.10d}$$

that is, to the second order, the energy is

$$E = H_o + \langle H_1\rangle + \left\langle H_2 + \sum (\partial G_1/\partial w_{ko})(\partial H_1/\partial J_k)\right\rangle. \tag{8.16.10e}$$

Due to the above [and recalling (8.16.5j)], we can rewrite the perturbation equations (8.16.9c, d), respectively, as

$$\sum \nu_{ko}(\partial G_1/\partial w_{ko}) = -[H_1(w_o, J) - \langle H_1(w_o, J)\rangle] \equiv -\Delta H_1(w_o, J), \tag{8.16.11a}$$

$$\sum \nu_{ko}(\partial G_2/\partial w_{ko}) = -[K_2(w_o, J) - \langle K_2(w_o, J)\rangle] \equiv -\Delta K_2(w_o, J), \tag{8.16.11b}$$

and, from these, G_1, G_2 can be determined (see below). Then, equations (8.16.8a, b) yield the new action–angle variables, correct to second order.

The above show that (i) knowledge of K_2 ($\rightarrow \langle K_2\rangle = E_2$) requires knowledge of G_1; then G_2 can be calculated; and (ii) in a one-DOF system, both G_1 and G_2 can be found by direct quadrature:

$$\partial G_1/\partial w_o = (1/\nu_o)(\langle H_1\rangle - H_1) = \textit{known function of } w_o \textit{ and } J, \tag{8.16.11c}$$

$$\partial G_2/\partial w_o = (1/\nu_o)(\langle K_2\rangle - K_2) = \textit{known function of } w_o \textit{ and } J; \tag{8.16.11d}$$

and can be easily extended to higher ε-orders.

Finally, by (8.16.10b–d), the perturbed frequencies equal, to the second order,

$$\nu_k = \partial E/\partial J_k = \partial E_o/\partial J_k + \varepsilon(\partial E_1/\partial J_k) + \varepsilon^2(\partial E_2/\partial J_k)$$
$$\approx \nu_{ko} + \varepsilon(\partial\langle H_1\rangle/\partial J_k) + \varepsilon^2(\partial\langle K_2\rangle/\partial J_k), \tag{8.16.11e}$$

in agreement with (8.16.5h).

[For the extension of this perturbation scheme to the (p)th order; that is, the differential equation that results by equating the coefficients of ε^p in (8.16.6e), see Born (1927, p. 254 ff.); also prob. 8.16.3. It is not hard to see that finding E_p requires knowledge of G_{p-1}; *then* G_p can be calculated.]

Small Divisors

Now, let us resume the calculation of G_1, G_2. To express the (unknown) Fourier coefficients of the left sides of (8.16.11a, b) in terms of the (known) Fourier coefficients of their right sides, we proceed as follows. The *right* side of (8.16.11a) is a *known* periodic function of the w_o's without constant term, and so we can write

$$-\Delta H_1(w_o, J) = -\sum{}' h_{1,s}(J)\exp(2\pi i\,\boldsymbol{s}\cdot\boldsymbol{w_o}). \tag{8.16.12a}$$

Similarly, by (8.16.10a) with $p = 1$, we have

$$G_1(w_o, J) = \sum g_{1,s}(J)\exp(2\pi i\,\boldsymbol{s}\cdot\boldsymbol{w_o}), \tag{8.16.12b}$$

and therefore the *left* side of (8.16.11a) can be expressed as

$$\sum \nu_{ko}(\partial G_1/\partial w_{ko}) = \sum{}' [2\pi i(\boldsymbol{s}\cdot\boldsymbol{v_o})g_{1,s}(J)]\exp(2\pi i\,\boldsymbol{s}\cdot\boldsymbol{w_o}), \tag{8.16.12c}$$

where $s_k \neq 0$ (i.e., no constant term) and $\boldsymbol{s}\cdot\boldsymbol{v_o} \equiv \sum s_k\nu_{ko} \neq 0$ $(k = 1, \ldots, n)$.

Hence, equating coefficients of equal harmonics of (8.16.12a) and (8.16.12c), as required by (8.16.11a), we immediately obtain the sought relations for the Fourier coefficients:

$$g_{1,s}(J) \equiv g_1(\boldsymbol{s};\, J) = -[2\pi i(\boldsymbol{s}\cdot\boldsymbol{v_o})]^{-1}h_{1,s}(J); \tag{8.16.12d}$$

and so, finally, (8.16.12b) becomes

$$G_1(w_o, J) = -\sum{}' [2\pi i(\boldsymbol{s}\cdot\boldsymbol{v_o})]^{-1}h_{1,s}(J)\exp(2\pi i\,\boldsymbol{s}\cdot\boldsymbol{w_o}). \tag{8.16.12e}$$

Similarly, expanding both sides of (8.16.11b) à la Fourier, and equating coefficients, we determine G_2. This, as (8.16.9e) shows, requires knowledge of G_1. Continuing in this way, we can determine $G_3, G_4, \ldots$, and hence G to any accuracy desired.

Now, it is not too hard to see that for the representation (8.16.12e) to be meaningful, not only *the unperturbed frequencies* ν_{ko} *should be nondegenerate* (i.e., $\sum s_k\,\nu_{ko} \neq 0$; unless the coefficients $h_1, \ldots$ obtained from all sets of integers that cause degeneracies also vanish), but also, since by an appropriate choice of the integers s_k *the sum* $\sum s_k\nu_{ko}$ *may come arbitrarily close to zero* (and, worse, such a *near-degeneracy* situation may occur an infinite number of times, as the s_k roam from $-\infty$ *to* $+\infty$), for all these very unpleasant reasons *the amplitudes* $h_{1,s}$ *must converge very rapidly*. Hence, from a rigorous mathematical viewpoint, the series (8.16.12b, e) *does not converge*; and this inescapable fact casts serious reservations on the unconditional validity of the entire method of canonical perturbations.

REMARKS

(i) This is the Hamiltonian version of the famous *problem of small divisors* (or *resonant denominators*), first recognized by Poincaré in his epoch-making researches on the nonlinear ordinary differential equations of celestial mechanics [late 19th century, culminating in his classic three-volume work: *Les Méthodes Nouvelles de la Mécanique Céleste* (1890s)]; and on which, understandably, there exists an enormous (astronomical size) literature!

Briefly, Poincaré has shown that the series (8.16.12b) is *semiconvergent*; that is, *if it is truncated (discontinued) after a certain finite number of terms, it represents the motion of the perturbed system very accurately; not for long periods of time, but long enough for many practical purposes*. It is theoretical reasons like this that had made it so difficult to prove the stability of our solar system; that is, to show that the mutual distances among the planets and the sun remain bounded for infinitely long time intervals. (And, of course, it should not be forgotten that a realistic stability investigation of this problem must include *nonmechanical* causes, such as electromagnetic and thermal interactions.) Several decades later, it was shown that the situation is not fatal: Kolmogorov (mid-1950s)/Arnold/Moser (early 1960s) (KAM theorem) demonstrated that *if the ν_{ko} are "very irrational," then the series (8.16.12b) converges for all time*.

(ii) For in-depth analyses of these fundamental difficulties [for a long time viewed as mathematically insuperable, but whose resolution in the 1960s led straight up to the frontier of contemporary nonlinear dynamics (regular and stochastic, or chaotic, motion) and the threshold with quantum mechanics], we can do no more than refer the reader to the following excellent references: Dittrich and Reuter (1994, chaps. 11–14: pp. 137–171), Lichtenberg and Lieberman (1992), McCauley (1997), Stoker (1950, pp. 112–114, 235–239; elementary but enlightening introduction to the problem of small divisors), Straumann (1987, chap. 10: pp. 259–307), Tabor (1989, chap. 3: pp. 89–117); also Born (1927, pp. 255–256), and our *Elementary Mechanics* [under production, Part I (20th cent.): an encyclopaedic summary]. Mathematically oriented readers (or mathematicians) may wish to consult (the not so readable) Arnold (1976, chap. 10: pp. 269–299, appendix 8: pp. 405–423).]

Finally, we recall that our discussion of perturbation theory has been limited not only to *nondegenerate* cases, but also to *time-independent* Hamiltonians. For classical (pre-KAM) treatments of the effects of degeneracies and/or time-dependence, with an eye toward their older quantum-mechanical applications, we recommend Born (1927, pp. 261–286; best reference in English) and Fues (1927, pp. 161–177; comprehensive handbook exposition); also Birtwistle (1926, pp. 216–217) and Haar (1971, pp. 160–162).

Example 8.16.1 *Weakly Nonlinear Planar Mathematical Pendulum; First-Order Perturbation* (Dittrich and Reuter, 1994, pp. 113–115). Let us consider a plane mathematical pendulum of mass m and length l undergoing (free and undamped) *small but nonlinear* angular oscillations ϕ, under gravity, about a fixed point O. Expanding its exact Hamiltonian

$$H = p^2/2ml^2 + mgl(1 - \cos\phi) = p^2/2ml^2 - mgl\cos\phi + constant \qquad \text{(a)}$$

in powers of ϕ, and *keeping only up to the first term after its quadratic ones*, we find

$$H = p^2/2ml^2 + mgl\left[(\phi^2/2) - (\phi^4/24)\right] \equiv H_o + \varepsilon H_1, \tag{b}$$

$$H_o \equiv p^2/2A + (A\omega_o{}^2/2)\phi^2, \qquad \varepsilon H_1 \equiv -(A\omega_o{}^2/24)\phi^4, \tag{c}$$

where $A \equiv m\,l^2$ = moment of inertia of pendulum bob about O, $\omega_o{}^2 \equiv g/l$ = circular frequency (squared) of unperturbed = linearized problem. We have already seen (ex. 8.14.1) that the solution of the latter in action–angle variables is (with $m \to A,\ q \to \phi$)

$$\phi = (J_o/A\pi\,\omega_o)^{1/2}\sin(2\pi w_o), \qquad p = (A\,\omega_o\,J_o/\pi)^{1/2}\cos(2\pi w_o), \tag{d}$$

and so H, eq. (b), assumes the action–angle variable form

$$\begin{aligned} H &= (\omega_o/2\pi)J_o - (1/24)(J_o{}^2/A\pi^2)\,\sin^4(2\pi w_o) \\ &= \nu_o J_o - (J_o{}^2/24A\pi^2)\sin^4(2\pi w_o) = H_o + \varepsilon H_1. \end{aligned} \tag{e}$$

Choosing as perturbation parameter ε the square of the maximum angular amplitude of the unperturbed problem $\phi_o{}^2$, and applying (8.16.5e), we obtain

$$E_1(J) = \langle H_1(w_o, J)\rangle = -(J^2/24A\pi^2\phi_o{}^2)\langle\sin^4(2\pi w_o)\rangle, \tag{f}$$

or, since by simple trigonometry and calculus

$$\begin{aligned} \sin^4(\ldots) &= \left\{[\exp(i\ldots) - \exp(-i\ldots)]/2i\right\}^4 \\ &= \cdots = (1/8)\,[\cos(4\ldots) - 6\cos(2\ldots) + 3] \\ \Rightarrow\ \langle\sin^4(2\pi w_o)\rangle &= \int_0^1 \sin^4(2\pi w_o)\,dw_o = \cdots = 3/8, \end{aligned} \tag{g}$$

we get

$$E_1(J) = -J^2/64A\pi^2\phi_o{}^2. \tag{h}$$

Hence, by (8.16.5i), the *first-order* change of the fundamental frequency is

$$\Delta\nu \equiv \nu - \nu_o = \varepsilon[\partial E_1(J)/\partial J] \ = \ -J/32A\pi^2 \ \approx \ -J_o/32A\pi^2, \tag{i}$$

or, since

$$\begin{aligned} J_o &= (2\pi/\omega_o)E_o = (2\pi/\omega_o)T_{\max} = (2\pi/\omega_o)(A\omega_o{}^2\phi_o{}^2/2) \\ &= \pi A\,\omega_o\phi_o{}^2 = 2\pi^2 A\phi_o{}^2\nu_o, \end{aligned} \tag{j}$$

finally,

$$\Delta\nu = -(\phi_o{}^2/16)\nu_o; \tag{k}$$

which agrees with the first-order correction found by other means (e.g., Lur'e, 1968, pp. 702–703) for a derivation based on integral variational calculus; see also examples/problems in §7.9 of this book.

Example 8.16.2 *One-DOF Nonlinear Oscillator; Second-Order Perturbation.* (Birtwistle, 1926, pp. 213–216; with $c_o = 0$ and $\omega \to \nu$). Let us consider a one-DOF oscillator, with mass m and unperturbed circular frequency $\omega_o = 2\pi\nu_o$, and perturbed Hamiltonian, to second ε-order:

$$H = H_o + \varepsilon H_1 + \varepsilon^2 H_2, \tag{a}$$

where

$$H_o = p^2/2m + m\,\omega_o{}^2 q^2/2, \tag{a1}$$

$$H_1 = h_1 q^3, \qquad H_2 = h_2\, q^4 \qquad (h_1, h_2\text{: known physical constants}). \tag{a2}$$

We already know that the unperturbed solution is (ex. 8.14.1)

$$q_o = (J_o/\pi\omega_o\, m)^{1/2} \sin(2\pi w_o), \qquad p_o = (\omega_o\, m\, J_o/\pi)^{1/2} \cos(2\pi w_o), \tag{b}$$

and so the perturbed Hamiltonian H can be expressed in terms of the unperturbed variables (w_o, J_o) as follows:

$$H_o = \nu_o J_o, \tag{c1}$$

$$H_1 = h_1 (J_o/\pi\omega_o\, m)^{3/2} \sin^3(2\pi w_o), \tag{c2}$$

$$H_2 = h_2 (J_o/\pi\omega_o\, m)^2 \sin^4(2\pi w_o). \tag{c3}$$

Now, let us apply the perturbation equations (8.16.10b–11b):

(i) Since, here,

$$E_1(J) = \langle H_1(w_o, J)\rangle \;\sim\; \langle \sin^3(2\pi w_o)\rangle = \cdots = 0, \tag{d1}$$

we will have

$$\begin{aligned}\partial G_1/\partial w_o &= -(1/\nu_o) H_1(w_o, J) = -(1/\nu_o)\, \Delta H_1(w_o, J)\\ &= -(h_1/\nu_o)(J/\pi\omega_o\, m)^{3/2} \sin^3(2\pi w_o);\end{aligned} \tag{d2}$$

that is, the ε-order perturbation does not change the energy ($E_1 = 0$), but does change the action–angle variables ($G_1 \neq 0$).

(ii) To find the ε^2-order energy correction equation, we employ the equations

$$\begin{aligned}&K_2 + \nu_o(\partial G_2/\partial w_o)\\ &\qquad = H_2 + (\partial G_1/\partial w_o)(\partial H_1/\partial J) + \nu_o(\partial G_2/\partial w_o) = E_2,\end{aligned} \tag{e1}$$

$$\langle K_2\rangle = \langle H_2\rangle + \langle(\partial G_1/\partial w_o)(\partial H_1/\partial J)\rangle = E_2. \tag{e2}$$

Using (c2, 3) and (d2) in (e2), and carrying out the indicated w_o-averagings, we obtain, after some algebra (since $\langle \sin^4(2\pi w_o)\rangle = 3/8$ and $\langle \sin^6(2\pi w_o)\rangle = 5/16$),

$$E_2 = -(15/4) h_1{}^2 [J^2/(2\pi)^6 \nu_o{}^4 m^3] + (3/2) h_2 [J^2/(2\pi)^4 \nu_o{}^2 m^2]. \tag{e3}$$

Then, to the second order, the perturbed energy and frequency are, respectively,

$$E(J) = E_o + \varepsilon E_1 + \varepsilon^2 E_2 = \nu_o J + \varepsilon^2 E_2 = \cdots, \tag{e4}$$

$$\begin{aligned} \nu(J) &= \nu_o + \varepsilon(\partial\langle H_1\rangle/\partial J) + \varepsilon^2(\partial\langle K_2\rangle/\partial J) \\ &= \nu_o + \varepsilon^2(\partial E_2/\partial J) = \cdots; \end{aligned} \tag{e5}$$

and then set in them $J = J_o - \varepsilon(\partial G_1/\partial w_o) = \cdots$ (see below). We notice the weak dependence of the frequency on the amplitude.

(iii) To find the ε-order effect on the motion — that is, on q — first we integrate (d2), thus finding

$$G_1 = [h_1/(2\pi)^4\nu_o]\,(2J/\nu_o\,m)^{3/2}\left[(1/3)\sin^2(2\pi w_o)\cos(2\pi w_o) + (2/3)\cos(2\pi w_o)\right], \tag{f1}$$

then, applying the old/new variable perturbation equations, we get

$$J_o = J + \varepsilon(\partial G_1/\partial w_o) = J - \varepsilon(h_1/\nu_o)(J/2\pi^2\nu_o m)^{3/2}\sin^3(2\pi w_o), \tag{f2}$$

$$\begin{aligned} w &= w_o + \varepsilon(\partial G_1/\partial J) \\ &= w_o + \varepsilon[h_1/(2\pi)^4 2J\nu_o](2J/\nu_o m)^{3/2}\left[\sin^3(2\pi w_o)\cos(2\pi w_o) + 2\cos(2\pi w_o)\right]; \end{aligned} \tag{f3}$$

and, finally, solving (f3) for w_o and substituting that result, and J_o from (f2), into the unperturbed form of motion of the first of (b):

$$q_o = (J_o/\pi\omega_o m)^{1/2}\sin(2\pi w_o) = (J_o/2\pi^2\nu_o m)^{1/2}\sin(2\pi w_o), \tag{f4}$$

we obtain

$$\begin{aligned} q_o \;\to\; q &= q_o + \varepsilon q_1 \\ &= (J/2\pi^2\nu_o m)^{1/2}\sin(2\pi w) - \varepsilon h_1\,[J/(2\pi)^4\nu_o{}^3 m^2]\,[3 + \cos(4\pi w)]; \end{aligned} \tag{f5}$$

that is, the *nonlinearity* (h_1) produces oscillatory *overtones* ($4\pi w$). These results agree with those found by quadrature (since this is a one-DOF system) for $h_2 = 0$ (see, e.g., Born, 1927, pp. 66–70). Proceeding similarly, we may obtain the ε^2-order effect on (w_o, J_o) [after finding G_2 from (e1)] and hence on q. The details are left to the reader (for confirmation of those results, see, e.g., Haar, 1971, pp. 157–158).

Example 8.16.3 *Two-DOF Nonlinear Oscillator; First-Order Perturbation.* Let us consider an oscillating system with perturbed Hamiltonian

$$\begin{aligned} H(q,p;\varepsilon) &= (1/2)(p_1{}^2 + p_2{}^2) + (1/2)(k_1 q_1{}^2 + k_2 q_2{}^2) + \varepsilon\, k_1 k_2 q_1{}^2 q_2{}^2 \\ &= H_o + \varepsilon\, H_1, \end{aligned} \tag{a}$$

where

$$H_o = H_o(q,p;0) = \sum (1/2)(p_l{}^2 + k_l\, q_l{}^2) \qquad (l = 1,2), \tag{a1}$$

$$H_1 = H_1(q,p;0) = k_1 k_2 q_1{}^2 q_2{}^2; \tag{a2}$$

that is, the unperturbed Hamiltonian represents two uncoupled harmonic oscillators, each of unit mass and stiffness k_l (> 0), and hence unperturbed circular frequency (squared) ${\omega_{lo}}^2 = k_l$. As we already know (exs. 8.14.1 and 8.14.6), the unperturbed solutions are

$$q_{ko} = (J_{ko}/\pi\omega_{ko})^{1/2}\sin(2\pi w_{ko}), \tag{b1}$$

$$p_{ko} = (\omega_{ko} J_{ko}/\pi)^{1/2}\cos(2\pi w_{ko}) \qquad (k = 1, 2), \tag{b2}$$

and so the perturbed Hamiltonian H, (a–a2), can be expressed in terms of the unperturbed variables (w_o, J_o) as follows:

$$H_o = (1/2\pi)\sum \omega_{ko} J_k = \sum \nu_{ko} J_k = E_o, \tag{c1}$$

$$H_1 = (1/\pi^2)\omega_{1o}\,\omega_{2o}\,J_{1o}\,J_{2o}\sin^2(2\pi w_{1o})\sin^2(2\pi w_{2o})$$
$$= 4\nu_{1o}\,\nu_{2o}\,J_{1o}\,J_{2o}\sin^2(2\pi w_{1o})\sin^2(2\pi w_{2o}); \tag{c2}$$

where $\nu_{lo} = \omega_{lo}/2\pi =$ unperturbed frequencies. Hence, the first-order energy correction yields

$$E_1(J) = \langle H_1(w_o, J)\rangle \equiv \int_0^1\int_0^1 H_1(w_{1o}, w_{2o}; J_1, J_2)\,dw_{1o}\,dw_{2o}$$
$$= \cdots = (1/4\pi^2)\omega_{1o}\,\omega_{2o}\,J_1 J_2 = \nu_{1o}\,\nu_{2o}\,J_1 J_2, \tag{d1}$$

$$\Rightarrow\ E(J) = E_o(J) + \varepsilon E_1(J) = \nu_{o1}J_1 + \nu_{o2}\,J_2 + \varepsilon\,\nu_{1o}\,\nu_{2o}\,J_1 J_2, \tag{d2}$$

(w-integration limits from 0 to 1) and so, to the same accuracy, the perturbed frequencies are (whether the system is degenerate or not)

$$\nu_1 = \partial E/\partial J_1 = \nu_{1o} + \varepsilon\,\nu_{1o}\,\nu_{2o} J_2, \tag{d3}$$

$$\nu_2 = \partial E/\partial J_2 = \nu_{2o} + \varepsilon\,\nu_{1o}\,\nu_{2o} J_1; \tag{d4}$$

and these show clearly the coupling of the two oscillators and the effect of the amplitudes (initial conditions) on the frequencies.

Next, to express the perturbed coordinates and momenta in terms of the new action–angle variables (w, J), we must calculate G_1:

(i) On one hand, in view of (c2), (d1), we have

$$\langle H_1(w_o, J)\rangle - H_1(w_o, J) \equiv -\Delta H_1(w_o, J)$$
$$= \nu_{1o}\,\nu_{2o}\,J_1 J_2[1 - 4\sin^2(2\pi w_{1o})\sin^2(2\pi w_{2o})]$$
$$\equiv (\nu_{1o}\,\nu_{2o}\,J_1 J_2/4)\sum\sum{}' h_{1,s}\exp[2\pi i(s_1 w_{1o} + s_2 w_{2o})] \tag{e1}$$

(where $s \equiv (s_1, s_2) =$ *nonzero* integers ranging from $-\infty$ to $+\infty$); from which we readily conclude that the sole *nonvanishing* Fourier coefficients of $-\Delta H_1$, $h_{1,\ldots} \equiv h_{1;\,\ldots,\ldots}$, are

$$h_{1;\,2,2} = h_{1;\,2,-2} = h_{1;\,-2,2} = h_{1;\,-2,-2} = -1, \tag{e2}$$

$$h_{1;\,2,0} = h_{1;\,0,2} = h_{1;\,0,-2} = h_{1;\,-2,0} = 2. \tag{e3}$$

(ii) On the other hand, recalling (8.16.12b, c), we can write

$$
\begin{aligned}
&G_1(w_o, J) = \sum g_{1,s}(J)\exp(2\pi i\boldsymbol{s}\cdot\boldsymbol{w_o}),\\
&\Rightarrow \sum{}' \nu_{ko}(\partial G_1/\partial w_{ko})\\
&= \sum\sum{}' \left[(2\pi i)\,(s_1\nu_{1o} + s_2\nu_{2o})\right] g_{1,s}\exp\left[2\pi i(s_1 w_{1o} + s_2 w_{2o})\right]. \qquad \text{(e4)}
\end{aligned}
$$

Hence, substituting these Fourier series into the first-order averaged equation (8.16.11a):

$$\sum{}' \nu_{ko}(\partial G_1/\partial w_{ko}) = \langle H_1(w_o, J)\rangle - H_1(w_o, J) \equiv -\Delta H_1(w_o, J), \qquad \text{(e5)}$$

and equating coefficients of like harmonics, we find [with $h \equiv \nu_{1o}\,\nu_{2o}J_1J_2/4$]

$$
\begin{aligned}
g_{1,\ldots} \equiv g_{1;\,\ldots,\ldots} &= \left[h/(2\pi i)(s_1\nu_{1o} + s_2\nu_{2o})\right]h_{1;\,\ldots,\ldots}:\\
g_{1;\,0,2} = -g_{1;\,0,-2} &= (2\pi i\nu_{2o})^{-1}h, && \text{(e6)}\\
g_{1;\,2,0} = -g_{1;\,-2,0} &= (2\pi i\nu_{1o})^{-1}h, && \text{(e7)}\\
g_{1;\,2,2} = -g_{1;\,-2,-2} &= -[4\pi i(\nu_{1o} + \nu_{2o})]^{-1}h, && \text{(e8)}\\
g_{1;\,2,-2} = -g_{1;\,-2,2} &= -[4\pi i(\nu_{1o} - \nu_{2o})]^{-1}h. && \text{(e9)}
\end{aligned}
$$

Hence, to the first order, the generating function equals

$$
\begin{aligned}
G = \sum w_{ko}J_k + (\varepsilon/4\pi)J_1J_2\big\{&\nu_{2o}\sin(4\pi w_{1o}) + \nu_{1o}\sin(4\pi w_{2o})\\
&- [2\nu_{1o}\nu_{2o}/(\nu_{1o} + \nu_{2o})]\sin[4\pi(w_{1o} + w_{2o})]\\
&- [2\nu_{1o}\nu_{2o}/(\nu_{1o} - \nu_{2o})]\sin[4\pi(w_{1o} - w_{2o})]\big\}; \qquad \text{(e10)}
\end{aligned}
$$

and from this the w_k and J_k follow:

$$w_k = w_{ko} + \varepsilon(\partial G/\partial J_k) \;\Rightarrow\; w_{ko} = w_k - \varepsilon\;(\textit{function of } w \textit{ and } J), \qquad \text{(f1)}$$

$$J_{ko} = J_k + \varepsilon(\partial G/\partial w_{ko}) \;\Rightarrow\; J_k = J_{ko} + \varepsilon\;(\textit{function of } w \textit{ and } J) \qquad \text{(f2)}$$

(because, replacing w_o with w in the ε-terms causes an ε^2-error), where $J_k = \textit{constant}$ and $w_k = \nu_k t + \gamma_k$; and then inserting (f1, 2) into (b1, 2) yields the perturbed motion $q_k(w, J), p_k(w, J)$. The details are left to the reader.

REMARKS ON DEGENERACIES

As (e10) shows, if $\nu_{1o} = \nu_{2o}$ (degeneracy, or internal resonance), this approach fails — G diverges; then we have to develop special methods. In view of (e2, 3, 6–9), other degeneracies do not seem to create problems; for example, that would happen to the degeneracy $\nu_{1o} = 2\nu_{2o}$ [i.e., $(1)\nu_{1o} + (-2)\nu_{2o} = 0$] if $h_{1;\,s,-2s} \neq 0$, for some integer s. However, such difficulties may arise in the higher ε-order terms; that is, G_l $(l \geq 2)$; and for their full treatment, we recommend the earlier-given references on small divisors.

Problem 8.16.1 For a 1-DOF system, the earlier-given general n-DOF *second*-order formalism specializes to

$$E_o(J) = H_o(J), \tag{a1}$$

$$E_1(J) = H_1(w_o, J) + \nu_o(J)\,(\partial G_1/\partial w_o) = H_1(w_o, J) + (\partial H_o/\partial J)\,(\partial G_1/\partial w_o), \tag{a2}$$

$$E_2(J) = H_2(w_o, J) + (\partial H_1/\partial J)\,(\partial G_1/\partial w_o) + (\partial H_o/\partial J)\,(\partial G_2/\partial w_o) + (1/2)(\partial^2 H_o/\partial J^2)(\partial G_1/\partial w_o)^2. \tag{a3}$$

We have already seen that since

$$\langle \partial G_1/\partial w_o \rangle \equiv \int_0^1 (\partial G_1/\partial w_o)\,dw_o = 0, \tag{b}$$

eq. (a2) averages to

$$E_1(J) = \langle H_1 \rangle \;\Rightarrow\; \partial G_1/\partial w_o = (1/\nu_o)\big(\langle H_1 \rangle - H_1\big) = -(1/\nu_o)\,\Delta H_1. \tag{c}$$

Show that:

(i) The second-order correction (a3) averages, similarly, to

$$\begin{aligned} E_2(J) &= \langle H_2 \rangle + \big\langle (\partial H_1/\partial J)(\partial G_1/\partial w_o) \big\rangle + (1/2)(\partial^2 H_o/\partial J^2)\big\langle (\partial G_1/\partial w_o)^2 \big\rangle \\ &= \langle H_2 \rangle + (1/\nu_o)\big[\langle (\partial H_1/\partial J) \rangle\,\langle H_1 \rangle - \langle (\partial H_1/\partial J) H_1 \rangle\big] \\ &\quad + (1/2{\nu_o}^2)(\partial \nu_o/\partial J)\,\big[\langle {H_1}^2 \rangle - \langle H_1 \rangle^2\big]; \end{aligned} \tag{d}$$

and, therefore,

(ii)

$$\begin{aligned} \partial G_2/\partial w_o &= (1/\nu_o)(E_2 - K_2) \\ &= (1/\nu_o)\big[E_2 - H_2 - (\partial H_1/\partial J)(\partial G_1/\partial w_o) - (1/2)\,(\partial^2 H_o/\partial J^2)(\partial G_1/\partial w_o)^2\big] \\ &= (1/\nu_o)(\langle H_2 \rangle - H_2) \\ &\quad + (1/{\nu_o}^2)\big[\langle \partial H_1/\partial J \rangle \langle H_1 \rangle - \langle (\partial H_1/\partial J) H_1) \rangle \\ &\qquad - (\partial H_1/\partial J)\langle H_1 \rangle + (\partial H_1/\partial J) H_1\big] \\ &\quad + (1/2{\nu_o}^3)(\partial \nu_o/\partial J)\,\big[\langle {H_1}^2 \rangle - 2\langle H_1 \rangle^2 + 2H_1 \langle H_1 \rangle - {H_1}^2\big], \end{aligned} \tag{e}$$

and, by integration, yields G_2. Thus, (w, J) can be expressed in terms of (w_o, J_o), and so on.

(iii) Using the above, show that, to the second order, the perturbed energy equals (with no need to calculate G first)

$$\begin{aligned} E(J) &= H_o(J) + \varepsilon \langle H_1 \rangle \\ &\quad + \varepsilon^2 \big\{ \langle H_2 \rangle + (1/\nu_o)\big[\langle \partial H_1/\partial J \rangle \langle H_1 \rangle - \langle (\partial H_1/\partial J) H_1 \rangle\big] \\ &\qquad + (1/2{\nu_o}^2)(\partial \nu_o/\partial J)[\langle {H_1}^2 \rangle - \langle H_1 \rangle^2] \big\}; \end{aligned} \tag{f}$$

and readily supplies the perturbed frequencies via $\nu = \partial E/\partial J = \cdots$.

Problem 8.16.2 (Dittrich and Reuter, 1994, pp. 112–113). Consider a nonlinear mass–spring oscillator, of mass m and linearized circular frequency $\omega_o \equiv (k/m)^{1/2}$, with perturbed Hamiltonian

$$H = H_o + \varepsilon H_1, \tag{a}$$

$$H_o \equiv p^2/2m + (m\,\omega_o{}^2/2)q^2, \qquad H_1 \equiv (m/6)q^6. \tag{a1}$$

As shown in the preceding examples,

$$H_o = \nu_o J_o = (\omega_o/2\pi)J_o, \qquad w_o = \nu_o t + \gamma_o; \tag{a2}$$

$$q_o = (J_o/\pi m\,\omega_o)^{1/2}\sin(2\pi w_o), \qquad p_o = (m\,\omega_o\,J_o/\pi)^{1/2}\cos(2\pi w_o). \tag{a3}$$

(i) Show that

$$E_1(J) = \langle H_1 \rangle = \cdots = (5/16)(m/6)(J/\pi m\,\omega_o)^3. \tag{b}$$

(ii) Show that

$$\varDelta\nu \equiv \nu - \nu_o = \varepsilon(5/64\pi^2)(q_{\max}{}^4/\nu_o), \tag{c}$$

where $q_{\max}$ = maximum amplitude of unperturbed (harmonic) oscillator.

HINTS

(i) Verify that

$$\begin{aligned}\sin^6(\ldots) &\equiv \big\{\big[\exp(i\ldots) - \exp(-i\ldots)\big]/2i\big\}^6\\ &= \cdots = -(2/64)\big[\cos(6\ldots) - 6\cos(4\ldots) + 15\cos(2\ldots) - 10\big];\end{aligned} \tag{d}$$

(ii)

$$J \to J_o = E_o/\nu_o = \cdots = \pi\,m\,\omega_o q_{\max}{}^2 \qquad \text{(explain)}. \tag{e}$$

Problem 8.16.3 (Born, 1927, pp. 254–255). Continuing the perturbation scheme to the (p)th order in ε:

(i) Show that, then,

$$(\partial H_o/\partial J)\,(\partial G_p/\partial w_o) = E_p(J) - R_p(w_o, J), \tag{a}$$

where $R_p(w_o, J)$ stands for a term involving only results of the preceding orders of perturbation; that is, only up to those obtained in the $(p-1)$th order, and is periodic in the w_o's.

(ii) Verify that averaging (a) yields

$$E_p(J) = \big\langle R_p(w_o, J)\big\rangle; \tag{b}$$

from which it follows that (with the usual notations)

$$\partial G_p(w_o, J)/\partial w_o = -\big(1/\nu_o(J)\big)\,\varDelta R_p(w_o, J). \tag{c}$$

Equation (c) is solved by expanding both sides in Fourier series and then equating the same harmonic coefficients, thus expressing the unknown coefficients of the left side in terms of the known coefficients of the right side.

For additional related examples and problems, see, for example (alphabetically): Born (1927, pp. 259–261), Frank (1935, pp. 203–209, 214–218), Meirovitch (1970, pp. 376–377), Saletan and Cromer (1971, pp. 252–256), Straumann (1987, pp. 271–273).

Leimanis (1965) — analytical rigid-body dynamics until the mid-1960s

Mikhailov and Parton (1990) — advanced topics in analytical mechanics and stability of equilibrium/motion; complements and updates the list of Neimark and Fufaev

Neimark and Fufaev [1967 (1972)] — analytical mechanics, theory and applications; includes most Soviet/Russian works until the early 1960s

Papastavridis (*Elementary Mechanics*, under production) — comprehensive treatise/compendium of Newton-Euler (momentum) mechanics of particles, rigid bodies, and continua, with extensive reference/bibliography lists.

Roberson and Schwertassek (1988) — multibody and computational dynamics; see also Huston (1990)

Stäckel (1905) — elementary and intermediate theoretical dynamics until the early 1900s

Voss (1901) — principles of theoretical mechanics until 1900

Ziegler (1985) — geometrical methods in rigid-body mechanics

Abbreviations used below:

AIAA: American Institute of Aeronautics and Astronautics (U.S.)

PMM: Journal of Applied Mathematics and Mechanics (English translation from the Russian)

Springer: Springer-Verlag

ZAMM: Zeitschrift für angewandte Mathematik und Mechanik (German)

ZAMP: Zeitschrift für angewandte Mathematik und Physik (Swiss)

For a steady supply of worthwhile material from the frontier of (classical) theoretical/analytical dynamics, including archival papers, discussions, and book reviews, we recommend the following journals:

American Journal of Physics

Applied Mathematics and Mechanics (English translation from the Chinese)

Archive of Applied Mechanics (German, formerly *Ingenieur-Archiv*)

International Journal of Non-Linear Mechanics (U.S.)

PMM

ZAMM

ZAMP

Also:

Journal of Applied Mechanics (ASME)

Journal of the Astronautical Sciences

Journal of Guidance, Control, and Dynamics (AIAA)

Nonlinear Dynamics

For the historical and cultural aspects of mechanics, etc., we recommend the following journals:

Archive for History of Exact Sciences

Centaurus (International Magazine of the History of Mathematics, Science, and Technology; Munksgaard, Copenhagen)

Physics Today

A

Abbreviations, 15
Abbreviations, symbols, notations, formulae, 14–70
Absolute
 (or inertial) frame of reference, 90, 105–106
 integral invariant, 1233
Acatastatic/catastatic (Pfaffian) constraint, 247, 249, 303
Acceleration
 absolute (or inertial)/centripetal/Coriolis/relative/transport, 91 ff., 121, 278–279, 620, 623
 angular
  tensor, 191–192
  vector, 117, 379–380
 in orthogonal curvilinear coordinates, 96 ff.
 in system variables, 278–279, 308, 311
  Lagrangean, 537–542
  nonholonomic, 542–544
Accessibility, in configuration space, 263
Accompanying vectors (Heun's "begleitvektoren"), 279 ff.
Action
 (–angle) variables, 1254 ff.
  and atomic physics, 1273–1274
 averaged, 1062, 1065
 Hamiltonian, 991–992, 1055 ff., 1218 ff.
 integral (functional) of, 991 ff.
 reduced (or abbreviated), 1196, 1223, 1225–1226
 Lagrangean, 992 ff., 994
Action and Reaction, Law of (or Principle of), 108–109
Active/passive interpretations of a proper orthogonal tensor, 178–192
Actual displacements, 278 ff.
Addition theorem for angular velocities, 174, 189–190
Adiabatic
 invariance/invariants, 1013–1018, 1290–1305
 theorem
  Boltzmann–Clausius form of, 1296
  Ehrenfest form of, 1296
  Planck form of, 1296
Adjoining/embedding of constraints, 410 ff., 425, 707
Aizerman, M. A., 1061, 1237
Alishenas, T., 277
Alt, H., 140
Altmann, S. L., 14, 140
Amaldi, U., 323, 975
Ames, J. S., 138, 170
Analogies between forces/moments and velocities, 147–148
Analytical mechanics, 4 ff., 702 ff.
Analytical statics, 394–397, 602–604
Angeles, J., 129, 265, 312
Angle (–action) variables, 1254 ff.
Angles
 Cardanian (yaw, pitch, roll), 202–205
 Eulerian (nutation, precession, spin), 192–202
Angular
 acceleration
  tensor, 191–192
  vector, 117–118
 (or rotational) displacement, 141 ff., 155 ff.
 momentum, principle of, 107–113
 speed, 144, 173
 velocity
  addition theorem for, 174, 189 ff.
  components, for all Eulerian angle sequences, 205–212
  in orthogonal curvilinear coordinates, 137–138

Angular (*cont.*)
tensor, 131 ff., 137, 188 ff.
vector, 114, 118 ff., 144 ff., 172 ff., 188–192, 197–202, 204–205, 206 ff.
Anti- (or skew-) symmetric tensor, 76
Apparent indeterminacy of Lagrange's equations, 425–426
Appell, P. E., x, xv, 11, 404, 421, 466, 626, 645, 650, 689, 705, 714, 724, 787, 923, 1179, 1212
Appellian inertial terms
holonomic variables, 403
nonholonomic variables, 403–404
Appell's
classification of impulsive constraints, 725 ff.
equations, 418, 493, 704 ff., 755, 837
explicit forms, 563–566
function (or Appellian, or Gibbs–Appell function, or acceleration energy), 403
constrained, 424, 493
Archangelskii, Ju. A., 14
Areal velocity, 94, 466 ff.
Argyris, J., 164
Arnold, V. I., 8, 14, 457, 1314
Arrighi, G., 755
Astatic equilibrium, virtual work characterization of, 604
Astronomical (or absolute) frame of reference, 90, 104 ff.
Asymptotic
methods in nonlinear oscillations, 1047
stability, 551 ff., 1067, 1123 ff.
Atkin, R. H., 254
Atwood's machine, 477 ff.
Averaging, method of, 1049 ff., 1215
Axes
fixed (inertial)/moving (noninertial), 113 ff.
of inertia, principal, 216 ff.
Axial vector, of a second-order tensor, 80, 85
Axioms (or principles, or postulates) of mechanics, 102, 106 ff., 392
Axis
instantaneous, 144
of rotation, 155 ff.
screw, 143, 147 ff.

Chorlton, F., 228, 770, 772
Christoffel symbols
  of first kind, 538 ff., 543 ff., 929
  of second kind, 540 ff.
Circular frequency, 1250
Clausius, R., 939, 1296
Clifford, W. K., 279
Closed form solution, 571
Coe, C. J., 13, 140, 155, 170, 176, 263, 283, 714, 911
Coefficient(s) of
  Chaplygin, 339, 824, 831
  friction, 238–239
  Hamel, 313 ff., 321 ff., 342 ff., 824
  inertia, 795, 802 ff., 1022–1023
  restitution, 726, 735

Coefficient(s) of (*cont.*)
stiffness/stability, 1022
Voronets, 339, 824
Cole, J. D., 1303
Collision(s), elastic/inelastic, 725, 726, 734–736
Combination tones and overtones, 1288–1289
Commensurable (or commensurate) frequencies, 1261, 1267 ff., 1271 ff.
Components
of tensors, 75 ff.
of vectors, 72 ff.
physical, 95 ff.
vs. projections (nonorthogonal axes), 598–602
Composition of (finite) rotations, 168 ff.
Conditions (or tests) of
canonicity of a transformation, 1164 ff., 1180 ff.
compatibility (here, holonomicity), 269
Jacobi (of sufficiency variational theory), 1058–1061
Legendre–Weierstrass (of sufficiency variational theory), 1058–1059
Maurer–Appell–Chetaev–Johnsen–Hamel (in nonlinear constraints), 820–821, 957 ff.
Conditionally (or multiply, or quasi-) periodic motion, 1260 ff., 1267–1268, 1269 ff., 1287 ff.
Configuration
of a system, 243
space, 291 ff.
Conjugate kinetic focus (in sufficiency variational theory), 1058–1061
Conservation of
energy, 522, 575 ff.
mass, 107
momentum
angular, 107 ff.
generalized (i.e., system), 573 ff.
linear, 107
Constant
gravitational, 1248
of the motion, 569
spring (i.e., stiffness), 440
Constitutive postulate, Lagrange's principle as, 388–393
Constrained motion, 244 ff.
Constraint reactions (forces and/or moments), 382 ff.
Constraint(s)
acatastatic/catastatic, 247, 249
addition/relaxation of, 273–275
bilateral (or equality, or reversible)/ unilateral (or inequality, or irreversible), 248–249, 388, 410, 484 ff., 604
classifications of, 243
control (or servo-), 636–650
definitions of, 249
external/internal, 249
forces of (or reactions of), 382 ff.
geometrical interpretation of, 291 ff., 331 ff.
holonomic (or finite, or geometric, or integrable, or positional), 245
impulsive (Appellian classification), 724 ff.
inequality (or unilateral, or irreversible), 248, 388
linearly independent, 301 ff.
nonholonomic (or nonintegrable motional), 246
nonideal, 397–398
nonlinear, 818 ff.
Pfaffian, 245, 257 ff., 262, 287–288, 294, 323 ff.
rheonomic (or nonstationary)/scleronomic (or stationary), 247
second-order, 871
semiholonomic, 264
servo- (or control), 636–650
sudden rupture of, 726, 733
system forms of, 270 ff., 286 ff.
transitivity equations, 334 ff.
virtually workless, 386 ff.
Contact
of rigid bodies
kinematics, 153 ff.
kinetics, 237 ff.
transformation(s), 1190
Coordinate system vs. frame of reference transformation, 87 ff.
Coordinates
Cartesian, 72
controllable (or macroscopic)/ uncontrollable (molecular), 1290 ff.
curvilinear, 271
cylindrical/spherical, 95 ff., 97 ff.
equilibrium (or adapted), 275
excess, 276
generalized (or curvilinear), 271 ff.
holonomic, 271 ff., 305 ff.
ignorable (or cyclic, or absent, or kinosthenic, or speed), 1097 ff., 1199
inertial/noninertial, 272, 608 ff.

Lagrangean, 271 ff.
nonholonomic (or quasi coordinates), 212 ff., 301 ff., 304 ff.
normal, or principal, 435 ff., 1018 ff.
orthogonal curvilinear, 94 ff.
palpable (or positional, or essential), 1088, 1098
quasi (or nonholonomic), 212 ff., 301 ff., 304 ff.
regular, 292
spherical, 95, 97
system, 270 ff., 272
Corben, H. C., xi, 14, 323, 446, 527, 537, 941, 1079
Coriolis
acceleration, 121
force, 128 ff.
Correction/deviation, nonholonomic, 402, 824, 838
transformation properties, 508 ff., 840 ff.
Cotton, E., 421
Coulomb–Morin law of friction, 238 ff., 384, 397, 425
Couple, gyroscopic, 621–622, 1111
Coupling/uncoupling
gyroscopic, 1105, 1124
inertial (or dynamical), 539
of penduli, 430 ff., 1280–1281
Crandall, S. H., xi, 13, 155, 218, 1076
Cromer, A. H., 8, 572, 1249, 1298, 1305, 1322
Cunningham, W. J., 1069
Curvature
least (or straightest path, Hertz's principle), 930–933
radius of, 91 ff., 125 ff.
Cut principle (free-body diagrams), 392–393
Cyclic (or ignorable, or absent, or kinosthenic, or speed) coordinates/systems, 1097 ff.
Cylindrical coordinates, 95, 97

D

D'Abro, A., 12
D'Alembert, J. Le Rond, 4, 10
D'Alembert's
force decomposition (“ansatz”), 384
principle, in Lagrange's form, 386, 637
Damping, 519 ff.
forces (viscous), 519–520, 549–550
Darboux, G., 163
Darboux vector, 126
Davis, P. J., xiii, xiv
Deahna, H. W. F., 269
De Donder, T., 1294
Degeneracy, 1269 ff.
Degrees of freedom, global (geometrical)/local (motional), 246, 264
Delassus, E., 12, 701
Delaunay, C., 385, 1258
Delaunay's theorem on impulsive motion, 788 ff.

Delta of Kronecker, 73, 1248
Denman, H. H., 1043
Density of matter, 99
Derivative (or rate of change), absolute/relative/transport, 114
Desloge, E. A., xi, 323, 713
Determinant, characteristic, 82
Determinism, 570 ff., 1188
Deviation/correction, nonholonomic, 402, 824, 838
Dextral basis, 73
Differential
form(s) (or Pfaffian)/equations, 257 ff.
integrability (or holonomicity) of, 257 ff., 265 ff., 268 ff., 334 ff., 343 ff.
variational principles, 875–933
Direct variational methods of Galerkin and Ritz, 1034 ff.
Direction, cosines, 84, 178 ff.
Dirichlet, P. G. L., 1128, 1268
Disk (or coin, or ring, or hoop), rolling of, 235 ff., 351 ff., 359 ff., 590–591, 680 ff., 986 ff.
Displacement(s)
actual, 278 ff.
classification of, 280 ff.
infinitesimal, 144 ff.
irreversible (or one-sided)/reversible (or two-sided), 248, 388, 484 ff.
kinematically admissible (or possible), 280 ff.
of a particle, 278 ff.
of a rigid body, 138 ff., 140 ff., 155 ff., 177 ff.
plane (or planar), 140–141
screw, 143, 147–148
vector, 155 ff., 177 ff.
virtual, δ-operator, 280 ff., 290–291
Dissipation function, of Rayleigh, 519–520, 549–550
Dissipative forces, 519

Dittrich, W., 14, 1273, 1305, 1314, 1321
Divisors, elementary (or small), 444, 1310, 1313–1314
Djukic, D. S., 323
Dobronravov, V. V., xi, 12, 13, 14, 312, 317, 323, 382, 497, 529, 656, 855, 1198, 1249
Dolaptschiew, B., 901
Donkin, W. F., 1071, 1076
Double pendulum, 430 ff., 738, 804
Duffing's equation, 945, 1030 ff., 1037 ff., 1051 ff.
Dugas, R., 12, 231, 911, 1151
Duhamel's superposition integral, 1064
Duhem, P. M. M., 626
Dühring, E., 12
Dyad (-ic, i.e., second-order/rank tensor), 75 ff.
Dyname (or torsor) of a vector system, 148
Dynamic (or inertial) coupling, 539
Dysthe, K. B., 443

E

Easthope, C. E., 13, 219, 718, 785, 1095
Ehrenfest, P., 705, 933, 1290, 1294, 1296
Eigenvalues/eigenvectors of a second-order tensor, 81 ff.
Einstein, A., xiv, xxiii, 7, 9, 88, 90, 817, 1015
Ellipsoid of inertia, or momental ellipsoid, 218 ff.
Elsgolts, L., 1006, 1056
Embedding/adjoining of constraints, 410 ff., 425, 707
Energy
  conservation of, 522
  generalized, 521
    in cyclic systems, 1105–1106
  gyroscopic, 1124
  in relative motion, 631, 1084
  integral(s) of, 522, 524, 567 ff.
  kinetic
    of a rigid body, 582 ff., 585 ff.
    of a system, 511 ff.
  of acceleration (or Appellian), 403–405, 594–597
  potential, 515 ff.
  rate theorem, 520 ff., 938–939
  relation to frequency (frequency rule), 1256 ff.
  variation from a steady motion, 1119
Equality (or bilateral, or reversible) constraints, 248, 348
Equation(s) of
  Appell, 418, 493, 563 ff., 704 ff., 755, 837
  Boltzmann, 704 ff.
  central, 461 ff., 506–507, 832 ff., 1073, 1089, 1219
  Chaplygin, 495–497, 845, 847, 907
    generalized, 497–498
  Chaplygin–Hadamard, 491 ff.
  constitutive (in Lagrange's principle), 383 ff.
  Dolaptsiew, 886–887
  Euler (gyro–equations), 230
  Euler (impulse–momentum principles), 106 ff., 228 ff.
  Ferrers, 702 ff.
  geometrical interpretation, 427–428
  Gibbs, 595
  Greenwood, 704
  Hadamard, 844
  Hamel (or Lagrange–Euler), 419, 421 ff., 503–505
    Hadamard form of, 503
    mixed Hamel–Voronets, 505–508
    special, 503–505
  Hamilton (canonical), 1073 ff.
  Hamilton–Jacobi, 1193 ff.
  impulse–momentum, 718–720
  Jacobi (of sufficiency variational theory), 1057
  Jacobi–Synge, 562–563
  Johnsen (–Hamel), 833
  Kelvin–Tait, 1103 ff.
  Korteweg, 494
  Lagrange, 418 ff.
    explicit forms, 537–563
    of first kind, 411 ff.
    of second kind, 418 ff.
    special forms, 486–510
  Maggi, 418 ff., 752, 837
  Mangeron–Deleanu, 886–887, 891–892, 897
  Mathieu, 442 ff., 1068–1069
  mixed, of Hamel–Voronets, 505–508
  motion, 409 ff., 418 ff., 486 ff.
    first integral(s), 567 ff.
    integration and conservation theorems, 566 ff., 1249

  perturbations (Hamiltonian), 1147 ff.
  Poincaré, 1066
  Quanjel, 495

Routh, 1089
Routh–Voss (i.e., Lagrange's equations with multipliers), 419, 730, 836
special (Hamel), 503–505
Tzénoff, 885, 894 ff.
van der Pol–Krylov–Bogoliubov, 1050, 1242
variations
of Jacobi, 1057–1058
of Poincaré, 1066
Volterra, 419
Voronets, 498–500, 845
generalized, 501–503
work–energy rate, 520 ff.
Equilibrium, 387, 602–604
astatic, 604
Euclidean geometry/manifold(s)/space(s), 89–90, 269, 291 ff.
Euler, L., xviii, 4, 10, 102, 107
Euler–Lagrange
differential equation (of variational calculus), 962, 1056, 1058
operator, 280, 311, 615
Eulerian
angles [precession, nutation, proper (or eigen) spin], 192 ff.
equations (kinetic), 230
rigid-body formula, 144 ff.
Event/event space, 90, 293 ff.
Exactness conditions (of a Pfaffian form), 305
Extended configuration (or event, or film) space(s), 293
External/internal forces, 102–103, 108–109, 384–385, 392
Extremal properties of Hamiltonian action, 1055–1062

F

Falk, G., 945
Ferrarese, G., 176, 333
Ferrers, N. M., 10, 11, 702 ff.
Fetter, A. L., 451
Finch, J. D., 704
Finite rotation, 155 ff.
as an eigenvalue problem, 167–168
composition of, 168 ff.
tensor, 161 ff.
"vector(s)" (of Gibbs et al.), 156 ff.
Finzi, B., 935
First
integrals, 567 ff.
law of thermodynamics, 1296
Fischer, U., 323, 1041
Focus kinetic (in sufficiency variational theory), 1058–1061
Fomin, S. V., 935, 960, 1006, 1056
Föppl, A., 3

Force function, 522
Force(s)
apparent (i.e., frame-dependent, or relative), 127 ff.
arguments of the, 101–102, 385–386
centrifugal, 128, 221–222
circulatory, 548
classification, 102–103, 382 ff., 548 ff.
constraint (reactions), 382 ff.
contact, 237 ff.
Coriolis, 128 ff.
damping (dissipative), 519–520, 549
elastic (potential), 548
equipollent/equivalent, 603, 709
external/internal (or mutual), 108, 384 ff., 392
friction (Coulomb–Morin, i.e., solid/solid), 238–240, 384–385, 397, 425–426
generalized (i.e., system), 405 ff.
given (physically, or impressed), 382 ff.
gravitational, 103 ff., 1248
gyroscopic, 454, 517 ff., 549, 1104–1105
impressed (or physical, i.e., physically given), 382 ff.
impulsive, 719–723
inertial, 128 ff.
internal (or mutual), 108, 384 ff.
Lagrangean (or system, or generalized), 405 ff.
in relative motion (of translation, centrifugal, rotational, gyroscopic/ Coriolis), 615 ff., 618–619
lost (in Lagrange's form of d'Alembert's principle), 386
momental (or associated), 400
motional, 548
of constraint (or constraint reactions), 382 ff.
passive/servoreactions, 382, 636 ff.
positional, 548
potential, 515 ff.
reactions (of constraint), 382 ff.
reduction of a system of, 148
system (or Lagrangean, or generalized), 405 ff.
Form/equation, linear (Pfaffian), differential, 257 ff., 265 ff., 287–288, 296 ff.

Förster, W., 928
Forsyth, A. R., 260, 266, 270, 299, 343
Fourier, J. B., 604
Fourier series, 1034, 1049, 1250, 1266–1267, 1269, 1288–1289
Fox, C., 1006, 1056
Fox, E. A., 1, 13, 71, 99, 170, 237, 242, 704, 960
Frame(s) of reference, 87 ff., 90
  effect on
    impulsive motion, 731–732
    Routh–Voss equations, 451–452
  inertial (or fixed, or Newtonian), 90
  noninertial/rotating (or moving), 113 ff., 622–634
Frank, P., 1004, 1072, 1127, 1129, 1180, 1198, 1287, 1322
Free-body diagram (Euler's "cut principle"), 392–393
Free vector, 72
Freedom, degrees of, 246, 264
French, A. P., 5
Frenet–Serret (or Serret–Frenet) formulae, 125 ff.
Frequency (-ies)
  circular, 1250
  combination tones and overtones, 1287 ff.
  commensurable (or commensurate)/ noncommensurable (or noncommensurate), 1261, 1267 ff., 1271 ff.
  relation to energy, 1256 ff.
  rule, 1265 ff.
Friction (Coulomb–Morin, i.e., solid/solid), 238–240, 384–385, 397, 425–426

Identity of Poisson–Jacobi, 1178–1179
Ignorable (or cyclic, or absent, or kinosthenic, or speed) coordinate(s), 1097 ff., 1199
Ignoration of coordinates, 1097 ff., 1173, 1192 ff., 1199, 1206
Impact, elastic/inelastic, 726, 735
Impulsive
  constraint(s) (Appellian classification of), 724 ff.
  force, 719, 723
  motion
    Lagrangean theory, 721–724
      in quasi variables, 751 ff.
    Newton–Euler theory, 718–721, 733–736
  theorem of
    Bertrand (Delaunay–Sturm), 788 ff.
    Carnot, 785 ff.
    energy, 720
    Gauss, 793–794
    Kelvin, 787–788
    Robin, 791 ff.
    Taylor, 790–791
Indicial notation (Cartesian vectors/tensors), 73
Inelastic collision, 726, 735
Inequality (or unilateral) constraint, 248–249
Inertia
  coefficients, 511
  ellipsoid of, 218 ff.
  matrix, 512
  moments of, 216 ff.
  moments/products of, extremum properties, 220 ff.
  principal axes and moments of, 216 ff.
  products of, 216 ff.
  tensor (or dyadic), 215 ff.
  transfer (parallel axis) theorem, 217
Inertial
  coupling/decoupling, 539–540
  force, 127 ff.
  frame of reference, 90
Infinitesimal
  canonical transformations, 1188 ff.
  displacements, 144
  rotations, 171 ff.
Initial conditions (positions, velocities), 567 ff., 570–571
Instantaneous
  axis of rotation, 583
  center of zero
    acceleration, 151 ff.
    velocity, 150 ff.
Integrability
  conditions of
    nonlinear constraints, 824–825
    Pfaffian constraints, 268 ff., 1263
  via Hamilton–Jacobi theory (separability), 1192 ff., 1263 ff.
Integral(s)
  classical (of the equations of motion)/ conservation theorems, 566–580, 1249
  invariants, 1230–1243
    absolute/relative, 1233
  of energy/Jacobi–Painlevé, 131, 522 ff., 999
    in Routhian form, 1106
  stability criterion (of Blekhman), 1062–1069
  variants, 1239 ff.
Internal/external forces, 102–103, 108–109, 384 ff.
Interpretations of a proper orthogonal tensor, 178 ff.
Invariance
  à la Noether, 1243 ff.
  of Routh–Voss equations under frame of reference transformations, 451–452
  under gauge transformations, 1246 ff.

under time translations/rigid spatial translations/infinitesimal rigid rotations, 1245–1246
Invariants
adiabatic, 1290–1305
in general, 262
integral, 1230–1243
of a second-order tensor, 82
of antisymmetric (or skew-symmetric) tensor, 83
Inverse matrix/tensor, 77
Ishlinsky, A. Iu., 254
Ishlinsky's problem, 254–255

J

Jacobi, C. G. J., 10, 413, 562, 923, 1180
Jacobi instability criterion, 941 ff.
Jacobi–Painlevé integral, 522 ff.
Jacobi–Poisson theorem, 1179–1180
Jacobi's
(geodesic) form of principle of least action, 1001–1002, 1223–1224

invariants of a second-order tensor, 82
product, 73, 76 ff.
Schaefer, C., 715, 1294
Schaefer, H., xv, 323, 715, 882
Scheffler, H., 923
Schell, W., 439
Schering potential, 620
Schiehlen, W. O., 14, 714
Schieldrop, E., 883
Schild, A., 783
Schmutzer, E., 1249
Schönflies, A., 127, 140
Schouten, J. A., 246, 294, 306, 312, 317, 322, 323, 421, 505
Schräpel, H. D., 1044
Schwartz, B., xii, xxiii
Schwarzschild, K., 1258
Schwertassek, R., viii, xiii, 14, 264, 265, 1323
Scleronomic (/rheonomic) constraints, 247
Screw, axis/displacement/motion, 143, 147 ff.
Second variation of (Hamiltonian) action, 1056–1061
Secular (or characteristic) equation, 550, 1018, 1123, 1124
Segner, J., 222
Semenova, L. N., 868, 870
Separable system, 1197 ff.
Separation of variables/separability, Hamilton–Jacobi equation, 1197 ff.
Serbo, V. G., 1305
Serret–Frenet (or Frenet–Serret) formulae, 125 ff.
Serrin, J., 470
Shabana, A. A., 14, 265
Shepley, L. C., 1303
Shuster, M. D., 155
Simonyi, K., 12, 1274
Simply (or singly) periodic motion, 1271 ff., 1288 ff.
Skate (or knife, or narrow boat, or pizza cutter, or razor blade, or sled) problem, 345 ff., 650 ff., 889–890, 954 ff.

Skew- (or anti-) symmetric tensor, 76 ff.
Sleeping top, 1112–1113
  stability of, 1114–1115, 1141
Small
  (or resonant) denominators (or divisors), 444, 1310, 1313–1314
  oscillation(s) method, 545 ff.
Smart, E. H., x, 718, 766, 773, 785, 811, 813, 1023, 1114
Smilansky, U., 1056
Smith, C. E., 13
Sneddon, I. N., 263
Sokolnikoff, I. S., 269, 783
Sommerfeld, A., 8, 13, 264, 383, 911, 1262
Somoff, J., 279
Space
  axioms, 89–90
  configuration, 291 ff.
    constrained, 293 ff.
  Euclidean, 292
  event, 293
  extended, 293
  homogeneous/isotropic, 89, 577
  phase, 1071, 1074
  Riemannian, 292
Speed, 91, 95
  angular, 173
Sphere, 353 ff., 648 ff., 658 ff., 988 ff.
Spherical
  coordinates, 95, 97
  pendulum, 445 ff., 1083
Spiegel, M. R., vii, 13, 219, 633
Spin
  proper (or intrinsic) Eulerian angle of rotation (or eigen spin), 194–195 (fig. 1.26)
  total, 634, 1108, 1118
Spring, linear/nonlinear, 440 ff., 1288
Stability
  asymptotic (Lyapounov's theorems), 550 ff., 1067, 1123 ff.
  gyroscopic (in steady motion), 1122 ff.
  integral criterion of, 1062–1069
  linear(-ized)/nonlinear, 550 ff.
  of steady motion, 447–448, 550 ff., 1119–1142
  of (steady precession, etc., of) top, 1109, 1114–1115, 1140 ff.
  ordinary (or temporary, or dynamical) vs. practical (or permanent, or secular), 1127 ff.
Stäckel, P., 7, 13, 225, 231, 385, 683, 791, 923, 1258
Stäckel
  conditions, 1198
  form of Hamiltonian, 1198
Stadler, W., xvii
Steady (or stationary)
  motion, 548 ff., 1115 ff., 1122
    stability of, 447 ff., 550 ff., 1119–1142
  precession of top, 1118
    stability of, 1140 ff.
Stehle, P., 14, 323, 446, 527, 537, 941, 1079
Stepanovskii, Yu. P., 14, 1018, 1290
Stephan, W., 323, 1041
Stieltjes integral, 101, 103
Stoker, J. J., 1053, 1314
Stoneking, C. E., 708
Straumann, N., 14, 1322
Struik, D. J., 13, 312
Stückler, B., xv, 242, 323, 368, 421
Sturm–Liouville form (of Jacobi's variational equation), 1058
Sturm's theorem on impulsive motion, 788
Sudarshan, E. C. G., 1250
Suggestions to reader for background, concurrent, and further reading, 13–14
Summary of formulae, notations, etc., 15–70
Summation convention (for Cartesian vectors and tensors), 73
Superposition
  integral (of Duhamel), 1064
  of linear vibrations (theorem of Daniel Bernoulli), 1022
Suslov, G. K., x, 11, 13, 341, 590, 718, 975
Symbol(s) of
  Christoffel
    of first kind, 538 ff., 543 ff., 929
    of second kind, 540 ff.
  Hamel (or coefficients of)
    linear (Pfaffian), 313 ff., 321 ff., 342–343
    nonlinear, 824
Symmetric, matrix/tensor, 76
Symplectic matrix, 1187
Synge, J. L., x, 6, 13, 14, 71, 72, 221, 242, 312, 317, 322, 333, 337, 382, 562, 775, 783, 1021, 1070, 1129
System
  acatastatic/catastatic, 247, 249
  closed/open, 572 ff.
  conservative/nonconservative, 520 ff.
  coordinates (or positional parameters), 271 ff.
  holonomic/nonholonomic, 245
  nonseparable, 1273

System (*cont.*)
of Liouville, Stäckel et al., 578–580
quasi coordinates, 304 ff.
reduced (or apparent, or palpable, or visible), 1102
rheonomic (or nonstationary)/scleronomic (or stationary), 247
separable, 1197 ff., 1260 ff.
System of coordinates (orthogonal curvilinear), 94 ff.
Szabó, I., 12, 101, 323, 440, 446, 621

T

Tabarrok, B., 935
Tabor, M., 14, 571, 1072, 1087, 1199, 1263, 1273, 1305, 1314
Tait, P. G., x, 10, 106, 271, 272, 381, 439, 539, 788, 1056, 1070, 1129, 1134, 1148 ff.
Tangent vector, to a curve, 91 ff. (fig. 1.1), 94–95, 125 ff.
Tarleton, F. A., 1013
Taylor's theorem on impulsive motion, 790–791
Tchapligine, S. A., or Tchaplygine, S. A., *see* Chaplygin, S. A.
Tetherball, 860 ff.
Tensor
algebra, 75 ff.
alternating (Levi–Civita ε-symbol), 73
antisymmetric (or skew-symmetric), 76 ff.
Cartesian, 75
eigenvalues/eigenvectors of a, 81 ff.
notations, 87
orthogonal (proper), 84 ff.
active/passive interpretations of a, 178 ff.
symmetric, 76 ff.
transformation, 84 ff.
unit (or identity), 78
zero, 78
Tensor of
angular momentum, 234
angular velocity, 234
inertia, 215 ff.
moment, 234
(finite) rotation, 161 ff.
second order (or dyadic), Cartesian, 75 ff.
Test of canonicity of a transformation, 1164 ff., 1180 ff.
Theorem(s) of
Bertrand (and Delaunay), 788 ff.
Carnot, 785 ff.
Chasles (geometry of rigid motion), 143
cyclic power, 1105 ff.
Dirichlet, 1126, 1128, 1268
Ehrenfest, 1296
energy rate (or power), 520 ff., 670–674
in relative motion, 129 ff., 623, 627, 631, 635–636
equipartition, 941, 948, 1012, 1065
Euler (geometry of rigid motion), 141
extremum in impulsive motion, 784 ff., 794
Frobenius, 298 ff., 335 ff.
Gauss, 793 ff., 815 ff.
Hamilton–Jacobi, 1192–1218
Huygens–Steiner (generalized parallel axis theorem), 217–218
Jacobi, 1193 ff.
Kelvin, 787–788
König, 225 ff. [eq. (1.17.3d)], 583
Lagrange–Jacobi, 941
Lagrange–Poisson, 1143 ff.
Liouville, 1211–1212, 1236
mechanical transformability, 1298
moving axes, 86–87, 113 ff.
Mozzi (rigid-body kinematics), 145 ff.
Noether, 1243–1250
Poisson–Jacobi, 1179–1180
Robin, 791 ff.
spectral decomposition (of second-order tensors), 81 ff.
Stokes (–Kelvin), 1234, 1240
Taylor, 790–791
Vinti, 1268–1269, 1296–1297
virial, 939 ff.
work–energy in impulsive motion, 720
Thermodynamics, first law of, 1296
Thomas, R. B., Jr., 1043
Thomson, J. J., 7, 1018
Thomson, W. (Lord Kelvin), x, 7, 10, 106, 271, 272, 381, 439, 539, 635, 788, 1056, 1070, 1103, 1129, 1134
Time
absolute (and homogeneous), 89–90, 104 ff., 575
as canonical variable conjugate to energy, 1075–1076, 1165 ff.
as $(n+1)$th Lagrangean coordinate, 535–537
-dependent potential, 515 ff.
-derivative(s), 113 ff.
Timerding, H. E., 14, 140, 155
Timoshenko, S. P., 439, 440, 766
Tiolina, I. A., 12
Tomonaga, S.-I., 1018
Top (gyroscope)
Hamilton–Jacobi equation, 1204 ff.

Hamiltonian and Routhian treatments, 1107 ff.
heavy symmetrical, 1107 ff.
sleeping, 1109, 1112–1113
stability of, 1109, 1114–1115, 1141
stability of, 1109
steady precession of, 1140–1142
Torsor (or dyname), of a vector system, 148
Toupin, R., 103, 192, 244, 269, 924
Trace, of a matrix, 77
Transformation
canonical, 1161 ff.
contact, 1190
coordinate (geometrical) vs. frame of reference (kinematical/physical), 87 ff.
Galilean, 104 ff.
infinitesimal (canonical), 1188 ff.
Legendre, 1076–1077
matrices (all possible Eulerian sequences), 205–212
orthogonal, 83 ff.
orthonormal, 84
point, 116
proper orthogonal, 84
Transfer theorem for angular momentum, 109 ff.
Transitivity (or noncommutativity, or transpositional) relations
for a rigid body, 368 ff., 374 ff.
linear (Pfaffian), 312 ff.
nonlinear, 825 ff.
Translation, of a body, 141, 143, 177 ff.
Transposed matrix, 77
Triple vector product, scalar/vector, 74
Truesdell, C. A., xiii, xiv, xviii, xxiii, 7, 13, 101, 103, 192, 242, 244, 269, 817, 924
Tsenov (or Tzénoff), I. V., 886
Turner, J. D., 14, 192

U

Udwadia, F. E., 714, 924
Unilateral (or inequality, or irreversible)/ bilateral (or equality, or reversible) constraint(s), 248–249, 388, 410, 484 ff., 604
Uniqueness of Lagrangean, 452 ff., 1246 ff.
Unit
dyadic/matrix/tensor, 78
vector(s), binormal/normal/tangent, 91, 92 (fig. 1.1), 125 ff.
Unstable vs. stable, state of motion, 550 ff.

V

Vagner, V. V., 312, 313
Valeev, K. G., 1063
Variables, action–angle, 1254 ff.
Variation
admissible/possible/virtual, 280 ff., 290–291, 936 ff.
contemporaneous (or vertical), 936 ff.
Lagrangean action, 1056 ff.
noncontemporaneous (or skew), 937–938, 991 ff.
of constants (or parameters), 1143–1161, 1212 ff.
theorem of Lagrange–Poisson, 1143 ff., 1145
of kinetic energy, 528–529, 937, 950, 959, 972 ff., 976 ff., 979 ff.
of potential energy/work, 515 ff., 528–529
Variational
calculus and mechanics, 960 ff.
equations
of Jacobi, 1057 ff.
of Poincaré, 1066
methods in oscillations, 1034 ff.
principles
differential, 875–933
integral, 960 ff., 990, 1007, 1221 ff.
for cyclic systems, 1224–1225
theorems for gyroscopic systems, 947–948
Vector(s)
algebra, 72 ff.
axial/polar, 79 ff., 84 ff.
bound/free, etc., 72
cross (or vector) product of, 74
Darboux (of angular velocity of Frenet–Serret triad), 126
dot (or scalar) product of, 73
of second-order (antisymmetric) tensor, 79 ff.
tensor product of, 74 ff.
unit, 72 ff.
Velocity
absolute/relative/transport, 120 ff.
angular, 114
-dependent (or generalized) potential, 453–454, 516 ff.
in orthogonal curvilinear coordinates, 94 ff.
in a rigid body, 144 ff.
in system variables
holonomic (or Lagrangean, or generalized), 278 ff.

Velocity (*cont.*)
nonholonomic (or quasi variables), 306 ff.
initial (in initial conditions), 566 ff.
instantaneous center of zero, 150 ff.
linear (of a particle), 91 ff.
relative (of a particle), 120
Vesselovskii, I. N., 12
Vibration pressure (in adiabatic pendulum), 1016
Vibrations (or oscillations)
about (absolute) equilibrium, 429 ff.
stationary/extremum properties via Rayleigh's principle, 1018 ff.
about steady motion (or relative equilibrium), 548 ff., 1122 ff.
Vierkandt, A., 11
Vinti, J. P., 1268
Virial (of a force system), 939 ff.
Virtual
change of kinetic energy, 528–529, 937, 950, 959, 972 ff., 976 ff., 979 ff.
displacement
particle form, 280 ff., 290–291, 304, 821 ff.
system form, 708 ff., 820–821
velocity, 512
work(s), 386
in impulsive motion, 722, 723
of a force, 386 ff., 405 ff., 597 ff.
of a gyroscopic force, 518
of inertial forces, 399 ff.
principle of (in statics), 394–397, 604
Volkmann, P., 911
Volterra, V., 11, 313, 404, 419, 706 ff.
Voronets, P., 11, 974
Voronets coefficients, 339
Voss, A., 13, 413, 417, 704, 715, 972
Vranceanu, G., 312, 317, 322, 323, 333, 337
