To the living and loving memory of my father,

GEORGE S. PAPASTAVRIDIS
(ΓΕΩΡΓΙΟΥ Σ. ΠΑΠΑΣΤΑΥΡΙΔΗ)

A lawyer and fearless maverick, who, throughout his life, fought with fortitude, conviction, and class to better his world;
and to whom I owe a critical part of my *Weltanschauung*.

[The author's father is shown here in the traditional Greek *foustanélla*, in Athens, Greece (Themistokléous street, near *Lófos Stréfi*), ca.1924]

PREFACE TO THE CORRECTED REPRINT

This is a *corrected* reprint of a work first published in early 2002, by Oxford University Press, and which went out of print shortly thereafter.

A few sign misprints and similar errors have been corrected; some notations have been, hopefully, improved (especially in Chs. 1, 2); a useful addition has been made on p. 336, and a couple of sections have been thoroughly revised (e.g. §3.12, §8.13).

I am grateful to (a) the many reviewers, in some of the most prestigious professional journals and elsewhere (e.g. *Bulletin of the American Mathematical Society*, *IEEE Control Systems Magazine*, *Zentralblatt für Mathematik*; amazon.com and amazon.co.uk, private communications, and references in advanced works of mechanics), for their enthusiastic comments; (b) the *American Association of Publishers* for selecting, in January 2003, the book for their "Annual Award for Outstanding Professional and Scholarly Titles of 2002, in Engineering"; and (c) last but not least, my WSPC editor, Dr. S. W. Lim, and his most capable and courteous staff, for their continuous and effective support. All these have been of essential moral and practical help to me in the making of this "new" edition!

Here, I take the opportunity to restate that, in this book, I have:

(a) Sought to combine the best of the old and new, i.e. no age discrimination; no knee-jerk disdain for "dusty old stuff" nor automatic following of "progress/modernity" — even in the exact sciences, and especially in mechanics, new is not necessarily or uniformly better; and
(b) Avoided developments of considerable but nevertheless purely mathematical interest, especially those of the a-historical and intuition-deadening ("epsilonic") type.

May this treatise, as well as my other two works on mechanics ["*Tensor Calculus and Analytical Dynamics*" (CRC, 1999) and "*Elementary Mechanics*" (WSPC, under production)], keep making many and loyal readers!

John G. Papastavridis
Atlanta, Georgia, Spring 2014

PREFACE

Many of the scientific treatises today are formulated in a half-mystical language, as though to impress the reader with the uncomfortable feeling that he is in the permanent presence of a superman. The present book is conceived in a humble spirit and is written for humble people.

(Lanczos, 1970, pp. vii–viii)

GENERAL DESCRIPTION

This book is a classical and detailed introduction to advanced analytical mechanics (AM), with special emphasis on its basic principles and equations of motion, as they apply to the most general constrained mechanical systems with a finite number of degrees of freedom (this term is explained in Chapter 2). For the reasons detailed below, and in spite of the age of the subject, I think that *no other single volume exists, in English and in print, that is comparable to the one at hand in breadth and depth of the material covered—and, in this nontrivial sense, this ca. 1400-page and 174-figure long work is unique*.

The book is addressed to graduate students, professors, and researchers, in the areas of applied mechanics, engineering science, and mechanical, aerospace, structural, (even) electrical engineering, as well as physics and applied mathematics. Advanced undergraduates are also very welcome to browse, and thus get initiated into higher dynamics. The sole technical prerequisite here, a relatively modest one, is a solid working knowledge of "elementary/intermediate" (i.e., undergraduate) dynamics; roughly, equivalent to the (bulk of the) material covered in, say, Spiegel's *Theoretical Mechanics*, part of the well-known Schaum's outline series. Also, familiarity with the simplest aspects of Lagrange's equations, that is, how to take the partial and total derivatives of scalar energetic functions, would be helpful; although, strictly, it is not necessary. [See also "Suggestions to the Reader" (Introduction, §3).]

CONTENTS

Specifically, the book covers in what I consider to be a most logical and pedagogical sequence, the following topics:

Introduction: *Introduction* to analytical mechanics, brief summary of the history of theoretical mechanics; suggestions to the reader; and list of symbols/notations, abbreviations, and basic formulae.

Chapter 1: *Background*: Algebra of vectors and Cartesian tensors, and basic concepts and equations of Newton–Euler (or momentum) mechanics of particles and rigid bodies; that is, a highly selective compendium of undergraduate dynamics, and (some of) its mathematics, from a mature viewpoint.

Chapter 2: *Kinematics* of constrained systems (i.e., Lagrangean kinematics); including the general theory of up to linear velocity (i.e., Pfaffian) *constraints*, in both holonomic (or true) and nonholonomic (or quasi) *coordinates*; and a uniquely readable account of the fundamental *theorem of Frobenius*, for testing the nonholonomicity of such constraints.

Chapter 3: *Kinetics* of constrained systems (i.e., Lagrangean kinetics); including the fundamental principles of AM; that is, those of *d'Alembert–Lagrange* and of *relaxation of the constraints*, the *central equation* of Heun–Hamel; equations of motion with or without reactions, with or without multipliers, in true or quasi system variables; an introduction to *servoconstraints* (theories of Appell–Beghin, et al.); and rigid-body applications. This is the key chapter of the entire book, as far as engineering readers are concerned.

Chapter 4: *Impulsive motion*, under ideal constraints; including the associated extremum theorems of Carnot, Kelvin, Bertrand, Robin, et al.

Chapter 5: *Nonlinear nonholonomic constraints*; that is, kinematics and kinetics under nonlinear, and generally nonholonomic, *velocity* constraints.

Chapter 6: *Differential variational principles*, of Jourdain, Gauss, Hertz, et al., and their derivative higher-order equations of motion of Nielsen, Tsenov, et al.

Chapter 7: *Time-integral theorems and variational principles*, of Lagrange, Hamilton, Jacobi, O. Hölder, Voss, Suslov, Voronets, Hamel, et al.; for linear and nonlinear velocity constraints in true and quasi variables, with or without multipliers; plus energy and virial theorems.

Chapter 8: Introduction to *Hamiltonian/Canonical methods*; that is, equations of Hamilton and Routh–Helmholtz, cyclic systems, steady motion and its stability, variation of constants, canonical transformations and Poisson's brackets, Hamilton–Jacobi integration theory, integral invariants, Noether's theorem, and action–angle variables and their applications to adiabatic invariants and perturbation theory.

Chapters 2–8 each contain a large number of completely solved examples, and problems with their answers (and, occasionally, hints), to illustrate and extend the previous theories; short ones are integrated within each chapter section, and longer, more synthetic, ones are collected at each chapter's end; and also, critical comments/references for further study. The exposition ends with a relatively extensive, cumulative, and alphabetical list of References and Suggested Reading, including everything from standard textbooks all the way to epoch-making memoirs of the last (more than) two hundred years. This list complements those found in such well-known references as Neimark and Fufaev (1967/1972) and Roberson and Schwertassek (1988).

Parts of the text have, unavoidably, state-of-the-art flavor. However, as far as fundamental ideas go, very little, if anything, of the topics covered is truly new—today, no one can claim much originality in classical mechanics! The newness here, a nontrivial one, I think, consists in restoring, clarifying, putting together, and presenting, in what I hope is a readable form, material most of which has appeared over the past one hundred fifty, or so, years; frequently in little known, and/or hard to find and decipher, sources. (In view of the thousands of books, lecture notes, articles, and so on, used in the writing of this work, failure to acknowledge an author's particular contribution is not intentional, merely an oversight.) But, given the astonishing unfamiliarity, confusion, and intellectual provincialism so prevalent in many theoretical and applied mechanics circles today, even in the fundamental concepts and principles of analytical dynamics (like virtual displacements/work and principle of d'Alembert–Lagrange, which is, by far, the most misunderstood "principle" of physics!), I felt very strongly that this noble, beautiful, and powerful body of knowledge, that diamond of our cultural heritage, should be accurately preserved and represented, so as to benefit present and future workers in dynamics.

No single volume can even pretend to cover satisfactorily all aspects of this vast and fascinating subject; in particular, both its theoretical and applied aspects, let alone the currently popular computational ones. Since this is not an encyclopedia of theoretical and applied dynamics, an inescapable and necessary selection has operated, and so, the following important topics are *not* covered: applications of differential forms/exterior calculus (of Cartan, Gallissot, et al.) and symplectic geometry to Lagrangean and Hamiltonian mechanics; group theoretic applications; nonlinear dynamics (incl. regular and stochastic/chaotic motion) and stability of motion; theory of orbits; and computational/numerical techniques. For all these, there already exists an enormous and competent literature (see "Suggestions to the Reader"). However, with the help of this treatise, the conscientious reader will be able to move quickly and confidently into any particular theoretical and/or computational area of modern dynamics. In this sense, *the work at hand constitutes an optimal investment of the reader's precious energies.*

RAISON D'ÊTRE, AND SOME PHILOSOPHY

The customary words of explanation, or apology, for writing "another" book on advanced dynamics are now in order. The main theme of this work, like a Wagnerian leitmotiv, is deductive order, formal structure, and physical ideas, as they pertain to that particular energetic form of mechanics of constrained systems founded by Lagrange and known as analytical (= deductive) mechanics; to be differentiated from the also analytical but momentum, or "elementary," form of system mechanics, founded by Euler. *It is a book for people who place theory (theories), ideas, knowledge, and understanding above all else — and do not apologize for it.* Here, AM is studied not as the "maid" of some other (allegedly) more important discipline, but as a subject worth knowing in its own right; that is, as a "king or queen." As such, it will attract those with a qualitative and theoretical bent of mind; while it may not be as agreeable to those with purely computational and/or intellectually local predilections. [In the words of the late Professor R.M. Rosenberg (University of California, Berkeley): "The field of dynamics is plowed by two classes of people: those who enjoy the inherent beauty, symmetry and consistency of this discipline, and those who are satisfied with having a machine that manufactures equations of motion of complex mechanisms" (private communication, 1986).] Generally, science is more than a collection of particular problems and special techniques, even involved ones — it is much more than mere information. However, practical people should be reminded that theory and application are mutually *complementary* rather than adversarial; in fact, contemporary important practical problems and the availability of powerful computational capabilities have made the thorough understanding of the fundamental principles of mechanics more necessary today than before. Applications and computers have, among other things, helped resurrect, restore, and sharpen old academic curiosities (for engineers anyway), such as the *differential* variational principles of Jourdain and Gauss (which have found applications in such "unrelated" areas as multibody dynamics, nonlinear oscillations, even the elasto-plastic buckling of shells); and Hamilton's canonical equations in quasi variables (which have found applications in robotic manipulators).

A more concrete reason for writing this book is that, outside of the truly monumental British treatise of Pars (1965) and the English translations of the beautiful (former) Soviet monographs of Neimark and Fufaev (1967/1972) and Gantmacher (1966/1970), *there is no comprehensive exposition of advanced engineering-oriented dynamics in print, in the entire English language literature!* True, the famous treatise of Whittaker (1904/1917/1927/1937), for many years out of print, has recently been reprinted (1988). However, even Whittaker, although undeniably a classic and in many respects the single most influential dynamics volume of the twentieth century (primarily, to celestial and quantum mechanics), nevertheless leaves a lot to be desired in matters of logic, fundamental principles, and their earthly applications; for example, there is no clear and general formulation of the principle of d'Alembert–Lagrange and its use, in connection with Hamel's method of quasi variables, to uncouple the equations of motion and obtain constraint reactions; also, Whittaker would be totally unacceptable with the better of today's educational philosophies. Such drawbacks have plagued most British texts of that era; for example, the otherwise excellent works of Thomson/Tait, Routh, Lamb, Ramsey, Smart, and many of their U.S.-made descendants. [In a way, Whittaker et al. have been pretty lucky in that most of the great continental European works on advanced dynamics — for example, those of Boltzmann, Heun, Maggi, Appell, Marcolongo, Suslov, Nordheim et al. (vol. 5 of *Handbuch der Physik*, 1927), Winkelmann (vol. 1 of *Handbuch der Physikalischen und Technischen Mechanik*, 1929), Prange (vol. 4 of *Encyclopädie der Mathematischen Wissenschaften*, 1935), Rose, Hamel, Pérès, Lur'e, et al. were never translated into English.] Next, the comprehensive three-volume work of MacMillan (late 1920s to early 1930s) and the encyclopedic treatise of Webster (early 1900s), probably the two best U.S.-made mechanics texts, are, unfortunately, out of print. The very lively and deservedly popular monograph of Lanczos (1949–1970) does not go far enough in areas of engineering importance; for example, nonholonomic variables and constraints; and, also, lacks in examples and problems. Only the excellent encyclopedic article of Synge (1960) comes close to our objectives; but, that, too, has Lanczos' drawbacks for engineering students and classroom use.

The existing contemporary expositions on advanced dynamics, in English and in print, fall roughly into the following three groups:

Formalistic/Abstract, of the by-and-for-mathematicians variety, and, as such, of next to zero relevance and/or usefulness to most nonmathematicians. Considering the high mental effort and time that must be expended toward their mastery vis-à-vis their meager results in understanding mechanics better and/or solving new and nontrivial problems, these works represent a pretty poor investment of ever scarce intellectual resources; that is, they are not worth their "money." The effort should be commensurate to the returns. And, contrary to the impression given by authors of this group, even in the most exact sciences, books are written by and for concrete people; not by superlogical, detached, and cold machines. As Winner puts it: "The accepted form of 'objectivity' in scientific and technical reports (one can also include books and articles in social science) requires that the prose read as if there were no person in the room when the writing took place" (1986, p. 71). Also, I categorically reject soothing apologies of the type "oh, well, that is a book for mathematicians"; that is, the book has little or no consideration for ordinary folk. The distinguished physicist F. J. Dyson confirms our suspicions that “the marriage of mathematics and physics [about which we have been told so many nice things since our high school days] has ended in divorce” (quoted in M. Kline’s *Mathematics, The Loss of Certainty*, Oxford University Press, 1980, pp. 302–303).

Applied, which either emphasize the numerical/computational aspects of mechanics, but, perhaps unavoidably, are soft and/or sketchy on its fundamental principles; or are so theoretically/conceptually impoverished and unmotivated that the reader is soon led to a narrow and dead-end view of mechanics. [Notable and refreshing *exceptions* to this style are the recent compact but rich-in-ideas works by Bremer et al. [1988(a), (b), 1992] in dynamics/control/flexible multibody systems.]

Mainstream or traditionalist; for example, those by (alphabetically): Arya, Baruh, Calkin, Crandall et al., Corben et al., Desloge, Goldstein, Greenwood, Kilmister et al., Konopinski, Kuypers, Lanczos, Marion, McCauley, Meirovitch, Park, Rosenberg, Woodhouse. The problem with this group, however, is that its representatives either do not go far and deep enough (somehow, the more advanced topics seem to be monopolized by the expositions of the first group); or they could use some improvements in the quality and/or quantity of their engineeringly relevant examples and problems.

The book at hand belongs squarely and unabashedly to this last group, and aims to remedy its above-mentioned shortcomings by bridging the space between it and some of the earlier-mentioned classics, such as (chronologically): Heun (1906, 1914), Prange (1933–1935), Hamel (1927, 1949), Pérès (1953), Lur’e (1961/1968), Gantmacher (1966/1970), Neimark and Fufaev (1967/1972), Dobronravov (1970, 1976), and Novoselov (1966, 1967, 1979). Hence, my earlier claim that this treatise is unique in the entire contemporary literature; and my strong belief that it does meet real and long overdue needs of students and teachers of advanced (engineering) dynamics of the international community. I have sought to combine the best of the old and new — no age discrimination here — and I hope that this work will help counter the very real and disturbing trend, brought about by the proponents of the first two groups, toward a dynamical tower of Babel.

ON NOTATION

To make the exposition accessible to as many willing and able readers as possible, and following the admirable and ever applicable example of Lanczos (1949–1970), I have chosen, wherever possible, an *informal approach*; and I have, thus, deliberately avoided all set-theoretic and functional-analytic formalisms, all unnecessary rigor (“epsilonics”) and similar ahistorical/unmotivating/intuition-deadening tools and methods. For the same reasons, I have also avoided the currently popular direct/dyadic (coordinate-free) and matrix notations (except in a very small number of truly useful situations); and I have, instead, chosen good old-fashioned elementary/geometrical (undergraduate) form, for vectors, and/or indicial Cartesian tensorial notation for vectors, tensors, etc.

The ad nauseam advertised “advantages” of the coordinate-free (“direct”) notation and matrices are vastly exaggerated and misguiding. To begin with, it is no accident that the solution of all concrete physical problems is intimately connected with a specific and convenient (or natural, or canonical) system of coordinates. Indicial tensorial notation seems to kill two birds with one stone: it combines both coordinate invariance (generality) and coordinate specificity; that is, one knows exactly what to do in a given set of coordinates/axes; see, for example, Korenev

(1979), Maißer (1988) for robotics applications. However, the systematic use of general tensors in dynamics has been kept out of this book. [That is carried out in my monograph, *Tensor Calculus and Analytical Dynamics* (CRC Press, 1999).] The only thing tensorial used here amounts to nothing more than the earlier-mentioned indicial Cartesian tensor notation; and for reasons that will become clear later, *not even the well-known summation convention is employed*. Indicial tensorial notation turns out to be the best tool in ''unknown and rugged terrain''; and frequently it is the only available notation, for example, in dealing with nonvectorial/tensorial ''geometrical objects,'' such as the Christoffel symbols and the Ricci/Boltzmann/Hamel coefficients. Once the fundamental theory is thoroughly understood, and the numerical implementation of a (frequently large-scale) concrete problem is sought, then one can profitably use matrices, and so on. Heavy use of matrices, with their noncommutativity ''straitjacket,'' at an early stage [e.g., Haug, 1992(a)] is likely to restrict creativity and replace physical understanding with the local mechanical manipulation of symbols.

FURTHER PHILOSOPHY: On Computerization, Applications, and Ultimate Goals of Research

I do not think that the author of a book on analytical mechanics (AM) should be constantly defending it as simply a means to some other allegedly higher ends [e.g., a prerequisite to quantum mechanics, as Goldstein (1980) does], or in terms of its current ''real life'' applications in space or earth (e.g., artificial satellites, rocketry, robotics, etc.; i.e., in terms of dollars to be made); although, clearly, such connections do exist and can be helpful. What should worry us is that these days, under what B. Schwartz calls ''economic imperialism,'' or what R. Bellah calls ''market totalitarianism'' (i.e., the penetration of purely monetary values into every aspect of social life; or, to regard all aspects of human relations as matters of economic self-interest, and model them after the market) every activity is fast becoming a means for something else, preferably quantifiable and monetary. In the process, daily work, craftsmanship, and the pleasure derived from the practice of that activity, have all been degraded. Unless we restore some *internal*, *or intrinsic*, goals and rewards to our subject and disseminate them to our young students, pretty soon such an activity will be no different from clerical or assembly-line work; that is, just a paycheck. As stated earlier, we view AM as a course worth pursuing in its own terms. We study it because it is *worth learning*, and because it is a grand and glorious part of our intellectual/cultural heritage — those who do not care about the past cannot possibly care about the present, let alone the future.

On a more practical level, a few years from now such applied areas as multibody dynamics, a subject with which so many dynamicists are preoccupied today, will be exhausted — some say that that has already happened. What are the practical mechanicians going to do then? Most of their expositions (second of the earlier groups) are too narrow and do not prepare the reader for the long haul. But there is a more fundamental reason for adopting ''my'' particular approach to mechanics: I strongly believe that *every generation has to rediscover* (*better, reinvent*) *AM, and most other areas of knowledge for that matter, anew and on its own terms;* that is, replow the soil and not just be handed down from their predecessors, discontinuously, prepackaged and predigested ''information'' in a diskette (the electronic equivalent of ashes in an urn). To squeeze the ''entire'' mechanics into a huge master computer program, which (according to common but nevertheless vulgar advertisements) "does everything," and makes it available to the reader ("user") in the form of data inputs, is not only dangerous for the present (e.g., accidents, screw-ups, which are especially consequential in today's large-scale systems — recall the omnipresent Murphy's laws), but also, being a degradation and dehumanization of knowledge, it guarantees the intellectual death of our society. If the job makes the person (mentally, psychologically, and physically), then how are we going to answer the question "What are people for?"

Typical of such contemporary one-dimensional, or "digital," approaches to dynamics are sweeping statements like: "pre-computer analytical methods for deriving the system equations must be replaced by systematic computer oriented formalisms, which can be translated conveniently into efficient computer codes for $*$ *generating* the system equations based on simple user data describing the system model, $*$ *solving* those complex equations yielding results ready for design evaluation" and "Emphasis is on computer based derivation of the system equations thus freeing the user from the time consuming and error-prone task of developing equations of motion for various problems again and again." [From advertisement of Roberson and Schwertassek (1988) in *Ingenieur-Archiv*, **59**, p.A.3, 1989.] Here, the advertisers hide the well-known fact of how much error prone is the formulating and running of any complicated program; and how the combination of this with the absence of any physically simple and meaningful checks for finding errors — something of a certainty for the structureless/formless mechanics of Newton–Euler, on which so much of multibody dynamics rests — is a recipe for chaos ($\Rightarrow$ arbitrariness)! Our reading of this ad is that the whole process will, eventually, "free" the user from thinking at all — first, we replace the human functions and then we replace humans altogether [first industrial revolution: *mechanization* of muscles, second (current) industrial revolution: *automation* of both muscles and brains]; and anyone who dares to criticize, or inquire about *choices* (i.e., politics), is summarily and arrogantly dismissed as a technophobe or, worse, a neo-Luddite!

As the mathematicians Davis and Hersh put it accurately:

> By turning attention away from underlying physical mechanisms and towards the possibility of once-for-all algorithmization, it encourages the feeling that the purpose of computation is to spare mankind of the necessity of thinking deeply.... Excessive computerization would lead to a life of formal actions devoid of meaning, for the computer lives by precise languages, precise recipes, abstract and general programs wherein the underlying significance of what is done becomes secondary. [Inimitably captured in M. McLuhan's well-known dictum: The medium *is* the message.] It fosters a spirit-sapping formalism. The computer is often described as a neutral but willing slave. The danger is not that the computer is a robot but that humans will become robotized as they adapt to its abstractions and rigidities (1986, pp. 293, 16).

And, in a similar vein, H. R. Post adds: "You understand a subject when you have grasped its structure, not when you are merely informed of specific numerical results" (quoted in Truesdell, 1984, p. 601).

The issue is not whether the complete computer codification of (some version of) dynamics can be achieved or not; it clearly *can*, somehow. The issue is the desirability of it; that is, the *could* versus the *should*, its scale compared with the other approaches, and the *temporal order* of such a presentation to the student ("user"). The only safe way for using such heavily computerized schemes is for the student to already possess a very thorough grounding in the fundamentals of mechanics — like vaccination against a virus! There is no painless and short way to bypass several centuries of hard thinking by a handful of great fellow humans — no royal road to mechanics! Otherwise, we are headed for more confusion, degradation, errors, and accidents, and eventual *disengagement* from our subject. [For iconoclastic, devastating, and sobering critiques of the contemporary mindless and rabid computeritis, see, for example, Truesdell (1984, pp. 594–631), Davis and Hersh (1986), and Mander (1985).]

As for the applications of mechanics, there is nothing wrong with them; as long as they do not hurt or exploit people and nature — alas, several such contemporary applications do just that. Those preoccupied with them rarely, if ever, ask the natural question: What are the (most likely) applications of the applications; namely, their social/environmental consequences? In this light, common statements like "the computer is only a tool" are utterly naive and meaningless. I should also add that the current relentless emphasis, even in the academia, on applied research with quick tangible results — that is, dollars at the expense of every other nonmonetary aspect — is a *relatively recent* phenomenon imposed on us from *outside*; it is neither intrinsic nor accidental to science, but instead is an intensely socio-economic activity — technology is neither autonomous nor neutral! [And as Truesdell concurs, with depressing accuracy (1987, p. 91): "It is not philosophers of science who will enforce one kind of research or another. No, it will be the national funding agencies, the sources of manna, nectar, and ambrosia for the corrupted scientists. The directors of funds are birds of a feather, chattering mainly to each other and at any one moment singing more or less the same cacophonous tune. There may come a time when even the scholarly foundations will give preference to those who claim to promote national 'defense' by research on the basic principles governing some new, as yet totally secret — that is, known only to the directors of war in the U.S. and Russia — allegedly secret idea for a broader and more effective death by torture in a world full of humanitarians and their -isms."]

If applications, even worthwhile ones, are but one motive for studying mechanics, and science in general, then what else is? Here are some plausible (existential?) reasons offered by Einstein, which I have found particularly inspiring, since my high school years:

> Man tries to make for himself in the fashion that suits him best a simplified and intelligible picture of the world; he then tries to some extent to substitute this cosmos of his for the world of experience, and thus to overcome it. This is what the painter, the poet, the speculative philosopher, and the natural philosopher do, each in his own fashion. *Each makes this cosmos and its construction the pivot of his emotional life, in order to find in this way the peace and security which he cannot find in the narrow whirlpool of personal experience* (emphasis added; from "Principles of Research," an address delivered in 1918, on the occasion of M. Planck's sixtieth birthday).

From a broader perspective, I am convinced that the quality of our lives depends not so much on specific gadgets/artifacts, no matter how technically advanced they may be (e.g., from artificial hearts to space stations), but on our collective abilities to formulate simple, clear, and unifying ideas that will allow us to understand (and then change gently and gracefully — sustainably) our increasingly complicated, unstable and fragile societies; *and, in the process, understand ourselves*. The resulting psychological and intellectual peace of mind from such a liberal arts (= liberating) approach cannot be overstated. It is this kind of activity and attitude that gives human life meaning — we do not do science just to make money, merely to exchange and consume. This book is intended as a small but tangible contribution to this lofty goal.

SOME PERSONAL HISTORY

My interest in AM began during my undergraduate studies (mid-to-late 1960s) upon reading in Hamel (1949, pp. 233–236, 367) about the *differences* between the calculus of variations (mathematics) and Hamilton's variational principle (mechanics) for nonholonomic systems. The need for a deeper understanding of the underlying kinematical concepts led me, about twenty years later, to the study of the original epoch-making memoirs of such mechanics masters as Appell, Boltzmann, Heun, and Hamel. Then, in the spring of 1986, in related studies on variational calculus, I had the good fortune to stumble upon the virtually unknown but excellent papers of Schaefer (1951) and Stückler (1955), which, along with my earlier acquaintance with tensors, showed me the way toward the correct understanding of everything virtual: virtual displacements and virtual work/Lagrange's principle; that is, I arrived at AM via the calculus of variations, just like Lagrange in the 1760s! Finally, the emphasis on the fundamental distinction between *particle* and *system* quantities I owe to the writings of Heun, the founder of theoretical engineering dynamics (early 20th century), and especially to those of his students: Winkelmann and the great Hamel.

In closing, I would like to recommend the reading of the preface(s) of Lanczos (1949–1970); the present work has been conceived and driven by a similar overall philosophy.

May this book make many and loyal friends!

ACKNOWLEDGMENTS

(Where the author recognizes, with gratitude and pleasure, the social dimension of his activity)

Every book on analytical mechanics is better off the closer it comes to the simplicity, clarity, and thoroughness of Georg Hamel's classic *Theoretische Mechanik*, arguably the best (broadest and deepest) single work on mechanics; and, secondarily, of Anatolii I. Lur'e's outstanding *Analiticheskaya Mekhanika*. I hope that this treatise follows closely and loyally the tradition created by these great masters. My indebtedness to their monumental works is hereby permanently registered.

Next, I express my deep appreciation and thanks to

Ms. Katharine L. Calhoun, of the Georgia Tech library, for her most courteous and capable help in locating and obtaining for me, over the past several years (1986 to present), hundreds of rare and critically needed references, from all over the country. Katharine is an oasis of humanity and graciousness in an otherwise arid and grim campus.

Drs. Feng Xiang Mei, professor at the Beijing Institute of Technology, China, and Zhen Wu, professor at the University of Tsiao Tong, China; and Drs. Sergei A. Zegzhda and Mikhail P. Yushkov, professors at the Mathematics and Mechanics faculty of St. Petersburg University, Russia [birthplace of the *first* treatise on theoretical/analytical mechanics (Euler's, *Mechanica Sive Motus Scientia...*, 2 vols, 1736)] for making available to me copies of their excellent textbooks and papers on advanced dynamics, which are virtually unavailable in the West (see the list of References and Suggested Reading).

Dr. John L. Junkins, chaired (and distinguished) professor of aeronautical engineering at Texas A&M University, for early encouragement on a previous version (outline) of the manuscript (1986)—what John aptly dubbed "the zeroth approximation."

Dr. Donald T. Greenwood, professor of aerospace engineering at the University of Michigan (Ann Arbor) and a true Nestor among American dynamicists, also author of internationally popular and instructive graduate texts on dynamics, for his detailed and mature (and very time- and energy-consuming) comments on the entire technical part of the manuscript; and for sharing with me his (soon to appear in book form) notes on *Special Advanced Topics in Dynamics*.

Dr. Wolfram Stadler, professor and scholar of mechanics at San Francisco State University and author of uniquely encyclopaedic work on robotics/mechatronics, for qualitative and constructive criticism on Chapter 1 (Background). Wolf remains a staunch and creative individualist, in an age of ruthless academic collectivization.

A very special expression of indebtedness to my friend Dr. Hartmut Bremer (O. Univ.-Prof. Dr.-Ing. habil.), professor of mechatronics at the University of Linz, Austria (formerly, professor of mechanics at the Technical University of Munich, Germany) and author of two dense and comprehensive textbooks on dynamics/control/multibody systems, for extensive, thoughtful and critical discussions/comments on several topics of theoretical and applied dynamics, including their historical, cultural, and educational aspects; and for supplying me with rare and precious references on the subject. To Hartmut's persistent efforts (1989–1993), I owe a very rare photograph of Karl Heun (to appear in a special gallery of photos of mechanics masters, which will be included in my forthcoming *Elementary Mechanics*).

In addition, I consider myself very fortunate to have benefited from the "mechanical" knowledge and wisdom of my friend Dr. Leon Y. Bahar, professor of mechanical engineering and mechanics at Drexel University and another American Nestor. Leon, a veritable engineering science scholar, craftsman, and above all dedicated teacher (i.e., representative of an academic species that is somewhere between endangered and extinct, as professionalism goes up and scholarship goes down), has over the past several years selflessly provided me with critical and enlightening quanta of knowledge and insight (lecture notes, papers, and extensive letters), and much valued mentorship.

These are not the best of times for writing "another" book on advanced theoretical mechanics — to put it mildly. However, and this provides a certain consolation, even such all-time titans of mathematics and mechanics as Euler, Lagrange, and Gauss had considerable difficulties in publishing, respectively, their *Theoria Motus* ... (1765), *Méchanique Analitique* (1788), and *Disquisitiones Arithmeticae* (1801). [According to Truesdell (1984, p. 352), all that Euler received for his masterpiece on rigid-body dynamics (1765) was ... twelve free copies of it!] Aspiring academic writers in this area are forewarned that the contemporary "research" university is not particularly supportive to such scholarly activities; these latter, obviously "interfere" with the more lucrative business (to the university bureaucrats, but not necessarily to students and society at large) of contracts and grants from big business and big government. Such an inimical "academic" environment makes it much more natural than usual that I reserve the strongest expression of gratitude, by far, to my family, here in Atlanta, Georgia: my wife Kim Ann and daughter Julia Constantina; and in my native Athens, Greece: my mother Konstantina and brother Stavros (in my nonobjective but fair view, one of the brightest mathematicians of contemporary Greece, and an island of moral and intellectual nobility, in an archipelago of petty greed and irrationality) — for their continual and critical moral and material support throughout the several long and solitary years of writing of the book.

Last, this volume (as well as my other two mechanics books) could not have been written without (i) the institution of academic *tenure* (much maligned and curtailed recently by reactionary ideologues, demagogues, and ignoramuses) and (ii) the (alas, fast disappearing) policy of most university libraries, of *open*, *direct*, and *free access* to books and journals. Regrettably, and in spite of high-tech millennarian promises, the next generation of scholarly authors will not be as lucky as I have been, in both these areas!

INTRODUCTION 3
1 Introduction to Analytical Mechanics 4
2 History of Theoretical Mechanics: A Bird's-Eye View 9
3 Suggestions to the Reader 13
4 Abbreviations, Symbols, Notations, Formulae 14

1 BACKGROUND: BASIC CONCEPTS AND EQUATIONS OF PARTICLE AND RIGID-BODY MECHANICS 71
1.1 Vector and (Cartesian) Tensor Algebra 72
1.2 Space-Time Axioms; Particle Kinematics 89
1.3 Bodies and their Masses 98
1.4 Force; Law of Newton–Euler 101
1.5 Space-Time and the Principle of Galilean Relativity 104
1.6 The Fundamental Principles (or Balance Laws) of General System Mechanics 106
1.7 Accelerated (Noninertial) Frames of Reference (or Relative Motion, or Moving Axes); Angular Velocity and Acceleration 113
1.8 The Rigid Body: Introduction 138
1.9 The Rigid Body: Geometry of Motion and Kinematics (Summary of Basic Theorems) 140
1.10 The Rigid Body: Geometry of Rotational Motion; Finite Rotation 155
1.11 The Rigid Body: Active and Passive Interpretations of a Proper Orthogonal Tensor; Successive Finite Rotations 178
1.12 The Rigid Body: Eulerian Angles 192
1.13 The Rigid Body: Transformation Matrices (Direction Cosines) Between Space-Fixed and Body-Fixed Triads; and Angular Velocity Components along Body-Fixed Axes, for All Sequences of Eulerian Angles 205
1.14 The Rigid Body: An Introduction to Quasi Coordinates 212
1.15 The Rigid Body: Tensor of Inertia, Kinetic Energy 214
1.16 The Rigid Body: Linear and Angular Momentum 222
1.17 The Rigid Body: Kinetic Energy and Kinetics of Translation and Rotation (Eulerian "Gyro Equations") 225
1.18 The Rigid Body: Contact Forces, Friction 237

2 KINEMATICS OF CONSTRAINED SYSTEMS (i.e., LAGRANGEAN KINEMATICS) 242

2.1 Introduction 242
2.2 Introduction to Constraints and their Classifications 243
2.3 Quantitative Introduction to Nonholonomicity 257
2.4 System Positional Coordinates and System Forms of the Holonomic Constraints 270
2.5 Velocity, Acceleration, Admissible and Virtual Displacements; in System Variables 278
2.6 System Forms of Linear Velocity (Pfaffian) Constraints 286
2.7 Geometrical Interpretation of Constraints 291
2.8 Noncommutativity versus Nonholonomicity; Introduction to the Theorem of Frobenius 296
2.9 Quasi Coordinates, and their Calculus 301
2.10 Transitivity, or Transpositional, Relations; Hamel Coefficients 312
2.11 Pfaffian (Velocity) Constraints via Quasi Variables, and their Geometrical Interpretation 323
2.12 Constrained Transitivity Equations, and Hamel's Form of Frobenius' Theorem 334
2.13 General Examples and Problems 345

3 KINETICS OF CONSTRAINED SYSTEMS (i.e., LAGRANGEAN KINETICS) 381

3.1 Introduction 381
3.2 The Principle of Lagrange (LP) 382
3.3 Virtual Work of Inertial Forces (δI), and Related Kinematico-Inertial Identities 399
3.4 Virtual Work of Forces: Impressed ($\delta' W$) and Constraint Reactions ($\delta' W_R$) 405
3.5 Equations of Motion via Lagrange's Principle: General Forms 409
3.6 The Central Equation (The *Zentralgleichung* of Heun and Hamel) 461
3.7 The Principle of Relaxation of the Constraints (The Lagrange–Hamel *Befreiungsprinzip*) 469
3.8 Equations of Motion: Special Forms 486
3.9 Kinetic and Potential Energies; Energy Rate, or Power, Theorems 511
3.10 Lagrange's Equations: Explicit Forms; and Linear Variational Equations (or Method of Small Oscillations) 537
3.11 Appell's Equations: Explicit Forms 563
3.12 Equations of Motion: Integration and Conservation Theorems 566
3.13 The Rigid Body: Lagrangean–Eulerian Kinematico-Inertial Identities 581
3.14 The Rigid Body: Appellian Kinematico-Inertial Identities 594
3.15 The Rigid Body: Virtual Work of Forces 597

3.16 Relative Motion (or Moving Axes/Frames) via Lagrange's Method 606
3.17 Servo (or Control) Constraints 636
3.18 General Examples and Problems 650

APPENDIX 3.A1
Remarks on the History of the Hamel-type Equations of Analytical Mechanics 702

APPENDIX 3.A2
Critical Comments on Virtual Displacements/Work; and Lagrange's Principle 708

4 IMPULSIVE MOTION 718
4.1 Introduction 718
4.2 Brief Overview of the Newton–Euler Impulsive Theory 718
4.3 The Lagrangean Impulsive Theory; Namely, Constrained Discontinuous Motion 721
4.4 The Appellian Classification of Impulsive Constraints, and Corresponding Equations of Impulsive Motion 724
4.5 Impulsive Motion via Quasi Variables 751
4.6 Extremum Theorems of Impulsive Motion (of Carnot, Kelvin, Bertrand, Robin, et al.) 784

5 NONLINEAR NONHOLONOMIC CONSTRAINTS 817
5.1 Introduction 818
5.2 Kinematics; The Nonlinear Transitivity Equations 819
5.3 Kinetics: Variational Equations/Principles; General and Special Equations of Motion (of Johnsen, Hamel, et al.) 831
5.4 Second- and Higher-Order Constraints 871

6 DIFFERENTIAL VARIATIONAL PRINCIPLES, AND ASSOCIATED GENERALIZED EQUATIONS OF MOTION OF NIELSEN, TSENOV, ET AL. 875
6.1 Introduction 875
6.2 The General Theory 876
6.3 Principle of Jourdain, and Equations of Nielsen 879
6.4 Introduction to the Principle of Gauss and the Equations of Tsenov 884
6.5 Additional Forms of the Equations of Nielsen and Tsenov 894
6.6 The Principle of Gauss (Extensive Treatment) 911
6.7 The Principle of Hertz 930

7 TIME-INTEGRAL THEOREMS AND VARIATIONAL PRINCIPLES 934
7.1 Introduction 935

TIME-INTEGRAL THEOREMS 936
7.2 Time-Integral Theorems: Pfaffian Constraints, Holonomic Variables 936
7.3 Time-Integral Theorems: Pfaffian Constraints, Linear Nonholonomic Variables 948

7.4 Time-Integral Theorems: Nonlinear Velocity Constraints, Holonomic Variables 957
7.5 Time-Integral Theorems: Nonlinear Velocity Constraints, Nonlinear Nonholonomic Variables 958

TIME-INTEGRAL VARIATIONAL PRINCIPLES (IVP) 960
7.6 Hamilton's Principle versus Calculus of Variations 960
7.7 Integral Variational Equations of Mechanics 966
7.8 Special Integral Variational Principles (of Suslov, Voronets, et al.) 974
7.9 Noncontemporaneous Variations; Additional IVP Forms 990

APPENDIX 7.A
Extremal Properties of the Hamiltonian Action (Is the Action Really a Minimum; Namely, Least?) 1055

8 INTRODUCTION TO HAMILTONIAN/CANONICAL METHODS: EQUATIONS OF HAMILTON AND ROUTH; CANONICAL FORMALISM 1070
8.1 Introduction 1070
8.2 The Hamiltonian, or Canonical, Central Equation and Hamilton's Canonical Equations of Motion 1073
8.3 The Routhian Central Equation and Routh's Equations of Motion 1087
8.4 Cyclic Systems; Equations of Kelvin–Tait 1097
8.5 Steady Motion (of Cyclic Systems) 1115
8.6 Stability of Steady Motion (of Cyclic Systems) 1119
8.7 Variation of Constants (or Parameters) 1143
8.8 Canonical Transformations (CT) 1161
8.9 Canonicity Conditions via Poisson's Brackets (PB) 1176
8.10 The Hamilton–Jacobi Theory 1192
8.11 Hamilton's Principal and Characteristic Functions, and Associated Variational Principles/Differential Equations 1218
8.12 Integral Invariants 1230
8.13 Noether's Theorem 1243
8.14 Periodic Motions; Action–Angle Variables 1250
8.15 Adiabatic Invariants 1290
8.16 Canonical Perturbation Theory in Action–Angle Variables 1305

Words of Wisdom and Beauty

On Rigor

It is not so much important to be rigorous as to be right.

—A. N. KOLMOGOROV

On Theory

There is nothing more practical than a good theory.

—L. BOLTZMANN

We have no access to a *theory-independent* world — that is, a world unconditioned by our point of view . . . . The world we see is . . . *theory-laden*: it already bears the ineliminable mark of our involvement in it . . . . Knowledge is always a representation of reality from within a particular perspective . . . . We cannot assume . . . "the view from nowhere."

—T. W. CLARK

I really do not at all like the now fashionable "positivistic" tendency of clinging to what is observable . . . I think . . . that theory cannot be fabricated out of the results of observation, but that it can only be invented.

—A. EINSTEIN

On Method

In the sciences the subject is not only set by the method; at the same time it is set into the method and remains subordinate to the method . . . . *In the method lies all the power of knowledge. The subject belongs to the method.* (emphasis added)

—M. HEIDEGGER

The core of the practice of science — the thread that keeps it going as a coherent and developing activity — lies in the actions of those whose goals are internal to the practice. And *these internal goals are all noneconomic*. (emphasis added.)

—B. SCHWARTZ

On Beauty

My own students, few they have been, I have tried to teach how to ask questions humbly and to see ways to some taste in a vulgar, obscene epoch. Taste is acquired by those who can face questions, especially insoluble questions.

—C. A. TRUESDELL

It is by the steady elimination of everything which is ugly — thoughts and words no less than tangible objects — and by the substitution of things of true and lasting beauty that the whole progress of humanity proceeds.

—A. PAVLOVA

Introduction

ΚΟΣΜΟΝ ΤΟΝΔΕ, ΤΟΝ ΑΥΤΟΝ ΑΠΑΝΤΩΝ, ΟΥΤΕ ΤΙΣ ΘΕΩΝ ΟΥΤΕ ΑΝΘΡΩΠΩΝ ΕΠΟΙΗΣΕΝ, ΑΛΛ'ΗΝ ΑΕΙ ΚΑΙ ΕΣΤΙΝ ΚΑΙ ΕΣΤΑΙ ΠΥΡ ΑΕΙΖΩΟΝ, ΑΠΤΟΜΕΝΟΝ ΜΕΤΡΑ ΚΑΙ ΑΠΟΣΒΕΝΝΥΜΕΝΟΝ ΜΕΤΡΑ.

[ΗΡΑΚΛΕΙΤΟΣ (Herakleitos, Greek philosopher; Ephesos, Ionia, late 6th century B.C.)]

[Translation: ''This world [order], which is the same for all [beings], no one of gods or humans have created; but it was ever, is now, and ever shall be an ever-living Fire, that starts and goes out according to certain rules [laws].''
This magnificent statement marks the beginning of science—one of the countless, fundamental, and original gifts of Greece to the world. (See, e.g., Burnet, 1930, p. 134; also Frankfort et al., 1946, chap. 8.)]

Die Mechanik ist die Wissenschaft von der Bewegung; als ihre Aufgabe bezeichnen wir: die in der Natur vor sich gehenden Bewegungen *vollständig* und auf die *einfachste Weise* zu beschreiben.
(Translation: Mechanics is the science of motion; we define as its task the *complete* description and in the *simplest possible manner* of such motions as occur in nature.)

(Kirchhoff, 1876, p. 1, author's emphasis)

Dynamics or Mechanics is the science of motion . . . . The problem of dynamics according to Kirchhoff, is to describe all motions occurring in nature in an unambiguous and the simplest manner. In addition it is our object to classify them and to arrange them on the basis of the simplest possible laws.
The success which has attended the efforts of physicists, mathematicians, and astronomers in achieving this object from the time of Galileo and Newton through that of Lagrange and Laplace to that of Helmholtz and Kelvin, constitutes one of the greatest triumphs of the human intellect.

(Webster, 1912, p. 3, emphasis added)

Die Mechanik ist ein Teil der Physik.
(Translation: Mechanics is a part of physics.)

(Föppl, 1898, vol. 1, p. 1)

1 INTRODUCTION TO ANALYTICAL MECHANICS

What Is Analytical Mechanics?

Classical mechanics (CM)—that is, the exact science of nonrelativistic and nonquantum *motion* (effects) and *forces* (causes)—was founded in the 17th century (Galileo, 1638; Newton, 1687), and was brought to fruition and generality during the next century, almost single-handedly, by Euler (1752: principle of linear momentum; 1775: principle of *angular* momentum). [D'Alembert too had formulated separate laws of linear and angular momentum (1743, 1758), but his approach came nowhere near that of Euler in generality and power.] That was the *first complete dynamical theory* in history. We shall call it, conveniently (even though not quite accurately), the *Newton–Euler* method of mechanics (NEM).

The *second* such theory was also initiated in the (late) 17th century, this time by Huygens and Jakob Bernoulli; it was further developed during the 18th century by Johann Bernoulli (Jakob's brother) and d'Alembert (early 1740s), and was finally brought to relative mathematical and physical completion by the other great mathematician of that century, Lagrange (1760: principle of "least" action; 1764: principle of d'Alembert in Lagrange's form, or *Lagrange's principle*; 1780: *central equation* and *Lagrange's equations*; 1788: *Méchanique Analitique*; 1811–1812: *transitivity equations*). This second approach, what we shall call the method of *d'Alembert–Lagrange*, or, simply and more accurately, the method of *Lagrange*, forms the basis of what has come to be known as *analytical mechanics* (AM); or, equivalently, *Lagrangean mechanics* (LM). Although both these methods are, roughly, theoretically equivalent, since there is only one classical mechanics, the second approach proved much more influential and fertile to the subsequent development not only of mechanics, but also of practically all areas of physics: from generalized coordinates and configuration space to Riemannian geometry and tensors, and from there to general relativity; and similarly for quantum mechanics.

Analytical mechanics proved particularly significant and useful to engineers, although it took another century after Lagrange for this to be fully realized (see §2). The reason for this is that AM was specifically designed by its inventors to handle constrained (earthly) systems—*the concept of constraint is central to AM*. Not that NEM could not handle such systems, but AM proved incomparably more expedient both for formulating their simplest (or minimal) equations of motion, and also for offering numerous theoretical and practical insights and tools for their solution (e.g., theorems of conservation and invariance, variational "principles" and associated *direct* methods of approximation, etc.—detailed in chaps. 3–8).

In NEM, the basic principles (or axioms) are those of *linear* and *angular momentum*, and, secondarily, that of action–reaction, for the internal (or mutual) forces (see chap. 1); that is,

NEM is a mechanics of systems based on *momentum* principles.

In LM, on the other hand, the primary axiom is the *kinetic principle of virtual work* for the constraint reactions [=Lagrange's principle (LP)] and, secondarily, the *principle of relaxation* (or liberation, or freeing) of the constraints (see chap. 3); that is,

LM is a mechanics of systems based on *energetic* principles.

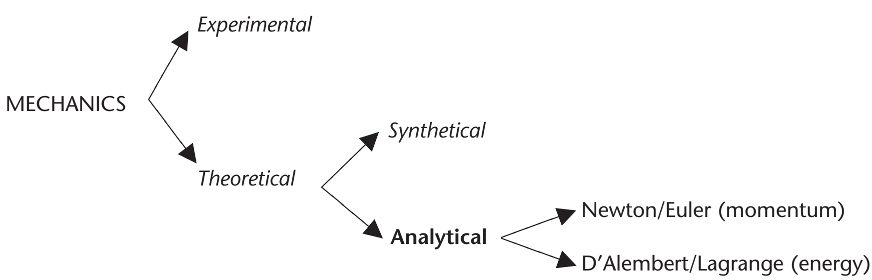
With the help of his LP, Lagrange and many others later (see §2) formulated the most general equations of motion of systems subject to general positional and/or motional constraints. [The former are called *holonomic*, while the latter, if they cannot be brought (integrated) to positional form are called *nonholonomic* (see chap. 2).]

Last, from the viewpoint of applications, AM constitutes the *theoretical foundation of advanced engineering dynamics*; which, in turn, is very useful to the following: *structural* dynamics (e.g., bridges, airport runways); *machine* dynamics (e.g., internal combustion engines); *vehicle* dynamics (e.g., automobiles, locomotives); *rotor* dynamics (e.g., turbines); *robot* dynamics (e.g., robotic manipulators); *aero-/astro-*dynamics (e.g., airplanes, artificial satellites); *control theory/system* dynamics (e.g., electromechanical systems, valves); *celestial* dynamics (e.g., astronomy), and so on.

Comments on the Methodology of AM

1. From the otherwise physically complete (particle) mechanics of Newton *two* things were missing: *rotation* and *constraints* (and, of course, *deformation*, but we do not deal with continua here). The first was taken care of by Euler, Mozzi, Cauchy, Chasles, Rodrigues et al. (1750s to the mid 19th century), and the second by Lagrange (1760s–1780s) and later many others (1870–1910). Of course, *special* cases of both problems had been examined earlier: for example, Newton discussed motions on specified curves and the associated forces, and, as Heun points out, with the help of his third law of action/reaction, he could have built a constrained particle mechanics, had he pursued that possibility; d'Alembert worked with particles "constrained in rigid body connections"; and even Huygens had such pendula involving several constrained particles. Much later (early 1810s), Lagrange brought rotation under his energetic plan (genesis of *nonholonomic*, or *quasi*-coordinates; special *transitivity* equations—see bridge between Euler and Lagrange below).

2. *Analytical versus synthetical, Euler versus Lagrange*. To begin with, CM holds quite satisfactorily for *sizes*, or lengths, from 10^{-10} m (atom) to 10^{20} m (galaxy), and for *speeds* up to $c/10$ ($c =$ speed of light $\approx 300{,}000$ km/s). Outside of these broad ranges, CM is replaced by *relativity* (high speeds) and *quanta* (small sizes) (see, e.g., French, 1971, p. 8). Now, depending on the method adopted, CM can be classified as follows:



This classification, a logically possible one out of many (see below; e.g., Hamel, 1917), stresses the following:

2(a). Contrary to popular declarations, and Lagrange himself is partly to blame for this, AM does not mean mechanics via mathematical *analysis*; that is, it does not mean an ageometrical and figureless mechanics. [Even such 20th century mechanics authorities as Whittaker state that "The name Analytical Dynamics is given to that branch of knowledge in which the motions of material bodies, . . . , are discussed by the aid of mathematical analysis" (1937, p. 1).] Instead, and in the sense used in philosophy/logic, AM means a *deductive* mechanics: everything flowing from a few selected initial postulates/principles/axioms by logical (mathematical) reasoning; that is, from the general to the particular—as contrasted with *inductive*, or *synthetic*, mechanics; that is, from the particular to the general. As such, AM is by no means ageometrical (and, similarly, synthetic mechanics does not necessarily mean geometrical and nonmathematical mechanics). Also, in the past (mainly 19th century) the terms *theoretical*, *rational*, and *analytical* have frequently been used synonymously.

2(b). In such a classification, the mechanics of Euler also deserves to be called analytical! The reason that we in this book, and most everybody else, do not have more to do with *historical* tradition and usage rather than with strict logic: today AM has come to mean, specifically,

$$\begin{aligned}\text{Lagrangean method} = {} & \text{Principle of Lagrange} \\ & (= \text{Principle of d'Alembert} + \text{Johann Bernoulli's principle} \\ & \quad \text{of virtual work}) \\ & + \ \text{Principle of relaxation of the constraints} \\ & \quad (\text{Hamel's } \textit{Befreiungsprinzip})\end{aligned}$$

After more than 200 years, AM is defined by its *practice*—that is, by its methods, tools, and range of problems dealt with by its practitioners—and because, contrary to the mechanics of Newton–Euler, it is capable of extending to other areas of physics: for example, statistical mechanics, electrodynamics. As the distinguished applied mathematician Gantmacher puts it

> [A]nalytical mechanics is characterized both by a specific system of presentation and also by a definite range of problems investigated. The characteristic feature . . . is that general principles (differential or integral) serve as the foundation; then the basic differential equations of motion are derived from these principles analytically. The basic content of analytical mechanics consists in describing the general principles of mechanics, deriving from them the fundamental differential equations of motion, and investigating the equations obtained and methods of integrating them (1970, p. 7).

2(c). Frequently, one is left with the impression that Eulerian mechanics is vectorial, whereas Lagrangean mechanics is scalar. This, however, is only superficially true: LM can be quite geometrical and vectorial, but in generalized *nonphysical/non-Euclidean* (*Riemannian and beyond*) *spaces* [see, e.g., Papastavridis (1999), Synge (1926–1927, 1936), and references therein].

2(d). Euler and Lagrange should be viewed as mutually complementary, not as adversarial—as some historians of mechanics do. And although it is undeniably true that, of the two, Euler was the greater "geometer" in both quantity and quality, yet it was the *method of Lagrange* that shaped and drove the subsequent epoch-making developments of theoretical physics and a fair part of applied mathematics (i.e., differential geometry/tensors → relativity; Hamiltonian mechanics/phase space → statistical mechanics, quantum mechanics). Lagrange himself, shortly before his death (in 1813), succeeded in building the bridge between his method and that of Euler (rigid-body equations) by obtaining a special case of "transitivity equations" [so named by Heun (early 20th century) because they allow the *transition* from Lagrangean to Eulerian], which appeared in the second volume of the second edition of his *Mécanique Analytique* (1815). And that is why the great mechanician Hamel, in 1903–1904, dubbed his own famous equations the "Lagrange–Euler equations"; and in his magnum opus *Theoretische Mechanik* (1949) he founded the entire mechanics on Lagrangean principles. [With the exception of Neimark and Fufaev (1972), the transitivity equations are completely and conspicuously absent from the entire English and French literature!]

3. *Newtonian particles versus Eulerian continua*. There is a certain viewpoint, particularly popular among celestial dynamicists/astronomers, (particle) physicists, and some applied mathematicians, according to which classical mechanics is the study of the motions of systems of particles under mutually attractive/repulsive forces, whose intensities depend only on the distances among these particles (molecules, etc.); and that, eventually, all physical phenomena are to be explained by such a "mechanistic" model. This Newtonian mindset dominated 19th century mechanics and physics almost completely, and obscured the fact that such a "central force + particle(s)" mechanics [launched, mainly, by P. S. de Laplace in his monumental five-volume *Traité de Mécanique Celeste* (1799–1825)] is but one possibility, even within the nonrelativistic and nonquantum confines of the 19th century. Under other, physically more realistic, possibilities the total interparticle force, generally, consists of a *reaction* to the geometrical and/or kinematical constraints imposed, and an *impressed*, or *physical*, part that can depend explicitly on time, position(s), and velocity(-ies) of some or all of the system particles. However, the introduction of such forces to mechanics creates effects that *cannot* be accounted by mechanics alone, such as thermal and/or electromagnetic phenomena; whereas, the consequences of Newtonian forces stay within mechanics.

The "mechanistic theory of matter"—namely, to explain all nonmechanical phenomena via simple models of internal nonvisible (concealed) motions of the system's molecules (second half of 19th century, proposed by physicists like W. Thomson, J. Thomson, Helmholtz, Hertz et al.)—was only partially successful, and eventually evolved to *statistical* mechanics and physics (Boltzmann, Gibbs) and *quantum* mechanics [Planck, Einstein, Bohr, Born, Heisenberg, Schrödinger, Dirac et al.; see also Stäckel (1905, p. 453 ff.)].

Finally, as Hamel (1917) points out, it should be remembered that AM is not restricted to particles: even though Lagrange himself starts with particles, that fact is totally unimportant to his method; he could have just as well spoken of "volume elements."

4. *Theory versus experiment*. The logical consequences of the principles of AM should *not* contradict experience. This, however, does not mean that these consequences (theorems, corollaries, etc.) should be derived from experiments; the latter cannot supply missing mathematics, or be used to prove and/or verify something, but they can be used to disprove a hypothesis. As H. R. Post puts it:

> [There are] three items of religious worship *inside* present-day science, the third of which is experiment. [I]n the main the role of experiment constitutes a harmless *myth* in the philosophy of scientists. The myth considers experiment to be a generator of theories. In fact the role of experiment ... is solely to decide between two or more existing theories ... Experiment does not generate theories but rather is suggested by them. [As quoted in Truesdell (1987, p. 83). And, in a similar vein, Einstein declares: "Experiment never responds with a 'yes' to theory. At best, it says 'maybe' and, most frequently, simply 'no.' When it agrees with theory, this means 'maybe' and, if it does not, the verdict is 'no.' "]

But if the axioms of mechanics do not flow simply (“mechanically”) and uniquely out of experiments, then where do they come from? Paraphrasing Hamel, Einstein et al., we may say that *these axioms are erected from the facts of experience (the object) by the human mind (the subject) as an equal and imaginative partner, from a little observation, a lot of thought and eventually a rather sudden (qualitative) understanding and insight into nature*. In other words, humans are not passive at all in the formation of scientific theories, but because of the enormous difficulty involved, the creation of a successful set of axioms is the rare act of genius [e.g. (chronologically): Euclid, Archimedes, Newton, Euler, Lagrange, Maxwell, Gibbs, Boltzmann, Planck, Einstein, Heisenberg, Schrödinger].

In CM, although open and nontrivial problems still remain, yet they are to be solved by the adoped principles; namely, we do not risk much in stating that this science is essentially closed, and that is why here the analytical/deductive method is possible. Otherwise, we would have to adopt a synthetic/inductive approach and change it slowly, depending on the new empirical facts.

5. In addition to the Lagrangean (and Hamiltonian) analytical formulation of mechanics—namely, the classical tradition of Whittaker, Hamel, Lur’e, Pars, Gantmacher et al. followed here, and depending on the emphasis laid on their most significant aspects, the following *complementary* formulations of CM also exist:

Variational (e.g., Lanczos, Rund).

Vako-nomic (= **V**ariational **A**xiomatic **K**ind; e.g., Arnold, Kozlov).

Algebraic (= infinitesimal and finite canonical transformations, Lie algebras and groups, symmetries and conservation theorems; e.g., McCauley, Mittelstaedt, Saletan and Cromer, Sudarshan and Mukunda).

Nonlinear dynamics (= regular and stochastic/chaotic motion; e.g., Gabor, Guggenheimer and Holmes, Lichtenberg and Lieberman, McCauley).

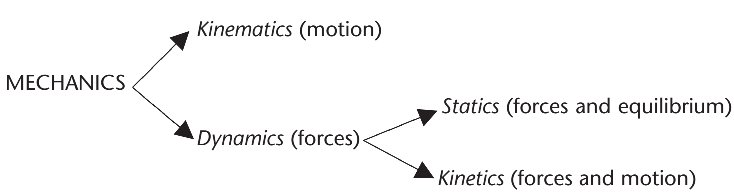
Geometrical (= symplectic geometry, canonical structure; e.g., Arnold, Abraham and Marsden, MacLane).

Statistical and thermodynamical (= Liouville’s theorem, equilibrium and nonequilibrium statistical mechanics, irreversible processes, entropy, etc.; e.g., Gibbs, Katz, Fürth, Sommerfeld, Tolman).

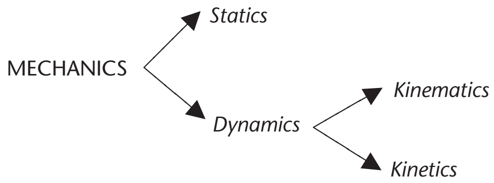
Many-body and celestial mechanics (= orbits and their stability, many-body problem; e.g., Charlier, Hagihara, Happel, Siegel and Moser, Szebehely, Wintner).

All these, and other, formulations testify once more to the vitality and importance of CM for the entire natural science, even today.

6. For *engineering* purposes, the following (nonunique) partitioning of mechanics seems useful:



[We consider this preferable to the following partitioning, customary in the U.S. undergraduate engineering education:



In addition, we will be using the following, not so common, terms:

> *Stereomechanics*: mechanics of rigid bodies (and, accordingly, stereostatics, stereokinetics, etc.—mainly, after Maggi, late 1800s to early 1900s);
>
> *Kinetostatics*: study of internal and external reactions in rigid bodies in motion (after Heun, early 1900s).

7. Finally, the *problem of AM* consists in the following:

(a). Formulation of the smallest, or minimal, number of equations of motion without (external and/or internal) constraint reactions; namely, the so-called *kinetic* equations; and also the ability to retrieve these reactions if needed; namely, the so-called *kinetostatic* equations. And then,

(b). The ability to solve these equations for the motion and unknown forces, respectively, either analytically (exactly or approximately) or numerically (computationally or symbolically). This is aided by the possible existence of first integrals; for example, energy, momentum, and conservation/invariance principles; more on these in chapter 3.

2 HISTORY OF THEORETICAL MECHANICS: A BIRD'S-EYE VIEW

> For us believing physicists the distinction between past, present, and future is only an illusion, even if a stubborn one.
>
> (A. Einstein, *Aphorisms*)

> The past is intelligible to us only in the light of the present; and we can fully understand the present only in the light of the past . . . . Past, present, and future are linked together in the endless chain of history.
>
> (E. H. Carr, *What is History?*, 1961)

> But it is from the Greeks, and not from any other ancient society, that we derive our interest in history and our belief that events in the past have relevance for the present.
>
> (M. Lefkowitz, 1996, p. 6)

> For in a real sense, history isn't the past—it's a posture in the present toward the future.
>
> (L. Weschler, American author/journalist, 1986)

> Rootless men and women take no more interest in the future than they take in the past.
>
> (C. Lasch, *The Minimal Self*, 1984)

> The devaluation of history is a prerequisite for the free exercise of pure power.
>
> (J. Rifkin, *Time Wars*, 1988)

The complete history of analytical mechanics, including 20th century contributions, has not been written yet—in English, anyway—and lack of space prevents us from doing so here. However, we hope that the following brief, selective, subjective, and unavoidably incomplete (but essentially correct and fair) summary, and references, will inspire others to pursue such a worthwhile and long overdue task more fully.

Most Important Milestones in the Evolution of Theoretical Engineering Dynamics (from the Viewpoint of Analytical Mechanics)

Unconstrained System Mechanics (*Momentum* mechanics of Newton–Euler)

1638:	Special particle motions (Galileo)
1687:	*Physical* foundations of mechanics [Newton: *incomplete principles*, *no method* (no equations of motion in his *Principia*)]
1730s:	Mechanics of a *particle* (Euler)
1740s:	Mechanics of a *system of particles* (Euler, late 1740s: *Newtonian* equations of motion!)
1750s:	General principle of *linear momentum* (Euler); kinetics of *rigid bodies* (Euler)
1770s:	General principle of *angular momentum* (Euler); kinematics and geometry of rigid body motion (Euler)

Constrained System Mechanics (*Energetic* mechanics of Lagrange)

1743:	Principle of *d'Alembert* (Jakob Bernoulli → Jean Le Rond d'Alembert)
1760:	Principle of *least action* (Maupertuis → Euler → Lagrange)
1764:	*Principle of Lagrange* [Principle of virtual work (Johann Bernoulli, 1717, published 1725) + Principle of d'Alembert]
1780:	*Equations of Lagrange*
1788:	*Méchanique Analitique* (1st ed.; note old spelling)
1811:	Special *transitivity equations* (Lagrangean derivation of rigid-body Eulerian equations)
1811–1815:	*Mécanique Analytique* (2nd ed.; 3rd ed.: 1853–1855; 4th ed.: 1888–1889; English translation, from 2nd ed.: 1997!)
1829:	Gauss' Principle of *least constraint* (or *least deviation*, or *extreme compulsion*)
1830s:	*Canonical* formulation of mechanics (Hamilton)
1840s:	*Transformation/integration* theory of dynamics (Jacobi)
1860s:	*Gyroscopic* systems [Thomson (Lord Kelvin), Tait]
1870s:	*Cyclic coordinates, steady motion*, and its stability (Routh)
1873:	Earliest reactionless Lagrange-like equations for nonholonomic systems (Ferrers)

1879: Gauss' Principle for *inequality* constraints; Gibbs–Appell equations for unconstrained systems, but in general nonholonomic velocities (quasi velocities; Gibbs)

1870s–1910s: Dynamics of *nonholonomic systems*, under linear (or Pfaffian) velocity constraints, possibly nonholonomic (Routh, Appell, Chaplygin, Voronets, Maggi, Heun, Hamel et al.—see below)

1903–1904: Definitive and general study of nonholonomic systems (Pfaffian constraints) in nonholonomic variables; *Lagrange–Euler equations* (Hamel)

1910s–1930s: Dynamics of nonholonomic systems, under *nonlinear* velocity constraints (Appell, Delassus, Chetaev, Johnsen, Hamel); Study of nonholonomic systems via *general tensor calculus* (Schouten, Synge, Vranceanu, Wundheiler, Horák, Vagner et al.)

1970s–present: Applications of the above to *multi-body* dynamics, computational dynamics [(alphabetically): Bremer, Haug, Huston, Maiβer, Roberson and Schwertassek, Schiehlen, Wittenburg et al.]; Nonlinear dynamics (regular and stochastic/chaotic motion)

Let us elaborate a little on the dynamics of nonholonomic systems. The original Lagrangean equations (1780) were limited to holonomically constrained systems. At that time, and for several decades afterwards, *velocity* constraints (holonomic or not) were only a theoretical possibility; though one that could be easily handled by the Lagrangean *method* (i.e., principles of Lagrange and of the relaxation of the constraints (detailed in chap. 3)). But it was not until about a century later that such constraints were studied systematically. However, that necessitated a thorough reexamination of the entire edifice of Lagrangean mechanics: roughly between 1870 and 1910, what may be accurately called *the second golden age of analytical mechanics*, a host of first-rate mathematicians (Ferrers, Lindelöf, Hadamard, *Appell*, Volterra, Poincaré, Klein, Jourdain, Stäckel, Maurer), physicists (Gibbs, C. Neumann, Korteweg, Boltzmann), mechanicians (*Routh*, *Maggi*, Chaplygin, Voronets, Suslov, *Heun*, *Hamel*), and engineering scientists (Vierkandt, Beghin) developed the modern AM of constrained systems, including nonholonomic ones; and, also, the unified theory of *differential* variational principles of Lagrange, Jourdain, Gauss, Hertz et al. Up until then (ca. 1900), AM was used almost exclusively, by mathematicians and physicists, to study *unconstrained* systems: for example, celestial mechanics. The Promethean transition from heavens down to earth (i.e., constraints) was led by the great German mechanician Heun (1859–1929), who can be fairly considered as the *founder of modern engineering dynamics*; and, also, by his more famous student Hamel (1877–1954), arguably the greatest *mechaniker* of the 20th century. For instance, to these two we owe the correct formulation and interpretation of the d'Alembert–Lagrange principle (i.e., LP), and its successful application (along with additional geometrical and kinematical concepts, already in embryonic or special forms in Lagrange's works) to systems under general holonomic and/or linear *velocity* (or Pfaffian, possibly nonholonomic) constraints. Therein lie the roots of all correct treatments of the subject. [Heun also made important contributions to applied mathematics. For example, the well-known Runge–Kutta method in ordinary differential equations should be called method of *Runge–Kutta–Heun*; see, for example, Renteln (1995).]

Between the two world wars, on the basis of the so-accumulated powerful insights into the mathematical structure of LM (especially from the differential variational principles), its methods were extended to *nonlinear* nonholonomic constraints; first by Appell (1911–1925) and his student Delassus (1910s) [also by Prange and Müller (1923)] and then by Chetaev (1920s), Johnsen (1936–1941), and Hamel (1938). During the post World War II era, the entire field was summarized by Hamel himself in his magnum opus *Theoretische Mechanik* (1949); and then elaborated upon by a new generation of Soviet mechanicians [(alphabetically) Dobronravov, Fradlin, Fufaev, Lobas, Lur'e, Novoselov, Neimark, Poliahov, Rumyantsev (or Rumiantsev), et al.], whose efforts culminated in the unique and classic monograph *Dynamics of Nonholonomic Systems* by Neimark and Fufaev (1967, transl. 1972). Both of these works are most highly recommended to all serious dynamicists.

[(a) On the history of the nonholonomic equations of motion, see also chapter 3, appendix I. (b) Nonlinear (possibly nonholonomic) constraints are an area that, probably, constitutes the last theoretical frontier of LM and is of potential interest to nonlinear control theory. Also, the differential variational principles have rendered important services in the numerical treatment of problems of multibody dynamics, and promise to do more in the future.]

Guide Through the Literature on the History of Mechanics

1. *General (Mechanics and Physics):*

D'Abro (1939, 2nd ed.): Qualitative and quantitative tracing of the evolution of ideas from antiquity to modern quantum mechanics; excellent. **Hoppe** [1926(a), (b)]: Concise history of physics, with some quantitative detail; good place to start. **Hund** (1972): Panoramic, competent and compact history of physics, from antiquity to modern quantum mechanics, cosmology, and so on; one of the best places to start. **Simonyi** (1990): Comprehensive and sufficiently quantitative history of physics from antiquity to modern; beautifully and richly illustrated; most highly recommended.

2. *Mechanics—General:*

Dugas (1955): Comprehensive and quantitative history of classical and modern mechanics, from a French physicist's viewpoint; quite useful. **Dühring** (1887): Comprehensive treatment of the history of mechanics from antiquity to the middle of the 19th century; difficult to read due to its complete absence of figures and almost complete absence of mathematics; for specialists/scholars. **Haas** (1914): Detailed and pedagogical treatment of the principles of classical mechanics, from antiquity to the early 19th century; very warmly recommended, especially for undergraduates in science/engineering. **Mach** (1883–1933): Leisurely and mostly qualitative history of the principles of classical mechanics, from antiquity to the end of the 19th century; interesting and influential, but in some respects incomplete and misleading. **Papastavridis** [*Elementary Mechanics* (under production)] and references cited there. **Szabó** (1979): Selective history of entire mechanics, with lots of beautiful photographs and diagrams; combines features of Mach, Dugas, and Truesdell. **Tiolina** (1979) and **Vesselovskii** (1974): General histories of mechanics, with detailed accounts of Russian contributions; very highly recommended for both their contents and references.

3. *Mechanics—Specialized:*

Cayley (1858, 1863): Excellent and authoritative summaries of theoretical developments until the mid 19th century; by a very famous mathematician. **Hankins** (1970): Detailed account of the life and work of d'Alembert; highly recommended to mechanics historians/scholars. **Hankins** (1985): Physics during the 18th century (of enlightenment). **Kochina** (1985): Life and works of S. Kovalevskaya. **Oravas and**

McLean (1966): Detailed account of the development of energetic/variational principles, mainly of *elastostatics*. **Polak** (1959, 1960): Detailed and lively history of differential and integral variational principles of mechanics and classical/modern physics, from antiquity to the 20th century; most highly recommended. **Stäckel** (1905): Excellent quantitative history of particle and rigid-body dynamics (elementary to intermediate), from antiquity to the early 20th century; a must for mature dynamicists; complements Voss's article. **Truesdell** (1968, 1984, 1987): Authoritative and lively detailing of the life and contributions of Euler; but invariably unfair/misleading to Lagrange and to anything remotely connected to particles and physics; for mature mechanicians/physicists. **Voss** (1901): Detailed and quantitative history of the principles of theoretical mechanics; with extensive lists of original references, from antiquity to ca. 1900; very highly recommended to mechanics and physics specialists. **Wheeler** (1952): Life and works of J. W. Gibbs. **Wintner** (1941, pp. 410–443): Notes and references on the history of analytical mechanics, with special emphasis on the mathematical aspects of *celestial* mechanics—the book, in general, is not recommended to anyone but specialists in theoretical astronomy. **Ziegler** (1985): Detailed and quantitative history of geometrical approach to rigid-body mechanics; primarily for kinematicians, not dynamicists.

4. *Histories of Mathematics:*

Bell (1937): Lively and enjoyable; concentrates on the lives and times of famous mathematicians. **Bochner** (1966): Informative, unconventional. **Klein** (1926(b), 1927): Detailed and authoritative. **Kline** (1972): Arguably, the best of its kind in English; encyclopedic, reliable, insightful, witty; a scholarly masterpiece. **Kramer** (1970): Like a more elementary version of Kline's book; interesting account of the evolution of *determinism* in physics (pp. 204–245). **Struik** (1987): Compact, dependable; includes socioeconomic explanations of mathematical inventions. Also Dictionary of Scientific Biography (ed. Gillispie, 1970s).

3 SUGGESTIONS TO THE READER

A cumulative and alphabetical bibliography is located at the end of the book (see References and Suggested Reading, pp. 1323–1370). The following grouping of textbooks and treatises aims to better orient the reader relative to (some of) the best available international mechanics/dynamics literature, and thus obtain maximum benefit from this work. References in **bold**, below, happen to be our personal favorites, and have influenced us the most in the writing of this book.

1. *For Background (Elementary to Intermediate Level):*

Butenin et al. (1985), Coe (1938), Crandall et al. (1968), Easthope (1964), **Fox** (1967), **Hamel** (1912, 1st ed.; 1927), **Loitsianskii** and **Lur'e** (1983), Milne (1948), **Nielsen** (1935), Osgood (1937), Papastavridis (EM, in preparation), **Parkus** (1966), Rosenberg (1977), Smith (1982), **Sommerfeld** (1964), Spiegel (1967), **Stäckel** (1905), **Suslov** (1946), **Synge** and **Griffith** (1959), Wells (1967).

2. *For Concurrent Reading (Intermediate to Advanced Level):*

Boltzmann (1902, 1904), **Butenin** (1971), **Dobronravov** (1970, 1976), **Gantmacher** (1970), Gray (1918), **Greenwood** (1977, 2000), **Hamel** (1949), Heil and Kitzka (1984), **Heun** (1906), **Lamb** (1943), **Lanczos** (1970), **Lur'e** (1968), MacMillan (1927, 1936), **Mei** (1985, 1987), **Neimark** and **Fufaev** (1972), **Nordheim** (1927), Pars (1965), Päsler (1968), Pérès (1953), **Poliahov** et al. (1985), **Prange** (1935), **Rose** (1938), **Synge** (1960), Winkelman (1929, 1930).

3. *For Further Reading:*

Theoretical Physics, Nonlinear Dynamics, and so on:

Arnold (1989), Arnold et al. (1988), **Bakay** and **Stepanovskii** (1981), Birkhoff (1927), **Born** (1927), Corben and Stehle (1960), **Dittrich** and **Reuter** (1994), **Dobronravov** (1976), **Fues** (1927), **Hagihara** (1970), **Lichtenberg** and **Lieberman** (1983/1992), **McCauley** (1997), Mittelstaedt (1970), **Nordheim** and **Fues** (1927), Pars (1965), **Prange** (1935), Santilli (1978, 1980), **Straumann** (1987), **Synge** (1960), **Tabor** (1989), van Vleck (1926), Vujanovic and Jones (1989), Whittaker (1937).

Special Topics (Analytical):

Altmann (1986), Arhangelskii (1977), Chertkov (1960), Korenev (1967, 1979), **Koshlyakov** (1985), Leimanis (1965), **Lobas** (1986), **Lur'e** (1968), **Merkin** (1974, 1987), **Neimark** and **Fufaev** (1972), Novoselov (1969), **Timerding** (1908).

Applied (Multibody Dynamics/Computational/Numerical, etc.):

Battin (1987), **Bremer** [1988(a)], **Bremer** and **Pfeiffer** (1992), Haug (1992), Hughes (1986), **Huston** (1990), **Junkins** and **Turner** (1986), **Magnus** (1971), McCarthy (1990), Roberson and Schwertassek (1988), Schiehlen (1986), Shabana (1989), **Wittenburg** (1977).

4 ABBREVIATIONS, SYMBOLS, NOTATIONS, FORMULAE

These are the customary meanings; but, of course, some, hopefully easily understood, exceptions are possible. The reader is urged always to keep common sense handy!

Numbering of Equations, Examples, and Problems

Chapters are divided into sections; for example, §3.4 means chapter 3, section 4. Equations are numbered consecutively within each section. For example, reference to eq. (3.4.2) means equation (2) of chapter 3, section 4. Related equations are indicated, further, by letters; for example, eq. (3.4.2a) follows eq. (3.4.2) and somehow complements or explains it.

In chapters 2–8, examples and problems are placed anywhere within a section, and are numbered consecutively within it; for example, ex. 5.7.2 means the second example of chapter 5, section 7 and prob. 5.7.3 means the third problem of the same section. Within examples/problems, equations are numbered consecutively alphabetically; for example, reference to (ex. 5.7.3: b) means equation (b) of the third example of chapter 5, section 7. Related equations in examples/problems are followed by numbers; for example, (ex. 5.7.2: k2) is related to or explains (ex. 5.7.2: k).

Abbreviations

AD	Analytical dynamics
AM	Analytical mechanics
CM	Classical mechanics
GP	Gauss' principle (§6.4, §6.6)
H	Holonomic (coordinate/constraint/system)
HP	Hamilton's principle (ch. 7)
HZP	Hertz's principle (§6.7)
JP	Jourdain's principle (§6.3)
LP	Lagrange's principle (or D'Alembert's principle in Lagrange's form, §3.2)
NP	Nonholonomic (coordinate/constraint/system)
VD	Virtual displacement (§2.5)
PVW	Principle of virtual work (§3.2)

Chapter 1: Background

Scalars in *italics*: for example, $a,\ A,\ \omega,\ \Omega$
Vectors in *boldface italics*: for example, $\boldsymbol{a},\ \boldsymbol{A},\ \boldsymbol{\omega},\ \boldsymbol{\Omega}$
Tensors/Dyads in *boldface*, *upper case*, *italics*; **Matrices** in *boldface* (always), *upper case* (usually), *roman* (usually, but sometimes in italics, like tensors; should be clear from context, or clarified locally)

General symbols

N	Number of particles of a system ($P = 1, \ldots, N$)
h	Number of holonomic constraints ($H = 1, \ldots, h$)
n	Number of Lagrangean (or global) coordinates ($= 3N - h$)
m	Number of Pfaffian (holonomic and/or non-holonomic) constraints
f	Number of (local or global) degrees of freedom ($\equiv n - m$)
$k, l, p, r, \ldots$	General (system) indices ($= 1, \ldots, n$)
$I, I', I'', \ldots$	*Independent* variable indices ($= m + 1, \ldots, n$)
$D, D', D'', \ldots$	*Dependent* variable indices ($= 1, \ldots, m < n$)
$A \Rightarrow B$	A implies, or leads to, B ($A \Leftrightarrow B$, for both "directions")
$\sum$	*Discrete* summation; usually, over a pair of indices (one $\sum$ for each such pair)
$S(\ldots)$	*Summation over all the material points (particles) of a system, for a fixed time*; a three-dimensional material Stieltjes integral, equivalent to Lagrange's famous integration sign $\boldsymbol{S}\ldots$
$(\ldots)^{\cdot} \equiv d(\ldots)/dt$	Total/inertial time derivative
$(\ldots)'$	The $(\ldots)$ have been subjected to some kind of transformation
$(\ldots)_o \equiv (\ldots)$	Evaluated at some special value: for example, *initial* or *equilibrium*; or with some *constraints enforced* in it
$(\ldots)^* \equiv (\ldots)$	Expressed as function of the variables t, q, ω (quasi velocities)
$(\ldots)^{\mathrm{T}} \equiv$	Transpose of matrix $(\ldots)$
$(\ldots)^{-1} \equiv$	Inverse of matrix $(\ldots)$
δ_{kl}	Kronecker delta
ε_{krs}	Permutation symbol ($\rightarrow$ tensor, in rectangular Cartesian coordinates)

$\boldsymbol{r}/\boldsymbol{v}/\boldsymbol{a}$	(Instantaneous, and usually *inertial*) *position/velocity/acceleration* of a particle P
$\boldsymbol{r}_{A/B}/\boldsymbol{v}_{A/B}/\boldsymbol{a}_{A/B}$	Position/velocity/acceleration vector of particle A relative to particle B
dm	Mass of a particle P (Continuum approach)
m_P	Mass of a particle P (Discrete approach)
$d\boldsymbol{f}$	Total force on particle P $(= d\boldsymbol{f}_e + d\boldsymbol{f}_i$; Newton–Euler) $(= d\boldsymbol{F} + d\boldsymbol{R}$; D'Alembert–Lagrange)
$d\boldsymbol{f}_e$	Total *external* force on particle P
$d\boldsymbol{f}_i$	Total *internal*, or mutual, force on particle P
$d\boldsymbol{F}$	Total *impressed*, or physical, force on particle P
$d\boldsymbol{R}$	Total *constraint reaction*, or geometrical/kinematical force on particle P
$O - XYZ\ (O - \boldsymbol{IJK})$ or $O - x_{k'}\ (O - \boldsymbol{u}_{k'})$	Space-fixed; namely, *inertial*, axes (basis) at O
$\blacklozenge - xyz\ (\blacklozenge - \boldsymbol{ijk})$ or $\blacklozenge - x_k\ (\blacklozenge - \boldsymbol{u}_k)$	Body-fixed; namely, *moving*, axes (basis) at body point $\blacklozenge$
$\blacklozenge - XYZ\ (\blacklozenge - \boldsymbol{IJK})$ or $\blacklozenge - x_{k'}\ (\blacklozenge - \boldsymbol{u}_{k'})$	Comoving, *translating but nonrotating* (or intermediate, or accessory) axes at body point $\blacklozenge$
$d(\ldots)/dt$	Rate of change of vector or tensor $(\ldots)$ relative to *fixed* (inertial) axes
$\partial(\ldots)/\partial t$	Rate of change of vector or tensor $(\ldots)$ relative to *moving* (noninertial) axes
$\left.\begin{array}{r} d\boldsymbol{a}/dt = \partial\boldsymbol{a}/\partial t + \boldsymbol{\omega}\times\boldsymbol{a} \\ d\boldsymbol{T}/dt = \partial\boldsymbol{T}/\partial t + \boldsymbol{\omega}\times\boldsymbol{T} - \boldsymbol{T}\times\boldsymbol{\omega} \end{array}\right\}$	$\boldsymbol{a}$ arbitrary *vector*, $\boldsymbol{T}$ arbitrary (second-order) *tensor*, $\boldsymbol{\omega}$ *angular velocity vector* of moving axes relative to fixed ones
$\mathbf{A} = (A_{k'k})$	Matrix of direction cosines between moving (e.g., body-fixed) axes and space-fixed ones; a (proper) *orthogonal* matrix (*passive* interpretation): $A_{k'k} = A_{kk'} \equiv \text{cosine}\left[(\text{fixed})_{k'},\ (\text{moving})_k\right] \equiv \text{cosine}\left[x_{k'}, x_k\right] \equiv \text{cosine}\left[x_k, x_{k'}\right]$
$\mathbf{A}^{-1} = \mathbf{A}^{\mathrm{T}}$	Determinant of $\mathbf{A} \equiv \text{Det}\ \mathbf{A} = +1$
$\boldsymbol{R}$	Rotation tensor (*active* interpretation of $\mathbf{A}$)
$\boldsymbol{R}(\boldsymbol{n}, \chi)$	Rotation tensor about a point O and axis through it specified by the unit vector $\boldsymbol{n}$, by an angle χ
$\boldsymbol{R}' \equiv \boldsymbol{R} - \boldsymbol{1}$	Rotator tensor
χ	Angle of finite rotation about a point O and axis specified by the unit vector $\boldsymbol{n}$
$\boldsymbol{\gamma} \equiv \tan(\chi/2)\boldsymbol{n}$	Gibbs vector of finite rotation
$\boldsymbol{\gamma} = (\gamma_{1,2,3}) \equiv (\gamma_{X,Y,Z})$	Rodrigues parameters relative to $O - XYZ$
ϕ, θ, ψ	Eulerian angles (sequence $3 \to 1 \to 3$): precession $(\phi) \to$ nutation $(\theta) \to$ proper (or eigen-) spin (ψ)
$\boldsymbol{\omega}/\boldsymbol{\Omega} \equiv \mathbf{A}^{\mathrm{T}} \cdot (\mathrm{d}\mathbf{A}/\mathrm{dt})$	Angular velocity vector/tensor (moving axes components)
$\boldsymbol{\alpha} \equiv d\boldsymbol{\omega}/dt/\boldsymbol{\mathcal{A}} \equiv d\boldsymbol{\Omega}/dt$	Angular acceleration vector/tensor (moving axes components)
$\boldsymbol{\omega}'/\boldsymbol{\Omega}' \equiv (\mathrm{d}\mathbf{A}/\mathrm{dt}) \cdot \mathbf{A}^{\mathrm{T}}$	Angular velocity vector/tensor (space-fixed axes components)

$\boldsymbol{\alpha}'/\boldsymbol{\mathcal{A}}' \equiv \mathrm{d}\boldsymbol{\Omega}'/\mathrm{dt}$	Angular acceleration vector/tensor (space-fixed axes components)
$\boldsymbol{E} \equiv \boldsymbol{\mathcal{A}} + \boldsymbol{\Omega}\cdot\boldsymbol{\Omega}$	Sometimes referred to as tensor of angular acceleration
G	Center of mass of a rigid body
C	Contact point between two bodies
$\blacklozenge$	Generic/arbitrary *body* point
$\bullet$	Generic/arbitrary *space* point
$\boldsymbol{H}_{\bullet,\mathrm{absolute}} \equiv \boldsymbol{H}_{\bullet} \equiv \int (\boldsymbol{r} - \boldsymbol{r}_{\bullet}) \times dm\, \boldsymbol{v}$	*Absolute* angular momentum about $\bullet$
$\boldsymbol{H}_{\bullet,\mathrm{relative}} \equiv \boldsymbol{h}_{\bullet} \equiv \int (\boldsymbol{r} - \boldsymbol{r}_{\bullet}) \times dm\,(\boldsymbol{v} - \boldsymbol{v}_{\bullet}) \equiv \int \boldsymbol{r}_{/\bullet} \times dm\,\boldsymbol{v}_{/\bullet}$	*Relative* angular momentum about $\bullet$
$\boldsymbol{M}\ldots$	Moment of a force (or couple) about ...
$\boldsymbol{I}\ldots$	Moment of inertia tensor about ...
$T \equiv (1/2)\int \boldsymbol{v}\cdot\boldsymbol{v}\, dm$	(Usually inertial) kinetic energy of a system

Chapter 2: Kinematics

$q \equiv (q_1, \ldots, q_n)$	Holonomic, or global, or *Lagrangean*, or *system*, coordinates; otherwise known as *generalized coordinates*
$\boldsymbol{r} = \boldsymbol{r}(t, q)$	Fundamental *Lagrangean representation* of position of typical system particle P
$\boldsymbol{r}(t, q + \delta q) - \boldsymbol{r}(t, q) \approx \delta\boldsymbol{r} \equiv \sum (\partial\boldsymbol{r}/\partial q_k)\delta q_k$	(First-order) virtual displacement of P
$\boldsymbol{e}_k \equiv \partial\boldsymbol{r}/\partial q_k,\ \boldsymbol{e}_0 \equiv \boldsymbol{e}_{n+1} \equiv \partial\boldsymbol{r}/\partial t$	Fundamental holonomic particle and system vectors (Heun's *begleitvektoren*)
$\boldsymbol{v} \equiv (dq_1/dt \equiv \dot{q}_1 \equiv v_1, \ldots, dq_n/dt \equiv \dot{q}_n \equiv v_n)$	Holonomic, or global, or *Lagrangean*, or *system*, velocities; otherwise known as generalized velocities
$\boldsymbol{v} = \sum \boldsymbol{e}_k\dot{q}_k + \boldsymbol{e}_0$	Particle velocity expressed in holonomic variables
$\boldsymbol{a} = \sum \boldsymbol{e}_k\ddot{q}_k + \text{No other } \ddot{q}_k \text{ terms}$	Particle acceleration expressed in holonomic variables
$\partial\boldsymbol{r}/\partial q_k = \partial\boldsymbol{v}/\partial\dot{q}_k = \partial\boldsymbol{a}/\partial\ddot{q}_k = \cdots = \boldsymbol{e}_k$	Basic kinematical identity (holonomic variables)
$\omega_D \equiv \sum a_{Dk}\dot{q}_k + a_D = 0$	Pfaffian constraints in velocity form (a_{Dk}, a_D: constraint coefficients, functions of t and q; ω: quasi velocities)
$d\theta_D \equiv \sum a_{Dk}dq_k + a_D dt = 0$	Pfaffian constraints in *kinematically admissible*, or *possible*, form (θ: quasi coordinates)
$\delta\theta_D \equiv \sum a_{Dk}\delta q_k = 0$	Pfaffian constraints in *virtual* form

General, kinematically admissible, variations of (...):

$$d(\ldots) \equiv \sum (\partial\ldots/\partial q_k)\, dq_k + (\partial\ldots/\partial t)\, dt = \sum (\partial\ldots/\partial\theta_k)\, d\theta_k + (\partial\ldots/\partial\theta_{n+1})\, dt$$

Virtual variation of (...):

$$\delta(\ldots) \equiv \sum(\partial\ldots/\partial q_k)\delta q_k = \sum (\partial\ldots/\partial\theta_k)\delta\theta_k$$

Quasi chain rules

$$
\begin{aligned}
\partial \ldots / \partial \theta_k &\equiv \sum (\partial \ldots / \partial q_l)(\partial \dot{q}_l / \partial \omega_k) = \sum A_{lk}(\partial \ldots / \partial q_l) \\
\partial \ldots / \partial q_l &\equiv \sum (\partial \ldots / \partial \theta_k)(\partial \omega_k / \partial \dot{q}_l) = \sum a_{kl}(\partial \ldots / \partial \theta_k) \\
\partial \ldots / \partial \theta_{n+1} &\equiv \sum (\partial \ldots / \partial q_l)(\partial \dot{q}_l / \partial \omega_{n+1}) + \partial \ldots / \partial t \\
&= \sum A_l(\partial \ldots / \partial q_l) + \partial \ldots / \partial t \equiv \partial \ldots / \partial (t) + \partial \ldots / \partial t \\
\partial \ldots / \partial t &= \sum a_k(\partial \ldots / \partial \theta_k) + \partial \ldots / \partial \theta_{n+1} = -\sum A_k(\partial \ldots / \partial q_k) + \partial \ldots / \partial \theta_{n+1}
\end{aligned}
$$

GENERAL (LOCAL) QUASI-VELOCITY TRANSFORMATIONS

Velocity form

$$\omega_D \equiv \sum a_{Dk}\dot{q}_k + a_D = 0, \qquad \omega_I \equiv \sum a_{Ik}\dot{q}_k + a_I \neq 0, \qquad \omega_{n+1} \equiv \dot{q}_{n+1} = \dot{t} = 1$$

Kinematically admissible (or possible) form

$$d\theta_D \equiv \sum a_{Dk}\, dq_k + a_D\, dt = 0, \qquad d\theta_I \equiv \sum a_{Ik}\, dq_k + a_I\, dt \neq 0,$$
$$d\theta_{n+1} \equiv dq_{n+1} = dt \neq 0$$

Virtual form

$$\delta\theta_D \equiv \sum a_{Dk}\delta q_k = 0, \qquad \delta\theta_I \equiv \sum a_{Ik}\delta q_k \neq 0, \qquad \delta\theta_{n+1} \equiv \delta q_{n+1} = \delta t = 0$$

HOLONOMIC VELOCITIES EXPRESSED IN TERMS OF QUASI VELOCITIES [(a_{kl}) and (A_{kl}) are *inverse* matrices]

Velocity form

$$\dot{q}_k \equiv v_k = \sum A_{kl}\omega_l + A_k = \sum A_{kI}\omega_I + A_k \neq 0$$

Kinematically admissible (or possible) form

$$dq_k = \sum A_{kl}\, d\theta_l + A_k\, dt = \sum A_{kI}\, d\theta_I + A_k\, dt \neq 0 \qquad (\text{under } d\theta_D = 0)$$

Virtual form

$$\delta q_k = \sum A_{kl}\delta\theta_l = \sum A_{kI}\, \delta\theta_I \neq 0 \qquad (\text{under } \delta\theta_D = 0)$$

PARTICLE KINEMATICS IN TERMS OF QUASI VARIABLES (θ, ω, etc.)

Virtual displacement

$$\delta\mathbf{r} \equiv \sum \mathbf{e}_k\, \delta q_k = \sum \boldsymbol{\varepsilon}_k\, \delta\theta_k = \sum \boldsymbol{\varepsilon}_I\, \delta\theta_I$$

Velocity

$$\boldsymbol{v} = \sum \omega_I \boldsymbol{\varepsilon}_I + \boldsymbol{\varepsilon}_{n+1} \equiv \sum \omega_I \boldsymbol{\varepsilon}_I + \boldsymbol{\varepsilon}_0$$

Acceleration

$$\begin{aligned} \boldsymbol{a} &= \sum \dot{\omega}_k \boldsymbol{\varepsilon}_k + \text{No other } \dot{\omega} \text{ terms} \\ &= \sum \dot{\omega}_I \boldsymbol{\varepsilon}_I + \text{No other } \dot{\omega} \text{ terms} \end{aligned}$$

Basic kinematical identity [where $f = f(t, q, \dot{q}) = f^*(t, q, \omega) = f^*$]

$$\partial \boldsymbol{r}/\partial \theta_k = \partial \boldsymbol{v}^*/\partial \omega_k = \partial \boldsymbol{a}^*/\partial \dot{\omega}_k = \cdots = \boldsymbol{\varepsilon}_k$$

Transformation relations between the holonomic and nonholonomic bases $\boldsymbol{e}_{\ldots}$, $\boldsymbol{\varepsilon}_{\ldots}$

$$\begin{aligned} \boldsymbol{\varepsilon}_k &= \sum (\partial \dot{q}_l/\partial \omega_k)\boldsymbol{e}_l = \sum A_{lk}\boldsymbol{e}_l \\ \boldsymbol{\varepsilon}_{n+1} &\equiv \sum \boldsymbol{\varepsilon}_0 = \sum A_l \boldsymbol{e}_l + \boldsymbol{e}_{n+1} = -\sum a_k \boldsymbol{\varepsilon}_k + \boldsymbol{e}_{n+1} \\ \boldsymbol{e}_l &= \sum (\partial \omega_k/\partial \dot{q}_l)\boldsymbol{\varepsilon}_k = \sum a_{kl}\boldsymbol{\varepsilon}_k \\ \boldsymbol{e}_{n+1} &\equiv \boldsymbol{e}_0 \equiv \boldsymbol{e}_t = \sum a_k \boldsymbol{\varepsilon}_k + \boldsymbol{\varepsilon}_{n+1} = -\sum A_l \boldsymbol{e}_l + \boldsymbol{\varepsilon}_{n+1} \end{aligned}$$

FROM PARTICLE TO SYSTEM VECTORS
(i.e., vectors characterizing, or expressing, system variables)

$$S\,(\textit{particle}\text{ vector}) \cdot \boldsymbol{e}_k = (\textit{system}\text{ vector})_k \qquad (\textit{holonomic}\text{ components})$$
$$S\,(\textit{particle}\text{ vector}) \cdot \boldsymbol{\varepsilon}_k = (\textit{system}\text{ vector})_k \qquad (\textit{nonholonomic}\text{ components})$$

SPECIAL FORMS OF PFAFFIAN CONSTRAINTS

Chaplygin

$$\omega_D \equiv \dot{q}_D - \sum b_{DI}\dot{q}_I = 0; \qquad b_{DI}\text{: functions of } q_I \equiv (q_{m+1}, \ldots, q_n)$$
$$\omega_I \equiv \dot{q}_I \neq 0$$

Voronets

$$\omega_D \equiv \dot{q}_D - \sum b_{DI}\dot{q}_I - b_D = 0; \qquad b_{DI}, b_D\text{: functions of } t \text{ and } \textit{all } q\text{s}$$
$$\omega_I \equiv \dot{q}_I \neq 0$$
$$\left[\Rightarrow \dot{q}_D = \sum b_{DI}\omega_I + b_D, \qquad \dot{q}_I \equiv \omega_I\right]$$

Corresponding particle virtual displacement

$$\delta \boldsymbol{r} \equiv \sum \boldsymbol{e}_k \delta q_k = \sum \boldsymbol{\beta}_I \delta q_I$$

Corresponding particle velocity

$$\boldsymbol{v} = \sum \dot{q}_I \boldsymbol{\beta}_I + \boldsymbol{\beta}_{n+1} \equiv \boldsymbol{v}_o$$

HAMEL COEFFICIENTS

$$\begin{aligned}
\gamma^k{}_{rs} = -\gamma^k{}_{sr} &= \sum\sum (\partial a_{kb}/\partial q_c - \partial a_{kc}/\partial q_b) A_{br} A_{cs} \\
&= \sum\sum a_{kb}[A_{cr}(\partial A_{bs}/\partial q_c) - A_{cs}(\partial A_{br}/\partial q_c)] \\
&= \sum\sum (A_{br}A_{cs} - A_{cr}A_{bs})(\partial a_{kb}/\partial q_c) \\
\gamma^k{}_{r,n+1} = -\gamma^k{}_{n+1,r} \equiv \gamma^k{}_r &= \sum\sum (\partial a_{kb}/\partial q_c - \partial a_{kc}/\partial q_b) A_{br} A_c \\
&\quad + \sum (\partial a_{kb}/\partial t - \partial a_k/\partial q_b) A_{br} \\
\gamma^{n+1}{}_{kl} = 0, \qquad \gamma^{n+1}{}_{k,n+1} &= -\gamma^{n+1}{}_{n+1,k} = 0, \qquad \gamma^{n+1}{}_{n+1,n+1} = 0
\end{aligned}$$

TRANSITIVITY EQUATIONS

$$\begin{aligned}
&(\delta\theta_k)^{\cdot} - \delta\omega_k = \sum a_{kl}[(\delta q_l)^{\cdot} - \delta(\dot{q}_l)] + \sum\sum \gamma^k{}_{bs}\omega_s\delta\theta_b + \sum \gamma^k{}_b\delta\theta_b \\
&(\delta q_k)^{\cdot} - \delta(\dot{q}_k) = \sum A_{kl}\Big\{[(\delta\theta_l)^{\cdot} - \delta\omega_l] - \sum\sum \gamma^l{}_{bs}\omega_s\delta\theta_b - \sum \gamma^l{}_b\delta\theta_b\Big\} \\
&(\delta\theta_{n+1})^{\cdot} - \delta\omega_{n+1} \equiv (\delta q_{n+1})^{\cdot} - \delta(\dot{q}_{n+1}) \equiv (\delta t)^{\cdot} - \delta(\dot{t}) = 0
\end{aligned}$$

or, equivalently,

$$\begin{aligned}
&d(\delta\theta_k) - \delta(d\theta_k) = \sum a_{kl}[d(\delta q_l) - \delta(dq_l)] + \sum\sum \gamma^k{}_{bs}\, d\theta_s\, \delta\theta_b + \sum \gamma^k{}_b\, dt\, \delta\theta_b \\
&d(\delta q_k) - \delta(dq_k) = \sum A_{kl}\Big\{[d(\delta\theta_l) - \delta(d\theta_l)] - \sum\sum \gamma^l{}_{bs}\, d\theta_s\, \delta\theta_b - \sum \gamma^l{}_b\, dt\, \delta\theta_b\Big\} \\
&d(\delta\theta_{n+1}) - \delta(d\theta_{n+1}) = d(\delta t) - \delta(dt) = d(0) - \delta(dt) = 0 - 0 = 0;
\end{aligned}$$

or, assuming (Hamel viewpoint)

$$\begin{aligned}
(\delta q_k)^{\cdot} &= \delta(\dot{q}_k) \qquad \text{or} \qquad d(\delta q_k) = \delta(dq_k) \\
(\delta\theta_k)^{\cdot} - \delta\omega_k &= \sum\sum \gamma^k{}_{bs}\, \omega_s\, \delta\theta_b + \sum \gamma^k{}_b\, \delta\theta_b \equiv \sum h^k{}_b\, \delta\theta_b \\
d(\delta\theta_k) - \delta(d\theta_k) &= \sum\sum \gamma^k{}_{bs}\, d\theta_s\, \delta\theta_b + \sum \gamma^k{}_b\, dt\, \delta\theta_b \\
&= \sum\sum{}' \gamma^k{}_{bs}(d\theta_s\, \delta\theta_b - \delta\theta_s\, d\theta_b) + \sum \gamma^k{}_b\, dt\, \delta\theta_b
\end{aligned}$$

(where $\sum\sum{}'$ means that the summation extends over b and s only *once*; say, $s < b$)

Generally [with $o, \bullet = 1, \ldots, n$; $\delta\theta_{n+1} \equiv \delta t = 0$]

$$d(\delta\theta_*) - \delta(d\theta_*) = \sum\sum \gamma^*{}_{\bullet o}\, d\theta_o\, \delta\theta_\bullet + \sum \gamma^*{}_\bullet\, dt\, \delta\theta_\bullet$$

FROBENIUS' THEOREM

(Necessary and sufficient conditions for holonomicity = complete integrability of a system of m Pfaffian constraints in the $n+1$ variables $q_1, \ldots, q_n; q_{n+1}$)

$$\gamma^D{}_{II'} = 0, \qquad \gamma^D{}_{I,n+1} \equiv \gamma^D{}_I = 0 \qquad (D = 1, \ldots, m; I, I' = m+1, \ldots, n)$$

Chapter 3: Kinetics

BASIC QUANTITIES

$T \equiv (1/2) S\, \boldsymbol{v} \cdot \boldsymbol{v}\, dm$ (Usually inertial) Kinetic Energy of system

$S \equiv (1/2) S\, \boldsymbol{a} \cdot \boldsymbol{a}\, dm$ (Usually inertial) Gibbs–Appell function of system, or simply Appellian

NOTATION

$$f(t, q, \dot{q}) = f[t, q, \dot{q}_D(t, q, \omega)] \equiv f^*(t, q, \omega) \equiv f^* \quad \text{[arbitrary function]};$$

for example,

$$\begin{aligned} T(t, q, \dot{q}) &= T[t, q, \dot{q}_D(t, q, \omega)] \equiv T^*(t, q, \omega) \equiv T^* \\ &\Rightarrow T^*(t, q, \omega_D = 0, \omega_I) \equiv T^*_o(t, q, \omega_I) \equiv T^*_o \\ T(t, q, \dot{q}) &= T[t, q, \dot{q}_D(t, q, \dot{q}_I), \dot{q}_I] \equiv T_o(t, q, \dot{q}_I) \equiv T_o \qquad \text{(and similarly for } S) \end{aligned}$$

LAGRANGE'S PRINCIPLE

$$\delta' W_R \geq 0 \quad \Rightarrow \quad \delta I \geq \delta' W$$

(for *unilateral* constraints; for *bilateral* constraints, $\geq$ is replaced by $=$)

Particle (or raw) forms

$$\delta' W_R \equiv S\, d\boldsymbol{R} \cdot \delta \boldsymbol{r}, \qquad \delta' W \equiv S\, d\boldsymbol{F} \cdot \delta \boldsymbol{r}, \qquad \delta I \equiv S\, dm\, \boldsymbol{a} \cdot \delta \boldsymbol{r}$$

Holonomic variable forms

$$\begin{aligned} \delta' W_R &= \sum R_k\, \delta q_k, \qquad R_k \equiv S\, d\boldsymbol{R} \cdot \boldsymbol{e}_k, \\ \delta' W &= \sum Q_k\, \delta q_k, \qquad Q_k \equiv S\, d\boldsymbol{F} \cdot \boldsymbol{e}_k, \\ \delta I &= \sum [(\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k]\, \delta q_k = \sum (\partial S/\partial \ddot{q}_k)\, \delta q_k \equiv \sum E_k\, \delta q_k \end{aligned}$$

Nonholonomic variable forms

$$\delta' W_R = \sum \Lambda_k\,\delta\theta_k = \sum \Lambda_I\,\delta\theta_I, \qquad \Lambda_k \equiv \mathbf{S}\, d\boldsymbol{R}\cdot\boldsymbol{\varepsilon}_k,$$

$$\delta' W = \sum \Theta_k\,\delta\theta_k, \qquad \Theta_k \equiv \mathbf{S}\, d\boldsymbol{F}\cdot\boldsymbol{\varepsilon}_k,$$

$$\delta I = \sum [(\partial T^*/\partial\omega_k)^{\cdot} - \partial T^*/\partial\theta_k - \Gamma_k]\,\delta\theta_k = \sum (\partial S^*/\partial\dot{\omega}_k)\,\delta\theta_k \equiv \sum I_k\,\delta\theta_k$$

INERTIAL "FORCES" IN HOLONOMIC VARIABLES

$$\begin{aligned} E_k &\equiv \mathbf{S}\, dm\,\boldsymbol{a}\cdot\boldsymbol{e}_k \\ &= (\partial T/\partial\dot{q}_k)^{\cdot} - \partial T/\partial q_k && \text{(Lagrangean form)} \\ &= \partial S/\partial\ddot{q}_k && \text{(Appellian form)} \\ &= \partial\dot{T}/\partial\dot{q}_k - 2(\partial T/\partial q_k) \equiv N_k(T) \equiv N_k && \text{(Nielsen form; see chap. 5)} \end{aligned}$$

INERTIAL "FORCES" IN NONHOLONOMIC VARIABLES

$$\begin{aligned} I_k &\equiv \mathbf{S}\, dm\,\boldsymbol{a}\cdot\boldsymbol{\varepsilon}_k \\ &= (\partial T^*/\partial\omega_k)^{\cdot} - \partial T^*/\partial\theta_k - \Gamma_k \equiv E_k{}^*(T^*) - \Gamma_k && \text{(Volterra–Hamel form)} \\ &= \partial S^*/\partial\dot{\omega}_k && \text{(Gibbs–Appell form)} \\ &= \sum (\partial\dot{q}_l/\partial\omega_k)E_l = \sum A_{lk}E_l && \text{(Maggi form)} \end{aligned}$$

Nonholonomic deviation

$$\begin{aligned} \Gamma_k &\equiv \mathbf{S}\, dm\,\boldsymbol{v}^*\cdot[(\partial\boldsymbol{v}^*/\partial\omega_k)^{\cdot} - \partial\boldsymbol{v}^*/\partial\theta_k] \\ &\equiv \mathbf{S}\, dm\,\boldsymbol{v}^*\cdot E_k{}^*(\boldsymbol{v}^*) \equiv \mathbf{S}\, dm\,\boldsymbol{v}^*\cdot\boldsymbol{\gamma}_k && \text{(particle/raw form)} \\ &= -\sum\sum \gamma^l_{ks}(\partial T^*/\partial\omega_l)\omega_s - \sum \gamma^l_k(\partial T^*/\partial\omega_l) \\ &= -\sum h^l_k(\partial T^*/\partial\omega_l) && \left[h^l_k \equiv \sum \gamma^l_{ks}\,\omega_s + \gamma^l_k\right] \end{aligned}$$

TRANSFORMATION EQUATIONS

$$R_l = \sum a_{kl}\Lambda_k \;\Leftrightarrow\; \Lambda_k = \sum A_{lk}R_l$$

$$Q_l = \sum a_{kl}\Theta_k \;\Leftrightarrow\; \Theta_k = \sum A_{lk}Q_l$$

$$E_l = \sum a_{kl}I_k \;\Leftrightarrow\; I_k = \sum A_{lk}E_l$$

THE CENTRAL EQUATION

(Lagrange–Heun–Hamel Zentralgleichung)

First Form

$$\delta T + \delta' W + \delta D = (\delta P)^{\cdot}$$

Second Form

$$\sum \dot{P}_k \, \delta\theta_k + \sum P_k[(\delta\theta_k)^{\cdot} - \delta\omega_k] - \sum (\partial T^*/\partial\theta_k)\, \delta\theta_k = \sum \Theta_k \, \delta\theta_k$$

where

$$\begin{aligned} \delta T = \int dm \, \boldsymbol{v} \cdot \delta\boldsymbol{v} &= \sum [(\partial T/\partial q_k)\, \delta q_k + (\partial T/\partial \dot{q}_k)\, \delta(\dot{q}_k)] \\ &= \sum [(\partial T^*/\partial q_k)\, \delta q_k + (\partial T^*/\partial \omega_k)\, \delta\omega_k] \\ &\equiv \sum [(\partial T^*/\partial \theta_k)\, \delta\theta_k + (\partial T^*/\partial \omega_k)\, \delta\omega_k] = \delta T^* \end{aligned}$$

$$\delta' W \equiv \int d\boldsymbol{F} \cdot \delta\boldsymbol{r} = \sum Q_k \, \delta q_k = \sum \Theta_k \, \delta\theta_k$$

$$\begin{aligned} \delta D &\equiv \int dm \, \boldsymbol{v} \cdot [(\delta\boldsymbol{r})^{\cdot} - \delta\boldsymbol{v}] \\ &= \sum (\partial T^*/\partial\omega_k)[(\delta\theta_k)^{\cdot} - \delta\omega_k] - \sum h^l_k (\partial T^*/\partial\omega_l)\, \delta\theta_k \end{aligned}$$

$$\delta P = \int dm \, \boldsymbol{v} \cdot \delta\boldsymbol{r} = \sum p_k \, \delta q_k = \sum P_k \, \delta\theta_k$$

$$p_k \equiv \int dm \, \boldsymbol{v} \cdot \boldsymbol{e}_k = \partial T/\partial v_k \qquad (\textit{holonomic}\text{ momentum})$$

$$P_k \equiv \int dm \, \boldsymbol{v}^* \cdot \boldsymbol{\varepsilon}_k = \partial T^*/\partial\omega_k \qquad (\textit{nonholonomic}\text{ momentum})$$

$$p_l = \sum a_{kl} P_k \;\Leftrightarrow\; P_k = \sum A_{lk} p_l \quad (\textit{transformation formulae})$$

EQUATIONS OF MOTION

COUPLED

Routh–Voss (adjoining of constraints via multipliers)

$$E_k = Q_k + R_k \qquad \text{(multipliers; holonomic variables)}$$

UNCOUPLED

Maggi (projections)

Kinetostatic: $\sum A_{Dk} E_D = \sum A_{Dk} Q_D + \Lambda_D$ (multipliers; holonomic variables)

Kinetic: $\sum A_{Ik} E_I = \sum A_{Ik} Q_I$ (no multipliers; holonomic variables)

Hamel (embedding of constraints via quasi variables)

Kinetostatic: $E_D{}^*(T^*) - \Gamma_D = \Theta_D + \Lambda_D$ (multipliers; nonholonomic variables)

Kinetic: $E_I{}^*(T^*) - \Gamma_I = \Theta_I$ (no multipliers; nonholonomic variables)

SPECIAL FORMS (constraints of form $\dot{q}_D = \sum b_{DI} \dot{q}_I + b_D$; b_{DI}, b_D functions of t, q)

Maggi → Hadamard

$$E_D = Q_D + \lambda_D \qquad \text{(kinetostatic)} \qquad E_I = Q_I - \sum b_{DI} \lambda_D$$

$$\Rightarrow E_I + \sum b_{DI} E_D = Q_I + \sum b_{DI} Q_D \equiv Q_{I,o} \equiv Q_{Io} \qquad \text{(kinetic)}$$

Hamel → Voronets

$$\left[T_o = T_o(t, q, \dot{q}_I), \qquad \dot{q}_D = \sum b_{DI}\dot{q}_I + b_D\right]$$

$$(\partial T_o/\partial \dot{q}_I)^{\cdot} - \partial T_o/\partial q_I - \sum b_{DI}(\partial T_o/\partial q_D)$$
$$- \sum\sum w^D{}_{II'}(\partial T/\partial \dot{q}_D)_o \dot{q}_{I'} - \sum w^D{}_I(\partial T/\partial \dot{q}_D)_o = Q_I + \sum b_{DI}Q_D,$$
$$w^D{}_{II'} \equiv \left[\partial b_{DI}/\partial q_{I'} + \sum b_{D'I}(\partial b_{DI'}/\partial q_{D'})\right] - \left[\partial b_{DI}/\partial q_{I'} + \sum b_{D'I'}(\partial b_{DI}/\partial q_{D'})\right]$$
$$w^D{}_I \equiv w^D{}_{I,n+1} \equiv \left[\partial b_D/\partial q_I + \sum b_{D'I}(\partial b_D/\partial q_{D'})\right] - \left[\partial b_{DI}/\partial t + \sum b_{D'}(\partial b_{DI}/\partial q_{D'})\right]$$

Voronets → Chaplygin

$$\left[T_o = T_o(q_I, \dot{q}_I), \qquad \dot{q}_D = \sum b_{DI}(q_{m+1}, \ldots, q_n)\dot{q}_I; \qquad \text{i.e., } b_D = 0\right]$$
$$(\partial T_o/\partial \dot{q}_I)^{\cdot} - \partial T_o/\partial q_I$$
$$- \sum\sum t^D{}_{II'}(\partial T/\partial \dot{q}_D)_o \dot{q}_{I'} = Q_I + \sum b_{DI}Q_D$$
$$t^D{}_{II'} \equiv \partial b_{DI}/\partial q_{I'} - \partial b_{DI'}/\partial q_I$$

POWER (OR ENERGY RATE) THEOREMS

Holonomic variables

$$dh/dt = -\partial L/\partial t + \sum Q_{k,\text{nonpotential}}\, \dot{q}_k - \sum \lambda_D a_D,$$
$$h \equiv \sum (\partial L/\partial \dot{q}_k)\, \dot{q}_k - L = T_2 + (V_0 - T_0), \qquad L \equiv T - V;$$
$$dE/dt = -\partial L/\partial t + d(T_1 + 2T_0)/dt + \sum Q_{k,\text{nonpotential}}\, \dot{q}_k - \sum \lambda_D a_D,$$
$$E \equiv T + V_0, \qquad L = T - V = T - (V_0 + V_1), \qquad h \equiv E - (T_1 + 2T_0)$$

Nonholonomic variables

$$dh^*/dt = -\partial L^*/\partial \theta_{n+1} + \sum \Theta_{I,\,\text{nonpotential}}\ \omega_I - R,$$
$$h^* \equiv \sum (\partial L^*/\partial \omega_I)\omega_I - L^* = T^*{}_2 + (V_0 - T^*{}_0)$$
$$\partial L^*/\partial \theta_{n+1} \equiv \partial L^*/\partial t + \sum A_k(\partial L^*/\partial q_k)$$
$$R \equiv \sum\sum \gamma^r{}_I(\partial L^*/\partial \omega_r)\omega_I \qquad (\textit{Rheonomic}\ \text{nonholonomic power})$$

EXPLICIT FORMS OF THE EQUATIONS OF MOTION

Lagrangean equations: with

$$T = T_2 + T_1 + T_0; \qquad 2T_2 \equiv \sum\sum M_{kr}\dot{q}_r\dot{q}_k, \qquad T_1 \equiv \sum M_r\dot{q}_r, \qquad 2T_0 \equiv M_0,$$
$$M_{kl} = M_{lk}, \qquad M_{k,n+1} = M_{n+1,k} \equiv M_{k0} = M_{0k} \equiv M_k,$$
$$M_{n+1,n+1} \equiv M_{00} \equiv M_0\text{: } \textit{Inertia coefficients},$$

$$2\Gamma_{k,rs} \equiv 2\Gamma_{k,sr} \equiv \partial M_{kr}/\partial q_s + \partial M_{ks}/\partial q_r - \partial M_{rs}/\partial q_k\text{: } 1st\ kind\ Christoffels,$$
$$G_k \equiv \sum g_{kr}\ \dot{q}_r \equiv \sum (\partial M_r/\partial q_k - \partial M_k/\partial q_r)\dot{q}_r\text{: } Gyroscopic\ \text{“}force\text{”},$$
$$Q_k = Q_{k,\text{nonpotential}} + (\partial V/\partial \dot{q}_k)^{\cdot} - \partial V/\partial q_k,$$
$$V = \sum V_k(t,q)\dot{q}_k + V_0(t,q) \equiv V_1(t,q,\dot{q}) + V_0(t,q)\text{: } Generalized\ \text{potential},$$

the Lagrangean-type equations, say $E_k = Q_k$, assume the form

$$E_k(T_2) + E_k(T_1) + E_k(T_0) = Q_k,$$
$$E_k(T_2) = \sum M_{kr}\ddot{q}_r + \sum\sum \Gamma_{k,rs}\dot{q}_r\dot{q}_s + \sum (\partial M_{kr}/\partial t)\dot{q}_r,$$
$$E_k(T_1) = \partial M_k/\partial t - G_k,$$
$$E_k(T_0) = -(1/2)(\partial M_0/\partial q_k).$$

Hamel equations (stationary case, no constraints), with

$$2T^* = 2T^*_2 = \sum\sum M^*_{kr}\ \omega_r\ \omega_k,$$
$$2\Gamma^*_{k,rs} \equiv 2\Gamma^*_{k,sr} \equiv \partial M^*_{kr}/\partial\theta_s + \partial M^*_{ks}/\partial\theta_r - \partial M^*_{rs}/\partial\theta_k,$$
$$\Lambda_{k,lp} \equiv \Gamma^*_{k,lp} + \sum \gamma^r{}_{kl} M^*_{rp} \qquad (\text{“nonholonomic Christoffels”})$$

Hamel-type equations, say $I_k = \Theta_k$, assume the form

$$\sum M^*_{kl}\dot{\omega}_l + \sum\sum \Lambda_{k,lp}\ \omega_l\ \omega_p = \Theta_k.$$

APPELLIAN FUNCTION

Holonomic variables

$$2S = \sum M_{kr}\ddot{q}_r\ddot{q}_k + 2\sum\sum\sum \Gamma_{k,lp}\ddot{q}_k\ \dot{q}_l\ \dot{q}_p + 4\sum\sum \Gamma_{k,l,n+1}\ddot{q}_k\ \dot{q}_l + 2\sum \Gamma_{k,n+1,n+1}\ddot{q}_k$$

Nonholonomic variables (stationary case)

$$2S^* = \sum\sum M^*_{kr}\ \dot{\omega}_k\ \dot{\omega}_r + 2\sum\sum\sum \Lambda_{k,lp}\ \dot{\omega}_k\ \omega_l\ \omega_p$$

LAGRANGEAN TREATMENT OF THE RIGID BODY

Kinetic energy

$$T = T_{\text{translation}} + T_{\text{rotation}} + T_{\text{coupling}}$$
$$2T_{\text{translation}} = m\,v_\blacklozenge{}^2 \qquad (\blacklozenge\text{: arbitrary } body \text{ point; } m\text{: mass of body})$$
$$2T_{\text{rotation}} = \boldsymbol{\omega}\cdot \int dm(\boldsymbol{r}_{/\blacklozenge} \times \boldsymbol{v}_{/\blacklozenge})$$
$$= \boldsymbol{\omega}\cdot \int dm\,[\boldsymbol{r}_{/\blacklozenge} \times (\boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge})] \equiv \boldsymbol{\omega}\cdot\boldsymbol{h}_\blacklozenge = \boldsymbol{\omega}\cdot\boldsymbol{I}_\blacklozenge\cdot\boldsymbol{\omega}$$
$$T_{\text{coupling}} = \boldsymbol{\omega}\cdot \int dm\,(\boldsymbol{r}_{/\blacklozenge} \times \boldsymbol{v}_\blacklozenge) = m\,\boldsymbol{v}_\blacklozenge\cdot(\boldsymbol{\omega}\times\boldsymbol{r}_{G/\blacklozenge}) = m\,\boldsymbol{v}_\blacklozenge\cdot\boldsymbol{v}_{G/\blacklozenge}$$

Momentum vectors

$$\delta P = \mathcal{S}\, dm\, \boldsymbol{v} \cdot \delta \boldsymbol{r} = \boldsymbol{p} \cdot \delta \boldsymbol{r}_{\blacklozenge} + \boldsymbol{H}_{\blacklozenge} \cdot \delta \boldsymbol{\theta} \qquad (\delta\boldsymbol{\theta}\text{: virtual rotation vector})$$

$\boldsymbol{p} \equiv \mathcal{S}\, dm\, \boldsymbol{v} = m\, \boldsymbol{v}_G$: *linear momentum* of body

$\boldsymbol{H}_{\blacklozenge} \equiv \mathcal{S}\, \boldsymbol{r}_{/\blacklozenge} \times (dm\, \boldsymbol{v}) = \boldsymbol{h}_{\blacklozenge} + \boldsymbol{r}_{G/\blacklozenge} \times (m\, \boldsymbol{v}_{\blacklozenge})$: *absolute angular momentum* of body about $\blacklozenge$

$$\boldsymbol{H}_O \equiv \mathcal{S}\, \boldsymbol{r} \times (dm\, \boldsymbol{v}) = \boldsymbol{H}_{\blacklozenge} + \boldsymbol{r}_{\blacklozenge/O} \times \boldsymbol{p} \qquad (O\text{: fixed point})$$

Kinetic energy in terms of the momentum vectors

$$2T = \boldsymbol{p} \cdot \boldsymbol{v}_{\blacklozenge} + \boldsymbol{H}_{\blacklozenge} \cdot \boldsymbol{\omega}, \qquad \boldsymbol{p} = \partial T/\partial \boldsymbol{v}_{\blacklozenge}, \qquad \boldsymbol{H}_{\blacklozenge} = \partial T/\partial \boldsymbol{\omega}$$

Kinematico-inertial (KI) acceleration vectors

$$\delta I = \mathcal{S}\, dm\, \boldsymbol{a} \cdot \delta \boldsymbol{r} = \boldsymbol{I} \cdot \delta \boldsymbol{r}_{\blacklozenge} + \boldsymbol{A}_{\blacklozenge} \cdot \delta \boldsymbol{\theta}$$

$\boldsymbol{I} \equiv \mathcal{S}\, dm\, \boldsymbol{a} = m\, \boldsymbol{a}_G$: *linear KI acceleration* of body

$\boldsymbol{A}_{\blacklozenge} \equiv \mathcal{S}\, \boldsymbol{r}_{/\blacklozenge} \times (dm\, \boldsymbol{a})$: *angular KI acceleration* of body about $\blacklozenge$

Eulerian principles in Lagrangean form

Linear momentum ($\boldsymbol{\Omega}$: vector of angular velocity of moving axes)

$$\boldsymbol{I} = d\boldsymbol{p}/dt = \partial \boldsymbol{p}/\partial t + \boldsymbol{\Omega} \times \boldsymbol{p} = \partial/\partial t(\partial T/\partial \boldsymbol{v}_{\blacklozenge}) + \boldsymbol{\Omega} \times (\partial T/\partial \boldsymbol{v}_{\blacklozenge})$$

Angular momentum

$$\begin{aligned}\boldsymbol{A}_{\blacklozenge} &= d\boldsymbol{H}_{\blacklozenge}/dt + \boldsymbol{v}_{\blacklozenge} \times \boldsymbol{p} \\ &= (\partial \boldsymbol{H}_{\blacklozenge}/\partial t + \boldsymbol{\Omega} \times \boldsymbol{H}_{\blacklozenge}) + \boldsymbol{v}_{\blacklozenge} \times \boldsymbol{p} \\ &= \partial/\partial t(\partial T/\partial \boldsymbol{\omega}) + \boldsymbol{\Omega} \times (\partial T/\partial \boldsymbol{\omega}) + \boldsymbol{v}_{\blacklozenge} \times (\partial T/\partial \boldsymbol{v}_{\blacklozenge})\end{aligned}$$

(also $\boldsymbol{A}_{\bullet} = d\boldsymbol{H}_{\bullet}/dt + \boldsymbol{v}_{\bullet} \times \boldsymbol{p}$; $\bullet$: any point)

APPELLIAN FUNCTION (to within acceleration-proportional terms)

$$\begin{aligned}2S &= m\, {a_{\blacklozenge}}^2 + 2\, m\, \boldsymbol{r}_{G/\blacklozenge} \cdot (\boldsymbol{a}_{\blacklozenge} \times \boldsymbol{\alpha}) + 2\, m\, (\boldsymbol{\omega} \times \boldsymbol{r}_{G/\blacklozenge}) \cdot (\boldsymbol{a}_{\blacklozenge} \times \boldsymbol{\omega}) \\ &\quad + \boldsymbol{\alpha} \cdot \boldsymbol{I}_{\blacklozenge} \cdot \boldsymbol{\alpha} + 2(\boldsymbol{\alpha} \times \boldsymbol{\omega}) \cdot \boldsymbol{I}_{\blacklozenge} \cdot \boldsymbol{\omega} \\ &= m\, {a_G}^2 + \boldsymbol{\alpha} \cdot \boldsymbol{I}_G \cdot \boldsymbol{\alpha} + 2(\boldsymbol{\alpha} \times \boldsymbol{\omega}) \cdot \boldsymbol{I}_G \cdot \boldsymbol{\omega}\end{aligned}$$

(Appellian counterpart of König's theorem)

RELATIVE MOTION (I: *inertial* origin; O: *moving* origin)

Positions

$$\boldsymbol{r}_I = \boldsymbol{r}_O(t) + \boldsymbol{r}(q_1, \ldots, q_n) \qquad (\text{motion of } O \text{ known, } q\text{: } \textit{noninertial} \text{ coordinates})$$

Velocities

$$\boldsymbol{v} = \boldsymbol{v}_O + \boldsymbol{v}_{\text{relative}} + \boldsymbol{\Omega} \times \boldsymbol{r}, \qquad \boldsymbol{v}_{\text{relative}} \equiv \partial \boldsymbol{r}/\partial t = \sum (\partial \boldsymbol{r}/\partial q_k)\, \dot{q}_k$$

Virtual displacements

$$\delta \boldsymbol{r}_I = \delta \boldsymbol{r}_O + \delta \boldsymbol{r} = \delta \boldsymbol{r}_O + \delta_{\text{rel}} \boldsymbol{r} + \delta \boldsymbol{\Theta} \times \boldsymbol{r} \qquad (\boldsymbol{\Omega} \equiv d\boldsymbol{\Theta}/dt\text{: frame angular velocity})$$

Kinetic energy

$$T = T_{\text{transport}} + T_{\text{relative}} + T_{\text{coupling}}$$

$$2T_{\text{transport}} = m\, v_O{}^2 + 2\, m\, \boldsymbol{v}_O \cdot (\boldsymbol{\Omega} \times \boldsymbol{r}_G) + \boldsymbol{\Omega} \cdot \boldsymbol{I}_O \cdot \boldsymbol{\Omega} \equiv 2T_0 \qquad [\sim \dot{q}^0]$$

$$2T_{\text{relative}} = \int dm\, \boldsymbol{v}_{\text{rel've}} \cdot \boldsymbol{v}_{\text{rel've}} \equiv 2T_2 \qquad [\sim \dot{q}^2]$$

$$T_{\text{coupling}} = \boldsymbol{p}_{\text{rel've}} \cdot \boldsymbol{v}_O + \boldsymbol{H}_{O,\text{rel've}} \cdot \boldsymbol{\Omega} \equiv T_1 \qquad [\sim \dot{q}^1]$$

$$\boldsymbol{p}_{\text{rel've}} \equiv \int dm\, \boldsymbol{v}_{\text{rel've}} = m(\partial \boldsymbol{r}_G/\partial t) = \sum \left(\int dm (\partial \boldsymbol{r}/\partial q_k) \right) \dot{q}_k$$

(*noninertial* linear momentum)

$$\boldsymbol{H}_{O,\text{rel've}} \equiv \int \boldsymbol{r} \times (\partial \boldsymbol{r}/\partial t) = \sum \left(\int dm\, \boldsymbol{r} \times (\partial \boldsymbol{r}/\partial q_k) \right) \dot{q}_k$$

(*noninertial* absolute angular momentum)

LAGRANGEAN TREATMENT OF RELATIVE MOTION
[equations of *carried* body; say, $E_k(T) = Q_k$]

$$E_k(T_2) = Q_k + Q_{k,\text{transport}\, \textbf{transl'n}} + Q_{k,\text{transport}\, \textbf{rotat'n}} + Q_{k,\text{transport rotat'n}\, \textbf{centrifugal}} + Q_{k,\,\textbf{Coriolis}},$$

$$Q_{k,\text{transport}\, \textbf{transl'n}} \equiv -\partial V_{\text{translation}}/\partial q_k, \qquad V_{\text{translation}} \equiv m\, \boldsymbol{a}_O \cdot \boldsymbol{r}_G;$$

$$Q_{k,\text{transport}\, \textbf{rotat'n}} \equiv -(d\boldsymbol{\Omega}/dt) \cdot (\partial \boldsymbol{H}_{O,\text{rel've}}/\partial q_k) = -(d\boldsymbol{\Omega}/dt) \cdot \left(\int dm\, \boldsymbol{r} \times (\partial \boldsymbol{r}/\partial q_k) \right);$$

$$Q_{k,\text{transport rotat'n}\, \textbf{centrifugal}}$$

$$2V_{\text{centrifugal}} \equiv -\int dm\, (\boldsymbol{\Omega} \times \boldsymbol{r})^2 = -\boldsymbol{\Omega} \cdot \boldsymbol{I}_O \cdot \boldsymbol{\Omega};$$

$$Q_{k,\textbf{Coriolis}} \equiv -2 \int \boldsymbol{\Omega} \times (dm\, \boldsymbol{v}_{\text{rel've}}) \cdot (\partial \boldsymbol{r}/\partial q_k) = \sum g_{kl} \dot{q}_l,$$

$$g_{kl} \equiv \boldsymbol{g}_{kl} \cdot \boldsymbol{\Omega}, \qquad \boldsymbol{g}_{kl} \equiv 2 \int dm\, [(\partial \boldsymbol{r}/\partial q_k) \times (\partial \boldsymbol{r}/\partial q_l)]$$

Chapter 4: Impulsive Motion

Fundamental impulsive variational equation (*impulsive principle of Lagrange—LIP*):

$$\delta \widehat{I} = \widehat{\delta' W},$$

where

$$\delta\hat{I} \equiv \widehat{\mathsf{S}\, dm\, \boldsymbol{a}\cdot\delta\boldsymbol{r}} = \mathsf{S}\, \Delta(dm\,\boldsymbol{v})\cdot\delta\boldsymbol{r}:$$

(first-order) *virtual work of impulsive momenta*, and

$$\widehat{\delta' W} \equiv \widehat{\mathsf{S}\, d\boldsymbol{F}\cdot\delta\boldsymbol{r}} = \mathsf{S}\, \widehat{d\boldsymbol{F}}\cdot\delta\boldsymbol{r}:$$

(first-order) *virtual work of impulsive impressed "forces."*

$$\begin{aligned}
\widehat{\delta' W_R} &= \mathsf{S}\, \widehat{d\boldsymbol{R}}\cdot\delta\boldsymbol{r} = \sum\Big(\mathsf{S}\, \widehat{d\boldsymbol{R}}\cdot\boldsymbol{e}_k\Big)\,\delta q_k \equiv \sum \hat{R}_k\,\delta q_k,\\
\widehat{\delta' W} &= \mathsf{S}\, \widehat{d\boldsymbol{F}}\cdot\delta\boldsymbol{r} = \sum\Big(\mathsf{S}\, \widehat{d\boldsymbol{F}}\cdot\boldsymbol{e}_k\Big)\,\delta q_k \equiv \sum \hat{Q}_k\,\delta q_k,\\
\delta\hat{I} &= \mathsf{S}\, \Delta(dm\,\boldsymbol{v})\cdot\delta\boldsymbol{r} = \sum\Big(\mathsf{S}\, dm\,\Delta\boldsymbol{v}\cdot\boldsymbol{e}_k\Big)\,\delta q_k\\
&= \sum \Delta\Big(\mathsf{S}\, dm\,\boldsymbol{v}\cdot\boldsymbol{e}_k\Big)\,\delta q_k \equiv \sum \Delta p_k\,\delta q_k,
\end{aligned}$$

and

$$\begin{aligned}
&p_k \equiv \mathsf{S}\,(dm\,\boldsymbol{v}\cdot\boldsymbol{e}_k) \equiv \partial T/\partial\dot{q}_k\\
&\Rightarrow \Delta p_k = \Delta\Big(\mathsf{S}\, dm\,\boldsymbol{v}\cdot\boldsymbol{e}_k\Big) = \mathsf{S}\,[\Delta(dm\,\boldsymbol{v})\cdot\boldsymbol{e}_k]:
\end{aligned}$$

[holonomic (k)th component] impulsive system *momentum change*,

$$\hat{Q}_k \equiv \widehat{\mathsf{S}\, d\boldsymbol{F}\cdot\boldsymbol{e}_k} = \mathsf{S}\, \widehat{d\boldsymbol{F}}\cdot\boldsymbol{e}_k:$$

[holonomic (k)th component] impulsive system *impressed* force; or, simply, impressed system *impulse*,

$$\hat{R}_k \equiv \widehat{\mathsf{S}\, d\boldsymbol{R}\cdot\boldsymbol{e}_k} = \mathsf{S}\, \widehat{d\boldsymbol{R}}\cdot\boldsymbol{e}_k:$$

[holonomic (k)th component] impulsive system *constraint reaction* force, we finally obtain LIP in *holonomic system variables*:

$$\sum \hat{R}_k\,\delta q_k = 0, \qquad \sum \Delta(\partial T/\partial\dot{q}_k)\,\delta q_k = \sum \hat{Q}_k\,\delta q_k,$$

and similarly in *quasi variables*.

Energetic theorem

$$\Delta T \equiv T^+ - T^- = W_{-/+},$$

where

$$2T^+ \equiv \mathsf{S}\, dm\,\boldsymbol{v}^+\cdot\boldsymbol{v}^+, \qquad 2T^- \equiv \mathsf{S}\, dm\,\boldsymbol{v}^-\cdot\boldsymbol{v}^-,$$

and

$$W_{-/+} \equiv \mathcal{S}\, \widehat{d\boldsymbol{F}} \cdot (\boldsymbol{v}^{+} + \boldsymbol{v}^{-})/2$$

In words: The sudden change of the kinetic energy of a moving system, due to arbitrary impressed impulses, equals the sum of the dot products of these impulses with the mean (average) velocities of their material points of application, immediately before and after their action.

APPELLIAN CLASSIFICATION OF IMPULSIVE CONSTRAINTS, AND CORRESPONDING EQUATIONS OF IMPULSIVE MOTION

At a given initial instant t', new constraints are suddenly introduced into the system and/or some old constraints are removed, or suppressed. As a result, mutual percussions are generated, which, in the very short time interval $\tau \equiv t'' - t'$ over which they are supposed to act and during which the shock lasts, produce finite velocity changes, but, according to our "first" approximation, produce negligible position changes; that is, for $\tau \to 0$: $\Delta q = 0$, $\Delta(dq/dt) \neq 0$. The constraints existing at the shock moment are either *persistent* or *nonpersistent*. By persistent we mean constraints that, existing at the shock "moment," exist also after it, so that the actual postimpact displacements are compatible with them; whereas by nonpersistent we mean constraints that, existing at the shock moment, do not exist after it, so that the actual postimpact displacements are incompatible with them.

The constraints that exist at the shock instant can be classified into the following four distinct kinds or types:

1. Constraints that exist *before*, *during*, *and after the shock*; that is, the latter neither introduces new constraints, nor does it change the old ones; the system, however, is acted on by impulsive forces. An example of such a constraint is the striking of a physical pendulum with a nonsticking (or nonplastic) hammer at one of its points, and the resulting communication to it of a specified impressed impulsive force.
2. Constraints that exist *during and after the shock, but not before it*; that is, the latter introduces suddenly new constraints on the system. Examples: (a) A rigid bar that falls freely, until the two inextensible slack strings that connect its endpoints to a fixed ceiling become taut (during) and do not break (after). (b) The inelastic central collision of two solid spheres ("coefficient of restitution" $\equiv e = 0$—see below). (c) In a ballistic pendulum, the pendulum is constrained to rotate about a fixed axis, which is a constraint that exists before, during, and after the percussion of the pendulum with a projectile (i.e., first-type constraint). The projectile, however, originally independent of the pendulum, strikes it and becomes embedded into it, which is a case of a new constraint whose sudden realization produces the shock, and which exists during and after the shock but not before it (i.e., second-type constraint).
3. Constraints that exist *before and during the shock*, *but not after it*. For example, let us imagine a system that consists of two particles connected by a light and inextensible bar, or thread, thrown up into the air. Then, let us assume that one of these particles is suddenly seized (persistent constraint introduced abruptly; i.e., second type), and, at the same time, the bar breaks (constraint that exists before the shock but does not exist after it; i.e., third type).
4. Constraints that exist *only during the shock*, *but neither before nor after it*. For example, when two solids collide, since their bounding surfaces come into contact, a constraint is abruptly introduced into this two-body system. If these bodies are

elastic ($e = 1$—see coefficient of restitution, below), they separate after the collision, which is a case of a constraint that exists during the percussion but neither before nor after it (i.e., fourth type); while if they are *plastic* ($e = 0$), they do not separate (projectile and pendulum, above; i.e., second type). If $0 < e < 1$, the bodies separate; that is, we have a fourth kind constraint.

Clearly, the first two types contain the persistent constraints, while the last two contain the nonpersistent ones. Schematically, we have the classification shown in table 1.

Table 1 Appellian Classification of Impulsive Constraints

	Preshock (before)	Shock (during)	Postshock (after)
1 (persistent)	▬	▬	▬
2 (persistent)		▬	▬
3 (nonpersistent)	▬	▬	
4 (nonpersistent)		▬	

In impulsive problems: the excess of the number of unknowns (postimpact velocities and constraint reactions) over that of the available equations [those obtained from Lagrange's impulsive principle; plus preimpact velocities, impressed impulsive forces, constraints, and, sometimes, knowledge of the postimpact state (second type; e.g., $e = 0$)]—namely, the degree of its indeterminancy—equals the number of its constraints, which, having existed before or during the shock, cease to do so at the end of it; that is:

$$\textit{Degree of indeterminacy} = \textit{Number of nonpersistent constraints};$$

that is, the persistent types 1 and 2 are determinate, while the nonpersistent ones 3 and 4 are indeterminate.

COEFFICIENT OF RESTITUTION (e)

$$e = -\frac{(\boldsymbol{v}_{2/1} \cdot \boldsymbol{n})^{+}}{(\boldsymbol{v}_{2/1} \cdot \boldsymbol{n})^{-}} \equiv -\frac{{v_{2/1,n}}^{+}}{{v_{2/1,n}}^{-}} = -\frac{\text{Relative velocity of } \textit{separation}}{\text{Relative velocity of } \textit{approach}}$$

where 1 and 2 are the two points of bodies A and B that come into contact during the collision, and $\boldsymbol{n}$ is the unit vector along the common normal to their bounding surfaces there, say from A to B. This coefficient ranges from 0 (*plastic* impact, no separation) to 1 (*elastic* impact, no energy loss); that is, $0 \leq e \leq 1$.

ANALYTICAL EXPRESSION OF THE APPELLIAN CLASSIFICATION; PERSISTENCY VERSUS DETERMINACY

1. In terms of *elementary* dynamics: Consider a system that consists of N solids, in contact with each other at K points, out of which C are of the nonpersistent type, and/or with a number of foreign solid obstacles that are either fixed or have *known* motions. Assuming *frictionless* collisions, we shall have a total of $6N + K$ *unknowns* ($6N$ postshock velocities, plus K percussions at the smooth contacts, along the common normals), and $6N + K - C$ *equations* ($6N$ impulsive momentum equations,

plus $K - C$ persistent-type constraints); and therefore *the degree of indeterminacy equals the number of nonpersistent contacts* C (i.e., the kind that disappear after the shock).

Hence: (a) a *free* (i.e., *unconstrained*) solid subjected to *given* percussions or (b) a system subjected only to *persistent* constraints are impulsively determinate.

2. From the Lagrangean viewpoint: (a) A number of constraints, imposed on a system originally defined by n Lagrangean coordinates, can *always* be put in the *equilibrium* form:

$$q_1 = 0, \quad q_2 = 0, \ldots, \quad q_m = 0 \qquad (m\text{: number of such constraints} < n).$$

(b) *Within our impulsive approximations*, even Pfaffian constraints (including nonholonomic ones) can be brought to the holonomic form; that is, in impulsive motion, *all* constraints behave as holonomic; and to solve them, either we use impulsive multipliers, or we avoid them by choosing the above equilibrium coordinates; or we use quasi variables.

Assuming, henceforth, such a choice of Lagrangean coordinates for all our impulsive constraints (and, for convenience, re-denoting these new equilibrium coordinates by $q_1, \ldots, q_m; \ldots, q_n$), we can quantify the four Appellian types of impulsive constraints as follows:

- *First-type constraints* (existing *before*, *during*, and *after* the shock). As a result of these constraints, let the system configurations depend on n, hitherto independent, Lagrangean parameters: $q \equiv (q_1, \ldots, q_n)$. During the shock interval (t', t''), the corresponding velocities $\dot{q} \equiv (\dot{q}_1, \ldots, \dot{q}_n)$ pass suddenly from the known values $(\dot{q})^-$, at t', to other values $(\dot{q})^+$, while the q's remain practically unchanged; that is, here we have

$$(q_k)_{\text{before}} = 0, \qquad (q_k)_{\text{during}} = 0, \qquad (q_k)_{\text{after}} = 0,$$
$$\Delta\dot{q}_k \equiv (\dot{q}_k)^+ - (\dot{q}_k)^- \neq 0 \qquad [(\dot{q}_k)^+\text{: unknown, } (\dot{q}_k)^-\text{: known}].$$

- *Second-type constraints* (additional constraints existing *during* and *after* the shock, but not before it). Here, with $q_{D''} \equiv (q_1, \ldots, q_{m''})$, where $m'' < n$, we have

$$(q_{D''})_{\text{before}} \neq 0, \qquad (q_{D''})_{\text{during}} = 0, \qquad (q_{D''})_{\text{after}} = 0;$$
$$(\dot{q}_{D''})^- \neq 0, \qquad (\dot{q}_{D''})^+ = 0 \Rightarrow \Delta(\dot{q}_{D''}) = -(\dot{q}_{D''})^- \neq 0.$$

- *Third-type constraints* (additional constraints existing *before and during* the shock, but not after it). Here, with $q_{D'''} \equiv (q_{m''+1}, \ldots, q_{m'''})$, where $m''' < n$, we have

$$(q_{D'''})_{\text{before}} = 0, \qquad (q_{D'''})_{\text{during}} = 0, \qquad (q_{D'''})_{\text{after}} \neq 0,$$
$$(\dot{q}_{D'''})^- = 0, \qquad (\dot{q}_{D'''})^+ \neq 0 \Rightarrow \Delta(\dot{q}_{D'''}) = (\dot{q}_{D'''})^+ \neq 0.$$

- *Fourth-type constraints* (additional constraints existing only *during* the shock, but neither before nor after it). Here, with $q_{D''''} \equiv (q_{m'''+1}, \ldots, q_{m''''})$, where $m'''' < n$, we have

$$(q_{D''''})_{\text{before}} \neq 0, \qquad (q_{D''''})_{\text{during}} = 0, \qquad (q_{D''''})_{\text{after}} \neq 0;$$
$$(\dot{q}_{D''''})^- \neq 0, \qquad (\dot{q}_{D''''})^+ \neq 0 \Rightarrow \Delta(\dot{q}_{D''''}) = (\dot{q}_{D''''})^+ - (\dot{q}_{D''''})^- \neq 0.$$

Hence, if no fourth-type constraints exist, $m''' = m''''$; and if no third-type constraints exist, $m'' = m'''$; etc.

Next, arguing as in the case of continuous motion (chap. 3), during the shock interval, we may view the constraints of the second, third, and fourth types as absent, provided that, in the spirit of the *impulsive principle of relaxation* (LIP), we add to the system the corresponding constraint reactions. All relevant equations of motion are contained in the LIP:

$$\sum \Delta(\partial T/\partial \dot{q}_k)\,\delta q_k = \sum \hat{Q}_k\,\delta q_k \qquad (k = 1, \ldots, n).$$

If the *virtual displacements* $\delta q \equiv (\delta q_1, \ldots, \delta q_n)$ are arbitrary, the right side of the above equation contains the impulsive virtual works of the reactions stemming from the second, third, and fourth type constraints, and operating during the shock interval (t', t''). Therefore, to eliminate these "forces," and thus produce $n - m''''$ reactionless, or kinetic, impulsive equations, we choose δq's that are compatible with *all constraints holding at the shock moment*; that is, we take

$$\delta q_1, \ldots, \delta q_{m''}; \qquad \delta q_{m''+1}, \ldots, \delta q_{m'''}; \qquad \delta q_{m'''+1}, \ldots, \delta q_{m''''} = 0;$$
$$\delta q_{m''''+1}, \ldots, \delta q_n \neq 0.$$

Corresponding *two* (uncoupled) sets of equations:

Impulsive *kinetostatic*: $\quad \Delta(\partial T/\partial \dot{q}_D) = \hat{Q}_D + \hat{\lambda}_D \quad (D = 1, \ldots, m'''')$,

Impulsive *kinetic*: $\quad \Delta(\partial T/\partial \dot{q}_I) = \hat{Q}_I \quad (I = m'''' + 1, \ldots, n)$.

Further, since the velocity jumps $\Delta\dot{q}$ are produced only by the very large impulsive constraint reactions, operating during the very small interval $t'' - t'$, within our approximations, the $\hat{Q}_I$ [since they derive only from ordinary (i.e., finite, nonimpulsive) forces, like gravity] vanish: $\hat{Q}_I = 0$; and so eq. (b) reduces to *Appell's rule*:

$$\Delta(\partial T/\partial \dot{q}_I) = 0 \;\Rightarrow\; (\partial T/\partial \dot{q}_I)^+ = (\partial T/\partial \dot{q}_I)^-.$$

In words: The partial derivatives of the kinetic energy relative to the velocities of those system coordinates q's that are not forced to vanish at the shock instant (i.e., $q_{\text{during}} \neq 0$) have the same values before and after the impact; or, these $n - m''''$ unconstrained momenta, $p_I \equiv \partial T/\partial \dot{q}_I$, are conserved.

To make the problem determinate, in the presence of nonpersistent-type constraints, we must make particular *constitutive* (*i.e.*, *physical*) *hypotheses*: for example, elasticity assumptions about the postshock state.

EXTREMUM THEOREMS OF IMPULSIVE MOTION

All based on the following master equation (impulsive Lagrange's principle):

$$\mathsf{S}\, dm\,(\boldsymbol{v}^+ - \boldsymbol{v}^-) \cdot \delta\boldsymbol{r} = \mathsf{S}\, \widehat{d\boldsymbol{F}} \cdot \delta\boldsymbol{r}$$

Carnot (first part—collisions)

$$\delta\boldsymbol{r} \sim \boldsymbol{v}^+, \qquad \widehat{d\boldsymbol{F}} = \boldsymbol{0} \;\rightarrow\; T^+ - T^- < 0$$

Carnot (second part—explosions)

$$\delta\boldsymbol{r} \sim \boldsymbol{v}^-, \qquad \widehat{d\boldsymbol{F}} = \boldsymbol{0} \;\rightarrow\; T^+ - T^- > 0$$

Kelvin (prescribed velocities)

$$\delta\boldsymbol{r} \sim \boldsymbol{v}^+, \qquad \delta\boldsymbol{r} \sim \boldsymbol{v}^+ + \delta_K\boldsymbol{v} = \boldsymbol{v}, \qquad \boldsymbol{v}^- = \boldsymbol{0} \;\rightarrow\; T(\boldsymbol{v}) - T(\boldsymbol{v}^+) > 0, \qquad \delta_K T^+ = 0$$

Bertrand–Delaunay (prescribed impulses)

$$\delta\boldsymbol{r} \sim \boldsymbol{v}^+, \qquad \delta\boldsymbol{r} \sim \boldsymbol{v}^+ + \delta_{B/D}\boldsymbol{v} = \boldsymbol{v} \quad \rightarrow \quad T(\boldsymbol{v}) - T(\boldsymbol{v}^+) < 0, \qquad \delta_{B/D} T^+ = 0$$

[Taylor: $T_{\text{Kelvin}}(\boldsymbol{v}) - T(\boldsymbol{v}^+) > T(\boldsymbol{v}^+) - T(\boldsymbol{v})_{\text{Bertrand-Delaunay}}$]

Robin (prescribed impulses and constraints)

$$\delta\boldsymbol{r} \sim \boldsymbol{v}^+, \qquad \delta\boldsymbol{r} \sim \boldsymbol{v}^+ + \delta_R\boldsymbol{v} = \boldsymbol{v}$$

$$\rightarrow P \equiv \mathsf{S}\,(dm/2)(\boldsymbol{v} - \boldsymbol{v}^-)^2 - \mathsf{S}\,\widehat{d\boldsymbol{F}} \cdot (\boldsymbol{v} - \boldsymbol{v}^-)\text{: stationary and minimum}$$

Gauss (impulsive compulsion)

$$\hat{Z} \equiv \mathsf{S}\,(dm/2)(\boldsymbol{v} - \boldsymbol{v}^- - \widehat{d\boldsymbol{F}}/dm)^2 \;=\; P + \mathsf{S}\,(\widehat{d\boldsymbol{F}})^2/2dm\text{: stationary and minimum}$$

Chapter 5: Nonlinear Nonholonomic Constraints

CONSTRAINTS

$$f_D(t, q, \dot{q}) = 0$$

QUASI VARIABLES

Velocity form

$$\omega_D \equiv f_D(t, q, \dot{q}) = 0, \qquad \omega_I \equiv f_I(t, q, \dot{q}) \neq 0, \qquad \omega_{n=1} \equiv \dot{q}_{n+1} = \dot{t} = 1$$

Virtual form (by Maurer–Appell–Chetaev–Johnsen–Hamel)

$$\begin{aligned}
\delta\theta_D &= \sum (\partial f_D/\partial\dot{q}_k)\,\delta q_k = \sum (\partial\omega_D/\partial\dot{q}_k)\,\delta q_k = 0,\\
\delta\theta_I &= \sum (\partial f_I/\partial\dot{q}_k)\,\delta q_k = \sum (\partial\omega_I/\partial\dot{q}_k)\,\delta q_k \neq 0,\\
\delta q_k &= \sum (\partial\dot{q}_k/\partial\omega_l)\,\delta\theta_l = \sum (\partial\dot{q}_k/\partial\omega_I)\,\delta\theta_I
\end{aligned}$$

Compatibility

$$\sum (\partial f_k/\partial\dot{q}_b)(\partial\dot{q}_b/\partial\omega_l) \equiv \sum (\partial\omega_k/\partial\dot{q}_b)(\partial\dot{q}_b/\partial\omega_l) = \partial\omega_k/\partial\omega_l = \delta_{kl},$$

$$\sum (\partial F_k/\partial\omega_b)(\partial\omega_b/\partial\dot{q}_l) \equiv \sum (\partial\dot{q}_k/\partial\omega_b)(\partial\omega_b/\partial\dot{q}_l) = \partial\dot{q}_k/\partial\dot{q}_l = \delta_{kl}$$

PARTICLE KINEMATICS

Virtual displacements

$$\delta \boldsymbol{r} = \sum (\partial \boldsymbol{r}^*/\partial\theta_l)\,\delta\theta_l \equiv \sum \boldsymbol{\varepsilon}_l\,\delta\theta_l \equiv \delta\boldsymbol{r}^*,$$

where

$$\begin{aligned}\boldsymbol{\varepsilon}_l &= \sum (\partial \boldsymbol{r}/\partial q_k)(\partial \dot{q}_k/\partial\omega_l) \equiv \sum (\partial\dot{q}_k/\partial\omega_l)\boldsymbol{e}_k,\\ \boldsymbol{e}_k &= \sum (\partial \boldsymbol{r}^*/\partial\theta_l)(\partial\omega_l/\partial\dot{q}_k) \equiv \sum (\partial\omega_l/\partial\dot{q}_k)\boldsymbol{\varepsilon}_l;\end{aligned}$$

that is,

$$\begin{aligned}\partial(\ldots)/\partial\theta_l &\equiv \sum [\partial(\ldots)/\partial q_k](\partial\dot{q}_k/\partial\omega_l),\\ \partial(\ldots)/\partial q_k &\equiv \sum [\partial(\ldots)/\partial\theta_l](\partial\omega_l/\partial\dot{q}_k)\end{aligned}$$

[nonlinear symbolic (nonvectorial/tensorial) quasi chain rules]

Velocities

$$\begin{aligned}\boldsymbol{v} &= \sum \dot{q}_k(t,q,\omega)\boldsymbol{e}_k + \boldsymbol{e}_0 \qquad [t \equiv q_{n+1}]\\ &= \sum \omega_k(t,q,\dot{q})\boldsymbol{\varepsilon}_k + \boldsymbol{\varepsilon}_0 \equiv \boldsymbol{v}^*(t,q,\omega) \equiv \boldsymbol{v}^*,\end{aligned}$$

where

$$\begin{aligned}\boldsymbol{\varepsilon}_0 \equiv \partial\boldsymbol{r}/\partial\theta_{n+1} &\equiv \sum (\partial\boldsymbol{r}/\partial q_\alpha)(\partial\dot{q}_\alpha/\partial\omega_{n+1}) \qquad [\alpha = 1,\ldots,n+1]\\ &= \sum (\partial\dot{q}_k/\partial\omega_{n+1})\boldsymbol{e}_k + \boldsymbol{e}_0\\ &= \sum (\dot{q}_k\boldsymbol{e}_k - \omega_k\boldsymbol{\varepsilon}_k) + \boldsymbol{e}_0\\ &= \boldsymbol{e}_0 + \sum \Big(\dot{q}_k - \sum (\partial\dot{q}_k/\partial\omega_l)\omega_l\Big)\boldsymbol{e}_k,\end{aligned}$$

and, inversely,

$$\begin{aligned}\boldsymbol{e}_0 \equiv \partial\boldsymbol{r}/\partial t &\equiv \sum (\partial\boldsymbol{r}/\partial\theta_\alpha)(\partial\omega_\alpha/\partial\dot{q}_{n+1}) \qquad [\alpha = 1,\ldots,n+1]\\ &= \boldsymbol{\varepsilon}_0 + \sum \Big(\omega_k - \sum (\partial\omega_k/\partial\dot{q}_l)\dot{q}_l\Big)\boldsymbol{\varepsilon}_k.\end{aligned}$$

For any function $f^* = f^*(t,q,\omega)$,

$$\partial f^*/\partial\theta_{n+1} \equiv \sum (\partial f^*/\partial q_k)\Big(\dot{q}_k - \sum (\partial\dot{q}_k/\partial\omega_l)\omega_l\Big) + \partial f^*/\partial t;$$

which in the Pfaffian case reduces to the earlier

$$\partial f^*/\partial\theta_{n+1} = \sum (\partial f^*/\partial q_k)A_k + \partial f^*/\partial t \equiv \partial f^*/\partial(t) + \partial f^*/\partial t.$$

In particular, for $f^* = q_b$ we find

$$\partial q_b/\partial\theta_s = \partial\dot{q}_b/\partial\omega_s,$$
$$\partial q_b/\partial\theta_{n+1} = \partial\dot{q}_b/\partial\omega_{n+1} = \dot{q}_b - \sum (\partial\dot{q}_b/\partial\omega_l)\omega_l$$
$$[= \dot{q}_b - \sum A_{bl}\omega_l = A_b, \text{ in the Pfaffian case}];$$

and, inversely,

$$\partial\theta_k/\partial t \equiv \partial\omega_k/\partial\dot{q}_{n+1} = \omega_k - \sum (\partial\omega_k/\partial\dot{q}_l)\dot{q}_l.$$

Accelerations

$$\begin{aligned} \boldsymbol{a} \equiv d\boldsymbol{v}/dt &= \sum (\partial\boldsymbol{v}/\partial\dot{q}_k)\ddot{q}_k + \textit{No other } \ddot{q}/\dot{\omega} \text{ terms} \\ &\equiv \sum (\partial\boldsymbol{v}^*/\partial\omega_l)\dot{\omega}_l + \cdots \\ &= \sum \boldsymbol{\varepsilon}_l\dot{\omega}_l + \cdots = \sum (\partial\boldsymbol{a}^*/\partial\dot{\omega}_l)\dot{\omega}_l + \cdots \\ &\equiv \boldsymbol{a}^*(t, q, \omega, \dot{\omega}) \equiv \boldsymbol{a}^*, \end{aligned}$$

where

$$\partial\boldsymbol{v}^*/\partial\omega_l = \sum (\partial\boldsymbol{v}/\partial\dot{q}_k)(\partial\dot{q}_k/\partial\omega_l) \qquad \text{or} \qquad \boldsymbol{\varepsilon}_l = \sum \boldsymbol{e}_k(\partial\dot{q}_k/\partial\omega_l)$$

(which is a vectorial transformation equation, and not some quasi chain rule).

BASIC KINEMATIC IDENTITIES

Holonomic variables

$$\partial\boldsymbol{r}/\partial q_k = \partial\boldsymbol{v}/\partial\dot{q}_k = \partial\boldsymbol{a}/\partial\ddot{q}_k = \cdots = \boldsymbol{e}_k$$

Nonholonomic variables

$$\partial\boldsymbol{r}^*/\partial\theta_k = \partial\boldsymbol{v}^*/\partial\omega_k = \partial\boldsymbol{a}^*/\partial\dot{\omega}_k = \cdots = \boldsymbol{\varepsilon}_k$$

System forms

$$\partial q_k/\partial\theta_l \equiv \partial\dot{q}_k/\partial\omega_l = \partial\ddot{q}_k/\partial\ddot{\omega}_l = \cdots$$
$$\partial\theta_l/\partial q_k \equiv \partial\omega_l/\partial\dot{q}_k = \partial\dot{\omega}_l/\partial\ddot{q}_k = \cdots$$

NONINTEGRABILITY RELATIONS

Nonholonomic deviation (vector)

$$\boldsymbol{\gamma}_k \equiv E_k^*(\boldsymbol{v}^*) = \sum E_k{}^*(\dot{q}_l)\boldsymbol{e}_l \equiv \sum V^l{}_k\boldsymbol{e}_l = -\sum H^b{}_k\boldsymbol{\varepsilon}_b$$

where

Nonlinear Voronets–Chaplygin coefficients

$$V^l{}_k \equiv (\partial\dot{q}_l/\partial\omega_k)^{\cdot} - \partial\dot{q}_l/\partial\theta_k \equiv E_k{}^*(\dot{q}_l).$$

Nonlinear Hamel coefficients

$$H^k{}_b \equiv \sum (\partial \dot{q}_l/\partial \omega_b)[(\partial \omega_k/\partial \dot{q}_l)^{\cdot} - \partial \omega_k/\partial q_l] \equiv \sum (\partial \dot{q}_l/\partial \omega_b) E_l(\omega_k)$$

$$\left[\Rightarrow h^k{}_b \equiv \sum \gamma^k{}_{b\alpha}\omega_\alpha = \sum \gamma^k{}_{bs}\omega_s + \gamma^k{}_{b,n+1} \text{ (in the } \textit{Pfaffian} \text{ case)} \right]$$

$$H^b{}_k \equiv -\sum (\partial \omega_b/\partial \dot{q}_l) V^l{}_k \Leftrightarrow V^l{}_k = -\sum (\partial \dot{q}_l/\partial \omega_b) H^b{}_k$$

$$E_l(\omega_k) = -\sum\sum (\partial \omega_b/\partial \dot{q}_l)(\partial \omega_k/\partial \dot{q}_s) E_b{}^*(\dot{q}_s)$$

$$E_b{}^*(\dot{q}_s) = -\sum\sum (\partial \dot{q}_l/\partial \omega_b)(\partial \dot{q}_s/\partial \omega_k) E_l(\omega_k)$$

For a general function $f^* = f^*(t, q, \omega)$, the following *noncommutativity* relations hold:

$$\partial/\partial\theta_l(\partial f^*/\partial\theta_k) - \partial/\partial\theta_k(\partial f^*/\partial\theta_l) = \sum\sum\sum [(\partial^2 \dot{q}_b/\partial q_s\, \partial\omega_k)(\partial \dot{q}_s/\partial \omega_l) - (\partial^2 \dot{q}_b/\partial q_s\, \partial\omega_l)(\partial \dot{q}_s/\partial \omega_k)](\partial \omega_p/\partial \dot{q}_b)(\partial f^*/\partial \theta_p)$$

THE NONLINEAR TRANSITIVITY EQUATIONS

$$\begin{aligned}
(\delta\theta_k)^{\cdot} - \delta\omega_k &= \sum (\partial\omega_k/\partial\dot{q}_l)[(\delta q_l)^{\cdot} - \delta(\dot{q}_l)] + \sum E_l(\omega_k)\, \delta q_l \\
&= \sum (\partial\omega_k/\partial\dot{q}_l)[(\delta q_l)^{\cdot} - \delta(\dot{q}_l)] + \sum H^k{}_b\, \delta\theta_b \\
&= \sum (\partial\omega_k/\partial\dot{q}_l)[(\delta q_l)^{\cdot} - \delta(\dot{q}_l)] - \sum\sum V^l{}_b(\partial\omega_k/\partial\dot{q}_l)\, \delta\theta_b \\
(\delta q_l)^{\cdot} - \delta(\dot{q}_l) &= \sum (\partial\dot{q}_l/\partial\omega_k)[(\delta\theta_k)^{\cdot} - \delta\omega_k] + \sum V^l{}_k\, \delta\theta_k \\
&= \sum (\partial\dot{q}_l/\partial\omega_k)[(\delta\theta_k)^{\cdot} - \delta\omega_k] - \sum\sum (\partial\dot{q}_l/\partial\omega_b) H^b{}_k\, \delta\theta_k
\end{aligned}$$

SPECIAL CHOICE OF QUASI VELOCITIES

$$\omega_D \equiv f_D(t, q, \dot{q}) = 0, \qquad \omega_I = f_I(t, q, \dot{q}) = \dot{q}_I \neq 0;$$
$$\Rightarrow \dot{q}_D = \dot{q}_D(t, q, \dot{q}_I) \equiv \phi_D(t, q, \dot{q}_I)$$

System virtual displacements

$$\delta q_k\colon \delta q_D = \sum (\partial\phi_D/\partial\dot{q}_I)\, \delta q_I,$$
$$\delta q_I = \sum (\partial\dot{q}_I/\partial\dot{q}_{I'})\, \delta q_{I'} = \sum (\delta_{II'})\, \delta q_{I'} = \delta q_I$$

Particle virtual displacements

$$\delta \boldsymbol{r} = \sum \boldsymbol{e}_k\, \delta q_k = \sum \boldsymbol{B}_I\, \delta q_I,$$

where

$$\boldsymbol{B}_I \equiv \partial\boldsymbol{r}/\partial(q_I) \equiv \partial\boldsymbol{r}/\partial q_I + \sum (\partial\boldsymbol{r}/\partial q_D)(\partial\phi_D/\partial\dot{q}_I) \equiv \boldsymbol{e}_I + \sum (\partial\phi_D/\partial\dot{q}_I)\boldsymbol{e}_D;$$

and, in general,

$$\partial \boldsymbol{B}_I/\partial q_{I'} \neq \partial \boldsymbol{B}_{I'}/\partial q_I \qquad (\text{i.e., the } \boldsymbol{B}_I \text{ are } \textit{nongradient} \text{ vectors})$$

Particle velocities and acceleration

$$\boldsymbol{v} \to \boldsymbol{v}_o = \sum \boldsymbol{B}_I \dot{q}_I + \text{No other } \dot{q} \text{ terms},$$
$$\boldsymbol{a} \to \boldsymbol{a}_o = \sum \boldsymbol{B}_I \ddot{q}_I + \text{No other } \ddot{q} \text{ terms};$$
$$\Rightarrow \partial \boldsymbol{r}/\partial(q_I) \equiv \partial \boldsymbol{v}_o/\partial \dot{q}_I \equiv \partial \boldsymbol{a}_o/\partial \ddot{q}_I \equiv \cdots \equiv \boldsymbol{B}_I$$

Special transitivity relations

$$\delta q_D = \sum (\partial \phi_D/\partial \dot{q}_I)\, \delta q_I \qquad \text{and} \qquad \dot{q}_D = \dot{q}_D(t, q, \dot{q}_I) \equiv \phi_D(t, q, \dot{q}_I)$$
$$(\delta q_D)^{\cdot} - \delta \dot{q}_D = \sum (\partial \phi_D/\partial \dot{q}_I)[(\delta q_I)^{\cdot} - \delta(\dot{q}_I)] + \sum [(\partial \phi_D/\partial \dot{q}_I)^{\cdot} - \partial \phi_D/\partial(q_I)]\, \delta q_I,$$

where

$$\partial \phi_D/\partial(q_I) \equiv \partial \phi_D/\partial q_I + \sum (\partial \phi_D/\partial q_{D'})(\partial \phi_{D'}/\partial \dot{q}_I),$$
$$\partial(\ldots)/\partial(q_I) \equiv \partial(\ldots)/\partial q_I + \sum [\partial(\ldots)/\partial q_D](\partial \dot{\phi}_D/\partial \dot{q}_I)$$

Nonlinear Suslov transitivity relations

$$(\delta q_k)^{\cdot} - \delta(\dot{q}_k): \qquad (\delta q_D)^{\cdot} - \delta \dot{q}_D = \sum W^D{}_I\, \delta q_I \qquad (\neq 0)$$
$$(\delta q_I)^{\cdot} - \delta \dot{q}_I = 0 \qquad [= 0;\ \text{i.e., } W^{I'}{}_I = 0],$$

where

$$W^D{}_I \equiv E_I(\phi_D) - \sum (\partial \phi_D/\partial q_{D'})(\partial \phi_{D'}/\partial \dot{q}_I)$$
$$\equiv (\partial \phi_D/\partial \dot{q}_I)^{\cdot} - \partial \phi_D/\partial(q_I) \equiv E_{(I)}(\phi_D)$$

[special nonlinear Voronets coefficients]

Nonlinear Chaplygin system

$$\dot{q}_D = \dot{q}_D(q_I, \dot{q}_I) \equiv \phi_D(q_I, \dot{q}_I)$$
$$W^D{}_I \to T^D{}_I \equiv (\partial \phi_D/\partial \dot{q}_I)^{\cdot} - \partial \phi_D/\partial q_I \equiv E_I(\phi_D)$$

[special nonlinear Chaplygin coefficients]

KINETIC PRINCIPLES ($P_k \equiv \partial T^*/\partial \omega_k$)

Central equation

$$\sum (dP_k/dt)\, \delta\theta_k - \sum (\partial T^*/\partial \theta_k)\, \delta\theta_k + \sum P_k[(\delta\theta_k)^{\cdot} - \delta\omega_k] = \sum \Theta_k\, \delta\theta_k$$

Lagrange's principle in NNH variables

$$\sum \left(dP_k/dt - \partial T^*/\partial\theta_k + \sum H^l{}_k P_l - \Theta_k \right) \delta\theta_k = 0$$

EQUATIONS OF MOTION ($D = 1, \ldots, m$; $I = m + 1, \ldots, n$)

Coupled

$$E_k(T) = Q_k + \sum \lambda_D(\partial f_D/\partial \dot{q}_k) \qquad (\textit{Routh–Voss}\ \text{form})$$

Uncoupled

$$I_D = \Theta_D + \Lambda_D \quad \text{(Kinetostatic)} \qquad\qquad I_I = \Theta_I \quad \text{(Kinetic)}$$

where

$$\begin{aligned} I_k &\equiv S\, dm\, \boldsymbol{a}^* \cdot \boldsymbol{\varepsilon}_k && (\textit{Raw}\ \text{form}) \\ &= \sum (\partial \dot{q}_l/\partial\omega_k) E_l && (\textit{Maggi}\ \text{form}) \\ &= \partial S^*/\partial\dot{\omega}_k && (\textit{Appell}\ \text{form}) \\ &= (\partial T^*/\partial\omega_k)^{\cdot} - \partial T^*/\partial\theta_k - \Gamma_k && (\textit{Johnsen–Hamel}\ \text{form}) \end{aligned}$$

and

$$\Gamma_k \equiv S\, dm\, \boldsymbol{v}^* \cdot E_k{}^*(\boldsymbol{v}^*) = \sum V^l{}_k\, p_l = -\sum H^l{}_k P_l$$

[nonholonomic correction term]

Transformation equations between holonomic and nonholonomic components

$$\begin{aligned} I_k &= \sum (\partial\dot{q}_l/\partial\omega_k) E_l \Leftrightarrow E_l = \sum (\partial\omega_k/\partial\dot{q}_l) I_k, \\ \Theta_k &= \sum (\partial\dot{q}_l/\partial\omega_k) Q_l \Leftrightarrow Q_l = \sum (\partial\omega_k/\partial\dot{q}_l) \Theta_k, \\ E_{k'}{}^* - \Gamma_{k'} &= \sum (\partial\omega_k/\partial\omega_{k'})(E_k{}^* - \Gamma_k) \end{aligned}$$

Transformation equations of $E_k{}^*(T^*)$ and Γ_k between the quasi velocities $\omega \leftrightarrow \omega'$

$$\begin{aligned} E_{k'}{}^*(T^{*\prime}) &= \sum (\partial\omega_k/\partial\omega_{k'}) E_k{}^*(T^*) + \sum (\partial T^*/\partial\omega_k) E_{k'}{}^*(\omega_k), \\ \Gamma_{k'} &= \sum (\partial T^*/\partial\omega_k) E_{k'}{}^*(\omega_k) + \sum (\partial\omega_k/\partial\omega_{k'}) \Gamma_k \end{aligned}$$

Johnsen–Hamel forms in extenso

$$\begin{aligned} I_k &= dP_k/dt - \partial T^*/\partial\theta_k + \sum H^l{}_k P_l \\ &= dP_k/dt - \partial T^*/\partial\theta_k - \sum\sum (\partial\omega_l/\partial\dot{q}_b) V^b{}_k P_l \\ &= dP_k/dt - \partial T^*/\partial\theta_k - \sum V^b{}_k\, p_b{}^* \end{aligned}$$

$$\left[\sum (\partial\omega_l/\partial\dot{q}_k) P_l = p_k = p_k(t, q, \dot{q}) = p_k{}^*(t, q, \omega) \equiv (\partial T/\partial\dot{q}_k)^* \right]$$

SPECIAL FORMS OF THE EQUATIONS OF MOTION FOR THE CHOICE

$$\omega_D \equiv f_D(t, q, \dot{q}) = \dot{q}_D - \phi_D(t, q, \dot{q}_I) = 0, \qquad \omega_I \equiv f_I(t, q, \dot{q}) = \dot{q}_I \neq 0$$

and its inverse

$$\dot{q}_D = \omega_D + \phi_D(t, q, \dot{q}_I) = \omega_D + \phi_D(t, q, \omega_I), \qquad \dot{q}_I = \omega_I,$$

and with the notation

$$E_k \equiv E_k(T) \equiv (\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k = \partial S/\partial \ddot{q}_k$$

Maggi equations $\Rightarrow$ nonlinear Hadamard equations

Kinetostatic: $E_D = Q_D + \lambda_D$

Kinetic: $E_I + \sum (\partial\phi_D/\partial\dot{q}_I)E_D = Q_I + \sum (\partial\phi_D/\partial\dot{q}_I)Q_D$

or

$$\partial S_o/\partial \ddot{q}_I = Q_I + \sum (\partial\phi_D/\partial\dot{q}_I)Q_D \qquad (\equiv Q_{I,o} \equiv Q_{Io}),$$

where

$$S = S(t, q, \dot{q}, \ddot{q}) = \cdots = S_o(t, q, \dot{q}_I, \ddot{q}_I) = S_o, \ \textit{constrained} \text{ Appellian } S_o$$

Hamel equations $\Rightarrow$ nonlinear Voronets equations

$$E_I(T_o) - \sum (\partial\phi_D/\partial\dot{q}_I)(\partial T_o/\partial q_D) - \Gamma_{Io} \equiv E_{(I)}(T_o) - \Gamma_{Io} = Q_{Io},$$
$$H^D{}_I \to -E_{(I)}(\phi_D) = -W^D{}_I,$$
$$\Gamma_I \to \Gamma_{I,o} \equiv \Gamma_{Io} = \sum W^D{}_I(\partial T/\partial\dot{q}_D)_o \equiv \sum W^D{}_I\, p_{Do}$$

Voronets equations $\Rightarrow$ Chaplygin equations

$$\Big[\dot{q}_D = \dot{q}_D(q_I, \dot{q}_I) \equiv \phi_D(q_I, \dot{q}_I) \qquad \text{and} \qquad T_o = T_o(q_I, \dot{q}_I)$$
$$\Rightarrow W^D{}_I \equiv E_{(I)}(\phi_D) \to E_I(\phi_D) \equiv (\partial\phi_D/\partial\dot{q}_I)^{\cdot} - \partial\phi_D/\partial q_I \equiv T^D{}_I$$
$$\Rightarrow \Gamma_{Io} \to \sum T^D{}_I(\partial T/\partial\dot{q}_D)_o\Big]$$
$$(\partial T_o/\partial\dot{q}_I)^{\cdot} - \partial T_o/\partial q_I - \sum T^D{}_I(\partial T/\partial\dot{q}_D)_o = Q_{Io}$$

Transformation of the nonlinear Hamel and Voronets coefficients $V^l{}_k, H^l{}_k$ under

$$\omega_{b'} = \omega_{b'}(t, q, \dot{q}) \ \Leftrightarrow \ \dot{q}_l = \dot{q}_l(t, q, \omega'):$$
$$\Gamma_k = \sum V^l{}_k\, p_l = -\sum H^l{}_k P_l,$$
$$V^l{}_{k'} = \sum (\partial\omega_k/\partial\omega_{k'})V^l{}_k + \sum [(\partial\omega_k/\partial\omega_{k'})^{\cdot} - \partial\omega_k/\partial\theta_{k'}](\partial\dot{q}_l/\partial\omega_k),$$

$$H^{l'}{}_{k'} = \sum \sum (\partial\omega_k/\partial\omega_{k'})(\partial\omega_{l'}/\partial\omega_l) H^l{}_k - \sum [(\partial\omega_k/\partial\omega_{k'})^{\cdot} - \partial\omega_k/\partial\theta_{k'}](\partial\omega_{l'}/\partial\omega_k),$$
$$H^{l'}{}_{k'} = -\sum (\partial\omega_{l'}/\partial\dot{q}_l) V^l{}_{k'} \quad \Leftrightarrow \quad V^l{}_{k'} = -\sum (\partial\dot{q}_l/\partial\omega_{l'}) H^{l'}{}_{k'}$$

Chapter 6: Differential Variational Principles

VIRTUAL DISPLACEMENTS NEEDED TO PRODUCE THE CORRECT EQUATIONS OF MOTION

Constraints	*Lagrange*	*Jourdain*	*Gauss*
$f(t, q) = 0$: $\partial f/\partial q$	$\delta f = (\partial f/\partial q)\,\delta q$	$\delta' f = 0$ $\delta' \dot{f} = (\partial f/\partial q)\,\delta\dot{q}$	$\delta'' f = 0$, $\delta'' \dot{f} = 0$ $\delta'' \ddot{f} = (\partial f/\partial q)\,\delta\ddot{q}$
$f(t, q, \dot{q}) = 0$: $\partial f/\partial \dot{q}$	—	$\delta' f = (\partial f/\partial \dot{q})\,\delta\dot{q}$	$\delta'' f = 0$ $\delta'' \dot{f} = (\partial f/\partial \dot{q})\,\delta\ddot{q}$
$f(t, q, \dot{q}, \ddot{q}) = 0$: $\partial f/\partial \ddot{q}$	—	—	$\delta'' f = (\partial f/\partial \ddot{q})\,\delta\ddot{q}$

CORRECT EQUATIONS OF MOTION

[Notation: $M_k \equiv E_k(T) - Q_k \equiv N_k(T) - Q_k \equiv \partial S/\partial \ddot{q}_k - Q_k$.
Principle: $\sum M_k\, \delta *_k = 0$, $\delta *_k = \delta q_k$, $\delta\dot{q}_k$, $\delta\ddot{q}_k, \ldots$]

Constraints	*Virtual Displacements*	*Equations of Motion*
$f_D(t, q) = 0$	$\delta f_D = \sum (\partial f_D/\partial q_k)\,\delta q_k$	$M_k = \sum \lambda_D(\partial f_D/\partial q_k)$
$f_D(t, q, \dot{q}) = 0$	$\delta' f_D = \sum (\partial f_D/\partial \dot{q}_k)\,\delta\dot{q}_k$	$M_k = \sum \lambda_D(\partial f_D/\partial \dot{q}_k)$
$f_D(t, q, \dot{q}, \ddot{q}) = 0$	$\delta'' f_D = \sum (\partial f_D/\partial \ddot{q}_k)\,\delta\ddot{q}_k$	$M_k = \sum \lambda_D(\partial f_D/\partial \ddot{q}_k)$

SPECIAL FORM OF CONSTRAINTS

$$\dot{q}_D = \phi_D(t, q, \dot{q}_I) \qquad (D = 1, \ldots, m; I = m+1, \ldots, n).$$

For an arbitrary differentiable function

$$f = f(t, q, \dot{q}) = f[t, q, \phi_D(t, q, \dot{q}_I), \dot{q}_I] = f_o(t, q, \dot{q}_I) \equiv f_o,$$

the following identity holds:

$$N_I(f_o) = E_I(f_o) + \sum (\partial f_o/\partial q_D)(\partial \phi_D/\partial \dot{q}_I)$$
$$\Rightarrow N_I(T_o) = E_I(T_o) + \sum (\partial T_o/\partial q_D)(\partial \phi_D/\partial \dot{q}_I),$$
$$N_I(\dot{q}_D) = E_I(\dot{q}_D) + \sum (\partial \dot{q}_D/\partial q_{D'})(\partial \phi_{D'}/\partial \dot{q}_I).$$

NIELSEN FORM OF SPECIAL NONLINEAR VORONETS EQUATIONS

$$N_I(T_o) - \sum (\partial T/\partial \dot{q}_D)_o N_I(\dot{q}_D) - 2\sum (\partial T/\partial \dot{q}_D)_o (\partial \phi_D/\partial \dot{q}_I) = Q_{Io}$$

NIELSEN FORM OF SPECIAL NONLINEAR CHAPLYGIN EQUATIONS

$$\partial \dot{T}_o/\partial \dot{q}_I - 2(\partial T_o/\partial q_I) - \sum (\partial T/\partial \dot{q}_D)_o [\partial \ddot{q}_D/\partial \dot{q}_I - 2(\partial \dot{q}_D/\partial q_I)] = Q_{Io}$$

Special Pfaffian $\rightarrow$ Voronets form

$$\dot{q}_D = \sum b_{DI}(t, q)\dot{q}_I + b_D(t, q)$$

Then the above Voronets equations assume the special Nielsen form:

$$\partial \dot{T}_o/\partial \dot{q}_I - 2(\partial T_o/\partial q_I) - \sum (\partial T/\partial \dot{q}_D)_o \left\{ \sum [b^D{}_{II'} - 2(\partial b_{DI'}/\partial q_I)]\dot{q}_{I'} + [b^D{}_I - 2(\partial b_D/\partial q_I)] \right\} - 2\sum (\partial T/\partial q_D)_o b_{DI} = Q_{Io},$$

where

$$b^D{}_{II'} \equiv \sum [(\partial b_{DI}/\partial q_{D'}) b_{D'I'} + (\partial b_{DI'}/\partial q_{D'}) b_{D'I}] + (\partial b_{DI}/\partial q_{I'} + \partial b_{DI'}/\partial q_I),$$
$$b^D{}_I \equiv b^D{}_{I,n+1} \equiv \sum [(\partial b_D/\partial q_{D'}) b_{D'I} + (\partial b_{DI}/\partial q_{D'}) b_{D'}] + (\partial b_{DI}/\partial t + \partial b_D/\partial q_I).$$

Special Voronets $\rightarrow$ Chaplygin form

$$\dot{q}_D = \sum b_{DI}(q_I)\dot{q}_I, \qquad \text{and} \qquad \partial T/\partial q_D = 0$$

Then the above Chaplygin equations assume the special Nielsen form:

$$\partial \dot{T}_o/\partial \dot{q}_I - 2(\partial T_o/\partial q_I) - \sum\sum (\partial T/\partial \dot{q}_D)_o (\partial b_{DI}/\partial q_{I'} - \partial b_{DI'}/\partial q_I)\dot{q}_{I'} = Q_{Io}$$
$$[b_D = 0, \qquad b^D{}_I = 0, \qquad b^D{}_{II'} = \partial b_{DI}/\partial q_{I'} + \partial b_{DI'}/\partial q_I]$$

NIELSEN FORMS OF HIGHER-ORDER EQUATIONS

Let

$$N_k{}^{(s)}(\ldots) \equiv \partial\overset{(s)}{(\ldots)}/\partial\overset{(s)}{q}_k - 2\left[\partial\overset{(s-1)}{(\ldots)}/\partial\overset{(s-1)}{q_k}\right],$$

$$E_k{}^{(s)}(\ldots) \equiv d/dt\left[\partial\overset{(s-1)}{(\ldots)}/\partial\overset{(s)}{q_k}\right] - \left[\partial\overset{(s-1)}{(\ldots)}/\partial\overset{(s-1)}{q_k}\right].$$

Then, for any sufficiently differentiable function $f = f(t, q, \dot{q})$, and any $k = 1, 2, \ldots, n$; $s = 1, 2, 3, \ldots,$

$$N_k{}^{(s)}(f) = E_k{}^{(s)}(f).$$

Let

$$N_k{}^{*(s)}(\ldots) \equiv \partial\overset{(s)}{(\ldots)}/\partial\overset{(s)}{\theta}_k - 2\left[\partial\overset{(s-1)}{(\ldots)}/\partial\overset{(s-1)}{\theta_k}\right],$$

$$E_k{}^{*(s)}(\ldots) \equiv d/dt\left[\partial\overset{(s-1)}{(\ldots)}/\partial\overset{(s)}{\theta_k}\right] - \left[\partial\overset{(s-1)}{(\ldots)}/\partial\overset{(s-1)}{\theta_k}\right],$$

where

$$\partial\overset{(s-1)}{(\ldots)}/\partial\overset{(s-1)}{\theta_k} \equiv \sum\left[\partial\overset{(s-1)}{(\ldots)}/\partial\overset{(s-1)}{q_l}\right]\left[\partial\overset{(s)}{q_l}/\partial\overset{(s)}{\theta_k}\right]$$

[(s)th-order quasi chain rule].

Then, for any sufficiently differentiable function $f^* = f^*(t, q, \omega)$, and any $k = 1, 2, \ldots, n$; $s = 1, 2, 3, \ldots,$

$$N_k{}^{*(s)}(f^*) = E_k{}^{*(s)}(f^*),$$

where

$$\begin{aligned}
&f(t, q, \dot{q}) \Rightarrow \dot{f} \Rightarrow \ldots \overset{(s-1)}{f} \Rightarrow \overset{(s)}{f},\\
&\quad \overset{(s-1)}{f^*} = \overset{(s-1)}{f}\left[t, q, \dot{q} \equiv \overset{(1)}{q}, \ldots, \overset{(s-1)}{q};\ \overset{(s)}{q}\left(t, q, \overset{(1)}{q}, \ldots, \overset{(s-1)}{q}, \overset{(s)}{\theta}\right)\right]\\
&\quad\quad = \overset{(s-1)}{f}\left(t, q, \overset{(1)}{q}, \ldots, \overset{(s-1)}{q}, \overset{(s)}{\theta}\right),\\
&\quad \overset{(s)}{f}{}^* = \overset{(s)}{f}\left[t, q, \overset{(1)}{q}, \ldots, \overset{(s-1)}{q};\ \overset{(s)}{q}\left(t, q, \overset{(1)}{q}, \ldots, \overset{(s-1)}{q}, \overset{(s)}{\theta}\right), \overset{(s+1)}{q}\left(t, q, \overset{(1)}{q}, \ldots, \overset{(s-1)}{q}, \overset{(s)}{\theta}, \overset{(s+1)}{\theta}\right)\right]\\
&\quad\quad = \overset{(s)}{f}\left(t, q, \overset{(1)}{q}, \ldots, \overset{(s-1)}{q}, \overset{(s)}{\theta}, \overset{(s+1)}{\theta}\right).
\end{aligned}$$

Hamel-type equations $(s = 1, 2, 3, \ldots)$

$$
\begin{aligned}
(s)\, d/dt\left[\partial \overset{(s-1)}{T^*}/\partial \overset{(s)}{\theta}_I\right] - \partial \overset{(s-1)}{T^*}/\partial \overset{(s-1)}{\theta}_I \\
- \sum \left[s\left(\partial \overset{(s)}{q}_k/\partial \overset{(s)}{\theta}_I\right)^{\bullet} - \partial \overset{(s)}{q}_k/\partial \overset{(s-1)}{\theta}_I \right] \left(\partial \overset{(s-1)}{T}/\partial \overset{(s)}{q}_k\right)^* \\
= \sum \left(\partial \overset{(s)}{q}_k/\partial \overset{(s)}{\theta}_I\right) Q_k \equiv \Theta_I
\end{aligned}
$$

Nielsen-type equations

$$
\begin{aligned}
(s)\left(\partial \overset{(s)}{T^*}/\partial \overset{(s)}{\theta}_I\right) - (s+1)\left(\partial \overset{(s-1)}{T^*}/\partial \overset{(s-1)}{\theta}_I\right) \\
- \sum \left[s\left(\partial \overset{(s+1)}{q}_k/\partial \overset{(s)}{\theta}_I\right) - (s+1)\left(\partial \overset{(s)}{q}_k/\partial \overset{(s-1)}{\theta}_I\right)\right] \left(\partial \overset{(s-1)}{T}/\partial \overset{(s)}{q}_k\right)^* = \Theta_I
\end{aligned}
$$

For $\boldsymbol{s} = 1$, the above yield, respectively,

$$
\begin{aligned}
& d/dt(\partial T^*/\partial \dot{\theta}_I) - \partial T^*/\partial \theta_I \\
& \qquad - \sum \left[(\partial \dot{q}_k/\partial \dot{\theta}_I)^{\cdot} - \partial \dot{q}_k/\partial \theta_I\right](\partial T/\partial \dot{q}_k)^* = \Theta_I, \\
& \partial \dot{T}^*/\partial \dot{\theta}_I - 2(\partial T^*/\partial \theta_I) \\
& \qquad - \sum \left[\partial \ddot{q}_k/\partial \dot{\theta}_I - 2(\partial \dot{q}_k/\partial \theta_I)\right](\partial T/\partial \dot{q}_k)^* = \Theta_I;
\end{aligned}
$$

and, for $\boldsymbol{s} = 2$,

$$
\begin{aligned}
& 2(\partial \dot{T}^*/\partial \ddot{\theta}_I)^{\cdot} - \partial \dot{T}^*/\partial \dot{\theta}_I \\
& \qquad - \sum \left[2(\partial \ddot{q}_k/\partial \ddot{\theta}_I)^{\cdot} - \partial \ddot{q}_k/\partial \dot{\theta}_I\right](\partial \dot{T}/\partial \ddot{q}_k)^* = \Theta_I, \\
& 2(\partial \ddot{T}^*/\partial \ddot{\theta}_I) - 3(\partial \dot{T}^*/\partial \dot{\theta}_I) \\
& \qquad - \sum \left[2(\partial \dddot{q}_k/\partial \ddot{\theta}_I) - 3(\partial \ddot{q}_k/\partial \dot{\theta}_I)\right](\partial \dot{T}/\partial \ddot{q}_k)^* = \Theta_I.
\end{aligned}
$$

GAUSS' PRINCIPLE

Compulsion

$$
\begin{aligned}
& Z \equiv (1/2) \mathsf{S}\, dm\,[\boldsymbol{a} - (d\boldsymbol{F}/dm)]^2 \equiv (1/2) \mathsf{S}\, (1/dm)(dm\,\boldsymbol{a} - d\boldsymbol{F})^2 \\
& \left[\equiv (1/2) \mathsf{S}\, (d\boldsymbol{R})^2/dm = \mathsf{S}\, (-d\boldsymbol{R})^2/2\,dm = \mathsf{S}\, (Lost\ force)^2/2\,dm \ \geq\ 0\right] \\
& \qquad = S - \mathsf{S}\, d\boldsymbol{F} \cdot \boldsymbol{a} + \text{terms not containing accelerations},
\end{aligned}
$$

where

$$S = (1/2) \mathsf{S}\, dm\, \boldsymbol{a} \cdot \boldsymbol{a}: \text{ Appellian.}$$

Gauss' principle

$$\delta'' Z = 0,$$

where

$$\delta'' t = 0, \qquad \delta'' \boldsymbol{r} = \boldsymbol{0}, \qquad \delta'' \boldsymbol{v} = \boldsymbol{0}, \qquad \delta''(d\boldsymbol{F}) = \boldsymbol{0}, \qquad \text{but} \;\; \delta'' \boldsymbol{a} \neq \boldsymbol{0}$$

$$[d\boldsymbol{F} = d\boldsymbol{F}(t, \boldsymbol{r}, \boldsymbol{v}) \Rightarrow \delta''(d\boldsymbol{F}) = \boldsymbol{0}, \qquad \delta'' Q_k = 0]$$

$$\boldsymbol{a} = \sum \boldsymbol{e}_k \ddot{q}_k + \text{no } \ddot{q}\text{-terms} = \sum \boldsymbol{\varepsilon}_I \dot{\omega}_I + \text{no } \dot{\omega}\text{-terms},$$

$$\Rightarrow \delta'' \boldsymbol{a} = \sum \boldsymbol{e}_k \, \delta \ddot{q}_k = \sum \boldsymbol{\varepsilon}_I \, \delta \dot{\omega}_I,$$

and so, explicitly,

$$\begin{aligned}
\delta'' Z &= (1/2) \mathsf{S}\, dm\, 2\, [\boldsymbol{a} - (d\boldsymbol{F}/dm)] \cdot \delta'' \boldsymbol{a} \\
&= \mathsf{S}\, (dm\, \boldsymbol{a} - d\boldsymbol{F}) \cdot \delta'' \boldsymbol{a} \\
&= \mathsf{S}\, (d\boldsymbol{R}/dm) \cdot \delta''(d\boldsymbol{R}) = \mathsf{S}\, (d\boldsymbol{R}/dm) \cdot \delta''(dm\, \boldsymbol{a} - d\boldsymbol{F}) \\
&= \mathsf{S}\, (d\boldsymbol{R}/dm) \cdot dm\, \delta'' \boldsymbol{a} = \mathsf{S}\, d\boldsymbol{R} \cdot \delta'' \boldsymbol{a} = 0.
\end{aligned}$$

COMPATIBILITY BETWEEN THE PRINCIPLES OF GAUSS AND LAGRANGE

$$\begin{aligned}
\delta q_k &\equiv \sum (\partial \dot{q}_k / \partial \omega_l)\, \delta \theta_l, \\
\delta \theta_I &\equiv \sum (\partial \omega_I / \partial \dot{q}_k)\, \delta q_k \equiv \sum (\partial f_I / \partial \dot{q}_k)\, \delta q_k \neq 0
\end{aligned}$$

Also,

$$\delta f_D \equiv \delta \omega_D = \mathsf{S}\, (\partial f_D / \partial \boldsymbol{v}) \cdot \delta \boldsymbol{r} = \sum (\partial f_D / \partial \dot{q}_k)\, \delta q_k = 0,$$

instead of the formal (calculus of variations) definition

$$\delta f_D = \sum (\partial f_D / \partial q_k)\, \delta q_k + \sum (\partial f_D / \partial \dot{q}_k)\, \delta \dot{q}_k = 0.$$

The same conclusion can be reached by requiring compatibility between the principles of Lagrange and Jourdain.

EQUATIONS OF MOTION

$$\delta'' Z + \sum \lambda_D\, \delta'' \dot{f}_D = 0,$$

where

$$\begin{aligned}
\delta'' Z &= \sum [E_k(T) - Q_k]\, \delta \ddot{q}_k && (\textit{Holonomic} \text{ system variables}) \\
&= \sum (\partial S^* / \partial \dot{\omega}_k - \Theta_k)\, \delta(\dot{\omega}_k) && (\textit{Nonholonomic} \text{ system variables})
\end{aligned}$$

$$\begin{aligned}
\delta''(\dot{f}_D) &= \delta''\Big\{\partial f_D/\partial t + \mathop{\mathsf{S}}[(\partial f_D/\partial \boldsymbol{r})\cdot\boldsymbol{v} + (\partial f_D/\partial \boldsymbol{v})\cdot\boldsymbol{a}]\Big\}\\
&= \mathop{\mathsf{S}}(\partial f_D/\partial \boldsymbol{v})\cdot\delta\boldsymbol{a} \qquad\qquad (\textit{Particle}\text{ form})\\
&= \delta''\Big\{\partial f_D/\partial t + \sum[(\partial f_D/\partial q_k)\dot{q}_k + (\partial f_D/\partial \dot{q}_k)\ddot{q}_k]\Big\}\\
&= \sum(\partial f_D/\partial \dot{q}_k)\,\delta\ddot{q}_k \qquad\qquad (\textit{Holonomic}\text{ system variables})
\end{aligned}$$

MINIMALITY OF THE COMPULSION

$$\begin{aligned}
\Delta'' Z &\equiv Z(\boldsymbol{a} + \delta''\boldsymbol{a}) - Z(\boldsymbol{a})\\
&= (1/2)\mathop{\mathsf{S}} dm\,[(\boldsymbol{a} + \delta''\boldsymbol{a}) - (d\boldsymbol{F}/dm)]^2 - (1/2)\mathop{\mathsf{S}} dm\,[\boldsymbol{a} - (d\boldsymbol{F}/dm)]^2\\
&= \delta'' Z + (1/2)\,\delta''^{\,2} Z \ge 0,
\end{aligned}$$

where

$$\begin{aligned}
\delta'' Z &= \mathop{\mathsf{S}}(dm\,\boldsymbol{a} - d\boldsymbol{F})\cdot\delta''\boldsymbol{a} \qquad (=0),\\
\delta''^{\,2} Z &= \mathop{\mathsf{S}}(dm\,\delta''\boldsymbol{a}\cdot\delta''\boldsymbol{a}) \qquad (\ge 0).
\end{aligned}$$

Chapter 7: Time-Integral Theorems and Variational Principles

GENERALIZED HOLONOMIC VIRIAL IDENTITY

$$\int\Big\{\sum(\partial T/\partial \dot{q}_k)\dot{z}_k + \sum\Big(\partial T/\partial q_k + Q_k + \sum \lambda_D a_{Dk}\Big)z_k\Big\}\,dt = \Big\{\sum(\partial T/\partial \dot{q}_k)z_k\Big\}_1^2$$

[$z_k = z_k(t)$: arbitrary functions, but as well behaved as needed; and integral extends from t_1 to t_2 (arbitrary time limits).

Specializations

$z_k \to \delta q_k$ [*virtual displacement of* q_k; and assuming $\delta\dot{q}_k = (\delta q_k)^{\cdot}$]:

$$\int(\delta T + \delta' W)\,dt = \Big\{\sum p_k\,\delta q_k\Big\}_1^2,$$

[Hamilton's law of virtually/vertically varying action]

$z_k \to \Delta q_k = \delta q_k + \dot{q}_k\,\Delta t$ (*noncontemporaneous*, *or skew*, *or oblique*, *variation of* q_k):

$$\int \left\{ \sum (\partial T/\partial \dot{q}_k)(\Delta q_k)^{\cdot} + \sum (\partial T/\partial q_k + Q_k)\, \Delta q_k - \sum \lambda_D a_D\, \Delta_D \right\} dt$$

$$= \left\{ \sum p_k\, \Delta \dot{q}_k \right\}_1^2$$

[Hamilton's law of skew-varying action]

$$(\Delta q_k)^{\cdot} - \Delta(\dot{q}_k) = \dot{q}_k(\Delta t)^{\cdot} \qquad \text{[i.e., } \Delta(\ldots) \text{ and } (\ldots)^{\cdot} \text{ do not commute]}$$

$z_k \to q_k$ (*actual system coordinate*):

$$\int \left\{ \sum (\partial T/\partial \dot{q}_k)\dot{q}_k + \sum \Big(\partial T/\partial q_k + Q_k + \sum \lambda_D a_{Dk} \Big) q_k \right\} dt$$

$$= \left\{ \sum p_k q_k \right\}_1^2$$

[Virial theorem (of Clausius, Szily et al.)]

$z_k \to \dot{q}_k$ (*actual system velocity*): power theorem in holonomic variables.

GENERALIZED NONHOLONOMIC VIRIAL IDENTITY

$$\int \Big(\sum (\partial T^*/\partial \omega_k)\dot{z}_k + \sum (\partial T^*/\partial \theta_k) z_k - \sum \sum h^b{}_k (\partial T^*/\partial \omega_b) z_k$$

$$+ \sum (\Theta_k + \Lambda_k) z_k \Big)\, dt = \left\{ \sum (\partial T^*/\partial \omega_k) z_k \right\}_1^2$$

Specializations

$z_k \to \delta\theta_k$ (recalling that $\delta\theta_D = 0$, $\delta\theta_{n+1} \equiv \delta t = 0$, while $\delta\theta_I \neq 0$):

$$\int \Big(\delta T^* + \sum \Theta_I\, \delta\theta_I \Big)\, dt = \left\{ \sum P_I\, \delta\theta_I \right\}_1^2$$

[Hamilton's law of virtual and nonholonomic action].

$z_k \to \dot{\theta}_k \equiv \omega_k$ (recalling that $\omega_D = 0$): power theorem in nonholonomic variables.

$z_k \to \theta_k$: This case is meaningless because there is no such thing as θ_k.

$z_k \to \dot{\omega}_k$: This case does not seem to lead to any readily useful and identifiable result.

$z_k \to \Delta\theta_k$:

$$\Big[\equiv \delta\theta_b + \dot{\theta}_b\, \Delta t \equiv \delta\theta_b + \omega_b\, \Delta t$$

$$\Rightarrow (\Delta\theta_b)^{\cdot} - \Delta\omega_b = (\delta\theta_b)^{\cdot} - \delta(\dot{\theta}_b) + \omega_b(\Delta t)^{\cdot} = \sum h^b{}_k\, \delta\theta_k + \omega_b(\Delta t)^{\cdot} \Big]$$

$$\int \Big\{ \sum (\partial T^*/\partial \theta_k)\, \Delta\theta_k + \sum (\partial T^*/\partial \omega_k)\, \Delta\omega_k$$

$$+ \sum (\partial T^*/\partial \omega_k) \Big[\omega_k(\Delta t)^{\cdot} - \sum \gamma^k{}_b \omega_b\, \Delta t \Big] + \sum (\Theta_k + \Lambda_k)\, \Delta\theta_k \Big\}\, dt$$

$$= \left\{ \sum (\partial T^*/\partial \omega_k)\, \Delta\theta_k \right\}_1^2$$

[Hamilton's law of skew-varying action in nonholonomic variables].

NONLINEAR NONHOLONOMIC CONSTRAINTS;
HOLONOMIC VARIABLES

$$\int \Big\{ \sum (\partial T/\partial \dot{q}_k)\dot{z}_k + \sum \Big[\partial T/\partial q_k + Q_k + \sum \lambda_D (\partial f_D/\partial \dot{q}_k) \Big] z_k \Big\}\, dt = \Big\{ \sum (\partial T/\partial \dot{q}_k) z_k \Big\}_1^2$$

Specializations

$z_k \to q_k$ (Virial theorem):

$$\int \Big\{ \sum (\partial T/\partial \dot{q}_k)\dot{q}_k + \sum \Big[\partial T/\partial q_k + Q_k + \sum \lambda_D (\partial f_D/\partial \dot{q}_k) \Big] q_k \Big\}\, dt = \Big\{ \sum (\partial T/\partial \dot{q}_k) q_k \Big\}_1^2$$

$z_k \to \dot{q}_k$ (Nonlinear (nonpotential) generalized power equation):

$$d/dt \Big(\sum (\partial T/\partial \dot{q}_k)\dot{q}_k - T \Big) = -\partial T/\partial t + \sum Q_k \dot{q}_k + \sum \sum \lambda_D (\partial f_D/\partial \dot{q}_k)\dot{q}_k$$

$z_k \to \delta q_k$ (Hamilton's law of varying action);

$z_k \to \Delta q_k$ (Hamilton's law of skew-varying action):

$$\int \Big\{ \sum (\partial T/\partial \dot{q}_k)(\Delta q_k)^{\cdot} + \sum (\partial T/\partial q_k + Q_k)\, \Delta q_k + \Big(\sum \sum \lambda_D (\partial f_D/\partial \dot{q}_k)\dot{q}_k \Big)\, \Delta t \Big\}\, dt = \Big\{ \sum (\partial T/\partial \dot{q}_k) z_k \Big\}_1^2$$

NONLINEAR NONHOLONOMIC CONSTRAINTS;
NONHOLONOMIC VARIABLES

$$\int (\delta T^* + \delta' W)\, dt = \Big\{ \sum P_k\, \delta\theta_k \Big\}_1^2,$$

where

$$\delta T^* = \cdots = \Big(\sum (\partial T^*/\partial \omega_k)\, \delta\theta_k \Big)^{\cdot} - \sum (\partial T^*/\partial \omega_k)^{\cdot}\, \delta\theta_k - \sum \sum H^k{}_b (\partial T^*/\partial \omega_k)\, \delta\theta_b + \sum (\partial T^*/\partial \theta_k)\, \delta\theta_k,$$

$$\Rightarrow \int \delta T^*\, dt = -\int \sum \Big[(\partial T^*/\partial \omega_k)^{\cdot} - \partial T^*/\partial \theta_k + \sum H^b{}_k (\partial T^*/\partial \omega_b) \Big]\, \delta\theta_k\, dt + \Big\{ \sum (\partial T^*/\partial \omega_k)\, \delta\theta_k \Big\}_1^2,$$

and

$$(\delta\theta_b)^{\cdot} - \delta\omega_b = \sum E_s(\omega_b)\,\delta q_s = \sum\sum E_s(\omega_b)(\partial\dot{q}_s/\partial\omega_k)\,\delta\theta_k \equiv \sum H^b{}_k\,\delta\theta_k$$
$$= -\sum\sum E_k(\dot{q}_l)(\partial\omega_b/\partial\dot{q}_l)\,\delta\theta_k \equiv -\sum\sum V^l{}_k(\partial\omega_b/\partial\dot{q}_l)\,\delta\theta_k,$$
$$\Gamma_k = -\sum H^b{}_k(\partial T^*/\partial\omega_b) = \sum V^b{}_k(\partial T/\partial\dot{q}_b)^*$$

[assuming again that $(\delta q_k)^{\cdot} = \delta(\dot{q}_k)$].

GENERAL INTEGRAL EQUATIONS

$$\int \Big\{\delta T + \sum(\partial T/\partial\dot{q}_k)[(\delta q_k)^{\cdot} - \delta(\dot{q}_k)] + \delta' W\Big\}\,dt$$
$$= \int \Big\{\delta T + \delta' W + \sum P_k[(\delta\theta_k)^{\cdot} - \delta\omega_k] + \sum\sum V^k{}_b\,p_k\,\delta\theta_b\Big\}\,dt$$
$$= \int \Big\{\delta T + \delta' W + \sum P_k[(\delta\theta_k)^{\cdot} - \delta\omega_k] - \sum\sum H^k{}_b P_k\,\delta\theta_b\Big\}\,dt$$
$$= \Big\{\sum(\partial T/\partial\dot{q}_k)\,\delta q_k\Big\}_1^2;$$

where

$$(\delta q_k)^{\cdot} - \delta(\dot{q}_k) = \sum(\partial\dot{q}_k/\partial\omega_b)[(\delta\theta_b)^{\cdot} - \delta\omega_b] + \sum V^k{}_b\,\delta\theta_b$$
$$= \sum(\partial\dot{q}_k/\partial\omega_b)[(\delta\theta_b)^{\cdot} - \delta\omega_b] - \sum\sum(\partial\dot{q}_k/\partial\omega_l)H^l{}_b\,\delta\theta_b$$
$$T = T[t, q, \dot{q}(t, q, \omega)] \equiv T^*(t, q, \omega) \equiv T^*.$$

The above yield the "equation of motion forms" [without the assumption $(\delta q_k)^{\cdot} = \delta(\dot{q}_k)$]:

$$-\int\sum\Big[(\partial T^*/\partial\omega_k)^{\cdot} - \partial T^*/\partial\theta_k - \sum(\partial T/\partial\dot{q}_b)^* V^b{}_k - \Theta_k\Big]\,\delta\theta_k\,dt = 0,$$
$$-\int\sum\Big[(\partial T^*/\partial\omega_k)^{\cdot} - \partial T^*/\partial\theta_k + \sum(\partial T^*/\partial\omega_b)H^b{}_k - \Theta_k\Big]\,\delta\theta_k\,dt = 0.$$

HÖLDER–VORONETS–HAMEL VIEWPOINT

$(\delta q_k)^{\cdot} = \delta\dot{q}_k$, whether the δq_k are further constrained or not. Then, with: $\delta' W^* \equiv \sum \Theta_k\,\delta\theta_k$, the above yield

$$\int(\delta T + \delta' W)\,dt = \int(\delta T^* + \delta' W^*)\,dt$$
$$= \Big\{\sum(\partial T^*/\partial\omega_k)\,\delta\theta_k\Big\}_1^2$$

CONSTRAINED INTEGRAL FORMS
[i.e., in terms of $T^* \to T^*{}_o = T^*(t, q, \omega_I)$]

Generally:

$$\delta T^* = \delta T^*_o + \sum (\partial T^*/\partial\omega_D)_o\, \delta\omega_D,$$
$$\delta T^*_o = \sum (\partial T^*_o/\partial\theta_I)\, \delta\theta_I + \sum (\partial T^*_o/\partial\omega_I)\, \delta\omega_I$$

Under the Hölder–Voronets–Hamel viewpoint:

$$\delta(\dot{q}_k) = (\delta q_k)^{\cdot}, \qquad \delta\theta_D = 0, \qquad d(\delta\theta_D) = 0 \Rightarrow (\delta\theta_D)^{\cdot} = 0;$$

but $\quad \delta(d\theta_D) \neq 0, \qquad \delta\omega_D = \sum\sum V^k{}_I (\partial\omega_D/\partial\dot{q}_k)\, \delta\theta_I = -\sum H^D{}_I\, \delta\theta_I \neq 0,$

and $\quad \delta\omega_I = (\delta\theta_I)^{\cdot} - \sum H^I{}_{I'}\, \delta\theta_{I'};$

we obtain the constrained integral equation

$$\int \Big[\delta T^*_o + \sum\sum (\partial T/\partial\dot{q}_k)_o V^k{}_I\, \delta\theta_I + \delta' W^*_o\Big]\, dt$$
$$= \int \Big[\delta T^*_o - \sum\sum (\partial T^*/\partial\omega_D)_o H^D{}_I\, \delta\theta_I + \delta' W^*_o\Big]\, dt$$
$$= \Big\{\sum (\partial T/\partial\dot{q}_k)\, \delta q_k\Big\}_1^2.$$

Special form of the constraints:

$$\dot{q}_D = \phi_D(t, q, \dot{q}_I)$$
$$\Rightarrow \omega_D \equiv \dot{q}_D - \phi_D(t, q, \dot{q}_I) = 0, \qquad \omega_I \equiv \dot{q}_I \neq 0,$$
$$\dot{q}_D = \omega_D + \phi_D[t, q, \dot{q}_I(t, q, \omega_I)] = \omega_D + \phi_D(t, q, \omega_I),$$
$$\delta\theta_D = \delta q_D - \sum (\partial\phi_D/\partial\dot{q}_I)\, \delta q_I = 0, \qquad \delta\theta_I = \delta q_I \neq 0.$$

Suslov transitivity assumptions and integral equation:

$$(\delta q_D)^{\cdot} \neq \delta(\dot{q}_D), \qquad (\delta q_I)^{\cdot} - \delta(\dot{q}_I) = 0;$$

but

$$\delta(d\theta_D) = 0$$

or

$$\delta\omega_D = \delta(\dot{q}_D - \phi_D) = \delta(\dot{q}_D) - \delta\phi_D = 0 \qquad [\text{and } (\delta\theta_D)^{\cdot} = 0]$$
$$\Rightarrow \delta(\dot{q}_D) = \delta\phi_D \qquad [\text{definition of } \delta(\dot{q}_D)];$$
$$\Rightarrow (\delta q_D)^{\cdot} - \delta(\dot{q}_D) = \Big(\sum (\partial\phi_D/\partial\dot{q}_I)\, \delta q_I\Big) - \delta\phi_D$$
$$= \cdots = \sum E_{(I)}(\phi_D)\, \delta q_I \equiv \sum W^D{}_I\, \delta q_I \neq 0;$$
$$\Rightarrow \delta T = \delta T_o.$$

Suslov principle:

$$\int \left\{ \delta T_o + \sum (\partial T/\partial \dot{q}_D)_o [(\delta q_D)^{\cdot} - \delta\phi_D] + \delta' W_o \right\} dt$$
$$= \int \left\{ \delta T_o + \sum\sum (\partial T/\partial \dot{q}_D) W^D{}_I \, \delta q_I + \delta' W_o \right\} dt$$
$$= \left\{ \sum (\partial T/\partial \dot{q}_k) \, \delta q_k \right\}_1^2$$

Hölder–Voronets–Hamel transitivity assumptions:

$$\delta(\dot{q}_k) = (\delta q_k)^{\cdot}, \qquad \delta\theta_D = 0, \qquad d(\delta\theta_D) = 0 \Rightarrow (\delta\theta_D)^{\cdot} = 0;$$

but

$$\delta(d\theta_D) \neq 0$$

or

$$\delta\omega_D = \delta(\dot{q}_D - \phi_D) = \delta(\dot{q}_D) - \delta\phi_D = (\delta q_D)^{\cdot} - \delta\phi_D$$
$$= \sum E_{(I)}(\phi_D) \, \delta q_I \equiv \sum W^D{}_I \, \delta q_I \neq 0 \qquad [\text{definition of } \delta(\dot{q}_D)];$$
$$\Rightarrow \delta T = \delta T_o + \sum\sum (\partial T/\partial \dot{q}_D) W^D{}_I \, \delta q_I.$$

Voronets principle:

$$\int \left[\delta T_o + \sum\sum (\partial T/\partial \dot{q}_D) W^D{}_I \, \delta q_I + \delta' W_o \right] dt$$
$$= \left\{ \sum (\partial T/\partial \dot{q}_k) \, \delta q_k \right\}_1^2.$$

In both cases:

$$T \to T_o(t, q, \dot{q}_I) \to \delta T_o \text{ (variation of constrained } T\text{)},$$
$$\partial T/\partial \dot{q}_D \to (\partial T/\partial \dot{q}_D)_o = p_D[t, q, \dot{q}_I, \phi_D(t, q, \dot{q}_I)] \equiv p_{D,o}(t, q, \dot{q}_I) \equiv p_{Do},$$
$$\left\{ \sum (\partial T/\partial \dot{q}_k) \, \delta q_k \right\}_1^2 = \cdots = \left\{ \sum (\ldots)_I \, \delta q_I \right\}_1^2,$$
$$\delta' W_o \equiv \sum Q_{Io} \, \delta q_I.$$

NONCONTEMPORANEOUS VARIATIONS AND RELATED THEOREMS

Definition:

$$\Delta(\ldots) \equiv \delta(\ldots) + [d(\ldots)/dt] \, \Delta t\text{: } \textit{noncontemporaneous variation operator}$$
$$\Rightarrow \Delta q_k = \delta q_k + \dot{q}_k \, \Delta t, \qquad \Delta t = \delta t + (dt/dt) \, \Delta t = 0 + (1) \, \Delta t = \Delta t.$$

Basic identities:

$$\begin{aligned}
\Delta \int (\ldots)\,dt &= \int \delta(\ldots)\,dt + \{(\ldots)\,\Delta t\}_1^2 \\
&= \int \{\Delta(\ldots) + (\ldots)[d(\Delta t)/dt]\}\,dt \\
&= \int [\Delta(\ldots)\,dt + (\ldots)\,d(\Delta t)], \\
\int \Delta(\ldots)\,dt &= \int \{\delta(\ldots) - (\ldots)[d(\Delta t)/dt]\}\,dt + \{(\ldots)\,\Delta t\}_1^2 \\
&= \int [\delta(\ldots)\,dt - (\ldots)\,d(\Delta t)] + \{(\ldots)\,\Delta t\}_1^2;
\end{aligned}$$

$$\begin{aligned}
\Rightarrow \Delta \int (\ldots)\,dt - \int \Delta(\ldots)\,dt &= \int (\ldots)\,d(\Delta t) \\
&= \int \{(\ldots)[d(\Delta t)/dt]\}\,dt;
\end{aligned}$$

$$\begin{aligned}
\Delta \int (\ldots)\,dt = \cdots &= -\int \sum E_k(\ldots)\,\Delta q_k\,dt \\
&\quad + \int [dh(\ldots)/dt + \partial(\ldots)/\partial t]\,\Delta t\,dt \\
&\quad + \Big\{\sum (\partial\ldots/\partial\dot{q}_k)\,\Delta q_k - h(\ldots)\,\Delta t\Big\}_1^2 \\
&= -\int \sum E_k(\ldots)\,\delta q_k\,dt + \Big\{\sum (\partial\ldots/\partial\dot{q}_k)\,\Delta q_k - h(\ldots)\,\Delta t\Big\}_1^2 \\
&= -\int \sum E_k(\ldots)\,\delta q_k\,dt + \Big\{\sum (\partial\ldots/\partial\dot{q}_k)\,\delta q_k + (\ldots)\,\Delta t\Big\}_1^2;
\end{aligned}$$

where

$$h(\ldots) \equiv \sum [\partial(\ldots)/\partial\dot{q}_k]\dot{q}_k - (\ldots)\text{: generalized energy operator.}$$

With

$$h \equiv h(L) \equiv \sum p_k\dot{q}_k - L = h(t, q, \dot{q})\text{: generalized energy,}$$

$$A_H \equiv \int (T - V)\,dt \equiv \int L\,dt\text{: Hamiltonian action (functional),}$$

$$A_L \equiv \int 2T\,dt\text{: Lagrangean action (functional),}$$

$$E \equiv T + V\text{: total energy of the system;}$$

we have the following mechanical integral theorems:

$$\Delta \int T\,dt + \int \delta' W\,dt = \Big\{\sum p_k\,\Delta q_k + \Big(T - \sum p_k\dot{q}_k\Big)\,\Delta t\Big\}_1^2,$$

$$
\begin{aligned}
\Delta A_H + \int \delta' W_{np}\, dt &= \Big\{ \sum p_k\, \Delta q_k - h\, \Delta t \Big\}_1^2 \\
&= \Big\{ \sum p_k\, \delta q_k + L\, \Delta t \Big\}_1^2, \\
\Delta A_L - \int (\delta E - \delta' W_{np})\, dt &= \Big\{ \sum p_k\, \Delta q_k - \Big(\sum p_k \dot{q}_k - 2T \Big)\, \Delta t \Big\}_1^2 \\
&= \Big\{ \sum p_k\, \delta q_k + 2T\, \Delta t \Big\}_1^2, \\
\Delta \int E\, dt &= \int \delta E\, dt + \{ E\, \Delta t \}_1^2, \\
\Delta \int 2T\, dt &= \int (\delta E - \delta' W_{np})\, dt \\
&\quad + \Big\{ \sum p_k\, \Delta q_k + \Big(2T - \sum p_k \dot{q}_k \Big)\, \Delta t \Big\}_1^2, \\
\Delta \int 2V\, dt &= \int (\delta E + \delta' W_{np})\, dt \\
&\quad + \Big\{ -\sum p_k\, \Delta q_k + \Big(2V + \sum p_k \dot{q}_k \Big)\, \Delta t \Big\}_1^2, \\
\int [\Delta T + 2T (\Delta t)^{\cdot} + \dot{T}\, \Delta t]\, dt + \int \delta' W\, dt & \\
&= \int [\Delta T\, dt + 2T\, d(\Delta t) + dT\, \Delta t + \delta' W\, dt] \\
&= \Big\{ \sum p_k\, \delta q_k + (2T)\, \Delta t \Big\}_1^2 \\
&= \Big\{ \sum p_k\, \Delta q_k - \Big(\sum p_k \dot{q}_k - 2T \Big)\, \Delta t \Big\}_1^2
\end{aligned}
$$

SECOND (VIRTUAL) VARIATION OF A_H

Total (virtual) variation:

$$\delta^T A_H \equiv A_H(q + \delta q) - A_H(q) = \delta A_H + (1/2)\, \delta^2 A_H + \cdots$$

First (virtual) variation:

$$\delta A_H = \int \delta L\, dt = \cdots = -\int E(q)\, \delta q\, dt + \{ p\, \delta q \}_1^2$$

Second (virtual) variation (*one* Lagrangean coordinate):

$$
\begin{aligned}
\delta^2 A_H \equiv \delta(\delta A_H) &= \int \delta^2 L\, dt \\
&= \cdots = -\int J(\delta q)\, \delta q\, dt + \{ \delta p\, \delta q \}_1^2,
\end{aligned}
$$

where

$$\delta^2 L \equiv \delta(\delta L) = [(\partial/\partial q)\,\delta q + (\partial/\partial \dot{q})\,\delta(\dot{q})]^2 L$$
$$= \cdots = (\partial^2 L/\partial \dot{q}^2)(\delta\dot{q})^2 + 2(\partial^2 L/\partial q\,\partial\dot{q})\,\delta q\,\delta\dot{q} + (\partial^2 L/\partial q^2)(\delta q)^2$$

Jacobi's variational equation:

$$J(\delta q) = \{d/dt[\partial/\partial(\delta\dot{q})] - [\partial/\partial(\delta q)]\}(1/2)\,\delta^2 L$$
$$= (\partial^2 L/\partial\dot{q}^2)\,\delta\ddot{q} + (\partial^2 L/\partial\dot{q}^2)^{\cdot}\,\delta\dot{q} + [(\partial^2 L/\partial q\,\partial\dot{q})^{\cdot} - (\partial^2 L/\partial q^2)]\,\delta q$$
$$= d/dt[(\partial^2 L/\partial\dot{q}^2)\,\delta\dot{q}] - \left[\partial^2 L/\partial q^2 - d/dt(\partial^2 L/\partial q\,\partial\dot{q})\right]\delta q = 0$$

Equivalently:

$$E[L(t, q + \delta q, \dot{q} + \delta\dot{q})] - E[L(t, q, \dot{q})] \approx \delta E(q, \delta q) \qquad \text{(to first-order)}$$
$$= J(\delta q; q) \equiv J(\delta q)$$

Chapter 8: Hamiltonian/Canonical Methods

CONJUGATE (HAMILTONIAN) KINETIC ENERGY

$$T' \equiv \left(\sum p_k \dot{q}_k - T\right)\Big|_{\dot{q}=\dot{q}(t,q,p)} = \sum p_k \dot{q}_k(t,q,p) - T_{(qp)} \equiv T'(t,q,p)$$
$$\Big[= \sum (\partial T/\partial \dot{q}_k)\dot{q}_k - T = (2T_2 + T_1) - (T_2 + T_1 + T_0) = T_2 - T_0;$$
$$\text{i.e., if } T = T_2 \text{ (e.g., stationary constraints), then } T' = T\Big]$$

CANONICAL, OR HAMILTONIAN, CENTRAL EQUATION

$$\sum (dp_k/dt + \partial T'/\partial q_k - Q_k)\,\delta q_k + \sum (dq_k/dt - \partial T'/\partial p_k)\,\delta p_k = 0$$

CANONICAL, OR HAMILTONIAN, EQUATIONS OF MOTION

(for unconstrained variations)

$$dp_k/dt = -(\partial T'/\partial q_k) + Q_k \qquad (= \partial T/\partial q_k + Q_k \Rightarrow \partial T/\partial q_k = -\partial T'/\partial q_k),$$
$$dq_k/dt = \partial T'/\partial p_k$$

If $Q_k = -\partial V(t,q)/\partial q_k$, the above assume the *antisymmetrical* form:

$$dp_k/dt = -\partial H/\partial q_k, \qquad dq_k/dt = \partial H/\partial p_k,$$

where

$$H \equiv T' + V = \left(\sum p_k \dot{q}_k - T + V\right)\Big|_{\dot{q}=\dot{q}(t,q,p)} \equiv \sum p_k \dot{q}_k(t,q,p) - (T_{(qp)} - V)$$
$$= \left(\sum p_k \dot{q}_k - L\right)\Big|_{\dot{q}=\dot{q}(t,q,p)} \equiv \sum p_k \dot{q}_k(t,q,p) - L_{(qp)}$$
$$\equiv H(t,q,p)\text{: } \textit{Hamiltonian} \text{ of system (function of } 2n+1 \text{ arguments).}$$

If both potential *and* nonpotential forces (Q_k) are present, the above are replaced by

$$dp_k/dt = -\partial H/\partial q_k + Q_k, \qquad dq_k/dt = \partial H/\partial p_k;$$

also,

$$\partial H/\partial q_k = -\partial L/\partial q_k \qquad \text{and} \qquad \partial L/\partial t = -\partial H/\partial t.$$

For *stationary* (holonomic) constraints,

$$H = T(t,q,p) + V_0(t,q) \equiv E(t,q,p) = \textit{total energy}, \text{ in Hamiltonian variables.}$$

In all cases, the following kinematico-inertial identities hold:

$$\partial T'/\partial t = -\partial T/\partial t, \qquad \partial T'/\partial q_k = -\partial T/\partial q_k, \qquad \partial T'/\partial p_k = dq_k/dt;$$
$$\partial H/\partial t = -\partial L/\partial t, \qquad \partial H/\partial q_k = -\partial L/\partial q_k, \qquad \partial H/\partial p_k = dq_k/dt.$$

LEGENDRE TRANSFORMATION (LT)

An LT transforms a function $Y(\ldots, y, \ldots)$ into its *conjugate* function $Z(\ldots, z, \ldots)$, where $z = \partial Y/\partial y$, so that $\partial Z/\partial z = y$. Here in dynamics we have the following identifications:

$$Y(\ldots) \to L, \qquad \ldots \to q, t, \qquad y \to \dot{q}, \qquad z = \partial Y/\partial y \to p = \partial L/\partial \dot{q},$$
$$Z(\ldots) \to H, \qquad \partial Z/\partial z = y \to \partial H/\partial p = \dot{q}.$$

POWER THEOREM

$$dH/dt = \partial H/\partial t + \sum Q_k \dot{q}_k$$

If $\partial H/\partial t = 0$ (e.g., stationary constraints) and $Q_k = 0$ (e.g., potential forces), then the Hamiltonian energy of the system is conserved:

$$H = H(q,p) = \textit{constant}.$$

CANONICAL ROUTH–VOSS EQUATIONS

Under the m Pfaffian constraints

$$\sum a_{Dk}\,\delta q_k = 0,$$

the canonical equations are

$$dp_k/dt = -\partial T'/\partial q_k + Q_k + \sum \lambda_D a_{Dk} = -\partial H/\partial q_k \; + Q_{k,\text{nonpotential}} + \sum \lambda_D a_{Dk},$$
$$dq_k/dt = \partial T'/\partial p_k \; (= \partial H/\partial p_k).$$

ROUTH'S EQUATIONS

Ignorable (or cyclic) coordinates and momenta

$$(q_1, \ldots, q_M) \equiv (\psi_1, \ldots, \psi_M) \equiv (\psi_i) \equiv \psi, \quad (p_1, \ldots, p_M) \equiv (\Psi_1, \ldots, \Psi_M) \equiv (\Psi_i) \equiv \Psi$$

Positional (or palpable) coordinates and velocities

$$(q_{M+1}, \ldots, q_n) \equiv (q_p) \equiv q \qquad (\dot{q}_{M+1}, \ldots, \dot{q}_n) \equiv (\dot{q}_p) \equiv \dot{q}$$

Kinetic energy

$$\begin{aligned} T &\equiv T(t; \psi_1, \ldots, \psi_M; q_{M+1}, \ldots, q_n; \dot{\psi}_1, \ldots, \dot{\psi}_M; \dot{q}_{M+1}, \ldots, \dot{q}_n) \\ &\equiv T(t, \psi, q; \dot{\psi}, \dot{q}) = T[t, \psi, q; \dot{\psi}(t, \psi, q; \Psi, \dot{q}), \dot{q}] \\ &= T(t, \psi, q; \Psi, \dot{q}) \equiv T_{\psi\Psi} \end{aligned}$$

Modified (Routhian) kinetic energy

$$T'' \equiv \left(T - \sum \Psi_i \dot{\psi}_i\right)\Big|_{\dot{\psi}=\dot{\psi}(t;\psi,q;\Psi,\dot{q})} = T''(t, \psi, q; \Psi, \dot{q})$$

Routhian central equation

$$\sum (dp_k/dt - \partial T''/\partial q_k - Q_k)\, \delta q_k + \sum (p_p - \partial T''/\partial \dot{q}_p)\, \delta \dot{q}_p$$
$$- \sum (d\psi_i/dt + \partial T''/\partial \Psi_i)\, \delta \Psi_i = 0$$

Routh's equations (for unconstrained variations)

$$\begin{aligned} &dp_k/dt = \partial T''/\partial q_k + Q_k: \quad && d\Psi_i/dt = \partial T''/\partial \psi_i + Q_i \quad && (i = 1, \ldots, M), \\ & && dp_p/dt = \partial T''/\partial q_p + Q_p \quad && (p = M+1, \ldots, n); \\ &d\psi_i/dt = -\partial T''/\partial \Psi_i && && (i = 1, \ldots, M), \\ &p_p = \partial T''/\partial \dot{q}_p && && (p = M+1, \ldots, n) \end{aligned}$$

Hamilton-like Routh's equations

$$d\Psi_i/dt = -\partial(-T'')/\partial \psi_i + Q_i, \qquad d\psi_i/dt = \partial(-T'')/\partial \Psi_i$$

Lagrange-like Routh's equations

$$dp_p/dt = \partial T''/\partial q_p + Q_p, \qquad p_p = \partial T''/\partial \dot{q}_p \qquad (= \partial T/\partial \dot{q}_p)$$
$$\Rightarrow \; (\partial T''/\partial \dot{q}_p)^{\cdot} - \partial T''/\partial q_p = Q_p$$

Additional Routhian kinematico-inertial identities

$$\partial T/\partial q_k = \partial T''/\partial q_k: \qquad \partial T/\partial \psi_i = \partial T''/\partial \psi_i \qquad (i = 1, \ldots, M),$$
$$\partial T/\partial q_p = \partial T''/\partial q_p \qquad (p = M+1, \ldots, n)$$

In sum, we have the following *two groups* of such kinematico-inertial identities:

$$\partial T''/\partial \psi_i = \partial T/\partial \psi_i \quad \text{and} \quad \partial T''/\partial \Psi_i = -d\psi_i/dt;$$
$$\partial T''/\partial q_p = \partial T/\partial q_p \quad \text{and} \quad \partial T''/\partial \dot{q}_p = \partial T/\partial \dot{q}_p \qquad (= p_p).$$

If $p_k \equiv \partial L/\partial \dot{q}_k$, the above are replaced by the following:

Hamilton-like Routh's equations

$$d\Psi_i/dt = \partial R/\partial \psi_i + Q_i, \qquad d\psi_i/dt = -\partial R/\partial \Psi_i$$

and Lagrange-like Routh's equations

$$dp_p/dt = \partial R/\partial q_p + Q_p, \qquad p_p = \partial R/\partial \dot{q}_p \qquad (= \partial L/\partial \dot{q}_p)$$
$$\Rightarrow \; E_p(R) \equiv (\partial R/\partial \dot{q}_p)^{\cdot} - \partial R/\partial q_p = Q_p;$$

where

$$R \equiv \left(L - \sum \Psi_i \dot{\psi}_i\right)\Big|_{\dot{\psi}=\dot{\psi}(t;\psi,q;\Psi,\dot{q})} = R(t; \psi, q; \Psi, \dot{q})$$
$$= \textit{Routhian function}, \text{ or } \textit{modified Lagrangean},$$
$$L = L(t; \psi, q; \Psi, \dot{q}) \equiv T_{\psi\Psi} - V \equiv L_{\psi\Psi}$$
$$= \text{Lagrangean expressed in Routhian variables;}$$

that is, the Routhian is a Hamiltonian [times (-1)] for the ψ_i, and a Lagrangean for the q_p.

Relation between Routhian and Hamiltonian

$$H \equiv \sum p_k \dot{q}_k - L, \qquad R = \sum p_p \dot{q}_p - H = L - \sum \Psi_i \dot{\psi}_i$$

STRUCTURE OF THE ROUTHIAN

Decomposition of T (scleronomic system):

$$T = T_{\dot{q}\dot{q}} + T_{\dot{q}\dot{\psi}} + T_{\dot{\psi}\dot{\psi}} = T(\psi, q; \dot{\psi}, \dot{q}),$$

where

$$2T_{\dot{q}\dot{q}} \equiv \sum\sum a_{pq} \dot{q}_p \dot{q}_q = \textit{homogeneous quadratic} \text{ in the } \dot{q}\text{'s}$$
$$(a_{pq} = a_{qp}\text{: positive definite}),$$
$$T_{\dot{q}\dot{\psi}} \equiv \sum\sum b_{pi} \dot{q}_p \dot{\psi}_i = \textit{homogeneous bilinear} \text{ in the } \dot{q}\text{'s and } \dot{\psi}\text{'s}$$
$$(\text{in general: } b_{pi} \neq b_{ip}; \text{ sign indefinite}),$$

$$2T_{\dot{\psi}\dot{\psi}} \equiv \sum\sum c_{ij}\dot{\psi}_i\dot{\psi}_j = \textit{homogeneous quadratic} \text{ in the } \dot{\psi}\text{'s}$$
$$(c_{ij} = c_{ji}\text{: positive definite})$$

[$i, j = 1, \ldots, M$; $p, q = M + 1, \ldots, n$; and the coefficients are functions of all n q_k's].

Next,

$$\Psi_i \equiv \partial T/\partial\dot{\psi}_i = \sum c_{ji}\dot{\psi}_j + \sum b_{pi}\dot{q}_p \Rightarrow \sum c_{ji}\dot{\psi}_j = \Psi_i - \sum b_{pi}\dot{q}_p,$$
$$d\psi_j/dt = \sum C_{ji}\Big(\Psi_i - \sum b_{pi}\dot{q}_p\Big)$$

(since $T_{\dot{\psi}\dot{\psi}}$ is positive definite $\Rightarrow c_{ij}$ is nonsingular), where

$$C_{ji} = [\text{cofactor of element } c_{ji} \textit{ in } \mathrm{Det}(c_{ji})]/\mathrm{Det}(c_{ji}) = C_{ij}$$
$$(= \text{known function of the } q\text{'s and } \psi\text{'s}).$$

Then

$$T = T_{2,0} + T_{0,2} = T(\psi, q; \Psi, \dot{q}),$$

where

$$2T_{2,0} \equiv \sum\sum\Big(a_{pq} - \sum\sum C_{ji}b_{pj}b_{qi}\Big)\dot{q}_p\dot{q}_q, \qquad 2T_{0,2} \equiv \sum\sum\sum C_{ji}\Psi_j\Psi_i;$$

that is, $T = T(\psi, q; \Psi, \dot{q})$ does *not* contain any bilinear terms in the $\dot{q}$'s and Ψ's; and so

$$\begin{aligned} T'' &\equiv T - \sum \Psi_i\dot{\psi}_i = T - \sum \Psi_i\Big(\sum C_{ij}\Big(\Psi_j - \sum b_{pj}\,\dot{q}_p\Big)\Big) \\ &= T_{2,0} + T''_{1,1} - T_{0,2} \equiv T''_{2,0} + T''_{1,1} + T''_{0,2} \\ &= T''(\psi, q; \Psi, \dot{q}), \end{aligned}$$

where

$$\begin{aligned} 2T''_{2,0} &\equiv \sum\sum\Big(a_{pq} - \sum\sum C_{ji}b_{pj}\,b_{qi}\Big)\dot{q}_p\dot{q}_q \equiv \sum\sum r_{pq}(q)\dot{q}_p\dot{q}_q \\ &= 2T_{2,0}\ (= \text{positive definite in the } \dot{q}\text{'s}), \\ T''_{1,1} &\equiv \sum\sum\Big(\sum C_{ji}b_{pi}\Big)\Psi_j\dot{q}_p \equiv \sum r_p(q, \Psi)\dot{q}_p \\ &\qquad [\text{No counterpart in } T = T(\psi, q; \Psi, \dot{q}), \text{i.e., } T_{1,1} = 0;\ \text{sign indefinite}], \\ 2T''_{0,2} &\equiv -\sum\sum C_{ji}\Psi_j\Psi_i = 2T''_{0,2}(q, \Psi) \\ &= -2T_{0,2}\ (= \text{negative definite in the } \Psi\text{'s}). \end{aligned}$$

Conversely,

$$\begin{aligned}T &\equiv T'' + \sum \Psi_i \dot{\psi}_i = T'' - \sum \Psi_i (\partial T''/\partial \Psi_i)\\ &= (T''_{2,0} + T''_{1,1} + T''_{0,2}) - (T''_{1,1} + 2T''_{0,2})\\ &= T''_{2,0} - T''_{0,2} = T(\psi, q; \Psi, \dot{q}).\end{aligned}$$

Hence,

$$\begin{aligned}L &= T - V = (T_{2,0} + T_{0,2}) - V = T_{2,0} - (V - T_{0,2})\\ &= (T''_{2,0} - T''_{0,2}) - V = T''_{2,0} - (V + T''_{0,2}) = L(\psi, q; \Psi, \dot{q})\\ \Rightarrow R &= L - \sum \Psi_i \dot{\psi}_i = L + \sum (\partial T''/\partial \Psi_i) \Psi_i\\ &\qquad = (T''_{2,0} - T''_{0,2} - V) + (2T''_{0,2} + T''_{1,1})\\ &\qquad \equiv R_2 + R_1 + R_0 = R(\psi, q; \Psi, \dot{q}),\end{aligned}$$

where

$$R_2 \equiv T''_{2,0} = T_{2,0}, \qquad R_1 \equiv T''_{1,1}, \qquad R_0 \equiv T''_{0,2} - V = -T_{0,2} - V.$$

Additional results

(i) With

$$\begin{aligned}&T = T_{\dot{q}\dot{q}} + T_{\dot{q}\dot{\psi}} + T_{\dot{\psi}\dot{\psi}} = T(\psi, q; \dot{\psi}, \dot{q})\\ &\quad \Rightarrow T'' = T - \sum \Psi_i \dot{\psi}_i = T - \sum (\partial T/\partial \dot{\psi}_i) \dot{\psi}_i = T_{\dot{q}\dot{q}} - T_{\dot{\psi}\dot{\psi}} = T''(t, \psi, q; \dot{\psi}, \dot{q});\end{aligned}$$

(ii) $$d\psi_i/dt = -\partial T''/\partial \Psi_i = \cdots = \partial T_{0,2}/\partial \Psi_i - \partial K_{2,2}/\partial \pi_i,$$

where

$$2T_{0,2} = -2T''_{0,2} \equiv \sum \sum C_{ji} \Psi_j \Psi_i,$$

and

$$2K_{2,2} \equiv \sum \sum C_{ji} \Big(\sum b_{pj}\, \dot{q}_p \Big) \Big(\sum b_{qi} \dot{q}_q \Big) \equiv \sum \sum C_{ji} \pi_j \pi_i.$$

Matrix form of these results:

$$\dot{\mathbf{q}}^{\mathrm{T}} = (\dot{q}_{M+1}, \ldots, \dot{q}_n), \qquad \dot{\boldsymbol{\psi}}^{\mathrm{T}} = (\dot{\psi}_1, \ldots, \dot{\psi}_M), \qquad \boldsymbol{\Psi}^{\mathrm{T}} = (\Psi_1, \ldots, \Psi_M),$$

$$\mathbf{a} = (a_{pq}) = (a_{qp}) = \mathbf{a}^{\mathrm{T}}, \qquad \mathbf{b} = (b_{ip}) \neq (b_{pi}) = \mathbf{b}^{\mathrm{T}}, \qquad \mathbf{c} = (c_{ij}) = (c_{ji}) = \mathbf{c}^{\mathrm{T}},$$

$$2T = \dot{\mathbf{q}}^{\mathrm{T}} \mathbf{a} \dot{\mathbf{q}} + 2\dot{\boldsymbol{\psi}}^{\mathrm{T}} \mathbf{b}^{\mathrm{T}} \dot{\mathbf{q}} + \dot{\boldsymbol{\psi}}^{\mathrm{T}} \mathbf{c}\, \dot{\boldsymbol{\psi}},$$

$$\begin{aligned}&\partial T/\partial \dot{\boldsymbol{\psi}} = \mathbf{b}^{\mathrm{T}} \dot{\mathbf{q}} + \mathbf{c} \dot{\boldsymbol{\psi}} = \boldsymbol{\Psi}\\ &\qquad \Rightarrow \dot{\boldsymbol{\psi}} = \mathbf{c}^{-1} (\boldsymbol{\Psi} - \mathbf{b}^{\mathrm{T}} \dot{\mathbf{q}}) \equiv \mathbf{C} (\boldsymbol{\Psi} - \mathbf{b}^{\mathrm{T}} \dot{\mathbf{q}}) \Rightarrow \dot{\boldsymbol{\psi}}^{\mathrm{T}} = (\boldsymbol{\Psi}^{\mathrm{T}} - \dot{\mathbf{q}}^{\mathrm{T}} \mathbf{b}) \mathbf{C}\end{aligned}$$

[since $\mathbf{c}$ is symmetric, so is its inverse $\mathbf{C} \equiv (C_{ji})$: $\mathbf{C} \equiv \mathbf{c}^{-1} = (\mathbf{c}^{-1})^{\mathrm{T}} \equiv \mathbf{C}^{\mathrm{T}}$],

$$T = \cdots = (1/2)\dot{\mathbf{q}}^{\mathrm{T}}(\mathbf{a} - \mathbf{b}\,\mathbf{C}\,\mathbf{b}^{\mathrm{T}})\dot{\mathbf{q}} + (1/2)\boldsymbol{\Psi}^{\mathrm{T}}\,\mathbf{C}\,\boldsymbol{\Psi} \equiv T_{2,0} + T_{0,2} = T''_{2,0} - T''_{0,2},$$
$$[\text{since } \boldsymbol{\Psi}^{\mathrm{T}}\,\mathbf{C}\,\mathbf{b}^{\mathrm{T}}\,\dot{\mathbf{q}} = \dot{\mathbf{q}}^{\mathrm{T}}\,\mathbf{b}\,\mathbf{C}\boldsymbol{\Psi}]$$
$$\boldsymbol{\Psi}^{\mathrm{T}}\dot{\boldsymbol{\psi}} = \cdots = \boldsymbol{\Psi}^{\mathrm{T}}\,\mathbf{C}\,\boldsymbol{\Psi} - \boldsymbol{\Psi}^{\mathrm{T}}\,\mathbf{C}\,\mathbf{b}^{\mathrm{T}}\dot{\mathbf{q}} = -2T''_{0,2} - \boldsymbol{\Psi}^{\mathrm{T}}\,\mathbf{C}\,\mathbf{b}^{\mathrm{T}}\dot{\mathbf{q}},$$
$$R = (T - V) - \boldsymbol{\Psi}^{\mathrm{T}}\dot{\boldsymbol{\psi}} = \cdots = R_2 + R_1 + R_0$$
$$R_2 \equiv T''_{2,0} = T_{2,0} = (1/2)\,\dot{\mathbf{q}}^{\mathrm{T}}\,(\mathbf{a} - \mathbf{b}\,\mathbf{C}\,\mathbf{b}^{\mathrm{T}})\dot{\mathbf{q}},$$
$$R_1 \equiv T''_{1,1} = \boldsymbol{\Psi}^{\mathrm{T}}\,\mathbf{C}\,\mathbf{b}^{\mathrm{T}}\,\dot{\mathbf{q}},$$
$$R_0 \equiv T''_{0,2} - V = -(V + T_{0,2}) = -(1/2)\boldsymbol{\Psi}^{\mathrm{T}}\,\mathbf{C}\,\boldsymbol{\Psi} - V.$$

If $\mathbf{b} = 0$ (i.e., $\dot{q}$'s and $\dot{\psi}$'s *uncoupled* in the original T), R reduces to

$$R = (1/2)\dot{\mathbf{q}}^{\mathrm{T}}\,\mathbf{a}\,\dot{\mathbf{q}} - (1/2)\boldsymbol{\Psi}^{\mathrm{T}}\,\mathbf{C}\,\boldsymbol{\Psi} - V.$$

CYCLIC (OR GYROSTATIC) SYSTEMS

(i) $$(q_1, \ldots, q_M) \equiv (\psi_1, \ldots, \psi_M) \equiv (\psi_i) \equiv \psi$$

do *not* appear explicitly, neither in its kinetic energy nor in its nonvanishing impressed forces; only the corresponding Lagrangean velocities

$$(\dot{q}_1, \ldots, \dot{q}_M) \equiv (\dot{\psi}_1, \ldots, \dot{\psi}_M) \equiv (\dot{\psi}_i) \equiv \dot{\psi}$$

appear there, and, of course, time t and the remaining coordinates and/or velocities

$$(q_{M+1}, \ldots, q_n) \equiv (q_p) \equiv q \qquad \text{and} \qquad (\dot{q}_{M+1}, \ldots, \dot{q}_n) \equiv (\dot{q}_p) \equiv \dot{q};$$

respectively; that is,

$$\partial T/\partial \psi_i = 0$$

but, in general,

$$\partial T/\partial \dot{\psi}_i \neq 0 \Rightarrow T = T(t; q, \dot{\psi}, \dot{q}).$$

(ii) The corresponding impressed forces vanish; that is,

$$Q_i = 0, \qquad \text{but} \qquad Q_p = Q_p(q) \neq 0.$$

If all impressed forces are wholly *potential*, the above requirements are replaced, respectively, by

$$\partial L/\partial \psi_i = 0 \qquad \text{and} \qquad \partial L/\partial \dot{\psi}_i \neq 0 \Rightarrow L = L(t; q, \dot{\psi}, \dot{q}).$$

The coordinates ψ, and corresponding velocities $\dot{\psi}$, are called *cyclic* (Helmholtz), or *absent* (Routh), or *kinosthenic*, or *speed* (J. J. Thomson), or *ignorable* (Whittaker). The remaining coordinates q, and corresponding velocities $\dot{q}$, are called *palpable*, or *positional*. Then the Lagrangean equations corresponding to the cyclic coordinates/variables, become

$$(\partial T/\partial\dot{\psi}_i)^{\cdot} - \partial T/\partial\psi_i = Q_i: \qquad (\partial T/\partial\dot{\psi}_i)^{\cdot} = 0 \Rightarrow \partial T/\partial\dot{\psi}_i \equiv \Psi_i = \text{constant} \equiv C_i;$$

that is, the momenta Ψ_i corresponding to the cylic coordinates ψ_i are *constants of the motion*. [Conversely, however, if $\partial T/\partial\dot{\psi}_i = 0$, then $\partial T/\partial\psi_i = 0$, and, as a result, $T = T(t; q, \dot{q})$; that is, the evolution of the ψ's does not affect that of the q's.] Hence, the Routhian of a cyclic system is a function of t, q, $\dot{q}$ and $\Psi \equiv (\Psi_i)$; that is, with $C \equiv (C_i)$,

$$\begin{aligned}
R &\equiv \Big(L - \sum \Psi_i\dot{\psi}_i\Big)\Big|_{\dot{\psi}=\dot{\psi}(t;q;\dot{q},C)} \\
&\qquad \text{[after solving } \partial T/\partial\dot{\psi}_i \equiv \Psi_i = C_i \text{ for the } \dot{\psi} \text{ in terms of } t, q, \dot{q}, C] \\
&= L[t, q, \dot{q}, \dot{\psi}(t; q; C, \dot{q}); C] - \sum \Psi_i\dot{\psi}_i(t; q, \dot{q}; C) \\
&= R(t; q, \dot{q}; C) \\
&\Big[\Rightarrow L = \sum C_i\dot{\psi}_i(t; q, \dot{q}; C) + R(t; q, \dot{q}; C)\Big];
\end{aligned}$$

that is, the system has been reduced to one with only $n - M$ Lagrangean coordinates, new "reduced Lagrangean" R, and, therefore, Lagrange-type Routhian equations for the positional coordinates and the "palpable motion" $q_p(t)$:

$$(\partial R/\partial\dot{q}_p)^{\cdot} - \partial R/\partial q_p = Q_{p,\text{nonpotential impressed positional forces}}.$$

Then,

$$\begin{aligned}
R &= \text{known function of time} \\
&\Rightarrow \partial R/\partial C_i = \text{known function of time} \equiv -f_i(t; C), \\
&\Rightarrow \psi_i = -\int (\partial R/\partial\Psi_i)\, dt + \text{constant} = \int f_i(t; C)\, dt + \text{constant} \\
&\qquad = \psi_i(t, C) + \text{constant}.
\end{aligned}$$

EQUATIONS OF KELVIN–TAIT

Let

$$\begin{aligned}
T &= T(q, \dot{q}, \dot{\psi}) = \text{homogeneous quadratic in the } \dot{\psi} \text{ and } \dot{q}, \\
&\Rightarrow R = R_2 + R_1 + R_0,
\end{aligned}$$

where

$$\begin{aligned}
R_2 &\equiv T''_{2,0} = (1/2)\sum\sum r_{pq}(q)\dot{q}_p\dot{q}_q (= T_{2,0}) \\
&= R_2(q, \dot{q}) = \text{homogeneous } \textit{quadratic} \text{ in the nonignorable velocities } \dot{q}, \\
R_1 &\equiv T''_{1,1} = \sum r_p(q, C)\dot{q}_p \\
&= R_1(q, \dot{q}, C) = \text{homogeneous } \textit{linear} \text{ in the nonignorable velocities } \dot{q}, \\
&\qquad [\textit{apparent kinetic} \text{ energy } T''_{1,1}];
\end{aligned}$$

and

$$r_p = \sum \rho_{pi} C_i \qquad \left[\rho_{pi} \equiv \sum C_{ij} b_{pj} = \rho_{pi}(q)\right],$$

$$R_0 \equiv T''_{0,2} - V = -(V - T''_{0,2}) \equiv -(1/2) \sum\sum C_{ji} C_j C_i - V \qquad [= -(V + T_{0,2})]$$

$$= R_0(q; C) = \text{homogeneous } \textit{quadratic} \text{ in the constant ignorable momenta } \Psi = C$$
$$[\textit{apparent potential} \text{ energy } T''_{0,2} = -T_{0,2}(< 0)].$$

Hence, the situation is *mathematically identical* to that of *relative motion* (§3.16) Lagrangean equations of palpable motion:

$$(\partial R/\partial \dot{q}_p)^{\cdot} - \partial R/\partial q_p = Q_{p,\text{nonpotential impressed positional forces}}.$$

From the above we obtain the following.

Kelvin–Tait equations (with $p, p' = M+1, \ldots, n$)

$$E_p(R) \equiv E_p(R_2 + R_1 + R_0) = E_p(R_2) + E_p(R_1) + E_p(R_0) = Q_p,$$

or

$$E_p(R_2) = Q_p - E_p(R_1) - E_p(R_0),$$

or, explicitly,

$$\begin{aligned}(\partial R_2/\partial \dot{q}_p)^{\cdot} - \partial R_2/\partial q_p &= Q_p + \partial R_0/\partial q_p - [(\partial R_1/\partial \dot{q}_p)^{\cdot} - \partial R_1/\partial q_p] \\ &= Q_p - \partial(V - T''_{0,2})/\partial q_p + \sum (\partial r_{p'}/\partial q_p - \partial r_p/\partial q_{p'})\dot{q}_{p'} \\ &= Q_p - \partial(V - T''_{0,2})/\partial q_p + G_p,\end{aligned}$$

where

$$\begin{aligned}G_p &\equiv -[(\partial R_1/\partial \dot{q}_p)^{\cdot} - \partial R_1/\partial q_p] \\ &= \sum (\partial r_{p'}/\partial q_p - \partial r_p/\partial q_{p'})\dot{q}_{p'} \equiv \sum G_{pp'} \dot{q}_{p'}\end{aligned}$$

[*Gyroscopic Routhian "force,"* since $G_{pp'} = -G_{p'p} = G_{pp'}(q; C)$].

These are the equations of motion of a *fictitious* scleronomic system (sometimes referred to as "conjugate" to the original, or reduced, system) with $n - M$ positional coordinates q, and subject, in addition to the impressed forces Q_p (nonpotential) and $-\partial V/\partial q_p$ (potential), to two special constraint forces: a centrifugal-like $\partial T''_{0,2}/\partial q_p$, and a gyroscopic one G_p.

Ignorable motion, once the palpable motion has been determined:

$$q_p(t) \Rightarrow d\psi_i/dt = -\partial R/\partial C_i = -\partial R_1/\partial C_i - \partial R_0/\partial C_i = -\partial T''_{0,2}/\partial C_i - \sum \rho_{pi} \dot{q}_p$$

Gyroscopic uncoupling $G_{pp'} = 0$

$$\Rightarrow \; E_p(R_2) \equiv (\partial R_2/\partial \dot{q}_p)^{\cdot} - \partial R_2/\partial q_p = Q_p + \partial R_0/\partial q_p$$

A system is gyroscopically uncoupled if, and only if, $R_1\,dt \equiv \sum r_p(q;C)\,dq_p$ is an *exact differential*. [A similar uncoupling occurs if all the C_i vanish: $r_p = 0 \Rightarrow R_1 = 0$; *and* $R_0 = -V(q)$.]

A cyclic power theorem

$$dh_R/dt = \sum Q_p\ \dot{q}_p,$$

where

$$\begin{aligned} h_R &\equiv R_2 - R_0 = T''_{2,0} + (V - T''_{0,2}) \\ &= T_{2,0} + (V + T_{0,2}) = T(q,\dot{q},C) + V(q) \equiv E(q,\dot{q},C) \\ &= \text{Modified (or cyclic) generalized energy;} \end{aligned}$$

if $\sum Q_p\ \dot{q}_p = 0$:

$$h_R \equiv T''_{2,0} + (V - T''_{0,2}) \equiv T(q,\dot{q},C) + V(q) = \text{constant.}$$

Alternatively,

$$\begin{aligned} H &\equiv \sum (\partial L/\partial \dot{q}_k)\dot{q}_k - L \qquad (= \text{constant, if } Q_p = 0 \quad \text{and} \quad \partial L/\partial t = \partial R/\partial t = 0) \\ &= -R + \sum (\partial R/\partial \dot{q}_p)\dot{q}_p \\ &= -(R_2 + R_1 + R_0) + (2R_2 + R_1) \\ &= R_2 - R_0 = H(q,\dot{q},C) \qquad (= h_R). \end{aligned}$$

For *rheonomic* cyclic systems; that is, $L = L(t,q,\dot{q},C)$

$$\Rightarrow R = L(t,q,\dot{q},C) - \sum C_i\dot{\psi}_i(t,q,\dot{q},C) = R(t,q,\dot{q},C).$$

STEADY MOTION (OR CYCLIC SYSTEMS)

$$\dot{\psi}_i = \text{constant} \equiv c_i \text{ (in addition to } \Psi_i = \text{constant} \equiv C_i),$$

$$\text{and } q_p = \text{constant} \equiv s_P \ (\Rightarrow \dot{q}_p = 0)$$

$$(\text{with } i = 1,\ldots,M;\ p = M+1,\ldots,n);$$

that is, *all* velocities are *constant* (and, hence, all accelerations vanish); and, for scleronomic such systems, the Lagrangean has the form $L = L(c_i, s_p)$.

Conditions for steady motion [necessary and sufficient conditions for the steady motion of an originally (scleronomic and holonomic) system; or, equivalently, for the equilibrium of the corresponding reduced q-system]:

$$Q_p + \partial R_0/\partial q_p \equiv Q_p + (\partial T''_{0,2}/\partial q_p - \partial V/\partial q_p) = 0,$$

or, if the forces are *wholly potential*:

$$\partial R_0/\partial q_p = 0, \qquad \text{or} \qquad \partial T''_{0,2}/\partial q_p = \partial V/\partial q_p.$$

Equivalently, since

$$R = R_2(\textit{homogeneous quadratic} \text{ in the } \dot{q}\text{'s})$$
$$+ R_1 \ (\textit{homogeneous bilinear} \text{ in the } \Psi\text{'s and } \dot{q}\text{'s})$$
$$+ R_0 \ (\textit{homogeneous quadratic} \text{ in the } \Psi\text{'s})$$

and

$$\partial R/\partial q_p = \partial L/\partial q_p,$$

the above equations can be rewritten as

$$(\partial R/\partial q_p)_o = (\partial L/\partial q_p)_o = 0 \qquad [(\ldots)_o \equiv (\ldots)|_{\dot{\psi}=c,\, q=s}],$$

expressing q's $\equiv s$'s in terms of the arbitrarily chosen Ψ's $\equiv C$'s. The $\dot{\psi}$'s can then be found from the *second* (Hamiltonian) group of Routh's equations:

$$\begin{aligned}
d\psi_i/dt &= -(\partial R/\partial \Psi_i)_o = -(\partial R_o/\partial \Psi_i)_o = -(\partial T''_{0,2}/\partial \Psi_i)_o \\
&= \sum C_{ij} C_j = \text{constant} \equiv c_i \qquad [\text{with } \dot{q}_p = 0] \\
&= \text{Function of the } s\text{'s and the (arbitrarily chosen) } C\text{'s}, \\
&\Rightarrow \psi_i(t) = -c_i(t - t_{\text{initial}}) + \psi_{i,\,\text{initial}} \\
&= \text{Function of the } s\text{'s and the (now) arbitrarily chosen } c_i\text{'s and } \psi_{\text{initial}}\text{'s;}
\end{aligned}$$

i.e., *in steady motion, the cyclic coordinates vary linearly with time*.

If we initially choose arbitrarily the Ψ's, then the above equations relate them to the q's. If, on the other hand, we choose the $\dot{\psi}$'s $\equiv c$'s, then, to relate them directly to the q's: first, we take $T''_{0,2}$, and, using $\Psi_i = \sum c_{ji}\dot{\psi}_j$, change it to a *homogeneous quadratic* function in the $\dot{\psi}$'s (with i, j, j', j'': $1, \ldots, M$):

$$\begin{aligned}
2T''_{0,2} &\equiv 2T''_{\Psi\Psi} \equiv -\sum\sum C_{ji}\Psi_j\Psi_i \qquad \left[\text{recalling that } \sum C_{ji}c_{j'j} = \delta_{ij'}\right] \\
&= \cdots = -\sum\sum c_{ij}\dot{\psi}_i\dot{\psi}_j \equiv 2T''_{\dot{\psi}\dot{\psi}} = -2T_{\dot{\psi}\dot{\psi}};
\end{aligned}$$

or, since

$$\partial T''_{\Psi\Psi}/\partial q_p = -(\partial T''_{\dot{\psi}\dot{\psi}}/\partial q_p) = \partial T_{\dot{\psi}\dot{\psi}}/\partial q_p,$$

we can, finally, replace the steady motion conditions by

$$-(\partial T''_{\dot{\psi}\dot{\psi}}/\partial q_p) = \partial V/\partial q_p, \qquad \text{or} \qquad \partial T_{\dot{\psi}\dot{\psi}}/\partial q_p = \partial V/\partial q_p,$$

relating the q's to the $\dot{\psi}$'s; and, using $\Psi_i = \sum c_{ji}\dot{\psi}_j$, we can relate both to the Ψ's.

VARIATION OF CONSTANTS (OR PARAMETERS)

Theorem of Lagrange–Poisson:

Equations of motion:

$$dp_k/dt = f_k(t, q, p) \qquad \text{and} \qquad dq_k/dt = g_k(t, q, p),$$
$$[f_k = -\partial H/\partial q_k + Q_k \qquad \text{and} \qquad g_k = \partial H/\partial p_k, \text{ for a Hamiltonian system}];$$

general solutions:

$$p_k = p_k(t; c) \qquad \text{and} \qquad q_k = q_k(t; c),$$

where

$$c \equiv (c_1, \ldots, c_{2n}) \equiv (c_\nu; \nu = 1, \ldots, 2n)\text{: constants of integration.}$$

Adjacent trajectory, $II = I + \delta(I)$,

$$\delta p_k = \sum (\partial p_k/\partial c_\nu)\, \delta c_\nu \qquad \text{and} \qquad \delta q_k = \sum (\partial q_k/\partial c_\nu)\, \delta c_\nu.$$

Linear *variational*, or perturbational, equations:

$$(\delta p_k)^{\cdot} = \delta(\dot{p}_k) = \sum [(\partial f_k/\partial p_l)\, \delta p_l + (\partial f_k/\partial q_l)\, \delta q_l],$$
$$(\delta q_k)^{\cdot} = \delta(\dot{q}_k) = \sum [(\partial g_k/\partial p_l)\, \delta p_l + (\partial g_k/\partial q_l)\, \delta q_l].$$

Then, for a Hamiltonian system,

$$d/dt\Big(\sum (\partial_1 p_k\, \delta_2 q_k - \delta_2 p_k\, \delta_1 q_k)\Big) = \sum (\delta_1 Q_k\, \delta_2 q_k - \delta_2 Q_k\, \delta_1 q_k).$$

Theorem of Lagrange–Poisson: In a holonomic and potential (i.e., $Q_k = 0$, or $\partial Q_k/\partial q_l = \partial Q_l/\partial q_k$, for all k, $l = 1, \ldots, n$), but possibly rheonomic, system, the bilinear expression

$$I \equiv \sum (\delta_1 p_k\, \delta_2 q_k - \delta_2 p_k\, \delta_1 q_k)$$

is *time-independent*; that is, it is a constant of the motion.

Lagrange's brackets (LB):

$$I = \sum \sum [c_\mu, c_\nu]\, \delta_1 c_\mu\, \delta_2 c_\nu,$$

where

$$[c_\mu, c_\nu] \equiv \sum [(\partial p_k/\partial c_\mu)(\partial q_k/\partial c_\nu) - (\partial p_k/\partial c_\nu)(\partial q_k/\partial c_\mu)]$$
$$= \textit{Lagrangean bracket} \text{ of } c_\mu, c_\nu.$$

Properties of LB:

$$[c_\mu, c_\mu] = 0; \qquad [c_\mu, c_\nu] = -[c_\nu, c_\mu];$$
$$\partial[c_\mu, c_\nu]/\partial c_\lambda + \partial[c_\nu, c_\lambda]/\partial c_\mu + \partial[c_\lambda, c_\mu]/\partial c_\nu = 0,$$
$$[c_\mu, c_\nu] \;=\; \partial/\partial c_\nu\Big(\sum q_k(\partial p_k/\partial c_\mu)\Big) - \partial/\partial c_\mu\Big(\sum q_k(\partial p_k/\partial c_\nu)\Big).$$

PERTURBATION EQUATIONS

Unperturbed problem and its solution

$$dp_k/dt = -\partial H/\partial q_k, \qquad dq_k/dt = \partial H/\partial p_k; \qquad p_k = p_k(t; c), \qquad q_k = q_k(t; c)$$

Slightly perturbed problem

$$dp_k/dt = -\partial H/\partial q_k + X_k, \qquad dq_k/dt = \partial H/\partial p_k,$$

where

$$\begin{aligned} X_k &= X_k(t, q, p) = \text{given function of its arguments} \\ &\approx X_k{}^{(1)}(t; c) \text{ [first-order approximation, upon substitution of \textit{unperturbed} solution in it]} \end{aligned}$$

$2n$ first-order differential equations for the $c_\mu = constant \rightarrow c_\mu(t)$:

$$\sum (\partial p_k/\partial c_\mu)(dc_\mu/dt) = X_k{}^{(1)}, \qquad \sum (\partial q_k/\partial c_\mu)(dc_\mu/dt) = 0.$$

Lagrangean form of the perturbation equations:

$$\sum [c_\nu, c_\mu](dc_\nu/dt) = \sum X_k{}^{(1)}(\partial q_k/\partial c_\mu).$$

If the perturbations are *potential*—that is, if $X_k = -\partial\Omega/\partial q_k$—then, since $q_k = q_k(t; c)$, the above specializes to

$$\sum [c_\nu, c_\mu](dc_\nu/dt) = -\partial\Omega/\partial c_\mu.$$

Inverting, we obtain

$$\begin{aligned} c_\mu &= h_\mu(t, q, p) = \text{first integral (constant) of the unperturbed problem}, \\ dc_\mu/dt &= \sum (\partial h_\mu/\partial p_k)X_k = \sum (\partial c_\mu/\partial p_k)X_k{}^{(1)}. \end{aligned}$$

Poisson's brackets. If the perturbations are *potential*—that is, if

$$X_k = -\partial\Omega/\partial q_k = -\sum (\partial\Omega/\partial c_\nu)(\partial c_\nu/\partial q_k),$$

then

$$dc_\mu/dt = -\sum (\partial\Omega/\partial c_\nu)(c_\mu, c_\nu),$$

where

$$\begin{aligned} (c_\mu, c_\nu) &\equiv \sum [(\partial c_\mu/\partial p_k)(\partial c_\nu/\partial q_k) - (\partial c_\mu/\partial q_k)(\partial c_\nu/\partial p_k)] \\ &= \textit{Poisson bracket} \text{ of } c_\mu, c_\nu. \end{aligned}$$

Compatibility with LB:

$$\sum [c_\nu, c_\mu](c_\nu, c_\lambda) = \delta_{\mu\lambda}.$$

First-order corrections. Setting in $c_\mu = c_{\mu o} + c_{\mu 1}$, where $c_{\mu o}$ = unperturbed values and $c_{\mu 1}$ = corresponding first-order corrections, we have

$$dc_{\mu 1}/dt = -\sum (\partial\Omega_o/\partial c_{\nu o})(c_{\mu o}, c_{\nu o}) \qquad [\text{where } \Omega_o \equiv \Omega(c_o)].$$

Lagrange's result. Let

$$q_k = q_{k0} + q_{k1}t + q_{k2}t^2 + \cdots, \qquad p_k = p_{k0} + p_{k1}t + p_{k2}t^2 + \cdots.$$

Then, with

$$c_k = q_{k0} \qquad \text{and} \qquad c_{n+l} = p_{l0} \qquad (k, l = 1, \ldots, n),$$

the perturbation equations assume the canonical form:

$$dc_k/dt = \partial\Omega/\partial c_{n+k}, \qquad dc_{n+k}/dt = -\partial\Omega/\partial c_k \qquad (k = 1, \ldots, n).$$

CANONICAL TRANSFORMATIONS

Transformations

$$q = q(t, q', p') \leftrightarrow q' = q'(t, q, p); \qquad p = p(t, q', p') \leftrightarrow p' = p'(t, q, p),$$

[with nonvanishing Jacobian $|\partial(q', p')/\partial(q, p)|$] that leave Hamilton's equations form invariant.

Requirements:

$$\begin{aligned} L\,dt &= L'\,dt + dF \\ &\Rightarrow \sum p_k\,dq_k - H\,dt = \sum p_{k'}\,dq_{k'} - H'\,dt + dF, \\ &\Rightarrow \sum p_k\,dq_k - \sum p_{k'}\,dq_{k'} = (H - H')\,dt + dF, \end{aligned}$$

where F is the *generating function* of the transformation (an arbitrary differentiable function of the coordinates, momenta, and time); and H' satisfies the Hamiltonian equations in the new variables.

Alternatively,

$$\begin{aligned} &\sum p_k\,dq_k - H\,dt = df(t, q, p) \qquad \text{and} \qquad \sum p_{k'}\,dq_{k'} - H'\,dt = df'(t, q', p'), \\ &\Rightarrow \sum p_k\,dq_k - \sum p_{k'}\,dq_{k'} - (H - H')\,dt \\ &\qquad = df(t, q, p) - df'(t, q', p') \equiv dF. \end{aligned}$$

Virtual form of a canonical transformation:

$$\sum p_k\,\delta q_k - \sum p_{k'}\,\delta q_{k'} = \delta F.$$

Forms of F and their relations with the corresponding conjugate variables:

$$
\begin{array}{llll}
F = F_1(t, q, q'): & p_k = \partial F_1/\partial q_k, & p_{k'} = -\partial F_1/\partial q_{k'}; & H' = H + \partial F_1/\partial t; \\
F = F_2(t, q, p'): & p_k = \partial F_2/\partial q_k, & q_{k'} = \partial F_2/\partial p_{k'}; & H' = H + \partial F_2/\partial t; \\
F = F_3(t, p, q'): & q_k = -\partial F_3/\partial p_k, & p_{k'} = -\partial F_3/\partial q_{k'}; & H' = H + \partial F_3/\partial t; \\
F = F_4(t, p, p'): & q_k = -\partial F_4/\partial p_k, & q_{k'} = \partial F_4/\partial p_{k'}; & H' = H + \partial F_4/\partial t;
\end{array}
$$

$$F_2 = F_1 + \sum p_{k'} q_{k'},$$

$$F_3 = F_1 - \sum p_k q_k,$$

$$F_4 = F_1 + \sum p_{k'} q_{k'} - \sum p_k q_k = F_2 - \sum p_k q_k = F_3 + \sum p_{k'} q_{k'}.$$

POISSON'S BRACKETS (PB) AND CANONICITY CONDITIONS

The PB of f, g (where f, g, h are arbitrary differentiable dynamical quantities) is

$$(f, g) \equiv \sum [(\partial f/\partial p_k)(\partial g/\partial q_k) - (\partial f/\partial q_k)(\partial g/\partial p_k)] \equiv \sum \partial(f, g)/\partial(p_k, q_k).$$

Then

$$df/dt = \partial f/\partial t + (H, f) + \sum (\partial f/\partial p_k) Q_k;$$

and so for f to be an *integral of the motion*, we must have

$$\partial f/\partial t + \sum (\partial f/\partial p_k) Q_k + (H, f) = 0 \;\Rightarrow\; (H, f) = 0, \quad \text{if } f = f(q, p) \text{ and } Q_k = 0,$$

that is, *its PB with the Hamiltonian of its variables must be zero*.

[Remarks on notation: A number of authors define PBs as the *opposite* of ours; that is, as

$$(f, g) \equiv \sum \big[(\partial f/\partial q_k)(\partial g/\partial p_k) - (\partial f/\partial p_k)(\partial g/\partial q_k)\big].$$

Therefore, a certain caution should be exercised when comparing references. Also, others denote our Lagrangean brackets, [...], by {...}; and our Poisson brackets, (...), by [...].]

Properties/theorems of PBs

$$
\begin{array}{ll}
(f, g) = -(g, f) = (-g, f) \;\Rightarrow f, f) = 0 & \text{(anti-symmetry)} \\
(f, c) = 0 & (c = \text{a constant}) \\
(f_1 + f_2, g) = (f_1, g) = (f_2, g) & \text{(distributivity)} \\
(f_1 f_2, g) = f_1(f_2, g) + f_2(f_1, g) & \\
\quad \Rightarrow (cf, g) = c(f, g) & (c = \text{a constant}) \\
\quad \Rightarrow \text{If } f = \sum c_k f_k, \text{ then } (f, g) = \sum c_k(f_k, g) & (c_k = \text{constants})
\end{array}
$$

$\partial/\partial t(f,g) = (\partial f/\partial t, g) + (f, \partial g/\partial t)$ ("Leibniz rule")

[Actually, $\partial/\partial x(f,g) = (\partial f/\partial x, g) + (f, \partial g/\partial x)$; $x =$ any variable]

$(f, q_k) = \partial f/\partial p_k,$

$(f, p_k) = -\partial f/\partial q_k,$

$(q_k, q_l) = 0,$

$(p_k, p_l) = 0,$

$(p_k, q_l) = \delta_{kl}$ ($=$ *Kronecker delta*).

[The last three types of brackets are called *fundamental*, or *basic*, PB]

$(f,(g,h)) + (g,(h,f)) + (h,(f,g)) = 0,$

$((f,g),h) + ((g,h),f) + ((h,f),g) = 0$ (Poisson–Jacobi identity)

Theorem of Poisson–Jacobi: If f and g are any two integrals of the motion, so is their PB; that is, if $f = c_1$ and $g = c_2$, then $(f,g) = c_3$ ($c_{1,2,3} =$ constants).

Theorem: The *PBs are invariant under CT*; that is, $(f,g)_{q,p} = (f,g)_{q',p'} = \cdots$; where f and g keep their *value*, but not necessarily their *form*, in the various canonical coordinates involved.

Canonicity conditions via PB

$$[p_{l'}, p_{k'}] = 0, \qquad [q_{l'}, q_{k'}] = 0, \qquad [p_{k'}, q_{l'}] = \delta_{kl},$$
$$(p_{l'}, p_{k'}) = 0, \qquad (q_{l'}, q_{k'}) = 0, \qquad (p_{l'}, q_{k'}) = \delta_{lk},$$

since *both* Poisson and Lagrange brackets are canonically invariant.

Theorem of Jacobi

(i) The integration of the canonical equations

$$dq_k/dt = \partial H/\partial p_k, \qquad dp_k/dt = -\partial H/\partial q_k,$$

is reduced to the integration of the Hamilton–Jacobi equation $(H - J)$:

$$H(t, q, \partial A/\partial q) + \partial A/\partial t = 0,$$

$A = A(t, q, p')$: generating function (Hamiltonian action).

(ii) If we have a complete solution of $H - J$; that is, a solution of the form

$$A = A(t; q_1, \ldots, q_n; \beta_1, \ldots, \beta_n) \equiv A(t; q, \beta),$$

where $\beta \equiv (\beta_1, \ldots, \beta_n) = n$ essential arbitrary constants, and $|\partial^2 A/\partial q\,\partial\beta| \neq 0$ (non-vanishing Jacobian), then the solution of the algebraic system:

$\partial A/\partial \beta_k = \alpha_k$

[Finite equations of motion, α: new arbitrary constants $\Rightarrow q_k = q_k(t, \alpha, \beta)$],

$\partial A/\partial q_k = p_k$

$[\Rightarrow p_k = p_k(t, \alpha, \beta)$: canonically conjugate (finite) equations of motion],

constitutes a complete solution of the canonical equations. Schematically, these are as follows.

Hamilton: *Differential* equations of motion:

$$dq/dt = \partial H/\partial p, \qquad dp/dt = -\partial H/\partial q$$

(If these equations can be integrated, an action function can be obtained)

Hamilton–Jacobi:

$$H(t, q, \partial A/\partial q) + \partial A/\partial t = 0 \Rightarrow A = A(t, q, \beta)$$

Jacobi: *Finite* equations of motion:

$$\partial A/\partial \beta = \alpha \rightarrow q = q(t, \alpha, \beta);$$
$$\partial A/\partial q = p \rightarrow p = p(t, \alpha, \beta)$$

(If an action function can be obtained, then Hamilton's equations can be integrated.)

No significant new notations are involved in the remaining sections §8.12–§8.16 (i.e. special topics on Hamiltonian mechanics).

1

Background

Basic Concepts and Equations of Particle and Rigid-Body Mechanics

> Therefore it would seem right that any systematic treatment of classical dynamics should start with axioms carefully laid down, on which the whole structure would rest as a house rests on its foundations. The analogy to a house is, however, a false one. *Theories are created in mid-air, so to speak, and develop both upward and downward*. Neither process is ever completed. Upward, the ramifications can extend indefinitely, downward, the axiomatic base must be rebuilt continually as our views change as to what constitutes logical precision. Indeed, there is little promise of finality here, as we seem to be moving towards the idea that logic is a man-made thing, a game played according to rules to some extent arbitrary.
>
> (Synge, 1960, p. 5, emphasis added)

In this chapter we summarize, without detailed proofs and/or elaborate discussions, in a *handbook* (*not textbook*) fashion, like a first-aid kit, but in a hopefully accurate and serviceable form, the basic concepts, definitions, axioms, and theorems of "elementary" (or momentum/Newton–Euler, or general) *theoretical mechanics*. This compact, highly selective, perhaps nonhomogeneous, and unavoidably incomplete account should help to establish a common background with readers, and thus enhance their understanding of the rest of this relatively self-contained book.

For complementary reading, we recommend (alphabetically):

Fox (1967): one of the best, and most economically written, U.S. texts on elementary–intermediate general mechanics.

Hamel (1909), (1912, 1st ed., 1922, 2nd ed.): arguably the best text on elementary–intermediate general mechanics written to date, (1927), (1949).

Hund (1972): concise, insightful.

Langner (1996–1997): dense, clear; "best buy."

Loitsianskii and Lur'e (1982, 1983): excellent.

Marcolongo (1905, 1911/1912): rigorous, comprehensive.

Milne (1948): interesting vectorial treatment of rigid dynamics.

Papastavridis: *Elementary Mechanics* (EM for short), under production: encyclopedia/handbook of Newton-Euler momentum mechanics, from an advanced and unified viewpoint; includes the elements of continuum mechanics.

Parkus (1966): an educational classic.

Synge and Griffith (1959): clear, reliable.

Synge (1960): comprehensive, encyclopedic, mature.

Winkelmann (1929, 1930): concise, comprehensive.

Additional references, at particular sections, and so on, will also be given, as deemed beneficial.

1.1 VECTOR AND (CARTESIAN) TENSOR ALGEBRA

Vectors: Basic Concepts/Definitions and Algebra

Geometrically, vectors are straight line segments that, in the most general case, have the following *five* characteristics: (i) *length*, (ii) *direction*, (iii) *sense*, (iv) *line of action* (or *carrier*), and (v) *origin* (or *point of application*) on carrier; (iv) and (v) can be replaced with *spatial origin*. Also, vectors obey the well-known *parallelogram law* of addition ($\Rightarrow$ commutativity); that is, not all line segments with characteristics (i)–(v) are vectors (e.g., finite rotations, §1.10). Next, if only characteristics (i)–(iii) matter, but (iv) and (v) do not, the vector is called *free*; if characteristics (i)–(iv) matter, but (v) does not, the vector is called *line bound* or *sliding*; and if all five characteristics matter, the vector is called *point bound*. As a rule, the *vectors* of *continuum mechanics* and the *system vectors* of *analytical mechanics* (chap. 2 ff.) are *point bound*; while those of rigid-body mechanics are *line bound*.

Notation for vectors: $\boldsymbol{a}$, $\boldsymbol{b}, \ldots$ (bold italic).

Length, or magnitude, or modulus, or intensity, or norm, of $\boldsymbol{a}$: $|\boldsymbol{a}| \equiv a \geq 0$. If $a = 0$, the vector is called *null*; if $a = 1$, the vector is called *unit* (or *normalized*).

The physical space of classical mechanics is a three-dimensional Euclidean *point* space, denoted by E_3 or E; while the associated (also Euclidean) *vector* space is denoted by $\boldsymbol{E}_3$ or $\boldsymbol{E}$.

An *orthonormal basis* (i.e., one whose vectors are unit *and* mutually orthogonal—see below)

$$\{\boldsymbol{u}_1, \boldsymbol{u}_2, \boldsymbol{u}_3\} \equiv \{\boldsymbol{u}_{1,2,3}\} \equiv \{\boldsymbol{u}_k; k = 1, 2, 3\} \equiv \{\boldsymbol{u}_k\}$$
$$\equiv \{\boldsymbol{u}_x, \boldsymbol{u}_y, \boldsymbol{u}_z\} \equiv \{\boldsymbol{u}_{x,y,z}\} \equiv \{\boldsymbol{i}, \boldsymbol{j}, \boldsymbol{k}\}, \tag{1.1.1}$$

together with an "origin," O, make up a (local) rectangular Cartesian *frame*: $\{O, \boldsymbol{u}_k\}$. If the origin is not important, we simply write $\{\boldsymbol{u}_k\}$.

[Since E is *flat* (noncurved), a single such frame, and associated rectilinear and mutually rectangular axes of coordinates O–$123 \equiv O$–xyz, can be extended to cover, or represent, the entire space: *local* frame $\rightarrow$ *global* frame. For details, see, for example, Papastavridis (1999, pp. 84–91, 211–218), or Lur'e (1968, p. 807).]

In such a basis, a vector $\boldsymbol{a}$ can be represented by its rectangular Cartesian *components*

$$\{a_1, a_2, a_3\} \equiv \{a_{1,2,3}\} \equiv \{a_k; k = 1, 2, 3\} \equiv \{a_k\} \equiv \{a_x, a_y, a_z\} \equiv \{a_{x,y,z}\}, \tag{1.1.2a}$$

or

$$\boldsymbol{a} = a_1\boldsymbol{u}_1 + a_2\boldsymbol{u}_2 + a_3\boldsymbol{u}_3 = a_x\boldsymbol{u}_x + a_y\boldsymbol{u}_y + a_z\boldsymbol{u}_z = \sum a_k\boldsymbol{u}_k. \tag{1.1.2b}$$

In terms of the famous Einsteinian *summation convention* [= lone, or *free*, subscripts range over the integers 1, 2, 3, or x, y, z, while *summation* is implied over repeated (i.e., pairs) of *subscripts*], we can simply write $\boldsymbol{a} = a_k \boldsymbol{u}_k$. In this book, however, and for reasons that will gradually become clear (chap. 2), we shall *NOT* use this convention!

Dotting (1.1.2b) with $\boldsymbol{u}_k$, and noting the *six orthonormality* (metric!) conditions or constraints:

$$\boldsymbol{u}_k \cdot \boldsymbol{u}_l\text{: } \textit{scalar}, \text{ or } \textit{dot}, \text{ or } \textit{inner}, \text{ product of } \boldsymbol{u}_k, \boldsymbol{u}_l = \delta_{kl} = \delta_{lk} \text{ (Kronecker delta)}$$
$$= 1 \quad \text{if } k = l, \qquad = 0 \quad \text{if } k \neq l \qquad (k, l = 1, 2, 3, \text{ or } x, y, z), \tag{1.1.3}$$

in extenso:

$$\boldsymbol{i} \cdot \boldsymbol{j} = \boldsymbol{j} \cdot \boldsymbol{j} = \boldsymbol{k} \cdot \boldsymbol{k} = 1 \text{ (normality)}, \qquad \boldsymbol{i} \cdot \boldsymbol{j} = \boldsymbol{i} \cdot \boldsymbol{k} = \boldsymbol{j} \cdot \boldsymbol{k} = 0 \text{ (orthogonality)}. \tag{1.1.3a, b}$$

we obtain the following expression for the $\boldsymbol{a}$-components:

$$a_k = \boldsymbol{a} \cdot \boldsymbol{u}_k. \tag{1.1.2c}$$

In such a basis, the dot product of two vectors $\boldsymbol{a}$ and $\boldsymbol{b}$ is expressed as

$$\boldsymbol{a} \cdot \boldsymbol{b} = \boldsymbol{b} \cdot \boldsymbol{a} = \left(\sum a_k \boldsymbol{u}_k\right) \cdot \left(\sum b_l \boldsymbol{u}_l\right) = \cdots = \sum a_k b_k. \tag{1.1.4}$$

For $\boldsymbol{a} = \boldsymbol{b}$, the above yields the *length*, or *norm*, or *magnitude*, of $\boldsymbol{a}$:

$$N(\boldsymbol{a}) \equiv a = |\boldsymbol{a}| = (\boldsymbol{a} \cdot \boldsymbol{a})^{1/2} = \left(\sum a_k a_k\right)^{1/2} \geq 0 \qquad \text{(this book)}. \tag{1.1.5}$$

The basis $\{\boldsymbol{u}_{1,2,3}\}$ is called $\mathrm{O_{rtho}N_{ormal}D_{extral\ (i.e.,\ right\text{-}handed)}}$ $\equiv$ OND, if, in addition to (1.1.3), it satisfies

$$\boldsymbol{u}_k \cdot (\boldsymbol{u}_r \times \boldsymbol{u}_s) \equiv (\boldsymbol{u}_k, \boldsymbol{u}_r, \boldsymbol{u}_s) \equiv \varepsilon_{krs} \text{ (permutation symbol, or alternator, of Levi–Civita)}$$
$$= +1/{-1}/0 \quad \text{according as } k, r, s \text{ are an } \textit{even/odd/no} \text{ permutation of } 1, 2, 3$$
$$[\text{i.e., } \varepsilon_{123} = \varepsilon_{231} = \varepsilon_{312} = +1, \ \varepsilon_{132} = \varepsilon_{213} = \varepsilon_{321} = -1,$$
$$\varepsilon_{112} = \varepsilon_{122} = \varepsilon_{313} = \varepsilon_{222} = \cdots = 0 \text{ (two or more indices equal)}], \tag{1.1.6}$$

or, equivalently, if

$$\boldsymbol{u}_r \times \boldsymbol{u}_s = \sum \varepsilon_{rsk} \boldsymbol{u}_k = \sum \varepsilon_{krs} \boldsymbol{u}_k \ \Leftrightarrow \ \boldsymbol{u}_k = (1/2) \sum \sum \varepsilon_{krs} (\boldsymbol{u}_r \times \boldsymbol{u}_s); \tag{1.1.6a}$$

that is, $(\boldsymbol{u}_r \times \boldsymbol{u}_s)_k = \varepsilon_{rsk}$; otherwise $\{\boldsymbol{u}_{1,2,3}\}$ is *left-handed*, or *sinister*, in which case $(\boldsymbol{u}_k, \boldsymbol{u}_r, \boldsymbol{u}_s) \equiv -\varepsilon_{krs}$. Henceforth, only OND bases will be used.

- The symbols of Kronecker and Levi–Civita are connected by the following "**ed** identity":

$$\sum \varepsilon_{krs} \varepsilon_{lms} = \sum \varepsilon_{skr} \varepsilon_{slm} = \delta_{kl} \delta_{rm} - \delta_{km} \delta_{rl}; \tag{1.1.6b}$$

which, for $r = m$ (and then summation over repeated subscripts), produces

$$\sum\sum \varepsilon_{krs}\varepsilon_{lrs} = 2\delta_{kl}; \tag{1.1.6c}$$

and this, for $k = l$, etc., yields

$$\sum\sum\sum \varepsilon_{krs}\varepsilon_{krs} = 2\Big(\sum \delta_{kk}\Big) = 2(3) = 6. \tag{1.1.6d}$$

- The dextrality of the orthonormal basis $(\boldsymbol{i}, \boldsymbol{j}, \boldsymbol{k})$ (i.e., $\boldsymbol{i} \times \boldsymbol{i} = \boldsymbol{j} \times \boldsymbol{j} = \boldsymbol{k} \times \boldsymbol{k} = \boldsymbol{0}$), is expressed by

$$\boldsymbol{i} \times \boldsymbol{j} = -(\boldsymbol{j} \times \boldsymbol{i}) = \boldsymbol{k},\ \ \boldsymbol{j} \times \boldsymbol{k} = -(\boldsymbol{k} \times \boldsymbol{j}) = \boldsymbol{i},\ \ \boldsymbol{k} \times \boldsymbol{i} = -(\boldsymbol{i} \times \boldsymbol{k}) = \boldsymbol{j}. \tag{1.1.6e}$$

With the help of the above, we express the *vector*, or *cross*, or *outer*, product of $\boldsymbol{a}$ and $\boldsymbol{b}$ as

$$\boldsymbol{a} \times \boldsymbol{b} = -(\boldsymbol{b} \times \boldsymbol{a}) = \sum\sum\sum \varepsilon_{klr} a_k b_l \boldsymbol{u}_r, \tag{1.1.7a}$$

that is,

$$(\boldsymbol{a} \times \boldsymbol{b})_r = \sum\sum \varepsilon_{klr} a_k b_l = \sum\sum \varepsilon_{rkl} a_k b_l. \tag{1.1.7b}$$

It can be shown that

$$|\boldsymbol{u}_1 \times \boldsymbol{u}_2|^2 = |\boldsymbol{u}_2 \times \boldsymbol{u}_3|^2 = |\boldsymbol{u}_3 \times \boldsymbol{u}_1|^2 = (\boldsymbol{u}_1, \boldsymbol{u}_2, \boldsymbol{u}_3)^2 = +1, \tag{1.1.8a}$$

where

$$\begin{aligned}(\boldsymbol{a}, \boldsymbol{b}, \boldsymbol{c}) &\equiv \boldsymbol{a} \cdot (\boldsymbol{b} \times \boldsymbol{c}) = \boldsymbol{b} \cdot (\boldsymbol{c} \times \boldsymbol{a}) = \boldsymbol{c} \cdot (\boldsymbol{a} \times \boldsymbol{b}) \\ &= (\boldsymbol{a} \times \boldsymbol{b}) \cdot \boldsymbol{c} = (\boldsymbol{b} \times \boldsymbol{c}) \cdot \boldsymbol{a} = (\boldsymbol{c} \times \boldsymbol{a}) \cdot \boldsymbol{b} \\ &= \sum\sum\sum \varepsilon_{krs} a_k b_r c_s: \end{aligned} \tag{1.1.8b}$$

[+, if ($\boldsymbol{a}$, $\boldsymbol{b}$, $\boldsymbol{c}$) is *right*; −, if ($\boldsymbol{a}$, $\boldsymbol{b}$, $\boldsymbol{c}$) is *left*; 0, if ($\boldsymbol{a}$, $\boldsymbol{b}$, $\boldsymbol{c}$) are *coplanar* or *zero*]: *scalar* triple product of $\boldsymbol{a}$, $\boldsymbol{b}$, $\boldsymbol{c}$ = *signed volume of parallelepiped* having $\boldsymbol{a}$, $\boldsymbol{b}$, $\boldsymbol{c}$ as sides; also

$$\begin{aligned}[\boldsymbol{a}, \boldsymbol{b}, \boldsymbol{c}] &\equiv \boldsymbol{a} \times (\boldsymbol{b} \times \boldsymbol{c}) = (\boldsymbol{a} \cdot \boldsymbol{c})\boldsymbol{b} - (\boldsymbol{a} \cdot \boldsymbol{b})\boldsymbol{c} \\ &\qquad [\neq (\boldsymbol{a} \times \boldsymbol{b}) \times \boldsymbol{c} = -\boldsymbol{c} \times (\boldsymbol{a} \times \boldsymbol{b}) = (\boldsymbol{a} \cdot \boldsymbol{c})\boldsymbol{b} - (\boldsymbol{b} \cdot \boldsymbol{c})\boldsymbol{a}]: \end{aligned} \tag{1.1.8c}$$

vector triple product of $\boldsymbol{a}$, $\boldsymbol{b}$, $\boldsymbol{c}$.

The *dyadic*, or *direct*, or *open*, or *tensor* product of two vectors $\boldsymbol{a}$ and $\boldsymbol{b}$,

$$\boldsymbol{a}\,\boldsymbol{b} \equiv \boldsymbol{a} \otimes \boldsymbol{b} \qquad (\neq \boldsymbol{b} \otimes \boldsymbol{a},\ \text{in general}), \tag{1.1.9a}$$

is defined as (the *tensor* — see below):

$$\boldsymbol{a}\,\boldsymbol{b} \equiv \boldsymbol{a} \otimes \boldsymbol{b} = \Big(\sum a_k \boldsymbol{u}_k\Big) \otimes \Big(\sum b_l \boldsymbol{u}_l\Big) = \sum\sum a_k b_l (\boldsymbol{u}_k \otimes \boldsymbol{u}_l). \tag{1.1.9b}$$

- This product can also be defined as the tensor that assigns to each vector $\boldsymbol{x}$ the vector $\boldsymbol{a}\,(\boldsymbol{b} \cdot \boldsymbol{x})$:

$$(\boldsymbol{a} \otimes \boldsymbol{b}) \cdot \boldsymbol{x} = \boldsymbol{a}\,(\boldsymbol{b} \cdot \boldsymbol{x}) = (\boldsymbol{b} \cdot \boldsymbol{x})\boldsymbol{a}, \tag{1.1.9c}$$

and also

$$\boldsymbol{x} \cdot (\boldsymbol{a} \otimes \boldsymbol{b}) = (\boldsymbol{x} \cdot \boldsymbol{a})\boldsymbol{b} = \boldsymbol{b}\,(\boldsymbol{x} \cdot \boldsymbol{a}). \tag{1.1.9d}$$

In components, these read, respectively,

$$(\boldsymbol{a} \otimes \boldsymbol{b}) \cdot \boldsymbol{x} = \sum\sum (a_k b_l x_l)\boldsymbol{u}_k, \qquad \boldsymbol{x} \cdot (\boldsymbol{a} \otimes \boldsymbol{b}) = \sum\sum (x_l a_l b_k)\boldsymbol{u}_k. \tag{1.1.9e}$$

- It can be shown that

$$[\boldsymbol{a}, \boldsymbol{b}, \boldsymbol{c}] = [(\boldsymbol{b} \otimes \boldsymbol{c}) - (\boldsymbol{c} \otimes \boldsymbol{b})] \cdot \boldsymbol{a}. \tag{1.1.8d}$$

Tensors: Basic Concepts/Definitions and Algebra

[For a detailed classical mostly indicial treatment of general tensors, see, for example, Papastavridis (1999), and our *Elementary Mechanics*.]

A second-order (or rank) *tensor* (or *dyadic*, from the Greek ΔYO = *two*) or, here, simply tensor $\boldsymbol{T}$ (bold, in italics *or* roman) is defined as a linear transformation from V to V; or as a linear mapping assigning to each vector $\boldsymbol{a}$ another vector $\boldsymbol{b}$:

$$\boldsymbol{b} = \boldsymbol{T} \cdot \boldsymbol{a}, \tag{1.1.10a}$$

or in components

$$\sum b_k \boldsymbol{u}_k = \sum\sum T_{kl} a_l \boldsymbol{u}_k \;\Rightarrow\; b_k = \sum T_{kl} a_l, \tag{1.1.10b}$$

or as

$$\boldsymbol{b} = \boldsymbol{a} \cdot \boldsymbol{T} = \sum\sum a_k T_{kl} \boldsymbol{u}_l \;\Rightarrow\; b_l = \sum T_{kl} a_k,$$

where

$$T_{kl} \equiv \boldsymbol{u}_k \cdot (\boldsymbol{T} \cdot \boldsymbol{u}_l) = (\boldsymbol{T} \cdot \boldsymbol{u}_l) \cdot \boldsymbol{u}_k = \boldsymbol{T} \cdot (\boldsymbol{u}_k \otimes \boldsymbol{u}_l), \tag{1.1.10c}$$

are the Cartesian components of $\boldsymbol{T}$ (see tensor *products*, below). Alternatively, a *vector*/*tensor*//(n)th *order tensor* associates a *scalar*/*vector*//($n-1$)th *order tensor* with each spatial direction $\boldsymbol{u}_d = (u_{(d)k}$: direction cosines of unit vector $\boldsymbol{u}_d$), via a *linear* and *homogeneous* expression in the $u_{(d)k}$; that is, for a (second-order) tensor:

$$\boldsymbol{T} \to \boldsymbol{v}_d = \boldsymbol{T} \cdot \boldsymbol{u}_d \quad \text{(direct notation)}, \qquad v_{(d)k} = \sum T_{kl} u_{(d)l} \quad \text{(component notation)}.$$

Thus (and in addition to the well-known 3×3 matrix form), $\boldsymbol{T}$ has the following representations:

$$\begin{aligned}
\boldsymbol{T} &= \sum\sum T_{kl} \boldsymbol{u}_k \otimes \boldsymbol{u}_l && (\textit{Dyadic} \text{ or } \textit{nonion} \text{ representation}) \\
&= \sum \boldsymbol{u}_k \otimes \boldsymbol{t}_k, && \text{where } \boldsymbol{t}_k \equiv \sum T_{kl} \boldsymbol{u}_l, && (1.1.10\text{d}) \\
&= \sum \boldsymbol{\tau}_l \otimes \boldsymbol{u}_l, && \text{where } \boldsymbol{\tau}_l \equiv \sum T_{kl} \boldsymbol{u}_k. && (1.1.10\text{e})
\end{aligned}$$

The nine tensors $\{\boldsymbol{u}_k \otimes \boldsymbol{u}_l\}$ span the set of all (second-order) tensors; they form an orthonormal "tensor basis" there. If $T_{12} = T_{21} (= -T_{21})$, etc., then $\boldsymbol{T}$ is called *symmetric* (*anti*-, or *skew*-symmetric). Generally [see definition of *transpose*, $(\ldots)^{\mathrm{T}}$, below]:

Symmetric tensor: $\quad \boldsymbol{T} = \boldsymbol{T}^{\mathrm{T}}, \quad T_{kl} = T_{lk};$ (1.1.11a)

Antisymmetric tensor: $\quad \boldsymbol{T} = -\boldsymbol{T}^{\mathrm{T}}, \quad T_{kl} = -T_{lk} \quad (\Rightarrow T_{kk} = 0,\ \text{no sum!})$ (1.1.11b)

Algebra of Tensors: Basic Operations

- *Sum/difference* of tensors $\boldsymbol{T}$ and $\boldsymbol{S}$:

$$\boldsymbol{T} \pm \boldsymbol{S} = \sum\sum (T_{kl} \pm S_{kl}) \boldsymbol{u}_k \otimes \boldsymbol{u}_l. \tag{1.1.12a}$$

- *Product* of $\boldsymbol{T}$ with a scalar (number) λ, $\lambda\boldsymbol{T}$:

$$\lambda\boldsymbol{T} = \sum\sum (\lambda T_{kl}) \boldsymbol{u}_k \otimes \boldsymbol{u}_l. \tag{1.1.12b}$$

- *Tensor product* of $\boldsymbol{T}$ and $\boldsymbol{S}$, $\boldsymbol{T} \cdot \boldsymbol{S}$, is defined by

$$\boldsymbol{T} \cdot \boldsymbol{S} = \sum\sum\sum T_{kr} S_{rl} \boldsymbol{u}_k \otimes \boldsymbol{u}_l \qquad (\neq \boldsymbol{S} \cdot \boldsymbol{T},\ \text{in general});$$

that is,

$$(\boldsymbol{T} \cdot \boldsymbol{S})_{kl} = \sum T_{kr} S_{rl} \ \neq \ (\boldsymbol{S} \cdot \boldsymbol{T})_{kl} = \sum S_{kr} T_{rl}. \tag{1.1.12c}$$

- *Inner*, or *dot*, *scalar* product of $\boldsymbol{T}$ and $\boldsymbol{S}$, $\boldsymbol{T} : \boldsymbol{S}$, is defined by (see *trace* below)

$$\begin{aligned} \boldsymbol{T} : \boldsymbol{S} &\equiv \sum\sum T_{kl} S_{kl} = Tr(\boldsymbol{T} \cdot \boldsymbol{S}^{\mathrm{T}}) \\ &= \sum\sum S_{kl} T_{kl} = Tr(\boldsymbol{S} \cdot \boldsymbol{T}^{\mathrm{T}}) \equiv \boldsymbol{S} : \boldsymbol{T}, \end{aligned} \tag{1.1.12d}$$

where Tr means "trace of." If $\boldsymbol{T} = \boldsymbol{S}$,

$$T \equiv |\boldsymbol{T}| = (\boldsymbol{T} : \boldsymbol{T})^{1/2}\text{: } \textit{magnitude} \text{ of } \boldsymbol{T} (> 0,\ \text{unless } \boldsymbol{T} = \boldsymbol{0}). \tag{1.1.12e}$$

If either of $\boldsymbol{T}$, $\boldsymbol{S}$ is *symmetric* (as is almost always the case in mechanics), then,

$$\begin{aligned} \boldsymbol{T} : \boldsymbol{S} &\equiv \sum\sum T_{kl} S_{kl} = \sum\sum T_{kl} S_{lk} \\ &\Big[= Tr(\boldsymbol{T} \cdot \boldsymbol{S}) \equiv \boldsymbol{T} \cdot\cdot\, \boldsymbol{S} \\ &= \sum\sum S_{lk} T_{kl} = Tr(\boldsymbol{S} \cdot \boldsymbol{T}) \equiv \boldsymbol{S} \cdot\cdot\, \boldsymbol{T} \Big]. \end{aligned} \tag{1.1.12f}$$

In sum, we have defined the following *three* tensorial products:

$$(\boldsymbol{T} \cdot \boldsymbol{S})_{kl} = \sum T_{kr} S_{rl} \quad \text{(Tensor)},$$

$$\boldsymbol{T} : \boldsymbol{S} \equiv \sum\sum T_{kl} S_{kl} \quad \text{(Scalar)}, \qquad \boldsymbol{T} \cdot\cdot\, \boldsymbol{S} \equiv \sum\sum T_{kl} S_{lk} \quad \text{(Scalar)}. \tag{1.1.12g}$$

The reader should be warned that these notations are by no means uniform, and so caution should be exercised in comparing various references.

- *Transpose* of $\boldsymbol{T}$, $\boldsymbol{T}^{\mathrm{T}}$, is defined uniquely by

$$(\boldsymbol{T}\cdot\boldsymbol{a})\cdot\boldsymbol{b} = \boldsymbol{a}\cdot(\boldsymbol{T}^{\mathrm{T}}\cdot\boldsymbol{b}),\ \text{for } \textit{all } \boldsymbol{a},\boldsymbol{b}. \tag{1.1.12h}$$

- *Trace* of $\boldsymbol{T}$ is defined by

$$\textit{Trace of } \boldsymbol{T} \equiv Tr(\boldsymbol{T}) \equiv T_{11} + T_{22} + T_{33} \equiv \sum T_{kk}. \tag{1.1.12i}$$

- *Determinant* of $\boldsymbol{T}$ is defined by

$$\textit{Determinant of } \boldsymbol{T} \equiv Det(\boldsymbol{T}) = Det(T_{kl}) \equiv |T_{kl}|. \tag{1.1.12j}$$

It can be shown that:

(i)
$$Tr(\boldsymbol{T}) = Tr(\boldsymbol{T}^{\mathrm{T}}), \qquad Det(\boldsymbol{T}) = Det(\boldsymbol{T}^{\mathrm{T}}), \tag{1.1.12k}$$

(ii) For any two vectors $\boldsymbol{a}$ and $\boldsymbol{b}$:

$$(\boldsymbol{a}\otimes\boldsymbol{b})^{\mathrm{T}} = \boldsymbol{b}\otimes\boldsymbol{a}, \qquad Tr(\boldsymbol{a}\otimes\boldsymbol{b}) = \boldsymbol{a}\cdot\boldsymbol{b} = \sum a_k b_k, \qquad Det(\boldsymbol{a}\otimes\boldsymbol{b}) = 0, \tag{1.1.12l}$$

(iii) For any two tensors $\boldsymbol{T}$ and $\boldsymbol{S}$:

$$(\boldsymbol{T}\cdot\boldsymbol{S})^{\mathrm{T}} = \boldsymbol{S}^{\mathrm{T}}\cdot\boldsymbol{T}^{\mathrm{T}}, \qquad Tr(\boldsymbol{T}\cdot\boldsymbol{S}) = Tr(\boldsymbol{S}\cdot\boldsymbol{T}) = \boldsymbol{T}\cdot\cdot\boldsymbol{S}, \tag{1.1.12m}$$

$$Det(\boldsymbol{T}\cdot\boldsymbol{S}) = Det(\boldsymbol{T})\,Det(\boldsymbol{S}); \tag{1.1.12n}$$

also (in *three* dimensions):

$$Det(t\boldsymbol{T}) = t^3\,Det(\boldsymbol{T}),\ \text{for any real number } t. \tag{1.1.12o}$$

- *Inverse* of $\boldsymbol{T}$, $\boldsymbol{T}^{-1}$, is defined uniquely by:

$$\boldsymbol{T}\cdot\boldsymbol{T}^{-1} = \boldsymbol{T}^{-1}\cdot\boldsymbol{T} = \boldsymbol{1}\ (\textit{unit}\ \text{tensor}), \qquad [Det(\boldsymbol{T}) \neq 0]. \tag{1.1.12p}$$

From the above, we can easily deduce that

(i)
$$Det(\boldsymbol{T}^{-1}) = (Det\ \boldsymbol{T})^{-1} \tag{1.1.12q}$$

(ii)
$$(\boldsymbol{T}\cdot\boldsymbol{S})^{-1} = \boldsymbol{S}^{-1}\cdot\boldsymbol{T}^{-1} \qquad (\boldsymbol{T},\boldsymbol{S}\text{: invertible}) \tag{1.1.12r}$$

(iii)
$$d/dx(Det\ \boldsymbol{T}) = (Det\ \boldsymbol{T})Tr[(d\boldsymbol{T}/dx)\cdot\boldsymbol{T}^{-1}], \tag{1.1.12s}$$

where $\boldsymbol{T} = \boldsymbol{T}(x) = \textit{invertible}$, $x = \textit{real parameter}$, and $d\boldsymbol{T}/dx \equiv (dT_{kl}/dx)$.

- A tensor can be built from two vectors; but, in general, it cannot be decomposed into two vectors.
- Every tensor can be decomposed uniquely into a sum of a *symmetric* part (T'_{kl}) and an *antisymmetric* part (T''_{kl}):

$$T_{kl} = T'_{kl} + T''_{kl},$$

$$2T'_{kl} \equiv T_{kl} + T_{lk} = 2T'_{lk}, \qquad 2T''_{kl} \equiv T_{kl} - T_{lk} = -2T''_{lk}; \tag{1.1.13a}$$

that is,

$$\boldsymbol{T} = \boldsymbol{T}' + \boldsymbol{T}'', \qquad \boldsymbol{T}' = (\boldsymbol{T}')^{\mathrm{T}}, \qquad \boldsymbol{T}'' = -(\boldsymbol{T}'')^{\mathrm{T}}. \tag{1.1.13b}$$

- For any tensor $\boldsymbol{T}$ and any three vectors $\boldsymbol{a}$, $\boldsymbol{b}$, $\boldsymbol{c}$, the following identities hold:

(i) $\boldsymbol{a}\cdot(\boldsymbol{T}\cdot\boldsymbol{b}) = \boldsymbol{T}:(\boldsymbol{a}\otimes\boldsymbol{b}),\ \sum a_k\left(\sum T_{kl}b_l\right) = \sum\sum T_{kl}(a_k b_l)$ (in components). (1.1.14a)

(ii) Since

$$\boldsymbol{T}\cdot\boldsymbol{a} = \sum\sum (T_{kl}a_l)\boldsymbol{u}_k, \qquad \boldsymbol{a}\cdot\boldsymbol{T} = \sum\sum (a_l T_{lk})\boldsymbol{u}_k,$$

we will have $\boldsymbol{T}\cdot\boldsymbol{a} = \boldsymbol{a}\cdot\boldsymbol{T}$, only if $\boldsymbol{T}$ is *symmetric*; from which we also conclude that

$$(\boldsymbol{u}_k\otimes\boldsymbol{u}_l) : (\boldsymbol{u}_r\otimes\boldsymbol{u}_s) = \delta_{kr}\,\delta_{ls}. \tag{1.1.14b}$$

(iii)

$$(\boldsymbol{a}\times\boldsymbol{T})\cdot\boldsymbol{b} = \boldsymbol{a}\times(\boldsymbol{T}\cdot\boldsymbol{b}), \qquad (\boldsymbol{T}\times\boldsymbol{a})\cdot\boldsymbol{b} = \boldsymbol{T}\cdot(\boldsymbol{a}\times\boldsymbol{b}), \tag{1.1.14c}$$

where

$$\boldsymbol{T}\times\boldsymbol{a} = \sum\sum\sum\sum (T_{kr}a_s\varepsilon_{rsl})\boldsymbol{u}_k\otimes\boldsymbol{u}_l;$$

that is,

$$(\boldsymbol{T}\times\boldsymbol{a})_{kl} = \sum\sum \varepsilon_{lrs}T_{kr}a_s, \tag{1.1.14d}$$

and

$$\boldsymbol{a}\times\boldsymbol{T} = \sum\sum\sum\sum (T_{sl}a_r\varepsilon_{rsk})\boldsymbol{u}_k\otimes\boldsymbol{u}_l, \quad (\boldsymbol{a}\times\boldsymbol{T})_{kl} = \sum\sum \varepsilon_{krs}a_r T_{sl}. \tag{1.1.14e}$$

(iv)

$$(\boldsymbol{T}\cdot\boldsymbol{a}, \boldsymbol{T}\cdot\boldsymbol{b}, \boldsymbol{T}\cdot\boldsymbol{c}) = (Det\,\boldsymbol{T})(\boldsymbol{a}, \boldsymbol{b}, \boldsymbol{c}). \tag{1.1.14f}$$

(v)

$$\boldsymbol{T}^{\mathrm{T}}\cdot(\boldsymbol{T}\cdot\boldsymbol{a}\times\boldsymbol{T}\cdot\boldsymbol{b}) = (Det\,\boldsymbol{T})(\boldsymbol{a}\times\boldsymbol{b}). \tag{1.1.14g}$$

Special Tensors

Zero tensor $\boldsymbol{O}$:

$$\boldsymbol{O}\cdot\boldsymbol{a} = \boldsymbol{0}, \qquad \text{for every vector } \boldsymbol{a}. \tag{1.1.15a}$$

Unit, or *identity*, tensor $\boldsymbol{1}$:

$$\boldsymbol{1}\cdot\boldsymbol{a} = \boldsymbol{a}, \qquad \text{for every vector } \boldsymbol{a}, \tag{1.1.15b}$$

$$\begin{aligned} \boldsymbol{1} &= \sum\sum \delta_{kl}\boldsymbol{u}_k\otimes\boldsymbol{u}_l = \boldsymbol{u}_1\otimes\boldsymbol{u}_1 + \boldsymbol{u}_2\otimes\boldsymbol{u}_2 + \boldsymbol{u}_3\otimes\boldsymbol{u}_3 && \text{(Dyadic form)} \\ &= (\delta_{kl}) = diagonal(1, 1, 1) && \text{(Matrix form)}, \\ &\Rightarrow Det\,\boldsymbol{1} = +1. \end{aligned} \tag{1.1.15c}$$

Diagonal tensor $\boldsymbol{D}$:

$$\begin{aligned}\boldsymbol{D} &= D_{11}\boldsymbol{u}_1 \otimes \boldsymbol{u}_1 + D_{22}\boldsymbol{u}_2 \otimes \boldsymbol{u}_2 + D_{33}\boldsymbol{u}_3 \otimes \boldsymbol{u}_3 \qquad \text{(Dyadic form)}\\ &= \mathit{diagonal}\ (D_{11}, D_{22}, D_{33}) \qquad \text{(Matrix form).} \qquad (1.1.15\text{d})\end{aligned}$$

If $D_{11} = D_{22}$, $\boldsymbol{D}$ reduces to

$$\boldsymbol{D} = D_{11}\boldsymbol{1} + (D_{33} - D_{11})\boldsymbol{u}_3 \otimes \boldsymbol{u}_3, \qquad (1.1.15\text{e})$$

a result that is useful in the representation of *moments of inertia of bodies of revolution*.

Alternator tensor $\boldsymbol{\varepsilon}$:

$$\boldsymbol{\varepsilon} = \sum\sum\sum \varepsilon_{klm}\, \boldsymbol{u}_k \otimes \boldsymbol{u}_l \otimes \boldsymbol{u}_m. \qquad (1.1.15\text{f})$$

It can be shown that

(i) $\quad \mathit{Det}\ \boldsymbol{T} \equiv |T_{kl}| = \sum\sum\sum\sum\sum\sum (1/6)\varepsilon_{klm}\varepsilon_{pqr} T_{kp} T_{lq} T_{mr}.$ (1.1.15g)

(ii) If $\boldsymbol{S}$ is *symmetric*, then $\boldsymbol{T} : \boldsymbol{S} = \boldsymbol{T}^{\mathrm{T}} : \boldsymbol{S} = (1/2)(\boldsymbol{T} + \boldsymbol{T}^{\mathrm{T}}) : \boldsymbol{S}$, (1.1.15h)

If $\boldsymbol{S}$ is *antisymmetric*, then $\boldsymbol{T} : \boldsymbol{S} = -(\boldsymbol{T}^{\mathrm{T}} : \boldsymbol{S}) = (1/2)(\boldsymbol{T} - \boldsymbol{T}^{\mathrm{T}}) : \boldsymbol{S}$, (1.1.15i)

If $\boldsymbol{S}$ is *symmetric* and $\boldsymbol{T}$ is *antisymmetric*, then $\boldsymbol{T} : \boldsymbol{S} = 0$. (1.1.15j)

(iii) If $\boldsymbol{T} : \boldsymbol{S} = 0$ for every tensor $\boldsymbol{S}$, then $\boldsymbol{T} = \boldsymbol{0}$, (1.1.15k)

If $\boldsymbol{T} : \boldsymbol{S} = 0$ for every *symmetric* tensor $\boldsymbol{S}$, then $\boldsymbol{T} = \mathit{antisymmetric}$, (1.1.15l)

If $\boldsymbol{T} : \boldsymbol{S} = 0$ for every *antisymmetric* tensor $\boldsymbol{S}$, then $\boldsymbol{T} = \mathit{symmetric}$. (1.1.15m)

Axial Vectors

There exists a one-to-one correspondence between antisymmetric tensors and vectors: given a (any) antisymmetric tensor $\boldsymbol{W}$—that is, $\boldsymbol{W} = -\boldsymbol{W}^{\mathrm{T}}$—there exists a unique vector $\boldsymbol{w}$, its *axial* (or *dual*) *vector* or *axis*, such that for every vector $\boldsymbol{a}$:

$$\boldsymbol{W} \cdot \boldsymbol{a} = \boldsymbol{w} \times \boldsymbol{a}; \qquad (1.1.16\text{a})$$

that is, (recalling the earlier definitions of products, etc.)

$$\boldsymbol{W} \cdot (\ldots) = (\boldsymbol{w} \times \boldsymbol{1}) \cdot (\ldots) = \boldsymbol{w} \times (\ldots) \qquad [\Rightarrow \boldsymbol{a} \cdot (\boldsymbol{W} \cdot \boldsymbol{a}) = 0]. \qquad (1.1.16\text{b})$$

And, conversely, given a vector $\boldsymbol{w}$, there exists a unique antisymmetric tensor $\boldsymbol{W}$, such that (1.1.16a,b) hold. In components, the above read:

$$w_k = -(1/2)\sum\sum \varepsilon_{klm} W_{lm} = (1/2)\sum\sum \varepsilon_{lkm} W_{lm}, \qquad (1.1.16\text{c})$$

$$W_{lm} = -\sum \varepsilon_{lmk} w_k = \sum \varepsilon_{lkm} w_k; \qquad (1.1.16\text{d})$$

or, in matrix form:

$$\boldsymbol{W} = (W_{lm}) = \left(\begin{array}{c|c|c} 0 & W_{12} = -w_3 & W_{13} = w_2 \\ \hline W_{21} = w_3 & 0 & W_{23} = -w_1 \\ \hline W_{31} = -w_2 & W_{32} = w_1 & 0 \end{array}\right). \qquad (1.1.16\text{e})$$

[Sometimes (especially in general indicial tensorial treatments) w_k is defined as the *negative of the above*; that is,

$$w_k = (1/2)\sum\sum \varepsilon_{klm} W_{lm} \;\Leftrightarrow\; W_{lm} = \sum \varepsilon_{lmk} w_k, \tag{1.1.16f}$$

or

$$\boldsymbol{W}\cdot\boldsymbol{a} = -\boldsymbol{w}\times\boldsymbol{a} = \boldsymbol{a}\times\boldsymbol{w}, \tag{1.1.16g}$$

and so, here too, the reader should be careful when comparing references.]

It can be shown that:

(i) The axial vector of a general *nonsymmetric* tensor equals the axial vector of its antisymmetric part; that is, the axial vector of its symmetric part (and, generally, of any symmetric tensor) vanishes; and, conversely, the vanishing of that vector shows that that tensor is symmetric.

(ii) The axial vector of $\boldsymbol{T}$, $\boldsymbol{t}$ (or $\boldsymbol{T}_{\mathrm{x}}$, or $\boldsymbol{t}_{\mathrm{x}}$), can be expressed as

$$\begin{aligned}-2\boldsymbol{t} &= (T_{23}-T_{32})\boldsymbol{u}_1 + (T_{31}-T_{13})\boldsymbol{u}_2 + (T_{12}-T_{21})\boldsymbol{u}_3\\ &= \boldsymbol{u}_1\times\boldsymbol{t}_1 + \boldsymbol{u}_2\times\boldsymbol{t}_2 + \boldsymbol{u}_3\times\boldsymbol{t}_3.\end{aligned} \tag{1.1.16h}$$

(iii) The axial vector of

$$\boldsymbol{W} = \sum\sum W_{kl}\,\boldsymbol{u}_k\otimes\boldsymbol{u}_l = \sum\sum (1/2)W_{kl}(\boldsymbol{u}_k\otimes\boldsymbol{u}_l - \boldsymbol{u}_l\otimes\boldsymbol{u}_k),$$

$\boldsymbol{w}$ has the following dyadic representation (note k, l order):

$$\boldsymbol{w} = \sum\sum\sum[-(1/2)\varepsilon_{rkl}W_{kl}]\boldsymbol{u}_r = \cdots = \sum\sum(1/2)W_{kl}(\boldsymbol{u}_l\times\boldsymbol{u}_k). \tag{1.1.16i}$$

(iv) Let $\boldsymbol{w} = w\boldsymbol{u}_1$. Then,

$$\boldsymbol{W} = w(\boldsymbol{u}_3\otimes\boldsymbol{u}_2 - \boldsymbol{u}_2\otimes\boldsymbol{u}_3), \qquad w = \boldsymbol{u}_3\cdot(\boldsymbol{W}\cdot\boldsymbol{u}_2); \tag{1.1.16j}$$

and cyclically for $\boldsymbol{w} = w\,\boldsymbol{u}_2$, $\boldsymbol{w} = w\,\boldsymbol{u}_3$.

(v) The antisymmetric part of the tensor $\boldsymbol{a}\otimes\boldsymbol{b}$ equals (in matrix form)

$$\begin{pmatrix} 0 & -w_3 & w_2\\ w_3 & 0 & -w_1\\ -w_2 & w_1 & 0\end{pmatrix}, \tag{1.1.16k}$$

where

$$\boldsymbol{w} = (1/2)\,\boldsymbol{b}\times\boldsymbol{a} \qquad \text{(note order).} \tag{1.1.16l}$$

(vi) The tensor $\boldsymbol{a}\otimes\boldsymbol{b} - \boldsymbol{b}\otimes\boldsymbol{a}$, where $\boldsymbol{a}$, $\boldsymbol{b}$ are arbitrary vectors, is antisymmetric; and, by the preceding, its axial vector is $\boldsymbol{b}\times\boldsymbol{a}$ (note order).

(vii) Let $\boldsymbol{w}_1$, $\boldsymbol{w}_2$ be the axial vectors of the antisymmetric tensors $\boldsymbol{W}_1$, $\boldsymbol{W}_2$, respectively. Then,

$$\boldsymbol{W}_1\cdot\boldsymbol{W}_2 = \boldsymbol{w}_2\otimes\boldsymbol{w}_1 - (\boldsymbol{w}_1\cdot\boldsymbol{w}_2)\boldsymbol{1}, \qquad Tr(\boldsymbol{W}_1\cdot\boldsymbol{W}_2) = -2(\boldsymbol{w}_1\cdot\boldsymbol{w}_2). \tag{1.1.16m}$$

$$\Rightarrow \boldsymbol{W}\cdot\boldsymbol{W} = \boldsymbol{w}\otimes\boldsymbol{w} - (\boldsymbol{w}\cdot\boldsymbol{w})\boldsymbol{1},\ \text{or}\ \boldsymbol{W}^2 = \boldsymbol{w}\otimes\boldsymbol{w} - w^2\boldsymbol{1}. \tag{1.1.16n}$$

Spectral Theory of Tensors

DEFINITION

A scalar λ is a *principal*, or *characteristic*, or *proper* value, or *eigenvalue*, of $\boldsymbol{T}$ if there exists a unit vector $\boldsymbol{n} = (n_1, n_2, n_3)$ such that

$$\boldsymbol{T} \cdot \boldsymbol{n} = \lambda \boldsymbol{n}, \qquad \text{or in components } \sum T_{kl} n_l = \lambda n_k. \tag{1.1.17a}$$

Then $\boldsymbol{n}$ is called a *principal*, or *characteristic*, or *proper*, or *eigen-direction* of $\boldsymbol{T}$ corresponding to that value of λ.

DEFINITION

The *principal*, or *characteristic*, or *proper*, or *eigen-space* of $\boldsymbol{T}$ corresponding to λ is the subspace of V consisting of *all* vectors $\boldsymbol{a}$ satisfying (1.1.17a): $\boldsymbol{T} \cdot \boldsymbol{a} = \lambda \boldsymbol{a}$; that is, *the subspace of all the eigenvectors of* $\boldsymbol{T}$.

If $\boldsymbol{T}$ is *positive definite*—that is, if $\boldsymbol{a} \cdot (\boldsymbol{T} \cdot \boldsymbol{a}) > 0$ for all $\boldsymbol{a} \neq \boldsymbol{0}$—then its eigenvalues are *strictly positive*.

THEOREM OF SPECTRAL DECOMPOSITION (of $\boldsymbol{T}$)

If $\boldsymbol{T} = \boldsymbol{T}^{\mathrm{T}}$ (i.e., *symmetric*), there exists an *orthonormal* basis $\{\boldsymbol{n}_1, \boldsymbol{n}_2, \boldsymbol{n}_3\}$ for V and three real, but not necessarily distinct, eigenvalues λ_1, λ_2, λ_3 of $\boldsymbol{T}$ such that

$$\boldsymbol{T} \cdot \boldsymbol{n}_k = \lambda_k \boldsymbol{n}_k \qquad (k = 1, 2, 3;\ \text{no sum}), \tag{1.1.17b}$$

and

$$\begin{aligned} \boldsymbol{T} = \boldsymbol{T} \cdot \boldsymbol{1} = \boldsymbol{T} \cdot \left(\sum \boldsymbol{n}_k \otimes \boldsymbol{n}_k \right) &= \sum (\boldsymbol{T} \cdot \boldsymbol{n}_k) \otimes \boldsymbol{n}_k \\ &= \sum \lambda_k (\boldsymbol{n}_k \otimes \boldsymbol{n}_k) \qquad (\textit{Dyadic} \text{ representation}) \\ &= \textit{diagonal}(\lambda_1, \lambda_2, \lambda_3) \qquad (\textit{Matrix} \text{ representation}); \end{aligned} \tag{1.1.17c}$$

$$\Rightarrow \boldsymbol{n}_k \cdot (\boldsymbol{T} \cdot \boldsymbol{n}_l) = \boldsymbol{T} \cdot \boldsymbol{n}_k \cdot \boldsymbol{n}_l = \lambda_k\, \delta_{kl}\, (= \lambda_k \text{ or } 0, \text{ according as } k = l \text{ or } k \neq l);$$

that is, with

$$\begin{aligned} \boldsymbol{n}_k &= (n_{(k)l}\text{: components of } \boldsymbol{n}_k), \\ T_{kl} &= \lambda_1 n_{(1)k} n_{(1)l} + \lambda_2 n_{(2)k} n_{(2)l} + \lambda_3 n_{(3)k} n_{(3)l}. \end{aligned} \tag{1.1.17d}$$

Conversely, if $\boldsymbol{T} = \sum \lambda_k (\boldsymbol{n}_k \otimes \boldsymbol{n}_k)$, with $\{\boldsymbol{n}_k\} =$ orthonormal, then $\boldsymbol{T} \cdot \boldsymbol{n}_k = \lambda_k \boldsymbol{n}_k$ (no sum).

Depending on the relative sizes of the three eigenvalues, we distinguish the following *three* cases:

(i) If λ_1, λ_2, $\lambda_3 =$ *distinct*, then the eigendirections of $\boldsymbol{T}$ are the three mutually orthogonal lines, through the origin, spanned by $\boldsymbol{n}_1$, $\boldsymbol{n}_2$, $\boldsymbol{n}_3$.

(ii) If $\lambda_1 \neq \lambda_2 = \lambda_3$ (i.e., *two* distinct eigenvalues), then the spectral decomposition (1.1.17c) reduces to the following (with $|\boldsymbol{n}_1| = 1$):

$$\boldsymbol{T} = \lambda_1 (\boldsymbol{n}_1 \otimes \boldsymbol{n}_1) + \lambda_2 (\boldsymbol{1} - \boldsymbol{n}_1 \otimes \boldsymbol{n}_1). \tag{1.1.17e}$$

Conversely, if (1.1.17e) holds with $\lambda_1 \neq \lambda_2 = \lambda_3$, then λ_1 and λ_2 are the sole distinct eigenvalues of $\boldsymbol{T}$; which, in this case, has the *two* distinct eigenspaces: (a) the *line* spanned by $\boldsymbol{n}_1$, and (b) the *plane* perpendicular to $\boldsymbol{n}_1$.

(iii) If $\lambda_1 = \lambda_2 = \lambda_3 = \lambda$, in which case

$$\begin{aligned} \boldsymbol{T} = \lambda \boldsymbol{1} &= \lambda(\boldsymbol{n}_1 \otimes \boldsymbol{n}_1 + \boldsymbol{n}_2 \otimes \boldsymbol{n}_2 + \boldsymbol{n}_3 \otimes \boldsymbol{n}_3) \qquad (\textit{Dyadic}\text{ representation}) \\ &= \textit{diagonal}(\lambda, \lambda, \lambda) \qquad (\textit{Matrix}\text{ representation}), \end{aligned} \tag{1.1.17f}$$

then the eigenspace of $\boldsymbol{T}$ is the entire space V. Conversely, if V is the eigenspace of $\boldsymbol{T}$, then $\boldsymbol{T}$ has the form (1.1.17f). [For extensions of the theorem to *polynomial functions of* $\boldsymbol{T}$ see books on linear algebra; also Bradbury (1968, pp. 113–116).] The requirement of nontrivial solutions for $\boldsymbol{n}$, in (1.1.17a), leads, in well-known ways, to the *characteristic* (polynomial) equation for $\boldsymbol{T}$:

$$-\,Det(\boldsymbol{T} - \lambda\boldsymbol{1}) = Det(\lambda\boldsymbol{1} - \boldsymbol{T}) \equiv D(\lambda) \equiv \lambda^3 - I_1\lambda^2 + I_2\lambda - I_3 = 0, \tag{1.1.18a}$$

where the coefficients, or *principal invariants* of $\boldsymbol{T}$ (i.e., quantities independent of the choice of the basis used for the representation of $\boldsymbol{T}$), are given by

$$\begin{aligned} I_1(\boldsymbol{T}) &\equiv I_1 \equiv Tr(\boldsymbol{T}) = \sum T_{kk} = \lambda_1 + \lambda_2 + \lambda_3, \\ I_2(\boldsymbol{T}) &\equiv I_2 \equiv (1/2)[(Tr\,\boldsymbol{T})^2 - Tr(\boldsymbol{T}^2)] \\ &= (1/2)\Big[\Big(\sum T_{kk}\Big)\Big(\sum T_{ll}\Big) - \Big(\sum\sum T_{kl}T_{lk}\Big)\Big] = \lambda_1\lambda_2 + \lambda_1\lambda_3 + \lambda_2\lambda_3, \\ I_3(\boldsymbol{T}) &\equiv I_3 \equiv Det\,\boldsymbol{T} = |T_{kl}| = \sum\sum\sum \varepsilon_{klm} T_{k1}T_{l2}T_{m3} = \lambda_1\lambda_2\lambda_3 \\ &= (1/6)\Big[(Tr\,\boldsymbol{T})^3 - 3(Tr\,\boldsymbol{T})(Tr\,\boldsymbol{T}^2) + 2\,Tr(\boldsymbol{T}^3)\Big]; \end{aligned} \tag{1.1.18b}$$

also

$$I_1{}^2 - 2I_2 = \lambda_1{}^2 + \lambda_2{}^2 + \lambda_3{}^2 = Tr(\boldsymbol{T}^2). \tag{1.1.18c}$$

[(a) It is shown in linear algebra/matrix theory that:

- In general, that is, $\boldsymbol{T} = \textit{nonsymmetric}$, eq. (1.1.18a) has either *three real roots*; or *one real* and *two complex* (*conjugate*) *roots*.
- Every tensor $\boldsymbol{T}$ satisfies its own characteristic equation; that is, eq. (1.1.18a) with λ replaced by $\boldsymbol{T}$: $\boldsymbol{T}^3 - I_1\boldsymbol{T}^2 + I_2\boldsymbol{T} - I_3\boldsymbol{1} = \boldsymbol{0}$ (*Cayley–Hamilton* theorem). And, more generally, if $f(\lambda) = \textit{real}$ polynomial in an eigenvalue λ of $\boldsymbol{T}$, then $f(\lambda)$ is an eigenvalue of $f(\boldsymbol{T})$; and, an eigenvector of $\boldsymbol{T}$ corresponding to λ is also an eigenvector of $f(\boldsymbol{T})$ corresponding to $f(\lambda)$.

(b) The above show that $Tr\,\boldsymbol{T}$, $Tr(\boldsymbol{T}^2)$, $Tr(\boldsymbol{T}^3)$ may also be considered as principal invariants of $\boldsymbol{T}$.]

Further, it can be shown, that:

(i) If $\boldsymbol{N}_{1,2,3}$ are the antisymmetric tensors whose axial vectors are, respectively, the three orthonormal eigenvectors of (the *symmetric* tensor) $\boldsymbol{T}$: $\boldsymbol{n}_{1,2,3}$, then $\boldsymbol{T}$ has, in addition to (1.1.17c), the following spectral decomposition:

$$\boldsymbol{T} = \lambda_1(\boldsymbol{N}_1 \cdot \boldsymbol{N}_1) + \lambda_2(\boldsymbol{N}_2 \cdot \boldsymbol{N}_2) + \lambda_3(\boldsymbol{N}_3 \cdot \boldsymbol{N}_3) + Tr(\boldsymbol{T})\boldsymbol{1}; \tag{1.1.18d}$$

and, therefore, for an arbitrary vector $\boldsymbol{a}$,

$$\boldsymbol{T}\cdot\boldsymbol{a} = \lambda_1(\boldsymbol{N}_1\cdot\boldsymbol{N}_1)\cdot\boldsymbol{a} + \lambda_2(\boldsymbol{N}_2\cdot\boldsymbol{N}_2)\cdot\boldsymbol{a} + \lambda_3(\boldsymbol{N}_3\cdot\boldsymbol{N}_3)\cdot\boldsymbol{a} + Tr(\boldsymbol{T})\boldsymbol{a}; \tag{1.1.18e1}$$

also,

$$Tr(\boldsymbol{N}_1\cdot\boldsymbol{N}_1) = Tr(\boldsymbol{N}_2\cdot\boldsymbol{N}_2) = Tr(\boldsymbol{N}_3\cdot\boldsymbol{N}_3) = -2. \tag{1.1.18e2}$$

(ii) If $\boldsymbol{a} =$ *axial vector* of $\boldsymbol{A}$, then

$$\boldsymbol{T}\cdot\boldsymbol{a} = \textit{axial vector} \text{ of } [-(\boldsymbol{T}\cdot\boldsymbol{A} + \boldsymbol{A}\cdot\boldsymbol{T}) + Tr(\boldsymbol{T})\boldsymbol{A}]. \tag{1.1.18f}$$

(iii) The principal invariants of

$$\boldsymbol{T} = \sum\sum T_{kl}\boldsymbol{u}_k\otimes\boldsymbol{u}_l = \sum \boldsymbol{u}_k\otimes\boldsymbol{t}_k, \qquad \text{where} \quad \boldsymbol{t}_k \equiv \sum T_{kl}\boldsymbol{u}_l, \tag{1.1.18g}$$

can be expressed as

$$I_1 = \boldsymbol{u}_1\cdot\boldsymbol{t}_1 + \boldsymbol{u}_2\cdot\boldsymbol{t}_2 + \boldsymbol{u}_3\cdot\boldsymbol{t}_3, \tag{1.1.18h}$$

$$I_2 = \boldsymbol{u}_1\cdot(\boldsymbol{t}_2\times\boldsymbol{t}_3) + \boldsymbol{u}_2\cdot(\boldsymbol{t}_3\times\boldsymbol{t}_1) + \boldsymbol{u}_3\cdot(\boldsymbol{t}_1\times\boldsymbol{t}_2), \tag{1.1.18i}$$

$$I_3 = \boldsymbol{t}_1\cdot(\boldsymbol{t}_2\times\boldsymbol{t}_3). \tag{1.1.18j}$$

(iv) The principal invariants of an *antisymmetric* tensor $\boldsymbol{W}$ are

$$I_1 = Tr\,\boldsymbol{W} = 0, \tag{1.1.18k}$$

$$\begin{aligned} I_2 &= {W_{23}}^2 + {W_{31}}^2 + {W_{12}}^2 \\ &= (-w_1)^2 + (-w_2)^2 + (-w_3)^2 = {w_1}^2 + {w_2}^2 + {w_3}^2, \end{aligned} \tag{1.1.18l}$$

$$I_3 = Det\,\boldsymbol{W} = 0 \qquad \left[|\boldsymbol{w}|^2 = w^2 = (\textit{axial vector} \text{ of } \boldsymbol{W})^2\right]; \tag{1.1.18m}$$

from which, and from (1.1.18a), we can deduce that $\boldsymbol{W}$ has a *single* real eigenvalue $\lambda = 0$.

(v) If $\boldsymbol{T}$ is a *symmetric* and *positive definite* tensor with ($\Rightarrow$ positive) eigenvalues, then

$$Det\,\boldsymbol{T} > 0 \quad (\text{i.e., } \boldsymbol{T} \text{ is invertible}), \qquad \boldsymbol{T}^{-1} = \sum {\lambda_k}^{-1}(\boldsymbol{n}_k\otimes\boldsymbol{n}_k). \tag{1.1.18n}$$

(vi) If $\boldsymbol{T}$ is an invertible tensor, and the characteristic equation of $\boldsymbol{T}^{-1}$ is

$$Det(\boldsymbol{T}^{-1} - \mu\boldsymbol{1}) = 0 \;\Rightarrow\; \mu^3 - {I'}_1\mu^2 + {I'}_2\mu - {I'}_3 = 0, \tag{1.1.18o}$$

then

$$\mu = 1/\lambda; \text{ i.e., the eigenvalues of } \boldsymbol{T}^{-1} \text{ are the inverse of those of } \boldsymbol{T}, \tag{1.1.18p}$$

$${I'}_1 = I_2/I_3, \qquad {I'}_2 = I_1/I_3, \qquad {I'}_3 = 1/I_3, \tag{1.1.18q}$$

$$\boldsymbol{T}^{-1} = (\boldsymbol{T}^2 - I_1\boldsymbol{T} + I_2\boldsymbol{1})/I_3. \tag{1.1.18r}$$

Orthogonal Transformations

A tensor $\boldsymbol{T}$ is called *orthogonal* (or *length-preserving*) if it satisfies

$$\boldsymbol{T}\cdot\boldsymbol{T}^{\mathrm{T}} = \boldsymbol{T}^{\mathrm{T}}\cdot\boldsymbol{T} = \boldsymbol{1} \;\Rightarrow\; \boldsymbol{T}^{-1} = \boldsymbol{T}^{\mathrm{T}}; \tag{1.1.19a}$$

or, in components,

$$\sum T_{kl}(\boldsymbol{T}^{\mathrm{T}})_{lr} = \sum T_{kl}T_{rl} = \delta_{kr}, \tag{1.1.19b}$$

$$\sum (\boldsymbol{T}^{\mathrm{T}})_{kl}T_{lr} = \sum T_{lk}T_{lr} = \delta_{kr}; \tag{1.1.19c}$$

from which, since $Det\,\boldsymbol{T} = Det\,\boldsymbol{T}^{\mathrm{T}}$ (always), and $Det(\boldsymbol{T}\cdot\boldsymbol{T}^{\mathrm{T}}) = (Det\,\boldsymbol{T})(Det\,\boldsymbol{T}^{\mathrm{T}})$ and $Det\,\boldsymbol{1} = 1$, it follows that

$$(Det\,\boldsymbol{T})^2 = 1 \;\Rightarrow\; Det\,\boldsymbol{T} = \pm 1. \tag{1.1.19d}$$

THEOREM

The set of all orthogonal tensors forms the (full) *orthogonal group*; and the set of all orthogonal tensors with $Det\,\boldsymbol{T} = +1$ forms the *proper* orthogonal (sub) group.

THEOREM (transformation of bases and preservation of their dextrality)

If $\boldsymbol{A} = (A_{k'k} = A_{kk'})$ is a proper orthogonal tensor, or a *rotation*, and the basis $\{\boldsymbol{u}_k;\ k = 1,2,3\}$ is ortho–normal–dextral (OND), the new basis $\{\boldsymbol{u}_{k'};\ k' = 1,2,3\}$ defined by

$$\boldsymbol{u}_{k'} = \sum A_{k'k}\boldsymbol{u}_k \;\Leftrightarrow\; \boldsymbol{u}_k = \sum A_{kk'}\boldsymbol{u}_{k'} \tag{1.1.19e}$$

is also OND. Conversely, if both $\{\boldsymbol{u}_k\}$ and $\{\boldsymbol{u}_{k'}\}$ are OND, then there exists a unique proper orthogonal tensor such that (1.1.19e) holds. It is not hard to see that

$$A_{k'k} = \cos(\boldsymbol{u}_{k'}, \boldsymbol{u}_k) = \cos(\boldsymbol{u}_k, \boldsymbol{u}_{k'}) = A_{kk'}; \tag{1.1.19f}$$

and in this *commutativity* of the indices lies one of the advantages of the non-accented/accented index notation: one does not have to worry about their *order*. [In a *matrix* representation: $\mathbf{A} = (A_{k'k})$, k': rows, k: columns; $\mathbf{A}^{\mathrm{T}} = (A_{kk'})$, k: rows, k': columns; where (in general): $A_{1'2} = A_{21'} \neq A_{2'1} = A_{12'}$ etc.] Also, in view of the earlier orthonormality conditions (or constraints):

$$\boldsymbol{u}_{k'}\cdot\boldsymbol{u}_{l'} = \delta_{k'l'} \qquad \text{and} \qquad \boldsymbol{u}_k\cdot\boldsymbol{u}_l = \delta_{kl}, \tag{1.1.19g}$$

[which, due to (1.1.19e) are none other than (1.1.19a): $\boldsymbol{A}\cdot\boldsymbol{A}^{\mathrm{T}} = \boldsymbol{A}^{\mathrm{T}}\cdot\boldsymbol{A} = \boldsymbol{1}$] only *three* of the *nine* elements (direction cosines) of $\boldsymbol{A}$ are independent.

- For a *vector* $\boldsymbol{a}$, we have the following component representations in $\{\boldsymbol{u}_k\}$, $\{\boldsymbol{u}_{k'}\}$:

$$\boldsymbol{a} = \sum a_k\boldsymbol{u}_k = \sum a_{k'}\boldsymbol{u}_{k'}; \tag{1.1.19h}$$

and from this, using the *basis transformation equations* (1.1.19e), we readily obtain the corresponding *component transformation equations*:

$$a_{k'} = \sum A_{k'k}a_k = \sum A_{kk'}a_k \;\Leftrightarrow\; a_k = \sum A_{kk'}a_{k'} = \sum A_{k'k}a_{k'}. \tag{1.1.19i}$$

- *Polar versus axial vectors*: In general tensor algebra, the word axial (vector, tensor) is frequently used in the following broader sense:

(a) Vectors that transform as (1.1.19i) under any/all orthogonal transformations $\{\boldsymbol{u}_k\} \Leftrightarrow \{\boldsymbol{u}_{k'}\}$ *proper or not*, are called *polar* (or *genuine*); whereas,

(b) Vectors that, under such transformations, transform as

$$a_{k'} = (Det\,\boldsymbol{A})^{-1} \sum A_{k'k} a_k = (Det\,\boldsymbol{A}) \sum A_{k'k} a_k \;\Leftrightarrow$$
$$a_k = (Det\,\boldsymbol{A}^{-1})^{-1} \sum A_{kk'} a_{k'} = (Det\,\boldsymbol{A}^{\mathrm{T}})^{-1} \sum A_{kk'} a_{k'} = (Det\,\boldsymbol{A}) \sum A_{kk'} a_{k'},$$

are called *axial* (or *pseudo*-) vectors. Hence, under a change from a right-hand system to a left-hand system (a reflection), in which case $Det\,\boldsymbol{A} = Det(A_{k'k}) = -1$, the components of the axial vectors are unaffected; while those of polar vectors are multiplied by -1. Since only proper orthogonal transformations are used in this book, this difference disappears—*all our vectors will be polar*, *in that sense*. This polar/axial distinction is of importance in other areas of physics; for example, relativity, electrodynamics (see, e.g., Bergmann, 1942, p. 56; Malvern, 1969, pp. 25–29).

• Every orthogonal tensor is either a *rotation*, $\boldsymbol{A} \to \boldsymbol{R}$, or the product of a rotation with $-\boldsymbol{1}$; that is, $\boldsymbol{R}$ or $-\boldsymbol{1} \cdot \boldsymbol{R}$ ($\boldsymbol{1}$: 3×3 unit tensor).

• The eigenvectors of $\boldsymbol{R}$ — that is, the set of vectors satisfying $\boldsymbol{R} \cdot \boldsymbol{x} = \boldsymbol{x}$ ($\boldsymbol{R} \neq \boldsymbol{1}$) — build a *one-dimensional* subspace of V called the *axis* (*of rotation*) of $\boldsymbol{R}$.

• Under $\{\boldsymbol{u}_k\} \Leftrightarrow \{\boldsymbol{u}_{k'}\}$ transformations, the components of a tensor $\boldsymbol{T} = (T_{kl}) = (T_{k'l'})$ transform as follows:

$$T_{k'l'} = \sum\sum A_{k'k} A_{l'l} T_{kl} = \sum\sum A_{kk'} A_{ll'} T_{kl}, \tag{1.1.19j}$$
$$T_{kl} = \sum\sum A_{kk'} A_{ll'} T_{k'l'} = \sum\sum A_{k'k} A_{l'l} T_{k'l'}; \tag{1.1.19k}$$

or, in *matrix* form (also shown, frequently, in bold but *roman*),

$$\text{(1.1.19j)}: (T_{k'l'}) = (A_{k'k})(T_{kl})(A_{ll'}) \qquad \text{or} \qquad \boldsymbol{T}' = \boldsymbol{A} \cdot \boldsymbol{T} \cdot \boldsymbol{A}^{\mathrm{T}}, \tag{1.1.19l}$$
$$\text{(1.1.19k)}: (T_{kl}) = (A_{kk'})(T_{k'l'})(A_{l'l}) \qquad \text{or} \qquad \boldsymbol{T} = \boldsymbol{A}^{\mathrm{T}} \cdot \boldsymbol{T}' \cdot \boldsymbol{A}. \tag{1.1.19m}$$

[(a) Here, $\boldsymbol{T}'$ should not be confused with the symmetrical part of $\boldsymbol{T}$, (1.1.13a, b). The precise meaning should be clear from the context.

(b) We do not see much advantage of (1.1.19l,m) over (1.1.19j,k), especially as a working tool in new and nontrivial situations. However, (1.1.19l,m) could be useful once the general theory has been thoroughly understood and is about to be applied to a concrete/numerical problem.]

It can be shown that:

(i) If $\boldsymbol{W}$ is antisymmetric, then
  (a) $\boldsymbol{1} + \boldsymbol{W}$ is *nonsingular*; that is, $Det(\boldsymbol{1} + \boldsymbol{W}) \neq 0$; and
  (b) $(\boldsymbol{1} - \boldsymbol{W}) \cdot (\boldsymbol{1} + \boldsymbol{W})^{-1}$ is *orthogonal*
  (a result useful in rigid-body rotations). (1.1.19n)

(ii) If O–$\boldsymbol{u}_{123}$ and O–$\boldsymbol{u}_{1'2'3'}$ originally coincide, then the rotation tensor of a counterclockwise (positive) rotation of O–$\boldsymbol{u}_{123}$ through an angle ϕ about $\boldsymbol{u}_3 = \boldsymbol{u}_{3'}$ has the matrix form (with $c\phi \equiv \cos\phi, s\phi \equiv \sin\phi$):

$$\boldsymbol{A} \to \boldsymbol{R} = \begin{pmatrix} c\phi & -s\phi & 0 \\ s\phi & c\phi & 0 \\ 0 & 0 & 1 \end{pmatrix}. \tag{1.1.19o}$$

Moving Axes Theorems for Vectors and Tensors

Let us consider the following representation of a vector $\boldsymbol{a}$ and a tensor $\boldsymbol{T}$, measured relative to inertial, or *fixed*, OND axes $\{\boldsymbol{u}_{k'}\}$, but expressed in terms of their components along (also OND) *moving* axes $\{\boldsymbol{u}_k\}$ rotating with *angular velocity* $\boldsymbol{\omega}$ relative to $\{\boldsymbol{u}_{k'}\}$:

$$\boldsymbol{a} = \sum a_k \boldsymbol{u}_k, \qquad \boldsymbol{T} = \sum\sum T_{kl} \boldsymbol{u}_k \otimes \boldsymbol{u}_l. \tag{1.1.20a}$$

Let us calculate their inertial rates of change [i.e., relative to the fixed axes, $d\boldsymbol{a}/dt$, $d\boldsymbol{T}/dt$ ($t = t'$: time)], but in terms of their moving axes representations (1.1.20a) and *their* rates of change.

(i) By $d(\ldots)/dt$-differentiating the first of (1.1.20a) and invoking the fundamental kinematical result (most likely known from undergraduate dynamics)—a result which, along with the concept of angular velocity, is detailed in §1.7:

$$d\boldsymbol{u}_k/dt = \boldsymbol{\omega} \times \boldsymbol{u}_k, \tag{1.1.20b}$$

we obtain

$$d\boldsymbol{a}/dt = \sum [(da_k/dt)\,\boldsymbol{u}_k + a_k(\boldsymbol{\omega} \times \boldsymbol{u}_k)] = \partial\boldsymbol{a}/\partial t + \boldsymbol{\omega} \times \boldsymbol{a}, \tag{1.1.20c}$$

where

$$\partial\boldsymbol{a}/\partial t \equiv \sum (da_k/dt)\boldsymbol{u}_k\text{: rate of change of } \boldsymbol{a} \text{ relative to the moving axes.} \tag{1.1.20d}$$

(ii) Repeating this process for the second of (1.1.20a) we obtain

$$\begin{aligned} d\boldsymbol{T}/dt &= \sum\sum \left\{(dT_{kl}/dt)\boldsymbol{u}_k \otimes \boldsymbol{u}_l + T_{kl}[(\boldsymbol{\omega} \times \boldsymbol{u}_k) \otimes \boldsymbol{u}_l + \boldsymbol{u}_k \otimes (\boldsymbol{\omega} \times \boldsymbol{u}_l)]\right\} \\ &= \partial\boldsymbol{T}/\partial t + \boldsymbol{\omega} \times \boldsymbol{T} - \boldsymbol{T} \times \boldsymbol{\omega}, \end{aligned} \tag{1.1.20e}$$

where

$$\begin{aligned} \partial\boldsymbol{T}/\partial t \equiv \sum (dT_{kl}/dt)\boldsymbol{u}_k \otimes \boldsymbol{u}_l&\text{: rate of change of } \boldsymbol{T} \text{ relative to the moving axes} \\ &\text{(or } \textit{Jaumann}\text{, or } \textit{corotational}\text{, derivative of } \boldsymbol{T}\text{).} \end{aligned} \tag{1.1.20f}$$

Recalling the earlier results on the algebra of vectors/tensors and axial vectors [eqs (1.1.12), (1.1.14), (1.1.16)] we can rewrite (1.1.20c,e) in $\boldsymbol{u}_k$-components as follows:

$$\begin{aligned} &\text{(i)} \quad (d\boldsymbol{a}/dt)_k = da_k/dt + (\boldsymbol{\omega} \times \boldsymbol{a})_k \qquad (\neq da_k/dt) \\ &\qquad = da_k/dt + \sum\sum \varepsilon_{krs}\,\omega_r a_s = da_k/dt + \sum \Omega_{ks} a_s, \qquad (1.1.20\text{g}) \\ &\text{(ii)} \quad (d\boldsymbol{T}/dt)_{kl} = (\partial\boldsymbol{T}/\partial t)_{kl} + (\boldsymbol{\omega} \times \boldsymbol{T})_{kl} - (\boldsymbol{T} \times \boldsymbol{\omega})_{kl} \\ &\qquad = dT_{kl}/dt + \sum\sum \varepsilon_{krs}\,\omega_r T_{sl} - \sum\sum \varepsilon_{lrs}\,\omega_s T_{kr} \\ &\qquad = dT_{kl}/dt + \sum \Omega_{ks} T_{sl} + \sum \Omega_{lr} T_{kr} \end{aligned}$$

[after some index renaming in the last (third) group of terms, and noting that $\Omega_{ls} = -\Omega_{sl}$]

$$= dT_{kl}/dt + \sum \Omega_{ks} T_{sl} - \sum T_{ks}\Omega_{sl}, \tag{1.1.20h}$$

where

$\boldsymbol{\Omega} = \sum\sum \Omega_{kl}\boldsymbol{u}_k \otimes \boldsymbol{u}_l$: *moving axes* representation of *angular velocity tensor* (of these axes relative to the fixed ones); i.e., antisymmetric tensor whose axial vector is $\boldsymbol{\omega}$: $\boldsymbol{\Omega}\cdot\boldsymbol{a} = \boldsymbol{\omega}\times\boldsymbol{a}$,

in components:

$$\omega_k = -(1/2)\sum\sum \varepsilon_{krs}\Omega_{rs} \Leftrightarrow \Omega_{rs} = -\sum \varepsilon_{krs}\omega_k\,. \tag{1.1.20i}$$

Thus, in dyadic/matrix notation (see table 1.1), eq. (1.1.20e) reads

$$d\boldsymbol{T}/dt = \partial\boldsymbol{T}/\partial t + \boldsymbol{\Omega}\cdot\boldsymbol{T} - \boldsymbol{T}\cdot\boldsymbol{\Omega} \tag{1.1.20j}$$

$$[\,= \partial\boldsymbol{T}/\partial t + \boldsymbol{\Omega}\cdot\boldsymbol{T} + (\boldsymbol{\Omega}\cdot\boldsymbol{T})^{\mathrm{T}}, \qquad \text{if } \boldsymbol{T} = \boldsymbol{T}^{\mathrm{T}}]. \tag{1.1.20k}$$

REMARKS

(i) Overdots, like $(\ldots)^{\cdot}$, are unambiguous only when applied to well-defined *components* of vectors/tensors; that is, $\dot{a}_k$, $\dot{a}_{k'}$, $\dot{T}_{kl}$, $\dot{T}_{k'l'}, \ldots$; *not* when applied to their *direct* or *dyadic*, and/or *matrix* representations; that is, does $\dot{\boldsymbol{a}}$ mean $d\boldsymbol{a}/dt$ or $\partial\boldsymbol{a}/\partial t$? This is a common source of confusion in rigid-body dynamics.

(ii) We hope that this has convinced the reader of the superiority of the *indicial* notation over the (currently popular but nevertheless cumbersome and after-the-factish) *dyadic/matrix* notations.

Coordinate Transformations versus Frame of Reference Transformations

See also §1.2, §1.5. Let $\boldsymbol{a}'$ and $\boldsymbol{a}$ be the values of a vector as measured, respectively, in the *fixed* (inertial) and *moving* (noninertial) frames. Then [recalling (1.1.19e–i)], we have

Inertial: $$\boldsymbol{a}' = \sum a'_k\boldsymbol{u}_k = \sum a'_{k'}\boldsymbol{u}_{k'}; \tag{1.1.20l}$$

$$\Rightarrow a'_{k'} = \sum A_{k'k}a'_k \Leftrightarrow a'_k = \sum A_{kk'}a'_{k'} \ \ (\text{definition of } a'_{k'}, a'_k) \tag{1.1.20m}$$

Noninertial: $$\boldsymbol{a} = \sum a_k\boldsymbol{u}_k = \sum a_{k'}\boldsymbol{u}_{k'}; \tag{1.1.20n}$$

$$\Rightarrow a_{k'} = \sum A_{k'k}a_k \Leftrightarrow a_k = \sum A_{kk'}a_{k'} \quad (\text{definition of } a_{k'}, a_k). \tag{1.1.20o}$$

Table 1.1 Common Tensor Notations

Direct/Dyadic	Matrix	Indicial/Component
$\boldsymbol{a}\cdot\boldsymbol{b} = \boldsymbol{b}\cdot\boldsymbol{a}$ (Dot product)	$\mathbf{a}^{\mathrm{T}}\cdot\mathbf{b} = \mathbf{b}^{\mathrm{T}}\cdot\mathbf{a}$	$\sum a_k b_k$
$\boldsymbol{T} = \boldsymbol{a}\otimes\boldsymbol{b}$ (Outer product)	$\mathbf{T} = \mathbf{a}\cdot\mathbf{b}^{\mathrm{T}}$	$T_{kl} = a_k b_l$
$\boldsymbol{b} = \boldsymbol{T}\cdot\boldsymbol{a}$	$\mathbf{b} = \mathbf{T}\cdot\mathbf{a}$	$b_k = \sum T_{kl}a_l$
$\boldsymbol{b} = \boldsymbol{a}\cdot\boldsymbol{T}$	$\mathbf{b}^{\mathrm{T}} = \mathbf{a}^{\mathrm{T}}\cdot\mathbf{T}$ or $\mathbf{b} = \mathbf{T}^{\mathrm{T}}\cdot\mathbf{a}$	$b_k = \sum a_l T_{lk}$
$\boldsymbol{a}\cdot\boldsymbol{T}\cdot\boldsymbol{b}$ (Bilinear form)	$\mathbf{a}^{\mathrm{T}}\cdot\mathbf{T}\cdot\mathbf{b}$	$\sum\sum T_{kl}a_k b_l$
$\boldsymbol{T}\cdot\boldsymbol{S}$ (Tensor product)	$\mathbf{T}\cdot\mathbf{S}$	$\sum T_{kr}S_{rl}$
$\boldsymbol{T}\cdot\boldsymbol{S}^{\mathrm{T}}$ (Tensor product)	$\mathbf{T}\cdot\mathbf{S}^{\mathrm{T}}$	$\sum T_{kr}S_{lr}$
$\boldsymbol{T}:\boldsymbol{S} = \boldsymbol{S}:\boldsymbol{T}$ (Dot product)	$\mathrm{Tr}(\mathbf{T}\cdot\mathbf{S}^{\mathrm{T}}) = \mathrm{Tr}(\mathbf{S}\cdot\mathbf{T}^{\mathrm{T}})$	$\sum\sum T_{kl}S_{kl}$
$\boldsymbol{T}\cdot\cdot\boldsymbol{S} = \boldsymbol{S}\cdot\cdot\boldsymbol{T}$ (Dot product)	$\mathrm{Tr}(\mathbf{T}\cdot\mathbf{S}) = \mathrm{Tr}(\mathbf{S}\cdot\mathbf{T})$	$\sum\sum T_{kl}S_{lk}$

Note: In *matrix* notation, the *product dot* is, frequently, omitted.

However, to relate the *noninertial* components $a_{k'}$, a_k to the *inertial* components $a'_{k'}$, a'_k, say, to be able to write something like

$$a_k = a'_k \Leftrightarrow a_{k'} = a'_{k'}, \tag{1.1.20p}$$

we need *additional* assumptions (postulates) or derivations—eqs. (1.1.20p) express frame of reference (*physical*) transformations; that is, they do *not* follow from eqs. (1.1.20m,o), which are simply coordinate system (*geometrical/projection*) transformations; (1.1.20p) have to be either postulated or derived from these postulates! Mathematically, a frame of reference transformation is equivalent to an *explicitly time-dependent* transformation between coordinate systems representing the two frames: $x_{k'} = x_{k'}(x_k, t) \Leftrightarrow x_k = x_k(x_{k'}, t)$, while an ordinary coordinate transformation is explicitly time-independent: $x_{k'} = x_{k'}(x_k) \Leftrightarrow x_k = x_k(x_{k'})$.

For example, let us consider an inertial frame represented by the (fixed) axes O–$x_{k'}$ and a noninertial one represented by the (moving) axes O–x_k, related by the homogeneous transformation (common origin!)

$$x_{k'} = \sum A_{k'k} x_k \Leftrightarrow x_k = \sum A_{kk'} x_{k'}, \tag{1.1.20q}$$

where

$$A_{k'k} = A_{kk'} = A_{k'k}(t).$$

Clearly, from geometry [i.e., (1.1.20p)-type postulates]:

$$x'_{k'} = x_{k'}, \qquad x'_k = x_k. \tag{1.1.20r}$$

By $(\ldots)^{\cdot}$-differentiating the first of (1.1.20q), and since $dx'_{k'}/dt = dx_{k'}/dt \equiv v'_{k'}$: inertial velocity of particle (with inertial coordinates $x_{k'}$) resolved along inertial axes, $dx'_k/dt = dx_k/dt \equiv v_k$: noninertial velocity of same particle (with noninertial coordinates x_k) resolved along noninertial axes, we get

$$v'_{k'} = \sum A_{k'k} v_k + \sum (dA_{k'k}/dt) x_k = v_{k'} + \sum (dA_{k'k}/dt) x_k, \tag{1.1.20s}$$

[invoking (1.1.20o)], where $dA_{k'k}/dt = \sum \Omega_{k'l'} A_{l'k} = \sum A_{k'l} \Omega_{lk}$ (see §1.7); that is, $v'_{k'} \neq v_{k'}$, even if the x_k and $x_{k'}$ are, instantaneously, aligned (i.e., $A_{k'k} = \delta_{k'k}$—see §1.7); and, similarly, from the second of (1.1.20q), $v'_k \neq v_k$, where $v'_k = \sum A_{kk'} v'_{k'}$. As eq. (1.1.20s) shows, $v'_{k'}$ depends on both the relative *orientation* between x_k and $x_{k'}$ (term $\sum A_{k'k} v_k = v_{k'}$: noninertial particle velocity, but resolved along inertial axes — a *geometrical* effect) as well as on their relative *motion* [term $\sum (dA_{k'k}/dt) x_k$ — a *kinematical* effect]. There is more on moving axes theorems/applications in §1.7. Vectors transforming between *frames* as (1.1.20p) are called *objective* — namely, frame-independent; otherwise they are called *nonobjective*. Similarly for tensors: if $T'_{k'l'} = T_{k'l'}$, or $T'_{kl} = T_{kl}$, where $T'_{k'l'} = \sum\sum A_{k'k} A_{l'l} T'_{kl}$ and $T_{k'l'} = \sum\sum A_{k'k} A_{l'l} T_{kl}$, that tensor is called objective.

These concepts are important in continuum mechanics: the *constitutive* (*physical*) *equations* — namely, those relating stresses with strains/deformations and their time rates of change — *must be objective*. They also constitute the fundamental, or guiding, philosophical principle of the "Theory of Relativity" [A. Einstein, 1905 (special theory); 1916 (general theory)]. Classical mechanics does not admit of a fully physically invariant formulation (although its geometrically invariant formulation is easy via tensor calculus), and the reason is that it *is based on Euclidean geometry* *and on a sharp separation between space and* (*absolute*, *or Newtonian*) *time*. Hence, to obtain such a physically invariant mechanics, one had to change these concepts—and this was the great achievement of relativity: The latter replaced classical space and time with a more general non-Euclidean "space-time," a fusion of both space *and* time (and gravity). In this new "space," physical invariance is again expressed as geometrical invariance, via a "physical tensor calculus." (See, e.g., Bergmann, 1942.)

Table 1.1 summarizes, for the readers' convenience, common vector and tensor operations in all three notations. [We are reminded that in *matrix* notation, vectors are displayed as 3×1 *column* matrices, so that, in order to save space, we write $\boldsymbol{a} \to \boldsymbol{a}^{\mathrm{T}} = (a_1, a_2, a_3)^{\mathrm{T}}$.]

Differential Operators (Field Theory)

The most important differential operators of scalar (f)/vector $(\boldsymbol{a})$/tensor $(\boldsymbol{T})$ field theory, needed not so much in analytical mechanics as in continuum mechanics/physics, are

$$(\partial/\partial\mathbf{r})f \equiv \boldsymbol{grad}\, f \equiv \partial f/\partial\mathbf{r} = \sum (\partial f/\partial x_k)\boldsymbol{u}_k; \tag{1.1.21a}$$

$$(\partial/\partial\mathbf{r}) \otimes \boldsymbol{a} \equiv \boldsymbol{grad}\ \boldsymbol{a} \equiv \partial\boldsymbol{a}/\partial\mathbf{r} = \sum\sum (\partial a_l/\partial x_k)(\boldsymbol{u}_k \otimes \boldsymbol{u}_l), \tag{1.1.21b}$$

$$(\partial/\partial\mathbf{r}) \cdot \boldsymbol{a} = Tr(\boldsymbol{grad}\ \boldsymbol{a}) \equiv div\, \boldsymbol{a} \equiv \sum (\partial a_k/\partial x_k), \tag{1.1.21c}$$

$$(\partial/\partial\mathbf{r}) \times \boldsymbol{a} \equiv \boldsymbol{curl}\ \boldsymbol{a} \equiv \sum\sum\sum \varepsilon_{krs}(\partial a_s/\partial x_r)\boldsymbol{u}_k; \tag{1.1.21d}$$

$$(\partial/\partial\mathbf{r}) \otimes \boldsymbol{T} \equiv \boldsymbol{grad}\ \boldsymbol{T} = \sum\sum\sum (\partial T_{rs}/\partial x_k)[\boldsymbol{u}_k \otimes (\boldsymbol{u}_r \otimes \boldsymbol{u}_s)], \tag{1.1.21e}$$

$$(\partial/\partial\mathbf{r}) \cdot \boldsymbol{T} = Tr(\boldsymbol{grad}\ \boldsymbol{T}) \equiv div\, \boldsymbol{T} \equiv \sum\sum (\partial T_{ks}/\partial x_k)\boldsymbol{u}_s; \tag{1.1.21f}$$

where $\boldsymbol{r} = (x, y, z)$: position vector, from some origin O, on which f, $\boldsymbol{a}$, $\boldsymbol{T}$ depend; and (a_k), (T_{kl}) are the respective components of $\boldsymbol{a}$, $\boldsymbol{T}$ relative to an OND basis $\{O, \boldsymbol{u}_k\}$.

1.2 SPACE-TIME AXIOMS; PARTICLE KINEMATICS

Space, Time, Events

Classical mechanics (CM), the only kind of mechanics studied here, and that of which analytical mechanics is the most illustrious exponent, studies the motions of material *bodies*, or systems, under the action of mechanical *loads* (forces, moments). Hence, *bodies*, *forces*, and *motions* are its fundamental ingredients. Before examining them, however, we must postulate a certain *space-time*, or stage, where these phenomena occur, so that we may describe them via numbers assigned to elements of *length/area/volume/time interval*. In CM: (i) space is assumed to be *three-dimensional* and *Euclidean* (E_3); that is, in good experimental agreement with the Pythagorean theorem, *both locally and globally*; and (ii) there is a definite method for assigning numbers to *time intervals*, which is based on the existence of *perfect clocks*; that is, on completely *periodic* physical systems (i.e., such that a certain of their configurations is repeated indefinitely; e.g., an oscillating pendulum in vacuo, or our Earth in its daily rotation about its axis). Further, we assume that space and time are *homogeneous* (i.e., no preferred positions), and that space is also *isotropic* (i.e., no preferred directions). A physical phenomenon that is more or less sharply localized spatially and temporally (i.e., one that is occurring in the immediate neighborhood of a space point at a definite time: e.g., the arrival of a train at a certain station at a certain time) is called an *event*. Geometrically, events can be viewed as points in *space-time*, or *event space*; that is, in a four-dimensional mathematical space formed jointly by three-dimensional space *and* time. There, the four coordinates of an event, three for space and one for time, are measured by *observers* using geometrically invariant, or rigid, yardsticks (space) and the earlier postulated perfect clocks (time). [Fuller understanding of this measurement process requires elaboration of the concepts of *immediate* (*spatial*) *neighborhood* and (*temporal*) *simultaneity*. This is done in relativistic physics. Here, we take them with their intuitive meaning.]

Frame of Reference

A frame of reference is a rigid material framework, or rigid body, relative to which spatial and temporal measurements of events are made, by a team of (equivalent) observers, distributed over that body (at rest relative to it), equipped with rigid yardsticks and mutually synchronized perfect clocks. Clearly, some, if not all, of these measurements will depend on the state of motion of the frame (relative to some other frame!); that is, this "coordinate-ization of events" is, generally, nonunique. The relation between the measurements of the same event(s), as registered in two such frames, *in relative motion to each other*, is called a *frame of reference transformation*; and the latter is expressed, mathematically, by an *explicitly time-dependent* coordinate transformation — one coordinate system rigidly embedded to each frame and "representing" it.

Inertial Frame of Reference

This is a frame determined by the center of mass ("origin") of our Sun and the so-called *fixed* stars (directions of axes of frame). This *primary*, or *astronomical*, frame is Newton's *absolute space*; and, like a cosmic substratum, is assumed to exist (in Newton's words) "in its own nature, and without reference to anything external, remains always similar and immovable." Similarly, Newton assumes the existence of *absolute time*, which is measured by standard clocks, and flows uniformly and *independently of any physical phenomena or processes* — something that, today, is considered physically absurd: "[I]t is contrary to the mode of thinking in science to conceive of a thing (the space-time continuum) which acts itself, but which cannot be acted upon" (Einstein, 1956, pp. 55–56). In spite of its logically/epistemologically crude and no longer tenable foundations, CM is astonishingly accurate in several areas. For example, the planet Mercury in its motion around our Sun sweeps out a total angle of *150,000°/century*; which is only *43″* more than the Newtonian prediction! In this sense, of Machean *Denkökonomie* (≈ Principle of economy, in the formation of concepts), CM is an extremely economical intellectual and practical investment.

As the mathematical structure of the Newton–Euler laws of motion shows (§1.4,5), any other frame moving with (vectorially) constant velocity, relative to the primary frame, is also inertial; so we have a family, or group, of *secondary* inertial frames. In inertial frames, the laws of motion have their simplest form [the familiar "force equals mass times acceleration (relative to that frame)"].

Particle Kinematics

The instantaneous *position*, or *place*, of a particle P relative to an *origin*, or *reference point*, O, fixed in a, say, inertial frame F in E_3, is given by its *position* vector $\boldsymbol{r} = (x, y, z)$; where x, y, z are at least twice (piecewise) continuously differentiable functions of time t. Clearly, $\boldsymbol{r}$ depends on O while x, y, z depend on the kind of coordinates used in F. (Also, we are reminded that in kinematics, the frame does not really matter; any frame is as good as any other.) At time t, a collection of particles, or body B, occupies in E_3 a certain shape, or *configuration*, described by the single-valued and invertible mapping

$$\boldsymbol{r} = \boldsymbol{f}(P, t)\text{: Place of } P, \text{ in } F, \text{ at time } t; \tag{1.2.1a}$$

from which, inverting (conceptually), we obtain

$$P = \boldsymbol{f}^{-1}(\boldsymbol{r}, t). \tag{1.2.1b}$$

A *motion* of B is a change of its configuration with time; that is, it is the locus of $\boldsymbol{r}$ of each and every P of B, for all time in a certain interval. Formally, this is a one-parameter family $\boldsymbol{f}$ of configurations with time as the (real) parameter.

Often, especially in continuum mechanics, the motion of P is described as

$$\boldsymbol{r} = \boldsymbol{f}(\boldsymbol{r}_o, t) \equiv \boldsymbol{r}(\boldsymbol{r}_o, t), \tag{1.2.2}$$

where $\boldsymbol{r}_o$ is the position of P at some "initial or reference" time; that is, *a reference configuration used as the name of P* (see also §2.2 ff.). The above representation — in addition to being single-valued, continuous, and twice (piecewise) continuously differentiable in t — must also be single-valued and invertible in $\boldsymbol{r}_o$; that is, one-to-one in both directions. (In mathematicians' jargon: *a configuration is a smooth homeomorphism of B onto a region of* E_3.)

The *velocity* and *acceleration* of P, relative to a frame F, are defined, respectively, by (assuming rectangular Cartesian coordinates)

$$\begin{aligned} \boldsymbol{v} &\equiv d\boldsymbol{r}/dt = (dx/dt, dy/dt, dz/dt), \\ \boldsymbol{a} &\equiv d\boldsymbol{v}/dt = d^2\boldsymbol{r}/dt^2 = (d^2x/dt^2, d^2y/dt^2, d^2z/dt^2). \end{aligned} \tag{1.2.3}$$

Clearly, $\boldsymbol{v}$ and $\boldsymbol{a}$ depend on the frame, but not on its chosen fixed origin O. The representation of the velocity and acceleration of P, relative to F, moving on a general space, or skew, (F-fixed) curve C, along its *natural*, or *intrinsic*, ortho–normal–dextral moving trihedron/triad $\{\boldsymbol{u}_t, \boldsymbol{u}_n, \boldsymbol{u}_b\} \equiv \{\boldsymbol{t}, \boldsymbol{n}, \boldsymbol{b}\}$ (see fig. 1.1 for definitions, etc.) is

$$\boldsymbol{v} = d\boldsymbol{r}/dt = (d\boldsymbol{r}/ds)(ds/dt) \equiv (ds/dt)\boldsymbol{t} \equiv v_t\boldsymbol{t} \qquad (= v_t\boldsymbol{t} + 0\boldsymbol{n} + 0\boldsymbol{b}), \tag{1.2.3a}$$

$$\begin{aligned} \boldsymbol{a} = d\boldsymbol{v}/dt &= (d^2s/dt^2)\boldsymbol{t} + [(ds/dt)^2/\rho]\boldsymbol{n} \equiv (dv_t/dt)\boldsymbol{t} + ({v_t}^2/\rho)\boldsymbol{n} \\ &= (dv_t/dt)\boldsymbol{t} + (v^2/\rho)\boldsymbol{n} \qquad (= a_t\boldsymbol{t} + a_n\boldsymbol{n} + 0\boldsymbol{b}, \text{ see below}). \end{aligned} \tag{1.2.3b}$$

- The *speed* of P is defined as the magnitude of its velocity:

$$\text{Speed } \equiv v \equiv |\boldsymbol{v}| = |v_t| = |ds/dt| = +\left[(dx/dt)^2 + (dy/dt)^2 + (dz/dt)^2\right]^{1/2} \geqslant 0\,;$$

$$\text{i.e.,}\quad v_t \equiv \boldsymbol{v}\cdot\boldsymbol{t} = \dot{s} = \pm v\,. \tag{1.2.3c}$$

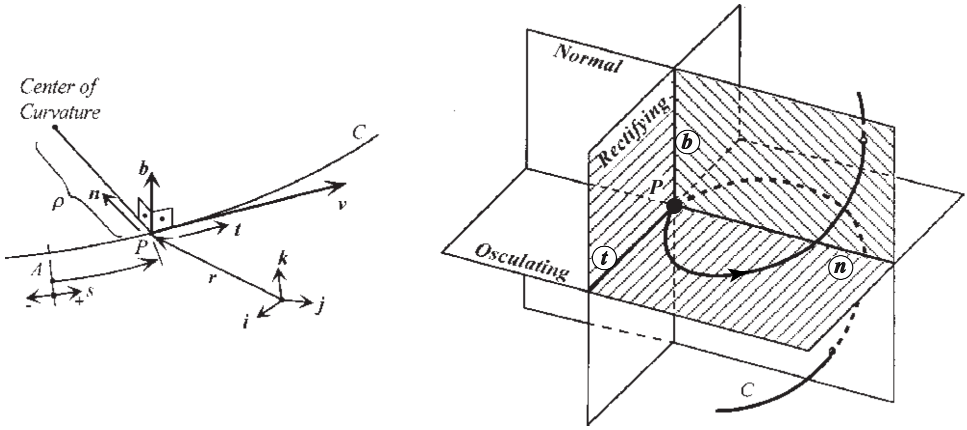

Figure 1.1 Natural, or intrinsic, triad representation in particle kinematics. s: arc coordinate along C, measured (positive or negative) from some origin A on C; ρ: radius of curvature of C at $P(0 \le \rho \le \infty)$; orthonormal and dextral (OND) triad: $\{\boldsymbol{u}_t, \boldsymbol{u}_n, \boldsymbol{u}_b\} \equiv \{\boldsymbol{t}, \boldsymbol{n}, \boldsymbol{b}\}$; (oriented) tangent: $\boldsymbol{u}_t \equiv \boldsymbol{t} \equiv d\boldsymbol{r}/ds$) [always pointing toward (algebraically) increasing values of s (= positive C-sense)]; (first, or principal) normal: $\boldsymbol{u}_n \equiv \boldsymbol{n} \equiv \rho(d\boldsymbol{t}/ds)$ (always in sense of concavity, toward center of curvature); (second) normal, or binormal: $\boldsymbol{u}_b \equiv \boldsymbol{b} \equiv \boldsymbol{t} \times \boldsymbol{n}$; osculating plane: plane spanned by $\boldsymbol{t}$ and $\boldsymbol{n}$ (locus of tip of acceleration vector); rectifying plane: plane spanned by $\boldsymbol{t}$ and $\boldsymbol{b}$; normal plane: plane spanned by $\boldsymbol{n}$ and $\boldsymbol{b}$; $\boldsymbol{t} \cdot (\boldsymbol{n} \times \boldsymbol{b}) \equiv (\boldsymbol{t}, \boldsymbol{n}, \boldsymbol{b}) = +1 > 0$. [More in §1.7: (1.7.18a)ff.]

Hence, in general, since $v^2 = v_t v_t = (\dot{s})^2$,

$$a \equiv |\boldsymbol{a}| \equiv |d\boldsymbol{v}/dt| = [(dv/dt)^2 + (v^4/\rho^2)]^{1/2} \neq |dv_t/dt| \equiv |d^2s/dt^2| = |dv/dt|;$$

i.e., $a_t \equiv \ddot{s}$ (*tangential* accel'n), $\quad a_n \equiv (\dot{s})^2/\rho$ (*normal* a.), $\quad a_b \equiv 0$ (*binormal* a.)

$$\Rightarrow \qquad \boldsymbol{v} \cdot \boldsymbol{a} = \dot{s}\,\ddot{s} = (\dot{s}^2/2)^{\boldsymbol{\cdot}}, \quad \boldsymbol{v} \times \boldsymbol{a} = (\dot{s}^3/\rho)\boldsymbol{b}. \tag{1.2.3.d}$$

REMARKS

(i) The difference between *speed* $v \equiv |d\boldsymbol{r}/dt| = |\boldsymbol{v}| = |ds/dt| > 0$ and the (*tangential*) *velocity component* $v_t \equiv \boldsymbol{v} \cdot \boldsymbol{t} = ds/dt = \pm v$ [i.e. by equation (1.2.3c): $v_t = +v > 0$ if $ds > 0$, and $v_t = -v < 0$ if $ds < 0$] results from the *oriented-ness* of the curve C [i.e. that it is equipped with (a) an *origin A*, and (b) a *positive/negative sense of traverse* $\Rightarrow \pm s$]; i.e. in *any* motion of P along it, the unit tangent vector $\boldsymbol{t} \equiv d\boldsymbol{r}/ds\,(\neq \boldsymbol{0})$ points *always* towards the *increasing* arcs s (just like $\boldsymbol{i} \equiv \partial\boldsymbol{r}/\partial x$ always points towards the positive/increasing x – see below). Fortunately, this v_t versus v difference (almost never noticed in the literature) rarely results in fatal errors.

(ii) Thus, it becomes clear that s [$\equiv$ (intrinsic) *arc/path/trajectory curvilinear coordinate/abscissa*, *of P relative to a chosen C-origin A*] is the "natural" curvilinear generalization of the rectilinear position (-al) coordinates x, y, z (and $\{\boldsymbol{t}, \boldsymbol{n}, \boldsymbol{b}\}$ are of $\{\boldsymbol{i}, \boldsymbol{j}, \boldsymbol{k}\}$, respectively).

(iii) The equation $s = s(t)$, resulting by integrating $ds = \pm|\boldsymbol{v}(t)|dt = \pm\, v(t)\, dt$ [say, from $t(A)$ to $t(P)$], is referred to as the *equation/law of motion* of P on C.

(iv) Last, (a) the *length* of the arc AP is defined as the absolute value of s, $|s| \geq 0$, while (b) the (total) *distance* traveled by our particle P, along C, *from an origin A to its current/final position* (i.e. what a car *odometer* shows) is defined by:

$$\int_{\textit{origin} \,\to\, \textit{current}\ C\text{-position}} |ds| \quad (\geq |s| \geq 0). \tag{1.2.3e}$$

For details on arc length, admissible curve parametrizations etc, see works on differential geometry.

It can be shown that [with the additional notation $(\ldots)' \equiv d(\cdots)/du$]:

(i) $$\boldsymbol{t} = \boldsymbol{r}'/s' = \boldsymbol{r}'/(\boldsymbol{r}' \cdot \boldsymbol{r}')^{1/2} = (dx/ds)\boldsymbol{i} + (dy/ds)\boldsymbol{j} + (dz/ds)\boldsymbol{k}, \tag{1.2.4a}$$

(ii) $$\begin{aligned}\boldsymbol{n} &= \rho(d\boldsymbol{t}/ds) = \rho(d^2\boldsymbol{r}/ds^2) = \rho[(d^2x/ds^2)\boldsymbol{i} + (d^2y/ds^2)\boldsymbol{j} + (d^2z/ds^2)\boldsymbol{k}]\\ &= \rho(\boldsymbol{t}'/s') = \rho\boldsymbol{t}'/(\boldsymbol{r}' \cdot \boldsymbol{r}')^{1/2}\\ &= [\rho/(\boldsymbol{r}' \cdot \boldsymbol{r}')^{3/2}][(\boldsymbol{r}' \cdot \boldsymbol{r}')^{1/2}\boldsymbol{r}'' - (\boldsymbol{r}' \cdot \boldsymbol{r}')^{-1/2}(\boldsymbol{r}' \cdot \boldsymbol{r}'')\boldsymbol{r}']\\ &= [\rho/(\boldsymbol{r}' \cdot \boldsymbol{r}')^2][(\boldsymbol{r}' \cdot \boldsymbol{r}')\boldsymbol{r}'' - (\boldsymbol{r}' \cdot \boldsymbol{r}'')\boldsymbol{r}'];\end{aligned} \tag{1.2.4b}$$

(iii) $\kappa \equiv 1/\rho = |d\boldsymbol{t}/ds| = |d^2\boldsymbol{r}/ds^2| \quad (\geqslant 0, \quad 0 \leqslant \rho \leqslant +\infty)$:

(first) curvature of C, at P, (1.2.4c)

(iv) $$\begin{aligned}\kappa^2 &= 1/\rho^2 = (\boldsymbol{r}' \times \boldsymbol{r}'')^2/(\boldsymbol{r}' \cdot \boldsymbol{r}')^3 = [(\boldsymbol{r}' \cdot \boldsymbol{r}')(\boldsymbol{r}'' \cdot \boldsymbol{r}'') - (\boldsymbol{r}' \cdot \boldsymbol{r}'')^2]\big/(\boldsymbol{r}' \cdot \boldsymbol{r}')^3\\ &[= (d^2x/ds^2)^2 + (d^2y/ds^2)^2 + (d^2z/ds^2)^2, \quad \text{if } u = s];\end{aligned} \tag{1.2.4d}$$

(v) $$\begin{aligned}\boldsymbol{r}' &= s'\boldsymbol{t},\\ \boldsymbol{r}'' &= s''\boldsymbol{t} + s'\boldsymbol{t}' = s''\boldsymbol{t} + s'[(d\boldsymbol{t}/ds)(ds/du)] \qquad [= s''\boldsymbol{t} + (s')^2(d\boldsymbol{t}/ds)]\\ &= s''\boldsymbol{t} + \kappa(s')^2\boldsymbol{n} = s''\boldsymbol{t} + [(s')^2/\rho]\boldsymbol{n}\\ &[= (dv_t/dt)\boldsymbol{t} + (v^2/\rho)\boldsymbol{n}, \quad v_t v_t = vv = (ds/dt)^2; \qquad \text{if } u = t];\end{aligned} \tag{1.2.4e}$$

(vi) $$\boldsymbol{t} = \boldsymbol{v}/(ds/dt) \equiv \boldsymbol{v}/v_t, \tag{1.2.4f}$$

$$\boldsymbol{n} = \rho[v^2\boldsymbol{a} - (\boldsymbol{v} \cdot \boldsymbol{a})\boldsymbol{v}]/v^4 = \frac{s'\boldsymbol{r}'' - s''\boldsymbol{r}'}{\kappa(s')^3}, \tag{1.2.4g}$$

$$\begin{aligned}\boldsymbol{b} &= \boldsymbol{t} \times \boldsymbol{n} = \rho[(d\boldsymbol{r}/ds) \times (d^2\boldsymbol{r}/ds^2)] = \rho(\boldsymbol{r}' \times \boldsymbol{r}'')/(\boldsymbol{r}' \cdot \boldsymbol{r}')^{3/2}\\ &= \rho(\boldsymbol{v} \times \boldsymbol{a})/{v_t}^3 = \rho(\boldsymbol{v} \times \boldsymbol{a})/v_t v^2;\end{aligned} \tag{1.2.4h}$$

(vii) $$\kappa^2 = 1/\rho^2 = (\boldsymbol{v} \times \boldsymbol{a})^2/v^6 = [v^2a^2 - (\boldsymbol{v} \cdot \boldsymbol{a})^2]/v^6; \tag{1.2.4i}$$

(viii) $$a_t \equiv \boldsymbol{a} \cdot \boldsymbol{t} = [v_x(dv_x/dt) + v_y(dv_y/dt) + v_z(dv_z/dt)]\big/v_t; \tag{1.2.4j}$$

(ix) $$\begin{aligned}a_n = |\boldsymbol{a} \times \boldsymbol{t}| &= \{[v_x(dv_y/dt) - v_y(dv_x/dt)]^2 + [v_y(dv_z/dt) - v_z(dv_y/dt)]^2\\ &+ [v_z(dv_x/dt) - v_x(dv_z/dt)]^2\}^{1/2}\big/({v_x}^2 + {v_y}^2 + {v_z}^2)^{1/2}.\end{aligned} \tag{1.2.4k}$$

• In plane *polar* coordinates, the *position/velocity/acceleration* of a particle P are (where $\boldsymbol{u}_r$, $\boldsymbol{u}_\phi$: unit vectors *along* OP and *perpendicular* to it, in the sense of increasing r, ϕ respectively):

$$d\boldsymbol{u}_r/dt = (d\phi/dt)\boldsymbol{u}_\phi \quad \text{and} \quad d\boldsymbol{u}_\phi/dt = -(d\phi/dt)\boldsymbol{u}_r;$$

$$\text{or} \quad d\boldsymbol{u}_r = d\phi\,\boldsymbol{u}_\phi \quad \text{and} \quad d\boldsymbol{u}_\phi = -d\phi\,\boldsymbol{u}_r,$$

$$\boldsymbol{r} = r\,\boldsymbol{u}_r \qquad [= (r)\boldsymbol{u}_r + (0)\boldsymbol{u}_\phi], \tag{1.2.5a}$$

$$\boldsymbol{v} = (dr/dt)\boldsymbol{u}_r + r(d\phi/dt)\boldsymbol{u}_\phi \equiv v_r\boldsymbol{u}_r + v_\phi\boldsymbol{u}_\phi, \tag{1.2.5b}$$

$$\begin{aligned}\boldsymbol{a} &= [d^2r/dt^2 - r(d\phi/dt)^2]\boldsymbol{u}_r + \{r^{-1}\,d/dt[r^2(d\phi/dt)]\}\boldsymbol{u}_\phi\\ &= [d^2r/dt^2 - r(d\phi/dt)^2]\boldsymbol{u}_r + [2(dr/dt)(d\phi/dt) + r(d^2\phi/dt^2)]\boldsymbol{u}_\phi\\ &\equiv a_{(r)}\boldsymbol{u}_r + a_{(\phi)}\boldsymbol{u}_\phi.\end{aligned} \tag{1.2.5c}$$

The vectors $(d\phi/dt)\boldsymbol{k}$ and $(d^2\phi/dt^2)\boldsymbol{k}$ are, respectively, the *angular velocity* and *angular acceleration* of the radius $\boldsymbol{OP} = \boldsymbol{r}$ relative to O–xy. It can be shown that

(i) $a_t \equiv \boldsymbol{a} \cdot \boldsymbol{t} = \pm(v_r a_r + v_\phi a_\phi) \big/ ({v_r}^2 + {v_\phi}^2)^{1/2} \qquad [+ \text{ if } v_t > 0, \quad - \text{ if } v_t < 0].$ (1.2.5d)

(ii) The rectangular Cartesian components of the velocity and acceleration are, respectively,

$$dx/dt = (dr/dt)\cos\phi - [r(d\phi/dt)]\sin\phi, \quad dy/dt = (dr/dt)\sin\phi + [r(d\phi/dt)]\cos\phi; \tag{1.2.5e}$$

$$d^2x/dt^2 = [d^2r/dt^2 - r(d\phi/dt)^2]\cos\phi - [2(dr/dt)(d\phi/dt) + r(d^2\phi/dt^2)]\sin\phi,$$
$$d^2y/dt^2 = [d^2r/dt^2 - r(d\phi/dt)^2]\sin\phi + [2(dr/dt)(d\phi/dt) + r(d^2\phi/dt^2)]\sin\phi, \tag{1.2.5f}$$

and, inversely,

$$dr/dt = (xv_x + yv_y)/(x^2 + y^2)^{1/2}, \qquad d\phi/dt = (xv_y - yv_x)/(x^2 + y^2), \text{ etc.} \tag{1.2.5g}$$

[A more precise notation of vector components along various bases of orthogonal curvilinear (i.e., nonrectangular Cartesian) coordinates is introduced below.]

• In general (i.e., not necessarily plane) motion, the *areal velocity* dA/dt of a particle equals

$$dA/dt = (1/2)|\boldsymbol{r} \times \boldsymbol{v}| = (1/2)|\textit{angular momentum of particle about origin, per unit mass}|. \tag{1.2.6a}$$

It can be shown that (assuming $\boldsymbol{r} \neq \boldsymbol{0}$)

$$d^2A/dt^2 = (\boldsymbol{r} \times \boldsymbol{v}) \cdot (\boldsymbol{r} \times \boldsymbol{a})/2|\boldsymbol{r} \times \boldsymbol{v}|. \tag{1.2.6b}$$

Velocity and Acceleration in Orthogonal Curvilinear Coordinates

(A certain familiarity with the latter is assumed—otherwise, this topic can be omitted at this point.) In such coordinates, say $q \equiv (q_1, q_2, q_3) \equiv (q_{1,2,3})$ [see fig. 1.2(a)] the position vector $\boldsymbol{r}$, of a particle P, is expressed as:

$$\boldsymbol{r} = x(q)\boldsymbol{i} + y(q)\boldsymbol{j} + z(q)\boldsymbol{k} \equiv \boldsymbol{r}(q), \tag{1.2.7a}$$

and so the corresponding *unit* tangent vectors along the coordinate lines $q_{1,2,3}$, $\boldsymbol{u}_{1,2,3}$, are

$$\boldsymbol{u}_1 = (1/h_1)(\partial\boldsymbol{r}/\partial q_1) \equiv \boldsymbol{e}_1/h_1,$$
$$\boldsymbol{u}_2 = (1/h_2)(\partial\boldsymbol{r}/\partial q_2) \equiv \boldsymbol{e}_2/h_2,$$
$$\boldsymbol{u}_3 = (1/h_3)(\partial\boldsymbol{r}/\partial q_3) \equiv \boldsymbol{e}_3/h_3,$$

where

$$\boldsymbol{u}_k \cdot \boldsymbol{u}_l = \delta_{kl} \qquad (k, l = 1, 2, 3); \tag{1.2.7b}$$

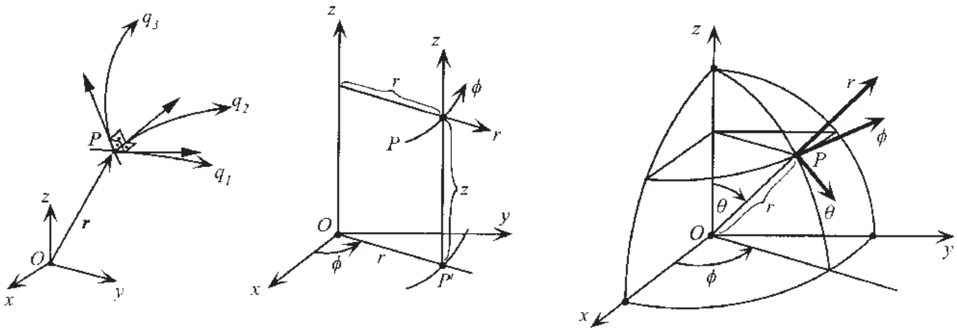

Figure 1.2 (a) General orthogonal curvilinear coordinates;
(b) cylindrical (polar) coordinates: $x = r\cos\phi$, $y = r\sin\phi$, $z = z$, $r = |\boldsymbol{OP}'|$; $h_{1,2,3} \equiv h_{r,\phi,z} = 1, r, 1$;
(c) spherical coordinates: $x = (r\sin\theta)\cos\phi$, $y = (r\cos\theta)\sin\phi$, $z = r\cos\theta$, $r = |\boldsymbol{OP}|$;
$h_{1,2,3} \equiv h_{r,\theta,\phi} = 1, r, r\sin\theta$.

and since

$$\partial \boldsymbol{r}/\partial q_1 = (\partial x/\partial q_1)\boldsymbol{i} + (\partial y/\partial q_1)\boldsymbol{j} + (\partial z/\partial q_1)\boldsymbol{k}, \qquad \partial \boldsymbol{r}/\partial q_2 = \cdots, \qquad \partial \boldsymbol{r}/\partial q_3 = \cdots, \tag{1.2.7c}$$

the (normalizing) *Lamé coefficients* $h_{1,2,3}$ are given by

$$h_1 \equiv |\partial \boldsymbol{r}/\partial q_1| = [(\partial x/\partial q_1)^2 + (\partial y/\partial q_1)^2 + (\partial z/\partial q_1)^2]^{1/2}, \quad h_2 = \cdots, h_3 = \cdots. \tag{1.2.7d}$$

We notice that

$$\cos(\boldsymbol{u}_k, x) = \boldsymbol{u}_k \cdot \boldsymbol{i} = \left[(1/h_k)(\partial \boldsymbol{r}/\partial q_k)\right] \cdot \boldsymbol{i} = (1/h_k)(\partial x/\partial q_k), \text{ etc.,}$$

or, generally, with $x \equiv x_1$, $y \equiv x_2$, $z \equiv x_3$, and $\boldsymbol{i} \equiv \boldsymbol{i}_1$, $\boldsymbol{j} \equiv \boldsymbol{i}_2$, $\boldsymbol{k} \equiv \boldsymbol{i}_3$,

$$\cos(\boldsymbol{u}_k, x_l) = \boldsymbol{u}_k \cdot \boldsymbol{i}_l = (1/h_k)(\partial x_l/\partial q_k). \tag{1.2.7e}$$

As a result of the above, and since $\partial \boldsymbol{r}/\partial q_k \equiv \boldsymbol{e}_k = h_k \boldsymbol{u}_k$, the *arc length element* ds, *velocity* $\boldsymbol{v}$, and *speed* $|\boldsymbol{v}|$ of P are given, respectively, by

(i) $$ds = |d\boldsymbol{r}| = \left|\sum (\partial \boldsymbol{r}/\partial q_k)\, dq_k\right| = ({h_1}^2\, {dq_1}^2 + {h_2}^2\, {dq_2}^2 + {h_3}^2\, {dq_3}^2)^{1/2}, \tag{1.2.7f}$$

(ii) $$\boldsymbol{v} \equiv d\boldsymbol{r}/dt = \sum (\partial \boldsymbol{r}/\partial q_k)(dq_k/dt) \equiv \sum v_k \boldsymbol{e}_k = \sum v_k (h_k \boldsymbol{u}_k) \equiv \sum v_{(k)} \boldsymbol{u}_k, \tag{1.2.7g}$$

(iii) $$|\boldsymbol{v}| \equiv v = ({h_1}^2 {v_1}^2 + {h_2}^2 {v_2}^2 + {h_3}^2 {v_3}^2)^{1/2}, \tag{1.2.7h}$$

where

$dq_k/dt \equiv v_k$: "contravariant" or *generalized* component of $\boldsymbol{v}$ along q_k, (1.2.7i)

$v_{(k)} \equiv h_k(dq_k/dt) \equiv h_k v_k$: corresponding *physical* component (with units of *length*/*time*), (1.2.7j)

Next, we define the *generalized* and *physical* components of the particle acceleration $\boldsymbol{a}$ as

$$a_k \equiv \boldsymbol{a}\cdot\boldsymbol{e}_k = (d\boldsymbol{v}/dt)\cdot(\partial\boldsymbol{r}/\partial q_k), \qquad a_{(k)} \equiv \boldsymbol{a}\cdot\boldsymbol{u}_k = \boldsymbol{a}\cdot(\boldsymbol{e}_k/h_k) = a_k/h_k. \quad (1.2.7\text{k})$$

REMARKS

(i) For an arbitrary vector $\boldsymbol{b}$, in general orthogonal curvilinear coordinates, we have the following representations:

$$\boldsymbol{b} = \sum b^k\boldsymbol{e}_k = \sum b_k\boldsymbol{e}^k = \sum b_k(\boldsymbol{e}_k/{h_k}^2) = \sum (b_k/h_k)(\boldsymbol{e}_k/h_k) \equiv \sum b_{(k)}\boldsymbol{u}_k$$

where

$$\boldsymbol{e}_k\cdot\boldsymbol{e}_l \equiv g_{kl} = 0,\ \text{if}\ k\neq l; \quad = {h_k}^2\ \text{if}\ k=l; \quad \boldsymbol{e}^k\cdot\boldsymbol{e}_l = \delta^k{}_l = \delta_{kl}, \quad \boldsymbol{e}^k\cdot\boldsymbol{e}^l = g^{kl} = g^{lk}$$

$$\Rightarrow g^{kk} = 1/{h_k}^2, \quad g_{kk} = 1/g^{kk} = {h_k}^2, \quad Det(g_{kl}) = {h_1}^2{h_2}^2{h_3}^2; \quad \boldsymbol{e}^k = \boldsymbol{e}_k/{h_k}^2;$$

$$b_k \equiv \boldsymbol{b}\cdot\boldsymbol{e}_k = \boldsymbol{b}\cdot(h_k\boldsymbol{u}_k) = h_k(\boldsymbol{b}\cdot\boldsymbol{u}_k) \equiv h_k b_{(k)}; \quad b^k \equiv \boldsymbol{b}\cdot\boldsymbol{e}^k = \boldsymbol{b}\cdot(\boldsymbol{u}_k/h_k) = b_{(k)}/h_k;$$

that is,

$$b_{(k)} = b^k h_k = b_k/h_k\text{: physical components of } \boldsymbol{b},\ b^k = b_k/{h_k}^2; \boldsymbol{u}_k = \boldsymbol{e}_k/h_k = h_k\boldsymbol{e}^k.$$

(ii) Strictly speaking, q_k should have been written as q^k; and, consequently, v_k as v^k!

(iii) In *rectangular Cartesian coordinates/axes* (this book), clearly, $h_k = 1 \Rightarrow b_{(k)} = b_k = b^k$.

(iv) For the extension of the above to *general* curvilinear coordinates, see books on tensor calculus; for example, Papastavridis (1999, chap. 2, especially §2.10).

From the first of (1.2.7k) we obtain successively (what are, in essence, the famous *Lagrangean kinematico-inertial transformations*, to be generalized and detailed in chaps. 2 and 3):

$$a_k \equiv \boldsymbol{a}\cdot\boldsymbol{e}_k \equiv (d\boldsymbol{v}/dt)\cdot(\partial\boldsymbol{r}/\partial q_k) = d/dt\,[\boldsymbol{v}\cdot(\partial\boldsymbol{r}/\partial q_k)] - \boldsymbol{v}\cdot d/dt(\partial\boldsymbol{r}/\partial q_k)$$

$\Big\{$and, using the basic kinematical *identities*:

(a) $\partial\boldsymbol{r}/\partial q_k = \partial\boldsymbol{v}/\partial v_k$ [from (1.2.7g)]

(b) $d/dt(\partial\boldsymbol{r}/\partial q_k)$

$$= \sum \partial/\partial q_l(\partial\boldsymbol{r}/\partial q_k)(dq_l/dt) + \partial/\partial t(\partial\boldsymbol{r}/\partial q_k)$$

$$= \partial/\partial q_k\Big(\sum (\partial\boldsymbol{r}/\partial q_l)(dq_l/dt) + \partial\boldsymbol{r}/\partial t\Big)$$

$$= \partial\boldsymbol{v}/\partial q_k;$$

i.e., $d/dt(\partial\boldsymbol{v}/\partial v_k) - \partial\boldsymbol{v}/\partial q_k = \boldsymbol{0}\Big\}$

$$= d/dt\big[\boldsymbol{v}\cdot(\partial\boldsymbol{v}/\partial v_k)\big] - \boldsymbol{v}\cdot(\partial\boldsymbol{v}/\partial q_k)$$

$$= d/dt[\partial/\partial v_k(v^2/2)] - \partial/\partial q_k(v^2/2)$$

$$(\text{since } \boldsymbol{v}\cdot\boldsymbol{v} = v^2); \qquad (1.2.7\text{l})$$

and, invoking the second of (1.2.7k), we get, finally, the *Lagrangean form*:

$$a_{(k)} = a_k/h_k = (1/h_k)\big[d/dt(\partial T/\partial v_k) - \partial T/\partial q_k\big], \tag{1.2.7m}$$

where

$$\begin{aligned} T \equiv v^2/2 &= (1/2)[h_1{}^2(dq_1/dt)^2 + h_2{}^2(dq_2/dt)^2 + h_3{}^2(dq_3/dt)^2]^{1/2} \\ &\equiv (1/2)(h_1{}^2 v_1{}^2 + h_2{}^2 v_2{}^2 + h_3{}^2 v_3{}^2)^{1/2}: \\ &\qquad \textit{kinetic energy of a particle of unit mass} \text{ (i.e., } m = 1). \end{aligned} \tag{1.2.7n}$$

Application

(i) *Cylindrical* (*polar*) coordinates [fig. 1.2(b)]. Here, $x = r\cos\phi$, $y = r\sin\phi$, $z = z$, and, therefore,

$$ds^2 = ds_r{}^2 + ds_\phi{}^2 + ds_z{}^2 = dr^2 + r^2\,d\phi^2 + dz^2, \tag{1.2.8a}$$

from which we immediately read off the following Lamé coefficients:

$$h_1 \to h_r = 1, \qquad h_2 \to h_\phi = r, \qquad h_3 \to h_z = 1. \tag{1.2.8b}$$

Hence, the "unit kinetic energy" equals

$$2T = (ds/dt)^2 = v^2 = [(dr/dt)^2 + r^2(d\phi/dt)^2 + (dz/dt)^2] \equiv v_r{}^2 + r^2 v_\phi{}^2 + v_z{}^2, \tag{1.2.8c}$$

and so, by (1.2.7l), the (physical) components of the acceleration are

$$a_{(1)} \to a_{(r)} = d/dt(\partial T/\partial v_r) - \partial T/\partial r = d^2r/dt^2 - r(d\phi/dt)^2, \tag{1.2.8d}$$

$$\begin{aligned} a_{(2)} \to a_{(\phi)} &= (1/r)\big[d/dt(\partial T/\partial v_\phi) - \partial T/\partial \phi\big] \\ &= (1/r)\big\{d/dt[r^2(d\phi/dt)]\big\} = r(d^2\phi/dt^2) + 2(dr/dt)(d\phi/dt), \end{aligned} \tag{1.2.8e}$$

$$a_{(3)} \to a_{(z)} = d/dt(\partial T/\partial v_z) - \partial T/\partial z = d^2z/dt^2. \tag{1.2.8f}$$

(ii) *Spherical* coordinates. Here, $x = (r\sin\theta)\cos\phi$, $y = (r\cos\theta)\sin\phi$, $z = r\cos\theta$ [fig. 1.2(c)]. Using similar steps, we can show that

$$a_{(1)} \to a_{(r)} = d/dt(\partial T/\partial v_r) - \partial T/\partial r = d^2r/dt^2 - r(d\theta/dt)^2 - r(d\phi/dt)^2\sin^2\theta; \tag{1.2.8g}$$

$$\begin{aligned} a_{(2)} \to a_{(\theta)} &= (1/r)[\partial T/\partial v_\theta - \partial T/\partial\theta] \\ &= (1/r)\big\{d/dt[r^2(d\theta/dt)] - r^2(d\phi/dt)^2\sin\theta\cos\theta\big\}; \end{aligned} \tag{1.2.8h}$$

$$\begin{aligned} a_{(3)} \to a_{(\phi)} &= (1/r\sin\theta)\big[d/dt(\partial T/\partial v_\phi) - \partial T/\partial\phi\big] \\ &= (1/r\sin\theta)\big\{d/dt[r^2(d\phi/dt)\sin^2\theta]\big\}; \end{aligned} \tag{1.2.8i}$$

$$v_x = dx/dt = (dr/dt)\sin\theta\cos\phi + r(d\theta/dt)\cos\theta\cos\phi - r(d\phi/dt)\sin\theta\sin\phi, \tag{1.2.8j}$$

$$v_y = dy/dt = (dr/dt)\sin\theta\sin\phi + r(d\theta/dt)\cos\theta\sin\phi + r(d\phi/dt)\sin\theta\cos\phi, \tag{1.2.8k}$$

$$v_z = dz/dt = (dr/dt)\cos\theta - r(d\theta/dt)\sin\theta; \tag{1.2.8l}$$

$$\begin{aligned} a_x = d^2x/dt^2 = {} & [d^2r/dt^2 - r(d\theta/dt)^2 - r(d\phi/dt)^2]\sin\theta\cos\phi \\ & + [r(d^2\theta/dt^2) + 2(dr/dt)(d\theta/dt)]\cos\theta\cos\phi \\ & - [r(d^2\phi/dt^2) + 2(dr/dt)(d\phi/dt)]\sin\theta\sin\phi \\ & - 2r(d\phi/dt)(d\theta/dt)\cos\theta\sin\phi; \end{aligned} \tag{1.2.8m}$$

$$\begin{aligned} a_y = d^2y/dt^2 = {} & [d^2r/dt^2 - r(d\theta/dt)^2 - r(d\phi/dt)^2]\sin\theta\sin\phi \\ & + [r(d^2\theta/dt^2) + 2(dr/dt)(d\theta/dt)]\cos\theta\sin\phi \\ & + [r(d^2\phi/dt^2) + 2(dr/dt)(d\phi/dt)]\sin\theta\cos\phi \\ & + 2r(d\phi/dt)(d\theta/dt)\cos\theta\cos\phi, \end{aligned} \tag{1.2.8n}$$

$$\begin{aligned} a_z = d^2z/dt^2 = {} & [d^2r/dt^2 - r(d\theta/dt)^2]\cos\theta \\ & - [r(d^2\theta/dt^2) + 2(dr/dt)(d\theta/dt)]\sin\theta; \end{aligned} \tag{1.2.8o}$$

and, inversely,

$$dr/dt = [x(dx/dt) + y(dy/dt) + z(dz/dt)]\Big/(x^2 + y^2 + z^2)^{1/2}, \tag{1.2.8p}$$

$$d\theta/dt = \big\{[x(dx/dt) + y(dy/dt)]z - (x^2 + y^2)(dz/dt)\big\}\Big/(x^2 + y^2)^{1/2}(x^2 + y^2 + z^2), \tag{1.2.8q}$$

$$d\phi/dt = [x(dy/dt) - y(dx/dt)]\Big/(x^2 + y^2); \tag{1.2.8r}$$

and

$$d^2r/dt^2 = \cdots, \qquad d^2\theta/dt^2 = \cdots, \quad d^2\phi/dt^2 = \cdots,$$

in complete agreement with (1.2.5).

REMARK

From now on, *parentheses around subscripts* (employed to denote physical components) will, normally, be omitted; that is, unless absolutely necessary, we shall simply write a_r, a_θ, a_ϕ for $a_{(r)}$, $a_{(\theta)}$, $a_{(\phi)}$, respectively, etc.

1.3 BODIES AND THEIR MASSES

Body or System

A body or system is an ordinary three-dimensional material object whose points fill a spatial region completely; or a *continuous* connected three-dimensional set of *material points*, or *mass points*, or *particles*, such that any part of it, no matter how small, possesses the same physical properties as the entire object. The interactions of bodies, under the action of forces/fields, produces the various physical phenomena.

Bodies are usually classified as *solids*, *fluids*, and *gases*.

- The *rigid body* is a special solid whose *deformation* (or *strain*), relative to its other motions, can be neglected; and whose geometric form/shape and spatial material distribution are invariable.
- The *particle* is a special rigid body whose *rotation*, relative to its other motions, can be neglected; it is small relative to its distance from other bodies, and its motion as a whole is virtually unaffected by its *internal* motion. It is a special *localized continuum* of infinite material density (see below).

The complete characterization of a particle requires specification of its *spatial position* and of the values of its associated *parameters* (e.g., mass, electric charge). The former varies with time but the latter, since they describe the internal constitution of our particle, do not; if they did, we would have a more complex system.

Whether one and the same body or system will be modeled as deformable continuum, or rigid, or particle, etc., depends on the problem at hand. Below, we show such a problem to model correspondence for the system Earth:

Problem	*Mathematical Model*
Orbit around the Sun	Particle
Tides and/or lunar eclipses	Rigid sphere
Precession of the equinoxes	Rigid ellipsoid
Earthquakes	Elastic sphere
etc.	

Mass

To each body, B, that instantaneously occupies continuously a spatial region of volume V, we assign, or order, a real, positive and *time-independent* number expressing the *quantity of matter in B*, its mass m; a primitive concept with dimensions independent of the (also primitives) length and time. Symbolically, we have

$$B \to m(B) \equiv m = \mathcal{S}_B \, dm = \int_V (dm/dV)\, dV \equiv \int_V \rho\, dV > 0, \tag{1.3.1}$$

where (continuity hypothesis)

$$\rho \equiv [\lim(\Delta m/\Delta V)]_{\Delta V \to 0} \equiv dm/dV: \qquad \text{mass } \textit{density}, \text{ or } \textit{specific mass}, \text{ of } B$$
$$\text{(a piecewise continuous function of } t \text{ and } \boldsymbol{r}) \tag{1.3.2}$$

and $m = constant$, for a given body (*conservation of mass*).

The above imply that the mass is *additive*: the mass of a body, or system, equals the sum of the masses of its parts; with some intuitively obvious notation:

$$m(B) = m(B_1 + B_2) = m(B_1) + m(B_2) = m_1 + m_2. \tag{1.3.3}$$

REMARKS

(i) For so-called "variable mass problems" (clearly, a misleading term); for example, rockets, chemical reactions, see Fox (1967, pp. 321–326) and, particularly, Novoselov (1969).

(ii) To describe several bodies, including possible gaps, via (1.3.1) and (1.3.2), we may have to assume that in some regions $\rho = 0$.

(iii) Mathematically, mass additivity can be expressed as follows: Consider an arbitrary subset of the body B, b. If we can associate with b a nonnegative real number $m(b)$, with physical dimensions independent of those of time and length, and such that

$$m(b_1 \cup b_2) = m(b_1) + m(b_2) \qquad [\cup \equiv \textit{union} \text{ of two sets}]$$

for all pairs b_1 and b_2 of disjoint subsets of b; and

$$m(b) \to 0,$$

as the volume occupied by b goes to zero; then we call B a *material body* with *mass function* m. The *additive set function* $m(b)$ is the mass of b; or the *mass content* of the corresponding set of points occupied by b. The above properties of $m(\ldots)$ imply the existence of a scalar field ρ = *mass density* of B, defined over the configuration of B, such that (1.3.1) holds.

Impenetrability Axiom (and One-to-One Event Occurrence)

Not more than one particle may occupy any position in space, at any given time. More generally (continuum form), if, during its motion, the material system initially occupies the spatial region V_o, and later the region V, then the relation between V_o and V is mutually one-to-one, and piecewise continuously differentiable (for the associated field functions). Discontinuities (e.g., rupture, impact) and accompanying loss of uniqueness can occur only across certain (two-dimensional) boundary surfaces.

Remarks on Particles, Bodies, Mathematical Modeling, and so on

(i) A finite, or *extended*, body B or system S can be treated exactly, or approximately, as a particle in the following three cases:

(a) If B undergoes pure *translation*; that is, all its points describe congruent paths with (vectorially) equal velocities and accelerations. In this case, *any point* of B can play the role of that particle.
(b) If the description of the kinetic properties of B requires only the investigation of the motion of its center of mass (§1.4).
(c) If B is such that its dimensions are so small (or its distances from other bodies, its environment, are so large) that its size can be neglected; and its motion can be represented satisfactorily by the motion of either its mass center or any other internal point of it. Such bodies we call *small*.

- In cases (b) (always) and (c) (usually) that particle is the mass center.
- Cases (a, b) are exact, while (c) is only approximate.
- In case (a), that particle describes the motion of B completely, in (b) only partially (the motion *about* the mass center is neglected), and in (c) with an *error* depending on the neglected dimensions of B.

From such a continuum viewpoint, a particle is viewed not as the building block of matter, but as *a rigid and rotationless body*! As Hamel (1909, p. 351) aptly summarizes: "What one understands, in practice, by particle mechanics

(Punktmechanik) is none other than the theorem of the center of mass (Schwerpunktsatz)."

(ii) Both models of a body—that is, the one based on the *atomistic* hypothesis (body as a finite, discrete, set of material points, or particles; namely, small hard balls with no rotational characteristics) and the other based on the *continuity* hypothesis (body as a family of measurable sets, with associated *additive set functions* representing the mass of that set)—have advantages and disadvantages; and both are useful for various purposes. The sometimes (in some engineering circles) fierce debate for/against one or the other viewpoint, we consider counterproductive and petty hair-splitting; and so we will use both models as needed. Such dualisms are no strangers to physics (e.g., particles/corpuscules vs. waves/fields in atomic phenomena) and constitute a creative, dialectical, stress in it.

Thus, we will view the rigid body (§1.8 ff.) either as a (finite or infinite) set of particles whose mutual distances are constrained to remain invariable (i.e., fixed in time); or, more conveniently, as *a rigid continuum*, and accept the Newton–Euler law of motion for its differential mass elements as for a particle (§1.4, §1.6). In the discrete model, the building block is the single "sizeless," but possibly quite "massive," particle of mass $m_k > 0\ (k = 1, 2, \ldots)$; while, in the continuum model, it is the differential element with mass $dm = \rho\, dV > 0$. In sum, we shall adopt the logically unorthodox, but quite fertile and successful, dialectical compromise: *particle language and continuum notation*; and eventually (chap. 3 ff.) we will end up with *ordinary differential equations*.

[In general, it is extremely difficult, if not impossible, to go by a limiting process from a statement about particles to one about continua; whereas, conversely, continuum statements formulated in terms of Stieltjes' integrals, like our earlier $\mathcal{S}(\ldots)$:

$$\mathcal{S}(\ldots)\, dm: \qquad \sum (\ldots)_k m_k \quad \text{(discrete)}, \qquad \text{or} \qquad \int_B (\ldots)\, dm \quad \text{(continuum)},$$

lead to the same statements for discrete systems without much difficulty, almost automatically. See, for example, Kilmister and Reeve (1966, pp. 129–131).]

1.4 FORCE; LAW OF NEWTON–EULER

> [I]n the concept of force lies the chief difficulty in the whole of mechanics.
>
> (Hamel, 1952; as quoted in Truesdell, 1984, p. 527)

> Jeder weiβ aus der Erfahrung, was Schwerkraft ist; jede gerichtete Physikalische Gröβe, die sich mit der Schwerkraft in Gleichgewicht befinden kann, ist eine Kraft!
> [Approximate translation: Everyone knows from experience what gravity is; *every directed physical quantity that can be in equilibrium with gravity is a force!* (emphasis added).]
>
> (How Hamel used to begin his mechanics lectures; quoted in Szabó, 1954, p. 26)

> The fundamental law of mechanics [i.e. mass $\times$ acceleration $=$ force] is a blank form which acquires a concrete content only when the conception of force occurring in it is filled in by physics.
>
> (Weyl, 1922, pp. 66–67)

Local Form of Newton–Euler Law

To each and every material particle P of elementary mass dm and inertial acceleration $\boldsymbol{a}$, of a body B or system S, we associate a *total* elementary force vector $d\boldsymbol{f}$ acting on it, such that

$$dm\,\boldsymbol{a} = d\boldsymbol{f}, \tag{1.4.1}$$

where $d\boldsymbol{f}$ itself is the resultant of other "partial" elementary forces of various origins (to be examined later); that is,

$$d\boldsymbol{f} = \sum d\boldsymbol{f}_k \qquad (k = 1, 2, \ldots). \tag{1.4.2}$$

Equation (1.4.1) is not simply a definition of one vector $(d\boldsymbol{f})$ in terms of another $(dm\,\boldsymbol{a})$, but is an equality of two physically very different vectors: one, *the effect* or *kinetic reaction* $(dm\,\boldsymbol{a})$, *depending only on the properties of the particle P itself*; and another, *the cause* $(d\boldsymbol{f})$, *depending on the interaction between P and the rest of the universe*—that is, on the action of the *external* world on the moving system, and the *mutual*, or *internal*, actions of the body parts on each other. Paraphrasing Hamel (1927, p. 3) slightly, we may state: The forces are determined by their "causes"; that is, by variables that represent the *geometrical*, *kinematical*, and *physical* state of the matter surrounding P (local causes) and away from it (global causes). This dependence is single-valued and, in general, continuous and differentiable; and, in addition, these forces are *objective*—that is, independent of the frame of reference (see also Hamel, 1949, pp. 509–512). In practice, this leads to *constitutive equations* for the forces (stresses) that, when combined with the *field*, or *ponderomotive*, equations (1.4.1) lead to relations of the form:

$$\boldsymbol{a} = \boldsymbol{a}(t, \boldsymbol{r}, \boldsymbol{v};\ \text{physical constants}); \tag{1.4.3}$$

where $\boldsymbol{a}$ may also depend on the $\boldsymbol{r}$'s and $\boldsymbol{v}$'s of *other system* (and even *external*) particles, but *not* on accelerations or other higher (than the first) $d/dt(\ldots)$-derivatives. Such an $\boldsymbol{a}$-dependence would introduce an *additional* constitutive, or constraint, equation of the form: $dm\,\boldsymbol{a} = d\boldsymbol{f}\ (\ldots, \boldsymbol{a}, \ldots)$. However, and this does not contradict (1.4.1), such equations *can* occur as *part of the solution process*; namely, through elimination of variables from the complete set of equations of the problem; that is, *elimination of forces related to the accelerations of other parts of the body*, so that the acceleration of point P depends on, among other things, the accelerations of points Q, $R, \ldots$. On this delicate and sometimes confusing point, see Hamel (1949, p. 49). In view of such difficulties in defining the force, a number of authors (mostly continuum mechanicians) consider it as a *primitive concept*—along with *space*, *time*, and *mass*.

Force Classification

[This also includes moments; and, in analytical mechanics, both forces and moments are replaced by *system*, or *generalized*, *forces* (§3.4).]

The most important such classifications are as follows:

Newton–Euler (or momentum) mechanics:

Internal: originating wholly from *within* the system; in pairs. They depend on the spatial limits of the system.

External: originating, even partially, from *outside* the system. Only such forces appear in the corresponding equations of equilibrium/motion.

Lagrangean (or energetic) mechanics:
Impressed: depending, even partially, on physical (material) coefficients (chap. 3).
Constraint reactions: depending exclusively on the constraints; geometrical and/or kinematical forces (chap. 3).

Continuum mechanics:
Surface, or *contact*: continuously distributed over material *surfaces* (and/or *lines* and *points*).
Volume, or *body*: continuously distributed over material *volumes*.

Usually, a given force is a combination of the above, and more. For example:

Gravity: external, impressed, body;

Stresses in rigid bodies: internal, reactions, surface;

Stresses in elastic bodies: internal, impressed, surface;

Dry rolling friction: internal or external, reaction, surface;

Dry sliding friction: internal or external, impressed, surface.

Other, more specialized force classifications are the following: *potential/nonpotential*, *conservative/nonconservative*, *gyroscopic/nongyroscopic*, *circulatory/noncirculatory*, *autonomous/nonautonomous*, etc. They will be introduced later, if and when needed. Occasionally, forces are classified with the help of the momentum principles as follows:

Linear or translatory loads: forces;

Angular or rotatory loads: moments of forces and moments of couples;

but such terminology is not uniform. For example, the authoritative Truesdell and Toupin (1960, p. 531) states that, in the general case, *the (total) torque consists of two parts: the moment of the force(s) and the couple*; also, virtually alone among mechanics works, it refuses to use the term *internal* forces, opting instead for the term *mutual* (loc. cit., pp. 533–535).

On Centers of Gravity and Mass, and Centroid

The *center of gravity* (*CG*) of a material system in a *parallel* gravitational field is a point defined uniquely by

$$\boldsymbol{r}_{CG} = \mathsf{S}\, \boldsymbol{r}\, dG \Big/ \mathsf{S}\, dG, \tag{1.4.4}$$

where $dG =$ elementary gravity force $= g\, dm = \rho g\, dV \equiv \gamma\, dV$; $g =$ acceleration of gravity; $\rho =$ density of matter; $\gamma =$ specific weight; $dm =$ element of mass; $dV =$ element of volume; and CG is *independent of the orientation of the system*, and through it passes the resultant gravity force, or weight, of the system, and: $\mathsf{S}(\ldots)$: *material summation*, for a fixed time, and valid for discrete and/or continuous distributions (Stieltjes' integral). This helpful notation, originated informally by Lagrange, is used a lot in the main body of this work.

The *center of mass*, or *inertial center*, (CM) of a material distribution is defined uniquely by

$$\boldsymbol{r}_{CM} \equiv \boldsymbol{r}_G = \mathsf{S}\, \boldsymbol{r}\, dm \Big/ \mathsf{S}\, dm. \tag{1.4.5}$$

The *centroid* (or *geometrical center*, or *geometrical* center of gravity) (C) of a figure is defined uniquely by

$$\boldsymbol{r}_C = \mathsf{S}\, \boldsymbol{r}\, dV \Big/ \mathsf{S}\, dV. \tag{1.4.6}$$

- If $g = \text{constant}$, the gravitational field is *uniform*. Then, $\boldsymbol{g} = g\,\boldsymbol{u} = constant$, $\boldsymbol{u} =$ vertical unit vector (positive downward).
- If $\rho = constant$, the body (matter) is *homogeneous*.

In a uniform field:

$$\boldsymbol{r}_{CG} = \boldsymbol{r}_{CM} \equiv \boldsymbol{r}_G; \tag{1.4.7a}$$

For a homogeneous body:

$$\boldsymbol{r}_{CM} \equiv \boldsymbol{r}_G = \boldsymbol{r}_C; \tag{1.4.7b}$$

For a homogeneous body in a uniform field:

$$\boldsymbol{r}_{CG} = \boldsymbol{r}_{CM} = \boldsymbol{r}_C. \tag{1.4.7c}$$

REMARK

In *nonuniform* fields, eq. (1.4.7a) is no longer true: the parts of the body closer to the attracting earth experience stronger gravity forces than those farther from it; and, therefore, upon rotation of the body, *the point of application of the resultant of such forces changes relative to the body*; that is, *the center of gravity is no longer definable as a unique body-fixed point*, *independent of the orientation of the body relative to the field*. The center of mass and centroid, however, are still defined uniquely by (1.4.5) and (1.4.6), respectively. Such complications may arise in problems of astronautics/spacecraft dynamics; there, we replace the constant $\boldsymbol{g}$ with a *central–symmetric* gravitational *field*.

1.5 SPACE-TIME AND THE PRINCIPLE OF GALILEAN RELATIVITY

Galilean Transformations (GT)

These are frame of reference transformations that leave the Newton–Euler law (1.4.1) *form invariant*. The most general such transformations have the following form (fig. 1.3):

$$\boldsymbol{r}' = \boldsymbol{A} \cdot \boldsymbol{r} + \boldsymbol{b}t + \boldsymbol{c} \qquad (\textit{Direct/matrix}\ \text{notation}) \tag{1.5.1a}$$

or

$$x_{k'} = \sum A_{k'k} x_k + b_{k'} t + c_{k'} \qquad (\textit{Component}\ \text{notation}), \tag{1.5.1b}$$

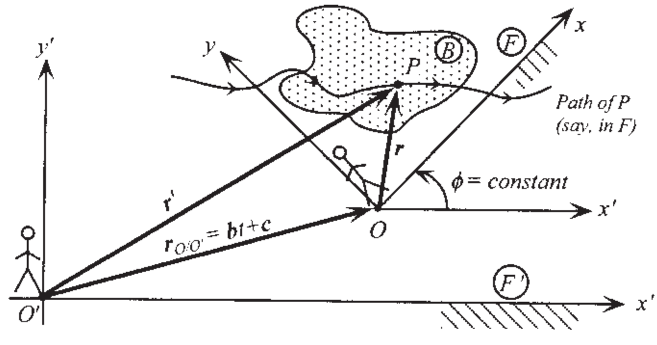

Figure 1.3 On the geometry of Galilean transformations.

where $\boldsymbol{A} = (A_{k'k})$ is a *proper orthogonal tensor with constant components*—that is, $\boldsymbol{A}^{-1} = \boldsymbol{A}^{\mathrm{T}}$; *Det* $\boldsymbol{A} = +1$; and $\boldsymbol{b} = (b_{k'})$ and $\boldsymbol{c} = (c_{k'})$ are *constant vectors*—that is, F and F' are in *nonrotating uniform motion* (*uniform translation*) relative to each other, with velocity $\boldsymbol{b}$; and

$$t' = \alpha t + \beta, \tag{1.5.1c}$$

where t is measured in F and t' in F', and α, β are constant scalars; α depends on the *units of time*, while β depends on its *origin* in the two systems of time measurement. Hence, if these units are taken to be the same, and these origins are made to coincide, then $\alpha = 1$ and $\beta = 0$; in which case (henceforth assumed in this book),

$$t' = t; \tag{1.5.1d}$$

that is, *in classical* (*Newtonian*) *mechanics there is*, *essentially*, *only one time scale*.

From the transformation equations (1.5.1a–d) we immediately obtain the following:

$$d^2\boldsymbol{r}'/dt^2 = \boldsymbol{A}\cdot(d^2\boldsymbol{r}/dt^2) \qquad \text{or} \qquad \boldsymbol{a}' = \boldsymbol{A}\cdot\boldsymbol{a}, \tag{1.5.2a}$$

or, explicitly, with some easily understood notation,

$$d^2x'/dt^2 = \cos(x',x)(d^2x/dt^2) + \cos(x',y)(d^2y/dt^2) + \cos(x',z)(d^2z/dt^2), \text{ etc.}; \tag{1.5.2b}$$

that is, the accelerations of a particle P as measured in F and F' differ only by an ordinary (time-independent) *geometrical* transformation due to the, possibly, different orientation of their axes; and, therefore, they are *physically* equal: that is, unaffected by the relative motion of F and F'. Hence, we may take, with no loss in physical generality, the corresponding axes of F and F' to be *ever parallel*, in which case $\boldsymbol{A} = \boldsymbol{1}$ (unit tensor), in which case (1.5.1a) simplifies to

$$\boldsymbol{r}' = \boldsymbol{r} + \boldsymbol{b}t + \boldsymbol{c} \;\Rightarrow\; \boldsymbol{a}' = \boldsymbol{a}. \tag{1.5.2c}$$

Since $dm|_F = dm|_{F'} \equiv dm$, and assuming that from $dm\,\boldsymbol{a} = d\boldsymbol{f}(t, \boldsymbol{r}, \boldsymbol{v})$ and (1.5.2c) it follows that

$$dm\,\boldsymbol{a}' = d\boldsymbol{f}\,(t, \boldsymbol{r}' - \boldsymbol{b}t - \boldsymbol{c}, d\boldsymbol{r}'/dt - \boldsymbol{b}) \equiv d\boldsymbol{f}\,'(t, \boldsymbol{r}', d\boldsymbol{r}'/dt \equiv \boldsymbol{v}') \equiv d\boldsymbol{f}\,'; \tag{1.5.3}$$

that is, $d\boldsymbol{f}$ is also invariant under GT, and, therefore, as far as the law of motion (1.4.1) is concerned, *there is no one* (*absolute*) *frame in which it holds*, *but*, *in fact*, *once* *one such "inertial" frame is established, there is a whole family of them dynamically equivalent to it*. More precisely, there is a (continuous linear) *group* that depends on *ten* (10) parameters: three for $\boldsymbol{A}$ [out of its nine components (direction cosines), due to the six orthonormality constraints, only three are independent], three for $\boldsymbol{b}$, three for $\boldsymbol{c}$, and one for β [equations (1.5.1c, d), $\alpha = 1$, with no loss in generality]. This Galilean, or Newtonian, *principle of relativity* can be summed up as follows: *an inertial frame — that is, one in which $dm(d^2\mathbf{r}/dt^2) = d\boldsymbol{f}$ holds — is determined only to within a Galilean transformation* (1.5.1a–d).

REMARKS

(i) The linear transformation (1.5.1c) can also be obtained by requiring that if

$$\boldsymbol{a} = d^2\mathbf{r}/dt^2 = \mathbf{0}, \tag{1.5.4a}$$

then also

$$d^2\mathbf{r}/d(t')^2 = \mathbf{0}, \tag{1.5.4b}$$

for arbitrary values of $\boldsymbol{r}$ and $d\mathbf{r}/dt$. Indeed, using chain rule, we find: $d\mathbf{r}/dt' = (d\mathbf{r}/dt)/(dt'/dt)$

$$\Rightarrow\ d^2\mathbf{r}/d(t')^2 = [(dt'/dt)(d^2\mathbf{r}/dt^2) - (d\mathbf{r}/dt)(d^2t'/dt^2)]\big/(dt'/dt)^3, \tag{1.5.4c}$$

and so, due to (1.5.4a), the requirement (1.5.4b) translates to

$$(d\mathbf{r}/dt)(d^2t'/dt^2) = \mathbf{0}, \qquad \text{for arbitrary } d\mathbf{r}/dt; \tag{1.5.4d}$$

that is,

$$d^2t'/dt^2 = 0\ \Rightarrow\ t' = \alpha t + \beta, \qquad \alpha, \beta\text{:}\quad \text{integration constants;}\quad \text{Q.E.D.} \tag{1.5.4e}$$

(ii) The logical circularity involved in the classical mechanics definition of inertial frames (i.e., "if $dm\,\boldsymbol{a} = d\boldsymbol{f}$ holds, the frame is inertial" and "if the frame is inertial frame then $dm\,\boldsymbol{a} = d\boldsymbol{f}$ holds") can be resolved only by *relativistic* physics. Here, we are content to postulate the existence of frames in which $dm\,\boldsymbol{a} = d\boldsymbol{f}$ holds exactly (or, equivalently, of frames in which *forceless motions are also unaccelerated motions*; i.e., the position vectors are linear functions of time, and vice versa); and to call such frames inertial. For detailed discussions of this important topic, see any good text on the physical foundations of relativity; e.g., Bergmann, 1942; Nevanlina, 1968.

1.6 THE FUNDAMENTAL PRINCIPLES (OR BALANCE LAWS) OF GENERAL SYSTEM MECHANICS

> An Axiom is a proposition, the truth of which must be admitted as soon as the terms in which it is expressed are clearly understood ... physical axioms are axiomatic to those only who have sufficient knowledge of the action of physical causes to enable them to see their truth.
>
> (Thomson and Tait, 1912, part 1, section 243, p. 240)

Conservation of Mass (Euler, Early 1760s)

$$dm(B)/dt \equiv dm/dt = d/dt\Big(\mathcal{S}\, dm\Big) = d/dt\Big(\int \rho\, dV\Big) = \int d/dt(\rho\, dV) = 0. \tag{1.6.1a}$$

(Henceforth, we shall, usually, omit the subscripts V, ∂V, etc., in the various integrals.)

In the absence of discontinuities, the above leads to the local (differential) form:

$$d/dt(\rho\, dV) = 0 \;\Rightarrow\; \rho\, dV = constant = \rho_o\, dV_o$$

$$[\textit{Material},\ \text{or}\ \textit{Lagrangean},\ \text{or}\ \textit{referential},\ \textit{equation of continuity}] \tag{1.6.1b}$$

where $\rho_o(dV_o)$ = density (element of volume) in some initial or *reference* configuration.

Principle of Linear Momentum [Euler, 1750 (publ. 1752)]

$$d/dt\Big(\mathcal{S}\, \boldsymbol{v}\, dm\Big) = \mathcal{S}\, d\boldsymbol{f} \qquad \text{or} \qquad d\boldsymbol{p}/dt = \boldsymbol{f}, \tag{1.6.2a}$$

where

$$\boldsymbol{p}(B,t) \equiv \boldsymbol{p} \equiv \mathcal{S}\, \boldsymbol{v}\, dm = \int \rho \boldsymbol{v}\, dV : \quad \textit{Linear momentum}\ \text{of}\ B, \tag{1.6.2b}$$

a system vector that depends on the frame, but not on the (fixed) origin in it; equivalent to Newton's "quantitas motus"; and $\mathcal{S}\, d\boldsymbol{f} \equiv \boldsymbol{f}$. From the above, and invoking mass conservation [§1.3:(1.3.1)ff.), (1.6.1a, b)] and the definition of mass center (§1.4), we obtain

$$\boldsymbol{p} = m\boldsymbol{v}_G \;\Rightarrow\; m\boldsymbol{a}_G = \boldsymbol{f}, \tag{1.6.2c}$$

where $\boldsymbol{r}_G/\boldsymbol{v}_G/\boldsymbol{a}_G$ are, respectively, the position/velocity/acceleration vectors of the center of mass of B, G. Equation (1.6.2c) shows that *the motion of the center of mass G, of a body (or any material system, rigid or not), B, is identical to that of a fictitious particle of mass m located at G and acted upon by the body resultant on B,* $\boldsymbol{f}$*;* that is, by the vector sum of all (→ external) forces transported parallel to themselves to G. Thus, the motion of G is taken care of by this simple principle → theorem. But the remaining problem of the *motion of B about G* (and, generally, of the motion of other body points) is far more difficult, and, unlike the motion of G, does depend on the specific material constitution of B (e.g., rigid, elastic), as well as on its motion (i.e., 1-, 2-, 3-dimensional); and, therefore, that problem necessitates additional considerations, such as the following.

Principle of Angular Momentum [Euler, 1775 (publ. 1776)]

$$d/dt\Big(\mathcal{S}\, (\boldsymbol{r} \times \boldsymbol{v}\, dm)\Big) = \mathcal{S}\, (\boldsymbol{r} \times d\boldsymbol{f}\,) \qquad \text{or} \qquad d\boldsymbol{H}_O/dt = \boldsymbol{M}_O, \tag{1.6.3a}$$

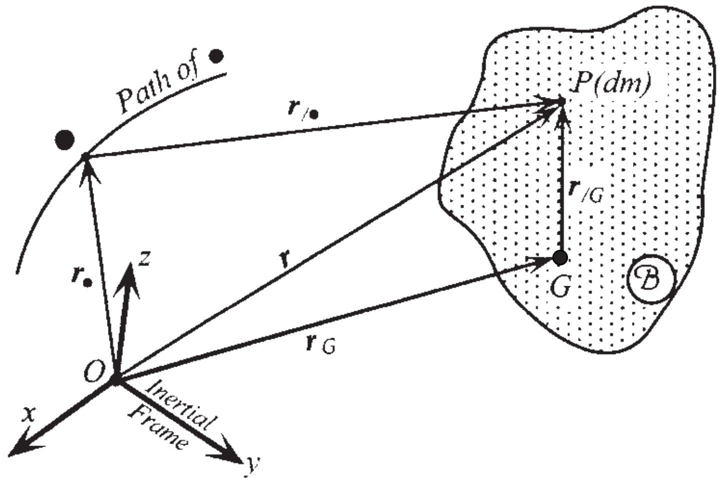

Figure 1.4 On the meaning of absolute and relative angular momentum.

where

$$\boldsymbol{H}_O(B, t) \equiv \boldsymbol{H}_O \equiv \mathsf{S}(\boldsymbol{r} \times \boldsymbol{v}\, dm)\text{: } \textit{absolute angular momentum} \text{ (or } \textit{moment of momentum}, \text{ or } \textit{kinetic moment}\text{), about the } \textit{fixed} \text{ point } O, \tag{1.6.3b}$$

and

$$\boldsymbol{M}_O \equiv \mathsf{S}(\boldsymbol{r} \times d\boldsymbol{f}\,)\text{: } \textit{total moment} \text{ about } O \text{ (fig. 1.4).} \tag{1.6.3c}$$

Other angular momenta, and their interrelations, are detailed in "Additional Forms of the Angular Momentum," below.

External and Internal Loads

In the Newton–Euler approach to system mechanics, whether discrete or continuous, we classify body and/or surface forces and moments as *internal* or *mutual* (i.e., those due *exclusively* to internal causes) and *external* [i.e., those whose cause(s) lie, even *partially*, outside of the body or system]. Stresses are caused by one or more of the following: (i) *deformations* (solids); (ii) *flows* (gases, liquids); (iii) *geometrical/kinematical constraints* [e.g., incompressibility, inextensibility (= incompressibility in one or two dimensions)].

Analytical mechanics necessitates a different force/moment classification (chap. 3).

Principle of Action–Reaction

(i) *Discrete version*. Let us consider a system of N particles $\{P_k;\ k = 1, \ldots, N\}$. Each particle P_k is acted upon by a total *external* (to that system) force $\boldsymbol{f}_{k,\mathrm{ext}}$ and a total *internal* force $\boldsymbol{f}_{k,\mathrm{int}}$ due to the other $N - 1$ particles:

$$\boldsymbol{f}_{k,\mathrm{int}} = \sum \boldsymbol{f}_{kl}, \qquad \text{with } l \neq k; \text{ i.e., } \boldsymbol{f}_{kk} \text{ is, as yet, undefined(!)} \tag{1.6.4a}$$

Now, by *Newton's third law of motion* (*action–reaction*) we shall understand the *constitutive* (i.e., *physical*) postulate;

(a) $\boldsymbol{f}_{kl} = -\boldsymbol{f}_{lk}$ and $\boldsymbol{f}_{kk} = \mathbf{0}$ (i.e., the particle cannot act on itself!) (1.6.4b)

and

(b) $(\boldsymbol{r}_k - \boldsymbol{r}_l) \times \boldsymbol{f}_{kl} = \mathbf{0}$ (i.e., the internal forces are *central* and *opposite*; or *oppositely directed pair by pair* and *collinear*). (1.6.4c)

[The *second* of (1.6.4b) is *not* included in the original Newtonian formulation. We follow Hamel (1949, p. 51).]

In the discrete/particle model, so popular among physicists and such an anathema among certain mechanicians, this postulate, plus the principle of linear momentum, lead to the *theorem* of angular momentum for the *external* loads only. However, the *converse* is not necessarily true; that is, *the angular momentum equation for a finite body* $d\boldsymbol{H}_O/dt = \boldsymbol{M}_{O,\text{external}}$ *does not necessarily lead to* (1.6.4b, c); other combinations of the internal forces may lead to the same effect (e.g., a sum of terms may vanish in a number of different ways). The converse *may* hold if we assume the validity of the angular momentum equation for *any* part of the system, or for any size subsystem.

(ii) *Continuum version.* For every pair of particles P_1 and P_2, with respective positions $\boldsymbol{r}_1$ and $\boldsymbol{r}_2$, the mutual forces and moments satisfy the following *constitutive* postulate:

$$d\boldsymbol{f}(\boldsymbol{r}_1, \boldsymbol{r}_2) = -d\boldsymbol{f}(\boldsymbol{r}_2, \boldsymbol{r}_1) \quad \text{and} \quad d\boldsymbol{M}(\boldsymbol{r}_1, \boldsymbol{r}_2) = -d\boldsymbol{M}(\boldsymbol{r}_2, \boldsymbol{r}_1). \tag{1.6.4d}$$

Without (1.6.4d), or something equivalent that supplies knowledge of the internal loads, the problem of mechanics would, in general, be *indeterminate* (i.e., the adopted model would produce more unknowns than the number of scalar equations furnished by its laws).

Additional Forms of the Angular Momentum

Although the results derived below hold for any body or system, they become useful only for *rigid* ones. We define the following *two* kinds of (inertial) angular momentum (fig. 1.4):

$$\boldsymbol{H}_{\bullet,\text{absolute}} \equiv \boldsymbol{H}_\bullet \equiv \int (\boldsymbol{r} - \boldsymbol{r}_\bullet) \times dm\, \boldsymbol{v} \equiv \int \boldsymbol{r}_{/\bullet} \times dm\, \boldsymbol{v}: \qquad [\boldsymbol{v} \equiv d\boldsymbol{r}/dt]$$

Absolute angular momentum of body B, about the arbitrarily moving point $\bullet$

[because it involves the absolute (inertial) velocity $\boldsymbol{v} \equiv d\boldsymbol{r}/dt$], (1.6.5a)

and

$$\boldsymbol{H}_{\bullet,\text{relative}} \equiv \boldsymbol{h}_\bullet \equiv \int (\boldsymbol{r} - \boldsymbol{r}_\bullet) \times dm\, (\boldsymbol{v} - \boldsymbol{v}_\bullet) \equiv \int \boldsymbol{r}_{/\bullet} \times dm\, \boldsymbol{v}_{/\bullet}:$$

Relative angular momentum of body B, about the arbitrarily moving point $\bullet$

[because it involves the relative (inertial) velocity $\boldsymbol{v} - \boldsymbol{v}_\bullet \equiv \boldsymbol{v}_{/\bullet}$]. (1.6.5b)

REMARKS

(i) Although these kinematico-inertial definitions hold for any frame of reference (with $\boldsymbol{r}$, $\boldsymbol{r}_\bullet$, $\boldsymbol{v}$, $\boldsymbol{v}_\bullet$ denoting the positions and velocities relative to points fixed or moving with respect to that frame—see §1.7), they will normally be understood to refer to a specific *inertial* frame, unless explicitly stated to the contrary.

(ii) Some authors define absolute angular momentum as in our (1.6.5a), but only for *fixed* points (i.e., $\boldsymbol{v}_\bullet = \mathbf{0}$); in which case, clearly, (1.6.5a) and (1.6.5b) coincide. Unfortunately, here too, there is no uniformity of terminology and or notation in the literature; but, as will be seen in kinetics, some angular momenta are more useful than others. The connection between the above two angular momenta is given by the following basic theorem.

THEOREM

The angular momenta $\boldsymbol{H}_\bullet$ and $\boldsymbol{h}_\bullet$, defined by equations (1.6.5a, b), are related by

$$\boldsymbol{H}_\bullet - \boldsymbol{h}_\bullet = m(\boldsymbol{r}_G - \boldsymbol{r}_\bullet) \times \boldsymbol{v}_\bullet \equiv m\boldsymbol{r}_{G/\bullet} \times \boldsymbol{v}_\bullet. \tag{1.6.5c}$$

PROOF

Subtracting (1.6.5b) from (1.6.5a) side by side, and then utilizing the properties of the center of mass of B, G, we obtain

$$\begin{aligned}\boldsymbol{H}_\bullet - \boldsymbol{h}_\bullet &= S\, \boldsymbol{r}_{/\bullet} \times (\boldsymbol{v} - \boldsymbol{v}_{/\bullet})\, dm = S\, (\boldsymbol{r}_{/\bullet} \times \boldsymbol{v}_\bullet)\, dm \\ &= S\, \boldsymbol{r} \times (dm\, \boldsymbol{v}_\bullet) - S\, (\boldsymbol{r}_\bullet \times \boldsymbol{v}_\bullet)\, dm = (m\boldsymbol{r}_G) \times \boldsymbol{v}_\bullet - \boldsymbol{r}_\bullet \times (m\boldsymbol{v}_\bullet), \quad \text{Q.E.D.}\end{aligned} \tag{1.6.5d}$$

Equations (1.6.5c, d) show immediately that, in the following three cases, the difference between absolute and relative angular momentum disappears:

(i) $\boldsymbol{r}_{G/\bullet} = \mathbf{0}$, i.e., $\bullet = G$: $\quad \boldsymbol{H}_G = \boldsymbol{h}_G = S\, \boldsymbol{r}_{/G} \times (dm\, \boldsymbol{v}_{/G})$, (1.6.5e)

(ii) $\boldsymbol{v}_\bullet = \mathbf{0}$, i.e., $\bullet$ = fixed origin, say O: $\quad \boldsymbol{H}_O = \boldsymbol{h}_O = S\, \boldsymbol{r} \times (dm\, \boldsymbol{v})$, (1.6.5f)

(iii) $\boldsymbol{r}_{G/\bullet}$ parallel to $\boldsymbol{v}_\bullet$. (1.6.5g)

The first and second cases, (1.6.5e, f), are, by far, the most important; (1.6.5g) may be hard to check *before* solving the (kinetic) problem.

Next, let us relate $\boldsymbol{H}_\bullet$ and $\boldsymbol{h}_\bullet$ with $\boldsymbol{H}_O$ (which appears in the basic Eulerian form of the angular momentum principle). We have, successively,

$$\begin{aligned}\boldsymbol{H}_O &= S\, \boldsymbol{r} \times (dm\, \boldsymbol{v}) \qquad \text{(introducing positions/velocities } \textit{relative} \text{ to } \bullet) \\ &= S\, [(\boldsymbol{r}_\bullet + \boldsymbol{r}_{/\bullet}) \times dm\, (\boldsymbol{v}_\bullet + \boldsymbol{v}_{/\bullet})] \\ &= \cdots = \boldsymbol{h}_\bullet + m(\boldsymbol{r}_\bullet \times \boldsymbol{v}_G) + m(\boldsymbol{r}_{G/\bullet} \times \boldsymbol{v}_\bullet), \qquad (1.6.5h) \\ &= \boldsymbol{H}_\bullet + m(\boldsymbol{r}_\bullet \times \boldsymbol{v}_G) \qquad \text{[thanks to (1.6.5c)].} \qquad (1.6.5i)\end{aligned}$$

The above leads easily to the following corollaries:

(i) If $\bullet = \textit{fixed} \Rightarrow \boldsymbol{v}_\bullet = \mathbf{0}$, then

$$\boldsymbol{H}_O = \boldsymbol{H}_\bullet + \boldsymbol{r}_\bullet \times (m\boldsymbol{v}_G) = \boldsymbol{h}_\bullet + m(\boldsymbol{r}_\bullet \times \boldsymbol{v}_G) \qquad [\boldsymbol{r}_\bullet \equiv \boldsymbol{r}_{\bullet/O},\ \boldsymbol{H}_\bullet = \boldsymbol{h}_\bullet]; \tag{1.6.5j}$$

a slight generalization over (1.6.5f).

(ii) If $\bullet = G$, then

$$\begin{aligned}\boldsymbol{H}_O &= \boldsymbol{H}_G + \boldsymbol{r}_G \times (m\boldsymbol{v}_G) = \boldsymbol{h}_G + m(\boldsymbol{r}_G \times \boldsymbol{v}_G) \\ &\quad [\boldsymbol{r}_G \equiv \boldsymbol{r}_{G/O}, \boldsymbol{v}_G \equiv d\boldsymbol{r}_G/dt; \quad \boldsymbol{H}_G = \boldsymbol{h}_G].\end{aligned} \tag{1.6.5k}$$

By comparing (1.6.5h,i) with (1.6.5k), it can be seen that

$$\boldsymbol{H}_\bullet = \boldsymbol{H}_G + \boldsymbol{r}_{G/\bullet} \times (m\boldsymbol{v}_G), \qquad \boldsymbol{h}_\bullet = \boldsymbol{H}_G + \boldsymbol{r}_{G/\bullet} \times (m\boldsymbol{v}_{G/\bullet}). \tag{1.6.5l}$$

(Interpret these "transfer" equations geometrically. What happens if $\bullet$ is *fixed*; say, an origin O?) Finally, by applying the transfer equations (1.6.5h, i) between O and the arbitrarily moving points 1 and 2, and then comparing, we can obtain the relation between the absolute, relative, and absolute–relative angular momenta of a body: $\boldsymbol{H}_1 \leftrightarrow \boldsymbol{H}_2$, $\boldsymbol{H}_1 \leftrightarrow \boldsymbol{h}_2$, $\boldsymbol{h}_1 \leftrightarrow \boldsymbol{h}_2$.

Additional Forms of the Principle of Angular Momentum

With the help of the preceding kinematico-inertial identities/results, and the purely geometrical theorem of transfer of moments (hopefully well known from elementary statics)

$$\boldsymbol{M}_\bullet = \boldsymbol{M}_G + \boldsymbol{r}_{G/\bullet} \times \boldsymbol{f} \qquad \text{[where the force resultant } \boldsymbol{f} \text{ goes through } G]$$

$$= \boldsymbol{M}_G + \boldsymbol{r}_{G/\bullet} \times (m\boldsymbol{a}_G) \qquad \text{[by the principle of \textit{linear} momentum]}, \tag{1.6.6a}$$

the Eulerian principle of angular momentum

$$S\, \boldsymbol{r} \times (dm\, \boldsymbol{a}) = d/dt\Big(S\, \boldsymbol{r} \times (dm\, \boldsymbol{v})\Big) = S\, \boldsymbol{r} \times d\boldsymbol{f};$$

that is,

$$d\boldsymbol{H}_O/dt = \boldsymbol{M}_O \tag{1.6.6b}$$

[$\Rightarrow \boldsymbol{M}_{O,\text{external}}$, by action–reaction (plus, in the continuum version, of *Boltzmann's axiom* $\Rightarrow$ *symmetry* of the stress tensor)],

assumes the following forms:

Center of Mass Form

By (1.6.5k):

$$d\boldsymbol{H}_O/dt = d/dt[\boldsymbol{H}_G + \boldsymbol{r}_G \times (m\boldsymbol{v}_G)] = d\boldsymbol{H}_G/dt + m(\boldsymbol{r}_G \times \boldsymbol{a}_G), \tag{1.6.6c}$$

and by (1.6.6a), for $\bullet \to O$:

$$\boldsymbol{M}_O = \boldsymbol{M}_G + \boldsymbol{r}_G \times (m\boldsymbol{a}_G); \tag{1.6.6d}$$

and comparing these expressions with (1.6.6b), we obtain the fundamental form

$$\boldsymbol{M}_G = d\boldsymbol{H}_G/dt \; (= d\boldsymbol{h}_G/dt). \tag{1.6.6e}$$

Absolute Form

Using the above, and (1.6.5l), we obtain, successively,

$$\begin{aligned}\boldsymbol{M}_\bullet &= \boldsymbol{M}_G + \boldsymbol{r}_{G/\bullet} \times (m\boldsymbol{a}_G) = d\boldsymbol{H}_G/dt + \boldsymbol{r}_{G/\bullet} \times (m\boldsymbol{a}_G)\\ &= d/dt\left[\boldsymbol{H}_\bullet - \boldsymbol{r}_{G/\bullet} \times (m\boldsymbol{v}_G)\right] + \boldsymbol{r}_{G/\bullet} \times (m\boldsymbol{a}_G)\\ &= d\boldsymbol{H}_\bullet/dt - \boldsymbol{v}_{G/\bullet} \times (m\boldsymbol{v}_G) - \boldsymbol{r}_{G/\bullet} \times (m\boldsymbol{a}_G) + \boldsymbol{r}_{G/\bullet} \times (m\boldsymbol{a}_G);\end{aligned}$$

that is, finally,

$$\begin{aligned} \boldsymbol{M}_\bullet &= d\boldsymbol{H}_\bullet/dt - \boldsymbol{v}_{G/\bullet} \times (m\boldsymbol{v}_G) \qquad (\text{using } \boldsymbol{v}_{G/\bullet} \equiv \boldsymbol{v}_G - \boldsymbol{v}_\bullet) \\ &= d\boldsymbol{H}_\bullet/dt + \boldsymbol{v}_\bullet \times (m\boldsymbol{v}_G) = d\boldsymbol{H}_\bullet/dt + \boldsymbol{v}_\bullet \times (m\boldsymbol{v}_{G/\bullet}). \end{aligned} \tag{1.6.6f}$$

Relative Form

Similarly, using the above, and (1.6.5l), we obtain, successively,

$$\begin{aligned} \boldsymbol{M}_\bullet &= \boldsymbol{M}_G + \boldsymbol{r}_{G/\bullet} \times (m\boldsymbol{a}_G) = d\boldsymbol{H}_G/dt + \boldsymbol{r}_{G/\bullet} \times (m\boldsymbol{a}_G) \\ &= d/dt\big(\boldsymbol{h}_\bullet - \boldsymbol{r}_{G/\bullet} \times (m\boldsymbol{v}_{G/\bullet})\big) + \boldsymbol{r}_{G/\bullet} \times (m\boldsymbol{a}_G) \\ &= d\boldsymbol{h}_\bullet/dt - \boldsymbol{v}_{G/\bullet} \times (m\boldsymbol{v}_{G/\bullet}) - \boldsymbol{r}_{G/\bullet} \times (m\boldsymbol{a}_{G/\bullet}) + \boldsymbol{r}_{G/\bullet} \times (m\boldsymbol{a}_G); \end{aligned}$$

that is, finally,

$$\boldsymbol{M}_\bullet = d\boldsymbol{h}_\bullet/dt + \boldsymbol{r}_{G/\bullet} \times (m\boldsymbol{a}_\bullet). \tag{1.6.6g}$$

In particular, if $\bullet$ is *fixed*, then (1.6.6f,g) reduce at once to

$$\boldsymbol{M}_\bullet = d\boldsymbol{H}_\bullet/dt \quad (= d\boldsymbol{h}_\bullet/dt); \tag{1.6.6h}$$

which, since it holds for *any* fixed point, is a slight generalization of (1.6.6b). These forms show clearly the importance of *fixed points* and of the *center of mass*, above all other points, in rotational dynamics, especially rigid-body dynamics. All these forms of the principle of angular momentum, and many more flowing from them, can be quite confusing, they are almost impossible to remember, and may be error-prone in concrete applications. They are stated here only for comparison purposes with the existing literature. From them, the most useful in both theoretical and practical situations, are, by far, (1.6.6b,e), and, secondarily, (1.6.6a) with (1.6.6e). We summarize them here:

$$\boldsymbol{M}_O = d\boldsymbol{H}_O/dt \quad \Big\{\equiv d/dt\Big(\int \boldsymbol{r} \times (dm\boldsymbol{v})\Big)\Big\}, \qquad O\text{: } \textit{fixed origin}; \tag{1.6.6i}$$

$$\boldsymbol{M}_G = d\boldsymbol{H}_G/dt \quad \Big\{\equiv d/dt\Big(\int \boldsymbol{r}_{/G} \times (dm\boldsymbol{v}_{/G})\Big)\Big\}, \qquad G\text{: } \textit{center of mass}; \tag{1.6.6j}$$

$$\boldsymbol{M}_\bullet = d\boldsymbol{H}_G/dt + \boldsymbol{r}_{G/\bullet} \times (m\boldsymbol{a}_G), \qquad \bullet\text{: } \textit{arbitrarily moving spatial point}, \tag{1.6.6k}$$

or, compactly,

$$\text{Kinetic vectors ("torsor") at } G\text{: } (m\boldsymbol{a}_G, d\boldsymbol{H}_G/dt)$$

$$\sim \text{Kinetic torsor at } \bullet\text{: } \big(m\boldsymbol{a}_G, d\boldsymbol{H}_G/dt + \boldsymbol{r}_{G/\bullet} \times (m\boldsymbol{a}_G)\big);$$

and we are reminded that their left sides, by action–reaction (plus Boltzmann's axiom, i.e., *symmetry* of stress tensor), include only *external* moments and couples.

By comparing the absolute and relative forms of the principle of angular momentum, eqs. (1.6.6f, g) [or by $d/dt(\ldots)$, eq. (1.6.5c)], we can show that

$$\begin{aligned} d\boldsymbol{H}_\bullet/dt - d\boldsymbol{h}_\bullet/dt &= \boldsymbol{r}_{G/\bullet} \times (m\boldsymbol{a}_\bullet) + \boldsymbol{v}_{G/\bullet} \times (m\boldsymbol{v}_\bullet) \\ &= \boldsymbol{r}_{G/\bullet} \times (m\boldsymbol{a}_\bullet) + \boldsymbol{v}_G \times (m\boldsymbol{v}_\bullet) = \boldsymbol{r}_{G/\bullet} \times (m\boldsymbol{a}_\bullet) + \boldsymbol{v}_G \times (m\boldsymbol{v}_{\bullet/G}). \end{aligned} \tag{1.6.6l}$$

Finally, crossing the local law of motion $dm\,\boldsymbol{a} = d\boldsymbol{f}$ with $\boldsymbol{r}_{/\bullet} \equiv \boldsymbol{r} - \boldsymbol{r}_{\bullet}$, and then integrating over the body, etc., we obtain the following additional form of the principle of angular momentum:

$$\boldsymbol{M}_{\bullet} = d\boldsymbol{H}_O/dt - \boldsymbol{r}_{\bullet} \times (m\boldsymbol{a}_G) \quad (= \boldsymbol{M}_O - \boldsymbol{r}_{\bullet} \times \boldsymbol{f}, \text{ with } \boldsymbol{f} \text{ applied at } \bullet). \qquad (1.6.6\text{m})$$

1.7 ACCELERATED (NONINERTIAL) FRAMES OF REFERENCE (OR RELATIVE MOTION, OR MOVING AXES); ANGULAR VELOCITY AND ACCELERATION

The theory of moving axes, a subject indispensable to rigid-body dynamics and other key areas of mechanics (including the transition to relativity), is based on the following fundamental kinematical theorem.

Theorem (of Moving Axes)

Let us consider two frames of reference in arbitrary relative motion, each represented by an ortho–normal–dextral (OND) basis and associated coordinate axes, rigidly attached to the frame; say, for concreteness but no loss in generality, one *fixed* or *inertial* F:

$$\begin{aligned}(O_F - \boldsymbol{I}, \boldsymbol{J}, \boldsymbol{K}/X, Y, Z) &\equiv (O_F - \boldsymbol{u}_X, \boldsymbol{u}_Y, \boldsymbol{u}_Z/X, Y, Z) \equiv (O_F - \boldsymbol{u}_{X,Y,Z}/X, Y, Z)\\ &\equiv (O_F - \boldsymbol{u}_{k'}/x_{k'};\ k' = 1, 2, 3/X, Y, Z), \qquad (1.7.1\text{a})\end{aligned}$$

and one *moving* or *noninertial* M:

$$\begin{aligned}(O_M - \boldsymbol{i}, \boldsymbol{j}, \boldsymbol{k}/x, y, z) &\equiv (O_M - \boldsymbol{u}_x, \boldsymbol{u}_y, \boldsymbol{u}_z/x, y, z) \equiv (O_M - \boldsymbol{u}_{x,y,z}/x, y, z)\\ &\equiv (O_M - \boldsymbol{u}_k/x_k;\ k = 1, 2, 3/x, y, z), \qquad (1.7.1\text{b})\end{aligned}$$

and an arbitrary (say free) vector $\boldsymbol{p}$ [fig. 1.5(a)]. Then its rate of change in F and M, $d\boldsymbol{p}/dt$ and $\partial\boldsymbol{p}/\partial t$, respectively, are related by

$$d\boldsymbol{p}/dt = \partial\boldsymbol{p}/\partial t + \boldsymbol{\omega} \times \boldsymbol{p}, \qquad (1.7.2\text{a})$$

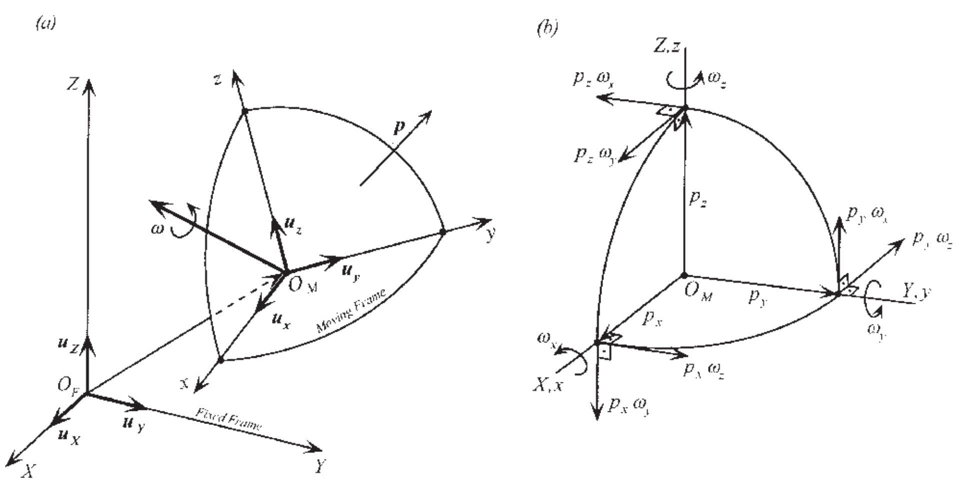

Figure 1.5 (a) Geometry of moving frames; (b) geometrical proof of (1.7.3c).

where (recalling the moving axes theory, §1.1)

$$\boldsymbol{p} = p_X \boldsymbol{u}_X + p_Y \boldsymbol{u}_Y + p_Z \boldsymbol{u}_Z \equiv \sum p_{k'} \boldsymbol{u}_{k'} = p_x \boldsymbol{u}_x + p_y \boldsymbol{u}_y + p_z \boldsymbol{u}_z \equiv \sum p_k \boldsymbol{u}_k,$$

$$[\textit{assumed}\ \text{instantaneous representation of}\ \boldsymbol{p}\ \text{in}\ F\ \text{and}\ M]; \tag{1.7.2b}$$

$$d\boldsymbol{p}/dt \equiv (dp_X/dt)\boldsymbol{u}_X + (dp_Y/dt)\boldsymbol{u}_Y + (dp_Z/dt)\boldsymbol{u}_Z = \sum (dp_{k'}/dt)\boldsymbol{u}_{k'}:$$

$$\textit{Absolute rate of change of}\ \boldsymbol{p}\ (\text{or}\ \textit{time flux});\ \text{i.e., relative to}\ F; \tag{1.7.2c}$$

$$\partial\boldsymbol{p}/\partial t \equiv (dp_x/dt)\boldsymbol{u}_x + (dp_y/dt)\boldsymbol{u}_y + (dp_z/dt)\boldsymbol{u}_z = \sum (dp_k/dt)\boldsymbol{u}_k:$$

$$\textit{Relative rate of change of}\ \boldsymbol{p};\ \text{i.e., relative to}\ M; \tag{1.7.2d}$$

$$\boldsymbol{\omega} = \omega_X \boldsymbol{u}_X + \omega_Y \boldsymbol{u}_Y + \omega_Z \boldsymbol{u}_Z \equiv \sum \omega_{k'} \boldsymbol{u}_{k'} = \omega_x \boldsymbol{u}_x + \omega_y \boldsymbol{u}_y + \omega_z \boldsymbol{u}_z \equiv \sum \omega_k \boldsymbol{u}_k$$

$$\equiv [(d\boldsymbol{u}_y/dt)\cdot\boldsymbol{u}_z]\boldsymbol{u}_x + [(d\boldsymbol{u}_z/dt)\cdot\boldsymbol{u}_x]\boldsymbol{u}_y + [(d\boldsymbol{u}_x/dt)\cdot\boldsymbol{u}_y]\boldsymbol{u}_z:$$

$$\textit{Angular velocity (vector) of}\ M_{\text{moving frame}}\ \textit{relative to}\ F_{\text{fixed frame}};$$

$$\text{i.e.,}\ \textit{of}\ (O_M - \boldsymbol{u}_{k'})\ \textit{relative to}\ (O_F - \boldsymbol{u}_k); \tag{1.7.2e}$$

$$\boldsymbol{\omega} \times \boldsymbol{p} = \textit{Transport rate of change of}\ \boldsymbol{p}\ \textit{relative to}\ F. \tag{1.7.2f}$$

NOTATIONAL CLARIFICATION

Here, *partial derivatives*, $\partial(\ldots)/\partial t$, are, normally, associated with *moving* frame(s); while, for simplicity, primed *subscripts* signify *fixed* axes/components.

To express this theorem in components, which is the best way to understand it, the simplest way is to *choose the axes O_F–XYZ and O_M–xyz so that*, instantaneously, *either they coincide or are parallel*. Then, since in such a case,

$$(d\boldsymbol{p}/dt)_X \equiv (d\boldsymbol{p}/dt)\cdot\boldsymbol{u}_X \equiv dp_X/dt = (d\boldsymbol{p}/dt)\cdot\boldsymbol{u}_x \equiv (d\boldsymbol{p}/dt)_x, \qquad \text{etc., cyclically,} \tag{1.7.3a}$$

$$(\partial\boldsymbol{p}/\partial t)_x \equiv (\partial\boldsymbol{p}/\partial t)\cdot\boldsymbol{u}_x \equiv dp_x/dt = (\partial\boldsymbol{p}/\partial t)\cdot\boldsymbol{u}_X \equiv (\partial\boldsymbol{p}/\partial t)_X, \quad \text{etc., cyclically,} \tag{1.7.3b}$$

the theorem assumes the component form:

$$\begin{aligned} dp_X/dt &= dp_x/dt + \omega_y p_z - \omega_z p_y, \\ dp_Y/dt &= dp_y/dt + \omega_z p_x - \omega_x p_z, \\ dp_Z/dt &= dp_z/dt + \omega_x p_y - \omega_y p_x; \end{aligned} \tag{1.7.3c}$$

and gives inertial rates of change, but expressed in terms of noninertial (relative) and transport rates. The above show clearly that

$$(d\boldsymbol{p}/dt)_k \neq dp_k/dt \qquad (k = x, y, z); \tag{1.7.3d}$$

even though, instantaneously,

$$p_X = p_x, \quad \text{etc., cyclically,} \tag{1.7.3e}$$

unless $\boldsymbol{\omega} \times \boldsymbol{p} = \boldsymbol{0}$ ($\Rightarrow \boldsymbol{\omega} = \boldsymbol{0}$, or $\boldsymbol{p} = \boldsymbol{0}$, or $\boldsymbol{\omega}$ parallel to $\boldsymbol{p}$).

A geometrical interpretation of (1.7.3c) is shown in fig. 1.5(b): the moving axes O_M–xyz momentarily coincide with the axes O_M–XYZ; the latter are always translating relative to O_F–XYZ—that is, they are "rotationally equivalent" to them.

PROOF OF EQUATION (1.7.2a)

By $d/dt(\ldots)$-differentiating (1.7.2b), we obtain

$$d\boldsymbol{p}/dt = (dp_x/dt)\boldsymbol{u}_x + p_x(d\boldsymbol{u}_x/dt) + \cdots = \partial\boldsymbol{p}/\partial t + \sum p_k(d\boldsymbol{u}_k/dt). \qquad (1.7.4a)$$

To transform the key second term in the above, we begin by $d/dt(\ldots)$-differentiating the six *geometrical orthonormality* ($\Rightarrow$ *rigidity*) *constraints* of these basis vectors $\boldsymbol{u}_k \cdot \boldsymbol{u}_l = \delta_{kl}$ $(k, l = x, y, z)$, thus translating them into the following six *kinematical constraints*:

$$(d\boldsymbol{u}_k/dt) \cdot \boldsymbol{u}_l + \boldsymbol{u}_k \cdot (d\boldsymbol{u}_l/dt) = 0; \qquad (1.7.4b)$$

that is, from the nine components of $\{d\boldsymbol{u}_k/dt\}$ only $9 - 6 = 3$ are *independent*.

Let us find them. By (1.7.4b) for k, $l = x$, $d\boldsymbol{u}_x/dt$ is perpendicular to $\boldsymbol{u}_x$; that is, it must lie in the plane of $\boldsymbol{u}_y$, $\boldsymbol{u}_z$. Therefore, we can write

$$d\boldsymbol{u}_x/dt = l_1\boldsymbol{u}_y + l_2\boldsymbol{u}_z; \qquad (1.7.4c)$$

and, cyclically,

$$d\boldsymbol{u}_y/dt = l_3\boldsymbol{u}_z + l_4\boldsymbol{u}_x, \qquad d\boldsymbol{u}_z/dt = l_5\boldsymbol{u}_x + l_6\boldsymbol{u}_y; \qquad (1.7.4d)$$

where $l_{1,\ldots,6}$ are scalar functions of time. Substituting these representations back into (1.7.4b) for $k = x$, $l = y$, and taking into account the geometrical constraints, we obtain

$$(d\boldsymbol{u}_x/dt) \cdot \boldsymbol{u}_y + \boldsymbol{u}_x \cdot (d\boldsymbol{u}_y/dt) = 0 \;\Rightarrow\; l_1 + l_4 = 0; \qquad (1.7.4e)$$

and, cyclically,

$$(d\boldsymbol{u}_y/dt) \cdot \boldsymbol{u}_z + \boldsymbol{u}_y \cdot (d\boldsymbol{u}_z/dt) = 0 \;\Rightarrow\; l_3 + l_6 = 0, \qquad (1.7.4f)$$

$$(d\boldsymbol{u}_z/dt) \cdot \boldsymbol{u}_x + \boldsymbol{u}_z \cdot (d\boldsymbol{u}_x/dt) = 0 \;\Rightarrow\; l_5 + l_2 = 0. \qquad (1.7.4g)$$

Hence, (1.7.4c,d) can be rewritten in terms of the following *three* independent (unconstrained) l's, or in terms of the three equivalent parameters ω_x, ω_y, ω_z:

$$l_1 = -l_4 \equiv \omega_z, \qquad l_3 = -l_6 \equiv \omega_x, \qquad l_5 = -l_2 \equiv \omega_y, \qquad (1.7.4h)$$

as

$$\begin{aligned} d\boldsymbol{u}_x/dt &= \omega_z\boldsymbol{u}_y - \omega_y\boldsymbol{u}_z = \boldsymbol{\omega} \times \boldsymbol{u}_x, \\ d\boldsymbol{u}_y/dt &= \omega_x\boldsymbol{u}_z - \omega_z\boldsymbol{u}_x = \boldsymbol{\omega} \times \boldsymbol{u}_y, \\ d\boldsymbol{u}_z/dt &= \omega_y\boldsymbol{u}_x - \omega_x\boldsymbol{u}_y = \boldsymbol{\omega} \times \boldsymbol{u}_z; \end{aligned} \qquad (1.7.4i)$$

where

$$\begin{aligned}\boldsymbol{\omega} &= \omega_x \boldsymbol{u}_x + \omega_y \boldsymbol{u}_y + \omega_z \boldsymbol{u}_z \\ &= \boldsymbol{u}_x[(d\boldsymbol{u}_y/dt)\cdot\boldsymbol{u}_z] + \boldsymbol{u}_y[(d\boldsymbol{u}_z/dt)\cdot\boldsymbol{u}_x] + \boldsymbol{u}_z[(d\boldsymbol{u}_x/dt)\cdot\boldsymbol{u}_y] \\ &\qquad \text{[a form that shows the } \textit{cyclicity} \text{ of the subscripts } x, y, z] \\ &= -\boldsymbol{u}_x[(d\boldsymbol{u}_z/dt)\cdot\boldsymbol{u}_y] - \boldsymbol{u}_y[(d\boldsymbol{u}_x/dt)\cdot\boldsymbol{u}_z] - \boldsymbol{u}_z[(d\boldsymbol{u}_y/dt)\cdot\boldsymbol{u}_x]. \end{aligned} \tag{1.7.4j}$$

Finally, substituting these results into (1.7.4a), we obtain (1.7.2a):

$$\begin{aligned} d\boldsymbol{p}/dt &= \partial\boldsymbol{p}/\partial t + \sum p_k(\boldsymbol{\omega}\times\boldsymbol{u}_k) = \partial\boldsymbol{p}/\partial t + \boldsymbol{\omega}\times\left(\sum p_k \boldsymbol{u}_k\right) \\ &= \partial\boldsymbol{p}/\partial t + \boldsymbol{\omega}\times\boldsymbol{p}. \end{aligned} \tag{1.7.4k}$$

REMARKS

(i) Frequently, and with some good reason, the notation $\delta\boldsymbol{p}/\delta t$ is employed for our $\partial\boldsymbol{p}/\partial t$. Here, however, we chose the latter because in analytical mechanics $\delta(\ldots)$ is reserved for *virtual* changes, under which $\delta t = 0$ (chap. 2ff.). Other popular notations for the relative rate of change are $\partial^*\boldsymbol{p}/\partial t$ (British authors; but some German authors use $\partial\boldsymbol{p}/\partial t$ for our $\boldsymbol{\omega}\times\boldsymbol{p}$), $(d\boldsymbol{p}/dt)_M$ or $(d\boldsymbol{p}/dt)_{\text{rel}}$ or $d^*\boldsymbol{p}/dt$; or with a tilde over d (Soviet/Russian authors) $\tilde{d}$. Also recall remarks made regarding eq. (1.1.20i) about the *overdot* notation.

(ii) The *vector* equation (1.7.2a) can be expressed in component form (i.e., it can be projected) along any axes, fixed or moving, by eqs. (1.7.3c), if O_M–xyz and O_M–XYZ momentarily coincide; and, if they do not, by

$$\begin{aligned}(d\boldsymbol{p}/dt)_x &= \cos(x,X)(dp_X/dt) + \cos(x,Y)(dp_Y/dt) + \cos(x,Z)(dp_Z/dt) \quad (\neq dp_x/dt) \\ &= \cos(x,X)(dp_1/dt + \omega_2 p_3 - \omega_3 p_2) + \cdots, \end{aligned} \tag{1.7.5a}$$

where the new axes O_M–123 coincide momentarily with O_M–XYZ, but, in general, have an angular velocity $\boldsymbol{\omega}' = (\omega_1, \omega_2, \omega_3)$ relative to them.

(iii) The above show that as long as no rates of change are involved, the components of a vector along the various axes (fixed or moving) are related by ordinary *coordinate* transformations, with possibly *time-dependent coefficients*—that is, like the *first* line of (1.7.5a), or (1.7.5b), below; all such axes are mechanically (though not mathematically) equivalent. But when rates of change between such moving axes (→ frames) are compared, then, in general, *a component of a vector derivative* $(d\boldsymbol{p}/dt)_x$ *does not equal the derivative of that component* dp_x/dt [(1.7.3d, e)]; these quantities are related by a *frame of reference* transformation—that is, like the *second* line of (1.7.5a). Mathematically, this is equivalent to an *explicitly time-dependent* coordinate transformation: $x = x(X, Y, Z; t), \ldots \Leftrightarrow X = X(x, y, z; t), \ldots$ (recall discussion following eq. (1.1.20k)). In such cases, to obtain equations like (1.7.3c), we begin with O_M–XYZ and O_M–xyz in *arbitrary relative orientations*, then we $d/dt(\ldots)$-differentiate the component transformations, like

$$p_x = \cos(x,X)p_X + \cos(x,Y)p_Y + \cos(x,Z)p_Z, \quad \text{etc., cyclically,} \tag{1.7.5b}$$

(*not* like $p_x = p_X$) and *then* we make O_M–XYZ and O_M–xyz coincide.

(iv) In kinematics, all frames are theoretically equivalent; and thus during the 17th century *both* Galileo and the Catholic church were ... kinematically correct! This is expressed by the following *geometrical*, or *Euclidean*, and *kinematical principle of relativity*: any system of rectangular Cartesian coordinates can be replaced by any other such system that moves in an arbitrary fashion relative to the first; or, alternatively, *the form of geometrical relationships must be invariant under the proper orthogonal group of rotations*—and this, in effect, constitutes a definition of Euclidean geometry—that is, any two such sets of coordinates $x_{k'}$ and x_k are related by

$$x_{k'} = \sum A_{k'k}(t)x_k + A_{k'}(t), \tag{1.7.6a}$$

where

$$\sum A_{k'k}(t)A_{l'k}(t) = \delta_{k'l'}, \qquad \sum A_{k'k}(t)A_{k'l}(t) = \delta_{kl},$$

and

$$\mathrm{Det}(A_{k'k}(t)) = +1, \tag{1.7.6b}$$

and $A_{k'k}(t)$, $A_{k'}(t)$ are continuous functions of time, with first and second time derivatives. Such transformations include all frames/motions produced from the moving frame M by a *continuous* rigid-body movement (*translations* and *rotations*, but not mirror reflections).

(v) If the moving triad $\boldsymbol{u}_{x,y,z}$ is *non-OND*, then its inertial angular velocity is, instead of (1.7.4j),

$$\boldsymbol{\omega} = \left\{\boldsymbol{u}_x[(d\boldsymbol{u}_y/dt)\cdot\boldsymbol{u}_z] + \boldsymbol{u}_y[(d\boldsymbol{u}_z/dt)\cdot\boldsymbol{u}_x] + \boldsymbol{u}_z[(d\boldsymbol{u}_x/dt)\cdot\boldsymbol{u}_y]\right\}\Big/[\boldsymbol{u}_x\cdot(\boldsymbol{u}_y\times\boldsymbol{u}_z)]. \tag{1.7.6c}$$

[See, for example, Truesdell and Toupin (1960, p. 437). In case such angular velocity vector definitions seem unmotivated, another more natural one, based on the *linearization of the finite rotation equation*, is detailed in §1.10.]

Corollaries of the Moving Axes Theorem

Applying (1.7.2a) for $\boldsymbol{\omega}$, we get

$$d\boldsymbol{\omega}/dt = \partial\boldsymbol{\omega}/\partial t + \boldsymbol{\omega}\times\boldsymbol{\omega} = \partial\boldsymbol{\omega}/\partial t \equiv \boldsymbol{\alpha}:$$

Angular acceleration of moving axes relative to fixed axes. (1.7.7a)

This result shows the special position of $\boldsymbol{\omega}$ in moving axes theory.

From eq. (1.7.2a) and its derivation, we easily obtain the following general *operator* form:

$$d(\ldots)/dt = \partial(\ldots)/\partial t + \boldsymbol{\omega}\times(\ldots), \qquad (\ldots)\text{: any } \textit{vector}. \tag{1.7.7b}$$

Applying (1.7.7b) to (1.7.2a), and invoking (1.7.7a), we obtain the following expression for the *second* absolute rate of $\boldsymbol{p}$, $d/dt(d\boldsymbol{p}/dt) \equiv d^2\boldsymbol{p}/dt^2$:

$$\begin{aligned} d^2\boldsymbol{p}/dt^2 &= d(\ldots)/dt(\partial\boldsymbol{p}/\partial t + \boldsymbol{\omega}\times\boldsymbol{p}) \\ &= [\partial(\ldots)/\partial t + \boldsymbol{\omega}\times(\ldots)](\partial\boldsymbol{p}/\partial t) + (d\boldsymbol{\omega}/dt)\times\boldsymbol{p} + \boldsymbol{\omega}\times(d\boldsymbol{p}/dt) \\ &= \cdots = \partial^2\boldsymbol{p}/\partial t^2 + [\boldsymbol{\alpha}\times\boldsymbol{p} + \boldsymbol{\omega}\times(\omega\times\boldsymbol{p})] + 2\omega\times(\partial\boldsymbol{p}/\partial t), \end{aligned} \tag{1.7.7c}$$

where

$$\partial^2 \boldsymbol{p}/\partial t^2 = (d^2 p_x/dt^2)\boldsymbol{u}_x + (d^2 p_y/dt^2)\boldsymbol{u}_y + (d^2 p_z/dt^2)\boldsymbol{u}_z\,. \tag{1.7.7d}$$

In general, if $\boldsymbol{a} \to \boldsymbol{b} = d\boldsymbol{a}/dt \to \boldsymbol{c} = d\boldsymbol{b}/dt = d^2\boldsymbol{a}/dt^2 \to \ldots$, then we shall have for their components:

$$b_X = b_x = da_x/dt + \omega_y a_z - \omega_z a_y, \tag{1.7.7e}$$

$$\begin{aligned} c_X = c_x &= db_x/dt + \omega_y b_z - \omega_z b_y \\ &= d/dt(da_x/dt + \omega_y a_z - \omega_z a_y) + \omega_y(da_z/dt + \omega_x a_y - \omega_y a_x) \\ &\qquad - \omega_z(da_y/dt + \omega_z a_x - \omega_x a_z), \quad \text{etc., cyclically.} \end{aligned} \tag{1.7.7f}$$

For example, application of (1.7.7c, d) to the moving basis vectors $\boldsymbol{u}_{x,y,z}$ yields

$$\begin{aligned} d^2\boldsymbol{u}_x/dt^2 &= \partial^2\boldsymbol{u}_x/\partial t^2 + [\boldsymbol{\alpha} \times \boldsymbol{u}_x + \boldsymbol{\omega} \times (\boldsymbol{\omega} \times \boldsymbol{u}_x)] + 2\boldsymbol{\omega} \times (\partial \boldsymbol{u}_x/\partial t) \\ &= \boldsymbol{0} + [\boldsymbol{\alpha} \times \boldsymbol{u}_x + \boldsymbol{\omega} \times (\boldsymbol{\omega} \times \boldsymbol{u}_x)] + \boldsymbol{0} \\ &= \boldsymbol{\alpha} \times \boldsymbol{u}_x + \boldsymbol{\omega} \times (\boldsymbol{\omega} \times \boldsymbol{u}_x), \quad \text{etc., cyclically.} \end{aligned} \tag{1.7.7g}$$

Since (1.7.2a) is a purely kinematical result, the roles of the frames F and M can be interchanged. Indeed, from it, we immediately obtain

$$\partial \boldsymbol{p}/\partial t = d\boldsymbol{p}/dt + (-\boldsymbol{\omega}) \times \boldsymbol{p}\,, \tag{1.7.7h}$$

where $-\boldsymbol{\omega}$ is the angular velocity of F relative to M.

In particular, *if* $\boldsymbol{p}$ *remains constant* (i.e., *fixed*) *relative to* F, (1.7.2a) and (1.7.7h) yield

$$\partial \boldsymbol{p}/\partial t = (-\boldsymbol{\omega}) \times \boldsymbol{p}\,; \tag{1.7.7i}$$

that is, an observer, stationed in M, sees the tip of $\boldsymbol{p}$ rotate relative to that frame with an angular velocity $-\boldsymbol{\omega}$. Application of (1.7.7i) to the fixed basis $\boldsymbol{u}_{X,Y,Z}$ gives

$$\begin{aligned} \partial \boldsymbol{u}_X/\partial t &= (-\boldsymbol{\omega}) \times \boldsymbol{u}_X = -(\omega_X, \omega_Y, \omega_Z) \times (1, 0, 0) \\ &\qquad = \cdots = (0)\boldsymbol{u}_X + (-\omega_Z)\boldsymbol{u}_Y + (\omega_Y)\boldsymbol{u}_Z\,, \\ \partial \boldsymbol{u}_Y/\partial t &= (-\boldsymbol{\omega}) \times \boldsymbol{u}_Y = \cdots = (\omega_Z)\boldsymbol{u}_X + (0)\boldsymbol{u}_Y + (-\omega_X)\boldsymbol{u}_Z\,, \\ \partial \boldsymbol{u}_Z/\partial t &= (-\boldsymbol{\omega}) \times \boldsymbol{u}_Z = \cdots = (-\omega_Y)\boldsymbol{u}_X + (\omega_X)\boldsymbol{u}_Y + (0)\boldsymbol{u}_Z\,; \end{aligned} \tag{1.7.7j}$$

and, therefore,

$$\begin{aligned} &(\partial \boldsymbol{u}_X/\partial t)\cdot \boldsymbol{u}_Y = -\omega_Z \ (= -\omega_z, \ \text{for coinciding axes}) \\ &(\partial \boldsymbol{u}_X/\partial t)\cdot \boldsymbol{u}_Z = +\omega_Y \ (= +\omega_y, \ \text{for coinciding axes}), \quad \text{etc., cyclically.} \end{aligned} \tag{1.7.7k}$$

Alternative Definition of Angular Velocity

(i) Below, we show that

$$\boldsymbol{\omega} = \sum (1/2)\big[\boldsymbol{u}_k \times (d\boldsymbol{u}_k/dt)\big] \qquad (\text{where } k = 1, 2, 3 \to x, y, z), \tag{1.7.8a}$$

which can be viewed as an alternative to (1.7.2e, 6c) definition of angular velocity.

Indeed, using the fundamental equations (1.7.4i), we obtain, successively,

$$\sum [\boldsymbol{u}_k \times (d\boldsymbol{u}_k/dt)] = \sum [\boldsymbol{u}_k \times (\boldsymbol{\omega} \times \boldsymbol{u}_k)] = \sum [(\boldsymbol{u}_k \cdot \boldsymbol{u}_k)\boldsymbol{\omega} - (\boldsymbol{u}_k \cdot \boldsymbol{\omega})\boldsymbol{u}_k)]$$
$$= \boldsymbol{\omega}\Big(\sum (\boldsymbol{u}_k \cdot \boldsymbol{u}_k)\Big) - \sum (\omega_k \boldsymbol{u}_k) = \boldsymbol{\omega}(3) - \boldsymbol{\omega} = 2\boldsymbol{\omega}, \quad \text{Q.E.D.} \tag{1.7.8b}$$

From the above, and using the results of §1.1, we can show that the (inertial) *angular velocity tensor* of the moving frame $\boldsymbol{\omega}$ [i.e., the antisymmetric tensor whose axial vector is the (inertial) angular velocity of that frame $\boldsymbol{\omega}$] can be expressed as

$$\boldsymbol{\omega} = (1/2) \sum \big[(d\boldsymbol{u}_k/dt) \otimes \boldsymbol{u}_k - \boldsymbol{u}_k \otimes (d\boldsymbol{u}_k/dt)\big]. \tag{1.7.8c}$$

(ii) Next, if the (orthonormal) basis vectors $\boldsymbol{u}_k$ are functions of the curvilinear coordinates $q = (q_1, q_2, q_3)$ — that is, $\boldsymbol{u}_k = \boldsymbol{u}_k(q)$ — then, applying (1.7.8a), we find, successively (with all Latin subscripts running from 1 to 3; i.e., x, y, z),

$$\boldsymbol{\omega} = \sum (1/2)\Big\{\boldsymbol{u}_k \times \Big(\sum (\partial \boldsymbol{u}_k/\partial q_l)(dq_l/dt)\Big)\Big\} = \cdots = \sum \boldsymbol{c}_k(dq_l/dt), \tag{1.7.9a}$$

where

$$\boldsymbol{c}_l \equiv \sum (1/2)\big[\boldsymbol{u}_k \times (\partial \boldsymbol{u}_k/\partial q_l)\big] \qquad \text{(“Eulerian basis” for } \boldsymbol{\omega}); \tag{1.7.9b}$$

that is, the dq_l/dt are the (contravariant) components of $\boldsymbol{\omega}$ in the (covariant) basis $\boldsymbol{c}_l$.

By formally comparing (1.7.8a) and the earlier equations (1.7.4i), (1.7.2e, 4j), with (1.7.9a, b) [i.e., $\boldsymbol{\omega} \to \boldsymbol{c}_l$ and $d\boldsymbol{u}_k/dt \to \partial \boldsymbol{u}_k/\partial q_l$], it is easy to conclude that

$$\partial \boldsymbol{u}_k/\partial q_l = \boldsymbol{c}_l \times \boldsymbol{u}_k, \tag{1.7.9c}$$

$$\boldsymbol{c}_l = \boldsymbol{u}_1[(\partial \boldsymbol{u}_2/\partial q_l) \cdot \boldsymbol{u}_3] + \boldsymbol{u}_2[(\partial \boldsymbol{u}_3/\partial q_l) \cdot \boldsymbol{u}_1] + \boldsymbol{u}_3[(\partial \boldsymbol{u}_1/\partial q_l) \cdot \boldsymbol{u}_2]. \tag{1.7.9d}$$

We leave it to the reader to extend the above to the “rheonomic” case: $\boldsymbol{u}_k = \boldsymbol{u}_k(q, t)$.

EXAMPLES

1. The absolute (i.e., inertial) components of the angular acceleration of a rigid body rotating with angular velocity $\boldsymbol{\omega}_B$ are (with the hitherto used notations)

$$d\omega_{B,X}/dt = d\omega_{B,x}/dt + \omega_y\, \omega_{B,z} - \omega_z\, \omega_{B,y}, \quad \text{etc., cyclically.} \tag{1.7.10a}$$

What happens if $\boldsymbol{\omega}_B = \boldsymbol{\omega}$?

2. The conditions for a straight line with direction cosines (relative to moving axes) l_x, l_y, l_z to have a *fixed inertial direction* are

$$dl_x/dt + \omega_y l_z - \omega_z l_y = 0, \quad \text{etc., cyclically.} \tag{1.7.10b}$$

How many of these three conditions are independent? Hint: $l_x{}^2 + l_y{}^2 + l_z{}^2 = 1$.

3. The moving axis theorem (1.7.2a), applied to the generic vector $\boldsymbol{p}$ expressed in *plane polar coordinates*:

$$\boldsymbol{p} = p_r \boldsymbol{u}_r + p_\phi \boldsymbol{u}_\phi, \tag{1.7.10c}$$

yields

$$d\boldsymbol{p}/dt = [dp_r/dt - p_\phi(d\phi/dt)]\boldsymbol{u}_r + [dp_\phi/dt + p_r(d\phi/dt)]\boldsymbol{u}_\phi. \tag{1.7.10d}$$

Apply (1.7.10d) for $\boldsymbol{p}$ = *position* vector of a particle $\boldsymbol{r}$, and *velocity* vector of a particle $\boldsymbol{v}$.

Hint: The angular velocity of the moving polar ortho–normal–dextral triad $\boldsymbol{u}_{r,\phi,z=Z}$, relative to the inertial one $\boldsymbol{u}_{X,Y,Z}$, is

$$\boldsymbol{\omega} = (d\phi/dt)\boldsymbol{u}_z = (d\phi/dt)\boldsymbol{u}_Z. \tag{1.7.10e}$$

Particle Kinematics in Moving Frames

Velocities

Application of the fundamental formula (1.7.2a) to the motion of a particle P, of inertial position vector $\Re = \boldsymbol{r}_O + \boldsymbol{r}$ (fig. 1.6) (i.e., for $\boldsymbol{p} \to \boldsymbol{r}$), yields

$$\begin{aligned}\boldsymbol{v} \equiv d\Re/dt &= d(\boldsymbol{r}_O + \boldsymbol{r})/dt = d\boldsymbol{r}_O/dt + d\boldsymbol{r}/dt \\ &= d\boldsymbol{r}_O/dt + (\partial\boldsymbol{r}/\partial t + \boldsymbol{\omega}\times\boldsymbol{r}),\end{aligned} \tag{1.7.11a}$$

(since, in general, $\boldsymbol{r}$ is known only along the moving axes) or, rearranging,

$$\boldsymbol{v} = (d\boldsymbol{r}_O/dt + \boldsymbol{\omega}\times\boldsymbol{r}) + \partial\boldsymbol{r}/\partial t \tag{1.7.11b}$$

or

$$\boldsymbol{v}_{\text{abs}} = \boldsymbol{v}_{\text{trans}} + \boldsymbol{v}_{\text{rel}}, \tag{1.7.11c}$$

where

$$\boldsymbol{v}_{\text{abs}} \equiv \boldsymbol{v} \equiv d\Re/dt = (dX/dt)\boldsymbol{u}_X + (dY/dt)\boldsymbol{u}_Y + (dZ/dt)\boldsymbol{u}_Z: \quad \textit{Absolute velocity of } P, \tag{1.7.11d}$$

$$\boldsymbol{v}_{\text{rel}} \equiv \partial\boldsymbol{r}/\partial t \equiv (dx/dt)\boldsymbol{u}_x + (dy/dt)\boldsymbol{u}_y + (dz/dt)\boldsymbol{u}_z: \quad \textit{Relative velocity of } P, \tag{1.7.11e}$$

$$\boldsymbol{v}_{\text{trans}} \equiv d\boldsymbol{r}_O/dt + \boldsymbol{\omega}\times\boldsymbol{r} = d\boldsymbol{r}_O/dt + [x(d\boldsymbol{u}_x/dt) + y(d\boldsymbol{u}_y/dt) + z(d\boldsymbol{u}_z/dt)]: \quad \textit{Transport velocity of } P. \tag{1.7.11f}$$

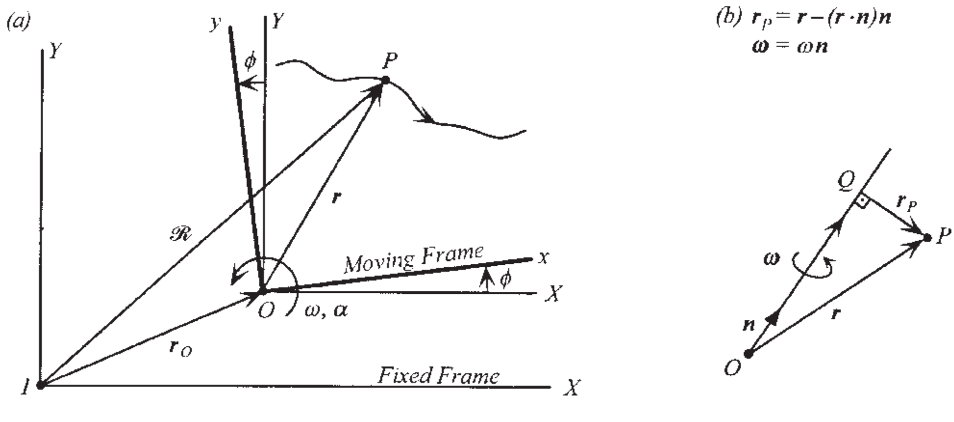

Figure 1.6 (a) Relative kinematics of particle P in two dimensions; (b) geometry of centripetal acceleration.

Clearly, if P is rigidly attached to M_{moving} frame (e.g., if it is one of the particles of the rigid body M), then $\boldsymbol{v}_{\text{rel}} = \mathbf{0}$ and $\boldsymbol{v} = \boldsymbol{v}_{\text{trans}}$; that is, generally, $\boldsymbol{v}_{\text{trans}}$ is the velocity of a particle rigidly attached to M and instantaneously coinciding with P.

Accelerations

Application of (1.7.2a) to (1.7.11a–f) yields

$$\boldsymbol{a}_{\text{abs}} = \boldsymbol{a}_{\text{rel}} + \boldsymbol{a}_{\text{trans}} + \boldsymbol{a}_{\text{cor}}, \tag{1.7.12a}$$

where

$$\boldsymbol{a}_{\text{abs}} \equiv \boldsymbol{a} \equiv d^2\Re/dt^2 = (d^2X/dt^2)\boldsymbol{u}_X + (d^2Y/dt^2)\boldsymbol{u}_Y + (d^2Z/dt^2)\boldsymbol{u}_Z\text{:}$$
$$\textit{Absolute acceleration of } P, \tag{1.7.12b}$$

$$\boldsymbol{a}_{\text{rel}} \equiv \partial\boldsymbol{v}_{\text{rel}}/\partial t = \partial^2\boldsymbol{r}/\partial t^2 \equiv (d^2x/dt^2)\boldsymbol{u}_x + (d^2y/dt^2)\boldsymbol{u}_y + (d^2z/dt^2)\boldsymbol{u}_z\text{:}$$
$$\textit{Relative acceleration of } P, \tag{1.7.12c}$$

$$\begin{aligned}\boldsymbol{a}_{\text{trans}} &\equiv d^2\boldsymbol{r}_O/dt^2 + \boldsymbol{\alpha}\times\boldsymbol{r} + \boldsymbol{\omega}\times(\boldsymbol{\omega}\times\boldsymbol{r})\\ &= d^2\boldsymbol{r}_O/dt^2 + [x(d^2\boldsymbol{u}_x/dt^2) + y(d^2\boldsymbol{u}_y/dt^2) + z(d^2\boldsymbol{u}_z/dt^2)]\text{:}\end{aligned}$$
$$\textit{Transport (or drag) acceleration of } P$$

[= Inertial acceleration of a particle fixed relative to M, and momentarily coinciding with P; its *first* term,

$$d^2\boldsymbol{r}_O/dt^2 = d\boldsymbol{v}_O/dt = \partial\boldsymbol{v}_O/\partial t + \boldsymbol{\omega}\times\boldsymbol{v}_O,$$

is due to the inertial acceleration of the origin of M; its *second*, $\boldsymbol{\alpha}\times\boldsymbol{r}$, to the inertial angular acceleration of M; and its *last* term,

$$\boldsymbol{\omega}\times(\boldsymbol{\omega}\times\boldsymbol{r}) \equiv (\boldsymbol{\omega}\cdot\boldsymbol{r})\boldsymbol{\omega} - \omega^2\boldsymbol{r} \equiv -\omega^2\boldsymbol{r}_p,$$

where $\boldsymbol{r}_p$ = vector of perpendicular distance from $\boldsymbol{\omega}$ – axis (through O) to P, (fig. 1.6(b)), is called *centripetal* acceleration of P],

(1.7.12d)

$$\begin{aligned}\boldsymbol{a}_{\text{cor}} \equiv 2\boldsymbol{\omega}\times\boldsymbol{v}_{\text{rel}} \equiv 2\boldsymbol{\omega}\times(\partial\boldsymbol{r}/\partial t) = 2\big[&(dx/dt)(d\boldsymbol{u}_x/dt) + (dy/dt)(d\boldsymbol{u}_y/dt)\\ &+ (dz/dt)(d\boldsymbol{u}_z/dt)\big]\text{:}\end{aligned}$$
$$\textit{Coriolis (or complementary) acceleration of } P$$

[= Acceleration due to the coupling between the relative motion of the particle P, $\boldsymbol{v}_{\text{rel}}$, and the absolute rotation (transport motion) of the frame $M, \boldsymbol{\omega}$; it vanishes if $\boldsymbol{v}_{\text{rel}} = \mathbf{0}$, or if $\boldsymbol{\omega}$ is parallel to $\boldsymbol{v}_{\text{rel}}$]. (1.7.12e)

If $\boldsymbol{\omega} = \mathbf{0}$ and $\boldsymbol{\alpha} = \mathbf{0}$—that is, if M *translates* relative to F—these equations reduce to

$$\boldsymbol{v} = \boldsymbol{v}_{\text{rel}} + \boldsymbol{v}_O = \partial\boldsymbol{r}/\partial t + d\boldsymbol{r}_O/dt = d\boldsymbol{r}/dt + d\boldsymbol{r}_O/dt, \tag{1.7.12f}$$

$$\boldsymbol{a} = \boldsymbol{a}_{\text{rel}} + \boldsymbol{a}_O = \partial^2\boldsymbol{r}/\partial t^2 + d^2\boldsymbol{r}_O/dt^2 = d^2\boldsymbol{r}/dt^2 + d^2\boldsymbol{r}_O/dt^2, \tag{1.7.12g}$$

Component Forms

To appreciate eqs. (1.7.11) and (1.7.12) better, and prepare the reader for the key concept of *nonholonomic coordinates*, and so on (§2.9 ff.), we present them below in terms of their components. In the general case of nonaligned axes we can project them on an arbitrary, fixed, or moving axis; that is, each of their terms can be resolved along any set of axes.

(i) The position relation $\mathfrak{R} = \boldsymbol{r}_O + \boldsymbol{r}$, with $\boldsymbol{r}_O = (X_O, Y_O, Z_O)$, reads

$$X = X_O + \cos(X, x)x + \cos(X, y)y + \cos(X, z)z, \quad \text{etc., cyclically.} \tag{1.7.13a}$$

(ii) The velocity equations (1.7.11a ff.) assume the following forms, along the *fixed* axes:

$$\begin{aligned} dX/dt = dX_O/dt &+ \cos(X, x)(dx/dt + \omega_y z - \omega_z y) \\ &+ \cos(X, y)(dy/dt + \omega_z x - \omega_x z) + \cos(X, z)(dz/dt + \omega_x y - \omega_y x) \\ &= dX_O/dt + d/dt(X - X_O), \quad \text{etc., cyclically;} \end{aligned} \tag{1.7.13b}$$

and, along the *moving* axes:

$$\boldsymbol{v} \cdot \boldsymbol{u}_x \equiv v_x = v_{O,x} + dx/dt + \omega_y z - \omega_z y, \quad \text{etc., cyclically,} \tag{1.7.13c}$$

where

$$v_{O,x} \equiv \boldsymbol{v}_O \cdot \boldsymbol{u}_x = \cos(x, X)(dX_O/dt) + \cos(x, Y)(dY_O/dt) + \cos(x, Z)(dZ_O/dt):$$

component of inertial velocity of moving origin O, along the moving axis Ox [in general, *not equal to the $d/dt(\ldots)$-derivative of a coordinate*, like dX_O/dt or dx/dt, and hence a *quasi velocity* (§2.9 ff.)], etc., cyclically.

(1.7.13d)

(iii) The acceleration equations (1.7.12a ff.) read, along the *fixed* axes:

$$\begin{aligned} d^2X/dt^2 = d^2X_O/dt^2 &+ \cos(X, x)[d/dt(dx/dt + \omega_y z - \omega_z y) \\ &+ \omega_y(dz/dt + y\omega_x - x\omega_y) - \omega_z(dy/dt + x\omega_z - z\omega_x)] + \cdots \\ = d^2X_O/dt^2 &+ \cos(X, x)\{(d^2x/dt^2) + [z(d\omega_y/dt) - y(d\omega_z/dt)] \\ &+ \omega_y(\omega_x y - \omega_y x) - \omega_z(\omega_z x - \omega_x z) \\ &+ 2[\omega_y(dz/dt) - \omega_z(dy/dt)]\} + \cdots \\ = d^2X_O/dt^2 &+ d^2/dt^2(X - X_O), \quad \text{etc., cyclically;} \end{aligned} \tag{1.7.13e}$$

$$= (d^2X/dt^2)_{\text{rel}} + (d^2X/dt^2)_{\text{trans}} + (d^2X/dt^2)_{\text{cor}}, \tag{1.7.13f}$$

where

$$\begin{aligned} (d^2X/dt^2)_{\text{rel}} &= \cos(X, x)(d^2x/dt^2) + \cos(X, y)(d^2y/dt^2) + \cos(X, z)(d^2z/dt^2), \\ (d^2X/dt^2)_{\text{trans}} &= d^2X_O/dt^2 + \cos(X, x)\big\{[z(d\omega_y/dt) - y(d\omega_z/dt)] \\ &\qquad + \omega_y(\omega_x y - \omega_y x) - \omega_z(\omega_z x - \omega_x z)\big\} + \cdots, \\ (d^2X/dt^2)_{\text{cor}} &= \cos(X, x)\big\{2[\omega_y(dz/dt) - \omega_z(dy/dt)]\big\} + \cdots, \quad \text{etc., cyclically;} \end{aligned} \tag{1.7.13g}$$

and, along the *moving* axes:

$$\begin{aligned}\boldsymbol{a}\cdot\boldsymbol{u}_x \equiv a_x = a_{O,x} + [d/dt(dx/dt + \omega_y\, z - \omega_z\, y) \\ + \omega_y(dz/dt + y\,\omega_x - x\,\omega_y) - \omega_z(dy/dt + x\,\omega_z - z\,\omega_x)] \\ = a_{x,\mathrm{rel}} + a_{x,\mathrm{trans}} + a_{x,\mathrm{cor}},\end{aligned} \tag{1.7.13h}$$

where

$$\begin{aligned}&a_{x,\mathrm{rel}} = d^2x/dt^2,\\ &a_{x,\mathrm{trans}} = a_{O,x} + [z(d\omega_y/dt) - y(d\omega_z/dt)] + \omega_y(\omega_x\, y - \omega_y\, x) - \omega_z(\omega_z\, x - \omega_x\, z),\\ &a_{x,\mathrm{cor}} = 2[\omega_y(dz/dt) - \omega_z(dy/dt)], \text{ and}\end{aligned} \tag{1.7.13i}$$

$$\begin{aligned}&a_{O,x} \equiv \boldsymbol{a}_O\cdot\boldsymbol{u}_x = \cos(x,X)(d^2X_O/dt^2) + \cos(x,Y)(d^2Y_O/dt^2) + \cos(x,Z)(d^2Z_O/dt^2),\\ &\qquad\text{(in general, a } \textit{quasi acceleration}\text{), etc., cyclically.}\end{aligned} \tag{1.7.13j}$$

EXAMPLES

1. It is not hard to show that the conditions for a particle, with coordinates x, y, z, relative to moving axes, to be stationary relative to absolute space are

$$u + dx/dt + z\omega_y - y\omega_z = 0, \quad \text{etc., cyclically,} \tag{1.7.14}$$

where (u, v, w) = inertial components of velocity of origin of moving frame.

2. *Plane Rotation Case*. Let us find the components of velocity and acceleration of a particle P in motion on a plane described by the two sets of *momentarily coincident* rectangular Cartesian axes, a fixed O–XY and a second O–xy rotating relative to the first so that always $OZ = Oz$, with angular velocity $\boldsymbol{\omega} = (0, 0, \omega_z = \omega_Z \equiv \omega)$. Here, momentarily,

$$X = x, \qquad Y = y. \tag{1.7.15a, b}$$

Application of the moving axes theorem (1.7.2a), or (1.7.3c), (1.7.7e), with $\omega_{x,y} = 0$ and $\omega_z = \omega$, yields the *velocity* components:

$$dX/dt = dx/dt - y\,\omega, \qquad dY/dt = dy/dt + x\,\omega; \tag{1.7.15c, d}$$

and application of that theorem, or (1.7.3c), (1.7.7f), to the above gives the *acceleration* components:

$$\begin{aligned}d^2X/dt^2 &= d/dt(dx/dt - y\,\omega) - (dy/dt + x\,\omega)\omega\\ &= d^2x/dt^2 - y(d\omega/dt) - x\,\omega^2 - 2(dy/dt)\omega\\ &\quad (= \textit{relative} + \textit{transport} + \textit{Coriolis}),\end{aligned} \tag{1.7.15e}$$

$$\begin{aligned}d^2Y/dt^2 &= d/dt(dy/dt + x\,\omega) + (dx/dt - y\,\omega)\omega\\ &= d^2y/dt^2 + x(d\omega/dt) - y\,\omega^2 + 2(dx/dt)\omega\\ &\quad (= \textit{relative} + \textit{transport} + \textit{Coriolis});\end{aligned} \tag{1.7.15f}$$

and similarly for higher $d/dt(\ldots)$-derivatives.

[Alternatively, we may start from the geometrical O–XY/O–xy relationship for a *generic angle of orientation* $\phi = \phi(t)$:

$$X = (\cos\phi)x + (-\sin\phi)y, \qquad Y = (\sin\phi)x + (\cos\phi)y, \tag{1.7.15g}$$

$d/dt(\ldots)$-differentiate it, and *then* set $\phi = 0$ $(d\phi/dt \equiv \omega \neq 0)$, thus obtaining (1.7.15c, d); then $d/dt(\ldots)$-differentiate once more, for general ϕ, and *then* set $\phi = 0$ $(\omega \neq 0,\ d\omega/dt \equiv \alpha \neq 0)$, thus obtaining (1.7.15e, f). The details of this straightforward calculation are left to the reader. In this way we do not have to remember any kinematical theorems—differential calculus does it for us!]

3. *Velocity and Acceleration in Plane Polar Coordinates via the Moving Axes Theorem* [continued from (1.7.10c–e)]. Here, with the usual notations,

$$\boldsymbol{r} = r\boldsymbol{u}_r \qquad \text{and} \qquad \boldsymbol{\omega} = (d\phi/dt)\boldsymbol{u}_z = (d\phi/dt)\boldsymbol{u}_Z, \tag{1.7.16a}$$

and, therefore, by direct $d/dt(\ldots)$-differentiation and then use of (1.7.4i) — that is, *treating the corresponding OND basis/axes through P*, $P - \boldsymbol{u}_r\boldsymbol{u}_\phi/r$, ϕ, *as the moving frame* — we obtain

$$\begin{aligned}
\text{(i)}\quad \boldsymbol{v} = d\boldsymbol{r}/dt &= (dr/dt)\boldsymbol{u}_r + r(d\boldsymbol{u}_r/dt) = (dr/dt)\boldsymbol{u}_r + r(\boldsymbol{\omega}\times\boldsymbol{u}_r)\\
&= (dr/dt)\boldsymbol{u}_r + r(d\phi/dt)(\boldsymbol{u}_z\times\boldsymbol{u}_r) = (dr/dt)\boldsymbol{u}_r + r(d\phi/dt)\boldsymbol{u}_\phi \equiv v_r\,\boldsymbol{u}_r + rv_\phi\,\boldsymbol{u}_\phi;
\end{aligned} \tag{1.7.16b}$$

$$\begin{aligned}
\text{(ii)}\quad \boldsymbol{a} = d\boldsymbol{v}/dt &= (dv_r/dt)\boldsymbol{u}_r + v_r(d\boldsymbol{u}_r/dt) + [d(rv_\phi)/dt)]\boldsymbol{u}_\phi + (rv_\phi)(d\boldsymbol{u}_\phi/dt)\\
&= (dv_r/dt)\boldsymbol{u}_r + v_r(\boldsymbol{\omega}\times\boldsymbol{u}_r) + [d(rv_\phi)/dt)]\boldsymbol{u}_\phi + (rv_\phi)(\boldsymbol{\omega}\times\boldsymbol{u}_\phi)\\
&= (dv_r/dt)\boldsymbol{u}_r + v_r[(d\phi/dt)\boldsymbol{u}_\phi] + [d(rv_\phi)/dt)]\boldsymbol{u}_\phi + (rv_\phi)[(-d\phi/dt)\boldsymbol{u}_r]\\
&= [dv_r/dt - (d\phi/dt)(rv_\phi)]\boldsymbol{u}_r + [v_r(d\phi/dt) + d(rv_\phi)/dt]\boldsymbol{u}_\phi\\
&= [d^2r/dt^2 - r(d\phi/dt)^2]\boldsymbol{u}_r + \{(dr/dt)(d\phi/dt) + d/dt[r(d\phi/dt)]\}\boldsymbol{u}_\phi\\
&= [d^2r/dt^2 - r(d\phi/dt)^2]\boldsymbol{u}_r + [2(dr/dt)(d\phi/dt) + r(d^2\phi/dt^2)]\boldsymbol{u}_\phi\\
&\equiv a_{(r)}\boldsymbol{u}_r + a_{(\phi)}\boldsymbol{u}_\phi.
\end{aligned} \tag{1.7.16c}$$

4. *Velocity and Acceleration in Spherical Coordinates via the Moving Axes Theorem*. Proceeding as in the preceding example, and since here $\boldsymbol{r} = r\boldsymbol{u}_r$ (not the r of the polar cylindrical case) and $\boldsymbol{\omega} = (d\phi/dt)\boldsymbol{u}_Z + (d\theta/dt)\boldsymbol{u}_\phi$, $\boldsymbol{u}_Z = -\sin\theta\boldsymbol{u}_\theta + \cos\theta\boldsymbol{u}_r$, we can show that the velocity and acceleration are given, respectively, by

$$\boldsymbol{v} = (dr/dt)\boldsymbol{u}_r + [r(d\theta/dt)]\boldsymbol{u}_\theta + [r(d\phi/dt)\sin\theta]\boldsymbol{u}_\phi \equiv v_r\,\boldsymbol{u}_r + rv_\theta\,\boldsymbol{u}_\theta + v_\phi\,\boldsymbol{u}_\phi, \tag{1.7.17a}$$

$$\begin{aligned}
\boldsymbol{a} &= [d^2r/dt^2 - r(d\theta/dt)^2 - r(d\phi/dt)^2\sin^2\theta]\boldsymbol{u}_r\\
&\qquad + [2(dr/dt)(d\theta/dt) + r(d^2\theta/dt^2) - r(d\phi/dt)^2\sin\theta\cos\theta]\boldsymbol{u}_\theta\\
&\qquad + [2(dr/dt)(d\phi/dt)\sin\theta + r(d^2\phi/dt^2)\sin\theta + 2r(d\phi/dt)(d\theta/dt)\cos\theta]\boldsymbol{u}_\phi\\
&\equiv a_{(r)}\boldsymbol{u}_r + a_{(\theta)}\boldsymbol{u}_\theta + a_{(\phi)}\boldsymbol{u}_\phi.
\end{aligned} \tag{1.7.17b}$$

The above are, naturally, in agreement with (1.2.8a ff.)

5. *Inertial Angular Velocity of the Natural, or Intrinsic, OND Triad* O_M–$\boldsymbol{u}_t\boldsymbol{u}_n\boldsymbol{u}_b \equiv$ O_M–$\boldsymbol{tnb}$; *Frenet–Serret Equations* (fig. 1.7). We have already seen (§1.2) that

$$d\boldsymbol{t}/ds = \boldsymbol{n}/\rho \Rightarrow d\boldsymbol{t}/dt = (d\boldsymbol{t}/ds)(ds/dt) = [(ds/dt)/\rho]\boldsymbol{n} \equiv (v_t/\rho)\boldsymbol{n}, \tag{1.7.18a}$$

also

$$\boldsymbol{b} = \boldsymbol{t} \times \boldsymbol{n}. \tag{1.7.18b}$$

Next, $d/dt(\ldots)$-differentiating $\boldsymbol{b}\cdot\boldsymbol{t} = 0$, we obtain

$$0 = (d\boldsymbol{b}/dt)\cdot\boldsymbol{t} + \boldsymbol{b}\cdot(d\boldsymbol{t}/dt) = (d\boldsymbol{b}/dt)\cdot\boldsymbol{t} + \boldsymbol{b}\cdot[(v_t/\rho)\boldsymbol{n}] = (d\boldsymbol{b}/dt)\cdot\boldsymbol{t}; \tag{1.7.18c}$$

and, similarly, $d/dt(\ldots)$-differentiating $\boldsymbol{b}\cdot\boldsymbol{b} = 1$ we readily conclude that

$$(d\boldsymbol{b}/dt)\cdot\boldsymbol{b} = 0. \tag{1.7.18d}$$

Equations (1.7.18c, d) show that $d\boldsymbol{b}/dt$ must be perpendicular to both $\boldsymbol{t}$ and $\boldsymbol{b}$. Hence, we can set

$$d\boldsymbol{b}/ds = -(1/\tau)\boldsymbol{n} \Rightarrow d\boldsymbol{b}/dt = (d\boldsymbol{b}/ds)(ds/dt) = -(v_t/\tau)\boldsymbol{n}, \tag{1.7.18e}$$

where τ = *radius of torsion* (or *second curvature*) of the curve C, traced by the moving origin $O_M \equiv O$, at O; positive (negative) whenever the tip of $d\boldsymbol{b}/dt$ turns around $\boldsymbol{t}$ positively (negatively); that is, like a right- (left-)hand screw; or, according as $d\boldsymbol{b}/dt$ has the opposite (same) direction as $\boldsymbol{n}$. [Some authors use τ for our *$1/\tau$*; others use ρ_κ and ρ_τ for our ρ and τ, respectively.]

Now, the angular velocity of O–$\boldsymbol{tnb}$, relative to some background fixed triad O_F–$\boldsymbol{u}_X\boldsymbol{u}_Y\boldsymbol{u}_Z$, is found by application of the basic formulae (1.7.4j), with the identification O_M–$\boldsymbol{u}_x\boldsymbol{u}_y\boldsymbol{u}_z = O$–$\boldsymbol{tnb}$, and eqs. (1.7.18a–e). Thus, we find

$$\textit{Tangent}:\ \omega_t \to \omega_x = \boldsymbol{u}_z\cdot(d\boldsymbol{u}_y/dt) = -\boldsymbol{u}_y\cdot(d\boldsymbol{u}_z/dt) = -\boldsymbol{n}\cdot(d\boldsymbol{b}/dt) = v_t/\tau; \tag{1.7.18f}$$

$$\textit{Normal}:\ \omega_n \to \omega_y = \boldsymbol{u}_x\cdot(d\boldsymbol{u}_z/dt) = -\boldsymbol{u}_z\cdot(d\boldsymbol{u}_x/dt) = -\boldsymbol{b}\cdot(d\boldsymbol{t}/dt) = 0; \tag{1.7.18g}$$

$$\textit{Binormal}:\ \omega_b \to \omega_z = \boldsymbol{u}_y\cdot(d\boldsymbol{u}_x/dt) = -\boldsymbol{u}_x\cdot(d\boldsymbol{u}_y/dt) = \boldsymbol{n}\cdot(d\boldsymbol{t}/dt) = v_t/\rho. \tag{1.7.18h}$$

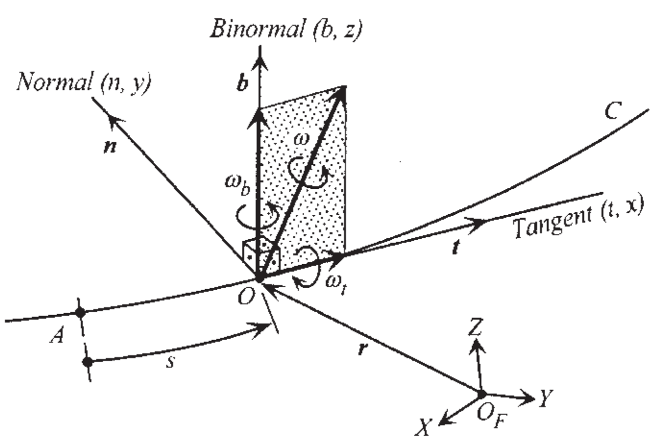

Figure 1.7 On the geometry and kinematics of the Frenet–Serret triad O–$\boldsymbol{tnb}$.

In sum, the triad *O–tnb* rotates with inertial angular velocity:

$$\boldsymbol{\omega} = (v_t/\tau)\boldsymbol{t} + (0)\boldsymbol{n} + (v_t/\rho)\boldsymbol{b} = v_t(\boldsymbol{t}/\tau + \boldsymbol{b}/\rho). \tag{1.7.18i}$$

In general, $\boldsymbol{\omega} \neq d\boldsymbol{\theta}/dt$, where $\boldsymbol{\theta}$ is some vector expressing angular displacement/rotation; that is, $\boldsymbol{\theta}$ is a *quasi vector* (§1.10, chap. 2). Further, from (1.7.18a–e) we also conclude that

$$\begin{aligned} d\boldsymbol{n}/ds &= d/ds(\boldsymbol{b} \times \boldsymbol{t}) = (d\boldsymbol{b}/ds) \times \boldsymbol{t} + \boldsymbol{b} \times (d\boldsymbol{t}/ds) \\ &= -(1/\tau)(\boldsymbol{n} \times \boldsymbol{t}) + (1/\rho)(\boldsymbol{b} \times \boldsymbol{n}) \\ &= -(1/\tau)(-\boldsymbol{b}) + (1/\rho)(-\boldsymbol{t}) = (-1/\rho)\boldsymbol{t} + (1/\tau)\boldsymbol{b}. \end{aligned} \tag{1.7.18j}$$

Equations (1.7.18a, e, j) (where $0 \leqslant \rho \leqslant +\infty$ and $-\infty \leqslant \tau \leqslant +\infty, \tau \neq 0$) are the famous *Frenet–Serret formulae* for a *space* (or *skew*, or *twisted*) curve. It is shown in differential geometry that: the "natural/intrinsic" curve equations $\rho = \rho(s)$ and $\tau = \tau(s)$ determine the spatial position of that curve to within a rigid displacement (i.e., a translation and a rotation).

The *F-S* equations can also be written in the following memorable "antisymmetric form":

$$d\boldsymbol{t}/dt = (0)\boldsymbol{t} + (v_t/\rho)\boldsymbol{n} + (0)\boldsymbol{b}, \tag{1.7.18k}$$

$$d\boldsymbol{n}/dt = (-v_t/\rho)\boldsymbol{t} + (0)\boldsymbol{n} + (v_t/\tau)\boldsymbol{b}, \tag{1.7.18l}$$

$$d\boldsymbol{b}/dt = (0)\boldsymbol{t} + (-v_t/\tau)\boldsymbol{n} + (0)\boldsymbol{b}. \tag{1.7.18m}$$

The above allow us to calculate the torsion, $1/\tau$. From (1.7.18j, k, l), with $(\ldots)' \equiv d(\ldots)/ds$, we get

$$\boldsymbol{b}/\tau = \boldsymbol{t}/\rho + (\rho\boldsymbol{t}')' = \boldsymbol{t}/\rho + \rho'\boldsymbol{t}' + \rho\boldsymbol{t}'' = \boldsymbol{t}/\rho + \rho'(\boldsymbol{n}/\rho) + \rho\boldsymbol{r}''', \tag{1.7.18n}$$

and so, dotting this equation with $\boldsymbol{b}$, we find

$$1/\tau = \rho(\boldsymbol{b} \cdot \boldsymbol{r}''') = \rho[(\boldsymbol{t} \times \boldsymbol{n}) \cdot \boldsymbol{r}'''] = \rho^2[(\boldsymbol{r}' \times \boldsymbol{r}'') \cdot \boldsymbol{r}'''], \tag{1.7.18o}$$

or, since [recalling (1.2.4c)]

$$1/\rho^2 = \boldsymbol{r}'' \cdot \boldsymbol{r}'' = |\boldsymbol{r}''|^2, \tag{1.7.18p}$$

finally,

$$\mathit{Torsion} \equiv 1/\tau = [(\boldsymbol{r}' \times \boldsymbol{r}'') \cdot \boldsymbol{r}''']\big/|\boldsymbol{r}''|^2. \tag{1.7.18q}$$

With the help of the above, we can easily show that

(i) The Frenet–Serret equations can be put in the following kinematical form:

$$d\boldsymbol{t}/dt = \boldsymbol{\omega} \times \boldsymbol{t}, \qquad d\boldsymbol{n}/dt = \boldsymbol{\omega} \times \boldsymbol{n}, \qquad d\boldsymbol{b}/dt = \boldsymbol{\omega} \times \boldsymbol{b}$$

$$(\boldsymbol{\omega}\text{: kinematical } \textit{Darboux} \text{ vector, (1.7.18i)}). \tag{1.7.19a}$$

(ii) If $\boldsymbol{t}, \boldsymbol{n}, \boldsymbol{b}$ can be expressed, in terms of their direction cosines along a fixed *OND* triad, as

$$\boldsymbol{t} = (t_1, t_2, t_3), \qquad \boldsymbol{n} = (n_1, n_2, n_3), \qquad \boldsymbol{b} = (b_1, b_2, b_3), \tag{1.7.19b}$$

then

$$dt_1/ds = n_1/\rho, \qquad dn_1/ds = b_1/\tau - t_1/\rho, \qquad db_1/ds = -n_1/\tau; \tag{1.7.19c}$$

and similarly for the other components.

(iii) The (inertial) *angular acceleration of the Frenet–Serret triad*, $\boldsymbol{\alpha} \equiv d\boldsymbol{\omega}/dt$, is given by

$$\boldsymbol{\alpha} = [(dv_t/dt)/\tau - (v_t{}^2/\tau^2)(d\tau/ds)]\boldsymbol{t} + [(dv_t/dt)/\rho - (v_t{}^2/\rho^2)(d\rho/ds)]\boldsymbol{b}. \qquad (1.7.19\text{d})$$

(iv) The (inertial) ***jerk*** vector of a particle, $\boldsymbol{j} \equiv d\boldsymbol{a}/dt$ (or hyperacceleration, or velocity of the acceleration) is expressed along the Frenet–Serret triad as

$$\begin{aligned}\boldsymbol{j} &= [d^2v_t/dt^2 - (v_t{}^3/\rho^2)]\boldsymbol{t} + \{v_t{}^2[d/dt(1/\rho)] + 3v_t(dv_t/dt)/\rho)]\}\boldsymbol{n} + (v_t{}^3/\rho\tau)\boldsymbol{b}\\ &= [d^2v_t/dt^2 - (v_t{}^3/\rho^2)]\boldsymbol{t} + [d/dt(v_t{}^3/\rho)/v_t]\boldsymbol{n} + (v_t{}^3/\rho\tau)]\boldsymbol{b}\\ &= [d^2v_t/dt^2 - (v_t{}^3/\rho^2)]\boldsymbol{t} + [(3v_t{}^2/\rho)(dv_t/ds) - (v_t{}^3/\rho^2)(d\rho/ds)]\boldsymbol{n} + (v_t{}^3/\rho\tau)]\boldsymbol{b},\end{aligned} \qquad (1.7.19\text{e})$$

where

$$d(\ldots)/dt = [d(\ldots)/ds](ds/dt) = v_t[d(\ldots)/ds];$$

that is, contrary to the acceleration, $\boldsymbol{a} = (dv_t/dt)\boldsymbol{t} + (v_t^2/\rho)\,\boldsymbol{n}$, the jerk vector has $\boldsymbol{t}$, $\boldsymbol{n}$, *and* $\boldsymbol{b}$ components, and involves both ρ and τ.

(v) The following kinematic formulae hold for the curvature and torsion:

$$\begin{aligned}\kappa = 1/\rho &= |\boldsymbol{v}\times\boldsymbol{a}|/|\boldsymbol{v}|^3 = \left[v^2a^2 - (\boldsymbol{v}\cdot\boldsymbol{a})^2\right]^{1/2}/v^3,\\ 1/\tau &= [\boldsymbol{v}\cdot(\boldsymbol{a}\times\boldsymbol{j})]/(\boldsymbol{a}\times\boldsymbol{j})^2 = (\boldsymbol{v}, \boldsymbol{a}, \boldsymbol{j})/\kappa^2v^6.\end{aligned} \qquad (1.7.19\text{f})$$

HISTORICAL

The theory of accelerations of *any order* (along general curvilinear coordinates) is due to the Russian mathematician/mechanician Somov (1860s), who also gave recurrence formulae, from the $(n-1)$th order to the (n)th order; and to the French mathematician Bouquet (1879). The *second* order shown above is due to the French mechanician Resal (1862), although the earliest such investigations seem to be due to a certain Transon (1845) (see, e.g., Schönflies and Grübler, 1902: 1901–1908). The jerk vector is called "accéleration du second ordre" (Resal), or "Beschleunigung $\boldsymbol{a}^{(2)}$" (Schönflies/Grübler), where the ordinary acceleration (of the first order) is denoted by $\boldsymbol{a}^{(1)} \equiv \boldsymbol{a}$. Clearly, such derivations are enormously aided with the use of vectors. These results allowed Möbius (1846, 1848) to give a geometrical interpretation to Taylor's expansion (with some standard notations):

$$\begin{aligned}\Delta\boldsymbol{r} &\equiv \boldsymbol{r}(t) - \boldsymbol{r}(0) = \boldsymbol{v}t + \boldsymbol{a}^{(1)}(t^2/2) + \boldsymbol{a}^{(2)}(t^3/1.2.3) + \cdots\\ &= \textit{chord} \text{ of particle trajectory between the times 0 and } t.\end{aligned}$$

Particle Kinetics in Moving Frames

Substituting the inertial acceleration $\boldsymbol{a}$ of a particle P of mass m, in terms of its moving axes representation, into its Newton–Euler equation of motion

$$m\,\boldsymbol{a} = \boldsymbol{f} \qquad (= \textit{total noninertial, or real, or objective, force on } P), \qquad (1.7.20\text{a})$$

and, rearranging slightly, we obtain its *fundamental equation of relative motion* (fig. 1.8):

$$m\boldsymbol{a}_{\text{rel}} = \boldsymbol{f} + \boldsymbol{f}_{\text{trans}} + \boldsymbol{f}_{\text{cor}}; \qquad (1.7.20\text{b})$$

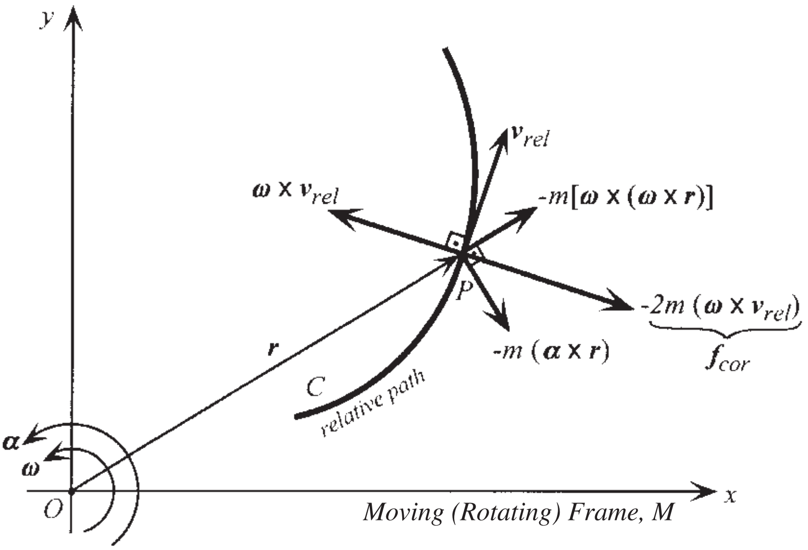

Figure 1.8 Geometry and forces in two-dimensional relative motion.

in words:

mass $\times$ *relative acceleration* $(\boldsymbol{a}_{\mathrm{rel}})$ = *total real* $(\boldsymbol{f})$ *plus inertial* $(\boldsymbol{f}_{\mathrm{trans}} + \boldsymbol{f}_{\mathrm{cor}})$ *force*, (1.7.20c)

where

$\boldsymbol{a}_{\mathrm{rel}} \equiv \partial \boldsymbol{v}_{\mathrm{rel}}/\partial t \equiv \partial^2 \boldsymbol{r}/\partial t^2$: *apparent or Relative acceleration of P*, (1.7.20d)

$\boldsymbol{f}_{\mathrm{trans}} \equiv -m\boldsymbol{a}_{\mathrm{trans}} \equiv -m[d^2\boldsymbol{r}_O/dt^2 + \boldsymbol{\alpha} \times \boldsymbol{r} + \boldsymbol{\omega} \times (\boldsymbol{\omega} \times \boldsymbol{r})]$:

total iniertial force of Transport on P

$= -m(d^2\boldsymbol{r}_O/dt^2)$ [due to the inertial acceleration of the origin of the moving

$-m(\boldsymbol{\alpha} \times \boldsymbol{r})$ [due to the inertial angular acceleration of frame M]

$-m[\boldsymbol{\omega} \times (\boldsymbol{\omega} \times \boldsymbol{r})] = -m[(\boldsymbol{\omega} \cdot \boldsymbol{r})\boldsymbol{\omega} - \omega^2 \boldsymbol{r}] = \cdots \equiv m\omega^2 \boldsymbol{r}_P$

[*centrifugal* force on P, due to the inertial angular velocity of frame M; always perpendicular to the instantaneous axis of $\boldsymbol{\omega}$, in the plane of P and that axis, and directed *away* from it (fig. 1.6(b))],

$\boldsymbol{f}_{\mathrm{cor}} \equiv -m\boldsymbol{a}_{\mathrm{cor}} \equiv -2m(\boldsymbol{\omega} \times \boldsymbol{v}_{\mathrm{rel}}) = -2m[\boldsymbol{\omega} \times (\partial \boldsymbol{r}/\partial t)]$:

inertial force of Coriolis (*or composite centrifugal force*) *on P* [due to the interaction of the relative motion of P ($\boldsymbol{v}_{\mathrm{rel}} = \partial \boldsymbol{r}/\partial t$) with the absolute rotation of the moving frame ($\boldsymbol{\omega}$); normal to both $\boldsymbol{v}_{\mathrm{rel}}$, $\boldsymbol{\omega}$, and such that $\boldsymbol{v}_{\mathrm{rel}}$, $\boldsymbol{\omega}$, and $\boldsymbol{f}_{\mathrm{cor}} = 2m(\boldsymbol{v}_{\mathrm{rel}} \times \boldsymbol{\omega})$, in that order, form a right-hand system]. (1.7.20f)

REMARKS

(i) In classical mechanics, only $\boldsymbol{f}$ is a frame independent, or *objective* (or absolute) force; $\boldsymbol{f}_{\text{trans}}$ and $\boldsymbol{f}_{\text{cor}}$ are relative (i.e., frame dependent). At most, $\boldsymbol{f}$ can depend explicitly on relative positions (displacements), relative velocities, and time; but not on relative accelerations (as an independent constitutive equation). [In relativity *all* forces are relative, and hence can be eliminated by proper frame choice. On the classical objectivity requirements for $\boldsymbol{f}$, see, for example, Pars (1965, pp. 11–12), Rosenberg (1977, pp. 12–16).] In addition, in general, *the relative forces are not additive*; for example, the total force acting on a particle P due to two or more attracting masses, each exerting separately on it the absolute forces $\boldsymbol{f}_1$ and $\boldsymbol{f}_2$, equals $(\boldsymbol{f}_1 + \boldsymbol{f}_2) + (\boldsymbol{f}_{\text{trans}} + \boldsymbol{f}_{\text{cor}})$; *not* $(\boldsymbol{f}_1 + \boldsymbol{f}_{\text{trans}} + \boldsymbol{f}_{\text{cor}}) + (\boldsymbol{f}_2 + \boldsymbol{f}_{\text{trans}} + \boldsymbol{f}_{\text{cor}})$. As for the Coriolis "force" $\boldsymbol{f}_{\text{cor}} = -2m(\boldsymbol{\omega} \times \boldsymbol{v}_{\text{rel}})$, even for the same problem (i.e., same m and $\boldsymbol{f}$) that term obviously does depend on the particular noninertial frame used. This, however, does not mean that its effects on people, property, and so on, are any less physically/technically real than those of the real force $\boldsymbol{f}$. [In fact, the study of such similarities between these forces led to the general theory of relativity (mid-1910s).]

For the *comoving* (noninertial) observer, both $\boldsymbol{f}_{\text{trans}}$ and $\boldsymbol{f}_{\text{cor}}$ are very real! Some of the most spectacular Coriolis effects occur in the atmospheric sciences (meteorology, etc.); that is, in phenomena involving the coupling between the motion of large liquid and/or gas masses and the Earth's rotation about its axis. A prime such example is *Baer's law of river displacements*: The inertia force on the northbound flowing water, along a meridian, presses against the right (left) bank in the northern (southern) hemisphere. The effects of this pressure are a stronger erosion of the right embankment; and a slightly but measurably higher water level at the right shore of the river. [In view of these realities, statements like the following cannot be taken seriously: "From the foregoing it is clear that the Coriolis-acceleration term arises from the description adopted, namely, via moving observers, and hence, contrary to popular belief *it bears no physical significance*" [Angeles, 1988, p. 74 (the italics are that author's)].]

Finally, since $\boldsymbol{f}_{\text{cor}}$ is perpendicular to $\boldsymbol{v}_{\text{rel}}$, its "relative power" $\boldsymbol{f}_{\text{cor}} \cdot \boldsymbol{v}_{\text{rel}}$ vanishes (more on such "gyroscopic forces" in §3.9).

(ii) In the case of a finite body, $\boldsymbol{v}_{\text{rel}}$ $(\boldsymbol{a}_{\text{rel}})$ in (1.7.20b) refers to the relative velocity (acceleration) of its *center of mass* G; and $\boldsymbol{r}$ is the position of G relative to the origin of the moving frame.

Power Theorem in Relative Motion

This constitutes the vector/particle form of theorems treated in detail in §3.9. Let us consider a system S in motion relative to the *noninertial* axes O–xyz. To find its power equation in relative variables, we start with the equation of relative motion of a generic particle P of S, of mass dm [recall (1.7.20b ff.)]

$$dm\, \boldsymbol{a}_{\text{rel}} = d\boldsymbol{f} + d\boldsymbol{f}_{\text{trans}} + d\boldsymbol{f}_{\text{cor}}, \tag{1.7.21a}$$

where

$$\boldsymbol{a}_{\text{rel}} \equiv \partial \boldsymbol{v}_{\text{rel}}/\partial t \equiv \partial^2 \boldsymbol{r}/\partial t^2\,, \tag{1.7.21b}$$

$$d\boldsymbol{f} = d\boldsymbol{F} + d\boldsymbol{R} \;\; (\textit{impressed} + \textit{constraint reaction} - \text{see §3.2}) \tag{1.7.21c}$$

$$d\boldsymbol{f}_{\text{trans}} \equiv -dm\, \boldsymbol{a}_{\text{trans}} \equiv -dm\,[d^2\boldsymbol{r}_O/dt^2 + \boldsymbol{\alpha} \times \boldsymbol{r} + \boldsymbol{\omega} \times (\boldsymbol{\omega} \times \boldsymbol{r})], \tag{1.7.21d}$$

$$d\boldsymbol{f}_{\text{cor}} \equiv -dm\, \boldsymbol{a}_{\text{cor}} \equiv -2\, dm(\boldsymbol{\omega} \times \boldsymbol{v}_{\text{rel}}) = -2\, dm[\boldsymbol{\omega} \times (\partial \boldsymbol{r}/\partial t)] \tag{1.7.21e}$$

Now, the system power equation corresponding to the particle equation (1.7.21a) is

$$\mathcal{S}\, dm\, \boldsymbol{a}_{\text{rel}} \cdot \boldsymbol{v}_{\text{rel}} = \mathcal{S}\, d\boldsymbol{f} \cdot \boldsymbol{v}_{\text{rel}} + \mathcal{S}\, d\boldsymbol{f}_{\text{rel}} \cdot \boldsymbol{v}_{\text{rel}} + \mathcal{S}\, d\boldsymbol{f}_{\text{cor}} \cdot \boldsymbol{v}_{\text{rel}}. \tag{1.7.21f}$$

Let us transform each of its terms:

(i)
$$\mathcal{S}\, dm\, \boldsymbol{a}_{\text{rel}} \cdot \boldsymbol{v}_{\text{rel}} = \mathcal{S}\, dm\, \boldsymbol{v}_{\text{rel}} \cdot (\partial \boldsymbol{v}_{\text{rel}}/\partial t)$$
$$= \partial/\partial t\left(\mathcal{S}\,(1/2)\, dm\, \boldsymbol{v}_{\text{rel}} \cdot \boldsymbol{v}_{\text{rel}}\right) \equiv \partial T_{\text{rel}}/\partial t\,, \tag{1.7.21g}$$

or, since

$$\boldsymbol{v}_{\text{rel}} \cdot (d\boldsymbol{v}_{\text{rel}}/dt) = \boldsymbol{v}_{\text{rel}} \cdot (\partial \boldsymbol{v}_{\text{rel}}/\partial t + \boldsymbol{\omega} \times \boldsymbol{v}_{\text{rel}}) = \boldsymbol{v}_{\text{rel}} \cdot (\partial \boldsymbol{v}_{\text{rel}}/\partial t)\,,$$

finally,

$$\mathcal{S}\, dm\, \boldsymbol{a}_{\text{rel}} \cdot \boldsymbol{v}_{\text{rel}} = \partial T_{\text{rel}}/\partial t = dT_{\text{rel}}/dt\,. \tag{1.7.21h}$$

(ii) We define

$$\mathcal{S}\, d\boldsymbol{f} \cdot \boldsymbol{v}_{\text{rel}} = \mathcal{S}\, d\boldsymbol{f} \cdot (\partial \boldsymbol{r}/\partial t) \equiv \partial' W/\partial t\,; \tag{1.7.21i}$$

where, in general, no W exists (i.e., W is a quasi variable—more on this in §2.9). If

$$\mathcal{S}\, d\boldsymbol{R} \cdot \boldsymbol{v}_{\text{rel}} = 0\,, \qquad \text{then} \qquad \partial' W/\partial t = \mathcal{S}\, d\boldsymbol{F} \cdot \boldsymbol{v}_{\text{rel}}\,.$$

(iii) Clearly,

$$\mathcal{S}\, d\boldsymbol{f}_{\text{cor}} \cdot \boldsymbol{v}_{\text{rel}} = \mathcal{S}\left[-2\, dm\, (\boldsymbol{\omega} \times \boldsymbol{v}_{\text{rel}})\right] \cdot \boldsymbol{v}_{\text{rel}} = 0. \tag{1.7.21j}$$

(iv)
$$\mathcal{S}\, d\boldsymbol{f}_{\text{rel}} \cdot \boldsymbol{v}_{\text{rel}} = -\mathcal{S}\, dm\left[\boldsymbol{a}_O + \boldsymbol{\alpha} \times \boldsymbol{r} + \boldsymbol{\omega} \times (\boldsymbol{\omega} \times \boldsymbol{r})\right] \cdot \boldsymbol{v}_{\text{rel}}. \tag{1.7.21k}$$

(a)
$$-\mathcal{S}\, dm\, \boldsymbol{a}_O \cdot \boldsymbol{v}_{\text{rel}} = -\boldsymbol{a}_O \cdot \left(\mathcal{S}\, dm\, \boldsymbol{v}_{\text{rel}}\right) = -m\, \boldsymbol{v}_{G,\text{rel}} \cdot \boldsymbol{a}_O \qquad (\boldsymbol{v}_{G,\text{rel}} \equiv \partial \boldsymbol{r}_G/dt)\,. \tag{1.7.21l}$$

(b)
$$-\mathcal{S}\, dm\, [\boldsymbol{v}_{\text{rel}} \cdot (\boldsymbol{\alpha} \times \boldsymbol{r})] = -\boldsymbol{\alpha} \cdot \left(\mathcal{S}\, dm\, (\boldsymbol{r} \times \boldsymbol{v}_{\text{rel}})\right) \equiv -\boldsymbol{\alpha} \cdot \boldsymbol{H}_{O,\text{rel}}. \tag{1.7.21m}$$

(c) We have, successively,

$$\boldsymbol{v}_{\text{rel}} \cdot [\boldsymbol{\omega} \times (\boldsymbol{\omega} \times \boldsymbol{r})] = (\boldsymbol{\omega} \times \boldsymbol{r}) \cdot (\boldsymbol{v}_{\text{rel}} \times \boldsymbol{\omega}) = -(\boldsymbol{\omega} \times \boldsymbol{r}) \cdot [\boldsymbol{\omega} \times (\partial \boldsymbol{r}/\partial t)]$$
$$= -\partial/\partial t[(\boldsymbol{\omega} \times \boldsymbol{r})^2/2] = -\partial/\partial t[|\boldsymbol{\omega} \times \boldsymbol{r}|^2/2] = -d/dt[|\boldsymbol{\omega} \times \boldsymbol{r}|^2/2]\,, \tag{1.7.21n}$$

(i.e., as if during $\partial/\partial t$ the vector $\boldsymbol{\omega}$ remains constant) and, therefore,

$$-\mathcal{S}\, dm\, \boldsymbol{v}_{\text{rel}} \cdot [\boldsymbol{\omega} \times (\boldsymbol{\omega} \times \boldsymbol{r})] = \partial/\partial t\left(\mathcal{S}\, dm\, [|\boldsymbol{\omega} \times \boldsymbol{r}|^2/2]\right)$$
$$= d/dt\left(\mathcal{S}\, dm\, [|\boldsymbol{\omega} \times \boldsymbol{r}|^2/2]\right). \tag{1.7.21o}$$

In view of (1.7.21g–o), eq. (1.7.21f) takes the following definitive form:

$$dT_{\mathrm{rel}}/dt = \partial' W/\partial t - (m\boldsymbol{v}_{G,\mathrm{rel}})\cdot \boldsymbol{a}_O - \boldsymbol{H}_{O,\mathrm{rel}}\cdot \boldsymbol{\alpha} + d/dt\Big(\mathsf{S}\, dm\,[|\boldsymbol{\omega}\times \boldsymbol{r}|^2/2]\Big). \quad (1.7.21\mathrm{p})$$

Specializations

If O–xyz spins about a *fixed* axis through O, Ol, then $\boldsymbol{a}_O = \boldsymbol{0}$ and eq. (1.7.21p) reduces to

$$dT_{\mathrm{rel}}/dt = \partial' W/dt - \boldsymbol{H}_{O,\mathrm{rel}}\cdot \boldsymbol{\alpha} + d/dt(I\omega^2/2)\,, \quad (1.7.21\mathrm{q})$$

where

$$I \equiv \mathsf{S}\, dm\, \boldsymbol{r}^2 = \textit{moment of inertia of } S \textit{ about } Ol. \quad (1.7.21\mathrm{r})$$

If, further, $\omega = \textit{constant}$, then (1.7.21q) simplifies to

$$dT_{\mathrm{rel}}/dt = \partial' W/\partial t + (dI/dt)\omega^2/2\,. \quad (1.7.21\mathrm{s})$$

Finally, if $\partial' W/\partial t = -dV_O(\boldsymbol{r})/t$, where $V_O = V_O(\boldsymbol{r})$ = *potential of impressed forces*, then (1.7.21s) yields the *conservation* theorem:

$$d/dt\big[T_{\mathrm{rel}} + (V_O - I\omega^2/2)\big] = 0 \;\Rightarrow\; T_{\mathrm{rel}} + (V_O - I\omega^2/2) = \textit{constant}. \quad (1.7.21\mathrm{t})$$

The above is a special case of the *Jacobi–Painlevé integral* (§3.9). As with the equations of motion, the "Newton–Euler" power equation (1.7.21p) may be physically clearer than its Lagrangean counterparts, but the latter have the same *form* in both inertial and noninertial frames, and hence are easier to remember and apply. For further details and insights, see Hamel (1912, pp. 440–443).

The Angular Velocity Tensor

Moving Axes Components

Let us consider two *OND* frames/axes with common origin $O_F \equiv O_M \equiv O$ (no loss in generality here), in arbitrary relative motion (rotation): one *fixed* O–$\boldsymbol{u}_X\boldsymbol{u}_Y\boldsymbol{u}_Z/$–$XYZ$ and another *moving* O–$\boldsymbol{u}_x\boldsymbol{u}_y\boldsymbol{u}_z/$–$xyz$; or, compactly (in view of the heavy indicial notation that follows), O–$\boldsymbol{u}_{k'}/$–$x_{k'}$ and O–$\boldsymbol{u}_k/$–x_k, respectively.

Now, $d/dt(\ldots)$-differentiating their transformation relations,

$$\boldsymbol{u}_k = \sum A_{kk'}\boldsymbol{u}_{k'}, \qquad A_{kk'} \equiv \boldsymbol{u}_k\cdot\boldsymbol{u}_{k'} = \cos(x_k, x_{k'}) = \cos(x_{k'}, x_k) \equiv A_{k'k}, \quad (1.7.22\mathrm{a})$$

and then employing their inverses, we find (since $d\boldsymbol{u}_{k'}/dt = \boldsymbol{0}$):

$$d\boldsymbol{u}_k/dt = \sum (dA_{kk'}/dt)\boldsymbol{u}_{k'} = \sum (dA_{kk'}/dt)\Big(\sum A_{k'l}\boldsymbol{u}_l\Big) \equiv \sum \Omega_{lk}\boldsymbol{u}_l\,, \quad (1.7.22\mathrm{b})$$

where

$$\begin{aligned}\Omega_{lk} &\equiv \sum A_{k'l}(dA_{kk'}/dt) = \sum A_{lk'}(dA_{kk'}/dt) = \sum (dA_{kk'}/dt)A_{lk'} = \cdots \\ &= \sum \big\{\cos(x_l, x_{k'})\, d/dt[\cos(x_k, x_{k'})]\big\} \\ &= \boldsymbol{u}_l\cdot(d\boldsymbol{u}_k/dt) = (d\boldsymbol{u}_k/dt)\cdot\boldsymbol{u}_l \qquad [= (l)\textit{th component of } d\boldsymbol{u}_k/dt]:\end{aligned}$$

Tensor of angular velocity of moving axes relative to the fixed axes; but resolved along the *moving axes*. (1.7.22c)

[As already pointed out (§1.1), this *commutativity of subscripts* in $A_{..}$ constitutes one of the big advantages of the accented indices over other notations, such as A_{kl}, A'_{kl}.] Below we show that this tensor is *antisymmetric*: $\Omega_{lk} = -\Omega_{kl}$. Indeed, $d/dt(\ldots)$-differentiating the orthonormality conditions (constraints!),

$$\boldsymbol{u}_k \cdot \boldsymbol{u}_l = \left(\sum A_{kk'}\boldsymbol{u}_{k'}\right) \cdot \left(\sum A_{ll'}\boldsymbol{u}_{l'}\right) = \cdots = \sum A_{kk'}A_{lk'} = \delta_{kl}, \tag{1.7.22d}$$

and then invoking the definition (1.7.22c) we obtain

$$\begin{aligned} 0 &= \sum (dA_{kk'}/dt)A_{lk'} + \sum A_{kk'}(dA_{lk'}/dt) \qquad [= \boldsymbol{u}_l \cdot (d\boldsymbol{u}_k/dt) + \boldsymbol{u}_k \cdot (d\boldsymbol{u}_l/dt)] \\ &= \Omega_{lk} + \Omega_{kl} \;\Rightarrow\; \Omega_{lk} = -\Omega_{kl}\,, \quad \text{Q.E.D.}; \end{aligned} \tag{1.7.22e}$$

that is, due to the six constraints (1.7.22d), only three of the nine components of Ω_{kl} are independent. Hence, we can replace this tensor by its axial vector (1.1.16a ff.)

$$\omega_k = -\sum\sum (1/2)\varepsilon_{krs}\Omega_{rs} = -\sum\sum\sum (1/2)\varepsilon_{krs}[A_{rp'}(dA_{sp'}/dt)], \tag{1.7.22f}$$

and, inversely,

$$\Omega_{rs} = -\sum \varepsilon_{krs}\,\omega_k = -\sum \varepsilon_{rsk}\,\omega_k. \tag{1.7.22g}$$

In extenso, and recalling the properties of ε_{krs} (§1.1), eqs. (1.7.22f) yield

$$\begin{aligned} \omega_1 \equiv \omega_x &= -(1/2)(\varepsilon_{123}\Omega_{23} + \varepsilon_{132}\Omega_{32}) = -\Omega_{23} = \Omega_{32} \\ &= -\sum A_{2k'}(dA_{3k'}/dt) \qquad [= -\boldsymbol{u}_2 \cdot (d\boldsymbol{u}_3/dt) \equiv -\boldsymbol{u}_y \cdot (d\boldsymbol{u}_z/dt)] \\ &= \sum A_{3k'}\,(dA_{2k'}/dt) \qquad [= \boldsymbol{u}_3 \cdot (d\boldsymbol{u}_2/dt) \equiv \boldsymbol{u}_z \cdot (d\boldsymbol{u}_y/dt)] \\ &\{\text{with } 1,2,3 \to x,y,z;\, 1',2',3' \to X,Y,Z: \\ &= -[A_{Xy}(dA_{Xz}/dt) + A_{Yy}(dA_{Yz}/dt) + A_{Zy}(dA_{Zz}/dt)] \\ &= A_{Xz}(dA_{Xy}/dt) + A_{Yz}(dA_{Yy}/dt) + A_{Zz}(dA_{Zy}/dt)\}; \end{aligned} \tag{1.7.23a}$$

$$\begin{aligned} \omega_2 \equiv \omega_y &= -(1/2)(\varepsilon_{231}\Omega_{31} + \varepsilon_{213}\Omega_{13}) = -\Omega_{31} = \Omega_{13} \\ &= -\sum A_{3k'}\,(dA_{1k'}/dt) \qquad [= -\boldsymbol{u}_3 \cdot (d\boldsymbol{u}_1/dt) \equiv -\boldsymbol{u}_z \cdot (d\boldsymbol{u}_x/dt)] \\ &= \sum A_{1k'}\,(dA_{3k'}/dt) \qquad [= \boldsymbol{u}_1 \cdot (d\boldsymbol{u}_3/dt) \equiv \boldsymbol{u}_x \cdot (d\boldsymbol{u}_z/dt)] \\ &\{ = -[A_{Xz}(dA_{Xx}/dt) + A_{Yz}(dY_{Yx}/dt) + A_{Zz}(dA_{Zx}/dt)] \\ &= A_{Xx}(dA_{Xz}/dt) + A_{Yx}(dA_{Yz}/dt) + A_{Zx}(dA_{Zz}/dt)\}; \end{aligned} \tag{1.7.23b}$$

$$\begin{aligned} \omega_3 \equiv \omega_z &= -(1/2)(\varepsilon_{312}\Omega_{12} + \varepsilon_{321}\Omega_{21}) = -\Omega_{12} = \Omega_{21} \\ &= -\sum A_{1k'}(dA_{2k'}/dt) \quad [= -\boldsymbol{u}_1 \cdot (d\boldsymbol{u}_2/dt) \equiv -\boldsymbol{u}_x \cdot (d\boldsymbol{u}_y/dt)] \\ &= \sum A_{2k'}(dA_{1k'}/dt) \qquad [= \boldsymbol{u}_2 \cdot (d\boldsymbol{u}_1/dt) \equiv \boldsymbol{u}_y \cdot (d\boldsymbol{u}_x/dt)] \\ &\{ = -[A_{Xx}(dA_{Xy}/dt) + A_{Yx}(dA_{Yy}/dt) + A_{Zx}(dA_{Zy}/dt)] \\ &= A_{Xy}(dA_{Xx}/dt) + A_{Yy}(dA_{Yx}/dt) + A_{Zy}\,(dA_{Zx}/dt)\}; \end{aligned} \tag{1.7.23c}$$

which are in complete agreement with (1.7.4j), and justify the name *angular velocity tensor* for (1.7.22c). In terms of *matrices*, the above assume the following memorable form:

$$(\Omega_{kl}) = \begin{pmatrix} 0 & -\omega_3 & \omega_2 \\ \omega_3 & 0 & -\omega_1 \\ -\omega_2 & \omega_1 & 0 \end{pmatrix}$$

$$= \left(\begin{array}{c|c|c} 0 & \sum A_{1k'}(dA_{2k'}/dt) & \sum A_{1k'}(dA_{3k'}/dt) \\ \hline \sum A_{2k'}(dA_{1k'}/dt) & 0 & \sum A_{2k'}(dA_{3k'}/dt) \\ \hline \sum A_{3k'}(dA_{1k'}/dt) & \sum A_{3k'}(dA_{2k'}/dt) & 0 \end{array}\right). \qquad (1.7.23d)$$

REMARKS

(i) The formulae (1.7.22f ff.) can be combined into the following useful form:

$$\omega_k = (d\boldsymbol{u}_r/dt) \cdot \boldsymbol{u}_s, \qquad (1.7.24)$$

where

$$k, r, s = cyclic\ (even)\ permutation\ of\ 1, 2, 3\ (\equiv\ x, y, z).$$

(ii) The final expressions (1.7.23d) would have resulted if we had employed the following common angular velocity tensor definitions:

$$\Omega_{kl} \equiv (d\boldsymbol{u}_k/dt) \cdot \boldsymbol{u}_l = -(d\boldsymbol{u}_l/dt) \cdot \boldsymbol{u}_k = \sum (dA_{kk'}/dt)A_{lk'} = -\sum (dA_{lk'}/dt)A_{kk'}, \qquad (1.7.25a)$$

but in connection with the also common *axial vector definition*:

$$\omega_k = \sum \sum (1/2)\varepsilon_{krs}\Omega_{rs} \qquad (1.7.25b)$$

Then, we would have

$$\begin{aligned} \omega_1 &= (1/2)(\varepsilon_{123}\Omega_{23} + \varepsilon_{132}\Omega_{32}) = \Omega_{23} = -\Omega_{32} \\ &= \sum (dA_{2k'}/dt)A_{3k'} = -\sum (dA_{3k'}/dt)A_{2k'},\ \text{etc.} \end{aligned} \qquad (1.7.25c)$$

Fixed Axes Components

Let us express the above inertial angular velocity tensor in terms of their components along the fixed axes $O\text{–}\boldsymbol{u}_X\boldsymbol{u}_Y\boldsymbol{u}_Z/\text{–}XYZ \equiv O\text{–}\boldsymbol{u}_{k'}/\text{–}x_{k'}$. Dotting the representations of the position vector of a typical particle P,

$$\boldsymbol{r} = \sum x_k \boldsymbol{u}_k = \sum x_{k'}\boldsymbol{u}_{k'}, \qquad (1.7.26a)$$

with $\boldsymbol{u}_l$ and $\boldsymbol{u}_{l'}$, respectively, and taking into account the orthonormality constraints of their basis vectors:

$$\boldsymbol{u}_k \cdot \boldsymbol{u}_l = \left(\sum A_{kk'}\boldsymbol{u}_{k'}\right) \cdot \left(\sum A_{ll'}\boldsymbol{u}_{l'}\right) = \sum A_{kk'}A_{lk'} = \delta_{kl}, \qquad (1.7.26b)$$

$$\boldsymbol{u}_{k'} \cdot \boldsymbol{u}_{l'} = \left(\sum A_{k'k}\boldsymbol{u}_k\right) \cdot \left(\sum A_{l'l}\boldsymbol{u}_l\right) = \sum A_{k'k}A_{l'k} = \delta_{k'l'}, \qquad (1.7.26c)$$

we easily obtain the component transformation equation

$$x_{k'} = \sum A_{k'k} x_k \Leftrightarrow x_k = \sum A_{kk'} x_{k'}. \tag{1.7.26d}$$

If the two sets of axes do *not* have a common origin, but [recalling fig. 1.6(a)]

$$\mathfrak{R} = \boldsymbol{r}_O + \boldsymbol{r}, \tag{1.7.26e}$$

where

$$\mathfrak{R} = \sum x_{k'} \boldsymbol{u}_{k'}, \tag{1.7.26f}$$

$$\boldsymbol{r}_O \equiv \boldsymbol{r}_{\text{moving origin/fixed origin}} = \sum b_k \boldsymbol{u}_k = \sum b_{k'} \boldsymbol{u}_{k'}$$

$$\Rightarrow \quad b_{k'} = \sum A_{k'k} b_k \quad \Leftrightarrow \quad b_k = \sum A_{kk'} b_{k'}, \tag{1.7.26g}$$

$$\boldsymbol{r} = \sum x_k \boldsymbol{u}_k, \tag{1.7.26h}$$

then (1.7.26d) are replaced by

$$x_{k'} = \sum A_{k'k} x_k + b_{k'} \equiv \sum A_{k'k}(x_k + b_k)$$
$$\Leftrightarrow x_k = \sum A_{kk'}(x_{k'} - b_{k'}) = \sum A_{kk'} x_{k'} - b_k. \tag{1.7.26i}$$

Now, let us consider P to be *rigidly* attached to the moving axes. Then $d/dt(\ldots)$-differentiating the $x_{k'}$, while recalling that in this case $x_k = constant \Rightarrow dx_k/dt = 0$, we obtain, successively,

$$dx_{k'}/dt = \sum (dA_{k'k}/dt) x_k = \sum (dA_{k'k}/dt)\Big(\sum A_{kl'} x_{l'}\Big) \equiv \sum \Omega_{k'l'} x_{l'}\,,$$

[which is none other than the familiar $\boldsymbol{v} = \boldsymbol{\omega} \times \boldsymbol{r}$, resolved along the *fixed* axes]
(1.7.26j)

where

$$\Omega_{k'l'} \equiv \sum (dA_{k'k}/dt) A_{kl'} \equiv \sum (dA_{k'k}/dt) A_{l'k}$$
$$= \sum \{\cos(x_{l'}, x_k)\; d/dt[\cos(x_{k'}, x_k)]\}:$$

Tensor of angular velocity of moving axes relative to the fixed axes;
but resolved along the *fixed axes* [Note order of *accented* indices, and
compare with order of unaccented indices in expression (1.7.22c, 25a).](1.7.26k)

The components $\Omega_{k'l'}$, just like the Ω_{kl}, are *antisymmetric*. Indeed, $d/dt(\ldots)$-differentiating (1.7.26c), we obtain

$$0 = \sum (dA_{k'k}/dt) A_{l'k} + \sum A_{k'k}(dA_{l'k}/dt) = \Omega_{l'k'} + \Omega_{k'l'}$$
$$\Rightarrow \Omega_{l'k'} = -\Omega_{k'l'}\,, \quad \text{Q.E.D.} \tag{1.7.26l}$$

$$\omega_{k'} = -\sum\sum (1/2)\varepsilon_{k'r's'} \Omega_{r's'} = -\sum\sum\sum (1/2)\varepsilon_{k'r's'}\big[A_{r'r}(dA_{s'r}/dt)\big], \tag{1.7.26m}$$

and, inversely,

$$\Omega_{r's'} = -\sum \varepsilon_{k'r's'}\,\omega_{k'} = -\sum \varepsilon_{r's'k'}\,\omega_{k'}; \tag{1.7.26n}$$

or, in extenso,

$$\begin{aligned}
\omega_{1'} \equiv \omega_{x'} \equiv \omega_X &= -(1/2)(\varepsilon_{1'2'3'}\Omega_{2'3'} + \varepsilon_{1'3'2'}\Omega_{3'2'}) = -\Omega_{2'3'} = \Omega_{3'2'}\\
&\quad \{\text{with } 1,2,3 \to x,y,z;\ 1',2',3' \to X,Y,Z:\\
&= -[A_{Zx}(dA_{Yx}/dt) + A_{Zy}(dA_{Yy}/dt) + A_{Zz}(dA_{Yz}/dt)]\\
&= A_{Yx}(dA_{Zx}/dt) + A_{Yy}(dA_{Zy}/dt) + A_{Yz}(dA_{Zz}/dt)\}; \qquad (1.7.27\text{a})\\
\omega_{2'} \equiv \omega_{y'} \equiv \omega_Y &= -(1/2)(\varepsilon_{2'3'1'}\Omega_{3'1'} + \varepsilon_{2'1'3'}\Omega_{1'3'}) = -\Omega_{3'1'} = \Omega_{1'3'}\\
&= -\sum A_{1'k}(dA_{3'k}/dt) = \sum A_{3'k}(dA_{1'k}/dt)\\
&\{ = -[A_{Xx}(dA_{Zx}/dt) + A_{Xy}(dA_{Zy}/dt) + A_{Xz}(dA_{Zz}/dt)]\\
&= A_{Zx}(dA_{Xx}/dt) + A_{Zy}(dA_{Xy}/dt) + A_{Zz}(dA_{Xz}/dt)\}; \qquad (1.7.27\text{b})\\
\omega_{3'} \equiv \omega_{z'} \equiv \omega_Z &= -(1/2)(\varepsilon_{3'1'2'}\Omega_{1'2'} + \varepsilon_{3'2'1'}\Omega_{2'1'}) = -\Omega_{1'2'} = \Omega_{2'1'}\\
&= -\sum A_{2'k}(dA_{1'k}/dt) = \sum A_{1'k}(dA_{2'k}/dt)\\
&\{ = -[A_{Yx}(dA_{Xx}/dt) + A_{Yy}(dA_{Xy}/dt) + A_{Yz}(dA_{Xz}/dt)]\\
&= A_{Xx}(dA_{Yx}/dt) + A_{Xy}(dA_{Yy}/dt) + A_{Xz}(dA_{Yz}/dt)\}; \qquad (1.7.27\text{c})
\end{aligned}$$

or, finally, in the following memorable matrix form:

$$\begin{aligned}
(\Omega_{k'l'}) &= \begin{pmatrix} 0 & -\omega_{3'} & \omega_{2'} \\ \omega_{3'} & 0 & -\omega_{1'} \\ -\omega_{2'} & \omega_{1'} & 0 \end{pmatrix}\\
&= \left(\begin{array}{c|c|c} 0 & \sum (dA_{1'k}/dt)A_{2'k} & \sum (dA_{1'k}/dt)A_{3'k} \\ \hline \sum (dA_{2'k}/dt)A_{1'k} & 0 & \sum (dA_{2'k}/dt)A_{3'k} \\ \hline \sum (dA_{3'k}/dt)A_{1'k} & \sum (dA_{3'k}/dt)A_{2'k} & 0 \end{array}\right);
\end{aligned} \tag{1.7.27d}$$

or $$\Omega_{k'l'} = \sum\sum A_{k'k}A_{l'l}\Omega_{kl} \Leftrightarrow \Omega_{kl} = \sum\sum A_{kk'}A_{ll'}\Omega_{k'l'}\,. \tag{1.7.27e}$$

A Special Case

If the axes x_k and $x_{k'}$ *coincide momentarily*—that is, if instantaneously $A_{k'k} = \delta_{k'k}$ (Kronecker delta), then eqs. (1.7.23) and (1.7.27) yield

$$\begin{aligned}
\omega_x &= dA_{Zy}/dt = -dA_{Yz}/dt, \qquad \omega_y = dA_{Xz}/dt = -dA_{Zx}/dt,\\
&\qquad \omega_z = dA_{Yx}/dt = -dA_{Xy}/dt; \qquad (1.7.28\text{a})\\
\omega_X &= dA_{Zy}/dt = -dA_{Yz}/dt, \qquad \omega_Y = dA_{Xz}/dt = -dA_{Zx}/dt,\\
&\qquad \omega_Z = dA_{Yx}/dt = -dA_{Xy}/dt. \qquad (1.7.28\text{b})
\end{aligned}$$

Rates of Change of Direction Cosines

Let us calculate $dA_{k'k}/dt$ in term of Ω_{kl}, $\Omega_{k'l'}$.

(i) *Fixed axes representation*: Multiplying both sides of (1.7.22c) with $A_{l'l}$ and summing over l, we obtain

$$\sum \Omega_{lk} A_{l'l} = \sum (dA_{k'k}/dt)\Big(\sum A_{k'l} A_{l'l}\Big) = \sum (dA_{k'k}/dt)(\delta_{k'l'}) = dA_{l'k}/dt. \tag{1.7.29a}$$

(ii) *Moving axes representation*: Multiplying both sides of (1.7.26k) with $A_{l's}$ and summing over l', we obtain

$$\sum \Omega_{k'l'} A_{l's} = \sum (dA_{k'k}/dt)\Big(\sum A_{kl'} A_{l's}\Big) = \sum (dA_{k'k}/dt)(\delta_{ks}) = dA_{k's}/dt; \tag{1.7.29b}$$

$$dA_{k'k}/dt = \sum A_{k'l}\Omega_{lk} = \sum \Omega_{k'l'} A_{l'k}\,; \tag{1.7.29c}$$

$$\begin{aligned} dA_{k'k}/dt &= A_{k'1}\Omega_{1k} + A_{k'2}\Omega_{2k} + A_{k'3}\Omega_{3k} \\ \Rightarrow dA_{k'1}/dt &= A_{k'2}\omega_3 - A_{k'3}\omega_2; \qquad \text{i.e., } dA_{k'x}/dt = A_{k'y}\omega_z - A_{k'z}\omega_y, \\ dA_{k'2}/dt &= A_{k'3}\omega_1 - A_{k'1}\omega_3; \qquad \text{i.e., } dA_{k'y}/dt = A_{k'z}\omega_x - A_{k'x}\omega_z, \\ dA_{k'3}/dt &= A_{k'1}\omega_2 - A_{k'2}\omega_1; \qquad \text{i.e., } dA_{k'z}/dt = A_{k'x}\omega_y - A_{k'y}\omega_x \\ & \qquad (k' = X, Y, Z); \end{aligned} \tag{1.7.29d}$$

$$\begin{aligned} dA_{k'k}/dt &= A_{1'k}\Omega_{k'1'} + A_{2'k}\Omega_{k'2'} + A_{3'k}\Omega_{k'3'} \\ \Rightarrow dA_{1'k}/dt &= A_{3'k}\omega_{2'} - A_{2'k}\omega_{3'}; \qquad \text{i.e., } dA_{Xk}/dt = A_{Zk}\omega_Y - A_{Yk}\omega_Z, \\ dA_{2'k}/dt &= A_{1'k}\omega_{3'} - A_{3'k}\omega_{1'}; \qquad \text{i.e., } dA_{Yk}/dt = A_{Xk}\omega_Z - A_{Zk}\omega_X, \\ dA_{3'k}/dt &= A_{2'k}\omega_{1'} - A_{1'k}\omega_{2'}; \qquad \text{i.e., } dA_{Zk}/dt = A_{Yk}\omega_X - A_{Xk}\omega_Y \\ & \qquad (k = x, y, z). \end{aligned} \tag{1.7.29e}$$

Additional Useful Results

(i) By $d/dt(\ldots)$-differentiating the fixed basis vectors:

$$\mathbf{0} = d\boldsymbol{u}_{k'}/dt = \sum \big[(dA_{k'k}/dt)\boldsymbol{u}_k + A_{k'k}(d\boldsymbol{u}_k/dt)\big] = \cdots, \tag{1.7.30a}$$

it can be shown that

$$d\boldsymbol{u}_k/dt = \sum \Omega_{k'k}\boldsymbol{u}_{k'}\,, \tag{1.7.30b}$$

where

$$\Omega_{k'k} \equiv \sum A_{l'k}\Omega_{k'l'} = \sum(\partial x_{l'}/\partial x_k)\Omega_{k'l'} = \cdots = dA_{k'k}/dt \qquad (\textit{mixed}\text{ "tensor"}) \tag{1.7.30c}$$

[Similarly, we can define the following *mixed angular velocity "tensor"*:

$$\Omega_{kk'} \equiv \sum \Omega_{kl} A_{lk'} = \sum(\partial x_l/\partial x_{k'})\Omega_{kl} = \sum A_{lk'}\Big(\sum\sum A_{kp'} A_{lq'}\Omega_{p'q'}\Big) = \cdots = \sum A_{kl'}\Omega_{l'k'}\,.\Big]$$

(ii) By $d/dt(\ldots)$-differentiating $x'_{k'} = x_{k'} = \sum A_{k'k} x_k$, and noticing that $v'_k = \sum A_{kk'} v'_{k'}$, it can be shown that the *inertial* velocity of a particle permanently fixed in the moving frame (i.e., $dx_k/dt \equiv v_k = 0 \Rightarrow v_{k'} = 0$) equals:

$$v'_k = \sum \Omega_{kl} x_l \qquad \text{(along the } moving \text{ axes)}, \tag{1.7.30d}$$

$$dx_{k'}/dt \equiv v'_{k'} = \sum \Omega_{k'l'} x_{l'} \qquad \text{(along the } fixed \text{ axes)}. \tag{1.7.30e}$$

(iii) Let us define the following *matrices*:

$\mathbf{\Omega} = (\Omega_{kl})$: matrix of angular velocity *tensor*, along the *moving* axes, (1.7.30f)

$\mathbf{\Omega'} = (\Omega_{k'l'})$: matrix of angular velocity *tensor*, along the *fixed* axes, (1.7.30g)

$\mathbf{A} = (A_{k'k})$: matrix of direction cosines between moving and fixed axes. (1.7.30h)

It can be shown that the earlier relations among them (i.e., among their elements) can be put in the following matrix forms [recalling that $\mathbf{A}^{-1} = \mathbf{A}^{\mathrm{T}}$ and $(\ldots)^{\mathrm{T}} \equiv$ *Transpose* of $(\ldots)$]:

$$\mathbf{\Omega} = \mathbf{A}^{\mathrm{T}} \cdot (\mathrm{d}\mathbf{A}/\mathrm{dt}) = -(\mathrm{d}\mathbf{A}/\mathrm{dt})^{\mathrm{T}} \cdot \mathbf{A} \Leftrightarrow \mathrm{d}\mathbf{A}/\mathrm{dt} = \mathbf{A} \cdot \mathbf{\Omega}\,, \tag{1.7.30i}$$

$$\mathbf{\Omega'} = (\mathrm{d}\mathbf{A}/\mathrm{dt}) \cdot \mathbf{A}^{\mathrm{T}} = -\mathbf{A} \cdot (\mathrm{d}\mathbf{A}/\mathrm{dt})^{\mathrm{T}} \Leftrightarrow \mathrm{d}\mathbf{A}/\mathrm{dt} = \mathbf{\Omega'} \cdot \mathbf{A}\,, \tag{1.7.30j}$$

$$\mathbf{\Omega'} = \mathbf{A} \cdot \mathbf{\Omega} \cdot \mathbf{A}^{\mathrm{T}} \Leftrightarrow \mathbf{\Omega} = \mathbf{A}^{\mathrm{T}} \cdot \mathbf{\Omega'} \cdot \mathbf{A}\,. \tag{1.7.30k}$$

[(a) Equation (1.7.30j) expresses the following important general theorem: *for an arbitrary (differentiable) orthogonal matrix (or tensor)* $\mathbf{A} = \mathbf{A}(\mathrm{t})$,

$$\mathrm{d}\mathbf{A}/\mathrm{dt} = (\text{matrix of } second\text{-}order\ antisymmetric\ tensor) \cdot \mathbf{A}; \tag{1.7.30l}$$

and similarly for equation (1.7.30i).
(b) Recall remarks on p. 84, below (1.1.19f), e.g. $A_{1'2} = A_{21'} \neq A_{2'1} = A_{12'}$.]

Angular Velocity Vector in General Orthogonal Curvilinear Coordinates

[This section may be omitted in a first reading. For background, see (1.2.7a ff.).]

In such coordinates, say $q \equiv (q_1, q_2, q_3) \equiv (q_{1,2,3})$, the inertial position vector of a particle $\boldsymbol{r}$ becomes

$$\boldsymbol{r} = X(q)\boldsymbol{u}_X + Y(q)\boldsymbol{u}_Y + Z(q)\boldsymbol{u}_Z \equiv \sum x_{k'}(q)\boldsymbol{u}_{k'}, \tag{1.7.31a}$$

and so the corresponding moving *OND* basis along $q_{1,2,3}$ (i.e., the earlier x_k) is

$$\boldsymbol{u}_k = (\partial\boldsymbol{r}/\partial q_k)\big/|\partial\boldsymbol{r}/\partial q_k| \equiv (1/h_k)(\partial\boldsymbol{r}/\partial q_k) \qquad (k = x, y, z), \tag{1.7.31b}$$

with

$$\boldsymbol{u}_k \cdot \boldsymbol{u}_l = \delta_{kl} \qquad (k, l = x, y, z). \tag{1.7.31c}$$

Next, $d/dt(\ldots)$-differentiating (1.7.31b), we obtain, successively,

$$\begin{aligned} d/dt(\partial \boldsymbol{r}/\partial q_r) &= d/dt(h_r \boldsymbol{u}_r) = (dh_r/dt)\boldsymbol{u}_r + h_r(d\boldsymbol{u}_r/dt) \\ &= (dh_r/dt)\boldsymbol{u}_r + h_r(\boldsymbol{\omega} \times \boldsymbol{u}_r) \qquad \text{[by (1.7.4i)]}, \qquad (1.7.31\text{d}) \end{aligned}$$

and dotting this with $\partial \boldsymbol{r}/\partial q_s = h_s \boldsymbol{u}_s$ ($\equiv \boldsymbol{e}_s$, where $r \neq s$), in order to isolate ω_k, we get

$$\begin{aligned} \left[d/dt(\partial \boldsymbol{r}/\partial q_r)\right] \cdot (\partial \boldsymbol{r}/\partial q_s) &= (dh_r/dt)h_s(\boldsymbol{u}_r \cdot \boldsymbol{u}_s) + h_r h_s[(\boldsymbol{\omega} \times \boldsymbol{u}_r) \cdot \boldsymbol{u}_s] \\ &= 0 + h_r h_s[(\boldsymbol{\omega} \cdot (\boldsymbol{u}_r \times \boldsymbol{u}_s)] = h_r h_s(\boldsymbol{\omega} \cdot \boldsymbol{u}_k) \equiv h_r h_s \omega_k \end{aligned}$$

[definition of ω_k's; where k, r, s = even (cyclic) permutation of 1, 2, 3 $\equiv x$, y, z],

that is, finally,

$$\begin{aligned} \omega_k &= (1/h_r h_s)\left[d/dt(\partial \boldsymbol{r}/\partial q_r) \cdot (\partial \boldsymbol{r}/\partial q_s)\right] \\ &\left\{ = (d\boldsymbol{u}_r/dt) \cdot \boldsymbol{u}_s = d/dt\left[(1/h_r)(\partial \boldsymbol{r}/\partial q_r)\right] \cdot \left[(1/h_s)(\partial \boldsymbol{r}/\partial q_s)\right]\right\}. \qquad (1.7.31\text{e}) \end{aligned}$$

Additional forms for these components exist in the literature; for example, with the help of the differential-geometric identities:

$$\partial \boldsymbol{u}_r/\partial q_s = (1/h_r)(\partial h_s/\partial q_r)\boldsymbol{u}_s \qquad (r \neq s), \qquad (1.7.31\text{f})$$

$$\partial \boldsymbol{u}_r/\partial q_r = -(1/h_s)(\partial h_r/\partial q_s)\boldsymbol{u}_s - (1/h_k)(\partial h_r/\partial q_k)\boldsymbol{u}_k \qquad (r \neq s \neq k \neq r), \qquad (1.7.31\text{g})$$

and applying the second line of (1.7.31e), we can easily show that

$$\omega_1 = (1/h_2)(\partial h_3/\partial q_2)(dq_3/dt) - (1/h_3)(\partial h_2/\partial q_3)(dq_2/dt), \qquad (1.7.31\text{h})$$

$$\omega_2 = (1/h_3)(\partial h_1/\partial q_3)(dq_1/dt) - (1/h_1)(\partial h_3/\partial q_1)(dq_3/dt), \qquad (1.7.31\text{i})$$

$$\omega_3 = (1/h_1)(\partial h_2/\partial q_1)(dq_2/dt) - (1/h_2)(\partial h_1/\partial q_2)(dq_1/dt). \qquad (1.7.31\text{j})$$

[See Richardson (1992), also Ames and Murnaghan (1929, pp. 26–34, 94–98), for an alternative derivation based on the direction cosines between the moving and fixed axes:

$$\begin{aligned} A_{k'k} = A_{kk'} \equiv \boldsymbol{u}_{k'} \cdot \boldsymbol{u}_k &= (\partial \boldsymbol{r}/\partial x_{k'}) \cdot \left[(1/h_k)(\partial \boldsymbol{r}/\partial q_k)\right] \\ &= (1/h_k)\left\{(\partial \boldsymbol{r}/\partial x_{k'}) \cdot \left(\sum (\partial \boldsymbol{r}/\partial x_{l'})(\partial x_{l'}/\partial q_k)\right)\right\} \\ &= (1/h_k)\left(\sum (\boldsymbol{u}_{k'} \cdot \boldsymbol{u}_{l'})(\partial x_{l'}/\partial q_k)\right) \qquad (\text{since } \boldsymbol{u}_{k'} \cdot \boldsymbol{u}_{l'} = \delta_{k'l'}) \\ &= (1/h_k)(\partial x_{k'}/\partial q_k), \qquad (1.7.31\text{k}) \end{aligned}$$

and their $d/dt(\ldots)$-derivatives.]

1.8 THE RIGID BODY: INTRODUCTION

The following material relies heavily on the preceding theory of moving axes (§1.7). The reason for this is that *every set of such axes can be thought of as a moving rigid body*; and, conversely, *every rigid body in motion carries along with it one or more sets of axes rigidly attached to it, or embedded in it*. To describe the translatory and

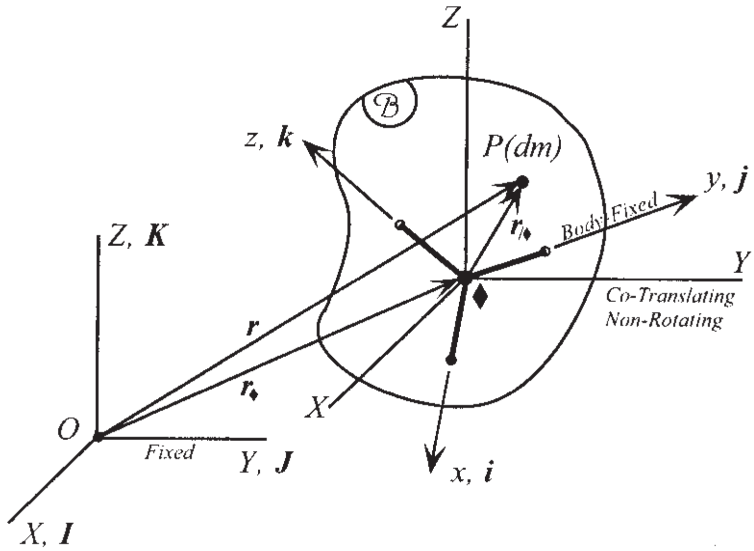

Figure 1.9 Axes used to describe rigid-body motion.
O–$XYZ/\boldsymbol{IJK}$: fixed axes/basis; $\blacklozenge$–$xyz/\boldsymbol{ijk}$: moving (body-fixed) axes/basis;
$\blacklozenge$–$XYZ/\boldsymbol{IJK}$: moving, translating but nonrotating axes/basis.

angular motion of a rigid body B, we consider (at least) *two* sets of rectangular Cartesian axes and associated bases:

(i) a *fixed*: that is, inertial, O–$XYZ/\boldsymbol{IJK}$ or compactly O–$x_{k'}/\boldsymbol{u}_{k'}$; and
(ii) a *moving*: that is, noninertial, and *body-fixed* set $\blacklozenge$–$xyz/\boldsymbol{ijk}$ or compactly $\blacklozenge$–$x_k/\boldsymbol{u}_k$, at the arbitrary body point $\blacklozenge$ (fig. 1.9).

In the language of constraints (chap. 2), a *free* rigid body in space is a mechanical system with *six* degrees of *global* freedom; that is, six independent possibilities of *finite* spatial mobility: (i) three for the location of its body point $\blacklozenge$, say its O–XYZ coordinates

$$X_\blacklozenge = f_1(t), \qquad Y_\blacklozenge = f_2(t), \qquad Z_\blacklozenge = f_3(t); \tag{1.8.1a}$$

and (ii) three for its *orientation*—that is, of $\blacklozenge$–xyz relative to either O–XYZ or $\blacklozenge$–XYZ; where the latter are a translating frame at $\blacklozenge$ *ever parallel* to O–XYZ—that is, one that is nonrotating but translating and hence is, generally, *noninertial*. Such "rotational freedoms" can be described via the nine direction cosines of $\blacklozenge$–xyz relative to $\blacklozenge$–XYZ (of which, as explained in §1.7, only three are independent); or via their three *attitude* angles: for example, their Eulerian or Cardanian angles

$$\phi = f_4(t), \qquad \theta = f_5(t), \qquad \psi = f_6(t); \tag{1.8.1b}$$

or via a directed line segment called *rotation "vector"* [or via *four* parameter formalisms (plus one constraint among them); for example, Hamiltonian quaternions, Euler–Rodrigues parameters, or complex numbers; detailed in kinematics treatises, also our *Elementary Mechanics*, ch. 16 (under production)]. With the help of the six *positional system parameters*, or *system coordinates*, $f_{1,\ldots,6}(t)$, the location/motion of any other body point P can be determined:

$$\boldsymbol{r} = \boldsymbol{r}(P,t) = \boldsymbol{r}(P; f_1,\ldots,f_6) = \boldsymbol{r}_\blacklozenge(f_1,f_2,f_3) + \boldsymbol{r}_{/\blacklozenge}(P; f_4,f_5,f_6), \tag{1.8.2a}$$

or, in components,

$$X = X_{\blacklozenge} + \cos(X, x)x_{/\blacklozenge} + \cos(X, y)y_{/\blacklozenge} + \cos(X, z)z_{/\blacklozenge}, \quad \text{etc., cyclically,} \tag{1.8.2b}$$

where

$$\boldsymbol{r}_{/\blacklozenge} = (x_{/\blacklozenge}, y_{/\blacklozenge}, z_{/\blacklozenge}):$$

constant rectangular Cartesian coordinates of P relative to $\blacklozenge$–xyz, (1.8.2c)

or, in compact (self-explanatory) indicial notation,

$$x_{k'} = x_{\blacklozenge,k'} + \sum A_{k'k}x_k. \tag{1.8.2d}$$

In addition to $\blacklozenge$–xyz and $\blacklozenge$–XYZ, we occasionally use other *intermediate* axes (or *accessory* axes, in Routh's terminology) that, like $\blacklozenge$–XYZ, are neither space- nor body-fixed, but have their own special translatory and/or rotatory motion.

1.9 THE RIGID BODY: GEOMETRY OF MOTION AND KINEMATICS (SUMMARY OF BASIC THEOREMS)

Sections §1.9–1.13 cover material that is due to Euler, Mozzi, Cauchy, Chasles, Poinsot, Rodrigues, Cayley et al. (late 18th to mid-19th century). For detailed discussions, proofs, insights, and so on, see for example (alphabetically): Alt (1927), Altmann (1986), Beyer (1929, 1963), Bottema and Roth (1979), Coe (1938), Garnier (1951, 1956, 1960), Hunt (1978), McCarthy (1990), Schönflies and Grübler (1902), Timerding (1902, 1908).

The *position*, or *configuration*, of a rigid body B is known when the positions of any three *noncollinear* of its points are known; hence, *six* independent parameters are needed to specify it [e.g., $3 \times 3 = 9$ rectangular Cartesian coordinates of these points, minus the three independent constraints of distance invariance (i.e., rigidity) among them; or six coordinates for two of its points defining an axis of rotation, minus one invariance constraint between them, plus the angle of rotation of a body-fixed plane with a space-fixed plane, both through that axis]. If the body is further constrained, this number is less than six. It follows that the most general change of position, or *displacement*, of B is determined by the displacements of any three noncollinear of its points; that is, given their initial and final positions and the initial (final) position of a fourth, fifth, and so on, we can find their final (initial) positions with no additional data.

Special Rigid-Body Displacements

(i) *Plane, or planar, displacement*: One in which the paths of all body points are plane curves on planes parallel to each other and to a fixed plane f [fig. 1.10(a)]: the body fiber $P'PP''$ remains perpendicular to f, and the distance $P\blacklozenge$ remains constant, so that we need to study only *the motion of a typical body section, or rigid lamina, b imagined superimposed on f and sliding on it*.

THEOREM

Every displacement of a rigid lamina in its plane is equivalent to a rotation about some plane point I [fig. 1.10(b)].

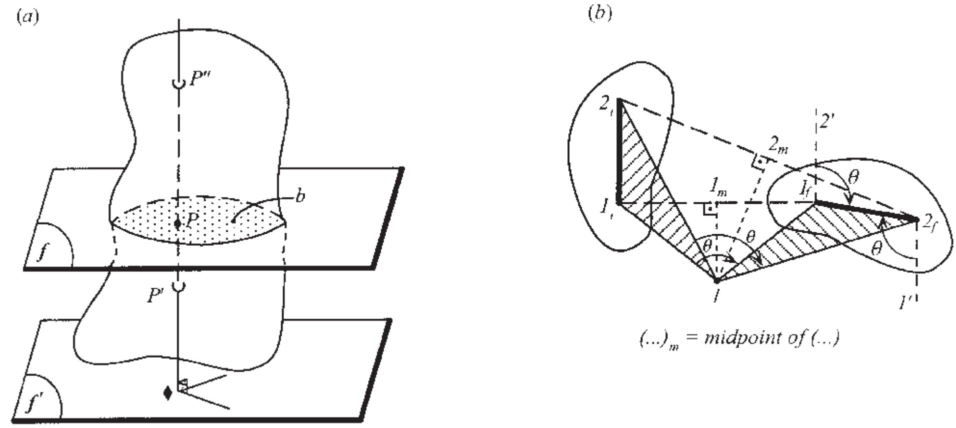

Figure 1.10 (a) Plane displacement of a rigid body. (b) The plane displacement of a rigid lamina on its plane is equivalent to a rotation about I; if $I \to \infty$, that displacement degenerates to a translation.

(ii) *Translational displacement*: One in which all body points have vectorially equal velocities. Translations can be either *rectilinear* or *curvilinear*, and can be represented by a *free* vector (three components).

(iii) *Rotational displacement*: One in which at least *two* points remain *fixed*. These points define the *axis of rotation*; and either they are actual body points, or belong to its appropriate *fictitious rigid extensions*. Rotations are, by far, the more complex and interesting part of rigid-body displacements/motions.

The rotation is specified by its axis (i.e., its *line of action*) and by its *angle of rotation*; and since a line is specified by, say, its two points of intersection with two coordinate planes — that is, four coordinates — and an angle is specified by one coordinate, *the complete characterization of rotation requires* $4 + 1 = 5$ *positional parameters*.

THEOREM

Every translation can be decomposed into rotations.

COROLLARY

All rigid displacements can be reduced to rotations. The above special displacements (plane, translations, rotations) are all examples of *constrained* motions; that is, they result from special geometrical [or finite, or holonomic (chap. 2)] *restrictions on the global mobility of the body*; as contrasted with *local* restrictions of its mobility [by nonholonomic constraints (chap. 2)].

EULER'S THEOREM (1775–1776)

Any displacement of a rigid body, one point of which is fixed but is otherwise free to move, can be achieved by a single rotation, of 180° or less, about some axis through that point; that is, any displacement of such a system is equivalent to a rotation. Or: any rigid displacement of a spherical surface into itself leaves two (diametrically opposed) points of that surface fixed; and hence, in such a displacement, an infinite number of points, lying on the axis of rotation defined by the preceding two points, remain fixed. (Under certain conditions this theorem extends to *deformable* bodies: one body-fixed line remains invariant.)

To understand this fundamental theorem, let us consider a body-fixed *unit sphere* S_B with center the fixed point ◆, representing the body, and let us follow its motion as it slides over another unit sphere S_S concentric to S_B but space-fixed and representing fixed space. (This is the spatial equivalent of the earlier plane motion problem where a representative rigid lamina slides over another fixed lamina.) Now, since this is a *three* degree-of-freedom system, its position can be specified by the coordinates of *two* of its points on S_B, P, and Q [fig. 1.11(a)]: $2 \times 2 = 4$ coordinates [of which, since the distance between P and Q (= length of arc of great circle joining P and Q) remains invariable, only *three* can be varied independently]. Hence, to study two positions of the body—that is, a displacement of it—it suffices to study two positions of an arbitrary pair of surface points of it: an initial PQ and a final $P'Q'$ [fig. 1.11(b)]. Then we join P and P', and Q and Q' by great arcs and draw the two symmetry planes of the arcs PP' and QQ'; that is, the two great circle planes that halve these two arcs. Their intersection, ◆C (which, contrary to the plane

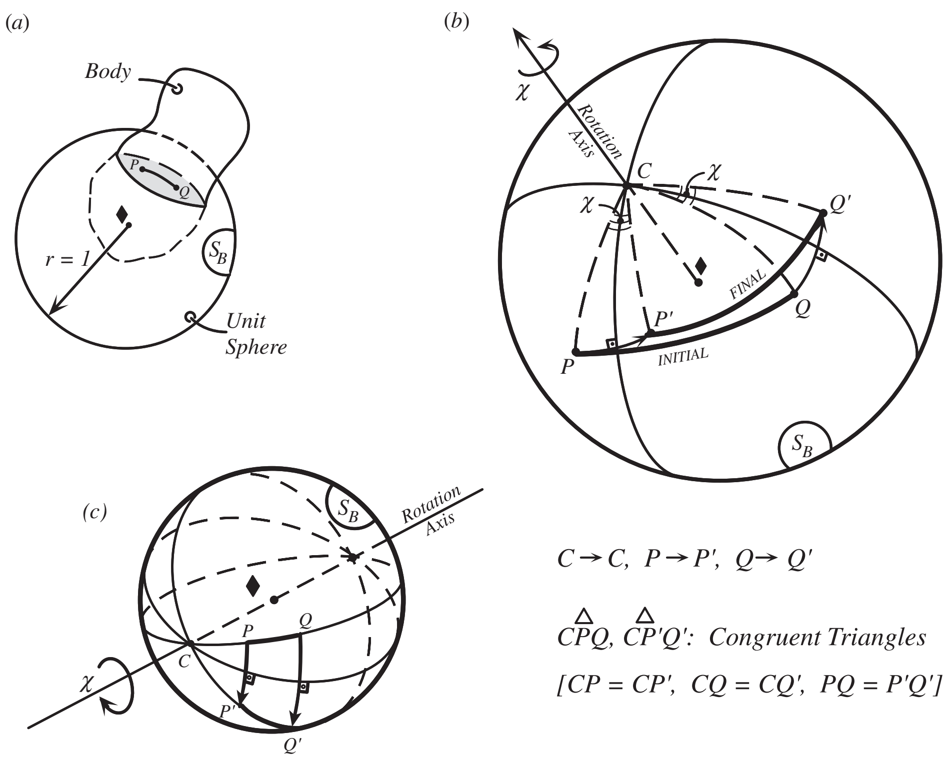

Figure 1.11 (a, b) The motion of a rigid body about a fixed point ◆ can be found by studying the motion of a pair of its points on the unit sphere with center ◆: from PQ to $P'Q'$; (c) special case of (b) where the planes of symmetry of the arcs PP' and QQ' coincide.

motion case, always lies a *finite* distance away), defines the axis of rotation; and their angle, χ, defines the angle of rotation (around $\blacklozenge C$) that brings the spherical triangle CPQ into coincidence with its congruent triangle $CP'Q'$; and hence *arc* (PP') into coincidence with *arc* (QQ'); and $\blacklozenge PQ$ into coincidence with $\blacklozenge P'Q'$, and similarly for any other point of S_B. In the special case where these two symmetry planes coincide [fig. 1.11(c)], the rotation axis is the intersection of the planes defined by $\blacklozenge PQ$ and $\blacklozenge P'Q'$.

FUNDAMENTAL THEOREM OF GEOMETRY OF RIGID-BODY MOTION

Any rigid-body displacement can be reduced to a succession of translations and rotations. Specifically, any such displacement can be produced by the translation of an arbitrary "base point," or "pole," of the body, from its initial to its final position, followed by a rotation about an axis through the final position of the chosen pole—and this is the most general rigid-body displacement. The translatory part varies with the pole, but the rotatory part (i.e., the axis direction and angle of rotation) is independent of it (fig. 1.12).

COROLLARY FOR PLANE MOTION

Any rigid planar displacement can be produced by a single rotation about a certain axis perpendicular to the plane of the motion; in the translation case, that axis recedes to infinity [fig. 1.10(b)].

THEOREMS OF CHASLES (1830) AND POINSOT (1830s, 1850s)

Any rigid-body displacement can be reduced, by a certain choice of pole, to a screw displacement; that is, to a rotation about an axis and a translation along that axis. In special cases, either of these two displacements may be missing.

In a screw displacement: (a) The axis of rotation is called *central axis*, and (for given initial and final body positions) it is unique, except when the displacement is a pure translation; (b) The ratio of the translation (l) to the rotation angle (χ), which

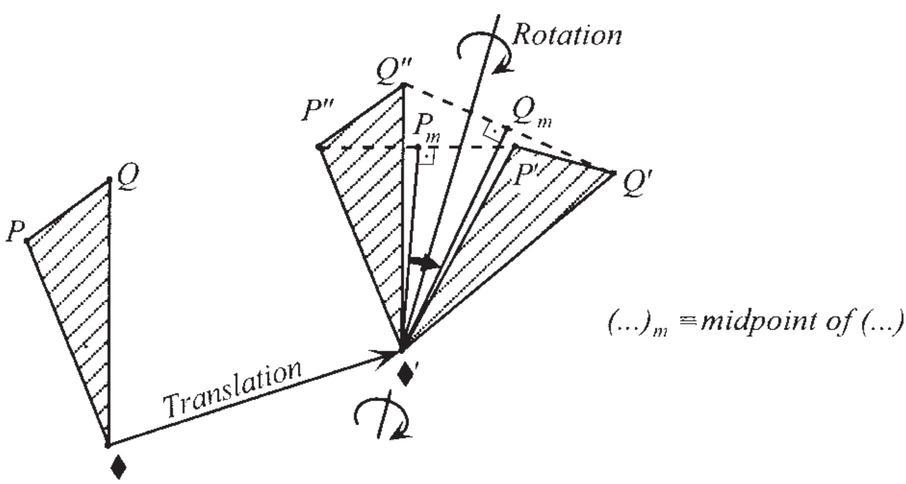

Figure 1.12 The most general displacement of the rigid body $\blacklozenge PQ$ can be effected by a translation of the pole $\blacklozenge$, from $\blacklozenge PQ$ to $\blacklozenge' P''Q''$; followed by a rotation about an axis through $\blacklozenge'$, from $\blacklozenge' P''Q''$ to $\blacklozenge' P'Q'$.

equals the *advance (p) per revolution* (2π), is called *pitch* of the screw: $p/2\pi = l/\chi \Rightarrow p = 2\pi(l/\chi)$; and (c) The translation and rotation commute.

EXTENSION TO DEFORMABLE BODIES

(Chasles' Theorem + Deformation = Cauchy's Theorem)

The total displacement of a generic point of a continuous medium, say a small deformable sphere (fig. 1.13), is the result of a *translation*, a rigid *rotation* [of the local *principal axes* (or directions) of *strain*], and *stretches* along these axes; that is, the sphere becomes a general ellipsoid. Hence, rigid-body kinematics is of interest to continuum mechanics too; the latter, however, will not be pursued any further here.

Rigid-Body Kinematics

Thus far, no restrictions have been placed on the size of the displacements; the above theorems hold whether the translations and rotations are *finite* or *infinitesimal*. The finite case is detailed quantitatively in the following sections.

Next, let us examine the important case of sequence of rigid infinitesimal displacements in time, namely, *rigid motion*. In particular, let us return to the motion about a fixed point (Euler's theorem) and consider the case where the initial and final positions of the arcs PQ (at time t) and $P'Q'$ (at time $t' = t + \Delta t$) *are very close to each other*. Now, as $\Delta t \to 0$ the earlier (great circle) planes that halve the arcs PP' and QQ' coincide with the normal planes to the *directions* of motion of P and Q, respectively, at time t; and their intersection yields the *instantaneous axis of rotation*. Then the velocity of the generic body point P equals

$$\boldsymbol{v}_P \equiv \boldsymbol{v} = [\lim(\boldsymbol{PP}'/\Delta t)]_{\Delta t \to 0} = \boldsymbol{\omega} \times \boldsymbol{r}_{P/\blacklozenge} \equiv \boldsymbol{\omega} \times \boldsymbol{r}, \tag{1.9.1}$$

since $v_P \equiv v \equiv |\boldsymbol{v}|$ equals the magnitude of the *angular velocity* of that rotation, $|\boldsymbol{\omega}|$, times the perpendicular distance of P from the rotation axis. [Euler (1750s), Poisson (1831); of course, in components.] Hence, the instantaneous rotation of the body B about the fixed point $\blacklozenge$ is described by the single vector $\boldsymbol{\omega}$, which combines all three characteristics of rotation: *axis*, *magnitude*, and *sense*. As the motion proceeds, and since only the point $\blacklozenge$ is fixed, the axis of rotation (carrier of $\boldsymbol{\omega}$) traces, or generates, two general and generally *open conical surfaces with common center* $\blacklozenge$: one fixed on the *body*, the

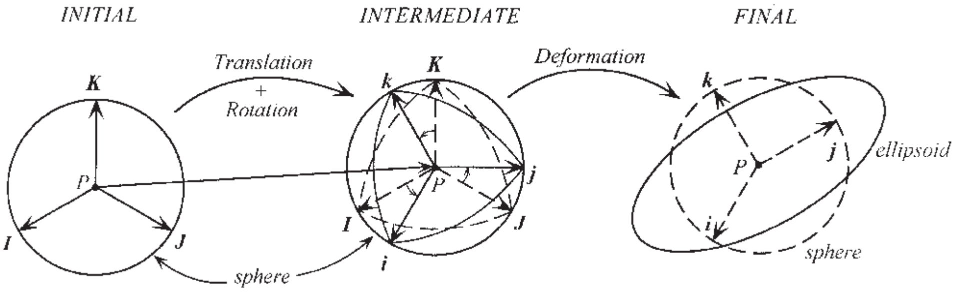

Figure 1.13 General displacement of a small deformable sphere: Translation → Rotation → Strain (Sphere → Ellipsoid).

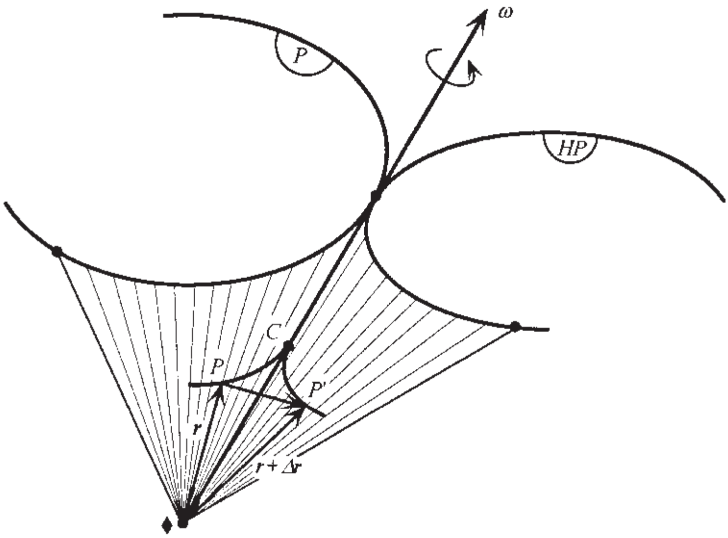

Figure 1.14 Rolling of body cone (P_{Polhode}) on space cone ($H_{er}P_{\text{Polhode}}$).

polhode cone; and one fixed in space, the *herpolhode* cone (fig. 1.14). Hence, the following theorem:

THEOREM

Every finite motion of a rigid body, having one of its points ◆ fixed, can be described by the pure (or slippingless) rolling of the polhode cone on the herpolhode cone; and, at every moment, their common generator (through ◆) gives the direction of the instantaneous axis of rotation/angular velocity. If ◆ recedes to infinity, these two cones reduce to cylinders and their normal sections become, respectively, the body and space centrodes.

Velocity Field (Mozzi, 1763)

Since, for the first-order geometrical changes involved here ("infinitesimal displacements") superposition holds, we conclude that the velocity of a generic body point P in general motion, $\boldsymbol{v}_P \equiv \boldsymbol{v}$, is given by the following fundamental formula of rigid body kinematics:

$$\boldsymbol{v} = \boldsymbol{v}_{\blacklozenge} + \boldsymbol{\omega} \times (\boldsymbol{r} - \boldsymbol{r}_{\blacklozenge}) \equiv \boldsymbol{v}_{\blacklozenge} + \boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge} \equiv \boldsymbol{v}_{\blacklozenge} + \boldsymbol{v}_{/\blacklozenge}$$

$$[\boldsymbol{v}_{/\blacklozenge} = \text{velocity of } P \text{ relative to } \blacklozenge \text{ (both measured in the same frame)}] \quad (1.9.2)$$

where ◆ is any body point (pole) (fig. 1.15); or, in terms of components (fig. 1.9) as follows:

Space-Fixed Axes

$$dX/dt \equiv dX_{\blacklozenge}/dt + \omega_Y(Z - Z_{\blacklozenge}) - \omega_Z(Y - Y_{\blacklozenge}), \quad \text{etc., cyclically,} \quad (1.9.2a)$$

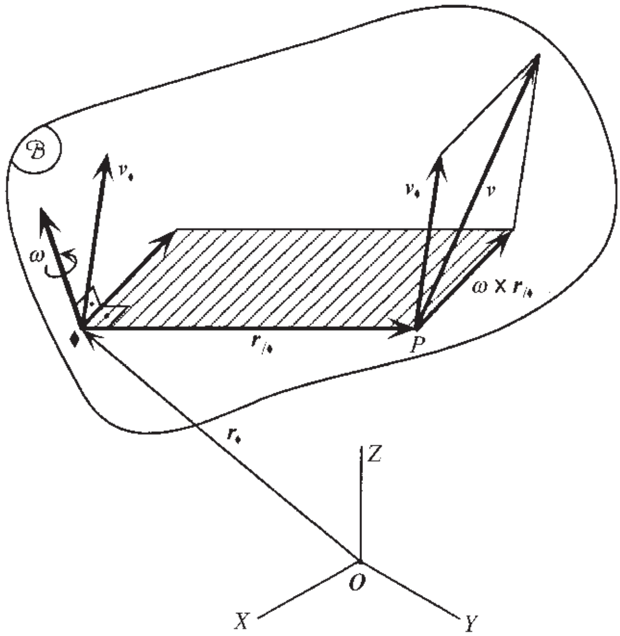

Figure 1.15 Geometrical interpretation of eq. (1.9.2).

or, equivalently,

$$v_X \equiv v_{\blacklozenge,X} + \omega_Y Z_{/\blacklozenge} - \omega_Z Y_{/\blacklozenge}, \quad \text{etc., cyclically.} \tag{1.9.2b}$$

Body-Fixed Axes

$$v_x \equiv v_{\blacklozenge,x} + \omega_y z_{/\blacklozenge} - \omega_z y_{/\blacklozenge}, \quad \text{etc., cyclically;} \tag{1.9.2c}$$

where

$$v_{\blacklozenge,x} = \cos(x, X) v_{\blacklozenge,X} + \cos(x, Y) v_{\blacklozenge,Y} + \cos(x, Z) v_{\blacklozenge,Z}, \quad \text{etc., cyclically;} \tag{1.9.2d1}$$

and, inversely,

$$v_{\blacklozenge,X} = \cos(X, x) v_{\blacklozenge,x} + \cos(X, y) v_{\blacklozenge,y} + \cos(X, z) v_{\blacklozenge,z}, \quad \text{etc., cyclically.} \tag{1.9.2d2}$$

The *six* functions of time $v_{\blacklozenge;x,y,z}, \omega_{x,y,z}$ (or $v_{\blacklozenge;X,Y,Z}, \omega_{X,Y,Z}$) characterize the rigid-body motion completely. The line-bound vectors $\boldsymbol{\omega}$ and $\boldsymbol{v}_\blacklozenge$ constitute the *torsor of motion*, or *velocity torsor*, at $\blacklozenge$, from which the rigid-body *velocity field* can be determined uniquely. [Just as, in elementary statics, the resultant force $\boldsymbol{f}$ (or $\boldsymbol{R}$) and moment $\boldsymbol{M}_\blacklozenge$ of a system of forces constitute the *force system torsor* at $\blacklozenge$ (see "Formal Analogies ..." section that follows.] In the case of motion about a fixed point $\blacklozenge$, that torsor reduces there to $(\boldsymbol{\omega}, \mathbf{0})$.

Now, from the displacement viewpoint, the *velocity transfer* equation (1.9.2) states that:

(i) The state of motion of the body consists of an *elementary translation* ($d\boldsymbol{r}_\blacklozenge \equiv \boldsymbol{v}_\blacklozenge\, dt$) of a *base point* (or *pole*) $\blacklozenge$, and an *elementary rotation* ($d\boldsymbol{\chi} \equiv \boldsymbol{\omega}\, dt$) about that point. Therefore, applying the earlier theorem of Chasles, we deduce that:

(ii) Any *infinitesimal rigid (nontranslatory) displacement* can be reduced uniquely to an *infinitesimal screw*; that is, an infinitesimal translation plus an infinitesimal rotation about a (central) axis parallel to the translation. (The *location* of that axis and the *pitch of the screw* are given in the "Formal Analogies ..." section below.) As the motion proceeds, that axis traces two (ruled) surfaces with it as common generator: one *fixed in space* (Γ_S) and another *fixed in the body* (Γ_B)—which constitute the "no fixed point" generalization of the herpolhode and polhode, respectively. Hence, the following theorem:

(iii) The general finite motion of a rigid body can be produced by the *rolling and sliding* of Γ_B over Γ_S. (In plane motion, sliding is absent.) Next, we prove that

(iv) The angular velocity vector $\boldsymbol{\omega}$ is *independent of the choice of the pole*. Applying the fundamental formula (1.9.2) for the two arbitrary and distinct poles $\blacklozenge$ and $\blacklozenge'$, we have

$$\begin{aligned} \boldsymbol{v} &= \boldsymbol{v}_{\blacklozenge} + \boldsymbol{\omega} \times (\boldsymbol{r} - \boldsymbol{r}_{\blacklozenge}) \equiv \boldsymbol{v}_{\blacklozenge} + \boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge} \\ &= \boldsymbol{v}_{\blacklozenge'} + \boldsymbol{\omega}' \times (\boldsymbol{r} - \boldsymbol{r}_{\blacklozenge'}) \equiv \boldsymbol{v}_{\blacklozenge'} + \boldsymbol{\omega}' \times \boldsymbol{r}_{/\blacklozenge'}, \end{aligned} \tag{1.9.2e}$$

where initially, we assume that $\boldsymbol{\omega}$ and $\boldsymbol{\omega}'$ are different and go through $\blacklozenge$ and $\blacklozenge'$, respectively. We shall show that

$$\boldsymbol{\omega} = \boldsymbol{\omega}'. \tag{1.9.2f}$$

Indeed, since

$$\boldsymbol{r}_{/\blacklozenge} = \boldsymbol{r}_{/\blacklozenge'} + \boldsymbol{r}_{\blacklozenge'/\blacklozenge} \qquad \text{and} \qquad \boldsymbol{v}_{\blacklozenge'} = \boldsymbol{v}_{\blacklozenge} + \boldsymbol{\omega} \times \boldsymbol{r}_{\blacklozenge'/\blacklozenge}, \tag{1.9.2g}$$

equating the right sides of (1.9.2e) we obtain

$$\boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge} = \boldsymbol{\omega} \times \boldsymbol{r}_{\blacklozenge'/\blacklozenge} + \boldsymbol{\omega}' \times \boldsymbol{r}_{/\blacklozenge'} \;\; \Rightarrow \;\; \boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge'} = \boldsymbol{\omega}' \times \boldsymbol{r}_{/\blacklozenge'}, \tag{1.9.2h}$$

from which, since $\boldsymbol{r}_{/\blacklozenge'}$ is arbitrary, (1.9.2f) follows.

[Since $\boldsymbol{\omega}$ is a *body* quantity (a *system* vector), it carries no body point subscripts (like $\boldsymbol{v}_{\ldots}$), just like a force resultant. The only "insignia" it may carry are those needed to specify a particular body and/or frame of reference. Perhaps this supposed "base point invariance" of it may have given rise to the false notion that "$\boldsymbol{\omega}$ [of a body-fixed basis relative to a space-fixed basis] is a *free* vector, not bound to any point or line in space" (Likins, 1973, p. 105, near page bottom); emphasis added. A correct interpretation of (1.9.2e,f), however, shows that $\boldsymbol{\omega}$ is a *line-bound*, or *sliding*, vector, not a *free* one (just like the force on a rigid body); hence, $\boldsymbol{\omega}$ in eq. (1.9.2), is understood to be going through point $\blacklozenge$.]

A USEFUL RESULT

Let $\boldsymbol{r}_1$ and $\boldsymbol{r}_2$ be the position vectors of two arbitrary points of a rigid body. Then, its angular velocity $\boldsymbol{\omega}$ equals

$$\boldsymbol{\omega} = (\boldsymbol{v}_1 \times \boldsymbol{v}_2)/(\boldsymbol{v}_1 \cdot \boldsymbol{v}_2), \qquad \text{where} \quad \boldsymbol{v}_{\ldots} \equiv d\boldsymbol{r}_{\ldots}/dt. \tag{1.9.2i}$$

Formal Analogies Between Forces/Moments and Linear/Angular Velocities

Comparing (1.9.2), rewritten as $\boldsymbol{v}_2 = \boldsymbol{v}_1 + \boldsymbol{r}_{1/2} \times \boldsymbol{\omega}$ (1, 2: two arbitrary body points) with the well-known moment transfer theorem of elementary statics (with some, hopefully, self-explanatory notation): $\boldsymbol{M}_2 = \boldsymbol{M}_1 + \boldsymbol{r}_{1/2} \times \boldsymbol{f}$, we may say that the velocity $\boldsymbol{v}_2$ is the moment of the *motion, or velocity torsor* $(\boldsymbol{\omega}, \boldsymbol{v}_1)$ about point 2; that is, $\boldsymbol{\omega}$ is the *kinematic counterpart of the force resultant* ($\boldsymbol{f}$ *or* $\boldsymbol{R}$), and hence is a *line-bound,* or *sliding vector;* while $\boldsymbol{v}$ . . . is the *counterpart of the point–dependent moment of the torsor* $\boldsymbol{M}$. Hence, recalling the (presumably, well-known) theorems of elementary statics, we can safely state the following:

- An elementary rotation $d\boldsymbol{\chi} \equiv \boldsymbol{\omega}\, dt$ about an axis can always be replaced with an elementary rotation of equal angle about another arbitrary but parallel axis, plus an elementary translation $d\boldsymbol{r} = \boldsymbol{v}\, dt$, where $\boldsymbol{v} = \boldsymbol{\omega} \times \boldsymbol{r}$ is perpendicular to (the plane of) both axes of rotation, and $\boldsymbol{r}$ is the vector from an arbitrary point of the original axis to an arbitrary point of the second axis; that is, an elementary rotation here is equivalent to an equal rotation plus an elementary perpendicular translation there.
- Several elementary rotations about a number of arbitrary axes can be replaced by a resultant motion as follows: (a) We choose a reference point O, and transport all these elementary rotations parallel to themselves to O, and then add them geometrically there. Then, (b) We combine the corresponding translational velocities, created by the parallel transport of the rotations in (a) (according to the preceding statement), to a single translational velocity at O. For example, two equal and opposite elementary rotations about *parallel* axes can be replaced by a single elementary translation perpendicular to (the plane of) both axes. These formal analogies between forces/moments and linear/angular velocities (also, linear/angular momenta), which are quite useful from the viewpoint of economy of *thought* (elimination of unnecessary duplication of proofs), are summarized in table 1.2.

Table 1.2 Formal Analogies Among Vectors/Forces/Rigid-Body Velocities

Vector Systems	*Forces/Moments* (On Rigid Bodies)	*Rigid-Body Velocities* (Instantaneous Geometry)
Single vector $\boldsymbol{a}$	Single force $\boldsymbol{f}$ (along line of action)	Angular velocity $\boldsymbol{\omega}$ (about axis of rotation)
Moment of $\boldsymbol{a}$ about point O	Moment of $\boldsymbol{f}$ about O	Linear velocity of body point $O\boldsymbol{v}_O$
Vector couple $(\boldsymbol{a}_1, \boldsymbol{a}_2 = -\boldsymbol{a}_1)$ $\Rightarrow$ Constant moment	Force couple $(\boldsymbol{f}_1, \boldsymbol{f}_2 = -\boldsymbol{f}_1)$ $\Rightarrow$ Constant moment; or couple	Rotational pair $(\boldsymbol{\omega}_1, \boldsymbol{\omega}_2 = -\boldsymbol{\omega}_1)$ $\Rightarrow$ Constant translational velocity
Vector resultant $\boldsymbol{R}$	Force resultant $\boldsymbol{R}$	Rotation resultant $\boldsymbol{\omega}$
Vector torsor ($\boldsymbol{R}$, $\boldsymbol{M}_O$)	Force torsor ($\boldsymbol{R}$, $\boldsymbol{M}_O$)	Motion torsor ($\boldsymbol{\omega}$, $\boldsymbol{v}_O$)
	Spatial Variation (or Transfer) Theorem: $O \to O'$ ($\boldsymbol{R}, \boldsymbol{\omega}$ at O)	
$\boldsymbol{M}_{O'} = \boldsymbol{M}_O + \boldsymbol{r}_{O/O'} \times \boldsymbol{R}$	$\boldsymbol{M}_{O'} = \boldsymbol{M}_O + \boldsymbol{r}_{O/O'} \times \boldsymbol{R}$	$\boldsymbol{v}_{O'} = \boldsymbol{v}_O + \boldsymbol{r}_{O/O'} \times \boldsymbol{\omega}$
Invariants: $\boldsymbol{R} \cdot \boldsymbol{R}$, $\boldsymbol{R} \cdot \boldsymbol{M} \ldots$	Invariants: $\boldsymbol{R} \cdot \boldsymbol{R}$, $\boldsymbol{R} \cdot \boldsymbol{M} \ldots$	Invariants: $\boldsymbol{\omega} \cdot \boldsymbol{\omega}$, $\boldsymbol{\omega} \cdot \boldsymbol{v} \ldots$
	Simplest Representation of Torsor	
Vector wrench (or screw) $(\boldsymbol{R}, \boldsymbol{M}_c)$	Force wrench $(\boldsymbol{R}, \boldsymbol{M}_c)$	Motion screw $(\boldsymbol{\omega}, \boldsymbol{v}_c)$
	Central Axis of Wrench/Screw	
$\boldsymbol{r} = \lambda \boldsymbol{R} + (\boldsymbol{R} \times \boldsymbol{M}_O)/R^2$ $[\lambda \equiv (\boldsymbol{r} \cdot \boldsymbol{R})/R^2]$	$\boldsymbol{r} = \lambda \boldsymbol{R} + (\boldsymbol{R} \times \boldsymbol{M}_O)/R^2$	$\boldsymbol{r} = \mu \boldsymbol{\omega} + (\boldsymbol{\omega} \times \boldsymbol{v}_O)/\omega^2$ $[\mu \equiv (\boldsymbol{r} \cdot \boldsymbol{\omega})/\omega^2]$
Pitch $\equiv p = \boldsymbol{M}_c/\boldsymbol{R} = \boldsymbol{R} \cdot \boldsymbol{M}_O/R^2$	$p = \boldsymbol{M}_c/\boldsymbol{R} = \boldsymbol{R} \cdot \boldsymbol{M}_O/R^2$	$p = \boldsymbol{v}_c/\boldsymbol{\omega} = \boldsymbol{\omega} \cdot \boldsymbol{v}_O/\omega^2$
• $p = 0$:		
Vector resultant $\boldsymbol{R}$	Pure force (resultant) $\boldsymbol{R}$	Pure rotation $\boldsymbol{\omega}$
• $p = \infty$:		
Couple	Pure couple	Pure translation*

* See also Hunt (1974).

Acceleration Field

By $d/dt(\ldots)$-differentiating (1.9.2), we readily obtain the *acceleration field* of a rigid body in *general motion*:

$$\begin{aligned}\boldsymbol{a} &= \boldsymbol{a}_\blacklozenge + \boldsymbol{\alpha}\times\boldsymbol{r}_{/\blacklozenge} + \boldsymbol{\omega}\times(\boldsymbol{\omega}\times\boldsymbol{r}_{/\blacklozenge}) = \boldsymbol{a}_\blacklozenge + \boldsymbol{\alpha}\times\boldsymbol{r}_{/\blacklozenge} + [(\boldsymbol{\omega}\cdot\boldsymbol{r}_{/\blacklozenge})\boldsymbol{\omega} - \omega^2\boldsymbol{r}_{/\blacklozenge}]\\ &= \boldsymbol{a}_\blacklozenge + (\boldsymbol{a}_{/\blacklozenge})_{\text{tangent}} + (\boldsymbol{a}_{/\blacklozenge})_{\text{normal}} \qquad (\equiv \boldsymbol{a}_\blacklozenge + \boldsymbol{a}_{/\blacklozenge});\end{aligned} \tag{1.9.3}$$

or in terms of components (figure 1.9):

Space-Fixed Axes

$$\begin{aligned}a_X &\equiv a_{\blacklozenge,X} + (\alpha_Y Z_{/\blacklozenge} - \alpha_Z Y_{/\blacklozenge})\\ &\qquad + \left[\omega_X(\omega_X X_{/\blacklozenge} + \omega_Y Y_{/\blacklozenge} + \omega_Z Z_{/\blacklozenge}) - \omega^2 X_{/\blacklozenge}\right], \quad \text{etc., cyclically.}\end{aligned} \tag{1.9.3a}$$

Body-Fixed Axes

$$\begin{aligned}a_x &\equiv a_{\blacklozenge,x} + (\alpha_y z_{/\blacklozenge} - \alpha_z y_{/\blacklozenge})\\ &\qquad + \left[\omega_x(\omega_x x_{/\blacklozenge} + \omega_y y_{/\blacklozenge} + \omega_z z_{/\blacklozenge}) - \omega^2 x_{/\blacklozenge}\right], \quad \text{etc., cyclically;}\end{aligned} \tag{1.9.3b}$$

where

$$\begin{aligned}a_{\blacklozenge,x} &= \cos(x,X)a_{\blacklozenge,X} + \cos(x,Y)a_{\blacklozenge,Y} + \cos(x,Z)a_{\blacklozenge,Z}\\ &\equiv \cos(x,X)(d^2X_\blacklozenge/dt^2) + \cos(x,Y)(d^2Y_\blacklozenge/dt^2) + \cos(x,Z)(d^2Z_\blacklozenge/dt^2),\\ &\qquad \text{etc., cyclically;}\end{aligned} \tag{1.9.3c}$$

and, inversely,

$$a_{\blacklozenge,X} = \cos(X,x)a_{\blacklozenge,x} + \cos(X,y)a_{\blacklozenge,y} + \cos(X,z)a_{\blacklozenge,z}, \quad \text{etc., cyclically;} \tag{1.9.3d}$$

and

$$\alpha_X = (d\boldsymbol{\omega}/dt)_X = d\omega_X/dt, \quad \text{etc., cyclically,} \tag{1.9.3e}$$

$$\begin{aligned}\alpha_x &= (d\boldsymbol{\omega}/dt)\cdot\boldsymbol{i} = d(\boldsymbol{\omega}\cdot\boldsymbol{i})/dt - \boldsymbol{\omega}\cdot(d\boldsymbol{i}/dt)\\ &= d\omega_x/dt - \boldsymbol{\omega}\cdot(\boldsymbol{\omega}\times\boldsymbol{i}) = d\omega_x/dt, \quad \text{etc., cyclically.}\end{aligned} \tag{1.9.3f}$$

Plane Motion

The distances of all body points from a fixed, say inertial, plane f' remain constant; and so the body B moves parallel to f' (fig. 1.10a). [For extensive discussions of this pedagogically and technically important topic, see, for example, Pars (1953, pp. 336–356), Loitsianskii and Lur'e (1982, pp. 227–261).] A rigid body in plane (but otherwise free) motion is a system with *three global, or finite, degrees of freedom*. As such, we choose (fig. 1.16): (a) The two positional coordinates of an arbitrary body point (pole) ◆ (that is, of a point belonging to the cross section of B with a generic

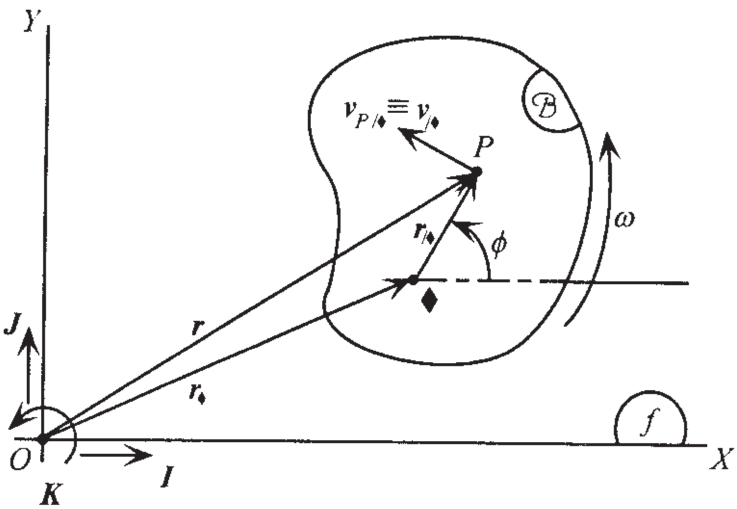

Figure 1.16 Plane motion of a rigid body *B*.

plane f ever parallel to f') relative to arbitrary but f-fixed rectangular Cartesian coordinates O–XY, $(X_\blacklozenge, Y_\blacklozenge)$; and (b) The angle between an arbitrary f-fixed line, say the axis OX, and an arbitrary B-fixed line, say $\blacklozenge P$, where P is a generic body point.

(i) The velocity field (i.e., the instantaneous spatial distribution of velocity)

Here,

$$\boldsymbol{\omega} = \omega_z \boldsymbol{k} = \omega_Z \boldsymbol{K} \equiv \omega \boldsymbol{K} = (d\phi/dt)\boldsymbol{K} \qquad \text{(i.e., } \boldsymbol{\omega} \text{ is perpendicular to } \boldsymbol{v}\text{)}, \quad (1.9.4a)$$

and so the general velocity formula (1.9.2) becomes

$$\begin{aligned} \boldsymbol{v}_P &\equiv d\boldsymbol{r}_{P/O} \equiv d\boldsymbol{r}/dt \\ &\equiv \boldsymbol{v} = \boldsymbol{v}_\blacklozenge + \boldsymbol{v}_{P/\blacklozenge} \equiv \boldsymbol{v}_\blacklozenge + \boldsymbol{v}_{/\blacklozenge} = \boldsymbol{v}_\blacklozenge + \boldsymbol{\omega} \times \boldsymbol{r}_{P/\blacklozenge} \equiv \boldsymbol{v}_\blacklozenge + \boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge}, \end{aligned} \quad (1.9.4b)$$

or, in components [along space-fixed (inertial) axes]

$$\begin{aligned} (dX/dt, dY/dt, 0) &= (dX_\blacklozenge/dt, dY_\blacklozenge/dt, 0) + (0, 0, \omega) \times (X_{/\blacklozenge}, Y_{/\blacklozenge}, 0), \\ \Rightarrow\ dX/dt &= dX_\blacklozenge/dt - \omega Y_{/\blacklozenge}, \qquad dY/dt = dY_\blacklozenge/dt + \omega X_{/\blacklozenge}. \end{aligned} \quad (1.9.4c)$$

The above show that, in plane motion, there exists—in every configuration—a point, either belonging to the body or to its fictitious rigid extension, called *instantaneous center of zero velocity*, or *velocity pole* (*IC*, or *I*, for short), whose velocity, at least momentarily, vanishes; that is, locally, at least, *the motion can be viewed as an elementary rotation about that point* (local version of fig. 1.10b). Indeed, setting in (1.9.4b,c)

$$\boldsymbol{v} \to \boldsymbol{v}_I = \boldsymbol{0}, \qquad \text{i.e., choosing } P = I, \quad (1.9.4d)$$

we obtain its inertial instantaneous coordinates relative to our originally chosen pole ◆:

$$X_{I/\blacklozenge} \equiv X_I - X_\blacklozenge = -(dY_\blacklozenge/dt)\big/\omega, \qquad Y_{I/\blacklozenge} \equiv Y_I - Y_\blacklozenge = +(dX_\blacklozenge/dt)\big/\omega. \quad (1.9.4e)$$

From these equations we conclude that, as long as $\omega \neq 0, I$ is located at a finite distance from the body and is unique; if $\omega = 0$, then I recedes to infinity, and the motion becomes a *translation*; and if we choose I as our pole — that is, $\blacklozenge = I$ — then (1.9.4b, c) yield

$$dX/dt = -\omega Y_{/I}, \quad dY/dt = \omega X_{/I}, \quad \text{or } v = \omega\, r_{/I} \quad [v^2 = (dX/dt)^2 + (dY/dt)^2]. \quad (1.9.4f)$$

[In the case of translation, eq. (1.9.4f) can be written *qualitatively/symbolically* as

finite velocity = (*zero angular velocity*) × (*infinite radius of rotation*)].

As the body moves, I traces *two* curves: one fixed on the *body* (*space centrode*) and one fixed in the *plane* (*space centrode*); so that the general plane motion can be described as *the slippingless rolling of the body centrode on the space centrode, with angular velocity* ω.

(ii) The acceleration field

Here,

$$\boldsymbol{\alpha} \equiv d\boldsymbol{\omega}/dt = (d\omega/dt)\boldsymbol{k} \equiv \alpha\,\boldsymbol{k} = \alpha\,\boldsymbol{K}, \quad (1.9.4g)$$

and $\boldsymbol{\omega}\cdot\boldsymbol{r}_{/\blacklozenge} = 0$, and so the general acceleration formula (1.9.3) becomes

$$\begin{aligned} \boldsymbol{a}_P \equiv \boldsymbol{a} \equiv \boldsymbol{a}_\blacklozenge + \boldsymbol{a}_{/\blacklozenge} &= \boldsymbol{a}_\blacklozenge + \boldsymbol{\alpha}\times\boldsymbol{r}_{/\blacklozenge} + \boldsymbol{\omega}\times(\boldsymbol{\omega}\times\boldsymbol{r}_{/\blacklozenge}) \\ &= \boldsymbol{a}_\blacklozenge + \boldsymbol{\alpha}\times\boldsymbol{r}_{/\blacklozenge} - \omega^2\boldsymbol{r}_{/\blacklozenge}, \end{aligned} \quad (1.9.4h)$$

or, in components [along space-fixed (inertial) axes],

$$\begin{aligned} (d^2X/dt^2, d^2Y/dt^2, 0) &= (d^2X_\blacklozenge/dt^2,\, d^2Y_\blacklozenge/dt^2,\, 0) \\ &\quad + (0,0,\alpha)\times(X_{/\blacklozenge}, Y_{/\blacklozenge}, 0) - \omega^2(X_{/\blacklozenge}, Y_{/\blacklozenge}, 0), \\ \Rightarrow d^2X/dt^2 = d^2X_\blacklozenge/dt^2 &- \alpha Y_{/\blacklozenge} - \omega^2 X_{/\blacklozenge}, \quad d^2Y/dt^2 = d^2Y_\blacklozenge/dt^2 + \alpha X_{/\blacklozenge} - \omega^2 Y_{/\blacklozenge}. \end{aligned} \quad (1.9.4i)$$

Along *body-fixed* axis ◆–xy, eq. (1.9.4h) yields the components (with some easily understood notation):

$$a_x = (\boldsymbol{a}_\blacklozenge)_x - \alpha y_{/\blacklozenge} - \omega^2 x_{/\blacklozenge}, \qquad a_y = (\boldsymbol{a}_\blacklozenge)_y + \alpha x_{/\blacklozenge} - \omega^2 y_{/\blacklozenge}; \quad (1.9.4j)$$

where

$$(\boldsymbol{a}_\blacklozenge)_x \equiv \boldsymbol{a}_\blacklozenge\cdot\boldsymbol{i} = \cos(x,X)(d^2X_\blacklozenge/dt^2) + \cos(x,Y)(d^2Y_\blacklozenge/dt^2), \text{ etc.};$$

and similarly for the velocity field (1.9.4b), if needed.

Here, too, there exists an *instantaneous center of zero acceleration*, or *acceleration pole*, I', whose coordinates are found by setting in (1.9.4i) $d^2X/dt^2 = 0$, $d^2Y/dt^2 = 0$ and then solving for $X_{/\blacklozenge}$, $Y_{/\blacklozenge}(P \to I')$:

$$X_{I'/\blacklozenge} \equiv X_{I'} - X_\blacklozenge = \left[\omega^2(d^2X_\blacklozenge/dt^2) - \alpha(d^2Y_\blacklozenge/dt^2)\right]\big/(\alpha^2 + \omega^4),$$
$$Y_{I'/\blacklozenge} \equiv Y_{I'} - Y_\blacklozenge = \left[\omega^2(d^2Y_\blacklozenge/dt^2) + \alpha(d^2X_\blacklozenge/dt^2)\right]\big/(\alpha^2 + \omega^4). \quad (1.9.4k)$$

These equations show that as long as $\alpha^2 + \omega^4 \neq 0$ (i.e., not both ω and α vanish), the acceleration pole I' exists and is unique. If $\omega, \alpha = 0$ (i.e., if the body translates), then I' (as well as I) recedes to infinity. Finally, with the choice $\blacklozenge = I'$ eqs. (1.9.4h,i) specialize to

$$\boldsymbol{a} \equiv \boldsymbol{a}_\blacklozenge + \boldsymbol{a}_{/\blacklozenge} = \boldsymbol{\alpha} \times \boldsymbol{r}_{/I'} + \boldsymbol{\omega} \times (\boldsymbol{\omega} \times \boldsymbol{r}_{/I'}) = \boldsymbol{\alpha} \times \boldsymbol{r}_{/I'} - \omega^2 \boldsymbol{r}_{/I'}, \quad (1.9.4l)$$

or, in components

$$d^2X/dt^2 = -\alpha Y_{/I'} - \omega^2 X_{/I'}, \qquad d^2Y/dt^2 = +\alpha X_{/I'} - \omega^2 Y_{/I'}. \quad (1.9.4m)$$

For the geometrical properties of I', the reader is referred to texts on kinematics.

Additional Useful Results

(i) Crossing $\mathbf{0} = \boldsymbol{v}_\blacklozenge + \boldsymbol{\omega} \times (\boldsymbol{r}_I - \boldsymbol{r}_\blacklozenge)$ with $\boldsymbol{\omega}$, expanding, and so on, it can be shown that the position of the instantaneous velocity center is given by

$$\boldsymbol{r}_{I/\blacklozenge} \equiv \boldsymbol{r}_I - \boldsymbol{r}_\blacklozenge = (\boldsymbol{\omega} \times \boldsymbol{v}_\blacklozenge)/\omega^2; \quad (1.9.4n)$$

and similarly for the location of the acceleration pole I'.

(ii) The location of the instantaneous center of zero velocity I, and zero acceleration I', in *body-fixed* coordinates $\blacklozenge$–xy, are given, respectively, by (fig. 1.17)

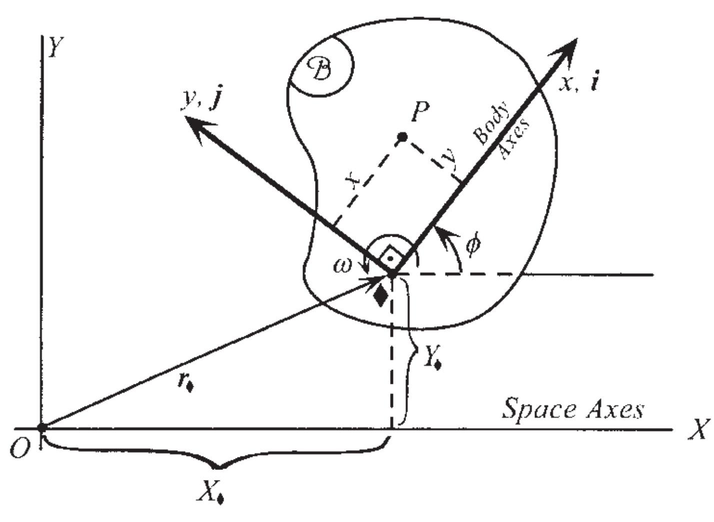

Figure 1.17 Body-fixed axes in plane motion.

$$x_I = (1/\omega)\big[(dX_\blacklozenge/dt)\sin\phi - (dY_\blacklozenge/dt)\cos\phi\big] = -(\boldsymbol{v}_\blacklozenge)_y/\omega, \qquad (1.9.4o)$$

$$y_I = (1/\omega)\big[(dX_\blacklozenge/dt)\cos\phi + (dY_\blacklozenge/dt)\sin\phi\big] = (\boldsymbol{v}_\blacklozenge)_x/\omega, \qquad (1.9.4p)$$

$$x_{I'} = [\omega^2(\boldsymbol{a}_\blacklozenge)_x - \alpha(\boldsymbol{a}_\blacklozenge)_y]\big/(\omega^4 + \alpha^2), \qquad y_{I'} = [\alpha(\boldsymbol{a}_\blacklozenge)_x + \omega^2(\boldsymbol{a}_\blacklozenge)_y]\big/(\omega^4 + \alpha^2), \qquad (1.9.4q)$$

where

$$(\boldsymbol{v}_\blacklozenge)_x \equiv \boldsymbol{v}_\blacklozenge \cdot \boldsymbol{i} = \cos(x, X)(dX_\blacklozenge/dt) + \cos(x, Y)(dY_\blacklozenge/dt), \quad \text{etc.}$$

Contact of Two Rigid Bodies; Slipping, Rolling, Pivoting

Let us consider a system of rigid bodies forced to remain in mutual *contact* at points, or along curves or surfaces of their boundaries. For simplicity and concreteness, we restrict the discussion to two rigid bodies, B' (fixed) and B (moving), in contact at a space point C; that is, a certain point P of the bounding surface of B, S, is in contact with a point P' of the bounding surface of B', S'; that is, then, $C = P = P'$ (fig. 1.18).

Now: (i) If C is fixed on both bodies, we call such a "bilateral constraint" (i.e., one expressible by equalities) a *hinge*, and we say that the bodies are *pivoting* about it.

(ii) If, on the other hand, C is not fixed on one (both) of the bodies, we say that it is *wandering* on it (them). In this case, we call the relative velocity of P and P', which are instantaneously at C, the *slip* velocity there:

$$\boldsymbol{v}_{P/P'} \equiv \boldsymbol{v}_P - \boldsymbol{v}_{P'} \equiv \boldsymbol{v}_s. \qquad (1.9.5a)$$

If we view the motion of C relative to B', C/B', as the resultant of C/B and B/B', then, since the velocities of the latter are tangent to the surfaces S and S', respectively, at C we conclude that $\boldsymbol{v}_s$ lies on their common tangent plane there, p. Analytically,

$$\boldsymbol{v}_s = \boldsymbol{v}_{s,T} + \boldsymbol{v}_{s,N} = \boldsymbol{v}_{s,T}, \qquad (1.9.5b)$$

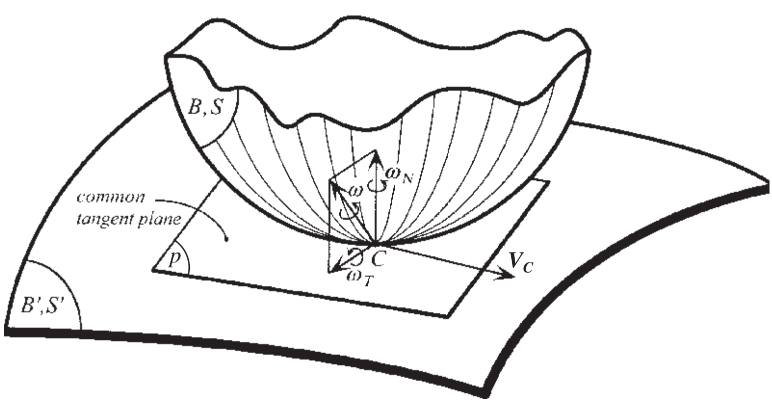

Figure 1.18 Two rigid bodies in contact at a space point C.

where

$\boldsymbol{v}_{s,T} = \textit{component of } \boldsymbol{v}_s \textit{ along } p, \qquad \boldsymbol{v}_{s,N} = \textit{component of } \boldsymbol{v}_s \textit{ normal to } p$

$(= \mathbf{0};$ i.e., contact is preserved; the two bodies cannot penetrate each other);

(1.9.5c)

and if, at that instant, B and B' *separate*, then $\boldsymbol{v}_{s,N}$ lies on the side of B'.

Next, if the angular velocity of B relative to B', at C, is $\boldsymbol{\omega}$ with components *along* and *normal* to p: $\boldsymbol{\omega}_T$, $\boldsymbol{\omega}_N$, respectively; that is,

$$\boldsymbol{\omega} = \boldsymbol{\omega}_T + \boldsymbol{\omega}_N, \tag{1.9.5d}$$

then we can say that the most general infinitesimal motion of B relative to B', B/B', is a superposition of the following special motions:

a *pure slipping*: $\quad \boldsymbol{v}_s \neq \mathbf{0}, \quad \boldsymbol{\omega}_T = \mathbf{0}, \quad \boldsymbol{\omega}_N = \mathbf{0};$ (1.9.5e)

a *pure rolling*: $\quad \boldsymbol{v}_s = \mathbf{0}, \quad \boldsymbol{\omega}_T \neq \mathbf{0}, \quad \boldsymbol{\omega}_N = \mathbf{0};$ (1.9.5f)

a *pure pivoting*: $\quad \boldsymbol{v}_s = \mathbf{0}, \quad \boldsymbol{\omega}_T = \mathbf{0}, \quad \boldsymbol{\omega}_N \neq \mathbf{0}.$ (1.9.5g)

If $\boldsymbol{v}_s = \mathbf{0}$ and $\boldsymbol{\omega} \neq \mathbf{0}$, the motion B/B' is an instantaneous rotation called *rolling and pivoting*; which results in two (scalar) equations of constraint. In this case, the point C has *identical* velocities relative to both B and B'; and hence its trajectories, or loci, on the bounding surfaces of B and B', γ and γ' respectively, are continuously tangent, and are *traced at the same pace*; that is, if, starting from C, we grade them in, say centimeters, then the points that will come into contact during the subsequent motion will have the same arc-coordinates numerically. Such a B/B' rolling is expressed by saying that P and P', both at C at the moment under consideration, have *equal velocities* relative to a (third) arbitrary body, or frame or reference; and the velocities of B about B' are the same as if B had only a rotation $\boldsymbol{\omega}$ about an axis through the "instantaneous hinge" C. If the locus of $\boldsymbol{\omega}$ on B is the ruled surface Σ, and on B' the also ruled surface Σ', then the slippingless motion B/B' can be obtained by rolling Σ on Σ' [The earlier curve $\gamma(\gamma')$ is the intersection of Σ with $S(\Sigma'$ with $S')$].

If B and B' are in contact at *two* points, say C and C', and if $\boldsymbol{v}_s = \boldsymbol{v}_{s'} = \mathbf{0}$, then the motion B/B' is an *instantaneous rotation* about the line CC'; that is, $\boldsymbol{\omega}$ is along it. And if B, B' contact each other at several points $C, C', C'', \ldots$, then slipping cannot vanish at all of them *unless they all lie on a straight line*. If, in addition, $\boldsymbol{\omega}_N = \mathbf{0}$ (or $\boldsymbol{\omega}_T = \mathbf{0}$), we have pure rolling (or pure pivoting). In sum, slippingless rolling along a curve can happen only if that curve is a straight line carrying $\boldsymbol{\omega}$ (like a long hinge).

Some Analytical Remarks on Rolling

(i) The *contact* among rigid bodies is expressed analytically by one or more equations of the form

$$f(t; q_1, q_2, \ldots, q_n) = 0, \tag{1.9.6a}$$

where $q \equiv (q_1, \ldots, q_n)$ are geometrical *parameters* that determine the position, or configuration, of the bodies of the system; hence, their alternative name: *system coordinates*. Equation (1.9.6a) is called a *holonomic* constraint.

(ii) If, in addition to contact, there is also slippingless *rolling*, and possibly *pivoting*, then equating the velocities of the two (or more pairs of) material points in contact, we obtain constraints of the form

$$a_1 dq_1 + a_2 dq_2 + \cdots + a_n dq_n + a_{n+1} dt = 0, \tag{1.9.6b}$$

or, (roughly) equivalently,

$$a_1(dq_1/dt) + a_2(dq_2/dt) + \cdots + a_n(dq_n/dt) + a_{n+1} = 0, \tag{1.9.6c}$$

where $a_k = a_k(t, q)$ $(k = 1, \ldots, n)$. If (1.9.6b,c) is not *integrable* [i.e., if it cannot be replaced, through mathematical manipulations, by a finite (1.9.6a)-like equation], it is called *nonholonomic*. In mechanical terms, *holonomic constraints* restrict the mobility of a system in the *large* (i.e., *globally*); whereas *nonholonomic constraints* restrict its mobility in the *small* (i.e., *locally*). The systematic study of both these types of constraints (chap. 2) and their fusion with the general principles and equations of motion (chap. 3 ff.) is the object of Lagrangean analytical mechanics.

1.10 THE RIGID BODY: GEOMETRY OF ROTATIONAL MOTION; FINITE ROTATION

> The peculiarities of the algebra of finite rotations are just the peculiarities of matrix multiplication.
>
> (Crandall et al., 1968, p. 58)

Recommended for concurrent reading with this section are (alphabetically): Bahar (1987), Coe (1938, pp. 157 ff.), Hamel (1949, pp. 103–117), Shuster (1993), Timerding (1908).

The Fundamental Equation of Finite Rotation

Since, by the fundamental theorem of the preceding section, the rotatory part of a general displacement of a rigid body is independent of the base point (pole), let us examine first, with no loss in generality, the *finite rotation of a rigid body B about the* (*body*- *and space*-) *fixed point O*; and later we will add to it the translatory displacement of O. Specifically, let us examine the finite rotation of B about an axis through O, with positive direction (unit) vector $\boldsymbol{n}$, by an angle χ that is counted positive in accordance with the right-hand (screw) rule (fig. 1.19).

As a result of such an angular displacement, a generic body point P moves from an *initial* position P_i to a *final* position P_f; or, symbolically,

$$(\boldsymbol{r}_i, \boldsymbol{p}_i) \to (\boldsymbol{r}_f, \boldsymbol{p}_f), \tag{1.10.1a}$$

where $\boldsymbol{p}$ is the projection, or component, of the actual position vector of P, $\boldsymbol{r}$, on the plane through it normal to the axis of rotation; that is, to $\boldsymbol{n}$. Our objective here is to express $\boldsymbol{r}_f$ in terms of $\boldsymbol{r}_i$, $\boldsymbol{n}$, and χ. To this end, we decompose the displacement $\Delta\boldsymbol{r} \equiv \boldsymbol{r}_f - \boldsymbol{r}_i = \boldsymbol{p}_f - \boldsymbol{p}_i \equiv \Delta\boldsymbol{p}$, which lies on the plane of the triangle AP_iP_f, into two components: one *along* $\boldsymbol{p}_i$, $\boldsymbol{P}_i\boldsymbol{B} = \Delta\boldsymbol{r}_1$, and one *perpendicular* to it, $\boldsymbol{BP}_f = \Delta\boldsymbol{r}_2$:

$$\Delta\boldsymbol{r} = \Delta\boldsymbol{r}_1 + \Delta\boldsymbol{r}_2. \tag{1.10.1b}$$

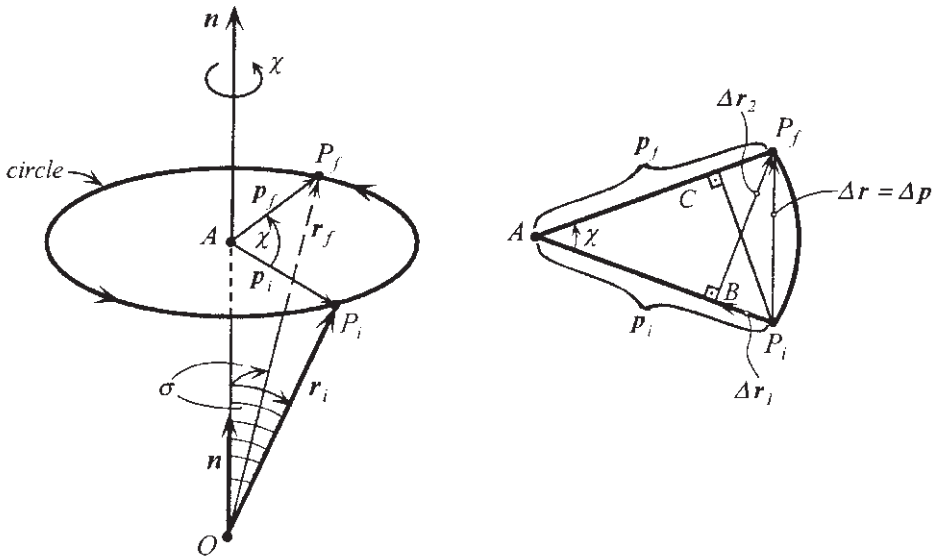

Figure 1.19 Finite rigid rotation about a fixed point O (axis $\boldsymbol{n}$, angle χ).

Now, from fig. 1.19 and some simple geometry, we find, successively,

(i) $\Delta\boldsymbol{r}_1 = -(\boldsymbol{AP}_i - \boldsymbol{AB}) = -(\boldsymbol{p}_i - \boldsymbol{p}_i \cos\chi) = -\boldsymbol{p}_i(1-\cos\chi) = -2\boldsymbol{p}_i \sin^2(\chi/2)$; or, since $\Delta\boldsymbol{r}_1$ is perpendicular to both $\boldsymbol{n}\times\boldsymbol{r}_i$ and $\boldsymbol{n}$, and

$$\boldsymbol{n}\times(\boldsymbol{n}\times\boldsymbol{r}_i) = (\boldsymbol{n}\cdot\boldsymbol{r}_i)\boldsymbol{n} - (\boldsymbol{n}\cdot\boldsymbol{n})\boldsymbol{r}_i = \boldsymbol{OA} - \boldsymbol{r}_i = \boldsymbol{P}_i\boldsymbol{A} = -\boldsymbol{p}_i,$$

finally,

$$\Delta\boldsymbol{r}_1 = \boldsymbol{n}\times(\boldsymbol{n}\times\boldsymbol{r}_i)2\sin^2(\chi/2). \tag{1.10.1c}$$

(ii) The component $\Delta\boldsymbol{r}_2$ is perpendicular to the plane OAP_i, and lies along $\boldsymbol{n}\times\boldsymbol{r}_i$; and since the length of the latter equals

$$|\boldsymbol{n}\times\boldsymbol{r}_i| = |\boldsymbol{n}||\boldsymbol{r}_i|\sin\sigma = |\boldsymbol{r}_i|\sin\sigma = |\boldsymbol{p}_i|,$$

and

$$|\boldsymbol{p}_i|\sin\chi = |\boldsymbol{CP}_i| = |\boldsymbol{BP}_f| \equiv |\Delta\boldsymbol{r}_2| \qquad \text{(the triangle } AP_iP_f \text{ being isosceles!)},$$

finally

$$\Delta\boldsymbol{r}_2 = (\boldsymbol{n}\times\boldsymbol{r}_i)\sin\chi. \tag{1.10.1d}$$

Substituting the expressions (1.10.1c, d) into (1.10.1b), we obtain the following *fundamental equation of finite rotation*:

$$\Delta\boldsymbol{r} \equiv \boldsymbol{r}_f - \boldsymbol{r}_i = (\boldsymbol{n}\times\boldsymbol{r}_i)\sin\chi + \boldsymbol{n}\times(\boldsymbol{n}\times\boldsymbol{r}_i)2\sin^2(\chi/2). \tag{1.10.1e}$$

All subsequent results on this topic are based on it.

Alternative Forms of the Fundamental Equation

(i) With the help of the so-called "*Gibbs* vector of finite rotation"

$$\boldsymbol{\gamma} \equiv \tan(\chi/2)\boldsymbol{n} \equiv (\gamma_1, \gamma_2, \gamma_3) \equiv (\gamma_X, \gamma_Y, \gamma_Z) = \textit{Rodrigues parameters}, \tag{1.10.2a}$$

relative to some background axes, say $O\text{–}XYZ$ [Rodrigues (*1840*) – Gibbs (*late 1800s*) 'vector'] and, since by simple trigonometry,

$$\sin\chi = 2\sin(\chi/2)\cos(\chi/2) = 2\tan(\chi/2)\big/[1+\tan^2(\chi/2)]$$
$$= 2\gamma/(1+\gamma^2), \qquad \text{where}\ \ \gamma = |\boldsymbol{\gamma}| = |\tan(\chi/2)|, \tag{1.10.2b}$$

$$\sin^2(\chi/2) = \tan^2(\chi/2)\big/[1+\tan^2(\chi/2)] = (1-\cos\chi)/2 = \gamma^2/(1+\gamma^2), \tag{1.10.2c}$$

we can easily rewrite (1.10.1e) as

$$\Delta\boldsymbol{r} = [2/(1+\gamma^2)][\boldsymbol{\gamma}\times\boldsymbol{r}_i + \boldsymbol{\gamma}\times(\boldsymbol{\gamma}\times\boldsymbol{r}_i)]; \tag{1.10.2d}$$

and from this, since $\boldsymbol{\gamma}\times(\boldsymbol{\gamma}\times\boldsymbol{r}_i) = -\gamma^2\boldsymbol{r}_i + (\boldsymbol{\gamma}\cdot\boldsymbol{r}_i)\boldsymbol{\gamma}$, we obtain the additional form

$$\boldsymbol{r}_f = [2/(1+\gamma^2)][\boldsymbol{\gamma}\times\boldsymbol{r}_i + (\boldsymbol{\gamma}\cdot\boldsymbol{r}_i)\boldsymbol{\gamma}] + [(1-\gamma^2)/(1+\gamma^2)]\boldsymbol{r}_i; \tag{1.10.2e}$$

which, clearly, has a singularity at $\gamma = \pm i$.

Further, in terms of the normal projection of $\boldsymbol{r}_i$ to the rotation axis $\boldsymbol{n}$, $\boldsymbol{r}_{i,n}$, defined by

$$\boldsymbol{r}_{i,n} \equiv \boldsymbol{r}_i - (\boldsymbol{\gamma}\cdot\boldsymbol{r}_i)\boldsymbol{\gamma}/\gamma^2 = \boldsymbol{r}_i - [(\boldsymbol{\gamma}\otimes\boldsymbol{\gamma})\cdot\boldsymbol{r}_i]/\gamma^2, \tag{1.10.2f}$$

we can rewrite (1.10.2e) successively as

$$\begin{aligned}\boldsymbol{r}_f &= \boldsymbol{r}_i + [2/(1+\gamma^2)](\boldsymbol{\gamma}\times\boldsymbol{r}_{i,n} - \gamma^2\boldsymbol{r}_{i,n})\\ &= \boldsymbol{r}_i + [2/(1+\gamma^2)][\boldsymbol{\gamma}\times\boldsymbol{r}_i - \gamma^2\boldsymbol{r}_i + (\boldsymbol{\gamma}\otimes\boldsymbol{\gamma})\cdot\boldsymbol{r}_i]\\ &= \boldsymbol{r}_i + [2/(1+\gamma^2)][\boldsymbol{\gamma}\times\boldsymbol{r}_i + \boldsymbol{\gamma}\times(\boldsymbol{\gamma}\times\boldsymbol{r}_i)]\\ &= \boldsymbol{r}_i + [2\boldsymbol{\gamma}/(1+\gamma^2)]\times(\boldsymbol{r}_i + \boldsymbol{\gamma}\times\boldsymbol{r}_i);\end{aligned} \tag{1.10.2g}$$

that is, express $\boldsymbol{r}_f$ in terms of $\boldsymbol{r}_i$ and the single vector $\boldsymbol{\gamma}$.

{It is not hard to show that the components, or projections, of a vector $\boldsymbol{a}$ *along* ($\boldsymbol{a}_{\text{along}} \equiv \boldsymbol{a}_l$) and *perpendicular to* ($\boldsymbol{a}_{\text{perpendicular/normal}} \equiv \boldsymbol{a}_n$) another vector $\boldsymbol{b}$ (of common origin) are

$$\boldsymbol{a}_l = (\boldsymbol{a}\cdot\boldsymbol{b})\boldsymbol{b}/b^2, \qquad \boldsymbol{a}_n = \boldsymbol{a} - \boldsymbol{a}_l = \boldsymbol{a} - (\boldsymbol{a}\cdot\boldsymbol{b})\boldsymbol{b}/b^2 = [\boldsymbol{b}\times(\boldsymbol{a}\times\boldsymbol{b})]/b^2\}.$$

Inversion of Eqs. (1.10.2e,g)

Since a rotation $-\boldsymbol{\gamma}$ should bring $\boldsymbol{r}_f$ back to $\boldsymbol{r}_i$, if in (1.10.2g) we swap the roles of $\boldsymbol{r}_i$ and $\boldsymbol{r}_f$ and replace $\boldsymbol{\gamma}$ with $-\boldsymbol{\gamma}$, we obtain the initial position in terms of the final one and its rotation:

$$\boldsymbol{r}_i = \boldsymbol{r}_f - [2\boldsymbol{\gamma}/(1+\gamma^2)]\times(\boldsymbol{r}_f - \boldsymbol{\gamma}\times\boldsymbol{r}_f); \tag{1.10.3}$$

and thus avoid complicated vector-algebraic inversions.

Rodrigues' Formula (1840)

Adding $\boldsymbol{r}_i$ to both sides of (1.10.2e), we obtain

$$\boldsymbol{r}_i + \boldsymbol{r}_f = [2/(1+\gamma^2)][\boldsymbol{r}_i + \boldsymbol{\gamma}\times\boldsymbol{r}_i + (\boldsymbol{\gamma}\cdot\boldsymbol{r}_i)\boldsymbol{\gamma}], \tag{1.10.4a}$$

and crossing both sides of the above with $\boldsymbol{\gamma}$, and then using simple vector identities and (1.10.2g) [or, adding (1.10.2g) and (1.10.3) and setting the coefficient of $2\boldsymbol{\gamma}/(1+\gamma^2)$ equal to zero, since it cannot be nonzero and parallel to $\boldsymbol{\gamma}$], we arrive at the *formula of Rodrigues*:

$$\boldsymbol{r}_f - \boldsymbol{r}_i = \boldsymbol{\gamma} \times (\boldsymbol{r}_i + \boldsymbol{r}_f) \equiv 2\boldsymbol{\gamma} \times \boldsymbol{r}_m = 2\boldsymbol{n} \times \boldsymbol{r}_m \tan(\chi/2), \tag{1.10.4b}$$

where

$$2\boldsymbol{r}_m \equiv \boldsymbol{r}_i + \boldsymbol{r}_f = 2\ (\textit{position vector of midpoint of } P_i P_f); \tag{1.10.4c}$$

or, rearranging,

$$\boldsymbol{r}_f + \boldsymbol{r}_f \times \boldsymbol{\gamma} = \boldsymbol{r}_i + \boldsymbol{\gamma} \times \boldsymbol{r}_i. \tag{1.10.4d}$$

Finally, dotting both sides of this equation with $\boldsymbol{\gamma}$ (or $\boldsymbol{n}$), we obtain

$$\boldsymbol{\gamma} \cdot \boldsymbol{r}_f = \boldsymbol{\gamma} \cdot \boldsymbol{r}_i, \tag{1.10.4e}$$

as expected.

(ii) With the help of the *finite rotation vector*

$$\boldsymbol{\chi} \equiv \chi \boldsymbol{n}, \tag{1.10.5a}$$

which is, obviously, related to the earlier Gibbs vector $\boldsymbol{\gamma}$ by

$$\boldsymbol{\gamma} = \tan(\chi/2)(\boldsymbol{\chi}/\chi), \tag{1.10.5b}$$

and since

$$1 + \gamma^2 = 1\big/\cos^2(\chi/2), \qquad 1 - \gamma^2 = \cos\chi\big/\cos^2(\chi/2), \tag{1.10.5c}$$

the preceding rotation equations yield

$$\boldsymbol{r}_f = 2\cos^2(\chi/2)\big[\tan(\chi/2)(\boldsymbol{\chi} \times \boldsymbol{r}_i)(1/\chi) + \tan^2(\chi/2)(\boldsymbol{\chi} \cdot \boldsymbol{r}_i)(\boldsymbol{\chi}/\chi^2)\big] + \cos\chi\, \boldsymbol{r}_i, \tag{1.10.5d}$$

or finally,

$$\boldsymbol{r}_f = \boldsymbol{r}_i \cos\chi + (\boldsymbol{\chi} \times \boldsymbol{r}_i)(\sin\chi/\chi) + (\boldsymbol{\chi} \cdot \boldsymbol{r}_i)\boldsymbol{\chi}[(1-\cos\chi)/\chi^2], \tag{1.10.5e}$$

a form that is symmetrical and (integral) transcendental function of $\boldsymbol{\chi} \cdot \boldsymbol{\chi} = \chi^2$.

The above can also be rewritten as

$$\begin{aligned} \boldsymbol{r}_f - \boldsymbol{r}_i &= (\sin\chi)(\boldsymbol{n} \times \boldsymbol{r}_i) + (1-\cos\chi)[\boldsymbol{n} \times (\boldsymbol{n} \times \boldsymbol{r}_i)] \\ &= (\sin\chi)(\boldsymbol{n} \times \boldsymbol{r}_i) + (1-\cos\chi)[(\boldsymbol{n} \cdot \boldsymbol{r}_i)\boldsymbol{n} - (\boldsymbol{n}^2)\boldsymbol{r}_i], \end{aligned} \tag{1.10.5f}$$

or, slightly rearranged (since $\boldsymbol{n}^2 = 1$),

$$\begin{aligned} \boldsymbol{r}_f &= \boldsymbol{r}_i \cos\chi + (\boldsymbol{n} \times \boldsymbol{r}_i)\sin\chi + (\boldsymbol{n} \cdot \boldsymbol{r}_i)\boldsymbol{n}(1-\cos\chi) \\ &= \boldsymbol{r}_i + \sin\chi(\boldsymbol{n} \times \boldsymbol{r}_i) + (\cos\chi - 1)[\boldsymbol{r}_i - (\boldsymbol{r}_i \cdot \boldsymbol{n})\boldsymbol{n}] \\ &[= \boldsymbol{r}_i + \sin\chi(\boldsymbol{n} \times \boldsymbol{r}_i) + (\cos\chi - 1)\ (\textit{component of } \boldsymbol{r}_i \textit{ perpendicular to } \boldsymbol{n})]. \end{aligned} \tag{1.10.5g}$$

REMARK

The preceding rotation equations give the final position vector $\boldsymbol{r}_f$ in terms of the initial position vector $\boldsymbol{r}_i$ and the various rotation vectors $\boldsymbol{\gamma}$, $\boldsymbol{\chi}$, $\boldsymbol{n}$ (and χ). It is shown later in this section that, despite appearances, $\boldsymbol{\gamma}$ is *not* a vector in all respects, but simply a *directed line segment*; that is, it has some *but not all* of the vector characteristics (§ 1.1). This is a crucial point in the theory of finite rotations.

Additional Useful Results

(i) In the preceding rotation formulae:

(a) For $\chi = \pm 2\pi n$ $(n = 1, 2, 3, \ldots)$ they yield

$$\boldsymbol{r}_f = \boldsymbol{r}_i, \tag{1.10.6a}$$

that is, the body point returns to its initial position, as it should; and

(b) If $\boldsymbol{r}_i \cdot \boldsymbol{n} = 0$, and $\chi = \pi/2$, then

$$\boldsymbol{r}_f = \boldsymbol{n} \times \boldsymbol{r}_i, \tag{1.10.6b}$$

that is, $\boldsymbol{n}$, $\boldsymbol{r}_i$, $\boldsymbol{r}_f$ form an orthogonal and dextral triad at O.

(ii) By swapping the roles of $\boldsymbol{r}_f$ and $\boldsymbol{r}_i$ and replacing χ with $-\chi$ in (1.10.5g) (i.e., inverting it), we get

$$\boldsymbol{r}_i = \boldsymbol{r}_f \cos\chi - (\boldsymbol{n} \times \boldsymbol{r}_f)\sin\chi + (\boldsymbol{n} \cdot \boldsymbol{r}_f)\boldsymbol{n}(1 - \cos\chi). \tag{1.10.6c}$$

(iii) For *small* χ, eqs. (1.10.5d, e) linearize to the earlier "Euler–Mozzi" formula:

$$\boldsymbol{r}_f = \boldsymbol{r}_i + \boldsymbol{\chi} \times \boldsymbol{r}_i \;\Rightarrow\; \Delta\boldsymbol{r} \equiv \boldsymbol{r}_f - \boldsymbol{r}_i = \boldsymbol{\chi} \times \boldsymbol{r}_i. \tag{1.10.6d}$$

Finite Rotation of a Line

By using the rotation formulae, one can show that the final position of a *body-fixed* straight fiber joining two arbitrary such points P_1 and P_2, or 1 and 2 (fig. 1.20), is given by

$$\begin{aligned}(\boldsymbol{r}_{2/1})_f &\equiv \boldsymbol{r}_{2,f} - \boldsymbol{r}_{1,f}\\ &= \cdots = (\sin\chi)\boldsymbol{n} \times (\boldsymbol{r}_{2/1})_i + (\cos\chi)(\boldsymbol{r}_{2/1})_i + (1 - \cos\chi)[\boldsymbol{n} \cdot (\boldsymbol{r}_{2/1})_i]\boldsymbol{n},\end{aligned} \tag{1.10.7a}$$

where

$$\textit{Initial position} \equiv (\boldsymbol{r}_{2/1})_i \to \textit{Final position} \equiv (\boldsymbol{r}_{2/1})_f, \tag{1.10.7b}$$

and

$$\boldsymbol{r}_{2/1} \equiv \boldsymbol{r}_2 - \boldsymbol{r}_1, \qquad \text{for both } i \text{ and } f. \tag{1.10.7c}$$

Finite Rotation of an Orthonormal Basis

By employing the finite rotation equations, let us find the relations between the two ortho–normal–dextral (OND) bases of common origin, O–$\boldsymbol{u}_{k'}$ (space-fixed) and

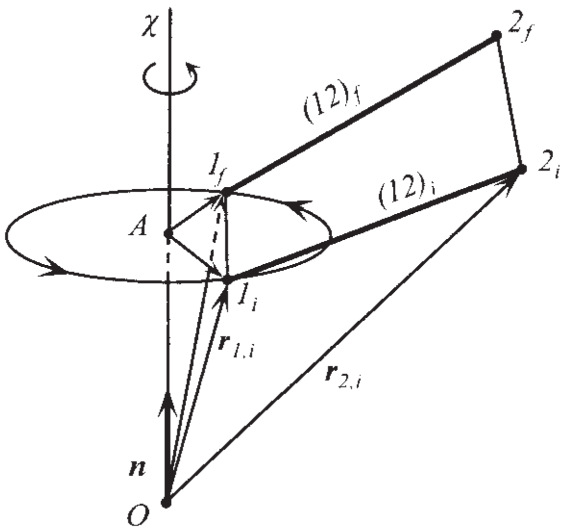

Figure 1.20 Finite rotation of straight segment *12*, from *(12)*$_i$ to *(12)*$_f$.

O–$\boldsymbol{u}_k$ (body-fixed), if the latter results from the former by a rotation χ about an axis $\boldsymbol{n}$; that is, symbolically,

$$\boldsymbol{u}_{k'} \xrightarrow{(\boldsymbol{n},\chi)} \boldsymbol{u}_k. \tag{1.10.8a}$$

Applying the earlier rotation equations to this transformation, with $\boldsymbol{r}_i = \boldsymbol{u}_{k'}$ and $\boldsymbol{r}_f = \boldsymbol{u}_k$, we obtain the following equivalent expressions:

(i)
$$\boldsymbol{u}_k = \boldsymbol{u}_{k'} + (\sin\chi)(\boldsymbol{n}\times\boldsymbol{u}_{k'}) + (\cos\chi - 1)\boldsymbol{u}_{k',n}, \tag{1.10.8b}$$

where

$$\begin{aligned}\boldsymbol{u}_{k',n} &\equiv \boldsymbol{u}_{k'} - (\boldsymbol{u}_{k'}\cdot\boldsymbol{n})\boldsymbol{n} = \boldsymbol{u}_{k'} - (\boldsymbol{n}\otimes\boldsymbol{n})\cdot\boldsymbol{u}_{k'} = (\boldsymbol{1} - \boldsymbol{n}\otimes\boldsymbol{n})\cdot\boldsymbol{u}_{k'}\\ &\equiv \boldsymbol{P}\cdot\boldsymbol{u}_{k'} = \textit{Component of } \boldsymbol{u}_{k'} \textit{ normal to } \boldsymbol{n}\\ &\quad [\boldsymbol{P} = \textit{projection operator},\ \boldsymbol{1} = \textit{unit tensor}\ (\S 1.1)]\,.\end{aligned} \tag{1.10.8c}$$

(ii)
$$\begin{aligned}\boldsymbol{u}_k &= (\cos\chi)\boldsymbol{u}_{k'} + (\sin\chi)(\boldsymbol{n}\times\boldsymbol{u}_{k'}) + (1-\cos\chi)(\boldsymbol{n}\cdot\boldsymbol{u}_{k'})\boldsymbol{n}\\ &= [(\cos\chi)\boldsymbol{1} + (\sin\chi)(\boldsymbol{n}\times\boldsymbol{1}) + (1-\cos\chi)(\boldsymbol{n}\otimes\boldsymbol{n})]\cdot\boldsymbol{u}_{k'}\\ &\equiv (\textit{rotation tensor})\cdot\boldsymbol{u}_{k'} \qquad \text{[examined in detail below]}\\ &= \boldsymbol{u}_{k'} + (\chi\boldsymbol{n})\times\boldsymbol{u}_{k'} \quad (\text{to the } \textit{first} \text{ order in } \chi)\\ &\approx \boldsymbol{u}_{k'} + (\chi\boldsymbol{n})\times\boldsymbol{u}_{k'}\\ &= \boldsymbol{u}_{k'} + \boldsymbol{\chi}\times\boldsymbol{u}_{k'} \qquad \text{[Euler–Mozzi formula for small rotations]}.\end{aligned} \tag{1.10.8d}$$

(iii)
$$\begin{aligned}\boldsymbol{u}_k &= \boldsymbol{u}_{k'} + [2/(1+\gamma^2)][\boldsymbol{\gamma}\times\boldsymbol{u}_{k'} - \gamma^2\boldsymbol{u}_{k'} + (\boldsymbol{\gamma}\otimes\boldsymbol{\gamma})\cdot\boldsymbol{u}_{k'}]\\ &= \boldsymbol{u}_{k'} + [2/(1+\gamma^2)][\boldsymbol{\gamma}\times\boldsymbol{u}_{k'} + \boldsymbol{\gamma}\times(\boldsymbol{\gamma}\times\boldsymbol{u}_{k'})]\\ &= \boldsymbol{u}_{k'} + [2\boldsymbol{\gamma}/(1+\gamma^2)]\times(\boldsymbol{u}_{k'} + \boldsymbol{\gamma}\times\boldsymbol{u}_{k'}).\end{aligned}\tag{1.10.8e}$$

To express the initial basis vectors $\boldsymbol{u}_{k'}$ in terms of the final ones $\boldsymbol{u}_k$, we simply replace in any of the above, say (1.10.8e), $\boldsymbol{\gamma}$ with $-\boldsymbol{\gamma}$. The result is

$$\boldsymbol{u}_{k'} = \boldsymbol{u}_k - [2\boldsymbol{\gamma}/(1+\gamma^2)]\times(\boldsymbol{u}_{k'} - \boldsymbol{\gamma}\times\boldsymbol{u}_{k'}).\tag{1.10.8f}$$

From the above, we can easily deduce that

$$\boldsymbol{\gamma}\cdot\boldsymbol{u}_k = \boldsymbol{\gamma}\cdot\boldsymbol{u}_{k'},\tag{1.10.8g}$$

as expected; or setting

$$\boldsymbol{\gamma} = \sum \gamma_k\boldsymbol{u}_k = \sum \gamma_{k'}\boldsymbol{u}_{k'},\tag{1.10.8h}$$

in component form

$$\gamma_k = \gamma_{k'}.\tag{1.10.8i}$$

The Tensor of Finite Rotation

Let us express the earlier rotation equations in direct/matrix and component forms. Along the rectangular Cartesian axes $O\text{–}XYZ \equiv O\text{–}X_k$, common to all vectors and tensors involved here, and with the component notations ($k = X, Y, Z$):

$$\boldsymbol{r}_i \equiv (X_k), \qquad \boldsymbol{r}_f \equiv (Y_k),$$
$$\boldsymbol{\gamma} = (\gamma_k\text{: } \textit{Rodrigues parameters}) \;\Rightarrow\; \gamma^2 = \sum {\gamma_k}^2 = (\gamma_X)^2 + (\gamma_Y)^2 + (\gamma_Z)^2,$$
$$\boldsymbol{n} = (n_k\text{: } \textit{direction cosines of unit vector defining the axis of rotation}),\tag{1.10.9a}$$

our rotation equations become

$$\boldsymbol{r}_f = \boldsymbol{R}\cdot\boldsymbol{r}_i\,, \qquad Y_k = \sum R_{kl}\,X_l = \sum [r_{kl}/(1+\gamma^2)]X_l\,,\tag{1.10.9b}$$

where, recalling (1.10.2e ff.) and the simple tensor algebra of §1.1, the (nonsymmetrical but proper orthogonal) *tensor of finite rotation*,

$$\boldsymbol{R} \equiv \boldsymbol{R}(\boldsymbol{n}, \chi) \equiv (R_{kl}) \equiv (r_{kl}/(1+\gamma^2))\,,\tag{1.10.9c}$$

has the following equivalent representations.

(i) *Direct/matrix form* (with $\boldsymbol{N}$: antisymmetric tensor of vector $\boldsymbol{n}$):

$$\boldsymbol{R} = \boldsymbol{1}\cos\chi + \boldsymbol{N}\sin\chi + \boldsymbol{n}\otimes\boldsymbol{n}(1-\cos\chi)$$

$$= \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}\cos\chi + \begin{pmatrix} 0 & -n_Z & n_Y \\ n_Z & 0 & -n_X \\ -n_Y & n_X & 0 \end{pmatrix}\sin\chi$$

$$+ \begin{pmatrix} {n_X}^2 & n_X n_Y & n_X n_Z \\ n_Y n_X & {n_Y}^2 & n_Y n_Z \\ n_Z n_X & n_Z n_Y & {n_Z}^2 \end{pmatrix}(1-\cos\chi)$$

$$= \begin{pmatrix} c\chi + {n_X}^2(1-c\chi) & -n_Z s\chi + n_X n_Y(1-c\chi) & n_Y s\chi + n_X n_Z(1-c\chi) \\ n_Z s\chi + n_X n_Y(1-c\chi) & c\chi + {n_Y}^2(1-c\chi) & -n_X s\chi + n_Y n_Z(1-c\chi) \\ -n_Y s\chi + n_X n_Z(1-c\chi) & n_X s\chi + n_Y n_Z(1-c\chi) & c\chi + {n_Z}^2(1-c\chi) \end{pmatrix}$$

$$= \boldsymbol{R}(n_X, n_Y, n_Z; \chi)\,, \qquad \text{under} \qquad {n_X}^2 + {n_Y}^2 + {n_Z}^2 = 1\,, \tag{1.10.10a}$$

where, as usual, $c(\ldots) \equiv \cos(\ldots)$, $s(\ldots) \equiv \sin(\ldots)$.

(ii) *Indicial* (*Cartesian tensor*) *form* [with $\boldsymbol{N} = (N_{kl})$, $\boldsymbol{n} = (n_k)$]:

$$R_{kl} \equiv R_{kl}(n_r, \chi) = (\delta_{kl})\cos\chi + (N_{kl})\sin\chi + n_k n_l(1-\cos\chi)$$

$$= (\delta_{kl})\cos\chi + \left(\sum \varepsilon_{krl} n_r\right)\sin\chi + n_k n_l(1-\cos\chi). \tag{1.10.10b}$$

Occasionally, the rotation formula is written as

$$\Delta\boldsymbol{r} = \boldsymbol{R}'\cdot\boldsymbol{r}\,, \qquad \text{where} \quad \Delta\boldsymbol{r} \equiv \boldsymbol{r_f} - \boldsymbol{r_i}\,, \qquad \boldsymbol{r} \equiv \boldsymbol{r_i}\,, \tag{1.10.10c}$$

and

$$\boldsymbol{R}' \equiv (R'_{kl}) \equiv \boldsymbol{R} - \boldsymbol{1} = (R_{kl} - \delta_{kl})\,; \qquad \textit{rotator}\ \text{tensor}\,,$$

$$R'_{kl} \equiv R_{kl} - \delta_{kl} = \cdots = \left(\sum \varepsilon_{krl} n_r\right)\sin\chi + (n_k n_l - \delta_{kl})(1-\cos\chi). \tag{1.10.10d}$$

We notice that the representation (1.10.10d) coincides with the decomposition of R'_{kl} into its *antisymmetric* part:

$$\sum(\varepsilon_{krl}\, n_r)\sin\chi = N_{kl}\sin\chi\,,$$

and *symmetric* part:

$$(n_k n_l - \delta_{kl})(1-\cos\chi);$$

of which, the former is of the *first order* in χ, while the latter is of the *second order*; a result that explains the antisymmetry of the *angular velocity tensor* [(1.7.22e)].

(iii) *In terms of the Rodrigues parameters* (a form, most likely, due to G. Darboux):

$$(r_{kl}) = \begin{pmatrix} 1+\gamma_X{}^2-(\gamma_Y{}^2+\gamma_Z{}^2) & 2(\gamma_X\gamma_Y-\gamma_Z) & 2(\gamma_X\gamma_Z+\gamma_Y) \\ 2(\gamma_X\gamma_Y+\gamma_Z) & 1+\gamma_Y{}^2-(\gamma_Z{}^2+\gamma_X{}^2) & 2(\gamma_Y\gamma_Z-\gamma_X) \\ 2(\gamma_X\gamma_Z-\gamma_Y) & 2(\gamma_Y\gamma_Z+\gamma_X) & 1+\gamma_Z{}^2-(\gamma_X{}^2+\gamma_Y{}^2) \end{pmatrix} \tag{1.10.10e}$$

The properties of $\boldsymbol{R}$ can be summarized as follows:

(i) $$\lim \boldsymbol{R}(\boldsymbol{n},\chi)\Big|_{\chi\to 0} = \boldsymbol{R}(\boldsymbol{n},0) = \boldsymbol{1}\,, \qquad \text{for all } \boldsymbol{n}\,; \tag{1.10.11a}$$

that is, $\boldsymbol{R}(\boldsymbol{n},\chi)$ is a continuous function of χ.

(ii) $$\boldsymbol{R}(\boldsymbol{n},\chi)\cdot\boldsymbol{n} = \boldsymbol{n}\,; \qquad \boldsymbol{n} = \textit{axis of rotation}\,. \tag{1.10.11b}$$

(iii) $$\boldsymbol{R}(\boldsymbol{n},\chi_1)\cdot\boldsymbol{R}(\boldsymbol{n},\chi_2) = \boldsymbol{R}(\boldsymbol{n},\chi_1+\chi_2)\,. \tag{1.10.11c}$$

(iv) $$\boldsymbol{R}(\boldsymbol{n},\chi)\cdot\boldsymbol{R}^{\mathrm{T}}(\boldsymbol{n},\chi) = \boldsymbol{1}\,, \tag{1.10.11d}$$

$$\boldsymbol{R}^{\mathrm{T}}(\boldsymbol{n},\chi) = \boldsymbol{R}^{-1}(\boldsymbol{n},\chi) = \boldsymbol{R}(\boldsymbol{n},-\chi)\,. \tag{1.10.11e}$$

Also, since the elements of $\boldsymbol{R}$, R_{kl}, depend continuously and differentiably on three independent parameters — for example, Euler's angles (§1.12) — we can say that the

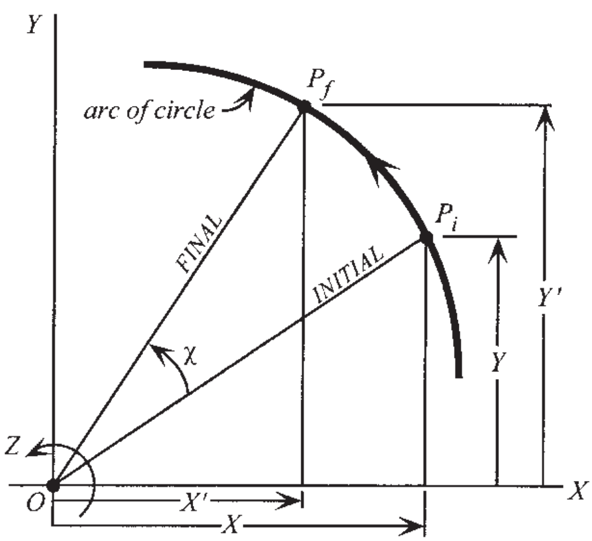

Figure 1.21 Plane rotation about *Oz*, through an angle χ.

rotation group is a *continuous* one; or a *Lie group*; see, for example, Argyris and Poterasu (1993).

Plane Rotation

This is a special rotation in which

$$\boldsymbol{\gamma} = \big(\gamma_X = 0, \gamma_Y = 0, \gamma_Z = \tan(\chi/2)\big) = \tan(\chi/2)\boldsymbol{n} \Rightarrow \boldsymbol{n} = \boldsymbol{K}. \tag{1.10.12a}$$

Then, with $X_k \equiv X,\ Y$ and $Y_k \equiv X',\ Y'$ (fig. 1.21), the rotational equations, (1.10.2g), and so on, specialize to

$$X' = [(1-\gamma^2)/(1+\gamma^2)]X - [2\gamma/(1+\gamma^2)]Y = \cdots = (\cos\chi)X + (-\sin\chi)Y, \tag{1.10.12b}$$

$$Y' = [2\gamma/(1+\gamma^2)]X + [(1-\gamma^2)/(1+\gamma^2)]Y = \cdots = (\sin\chi)X + (\cos\chi)Y, \tag{1.10.12c}$$

$$Z' = Z. \tag{1.10.12d}$$

Additional Useful Results

(i) *Alternative expressions of the rotation tensor*:

(a) Indicial notation:

$$\begin{aligned} R_{kl} &= \delta_{kl} + \left(\sum \varepsilon_{krl} n_r\right)\sin\chi + (n_k n_l - \delta_{kl})(1-\cos\chi) \\ &= \delta_{kl} + N_{kl}\sin\chi + \sum N_{ks}N_{sl}(1-\cos\chi) \end{aligned} \tag{1.10.13a}$$

(b) Direct/matrix form [$\boldsymbol{N} = (N_{kl})$ antisymmetric tensor of vector $\boldsymbol{n} = (n_k)$]:

$$\boldsymbol{R} = \boldsymbol{1} + \boldsymbol{N}\sin\chi + 2\boldsymbol{N}\cdot\boldsymbol{N}\sin^2(\chi/2) \tag{1.10.13b}$$

$$= \boldsymbol{1} + (\sin\chi)\boldsymbol{N} + [2\sin^2(\chi/2)]\boldsymbol{N}^2 \tag{1.10.13c}$$

$$= \boldsymbol{1} + (\sin\chi)\boldsymbol{N} + (1-\cos\chi)\boldsymbol{N}^2 \tag{1.10.13d}$$

$$= \boldsymbol{1} + 2\boldsymbol{N}\sin(\chi/2)[\boldsymbol{1}\cos(\chi/2) + \boldsymbol{N}\sin(\chi/2)] \tag{1.10.13e}$$

[Notice that $1-\cos\chi = 2\sin^2(\chi/2)$ and $\sum N_{ks}N_{sl} = n_k n_l - \delta_{kl}$, or, in direct notation, $\boldsymbol{N}\cdot\boldsymbol{N} = \boldsymbol{n}\otimes\boldsymbol{n} - \boldsymbol{1}$. See also Bahar (1970)].

(ii) By swapping the roles of $\boldsymbol{r}_i$ and $\boldsymbol{r}_f$ and setting $\chi \rightarrow -\chi$, in the preceding rotation formulae, one can show that

$$\boldsymbol{r}_i = \boldsymbol{R}^{-1}\cdot\boldsymbol{r}_f, \tag{1.10.14a}$$

where

$$\boldsymbol{R}^{-1} = \boldsymbol{1} - \boldsymbol{N}\sin\chi + 2\boldsymbol{N}\cdot\boldsymbol{N}\sin^2(\chi/2) = \boldsymbol{R}^{\mathrm{T}} = \boldsymbol{R}(\boldsymbol{n}, -\chi); \tag{1.10.14b}$$

that is, the rotation tensor is indeed *orthogonal*.

(iii) Let $\boldsymbol{\Gamma} \equiv \boldsymbol{N}\tan(\chi/2)$: antisymmetric tensor of the Gibbs vector $\boldsymbol{\gamma}$. By applying the Cayley–Hamilton theorem to $\boldsymbol{\Gamma}$ [i.e., *every tensor satisfies its own characteristic equation* (§1.1)],

$$\Delta(\lambda) \equiv |\boldsymbol{\Gamma} - \lambda \boldsymbol{1}| = 0 \Rightarrow \Delta(\boldsymbol{\Gamma}) = -\boldsymbol{\Gamma}^3 - [\tan^2(\chi/2)]\boldsymbol{\Gamma} = \boldsymbol{0}\,, \tag{1.10.15a}$$

(since $Tr\,\boldsymbol{\Gamma} = 0$ and $Det\,\boldsymbol{\Gamma} = 0$), one can show that

$$\boldsymbol{R} = \boldsymbol{1} + 2\cos^2(\chi/2)(\boldsymbol{\Gamma} + \boldsymbol{\Gamma}^2)\,, \qquad \boldsymbol{R} = (\boldsymbol{1} - \boldsymbol{\Gamma})^{-1}\cdot(\boldsymbol{1} + \boldsymbol{\Gamma})\,. \tag{1.10.15b}$$

Next, expanding (1.10.15b) symbolically in powers of $\boldsymbol{\Gamma}$, we obtain the representation

$$\boldsymbol{R} = (\boldsymbol{1} + \boldsymbol{\Gamma} + \cdots)\cdot(\boldsymbol{1} + \boldsymbol{\Gamma}) = \boldsymbol{1} + 2\boldsymbol{\Gamma}\,, \qquad \text{to first } \boldsymbol{\Gamma}\text{-order}\,; \tag{1.10.15c}$$

$$\Rightarrow \boldsymbol{R}' \equiv \boldsymbol{R} - \boldsymbol{1} = 2\boldsymbol{\Gamma}\,, \qquad \text{to first } \boldsymbol{\Gamma}\text{-order}\,. \tag{1.10.15d}$$

[Equations (1.10.15c, d) shed some light into the meaning of $\boldsymbol{\gamma}$ and $\boldsymbol{\Gamma}$, and prepare us for the treatment of *angular velocity* later in this section.] Similar results can be obtained in terms of $\boldsymbol{N}$.

The Mathematical Problem of Finite Rotation

Usually, this takes one of the following two forms: (i) given χ and $\boldsymbol{n}$, find $\boldsymbol{R}$; or (ii) given $\boldsymbol{R}$, find χ and $\boldsymbol{n}$. Now, from the preceding indicial forms, we easily obtain (with $k = X, Y, Z$):

$$\begin{aligned}\text{(i)}\ \ Tr\,\boldsymbol{R} \equiv \sum R_{kk} &= \cos\chi\Big(\sum \delta_{kk}\Big) + \sin\chi\Big(\sum\sum \varepsilon_{krk}\,n_r\Big)\\ &\qquad + (1-\cos\chi)\Big(\sum\sum n_k n_k\Big)\\ &= \cos\chi(3) + \sin\chi(0) + (1-\cos\chi)(1) = 2\cos\chi + 1.\end{aligned} \tag{1.10.16a}$$

$$\begin{aligned}\text{(ii)}\qquad \sum\sum \varepsilon_{skl}R_{kl} &= \cos\chi\Big(\sum\sum \varepsilon_{skl}\delta_{kl}\Big) + \sin\chi\Big(\sum\sum\sum \varepsilon_{skl}\varepsilon_{krl}n_r\Big)\\ &\qquad + (1-\cos\chi)\Big(\sum\sum \varepsilon_{skl}n_k n_l\Big)\\ &= \cos\chi(0) + \sin\chi\Big(\sum(-2\delta_{rs})n_r\Big) + (1-\cos\chi)(\boldsymbol{n}\times\boldsymbol{n})_s\\ &= -2(\sin\chi)n_s \qquad \text{[Thanks to the } \varepsilon\text{-identities (1.1.6b ff.)].}\end{aligned} \tag{1.10.16b}$$

In sum,

$$I_1 \equiv Tr\,\boldsymbol{R} \equiv \sum R_{kk} = 1 + 2\cos\chi = \textit{First invariant of } \boldsymbol{R}\,, \tag{1.10.16c}$$

$$-\sum\sum \varepsilon_{skl}R_{kl} = 2R_s = 2(\textit{Axial vector of } \boldsymbol{R})_s = 2(\sin\chi)n_s \Rightarrow R_k = (\sin\chi)n_k\,, \tag{1.10.16d}$$

or, explicitly,

$$R_1 = (-1/2)(\varepsilon_{123}R_{23} + \varepsilon_{132}R_{32}) = (R_{32} - R_{23})/2 = (\sin\chi)n_1, \tag{1.10.16e}$$

$$R_2 = (-1/2)(\varepsilon_{231}R_{31} + \varepsilon_{213}R_{13}) = (R_{13} - R_{31})/2 = (\sin\chi)n_2, \tag{1.10.16f}$$

$$R_3 = (-1/2)(\varepsilon_{312}R_{12} + \varepsilon_{321}R_{21}) = (R_{21} - R_{12})/2 = (\sin\chi)n_3. \tag{1.10.16g}$$

Now, the *first* problem of rotation is, clearly, answered by the earlier rotation formulae (1.10.10 ff.); while the *second* is answered by solving the system of the four equations (1.10.16c, e–g) for the four unknowns χ; $n_{1,2,3}$. Indeed,

(i) From (1.10.16c), we obtain

$$\cos\chi = (I_1 - 1)/2 \equiv (\mathrm{Tr}\,\boldsymbol{R} - 1)/2\,. \tag{1.10.17a}$$

(a) From (1.10.16e–g), if $\sin\chi \neq 0$,

$$n_1 = (R_{32} - R_{23})/2\sin\chi, \qquad n_2 = (R_{13} - R_{31})/2\sin\chi, \qquad n_3 = (R_{21} - R_{12})/2\sin\chi, \tag{1.10.17b}$$

or, vectorially,

$$\boldsymbol{n} = (1/n')\big[(R_{32} - R_{23})\boldsymbol{I} + (R_{13} - R_{31})\boldsymbol{J} + (R_{21} - R_{12})\boldsymbol{K}\big],$$

where

$$n' \equiv 2\sin\chi = \cdots = [(1 + \mathrm{Tr}\,\boldsymbol{R})\cdot(3 - \mathrm{Tr}\,\boldsymbol{R})]^{1/2} : \textit{normalizing factor}, \tag{1.10.17c}$$

(b) If $\sin\chi = 0$, then $\chi = 0$ or $\pm\pi$ (or some integral multiple thereof);
(b.1) If $\chi = 0$, then, as (1.10.11a) shows, $\boldsymbol{R} = (R_{kl}) = (\delta_{kl}) \equiv \boldsymbol{1}$; that is, $\boldsymbol{n}$ becomes undetermined: *no rotation occurs*; while
(b.2) If $\chi = \pm\pi \Rightarrow \cos\chi = -1$, then, as (1.10.10 ff.) show,

$$\boldsymbol{R} = (R_{kl}) = (2n_k n_l - \delta_{kl}) \qquad \text{(a } \textit{symmetric} \text{ tensor)}$$
$$= \begin{pmatrix} 2{n_1}^2 - 1 & 2n_1n_2 & 2n_1n_3 \\ 2n_2n_1 & 2{n_2}^2 - 1 & 2n_2n_3 \\ 2n_3n_1 & 2n_3n_2 & 2{n_3}^2 - 1 \end{pmatrix}, \tag{1.10.17d}$$

or, explicitly,

$$R_{11} = 2{n_1}^2 - 1 \;\Rightarrow\; n_1 = \pm[(1 + R_{11})/2]^{1/2}, \tag{1.10.17e}$$

$$R_{22} = 2{n_2}^2 - 1 \;\Rightarrow\; n_2 = \pm[(1 + R_{22})/2]^{1/2}, \tag{1.10.17f}$$

$$R_{33} = 2{n_3}^2 - 1 \;\Rightarrow\; n_3 = \pm[(1 + R_{33})/2]^{1/2}, \tag{1.10.17g}$$

and the ultimate signs of $n_{1,2,3}$ are chosen so that (1.10.17e–g) are consistent with the rest of (1.10.17d):

$$n_1n_2 = R_{12}/2 = R_{21}/2, \qquad n_1n_3 = R_{13}/2 = R_{31}/2, \qquad n_2n_3 = R_{23}/2 = R_{32}/2.$$

The angle χ can also be obtained from the off-diagonal elements of $\boldsymbol{R}$ as follows: multiplying (1.10.17b) with n_1, n_2, n_3, respectively, adding together, and invoking the normalization constraint ${n_1}^2 + {n_2}^2 + {n_3}^2 = 1$, we find

$$\sin\chi = (1/2)\left[n_1(R_{32} - R_{23}) + n_2(R_{13} - R_{31}) + n_3(R_{21} - R_{12})\right]. \tag{1.10.17h}$$

Rotation as an Eigenvalue Problem

(This subsection relies heavily on the spectral theory of § 1.1.) In view of the rotation formula

$$\boldsymbol{r}_f = \boldsymbol{R}\cdot\boldsymbol{r}_i\,, \tag{1.10.18a}$$

the earlier fundamental Eulerian theorem (§1.9: The most general displacement of a rigid body about a fixed point can be effected by a rotation about an axis through that point $\Rightarrow$ that axis is carried onto itself: $\boldsymbol{R}\cdot\boldsymbol{n} = \boldsymbol{n}$) translates to the following algebraic statement: *The real proper orthogonal tensor of rotation* $\boldsymbol{R}$ *has always the eigenvalue* $+1$; that is, at least one of the eigenvalues of the eigenvalue problem

$$(\boldsymbol{r}_f =)\,\boldsymbol{R}\cdot\boldsymbol{r}_i = \lambda\boldsymbol{r}_i\,, \tag{1.10.18b}$$

equals $+1$; or, *every rotation has an invariant vector*, which is Euler's theorem.

Let us examine these eigenvalues more systematically. The latter are the three roots of

$$|\boldsymbol{R} - \lambda\boldsymbol{1}| = 0 \qquad (\lambda : \lambda_{1,2,3})\,, \tag{1.10.18c}$$

and it is shown in linear algebra that:

(a) *They all have unit magnitude* [Since $\boldsymbol{r}_f\cdot\boldsymbol{r}_f = (\boldsymbol{R}\cdot\boldsymbol{r}_i)\cdot(\boldsymbol{R}\cdot\boldsymbol{r}_i) = (\boldsymbol{r}_i\cdot\boldsymbol{R}^{\mathrm{T}})\cdot(\boldsymbol{R}\cdot\boldsymbol{r}_i) = \boldsymbol{r}_i\cdot\boldsymbol{r}_i = {\boldsymbol{r}_i}^2$, the eigenvalue equation (1.10.18b) becomes

$$\boldsymbol{r}_f\cdot\boldsymbol{r}_f = \boldsymbol{r}_i\cdot\boldsymbol{r}_i = \lambda^2\boldsymbol{r}_i\cdot\boldsymbol{r}_i \;\Rightarrow\; \lambda^2 = 1 \qquad (\text{for } \boldsymbol{r}_i \neq \boldsymbol{0})\big];$$

(b) *At least one of them is real* [From the corresponding characteristic equation:

$$\Delta(\lambda) \equiv |\boldsymbol{R} - \lambda\boldsymbol{1}| = (-1)^3\lambda^3 + \cdots + (Det\,\boldsymbol{R})\lambda^0 = 0\,,$$

we readily see that

$$\lim \Delta(\lambda)\Big|_{\lambda\to-\infty} = +\infty, \qquad \text{and} \qquad \lim \Delta(\lambda)\Big|_{\lambda\to+\infty} = -\infty.$$

Hence, $\Delta(\lambda)$ crosses the λ axis *at least once*; that is, $\Delta(\lambda) = 0$ has *at least one real root*; and, by (i), that root is either $+1$ or -1.]

(c) *Complex eigenvalues occur in pairs of complex conjugate numbers* [since the coefficients of $\Delta(\lambda) = 0$ are real];

(d) $I_3(\boldsymbol{R}) \equiv I_3 = Det\,\boldsymbol{R} \equiv |R_{kl}| \equiv R = \lambda_1\lambda_2\lambda_3 = +1$. [Initially, that is before the rotation, $\boldsymbol{r}_f = \boldsymbol{R}\cdot\boldsymbol{r}_i = \boldsymbol{r}_i \Rightarrow \boldsymbol{R} = \boldsymbol{1} \Rightarrow Det\,\boldsymbol{1} = +1$, and since thereafter $\boldsymbol{R}$ evolves continuously from $\boldsymbol{1}$, it must be a *proper orthogonal tensor*; that is, $|\boldsymbol{R}| \equiv Det\,\boldsymbol{R} = +1 = \Delta(0)$. This expresses the "obvious" kinematical fact that, as long as we remain inside our Euclidean three-dimensional space, *a right-handed coordinate system cannot change to a left-handed one by a continuous rigid-body* *motion of its axes*; such "polarity" changes, called *inversions* or *reflections*, require continuous transformations in a higher dimensional space; for example, right-handed *two*-dimensional axes can be changed to left-handed *two*-dimensional axes by a continuous rotation inside the surrounding *three*-dimensional space.]

Combining these results, we conclude that either: (i) All three eigenvalues of $\boldsymbol{R}$ are real and equal to $+1$; which is the trivial case of the *identity transformation*; or, and this is the case of main interest (Euler's theorem), (ii) Only one of these eigenvalues is real and equals $+1\,[\Rightarrow \Delta(1) \equiv |\boldsymbol{R} - \boldsymbol{1}| = 0]$; while the other two are the complex conjugate numbers: $\cos\chi \pm i\sin\chi \equiv \exp(\pm i\chi)$. As a result of the above:

(a) The direction cosines of the axis of rotation $\boldsymbol{n} = (n_X, n_Y, n_Z)$ can be obtained by setting in eq. (1.10.18b) $\lambda = 1$, $\boldsymbol{r}_i = \boldsymbol{n}$:

$$(\boldsymbol{R} - \lambda\boldsymbol{1}) \cdot \boldsymbol{r}_i = 0 \Rightarrow \boldsymbol{R} \cdot \boldsymbol{n} = \boldsymbol{n}\,, \tag{1.10.19a}$$

and then solving for $n_{X,Y,Z}$ under the constraint ${n_X}^2 + {n_Y}^2 + {n_Z}^2 = 1$; and

(b) The invariants of $\boldsymbol{R}$ can be summarized as follows:

$$\begin{aligned} I_1(\boldsymbol{R}) &= Tr\,\boldsymbol{R} \equiv R_{11} + R_{22} + R_{33} \\ &= \lambda_1 + \lambda_2 + \lambda_3 = 1 + \exp(+i\chi) + \exp(-i\chi) = 1 + 2\cos\chi\,; \qquad (1.10.19\text{b}) \end{aligned}$$

$$\begin{aligned} I_2(\boldsymbol{R}) &= [(Tr\,\boldsymbol{R})^2 - Tr\,(\boldsymbol{R}^2)]/2 = (Det\,\boldsymbol{R})(Tr\,\boldsymbol{R}^{-1}) \\ &= (+1)(Tr\,\boldsymbol{R}^{\mathrm{T}}) = (+1)(Tr\,\boldsymbol{R}) = I_1(\boldsymbol{R}) \\ &\big[= \lambda_1\lambda_2 + \lambda_1\lambda_3 + \lambda_2\lambda_3 \\ &= (1)[\exp(i\chi)] + (1)[\exp(-i\chi)] + \exp(i\chi)\exp(-i\chi) = 2\cos\chi + 1\big]; \qquad (1.10.19\text{c}) \end{aligned}$$

$$I_3(\boldsymbol{R}) = Det\,\boldsymbol{R} = \lambda_1\lambda_2\lambda_3 = +1\,; \tag{1.10.19d}$$

that is, $\boldsymbol{R}$ has only *two* independent invariants.

Composition of Finite Rotations

Here we show that finite rotations are noncommutative; specifically, that two or more successive finite rotations of a rigid body with a fixed point O (or, generally, about axes *intersecting* at the real or fictitious rigid extension of the body) can be reproduced by a single rotation about an axis through O; but that resultant or equivalent single rotation *does* depend on the *order of the component or constituent rotations*.

Quantitatively, let the rotation vector γ_1 carry the generic body point position vector from $\boldsymbol{r}_1$ to $\boldsymbol{r}_2$; and, similarly, let γ_2 carry $\boldsymbol{r}_2$ to $\boldsymbol{r}_3$. We are seeking to express the vector of the *resultant* rotation $\gamma_{1,2}$ (i.e., of the one carrying $\boldsymbol{r}_1$ to $\boldsymbol{r}_3$) in terms of its "components" γ_1 and γ_2. Schematically,

$$\begin{tikzcd} \boldsymbol{r}_1 \arrow[r, "\gamma_1"] \arrow[rr, bend right, "\gamma_{1,2}"'] & \boldsymbol{r}_2 \arrow[r, "\gamma_2"] & \boldsymbol{r}_3 \end{tikzcd} \tag{1.10.20a}$$

By Rodrigues' formula (1.10.4b), applied to $\boldsymbol{r}_1 \to \boldsymbol{r}_2$ and $\boldsymbol{r}_2 \to \boldsymbol{r}_3$, we obtain

$$\boldsymbol{r}_2 - \boldsymbol{r}_1 = \boldsymbol{\gamma}_1 \times (\boldsymbol{r}_2 + \boldsymbol{r}_1), \qquad \boldsymbol{r}_3 - \boldsymbol{r}_2 = \boldsymbol{\gamma}_2 \times (\boldsymbol{r}_3 + \boldsymbol{r}_2), \tag{1.10.20b}$$

respectively. Now, on these two basic equations we perform the following operations:

(i) We dot the first of the above with $\boldsymbol{\gamma}_1$ and the second with $\boldsymbol{\gamma}_2$:

$$\boldsymbol{\gamma}_1 \cdot (\boldsymbol{r}_2 - \boldsymbol{r}_1) = \boldsymbol{\gamma}_1 \cdot [\boldsymbol{\gamma}_1 \times (\boldsymbol{r}_2 + \boldsymbol{r}_1)] = 0 \ \Rightarrow\ \boldsymbol{\gamma}_1 \cdot \boldsymbol{r}_2 = \boldsymbol{\gamma}_1 \cdot \boldsymbol{r}_1, \tag{1.10.20c}$$

$$\boldsymbol{\gamma}_2 \cdot (\boldsymbol{r}_3 - \boldsymbol{r}_2) = \boldsymbol{\gamma}_2 \cdot [\boldsymbol{\gamma}_2 \times (\boldsymbol{r}_3 + \boldsymbol{r}_2)] = 0 \ \Rightarrow\ \boldsymbol{\gamma}_2 \cdot \boldsymbol{r}_3 = \boldsymbol{\gamma}_2 \cdot \boldsymbol{r}_2. \tag{1.10.20d}$$

(ii) We cross the first of (1.10.20b) with $\boldsymbol{\gamma}_2$ and the second with $\boldsymbol{\gamma}_1$ and subtract side by side:

$$\begin{aligned}
\boldsymbol{\gamma}_2 \times (\boldsymbol{r}_2 - \boldsymbol{r}_1) - \boldsymbol{\gamma}_1 \times (\boldsymbol{r}_3 - \boldsymbol{r}_2) &= (\boldsymbol{\gamma}_1 + \boldsymbol{\gamma}_2) \times \boldsymbol{r}_2 - \boldsymbol{\gamma}_2 \times \boldsymbol{r}_1 - \boldsymbol{\gamma}_1 \times \boldsymbol{r}_3 \\
&= \boldsymbol{\gamma}_2 \times [\boldsymbol{\gamma}_1 \times (\boldsymbol{r}_2 + \boldsymbol{r}_1)] - \boldsymbol{\gamma}_1 \times [\boldsymbol{\gamma}_2 \times (\boldsymbol{r}_3 + \boldsymbol{r}_2)] \\
&= \{\boldsymbol{\gamma}_1[\boldsymbol{\gamma}_2 \cdot (\boldsymbol{r}_2 + \boldsymbol{r}_1)] - (\boldsymbol{\gamma}_1 \cdot \boldsymbol{\gamma}_2)(\boldsymbol{r}_2 + \boldsymbol{r}_1)\} \\
&\qquad - \{\boldsymbol{\gamma}_2[\boldsymbol{\gamma}_1 \cdot (\boldsymbol{r}_3 + \boldsymbol{r}_2)] - (\boldsymbol{\gamma}_1 \cdot \boldsymbol{\gamma}_2)(\boldsymbol{r}_3 + \boldsymbol{r}_2)\}
\end{aligned}$$

[expanding, and then rearranging while taking into account (1.10.20c, d)]

$$\begin{aligned}
&= [(\boldsymbol{\gamma}_2 \cdot \boldsymbol{r}_2 + \boldsymbol{\gamma}_2 \cdot \boldsymbol{r}_1)\boldsymbol{\gamma}_1 - (\boldsymbol{\gamma}_1 \cdot \boldsymbol{\gamma}_2)\boldsymbol{r}_2 - (\boldsymbol{\gamma}_1 \cdot \boldsymbol{\gamma}_2)\boldsymbol{r}_1] \\
&\qquad - [(\boldsymbol{\gamma}_1 \cdot \boldsymbol{r}_3 + \boldsymbol{\gamma}_1 \cdot \boldsymbol{r}_2)\boldsymbol{\gamma}_2 - (\boldsymbol{\gamma}_1 \cdot \boldsymbol{\gamma}_2)\boldsymbol{r}_3 - (\boldsymbol{\gamma}_1 \cdot \boldsymbol{\gamma}_2)\boldsymbol{r}_2] \\
&= [(\boldsymbol{\gamma}_2 \cdot \boldsymbol{r}_3 + \boldsymbol{\gamma}_2 \cdot \boldsymbol{r}_1)\boldsymbol{\gamma}_1 - (\boldsymbol{\gamma}_1 \cdot \boldsymbol{\gamma}_2)\boldsymbol{r}_2 - (\boldsymbol{\gamma}_1 \cdot \boldsymbol{\gamma}_2)\boldsymbol{r}_1] \\
&\qquad - [(\boldsymbol{\gamma}_1 \cdot \boldsymbol{r}_3 + \boldsymbol{\gamma}_1 \cdot \boldsymbol{r}_1)\boldsymbol{\gamma}_2 - (\boldsymbol{\gamma}_1 \cdot \boldsymbol{\gamma}_2)\boldsymbol{r}_3 - (\boldsymbol{\gamma}_1 \cdot \boldsymbol{\gamma}_2)\boldsymbol{r}_2] \\
&= [(\boldsymbol{\gamma}_2 \cdot \boldsymbol{r}_3 + \boldsymbol{\gamma}_2 \cdot \boldsymbol{r}_1)\boldsymbol{\gamma}_1] - [(\boldsymbol{\gamma}_1 \cdot \boldsymbol{r}_3 + \boldsymbol{\gamma}_1 \cdot \boldsymbol{r}_1)\boldsymbol{\gamma}_2] - (\boldsymbol{\gamma}_1 \cdot \boldsymbol{\gamma}_2)(\boldsymbol{r}_1 - \boldsymbol{r}_3) \\
&= [(\boldsymbol{\gamma}_2 \cdot \boldsymbol{r}_1)\boldsymbol{\gamma}_1 - (\boldsymbol{\gamma}_1 \cdot \boldsymbol{r}_1)\boldsymbol{\gamma}_2] + [(\boldsymbol{\gamma}_2 \cdot \boldsymbol{r}_3)\boldsymbol{\gamma}_1 - (\boldsymbol{\gamma}_1 \cdot \boldsymbol{r}_3)\boldsymbol{\gamma}_2] \\
&\qquad - (\boldsymbol{\gamma}_1 \cdot \boldsymbol{\gamma}_2)(\boldsymbol{r}_1 - \boldsymbol{r}_3) \\
&= (\boldsymbol{\gamma}_2 \times \boldsymbol{\gamma}_1) \times \boldsymbol{r}_1 + (\boldsymbol{\gamma}_2 \times \boldsymbol{\gamma}_1) \times \boldsymbol{r}_3 - (\boldsymbol{\gamma}_1 \cdot \boldsymbol{\gamma}_2)(\boldsymbol{r}_1 - \boldsymbol{r}_3) \\
&= (\boldsymbol{\gamma}_2 \times \boldsymbol{\gamma}_1) \times (\boldsymbol{r}_1 + \boldsymbol{r}_3) + (\boldsymbol{\gamma}_1 \cdot \boldsymbol{\gamma}_2)(\boldsymbol{r}_3 - \boldsymbol{r}_1),
\end{aligned} \tag{1.10.20e}$$

or, equating the *right side of the first line* with the *last* line of (1.10.20e) and rearranging,

$$\begin{aligned}
(\boldsymbol{\gamma}_1 + \boldsymbol{\gamma}_2) \times \boldsymbol{r}_2 = \boldsymbol{\gamma}_2 \times \boldsymbol{r}_1 + \boldsymbol{\gamma}_1 \times \boldsymbol{r}_3& \\
+ (\boldsymbol{\gamma}_2 \times \boldsymbol{\gamma}_1) \times (\boldsymbol{r}_1 + \boldsymbol{r}_3) + (\boldsymbol{\gamma}_1 \cdot \boldsymbol{\gamma}_2)(\boldsymbol{r}_3 - \boldsymbol{r}_1)&.
\end{aligned} \tag{1.10.20f}$$

(iii) We add (1.10.20b) side by side and rearrange to obtain

$$\begin{aligned}
\boldsymbol{r}_3 - \boldsymbol{r}_1 = \boldsymbol{\gamma}_1 \times (\boldsymbol{r}_2 + \boldsymbol{r}_1) + \boldsymbol{\gamma}_2 \times (\boldsymbol{r}_3 + \boldsymbol{r}_2) = \boldsymbol{\gamma}_1 \times \boldsymbol{r}_2 + \boldsymbol{\gamma}_1 \times \boldsymbol{r}_1 + \boldsymbol{\gamma}_2 \times \boldsymbol{r}_3 + \boldsymbol{\gamma}_2 \times \boldsymbol{r}_2& \\
\Rightarrow\ (\boldsymbol{\gamma}_1 + \boldsymbol{\gamma}_2) \times \boldsymbol{r}_2 = \boldsymbol{r}_3 - \boldsymbol{r}_1 - \boldsymbol{\gamma}_1 \times \boldsymbol{r}_1 - \boldsymbol{\gamma}_2 \times \boldsymbol{r}_3&.
\end{aligned} \tag{1.10.20g}$$

(iv) Finally, equating the two expressions for $(\boldsymbol{\gamma}_1 + \boldsymbol{\gamma}_2) \times \boldsymbol{r}_2$, right sides of (1.10.20f) and (1.10.20g), and rearranging, we obtain the Rodrigues-like formula [i.e., à la (1.10.4b)]

$$\boldsymbol{r}_3 - \boldsymbol{r}_1 = \boldsymbol{\gamma}_{1,2} \cdot (\boldsymbol{r}_3 + \boldsymbol{r}_1), \tag{1.10.20h}$$

where

$$\gamma_{1,2} \equiv \gamma_{1\to 2} \equiv [\gamma_1 + \gamma_2 + \gamma_2 \times \gamma_1]/(1 - \gamma_1 \cdot \gamma_2)$$
$$= \textit{Resultant single rotation ``vector,'' that brings } \boldsymbol{r}_1 \textit{ to } \boldsymbol{r}_3. \quad (1.10.20\text{i})$$

This is the sought fundamental formula for the *composition of finite rigid rotations*. [For additional derivations of (1.10.20h, i) see, for example, Hamel (1949, pp. 107–117; via complex number representations and quaternions), Lur'e (1968, pp. 101–104; via spherical trigonometry); also, Ames and Murnaghan (1929, pp. 82–85). The above vectorial proof seems to be due to Coe (1938, p. 170); see also Fox (1967, p. 8); and, for a simpler proof, Chester (1979, pp. 246–248).]

In terms of the corresponding rotation tensors, we would have (with some ad hoc notations),

$$\boldsymbol{r}_i \to \boldsymbol{r}_{f'}: \qquad \boldsymbol{r}_{f'} = \boldsymbol{R}_1 \cdot \boldsymbol{r}_i\,, \quad (1.10.21\text{a})$$

$$\boldsymbol{r}_{f'} \to \boldsymbol{r}_f: \qquad \boldsymbol{r}_f = \boldsymbol{R}_2 \cdot \boldsymbol{r}_{f'} = \boldsymbol{R}_2 \cdot (\boldsymbol{R}_1 \cdot \boldsymbol{r}_i) \equiv \boldsymbol{R}_{1,2,} \cdot \boldsymbol{r}_i\,, \quad (1.10.21\text{b})$$

where

$$\boldsymbol{R}_{1,2} \equiv \boldsymbol{R}_2 \cdot \boldsymbol{R}_1 \qquad (\neq \boldsymbol{R}_1 \cdot \boldsymbol{R}_2 \equiv \boldsymbol{R}_{2,1}): \textit{resultant rotation}\ \text{tensor}. \quad (1.10.21\text{c})$$

REMARKS ON $\gamma_{1,2}$

(i) Equation (1.10.20i) readily shows that the γ's are *not* genuine vectors; as the presence of $\gamma_2 \times \gamma_1$ there makes clear [or the noncommutativity in (1.10.21c)], in general, *finite rotations are noncommutative*. Indeed, had we applied γ_2 first, and γ_1 second, the resultant would have been [swap the order of γ_1 and γ_2 in (1.10.20i)]

$$(\gamma_2 + \gamma_1 + \gamma_1 \times \gamma_2)/(1 - \gamma_2 \cdot \gamma_1) \equiv \gamma_{2,1} \equiv \gamma_{2\to 1} \neq \gamma_{1,2} \equiv \gamma_{1\to 2}. \quad (1.10.22\text{a})$$

For rotations to commute, like genuine vectors, the term $\gamma_2 \times \gamma_1$ must vanish, either exactly or approximately. The former happens for rotations about the *same* axis; and the latter for *infinitesimal* (i.e., linear) rotations: there, $\gamma_2 \times \gamma_1 =$ *second*-order quantity $\approx \mathbf{0}$.

(ii) If $\gamma_1 \cdot \gamma_2 = 1$, the composition formula (1.10.20i), obviously, fails. Then, the corresponding "resultant angle" $\chi_{1,2}$ is an integral multiple of π.

(iii) From (1.10.20i) it is not hard to show that

$$1/(1 + \gamma_{1,2}{}^2)^{1/2} = (1 - \gamma_2 \cdot \gamma_1)/[(1 + \gamma_1{}^2)^{1/2}(1 + \gamma_2{}^2)^{1/2}], \quad (1.10.22\text{b})$$

and combining this, again, with (1.10.20i) we readily obtain

$$\gamma_{1,2}/(1 + \gamma_{1,2}{}^2)^{1/2} = [\gamma_1 + \gamma_2 + \gamma_2 \times \gamma_1]/[(1 + \gamma_1{}^2)^{1/2}(1 + \gamma_2{}^2)^{1/2}] \quad (1.10.22\text{c})$$

[which is the formula for the vector part of a product of two (unit) quaternions; see Papastavridis (*Elementary Mechanics*, under production)].

Finite rotations may not be commutative, but they are *associative*: the sequence of rotations, expressed in terms of their γ vectors—for example, $\gamma_1 \to \gamma_2 \to \gamma_3$—can be achieved either by combining the resultant of $\gamma_1 \to \gamma_2$ with γ_3, or by combining γ_1 with the resultant of $\gamma_2 \to \gamma_3$. In view of this, the sequence $-\gamma_1 \to \gamma_1 \to \gamma_2$ is equivalent to the rotation γ_2, and also to the sequence $-\gamma_1 \to \gamma_{1,2}$. Therefore, if in the fundamental "addition" formula (1.10.20i) we make the following replacements:

$$\gamma_1 \to -\gamma_1, \qquad \gamma_2 \to \gamma_{1,2}, \qquad \gamma_{1,2} \to \gamma_2, \tag{1.10.23a}$$

we obtain the "subtraction" formula:

$$\gamma_2 = [-\gamma_1 + \gamma_{1,2} + \gamma_{1,2} \times (-\gamma_1)]\big/[1 - (-\gamma_1) \cdot \gamma_{1,2}], \tag{1.10.23b}$$

or, finally,

$$\gamma_2 = [\gamma_{1,2} - \gamma_1 + \gamma_1 \times \gamma_{1,2}]\big/(1 + \gamma_1 \cdot \gamma_{1,2}), \tag{1.10.23c}$$

which allows us to find the *second* rotation "vector" from a knowledge of the *first* and the *compounded* rotation "vectors." Similarly, to find γ_1 from γ_2 and $\gamma_{1,2}$, we consider the rotation sequence $\gamma_{1,2} \to -\gamma_2$, which, clearly, is equivalent to the rotation γ_1. Hence, with the following replacements:

$$\gamma_1 \to \gamma_{1,2}, \qquad \gamma_2 \to -\gamma_2, \qquad \gamma_{1,2} \to \gamma_1, \tag{1.10.23d}$$

in (1.10.20i) we obtain the "subtraction" formula:

$$\gamma_1 = (\gamma_{1,2} - \gamma_2 + \gamma_{1,2} \times \gamma_2)/(1 + \gamma_2 \cdot \gamma_{1,2}). \tag{1.10.23e}$$

With such simple (and obviously *nonunique*) geometrical arguments, we can avoid solving (1.10.20i) for γ_1, γ_2. (These results prove useful in relating γ to the angular velocity $\boldsymbol{\omega}$.)

Infinitesimal (Linearized) Rotations Commute

First, let us apply the infinitesimal rotation $\boldsymbol{\chi}_1$ to $\boldsymbol{r}_i$ [recalling (1.10.6d)]:

$$\boldsymbol{r}_i \to \boldsymbol{r}_1{}' = \boldsymbol{r}_i + d\boldsymbol{r}_i = \boldsymbol{r}_i + \boldsymbol{\chi}_1 \times \boldsymbol{r}_i. \tag{1.10.24a}$$

Next, let us apply $\boldsymbol{\chi}_2$ to $\boldsymbol{r}_1{}'$:

$$\begin{aligned} \boldsymbol{r}_1{}' \to \boldsymbol{r}_f{}' &= \boldsymbol{r}_1{}' + d\boldsymbol{r}_1{}' = \boldsymbol{r}_1{}' + \boldsymbol{\chi}_2 \times \boldsymbol{r}_1{}' \\ &= (\boldsymbol{r}_i + \boldsymbol{\chi}_1 \times \boldsymbol{r}_i) + \boldsymbol{\chi}_2 \times (\boldsymbol{r}_i + \boldsymbol{\chi}_1 \times \boldsymbol{r}_i) \\ &= \boldsymbol{r}_i + (\boldsymbol{\chi}_1 + \boldsymbol{\chi}_2) \times \boldsymbol{r}_i + \boldsymbol{\chi}_2 \times (\boldsymbol{\chi}_1 \times \boldsymbol{r}_i). \end{aligned} \tag{1.10.24b}$$

Reversing the order of the process — that is, applying $\boldsymbol{\chi}_2$ first to $\boldsymbol{r}_i$, and then $\boldsymbol{\chi}_1$ to the result — we obtain

$$\begin{aligned} \boldsymbol{r}_f{}'' = \boldsymbol{r}_1{}'' + d\boldsymbol{r}_1{}'' &= \boldsymbol{r}_1{}'' + \boldsymbol{\chi}_1 \times \boldsymbol{r}_1{}'' \\ &= (\boldsymbol{r}_i + \boldsymbol{\chi}_2 \times \boldsymbol{r}_i) + \boldsymbol{\chi}_1 \times (\boldsymbol{r}_i + \boldsymbol{\chi}_2 \times \boldsymbol{r}_i) \\ &= \boldsymbol{r}_i + (\boldsymbol{\chi}_2 + \boldsymbol{\chi}_1) \times \boldsymbol{r}_i + \boldsymbol{\chi}_1 \times (\boldsymbol{\chi}_2 \times \boldsymbol{r}_i); \end{aligned} \tag{1.10.24c}$$

and, therefore, subtracting (1.10.24c) from (1.10.24b) side by side, we obtain

$$\boldsymbol{r}_f{}' - \boldsymbol{r}_f{}'' = \boldsymbol{\chi}_2 \times (\boldsymbol{\chi}_1 \times \boldsymbol{r}_i) - \boldsymbol{\chi}_1 \times (\boldsymbol{\chi}_2 \times \boldsymbol{r}_i) = \textit{second-order} \text{ vector in } \boldsymbol{\chi}_1, \boldsymbol{\chi}_2; \tag{1.10.24d}$$

that is, to the *first order* in $\boldsymbol{\chi}_1$, $\boldsymbol{\chi}_2$:

$$\boldsymbol{r}_f{}' = \boldsymbol{r}_f{}'', \quad \text{Q.E.D.} \tag{1.10.24e}$$

Similarly, for an arbitrary number of infinitesimal rotations $\boldsymbol{\chi}_1, \boldsymbol{\chi}_2, \ldots,$ to the first order:

$$\boldsymbol{r}_f = \boldsymbol{r}_i + (\boldsymbol{\chi}_1 + \boldsymbol{\chi}_2 + \cdots) \times \boldsymbol{r}_i. \tag{1.10.24f}$$

Angular Velocity

(i) Angular Velocity from Finite Rotation

Expanding the rotation tensor (1.10.10e) [with (1.10.9b)] in powers of $\gamma_{X,Y,Z}$, and since (with customary calculus notations)

$$\boldsymbol{\gamma} \equiv \tan(\chi/2)\boldsymbol{n} = (\chi/2)\boldsymbol{n} + \boldsymbol{O}(\chi^3) = \boldsymbol{\chi}/2 + \boldsymbol{O}(\chi^3), \tag{1.10.25a}$$

we find

$$\boldsymbol{R} = \begin{pmatrix} 1 & -2\gamma_Z & 2\gamma_Y \\ 2\gamma_Z & 1 & -2\gamma_X \\ -2\gamma_Y & 2\gamma_X & 1 \end{pmatrix} + \boldsymbol{O}(\gamma^2)$$

[*Linear* rotation tensor $\equiv \boldsymbol{R}_\text{o}$]

$$= \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} + \begin{pmatrix} 0 & -2\gamma_Z & 2\gamma_Y \\ 2\gamma_Z & 0 & -2\gamma_X \\ -2\gamma_Y & 2\gamma_X & 0 \end{pmatrix} + \boldsymbol{O}(\gamma^2)$$

[*Identity* tensor] [*Linear* rotator tensor $\equiv \boldsymbol{R}_\text{o}{}'$ (recall (1.10.10d, 15d))]

(1.10.25b)

$$= \boldsymbol{1} + \begin{pmatrix} 0 & -n_Z & n_Y \\ n_Z & 0 & -n_X \\ -n_Y & n_X & 0 \end{pmatrix} \chi + \boldsymbol{O}(\chi^2), \tag{1.10.25c}$$

$$= \boldsymbol{1} + \begin{pmatrix} 0 & -\chi_Z & \chi_Y \\ \chi_Z & 0 & -\chi_X \\ -\chi_Y & \chi_X & 0 \end{pmatrix} + \boldsymbol{O}(\chi^2); \tag{1.10.25d}$$

and, with the notations

$$\boldsymbol{r}_i = (X, Y, Z) \equiv \boldsymbol{r},$$
$$\boldsymbol{r}_f = \boldsymbol{r}_i + \Delta\boldsymbol{r}_i = (X + \Delta X, Y + \Delta Y, Z + \Delta Z) \equiv \boldsymbol{r} + \Delta\boldsymbol{r}, \tag{1.10.25e}$$

we obtain, to the first order in the rotation angle,

$$\boldsymbol{r} + \Delta\boldsymbol{r} = \boldsymbol{R}_\text{o} \cdot \boldsymbol{r} = (\boldsymbol{1} + \boldsymbol{R}_\text{o}{}') \cdot \boldsymbol{r} \Rightarrow \Delta\boldsymbol{r} = \boldsymbol{R}_\text{o}{}' \cdot \boldsymbol{r}, \tag{1.10.25f1}$$

or, in extenso,

$$\begin{pmatrix} \Delta X \\ \Delta Y \\ \Delta Z \end{pmatrix} = \begin{pmatrix} 0 & -\chi_Z & \chi_Y \\ \chi_Z & 0 & -\chi_X \\ -\chi_Y & \chi_X & 0 \end{pmatrix} \begin{pmatrix} X \\ Y \\ Z \end{pmatrix}. \qquad (1.10.25\text{f}2)$$

This basic kinematical result states that *any orthogonal tensor that differs infinitesimally from the identity tensor, that is, to within linear terms, differs from it by an antisymmetric tensor*.

Finally, dividing (1.10.25f1, 2) by Δt, during which $\Delta \boldsymbol{r}$ occurs, assuming continuity and with the following notations:

$$\lim(\Delta X/\Delta t)\big|_{\Delta t\to 0} = dX/dt \equiv v_X,\ \text{etc.}, \qquad \lim(\chi_X/\Delta t)\big|_{\Delta t\to 0} \equiv \omega_X,\ \text{etc.},$$

we obtain the earlier found (1.9.1) fundamental *kinematical equation of Poisson*:

$$\begin{pmatrix} v_X \\ v_Y \\ v_Z \end{pmatrix} = \begin{pmatrix} 0 & -\omega_Z & \omega_Y \\ \omega_Z & 0 & -\omega_X \\ -\omega_Y & \omega_X & 0 \end{pmatrix} \begin{pmatrix} X \\ Y \\ Z \end{pmatrix}; \qquad (1.10.25\text{g})$$

or, in direct notation,

$$\boldsymbol{v} \equiv d\boldsymbol{r}/dt = \boldsymbol{\Omega}\cdot\boldsymbol{r} = \boldsymbol{\omega}\times\boldsymbol{r}, \qquad (1.10.25\text{h})$$

where

$$\boldsymbol{\Omega} \equiv \lim(\boldsymbol{R}_\text{o}'/\Delta t)\big|_{\Delta t\to 0}: \qquad \textit{angular velocity tensor}, \qquad (1.10.25\text{i})$$

$$\boldsymbol{\omega} \equiv \lim(2\boldsymbol{\gamma}/\Delta t)\big|_{\Delta t\to 0}: \qquad \textit{angular velocity vector}$$

$$(\textit{axial vector of } \boldsymbol{\Omega} \textit{ — a genuine vector!}). \qquad (1.10.25\text{j})$$

As shown below [(1.10.26f)], (a) the velocities of the points of a rigid body moving with one point fixed are, at any instant, the same as they would be if the body were rotating in the positive sense about a fixed axis through the fixed point, in the direction and sense of $\boldsymbol{\omega}$ and with an *angular speed* equal to $|\boldsymbol{\omega}|$; and, (b) since both $\boldsymbol{r}$ and $\boldsymbol{v}$ are genuine vectors, so is $\boldsymbol{\omega}$ (a fact that is re-established below). From all existing definitions of the angular velocity, this seems to be the most natural; but, in return, requires knowledge of finite rotation.

(ii) $\boldsymbol{\omega}$ is a Genuine Vector

Using the Rodrigues equation (1.10.4b):

$$\boldsymbol{r}_f - \boldsymbol{r}_i = \boldsymbol{\gamma}\times(\boldsymbol{r}_i + \boldsymbol{r}_f), \qquad (1.10.26\text{a})$$

let us prove directly that the angular velocity $\boldsymbol{\omega}$, defined as

$$\boldsymbol{\omega} \equiv \lim(2\boldsymbol{\gamma}/\Delta t)\big|_{\Delta t\to 0}, \qquad \text{where} \quad \boldsymbol{\gamma} \equiv \tan(\chi/2)\boldsymbol{n}, \qquad (1.10.26\text{b})$$

is a genuine vector, even though $\boldsymbol{\gamma}$ is not.

PROOF

With this in mind, we introduce the following judicious renamings:

$$\boldsymbol{r}_i = \boldsymbol{r}, \qquad \boldsymbol{r}_f = \boldsymbol{r}_i + \Delta\boldsymbol{r} = \boldsymbol{r} + \Delta\boldsymbol{r}. \qquad (1.10.26\text{c})$$

Then, eq. (1.10.26a) yields

$$\Delta\boldsymbol{r} = \boldsymbol{\gamma} \times [(\boldsymbol{r} \times \Delta\boldsymbol{r}) + \boldsymbol{r}] = \boldsymbol{\gamma} \times (2\boldsymbol{r} + \Delta\boldsymbol{r}) = (2\boldsymbol{\gamma}) \times (\boldsymbol{r} + \Delta\boldsymbol{r}/2). \tag{1.10.26d}$$

Dividing both sides of the above by Δt, and then letting $\Delta t \to 0$ (while assuming existence of a unique limit as $\Delta\boldsymbol{r} \to \boldsymbol{0}$), we obtain

$$\begin{aligned} \boldsymbol{v} &\equiv \lim(\Delta\boldsymbol{r}/\Delta t)\big|_{\Delta t\to 0} = \lim[(2\boldsymbol{\gamma}/\Delta t) \times \boldsymbol{r}]\big|_{\Delta t\to 0} + \lim[2\boldsymbol{\gamma} \times (\Delta\boldsymbol{r}/2)]\big|_{\Delta t\to 0} \\ &= \boldsymbol{\omega} \times \boldsymbol{r} + \boldsymbol{0} = \boldsymbol{\omega} \times \boldsymbol{r} \quad (\boldsymbol{v}, \boldsymbol{r} : \text{vectors} \Rightarrow \boldsymbol{\omega} : \text{vector}); \text{Q.E.D.} \end{aligned} \tag{1.10.26e}$$

The physical significance of $\boldsymbol{\omega}$ is understood by examination of the following case: $\dot{\chi} =$ constant, in the direction and sense of the constant unit vector $\boldsymbol{n}$. Then, with $\chi \to \dot{\chi}\,\Delta t \Rightarrow \boldsymbol{\gamma} = [\tan(\dot{\chi}\,\Delta t/2)]\boldsymbol{n}$, and so (1.10.26b) specializes to:

$$\boldsymbol{\omega} = \lim(2\boldsymbol{\gamma}/\Delta t)\big|_{\Delta t\to 0} = \boldsymbol{n} \lim\left\{\frac{2[\tan(\dot{\chi}\,\Delta t/2)]}{\Delta t}\right\}_{\Delta t\to 0} = \cdots = \dot{\chi}\boldsymbol{n}; \tag{1.10.26f}$$

i.e., here, $\boldsymbol{\omega}$ has the direction and sense of $\boldsymbol{n}$ (= instantaneous rotation axis), and length equal to the angular speed. Hence, Poisson's formula, (1.10.25h), allows us to draw the conclusions following (1.10.25j).

To complete the proof, let us next show that the line segments $\boldsymbol{\omega}$ indeed commute. Dividing the composition of rotations equation (1.10.20i)

$$\boldsymbol{\gamma}_3 \equiv \boldsymbol{\gamma}_{1,2} = (\boldsymbol{\gamma}_1 + \boldsymbol{\gamma}_2 + \boldsymbol{\gamma}_2 \times \boldsymbol{\gamma}_1)\big/(1 - \boldsymbol{\gamma}_1 \cdot \boldsymbol{\gamma}_2) \tag{1.10.26g}$$

by $\Delta t/2$, we get

$$\begin{aligned} 2\boldsymbol{\gamma}_3/\Delta t = \big[&2\boldsymbol{\gamma}_1/\Delta t + 2\boldsymbol{\gamma}_2/\Delta t \\ &+ (\Delta t/2)(2\boldsymbol{\gamma}_2/\Delta t) \times (2\boldsymbol{\gamma}_1/\Delta t)\big]\big/\big[1 - (\Delta t/2)^2(2\boldsymbol{\gamma}_2/\Delta t) \cdot (2\boldsymbol{\gamma}_1/\Delta t)\big]; \end{aligned}$$

and then letting $\Delta t \to 0$, while recalling the earlier $\boldsymbol{\omega}$-definition (1.10.26b, f), we find

$$\boldsymbol{\omega}_3 \equiv \boldsymbol{\omega}_{1,2} = \boldsymbol{\omega}_1 + \boldsymbol{\omega}_2 = \boldsymbol{\omega}_2 + \boldsymbol{\omega}_1 \equiv \boldsymbol{\omega}_{2,1}, \tag{1.10.26h}$$

that is, simultaneous $\boldsymbol{\omega}$'s obey the parallelogram law for their addition and decomposition, Q.E.D.

(iii) $\boldsymbol{\omega} \leftrightarrow \boldsymbol{\gamma}$ Differential Equation

Let us consider a rigid body B with the fixed point O. Its instantaneous angular velocity $\boldsymbol{\omega}$ is related to its Gibbs "vector" $\boldsymbol{\gamma}$, which carries a typical B-particle

$$\text{from} \quad \boldsymbol{r}_i \equiv \boldsymbol{r}(t) \quad \text{to} \quad \boldsymbol{r}_f \equiv \boldsymbol{r}(t + \Delta t), \tag{1.10.27a}$$

by a differential equation. The latter is obtained as follows: in the composition of rotations equation (1.10.20i) and in order to create the difference $\Delta\boldsymbol{\gamma}$ there, we choose the rotation sequence

$$\boldsymbol{\gamma}_1 = -\boldsymbol{\gamma} \;\to\; \boldsymbol{\gamma}_2 = \boldsymbol{\gamma} + \Delta\boldsymbol{\gamma}, \tag{1.10.27b}$$

which, clearly, is equivalent to the single rotation $\gamma_{1,2} = \Delta\gamma$, and occurs in time Δt. With these identifications in (1.10.20i), the earlier angular velocity definition yields

$$\begin{aligned}
\boldsymbol{\omega} &= \lim(2\Delta\gamma/\Delta t)\big|_{\Delta t \to 0} = 2\{\lim(\Delta\gamma/\Delta t)\big|_{\Delta t\to 0}\} \\
&= 2\lim\big[(1/\Delta t)\{[(-\gamma) + (\gamma + \Delta\gamma) + (\gamma \times \Delta\gamma)]\big/[1 - (-\gamma)\cdot(\gamma + \Delta\gamma)]\}\big]\big|_{\Delta t\to 0} \\
&= 2\lim\{\big[(\Delta\gamma/\Delta t) + \gamma \times (\Delta\gamma/\Delta t)\big]\big/\big[1 + \gamma\cdot\gamma + \gamma\cdot\Delta\gamma\big]\}\big|_{\Delta t\to 0},
\end{aligned}$$

or, finally,

$$\boldsymbol{\omega} = [2/(1+\gamma^2)][d\gamma/dt + \gamma \times (d\gamma/dt)]. \tag{1.10.27c}$$

This remarkable formula, due to A. Cayley (*Cambridge and Dublin J.*, vol. 1, 1846), shows that, in general, $\boldsymbol{\omega}$ and $d\gamma/dt$ are not parallel!

REMARK

Equation (1.10.27c) also results if we apply to the formula for the subtraction of rotations (1.10.23c), the sequence

$$\gamma_1 = \gamma - \Delta\gamma \ \rightarrow \ \gamma_2 = \Delta\gamma', \tag{1.10.27d}$$

which is equivalent to $\gamma_{1,2} = \gamma$. Thus, we obtain

$$\begin{aligned}
\Delta\gamma' &= [\gamma - (\gamma - \Delta\gamma) + (\gamma - \Delta\gamma) \times \gamma]\big/[1 + (\gamma - \Delta\gamma)\cdot\gamma] \\
&= (\Delta\gamma + \gamma \times \Delta\gamma)\big/(1 + \gamma^2 - \gamma\cdot\Delta\gamma),
\end{aligned} \tag{1.10.27e}$$

then divide by Δt and take the limit as $\Delta t \to 0$ to obtain

$$\begin{aligned}
\boldsymbol{\omega} &= 2\lim(\Delta\gamma'/\Delta t)\big|_{\Delta t\to 0} \\
&= 2\big\{[\lim(\Delta\gamma/\Delta t) + \gamma \times \lim(\Delta\gamma/\Delta t)]\big/(1 + \gamma^2 - \gamma\cdot\Delta\gamma)\big\}\big|_{\Delta t\to 0} \\
&= [2/(1+\gamma^2)][d\gamma/dt + \gamma \times (d\gamma/dt)],
\end{aligned} \tag{1.10.27f}$$

as before. The reader may verify that the sequence $\gamma_1 = \gamma \rightarrow \gamma_2 = \Delta\gamma'$, which is equivalent to $\gamma_{1,2} = \gamma + \Delta\gamma$, also leads to the same formula.

(iv) Inversion of the Preceding Formula $\boldsymbol{\omega} = \boldsymbol{\omega}(\gamma, d\gamma/dt)$

First Derivation. Dotting both sides of that equation, (1.10.27c), by γ yields

$$\gamma\cdot\boldsymbol{\omega} = [2/(1+\gamma^2)][\gamma\cdot(d\gamma/dt)]; \tag{1.10.28a}$$

while crossing it with γ gives

$$\begin{aligned}
\gamma \times \boldsymbol{\omega} &= [2/(1+\gamma^2)]\big\{\gamma \times (d\gamma/dt) + \gamma \times [\gamma \times (d\gamma/dt)]\big\} \\
&= [2/(1+\gamma^2)]\big\{\gamma \times (d\gamma/dt) + [\gamma\cdot(d\gamma/dt)]\gamma - \gamma^2(d\gamma/dt)\big\}.
\end{aligned} \tag{1.10.28b}$$

Eliminating $\boldsymbol{\gamma}\cdot(d\boldsymbol{\gamma}/dt)$ between (1.10.28a, b) produces

$$\begin{aligned}\boldsymbol{\gamma}\times\boldsymbol{\omega} &= [2/(1+\gamma^2)]\boldsymbol{\gamma}\times(d\boldsymbol{\gamma}/dt)\\ &\quad - [2\gamma^2/(1+\gamma^2)](d\boldsymbol{\gamma}/dt) + (\boldsymbol{\gamma}\cdot\boldsymbol{\omega})\boldsymbol{\gamma}\\ &\qquad \text{[expressing the } \textit{first} \text{ right-side term of the above via (1.10.27c)]}\\ &= \{\boldsymbol{\omega} - [2/(1+\gamma^2)](d\boldsymbol{\gamma}/dt)\} - [2\gamma^2/(1+\gamma^2)](d\boldsymbol{\gamma}/dt) + (\boldsymbol{\gamma}\cdot\boldsymbol{\omega})\boldsymbol{\gamma}\\ &= \boldsymbol{\omega} - 2(d\boldsymbol{\gamma}/dt) + (\boldsymbol{\gamma}\cdot\boldsymbol{\omega})\boldsymbol{\gamma}, \end{aligned}\tag{1.10.28c}$$

or, rearranging, finally gives

$$2(d\boldsymbol{\gamma}/dt) = \boldsymbol{\omega} + (\boldsymbol{\gamma}\cdot\boldsymbol{\omega})\boldsymbol{\gamma} + \boldsymbol{\omega}\times\boldsymbol{\gamma}; \tag{1.10.28d}$$

which, for a given $\boldsymbol{\omega}(t)$, is a vector *first-order nonlinear* (*second-degree*) differential equation for $\boldsymbol{\gamma}(t)$ (and can be further reduced to a "Ricatti-type equation").

Equations (1.10.27d), and (1.10.27c) clearly demonstrate the one-to-one relation between $\boldsymbol{\omega}$ and $d\boldsymbol{\gamma}/dt$: *if one of them vanishes, so does the other*.

Second Derivation. Applying the earlier rotation sequence

$$\boldsymbol{\gamma}_1 = \boldsymbol{\gamma} \to \boldsymbol{\gamma}_2 = \Delta\boldsymbol{\gamma}', \tag{1.10.28e}$$

which is equivalent to $\boldsymbol{\gamma}_{1,2} = \boldsymbol{\gamma} + \Delta\boldsymbol{\gamma}$, both occurring in time Δt, to the composition formula (1.10.20i) we obtain

$$\boldsymbol{\gamma} + \Delta\boldsymbol{\gamma} = (\boldsymbol{\gamma} + \Delta\boldsymbol{\gamma}' + \Delta\boldsymbol{\gamma}'\times\boldsymbol{\gamma})\big/(1 - \Delta\boldsymbol{\gamma}'\cdot\boldsymbol{\gamma}), \tag{1.10.28f}$$

from which, subtracting $\boldsymbol{\gamma}$, we get

$$\Delta\boldsymbol{\gamma} = [\Delta\boldsymbol{\gamma}' + (\boldsymbol{\gamma}\cdot\Delta\boldsymbol{\gamma}')\boldsymbol{\gamma} + \Delta\boldsymbol{\gamma}'\times\boldsymbol{\gamma}]\big/(1 - \boldsymbol{\gamma}\cdot\Delta\boldsymbol{\gamma}'), \tag{1.10.28g}$$

and from this, dividing by Δt and taking the limit as $\Delta t \to 0$, while recalling that [eq. (1.10.27f)] $\boldsymbol{\omega} = 2\lim(\Delta\boldsymbol{\gamma}'/\Delta t)|_{\Delta t\to 0}$, we re-obtain (1.10.28d).

For still alternative derivations of the $\boldsymbol{\omega} \leftrightarrow \boldsymbol{\gamma}$ equations, via the compatibility of the Eulerian kinematic relation $\boldsymbol{v} \equiv d\boldsymbol{r}/dt = \boldsymbol{\omega}\times\boldsymbol{r}$ with the $d/dt(\ldots)$-derivative of the finite rotation equation $\boldsymbol{r}_f = \boldsymbol{r}_f\,(\gamma;\, \boldsymbol{r}_i)$ [eqs. (1.10.2–4)], see, for example (alphabetically): Coe (1938, chap. 5; best elementary/vectorial treatment), Ferrarese (1980, pp. 122–137), Hamel (1949, pp. 106–107; pp. 391–393).

(v) Additional Useful Results

(a) Starting with

$$\begin{aligned}&\boldsymbol{\gamma} = \boldsymbol{n}\tan(\chi/2)\\ &\Rightarrow d\boldsymbol{\gamma}/dt = (d\boldsymbol{n}/dt)\tan(\chi/2) + \boldsymbol{n}[(d\chi/dt)/2]\sec^2(\chi/2), \quad \text{etc.,}\end{aligned}$$

and then using the $\boldsymbol{\omega} \leftrightarrow \boldsymbol{\gamma}$ equation, we can show that

$$\boldsymbol{\omega} = (d\chi/dt)\boldsymbol{n} + (\sin\chi)(d\boldsymbol{n}/dt) + (1-\cos\chi)\boldsymbol{n}\times(d\boldsymbol{n}/dt). \tag{1.10.29a}$$

(What happens if $\boldsymbol{n} = constant$?)

(b) Again, starting with

$$\boldsymbol{\gamma} = \boldsymbol{n}\tan(\chi/2) = \tan(\chi/2)(\boldsymbol{\chi}/\chi) = [\tan(\chi/2)/\chi]\boldsymbol{\chi} \;\Rightarrow\; d\boldsymbol{\gamma}/dt = \cdots, \text{etc.},$$

and then using the $\boldsymbol{\omega} \leftrightarrow \boldsymbol{\gamma}$ equation, we can show that

$$\begin{aligned}\boldsymbol{\omega} &= (\sin\chi/\chi)(d\boldsymbol{\chi}/dt) + [(1-\cos\chi)/\chi^2][\boldsymbol{\chi}\times(d\boldsymbol{\chi}/dt)] \\ &\qquad + [(1/\chi) - (\sin\chi/\chi^2)](d\chi/dt)\boldsymbol{\chi} \\ &= d\boldsymbol{\chi}/dt + [(1-\cos\chi)/\chi^2][\boldsymbol{\chi}\times(d\boldsymbol{\chi}/dt)] \\ &\qquad + [(\chi - \sin\chi)/\chi^3]\{\boldsymbol{\chi}\times[\boldsymbol{\chi}\times(d\boldsymbol{\chi}/dt)]\}. \end{aligned} \tag{1.10.29b}$$

(c) By inverting (1.10.29b), we can show that

$$d\boldsymbol{\chi}/dt = \boldsymbol{\omega} - (\boldsymbol{\chi}\times\boldsymbol{\omega})/2 + (1/\chi^2)[1-(\chi/2)\cot(\chi/2)][\boldsymbol{\chi}\times(\boldsymbol{\chi}\times\boldsymbol{\omega})]\,. \tag{1.10.29c}$$

More in our *Elementary Mechanics* (§13.8 — under production).

General Rigid-Body Displacement (i.e., no point fixed)

We have already seen (§1.9) that the most general rigid-body displacement can be effected by the translation of an arbitrary *base point* or *pole* of it, from its initial to its final position, followed by a rotation about an axis through the final position of that point (see figs 1.12 and 1.22). Here, we show that *the translational part of the above total displacement does depend on the base point, but the rotational part — that is, the rotation tensor — does not.*

Referring to fig. 1.22, let

$$\boldsymbol{11'} \equiv \boldsymbol{r}_{1'/1}\,,\qquad \boldsymbol{PP''} \equiv \boldsymbol{r}_{f/i}\,,\qquad \boldsymbol{1P} \equiv \boldsymbol{r}_{/1}\,,\qquad \boldsymbol{1'P'} \equiv \boldsymbol{r}_{/1'}\,,\qquad \boldsymbol{1''P''} \equiv \boldsymbol{1'P''} \equiv \boldsymbol{r}_{/1''},$$

$$\boldsymbol{R}_1 \equiv \text{rotation tensor bringing } \boldsymbol{1'P'} \text{ to } \boldsymbol{1'P''};\ \text{i.e., } \boldsymbol{r}_{/1''} = \boldsymbol{R}_1\cdot\boldsymbol{r}_{/1'}. \tag{1.10.30a}$$

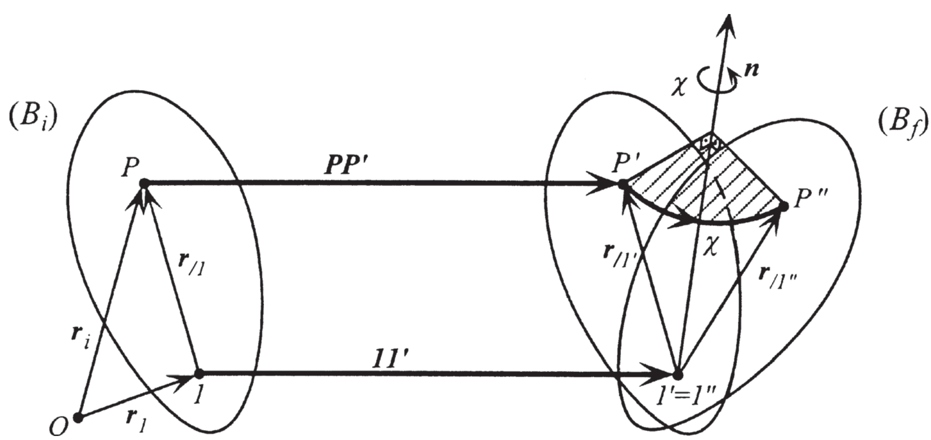

Figure 1.22 Most general rigid-body displacement; the rotation tensor is independent of the base point (or pole).

$\boldsymbol{r}_{/1} \to \boldsymbol{r}_{/1'} \to \boldsymbol{r}_{/1''} = \boldsymbol{R}_1\cdot\boldsymbol{r}_{/1'}$;

$\boldsymbol{r}_i = \boldsymbol{r}_1 + \boldsymbol{r}_{/1} \to \boldsymbol{r}_{i'} = \boldsymbol{r}_{1'} + \boldsymbol{r}_{/1'} \to \boldsymbol{r}_f = \boldsymbol{r}_{1''} + \boldsymbol{r}_{/1''} = \boldsymbol{r}_{1''} + \boldsymbol{R}_1\cdot\boldsymbol{r}_{/1'}$ $(\boldsymbol{r}_{1'} = \boldsymbol{r}_{1''})$.

Then, successively,

$$\boldsymbol{PP''} = \boldsymbol{P1} + \boldsymbol{11'} + \boldsymbol{1'P''} = -\boldsymbol{r}_{/1} + \boldsymbol{r}_{1'/1} + \boldsymbol{R}_1 \cdot \boldsymbol{r}_{/1'}\,, \tag{1.10.30b}$$

or since $\boldsymbol{1P} = \boldsymbol{1'P'}$ (i.e., $\boldsymbol{r}_{/1} = \boldsymbol{r}_{/1'}$),

$$\boldsymbol{r}_{f/i} = \boldsymbol{r}_{1'/1} + (\boldsymbol{R}_1 - \boldsymbol{1}) \cdot \boldsymbol{r}_{/1}\,. \tag{1.10.30c}$$

Had we chosen another base point, say 2, then reasoning as above we would have found (with some easily understood notations)

$$\boldsymbol{r}_{f/i} = \boldsymbol{r}_{2'/2} + (\boldsymbol{R}_2 - \boldsymbol{1}) \cdot \boldsymbol{r}_{/2}\,. \tag{1.10.30d}$$

But also, applying (1.10.30c) for $P = 2$, we have (since $\boldsymbol{r}_{2'} = \boldsymbol{r}_{2''}$)

$$\boldsymbol{r}_{2'/2} = \boldsymbol{r}_{1'/1} + (\boldsymbol{R}_1 - \boldsymbol{1}) \cdot \boldsymbol{r}_{2/1}\,. \tag{1.10.30e}$$

Therefore, substituting (1.10.30e) in (1.10.30d) and equating its right side to that of (1.10.30c), we obtain

$$\boldsymbol{r}_{1'/1} + (\boldsymbol{R}_1 - \boldsymbol{1}) \cdot \boldsymbol{r}_{2/1} + (\boldsymbol{R}_2 - \boldsymbol{1}) \cdot \boldsymbol{r}_{/2} = \boldsymbol{r}_{1'/1} + (\boldsymbol{R}_1 - \boldsymbol{1}) \cdot \boldsymbol{r}_{/1}\,,$$

from which, rearranging, we get

$$(\boldsymbol{R}_1 - \boldsymbol{1}) \cdot (\boldsymbol{r}_{/1} - \boldsymbol{r}_{2/1}) \equiv (\boldsymbol{R}_1 - \boldsymbol{1}) \cdot \boldsymbol{r}_{/2} = (\boldsymbol{R}_2 - \boldsymbol{1}) \cdot \boldsymbol{r}_{/2}\,, \tag{1.10.30f}$$

and since this must hold for all body point pairs P and 2 (i.e., it must be an identity in them), we finally conclude that

$$\boldsymbol{R}_1 = \boldsymbol{R}_2 = \cdots \equiv \boldsymbol{R}\,. \tag{1.10.30g}$$

In words: the rotation tensor is independent of the chosen base point; it is a *position-independent tensor*. This fundamental theorem simplifies rigid-body geometry enormously and brings out the intrinsic character of rotation. (In *kinetics*, however, as the reader probably knows, such a decoupling between translation and rotation is far more selective.)

1.11 THE RIGID BODY: ACTIVE AND PASSIVE INTERPRETATIONS OF A PROPER ORTHOGONAL TENSOR; SUCCESSIVE FINITE ROTATIONS

A 3×3 proper orthogonal tensor may be interpreted in the following consistent ways:

(i) As the matrix of the direction cosines orienting two orthonormal and dextral (OND) triads, or bases, and associated axes; say, a *body-fixed*, or *moving*, triad $\mathbf{t}$:

$$\mathbf{t} \equiv (\boldsymbol{u}_k) \equiv \begin{pmatrix} \boldsymbol{u}_1 \\ \boldsymbol{u}_2 \\ \boldsymbol{u}_3 \end{pmatrix} \equiv \begin{pmatrix} \boldsymbol{u}_x \\ \boldsymbol{u}_y \\ \boldsymbol{u}_z \end{pmatrix} \equiv \begin{pmatrix} \boldsymbol{i} \\ \boldsymbol{j} \\ \boldsymbol{k} \end{pmatrix}, \tag{1.11.1a}$$

relative to a *space-fixed* triad $\mathbf{T}$:

$$\mathbf{T} \equiv (\boldsymbol{u}_{k'}) \equiv \begin{pmatrix} \boldsymbol{u}_{1'} \\ \boldsymbol{u}_{2'} \\ \boldsymbol{u}_{3'} \end{pmatrix} \equiv \begin{pmatrix} \boldsymbol{u}_X \\ \boldsymbol{u}_Y \\ \boldsymbol{u}_Z \end{pmatrix} \equiv \begin{pmatrix} \boldsymbol{I} \\ \boldsymbol{J} \\ \boldsymbol{K} \end{pmatrix}. \tag{1.11.1b}$$

(ii) Then, since

$$\boldsymbol{I} = (\boldsymbol{I}\cdot\boldsymbol{i})\boldsymbol{i} + (\boldsymbol{I}\cdot\boldsymbol{j})\boldsymbol{j} + (\boldsymbol{I}\cdot\boldsymbol{k})\boldsymbol{k} \equiv A_{Xx}\boldsymbol{i} + A_{Xy}\boldsymbol{j} + A_{Xz}\boldsymbol{k}, \quad \text{etc., cyclically,}$$

$$\boldsymbol{i} = (\boldsymbol{i}\cdot\boldsymbol{I})\boldsymbol{I} + (\boldsymbol{i}\cdot\boldsymbol{J})\boldsymbol{J} + (\boldsymbol{i}\cdot\boldsymbol{K})\boldsymbol{K} \equiv A_{Xx}\boldsymbol{I} + A_{Yx}\boldsymbol{J} + A_{Zx}\boldsymbol{K}, \quad \text{etc., cyclically,}$$

the two triads are related by

$$\mathbf{T} = \mathbf{A}\cdot\mathbf{t} \;\Leftrightarrow\; \mathbf{t} = \mathbf{A}^{-1}\cdot\mathbf{T} = \mathbf{A}^{\mathrm{T}}\cdot\mathbf{T}, \tag{1.11.1c}$$

where

$$\mathbf{A} \equiv \begin{pmatrix} \boldsymbol{I}\cdot\boldsymbol{i} & \boldsymbol{I}\cdot\boldsymbol{j} & \boldsymbol{I}\cdot\boldsymbol{k} \\ \boldsymbol{J}\cdot\boldsymbol{i} & \boldsymbol{J}\cdot\boldsymbol{j} & \boldsymbol{J}\cdot\boldsymbol{k} \\ \boldsymbol{K}\cdot\boldsymbol{i} & \boldsymbol{K}\cdot\boldsymbol{j} & \boldsymbol{K}\cdot\boldsymbol{k} \end{pmatrix} \equiv \begin{pmatrix} A_{Xx} & A_{Xy} & A_{Xz} \\ A_{Yx} & A_{Yy} & A_{Yz} \\ A_{Zx} & A_{Zy} & A_{Zz} \end{pmatrix} \tag{1.11.1d}$$

$$= (A_{k'k}), \quad A_{k'k} \equiv \cos(x_{k'}, x_k) = \boldsymbol{u}_{k'}\cdot\boldsymbol{u}_k \;\; [= \cos(x_k, x_{k'}) = A_{kk'}]. \tag{1.11.1e}$$

The rotation of an OND triad, equation (1.11.1c), $\mathbf{T} \to \mathbf{t}$, constitutes the *second* interpretation of a proper orthogonal tensor.

(iii) The *third* such interpretation is that of a *coordinate* transformation from the $\mathbf{T}$-axes: O–$x_{k'} \equiv O$–XYZ to the $\mathbf{t}$-axes: O–$x_k \equiv O$–xyz (of common origin, with no loss in generality). In this interpretation, known as *passive* or *alias* (meaning otherwise known as), the point P is fixed in $\mathbf{T}$-space and the $\mathbf{t}$-axes rotate. Then [fig. 1.23(a)],

$$\boldsymbol{OP} \equiv \boldsymbol{r} = \sum x_{k'}\boldsymbol{u}_{k'} = X\boldsymbol{I} + Y\boldsymbol{J} + Z\boldsymbol{K} = \sum x_k\boldsymbol{u}_k = x\boldsymbol{i} + y\boldsymbol{j} + z\boldsymbol{k}, \tag{1.11.2a}$$

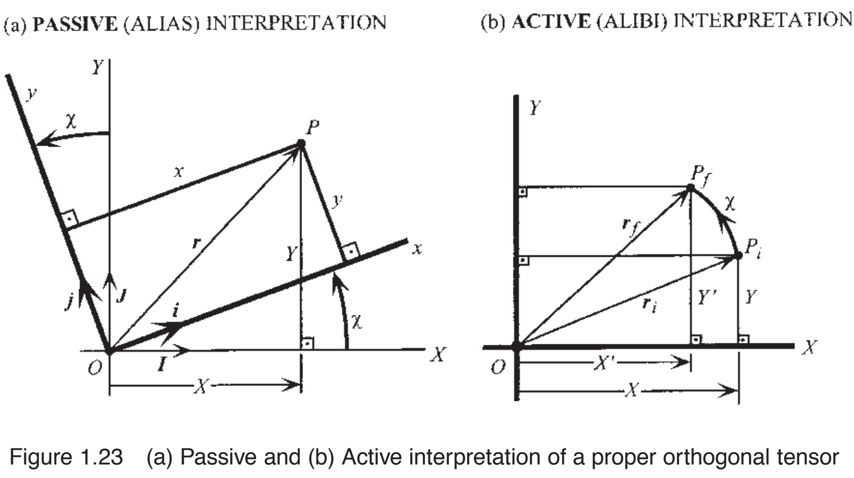

Figure 1.23 (a) Passive and (b) Active interpretation of a proper orthogonal tensor (two dimensions).

and so we easily find

$$x_{k'} \equiv \boldsymbol{r} \cdot \boldsymbol{u}_{k'} = \cdots = \sum A_{k'k} x_k,$$
$$x_k \equiv \boldsymbol{r} \cdot \boldsymbol{u}_k = \cdots = \sum A_{kk'} x_{k'} \qquad \Big(= \sum A_{k'k} x_{k'}\Big), \tag{1.11.2b}$$

or explicitly, in matrix form,

$$\begin{pmatrix} X \\ Y \\ Z \end{pmatrix} = \begin{pmatrix} A_{Xx} & A_{Xy} & A_{Xz} \\ A_{Yx} & A_{Yy} & A_{Yz} \\ A_{Zx} & A_{Zy} & A_{Zz} \end{pmatrix} \begin{pmatrix} x \\ y \\ z \end{pmatrix}$$
$$\boldsymbol{r}' = \mathbf{A} \cdot \boldsymbol{r}$$
$$\textit{Old}\text{ axes} \qquad\qquad \textit{New}\text{ axes}, \tag{1.11.2c}$$

$$\begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} A_{Xx} & A_{Yx} & A_{Zx} \\ A_{Xy} & A_{Yy} & A_{Zy} \\ A_{Xz} & A_{Yz} & A_{Zz} \end{pmatrix} \begin{pmatrix} X \\ Y \\ Z \end{pmatrix}$$
$$\boldsymbol{r} = \mathbf{A}^{\mathrm{T}} \cdot \boldsymbol{r}'$$
$$\textit{New}\text{ axes} \qquad\qquad \textit{Old}\text{ axes}. \tag{1.11.2d}$$

For example, in two dimensions [fig. 1.23(a)], the above yield

$$\begin{pmatrix} X \\ Y \end{pmatrix} = \begin{pmatrix} \cos\chi & -\sin\chi \\ \sin\chi & \cos\chi \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} \qquad \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} \cos\chi & \sin\chi \\ -\sin\chi & \cos\chi \end{pmatrix} \begin{pmatrix} X \\ Y \end{pmatrix}$$
$$\boldsymbol{r}' = \mathbf{A} \cdot \boldsymbol{r}, \qquad\qquad \boldsymbol{r} = \mathbf{A}^{\mathrm{T}} \cdot \boldsymbol{r}' \tag{1.11.2e}$$

(iv) Under the *fourth* interpretation, known as *active* or *alibi* (meaning elsewhere), the axes remain fixed in space, say $\mathbf{T} = \mathbf{t}$, and the point P rotates about O, from an *initial* position $\boldsymbol{r}_i = X\boldsymbol{I} + Y\boldsymbol{J} + Z\boldsymbol{K}$ to a *final* one $\boldsymbol{r}_f = X'\boldsymbol{I} + Y'\boldsymbol{J} + Z'\boldsymbol{K}$. Then, following §1.10, and with $\mathbf{A} \to \mathbf{R}$ (rotation tensor),

$$\begin{pmatrix} X' \\ Y' \\ Z' \end{pmatrix} = \mathbf{R} \begin{pmatrix} X \\ Y \\ Z \end{pmatrix} = \mathbf{A} \begin{pmatrix} X \\ Y \\ Z \end{pmatrix}$$
$$\boldsymbol{r}_f = \mathbf{R} \cdot \boldsymbol{r}_i$$
$$\textit{Final}\text{ position} \qquad\qquad \textit{Initial}\text{ position}, \tag{1.11.2f}$$

$$\begin{pmatrix} X \\ Y \\ Z \end{pmatrix} = \mathbf{R}^{\mathrm{T}} \begin{pmatrix} X' \\ Y' \\ Z' \end{pmatrix} = \mathbf{A}^{\mathrm{T}} \begin{pmatrix} X' \\ Y' \\ Z' \end{pmatrix}$$
$$\boldsymbol{r}_i = \mathbf{R}^{\mathrm{T}} \cdot \boldsymbol{r}_f$$
$$\textit{Initial}\text{ position} \qquad\qquad \textit{Final}\text{ position}. \tag{1.11.2g}$$

Equations (1.11.2f, g) hold about any *common* axes; and, clearly, the components of **R** depend on the *particular axes* used. For example, in two dimensions [fig. 1.23(b)], the above yield

$$\begin{pmatrix} X' \\ Y' \end{pmatrix} = \begin{pmatrix} \cos\chi & -\sin\chi \\ \sin\chi & \cos\chi \end{pmatrix} \begin{pmatrix} X \\ Y \end{pmatrix} \qquad \begin{pmatrix} X \\ Y \end{pmatrix} = \begin{pmatrix} \cos\chi & \sin\chi \\ -\sin\chi & \cos\chi \end{pmatrix} \begin{pmatrix} X' \\ Y' \end{pmatrix}$$

$$\boldsymbol{r}_f = \mathbf{R}\cdot\boldsymbol{r}_i, \qquad \boldsymbol{r}_i = \mathbf{R}^{\mathrm{T}}\cdot\boldsymbol{r}_f; \tag{1.11.2h}$$

and for the new triad (actually a *dyad*) $\boldsymbol{i}, \boldsymbol{j}$ in terms of the old triad $\boldsymbol{I}$, $\boldsymbol{J}$ [along the same (old) axes], they readily yield

$$\begin{pmatrix} \cos\chi \\ \sin\chi \end{pmatrix} = \begin{pmatrix} \cos\chi & -\sin\chi \\ \sin\chi & \cos\chi \end{pmatrix} \begin{pmatrix} 1 \\ 0 \end{pmatrix} \qquad \begin{pmatrix} -\sin\chi \\ \cos\chi \end{pmatrix} = \begin{pmatrix} \cos\chi & -\sin\chi \\ \sin\chi & \cos\chi \end{pmatrix} \begin{pmatrix} 0 \\ 1 \end{pmatrix}$$

$$\boldsymbol{i} = \mathbf{R}\cdot\boldsymbol{I}, \qquad \boldsymbol{j} = \mathbf{R}\cdot\boldsymbol{J}. \tag{1.11.2i}$$

The passive and active interpretations are based on the fact that: The rigid body rotation relative to space-fixed axes (*active* interpretation), and the axes rotation relative to a fixed body (*passive* interpretation) are mutually reciprocal motions. Hence [fig. 1.24(a, b)]: The coordinates of a rotated body-fixed vector along the old axes (*final* position, *active* interpretation), equal the coordinates of the unrotated rigid body along the inversely rotated axes (*new* axes, *passive* interpretation).

It follows that if the *body is fixed* relative to the new axes and $\boldsymbol{r}' = X\boldsymbol{I} + Y\boldsymbol{J}$, $\boldsymbol{r} = x\boldsymbol{i} + y\boldsymbol{j}$, then the rotation equations—for example, (1.10.2e)—yields (with $\boldsymbol{r}_i \to \boldsymbol{r}_{\text{new (body-fixed) axes}} \equiv \boldsymbol{r}$ and $\boldsymbol{r}_f \to \boldsymbol{r}'_{\text{old axes}} \equiv \boldsymbol{r}'$)

$$\boldsymbol{r}' = [2/(1+\gamma^2)][\boldsymbol{\gamma}\times\boldsymbol{r} + (\boldsymbol{\gamma}\cdot\boldsymbol{r}_i)\boldsymbol{\gamma}] + [(1-\gamma^2)/(1+\gamma^2)]\boldsymbol{r}. \tag{1.11.3}$$

A correct understanding of the above four interpretations—in particular, the interchange of **A** with $\mathbf{A}^{\mathrm{T}} = \mathbf{A}(-\chi)$ [and **R** with $\mathbf{R}^{\mathrm{T}} = \mathbf{R}(-\chi)$] in single, and, especially, successive rotations (see below)—is crucial to spatial rigid-body kinematics. Lack of it, as Synge (1960, p. 16) accurately puts it "can be a source of such petty confusion."

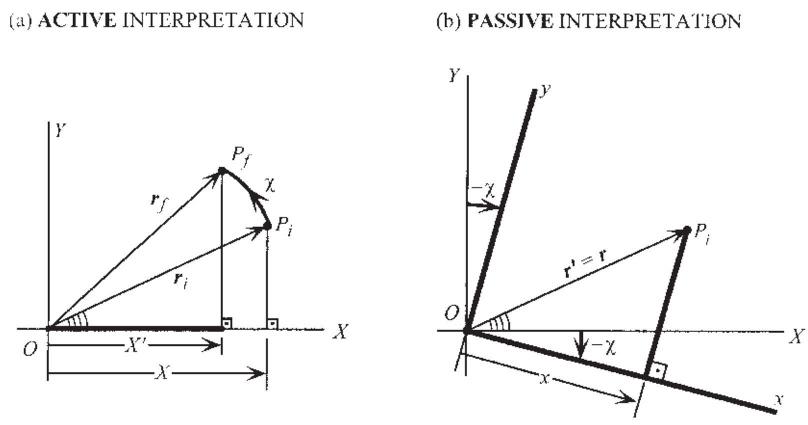

Figure 1.24 The *final* coordinates under χ [*active* interpretation (a)] equal the *new* coordinates under $-\chi$ [*passive* interpretation (b)], and vice versa. ($X'_{\chi\text{-rotated vector, old axes}} = x_{\text{unrotated vector}, -\chi\text{-rotated axes}}$, etc.)

Below, we summarize these four interpretations of an orthogonal tensor **A** or **R**:

(i) $\mathbf{A} = (A_{k'k}) = (\boldsymbol{u}_{k'} \cdot \boldsymbol{u}_k)$: *Direction cosine* matrix;

(ii) $$\begin{pmatrix} \boldsymbol{I} \\ \boldsymbol{J} \\ \boldsymbol{K} \end{pmatrix} = \mathbf{A} \begin{pmatrix} \boldsymbol{i} \\ \boldsymbol{j} \\ \boldsymbol{k} \end{pmatrix}$$

or $\mathbf{T} = \mathbf{A} \cdot \mathbf{t}$: *Triad* rotation;

(iii) $$\begin{pmatrix} X \\ Y \\ Z \end{pmatrix} = \mathbf{A} \begin{pmatrix} x \\ y \\ z \end{pmatrix}$$

or $\boldsymbol{r}_{old\,\mathrm{axes}} \equiv \boldsymbol{r}' = \mathbf{A} \cdot \boldsymbol{r}_{new\,\mathrm{axes}} \equiv \mathbf{A} \cdot \boldsymbol{r}$: *Passive* interpretation

(*Vector* fixed; *axes* rotated);

(iv) $$\begin{pmatrix} X' \\ Y' \\ Z' \end{pmatrix} = \mathbf{R} \begin{pmatrix} X \\ Y \\ Z \end{pmatrix}$$

or $\boldsymbol{r}_f = \mathbf{R} \cdot \boldsymbol{r}_i$: *Active* interpretation $\mathbf{A} = \mathbf{R}$

(*Vector* rotated; *axes* fixed, and common).

REMARKS

(i) In the *passive* interpretation, we denote the components of **A** as $A_{k'k}$; whereas, in the *active* one, we denote them, in an arbitrary but common set of axes, as R_{kl} (or $R_{k'l'}$). This is an extra advantage of the accented indicial notation, especially in cases where both interpretations are needed.

(ii) The passive interpretation also holds for the components of *any* other vector; for example, angular velocity.

Successive Rotations

Let us consider a sequence of rotations compounded according to the following scheme:

$$\mathbf{T} \underset{\mathbf{A}_1}{\rightarrow} \mathbf{T}_1 \underset{\mathbf{A}_2}{\rightarrow} \mathbf{T}_2 \underset{\mathbf{A}_3}{\rightarrow} \cdots \underset{\mathbf{A}_{n-1}}{\rightarrow} \mathbf{T}_{n-1} \underset{\mathbf{A}_n}{\rightarrow} \mathbf{T}_n \equiv \mathbf{t} \tag{1.11.4a}$$

Then we shall have the following *composition formulae*, for the various interpretations.

(i) Triad Rotation

$$\mathbf{T} = (\mathbf{A}_1 \cdot \mathbf{A}_2 \cdot \cdots \cdot \mathbf{A}_n) \cdot \mathbf{t} \quad \Leftrightarrow \quad \mathbf{t} = (\mathbf{A}_n{}^{\mathrm{T}} \cdot \mathbf{A}_{n-1}{}^{\mathrm{T}} \cdot \cdots \cdot \mathbf{A}_1{}^{\mathrm{T}}) \cdot \mathbf{T}; \tag{1.11.4b}$$

or, in extenso,

$$\begin{pmatrix} \boldsymbol{I} \\ \boldsymbol{J} \\ \boldsymbol{K} \end{pmatrix} = (\mathbf{A}_1 \cdot \mathbf{A}_2 \cdot \cdots \cdot \mathbf{A}_n) \begin{pmatrix} \boldsymbol{i} \\ \boldsymbol{j} \\ \boldsymbol{k} \end{pmatrix}$$

Initial triad (natural order of component matrices) *Final* triad, (1.11.4c)

$$\begin{pmatrix} \boldsymbol{i} \\ \boldsymbol{j} \\ \boldsymbol{k} \end{pmatrix} = (\mathbf{A}_n{}^T \cdot \mathbf{A}_{n-1}{}^T \cdot \cdots \cdot \mathbf{A}_1{}^T) \begin{pmatrix} \boldsymbol{I} \\ \boldsymbol{J} \\ \boldsymbol{K} \end{pmatrix}$$

Final triad *Initial* triad. (1.11.4d)

(ii) Passive Interpretation

Here, with some easily understood ad hoc notations, we will have

$$\boldsymbol{r}_{\text{old axes}} \equiv \boldsymbol{r}' = \mathbf{A}_1 \cdot \boldsymbol{r}_1 = \mathbf{A}_1 \cdot (\mathbf{A}_2 \cdot \boldsymbol{r}_2) = \cdots = (\mathbf{A}_1 \cdot \mathbf{A}_2 \cdot \cdots \cdot \mathbf{A}_n) \cdot \boldsymbol{r}, \tag{1.11.4e}$$

$$\boldsymbol{r}_{\text{new axes}} \equiv \boldsymbol{r} = (\mathbf{A}_1 \cdot \mathbf{A}_2 \cdot \cdots \cdot \mathbf{A}_n)^T \cdot \boldsymbol{r}' = (\mathbf{A}_n{}^T \cdot \mathbf{A}_{n-1}{}^T \cdot \cdots \cdot \mathbf{A}_1{}^T) \cdot \boldsymbol{r}'; \tag{1.11.4f}$$

or, in extenso,

$$\begin{pmatrix} X \\ Y \\ Z \end{pmatrix} = (\mathbf{A}_1 \cdot \mathbf{A}_2 \cdot \cdots \cdot \mathbf{A}_n) \begin{pmatrix} x \\ y \\ z \end{pmatrix}$$

Old axes *New* axes, (1.11.4g)

$$\begin{pmatrix} x \\ y \\ z \end{pmatrix} = (\mathbf{A}_n{}^T \cdot \mathbf{A}_{n-1}{}^T \cdot \cdots \cdot \mathbf{A}_1{}^T) \begin{pmatrix} X \\ Y \\ Z \end{pmatrix}$$

New axes *Old* axes. (1.11.4h)

(iii) Active Interpretation

Here, choosing common axes corresponding to **T**; that is,

$$\boldsymbol{r}_i = X\boldsymbol{I} + Y\boldsymbol{J} + Z\boldsymbol{K} \ \rightarrow \ \boldsymbol{r}_f = X'\boldsymbol{I} + Y'\boldsymbol{J} + Z'\boldsymbol{K} \quad (= X\boldsymbol{i} + Y\boldsymbol{j} + Z\boldsymbol{k}), \tag{1.11.4i}$$

we obtain, successively,

$$\boldsymbol{r}_i = \mathbf{A}_1{}^{\mathrm{T}} \cdot \boldsymbol{r}_{f,1} = \mathbf{A}^{\mathrm{T}}{}_1 \cdot (\mathbf{A}^{\mathrm{T}}{}_2 \cdot \boldsymbol{r}_{f,2}) = \cdots = (\mathbf{A}_1{}^{\mathrm{T}} \cdot \mathbf{A}_2{}^{\mathrm{T}} \cdot \cdots \cdot \mathbf{A}_{\mathrm{n}}{}^{\mathrm{T}}) \cdot \boldsymbol{r}_f$$
$$\equiv (\mathbf{R}_1{}^{\mathrm{T}} \cdot \mathbf{R}_2{}^{\mathrm{T}} \cdot \cdots \cdot \mathbf{R}_{\mathrm{n}}{}^{\mathrm{T}}) \cdot \boldsymbol{r}_f, \tag{1.11.4j}$$

$$\Rightarrow \boldsymbol{r}_f = (\mathbf{A}_{\mathrm{n}} \cdot \mathbf{A}_{\mathrm{n}-1} \cdot \cdots \cdot \mathbf{A}_1) \cdot \boldsymbol{r}_i \equiv (\mathbf{R}_{\mathrm{n}} \cdot \mathbf{R}_{\mathrm{n}-1} \cdot \cdots \cdot \mathbf{R}_1) \cdot \boldsymbol{r}_i; \tag{1.11.4k}$$

or, in extenso,

$$\begin{pmatrix} X' \\ Y' \\ Z' \end{pmatrix} = (\mathbf{R}_{\mathrm{n}} \cdot \mathbf{R}_{\mathrm{n}-1} \cdot \cdots \cdot \mathbf{R}_1) \begin{pmatrix} X \\ Y \\ Z \end{pmatrix}$$
$$\textit{Final}\text{ position} \qquad\qquad \textit{Initial}\text{ position}, \tag{1.11.4l}$$

$$\begin{pmatrix} X \\ Y \\ Z \end{pmatrix} = (\mathbf{R}_1{}^{\mathrm{T}} \cdot \mathbf{R}_2{}^{\mathrm{T}} \cdot \cdots \cdot \mathbf{R}_{\mathrm{n}}{}^{\mathrm{T}}) \begin{pmatrix} X' \\ Y' \\ Z' \end{pmatrix}$$
$$\textit{Initial}\text{ position} \qquad\qquad \textit{Final}\text{ position}. \tag{1.11.4m}$$

Body-Fixed versus Space-Fixed Axes

The moving triad **t** and associated axes (O–xyz) may be considered as a rigid body going through a sequence of rotations, either about these *body-fixed* axes themselves, or about the *space-fixed* axes O–XYZ with which it originally coincided. Either of these two types of sequences may be used (although the tensors/matrices of rotations about body-fixed axes have simpler structure than those about space-fixed axes), and their outcomes are related by the following remarkable theorem: The sequence of rotations about Ox, Oy, Oz has the same effect as the sequence of rotations of equal amounts about OX, OY, OZ, but carried out in the *reverse order*. Symbolically,

$$(\mathbf{R}_1\mathbf{R}_2)_{\textit{body}\text{-fixed axes}} = (\mathbf{R}_2\mathbf{R}_1)_{\textit{space}\text{-fixed axes}}.$$

This nontrivial result will be proved in §1.12.

Thus, for a sequence about space-fixed axes, eq. (1.11.4h) (which expresses the passive interpretation for a body-fixed sequence) should be replaced by

$$\begin{pmatrix} x \\ y \\ z \end{pmatrix} = (\mathbf{S}_1{}^{\mathrm{T}} \cdot \mathbf{S}_2{}^{\mathrm{T}} \cdot \cdots \cdot \mathbf{S}_{\mathrm{n}}{}^{\mathrm{T}}) \begin{pmatrix} X \\ Y \\ Z \end{pmatrix}$$
$$= (\mathbf{S}_{\mathrm{n}} \cdot \mathbf{S}_{\mathrm{n}-1} \cdot \cdots \cdot \mathbf{S}_1)^{\mathrm{T}} \begin{pmatrix} X \\ Y \\ Z \end{pmatrix}$$
$$\textit{New}\text{ axes} \qquad\qquad \textit{Old}\text{ axes}, \tag{1.11.4n}$$

where the $\mathbf{S}_k$ are the space-fixed axes counterparts (of equal angle of rotation) of the $\mathbf{R}_k$; and similarly for the other compounded rotation equations.

REMARKS

(i) In algebraic terms, we say that such successive rotations form the **S**pecial **O**rthogonal (Unit Determinant)—Three Dimensional *group* of **R**eal Matrices [$\equiv$ SO(3, R)], and are representable by *three independent* parameters; for example, Eulerian angles (§1.12).

[By group, we mean, briefly, that (a) an identity rotation exists (i.e., one that leaves the body unchanged); (b) the product of two successive rotations is also a rotation; (c) every rotation has an inverse; and (d) these rotations are associative. See books on algebra/group theory.]

(ii) Some authors call rotation tensor/matrix the *transpose* of this book's, while others, in addition, fail to mention the distinction between active and passive interpretations. Hence, a certain caution is needed when comparing various references. Our choice was based on the fact that when the rotation tensor of the *active* interpretation is expanded à la Taylor around the identity tensor, and so on (1.10.25a ff.), it leads to an angular velocity compatible with the definition of the axial vector ($\boldsymbol{\omega}$) of an antisymmetric tensor (1.1.16a ff.) $\boldsymbol{\Omega}$: $\boldsymbol{\Omega}\cdot\boldsymbol{r} = \boldsymbol{\omega}\times\boldsymbol{r}$; otherwise we would have $\boldsymbol{\Omega}\cdot\boldsymbol{r} = -\boldsymbol{\omega}\times\boldsymbol{r}$.

Tensorial Derivation of the Finite Rotation Tensor

Let us consider the following two rectangular Cartesian sets of axes, O–$x_{k'}$ ($\equiv O$–XYZ, *fixed*) and O–x_k ($\equiv O$–xyz, *moving*), related by the proper orthogonal transformation:

$$x_{k'} = \sum A_{k'k}x_k \Leftrightarrow x_k = \sum A_{kk'}x_{k'}, \qquad A_{k'k} = A_{kk'} = \cos(x_{k'}, x_k). \quad (1.11.5a)$$

The corresponding components of the rotation tensor, $R_{k'l'}$ and R_{kl}, respectively, will be related by the well-known transformation rule for second-order tensors (1.1.19j ff.):

$$R_{k'l'} = \sum\sum A_{k'k}A_{l'l}R_{kl} \;\Leftrightarrow\; R_{kl} = \sum\sum A_{k'k}A_{l'l}R_{k'l'}, \quad (1.11.5b)$$

or, in matrix form,

$$\mathbf{R}' = \mathbf{A}\cdot\mathbf{R}\cdot\mathbf{A}^{\mathrm{T}} \;\Leftrightarrow\; \mathbf{R} = \mathbf{A}^{\mathrm{T}}\cdot\mathbf{R}'\cdot\mathbf{A}, \quad (1.11.5c)$$

where

$$\mathbf{R}' = (R_{k'l'}), \qquad \mathbf{R} = (R_{kl}), \qquad \mathbf{A} = (A_{k'k}). \quad (1.11.5d)$$

Here, choosing axes O–x_k in which R_{kl} have the *simplest form possible*, and then applying (1.11.5b, c), we will obtain the rotation tensor components in the general axes O–$x_{k'}$, $R_{k'l'}$; that is, eq. (1.10.10a). To this end, we select Ox_k so that $x_1 \equiv x$ is along the positive sense of the rotation axis $\boldsymbol{n}$, while $x_2 \equiv y$, $x_3 \equiv z$ are on the plane through O perpendicular to $\boldsymbol{n}$ (fig. 1.25). For such special axes, the finite rotation is a

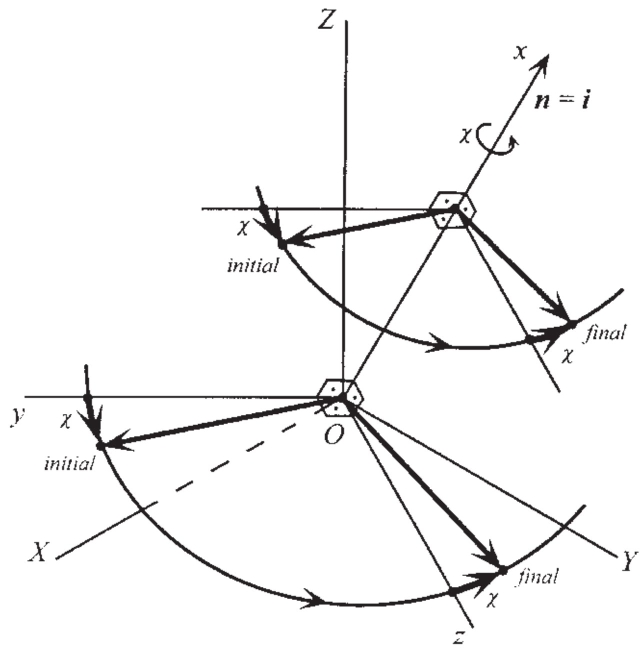

Figure 1.25 Tensor transformation of rotation tensor, between the general fixed axes *O–XYZ* and the special moving axes *O–xyz*; *Ox* axis of rotation.

plane rotation of (say, right-hand rule) angle χ about Ox, and, hence, there the rotation tensor has the following simple planar form:

$$\mathbf{R} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos\chi & -\sin\chi \\ 0 & \sin\chi & \cos\chi \end{pmatrix}. \tag{1.11.5e}$$

Now, to apply (1.11.5c) we need **A**. The latter, since

$$\boldsymbol{i} = A_{xX}\boldsymbol{I} + A_{xY}\boldsymbol{J} + A_{xZ}\boldsymbol{K} = \boldsymbol{n} \equiv n_X\boldsymbol{I} + n_Y\boldsymbol{J} + n_Z\boldsymbol{K}, \tag{1.11.5f}$$

becomes

$$\mathbf{A} = \begin{pmatrix} n_X & A_{Xy} & A_{Xz} \\ n_Y & A_{Yy} & A_{Yz} \\ n_Z & A_{Zy} & A_{Zz} \end{pmatrix}; \tag{1.11.5g}$$

and so, with the abbreviations $\cos(\ldots) \equiv c(\ldots)$, $\sin(\ldots) \equiv s(\ldots)$, (1.11.5c) specializes to

$$\mathbf{R}' = \begin{pmatrix} n_X & A_{Xy} & A_{Xz} \\ n_Y & A_{Yy} & A_{Yz} \\ n_Z & A_{Zy} & A_{Zz} \end{pmatrix} \begin{pmatrix} 1 & 0 & 0 \\ 0 & c\chi & -s\chi \\ 0 & s\chi & c\chi \end{pmatrix} \begin{pmatrix} n_X & n_Y & n_Z \\ A_{Xy} & A_{Yy} & A_{Zy} \\ A_{Xz} & A_{Yz} & A_{Zz} \end{pmatrix},$$

or, carrying out the matrix multiplications, and recalling that $R_{1'1'} \equiv R_{XX}$, $R_{1'2'} \equiv R_{XY}$, and so on,

$$
\begin{aligned}
R_{XX} &= n_X{}^2 + (A_{Xy}{}^2 + A_{Xz}{}^2)\cos\chi,\\
R_{XY} &= n_X n_Y + (A_{Xy}A_{Yy} + A_{Xz}A_{Yz})\cos\chi - (A_{Xy}A_{Yz} - A_{Yy}A_{Xz})\sin\chi,\\
R_{XZ} &= n_X n_Z + (A_{Xy}A_{Zy} + A_{Xz}A_{Zz})\cos\chi + (A_{Zy}A_{Xz} - A_{Xy}A_{Zz})\sin\chi;\\
R_{YX} &= n_Y n_X + (A_{Yy}A_{Xy} + A_{Yz}A_{Xz})\cos\chi + (A_{Xy}A_{Zz} - A_{Yy}A_{Xz})\sin\chi,\\
R_{YY} &= n_Y{}^2 + (A_{Yy}{}^2 + A_{Yz}{}^2)\cos\chi,\\
R_{YZ} &= n_Y n_Z + (A_{Yy}A_{Zy} + A_{Yz}A_{Zz})\cos\chi - (A_{Yy}A_{Zz} - A_{Zy}A_{Yz})\sin\chi;\\
R_{ZX} &= n_Z n_X + (A_{Zy}A_{Xy} + A_{Zz}A_{Xz})\cos\chi - (A_{Zy}A_{Xz} - A_{Xy}A_{Zz})\sin\chi,\\
R_{ZY} &= n_Z n_Y + (A_{Zy}A_{Yy} + A_{Zz}A_{Yz})\cos\chi + (A_{Yy}A_{Zz} - A_{Zy}A_{Yz})\sin\chi,\\
R_{ZZ} &= n_Z{}^2 + (A_{Zy}{}^2 + A_{Zz}{}^2)\cos\chi.
\end{aligned}
\tag{1.11.5h}
$$

However, the nine $A_{k'k}$ are constrained by the *six* orthonormality conditions:

$$
\begin{aligned}
\boldsymbol{I}\cdot\boldsymbol{J} &= n_X n_Y + A_{Xy}A_{Yy} + A_{Xz}A_{Yz} = 0,\\
\boldsymbol{J}\cdot\boldsymbol{K} &= n_Y n_Z + A_{Yy}A_{Zy} + A_{Yz}A_{Zz} = 0,\\
\boldsymbol{K}\cdot\boldsymbol{I} &= n_Z n_X + A_{Zy}A_{Xy} + A_{Zz}A_{Xz} = 0;\\
\boldsymbol{I}\cdot\boldsymbol{I} &= n_X{}^2 + A_{Xy}{}^2 + A_{Xz}{}^2 = 1,\\
\boldsymbol{J}\cdot\boldsymbol{J} &= n_Y{}^2 + A_{Yy}{}^2 + A_{Yz}{}^2 = 1,\\
\boldsymbol{K}\cdot\boldsymbol{K} &= n_Z{}^2 + A_{Zy}{}^2 + A_{Zz}{}^2 = 1;
\end{aligned}
\tag{1.11.5i}
$$

and also $\boldsymbol{n} = \boldsymbol{u}_y \times \boldsymbol{u}_z$, or, in components,

$$
n_X = A_{Yy}A_{Zz} - A_{Zy}A_{Yz}, \qquad n_Y = A_{Zy}A_{Xz} - A_{Xy}A_{Zz}, \qquad n_Z = A_{Xy}A_{Yz} - A_{Yy}A_{Xz}.
\tag{1.11.5j}
$$

As a result of the above, it is not hard to verify that the $R_{k'l'}$, (1.11.5h), reduce to

$$
\begin{aligned}
R_{XX} &= n_X{}^2 + (1 - n_X{}^2)\cos\chi,\\
R_{XY} &= n_X n_Y + (-n_X n_Y)\cos\chi + (n_Z)\sin\chi,\\
R_{XZ} &= n_X n_Z + (-n_X n_Z)\cos\chi + (n_Y)\sin\chi;\\
R_{YX} &= n_Y n_X + (-n_X n_Y)\cos\chi + (n_Z)\sin\chi,\\
R_{YY} &= n_Y{}^2 + (1 - n_Y{}^2)\cos\chi,\\
R_{YZ} &= n_Y n_Z + (-n_Y n_Z)\cos\chi + (-n_X)\sin\chi;\\
R_{ZX} &= n_Z n_X + (-n_Z n_X)\cos\chi + (-n_Y)\sin\chi,\\
R_{ZY} &= n_Z n_Y + (-n_Z n_Y)\cos\chi + (n_X)\sin\chi,\\
R_{ZZ} &= n_Z{}^2 + (1 - n_Z{}^2)\cos\chi;
\end{aligned}
\tag{1.11.5k}
$$

and when put to matrix form is none other than eq. (1.10.10a). We notice that the components $R_{k'l'}$ are *independent of the orientation of the O–xyz axes*, as expected.

Angular Velocity via the Passive Interpretation

Let us consider a generic body point P fixed in the moving frame $\mathbf{t}$: $O\text{–}\boldsymbol{ijk}/O\text{–}xyz$, and hence representable by

$$\boldsymbol{r}' = X\boldsymbol{I} + Y\boldsymbol{J} + Z\boldsymbol{K} \qquad \text{(space-fixed frame } \mathbf{T}\text{: } O\text{–}\boldsymbol{IJK}/O\text{–}XYZ), \tag{1.11.6a}$$

$$\boldsymbol{r} = x\boldsymbol{i} + y\boldsymbol{j} + z\boldsymbol{k} \qquad \text{(body-fixed frame; i.e. } x, y, z = \text{constant}); \tag{1.11.6b}$$

or, in matrix form,

$$\boldsymbol{r}'^{\mathrm{T}} = (X, Y, Z), \qquad \boldsymbol{r}^{\mathrm{T}} = (x, y, z). \tag{1.11.6c}$$

According to the passive interpretation (1.11.2c) (with $\mathbf{A}$ replaced by the rotation tensor/matrix $\mathbf{R}$),

$$\boldsymbol{r}' = \mathbf{R}\cdot\boldsymbol{r}, \tag{1.11.6d}$$

and, therefore, the inertial velocity of P, resolved along the fixed axes $O\text{–}XYZ$ equals

$$\begin{aligned}\boldsymbol{v}' \equiv d\boldsymbol{r}'/dt &= (\mathrm{d}\mathbf{R}/\mathrm{dt})\cdot\boldsymbol{r} + \mathbf{R}\cdot(d\boldsymbol{r}/dt) = (\mathrm{d}\mathbf{R}/\mathrm{dt})\cdot\boldsymbol{r} + \mathbf{R}\cdot\mathbf{0}\\ &= (\mathrm{d}\mathbf{R}/\mathrm{dt})\cdot(\mathbf{R}^{\mathrm{T}}\cdot\boldsymbol{r}') = \boldsymbol{\Omega}'\cdot\boldsymbol{r}' \equiv \boldsymbol{\omega}'\times\boldsymbol{r}',\end{aligned} \tag{1.11.6e}$$

where [recalling (1.7.30f ff.), with $\mathbf{A}\rightarrow\mathbf{R}$]

$\boldsymbol{\Omega}' \equiv (\mathrm{d}\mathbf{R}/\mathrm{dt})\cdot\mathbf{R}^{\mathrm{T}} =$ *angular velocity tensor* of body frame $\mathbf{t}$ relative to the fixed frame $\mathbf{T}$, but resolved along the fixed axes *O–XYZ*, (1.11.6f)

$\boldsymbol{\omega}' =$ *axial vector* of $\boldsymbol{\Omega}'$; angular velocity *vector* of $\mathbf{t}$ relative to $\mathbf{T}$, along $\mathbf{T}$. (1.11.6g)

The components of the angular velocity along the moving axes can then be found easily from the vector transformation (passive interpretation):

$\boldsymbol{v} =$ *inertial* velocity of P, but resolved along the moving axes (*not* to be confused with the velocity of P relative to $\mathbf{t}$, which is zero: $d\boldsymbol{r}/dt = \mathbf{0}$)

$$= \mathbf{R}^{\mathrm{T}}\cdot\boldsymbol{v}' = \mathbf{R}^{\mathrm{T}}\cdot[(\mathrm{d}\mathbf{R}/\mathrm{dt})\cdot\boldsymbol{r}] = \boldsymbol{\Omega}\cdot\boldsymbol{r} \equiv \boldsymbol{\omega}\times\boldsymbol{r}, \tag{1.11.6h}$$

where

$\boldsymbol{\Omega} \equiv \mathbf{R}^{\mathrm{T}}\cdot(\mathrm{d}\mathbf{R}/\mathrm{dt}) =$ *angular velocity tensor* of body frame $\mathbf{t}$ relative to the fixed frame $\mathbf{T}$, but resolved along the moving axes *O–xyz*

$$\begin{aligned}\{ &= [\mathbf{R}^{\mathrm{T}}\cdot(\mathrm{d}\mathbf{R}/\mathrm{dt})]\cdot(\mathbf{R}^{\mathrm{T}}\cdot\mathbf{R}) = \mathbf{R}^{\mathrm{T}}\cdot[(\mathrm{d}\mathbf{R}/\mathrm{dt})\cdot\mathbf{R}^{\mathrm{T}}]\cdot\mathbf{R}\\ &= \mathbf{R}^{\mathrm{T}}\cdot\boldsymbol{\Omega}'\cdot\mathbf{R}; \text{ a second-order tensor transformation, as it should be}\},\end{aligned} \tag{1.11.6i}$$

$\boldsymbol{\omega} =$ *axial vector of* $\boldsymbol{\Omega}$; angular velocity of $\mathbf{t}$ relative to $\mathbf{T}$, along $\mathbf{t}$ $[= \mathbf{R}^{\mathrm{T}}\cdot\boldsymbol{\omega}']$. (1.11.6j)

REMARK

If $\mathbf{R} = \mathbf{R}(q_1, q_2, q_3) \equiv \mathbf{R}(q_\alpha)$, where the q_α are system *rotational* parameters (e.g., the three Eulerian angles, §1.12), then $\boldsymbol{\Omega}'$ and $\boldsymbol{\omega}'$ can be expressed, respectively as follows:

$$\text{Tensor: } \boldsymbol{\Omega}' = \sum \boldsymbol{\Omega}'_\alpha (dq_\alpha/dt)\,, \qquad \text{Vector: } \boldsymbol{\omega}' = \sum \boldsymbol{\omega}'_\alpha (dq_\alpha/dt)\,, \tag{1.11.6k}$$

where

$$\boldsymbol{\Omega}'_\alpha \equiv (\partial \mathbf{R}/\partial q_\alpha)\cdot \mathbf{R}^{\mathrm{T}} \qquad \text{and} \qquad \boldsymbol{\Omega}'_\alpha \cdot \boldsymbol{x} = \boldsymbol{\omega}'_\alpha \times \boldsymbol{x}\,, \tag{1.11.6l}$$

for an arbitrary vector $\boldsymbol{x}$; that is, $\boldsymbol{\Omega}'$ can be expressed in terms of the local basis $\{\boldsymbol{\Omega}'_\alpha;\ \alpha = 1, 2, 3\}$; and similarly for $\boldsymbol{\Omega}$ and $\boldsymbol{\omega}$.

Additional Useful Results

1. Consider the following two successive (component) rotations: First, from the "fixed" frame 0 to the moving frame 1, $\mathbf{R}_{1/0} \equiv \mathbf{R}_1$, and, next, from 1 to the also moving frame 2, $\mathbf{R}_{2/1} \equiv \mathbf{R}_2$. Then, by (1.11.4a ff.), the resultant rotation from 0 to 2 will be $\mathbf{R} = \mathbf{R}_1 \cdot \mathbf{R}_2$. Now, let:

$\boldsymbol{\Omega}_{1/0,0} \equiv (\mathrm{d}\mathbf{R}_1/\mathrm{dt})\cdot \mathbf{R}_1{}^{\mathrm{T}}$: angular velocity tensor of frame 1 relative to frame 0, *along 0-axes*;

$\boldsymbol{\Omega}_{1/0,1} \equiv \mathbf{R}_1{}^{\mathrm{T}}\cdot (\mathrm{d}\mathbf{R}_1/\mathrm{dt})$: angular velocity tensor of frame 1 relative to frame 0, *along 1-axes*;

$\boldsymbol{\Omega}_{2/1,1} \equiv (\mathrm{d}\mathbf{R}_2/\mathrm{dt})\cdot \mathbf{R}_2{}^{\mathrm{T}}$: angular velocity tensor of frame 2 relative to frame 1, *along 1-axes*;

$\boldsymbol{\Omega}_{2/1,2} \equiv \mathbf{R}_2{}^{\mathrm{T}}\cdot (\mathrm{d}\mathbf{R}_2/\mathrm{dt})$: angular velocity tensor of frame 2 relative to frame 1, *along 2-axes*;

$\boldsymbol{\Omega}_{2/0,0} \equiv (\mathrm{d}\mathbf{R}/\mathrm{dt})\cdot \mathbf{R}^{\mathrm{T}}$: angular velocity tensor of frame 2 relative to frame 0, *along 0-axes*;

$\boldsymbol{\Omega}_{2/0,2} \equiv \mathbf{R}^{\mathrm{T}}\cdot (\mathrm{d}\mathbf{R}/\mathrm{dt})$: angular velocity tensor of frame 2 relative to frame 0, *along 2-axes*; (1.11.7a)

(this or some similar intricate notation is a must in matrix territory!) and therefore

$$\begin{aligned}
\boldsymbol{\Omega}_{1/0,0} &= \mathbf{R}_1 \cdot \boldsymbol{\Omega}_{1/0,1} \cdot \mathbf{R}_1{}^{\mathrm{T}} \Leftrightarrow \boldsymbol{\Omega}_{1/0,1} = \mathbf{R}_1{}^{\mathrm{T}} \cdot \boldsymbol{\Omega}_{1/0,0} \cdot \mathbf{R}_1\,,\\
\boldsymbol{\Omega}_{2/1,0} &= \mathbf{R}_1 \cdot \boldsymbol{\Omega}_{2/1,1} \cdot \mathbf{R}_1{}^{\mathrm{T}} \Leftrightarrow \boldsymbol{\Omega}_{2/1,1} = \mathbf{R}_1 \cdot \boldsymbol{\Omega}_{2/1,0} \cdot \mathbf{R}_1{}^{\mathrm{T}}\,,\\
\boldsymbol{\Omega}_{2/1,1} &= \mathbf{R}_2 \cdot \boldsymbol{\Omega}_{2/1,2} \cdot \mathbf{R}_2{}^{\mathrm{T}} \Leftrightarrow \boldsymbol{\Omega}_{2/1,2} = \mathbf{R}_2{}^{\mathrm{T}} \cdot \boldsymbol{\Omega}_{2/1,1} \cdot \mathbf{R}_2\,,\\
\boldsymbol{\Omega}_{2/0,1} &= \mathbf{R}_1{}^{\mathrm{T}} \cdot \boldsymbol{\Omega}_{2/0,0} \cdot \mathbf{R}_1 = \mathbf{R}_2 \cdot \boldsymbol{\Omega}_{2/0,2} = \mathbf{R}_2{}^{\mathrm{T}}\ :
\end{aligned}$$

angular velocity of frame 2 relative to frame 0, *but expressed along 1-axes;* etc.; i.e., *the multiplications* $\mathbf{R}_1 \cdot (\ldots) \cdot \mathbf{R}_1{}^{\mathrm{T}}$ *convert components from 1-frame axes to 0-frame axes; while* $\mathbf{R}_1{}^{\mathrm{T}}(\ldots)\cdot \mathbf{R}_1$ *convert components from 0-frame axes to 1-frame axes;* and analogously for $\mathbf{R}_2 \cdot (\ldots) \cdot \mathbf{R}_2{}^{\mathrm{T}}$, $\mathbf{R}_2{}^{\mathrm{T}} \cdot (\ldots) \cdot \mathbf{R}_2$.
Then, and since $\mathbf{R}$, $\mathbf{R}_1$, $\mathbf{R}_2$ are orthogonal tensors,

(a) $$\begin{aligned}
\boldsymbol{\Omega}_{2/0,0} &= (\mathrm{d}\mathbf{R}/\mathrm{dt})\cdot \mathbf{R}^{\mathrm{T}} = [\mathrm{d}/\mathrm{dt}(\mathbf{R}_1 \cdot \mathbf{R}_2)]\cdot (\mathbf{R}_1 \cdot \mathbf{R}_2)^{\mathrm{T}}\\
&= \cdots = (\mathrm{d}\mathbf{R}_1/\mathrm{dt})\cdot \mathbf{R}_1{}^{\mathrm{T}} + \mathbf{R}_1 \cdot [(\mathrm{d}\mathbf{R}_2/\mathrm{dt})\cdot \mathbf{R}_2{}^{\mathrm{T}}]\cdot \mathbf{R}_1{}^{\mathrm{T}}\\
&= \boldsymbol{\Omega}_{1/0,0} + \mathbf{R}_1 \cdot \boldsymbol{\Omega}_{2/1,1} \cdot \mathbf{R}_1{}^{\mathrm{T}} \equiv \boldsymbol{\Omega}_{1/0,0} + \boldsymbol{\Omega}_{2/1,0}
\end{aligned}$$

(theorem of additivity of angular velocities, along *0-axes*) ; (1.11.7b)

$$\mathbf{\Omega}_{2/0,1} = \mathbf{R}_1{}^{\mathrm{T}} \cdot \mathbf{\Omega}_{2/0,0} \cdot \mathbf{R}_1 = \mathbf{R}_1{}^{\mathrm{T}} \cdot \mathbf{\Omega}_{1/0,0} \cdot \mathbf{R}_1 + \mathbf{\Omega}_{2/1,1} \equiv \mathbf{\Omega}_{1/0,1} + \mathbf{\Omega}_{2/1,1}$$

(theorem of additivity of angular velocities, along *1-axes*) ; (1.11.7c)

$$\begin{aligned}\mathbf{\Omega}_{2/0,2} &= \mathbf{R}^{\mathrm{T}} \cdot (\mathrm{d}\mathbf{R}/\mathrm{dt}) \quad [= \mathbf{R}_2{}^{\mathrm{T}} \cdot \mathbf{\Omega}_{2/0,1} \cdot \mathbf{R}_2 = \mathbf{R}^{\mathrm{T}} \cdot \mathbf{\Omega}_{2/0,0} \cdot \mathbf{R}] \\ &\equiv (\mathbf{R}_1 \cdot \mathbf{R}_2)^{\mathrm{T}} \cdot [\mathrm{d}/\mathrm{dt}(\mathbf{R}_1 \cdot \mathbf{R}_2)] \\ &= \cdots = \mathbf{R}_2{}^{\mathrm{T}} \cdot [\mathbf{R}_1{}^{\mathrm{T}} \cdot (\mathrm{d}\mathbf{R}_1/\mathrm{dt})] \cdot \mathbf{R}_2 + \mathbf{R}_2{}^{\mathrm{T}} \cdot (\mathrm{d}\mathbf{R}_2/\mathrm{dt}) \\ &= \mathbf{R}_2{}^{\mathrm{T}} \cdot \mathbf{\Omega}_{1/0,1} \cdot \mathbf{R}_2 + \mathbf{\Omega}_{2/1,2} \equiv \mathbf{\Omega}_{1/0,2} + \mathbf{\Omega}_{2/1,2}\end{aligned}$$

(theorem of additivity of angular velocities, along *2-axes*) . (1.11.7d)

(b) Next, $\mathrm{d}(\ldots)/\mathrm{dt}$-differentiating the above, say (1.11.7b), it is not hard to show that:

$$\begin{aligned}\mathrm{d}\mathbf{\Omega}_{2/0,0}/\mathrm{dt} &= \mathrm{d}\mathbf{\Omega}_{1/0,0}/\mathrm{dt} + \mathrm{d}/\mathrm{dt}(\mathbf{R}_1 \cdot \mathbf{\Omega}_{2/1,1} \cdot \mathbf{R}_1{}^{\mathrm{T}}) \\ &= \mathrm{d}\mathbf{\Omega}_{1/0,0}/\mathrm{dt} + \mathbf{R}_1 \cdot (\mathrm{d}\mathbf{\Omega}_{2/1,1}/\mathrm{dt}) \cdot \mathbf{R}_1{}^{\mathrm{T}} + \mathbf{R}_1 \cdot (\mathbf{\Omega}_{1/0,1} \cdot \mathbf{\Omega}_{2/1,1} - \mathbf{\Omega}_{2/1,1} \cdot \mathbf{\Omega}_{1/0,1}) \cdot \mathbf{R}_1{}^{\mathrm{T}}\end{aligned}$$

(theorem of *non-additivity* of angular accelerations, along *0-axes*) ; (1.11.7e)

and similarly for $\mathrm{d}\mathbf{\Omega}_{2/0,1}/\mathrm{dt}$, $\mathrm{d}\mathbf{\Omega}_{2/0,2}/\mathrm{dt}$. The last (third) term of (1.11.7e) shows that *if the elements of the matrices*, $\mathbf{\Omega}_{1/0,0}$, $\mathbf{\Omega}_{2/1,1}$ *are constant, then, in general, the elements of* $\mathbf{\Omega}_{2/0,0}$ *will also be constant if* $\mathbf{\Omega}_{1/0,1}$ *and* $\mathbf{\Omega}_{2/1,1}$ *commute*, a well-known result from vectorial (undergraduate) kinematics. The extension of the above to three or more successive rotations is obvious.

[As Professor D. T. Greenwood has aptly remarked: "Equations (1.11.7b–e) illustrate how the use of matrix notation can make the simple seem obscure."]

2. *Matrix forms of relative motion of a particle, in two frames with common origin.* By $d/dt(\ldots)$-differentiating the passive interpretation (1.11.2c),

$$\underset{\textit{Fixed axes}}{\begin{pmatrix} X \\ Y \\ Z \end{pmatrix}} = \underset{\textit{Moving axes},}{\mathbf{A} \cdot \begin{pmatrix} x \\ y \\ z \end{pmatrix}} \tag{1.11.8a}$$

we can show that

(i)
$$\mathrm{d}/\mathrm{dt}\begin{pmatrix} X \\ Y \\ Z \end{pmatrix} = \mathbf{A} \cdot \left[\mathrm{d}/\mathrm{dt}\begin{pmatrix} x \\ y \\ z \end{pmatrix} + \mathbf{\Omega} \cdot \begin{pmatrix} x \\ y \\ z \end{pmatrix}\right]$$

$\{ = \mathbf{A} \cdot [$*relative* velocity + *transport* velocity$]\}$. (1.11.8b)

(ii)
$$\mathrm{d}^2/\mathrm{dt}^2 \begin{pmatrix} X \\ Y \\ Z \end{pmatrix} = \mathbf{A}\cdot \left[\mathrm{d}^2/\mathrm{dt}^2 \begin{pmatrix} x \\ y \\ z \end{pmatrix} + (\mathrm{d}\boldsymbol{\Omega}/\mathrm{dt})\cdot \begin{pmatrix} x \\ y \\ z \end{pmatrix} \right.$$
$$\left. + \boldsymbol{\Omega}^2 \cdot \begin{pmatrix} x \\ y \\ z \end{pmatrix} + 2\boldsymbol{\Omega}\cdot \mathrm{d}/\mathrm{dt} \begin{pmatrix} x \\ y \\ z \end{pmatrix} \right]$$
$\big\{ = \mathbf{A}\cdot$ [*relative* acceleration $(\partial^2 \boldsymbol{r}/\partial t^2)$ + *transport* acceleration $(\boldsymbol{\alpha} \times \boldsymbol{r} + \boldsymbol{\omega} \times (\boldsymbol{\omega} \times \boldsymbol{r}))$
+ *Coriolis* acceleration $(2\boldsymbol{\omega} \times (\partial \boldsymbol{r}/\partial t))]\big\}$;
(1.11.8c)

we point out that, in the *matrix* notation, the d/dt vs. ∂/∂t difference (§1.7) disappears.

(iii) If the position of the origin of the moving axes, relative to that of the fixed ones, is $\boldsymbol{r}_o = (X_o, Y_o, Z_o)^{\mathrm{T}}$, so that [instead of (1.11.8a)]

$$\begin{pmatrix} X \\ Y \\ Z \end{pmatrix} = \begin{pmatrix} X_o \\ Y_o \\ Z_o \end{pmatrix} + \mathbf{A}\cdot \begin{pmatrix} x \\ y \\ z \end{pmatrix}, \tag{1.11.8d}$$

then we simply add $\mathrm{d}/\mathrm{dt}(X_o, Y_o, Z_o)^{\mathrm{T}}$ to the right side of (1.11.8b) and $\mathrm{d}^2/\mathrm{dt}^2(X_o, Y_o, Z_o)^{\mathrm{T}}$ to the right side of (1.11.8c).

3. *Tensor of Angular Acceleration,* and so on.

(i) By d(...)/dt-differentiating (1.7.30i, j): $\mathrm{d}\mathbf{A}/\mathrm{dt} = \mathbf{A}\cdot\boldsymbol{\Omega} = \boldsymbol{\Omega}'\cdot\mathbf{A}$, we can show that

$$\mathrm{d}^2\mathbf{A}/\mathrm{dt}^2 = \mathbf{A}\cdot\mathbf{E} \Rightarrow \mathbf{E} = \mathbf{A}^{\mathrm{T}}\cdot(\mathrm{d}^2\mathbf{A}/\mathrm{dt}^2)\,, \tag{1.11.9a}$$

where

$$\mathbf{E} \equiv \boldsymbol{\mathcal{A}} + \boldsymbol{\Omega}\cdot\boldsymbol{\Omega} \equiv \boldsymbol{\mathcal{A}} + \boldsymbol{\Omega}^2\,, \tag{1.11.9b}$$

$\boldsymbol{\mathcal{A}} \equiv \mathrm{d}\boldsymbol{\Omega}/\mathrm{dt}$: (Matrix of components, along the *moving* axes, of the) *tensor of angular acceleration* of the moving axes relative to the fixed ones (1.11.9c)

$$\big\{ = \mathrm{d}/\mathrm{dt}[\mathbf{A}^{\mathrm{T}}\cdot(\mathrm{d}\mathbf{A}/\mathrm{dt})] = (\mathrm{d}\mathbf{A}^{\mathrm{T}}/\mathrm{dt})\cdot(\mathrm{d}\mathbf{A}/\mathrm{dt}) + \mathbf{A}^{\mathrm{T}}\cdot(\mathrm{d}^2\mathbf{A}/\mathrm{dt}^2)$$
$$= -\boldsymbol{\Omega}\cdot\boldsymbol{\Omega} + \mathbf{E}\big\}\,. \tag{1.11.9d}$$

[In fact, both $\boldsymbol{\mathcal{A}}$ and $\mathbf{E}$ appear in (1.11.8c). Also, some authors call $\mathbf{E}$ the angular acceleration tensor, but we think that that term should apply to $\mathrm{d}\boldsymbol{\Omega}/\mathrm{dt}$; that is, definition (1.11.9c).]

(ii) Both $\mathbf{E}$ and $\boldsymbol{\mathcal{A}}$ are (second-order) tensors; that is,

$$\mathbf{E}'(= \boldsymbol{\mathcal{A}}' + \boldsymbol{\Omega}'\cdot\boldsymbol{\Omega}') = \mathbf{A}\cdot\mathbf{E}\cdot\mathbf{A}^{\mathrm{T}} \Leftrightarrow \mathbf{E} = \mathbf{A}^{\mathrm{T}}\cdot\mathbf{E}'\cdot\mathbf{A}\,, \tag{1.11.9e}$$

$$\boldsymbol{\mathcal{A}}'(= \mathrm{d}\boldsymbol{\Omega}'/\mathrm{dt}) = \mathbf{A}\cdot\boldsymbol{\mathcal{A}}\cdot\mathbf{A}^{\mathrm{T}} \Leftrightarrow \boldsymbol{\mathcal{A}} = \mathbf{A}^{\mathrm{T}}\cdot\boldsymbol{\mathcal{A}}'\cdot\mathbf{A}\,; \tag{1.11.9f}$$

where, as before, an *accent* (prime) denotes matrix of components along the *fixed* axes.

(iii) The *fixed* axes counterpart of (1.11.9a) is:

$$d^2\mathbf{A}/dt^2 = \mathbf{E}' \cdot \mathbf{A} \Rightarrow \mathbf{E}' = (d^2\mathbf{A}/dt^2) \cdot \mathbf{A}^T, \tag{1.11.9g}$$

(iv) It can be verified, independently of (1.11.9a–d) and (1.11.9e–g), that

$$\begin{aligned}\boldsymbol{\Omega}^2 \equiv \boldsymbol{\Omega} \cdot \boldsymbol{\Omega} &= -\boldsymbol{\Omega}^T \cdot \boldsymbol{\Omega} = -\boldsymbol{\Omega} \cdot \boldsymbol{\Omega}^T \\ &= \cdots = -(d\mathbf{A}/dt)^T \cdot (d\mathbf{A}/dt) = -(d\mathbf{A}^T/dt) \cdot (d\mathbf{A}/dt),\end{aligned} \tag{1.11.9h}$$

$$\begin{aligned}(\boldsymbol{\Omega}')^2 \equiv \boldsymbol{\Omega}' \cdot \boldsymbol{\Omega}' &= -(\boldsymbol{\Omega}')^T \cdot \boldsymbol{\Omega}' = -\boldsymbol{\Omega}' \cdot (\boldsymbol{\Omega}')^T \\ &= \cdots = -(d\mathbf{A}/dt) \cdot (d\mathbf{A}/dt)^T = -(d\mathbf{A}/dt) \cdot (d\mathbf{A}^T/dt).\end{aligned} \tag{1.11.9i}$$

(v) Since $d\boldsymbol{\Omega}/dt$ is *antisymmetric*, and $\boldsymbol{\Omega} \cdot \boldsymbol{\Omega}$ is *symmetric* (explain this), show that the axial vectors of (the *nonsymmetric*) $\mathbf{E}$ and $\boldsymbol{\mathcal{A}}$ coincide, and are both equal to none other than the *vector of angular acceleration* $\boldsymbol{\alpha}$; thus justifying calling $\boldsymbol{\mathcal{A}}$ the tensor of angular acceleration.

Finally, if the moving axes are fixed relative to a body B, then $\boldsymbol{\Omega}/\boldsymbol{\Omega}'$ and $\boldsymbol{\mathcal{A}}/\boldsymbol{\mathcal{A}}'$ are respectively, the tensors of angular velocity and acceleration of that body relative to the space-fixed axes; and if the earlier particle is frozen (fixed) relative to B (i.e., $dx/dt = 0$, $d^2x/dt^2 = 0$, etc.), then (1.11.8b, c) give, respectively, the matrix forms of the well-known formulae for the distribution of velocities and acceleration of the various points of B (from body-axes components to space-axes components). [For an indicial treatment of these tensors, and recursive formulae for their higher rates, see Truesdell and Toupin (1960, pp. 439–440).]

1.12 THE RIGID BODY: EULERIAN ANGLES

We recommend for concurrent reading with this section: Junkins and Turner (1986, chap. 2), Morton (1984).

As explained already (§1.7, §1.11), the *nine* elements of the proper orthogonal tensor $\mathbf{A}$ (or $\mathbf{R}$), in all its four interpretations, depend on only *three* independent parameters. A particularly popular such parametrization is afforded by the three (generalized) Eulerian angles. These latter appear naturally as we describe the general orientation of an ortho–normal–dextral (OND) *body-fixed* triad, or local frame $\mathbf{t} = \{\boldsymbol{u}_k\} \equiv (\boldsymbol{i}, \boldsymbol{j}, \boldsymbol{k})$ relative to an OND *space-fixed* frame $\mathbf{T} = \{\boldsymbol{u}_{k'}\} \equiv (\boldsymbol{I}, \boldsymbol{J}, \boldsymbol{K})$, with which it originally coincides, via the following sequence of *three*, *possibly hypothetical*, *simple planar rotations* (i.e., in each of them, the two triads have one axis in common, or parallel, and so the corresponding "partial rotation tensor" depends on a *single* angle):

(i) Rotation about the (i)th body axis through an angle $\chi_{(i)} \equiv \chi_1 \equiv \phi$; followed by a
(ii) Rotation about the (j)th body axis $(j \neq i)$ through an angle $\chi_{(j)} \equiv \chi_2 \equiv \theta$; followed by a
(iii) Rotation about the (k)th body axis $(k \neq j)$ through an angle $\chi_{(k)} \equiv \chi_3 \equiv \psi$.

The angles $\chi_1 = \phi$ (about the original $\boldsymbol{u}_i = \boldsymbol{u}_{i'}$), $\chi_2 = \theta$ (about the ϕ-rotated $\boldsymbol{u}_j \rightarrow \boldsymbol{u}_{j'}$), and $\chi_3 = \psi$ (about the θ-rotated $\boldsymbol{u}_k \rightarrow \boldsymbol{u}_{k''}$) are known as the $i \rightarrow j \rightarrow k$ *Eulerian angles*.

Of the *twelve* possible such angle triplets, *six* form a group for which $i \neq j \neq k = i$ (*two*-axes group):

$$1 \to 2 \to 1, \quad 1 \to 3 \to 1, \quad 2 \to 1 \to 2, \quad 2 \to 3 \to 2, \quad 3 \to 1 \to 3, \quad 3 \to 2 \to 3;$$

and *six* form a group for which $i \neq j \neq k \neq i$ (*three*-axes group):

$$1 \to 2 \to 3, \quad 1 \to 3 \to 2, \quad 2 \to 1 \to 3, \quad 2 \to 3 \to 1, \quad 3 \to 1 \to 2, \quad 3 \to 2 \to 1.$$

[Similar results, but with more complicated rotation tensors, would hold for rotations about the *space-fixed* axes $\{\boldsymbol{u}_{k'}: \boldsymbol{I}, \boldsymbol{J}, \boldsymbol{K}\}$. If the partial rotations were about arbitrary (body- or space-fixed) axes, then, due to the infinity of their possible directions, we would have an infinity of angle triplets. It is the restriction that these rotations are about the *body-fixed* axes $\{\boldsymbol{u}_k\}$ that brings them down to twelve.]

Eulerian Angles

The sequence $3 \to 1 \to 3$, shown and described in fig. 1.26 [with the customary abbreviations: $\cos(\ldots) \equiv c(\ldots)$, $\sin(\ldots) \equiv s(\ldots)$] is considered to be the classical Eulerian angle description, originated and frequently used in astronomy and physics, [although "In his original work in 1760, Euler used a combination of right-handed and left-handed rotations; a convention unacceptable today" Likins (1973, p. 97)].
(1973, p. 97)].

Using the *passive* interpretation and fig. 1.26, we readily find that the corresponding coordinates of the compounded transformation resulting from the above sequence of *partial* rotations about the *nonmutually orthogonal* axes OZ, Ox', Oz'' [i.e., the (originally assumed coinciding) space-fixed O–XYZ and body-fixed O–xyz] are related by

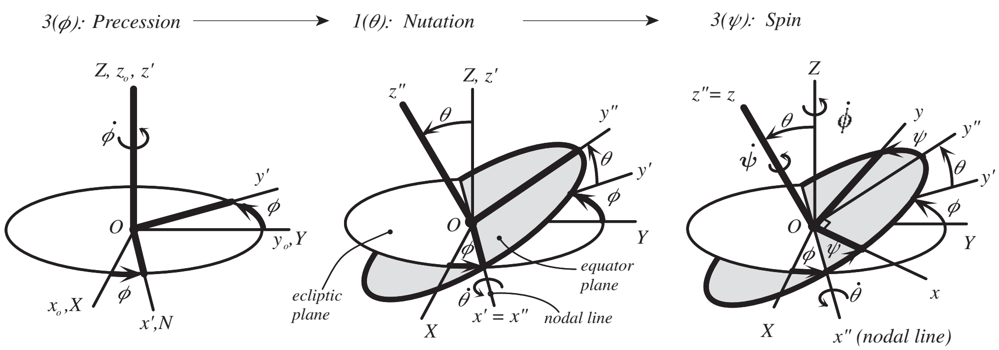
$$\begin{aligned}
\begin{pmatrix} X \\ Y \\ Z \end{pmatrix} &= \begin{pmatrix} c\phi & -s\phi & 0 \\ s\phi & c\phi & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} x' \\ y' \\ z' \end{pmatrix} \\
&= \begin{pmatrix} c\phi & -s\phi & 0 \\ s\phi & c\phi & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 & 0 \\ 0 & c\theta & -s\theta \\ 0 & s\theta & c\theta \end{pmatrix} \begin{pmatrix} x'' \\ y'' \\ z'' \end{pmatrix} \\
&= \begin{pmatrix} c\phi & -s\phi & 0 \\ s\phi & c\phi & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 & 0 \\ 0 & c\theta & -s\theta \\ 0 & s\theta & c\theta \end{pmatrix} \begin{pmatrix} c\psi & -s\psi & 0 \\ s\psi & c\psi & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} x \\ y \\ z \end{pmatrix}
\end{aligned}$$

$$\mathbf{R}(\boldsymbol{K}, \phi) \cdot \mathbf{R}(\boldsymbol{i}', \theta) \cdot \mathbf{R}(\boldsymbol{k}'', \psi) \equiv \mathbf{R}_\phi \cdot \mathbf{R}_\theta \cdot \mathbf{R}_\psi \equiv \mathbf{R}, \qquad (1.12.1a)$$

$$= \left(\begin{array}{c|c|c} c\phi\, c\psi - s\phi\, c\theta\, s\psi & -c\phi\, s\psi - s\phi\, c\theta\, c\psi & s\phi\, s\theta \\ \hline s\phi\, c\psi + c\phi\, c\theta\, s\psi & -s\phi\, s\psi + c\phi\, c\theta\, c\psi & -c\phi\, s\theta \\ \hline s\theta\, s\psi & s\theta\, c\psi & c\theta \end{array}\right) \begin{pmatrix} x \\ y \\ z \end{pmatrix}$$

$$\mathbf{R} \text{ or } \mathbf{A} = (A_{k'k}) \quad (= \mathbf{1}, \quad \text{if } \phi, \theta, \psi = 0). \tag{1.12.1b}$$

> Classical Eulerian Sequence: $(\boldsymbol{I}, \boldsymbol{J}, \boldsymbol{K})$: $3(\phi) \to 1(\theta) \to 3(\psi)$: $(\boldsymbol{i}, \boldsymbol{j}, \boldsymbol{k})$
> $0 \leq \phi$ (*precession*, or *azimuth*, angle) $< 2\pi$,
> $0 \leq \theta$ [*nutation* (i.e., nodding), or pole, angle] $\leq \pi$,
> $0 \leq \psi$ [*proper*, or *intrinsic*, rotation angle; or (*eigen*-) *spin*] $< 2\pi$.



$$\begin{pmatrix} \boldsymbol{I} \\ \boldsymbol{J} \\ \boldsymbol{K} \end{pmatrix} = \begin{pmatrix} c\phi & -s\phi & 0 \\ s\phi & c\phi & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} \boldsymbol{i}' \\ \boldsymbol{j}' \\ \boldsymbol{k}' \end{pmatrix}$$

$$\mathbf{T} = \mathbf{R}(\boldsymbol{k}^o \equiv \boldsymbol{K}, \phi) \cdot \mathbf{t}' \equiv \mathbf{R}_\phi \cdot \mathbf{t}'$$

$$\begin{pmatrix} \boldsymbol{i}' \\ \boldsymbol{j}' \\ \boldsymbol{k}' \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & c\theta & -s\theta \\ 0 & s\theta & c\theta \end{pmatrix} \begin{pmatrix} \boldsymbol{i}'' \\ \boldsymbol{j}'' \\ \boldsymbol{k}'' \end{pmatrix}$$

$$\mathbf{t}' = \mathbf{R}(\boldsymbol{i}', \theta) \cdot \mathbf{t}'' \equiv \mathbf{R}_\theta \cdot \mathbf{t}''$$

$$\begin{pmatrix} \boldsymbol{i}'' \\ \boldsymbol{j}'' \\ \boldsymbol{k}'' \end{pmatrix} = \begin{pmatrix} c\psi & -s\psi & 0 \\ s\psi & c\psi & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} \boldsymbol{i} \\ \boldsymbol{j} \\ \boldsymbol{k} \end{pmatrix}$$

$$\mathbf{t}'' = \mathbf{R}(\boldsymbol{k}'' = \boldsymbol{k}, \psi) \cdot \mathbf{t} \equiv \mathbf{R}_\psi \cdot \mathbf{t}$$

In sum: $\mathbf{T} = \mathbf{R}_\phi \cdot [\mathbf{R}_\theta \cdot (\mathbf{R}_\psi \cdot \mathbf{t})] \equiv (\mathbf{R}_\phi \cdot \mathbf{R}_\theta \cdot \mathbf{R}_\psi) \cdot \mathbf{t} \equiv \mathbf{R} \cdot \mathbf{t}$

Figure 1.26 Partial, or elementary, rotations of classical Eulerian sequence: $\phi \to \theta \to \psi$ (originally: O—$xyz = O$—$x_o y_o z_o \equiv O$—XYZ).

REMARKS

(i) Equation (1.12.1b) readily shows that if the direction cosines $A_{k'k}$ are known, the three Eulerian angles can be calculated from

$$\phi = \tan^{-1}(-A_{1'3}/A_{2'3}), \qquad \theta = \cos^{-1}(A_{3'3}), \qquad \psi = \tan^{-1}(A_{3'1}/A_{3'2}). \tag{1.12.1c}$$

(ii) If the origin of the body-fixed axes $\blacklozenge$ is moving relative to the space-fixed frame O–XYZ, then in the above we simply replace X with $X - X_\blacklozenge$ and so on, cyclically. Then, x, y, z [or $x_{/\blacklozenge}, y_{/\blacklozenge}, z_{/\blacklozenge}$ (§1.8)] are the particle coordinates relative to $\blacklozenge$–xyz. In this case, eq. (1.12.1b) shows clearly that a *free* (i.e., *unconstrained*) rigid body has *six (global) degrees of freedom*:

$q_{1,2,3} = X_\blacklozenge, Y_\blacklozenge, Z_\blacklozenge$: inertial coordinates of base point (pole) $\blacklozenge$,

$q_{4,5,6} = \phi, \theta, \psi$: Eulerian angles of body-fixed $\blacklozenge$–xyz relative to $\blacklozenge$–XYZ;

and the constant x, y, z is the "name" of a generic body particle [more on this in chap. 2].

Inverting (1.12.1b) — while noting that, since all three component matrices $\mathbf{R}_{\phi,\theta,\psi}$ are orthogonal, the inverse of each equals its transpose (or using the passive interpretation equations in §1.11) — we readily obtain

$$\begin{pmatrix} x \\ y \\ z \end{pmatrix} = \mathbf{R}^{\mathrm{T}} \cdot \begin{pmatrix} X \\ Y \\ Z \end{pmatrix}, \tag{1.12.2}$$

where

$$\mathbf{R}^{\mathrm{T}} = (\mathbf{R}_\phi \cdot \mathbf{R}_\theta \cdot \mathbf{R}_\psi)^{\mathrm{T}} = \mathbf{R}_\psi{}^{\mathrm{T}} \cdot \mathbf{R}_\theta{}^{\mathrm{T}} \cdot \mathbf{R}_\phi{}^{\mathrm{T}} = \mathbf{R}_{-\psi} \cdot \mathbf{R}_{-\theta} \cdot \mathbf{R}_{-\phi}$$

$$= \begin{pmatrix} c\psi & s\psi & 0 \\ -s\psi & c\psi & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 & 0 \\ 0 & c\theta & s\theta \\ 0 & -s\theta & c\theta \end{pmatrix} \begin{pmatrix} c\phi & s\phi & 0 \\ -s\phi & c\phi & 0 \\ 0 & 0 & 1 \end{pmatrix}. \tag{1.12.2a}$$

By adopting the *active* interpretation, we can show that (along arbitrary but common axes)

(a) $$\boldsymbol{r}_f = \mathbf{R}(\boldsymbol{k}'', \psi) \cdot \mathbf{R}(\boldsymbol{i}', \theta) \cdot \mathbf{R}(\boldsymbol{k}^o = \boldsymbol{K}, \phi) \cdot \boldsymbol{r}_i = (\mathbf{R}_\psi \cdot \mathbf{R}_\theta \cdot \mathbf{R}_\phi) \cdot \boldsymbol{r}_i, \tag{1.12.3a}$$

(b) $$\begin{aligned} \boldsymbol{r}_i &= (\mathbf{R}_\psi \cdot \mathbf{R}_\theta \cdot \mathbf{R}_\phi)^{\mathrm{T}} \cdot \boldsymbol{r}_f = \mathbf{R}_\phi{}^{\mathrm{T}} \cdot \mathbf{R}_\theta{}^{\mathrm{T}} \cdot \mathbf{R}_\psi{}^{\mathrm{T}} \cdot \boldsymbol{r}_f = (\mathbf{R}_{-\phi} \cdot \mathbf{R}_{-\theta} \cdot \mathbf{R}_{-\psi}) \cdot \boldsymbol{r}_f \\ &= \left[\mathbf{R}(\boldsymbol{K}, -\phi) \cdot \mathbf{R}(\boldsymbol{i}', -\theta) \cdot \mathbf{R}(\boldsymbol{k}'', -\psi)\right] \cdot \boldsymbol{r}_i; \end{aligned} \tag{1.12.3b}$$

while, by adopting the *rotation of a triad* interpretation, we can show that

(a) $$\mathbf{T} = (\mathbf{R}_\phi \cdot \mathbf{R}_\theta \cdot \mathbf{R}_\psi) \cdot \mathbf{t}, \tag{1.12.4a}$$

(b) $$\mathbf{t} = (\mathbf{R}_{-\psi} \cdot \mathbf{R}_{-\theta} \cdot \mathbf{R}_{-\phi}) \cdot \mathbf{T}; \tag{1.12.4b}$$

where $\mathbf{T} = (\boldsymbol{I}, \boldsymbol{J}, \boldsymbol{K})^{\mathrm{T}}$, $\mathbf{t} = (\boldsymbol{i}, \boldsymbol{j}, \boldsymbol{k})^{\mathrm{T}}$.
Next, we prove the following remarkable theorem.

THEOREM (on Compounded Rotations about Body-fixed versus Space-fixed Axes)

$$\begin{aligned} \mathbf{R}_\psi \cdot \mathbf{R}_\theta \cdot \mathbf{R}_\phi &\equiv \mathbf{R}(\boldsymbol{k}'', \psi) \cdot \mathbf{R}(\boldsymbol{i}', \theta) \cdot \mathbf{R}(\boldsymbol{k}^o = \boldsymbol{K}, \phi) \\ &= \mathbf{R}(\boldsymbol{K}, \phi) \cdot \mathbf{R}(\boldsymbol{I}, \theta) \cdot \mathbf{R}(\boldsymbol{K}, \psi). \end{aligned} \tag{1.12.5a}$$

In words: *the resultant rotation tensor of the classical Eulerian sequence about the body-fixed axes: $\phi(\boldsymbol{k} \equiv \boldsymbol{k}^o = \boldsymbol{K}) \to \theta(\boldsymbol{i}') \to \psi(\boldsymbol{k}'')$, equals the resultant rotation of the reverse-order sequence about the corresponding space-fixed axes: $\psi(\boldsymbol{K}) \to \theta(\boldsymbol{I}) \to \phi(\boldsymbol{K})$.*

(i) To this end, we first prove the following auxiliary theorem.

Shift of the Axis Theorem

Let us consider two concurrent axes of rotation described by the unit vectors $\boldsymbol{n}$ and $\boldsymbol{n}'$, and related by a rotation through an angle μ about a third (also concurrent) axis described by the unit vector $\boldsymbol{m}$; that is,

$$\boldsymbol{n}' = \mathbf{R}(\boldsymbol{m}, \mu) \cdot \boldsymbol{n} = \boldsymbol{n} \cdot \mathbf{R}^{\mathrm{T}}(\boldsymbol{m}, \mu). \tag{1.12.5b}$$

Then, the corresponding rotation tensors about $\boldsymbol{n}$ and $\boldsymbol{n}'$, but with a common angle χ, are related by the tensor-like (or, generally, "similarity") transformation:

$$\mathbf{R}(\boldsymbol{n}', \chi) = \mathbf{R}(\boldsymbol{m}, \mu) \cdot \mathbf{R}(\boldsymbol{n}, \chi) \cdot \mathbf{R}^{\mathrm{T}}(\boldsymbol{m}, \mu). \tag{1.12.5c}$$

PROOF

Applying the rotation formula (1.10.10a) for $\boldsymbol{n} \to \boldsymbol{n}'$ and χ, we obtain, successively,

$$\begin{aligned}
\mathbf{R}(\boldsymbol{n}', \chi) &= \mathbf{R}[\mathbf{R}(\boldsymbol{m}, \mu) \cdot \boldsymbol{n}, \chi] \\
&= (\cos\chi)\mathbf{1} + (\sin\chi)[\mathbf{R}(\boldsymbol{m}, \mu) \cdot \boldsymbol{n}] \times \mathbf{1} \\
&\qquad + (1 - \cos\chi)[\mathbf{R}(\boldsymbol{m}, \mu) \cdot \boldsymbol{n}] \otimes [\mathbf{R}(\boldsymbol{m}, \mu) \cdot \boldsymbol{n}]
\end{aligned}$$

[using the fact that, for any vector, $\boldsymbol{v}$: $(\mathbf{R} \cdot \boldsymbol{v}) \times \mathbf{1} = \mathbf{R} \cdot (\boldsymbol{v} \times \mathbf{1}) \cdot \mathbf{R}^{\mathrm{T}}$ — see proof below]

$$\begin{aligned}
&= (\cos\chi)\mathbf{1} + (\sin\chi)[\mathbf{R}(\boldsymbol{m}, \mu) \cdot (\boldsymbol{n} \times \mathbf{1}) \cdot \mathbf{R}^{\mathrm{T}}(\boldsymbol{m}, \mu)] \\
&\qquad + (1 - \cos\chi)[\mathbf{R}(\boldsymbol{m}, \mu) \cdot (\boldsymbol{n} \otimes \boldsymbol{n}) \cdot \mathbf{R}^{\mathrm{T}}(\boldsymbol{m}, \mu)]
\end{aligned}$$

[recalling that $\mathbf{R}(\boldsymbol{m}, \mu) \cdot \mathbf{R}^{\mathrm{T}}(\boldsymbol{m}, \mu) = \mathbf{1}$]

$$\begin{aligned}
&= \mathbf{R}(\boldsymbol{m}, \mu) \cdot [(\cos\chi)\mathbf{1} + (\sin\chi)(\boldsymbol{n} \times \mathbf{1}) + (1 - \cos\chi)(\boldsymbol{n} \otimes \boldsymbol{n})] \cdot \mathbf{R}^{\mathrm{T}}(\boldsymbol{m}, \mu) \\
&= \mathbf{R}(\boldsymbol{m}, \mu) \cdot [(\cos\chi)\mathbf{1} + (\sin\chi)\mathbf{N} + (1 - \cos\chi)(\boldsymbol{n} \otimes \boldsymbol{n})] \cdot \mathbf{R}^{\mathrm{T}}(\boldsymbol{m}, \mu)
\end{aligned}$$

[recalling again (1.10.10a)]

$$= \mathbf{R}(\boldsymbol{m}, \mu) \cdot \mathbf{R}(\boldsymbol{n}, \chi) \cdot \mathbf{R}^{\mathrm{T}}(\boldsymbol{m}, \mu), \quad \text{Q.E.D.} \tag{1.12.5d}$$

[PROOF that $(\mathbf{R} \cdot \boldsymbol{v}) \times \mathbf{1} = \mathbf{R} \cdot (\boldsymbol{v} \times \mathbf{1}) \cdot \mathbf{R}^{\mathrm{T}}$

According to the *passive interpretation*, $\boldsymbol{v}$ and its corresponding antisymmetric tensor $\boldsymbol{V} = \boldsymbol{v} \times \mathbf{1}$ transform as follows:

$$\mathbf{R} \cdot \boldsymbol{v} = \text{components of } \boldsymbol{v} \text{ along the } \textit{old} \text{ axes} \equiv \boldsymbol{v}',$$

$$\mathbf{R} \cdot \boldsymbol{V} \cdot \mathbf{R}^{\mathrm{T}} = \text{components of } \boldsymbol{V} \text{ along the } \textit{old} \text{ axes} \equiv \boldsymbol{V}'.$$

Therefore,

$$(\mathbf{R} \cdot \boldsymbol{v}) \times \mathbf{1} = \boldsymbol{v}' \times \mathbf{1} = \boldsymbol{V}' = \mathbf{R} \cdot \boldsymbol{V} \cdot \mathbf{R}^{\mathrm{T}} = \mathbf{R} \cdot (\boldsymbol{v} \times \mathbf{1}) \cdot \mathbf{R}^{\mathrm{T}}, \quad \text{Q.E.D.]}$$

This theorem allows one to relate the rotation tensors about the initial ($\boldsymbol{n}$) and final (i.e., rotated) ($\boldsymbol{n}'$) positions of a body-fixed axis.

(ii) Now, back to the proof of (1.12.5a). Applying the preceding shift of axis theorem (1.12.5b, c), we get

(a) $$\mathbf{R}(\boldsymbol{k}'', \psi) = \mathbf{R}(\boldsymbol{i}', \theta) \cdot \mathbf{R}(\boldsymbol{k}', \psi) \cdot \mathbf{R}^{\mathrm{T}}(\boldsymbol{i}', \phi), \tag{1.12.5e}$$

where

$$\boldsymbol{k}'' = \mathbf{R}(\boldsymbol{i}', \theta) \cdot \boldsymbol{k}'. \tag{1.12.5f}$$

(b)

$$\mathbf{R}(\boldsymbol{i}', \theta) = \mathbf{R}(\boldsymbol{K}, \phi) \cdot \mathbf{R}(\boldsymbol{I}, \theta) \cdot \mathbf{R}^{\mathrm{T}}(\boldsymbol{K}, \phi), \tag{1.12.5g}$$

$$\Rightarrow \mathbf{R}^{\mathrm{T}}(\boldsymbol{i}', \phi) = \mathbf{R}(\boldsymbol{K}, \phi) \cdot \mathbf{R}^{\mathrm{T}}(\boldsymbol{I}, \theta) \cdot \mathbf{R}^{\mathrm{T}}(\boldsymbol{K}, \phi), \tag{1.12.5h}$$

where

$$\boldsymbol{i}' = \mathbf{R}(\boldsymbol{K}, \phi) \cdot \boldsymbol{I}; \tag{1.12.5i}$$

(c)

$$\mathbf{R}(\boldsymbol{k}', \psi) = \mathbf{R}(\boldsymbol{K}, \phi) \cdot \mathbf{R}(\boldsymbol{K}, \psi) \cdot \mathbf{R}^{\mathrm{T}}(\boldsymbol{K}, \phi), \tag{1.12.5j}$$

where

$$\boldsymbol{k}' = \mathbf{R}(\boldsymbol{K}, \phi) \cdot \boldsymbol{K}. \tag{1.12.5k}$$

Substituting (1.12.5g, h, j) into the right side of (1.12.5e), while recalling that all these **R**'s are orthogonal tensors, yields

$$\begin{aligned}
\mathbf{R}(\boldsymbol{k}'', \psi) &= [\mathbf{R}(\boldsymbol{K}, \phi) \cdot \mathbf{R}(\boldsymbol{I}, \theta) \cdot \mathbf{R}^{\mathrm{T}}(\boldsymbol{K}, \phi)] \\
&\quad \cdot [\mathbf{R}(\boldsymbol{K}, \phi) \cdot \mathbf{R}(\boldsymbol{K}, \psi) \cdot \mathbf{R}^{\mathrm{T}}(\boldsymbol{K}, \phi)] \\
&\quad \cdot [\mathbf{R}(\boldsymbol{K}, \phi) \cdot \mathbf{R}^{\mathrm{T}}(\boldsymbol{I}, \theta) \cdot \mathbf{R}^{\mathrm{T}}(\boldsymbol{K}, \phi)] \\
&= \mathbf{R}(\boldsymbol{K}, \phi) \cdot \mathbf{R}(\boldsymbol{I}, \theta) \cdot \mathbf{R}(\boldsymbol{K}, \psi) \cdot \mathbf{R}^{\mathrm{T}}(\boldsymbol{I}, \theta) \cdot \mathbf{R}^{\mathrm{T}}(\boldsymbol{K}, \phi).
\end{aligned} \tag{1.12.5l}$$

In view of (1.12.5g) and (1.12.5l), the left side of (1.12.5a) transforms successively to

$$\begin{aligned}
&\mathbf{R}(\boldsymbol{k}'', \psi) \cdot \mathbf{R}(\boldsymbol{i}', \theta) \cdot \mathbf{R}(\boldsymbol{K}, \phi) \\
&\quad = \left[\mathbf{R}(\boldsymbol{K}, \phi) \cdot \mathbf{R}(\boldsymbol{I}, \theta) \cdot \mathbf{R}(\boldsymbol{K}, \psi) \cdot \mathbf{R}^{\mathrm{T}}(\boldsymbol{I}, \theta) \cdot \mathbf{R}^{\mathrm{T}}(\boldsymbol{K}, \phi)\right] \\
&\qquad \cdot \left[\mathbf{R}(\boldsymbol{K}, \phi) \cdot \mathbf{R}(\boldsymbol{I}, \theta) \cdot \mathbf{R}^{\mathrm{T}}(\boldsymbol{K}, \phi)\right] \cdot \mathbf{R}(\boldsymbol{K}, \phi) \\
&\quad = \mathbf{R}(\boldsymbol{K}, \phi) \cdot \mathbf{R}(\boldsymbol{I}, \theta) \cdot \mathbf{R}(\boldsymbol{K}, \psi), \quad \text{Q.E.D.}
\end{aligned} \tag{1.12.5m}$$

Generally, consider a body-fixed frame O–xyz originally coinciding with the space-fixed frame O–XYZ. Then the sequence of rotations about Ox (*first*, χ_1) $\rightarrow$ Oy (*second*, χ_2) $\rightarrow$ Oz (*third*, χ_3) has the same final orientational effect as the sequence about OZ (*first*, χ_3) $\rightarrow$ OY (*second*, χ_2) $\rightarrow$ OX (*third*, χ_1). [See also Pars, 1965, pp. 103–105.]

Angular Velocity via Eulerian Angle Rates

Let us calculate the vector of angular velocity of the body frame O–xyz relative to the space frame O–XYZ, in terms of the Eulerian angles ϕ, θ, ψ and their rates $\omega_\phi \equiv d\phi/dt$, $\omega_\theta \equiv d\theta/dt$, $\omega_\psi \equiv d\psi/dt$; both along the body- and the space-fixed axes. We present several approaches.

(i) Geometrical Derivation

By inspection of fig. 1.26 we easily find that

$$\boldsymbol{\omega} = \omega_\phi \boldsymbol{K} + \omega_\theta \boldsymbol{i}' + \omega_\psi \boldsymbol{k}''. \tag{1.12.6a}$$

But, again by inspection, along the *space* basis,

$$\begin{aligned}
\boldsymbol{K} &= (0)\boldsymbol{I} + (0)\boldsymbol{J} + (1)\boldsymbol{K},\\
\boldsymbol{i}' &= (\cos\phi)\boldsymbol{I} + (\sin\phi)\boldsymbol{J} + (0)\boldsymbol{K},\\
\boldsymbol{k}'' &= (-\sin\theta)\boldsymbol{j}' + (\cos\theta)\boldsymbol{k}'\\
&= (-\sin\theta)[(-\sin\phi)\boldsymbol{I} + (\cos\phi)\boldsymbol{J}] + (\cos\theta)\boldsymbol{K}\\
&= (\sin\theta\sin\phi)\boldsymbol{I} + (-\sin\theta\cos\phi)\boldsymbol{J} + (\cos\theta)\boldsymbol{K};
\end{aligned} \tag{1.12.6b}$$

and along the *body* basis,

$$\begin{gathered}
\boldsymbol{K} = \boldsymbol{j}''(\sin\theta) + \boldsymbol{k}''(\cos\theta) = (\boldsymbol{i}\sin\psi + \boldsymbol{j}\cos\psi)\sin\theta + \boldsymbol{k}\cos\theta,\\
\boldsymbol{i}' = \boldsymbol{i}\cos\psi - \boldsymbol{j}\sin\psi, \qquad \boldsymbol{k}'' = \boldsymbol{k}.
\end{gathered} \tag{1.12.6c}$$

Inserting (1.12.6b, c) in (1.12.6a) and rearranging, we obtain the representations

$$\boldsymbol{\omega} = \omega_X\boldsymbol{I} + \omega_Y\boldsymbol{J} + \omega_Z\boldsymbol{K} = \omega_x\boldsymbol{i} + \omega_y\boldsymbol{j} + \omega_z\boldsymbol{k}, \tag{1.12.7a}$$

where, in matrix form

$$\begin{array}{ccc}
\begin{pmatrix}\omega_X\\ \omega_Y\\ \omega_Z\end{pmatrix} & = & \begin{pmatrix}0 & c\phi & s\phi\, s\theta\\ 0 & s\phi & -c\phi\, s\theta\\ 1 & 0 & c\theta\end{pmatrix}\begin{pmatrix}\omega_\phi\\ \omega_\theta\\ \omega_\psi\end{pmatrix}\\
\textit{Space}\text{ axes} & & \mathbf{E}_{\mathbf{s}(\text{pace})}(\phi,\theta) \quad [\text{no } \psi\text{-dependence}],
\end{array} \tag{1.12.7b}$$

$$\begin{array}{ccc}
\begin{pmatrix}\omega_x\\ \omega_y\\ \omega_z\end{pmatrix} & = & \begin{pmatrix}s\theta\, s\psi & c\psi & 0\\ s\theta\, c\psi & -s\psi & 0\\ c\theta & 0 & 1\end{pmatrix}\begin{pmatrix}\omega_\phi\\ \omega_\theta\\ \omega_\psi\end{pmatrix}\\
\textit{Body}\text{ axes} & & \mathbf{E}_{\mathbf{b}(\text{ody})}(\theta,\psi) \quad [\text{no } \phi\text{-dependence}],
\end{array} \tag{1.12.7c}$$

Inverting (1.12.7b, c) (noting that, since the axes of $\omega_{\phi,\theta,\psi}$ are *non-orthogonal*, the transformation matrices $\mathbf{E_s}$, $\mathbf{E_b}$ are *nonorthogonal* also; that is, *their inverses do not equal their transposes*), we obtain, respectively,

$$\begin{pmatrix}\omega_\phi\\ \omega_\theta\\ \omega_\psi\end{pmatrix} = (1/\sin\theta)\underbrace{\begin{pmatrix}-s\phi\, c\theta & c\phi\, c\theta & s\theta\\ c\phi\, s\theta & s\phi\, s\theta & 0\\ s\phi & -c\phi & 0\end{pmatrix}}_{\mathbf{E_s}^{-1}(\phi,\theta),}\begin{pmatrix}\omega_X\\ \omega_Y\\ \omega_Z\end{pmatrix} \tag{1.12.7d}$$

$$= (1/\sin\theta)\underbrace{\begin{pmatrix}s\psi & c\psi & 0\\ s\theta\, c\psi & -s\theta\, s\psi & 0\\ -c\theta\, s\psi & -c\theta\, c\psi & s\theta\end{pmatrix}}_{\mathbf{E_b}^{-1}(\theta,\psi);}\begin{pmatrix}\omega_x\\ \omega_y\\ \omega_z\end{pmatrix} \tag{1.12.7e}$$

from which we can also calculate the $\omega_{X,\,Y,\,Z} \Leftrightarrow \omega_{x,\,y,\,z}$ (orthogonal!) transformation matrices.

REMARKS

(a) The transformations (1.12.7b–e) readily reveal a serious drawback of the $3 \to 1 \to 3$ Eulerian angle description, for $\theta = 0$ (or $\pm\pi$); that is, when Oz coincides with OZ (or $-OZ$), in which case the nodal line ON disappears, $\sin\theta = 0$, and, so, assuming $\phi,\ \psi \neq 0$, eqs. (1.12.7b, c) yield, respectively,

$$\omega_X = (c\phi)\omega_\theta, \qquad \omega_Y = (s\phi)\omega_\theta, \qquad \omega_Z = \omega_\phi + \omega_\psi \ \Rightarrow\ {\omega_X}^2 + {\omega_Y}^2 = {\omega_\theta}^2; \quad (1.12.7f)$$

$$\omega_x = (-c\psi)\omega_\theta, \qquad \omega_y = (-s\psi)\omega_\theta, \qquad \omega_z = \omega_\phi + \omega_\psi \ \Rightarrow\ {\omega_x}^2 + {\omega_y}^2 = {\omega_\theta}^2; \ (1.12.7g)$$

which means that knowing $\omega_{X,\,Y,\,Z/x,\,y,\,z}(t)$ [say, after solving the kinetic Eulerian equations (§1.17)], we can determine ω_θ *uniquely*, but not ω_ϕ and ω_ψ!

Actually, *all* twelve generalized Eulerian angle descriptions mentioned earlier, $\chi_1 \to \chi_2 \to \chi_3$, exhibit such *singularities* for some value(s) of their *second* rotation angle χ_2; in which case, *the planes of the other two angles become indistinguishable*! From the numerical viewpoint, this means that in the close neighborhood of these values of χ_2, it becomes difficult to integrate for the rates $d\chi_k/dt$ ($k = 1, 2, 3$). This is the main reason that, in rotational (or "attitude") rigid-body dynamics, (singularity free) *four-parameter formalisms* are sought, and the reason that the classical Eulerian sequence $3 \to 1 \to 3$ has been of much use in astronomy (where x, y, z have origin at the center of the Earth, and point to three distant stars) and physics; whereas other Eulerian sequences, such as $1 \to 2 \to 3$ or $3 \to 2 \to 1$ [associated with the names of Cardan (1501–1576) (continental European literature), Tait (1869), Bryan (1911) (British literature); and examined below] are more preferable in engineering rigid-body dynamics; for example, airplanes, ships, railroads, satellites, and so on. [Similarly, the position $(\phi, \theta, \psi) = (0, 0, 0)$ represents a singular "gimbal lock": the motions ω_ϕ and ω_ψ are indistinguishable since each is about the vertical axis Z; only $\omega_\phi + \omega_\psi$ is known. The ω_θ motion is about the X-axis, and so it is impossible to represent rotations about the Y-axis; it is "locked out"; that is (0, 0, 0) introduces artificially a constraint, $\omega_Y = 0$, $\omega_y = 0$ that *mechanically* is not there (then, $\omega_X = \omega_\theta$, $\omega_Y = 0$, $\omega_Z = \omega_\phi + \omega_\psi$; $\omega_x = \omega_\theta$, $\omega_z = \omega_\phi + \omega_\psi$).]

(b) Equations (1.12.7b, c) also show that the components $\omega_{X,\,Y,\,Z/x,\,y,\,z}$ are *quasi* or *nonholonomic velocities*; that is, although they are linear and homogeneous combinations of the Eulerian angle rates $\omega_\phi \equiv d\phi/dt$, $\omega_\theta \equiv d\theta/dt$, $\omega_\psi \equiv d\psi/dt$, they do not equal the rates of other angles. Indeed, if, for example, $\omega_X = d\theta_X/dt$, where $\theta_X = \theta_X(\phi, \theta, \psi)$, then we should have

$$\begin{aligned} d\theta_X/dt &= (\partial\theta_X/\partial\phi)(d\phi/dt) + (\partial\theta_X/\partial\theta)(d\theta/dt) + (\partial\theta_X/\partial\psi)(d\psi/dt) \\ &= (0)(d\phi/dt) + (c\phi)(d\theta/dt) + (s\phi\, s\theta)(d\psi/dt) \qquad \text{[by (1.12.7b)]}, \end{aligned} \quad (1.12.7h)$$

that is,

$$\partial\theta_X/\partial\phi = 0\,, \qquad \partial\theta_X/\partial\theta = c\theta\,, \qquad \partial\theta_X/\partial\psi = s\phi\, s\theta\,. \quad (1.12.7i)$$

But, from (1.12.7i), it follows that, *in general*,

$$\partial/\partial\theta(\partial\theta_X/\partial\phi) = 0 \neq \partial/\partial\phi(\partial\theta_X/\partial\theta) = -s\phi\,. \quad (1.12.7j)$$

Hence, no such θ_X exists; and similarly for the other ω's. (An introduction to quasi coordinates is given in §1.14; and a detailed treatment is given in chap. 2.)

(ii) Passive Interpretation Derivation

(a) Body-fixed axes representation. Since $\boldsymbol{\omega}$ is a vector, we can express it as the sum of its three *Eulerian angular velocities*:

$$\boldsymbol{\omega} = \boldsymbol{\omega}_\phi + \boldsymbol{\omega}_\theta + \boldsymbol{\omega}_\psi, \tag{1.12.8a}$$

where

$$\boldsymbol{\omega}_\phi = (d\phi/dt)\boldsymbol{K}, \qquad \boldsymbol{\omega}_\theta = (d\theta/dt)\boldsymbol{i}', \qquad \boldsymbol{\omega}_\psi = (d\psi/dt)\boldsymbol{k}''. \tag{1.12.8b}$$

Then, using the passive interpretation, (1.11.4h, 7a ff.), we can express (1.12.8a, b) along the (new) *body* axes basis $(\boldsymbol{i}, \boldsymbol{j}, \boldsymbol{k})$. Since the Eulerian basis $(\boldsymbol{K}, \boldsymbol{i}', \boldsymbol{k}'')$ is *non-orthogonal*, we carry out this transformation, not for the entire $\boldsymbol{\omega}$, but for each of its above components $\boldsymbol{\omega}_\phi, \boldsymbol{\omega}_\theta, \boldsymbol{\omega}_\psi$, and then, adding the results, we obtain

$$\boldsymbol{\omega}_{\phi,\, body\,\text{components}} = \mathbf{R}_\psi{}^{\mathrm{T}} \cdot \mathbf{R}_\theta{}^{\mathrm{T}} \cdot \begin{pmatrix} 0 \\ 0 \\ \omega_\phi \end{pmatrix}_{(\boldsymbol{I\,J\,K})} = \mathbf{R}_{-\psi} \cdot \mathbf{R}_{-\theta} \cdot \begin{pmatrix} 0 \\ 0 \\ \omega_\phi \end{pmatrix}$$

$$= \begin{pmatrix} c\psi & s\psi & 0 \\ -s\psi & c\psi & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 & 0 \\ 0 & c\theta & s\theta \\ 0 & -s\theta & c\theta \end{pmatrix} \begin{pmatrix} 0 \\ 0 \\ \omega_\phi \end{pmatrix} = \begin{pmatrix} (s\theta\, s\psi)\omega_\phi \\ (s\theta\, c\psi)\omega_\phi \\ (c\theta)\omega_\phi \end{pmatrix}, \tag{1.12.8c}$$

$$\boldsymbol{\omega}_{\theta,\, body\,\text{components}} = \mathbf{R}_\psi{}^{\mathrm{T}} \cdot \begin{pmatrix} \omega_\theta \\ 0 \\ 0 \end{pmatrix}_{(\boldsymbol{i}'\,\boldsymbol{j}'\,\boldsymbol{k}')} = \mathbf{R}_{-\psi} \cdot \begin{pmatrix} \omega_\theta \\ 0 \\ 0 \end{pmatrix}$$

$$= \begin{pmatrix} c\psi & s\psi & 0 \\ -s\psi & c\psi & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} \omega_\theta \\ 0 \\ 0 \end{pmatrix} = \begin{pmatrix} (c\psi)\omega_\theta \\ (-s\psi)\omega_\theta \\ (0)\omega_\theta \end{pmatrix}, \tag{1.12.8d}$$

$$\boldsymbol{\omega}_{\psi,\, body\,\text{components}} = \begin{pmatrix} 0 \\ 0 \\ \omega_\psi \end{pmatrix}_{(\boldsymbol{i\,j\,k})}. \tag{1.12.8e}$$

Adding (1.12.8c–e), we obtain the body axes components, equations (1.12.7c), as expected.

(b) Space-fixed axes representation. Proceeding similarly, we find

$$\boldsymbol{\omega} = \begin{pmatrix} 0 \\ 0 \\ \omega_\phi \end{pmatrix} + \underbrace{\begin{pmatrix} c\phi & -s\phi & 0 \\ s\phi & c\phi & 0 \\ 0 & 0 & 1 \end{pmatrix}}_{\mathbf{R}_\phi} \begin{pmatrix} \omega_\theta \\ 0 \\ 0 \end{pmatrix}$$

$$+ \underbrace{\begin{pmatrix} c\phi & -s\phi & 0 \\ s\phi & c\phi & 0 \\ 0 & 0 & 1 \end{pmatrix}}_{\mathbf{R}_\phi} \underbrace{\begin{pmatrix} 1 & 0 & 0 \\ 0 & c\theta & -s\theta \\ 0 & s\theta & c\theta \end{pmatrix}}_{\mathbf{R}_\theta} \begin{pmatrix} 0 \\ 0 \\ \omega_\psi \end{pmatrix}$$

$$= \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} \omega_\phi + \begin{pmatrix} c\phi \\ s\phi \\ 0 \end{pmatrix} \omega_\theta + \begin{pmatrix} s\phi\, s\theta \\ -c\phi\, s\theta \\ c\theta \end{pmatrix} \omega_\psi, \tag{1.12.8f}$$

which is none other than (1.12.7b).

Let the reader verify that the *space*-axes representation (1.12.8f) can also be rewritten as

$$\boldsymbol{\omega} = \mathbf{R}_\phi \cdot \begin{pmatrix} 0 \\ 0 \\ \omega_\phi \end{pmatrix} + \mathbf{R}_\phi \cdot \mathbf{R}_\theta \cdot \begin{pmatrix} \omega_\theta \\ 0 \\ 0 \end{pmatrix} + \mathbf{R}_\phi \cdot \mathbf{R}_\theta \cdot \mathbf{R}_\psi \cdot \begin{pmatrix} 0 \\ 0 \\ \omega_\psi \end{pmatrix}, \tag{1.12.8g}$$

while the *body*-axes representation (1.12.8c–e) can be rewritten as

$$\boldsymbol{\omega} = \mathbf{R}_{-\psi} \cdot \mathbf{R}_{-\theta} \cdot \mathbf{R}_{-\phi} \cdot \begin{pmatrix} 0 \\ 0 \\ \omega_\phi \end{pmatrix} + \mathbf{R}_{-\psi} \cdot \mathbf{R}_{-\theta} \cdot \begin{pmatrix} \omega_\theta \\ 0 \\ 0 \end{pmatrix} + \mathbf{R}_{-\psi} \cdot \begin{pmatrix} 0 \\ 0 \\ \omega_\psi \end{pmatrix}. \tag{1.12.8h}$$

(iii) Tensor (Matrix) Derivation

We have already seen [(1.7.27e) and (1.7.30i–k)] that the space-axes components of the angular velocity tensor (vector) $\boldsymbol{\Omega}'(\omega')$ are related to its body-axes components $\boldsymbol{\Omega}(\omega)$ by the tensor (vector) transformation

$$\boldsymbol{\Omega}' = \mathbf{R} \cdot \boldsymbol{\Omega} \cdot \mathbf{R}^{\mathrm{T}} \Leftrightarrow \boldsymbol{\Omega} = \mathbf{R}^{\mathrm{T}} \cdot \boldsymbol{\Omega}' \cdot \mathbf{R}$$
$$(\boldsymbol{\omega}' = \mathbf{R} \cdot \boldsymbol{\omega} \Leftrightarrow \boldsymbol{\omega} = \mathbf{R}^{\mathrm{T}} \cdot \boldsymbol{\omega}'), \tag{1.12.9a}$$

where $\mathbf{R}$, or $\mathbf{A}$, is the matrix of the direction cosines between these axes; and also that

$$\begin{aligned} &\boldsymbol{\Omega}' = (\mathrm{d}\mathbf{R}/\mathrm{d}t) \cdot \mathbf{R}^{\mathrm{T}} = -\mathbf{R} \cdot (\mathrm{d}\mathbf{R}/\mathrm{d}t)^{\mathrm{T}} \qquad [\text{due to } \mathrm{d}/\mathrm{d}t(\mathbf{R} \cdot \mathbf{R}^{\mathrm{T}}) = \mathrm{d}\mathbf{1}/\mathrm{d}t = \mathbf{0}] \\ &\boldsymbol{\Omega} = \mathbf{R}^{\mathrm{T}} \cdot (\mathrm{d}\mathbf{R}/\mathrm{d}t) = -(\mathrm{d}\mathbf{R}/\mathrm{d}t)^{\mathrm{T}} \cdot \mathbf{R}, \\ &\mathrm{d}\mathbf{R}'/\mathrm{d}t = \boldsymbol{\Omega}' \cdot \mathbf{R} \quad [= (\mathbf{R} \cdot \boldsymbol{\Omega} \cdot \mathbf{R}^{\mathrm{T}}) \cdot \mathbf{R}] = \mathbf{R} \cdot \boldsymbol{\Omega} \end{aligned} \tag{1.12.9b}$$

(a) Space-fixed axes representation. As we have seen, in the case of the classical Eulerian sequence $\phi \to \theta \to \psi$: $\mathbf{R} \equiv \mathbf{R}_\phi \cdot \mathbf{R}_\theta \cdot \mathbf{R}_\psi$, and therefore (1.12.9b) yields, successively,

$$\begin{aligned}
\boldsymbol{\Omega}' &= (\mathrm{d}\mathbf{R}/\mathrm{dt}) \cdot \mathbf{R}^{\mathrm{T}} = \mathrm{d}/\mathrm{dt}(\mathbf{R}_\phi \cdot \mathbf{R}_\theta \cdot \mathbf{R}_\psi) \cdot (\mathbf{R}_\phi \cdot \mathbf{R}_\theta \cdot \mathbf{R}_\psi)^{\mathrm{T}} \\
&= [(\mathrm{d}\mathbf{R}_\phi/\mathrm{dt}) \cdot \mathbf{R}_\theta \cdot \mathbf{R}_\psi + \mathbf{R}_\phi \cdot (\mathrm{d}\mathbf{R}_\theta/\mathrm{dt}) \cdot \mathbf{R}_\psi + \mathbf{R}_\phi \cdot \mathbf{R}_\theta \cdot (\mathrm{d}\mathbf{R}_\psi/\mathrm{dt})] \cdot ({\mathbf{R}_\psi}^{\mathrm{T}} \cdot {\mathbf{R}_\theta}^{\mathrm{T}} \cdot {\mathbf{R}_\phi}^{\mathrm{T}}) \\
&= (\mathrm{d}\mathbf{R}_\phi/\mathrm{dt}) \cdot [\mathbf{R}_\theta \cdot (\mathbf{R}_\psi \cdot {\mathbf{R}_\psi}^{\mathrm{T}}) \cdot {\mathbf{R}_\theta}^{\mathrm{T}}] \cdot {\mathbf{R}_\phi}^{\mathrm{T}} \\
&\qquad + \mathbf{R}_\phi \cdot [(\mathrm{d}\mathbf{R}_\theta/\mathrm{dt}) \cdot (\mathbf{R}_\psi \cdot {\mathbf{R}_\psi}^{\mathrm{T}}) \cdot {\mathbf{R}_\theta}^{\mathrm{T}}] \cdot {\mathbf{R}_\phi}^{\mathrm{T}} \\
&\qquad + \mathbf{R}_\phi \cdot \{\mathbf{R}_\theta \cdot [(\mathrm{d}\mathbf{R}_\psi/\mathrm{dt}) \cdot {\mathbf{R}_\psi}^{\mathrm{T}}] \cdot {\mathbf{R}_\theta}^{\mathrm{T}}\} \cdot {\mathbf{R}_\phi}^{\mathrm{T}} \\
&= (\mathrm{d}\mathbf{R}_\phi/\mathrm{dt}) \cdot {\mathbf{R}_\phi}^{\mathrm{T}} + \mathbf{R}_\phi \cdot [(\mathrm{d}\mathbf{R}_\theta/\mathrm{dt}) \cdot {\mathbf{R}_\theta}^{\mathrm{T}}] \cdot {\mathbf{R}_\phi}^{\mathrm{T}} + \mathbf{R}_\phi \cdot \mathbf{R}_\theta \cdot [(\mathrm{d}\mathbf{R}_\psi/\mathrm{dt}) \cdot {\mathbf{R}_\psi}^{\mathrm{T}}] \cdot (\mathbf{R}_\phi \cdot \mathbf{R}_\theta)^{\mathrm{T}}
\end{aligned}$$

[recalling the definition of tensor transformation (1.12.9a), and (1.12.9b)], (1.12.9c)

$$= \boldsymbol{\Omega}'_\phi + \mathbf{R}_\phi \cdot \boldsymbol{\Omega}'_\theta \cdot {\mathbf{R}_\phi}^{\mathrm{T}} + \mathbf{R}_\phi \cdot \mathbf{R}_\theta \cdot \boldsymbol{\Omega}'_\psi \cdot (\mathbf{R}_\phi \cdot \mathbf{R}_\theta)^{\mathrm{T}}$$

[$\boldsymbol{\Omega}'_{\phi,\theta,\psi}$: "partial" rotation tensors, along the space-fixed axes], (1.12.9d)

from which, after some long but straightforward algebra, we obtain [recalling (1.12.1a ff.)]

$$\begin{aligned}
&\Omega_{1'1'} \equiv \Omega_{XX} = 0\,, \\
&\Omega_{1'2'} = -\Omega_{2'1'} \equiv \Omega_{XY} = -\Omega_{YX} = -\omega_Z = -[d\phi/dt + (c\theta)(d\psi/dt)]\,, \\
&\Omega_{1'3'} = -\Omega_{3'1'} \equiv \Omega_{XZ} = -\Omega_{ZX} = -\omega_Y = (s\phi)(d\theta/dt) - (c\phi\, s\theta)(d\psi/dt)\,, \\
&\Omega_{2'2'} \equiv \Omega_{YY} = 0\,, \\
&\Omega_{2'3'} = -\Omega_{3'2'} \equiv \Omega_{YZ} = -\Omega_{ZY} = -\omega_X = -[(c\phi)(d\theta/dt) + (s\phi\, s\theta)(d\psi/dt)]\,, \\
&\Omega_{3'3'} \equiv \Omega_{ZZ} = 0\,,
\end{aligned} \tag{1.12.9e}$$

which coincide with (1.12.7b), as expected.

(b) Body-fixed axes representation. Proceeding analogously, we obtain

$$\begin{aligned}
\boldsymbol{\Omega} &= \mathbf{R}^{\mathrm{T}} \cdot (\mathrm{d}\mathbf{R}/\mathrm{dt}) = (\mathbf{R}_\phi \cdot \mathbf{R}_\theta \cdot \mathbf{R}_\psi)^{\mathrm{T}} \cdot [\mathrm{d}/\mathrm{dt}(\mathbf{R}_\phi \cdot \mathbf{R}_\theta \cdot \mathbf{R}_\psi)] \\
&= \cdots = {\mathbf{R}_\psi}^{\mathrm{T}} \cdot {\mathbf{R}_\theta}^{\mathrm{T}} \cdot [{\mathbf{R}_\phi}^{\mathrm{T}} \cdot (\mathrm{d}\mathbf{R}_\phi/\mathrm{dt})] \cdot \mathbf{R}_\theta \cdot \mathbf{R}_\psi \\
&\qquad + {\mathbf{R}_\psi}^{\mathrm{T}} \cdot [{\mathbf{R}_\theta}^{\mathrm{T}} \cdot (\mathrm{d}\mathbf{R}_\theta/\mathrm{dt})] \cdot \mathbf{R}_\psi + {\mathbf{R}_\psi}^{\mathrm{T}} \cdot (\mathrm{d}\mathbf{R}_\psi/\mathrm{dt}) \\
&\equiv {\mathbf{R}_\psi}^{\mathrm{T}} \cdot {\mathbf{R}_\theta}^{\mathrm{T}} \cdot \boldsymbol{\Omega}_\phi \cdot \mathbf{R}_\theta \cdot \mathbf{R}_\psi + {\mathbf{R}_\psi}^{\mathrm{T}} \cdot \boldsymbol{\Omega}_\theta \cdot \mathbf{R}_\psi + \boldsymbol{\Omega}_\psi
\end{aligned}$$

[$\boldsymbol{\Omega}_{\phi,\theta,\psi}$: "partial" rotation tensors, along the body-fixed axes]. (1.12.9f)

We leave it to the reader to verify that the above coincides with (1.12.7c). Alternatively, one can use the transformation equations (1.12.9a) to calculate $\boldsymbol{\Omega}/\boldsymbol{\omega}$ from $\boldsymbol{\Omega}'/\boldsymbol{\omega}'$. (See also Hamel, 1949, pp. 735–739.)

Cardanian Angles

This is the Eulerian rotation sequence $3 \to 2 \to 1$ (fig. 1.27). The angles $\chi_1 = \gamma(3) \to \chi_2 = \beta(2) \to \chi_3 = \alpha(1)$ are commonly (but not uniformly) referred to as *Cardanian*

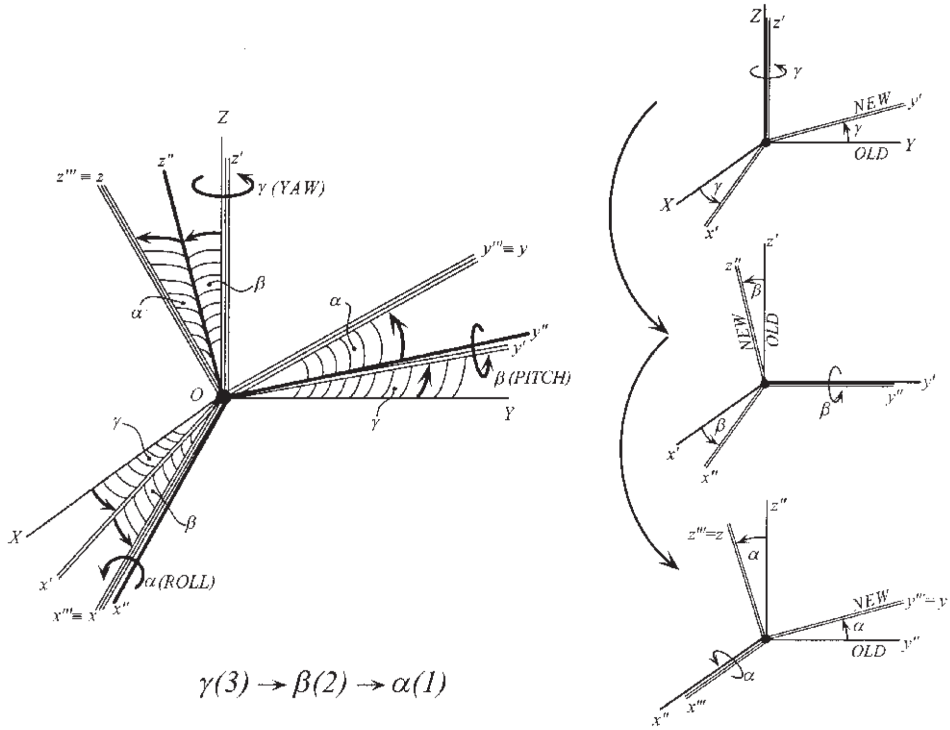


Figure 1.27 Cardanian angles: $\chi_1 = \gamma(3) \to \chi_2 = \beta(2) \to \chi_3 = \alpha(1)$.
(i) Rotation (OZ, $\chi_1 = \gamma$): O–XYZ (space axes) = O–$x_o y_o z_o$ (initial body axes) → O–$x'y'z'$.
(ii) Rotation (Oy', $\chi_2 = \beta$): O–$x'y'z'$ → O–$x''y''z''$.
(iii) Rotation (Ox'', $\chi_3 = \alpha$): O–$x''y''z''$ → O–xyz (final body axes).

angles. In vehicle and aeronautical dynamics, where such an attitude representation is popular, they are called *yaw* (γ), *pitch* (β), and *roll* (α).

Following the passive interpretation, we readily obtain

$$\begin{pmatrix} X \\ Y \\ Z \end{pmatrix} = \mathbf{R}\cdot\begin{pmatrix} x \\ y \\ z \end{pmatrix} = \mathbf{R}_\gamma \cdot \left\{ \mathbf{R}_\beta \cdot \left[\mathbf{R}_\alpha \cdot \begin{pmatrix} x \\ y \\ z \end{pmatrix} \right] \right\}$$

$$= \underset{\mathbf{R}_\gamma}{\begin{pmatrix} c\gamma & -s\gamma & 0 \\ s\gamma & c\gamma & 0 \\ 0 & 0 & 1 \end{pmatrix}} \cdot \underset{\mathbf{R}_\beta}{\begin{pmatrix} c\beta & 0 & s\beta \\ 0 & 1 & 0 \\ -s\beta & 0 & c\beta \end{pmatrix}} \cdot \underset{\mathbf{R}_\alpha,}{\begin{pmatrix} 1 & 0 & 0 \\ 0 & c\alpha & -s\alpha \\ 0 & s\alpha & c\alpha \end{pmatrix}} \begin{pmatrix} x \\ y \\ z \end{pmatrix} \tag{1.12.10a}$$

$$= \begin{pmatrix} c\beta\, c\gamma & s\alpha\, s\beta\, c\gamma - c\alpha\, s\gamma & c\alpha\, s\beta\, c\gamma + s\alpha\, s\gamma \\ c\beta\, s\gamma & s\alpha\, s\beta\, s\gamma + c\alpha\, c\gamma & c\alpha\, s\beta\, s\gamma - s\alpha\, c\gamma \\ -s\beta & s\alpha\, c\beta & c\alpha\, c\beta \end{pmatrix} \begin{pmatrix} x \\ y \\ z \end{pmatrix}, \tag{1.12.10b}$$

and, inversely, since $\mathbf{R}_{\alpha,\beta,\gamma}$ are proper orthogonal,

$$\begin{pmatrix} x \\ y \\ z \end{pmatrix} = \mathbf{R}^{\mathrm{T}} \cdot \begin{pmatrix} X \\ Y \\ Z \end{pmatrix} = (\mathbf{R}_{\alpha}{}^{\mathrm{T}} \cdot \mathbf{R}_{\beta}{}^{\mathrm{T}} \cdot \mathbf{R}_{\gamma}{}^{\mathrm{T}}) \cdot \begin{pmatrix} X \\ Y \\ Z \end{pmatrix}$$

$$= (\mathbf{R}_{-\alpha} \cdot \mathbf{R}_{-\beta} \cdot \mathbf{R}_{-\gamma}) \cdot \begin{pmatrix} X \\ Y \\ Z \end{pmatrix}. \qquad (1.12.10c)$$

Angular Velocity Tensors

Using the basic relations (1.12.9a, b), we can show, after some long and careful but straightforward algebra, that (with $\omega_\gamma \equiv d\gamma/dt$, $\omega_\beta \equiv d\beta/dt$, $\omega_\alpha \equiv d\alpha/dt$)

$$\underset{\textit{Space}\text{ axes}}{\begin{pmatrix} \omega_X \\ \omega_Y \\ \omega_Z \end{pmatrix}} = \underset{\mathbf{E}_{\mathbf{s}(\mathrm{pace})}(\gamma,\beta)}{\begin{pmatrix} 0 & -s\gamma & c\gamma\, c\beta \\ 0 & c\gamma & s\gamma\, c\beta \\ 1 & 0 & -s\beta \end{pmatrix}} \begin{pmatrix} \omega_\gamma \\ \omega_\beta \\ \omega_\alpha \end{pmatrix} \quad [\text{no } \alpha\text{-dependence}], \qquad (1.12.10d)$$

$$\underset{\textit{Body}\text{ axes}}{\begin{pmatrix} \omega_x \\ \omega_y \\ \omega_z \end{pmatrix}} = \underset{\mathbf{E}_{\mathbf{b}(\mathrm{ody})}(\beta,\alpha)}{\begin{pmatrix} -s\beta & 0 & 1 \\ c\beta\, s\alpha & c\alpha & 0 \\ c\alpha\, c\beta & -s\alpha & 0 \end{pmatrix}} \begin{pmatrix} \omega_\gamma \\ \omega_\beta \\ \omega_\alpha \end{pmatrix} \quad [\text{no } \gamma\text{-dependence}]. \qquad (1.12.10e)$$

Inverting (1.12.10d, e) (noting that, since the axes of $\omega_{\alpha,\beta,\gamma}$ are *non-orthogonal*, the transformation matrices $\mathbf{E}_{\mathbf{s}}(\gamma,\beta)$, $\mathbf{E}_{\mathbf{b}}(\beta,\alpha)$ are *nonorthogonal* also; that is, *their inverses do not equal their transposes*), we obtain respectively,

$$\begin{pmatrix} \omega_\gamma \\ \omega_\beta \\ \omega_\alpha \end{pmatrix} = (1/\cos\beta) \underset{\mathbf{E}_{\mathbf{s}}{}^{-1}(\beta,\gamma),}{\begin{pmatrix} s\beta\, c\gamma & s\beta\, s\gamma & c\beta \\ -s\gamma\, c\beta & c\gamma\, c\beta & 0 \\ c\gamma & s\gamma & 0 \end{pmatrix}} \begin{pmatrix} \omega_X \\ \omega_Y \\ \omega_Z \end{pmatrix} \qquad (1.12.10f)$$

$$= (1/\cos\beta) \underset{\mathbf{E}_{\mathbf{b}}{}^{-1}(\alpha,\beta);}{\begin{pmatrix} 0 & s\alpha & c\alpha \\ 0 & c\alpha\, c\beta & -s\alpha\, c\beta \\ c\beta & s\beta\, s\alpha & s\beta\, c\alpha \end{pmatrix}} \begin{pmatrix} \omega_x \\ \omega_y \\ \omega_z \end{pmatrix} \qquad (1.12.10g)$$

from which it is clear that the Cardanian sequence $3(\gamma) \to 2(\beta) \to 1(\alpha)$ has a singularity at $\beta = \pm(\pi/2)$. There, (1.12.10d, e) become, respectively (for $\beta = \pi/2$),

$$\omega_X = (-s\gamma)\omega_\beta, \quad \omega_Y = (c\gamma)\omega_\beta, \quad \omega_Z = \omega_\gamma - \omega_\alpha \;\Rightarrow\; \omega_X{}^2 + \omega_Y{}^2 = \omega_\beta{}^2, \quad (1.12.10h)$$

$$\omega_x = -\omega_\gamma + \omega_\alpha, \quad \omega_y = (c\alpha)\omega_\beta, \quad \omega_z = (-s\alpha)\omega_\beta \;\Rightarrow\; \omega_x{}^2 + \omega_y{}^2 = \omega_\beta{}^2; \quad (1.12.10i)$$

that is, a unique determination of ω_γ and ω_α from ω_Z, or ω_x, is impossible.

Finally, using (1.12.10f, g), we can obtain the $\omega_{X,Y,Z} \leftrightarrow \omega_{x,y,z}$ transformation. For a complete listing of the transformations between $\omega_{x,y,z} \equiv \omega_{1,2,3}$ (body-fixed axes) and the Eulerian rates $d\chi_{1,2,3}/dt \equiv v_{1,2,3}$ (and corresponding singularities), for all body-/space-axis Eulerian rotation sequences, see the next section.

1.13 THE RIGID BODY: TRANSFORMATION MATRICES (DIRECTION COSINES) BETWEEN SPACE-FIXED AND BODY-FIXED TRIADS; AND ANGULAR VELOCITY COMPONENTS ALONG BODY-FIXED AXES, FOR ALL SEQUENCES OF EULERIAN ANGLES

Summary of Theory, Notations

$$\mathbf{T} = (\boldsymbol{u}_{k'})^{\mathrm{T}} \equiv (\boldsymbol{u}_{1'}, \boldsymbol{u}_{2'}, \boldsymbol{u}_{3'})^{\mathrm{T}} \equiv (\boldsymbol{I}, \boldsymbol{J}, \boldsymbol{K})^{\mathrm{T}}: \ \textit{Space-fixed (fixed) triad}.$$

$$\mathbf{t} = (\boldsymbol{u}_{k})^{\mathrm{T}} \equiv (\boldsymbol{u}_{1}, \boldsymbol{u}_{2}, \boldsymbol{u}_{3})^{\mathrm{T}} \equiv (\boldsymbol{i}, \boldsymbol{j}, \boldsymbol{k})^{\mathrm{T}}: \ \textit{Body-fixed (moving) triad}.$$

All triads are assumed *ortho–normal–dextral* (OND), and such that, initially, $\mathbf{T} = \mathbf{t}$. Eulerian angles (see §1.12): χ_1, χ_2, χ_3 (the earlier ϕ, θ, ψ; or α, β, γ).

1. Basic Triad Transformation Formula

$$\mathbf{T} = \mathbf{R} \cdot \mathbf{t} \ \Leftrightarrow \ \mathbf{t} = \mathbf{R}^{\mathrm{T}} \cdot \mathbf{T},$$

where

$$\begin{aligned}
\mathbf{R} &= (R_{k'k}) \equiv (\boldsymbol{u}_{k'} \cdot \boldsymbol{u}_k) \qquad [\text{or } (A_{k'k})]: \ \textit{Tensor/Matrix of rotation} \\
&= \mathbf{R}(\boldsymbol{u}_i, \chi_1) \cdot \mathbf{R}(\boldsymbol{u}_j, \chi_2) \cdot \mathbf{R}(\boldsymbol{u}_k, \chi_3) \equiv [i(\chi_1), j(\chi_2), k(\chi_3)] \\
&\qquad [\text{Rotation sequence } \chi_1 \to \chi_2 \to \chi_3 \text{ about the } \textit{body}\text{-fixed axes } \boldsymbol{u}_i \to \boldsymbol{u}_j \to \boldsymbol{u}_k] \\
&= \mathbf{R}(\boldsymbol{u}_{k'}, \chi_3) \cdot \mathbf{R}(\boldsymbol{u}_{j'}, \chi_2) \cdot \mathbf{R}(\boldsymbol{u}_{i'}, \chi_1) \equiv [k'(\chi_3), j'(\chi_2), i'(\chi_1)] \\
&\qquad [\text{Rotation sequence } \chi_3 \to \chi_2 \to \chi_1 \text{ about the } \textit{space}\text{-fixed axes } \boldsymbol{u}_{k'} \to \boldsymbol{u}_{j'} \to \boldsymbol{u}_{i'}] \\
&\qquad\qquad [i, j, k = 1, 2, 3; \ i', j', k' = 1', 2', 3'];
\end{aligned}$$

and, by the basic theorem on compounded rotations (§1.12), the *inverse* rotation

$$\begin{aligned}
\mathbf{R}^{-1} = \mathbf{R}^{\mathrm{T}} &= \mathbf{R}(\boldsymbol{u}_k, -\chi_3) \cdot \mathbf{R}(\boldsymbol{u}_j, -\chi_2) \cdot \mathbf{R}(\boldsymbol{u}_i, -\chi_1) \\
&= \mathbf{R}(\boldsymbol{u}_{i'}, -\chi_1) \cdot \mathbf{R}(\boldsymbol{u}_{j'}, -\chi_2) \cdot \mathbf{R}(\boldsymbol{u}_{k'}, -\chi_3)
\end{aligned}$$

returns the body-triad $\mathbf{t}$ to its original position, i.e. realigns it with the space-triad $\mathbf{T}$.

How to obtain *space-axis* rotations; i.e., $[k'(\chi_1), \ j'(\chi_2), \ i'(\chi_3)]$, from a knowledge of *body-axis* rotations with the *same rotation sequence*: $\chi_1 \to \chi_2 \to \chi_3$; i.e., from $[i(\chi_1), \ j(\chi_2), \ k(\chi_3)]$, and vice versa. An example should suffice; by the above theorem, we will have

$$[2(\chi_1), 3(\chi_2), 1(\chi_3)] = [1'(\chi_3), 3'(\chi_2), 2'(\chi_1)]$$

and, therefore, swapping in the latter χ_3 with χ_1 (and vice versa), we obtain $[1'(\chi_1), 3'(\chi_2), 2'(\chi_3)]$, which appears in the listing below. Similarly, we have

$$[2'(\chi_1), 3'(\chi_2), 1'(\chi_3)] = [1(\chi_3), 3(\chi_2), 2(\chi_1)]$$

and swapping in there χ_3 with χ_1 (and vice versa) we obtain $[1(\chi_1), 3(\chi_2), 2(\chi_3)]$. Abbreviations: $s_i(\ldots) \equiv \sin(\chi_i),\ c_i(\ldots) \equiv \cos(\chi_i)$.

2. Angular Velocity Components

Body-fixed (moving) axes components:

$$\mathbf{\Omega} = \mathbf{R}^{\mathrm{T}} \cdot (\mathrm{d}\mathbf{R}/\mathrm{dt}) = -(\mathrm{d}\mathbf{R}/\mathrm{dt})^{\mathrm{T}} \cdot \mathbf{R}, \qquad [\text{due to } \mathrm{d}/\mathrm{dt}(\mathbf{R} \cdot \mathbf{R}^{\mathrm{T}}) = \mathrm{d}\mathbf{1}/\mathrm{dt} = \mathbf{0}]$$

Space-fixed (fixed) axes components:

$$\begin{aligned}
&\mathbf{\Omega}' = (\mathrm{d}\mathbf{R}/\mathrm{dt}) \cdot \mathbf{R}^{\mathrm{T}} = -\mathbf{R} \cdot (\mathrm{d}\mathbf{R}/\mathrm{dt})^{\mathrm{T}}\,; \\
&\qquad \text{with mutual transformations:} \\
&\mathbf{\Omega}' = \mathbf{R} \cdot \mathbf{\Omega} \cdot \mathbf{R}^{\mathrm{T}} \Leftrightarrow \mathbf{\Omega} = \mathbf{R}^{\mathrm{T}} \cdot \mathbf{\Omega}' \cdot \mathbf{R}\,, \qquad \boldsymbol{\omega}' = \mathbf{R} \cdot \boldsymbol{\omega} \Leftrightarrow \boldsymbol{\omega} = \mathbf{R}^{\mathrm{T}} \cdot \boldsymbol{\omega}' \\
&\qquad \text{where} \quad \boldsymbol{\omega} = \textit{axial} \text{ vector of } \mathbf{\Omega}\,, \qquad \boldsymbol{\omega}' = \textit{axial} \text{ vector of } \mathbf{\Omega}' \\
&[\text{i.e.} \quad \mathbf{\Omega} \cdot (\textit{vector}) = \boldsymbol{\omega} \times (\textit{vector}), \text{etc.}]\,;
\end{aligned}$$

Rotation tensor derivative:

$$\mathrm{d}\mathbf{R}/\mathrm{dt} = \mathbf{\Omega}' \cdot \mathbf{R} \quad [= (\mathbf{R} \cdot \mathbf{\Omega} \cdot \mathbf{R}^{\mathrm{T}}) \cdot \mathbf{R}] \quad = \mathbf{R} \cdot \mathbf{\Omega}\,.$$

Listing of Transformation Matrices; and Angular Velocity Components

(Body-fixed vs. Eulerian rates; and corresponding singularities. Notation: $d\chi_{1,2,3}/dt \equiv v_{1,2,3}$)

1(a) $[1(\chi_1), 2(\chi_2), 3(\chi_3)] = [3'(\chi_3), 2'(\chi_2), 1'(\chi_1)]$ [Singularity at $\chi_2 = \pm(\pi/2)$]:

$$\begin{pmatrix} c_2c_3 & -c_2s_3 & s_2 \\ s_1s_2c_3 + s_3c_1 & -s_1s_2s_3 + c_1c_3 & -s_1c_2 \\ -c_1s_2c_3 + s_1s_3 & c_1s_2s_3 + s_1c_3 & c_1c_2 \end{pmatrix};$$

$$\begin{array}{l|l}
\omega_1 = (c_2c_3)v_1 + (s_3)v_2 + (0)v_3 & v_1 = (c_2)^{-1}[(c_3)\omega_1 + (-s_3)\omega_2 + (0)\omega_3] \\
\omega_2 = (-c_2s_3)v_1 + (c_3)v_2 + (0)v_3 & v_2 = (c_2)^{-1}[(c_2s_3)\omega_1 + (c_2c_3)\omega_2 + (0)\omega_3] \\
\omega_3 = (s_2)v_1 + (0)v_2 + (1)v_3 & v_3 = (c_2)^{-1}[(-s_2c_3)\omega_1 + (s_2s_3)\omega_2 + (c_2)\omega_3].
\end{array}$$

1(b) $[1'(\chi_1), 2'(\chi_2), 3'(\chi_3)] = [3(\chi_3), 2(\chi_2), 1(\chi_1)]$ [Singularity at $\chi_2 = \pm(\pi/2)$]:

$$\begin{pmatrix} c_2c_3 & s_1s_2c_3 - c_1s_3 & c_1s_2c_3 + s_1s_3 \\ c_2s_3 & s_1s_2s_3 + c_1c_3 & c_1s_2s_3 - s_1c_3 \\ -s_2 & s_1c_2 & c_1c_2 \end{pmatrix};$$

$$\begin{array}{l|l} \omega_1 = (1)v_1 + (0)v_2 + (-s_2)v_3 & v_1 = (c_2)^{-1}[(c_2)\omega_1 + (s_1s_2)\omega_2 + (c_1s_2)\omega_3] \\ \omega_2 = (0)v_1 + (c_1)v_2 + (s_1c_2)v_3 & v_2 = (c_2)^{-1}[(0)\omega_1 + (c_1c_2)\omega_2 + (-s_1c_2)\omega_3] \\ \omega_3 = (0)v_1 + (-s_1)v_2 + (c_1c_2)v_3 & v_3 = (c_2)^{-1}[(0)\omega_1 + (s_1)\omega_2 + (c_1)\omega_3]. \end{array}$$

2(a) $[2(\chi_1), 3(\chi_2), 1(\chi_3)] = [1'(\chi_3), 3'(\chi_2), 2'(\chi_1)]$ [Singularity at $\chi_2 = \pm(\pi/2)$]:

$$\begin{pmatrix} c_1c_2 & -c_1s_2c_3 + s_1s_3 & c_1s_2s_3 + s_1c_3 \\ s_2 & c_2c_3 & -c_2s_3 \\ -s_1c_2 & s_1s_2c_3 + c_1s_3 & -s_1s_2s_3 + c_1c_3 \end{pmatrix};$$

$$\begin{array}{l|l} \omega_1 = (s_2)v_1 + (0)v_2 + (1)v_3 & v_1 = (c_2)^{-1}[(0)\omega_1 + (c_3)\omega_2 + (-s_3)\omega_3] \\ \omega_2 = (c_2c_3)v_1 + (s_3)v_2 + (0)v_3 & v_2 = (c_2)^{-1}[(0)\omega_1 + (c_2s_3)\omega_2 + (c_2c_3)\omega_3] \\ \omega_3 = (-c_2s_3)v_1 + (c_3)v_2 + (0)v_3 & v_3 = (c_2)^{-1}[(c_2)\omega_1 + (-s_2c_3)\omega_2 + (s_2s_3)\omega_3]. \end{array}$$

2(b) $[2'(\chi_1), 3'(\chi_2), 1'(\chi_3)] = [1(\chi_3), 3(\chi_2), 2(\chi_1)]$ [Singularity at $\chi_2 = \pm(\pi/2)$]:

$$\begin{pmatrix} c_1c_2 & -s_2 & s_1c_2 \\ c_1s_2c_3 + s_1s_3 & c_2c_3 & s_1s_2c_3 - c_1s_3 \\ c_1s_2s_3 - s_1c_3 & c_2s_3 & s_1s_2s_3 + c_1c_3 \end{pmatrix};$$

$$\begin{array}{l|l} \omega_1 = (0)v_1 + (-s_1)v_2 + (c_1c_2)v_3 & v_1 = (c_2)^{-1}[(c_1s_2)\omega_1 + (c_2)\omega_2 + (s_1s_2)\omega_3] \\ \omega_2 = (1)v_1 + (0)v_2 + (-s_2)v_3 & v_2 = (c_2)^{-1}[(-s_1c_2)\omega_1 + (0)\omega_2 + (c_1c_2)\omega_3] \\ \omega_3 = (0)v_1 + (c_1)v_2 + (s_1c_2)v_3 & v_3 = (c_2)^{-1}[(c_1)\omega_1 + (0)\omega_2 + (s_1)\omega_3]. \end{array}$$

3(a) $[3(\chi_1), 1(\chi_2), 2(\chi_3)] = [2'(\chi_3), 1'(\chi_2), 3'(\chi_1)]$ [Singularity at $\chi_2 = \pm(\pi/2)$]:

$$\begin{pmatrix} -s_1s_2s_3 + c_1c_3 & -s_1c_2 & s_1s_2c_3 + c_1s_3 \\ c_1s_2s_3 + s_1c_3 & c_1c_2 & -c_1s_2c_3 + s_1s_3 \\ -c_2s_3 & s_2 & c_2c_3 \end{pmatrix};$$

$$\begin{array}{l|l} \omega_1 = (-c_2s_3)v_1 + (c_3)v_2 + (0)v_3 & v_1 = (c_2)^{-1}[(-s_3)\omega_1 + (0)\omega_2 + (c_3)\omega_3] \\ \omega_2 = (s_2)v_1 + (0)v_2 + (1)v_3 & v_2 = (c_2)^{-1}[(c_2c_3)\omega_1 + (0)\omega_2 + (c_2s_3)\omega_3] \\ \omega_3 = (c_2c_3)v_1 + (s_3)v_2 + (0)v_3 & v_3 = (c_2)^{-1}[(s_2s_3)\omega_1 + (c_2)\omega_2 + (-s_2c_3)\omega_3]. \end{array}$$

3(b) $[3'(\chi_1), 1'(\chi_2), 2'(\chi_3)] = [2(\chi_3), 1(\chi_2), 3(\chi_1)]$ [Singularity at $\chi_2 = \pm(\pi/2)$]:

$$\begin{pmatrix} s_1s_2s_3 + c_1c_3 & c_1s_2s_3 - s_1c_3 & c_2s_3 \\ s_1c_2 & c_1c_2 & -s_2 \\ s_1s_2c_3 - c_1s_3 & c_1s_3c_3 + s_1s_3 & c_2c_3 \end{pmatrix};$$

$$\begin{array}{l|l} \omega_1 = (0)v_1 + (c_1)v_2 + (s_1c_2)v_3 & v_1 = (c_2)^{-1}[(s_1s_2)\omega_1 + (c_1s_2)\omega_2 + (c_2)\omega_3] \\ \omega_2 = (0)v_1 + (-s_1)v_2 + (c_1c_2)v_3 & v_2 = (c_2)^{-1}[(c_1c_2)\omega_1 + (-s_1c_2)\omega_2 + (0)\omega_3] \\ \omega_3 = (1)v_1 + (0)v_2 + (-s_2)v_3 & v_3 = (c_2)^{-1}[(s_1)\omega_1 + (c_1)\omega_2 + (0)\omega_3]. \end{array}$$

4(a) $[1(\chi_1), 3(\chi_2), 2(\chi_3)] = [2'(\chi_3), 3'(\chi_2), 1'(\chi_1)]$ [Singularity at $\chi_2 = \pm(\pi/2)$]:

$$\begin{pmatrix} c_2c_3 & -s_2 & c_2s_3 \\ c_1s_2c_3 + s_1s_3 & c_1c_2 & c_1s_2s_3 - s_1c_3 \\ s_1s_2c_3 - c_1s_3 & s_1c_2 & s_1s_2s_3 + c_1c_3 \end{pmatrix};$$

$$\begin{array}{l|l} \omega_1 = (c_2c_3)v_1 + (-s_3)v_2 + (0)v_3 & v_1 = (c_2)^{-1}[(c_3)\omega_1 + (0)\omega_2 + (s_3)\omega_3] \\ \omega_2 = (-s_2)v_1 + (0)v_2 + (1)v_3 & v_2 = (c_2)^{-1}[(-c_2s_3)\omega_1 + (0)\omega_2 + (c_2c_3)\omega_3] \\ \omega_3 = (c_2s_3)v_1 + (c_3)v_2 + (0)v_3 & v_3 = (c_2)^{-1}[(s_2c_3)\omega_1 + (c_2)\omega_2 + (s_2s_3)\omega_3]. \end{array}$$

1.14 THE RIGID BODY: AN INTRODUCTION TO QUASI COORDINATES

As an introduction to quasi coordinates, and quasi variables in general (a topic to be detailed in chap. 2), we show in this section that the angular velocity, although a vector, does not result by simple $d/dt(\ldots)$-differentiation of an angular displacement; *its components along space-/body-fixed axes, say ω_k, do not equal the total time derivatives of angles or any other genuine (global) rotational coordinates/parameters, say θ_k; that is, $\omega_k \neq d\theta_k/dt$*. This is another complication of rotational mechanics, one that is intimately connected with the noncommutativity of finite rotations; and it necessitates the hitherto search for connections of the ω_k's with genuine angular coordinates and their rates, like the Eulerian angles ϕ, θ, ψ.

Let us consider, for concreteness, the *body-axes* components of the angular velocity tensor. From

$$\mathbf{\Omega} = \mathbf{A}^{\mathrm{T}} \cdot (\mathrm{d}\mathbf{A}/\mathrm{dt}) = -(\mathrm{d}\mathbf{A}^{\mathrm{T}}/\mathrm{dt}) \cdot \mathbf{A}\,, \tag{1.14.1a}$$

(1.7.30f ff.) we have

$$\omega_x = A_{Xz}(dA_{Xy}/dt) + A_{Yz}(dA_{Yy}/dt) + A_{Zz}(dA_{Zy}/dt), \quad \text{etc., cyclically,} \tag{1.14.1b}$$

or, multiplying through by dt and setting $\omega_x dt \equiv d\theta_x$ (just a suggestive shorthand!),

$$d\theta_x \equiv A_{Xz} dA_{Xy} + A_{Yz} dA_{Yy} + A_{Zz} dA_{Zy}\,, \text{ etc., cyclically.} \tag{1.14.1c}$$

We shall show that

$$\delta(d\theta_x) - d(\delta\theta_x) \neq 0, \quad \text{etc., cyclically,} \tag{1.14.2a}$$

where, for our purposes, $\delta(\ldots)$ can be viewed as just a differential of $(\ldots)$, along a different direction from $d(\ldots)$; that is, with $d(\ldots) \equiv d_1(\ldots)$ and $\delta(\ldots) \equiv d_2(\ldots)$,

$$\delta(d\theta_x) \equiv d_2(d_1\theta_x), \qquad d(\delta\theta_x) \equiv d_1(d_2\theta_x); \tag{1.14.2b}$$

and

$$\delta\theta_x \equiv A_{Xz}\delta A_{Xy} + A_{Yz}\delta A_{Yy} + A_{Zz}\delta A_{Zy}\,, \text{ etc., cyclically.} \tag{1.14.2c}$$

Now, $\delta(\ldots)$-differentiating $d\theta_x$ and $d(\ldots)$-differentiating $\delta\theta_x$, and then subtracting side by side, while noticing that

$$\delta(dA_{k'k}) = d(\delta A_{k'k}) \qquad (k' = X, Y, Z;\ k = x, y, z), \tag{1.14.3a}$$

we get

$$\begin{aligned}\delta(d\theta_x) - d(\delta\theta_x) = \delta A_{Xz} dA_{Xy} - dA_{Xz}\delta A_{Xy} + \delta A_{Yz} dA_{Yy} - dA_{Yz}\delta A_{Yy} \\ + \delta A_{Zz} dA_{Zy} - dA_{Zz}\,\delta A_{Zy}.\end{aligned} \tag{1.14.3b}$$

Next, in order to express $\delta A_{k'k}$, $dA_{k'k}$ in terms of $\delta\theta_k$ and $d\theta_k$, we multiply the components of $\mathrm{d}\mathbf{A}/\mathrm{dt} = \mathbf{A} \cdot \mathbf{\Omega}$ (1.7.30i) with dt, thus obtaining

$$dA_{Xz} = A_{Xx} d\theta_y - A_{Xy} d\theta_x \ \Rightarrow\ \delta A_{Xz} = A_{Xx}\delta\theta_y - A_{Xy}\delta\theta_x, \tag{1.14.4a}$$

$$dA_{Yz} = A_{Yx} d\theta_y - A_{Yy} d\theta_x \ \Rightarrow\ \delta A_{Yz} = A_{Yx}\delta\theta_y - A_{Yy}\delta\theta_x, \tag{1.14.4b}$$

$$dA_{Zz} = A_{Zx} d\theta_y - A_{Zy} d\theta_x \ \Rightarrow\ \delta A_{Zz} = A_{Zx}\delta\theta_y - A_{Zy}\delta\theta_x, \tag{1.14.4c}$$

$$dA_{Xy} = A_{Xz} d\theta_x - A_{Xx} d\theta_z \ \Rightarrow\ \delta A_{Xy} = A_{Xz}\delta\theta_x - A_{Xx}\delta\theta_z, \tag{1.14.4d}$$

$$dA_{Yy} = A_{Yz} d\theta_x - A_{Yx} d\theta_z \ \Rightarrow\ \delta A_{Yy} = A_{Yz}\delta\theta_x - A_{Yx}\delta\theta_z, \tag{1.14.4e}$$

$$dA_{Zy} = A_{Zz} d\theta_x - A_{Zx} d\theta_z \ \Rightarrow\ \delta A_{Zy} = A_{Zz}\delta\theta_x - A_{Zx}\delta\theta_z. \tag{1.14.4f}$$

Substituting (1.14.4a–f) into the right side of (1.14.3b), and invoking the orthogonality of $\mathbf{A} = (A_{k'k})$ [e.g., (1.7.6a, b; 1.7.22d)], we find, after some straightforward algebra, the noncommutativity equation

$$\delta(d\theta_x) - d(\delta\theta_x) = d\theta_y\delta\theta_z - d\theta_z\delta\theta_y. \tag{1.14.5a}$$

Working in complete analogy with the above, we obtain

$$\delta(d\theta_y) - d(\delta\theta_y) = d\theta_z\delta\theta_x - d\theta_x\delta\theta_z, \tag{1.14.5b}$$

$$\delta(d\theta_z) - d(\delta\theta_z) = d\theta_x\delta\theta_y - d\theta_y\delta\theta_x. \tag{1.14.5c}$$

These remarkable *transitivity* equations [because they allow for a smooth *transition* from Lagrangean mechanics (chap. 2 ff.) to Eulerian mechanics (§1.15 ff.)] show clearly that the $\theta_{x,\,y,\,z}$ are not ordinary (or genuine, or holonomic, or global; or as Lagrange puts it "variables finies") coordinates, like the Eulerian angles ϕ, θ, ψ; that is why they are called *pseudo*- or *quasi coordinates*. Their general theory, along with a simpler derivation of the above, are detailed in chap. 2.

Similarly, we can show that in terms of *space-axes* components, the transitivity equations are

$$\delta(d\theta_X) - d(\delta\theta_X) = d\theta_Z\delta\theta_Y - d\theta_Y\delta\theta_Z, \tag{1.14.6a}$$

$$\delta(d\theta_Y) - d(\delta\theta_Y) = d\theta_X\delta\theta_Z - d\theta_Z\delta\theta_X, \tag{1.14.6b}$$

$$\delta(d\theta_Z) - d(\delta\theta_Z) = d\theta_Y\delta\theta_X - d\theta_X\delta\theta_Y\,. \tag{1.14.6c}$$

In compact vector form, (1.14.5a, b, c) and (1.14.6a, b, c) read, respectively,

$$\delta_{rel}(d\boldsymbol{\theta}) - \partial(\delta\boldsymbol{\theta}) = d\boldsymbol{\theta} \times \delta\boldsymbol{\theta}\,, \tag{1.14.7a}$$

$$\delta(d\boldsymbol{\theta}) - d(\delta\boldsymbol{\theta}) = \delta\boldsymbol{\theta} \times d\boldsymbol{\theta}\,, \tag{1.14.7b}$$

where $d\boldsymbol{\theta} = d\theta_x\boldsymbol{i} + d\theta_y\boldsymbol{j} + d\theta_z\boldsymbol{k} = d\theta_X\boldsymbol{I} + d\theta_Y\boldsymbol{J} + d\theta_Z\boldsymbol{K} \Rightarrow \delta\boldsymbol{\theta} = \delta\theta_x\boldsymbol{i} + \delta\theta_y\boldsymbol{j} + \delta\theta_z\boldsymbol{k} = \delta\theta_X\boldsymbol{I} + \delta\theta_Y\boldsymbol{J} + \delta\theta_Z\boldsymbol{K} \Rightarrow \delta_{rel}(d\boldsymbol{\theta}) \equiv \delta(d\theta_x)\boldsymbol{i} + \delta(d\theta_y)\boldsymbol{j} + \delta(d\theta_z)\boldsymbol{k}, \partial(\delta\boldsymbol{\theta}) \equiv d(\delta\theta_x)\boldsymbol{i} + d(\delta\theta_y)\boldsymbol{j} + d(\delta\theta_z)\boldsymbol{k}$; that is, again, $\boldsymbol{\theta}$ is a *quasi vector*. Here (recall 1.7.30j), $\boldsymbol{\Omega}' = (\mathrm{d}\mathbf{A}/\mathrm{dt}) \cdot \mathbf{A}^{\mathrm{T}}$ and $\mathrm{d}\mathbf{A}/\mathrm{dt} = \boldsymbol{\Omega}' \cdot \mathbf{A}$. [More in Examples 2.13.9 and 2.13.11 (pp. 368 ff.).]

HISTORICAL

Equations (1.14.5a–c), along with the systematic use of direction cosines to rigid-body dynamics, are due to Lagrange. They appeared posthumously in the 2nd edition of the 2nd volume of his *Mécanique Analytique* (1815/1816). See also (alphabetically): Funk (1962, pp. 334–335), Kirchhoff (1876, sixth lecture, §2), Mathieu (1878, pp. 138–139).

1.15 THE RIGID BODY: TENSOR OF INERTIA, KINETIC ENERGY

Introduction, Basic Definitions

To get motivated, let us begin by calculating the (inertial) kinetic energy T of a rigid body B rotating about a fixed point O; the extension to the case of general motion follows easily. If $\boldsymbol{\omega}$ is the inertial angular velocity of B, then, since the inertial velocity of a genetic body particle P, of inertial position $\boldsymbol{r}$, is $\boldsymbol{\omega} \times \boldsymbol{r} = \boldsymbol{v}$, we have, successively,

$$\begin{aligned} 2T &\equiv \mathcal{S}\, dm\ \boldsymbol{v}\cdot\boldsymbol{v} = \mathcal{S}\, dm(\boldsymbol{\omega}\times\boldsymbol{r})\cdot(\boldsymbol{\omega}\times\boldsymbol{r}) \\ &= \mathcal{S}\, dm\big[(\boldsymbol{\omega}\cdot\boldsymbol{\omega})(\boldsymbol{r}\cdot\boldsymbol{r}) - (\boldsymbol{\omega}\cdot\boldsymbol{r})(\boldsymbol{\omega}\cdot\boldsymbol{r})\big] \qquad \text{(by simple vector algebra)} \\ &= \mathcal{S}\, dm[\omega^2 r^2 - (\boldsymbol{\omega}\cdot\boldsymbol{r})^2], \end{aligned} \tag{1.15.1a}$$

or, in terms of components along arbitrary (i.e., not necessarily body-fixed) rectangular Cartesian axes $O\text{–}xyz \equiv O\text{–}x_k$, in which $\boldsymbol{r} = (x, y, z) \equiv (x_k)$, $\boldsymbol{\omega} = (\omega_x, \omega_y, \omega_z) \equiv (\omega_k)$ $(k = 1, 2, 3)$,

$$2T = S\, dm\Big[\Big(\sum \omega_k{}^2\Big)\Big(\sum x_k{}^2\Big) - \Big(\sum \omega_k x_k\Big)\Big(\sum \omega_l x_l\Big)\Big]$$

$$= S\, dm\Big[\Big(\sum\sum \delta_{kl}\,\omega_k\,\omega_l\Big)\Big(\sum x_r{}^2\Big) - \Big(\sum\sum \omega_k\,\omega_l\,x_k x_l\Big)\Big]$$

$$= \sum\sum I_{kl}\,\omega_k\,\omega_l \qquad (\textit{Indicial}\ \text{notation}) \tag{1.15.1b}$$

$$= \boldsymbol{\omega}\cdot\boldsymbol{I}\cdot\boldsymbol{\omega} \qquad (\textit{Direct}\ \text{notation}) \tag{1.15.1c}$$

$$= \boldsymbol{\omega}^{\mathrm{T}}\cdot\mathbf{I}\cdot\boldsymbol{\omega} \qquad (\textit{Matrix}\ \text{notation};\, \boldsymbol{\omega}\text{: } \textit{column}\ \text{vector}), \tag{1.15.1d}$$

where

$$\boldsymbol{I}_O \equiv \boldsymbol{I} = (I_{O,kl}) \equiv (I_{kl}), \tag{1.15.2a}$$

$$I_{kl} \equiv S\, dm(r^2\delta_{kl} - x_k x_l):$$

Components of *tensor of inertia* of B, $\boldsymbol{I}$, at O, along $O\text{–}x_k$, (1.15.2b)

$$r^2 \equiv \sum x_k{}^2 = \sum x_k x_k; \tag{1.15.2c}$$

or, equivalently,

$$I_{kl} = J_o\,\delta_{kl} - J_{kl}, \tag{1.15.2d}$$

where

$$\boldsymbol{J}_O \equiv \boldsymbol{J} = (J_{O,kl}) \equiv (J_{kl}), \tag{1.15.2e}$$

$$J_{kl} \equiv S\, x_k x_l\ dm$$

$\equiv$ Components of *Binet's tensor* of B, $\boldsymbol{J}$, at O, along $O\text{–}x_k$, (1.15.2f)

$$J_o \equiv J_{11} + J_{22} + J_{33} = S\, r^2 dm = \mathrm{Tr}\,\boldsymbol{J}. \tag{1.15.2g}$$

In direct notation, the above read

$$\boldsymbol{I} = S\,[(\boldsymbol{r}\cdot\boldsymbol{r})\boldsymbol{1} - \boldsymbol{r}\otimes\boldsymbol{r}]dm, \qquad \boldsymbol{J} = S\,(\boldsymbol{r}\otimes\boldsymbol{r})\ dm. \tag{1.15.2h}$$

That $\boldsymbol{I}$ is a (second-order) tensor follows from the fact that, under rotations of the axes, T is a scalar invariant while $\boldsymbol{\omega}$ is a vector (what, in effect, constitutes a simple application of the tensorial "quotient rule"). This means that the components of $\boldsymbol{I}$ along $O\text{–}x_k, I_{kl}$, and along $O\text{–}x_{k'}$, $I_{k'l'}$, where $x_{k'} = \sum A_{k'k}x_k$ (proper orthogonal transformation), are related by

$$I_{k'l'} = \sum\sum A_{k'k}A_{l'l}I_{kl} = \sum\sum A_{k'k}I_{kl}A_{ll'}$$

$$= (\boldsymbol{A}\cdot\boldsymbol{I}\cdot\boldsymbol{A}^{\mathrm{T}})_{k'l'} \qquad [\text{recalling eqs. (1.1.19j ff.)}]$$

$$\Big[\Leftrightarrow I_{kl} = \sum\sum A_{kk'}A_{ll'}I_{k'l'} \qquad (\text{Since, indicially, } A_{k'k} = A_{kk'})\Big]. \tag{1.15.2i}$$

Properties of the Inertia Tensor

Clearly (and like most mechanics tensors), $\boldsymbol{I}$ is *symmetric*: $I_{kl} = I_{lk}$; that is, at most *six*, of its nine components, are independent. In extenso, (1.15.2a, b) read

$$\boldsymbol{I} = \begin{pmatrix} I_{xx} & I_{xy} & I_{xz} \\ I_{yx} & I_{yy} & I_{yz} \\ I_{zx} & I_{zy} & I_{zz} \end{pmatrix}$$

$$= \begin{pmatrix} \mathsf{S}\, dm\,(y^2+z^2) & -\mathsf{S}\, dm\, x\, y & -\mathsf{S}\, dm\, x\, z \\ -\mathsf{S}\, dm\, y\, x & \mathsf{S}\, dm\,(z^2+x^2) & -\mathsf{S}\, dm\, y\, z \\ -\mathsf{S}\, dm\, z\, x & -\mathsf{S}\, dm\, z\, y & \mathsf{S}\, dm\,(x^2+y^2) \end{pmatrix}. \qquad (1.15.3)$$

The *diagonal* elements of $\boldsymbol{I}$, I_{xx}, I_{yy}, I_{zz}, are called *moments of inertia* of B about O–xyz; and they are *nonnegative*; that is, $I_{xx,\,yy,\,zz} \geq 0$. The *off-diagonal* elements of $\boldsymbol{I}$, $I_{xy} = I_{yx}$, $I_{xz} = I_{zx}$, $I_{yz} = I_{zy}$, are called *products of inertia* of B about O–xyz, and they are *sign-indefinite*; that is, they may be >0, <0, or $=0$.

In view of the above, T can be rewritten as

$$2T = I_{xx}\,\omega_x{}^2 + I_{yy}\,\omega_y{}^2 + I_{zz}\,\omega_z{}^2 + 2I_{xy}\,\omega_x\,\omega_y + 2I_{xz}\,\omega_x\,\omega_z + 2I_{yz}\,\omega_y\,\omega_z. \qquad (1.15.4)$$

Now, evidently, the choice of the axes O–xyz is *nonunique*. Not only can they be *non–body-fixed* (in which case, the I_{kl} are, in general, time-dependent); but even if they are taken as body-fixed, (1.15.3, 4) are still fairly complicated. Hence, to simplify matters as much as possible, and since the kinetic energy is so central to analytical mechanics, we, in general, strive to choose *principal axes* at O: O–$xyz \to O$–123; usually, but not always, body-fixed. Since $\boldsymbol{I}$ is symmetric, such (mutually orthogonal) axes exist always; and along them $\boldsymbol{I}$ becomes

$$\boldsymbol{I} \to \begin{pmatrix} I_1 & 0 & 0 \\ 0 & I_2 & 0 \\ 0 & 0 & I_3 \end{pmatrix} = \textit{Principal axes representation of inertia tensor}, \qquad (1.15.5)$$

where the *principal moments of inertia*, at O, $I_{1,2,3}$ are the eigenvalues of

$$\sum I_{kl}\,\omega_l = \lambda\,\omega_k, \qquad (1.15.6a)$$

that is, they are the roots of its characteristic equation:

$$D(\lambda) \equiv -\mathrm{Det}(I_{kl} - \lambda\delta_{kl}) = 0; \qquad \lambda_{1,2,3} \equiv I_{1,2,3}. \qquad (1.15.6b)$$

Using basic theorems of the spectral theory of tensors [(1.1.17a ff.)] we can show the following:

(i) At each point of a rigid body B there exists *at least one set of principal axes*.
(ii) Since, by (1.15.1b–d), the inertia tensor is not only *symmetric*, but also *positive definite* [i.e., $\sum\sum I_{kl} a_k a_l > 0$, for all vectors $\boldsymbol{a} = (a_k) \neq \boldsymbol{0}$], all three roots of (1.15.6b) are not only *real* but also *strictly positive*.

Further

- If $\lambda_1 \neq \lambda_2 \neq \lambda_3 \neq \lambda_1$ (all three eigenvalues distinct), then *O–123* is unique.
- If $\lambda_1 \neq \lambda_2 = \lambda_3$ (two distinct eigenvalues), there exists a *single* infinity of such sets of principal axes; *O1* and every line perpendicular to it are principal axes; that is, the direction of either *O2* or *O3*, in the plane perpendicular to *O1*, can be chosen arbitrarily (e.g., a homogeneous right circular cylinder, with O on its axis of symmetry).
- If $\lambda_1 = \lambda_2 = \lambda_3$ (only one distinct eigenvalue), there exists a *double* infinity: any three mutually perpendicular axes can be chosen arbitrarily as *O–123* (e.g., O being the center of a homogeneous sphere). Along principal axes, T, (1.15.4), with $\boldsymbol{\omega} = (\omega_1,\ \omega_2,\ \omega_3)$, reduces to

$$2T = I_1 {\omega_1}^2 + I_2 {\omega_2}^2 + I_3 {\omega_3}^2. \tag{1.15.6c}$$

The Generalized Parallel Axis Theorem ("Huygens–Steiner")

This explains how $\boldsymbol{I}$ changes from point to point, among parallel sets of axes.

THEOREM

Let *O–xyz* and *G–xyz* be two sets of mutually parallel axes, and let the coordinates of the center of mass of B, G, relative to O, be

$$\boldsymbol{OG} \equiv \boldsymbol{r}_G \equiv (x_G,\ y_G,\ z_G) \equiv (G_1,\ G_2,\ G_3) \equiv (-a, -b, -c)\,, \tag{1.15.7a}$$

that is, $a, b, c =$ coordinates of O relative to *G–xyz*. Then, the components of the inertia tensor of B at O, $I_{O,kl}$, and at G, $I_{G,kl}$, are related by

Direct notation :
$$\boldsymbol{I}_O = \boldsymbol{I}_G + m({r_G}^2 \boldsymbol{1} - \boldsymbol{r}_G \otimes \boldsymbol{r}_G)\,, \tag{1.15.7b}$$

Indicial notation:
$$I_{O,kl} = I_{G,kl} + m\Big[\Big(\sum G_r G_r\Big)\delta_{kl} - G_k G_l\Big]; \tag{1.15.7c}$$

or, in extenso,

$$\boldsymbol{I}_O = \boldsymbol{I}_G + \begin{pmatrix} m(b^2+c^2) & -mab & -mac \\ -mba & m(c^2+a^2) & -mbc \\ -mca & -mcb & m(a^2+b^2) \end{pmatrix}. \tag{1.15.7d}$$

PROOF

We have, successively,

(i) $$\begin{aligned} I_{O,xx} &= \int dm[(y-b)^2 + (z-c)^2] \\ &= \int dm(y^2+z^2) - 2b\Big(\int dm\ y\Big) - 2b\Big(\int dm\ z\Big) + \int dm(b^2+c^2) \\ &= I_{G,xx} + 0 + 0 + m(b^2+c^2); \quad \text{etc., cyclically, for } I_{O,yy}, I_{O,zz}. \end{aligned} \tag{1.15.7e}$$

(ii) $$\begin{aligned} I_{O,yz} &= -\int dm[(y-b)(z-c)] \\ &= -\int dm\ yz + c\Big(\int dm\ y\Big) + b\Big(\int dm\ z\Big) - \int dm\ bc \\ &= I_{G,yz} + 0 + 0 - mbc; \quad \text{etc., cyclically, for } I_{O,xz}, I_{O,xy}. \end{aligned} \tag{1.15.7f}$$

More generally, it can be shown that between *any two* points A, B (with some ad hoc but, hopefully, self-explanatory notation),

$$\boldsymbol{I}_B = \boldsymbol{I}_A + m({r_{A/B}}^2 \boldsymbol{1} - \boldsymbol{r}_{A/B} \otimes \boldsymbol{r}_{A/B}) \\ + 2m\big[(\boldsymbol{r}_{A/B} \cdot \boldsymbol{r}_{G/A})\boldsymbol{1} - (1/2)(\boldsymbol{r}_{A/B} \otimes \boldsymbol{r}_{G/A} + \boldsymbol{r}_{G/A} \otimes \boldsymbol{r}_{A/B})\big]; \quad (1.15.7\text{g})$$

which, when $A \to G$ and $\boldsymbol{r}_{G/A} \to \boldsymbol{0}$, reduces to (1.15.7b) (see below). (See, e.g., Lur'e, 1968, p. 143; also Crandall et al., 1968, pp. 180–182, Magnus, 1974, pp. 200–201.)

It should be noted that the transfer formulae (1.15.7b, g) are based on definitions of moments of inertia about *points*, like (1.15.2h), not axes, and therefore hold for any set of axes through these points; that is, they are independent of the axes orientation at A, B. If, however, these axes are parallel, certain simplifications occur; indeed, (1.15.7g) then yields the component form,

$$I_{B,kl} = I_{A,kl} + m\big[({x_{A/B,1}}^2 + {x_{A/B,2}}^2 + {x_{A/B,3}}^2)\delta_{kl} - x_{A/B,k}x_{A/B,l}\big] \\ + 2m\big[(x_{A/B,1}\, x_{G/A,1} + x_{A/B,2}\, x_{G/A,2} + x_{A/B,3}\, x_{G/A,3})\delta_{kl} \\ - (1/2)(x_{A/B,k}\, x_{G/A,l} + x_{G/A,k}\, x_{A/B,l})\big], \quad (1.15.7\text{h})$$

where $\boldsymbol{r}_{A/B} \equiv (x_{A/B,1},\ x_{A/B,2},\ x_{A/B,3}) =$ coordinates of A relative to B, along axes $B\text{–}xyz \equiv B\text{–}x_k$, and $\boldsymbol{r}_{G/A} \equiv (x_{G/A,1},\ x_{G/A,2},\ x_{G/A,3}) =$ coordinates of G relative to A, along axes $A\text{–}xyz \equiv A\text{–}x_k$ (parallel to $B\text{–}x_k$); or, in extenso, with $x_{A/B,1} \equiv x_{A/B}$, $x_{A/B,2} \equiv y_{A/B}$, $x_{A/B,3} \equiv z_{A/B}$, $x_{G/A,1} \equiv x_{G/A}$, etc.,

$$I_{B,xx} = I_{A,xx} + m({y_{A/B}}^2 + {z_{A/B}}^2) + 2m(y_{A/B}\, y_{G/A} + z_{A/B} z_{G/A}), \quad \text{etc., cyclically,} \quad (1.15.7\text{i})$$

$$I_{B,xy} = I_{A,xy} - m(y_{A/B} x_{G/A} + x_{A/B}\, y_{G/A}) - m(x_{A/B}\, y_{A/B}), \quad \text{etc., cyclically.} \quad (1.15.7\text{j})$$

If $A \to G$, then $\boldsymbol{r}_{G/A} \to \boldsymbol{0}$, $\boldsymbol{r}_{A/B} \to \boldsymbol{r}_{G/B}$, and the above reduces to

$$I_{B,kl} = I_{G,kl} + m\big[({x_{G/B,1}}^2 + {x_{G/B,2}}^2 + {x_{G/B,3}}^2)\delta_{kl} - x_{G/B,k}x_{G/B,l}\big], \quad (1.15.7\text{k})$$

from which, in extenso,

$$I_{B,xx} = I_{G,xx} + m({y_{G/B}}^2 + {z_{G/B}}^2) = I_{G,xx} + m[(-b)^2 + (-c)^2], \quad \text{etc., cyclically,} \quad (1.15.7\text{l})$$

$$I_{B,xy} = I_{G,xy} - m(x_{G/B}\, y_{G/B}) = I_{G,xy} - m[(-a)(-b)], \quad \text{etc., cyclically; i.e., (1.15.7b–f).} \quad (1.15.7\text{m})$$

Ellipsoid of Inertia

Let us consider a rectangular Cartesian coordinate system/basis $O\text{–}xyz/\boldsymbol{ijk}$, and an axis u through O defined by the unit vector $\boldsymbol{u} = (u_x,\ u_y,\ u_z)$. Then, as the transformation equations against rotations (1.15.2i) show, the moment of inertia of a body B about u, $I_{uu} \equiv I$, will be (with $k' = l' = u; k, l = x, y, z;$ $A_{k'k} = u_k = u_{1,2,3}$, $A_{k'l} = u_l = u_{1,2,3}$, etc.)

$$I = I_{xx}{u_x}^2 + I_{yy}{u_y}^2 + I_{zz}{u_z}^2 + 2I_{xy}u_x u_y + 2I_{yz}u_y u_z + 2I_{xz}u_x u_z. \quad (1.15.8\text{a})$$

[For *nontensorial* derivations of (1.15.8a), see, for example, Lamb (1929, pp. 66–67), Spiegel (1967, pp. 263–264)]. We notice that if $\boldsymbol{\omega} = \omega \boldsymbol{u} = (\omega u_x, \omega u_y, \omega u_z) = (\omega_x, \omega_y, \omega_z)$, then the kinetic energy of B, moving about the fixed point O, eq. (1.15.4), becomes

$$2T = I\omega^2. \tag{1.15.8b}$$

Now, by defining the radius vector

$$\boldsymbol{r} \equiv \boldsymbol{u}/I^{1/2} = x\boldsymbol{i} + y\boldsymbol{j} + z\boldsymbol{k} \qquad [\text{i.e., } |\boldsymbol{r}| \equiv r = (1/I)^{1/2}], \tag{1.15.8c}$$

we can rewrite (1.15.8a) as

$$I_{xx}x^2 + I_{yy}\,y^2 + I_{zz}z^2 + 2I_{xy}xy + 2I_{yz}yz + 2I_{zx}zx = 1. \tag{1.15.8d}$$

Since I is positive [except when all the mass lies on u; then one of the principal moments of inertia, roots of (1.15.6b), is zero and the other two are equal and positive], every radius through O meets the quadric surface represented by (1.15.8d), in O–xyz, in real points located a distance $r = (1/I)^{1/2}$ from O, and therefore (1.15.8d) is an ellipsoid; appropriately called *ellipsoid of inertia* or *momental ellipsoid*. [A term most likely introduced by Cauchy (1827), who also carried out similar investigations in the theory of stress in continuous media ("stress quadric").]

If the axes are rotated so as to coincide with the principal axes of the ellipsoid—that is, O–$xyz \to O$–123—then (1.15.8d) simplifies to

$$I_1{r_1}^2 + I_2{r_2}^2 + I_3{r_3}^2 = 1,$$

or

$$[r_1\big/(1/I_1)^{1/2}]^2 + [r_2\big/(1/I_2)^{1/2}]^2 + [r_3\big/(1/I_3)^{1/2}]^2 = 1, \tag{1.15.8e}$$

where $r_{1,2,3}$ are the "principal" coordinates of $\boldsymbol{r}$, and $(1/I_{1,2,3})^{1/2}$ are the semidiameters of the ellipsoid. [Some authors (mostly British) define the radius of the momental ellipsoid along $\boldsymbol{u}$ (i.e., our r) as

$$r = m\varepsilon^4/I^{1/2} \sim I^{1/2}, \tag{1.15.8c.1}$$

where $m =$ mass of body, and $\varepsilon =$ any linear magnitude (taken in the fourth power for purely dimensional purposes), so that the ellipsoid equations (1.15.8d) and (1.15.8e) are replaced, respectively, by

$$I_{xx}x^2 + I_{yy}\,y^2 + I_{zz}z^2 + 2I_{xy}xy + 2I_{yz}yz + 2I_{zx}zx = m\varepsilon^4, \tag{1.15.8d.1}$$

$$I_1{r_1}^2 + I_2{r_2}^2 + I_3{r_3}^2 = m\varepsilon^4. \tag{1.15.8e.1}$$

Also, for a discussion of the closely related concept of the *ellipsoid of gyration* (introduced by MacCullagh, 1844), see, for example, Easthope (1964, p. 134 ff.), Lamb (1929, p. 68 ff.)] However, it should be remarked that *not every ellipsoid* can represent an inertia ellipsoid; in view of the "triangle inequalities" (see below), certain restrictions apply on the relative magnitudes of the semidiameters, and hence the possible forms of the momental ellipsoid.

Now, and these constitute a geometrical sequel to the discussion of the roots of the characteristic equation (1.15.6b):

- If $I_1 = I_2 = I_3$, the momental ellipsoid is a sphere. All axes through O are principal, and all moments of inertia are mutually equal. Such a body is called *kinetically symmetrical about O*.
- If, say, $I_2 = I_3$, the ellipsoid is one of revolution about Ox—all perpendicular diameters to Ox are principal axes. Such a body is called *kinetically symmetric about that axis*; or simply *uniaxial* (Routh).

The above show that, in general, the ellipsoid of inertia, at a point, is nonunique. The ellipsoid of inertia of a body at its mass center G, commonly referred to as its *central ellipsoid* (Poinsot), is of particular importance: As the parallel axis theorem shows, if the moment of inertia about an axis through G is known, I_G, then the moment of inertia about any other axis parallel to it is obtained by adding to I_G the nonnegative quantity md^2, where d is the distance between the two axes.

Finally, the momental ellipsoid interpretation, plus the above parallel axis theorem, allow us to conclude the following *extremum* (i.e., *maximum/minimum*) *properties* of the principal axes:

- The principal axes of inertia, at a point O, are those with the larger or smaller moment of inertia than those about any other line through that point, I. Quantitatively, if

$$I_1 \equiv I_{\max} \geq I_2 \geq I_3 \equiv I_{\min} \tag{1.15.8f}$$

$\left[\Rightarrow (1/I_1)^{1/2} \leq (1/I_2)^{1/2} \leq (1/I_3)^{1/2}\right]$, something that can always be achieved by appropriate numbering of the principal axes, then

$$I_{\max} \geq I \geq I_{\min}. \tag{1.15.8g}$$

- The smallest *central* principal moment of inertia of a body, say $I_{G,3} \equiv I_{G,\min}$, is smaller than or equal to *any* other possible moment of inertia of the body (i.e., moment of inertia about any other space point and direction there); that is, $I_{G,\min} \geq I_{\ldots,uu}$.

Additional Useful Results

(i) It can be shown that

$$I_1 \leq I_2 + I_3, \qquad I_2 \leq I_3 + I_1, \qquad I_3 \leq I_1 + I_2; \tag{1.15.8h}$$

that is, no principal moment of inertia can exceed the *sum of the other two*. Equations (1.15.8h) are referred to as the *triangle inequalities* (since similar relations hold for the sides of a plane triangle). Actually, this theorem holds for the moments of inertia about *any* mutually orthogonal axes (McKinley, 1981).

(ii) Let $\rho_{1,2,3}$ be the semidiameters (semiaxes) of the ellipsoid of inertia; that is, $\rho_{1,2,3} \equiv (I_{1,2,3})^{-1/2}$. Then, the third and second of (1.15.8h) lead, respectively, to the following *lower and upper bounds* for ρ_3, if $\rho_{1,2}$ are given,

$$(\rho_2{}^{-2} + \rho_1{}^{-2})^{-1/2} \leq \rho_3 \leq |\rho_2{}^{-2} - \rho_1{}^{-2}|^{-1/2}; \tag{1.15.8i}$$

and, cyclically, for $\rho_{1,2}$; that is, *arbitrary inertia tensors*, upon *diagonalization*, may yield (mathematically correct but) physically impossible principal moments of inertia!

As a result of the above, if two axes, say ρ_1 and ρ_2, are approximately equal, the corresponding inertia ellipsoid can be quite *prolate* (longer in the third direction, cigar shaped), but not too *oblate* (shorter in the third direction; flattened at the poles, like the Earth).

(iii) The quantity $\mathrm{Tr}\boldsymbol{I} \equiv I_{xx} + I_{yy} + I_{zz}$ (first invariant of $\boldsymbol{I}$) depends on the origin of the coordinates, but *not on their orientation*.

$$\text{(iv)} \quad -I_{xx}/2 \le I_{yz} \le I_{xx}/2, \qquad -I_{yy}/2 \le I_{zx} \le I_{yy}/2, \qquad -I_{zz}/2 \le I_{xy} \le I_{zz}/2. \tag{1.15.8j}$$

(v) Consider the following three sets of axes: (a) $O\text{–}XYZ$: arbitrary "background" (say, inertial) axes; (b) $G\text{–}XYZ \equiv G\text{–}xyz$: translating but nonrotating axes, at center of mass G; and (c) $G\text{–}123$: *principal* axes at G. By combining the transformation formulae for I_{kl}, between parallel axes of differing origins (like $O\text{–}XYZ$ and $G\text{–}xyz$) and arbitrary oriented axis of common origin (like $G\text{–}xyz$ and $G\text{–}123$), we can show that

$$I_{XX} = m({Y_G}^2 + {Z_G}^2) + {A_{X1}}^2 I_1 + {A_{X2}}^2 I_2 + {A_{X3}}^2 I_3, \tag{1.15.8k}$$

$$I_{YY} = m({Z_G}^2 + {X_G}^2) + {A_{Y1}}^2 I_1 + {A_{Y2}}^2 I_2 + {A_{Y3}}^2 I_3, \tag{1.15.8l}$$

$$I_{ZZ} = m({X_G}^2 + {Y_G}^2) + {A_{Z1}}^2 I_1 + {A_{Z2}}^2 I_2 + {A_{Z3}}^2 I_3; \tag{1.15.8m}$$

$$I_{XY} = -mX_G Y_G + A_{X1}A_{Y1}(I_3 - I_1) + A_{X2}A_{Y2}(I_3 - I_2), \tag{1.15.8n}$$

$$I_{YZ} = -mY_G Z_G + A_{Y1}A_{Z1}(I_3 - I_1) + A_{Y2}A_{Z2}(I_3 - I_2), \tag{1.15.8o}$$

$$I_{ZX} = -mZ_G X_G + A_{Z1}A_{X1}(I_3 - I_1) + A_{Z2}A_{X2}(I_3 - I_2); \tag{1.15.8p}$$

where $A_{X1} \equiv \cos(OX,\, G1) = \cos(Gx,\, G1)$, etc., and $X_G,\ Y_G,\ Z_G$ are the coordinates of G relative to $O\text{–}XYZ$. The usefulness of (1.15.8k–p) lies in the fact that they yield the moments/products of inertia about arbitrary axes, once the principal moments of inertia at the center of mass are known.

(vi)

(a) If a body has a *plane of symmetry*, then (α) its center of mass and (β) two of its principal axes of inertia there lie on that plane; while the third principal axis is perpendicular to it.
(b) If a body has an *axis of symmetry*, then (α) its center of a mass lies there, and (β) that axis is one of its principal axes of inertia; while the other two are perpendicular to it.
(c) If two perpendicular axes, through a body point, are axes of symmetry, then they are principal axes there. (But principal axes are not necessarily axes of symmetry!)
(d) If the products of inertia vanish, for three mutually perpendicular axes at a point, these axes are principal axes there. [For a general discussion of the relations between principal axes and symmetry (via the concept of *covering operation*), see, for example, Synge and Griffith (1959, p. 288 ff.).]
(e) A principal axis at the center of mass of a body is a principal axis at all points of that axis.
(f) If an axis is principal at any two of its points, then it passes through the center of mass of the body, and is a principal axis at all its points.

(vii) *Centrifugal forces*: whence the products of inertia originate. Let us consider an arbitrary rigid body rotating about a *fixed* axis OZ with constant angular velocity $\boldsymbol{\omega}$. Then, since the centripetal acceleration of a generic particle of it P, of mass dm, equals $v^2/r = \omega^2 r$, where $r =$ distance of P from OZ, the associated centrifugal force

$d\boldsymbol{f}_c$ has magnitude $df_c = dm(\omega^2 r)$, and hence components along a, say, *body-fixed* set of axes $O\text{–}xyz(OZ = Oz)$ will be

$$df_{c,x} = df_c(x/r) = dm\, x\,\omega^2, \qquad df_{c,y} = df_c(y/r) = dm\, y\,\omega^2, \qquad df_{c,z} = 0; \quad (1.15.9a)$$

where x, y, z are the coordinates of P. Therefore, the components of the *moment* of $d\boldsymbol{f}_c$ along these axes are

$$\begin{aligned} dM_{c,x} &= y\ df_{c,z} - z\ df_{c,y} = -dm\ y\,z\,\omega^2, \\ dM_{c,y} &= z\ df_{c,x} - x\ df_{c,z} = +dm\ x\,z\,\omega^2, \\ dM_{c,z} &= x\ df_{c,y} - y\ df_{c,x} = 0. \end{aligned} \qquad (1.15.9b)$$

From the above, it follows that these centrifugal forces, when summed over the entire body and reduced to the origin O, yield a *resultant centrifugal force* $\boldsymbol{f}_c$:

$$\begin{aligned} f_{c,x} &\equiv S\, df_{c,x} = \omega^2 S\, dm\ x \equiv \omega^2 m\, x_G, \\ f_{c,y} &\equiv S\, df_{c,y} = \omega^2 S\, dm\ y \equiv \omega^2 m\, y_G, \\ f_{c,z} &\equiv S\, df_{c,z} = 0, \end{aligned} \qquad (1.15.9c)$$

where x_G, y_G are the coordinates of the mass center of B, G; and a *resultant centrifugal moment* $\boldsymbol{M}_c$:

$$\begin{aligned} M_{c,x} &\equiv S\, dM_{c,x} = -\omega^2 S\, dm\ y\,z \equiv +\omega^2 I_{yz}, \\ M_{c,y} &\equiv S\, dM_{c,y} = \omega^2 S\, dm\ z\,x \equiv -\omega^2 I_{xz}, \\ M_{c,z} &\equiv S\, dM_{c,z} = 0. \end{aligned} \qquad (1.15.9d)$$

Equations (1.15.9c, d) show clearly that if G lies on the $Z = z$ axis, then $\boldsymbol{f}_c$ vanishes, but $\boldsymbol{M}_c$ does not. For the moment to vanish, we must have $I_{yz} = 0$ *and* $I_{xz} = 0$; that is, Oz must be a *principal axis*. In sum: *The centrifugal forces on a spinning body tend to change the orientation of its instantaneous axis of rotation, unless the latter goes through the center of mass of the body and is a principal axis there*. Such kinetic considerations led to the formulation of the concept of principal axes of inertia, at a point of a rigid body [Euler, Segner (1750s)]; and to the alternative term *deviation moments*, for the products of inertia. We shall return to this important topic in §1.17.

1.16 THE RIGID BODY: LINEAR AND ANGULAR MOMENTUM

(i) The *inertial*, or *absolute*, linear momentum of a rigid body B (or system S), relative to an inertial frame F, represented by the axes $I\text{–}XYZ$ (fig. 1.28), is defined as

$$\boldsymbol{p} \equiv S\, dm\, \boldsymbol{v} = m\boldsymbol{v}_G \qquad (G\text{: } center\ of\ mass \text{ of } B). \qquad (1.16.1a)$$

Substituting in the above [recalling (1.7.11a ff.), and with $\boldsymbol{r}_{G/O} = \boldsymbol{r}_G$, $\boldsymbol{\omega} \to \boldsymbol{\Omega}$: angular velocity vector of noninertial frame $\to$ axes $O\text{–}xyz$ relative to inertial ones $I\text{–}XYZ$]

$$\boldsymbol{v}_G = \boldsymbol{v}_O + \boldsymbol{v}_{G/O} = \boldsymbol{v}_O + \boldsymbol{v}_{G,\text{rel}} + \boldsymbol{\Omega} \times \boldsymbol{r}_G \qquad (\boldsymbol{v}_{G,\text{rel}} \equiv \partial \boldsymbol{r}_G/\partial t) \qquad (1.16.1b)$$

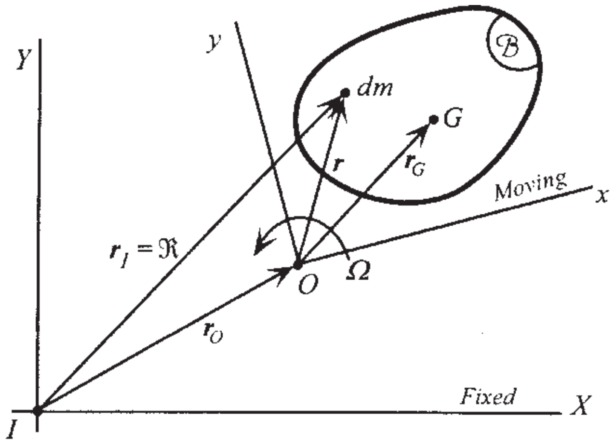

Figure 1.28 Rigid body (*B*), or system (*S*), in general motion relative to the noninertial frame *O–xyz*; $\boldsymbol{\Omega}$: inertial angular velocity of *O–xyz* (two-dimensional case).

readily yields

$$\boldsymbol{p} \equiv \boldsymbol{p}_{\text{trans}} + \boldsymbol{p}_{\text{rel}}, \tag{1.16.1c}$$

$$\boldsymbol{p}_{\text{trans}} \equiv m(\boldsymbol{v}_O + \boldsymbol{\Omega} \times \boldsymbol{r}_G): \text{ Linear momentum of } \textit{transport}, \tag{1.16.1d}$$

$$\boldsymbol{p}_{\text{rel}} \equiv m\boldsymbol{v}_{G,\text{rel}} \equiv m(\partial \boldsymbol{r}_G/\partial t) : \text{Linear momentum of } \textit{relative motion}. \tag{1.16.1e}$$

If B is rigidly attached to the moving frame M, represented by the axes O–xyz (fig. 1.28), then, clearly, $\boldsymbol{p}_{\text{rel}} = \boldsymbol{0}$.

(ii) The *inertial and absolute* angular momentum of B, relative to the inertial origin I, $\boldsymbol{H}_{I,\text{abs}} \equiv \boldsymbol{H}_I$, is defined as

$$\begin{aligned}
\boldsymbol{H}_1 &\equiv \mathcal{S}\, [\boldsymbol{r}_I \times dm\,(d\boldsymbol{r}_I/dt)] \equiv \mathcal{S}\, [\Re \times dm\,(d\Re/dt)] \\
&\quad [\text{substituting } \Re = \boldsymbol{r}_{O/I} + \boldsymbol{r} \equiv \boldsymbol{r}_O + \boldsymbol{r} \;\Rightarrow\; d\Re/dt = \boldsymbol{v}_O + \boldsymbol{v}_{\text{rel}} + \boldsymbol{\Omega} \times \boldsymbol{r},\, \boldsymbol{v}_{\text{rel}} \equiv \partial \boldsymbol{r}/\partial t] \\
&= m\boldsymbol{r}_O \times (\boldsymbol{v}_O + \boldsymbol{\Omega} \times \boldsymbol{r}_G) + m\boldsymbol{r}_G \times \boldsymbol{v}_O \\
&\qquad + \mathcal{S}\, dm\,[\boldsymbol{r} \times (\boldsymbol{\Omega} \times \boldsymbol{r})] + \mathcal{S}\, dm\,(\boldsymbol{r} \times \boldsymbol{v}_{\text{rel}}),
\end{aligned} \tag{1.16.2a}$$

or, since

$$\begin{aligned}
\mathcal{S}\, dm\,[\boldsymbol{r} \times (\boldsymbol{\Omega} \times \boldsymbol{r})] &= \mathcal{S}\, dm\,[r^2\boldsymbol{\Omega} - (\boldsymbol{r} \otimes \boldsymbol{r}) \cdot \boldsymbol{\Omega}] \\
&= \mathcal{S}\, dm\,[r^2\boldsymbol{1} - (\boldsymbol{r} \otimes \boldsymbol{r})] \cdot \boldsymbol{\Omega} \equiv \boldsymbol{I}_O \cdot \boldsymbol{\Omega}\,,
\end{aligned} \tag{1.16.2b}$$

and calling

$$\boldsymbol{H}_{O,\,\text{rel}} \equiv \mathcal{S}\, \boldsymbol{r} \times (dm\, \boldsymbol{v}_{\text{rel}}): \textit{Noninertial and absolute angular momentum of } B\textit{, about } O, \tag{1.16.2c}$$

we finally obtain the following general kinematico-inertial result:

$$\boldsymbol{H}_I = \boldsymbol{H}_O + \boldsymbol{r}_O \times \boldsymbol{p} + m\boldsymbol{r}_G \times \boldsymbol{v}_O, \qquad \boldsymbol{H}_O = \boldsymbol{I}_O \cdot \boldsymbol{\Omega} + \boldsymbol{H}_{O,\mathrm{rel}} \,. \tag{1.16.2d}$$

Special Cases

(i) If the body B is rigidly attached to the moving frame M, then

$$\boldsymbol{v}_{\mathrm{rel}} = \boldsymbol{0}, \qquad \boldsymbol{p}_{\mathrm{rel}} = \boldsymbol{0}, \qquad \boldsymbol{H}_{O,\,\mathrm{rel}} = \boldsymbol{0}, \qquad \boldsymbol{\Omega} = \boldsymbol{\omega} = \text{inertial angular velocity of } B, \tag{1.16.3a}$$

and, therefore,

$$\boldsymbol{p} = m(\boldsymbol{v}_O + \boldsymbol{\omega} \times \boldsymbol{r}_G) = m\boldsymbol{v}_G, \qquad \boldsymbol{H}_I = \boldsymbol{I}_O \cdot \boldsymbol{\omega} + \boldsymbol{r}_O \times \boldsymbol{p} + m\boldsymbol{r}_G \times \boldsymbol{v}_O \,. \tag{1.16.3b}$$

(ii) If, *further*, $O = G$, then $\boldsymbol{r}_G = \boldsymbol{0}$, $\boldsymbol{r}_O = \boldsymbol{r}_G$, and, therefore,

$$\boldsymbol{p} = m\boldsymbol{v}_G, \qquad \boldsymbol{H}_I = \boldsymbol{I}_O \cdot \boldsymbol{\omega} + \boldsymbol{r}_O \times \boldsymbol{p} \,. \tag{1.16.3c}$$

(iii) If $I = O$ (i.e., rigid-body motion with one point, O, fixed), then $\boldsymbol{r}_O = \boldsymbol{0}$, $\boldsymbol{v}_O = \boldsymbol{0}$, and, therefore,

$$\boldsymbol{p} = m(\boldsymbol{\omega} \times \boldsymbol{r}_G) = m\boldsymbol{v}_G, \qquad \boldsymbol{H}_I = \boldsymbol{H}_O = \boldsymbol{I}_O \cdot \boldsymbol{\omega} \qquad \left[\equiv \int \boldsymbol{r} \times dm\, \boldsymbol{v}\right]. \tag{1.16.3d1, 2}$$

It should be pointed out that the above hold for any set of axes, including *non–body-fixed* ones, at the fixed point O; but along such axes the components of $\boldsymbol{I}_O$ will, in general, not be constant. Equation (1.16.3d2) would then yield, in components [omitting the subscript O and with $\boldsymbol{r} = (x_k)$],

$$H_k = \sum I_{kl}\,\omega_l, \tag{1.16.4a}$$

$$I_{kl} = \int dm\big[(\boldsymbol{r} \cdot \boldsymbol{r})\boldsymbol{1} - (\boldsymbol{r} \otimes \boldsymbol{r})\big]_{kl} = \int dm\Big[\Big(\sum x_r x_r\Big)\,\delta_{kl} - x_k x_l\Big]. \tag{1.16.4b}$$

If the axes at O are *body-fixed*, then the I_{kl} are constant; and, further, if they are *principal*, then

$$H_k = I_k\,\omega_k. \tag{1.16.4c}$$

Linear Momentum of a Rotating Body

To dispel possible notions that the linear momentum is associated only with translation, let us calculate the linear momentum of a rigid body rotating about a *fixed point* ◆. We have, successively, with the usual notations,

$$\begin{aligned}
\boldsymbol{p} = m\boldsymbol{v}_G &= m(\boldsymbol{\omega} \times \boldsymbol{r}_{G/\blacklozenge}) \equiv m(\boldsymbol{\omega} \times \boldsymbol{r}_G) \\
&= m(\omega_x, \omega_y, \omega_z) \times (x_G, y_G, z_G) \qquad [\text{components along any } \blacklozenge\text{-axes}] \\
&= m(\omega_y z_G - \omega_z y_G, \qquad \omega_z x_G - \omega_x z_G, \qquad \omega_x y_G - \omega_y x_G).
\end{aligned} \tag{1.16.5a}$$

In particular, if the body rotates about a *fixed axis through* $\blacklozenge$, say $\blacklozenge z$ [recalling (1.15.9a ff.)], then $\boldsymbol{\omega} = \omega_z\, \boldsymbol{k} \equiv (d\phi/dt)\, \boldsymbol{k}$, and so (1.16.5a) reduces to

$$p_x = -(my_G)\omega_z \equiv -m_y\, \omega_z, \qquad p_y = (mx_G)\omega_z \equiv m_x\, \omega_z, \qquad p_z = 0. \qquad (1.16.5b)$$

These expressions appear in the problem of rotation of a rigid body about a fixed axis, treated via body-fixed axes $\blacklozenge$–xyz [see, e.g., Butenin et al. (1985, pp. 266–278) and Papastavridis (EM, in preparation)].

It is not hard to show that, in this case, the (inertial and absolute) angular momentum of the body

$$\boldsymbol{H}_\blacklozenge \equiv \mathsf{S}\, \boldsymbol{r} \times dm\, \boldsymbol{v} = (H_x, H_y, H_z), \qquad (1.16.5c)$$

reduces to

$$H_x = I_{xz}\, \omega_z, \qquad H_y = I_{yz}\, \omega_z, \qquad H_z = I_{zz}\, \omega_z \equiv I_z\, \omega_z. \qquad (1.16.5d)$$

1.17 THE RIGID BODY: KINETIC ENERGY AND KINETICS OF TRANSLATION AND ROTATION (EULERIAN "GYRO EQUATIONS")

We recommend, for this section, the concurrent reading of a good text on rigid-body dynamics; for example (alphabetically): Grammel (1950), Gray (1918), Hughes (1986), Leimanis (1965), Magnus (1971, 1974), Mavraganis (1987), Stäckel (1905, pp. 556–563).

(i) The inertial kinetic energy of a rigid body B in general motion, T, is defined as the sum of the (inertial) kinetic energies of its particles:

$$2T(B, t) \equiv 2T \equiv \mathsf{S}\, dm\, \boldsymbol{v} \cdot \boldsymbol{v}, \qquad (1.17.1)$$

or, since

$$\boldsymbol{v} = \boldsymbol{v}_\blacklozenge + \boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge} \qquad (\blacklozenge\text{: arbitrary } \textit{body-fixed} \text{ point}), \qquad (1.17.2)$$

$$2T = \mathsf{S}\, dm(\boldsymbol{v}_\blacklozenge + \boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge}) \cdot (\boldsymbol{v}_\blacklozenge + \boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge}) = 2(T_{\text{transl'n}} + T_{\text{rot'n}} + T_{\text{cpl'g}}), \quad (1.17.3)$$

where

$$2T_{\text{transl'n}} \equiv m\boldsymbol{v}_\blacklozenge \cdot \boldsymbol{v}_\blacklozenge = m{\boldsymbol{v}_\blacklozenge}^2:$$

(twice of) *Translatory* (or sliding) kinetic energy of B, (1.17.3a)

$$2T_{\text{rot'n}} \equiv \mathsf{S}\, dm(\boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge}) \cdot (\boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge}) = \boldsymbol{\omega} \cdot \boldsymbol{I}_\blacklozenge \cdot \boldsymbol{\omega}: \quad \text{(recalling §1.15)}$$

(twice of) *Rotatory* kinetic energy of B, (1.17.3b)

$$T_{\text{cpl'g}} \equiv m(\boldsymbol{\omega} \times \boldsymbol{r}_{G/\blacklozenge}) \cdot \boldsymbol{v}_\blacklozenge = m\boldsymbol{v}_{G/\blacklozenge} \cdot \boldsymbol{v}_\blacklozenge = (m\, \boldsymbol{r}_{G/\blacklozenge})^{\boldsymbol{\cdot}} \cdot \boldsymbol{v}_\blacklozenge \equiv (d\boldsymbol{m}_{G/\blacklozenge}/dt) \cdot \boldsymbol{v}_\blacklozenge,$$

or

$$T_{\text{cpl'g}} \equiv m\boldsymbol{r}_{G/\blacklozenge} \cdot (\boldsymbol{v}_{\blacklozenge} \times \boldsymbol{\omega}) \equiv \boldsymbol{m}_{G/\blacklozenge} \cdot (\boldsymbol{v}_{\blacklozenge} \times \boldsymbol{\omega}): \tag{1.17.3c}$$

Kinetic energy of *coupling* between $\boldsymbol{v}_{\blacklozenge}$ and $\boldsymbol{\omega}$ (where $\boldsymbol{m}_{G/\blacklozenge} \equiv m\boldsymbol{r}_{G/\blacklozenge}$) [$= 0$; e.g. if $G = \blacklozenge$, or if $\boldsymbol{v}_{\blacklozenge}$ and $\boldsymbol{\omega}$ are parallel [$\blacklozenge$ on instantaneous screw axis of motion (§1.9)]; in which case, T decouples into translatory and rotatory kinetic energy]. (1.17.3d)

• These expressions hold for any axes, either body-fixed or moving in an arbitrary manner, or even inertial. But if they are *non–body-fixed*, the components of $\boldsymbol{r}_{G/\blacklozenge}$ and $\boldsymbol{I}_{\blacklozenge}$ will, in general, not be constant.

• We also notice that, in there, the mass m appears as a *scalar* (m: $T_{\text{transl'n}}$), as a *vector* of a first-order moment ($\boldsymbol{m}_{G/\blacklozenge}$: $T_{\text{cpl'g}}$), and as a second-order *tensor* ($\boldsymbol{I}_{\blacklozenge} : T_{\text{rot'n}}$).

• From (1.17.3b), we obtain, successively,

$$\begin{aligned} \boldsymbol{grad}_{\boldsymbol{\omega}} T_{\text{rot'n}} &\equiv \partial T_{\text{rot'n}}/\partial\boldsymbol{\omega} \\ &= \mathcal{S}\, dm\, \boldsymbol{v}_{/\blacklozenge} \cdot (\partial \boldsymbol{v}_{/\blacklozenge}/\partial\boldsymbol{\omega}) = \mathcal{S}\, \boldsymbol{r}_{/\blacklozenge} \times (\boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge})\, dm = \mathcal{S}\, \boldsymbol{r}_{/\blacklozenge} \times (dm\, \boldsymbol{v}_{/\blacklozenge}) \\ &\equiv \boldsymbol{H}_{\blacklozenge,\,\text{relative}} \equiv \boldsymbol{h}_{\blacklozenge} \qquad \text{[recalling (1.6.5b)]}; \end{aligned} \tag{1.17.4}$$

that is, the angular momentum is normal to the surface $T_{\text{rot'n}} = \textit{constant}$, in the space of the ω's.

• If $\boldsymbol{v}_{\blacklozenge} = \boldsymbol{0}$—for example, gyro spinning about a fixed point—(1.17.3b) yield

$$2T \;\Rightarrow\; 2T_{\text{rot'n}} = I_{xx}\,{\omega_x}^2 + \cdots + 2I_{xy}\,\omega_x\,\omega_y + \cdots = \boldsymbol{H}_{\blacklozenge} \cdot \boldsymbol{\omega} = \boldsymbol{h}_{\blacklozenge} \cdot \boldsymbol{\omega} \geq 0; \tag{1.17.4a}$$

that is, since T is positive definite, the *angle between* $\boldsymbol{H}_{\blacklozenge} = \boldsymbol{h}_{\blacklozenge}$ *and* $\boldsymbol{\omega}$ is *never obtuse*:

$$0^\circ \leq \text{angle } (\boldsymbol{H}_{\blacklozenge}, \boldsymbol{\omega}) < 90^\circ. \tag{1.17.4b}$$

• Similarly, we can express T in terms of relative velocities; that is, with

$$\boldsymbol{v} = \boldsymbol{v}_{\blacklozenge} + \boldsymbol{\Omega} \times \boldsymbol{r}_{/\blacklozenge} + \boldsymbol{v}_{/\blacklozenge,\,\text{relative}}, \qquad \boldsymbol{v}_{/\blacklozenge,\,\text{relative}} \equiv \partial \boldsymbol{r}_{/\blacklozenge}/\partial t, \tag{1.17.5}$$

where $\boldsymbol{\Omega}$ is the inertial angular velocity of the moving axes.

Another Useful T-Representation

We have, successively,

$$\begin{aligned} 2T &= \mathcal{S}\, dm\, \boldsymbol{v} \cdot \boldsymbol{v} = \mathcal{S}\, \boldsymbol{v} \cdot (dm\, \boldsymbol{v}) = \mathcal{S}\, (\boldsymbol{v}_{\blacklozenge} + \boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge}) \cdot (dm\, \boldsymbol{v}) \\ &= \boldsymbol{v}_{\blacklozenge} \cdot \left(\mathcal{S}\, dm\, \boldsymbol{v}\right) + \mathcal{S}\, d\boldsymbol{p} \cdot (\boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge}) \qquad (\text{since } dm\, \boldsymbol{v} \equiv d\boldsymbol{p}) \\ &= \boldsymbol{v}_{\blacklozenge} \cdot \boldsymbol{p} + \boldsymbol{\omega} \cdot \left(\mathcal{S}\, \boldsymbol{r}_{/\blacklozenge} \times d\boldsymbol{p}\right) \;=\; \boldsymbol{v}_{\blacklozenge} \cdot \boldsymbol{p} + \boldsymbol{\omega} \cdot \boldsymbol{H}_{\blacklozenge,\,\text{absolute}}. \end{aligned} \tag{1.17.6}$$

Kinetic Energy of a Thin Plate of Mass m
in Plane Motion on its Own Plane (fig. 1.17)

Using *plate-fixed* axes $\blacklozenge$–xy, we find [with $\cos(\ldots) \equiv c(\ldots)$, $\sin(\ldots) \equiv s(\ldots)$]

$$\boldsymbol{r}_{G/\blacklozenge} = x_G\,\boldsymbol{i} + y_G\,\boldsymbol{j} \equiv x\,\boldsymbol{i} + y\,\boldsymbol{j}, \qquad (x, y\text{: } constant) \tag{1.17.7a}$$

$$\begin{aligned}
\boldsymbol{v}_\blacklozenge &= (dX_\blacklozenge/dt)\boldsymbol{I} + (dY_\blacklozenge/dt)\boldsymbol{J} \equiv (dX/dt)\boldsymbol{I} + (dY/dt)\boldsymbol{J} \\
&= (dX/dt)(c\phi\,\boldsymbol{i} - s\phi\,\boldsymbol{j}) + (dY/dt)(s\phi\,\boldsymbol{i} + c\phi\,\boldsymbol{j}) \\
&= \big[(dX/dt)c\phi + (dY/dt)s\phi\big]\boldsymbol{i} + \big[-(dX/dt)s\phi + (dY/dt)c\phi\big]\boldsymbol{j} \\
&\equiv v_x\,\boldsymbol{i} + v_y\,\boldsymbol{j}, \qquad \boldsymbol{\omega} = (d\phi/dt)\boldsymbol{K} = (d\phi/dt)\boldsymbol{k};
\end{aligned} \tag{1.17.7b, c}$$

and so, successively,

$$2T_{\text{transl'n}} \equiv m\,\boldsymbol{v}_\blacklozenge \cdot \boldsymbol{v}_\blacklozenge = m\big[(dX/dt)^2 + (dY/dt)^2\big]; \tag{1.17.7d}$$

$$\begin{aligned}
T_{\text{cpl'g}} &\equiv m\,\boldsymbol{r}_{G/\blacklozenge} \cdot (\boldsymbol{v}_\blacklozenge \times \boldsymbol{\omega}) = m(x, y, 0) \cdot [(v_x, v_y, 0) \times (0, 0, d\phi/dt)] \\
&= m(d\phi/dt)(v_y\,x - v_x\,y) \\
&= m(d\phi/dt)\big\{[(dY/dt)x - (dX/dt)y]c\phi - [(dX/dt)x + (dY/dt)y]\,s\phi\big\};
\end{aligned} \tag{1.17.7e}$$

$$2T_{\text{rot'n}} \equiv \boldsymbol{\omega} \cdot \boldsymbol{I}_\blacklozenge \cdot \boldsymbol{\omega} = I_{\blacklozenge,zz}\,{\omega_z}^2 \equiv I(d\phi/dt)^2; \tag{1.17.7f}$$

that is,

$$\begin{aligned}
2T &= 2T(dX/dt, dY/dt, d\phi/dt) \\
&= m[(dX/dt)^2 + (dY/dt)^2] + I(d\phi/dt)^2 \\
&\quad + 2m(d\phi/dt)\big\{[(dY/dt)x - (dX/dt)y]c\phi - [(dX/dt)x + (dY/dt)y]s\phi\big\}.
\end{aligned} \tag{1.17.7g}$$

An Application

It is shown in chap. 3 that for this *three* degrees of freedom (*DOF*) (unconstrained) system, defined by the positional coordinates $q_1 = X$, $q_2 = Y$, $q_3 = \phi$, the Lagrangean equations of motion $d/dt\big[\partial T/\partial(dq_k/dt)\big] - (\partial T/\partial q_k) = Q_k$ [= *system* (*impressed*) *force* corresponding to q_k]; or, explicitly, *angular equation* (with M = total external moment about $\blacklozenge$):

$$\begin{aligned}
I(d^2\phi/dt^2) + m\big\{&[(d^2Y/dt^2)x - (d^2X/dt^2)y]c\phi \\
&- [(d^2X/dt^2)x + (d^2Y/dt^2)y]s\phi\big\} = M;
\end{aligned} \tag{1.17.7h}$$

which is none other than the (not-so-common form of the) angular momentum equation:

$$I_\blacklozenge\alpha_z + (\boldsymbol{r}_{G/\blacklozenge} \times m\,\boldsymbol{a}_\blacklozenge)_z = I(d^2\phi/dt^2) + m\big[x(\boldsymbol{a}_\blacklozenge)_y - y(\boldsymbol{a}_\blacklozenge)_x\big] = M, \tag{1.17.7i}$$

where (fig. 1.17),

$$\boldsymbol{r}_{G/\blacklozenge} = x_G\,\boldsymbol{i} + y_G\,\boldsymbol{j} \equiv x\,\boldsymbol{i} + y\,\boldsymbol{j} = \cdots$$
$$= (x\,c\phi - y\,s\phi)\boldsymbol{I} + (x\,s\phi + y\,c\phi)\boldsymbol{J} \equiv X\boldsymbol{I} + Y\boldsymbol{J}, \tag{1.17.7j}$$
$$\boldsymbol{a}_\blacklozenge = (d^2X_\blacklozenge/dt^2)\boldsymbol{I} + (d^2Y_\blacklozenge/dt^2)\boldsymbol{J} \equiv (d^2X/dt^2)\boldsymbol{I} + (d^2Y/dt^2)\boldsymbol{J}$$
$$= (d^2X/dt^2)(c\phi\boldsymbol{i} - s\phi\boldsymbol{j}) + (d^2Y/dt^2)(s\phi\,\boldsymbol{i} + c\phi\boldsymbol{j})$$
$$= [(d^2X/dt^2)c\phi + (d^2Y/dt^2)s\phi]\,\boldsymbol{i} + [-(d^2X/dt^2)s\phi + (d^2Y/dt^2)c\phi]\,\boldsymbol{j}$$
$$\equiv (\boldsymbol{a}_\blacklozenge)_x\,\boldsymbol{i} + (\boldsymbol{a}_\blacklozenge)_y\,\boldsymbol{j} \equiv a_x\,\boldsymbol{i} + a_y\,\boldsymbol{j}; \tag{1.17.7k}$$

x, y-equations (with $f_{x,y}$ = components of total external force about x, y-axes, respectively):

$$m[d^2X/dt^2 - (d^2\phi/dt^2)(x\,s\phi + y\,c\phi) - (d\phi/dt)^2(x\,c\phi - y\,s\phi)] = f_x, \tag{1.17.7l}$$
$$m[d^2Y/dt^2 + (d^2\phi/dt^2)(x\,c\phi - y\,s\phi) - (d\phi/dt)^2(x\,s\phi + y\,c\phi)] = f_y, \tag{1.17.7m}$$

which are none other than

$$m(\boldsymbol{a}_\blacklozenge)_x - m[(d^2\phi/dt^2)Y + (d\phi/dt)^2X] = f_x, \tag{1.17.7n}$$
$$m(\boldsymbol{a}_\blacklozenge)_y + m[(d^2\phi/dt^2)X - (d\phi/dt)^2Y] = f_y. \tag{1.17.7o}$$

For additional related plane motion problems, see, for example, Wells (1967, pp. 150–152).

“British Theorem”

It can be shown that the (inertial) kinetic energy of a thin homogeneous bar AB of mass m equals

$$T = (m/6)(\boldsymbol{v}_A \cdot \boldsymbol{v}_A + \boldsymbol{v}_B \cdot \boldsymbol{v}_B + \boldsymbol{v}_A \cdot \boldsymbol{v}_B) = (m/6)({v_A}^2 + {v_B}^2 + \boldsymbol{v}_A \cdot \boldsymbol{v}_B). \tag{1.17.8}$$

(This useful result appears almost exclusively in British texts on dynamics; hence, the name; see, for example, Chorlton, 1983, pp. 165–166.)

Principle of Linear Momentum; Motion of Mass Center

Since

$$\boldsymbol{v}_G = \boldsymbol{v}_\blacklozenge + \boldsymbol{\omega} \times \boldsymbol{r}_{G/\blacklozenge} \qquad (\blacklozenge\text{: } \textit{body-fixed} \text{ point}), \tag{1.17.9a}$$

the principle of linear momentum (§1.6)

$$m(d\boldsymbol{v}_G/dt) = \boldsymbol{f} \qquad \text{(total external force, acting at } G), \tag{1.17.9b}$$

along *body-fixe d*axes (i.e., $\boldsymbol{\omega} = \boldsymbol{\Omega}$) yields, successively,

$$
\begin{aligned}
&m\, d/dt(\boldsymbol{v}_\blacklozenge + \boldsymbol{\omega} \times \boldsymbol{r}_{G/\blacklozenge}) \\
&\quad = m(\partial \boldsymbol{v}_\blacklozenge/\partial t + \boldsymbol{\omega} \times \boldsymbol{v}_\blacklozenge) + m\big[(d\boldsymbol{\omega}/dt) \times \boldsymbol{r}_{G/\blacklozenge} + \boldsymbol{\omega} \times (d\boldsymbol{r}_{G/\blacklozenge}/dt)\big] \\
&\qquad\qquad [\text{with } d\boldsymbol{\omega}/dt \equiv \boldsymbol{\alpha}, \qquad d\boldsymbol{r}_{G/\blacklozenge}/dt \equiv \boldsymbol{v}_{G/\blacklozenge} = \boldsymbol{\omega} \times \boldsymbol{r}_{G/\blacklozenge}] \\
&\quad = m(\partial \boldsymbol{v}_\blacklozenge/\partial t) + m(\boldsymbol{\omega} \times \boldsymbol{v}_\blacklozenge) + \boldsymbol{\alpha} \times (m\boldsymbol{r}_{G/\blacklozenge}) + \boldsymbol{\omega} \times [\boldsymbol{\omega} \times (m\boldsymbol{r}_{G/\blacklozenge})] = \boldsymbol{f},
\end{aligned}
\tag{1.17.9c}
$$

or, in terms of the *center of mass vector of the mass moment* $\boldsymbol{m}_{G/\blacklozenge} \equiv m\,\boldsymbol{r}_{G/\blacklozenge}$ [as in (1.17.3c, d)],

$$m(\partial \boldsymbol{v}_\blacklozenge/\partial t) + m(\boldsymbol{\omega} \times \boldsymbol{v}_\blacklozenge) + \boldsymbol{\alpha} \times (\boldsymbol{m}_{G/\blacklozenge} + \boldsymbol{\omega} \times (\boldsymbol{\omega} \times \boldsymbol{m}_{G/\blacklozenge}) = \boldsymbol{f}. \tag{1.17.9d}$$

Along *body-fixed* axes $\blacklozenge$–xyz, and with $\boldsymbol{m}_{G/\blacklozenge} = (m_{x,y,z})$, $\boldsymbol{v}_\blacklozenge = (v_{x,y,z})$ there, the x-component of (1.17.9d) is

$$
\begin{aligned}
&m[dv_x/dt + \omega_y v_z - \omega_z v_y] + \big[m_z(d\omega_y/dt) - m_y(d\omega_z/dt)\big] \\
&\qquad + \big[\omega_y(m_y\omega_x - m_x\omega_y) - \omega_z(m_x\omega_z - m_z\omega_x)\big] = f_x, \\
&\qquad\quad \text{etc., cyclically.}
\end{aligned}
\tag{1.17.9e}
$$

Special Cases

(i) If $\blacklozenge = G$, then $\boldsymbol{m}_{G/\blacklozenge} = \boldsymbol{0}$ and, clearly, (1.17.9d) reduces to

$$m(\partial \boldsymbol{v}_G/\partial t + \boldsymbol{\omega} \times \boldsymbol{v}_G) = \boldsymbol{f}. \tag{1.17.9f}$$

(ii) Along *non–body-fixed* axes at G, rotating with inertial angular velocity $\boldsymbol{\Omega}$, (1.17.9b) yields

$$m(\partial \boldsymbol{v}_G/\partial t + \boldsymbol{\Omega} \times \boldsymbol{v}_G) = \boldsymbol{f}; \tag{1.17.9g}$$

or, in components, with $\boldsymbol{v}_G = (v_{G;\,x,y,z})$,

$$m(d\boldsymbol{v}_G/dt)_x = m\big(dv_{G,x}/dt + \Omega_y\, v_{G,z} - \Omega_z v_{G,y}\big) = f_x, \quad \text{etc., cyclically,} \tag{1.17.9h}$$

where $(d\boldsymbol{v}_G/dt)_x =$ component of $\boldsymbol{a}_G$ along an inertial axis that instantaneously coincides with the moving axis Gx, and so on. In general, the $v_{G;\,x,y,z}$ are quasi velocities.

Principle of Angular Momentum; Motion (Rotation) about the Mass Center

Along *body-fixed* axes $\blacklozenge$–xyz, the principle of angular momentum [§1.6, with $\bullet$ (arbitrary spatial point) $\to \blacklozenge$ (arbitrary body point), and $\boldsymbol{H}_{\blacklozenge,\,\text{relative}} \equiv \boldsymbol{h}_\blacklozenge$],

$$d\boldsymbol{h}_\blacklozenge/dt + \boldsymbol{r}_{G/\blacklozenge} \times [m(d\boldsymbol{v}_\blacklozenge/dt)] = \boldsymbol{M}_\blacklozenge, \tag{1.17.10a}$$

becomes

$$\partial \boldsymbol{h}_\blacklozenge/\partial t + \boldsymbol{\omega} \times \boldsymbol{h}_\blacklozenge + \boldsymbol{m}_{G/\blacklozenge} \times (\partial \boldsymbol{v}_\blacklozenge/\partial t) + \boldsymbol{m}_{G/\blacklozenge} \times (\boldsymbol{\omega} \times \boldsymbol{v}_\blacklozenge) = \boldsymbol{M}_\blacklozenge\,; \tag{1.17.10b}$$

or, in components, with $\boldsymbol{h}_\blacklozenge = (h_{x,y,z})$, $\boldsymbol{m}_{G/\blacklozenge} \equiv m\boldsymbol{r}_{G/\blacklozenge} = (m_{x,y,z})$, $\boldsymbol{v}_\blacklozenge = (v_{x,y,z})$, and so on,

$$dh_x/dt + \omega_y h_z - \omega_z h_y + m_y[dv_z/dt + \omega_x v_y - \omega_y v_x] \\ - m_z[dv_y/dt + \omega_z v_x - \omega_x v_z] = M_x, \quad \text{etc., cyclically.} \quad (1.17.10c)$$

[The forms (1.17.9d, e) and (1.17.10b–c) seem to be due to Heun (1906, 1914); see also Winkelmann and Grammel (1927) for a concise treatment via von Mises' (not very popular) "motor calculus."]

Special Cases

(i) If $\blacklozenge = G$, then $\boldsymbol{m}_{G/\blacklozenge} = \boldsymbol{0}$, and (1.17.10b) reduces to

$$\partial \boldsymbol{h}_G/\partial t + \boldsymbol{\omega} \times \boldsymbol{h}_G = \boldsymbol{M}_G. \quad (1.17.10d)$$

(ii) Along *non–body-fixed* axes at G, rotating with inertial angular velocity $\boldsymbol{\Omega}$, (1.17.10a) yields

$$\partial \boldsymbol{h}_G/\partial t + \boldsymbol{\Omega} \times \boldsymbol{h}_G = \boldsymbol{M}_G; \quad (1.17.10e)$$

or, in components,

$$(d\boldsymbol{h}_G/dt)_x = dh_{G,x}/dt + \Omega_y h_{G,z} - \Omega_z h_{G,y} = M_{G,x}, \quad \text{etc., cyclically.} \quad (1.17.10f)$$

(iii) If the axes are *body-fixed*, then $\boldsymbol{\Omega} = \boldsymbol{\omega}$; and if they are also *principal axes*, then, since (omitting the subscript G throughout) $\boldsymbol{h} = \boldsymbol{I} \cdot \boldsymbol{\omega} : h_k = I_k \omega_k$, $k = 1, 2, 3$, eqs. (1.17.10f) assume the famous *Eulerian form* (1758, publ. 1765):

$$\begin{aligned} I_1(d\omega_1/dt) - (I_2 - I_3)\omega_2\omega_3 &= M_1, \\ I_2(d\omega_2/dt) - (I_3 - I_1)\omega_3\omega_1 &= M_2, \\ I_3(d\omega_3/dt) - (I_1 - I_2)\omega_1\omega_2 &= M_3; \end{aligned} \quad (1.17.11a)$$

or, alternatively,

$$d\omega_1/dt - [(I_2 - I_3)/I_1]\omega_2\omega_3 = M_1/I_1, \quad \text{etc., cyclically.} \quad (1.17.11b)$$

From the above we readily conclude that:

- A force-free rigid body in space can rotate permanently [i.e., $d\boldsymbol{\omega}/dt = \boldsymbol{0} \Rightarrow \boldsymbol{\omega} = (\omega_1, 0, 0)$, or $(0, \omega_2, 0)$, or $(0, 0, \omega_3)$ = *constant*] only about a central principal axis of inertia. Or, if a free rigid body under no external forces begins to rotate about one of its central principal axes, it will continue to rotate uniformly about that axis; and, if a rigid body *with a fixed point*, and zero torque about that point, begins to rotate about a principal axis through that point, it will continue to do so uniformly about that axis.
- The principle of angular momentum takes the "elementary" form $M = d/dt\,(I\omega)$ only for principal axes of inertia, or if the body rotates about a (body- and space-) fixed axis. That is why a central principal axis was called a *permanent* axis (Ampère, 1823).

REMARKS

(i) Equations (1.17.10a ff.) also hold for any *fixed point* O.

(ii) The principles of linear and angular momentum are summarized as follows: the vector system of mechanical loads, or inputs [$\boldsymbol{f}$ at G, $\boldsymbol{M}_G$ (*moments of forces and couples*)] is equivalent to the kinematico-inertial vector system of the responses, or outputs, ($m\boldsymbol{a}_G$ at G, $d\boldsymbol{h}_G/dt$); and this equivalence, holding about any other space point $\bullet$, can be expressed via the (hopefully familiar from elementary statics) purely geometrical transfer theorem:

$$\boldsymbol{M}_\bullet = \boldsymbol{M}_G + \boldsymbol{r}_{G/\bullet} \times \boldsymbol{f}_{\text{at}\,G} = \boldsymbol{M}_G + \boldsymbol{r}_{G/\bullet} \times m\boldsymbol{a}_G \equiv d\boldsymbol{h}_G/dt + \boldsymbol{m}_{G/\bullet} \times \boldsymbol{a}_G. \tag{1.17.12}$$

(iii) In general, the direct application of the *vectorial* forms of the principle of angular momentum, either about the mass center G, or a fixed point O, and then taking components of all quantities involved about common axes in which the inertia tensor components remain constant, is much preferable to trying to match a (any) particular problem to the various scalar components forms of the principle.

(iv) The *relative magnitudes* of the principal moments of inertia of a rigid body at, say its mass center G, $I_{G;1,2,3} \equiv I_{1,2,3}$ (i.e., its *mass distribution* there) provide an important means of classifying such systems. Thus, we have the following classification (§1.15: subsection "Ellipsoid of Inertia"):

- If $I_1 = I_2 = I_3 \equiv I$, we have a *spherical top*, or a *kinetically symmetrical* body. Then,

$$\boldsymbol{H}_G = \boldsymbol{h}_G = \boldsymbol{I}_G \cdot \boldsymbol{\omega} = (I\boldsymbol{1}) \cdot \boldsymbol{\omega} = I\boldsymbol{\omega}\,.$$

- If $I_1 = I_2 \neq I_3$, the body (or "top") is *symmetric*; if $I_1 > I_3$, it is *elongated*, and if $I_1 < I_3$, it is *flattened*.
- If $I_1 \neq I_2 \neq I_3 \neq I_1$, the body is *unsymmetric*.

For further details and insights on these fascinating equations, see Cayley (1863, pp. 230–231), Dugas (1955, pp. 276–278), Stäckel (1905, pp. 581–589).

Energy Rate, or Power, Theorem for a Rigid Body

By $d/dt(\ldots)$-differentiating the kinetic energy definition $2T = \int dm\, \boldsymbol{v}\cdot\boldsymbol{v}$, and then utilizing in there the rigid-body kinetic equation $\boldsymbol{v} = \boldsymbol{v}_\blacklozenge + \boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge}$, we obtain, successively,

$$\begin{aligned}
dT/dt &= \int dm\, \boldsymbol{v}\cdot(d\boldsymbol{v}/dt) = \int dm\, \boldsymbol{v}\cdot\boldsymbol{a} = \int dm\,(\boldsymbol{v}_\blacklozenge + \boldsymbol{\omega}\times\boldsymbol{r}_{/\blacklozenge})\cdot\boldsymbol{a} \\
&= \int dm\, \boldsymbol{v}_\blacklozenge\cdot\boldsymbol{a} + \int dm(\boldsymbol{\omega}\times\boldsymbol{r}_{/\blacklozenge})\cdot\boldsymbol{a} = \boldsymbol{v}_\blacklozenge\cdot\left(\int dm\,\boldsymbol{a}\right) + \boldsymbol{\omega}\cdot\left(\int dm\,\boldsymbol{r}_{/\blacklozenge}\times\boldsymbol{a}\right) \\
&= \boldsymbol{v}_\blacklozenge\cdot(m\,\boldsymbol{a}_G) + \boldsymbol{\omega}\cdot\left\{\int dm\,[d/dt(\boldsymbol{r}_{/\blacklozenge}\times\boldsymbol{v}) + \boldsymbol{v}_\blacklozenge\times\boldsymbol{v}]\right\} \\
&= \boldsymbol{v}_\blacklozenge\cdot(d\boldsymbol{p}/dt) + \boldsymbol{\omega}\cdot(d\boldsymbol{H}_\blacklozenge/dt + \boldsymbol{v}_\blacklozenge\times\boldsymbol{p}),
\end{aligned} \tag{1.17.13a}$$

where (recalling the definitions in §1.6),

$$\boldsymbol{p} \equiv \int dm\,\boldsymbol{v} = m\,\boldsymbol{v}_G: \quad \text{Linear momentum of body,} \tag{1.17.13b}$$

$$\boldsymbol{H}_\blacklozenge \equiv \int dm\,(\boldsymbol{r}_{/\blacklozenge}\times\boldsymbol{v}): \quad \text{Absolute (and inertial) angular momentum of body, about the body-fixed point } \blacklozenge. \tag{1.17.13c}$$

Invoking the principles of linear and angular momentum (§1.6), we can rewrite (1.17.13a) as

$$dT/dt = \boldsymbol{v}_\blacklozenge \cdot \boldsymbol{f} + \boldsymbol{\omega} \cdot \boldsymbol{M}_\blacklozenge. \tag{1.17.13d}$$

On the other hand, the *power* of all forces, $d'W/dt \equiv \mathbf{S}\, d\boldsymbol{f} \cdot \boldsymbol{v}$, transforms, successively, to

$$\begin{aligned} d'W/dt &= \mathbf{S}\, d\boldsymbol{f} \cdot (\boldsymbol{v}_\blacklozenge + \boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge}) = \boldsymbol{v}_\blacklozenge \cdot \left(\mathbf{S}\, d\boldsymbol{f}\right) + \boldsymbol{\omega} \cdot \left(\mathbf{S}\, \boldsymbol{r}_{/\blacklozenge} \times d\boldsymbol{f}\right) \\ &= \boldsymbol{v}_\blacklozenge \cdot \boldsymbol{f} + \boldsymbol{\omega} \cdot \boldsymbol{M}_\blacklozenge; \end{aligned} \tag{1.17.13e}$$

that is,

$$dT/dt = d'W/dt, \tag{1.17.13f}$$

which is the well-known power theorem, proved here for a rigid system.

Special Case

If $\boldsymbol{v}_\blacklozenge = \boldsymbol{0}$ (i.e., rotation about a *fixed point*), (1.17.13d–f) reduce to

$$dT/dt = d'W/dt = \boldsymbol{\omega} \cdot \boldsymbol{M}_\blacklozenge. \tag{1.17.13g}$$

If, in addition, $\boldsymbol{M}_\blacklozenge = \boldsymbol{0}$ (*torque-free* motion), then $d'W/dt = 0$ and $T = constant$ (energy integral), and $\boldsymbol{M}_\blacklozenge = d\boldsymbol{H}_\blacklozenge/dt = d\boldsymbol{h}_\blacklozenge/dt = \boldsymbol{0} \Rightarrow \boldsymbol{H}_\blacklozenge = \boldsymbol{h}_\blacklozenge = constant$ (angular momentum integral). These *two* integrals of the torque-free and fixed-point motion form the basis of an interesting geometrical interpretation of rigid-body motion, due to Poinsot (1850s). For details see, for example (alphabetically): MacMillan (1936, pp. 204–216), Webster (1912, pp. 252–270), Winkelmann and Grammel (1927, pp. 392–398).

Additional Useful Results

(i) By multiplying the Eulerian (rotational) equations with $\omega_{x,y,z}$, respectively, and then adding them, we obtain the following power equation:

$$d/dt[(A\omega_x{}^2 + B\omega_y{}^2 + C\omega_z{}^2)/2] = M_x\omega_x + M_y\omega_y + M_z\omega_z,$$

i.e., d/dt (*Rotational kinetic energy*) = *Power of external moments.* (1.17.14)

(ii) *Plane motion*: Principle of angular momentum for a rigid body B, about its instantaneous center of rotation I. We have already seen (1.9.4d ff.) that the inertial coordinates of the *instantaneous center* (*of zero velocity*) I, relative to the center of mass G, are

$$\boldsymbol{r}_{I/G} = (X_{I/G}, Y_{I/G}, 0) = (-dY_G/dt\big/\omega,\ +dX_G/dt\big/\omega,\ 0). \tag{1.17.15a}$$

Therefore, application of the principle of angular momentum about I:

$$M_I = I_G(d\omega/dt) + (\boldsymbol{r}_{G/I} \times m\boldsymbol{a}_G)_Z, \tag{1.17.15b}$$

yields, successively (with $I_G \equiv mk^2$),

$$\begin{aligned}
M_I &= I_G(d\omega/dt) + (m/\omega)\big[(dY_G/dt, -dX_G/dt, 0) \times (d^2X_G/dt^2, d^2Y_G/dt^2, 0)\big] \\
&= I_G(d\omega/dt) + (m/\omega)\big[(dY_G/dt)(d^2Y_G/dt^2) - (-dX_G/dt)(d^2X_G/dt^2)\big] \\
&= I_G(d\omega/dt) + (m/\omega)\big[(dX_G/dt)(d^2X_G/dt^2) + (dY_G/dt)(d^2Y_G/dt^2)\big] \\
&= (m/\omega)\big[k^2\omega(d\omega/dt) + (dX_G/dt)(d^2X_G/dt^2) + (dY_G/dt)(d^2Y_G/dt^2)\big] \\
&= (m/\omega)\big(d/dt\{(1/2)[k^2\omega^2 + (dX_G/dt)^2 + (dY_G/dt)^2]\}\big) \\
&\qquad [\text{noting that } (dX_G/dt)^2 + (dY_G/dt)^2 = v_G{}^2 = r^2\omega^2, \qquad r = |\boldsymbol{r}_{G/I}|] \\
&= (1/2\omega)\{d/dt[m(k^2 + r^2)\omega^2]\},
\end{aligned}$$

or, finally, with $I_I \equiv m(k^2 + r^2) \equiv mK^2$: *moment of inertia of B about I* (by the parallel axis theorem),

$$\begin{aligned}
M_I = (1/2\omega)[d/dt\,(I_I\omega^2)] &= I_I(d\omega/dt) + (1/2)\omega(dI_I/dt) \\
&= I_I(d\omega/dt) + mr(dr/dt)\omega. \qquad (1.17.15c)
\end{aligned}$$

Special Cases

(a) If B is turning about a *fixed* axis, or if I is at a constant distance from G, then $dr/dt = 0$ and (1.17.15c) reduces to

$$M_I = I_I(d\omega/dt). \qquad (1.17.15d)$$

(b) If the axis of rotation is mobile, but *the body starts from rest*, then, since initially $\omega = 0$ and $dr/dt = 0$, the *initial* value of its angular acceleration is given by (1.17.15d):

$$d\omega/dt = M_I/I_I. \qquad (1.17.15e)$$

(c) If the body undergoes *small* angular oscillations about a position of equilibrium, then the term $dI_I/dt = 2mr(dr/dt)$ is of the order of the rate dr/dt, and therefore $(dI_I/dt)\omega$ is of the order of the *square* of a small velocity and so, to the first order (linear angular oscillations), it can be neglected; thus reducing (1.17.15c) to (1.17.15d), with I_I given by its equilibrium value.

In sum, eq. (1.17.15d) holds if the instantaneous axis of rotation is either *fixed*, or remains at a *constant distance* from the *center of mass*; or if the problem is one of *initial motion*, or of a *small oscillation*. In all other cases of moments about I, we must use (1.17.15c). For further details and applications, see, for example (alphabetically): Besant (1914, pp. 310–314), Loney (1909, pp. 287, 346–347), Pars (1953, pp. 403–404), Ramsey (1933, part I, pp. 241–242), Routh (1905(a), pp. 103–104, 171–172). Somehow this topic is treated only in older British treatises!

Rigid-Body Mechanics in Matrix Form

[Here, following earlier remarks on notation (§1.1), we denote vectors by bold italics, and matrices/tensors by bold, roman, upper case (capital) letters; for example, $\boldsymbol{a}$, $\boldsymbol{A}$ (vectors),

A, **B** (matrices, tensors). This material (notation) is presented here not because we think that it adds anything significant to our *conceptual* understanding of mechanics, but because it happens to be fashionable among some contemporary applied dynamicists.]

By recalling the tensor results of §1.1, and the earlier definitions and notations, (1.15.2a ff.),

$$\mathbf{I} \equiv \int [(\boldsymbol{r}\cdot\boldsymbol{r})\mathbf{1} - \boldsymbol{r}\otimes\boldsymbol{r}]\, dm = -\int (\mathbf{r}\cdot\mathbf{r})\, dm = (1/2)(\mathrm{Tr}\,\mathbf{I})\mathbf{1} - \mathbf{J} \tag{1.17.16a1}$$

$$[\Rightarrow \mathrm{Tr}\,\mathbf{I} = 2\,\mathrm{Tr}\,\mathbf{J}],$$

$$\mathbf{J} \equiv \int (\boldsymbol{r}\otimes\boldsymbol{r})\, dm, \tag{1.17.16a2}$$

[$\boldsymbol{r}$ = axial vector of tensor $\mathbf{r}$ and $d(\ldots)/dt$ is inertial rate of change], we can verify the following matrix forms of the earlier (§1.15–1.17) basic equations of rigid-body mechanics [while assuming that, in a given equation, all moments of inertia and moments of forces are taken either about the body's center of mass, or about a body-and-space-fixed point (if one exists), and along body-fixed axes; and *suppressing all such point-dependence* for notational simplicity, except in eqs. (1.17.16b1–3) for obvious reasons]:

(i) $$\mathbf{I}_O = \mathbf{I}_G - m\,\mathbf{r}_G\cdot\mathbf{r}_G = \mathbf{I}_G + m\big[(\boldsymbol{r}_G\cdot\boldsymbol{r}_G)\mathbf{1} - \boldsymbol{r}_G\otimes\boldsymbol{r}_G\big]$$

[$\boldsymbol{r}_G \equiv \boldsymbol{r}_{G/O}$, etc., parallel axis theorem in terms of **I**: (1.15.7b)], (1.17.16b1)

$$\Rightarrow \mathrm{Tr}\,\mathbf{I}_O = \mathrm{Tr}\,\mathbf{I}_G + 2m\,\boldsymbol{r}_G\cdot\boldsymbol{r}_G, \tag{1.17.16b2}$$

$$\mathbf{J}_O = \mathbf{J}_G + m\,\boldsymbol{r}_G\otimes\boldsymbol{r}_G = (\mathrm{Tr}\,\mathbf{I}_G/2)\mathbf{1} - \mathbf{I}_G + m\,\boldsymbol{r}_G\otimes\boldsymbol{r}_G$$

[Parallel axis theorem in terms of **J**]; (1.17.16b3)

(ii) $$\mathrm{d}\mathbf{I}/\mathrm{dt} = \boldsymbol{\Omega}\cdot\mathbf{I} + \mathbf{I}\cdot\boldsymbol{\Omega}^{\mathrm{T}} = \boldsymbol{\Omega}\cdot\mathbf{I} - \mathbf{I}\cdot\boldsymbol{\Omega}$$

[recalling results of 1.1.20a ff.; $\boldsymbol{\omega}$ = *axial vector of tensor* $\boldsymbol{\Omega}$]; (1.17.16c)

(iii) $$\mathrm{d}\mathbf{I}/\mathrm{dt} = -(\mathrm{d}\mathbf{J}/\mathrm{dt}) \quad [= -(\boldsymbol{\Omega}\cdot\mathbf{J} - \mathbf{J}\cdot\boldsymbol{\Omega})] \tag{1.17.16d}$$

(iv) $$\boldsymbol{H} = \mathbf{I}\cdot\boldsymbol{\omega} = -\mathbf{J}\cdot\boldsymbol{\omega} + (\mathrm{Tr}\,\mathbf{J})\boldsymbol{\omega}$$

(v) $$\mathbf{H} = \mathbf{I}\cdot\boldsymbol{\Omega}^{\mathrm{T}} - \boldsymbol{\Omega}\cdot\mathbf{I} + (\mathrm{Tr}\,\mathbf{I})\cdot\boldsymbol{\Omega} = (\boldsymbol{\Omega}\cdot\mathbf{I})^{\mathrm{T}} - \boldsymbol{\Omega}\cdot\mathbf{I} + (\mathrm{Tr}\,\mathbf{I})\cdot\boldsymbol{\Omega} \tag{1.17.16e1}$$

$$= \mathbf{J}\cdot\boldsymbol{\Omega} + \boldsymbol{\Omega}\cdot\mathbf{J} = \mathbf{J}\cdot\boldsymbol{\Omega} - (\mathbf{J}\cdot\boldsymbol{\Omega})^{\mathrm{T}} = \mathbf{J}\cdot\boldsymbol{\Omega} - \boldsymbol{\Omega}^{\mathrm{T}}\cdot\mathbf{J}; \tag{1.17.16e2}$$

[$\boldsymbol{H}$ = *axial vector of* **H** (*angular momentum tensor*)]

(vi) $$\boldsymbol{M} = \mathrm{d}/\mathrm{dt}\,(\mathbf{I}\cdot\boldsymbol{\omega}) = (\mathrm{d}\mathbf{I}/\mathrm{dt})\cdot\boldsymbol{\omega} + \mathbf{I}\cdot(d\boldsymbol{\omega}/dt) \quad [\text{then invoking (1.17.16c)}]$$

$$= \mathbf{I}\cdot(d\boldsymbol{\omega}/dt) + \boldsymbol{\Omega}\cdot(\mathbf{I}\cdot\boldsymbol{\omega}) = \mathbf{I}\cdot(d\boldsymbol{\omega}/dt) + \boldsymbol{\omega}\times(\boldsymbol{I}\cdot\boldsymbol{\omega}) \tag{1.17.16f1}$$

$$= -[\mathbf{J}\cdot(d\boldsymbol{\omega}/dt) + \boldsymbol{\Omega}\cdot(\mathbf{J}\cdot\boldsymbol{\omega})] + (\mathrm{Tr}\,\mathbf{J})(\mathrm{d}\boldsymbol{\omega}/\mathrm{dt}); \tag{1.17.16f2}$$

(vii) $$\mathbf{M} = (\mathbf{E}\cdot\mathbf{I})^{\mathrm{T}} - \mathbf{E}\cdot\mathbf{I} + (\mathrm{Tr}\,\mathbf{I})\cdot(\mathrm{d}\boldsymbol{\Omega}/\mathrm{dt}) \tag{1.17.16g1}$$

$$= \mathbf{E}\cdot\mathbf{J} - (\mathbf{E}\cdot\mathbf{J})^{\mathrm{T}} \tag{1.17.16g2}$$

[$\boldsymbol{M}$ = *axial vector of* **M** (*moment*, *or torque*, *tensor*);

recalling (1.11.9a ff.): $\mathbf{E} \equiv \mathrm{d}\boldsymbol{\Omega}/\mathrm{dt} + \boldsymbol{\Omega}\cdot\boldsymbol{\Omega} \equiv \boldsymbol{\mathcal{A}} + \boldsymbol{\Omega}\cdot\boldsymbol{\Omega}$].

Additional forms of the above are, of course, possible.

A Comprehensive Example: The Rolling Disk

Let us discuss the motion of a thin homogeneous disk D (or coin, or hoop) of mass m and radius r, on a fixed, horizontal, and rough plane P (fig. 1.29).

Kinematics

Relative to the *intermediate* axes/basis $G\text{–}xyz/\boldsymbol{ijk}$ (defined so that $\boldsymbol{k}$ is perpendicular to D, at its center of mass G; $\boldsymbol{i}$ is continuously horizontal and parallel to the tangent to D, at its contact point C; and $\boldsymbol{j}$ goes through G, along the steepest diameter of D, and is such that $\boldsymbol{ijk}$ form an ortho–normal–dextral triad), whose inertial angular velocity $\boldsymbol{\Omega}$ is

$$\boldsymbol{\Omega} = \Omega_x\,\boldsymbol{i} + \Omega_y\,\boldsymbol{j} + \Omega_z\,\boldsymbol{k} = (\omega_\theta)\boldsymbol{i} + (\omega_\phi \sin\theta)\boldsymbol{j} + (\omega_\phi \cos\theta)\boldsymbol{k}, \tag{1.17.17a}$$

[where $\omega_\phi \equiv d\phi/dt$, $\omega_\theta \equiv d\theta/dt$, $\omega_\psi \equiv d\psi/dt$] the inertial angular velocity of D, $\boldsymbol{\omega}$, equals

$$\begin{aligned}\boldsymbol{\omega} = \omega_x\,\boldsymbol{i} + \omega_y\,\boldsymbol{j} + \omega_z\,\boldsymbol{k} &= (\omega_\theta)\boldsymbol{i} + (\omega_\phi \sin\theta)\boldsymbol{j} + (\omega_\phi \cos\theta + \omega_\psi)\boldsymbol{k}\\ &= \boldsymbol{\Omega} + \omega_\psi\,\boldsymbol{k}.\end{aligned} \tag{1.17.17b}$$

In view of the above, the rolling constraint $\boldsymbol{v}_C = \boldsymbol{0}$, becomes

$$\begin{aligned}\boldsymbol{v}_C &= \boldsymbol{v}_G + \boldsymbol{\omega} \times \boldsymbol{r}_{C/G} = v_x\,\boldsymbol{i} + v_y\,\boldsymbol{j} + v_z\,\boldsymbol{k} + (\omega_x, \omega_y, \omega_z) \times (0, -r, 0)\\ &= (v_x + r\omega_z)\boldsymbol{i} + (v_y)\boldsymbol{j} + (v_z - \omega_x r)\boldsymbol{k} = \boldsymbol{0},\end{aligned} \tag{1.17.17c}$$

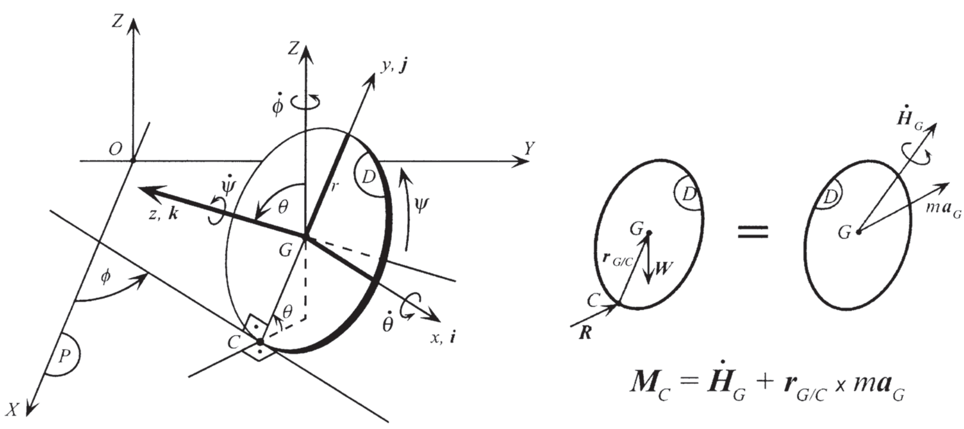

Figure 1.29 Rolling of thin disk/coin D on a fixed, rough, and horizontal plane P. *O–XYZ*: *space-fixed* (inertial) axes; *O–xyz*: *intermediate* axes (of angular velocity Ω). A, $B = A$, C: *principal* moments of inertia at G. For our disk: $A = mr^2/4$, $C = mr^2/2$.

from which it follows that

$$v_x + r\omega_z = 0 \;\Rightarrow\; v_x = -r\omega_z = -r\,(\omega_\phi \cos\theta + \omega_\psi), \tag{1.17.17d}$$

$$v_y = 0, \tag{1.17.17e}$$

$$v_z - \omega_x r = 0 \;\Rightarrow\; v_z = r\omega_x = r\omega_\theta. \tag{1.17.17f}$$

These equations connect the velocity of G with the angular velocity and the rates of the Eulerian angles.

Kinetics

To eliminate the rolling contact reaction $\boldsymbol{R}$, we apply the principle of angular momentum about C; that is, we take moments of all forces and couples [including inertial ones at G; i.e., $-m\,(d\boldsymbol{v}_G/dt)$ and $-d\boldsymbol{h}_G/dt$] about G (recalling 1.6.6a ff.) to give

$$\boldsymbol{M}_C = d\boldsymbol{h}_G/dt + \boldsymbol{r}_{G/C} \times [m(d\boldsymbol{v}_G/dt)]. \tag{1.17.18a}$$

But, with W = weight of disk, and $\sin(\ldots) \equiv s(\ldots)$, $\cos(\ldots) \equiv c(\ldots)$, we have

(i) $$\boldsymbol{M}_C = \boldsymbol{r}_{G/C} \times \boldsymbol{W} = (0, r, 0) \times (0, -Ws\theta, -Wc\theta) = (-rWc\theta)\boldsymbol{i}; \tag{1.17.18b}$$

(ii) $$\begin{aligned} d\boldsymbol{v}_G/dt &= \partial\boldsymbol{v}_G/\partial t + \boldsymbol{\Omega} \times \boldsymbol{v}_G \quad \text{[with the ad hoc notation} \quad dv_{x,y,z}/dt \equiv a_{x,y,z}] \\ &= a_x\,\boldsymbol{i} + a_y\,\boldsymbol{j} + a_z\,\boldsymbol{k} + (\Omega_x, \Omega_y, \Omega_z) \times (v_x, v_y, v_z) \\ &= (a_x + \Omega_y v_z - \Omega_z v_y)\boldsymbol{i} \\ &\qquad + (a_y + \Omega_z v_x - \Omega_x v_z)\boldsymbol{j} + (a_z + \Omega_x v_y - \Omega_y v_x)\boldsymbol{k} \\ &= (a_x + v_z\,\omega_\phi\,s\theta - v_y\,\omega_\phi\,c\theta)\boldsymbol{i} + (a_y + v_x\,\omega_\phi\,c\theta - v_z\,\omega_\theta)\boldsymbol{j} \\ &\qquad + (a_z + v_y\,\omega_\theta - v_x\,\omega_\phi\,s\theta)\boldsymbol{k}; \end{aligned} \tag{1.17.18c}$$

(iii) $$\begin{aligned} d\boldsymbol{h}_G/dt &= \partial\boldsymbol{h}_G/\partial t + \boldsymbol{\Omega} \times \boldsymbol{h}_G \quad \text{[with the ad hoc notation} \quad d\omega_{x,y,z}/dt \equiv \alpha_{x,y,z}] \\ &= \big[(A\alpha_x)\boldsymbol{i} + (A\alpha_y)\boldsymbol{j} + (C\alpha_z)\boldsymbol{k}\big] + (\Omega_x, \Omega_y, \Omega_z) \times (A\omega_x, B\omega_y, C\omega_z) \\ &= (A\alpha_x + C\Omega_y\omega_z - A\Omega_z\omega_y)\boldsymbol{i} + (A\alpha_y + A\Omega_z\omega_x - C\Omega_x\omega_z)\boldsymbol{j} \\ &\qquad + (C\alpha_z + A\Omega_x\omega_y - A\Omega_y\omega_x)\boldsymbol{k} \\ &= (A\alpha_x + C\omega_z\,\omega_\phi\,s\theta - A\omega_y\,\omega_\phi\,c\theta)\boldsymbol{i} + (A\alpha_y + A\omega_x\,\omega_\phi\,c\theta - C\omega_z\,\omega_\theta)\boldsymbol{j} \\ &\qquad + (C\alpha_z + A\omega_y\,\omega_\theta - A\omega_x\,\omega_\phi\,s\theta)\boldsymbol{k}, \end{aligned} \tag{1.17.18d}$$

and so (1.17.18a) yields the three component equations of angular motion:

$$mr(a_z + v_y\,\omega_\theta - v_x\,\omega_\phi\,s\theta) + (A\alpha_x + C\omega_z\,\omega_\phi\,s\theta - A\omega_y\,\omega_\phi\,c\theta) = -Wr\,c\theta, \tag{1.17.18e}$$

$$A\alpha_y + A\omega_x\,\omega_\phi c\theta - C\omega_z\,\omega_\theta = 0, \tag{1.17.18f}$$

$$-\,mr(a_x + v_z\,\omega_\phi\,s\theta - v_y\,\omega_\phi\,c\theta) + (C\alpha_z + A\omega_y\,\omega_\theta - A\omega_x\,\omega_\phi\,s\theta) = 0. \tag{1.17.18g}$$

The nine equations (1.17.18e, f, g) + (1.17.17d, e, f) + (1.17.17b, in components) constitute a determinate system for the nine functions (of time): ϕ, θ, ψ; $\omega_{x,y,z}$ (quasi velocities); $v_{x,y,z}$ (quasi velocities). We may reduce it further to two steps:

(i) Using (1.17.17d, e, f) in (1.17.18e, f, g) (i.e., eliminating $v_{x,y,z}$), we obtain

$$mr(r\alpha_x + r\omega_z\,\omega_\phi\,s\theta) + A\alpha_x + C\omega_z\,\omega_\phi\,s\theta - A\omega_y\,\omega_\phi\,c\theta = -Wr\,c\theta, \tag{1.17.19a}$$

$$A\alpha_y + A\omega_x\,\omega_\phi\,c\theta - C\omega_z\,\omega_\theta = 0, \tag{1.17.19b}$$

$$-mr(-r\alpha_z + r\omega_x\,\omega_\phi\,s\theta) + C\alpha_z + A\omega_y\,\omega_\theta - A\omega_x\,\omega_\phi\,s\theta = 0. \tag{1.17.19c}$$

(ii) Using (1.17.17b) in (1.17.19a, b, c) (i.e., eliminating $\omega_{x,y}$), we get three equations of *rotational motion* in terms of θ, the *rates of* ϕ, θ, and the *total spin* $\omega_z = \omega_\psi + \omega_\phi c\theta$:

$$(A + mr^2)(d^2\theta/dt^2) + (C + mr^2)\omega_z(d\phi/dt)s\theta - A(d\phi/dt)^2 c\theta s\theta = -Wr\,c\theta, \tag{1.17.20a}$$

$$A\,d/dt\,[(d\phi/dt)s\theta] + A(d\phi/dt)(d\theta/dt)c\theta - C\omega_z(d\theta/dt) = 0, \tag{1.17.20b}$$

$$(C + mr^2)(d\omega_z/dt) - mr^2(d\phi/dt)(d\theta/dt)s\theta = 0; \tag{1.17.20c}$$

or, since $A = B = mr^2/4 = (1/2)(mr^2/2) = C/2$,

$$\theta:\quad 5r(d^2\theta/dt^2) + 6r\omega_z(d\phi/dt)\sin\theta - r(d\phi/dt)^2\sin\theta\cos\theta + 4g\cos\theta = 0, \tag{1.17.21a}$$

$$\phi:\quad 2\omega_z(d\theta/dt) - 2(d\phi/dt)(d\theta/dt)\cos\theta - (d^2\phi/dt^2)\sin\theta = 0, \tag{1.17.21b}$$

$$\omega_z:\quad 3(d\omega_z/dt) - 2(d\phi/dt)(d\theta/dt)\sin\theta = 0. \tag{1.17.21c}$$

These three nonlinear coupled equations contain an enormous variety of disk motions. For simple particular solutions of them, see, for example, MacMillan (1936, pp. 276–281); also Fox (1967, pp. 263–267). Once $\phi(t)$, $\theta(t)$, $\psi(t)$ have been found, the rolling contact reaction $\boldsymbol{R} = (R_{x,y,z})$ can be easily obtained from the principle of linear momentum:

$$m\boldsymbol{a}_G = m(\partial\boldsymbol{v}_G/\partial t + \boldsymbol{\Omega}\times\boldsymbol{v}_G) = \boldsymbol{W} + \boldsymbol{R} \Rightarrow \boldsymbol{R} = \cdots = \boldsymbol{R}(t)\,. \tag{1.17.22}$$

The details are left to the reader.

1.18 THE RIGID BODY: CONTACT FORCES, FRICTION

Recommended for concurrent reading with this section are (alphabetically): Beghin (1967, pp. 139–145), Kilmister and Reeve (1966, pp. 81–84, 141–143, 164–177), Pérès (1953; pp. 62–66); also, our *Elementary Mechanics* (§20.1, 2, under production).

Introduction and Constitutive Equations

The forces between two rigid bodies, B and B_1, at a mutual contact point C (actually, a small area around C that is practically independent of the macroscopic shape of the bodies and increases with pressure), say from B to B_1, reduce, in general, to a resultant *force* $\boldsymbol{R}$ and a *couple* $\boldsymbol{C}$; frequently, $\boldsymbol{C}$ can be neglected. Decomposing $\boldsymbol{R}$

and $\boldsymbol{C}$ along the common *normal* to the bounding surfaces of B, B_1, say from B towards B_1, and along the common tangent plane, at C, we obtain

$$\begin{aligned}\boldsymbol{R} &= \boldsymbol{R}_N + \boldsymbol{R}_T \\ &= \textit{Normal reaction (opposing mutual penetration)} \\ &\quad + \textit{Tangential reaction (opposing relative slipping)}, \qquad (1.18.1)\\ \boldsymbol{C} &= \boldsymbol{C}_N + \boldsymbol{C}_T \\ &= \textit{Pivoting couple (opposing mutual pivoting)} \\ &\quad + \textit{Rolling couple (opposing relative rolling)}. \qquad (1.18.2)\end{aligned}$$

These components satisfy the following "laws" (better, *constitutive* equations) of *dry* friction; that is, for a solid rubbing against solid, without lubrication:

(i) As soon as an existing contact ceases, $\boldsymbol{R} = \boldsymbol{0}$.

(ii) Whenever there is *slipping*—that is, relative motion of B and B_1 $(\boldsymbol{v}_C \neq \boldsymbol{0})$—$\boldsymbol{R}_N$ points toward B_1; and $\boldsymbol{R}_T$ and $\boldsymbol{v}_C$ are *collinear* and in *opposite* directions:

$$\boldsymbol{R}_T \times \boldsymbol{v}_C = \boldsymbol{0}, \qquad \boldsymbol{R}_T \cdot \boldsymbol{v}_C < 0, \tag{1.18.3}$$

and

$$R_T = f(R_N, v_C), \tag{1.18.4}$$

or, approximately (for small relative velocities),

$$|R_T/R_N| = \mu: \textit{coefficient of friction between } B \textit{ and } B_1; \textit{ a nonnegative constant.} \tag{1.18.5}$$

Frequently, we use the following notation:

$$R_T \equiv F \qquad \text{and} \qquad R_N \equiv N. \tag{1.18.6}$$

Then, with $|F| = \mu|N|$, the above read

$$\boldsymbol{R} = \boldsymbol{R}_N + \boldsymbol{R}_T; \qquad \boldsymbol{R}_N = N\boldsymbol{n}, \qquad \boldsymbol{R}_T = F\boldsymbol{t} = -\mu|N|\boldsymbol{t}, \tag{1.18.7}$$

where

$$\boldsymbol{n} = \text{common unit normal vector, from } B \text{ towards } B_1, \tag{1.18.7a}$$

$$\boldsymbol{t} = \text{unit tangent vector, in direction of } \textit{slipping} \text{ velocity.} \tag{1.18.7b}$$

(iii) When $\boldsymbol{v}_C = \boldsymbol{0}$ (no slipping—relative rest), $\boldsymbol{R}_N$ points toward B_1, while $\boldsymbol{R}_T$ can have any arbitrary direction and value on the common tangent plane, as long as

$$|R_T/R_N| \equiv |F/N| \leq \mu; \qquad \text{or, vectorially,} \qquad |\boldsymbol{R} \times \boldsymbol{n}| \leq \mu|\boldsymbol{R} \cdot \boldsymbol{n}|; \tag{1.18.8}$$

with the equality sign holding for *impending* tangential motion. Actually, the μ in (1.18.8) is called coefficient of *static* friction, μ_S; and the μ in (1.18.5) is called coefficient of *kinetic* friction, μ_K; and, generally,

$$\mu_S \geq \mu_K. \tag{1.18.9}$$

Here, unless specified otherwise, μ will mean μ_K.

The friction coefficient μ is, in general, not a constant but a function of: (a) the *nature of the contacting surfaces*; (b) the *conditions of contact* (e.g., dry vs. lubricated surfaces); (c) the *normal* forces (pressure) between the surfaces; and (d) the velocity of slipping. Further, in the dry friction case (solid/solid, no lubricant), μ *increases with pressure*, and *decreases with* v_C; and this dependence is particularly pronounced for *small values of* v_C, so that, if $\mu = \mu(v_C)$, then $\mu < \mu_o$, where $\mu_o \equiv \mu(0)$. In most such applications, we assume that μ is, approximately, a *positive constant* (*rough* surface). Then the relation $\mu = \tan\phi$ defines the "angle of friction." If $\mu \approx 0$ (*smooth* surfaces), then $\boldsymbol{R} \approx \boldsymbol{R}_N \equiv \boldsymbol{N}$, $\boldsymbol{R}_T \approx \boldsymbol{0}$. If, on the other end, $\mu \to \infty$ (*perfect* roughness), then $\boldsymbol{v}_C = \boldsymbol{0}$ throughout the motion, and $\boldsymbol{R}$ can have *any* direction, as long as $\boldsymbol{R}_N \equiv \boldsymbol{N}$ points toward B_1.

(iv) The contact couple $\boldsymbol{C}$ is included in the cases of *small* μ and/or *slippingless* motion as follows:

(a) If at a given instant and immediately afterwards $\boldsymbol{\omega}_N = \boldsymbol{0}$ (i.e., no instantaneous pivoting), then

$$|C_N| \leq |C_{N,\max}|, \qquad C_{N,\max} \equiv f_p R_N = \text{limiting } \textit{pivoting} \text{ moment}, \tag{1.18.10}$$

$$f_p \equiv \textit{pivoting} \text{ friction/resistance coefficient.} \tag{1.18.10a}$$

(b) If at a given instant $\boldsymbol{\omega}_N \neq \boldsymbol{0}$, or if it stops being zero at that instant, then

$$|C_N| = |C_{N,\max}|; \tag{1.18.11}$$

and $\boldsymbol{C}_N$ and $\boldsymbol{\omega}_N$ have opposite senses.

(c) If $\boldsymbol{\omega}_T = \boldsymbol{\omega}_{\text{rolling}} \equiv \boldsymbol{\omega}_R = \boldsymbol{0}$, then

$$|C_T| \leq |C_{T,\max}|, \qquad C_{T,\max} \equiv f_r R_N = \text{limiting } \textit{rolling} \text{ moment}, \tag{1.18.12}$$

$$f_r \equiv \textit{rolling} \text{ friction/resistance coefficient.} \tag{1.18.12a}$$

(d) If at a given instant $\boldsymbol{\omega}_T \neq \boldsymbol{0}$, or if it stops being zero at that instant, then

$$|C_T| = |C_{T,\max}|; \tag{1.18.13}$$

and $\boldsymbol{C}_T$ and $\boldsymbol{\omega}_T$ have opposite senses.

The coefficients f_p and f_r have dimensions of *length* (whereas μ is dimensionless!), and their values are to be determined experimentally. Theoretically, f_p can be related to μ, if $\boldsymbol{C}_N$ is viewed as resulting from the slipping friction over a small area around the contact point C—something requiring use of the theory of elasticity (no such relationship can be established for f_r). It turns out that f_p is, generally, five to ten times smaller than f_r; in general, *pivoting is produced faster than rolling*.

In closing this very brief summary, we point out that the above "friction laws" supply only *indirect* criteria for relative rest or motion (rolling and slipping); that is, if, for example, we assume rest and the resulting equations are consistent with it, it means that rest is possible, not that it will happen. And if we end up with an inconsistency, it means that the particular assumption(s) that led to it is (are) false. Thus, to show that two contacting bodies roll (slip) on each other, all we can do is show that the assumptions of their slipping (rolling) lead to a contradiction. [For detailed examples illustrating these points, see, for example (alphabetically): Hamel (1949, pp. 543–549, 629–639), Kilmister and Reeve (1966, pp. 165–177); also Pöschl (1927, pp. 484–497).]

Work of Contact Forces

Under a *kinematically possible* infinitesimal displacement of B_1 relative to B (assumed fixed) that preserves their mutual contact at C, the total elementary (first-order) work of the contact actions (of B on B_1) is:

$$d'W = \boldsymbol{R} \cdot d\boldsymbol{r}_C + \boldsymbol{C} \cdot d\boldsymbol{\theta} \tag{1.8.14}$$

where

$d\boldsymbol{r}_C =$ elementary *translatory* displacement of the B_1-fixed point, at contact, relative to B

$$(\equiv \boldsymbol{v}_C\, dt, \text{ in an } actual \text{ such displacement}), \tag{1.18.14a}$$

$d\boldsymbol{\theta} =$ elementary *rotatory* displacement of B_1 relative to B

$$(\equiv \boldsymbol{\omega}\, dt, \text{ in an } actual \text{ such displacement}), \tag{1.18.14b}$$

• Since $d\boldsymbol{r}_C$ preserves the B/B_1 contact, it lies on their *common tangent plane* at C. Then: (α) if $\boldsymbol{R}_T \approx \boldsymbol{0}$ (i.e., negligible slipping friction), or (β) if $d\boldsymbol{r}_C = \boldsymbol{0}$ (i.e., no slipping) and $d\boldsymbol{\theta} = \boldsymbol{0}$ (i.e., no rotating), then:

$$d'W = 0. \tag{1.18.15}$$

• If $d\boldsymbol{r}_C$ violates contact, but remains compatible with the unilateral constraints, it makes an *acute* angle with the normal toward B_1. In this case, if $\boldsymbol{R}_T \approx \boldsymbol{0} \;\Rightarrow\; \boldsymbol{R} \approx \boldsymbol{R}_N$, and therefore

$$d'W > 0; \tag{1.18.16}$$

while for elementary displacements *incompatible* with the constraints,

$$d'W < 0. \tag{1.18.17}$$

• In a real, or actual, displacement $d'W$ becomes

$$d'W = (\boldsymbol{R} \cdot \boldsymbol{v}_C + \boldsymbol{C} \cdot \boldsymbol{\omega})\, dt.$$

From the earlier constitutive laws, we see that, as long as $\boldsymbol{v}_C$, $\boldsymbol{\omega}_N$, $\boldsymbol{\omega}_T$ *do not vanish*, the pairs

$$(\boldsymbol{R}_T, \boldsymbol{v}_C), \qquad (\boldsymbol{C}_N, \boldsymbol{\omega}_N), \qquad (\boldsymbol{C}_T, \boldsymbol{\omega}_T),$$

are *collinear* and *oppositely directed*. Hence, *frictions do negative work*; that is, in general,

$$d'W \leq 0. \tag{1.18.18}$$

If, as commonly assumed, $\boldsymbol{C} \approx \boldsymbol{0}$, then

$$\begin{aligned} d'W &= (\boldsymbol{R}_T \cdot \boldsymbol{v}_C)\, dt \equiv (\boldsymbol{F} \cdot \boldsymbol{v}_C)\, dt \\ &= 0; \quad \text{if } \boldsymbol{F} = \boldsymbol{0} \qquad \text{(frictionless, or } \textit{smooth}\text{, contact)} \\ &= 0; \quad \text{if } \boldsymbol{v}_C = \boldsymbol{0} \qquad \text{(slippingless, or } \textit{rough}\text{, contact).} \end{aligned} \tag{1.18.19}$$

It should be stressed that, in all these considerations, the relevant *velocities* are those of *material particles*, and not those of geometrical points of application of the loads.

2

Kinematics of Constrained Systems

(i.e., Lagrangean Kinematics)

I cannot too strongly urge that a kinematical result is a result valid forever, no matter how time and fashion may change the ''laws'' of physics.

(Truesdell, 1954, p. 2)

It is my belief that students have difficulty with mechanics because of an inadequate knowledge of kinematics.

(Fox, 1967, p. xi)

2.1 INTRODUCTION

As complementary reading for this chapter, we recommend the following (alphabetically):

General: Hamel (1904(a), (b)), Heun (1906, 1914), Lur'e (1968), Neimark and Fufaev (1972), Novoselov (1979), Papastavridis (1999), Prange (1935).

Special problems, extensions: Carvallo (1900, 1901), Lobas (1986), Lur'e (1968), Stückler (1955), Synge (1960).

Research journals (see the references at the end of this book): *Acta Mechanica Sinica* (Chinese), *Applied Mathematics and Mechanics* (Chinese), *Archive of Applied Mechanics* (former *Ingenieur Archiv*; German), *Journal of Applied Mechanics* (ASME; American), *Applied Mechanics* (Soviet → Ukrainian), *Journal of Guidance, Control, and Dynamics* (AIAA; American), *PMM* (Soviet → Russian), *ZAMM* (German), *ZAMP* (Swiss); also the various journals on kinematics, mechanisms, machine theory, design, robotics, etc.

In this chapter we begin the study of analytical mechanics proper with a detailed treatment of Lagrangean kinematics, i.e., the theory of *position* and linear *velocity* constraints (or Pfaffian constraints) in mechanical systems with a finite number of *degrees of freedom*; that is, a finite number of movable parts; as opposed to continuous systems that have a *countably infinite* set of such freedoms. All relevant fundamental concepts, definitions, equations — such as velocity, acceleration, constraint, *holonomicity* versus *nonholonomicity,* constraint stationarity (or *scleronomicity*) versus nonstationarity (or *rheonomicity*) — are detailed in both particle and system variables, along with elaborate discussions of *quasi coordinates* and the associated *transitivity equations* and *Hamel coefficients*; as well as a direct and readable (and very rare) treatment of *Frobenius*' fundamental necessary and sufficient conditions for the holonomicity, or lack thereof, of a system of Pfaffian constraints.

The examples and problems, some at the ends of the paragraphs and some (the more comprehensive ones) at the end of the chapter, are an indispensable part of the material; several secondary theoretical points and results are presented there.

This chapter, and the next one on Kinetics, constitute the fundamental essence and core of Lagrangean analytical mechanics.

2.2 INTRODUCTION TO CONSTRAINTS AND THEIR CLASSIFICATIONS

Positions, Configurations, Motions

Let us consider a general finite mechanical system S consisting of N (= positive integer), *free*, or *unconstrained*, material particles. The *position* $\boldsymbol{r}$ of a generic S-particle, P, at the generic time instant, t, relative to an "origin" fixed in a, say inertial, frame of reference, F, is defined by the vector function

$$\boldsymbol{r} = \boldsymbol{f}(P, t) \equiv \boldsymbol{r}(P, t). \tag{2.2.1}$$

The collection of all these particle vectors, at a *current* instant t, make up a current *system position*, or current *configuration* of $S, C(t)$, and its evolution in time constitutes a *motion* of S. The latter, clearly, depends on the frame of reference. Thus, the complete description of a motion of S, if the latter is modeled as a collection of N particles, requires (at most) knowledge of $3N$ functions of time; for example, the $3N$ rectangular Cartesian components = coordinates of the N $\boldsymbol{r}$'s:

$$(x_1, y_1, z_1; \ldots; x_N, y_N, z_N) \equiv (x, y, z) \equiv (\xi_1, \ldots, \xi_{3N}) \equiv \boldsymbol{\xi}. \tag{2.2.1a}$$

These numbers can be viewed as the rectangular Cartesian coordinates of the $3N$-dimensional position vector of a *single* fictitious, or *figurative*, particle representing S, in a $3N$-dimensional Euclidean space, E_{3N}, henceforth called the system's *unconstrained configuration space*; and, therefore, a motion of S can be visualized as the path traced by the tip of that *system position vector* in E_{3N}. Equation (2.2.1) can be replaced by

$$\boldsymbol{r} = \boldsymbol{f}(\boldsymbol{r}_o, t; t_o) \equiv \boldsymbol{r}(\boldsymbol{r}_o, t; t_o), \tag{2.2.2}$$

where (fig. 2.1): $\boldsymbol{r}_o$ = "reference position" of P at the "reference time" $t = t_o$, is used to distinguish, or label, the various S-particles; and the totality of $\boldsymbol{r}_o$'s constitutes the *reference* configuration of S at t_o, $C(t_o)$. For a fixed $\boldsymbol{r}_o$ and variable t (i.e., a motion

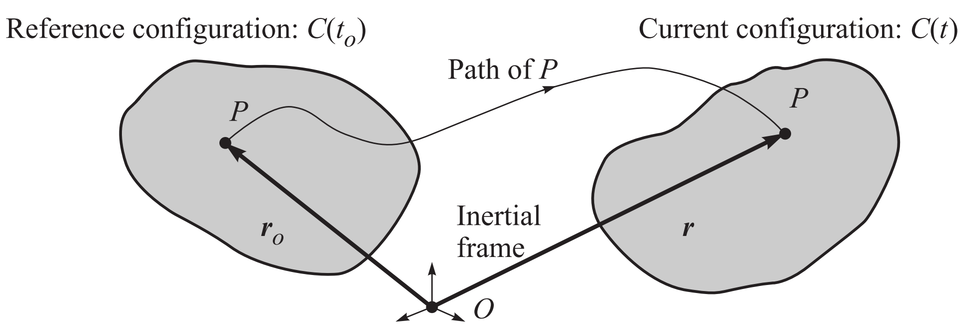

Figure 2.1 Position vectors, configurations, and paths of system particles.

of P), eqs. (2.2.1, 2) give the *path* of a particle P that was initially at $\boldsymbol{r}_o$. (The same equations for fixed t and variable $\boldsymbol{r}_o$ would give us the *transformation* of the spatial region initially occupied by the system, to its current position at time t.)

The one-to-one correspondence between $\boldsymbol{r}$ (and t) and $\boldsymbol{r}_o$ (and t_o), of the same particle P—that is, the physical fact that "initially distinct particles must remain distinct throughout the motion"—requires that (2.2.2) has an *inverse*:

$$\boldsymbol{r}_o = \boldsymbol{f}^{-1}(\boldsymbol{r}, t; t_o) \equiv \boldsymbol{g}(\boldsymbol{r}, t_o; t): \text{ reference configuration at (variable) time } t_o. \tag{2.2.2a}$$

Switching the roles of $(\boldsymbol{r}, t)$ and $(\boldsymbol{r}_o, t_o)$, we can view (2.2.2a) as expressing the "current" position $\boldsymbol{r}_o$ in terms of the "reference" position and time $(\boldsymbol{r}, t)$ and "current" time t_o. From now on, for simplicity, we shall drop, in the above, the explicit $(\boldsymbol{r}_o, t_o)$ and/or P-dependence [also, replace the rigorous notation $\boldsymbol{f}(\ldots)$ with $\boldsymbol{r}(\ldots)$, as done frequently in engineering mathematics, except whenever extra clarity is needed], and write (2.2.1) simply as

$$\boldsymbol{r} = \boldsymbol{r}(t). \tag{2.2.3}$$

REMARKS

(i) For (2.2.2) and (2.2.2a) to be mutually consistent, we must have

$$\begin{aligned}
&(2.2.2) \text{ for } t = t_o \Rightarrow (2.2.2\text{a}): \quad \boldsymbol{r} = \boldsymbol{f}(\boldsymbol{r}_o, t; t_o) \Rightarrow \boldsymbol{r}_o = \boldsymbol{f}(\boldsymbol{r}_o, t_o; t_o) = \boldsymbol{f}^{-1}(\boldsymbol{r}, t; t_o);\\
&(2.2.2\text{a}) \text{ for } t_o = t \Rightarrow (2.2.2): \quad \boldsymbol{r}_o = \boldsymbol{f}^{-1}(\boldsymbol{r}, t; t_o) \Rightarrow \boldsymbol{r} = \boldsymbol{f}^{-1}(\boldsymbol{r}, t; t) = \boldsymbol{f}(\boldsymbol{r}_o, t; t_o);
\end{aligned} \tag{2.2.2b}$$

hence, also

$$\boldsymbol{r} = \boldsymbol{f}\big[\boldsymbol{f}(\boldsymbol{r}_o, t_1; t_o), t; t_1\big] = \boldsymbol{f}(\boldsymbol{r}_o, t; t_o), \tag{2.2.2c}$$

where t_1 is another reference time.

(ii) In continuum mechanics, $(\boldsymbol{r}_o, t)$ and $(\boldsymbol{r}, t)$ are called, respectively, *material* (or *Lagrangean*) and *spatial* (or *Eulerian*) variables; with the former preferred in *solid* mechanics (e.g., nonlinear elasticity), and the latter dominating *fluid* mechanics (e.g., hydrodynamics). (See, e.g., Truesdell and Toupin, 1960, and Truesdell and Noll, 1965.)

(iii) For systems with a finite number of particles, the dependence on the latter is, frequently, expressed by the discrete subscript notation (i.e., $\boldsymbol{r}_o \to$ positive integer denoting the "name" of the particle):

$$\boldsymbol{r}_P = \boldsymbol{r}_P(t) = \{x_P(t), y_P(t), z_P(t)\} \qquad (P = 1, \ldots, N). \tag{2.2.4}$$

The simpler continuum mechanics notation, eqs. (2.2.1, 3), dispenses with all unnecessary *particle* indices, and allows one to concentrate on the *system indices* (as we begin to show later), which is the essence of the method of analytical mechanics. It also allows for a more general exposition; for example, a unified treatment of systems containing both rigid (discrete) and flexible (continuous) parts.

Constraints

If the N vectors $\boldsymbol{r}$, and/or corresponding (inertial) velocities $\boldsymbol{v} \equiv d\boldsymbol{r}/dt$, are *functionally unrelated* and *uninfluenced* from each other (*internally*) or from their environment (*externally*), apart from continuity and consistency requirements, like (2.2.2b,c)—

something we will normally assume — that is, if, and prior to any *kinetic considerations*, the $\boldsymbol{r}$'s and $\boldsymbol{v}$'s are free to vary *arbitrarily and independently* from each other, then S is called (internally and/or externally) *free or unconstrained*; if not, S is called (internally and/or externally) *constrained*. In the latter case, certain configurations and/or (velocities $\Rightarrow$) motions are unattainable, or inadmissible; or, alternatively, if we know the positions and velocities of some of the particles of the system, we can deduce those of the rest, without recourse to kinetics. [Outside of areas like astronomy/celestial mechanics, ballistics, etc., almost all other Earthly systems of relevance, and a lot of non-Earthly ones, are constrained — hence, the importance of analytical mechanics, especially to engineers.]

Such restrictions, or *constraints*, on the positions and/or velocities of S are expressed analytically by one or more ($< 3N$) scalar functional relations of the form

$$f(t, \boldsymbol{r}_1, \ldots, \boldsymbol{r}_N; \boldsymbol{v}_1, \ldots, \boldsymbol{v}_N) = 0, \qquad \text{or, compactly,} \qquad f(t, \boldsymbol{r}, \boldsymbol{v}) = 0. \tag{2.2.5}$$

These equalities are assumed to be: (i) *continuous* and as many times *differentiable in their arguments* as needed (usually, continuity of the zeroth, first-, and second-order partial derivatives will suffice), in some region of the $(x, y, z; dx/dt, dy/dt, dz/dt; t)$; (ii) *mutually consistent* (i.e., kinematically possible, or admissible); (iii) *independent* [i.e., not connected by additional functional relations like $F(f_1, f_2, \ldots) = 0$]; and (iv) *valid for any forces acting on S, any motions of it, and any temporal boundary/initial conditions on these motions* (see also *semiholonomic* systems below).

Following ordinary differential equation terminology, we call (2.2.5) a first-order (nonlinear) constraint, or nonlinear velocity constraint. With few exceptions [as in chaps. 5 and 6, where generally nonlinear constraints of the form $f(\boldsymbol{r}, \boldsymbol{v}, \boldsymbol{a}, t) = 0$ ($\boldsymbol{a}$: accelerations) are discussed], the *velocity constraint* (2.2.5) is the most general constraint examined here.

[Other, perhaps more suggestive terms, for constraints are *conditions* (Victorian English: *equations of condition*; German: *bedingungen*), and *connections* or *couplings* (French: *liaisons*; German: *bindungen*; Greek: *σύνδεσμοι*; Russian: *svyaz'*).]

Special Cases of Equation (2.2.5)

(i) Constraints like

$$\phi(t, \boldsymbol{r}) = 0, \qquad \text{or [recalling (2.2.1a)],} \qquad \phi(t, \xi) = 0, \tag{2.2.6}$$

are called *finite*, or *geometrical* , or *positional*, or *configurational*, or *holonomic*. [From the Greek: *hólos* = complete, whole, integral; that is, finite, nondifferential; and *nómos* = law, rule, (here) condition, constraint. After Hertz (early 1890s); also C. Neumann (mid-1880s).]

(ii) Again, with the exception of chapters 5, 6, and 7, all velocity constraints treated here have the practically important *linear velocity*, or *Pfaffian*, form

$$f \equiv \mathcal{S}(\boldsymbol{B} \cdot \boldsymbol{v}) + B = 0, \tag{2.2.7}$$

where $\boldsymbol{B} = \boldsymbol{B}(t, \boldsymbol{r})$, $B = B(t, \boldsymbol{r})$ are known functions of the $\boldsymbol{r}$'s and t, and *Lagrange's symbol* $\mathcal{S}(\ldots)$ signifies summation over all the material particles of S, at a given instant, like a Stieltjes' integral (so it can handle uniformly both continuous and discrete situations). Those uncomfortable with it may replace it with the more familiar Leibnizian $\int(\ldots)$.

Multiplying (2.2.7) by dt, which does not interact with $\mathcal{S}(\ldots)$, we obtain the *kinematically possible,* or *kinematically admissible*, form of the Pfaffian constraint,

$$f\,dt \equiv \mathcal{S}(\boldsymbol{B}\cdot d\boldsymbol{r}) + B\,dt = 0. \tag{2.2.7a}$$

Degrees of Freedom

A system of N particles subject to h (independent) positional constraints:

$$\phi_H(t, \boldsymbol{r}) = 0 \qquad (H = 1, \ldots, h), \tag{2.2.8}$$

and m (independent) Pfaffian constraints:

$$f_D \equiv \mathcal{S}(\boldsymbol{B}_D\cdot\boldsymbol{v}) + B_D = 0 \qquad (D = 1, \ldots, m), \tag{2.2.9}$$

that is, a total of $h + m$ constraints, is said to have a total of $3N - (h + m)(>0)$ *degrees of freedom* (*DOF*). This is a fundamental concept whose significance to both kinematics and kinetics (of constrained systems) will emerge gradually in what follows.

[Quick preview: DOF = Number of independent components of system vector of virtual displacement (§ 2.3–7)
= Number of kinetic (i.e., reactionless) equations of motion of system (chap. 3).]

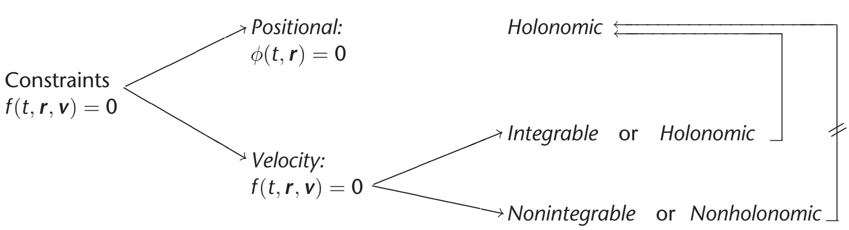
Holonomicity versus Nonholonomicity

A positional constraint like (2.2.6), since it holds identically during all system motions, can *always* be brought to the velocity form (2.2.7) by $d(\ldots)/dt$-differentiation:

$$d\phi/dt = \mathcal{S}(\partial\phi/\partial\boldsymbol{r})\cdot\boldsymbol{v} + \partial\phi/\partial t = 0; \tag{2.2.10}$$

that is, $\boldsymbol{B} \to \partial\phi/\partial\boldsymbol{r} \equiv \textbf{\textit{grad}}\,\phi$ (normal to the E_{3N}-surface $\phi = 0$) and $B \to \partial\phi/\partial t$. However, the converse is *not* always true: the velocity constraint (2.2.7) may or may not be (able to be) brought to the positional form (2.2.6); that is, by integration and with no additional knowledge of the motion of the system; namely, without recourse to kinetics. If (2.2.7) *can* be brought to the form (2.2.6), then it is called *completely integrable*, or *holonomic* (H); if it *cannot*, it is called nonintegrable, or *nonholonomic* (NH); or, sometimes, anholonomic. This holonomic/nonholonomic distinction of velocity constraints is fundamental to analytical mechanics; it is by far the most important of all other constraint classifications. [The term anholonomic, more consistent than the term nonholonomic seems to be due to Schouten (1954).]

Schematically, we have



Hence, a H velocity constraint, like (2.2.10), is actually a positional constraint disguised in kinematical form. Before embarking into a detailed study of H/NH constraints, we will mention some additional, secondary but useful, constraint classifications.

Scleronomicity versus Rheonomicity

Velocity constraints of the form

$$f(\boldsymbol{r}, \boldsymbol{v}) = 0 \;\Rightarrow\; \partial f/\partial t = 0 \tag{2.2.7b}$$

are called *stationary*; otherwise (i.e., if $\partial f/\partial t \neq 0$), they are called *nonstationary*. If *all* the constraints of a system are stationary, the system is called *scleronomic*; if not, the system is called *rheonomic*. [From the Greek: *sclerós* = hard, rigid, invariable; *rhéo* = to flow; and the earlier *nómos* = law, rule, decree, (here) condition; that is, *scleronomic* = invariable constraint, *rheonomic* = variable/fluid constraint. After Boltzmann (1897–1904).] For positional constraints and Pfaffian constraints, stationarity means, respectively,

$$\phi(\boldsymbol{r}) = 0 \qquad \text{and} \qquad \mathcal{S}\, \boldsymbol{B}(\boldsymbol{r}) \cdot \boldsymbol{v} = 0. \tag{2.2.11}$$

Catastaticity versus Acatastaticity

Pfaffian constraints of the form

$$\mathcal{S}\, \boldsymbol{B}(t, \boldsymbol{r}) \cdot \boldsymbol{v} + B(t, \boldsymbol{r}) = 0, \tag{2.2.11a}$$

are called *acatastatic*; while those of the form

$$\mathcal{S}\, \boldsymbol{B}(t, \boldsymbol{r}) \cdot \boldsymbol{v} = 0 \qquad [\text{i.e., } B(t, \boldsymbol{r}) = 0] \tag{2.2.11b}$$

are called *catastatic*. It is this classification [due to Pars (1965, pp. 16, 24) and, obviously, having meaning only for Pfaffian constraints], and not the earlier one of scleronomicity versus rheonomicity, that is important in the kinetics of systems under such constraints.

REMARKS

(i) The reason for calling the second of (2.2.11) scleronomic, instead of

$$\mathcal{S}\, \boldsymbol{B}(\boldsymbol{r}) \cdot \boldsymbol{v} + B(\boldsymbol{r}) = 0, \tag{2.2.11c}$$

that is, for requiring that scleronomic constraints linear in the velocities be also *homogeneous* in them (i.e., have $B = 0 \Rightarrow$ catastaticity), is so that it matches the kinematic *form* generated by $d/dt(\ldots)$-differentiating the scleronomic positional constraint (first of 2.2.11):

$$\phi(\boldsymbol{r}) = 0 \;\Rightarrow\; d\phi/dt = \mathcal{S}\, (\partial\phi/\partial\boldsymbol{r}) \cdot \boldsymbol{v} = 0. \tag{2.2.11d}$$

Geometrical interpretation of this requirement: Otherwise, the corresponding constraint surface, in "velocity space," would be a plane with distance from the origin proportional to B. That term, representing the (negative of the) velocity of the constraint plane normal to itself, is clearly a rheonomic effect. (Remark due to Prof. D. T. Greenwood, private communication.)

(ii) Clearly, every scleronomic Pfaffian constraint is catastatic ($B = 0$); but catastatic Pfaffian constraints may be scleronomic [$\boldsymbol{B} = \boldsymbol{B}(\boldsymbol{r})$, second of (2.2.11)] or rheonomic [$\boldsymbol{B} = \boldsymbol{B}(t, \boldsymbol{r})$, (2.2.11b)].

Bilateral versus Unilateral Constraints

Equality constraints of the form (2.2.5) are called *bilateral*, or *two-sided*, or *equality*, or *reversible*, or *unchecked* (after Langhaar, 1962, p. 16); while constraints of the form

$$f(t, \boldsymbol{r}, \boldsymbol{v}) \geq 0 \qquad \text{or} \qquad f(t, \boldsymbol{r}, \boldsymbol{v}) \leq 0 \tag{2.2.11e}$$

are called *unilateral*, or *one-sided*, or *inequality*, or *irreversible*. Physically, bilateral constraints occur when the bodies in contact *cannot* separate from each other: for example, a rigid sphere moving between two parallel fixed planes, in continuous contact with both. In the unilateral case, the bodies in contact *can* separate: for example, a sphere in contact with only one plane, or a system of two particles connected by an inextensible string—their distance cannot exceed the string's length. Following Gantmacher (1970, p. 12), we can state that the general motion of a unilaterally constrained motion may be divided into segments, such that: (i) in certain segments the constraint is "taut" [(2.2.11e) with the $=$ sign; e.g., particle on a light, inextensible, and taut string], and motion occurs as if the constraint were *bilateral*; and (ii) in other segments, the constraint is not taut, it is "loose," and motion occurs as if the constraint were *absent*. Concisely, a *unilateral constraint* is either *replaced by a bilateral one,* or is *eliminated altogether*. Hence, in what follows, we shall limit ourselves to bilateral constraints.

REMARKS

(i) A small number of authors call all constraints of the form (2.2.6) holonomic, as well as those reducible to that form; and call all others nonholonomic. According to such a definition, bilateral constraints like (2.2.11e) would be nonholonomic! The reader should be aware of such historically unorthodox practices.

(ii) The equations $\phi(\boldsymbol{r}, t) = 0$ and $d\phi/dt \equiv \mathcal{S}\,(\partial\phi/\partial\boldsymbol{r}) \cdot \boldsymbol{v} + \partial\phi/\partial t = 0$ restrict a system's positions and velocities; equation $d\phi/dt = 0$ is the compatibility of velocities with $\phi = 0$. Similarly, the equation

$$d^2\phi/dt^2 = \mathcal{S}\left[d/dt(\partial\phi/\partial\boldsymbol{r}) \cdot \boldsymbol{v} + (\partial\phi/\partial\boldsymbol{r}) \cdot \boldsymbol{a}\right] + d/dt(\partial\phi/\partial t) = 0$$

is the compatibility of *accelerations* with $\phi = 0$, $d\phi/dt = 0$; and likewise for higher such derivatives.

(iii) In the case of *unilateral* constraints, if at a certain time t: $f > 0$, then, as explained earlier, that constraint plays no role in the system's motion. But if $f = 0$, then, as a Taylor expansion around t shows, motion that satisfies either of these two relations may occur; in the former case $df/dt = 0$, and in the latter $df/dt \geq 0$. Thus, the simultaneous conditions $f = 0$ and $df/dt < 0$ allow us to detect a *possible incompatibility* between velocities and $f \geq 0$. Usually, such conditions occur in impact problems (chap. 4; also Kilmister and Reeve, 1966, pp. 67–68).

(iv) *Geometrical/physical remarks:* In a system S consisting of several rigid bodies, and its *environment* (i.e., other bodies/foreign obstacles, massless coupling elements:

e.g., springs, cables) the following conditions apply:

(a) Every condition expressing the direct *contact* of two rigid bodies of S, or the contact of one of its bodies with a foreign obstacle (environment) that is either *fixed* or has *known motion* (i.e., its position coordinates are known functions of time only), results in a holonomic equation of the form (2.2.6); and the corresponding contact forces are the reactions of that constraint.

(b) If, further, at those contact points, *friction is high enough* to guarantee us (in advance of kinetic considerations) *slippinglessness*, then the positions and velocities there satisfy (2.2.7)-like Pfaffian equations (usually, but not always, nonholonomic). These conditions express the vanishing of a component of (relative) slipping velocity in a certain direction; and, therefore, there are as many as the number of independent such nonslipping directions.

(c) If, in addition, friction there is *very high*, so that not only slipping but also *pivoting* vanishes, then we have additional (usually nonholonomic) (2.2.7)-like equations; that is, linear velocity constraints arise quite naturally and frequently in daily life. [Nonslipping and nonpivoting are maintained by constraint forces (and couples), just like contact. All these constraint forces are examples of *passive* reactions; for more general, *active*, constraint reactions, see, for example, § 3.17.]

(v) Holonomic and/or nonholonomic constraints due exclusively to the mutual interaction of the system bodies are called *internal* (or *mutual*); while those arising, even partially, from the interaction of the system with its environment are called *external*. The associated constraint reactions are called, respectively, *internal* (or *mutual*) and *external*.

(vi) Finally, we repeat that such holonomic and/or nonholonomic constraints express restrictions among positions and velocities *independently* of the equations of motion and associated (temporal) initial/boundary conditions, and *before* the complete solution of the problem is carried out. Solving the problem means finding $\boldsymbol{r} = \boldsymbol{r}(t)$: known function of time; then $\boldsymbol{v} = d\boldsymbol{r}/dt = \boldsymbol{v}(t)$: known function of time; and these $\boldsymbol{r}$'s and $\boldsymbol{v}$'s automatically satisfy the constraints. Under such a viewpoint, integrals of the system, like those of linear/angular momentum and energy, assuming they exist, *do not qualify* as constraint equations.

The (bilateral) constraints, discussed above, are summarized as follows:

General first-order constraints

$f(\boldsymbol{r}) = 0$:	Holonomic (integrable) and scleronomic (stationary)
$f(t, \boldsymbol{r}) = 0$:	Holonomic (integrable) and rheonomic (nonstationary)
$f(\boldsymbol{r}, \boldsymbol{v}) = 0$:	Nonholonomic (if nonintegrable) and scleronomic (stationary)
$f(t, \boldsymbol{r}, \boldsymbol{v}) = 0$:	Nonholonomic (if nonintegrable) and rheonomic (nonstationary)

Pfaffian velocity constraints

$\mathsf{S}\, \boldsymbol{B}(t, \boldsymbol{r}) \cdot \boldsymbol{v} + B(t, \boldsymbol{r}) = 0$:	Rheonomic and acatastatic
$\mathsf{S}\, \boldsymbol{B}(\boldsymbol{r}) \cdot \boldsymbol{v} + B(\boldsymbol{r}) = 0$:	Rheonomic and acatastatic
$\mathsf{S}\, \boldsymbol{B}(t, \boldsymbol{r}) \cdot \boldsymbol{v} = 0$:	Rheonomic and catastatic
$\mathsf{S}\, \boldsymbol{B}(\boldsymbol{r}) \cdot \boldsymbol{v} = 0$:	Scleronomic and catastatic

(There is no such thing as scleronomic and acatastatic Pfaffian constraint.)

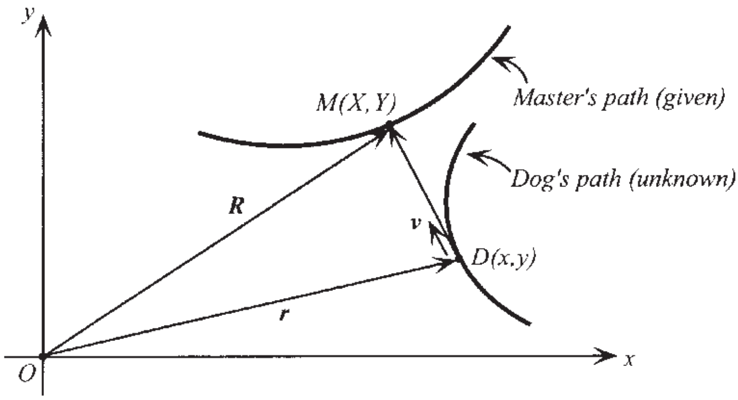


Figure 2.2 Plane pursuit problem: a dog (D) moving continuously toward its master (M).

Example 2.2.1 *Plane Pursuit Problem — Catastatic but Rheonomic* (*or Nonstationary*) *Pfaffian constraint*. The master (M) of a dog (D) walks along a *given* plane curve: $\boldsymbol{R} = \boldsymbol{R}(t) = \{X = X(t), Y = Y(t)\}$. Let us find the differential equation of the path of D: $\boldsymbol{r} = \boldsymbol{r}(t) = \{x = x(t), y = y(t)\}$, if D moves, with instantaneous velocity $\boldsymbol{v}$, to meet M, so that at every instant its velocity is directed toward M (fig. 2.2).

We must have:

$$\boldsymbol{v} = \text{parallel to } \boldsymbol{R} - \boldsymbol{r} = v\big[(\boldsymbol{R} - \boldsymbol{r})/|\boldsymbol{R} - \boldsymbol{r}|\big] \equiv v\boldsymbol{e},$$

or, in components,

$$dx/dt = v\big[(X - x)/|\boldsymbol{R} - \boldsymbol{r}|\big], \qquad dy/dt = v\big[(Y - y)/|\boldsymbol{R} - \boldsymbol{r}|\big]; \tag{a}$$

or, eliminating v between them,

$$[Y(t) - y](dx/dt) - [X(t) - x](dy/dt) = 0. \tag{b}$$

It is not hard to show that this pursuit problem in *space* leads to the following constraints (with some obvious notation):

$$[Y(t) - y](dx/dt) - [X(t) - x](dy/dt) = 0, \tag{c}$$

$$[Z(t) - z](dx/dt) - [X(t) - x](dz/dt) = 0, \tag{d}$$

$$[Z(t) - z](dy/dt) - [Y(t) - y](dz/dt) = 0. \tag{e}$$

See also Hamel (1949, pp. 770–773).

Example 2.2.2 *Acatastatic Constraints*. Let us consider the rolling of a sphere S of radius r and center G on the rough inner surface of a vertical circular cylinder A of radius $R(> r)$. Let us introduce the following convenient *intermediate* axes/basis G–123/G–$\boldsymbol{ijk}$ (fig. 2.3): Let ϕ be the *azimuth*, or *precession*-like, angle of the plane G–13, and z = vertical coordinate of G (positive upward from some fixed

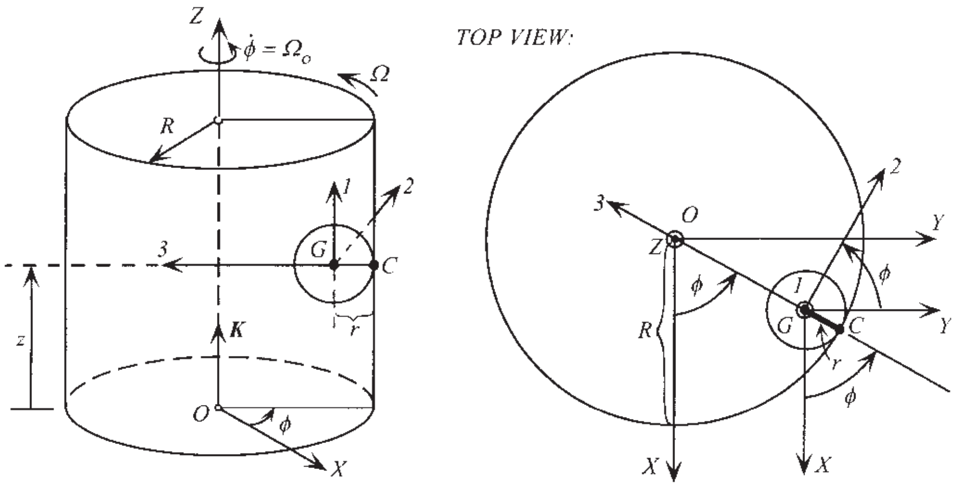

Figure 2.3 Rolling of a sphere on a vertical circular cylinder. *G1*: vertically upward; *G3*: horizontally intersects the (vertical) cylinder axis; *G2*: horizontal, so that *G–123* is orthogonal–normalized–dextral (OND).

plane, perpendicular to the cylinder axis). Then,

$$\boldsymbol{v}_G = \text{inertial velocity of } G = (v_1 = dz/dt, v_2 = (R - r)(d\phi/dt) \equiv (R - r)\omega_\phi, v_3 = 0); \tag{a}$$

or, alternatively, if $\boldsymbol{OG} = z\boldsymbol{K} + (R - r)(-\boldsymbol{k})$, then (with $d\phi/dt \equiv \omega_\phi$)

$$\boldsymbol{v}_G = d(\boldsymbol{OG})/dt = (dz/dt)\boldsymbol{K} + (R - r)(-d\boldsymbol{k}/dt) = (dz/dt)\boldsymbol{i} + (R - r)(\omega_\phi\, \boldsymbol{j}). \tag{b}$$

If $\boldsymbol{\omega}$ = inertial angular velocity of sphere = $(\omega_1, \omega_2, \omega_3)$, then the inertial velocity of the contact point C, $\boldsymbol{v}_C$, is

$$\begin{aligned}\boldsymbol{v}_C = \boldsymbol{v}_G + \boldsymbol{\omega} \times \boldsymbol{r}_{C/G} &= (v_1, v_2, v_3) + (\omega_1, \omega_2, \omega_3) \times (0, 0, -r)\\ &= (v_1 - \omega_2 r, \quad v_2 + \omega_1 r, \quad v_3).\end{aligned} \tag{c}$$

Therefore: (i) If the cylinder is *stationary* (i.e., fixed), the rolling constraint is $\boldsymbol{v}_C = \boldsymbol{0}$, or, in components,

$$v_1 - \omega_2 r = 0 \;\Rightarrow\; \omega_2 = (dz/dt)\big/r, \quad v_2 + \omega_1 r = 0 \;\Rightarrow\; \omega_1 = [1 - (R/r)]\omega_\phi, \quad v_3 = 0. \tag{d}$$

(ii) If the cylinder is made to rotate about its axis with an (inertial) angular velocity $\boldsymbol{\Omega} = \boldsymbol{\Omega}(t)$ = *given function of time*, the rolling constraint is

$$\boldsymbol{v}_C = \boldsymbol{\Omega} \times \boldsymbol{r}_{C/O} = (\Omega\boldsymbol{K}) \times (-R\boldsymbol{k}) = (\Omega\boldsymbol{i}) \times (-R\boldsymbol{k}) = (\Omega R)\boldsymbol{j} \equiv (0, \Omega R, 0),$$

or, in components [invoking (c)],

$$\begin{aligned}&v_1 - \omega_2 r = 0 \;\Rightarrow\; \omega_2 = (dz/dt)\big/r \equiv v_z/r,\\ &v_2 + \omega_1 r = \Omega(t)R \;\Rightarrow\; \omega_1 = \omega_\phi + (R/r)\omega_r, \qquad v_3 = 0,\end{aligned} \tag{e}$$

where $\omega_r \equiv \Omega - \omega_\phi$ = relative angular velocity of cylinder about meridian plane G–13. The first of the constraints (e) is nonstationary and acatastatic, even if $\Omega = constant$. [As explained in §2.5 ff., the *virtual* form of that constraint is $\delta p_2 + \delta\theta_1 r = 0$, where $dp_2 \equiv v_2\,dt$ and $d\theta_1 \equiv \omega_1\,dt$; and this coincides with the virtual form of the catastatic second of the constraints (d). In general, p_2 and θ_1 are "quasi coordinates"—see §2.9 ff.]

First and second of the constraints (*d*) in terms of the Eulerian angles of the sphere Φ, Θ, Ψ, relative to the "semiinertial" (translating but nonrotating) axes G–XYZ

We have, successively (recalling §1.12,13),

$$\begin{aligned} v_1 &= dz/dt \equiv v_Z,\\ \omega_2 &= \cos(2,X)\omega_X + \cos(2,Y)\omega_Y + \cos(2,Z)\omega_Z\\ &= (-\sin\phi)\omega_X + (\cos\phi)\omega_Y + (0)\omega_Z\\ &= (-\sin\phi)[\cos\Phi(d\Theta/dt) + \sin\Phi\sin\Theta(d\Psi/dt)]\\ &\quad + (\cos\phi)[\sin\Phi(d\Theta/dt) - \cos\Phi\sin\Theta(d\Psi/dt)]\\ &= \cdots = \sin(\Phi-\phi)(d\Theta/dt) - \cos(\Phi-\phi)\sin\Theta(d\Psi/dt), \end{aligned} \tag{f}$$

that is, the familiar ω_Y component but with ϕ replaced by $\Phi - \phi$;

$$\begin{aligned} v_2 &= (R-r)(d\phi/dt),\\ \omega_1 &= \cos(1,X)\omega_X + \cos(1,Y)\omega_Y + \cos(1,Z)\omega_Z\\ &= (0)\omega_X + (0)\omega_Y + (1)\omega_Z = d\Phi/dt + \cos\Theta(d\Psi/dt). \end{aligned} \tag{g}$$

Therefore, the first and second constraints (d) transform to

$$v_1 - \omega_2 r = dz/dt - r\big[\sin(\Phi-\phi)(d\Theta/dt) - \cos(\Phi-\phi)\sin\Theta(d\Psi/dt)\big] = 0, \tag{h}$$

$$v_2 + \omega_1 r = (R-r)(d\phi/dt) + r\big[d\Phi/dt + \cos\Theta(d\Psi/dt)\big] = 0; \tag{i}$$

and similarly for the first two of (e).

Example 2.2.3 *Acatastatic Constraints*. Let us consider the rolling of a sphere S of radius r and center G on a rough surface of revolution with a vertical axis. Let us introduce the convenient frame/axes/basis G–123/G–$\boldsymbol{ijk}$ shown in fig. 2.4. Further, let ϕ be the *azimuth*, or *precession*-like, angle of the meridian plane (and of plane G–23); and θ be the *nutation*-like angle between the positive surface axis and the common (outward) normal. Then, with $d\phi/dt \equiv \omega_\phi$, $d\theta/dt \equiv \omega_\theta$, we will have

$$\begin{aligned} \boldsymbol{\Omega}_o &= \text{inertial angular velocity of } G\text{–}123 \equiv (\Omega_1, \Omega_2, \Omega_3)\\ &= (-\omega_\phi\sin\theta,\ \omega_\theta,\ \omega_\phi\cos\theta), \end{aligned} \tag{a}$$

$$\boldsymbol{v}_G = \text{inertial velocity of } G \equiv (v_1, v_2, v_3) = (\rho\,\omega_\theta,\ R\,\omega_\phi = \rho\sin\theta\,\omega_\phi,\ 0), \tag{b}$$

where ρ = radius of curvature of meridian curve of parallel surface at G.

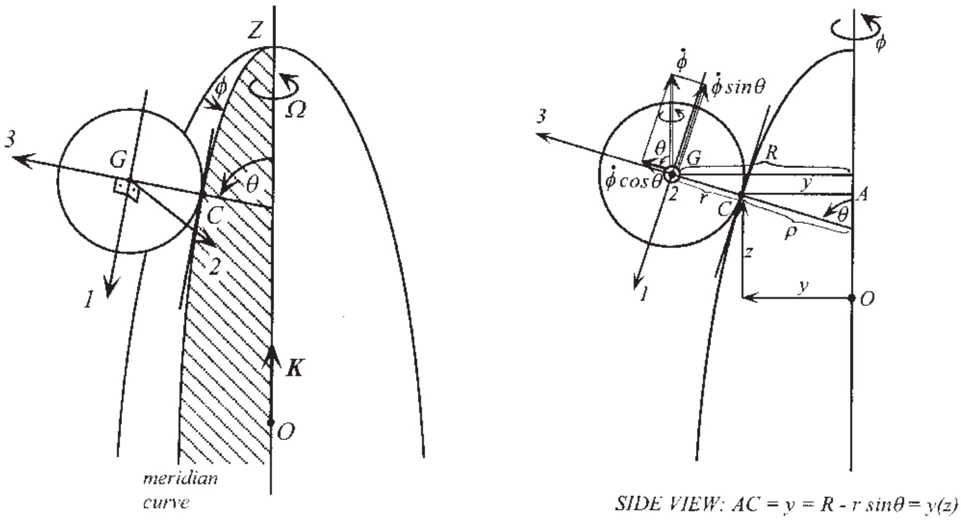

Figure 2.4 Rolling of a sphere on a vertical surface of revolution. *G3*: along common normal, outward; *G1*: parallel to tangent to meridian curve, at contact point *C*; *G2*: parallel to tangent to circular section through *C* (or, so that *G–123* is OND).

If $\boldsymbol{\omega}$ = inertial angular velocity of sphere $= (\omega_1, \omega_2, \omega_3)$, then the inertial velocity of the contact point C, $\boldsymbol{v}_C$, equals

$$\begin{aligned} \boldsymbol{v}_C &= \boldsymbol{v}_G + \boldsymbol{\omega} \times \boldsymbol{r}_{C/G} \\ &= (v_1, v_2, v_3) + (\omega_1, \omega_2, \omega_3) \times (0, 0, -r) = (v_1 - \omega_2 r,\ v_2 + \omega_1 r,\ v_3). \end{aligned} \tag{c}$$

Therefore: (i) If the surface is *stationary*, the rolling constraint is $\boldsymbol{v}_C = \mathbf{0}$, or, in components,

$$v_1 - \omega_2 r = 0, \qquad v_2 + \omega_1 r = 0, \qquad v_3 = 0. \tag{d}$$

(ii) If the surface is compelled to rotate about its axis with (inertial) angular velocity $\boldsymbol{\Omega} = \boldsymbol{\Omega}(t)$ = *given function of time*, the rolling constraint is

$$\boldsymbol{v}_C = \boldsymbol{\Omega} \times \boldsymbol{r}_{C/O} = \big(0, \Omega(R - r\sin\theta), 0\big), \tag{e}$$

or, in components,

$$v_1 - \omega_2 r = 0 \;\Rightarrow\; \omega_2 = v_1/r = \rho\,\omega_\theta/r, \tag{f}$$

$$v_2 + \omega_1 r = \Omega(R - r\sin\theta) \;\Rightarrow\; \omega_1 = (R/r)\omega_r - \Omega\sin\theta, \qquad v_3 = 0, \tag{g}$$

where $\omega_r \equiv \Omega - \omega_\phi$ = relative angular velocity of surface about meridian plane G–13. The first constraint (g) is nonstationary and acatastatic, even if $\Omega = constant$. [As explained in §2.5 ff., the *virtual* form of that constraint is $\delta p_2 + \delta\theta_1 r = 0$, where $dp_2 \equiv v_2\,dt$ and $d\theta_1 \equiv \omega_1\,dt$; and it coincides with the virtual form of the catastatic second constraint (d). In general, p_2 and θ_1 are "quasi coordinates"— see §2.9 ff.]

SPECIALIZATIONS

(i) If the surface of revolution is another *sphere* with radius $\rho_o \equiv \rho - r = constant$, since then $v_1 = (\rho_o + r)\omega_\theta$, $v_2 = [(\rho_o + r)\sin\theta]\omega_\phi$, the constraints (f) and the second of (g) reduce, respectively, to

$$\omega_2 = [(\rho_o + r)/r]\omega_\theta = [(\rho_o/r) + 1]\omega_\theta, \tag{h}$$

$$\omega_1 = [(\rho_o/r) + 1]\sin\theta\,\omega_r - \Omega\sin\theta. \tag{i}$$

(ii) If the surface of revolution is another *sphere* with radius $\rho_o \equiv \rho - r$, that is free (i.e., *unconstrained*) to rotate about its fixed center with inertial angular velocity $\boldsymbol{\omega}' \equiv (\omega'_1, \omega'_2, \omega'_3)$, then, reasoning as earlier, we obtain the catastatic constraint equations

$$v_1 - \omega_2 r = \rho_o\omega'_2, \qquad v_2 + \omega_1 r = -\rho_o\omega'_1, \qquad v_3 = 0. \tag{j}$$

However, if the ω'_1, ω'_2, ω'_3 are *prescribed functions of time*, then the first and second of (j) become *nonstationary* (and *acatastatic*).

For additional such rolling examples, including the corresponding Newton–Euler (kinetic) equations, and so on, see the older British textbooks: for example, Atkin (1959, pp. 253–259), Besant (1914, pp. 353–359), Lamb (1929, pp. 162–170), Milne (1948, chaps. 15, 17).

Example 2.2.4 *Problem of Ishlinsky (or Ishlinskii).* Let us consider the rolling of a circular rough cylinder of radius R on top of two other identical circular and rough cylinders, each of radius r, rolling on a rough, fixed, and horizontal plane (fig. 2.5).

Let O–xyz and O–$x'y'z'$ be inertial axes, such that O–xy and O–$x'y'$ are both on that plane, while their axes Ox and Ox' are parallel to the lower cylinder generators

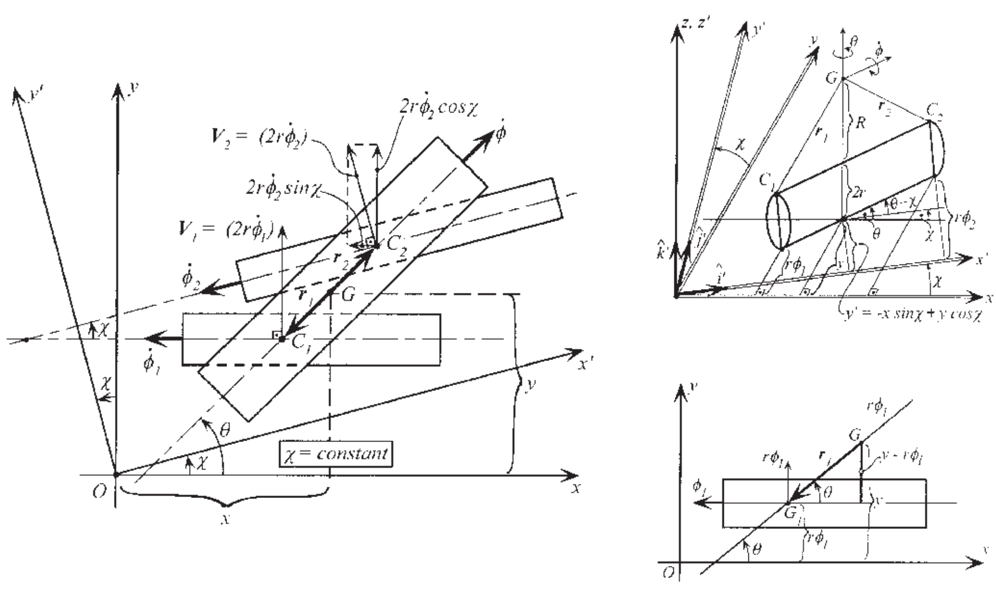

Figure 2.5 Rolling of a cylinder on top of two other rolling cylinders. Transformation equations: $x = x'\cos\chi - y'\sin\chi$, $y = x'\sin\chi + y'\cos\chi$.

and make, with each other, a *constant* angle χ. To describe the (global) system motion, let us choose the following *six* position coordinates: (i) (x, y) = inertial coordinates of *mass center* of upper cylinder G (as for its third, vertical, coordinate we have $z = 2r + R$); (ii) θ = angle between $+Ox$ and upper cylinder generator; (iii) ψ, ψ_1, ψ_2 = spin angles of the upper and two lower cylinders, respectively. Finally, let $\boldsymbol{r}_1$ and $\boldsymbol{r}_2$ be the *position vectors* of the contact points of the lower cylinders with the upper one, relative to G, and $\boldsymbol{v}_1$, $\boldsymbol{v}_2$ be the corresponding (inertial) velocities.

The rolling constraints are

$$\boldsymbol{v}_G + \boldsymbol{\omega} \times \boldsymbol{r}_1 = \boldsymbol{v}_1 \qquad \text{and} \qquad \boldsymbol{v}_G + \boldsymbol{\omega} \times \boldsymbol{r}_2 = \boldsymbol{v}_2. \tag{a}$$

Let us express them in terms of components along O–xyz. We have

$$\begin{aligned}
\boldsymbol{v}_G &= (dx/dt, dy/dt, 0) \equiv (v_x, v_y, 0)\\
\boldsymbol{\omega}&\text{: inertial angular velocity of upper cylinder}\\
&= \big((d\phi/dt)\cos\theta, (d\phi/dt)\sin\theta, d\theta/dt\big) \equiv (\omega_\phi \cos\theta, \omega_\phi \sin\theta, \omega_\theta),\\
\boldsymbol{r}_1 &= \big(-(y - r\phi_1)\cot\theta, -(y - r\phi_1), -R\big),\\
\boldsymbol{r}_2 &= [r\phi_2 - (y\cos\chi - x\sin\chi)]\cot(\theta - \chi)\boldsymbol{i}' + [r\phi_2 - (y\cos\chi - x\sin\chi)]\boldsymbol{j}' - R\boldsymbol{k}'\\
&= \big((r\phi_2 + x\sin\chi - y\cos\chi)\cos\theta/\sin(\theta - \chi),\\
&\qquad\qquad (r\phi_2 + x\sin\chi - y\cos\chi)\sin\theta/\sin(\theta - \chi), -R\big),\\
\boldsymbol{v}_1 &= (0, 2r\omega_1, 0) \qquad [\text{where } \omega_{1,2} \equiv d\phi_{1,2}/dt],\\
\boldsymbol{v}_2 &= (-2r\omega_2 \sin\chi, 2r\omega_2\cos\chi, 0).
\end{aligned} \tag{b}$$

Substituting the above into (a), we obtain the following *four* constraint components:

$$\begin{aligned}
&v_x - R\omega_\phi \sin\theta - \omega_\theta(r\phi_1 - y) = 0,\\
&v_y + R\omega_\phi \cos\theta + \omega_\theta(r\phi_1 - y)\cot\theta - 2r\omega_1 = 0;\\
&v_x \sin(\theta - \chi) - R\omega_\phi \sin\theta \sin(\theta - \chi) - \omega_\theta(r\phi_2 + x\sin\chi - y\cos\chi)\sin\theta\\
&\qquad\qquad\qquad\qquad + 2r\omega_2 \sin\chi \sin(\theta - \chi) \ = \ 0,\\
&v_y \sin(\theta - \chi) + R\omega_\phi \cos\theta \sin(\theta - \chi) + \omega_\theta(r\phi_2 + x\sin\chi - y\cos\chi)\cos\theta\\
&\qquad\qquad\qquad\qquad - 2r\omega_2 \cos\chi \sin(\theta - \chi) \ = \ 0.
\end{aligned} \tag{c}$$

For further details, see, for example, Mei (1985, pp. 33–35), Neimark and Fufaev (1972, pp. 99–101). It can be shown (§2.11, 12) that these constraints are nonholonomic. Therefore, the system has $n = 6$ *global DOF*, and $n - m = 6 - 4 = 2$ *local DOF* (concepts explained in §2.3 ff.).

Example 2.2.5 *When is Rolling Holonomic?* So as to dispell the possible notion that all problems of (slippingless) rolling among rigid bodies lead to nonholonomic constraints, let us summarize below the cases of rolling that lead to holonomic constraints. It has been shown by Beghin (1967, pp. 436–438) that these are the following *two* kinds:

(i) The paths of the contact point(s) of the rolling bodies are known *ahead of time*; that is, before any dynamical consideration of the system involved and as function of its original position, on these bodies. Consider two such bodies whose bounding surfaces, S_1 and S_2, are described by the curvilinear surface (Gaussian) coordinates (u_1, v_1) and (u_2, v_2), respectively, in contact at a point C. Their relative positions, say of S_1 relative to S_2, are determined by the values of these coordinates at C and the angle ϕ formed by the tangents to the lines $u_1 = constant$ and $u_2 = constant$ (or v_1, $v_2 = constant$) there. Knowledge of the paths of C on both S_1 and S_2 translates to knowledge of the four holonomic functional relations:

$$u_1 = u_1(v_1), \qquad u_2 = u_2(v_2), \qquad \phi = \phi(u_1, u_2), \qquad s_1(u_1) = s_2(u_2) \pm c; \qquad \text{(a)}$$

where s_1 and s_2 are the arc lengths (or curvilinear abscissas) of the contact point paths S_1 and S_2, and c is an integration constant. It follows that, out of the *five* surface positional parameters, u_1, v_1, u_2, v_2, ϕ, only *one* is independent; the other four can be expressed in terms of that one by finite (holonomic) relations.

(ii) The bounding surfaces S_1 and S_2 are applicable on each other; they touch at homologous points and their homologous curves (trajectories of the contact point C on them) join together there. This is expressed by the condition of contact, and by

$$u_1 = u_2, \qquad v_1 = v_2, \qquad \phi = 0, \qquad \text{(b)}$$

at C; that is, again, a total of four holonomic equations. This condition is guaranteed to hold continuously if it holds initially and, afterwards, the pivoting vanishes. Such conditions are met in the following examples:

(a) Rolling of two plane curves (or normal cross sections of cylindrical surfaces S_1 and S_2) on each other, and expressed by $s_1 = s_2 \pm c$.
(b) Rolling of a body on a fixed surface, which it touches on only two points. For example, the rolling of a sphere on a system made up of a fixed circular cylinder and a fixed plane perpendicular to it [fig. 2.6(a)]. (If the cylinder rotates about its axis in a known fashion, the trajectories of the contact points on both plane and cylinder are known, but they are unknown on the sphere and, hence, such rolling is nonholonomic.)
(c) Rolling of two equal bodies of revolution whose axes are constrained to meet and, initially, are in contact along homologous parallels, or meridians [fig. 2.6(b)]. The pivoting of such applicable surfaces vanishes.

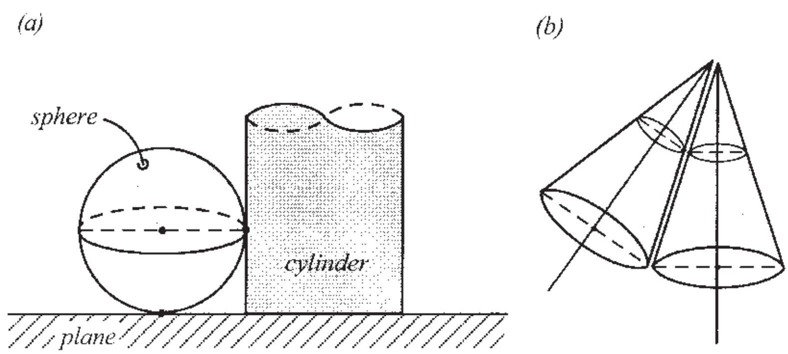

Figure 2.6 Examples of holonomic rolling: (a) rolling of a sphere on a fixed circular cylinder and a fixed plane perpendicular to it; (b) rolling of a cone on another equal fixed cone.

2.3 QUANTITATIVE INTRODUCTION TO NONHOLONOMICITY

Let us examine the differences between holonomic and nonholonomic constraints, in some mathematical detail, for the simplest possible case: a single particle, with (inertial) rectangular Cartesian coordinates x, y, z, moving in space under the Pfaffian equation

$$a\,dx + b\,dy + c\,dz = 0, \tag{2.3.1}$$

where a, b, c = continuously differentiable functions of x, y, z.

[The Pfaffian *expression* $a\,dx + b\,dy + c\,dz$ is a special *differential form* of the *first* degree. The *total* or Pfaffian *differential equation* (2.3.1) is a specialization of the *Monge* form:

$0 = f(x, y, z; dx, dy, dz) =$ *stationary* and *homogeneous* in the velocity components $(dx/dt, dy/dt, dz/dt)$, and hence (since t is absent) only *path restricting*.

The Monge form is, in turn, a specialization of the general first-order partial differential equation:

$$F(t; x, y, z; dx/dt, dy/dt, dz/dt) = 0.]$$

Now, the constraint (2.3.1) may be nonholonomic or it may be holonomic in differential (or velocity) form; specifically, if (2.3.1) can become, through multiplication with an appropriate *integrating factor*, $\mu = \mu(x, y, z)$, an *exact*, or *perfect*, or *total* differential $d\phi = d\phi(x, y, z)$ of a scalar function $\phi = \phi(x, y, z)$:

$$\mu(a\,dx + b\,dy + c\,dz) = d\phi, \tag{2.3.1a}$$

from which, by integration, we may obtain the (rigid and stationary) surface:

$$\phi(x, y, z) = constant, \qquad \text{or} \qquad z = z(x, y), \tag{2.3.1b}$$

then (2.3.1) is holonomic; if not, it is nonholonomic.

[Since, as is well known, the *two*-variable Pfaffian $a(x, y)\,dx + b(x, y)\,dy$ has *always* an integrating factor (in fact, an infinity of them), eq. (2.3.1) is the simplest possibly nonholonomic constraint. More on this below.]

In particular, if $\mu = 1$ (i.e., $d\phi = a\,dx + b\,dy + c\,dz$), the integrable Pfaffian $d\phi$ is *exact*. Then,

$$a = \partial\phi/\partial x, \qquad b = \partial\phi/\partial y, \qquad c = \partial\phi/\partial z, \tag{2.3.2}$$

and so the *necessary and sufficient* conditions for (2.3.1) to be exact are that the first partial derivatives of a, b, c, exist and satisfy (by equating the second mixed ϕ-derivatives):

$$\partial a/\partial y = \partial b/\partial x, \qquad \partial a/\partial z = \partial c/\partial x, \qquad \partial b/\partial z = \partial c/\partial y. \tag{2.3.3}$$

Equations (2.3.3) are *sufficient* for (2.3.1) to be completely integrable = holonomic; but they are *not necessary: every exact Pfaffian equation is integrable, but every integrable Pfaffian equation need not be exact*; in general, a $\mu \neq 1$ may exist, even though not all of (2.3.3) hold. In mechanics, we are interested in the holonomicity ($\equiv$ *complete* or *unconditional*) *integrability*, or absence thereof, of the constraints.

Let us now make a brief detour to the *general case*: the system of m Pfaffian constraints in the $n(> m)$ variables $x = (x_1, \ldots, x_n)$,

$$d'\theta_D \equiv \sum a_{Dk}(x)dx_k = 0 \quad [D = 1, \ldots, m(< n)], \tag{2.3.4}$$

where $rank(a_{Dk}) = m$ (i.e., these equations are linearly *independent* in a certain x-region), is called *completely* (or *unconditionally*) *integrable*, or *complete*, or *holonomic*, if either (i) it is *immediately integrable*, or *exact*; that is, if the m $d'\theta_D$'s are the exact, or total, or perfect, differentials of m functions $\phi_D = \phi_D(x)$:

$$\sum a_{Dk}(x)\, dx_k = d\phi_D(x); \tag{2.3.4a}$$

or (ii) each $d'\theta_D$, although not immediately integrable, nevertheless admits a (nonzero) *integrating factor* $\Phi_D(x)$; that is, if the $2m$ (not all zero) functions $\{\Phi_D(x),\, \phi_D(x);\, D = 1, \ldots, m(< n)\}$ and (2.3.4) satisfy

$$\begin{aligned} &\Phi_1\, d'\theta_1 = \Phi_1(a_{11}\, dx_1 + \cdots + a_{1n}\, dx_n) = d\phi_1(x),\\ &\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\\ &\Phi_m\, d'\theta_m = \Phi_m(a_{m1}\, dx_1 + \cdots + a_{mn}\, dx_n) = d\phi_m(x); \end{aligned} \tag{2.3.4b}$$

or, compactly, $\Phi_D\, d'\theta_D = \Phi_D(\sum a_{Dk}\, dx_k) = d\phi_D(x)$, where the $\{d\phi_D\}$ are (linearly) independent. Summing (2.3.4b), over D, we also obtain its following consequence:

$$\sum \Phi_D\, d'\theta_D = \sum \Phi_D\Big(\sum a_{Dk}\, dx_k\Big) = \sum d\phi_k \equiv d\phi = \sum(\partial\phi/\partial x_k)\, dx_k$$
$$\Rightarrow \sum \Phi_D a_{Dk} = \partial\phi/\partial x_k.$$

Clearly, in both cases, (2.3.4a, b), the constraints (2.3.4) are equivalent to the *holonomic* equations

$$\phi_1(x) = C_1, \ldots, \phi_m(x) = C_m, \tag{2.3.4c}$$

where the m constants $\{C_D;\, D = 1, \ldots, m\}$ are fixed throughout the motion of the system. (Elaboration of this leads to the concept of *semiholonomic* constraints, treated later in this section.) If the constraints (2.3.4) are nonintegrable, neither immediately nor with integrating factors, they are called *nonholonomic*; and the mechanical system whose motion obeys, in addition to the kinetic equations, such nonholonomic constraints, either *internally* (constitution of its bodies) or *externally* (interaction with its environment, obstacles, etc.), is called a nonholonomic system.

An alternative definition of complete integrability of the system (2.3.4), equivalent to (2.3.4b), is the existence of *m independent*, *that is*, *distinct*, *linear*, *combinations of the m* $d'\theta_D$ that are exact differentials of the m independent functions $f_D(x)$:

$$\mu_{11}\, d'\theta_1 + \cdots + \mu_{1m}\, d'\theta_m = df_1, \ldots, \mu_{m1}\, d'\theta_1 + \cdots + \mu_{mm}\, d'\theta_m = df_m, \tag{2.3.4d}$$

where $\mu_{DD'} = \mu_{DD'}(x)$, or, compactly,

$$\sum \mu_{DD'}\, d'\theta_{D'} = df_D \Leftrightarrow d'\theta_D = \sum M_{DD'}\, df_{D'} \qquad (D, D' = 1, \ldots, m), \tag{2.3.4e}$$

[where $(M_{DD'})$ is the inverse matrix of $(\mu_{DD'})$, and both $(m \times m)$ matrices are nonsingular] and, hence, yield the m *independent* integrals (hypersurfaces):

$f_1 = c_1, \ldots, f_m = c_m$; that is, the system of eqs. (2.3.4) is completely integrable if there exists an *m-parameter* $(n - m)$-dimensional manifold that solves them. [Frobenius (1877) has shown that if $m = n$, or $n - 1$, then the system (2.3.4) is *always* completely integrable—more on this later.]

Finally, calling the determinant of the coefficients $\mu_{DD'}$ the *multiplicator* of (2.3.4) [i.e., $|\mu_{DD'}| \equiv \mu(\neq 0)$], and generalizing from the single constraint case (2.3.1), we can state that every multiplicator has always the form $\mu\, F(f_1, \ldots, f_D)$, where $F(\ldots)$ is an arbitrary differentiable function of the f's; that is, there exists an *infinity* of multiplicators.

From the above, it immediately follows that in the case of a *single* Pfaffian equation in the n variables $x = (x_1, \ldots, x_n)$ (i.e., for $m = 1$), complete integrability, in a certain x-domain, means that there exists, locally at least, a *one-parameter family of* $(n-1)$-*dimensional manifolds* $f(x) \equiv \phi(x) - constant = 0$, which solves that equation.

[We remark that the solutions of $d'\theta \equiv \sum a_k(x)\, dx_k = 0$ are *always one-dimensional* manifolds, or *curves*: $x_k = x_k(u)$, where $u =$ curve parameter. And, generally, if the x are functions of the $m(< n)$ new variables $(u_1, \ldots, u_m)$, then $x_k = x_k(u_1, \ldots, u_m)$ is called an *m-dimensional* solution manifold of $d'\theta = 0$, if, upon substitution into it, identical satisfaction results.]

Problem 2.3.1 Verify that the *sufficient* (but *non-necessary*!) conditions for the complete integrability of the system of m Pfaffian equations [essentially the discrete version of (2.2.9) for a system of N particles],

$$f_D\, dt \equiv \sum (a_{Dk}\, dx_k + b_{Dk}\, dy_k + c_{Dk}\, dz_k) + e_D\, dt = 0, \tag{a}$$

where $D = 1, \ldots, m(< 3N)$, $k = 1, \ldots, N$, and $(a, b, c, e) =$ continuously differentiable functions of (x, y, z, t), are that

$$\partial a_{Dk}/\partial x_l = \partial a_{Dl}/\partial x_k, \qquad \partial a_{Dk}/\partial y_l = \partial b_{Dl}/\partial x_k, \qquad \partial a_{Dk}/\partial z_l = \partial c_{Dl}/\partial x_k,$$
$$\partial a_{Dk}/\partial t = \partial e_D/\partial x_k; \tag{b}$$
$$\partial b_{Dk}/\partial y_l = \partial b_{Dl}/\partial y_k, \qquad \partial b_{Dk}/\partial z_l = \partial c_{Dl}/\partial y_k, \qquad \partial b_{Dk}/\partial t = \partial e_D/\partial y_k; \tag{c}$$
$$\partial c_{Dk}/\partial z_l = \partial c_{Dl}/\partial z_k, \qquad \partial c_{Dk}/\partial t = \partial e_D/\partial z_k; \tag{d}$$

for *all* $k, l = 1, \ldots, N$, for a fixed D. [In fact, the (obvious) choice: $a_{Dk} = \partial\phi_D/\partial x_k$, $b_{Dk} = \partial\phi_D/\partial y_k$, $c_{Dk} = \partial\phi_D/\partial z_k$, $e_D = \partial\phi_D/\partial t$; $\phi_D = \phi_D(t; x, y, z)$ satisfies (b–d).] Then, (a) simply states that $d\phi_D = 0$; and the latter integrates immediately to the holonomic constraints: $\phi_D = \phi_D(t; x, y, z) = (constant)_D$.

Introduction to Necessary and Sufficient Conditions for Holonomicity

Let us, for the time being, postpone the discussion of the general case and return to the *single* Pfaffian equation in *three* variables, eq. (2.3.1), and find the necessary and sufficient conditions for its holonomicity. Assuming that this is indeed the case, then from (2.3.1) and the second of (2.3.1b) we readily see that

$$dz = (\partial z/\partial x)\, dx + (\partial z/\partial y)\, dy = (-a/c)\, dx + (-b/c)\, dy \tag{2.3.5}$$

must hold for all dx, dy, dz. Therefore, equating the coefficients of dx and dy of both sides, we obtain [assuming $c \neq 0$, and that $z(x, y)$ is substituted for z in a, b, c]

$$\partial z/\partial x = -(a/c) \qquad \text{and} \qquad \partial z/\partial y = -(b/c), \tag{2.3.5a}$$

and since $\partial/\partial y(\partial z/\partial x) = \partial/\partial x(\partial z/\partial y)$, we obtain $\partial/\partial y(a/c) = \partial/\partial x(b/c)$, or, explicitly,

$$\begin{aligned} &c[\partial a/\partial y + (\partial a/\partial z)(\partial z/\partial y)] - a[\partial c/\partial y + (\partial c/\partial z)(\partial z/\partial y)] \\ &\qquad = c[\partial b/\partial x + (\partial b/\partial z)(\partial z/\partial x)] - b[\partial c/\partial x + (\partial c/\partial z)(\partial z/\partial x)], \end{aligned}$$

and inserting in it the $\partial z/\partial x$- and $\partial z/\partial y$-values from (2.3.5a), and simplifying, we finally find

$$I \equiv a(\partial b/\partial z - \partial c/\partial y) + b(\partial c/\partial x - \partial a/\partial z) + c(\partial a/\partial y - \partial b/\partial x) = 0. \tag{2.3.6}$$

Equation (2.3.6), being a direct consequence of the earlier mixed partial derivative equality, is the *necessary and sufficient* condition for (2.3.1) to be holonomic. If $I = 0$ *identically* (i.e., for arbitrary x, y, z), then (2.3.1) is holonomic; if $I \neq 0$ *identically*, then (2.3.1) is nonholonomic.

REMARKS

(i) The form I is *symmetric* in (x, y, z) and (a, b, c); that is, it remains unchanged under simultaneous cyclic changes of (x, y, z) *and* (a, b, c).

(ii) *Alternative derivation of equation (2.3.6):* The mixed partial derivatives rule applied to (2.3.1a) readily yields

$$\partial(\mu b)/\partial x = \partial(\mu a)/\partial y, \qquad \partial(\mu c)/\partial x = \partial(\mu a)/\partial z, \qquad \partial(\mu c)/\partial y = \partial(\mu b)/\partial z.$$

Multiplying the above equalities with c, b, a, respectively, and adding them together, we obtain (2.3.6); so, clearly, the latter is *necessary and sufficient* for the existence of an integrating factor (for further details, see, e.g., Forsyth, 1885 and 1954, pp. 247 ff.).

(iii) *A special case:* If $a = a(x, y)$, $b = b(x, y)$, and $c = 0$, then, clearly, $I = 0$; which proves the earlier claim that the two-variable Pfaffian equation $a(x, y)\,dx + b(x, y)\,dy = 0$ is *always holonomic*; that is, for nonholonomicity, we need at least three variables.

(iv) *A special form:* If (2.3.1) has the equivalent form

$$\begin{aligned} dz &= (-a/c)\,dx + (-b/c)\,dy \equiv A(x, y, z)\,dx + B(x, y, z)\,dy \\ &= A[x, y, z(x, y)]\,dx + B[x, y, z(x, y)]\,dy \\ &\equiv A^*(x, y)\,dx + B^*(x, y)\,dy, \end{aligned} \tag{2.3.7}$$

(or, similarly, $dx = \cdots$, $dy = \cdots$; depending on analytical convenience and/or avoidance of singularities), then the mixed partial derivative rule

$$\partial A^*(x, y)/\partial y = \partial B^*(x, y)/\partial x, \tag{2.3.7a}$$

due to the chain rule (one should be extra careful here):

$$\partial A^*/\partial y = \partial A/\partial y + (\partial A/\partial z)(\partial z/\partial y) = \partial A/\partial y + (\partial A/\partial z)B, \tag{2.3.7b}$$

$$\partial B^*/\partial x = \partial B/\partial x + (\partial B/\partial z)(\partial z/\partial x) = \partial B/\partial x + (\partial B/\partial z)A, \tag{2.3.7c}$$

finally yields

$$\partial A/\partial y + (\partial A/\partial z)B = \partial B/\partial x + (\partial B/\partial z)A; \tag{2.3.7d}$$

whose *identical* satisfaction in x, y, z, is the necessary and sufficient condition for the complete integrability, or holonomicity, of (2.3.7).

It is not hard to verify that (i) replacing, in (2.3.7d), A with $-a/c$ and B with $-b/c$, we recover (2.3.6); and, conversely, (ii) since (2.3.7) can be written in the (2.3.1)-like form: $A\,dx + B\,dy + (-1)\,dz = 0$, replacing, in (2.3.6), a, b, c, with A, B, -1, respectively, we recover (2.3.7d). If, in (2.3.7), $\partial A/\partial z = 0$ and $\partial B/\partial z = 0$, then (2.3.7d) reduces to $\partial A/\partial y = \partial B/\partial x$. Finally, the sole analytical requirement here is the *continuity* of all partial derivatives appearing in these conditions (but not those of the nonappearing ones, such as $\partial A/\partial x$ and $\partial B/\partial y$).

Example 2.3.1 Let us test, for complete integrability, the following constraints:

$$\text{(i)}\ \ dz = (z)\,dx + (z^2 + a^2)\,dy; \qquad \text{(ii)}\ \ dz = z(dx + x\,dy).$$

(i) Here, $A = z$ and $B = z^2 + a^2$, and therefore (2.3.7d) yields

$$(1)(z^2 + a^2) = (2z)z \ \Rightarrow\ z^2 = a^2,$$

that is, no identical satisfaction; or, our constraint is not completely integrable—it is nonholonomic. Then, the original equation becomes

$$dz = z\,dx + 2z^2\,dy;$$

and so (a) if $a = 0$, then $z = 0$ is a constraint integral; but (b) if $a \neq 0$, then there is no integral. For complete integrability, we should have an infinity of integrals depending on an arbitrary integration constant.

(ii) Here, the test (2.3.7d) gives $xz = z + xz \ \Rightarrow\ z = 0$; that is, no identical satisfaction, and therefore no holonomicity. As the original equation shows, this is the sole integral.

Problem 2.3.2 Show that the constraint of the plane pursuit problem (ex. 2.2.1):

$$[Y(t) - y](dx/dt) - [X(t) - x](dy/dt) = 0, \tag{a}$$

or, equivalently,

$$[Y(t) - y]\,dx - [X(t) - x]\,dy + (0)\,dt = 0, \tag{b}$$

is holonomic if and only if

$$[X(t) - x]\big/[Y(t) - y] = (dX/dt)\big/(dY/dt) \qquad [= (dx/dt)\big/(dy/dt)]. \tag{c}$$

Problem 2.3.3 Show that under a general one-to-one (nonsingular) coordinate transformation $(x, y, z) \ \Leftrightarrow\ (u, v, w)$: $x = x(u, v, w)$, $y = \cdots, z = \cdots$,

$$I = [\partial(u, v, w)/\partial(x, y, z)] \cdot I'; \tag{a}$$

where (with subscripts denoting partial derivatives)

$$d\theta \equiv a\,dx + b\,dy + c\,dz = p\,du + q\,dv + r\,dw, \tag{b}$$

$$I = I(x, y, z) \equiv a(b_z - c_y) + b(c_x - a_z) + c(a_y - b_x), \tag{c}$$

$$I' = I'(u, v, w) \equiv p(q_w - r_v) + q(r_u - p_w) + r(p_v - q_u), \tag{d}$$

and $\partial(u, v, w)/\partial(x, y, z) = Jacobian$ of the transformation ($\neq 0$); that is, I and I' vanish simultaneously; or, the holonomicity of $d\theta = 0$, or absence thereof, is *coordinate invariant*, and hence an *intrinsic* property of the constraint (a proof of this fundamental fact, for a general Pfaffian system, will be given later).

[Incidentally, the transformation law (a) also shows that scalars like I are *not necessarily invariants* ($I \neq I'$, in general); in fact, in the more precise language of tensor calculus, they are called *relative scalars of weight* $+1$, or *scalar densities*; see, e.g., Papastavridis (1999, pp. 46–49).]

Geometrical Interpretation of the Pfaffian Equation (2.3.1)

The latter, rewritten with the help of the vectors $\boldsymbol{dr} = (dx, dy, dz)$ and $\boldsymbol{h} = (a, b, c)$ as

$$\boldsymbol{h} \cdot \boldsymbol{dr} = 0, \tag{2.3.8}$$

means that, at each specified point $Q(x, y, z)$, $\boldsymbol{dr}$ must lie on a local plane *perpendicular* to the "constraint coefficient vector" $\boldsymbol{h}$ there; or, that the particle P can move only along those curves, emanating from Q, whose tangent is perpendicular to $\boldsymbol{h}$. Such curves are called *kinematically admissible*, or *kinematically possible*. If (2.3.1, 8) is holonomic, then all motions lie on the integral surface (2.3.1b); that is, (2.3.6) is the necessary and sufficient condition for the existence of an orthogonal surface through Q, for the field $\boldsymbol{h} = (a, b, c)$ [actually, *a family of surfaces* $\phi = \phi(x, y, z) = constant$, *everywhere normal to* $\boldsymbol{h}$—see below]. We also notice that, with the help of $\boldsymbol{h}$, the condition (2.3.6) takes the memorable (invariant) form:

$$I \equiv \boldsymbol{h} \cdot \boldsymbol{curl}\ \boldsymbol{h} = 0; \qquad \text{or, symbolically,} \qquad \begin{vmatrix} a & b & c \\ \partial/\partial x & \partial/\partial y & \partial/\partial z \\ a & b & c \end{vmatrix} = 0; \tag{2.3.8a}$$

that is, at every field point, $\boldsymbol{h}$ is parallel to the plane of its rotation, or perpendicular to that rotation and tangent to the surface $\phi = constant$ there [W. Thomson (Lord Kelvin) called such fields *doubly lamellar*]; while (2.3.7d), with $\boldsymbol{h} \to \boldsymbol{H} \equiv (A, B, -1)$, becomes

$$\boldsymbol{H} \cdot \boldsymbol{curl}\ \boldsymbol{H} = \partial A/\partial y + B(\partial A/\partial z) - \partial B/\partial x - A(\partial B/\partial z) = (1/c^2)\boldsymbol{h} \cdot \boldsymbol{curl}\ \boldsymbol{h} = 0. \tag{2.3.8b}$$

Vectorial Derivation of Equation (2.3.8a)

We recall from vector analysis that a (continuously differentiable) vector is called *irrotational*, or *singly lamellar*, if (a) its line integral around every closed circuit vanishes, or, equivalently, (b) if its ***curl*** (rotation) vanishes, or (c) if it equals the gradient of a scalar.

Now: (i) If $\boldsymbol{h} = (a, b, c)$ is irrotational, then there is a $\phi = \phi(x, y, z)$ such that $\boldsymbol{h} = \boldsymbol{grad}\,\phi$, and, therefore, $\boldsymbol{h} \cdot \boldsymbol{dr} = \boldsymbol{grad}\ \phi \cdot \boldsymbol{dr} = d\phi =$ *exact differential.*

(ii) If $\boldsymbol{h} \neq$ irrotational, still an *integrating factor (IF)* $\mu = \mu(x, y, z)$ may exist so that $\mu\,\boldsymbol{h} = \boldsymbol{grad}\,\phi$. Then, as before, $\mu\,\boldsymbol{h} \cdot \boldsymbol{dr} = \boldsymbol{grad}\ \phi \cdot \boldsymbol{dr} = d\phi =$ *exact differential.*

(iii) Conversely, if $\mu = IF$, then $\mu\,\boldsymbol{h} = \boldsymbol{grad}\ \phi =$ irrotational; and "curling" both sides of this latter, we obtain: $\boldsymbol{0} = \boldsymbol{curl}(\boldsymbol{grad}\ \phi) = \mu\,\boldsymbol{curl}\ \boldsymbol{h} + \boldsymbol{grad}\ \mu \times \boldsymbol{h}$, and dotting this with $\boldsymbol{h}$: $0 = \mu(\boldsymbol{h} \cdot \boldsymbol{curl}\ \boldsymbol{h})$, from which, since $\mu \neq 0$, we finally get (2.3.8a). In this case, since $\boldsymbol{h}$ and $\boldsymbol{grad}\ \phi$ are parallel: $\boldsymbol{h} = (1/\mu)\ \boldsymbol{grad}\ \phi \equiv \nu(\boldsymbol{grad}\ \phi)$, and, therefore, $\boldsymbol{curl}\ \boldsymbol{h} = \boldsymbol{curl}(\nu\ \boldsymbol{grad}\ \phi) = \boldsymbol{grad}\ \nu \times \boldsymbol{grad}\ \phi$, so that

$$\boldsymbol{h} \cdot \boldsymbol{curl}\ \boldsymbol{h} = \nu\ \boldsymbol{grad}\ \phi \cdot (\boldsymbol{grad}\ \nu \times \boldsymbol{grad}\ \phi) = 0; \tag{2.3.8c}$$

that is, the *doubly lamellar field* $\boldsymbol{h}$ is *perpendicular* to its *rotation* $\boldsymbol{curl}\ \boldsymbol{h}$. [This condition is *necessary* for the existence of an *IF*. For its *sufficiency*, see, for example, Brand (1947, pp. 200, 230–231), Sneddon (1957, pp. 21–23); also Coe (1938, pp. 477–478), for an *integral* vector calculus treatment.] These derivations are based on a general vector field theorem according to which an *arbitrary* vector field can be written as the sum of a *simple* and a *complex* (or *doubly*) *lamellar* field: $\boldsymbol{h} = \boldsymbol{grad}\,f + \nu\ \boldsymbol{grad}\ \phi$.

Finally, if the Pfaffian constraint is, nonholonomic, then (2.3.1, 7) yield one-dimensional "nonholonomic manifolds"; that is, space curves orthogonal to the field $\boldsymbol{h}$ (or $\boldsymbol{H}$), and constituting a one-parameter family on an arbitrary surface.

Accessibility

The restrictions on the motion of the particle P in the two cases $I = 0$ (holonomic) and $I \neq 0$ (nonholonomic) are of entirely different nature. If $I = 0$, then P is obliged to *move on the surface* $\phi = \phi(x, y, z) = 0$. If, on the other hand, $I \neq 0$, then the constraint (2.3.1) does *not* restrict the (x, y, z), but does restrict the *direction* (*velocity*) of the curves through a given point (x, y, z). The cumulative effect of these local restrictions in the direction of motion (velocity) is that the transition between two arbitrary points is *not arbitrary*; P can move (or be guided through) from an *arbitrary initial* (analytically possible) position, to any other *arbitrary final* (analytically possible) position, while at every point of its path satisfying (2.3.1, 8); that is, the particle can move from "anywhere" to "anywhere," not via any route we want, but along restricted paths. As Langhaar puts it, the particle is "constrained to follow routes that coincide with a *certain dense network of paths*" (1962, pp. 5–6); like kinematically possible tracks guiding the system.

In sum: (i) Holonomic constraints *do* reduce the dimension of the space of accessible configurations, but do not restrict motion and paths in there; in Hertz's words: "all conceivable continuous motions [between two arbitrary accessible positions] are also possible motions."

(ii) Nonholonomic constraints do *not* affect the dimension of the space of accessible configurations, but do restrict the motions locally (and, cumulatively, also globally) in there; *not all conceivable continuous motions (between two arbitrary accessible positions) are possible motions* (Hertz, 1894, p. 78 ff.).

These geometrical interpretations and associated concepts are extended to general systems in §2.7.

Degrees of Freedom

The above affect the earlier DOF definition: they force us to distinguish between *DOF in the large* (measure of global accessibility, or global mobility) and *DOF in the small* (measure of local/infinitesimal mobility). We define the former, $DOF(L)$, as the number of independent global positional (or holonomic) "parameters," or Lagrangean coordinates $\equiv n(=3$ in our examples, so far); and the latter, $DOF(S) \equiv f$, as n minus the number of additional (possibly nonholonomic) independent Pfaffian constraints: $f = n - m(> 0)$. In the absence of the latter, $DOF(L) = DOF(S)$: $f = n$. This fine distinction between DOFs rarely appears in the literature, where, as a rule, DOF means DOF in the *small*. {For enlightening *exceptions*, see, for example, Sommerfeld (1964, pp. 48–51); also Roberson and Schwertassek (1988, p. 96), who call these DOFs, respectively, *positional*(L) and *motional*(S); and the pioneering Korteweg (1899, p. 134), who states that "Die anzahl der Freiheitsgrade sei bei ihr eine andere (kleinere) für unendlich kleine wie für endliche Verrückungen" [Translation: The number of degrees of freedom is different (smaller) for infinitesimal displacements than for finite displacements.]}

As explained later in this chapter (§2.5 ff.), $DOF(S) \equiv f$ equals the *number of independent virtual displacements of the system*; and this, in turn (chap. 3), equals the smallest, or minimal, number of kinetic (i.e., reactionless) equations of motion of it. In view of this, from now on by DOF we shall understand DOF *in the small*; that is, $DOF \equiv DOF(S) \equiv n - m \equiv f$, unless explicitly specified otherwise. The concept of DOF in the large is more important in pure kinematics (mechanisms).

Finally, in the general constraint case, all these results hold intact, but for the figurative system "particle" in a higher dimensional space—more on this later.

Semiholonomic Constraints

We stated earlier that if $I = 0$, the Pfaffian constraint (2.3.1) is holonomic; that is, it can be brought to the form

$$d\phi/dt = 0 \ \Rightarrow\ \phi = constant \equiv c. \tag{2.3.9}$$

Such situations necessitate an additional, albeit minor, classification of holonomic constraints into *proper* holonomic, or simply holonomic, and *improper* holonomic, or *semiholonomic* ones. In both cases, the constraints are finite (i.e., holonomic), but, in the proper case, the constraint constants have a priori fixed values, independent of the system's position/motion; whereas, in the semiholonomic case, those constants depend on the arbitrarily specified values of the system coordinates at some "initial" instant; that is, semiholonomic constraints are completely integrable velocity (Pfaffian) constraints $\Rightarrow$ (generally) initial condition-depending holonomic constraints. In the proper holonomic case, the initial values of the coordinates must be determined *in conjunction* with the given constraints and their constants; that is, *they* must be compatible with the latter. However, semiholonomic constraints, being essentially holonomic, can be used to reduce the number of independent global/Lagrangean coordinates; and, thus, differ profoundly from the nonholonomic ones. Clearly, the proper/semiholonomic distinction applies to *rheonomic* holonomic constraints, like $\phi(x, y, z, t) = c$. For further details, see (alphabetically): Delassus (1913(b), pp. 23–25: earliest extensive discussion of semiholonomicity), Moreau (1971, pp. 228–232), and Pérès (1953, pp. 60–62, 218–219).

Critical Comments on Nonholonomic Constraints

The concept of nonholonomicity (in mechanics) has been around since the 1880s, and has been thoroughly studied and expounded by some of the greatest mathematicians, physicists, and mechanicians, for example (approximately chronologically): Voss, Hertz, Hadamard, Appell, Chaplygin, Voronets, Maggi, Boltzmann, Hamel, Heun, Delassus, Carathéodory, Schouten, Struik, Goursat, Cartan, Synge, Vranceanu, Vagner, Dobronravov, Lur'e, Neimark, Fufaev, et al. Direct definitions of nonholonomicity and analytical tests have been available, on a large and readable scale, at least since the 1920s. And yet, on this topic, there exists widespread misunderstanding and confusion; especially in the engineering literature. For example, some authors state that constraints that can be represented by equations like $\phi(\boldsymbol{r}, t) = 0$, or $\phi(x, y, z, t) = 0$, are called holonomic, and that *all* others are called nonholonomic; for example, Goldstein (1980, p. 12 ff.), Kane (1968, p. 14), Kane and Levinson (1985, p. 43), Likins (1973, pp. 184, 295), Matzner and Shepley (1991, pp. 23–24). Under such an indirect, vague, negative definition, *inequality* constraints like $\phi \geq 0$, or (perhaps?!) holonomic ones, but in velocity form, like

$$d\phi/dt = \mathcal{S}\,(\partial\phi/\partial\boldsymbol{r}) \cdot \boldsymbol{v} + \partial\phi/\partial t = 0, \tag{2.2.10}$$

would be called nonholonomic! Or, we read blatantly contradictory and erroneous statements like "With nonholonomic systems the generalized coordinates are not independent of each other, and it is not possible to reduce them further by means of equations of constraint of the form $f(q_1, \ldots, q_n, t) = 0$. *Hence it is no longer true that the* q_j's *are independent*" (Goldstein (1980, p. 45), emphasis added). Others call nonholonomic all velocity constraints that *cannot* be written in the above form $\phi = 0$, which is correct; but they fail to supply the reader with analytical (or geometrical, or even numerical) tools on how to test this; for example, Roberson and Schwertassek (1988, p. 96), Shabana (1989, pp. 123, 128). The more careful of this last group talk clearly about integrability, exactness, and so on, but restrict themselves to only *one* velocity constraint; for example, Haug (1992, pp. 87–89). Still others mix nonholonomic *coordinates* (*quasi coordinates*, etc.) with nonholonomic *constraints*, and *exactness* of Pfaffian *forms* with (complete) *integrability* of a system of Pfaffian *equations*, without ever supplying clear and general definitions, let alone analytical tests. And this results in defective definitions of the concept of DOF; for example, Angeles (1988, pp. 80, 103). Even the (otherwise monumental) treatise of Pars (1965, pp. 16–19, 22–24, 35–37, 64–72, 196) is limited to an introduction to the subject, albeit a careful and precise one. Finally, there is the recent crop of texts on "modern" dynamics, where the problem of nonholonomicity is "solved" by ignoring it altogether; for example, Rasband (1983). Only Neimark and Fufaev (1967/1972) discuss the nonholonomicity issue clearly, competently, and in sufficient generality and completeness to be useful. We hope that our treatment complements and extends their beautiful work.

Extensions/Generalizations of the Integrability Conditions (May be omitted in a first reading)

(i) Single Pfaffian Equation in the n Variables $x = (x_1, \ldots, x_n)$:

$$d'\theta \equiv \sum a_k\, dx_k = 0, \qquad a_k = a_k(x). \tag{2.3.10}$$

It can be shown that the necessary and sufficient condition for the complete integrability = holonomicity of (2.3.10) is the identical satisfaction of the following "symmetric" equations:

$$I_{klp} \equiv a_k(\partial a_l/\partial x_p - \partial a_p/\partial x_l) + a_l(\partial a_p/\partial x_k - \partial a_k/\partial x_p) \\ + a_p(\partial a_k/\partial x_l - \partial a_l/\partial x_k) = 0, \tag{2.3.10a}$$

for *all* combinations of the indices k, l, $p = 1, \ldots, n$. [For example, one may start with the integrability condition of (2.3.1), (2.3.6) (i.e., $n = 3$) and then use the method of induction; or perform similar steps as in the three-dimensional case; see, for example, Forsyth (1885 and 1954, pp. 259–260).] Further, it can be shown (e.g., again, by induction) that out of a total of $n(n-1)(n-2)/6$ equations (2.3.10a), equal to the number of triangles that can be formed with n given points as corners, *only* $n_I \equiv (n-1)(n-2)/2$ *are independent*. For $n = 3$, that number is indeed 1: eqs. (2.3.6) or (2.3.8a). Also, if $a_k \neq 0$, it suffices to apply (2.3.10) only for l and p different from k. Finally, with appropriate extension of the ***curl*** of a vector to n-dimensional spaces, (2.3.10) can be cast into a (2.3.8a)-like form (see, e.g., Papastavridis, 1999, chaps. 3, 6).

Problem 2.3.4 (i) Specialize (2.3.10a) to the *acatastatic* constraint ($n = 4$):

$$a(t, x, y, z)\, dx + b(t, x, y, z)\, dy + c(t, x, y, z)\, dy + e(t, x, y, z)\, dt = 0. \tag{a}$$

(ii) Show that (a) is *holonomic* if, and only if, the *symbolic* matrix

$$\begin{pmatrix} a & b & c & e \\ \partial/\partial x & \partial/\partial y & \partial/\partial z & \partial/\partial t \\ a & b & c & e \end{pmatrix}, \tag{b}$$

has rank 2 (actually, less than 3); that is, all possible four of its 3×3 symbolic subdeterminants, each to be developed along its first row, vanish.

(iii) Further, show that if all such 2×2 subdeterminants of (b) vanish, then (a) is *exact*.

(iv) Specialize the preceding result to the catastatic case $e \equiv 0$; verify that, then, we obtain (2.3.6).

Problem 2.3.5 For the Pfaffian equation (2.3.10), define the $(n+1) \times n$ matrix

$$\mathbf{P} = \begin{pmatrix} a_1 & \ldots & a_n \\ \hline a_{11} & \ldots & a_{1n} \\ \ldots & \ldots & \ldots \\ a_{n1} & \ldots & a_{nn} \end{pmatrix}, \tag{a}$$

where $a_{kl} \equiv \partial a_k/\partial x_l - \partial a_l/\partial x_k \; (= -a_{lk})$; $k, l = 1, \ldots, n$. Clearly, $a_{11} = \cdots = a_{nn} = 0$. Now, it is shown in differential equations/differential geometry that for the *holonomicity* of (2.3.10), it is necessary and sufficient that the rank of $\mathbf{P}$ *equal* 1 *or* 2.

Show that (i) *rank* $\mathbf{P} = 1$ (i.e., *all* its 2×2 subdeterminants vanish) leads to the *exactness* conditions

$$a_{kl} = 0; \tag{b}$$

(ii) *rank* $\mathbf{P} = 2$ (i.e., *all* its 3×3 subdeterminants vanish) leads to the earlier *complete integrability* conditions (2.3.10a)

$$a_k a_{lp} + a_l a_{pk} + a_p a_{kl} = 0. \tag{c}$$

Problem 2.3.6 Show that for $n = 3$, equations (b, c) of the preceding problem become, respectively,

$$a_{kl} = 0 \qquad (k, l = 1, 2, 3), \tag{a}$$

and

$$a_1 a_{23} + a_2 a_{31} + a_3 a_{12} = 0 \qquad [\text{i.e., (2.3.6)}]. \tag{b}$$

Problem 2.3.7 Consider the Pfaffian equation (2.3.10). Subject its variables x to the invertible coordinate transformation (with nonvanishing Jacobian) $x \to x'$; in extenso:

$$x_k = x_k(x_{k'}) \;\Leftrightarrow\; x_{k'} = x_{k'}(x_k) \qquad (k, k' = 1, \ldots, n). \tag{a}$$

Show that the requirement that, under that transformation, the Pfaffian form $d'\theta$ remain (form) *invariant*; that is,

$$d'\theta \to (d'\theta)' \equiv \sum a_{k'}\, dx_{k'} = d'\theta \quad (= 0), \qquad a_{k'} = a_{k'}(x'), \tag{b}$$

leads to the following (covariant vector) transformations for the form coefficients:

$$a_{k'} = \sum (\partial x_k / \partial x_{k'}) a_k \;\Leftrightarrow\; a_k = \sum (\partial x_{k'} / \partial x_k) a_{k'}. \tag{c}$$

Problem 2.3.8 Continuing from the previous problem, define the antisymmetric quantities

$$a_{kl} = \partial a_k / \partial x_l - \partial a_l / \partial x_k \qquad (= -a_{lk}), \tag{a}$$

$$a_{k'l'} = \partial a_{k'} / \partial x_{l'} - \partial a_{l'} / \partial x_{k'} \qquad (= -a_{l'k'}), \qquad (k', l' = 1, \ldots, n). \tag{b}$$

Show that under the earlier invariance requirement $d'\theta \to (d'\theta)' = d'\theta$, the above quantities transform as (second-order covariant tensors):

$$a_{k'l'} = \sum\sum (\partial x_k / \partial x_{k'})(\partial x_l / \partial x_{l'}) a_{kl} \;\Leftrightarrow\; a_{kl} = \sum\sum (\partial x_{k'} / \partial x_k)(\partial x_{l'} / \partial x_l) a_{k'l'}. \tag{c}$$

Problem 2.3.9 Continuing from the preceding problems, assume that the x (and, therefore, also the x') depend on *two* parameters u_1 and u_2:

$$x_k = x_k(u_1, u_2) \qquad \text{and} \qquad x'_k = x'_k(u_1, u_2). \tag{a}$$

Introducing the simpler notation $d'\theta \equiv d\theta$ and $(d'\theta)' \equiv d\theta'$, show that

$$d_2(d_1\theta) - d_1(d_2\theta) = d_2(d_1\theta') - d_1(d_2\theta'), \tag{b}$$

where

$$d_1\theta = \sum a_k\, d_1x_k = \sum a_k[(\partial x_k/\partial u_1)du_1],$$
$$d_2\theta = \sum a_k\, d_2x_k = \sum a_k[(\partial x_k/\partial u_2)du_2],$$

are equivalent to

$$\sum\sum (\partial x_k/\partial u_1)(\partial x_l/\partial u_2)a_{kl} = \sum\sum (\partial x_{k'}/\partial u_1)(\partial x_{l'}/\partial u_2)a_{k'l'}. \qquad \text{(c)}$$

(ii) If the Pfaffian Constraint (2.3.10) has the Equivalent, (2.3.5, 7)-like, Special Form:

$$dz = \sum b_k(x, z)\, dx_k \qquad (k = 1, \ldots, n), \qquad \text{(2.3.10b)}$$

then, proceeding as in the three-dimensional case, or specializing (2.3.10a), we can show that the necessary and sufficient integrability conditions are the $n(n-1)/2$ independent identities [replacing n with $n+1$ in the earlier n_I, following (2.3.10a)]:

$$\partial b_k/\partial x_l + (\partial b_k/\partial z)b_l = \partial b_l/\partial x_k + (\partial b_l/\partial z)b_k \qquad (k, l = 1, \ldots, n). \qquad \text{(2.3.10c)}$$

Here, too, only the *existence* and *continuity* of the partial derivatives involved is needed.

(iii) General Case of $m(< n)$ Independent Pfaffian Equations in n Variables

[In the slightly special *total differential equation* form, with $x \equiv (x_D, x_I)$]:

$$dx_D = \sum b_{DI}(x)\, dx_I \qquad \text{or} \qquad \partial x_D/\partial x_I = b_{DI}(x) \qquad \text{(general form)}, \quad \text{(2.3.11)}$$

where (*here and throughout this book*)

$$D = 1, \ldots, m \text{ (for } \textbf{\textit{D}}\textit{ependent}) \qquad \text{and} \qquad I = m+1, \ldots, n \text{ (for } \textbf{\textit{I}}\textit{ndependent}),$$

$$b_{DI} = \text{given (continuously differentiable) functions of the } m \quad x_D = (x_1, \ldots, x_m),$$
$$\text{and the } (n-m) \quad x_I = (x_{m+1}, \ldots, x_n). \qquad \text{(2.3.11a)}$$

The system (2.3.11) is called holonomic or completely integrable [i.e., functions $x_D(x_I)$ can be found whose total differentials are given by (2.3.11)], if, for any set of initial values $x_{I,o}$, $x_{D,o}$, for which the b_{DI} are analytic, there exists one, and only one, set of D functions $x_D(x_I)$ satisfying (2.3.11) and taking on the initial values $x_{D,o}$ at $x_{I,o}$. It is shown in the theory of partial (total) differential equations—see references below—that:

For the system (2.3.11) to be *holonomic*, it is necessary and sufficient that the following conditions hold:

$$\partial b_{DI}/\partial x_{I'} + \sum b_{D'I'}(\partial b_{DI}/\partial x_{D'}) \;=\; \partial b_{DI'}/\partial x_I + \sum b_{D'I}(\partial b_{DI'}/\partial x_{D'})$$
$$[D, D' = 1, \ldots, m; \quad I, I' = m+1, \ldots, n], \qquad \text{(2.3.11b)}$$

identically in the x_D, x_I's [i.e., not just for some particular motion(s)] and for all combinations of the above values of their indices; if they hold for some, but not all, m values of D, then the system (2.3.11) is called "partially integrable."

Now, and this is very important, as the *second (sum)* term, on each side of (2.3.11b), shows, the *integrability* of the Dth constraint equation of (2.3.11) depends, through the coupling with $b_{D'I'}$ and $b_{D'I}$, on *all* the other constraint equations of that system; that is, each (2.3.11b) tests the integrability of the corresponding constraint equation (i.e., same D) against the *entire* system—in general, holonomicity/nonholonomicity are *system* not *individual* constraint properties.

Geometrically, integrability means that the system (2.3.11) yields a field of $(n-m)$*-dimensional surfaces in the n-dimensional space of the* x's; that is, mechanically, the system has $(n-m)$ *global* positional/Lagrangean coordinates, namely, $DOF(L) = DOF(S) = n - m$.

Further:

- With the notation

$$b_{DI} = b_{DI}(x_D, x_I) = b_{DI}[x_D(x_I), x_I] \equiv \beta_{DI}(x_I) \equiv \beta_{DI}, \qquad (2.3.11c)$$

  and since, by careful application of chain rule to the above,

$$\begin{aligned}\partial\beta_{DI}/\partial x_{I'} &= \partial b_{DI}/\partial x_{I'} + \sum (\partial b_{DI}/\partial x_{D'})(\partial x_{D'}/\partial x_{I'})\\ &= \partial b_{DI}/\partial x_{I'} + \sum (\partial b_{DI}/\partial x_{D'}) b_{D'I'},\end{aligned}$$

  [if $x_D = x_D(x_I)$, then $dx_D = \sum (\partial x_D/\partial x_I)\, dx_I = \sum b_{DI}(x)\, dx_I$] the holonomicity conditions (2.3.11b) can also be expressed in the following perhaps more intelligible/memorable ("exactness") form:

$$\partial\beta_{DI}/\partial x_{I'} = \partial\beta_{DI'}/\partial x_I \qquad (I' = m+1, \ldots, n); \qquad (2.3.11d)$$

- It is not hard to verify that the system (2.3.11b, d) stands for a total of $m(n-1)(n-2)/2$ identities, out of which, however, only $m(n-m)(n-m-1)/2 \equiv mf(f-1)/2$ are independent [$f \equiv n - m$; as in the general case of the first of (2.12.5)].
- In the special case where $b_{DI} = b_{DI}(x_I)$ [Chaplygin systems (§3.8)], (2.3.11b) reduce to the conditions:

$$\partial b_{DI}/\partial x_{I'} = \partial b_{DI'}/\partial x_I \qquad \text{[compare with (2.3.11d)]}, \qquad (2.3.11e)$$

  which, being *uncoupled*, test each constraint equation (2.3.11) *independently* of the others. Last, we point out that all these holonomicity conditions are special cases of the general theorem of Frobenius, which is discussed in §2.8–2.11.
- Equations (2.3.11b, d) also appear as necessary and sufficient conditions for a Riemannian ("curved") space to be Euclidean ("flat") $\Rightarrow$ vanishing of Riemann–Christoffel "curvature tensor"; and in the related *compatibility* conditions in nonlinear theory of strain—see, for example, Sokolnikoff (1951, pp. 96–100), Truesdell and Toupin (1960, pp. 271–274).
- *Historical*: The fundamental partial differential equations (2.3.11b) are due to the German mathematician H. W. F. Deahna [*J. für die reine und angewandte Mathematik* (*Crelle's Journal*) **20**, 340–349, 1840] and, also, the French mathematician J. C. Bouquet [*Bull. Sci. Math. et Astron.*, **3**(1), 265 ff., 1872]. For extensive and readable discussions, proofs, and so on, see, for example, De la Valée Poussin (1912,

pp. 312–336), Levi-Civita (1926, pp. 13–33), and the earlier Forsyth (1885/1954). Regrettably, most contemporary treatments of Pfaffian system integrability are written in the language of Cartan's "exterior forms," and so are virtually inaccessible to the average nonmathematician.

2.4 SYSTEM POSITIONAL COORDINATES AND SYSTEM FORMS OF THE HOLONOMIC CONSTRAINTS

So far, we have examined constraints in terms of *particle* vectors, and so on. Here, we begin to move into the main task of this chapter: to describe constrained systems in terms of general *system* variables. Let us assume that our originally free, or *unconstrained*, mechanical system S, consisting of N particles with inertial position vectors [recalling (2.2.4)]

$$\boldsymbol{r}_P = \boldsymbol{r}_P(t) = \{x_P(t),\ y_P(t), z_P(t)\} \qquad (P = 1, \ldots, N), \tag{2.4.1}$$

is now subject to $h(< 3N)$ *independent positional/geometrical/holonomic* (internal and/or external) constraints

$$\phi_H(t, \boldsymbol{r}_P) \equiv \phi_H(t, \boldsymbol{r}) \equiv \phi_H(t; x, y, z) = 0 \qquad [H = 1, \ldots, h(< 3N)], \tag{2.4.2}$$

or, in extenso,

$$\begin{gathered} \phi_1(t; x_1, y_1, z_1, \ldots, x_N, y_N, z_N) = 0, \\ \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots \\ \phi_h(t; x_1,\ y_1, z_1, \ldots, x_N, y_N, z_N) = 0; \end{gathered} \tag{2.4.2a}$$

where *independent* means that the $\phi_1, \ldots, \phi_h$ are not related by a(ny) functional equation of the form $\Phi(\phi_1, \ldots, \phi_h) = 0$ {In that case we would have, e.g., $\phi_h = F(t; \phi_1, \ldots, \phi_{h-1})$, so that one of the constraints (2.4.2, 2a), i.e., here $\phi_h = 0$, would either be a consequence of the rest of them [if $F(t; 0, \ldots, 0) \equiv 0$, while $\phi_h = 0$], or it would contradict them [if $F(t; 0, \ldots, 0) \neq 0$, while $\phi_h = 0$]}.

At this point, to simplify our discussion and improve our understanding, we rename the particle coordinates (x, y, z) as follows [recalling (2.2.1a)]:

$$x_1 \equiv \xi_1, \quad y_1 \equiv \xi_2, \quad z_1 \equiv \xi_3, \ldots, \quad x_N \equiv \xi_{3N-2}, \quad y_N \equiv \xi_{3N-1}, \quad z_N \equiv \xi_{3N}, \tag{2.4.3}$$

or, compactly,

$$x_P \equiv \xi_{3P-2}, \qquad y_P \equiv \xi_{3P-1}, \qquad z_P \equiv \xi_{3P} \qquad (P = 1, \ldots, N); \tag{2.4.3a}$$

in which case, the constraints (2.4.2a) read simply

$$\phi_H(t; \xi_1, \ldots, \xi_{3N}) \equiv \phi_H(t, \xi_*) = 0 \qquad [H = 1, \ldots, h(< 3N); \quad * = 1, \ldots, 3N]. \tag{2.4.3b}$$

Therefore, using the h constraints (2.4.2a, 3b), we can express h out of the $3N$ coordinates $\xi \equiv (x, y, z)$, say the first h of them ("dependent") in terms of the remaining $n \equiv 3N - h$ ("independent"), and time:

$$\xi_d = \Xi_d(t; \xi_{h+1}, \ldots, \xi_{3N}) \equiv \Xi_d(t; \xi_i) \qquad [d = 1, \ldots, h; \quad i = h + 1, \ldots, 3N]; \tag{2.4.4}$$

and so it is now clear that our system has n (*global*) *DOF*, h down from the previous $3N$ of the unconstrained situation. Further, since for $h = 3N$ (i.e., $n = 0$) the solutions of (2.4.2a) would, in general, be incompatible with the equations of motion and/or initial conditions, while for $h = 0$ (i.e., $n = 3N$) we are back to the original unconstrained system; therefore, we should always assume tacitly that

$$0 < h < 3N \qquad \text{or} \qquad 0 < n < 3N. \tag{2.4.5}$$

Now, to express this n-parameter freedom of our system, we can use either the last n of the ξ's [i.e., the earlier $\xi_i \equiv (\xi_{h+1}, \ldots, \xi_{3N})$], or, more generally, any other set of n independent (or unconstrained, or minimal), and generally *curvilinear*, coordinates, or *holonomic positional parameters*

$$\boldsymbol{q} \equiv [q_1 = q_1(t), \ldots, q_n = q_n(t)] \equiv \{q_k = q_k(t);\ k = 1, \ldots, n\},$$

or, simply,

$$q = (q_1, \ldots, q_n), \tag{2.4.6}$$

related to the ξ_i via invertible transformations of the type

$$\xi_i = \xi_i(t; q) \ \Leftrightarrow\ q_k = q_k(t; \xi_i). \tag{2.4.6a}$$

[The reader has, no doubt, already noticed that sometimes we use ξ_i for the *totality* of the independent ξ's; i.e., $(\xi_{h+1}, \ldots, \xi_{3N})$, and sometimes for *a generic one* of them; and similarly for other variables. We hope the meaning will be clear from the context.] In view of (2.4.6a), eq. (2.4.4) can be rewritten as

$$\xi_d = \Xi_d(t; \xi_i) = \Xi_d\big[t; \xi_i(t; q)\big] = \Xi_d(t; q), \tag{2.4.6b}$$

that is, in toto, $\xi_* = \xi_*(t, q)$, $* = 1, \ldots, 3N$; and so (2.2.4), (2.4.1) can be replaced by

$$x_P = x_P(t, q), \qquad y_P = y_P(t, q), \qquad z_P = z_P(t, q),$$

or

$$\boldsymbol{r}_P = \boldsymbol{r}_P(t, q), \tag{2.4.6c}$$

or, finally, by the definitive continuum notation,

$$\boldsymbol{r} = \boldsymbol{r}(t, q). \tag{2.4.7}$$

Let us pause and re-examine our findings.

(i) The $n \equiv 3N - h$ independent positional parameters $q = q(t)$ are, at every instant t, common to all particles of the system (even though not every particle, necessarily, depends on all of them); that is, the q's are *system* coordinates; but once known as functions of time they allow us, through (2.4.7), to calculate the motion of the *individual* particles of our system S. The q's are also called holonomic (or true, or genuine, or global), independent (or unconstrained, or minimal) coordinates, although they might be constrained later (!); for short, *Lagrangean coordinates*; and the problem of analytical mechanics (AM) is to calculate them as *functions of time*. Most authors call them "generalized coordinates" (and, similarly, "generalized velocities, accelerations, forces, momenta, etc."). This pretensorial/Victorian terminology, introduced (most likely) by Thomson and Tait [1912, pp. 157–60, 286 ff.; also 1867 (1st ed.)], though inoffensive, we think is misguiding, because it directs attention away from the true role of the q's: the key word here is not generalized but *system* (coordinates)! The fact that they are, or can be, general—that is, *curvilinear* (nonrectangular Cartesian, nonrectilinear)—which is the meaning intended by Thomson and Tait, is, of course, very welcome but secondary to AM, whose task is, among others, to express all its concepts, principles, and theorems in terms of system variables. Nevertheless, to avoid breaking with such an entrenched tradition, we shall be using both terms, generalized and system coordinates, and the earlier compact expression, Lagrangean coordinates.

(ii) The ability to represent by (2.4.7) the most general position (and, through it, motion) of every system particle (i.e., in terms of a *finite* number of parameters), before any other kinetic consideration, is absolutely critical ("nonnegotiable") to AM; without it, no further progress toward the derivation of (the smallest possible number of) equations of motion could be made.

(iii) Further, as pointed out by Hamel, as long as the representation (2.4.7) holds, the original assumption of discrete mass-points/particles is not really necessary. We could, just as well, have modeled our system as a rigid *continuum*; for example, a rigid body moving about a fixed point, whether assumed discrete or continuum, needs three q's to describe its most general (angular) motion, such as its three Eulerian angles (§1.12). In sum, as long as (2.4.7) is valid, AM does not care about the molecular structure/constitution of its systems. [However, as $n \to \infty$ (continuum mechanics), the description of motion changes so that the corresponding differential equations of motion experience a "qualitative" change from ordinary to partial.]

(iv) Even though, so far, $\boldsymbol{r}$ has been assumed inertial, nevertheless, the q's do *not* have to be inertial; they may define the system's configuration(s) relative to a *noninertial* body, or frame, of known or unknown motion, and that (on top of the possible curvilinearity of the q's) is an additional advantage of the Lagrangean method. (As shown later, the $\boldsymbol{r}$'s may also be noninertial.) For example, in the double pendulum of fig. 2.7, ϕ_1, ϕ_2, θ_1 are inertial angles, whereas θ_2 is not.

If the constraints are *stationary* ($\to$ *scleronomic system*), then we can choose the q's so that (2.4.7) assumes the stationary form [recalling (2.2.2 ff.)]:

$$\boldsymbol{r}_P = \boldsymbol{r}_P(q) \qquad \text{or} \qquad \boldsymbol{r} = \boldsymbol{r}(\boldsymbol{r}_o, q) \equiv \boldsymbol{r}(q); \tag{2.4.7a}$$

and, therefore, scleronomicity/rheonomicity (= absence/presence of $\partial\boldsymbol{r}/\partial t$) are q-dependent properties, unlike holonomicity/nonholonomicity.

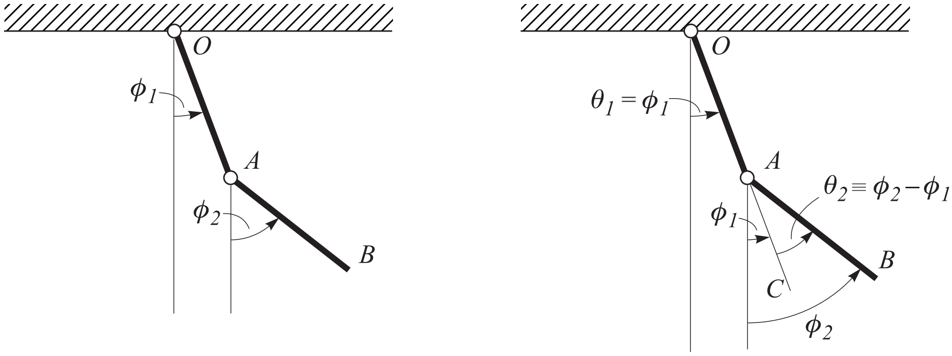

Figure 2.7 Inertial and noninertial descriptions of a double pendulum: *OA*, *AB*. Coordinates: $\phi_{1,2}$: inertial; $\theta_1 = \phi_1$: inertial; $\theta_2 \equiv \phi_2 - \phi_1$: noninertial; *O*, *A*, *C*: collinear.

Analytical Requirements on Equations (2.4.6a–c, 7)

The n q's are arbitrary, that is, nonunique, except that when the representations (2.4.6c, 7) are inserted back into the constraints (2.4.2, 2a) they must satisfy them identically in the q's, which, analytically, means that

$$\phi_H(t;\xi_*) = 0 \;\Rightarrow\; \phi_H[t;\xi_*(t;q)] \equiv 0 \;\Rightarrow\; \sum (\partial\phi_H/\partial\xi_*)(\partial\xi_*/\partial q_k) \equiv \partial\phi_H/\partial q_k \equiv 0,$$

where

$$H = 1, \ldots, h; \qquad * = 1, \ldots, 3N; \qquad k = 1, \ldots, n\,(\equiv 3N - h); \tag{2.4.8}$$

and where, due to the constraint independence and to (2.4.5), the Jacobians of the transformations $\phi_H \;\Leftrightarrow\; \xi_*$ and $\xi_* \;\Leftrightarrow\; q_k$ must satisfy

$$rank(\partial\phi_H/\partial\xi_*) = h, \qquad rank(\partial\xi_*/\partial q_k) = n \tag{2.4.8a}$$

[and since $|\partial\xi_i/\partial q_k| \neq 0 \;\Rightarrow\; rank(\partial\xi_i/\partial q_k) = n$], in the region of definition of the ξ and t. In addition, the functions in the transformations (2.4.6a, b) must be of class C^2 (i.e., have continuous partial derivatives of *zeroth*, *first*, and *second* order, at least, to accommodate accelerations) in the region of definition of the q's and t.

Last, conditions (2.4.8a) imply that the representations (2.4.6a, b) have a (nonunique) inverse:

$$q_k = q_k(t, \xi) \equiv q_k(t, x, y, z) = q_k = q_k(t, \boldsymbol{r}). \tag{2.4.8b}$$

Additional "regularity" requirements are presented in §2.7.

Example 2.4.1 Let us express the above analytical requirements in *particle* variables. Indeed, substituting into (2.2.8) and (2.2.10):

$$\boldsymbol{v} = d\boldsymbol{r}/dt = \sum (\partial\boldsymbol{r}/\partial q_k)(dq_k/dt) + \partial\boldsymbol{r}/\partial t \qquad (k = 1, \ldots, n), \tag{a}$$

we obtain, successively,

$$\begin{aligned} 0 = d\phi_H/dt &= S\,(\partial\phi_H/\partial\boldsymbol{r})\cdot\Big(\sum (\partial\boldsymbol{r}/\partial q_k)(dq_k/dt) + \partial\boldsymbol{r}/\partial t\Big) + \partial\phi_H/\partial t \\ &= \sum \Big(S\,(\partial\phi_H/\partial\boldsymbol{r})\cdot(\partial\boldsymbol{r}/\partial q_k)\Big)(dq_k/dt) \\ &\qquad\qquad + \Big(S\,(\partial\phi_H/\partial\boldsymbol{r})\cdot(\partial\boldsymbol{r}/\partial t) + \partial\phi_H/\partial t\Big) \\ &\equiv \sum (\partial\Phi_H/\partial q_k)(dq_k/dt) + \partial\Phi_H/\partial t, \end{aligned} \tag{b}$$

from which, since the *holonomic system velocities* dq_k/dt are independent,

$$\partial\Phi_H/\partial q_k = 0, \tag{c}$$

$$\partial\Phi_H/\partial t = 0. \tag{d}$$

Constraint Addition and Constraint Relaxation

The n q's (just like the h ϕ_H's) are *independent*; that is, we *cannot* couple them by *nontrivial* functions $\Phi(q) = 0$, independent of the problem's initial conditions, and such that upon substitution of the q's from (2.4.8b) into them they vanish identically in the ξ's and t (i.e., $\Phi[t, q(t, \xi)] \equiv \Phi(t, \xi) = 0$ is impossible). Thus, as in differential calculus, when all the q's except (any) one of them remain fixed, we are still left with a "nonempty" continuous numerical range for the nonfixed q's; and these latter correspond to a "nonempty" continuous kinematically admissible range of system configurations (a similar conception of independence will apply to the various q-differentials, $dq, \delta q, \ldots$, to be introduced later). However, upon subsequent imposition of *additional* holonomic constraints to the system, the n q's will no longer be independent, or minimal. To elaborate: in the "beginning," the system of particles is free, or unconstrained ("brand new"); then, its q's are the $3N$ ξ's. Next, it is subjected to a mix of constraints; say, h holonomic ones like (2.4.2, 2a), and m Pfaffian (possibly nonholonomic) ones like (2.2.7, 9). Now, the introduction of the $n = 3N - h$ q's, as explained above, allows us to *absorb*, or *build in*, or *embed*, the h holonomic constraints into our description; the representations (2.4.6c, 7) guarantee automatically the satisfaction of the holonomic constraints, and thus achieve the primary goal of Lagrangean kinematics, which is the expression of the system's configurations, at every constrained stage, by the *smallest*, or *minimal*, number of positional coordinates needed [which, in turn (chap. 3) results in the smallest number of equations of motion. The corresponding embedding of the Pfaffian constraints, which is the next important objective of Lagrangean kinematics (to be presented later, §2.11 ff.), follows a conceptually identical methodology, but requires new "nonholonomic, or quasi, coordinates"]. Specifically, if at a later stage, $h'(< n)$ *additional*, or residual, or non–built-in, independent holonomic constraints, say of the form

$$\Phi_{H'}(t, q) = 0 \qquad (H' = 1, \ldots, h'), \tag{2.4.9}$$

are imposed on our already constrained system, then, repeating the earlier procedure, we express the n q's in terms of $n' \equiv n - h'$ new positional parameters $q' \equiv (q_{k'}; k' = 1, \ldots, n')$:

$$q_k = q_k(t, q_{k'}), \qquad rank(\partial q/\partial q') = n', \tag{2.4.10}$$

so that, now, (2.4.7) may be replaced by

$$\boldsymbol{r} = \boldsymbol{r}(t, q) = \boldsymbol{r}[t, q(t, q')] \equiv \boldsymbol{r}(t, q'); \tag{2.4.11}$$

the representation (2.4.7) still holds, no matter how many holonomic and nonholonomic constraints are imposed on the system; but then our q's will not be independent: they have become the earlier ξ's.

This process of adding holonomic constraints to an already constrained system, one or more at a time, can be continued until the number of (global) DOF reduces to zero: $3N - (h + h' + h'' + \cdots) \to 0$. Also, no matter what the actual sequence (history) of constraint imposition is, it helps to imagine that they are applied successively, one or more at a time, in any desired order, until we reach the current, or last, state of "constrainedness" of the system. It helps to think of a given constrained system as being somewhere "in the middle of the constraint scale": when we first encounter it, it already has some constraints built into it; say, it was not born yesterday. Then, as part of a problem's requirements, it is being added new constraints that reduce its $DOF(L)$, eventually to zero; and, similarly, proceeding in the opposite direction, we may subtract some of its built-in constraints, thus *relaxing* the system and increasing its $DOF(L)$, eventually to $3N$. [Usually, such a (mental) relaxation of one or more built-in constraints is needed to calculate the reaction forces caused by them (→ principle of "relaxation," §3.7).]

In sum: Any given system may be viewed as having evolved from a former "relaxed" (younger) one by imposition of constraints; and it is capable of becoming a more "rigid" (older) one by imposition of additional constraints.

For example, let us consider a "newborn" free rigid body. The meaning of rigidity is that our system is *internally* constrained; and the meaning of free(dom) is that, when presented to us and unless additionally constrained later, the system is *externally* unconstrained; that is, at this point, its built-in constraints are all internal: hence, $n = 6$. If, from there on, we require it to have, say, one of its points fixed (or move in a prescribed way), then, essentially, we add to it three external (holonomic) constraints; that is, $n' = n - 3 = 6 - 3 = 3$. If, further, we require it to have one more point fixed, then we add two more such constraints; that is, $n'' = n' - 2 = 3 - 2 = 1$. And if, finally, we require that one more of its points (noncollinear with its previous two) be fixed, then we add one more such constraint; that is, $n''' = n'' - 1 = 1 - 1 = 0$. But if, on the other hand, we, mentally or actually, separate the original single free rigid body into two free rigid bodies, then we subtract from it six internal built-in constraints (in Hamel's terminology, we "liberate" the system from those constraints) so that this new relaxed system has $n + 6 = 6 + 6 = 12$ (global) DOF.

Equilibrium, or Adapted, Coordinates

Frequently, we choose, in E_{3N}, the following "equilibrium," or "adapted (to the constraints)" curvilinear coordinates:

$$\chi_1 \equiv \phi_1(t; x, y, z) \quad (= 0), \ldots, \qquad \chi_h \equiv \phi_h(t; x, y, z) \quad (= 0);$$
$$\chi_{h+1} \equiv \phi_{h+1}(t; x, y, z) \quad (\neq 0), \ldots, \qquad \chi_{3N} \equiv \phi_{3N}(t; x, y, z) \quad (\neq 0);$$

or, compactly,

$$\begin{aligned} \chi_d &\equiv \phi_d(t; x, y, z) \quad (= 0) \qquad (d = 1, \ldots, h); \\ \chi_i &\equiv \phi_i(t; x, y, z) \quad (\neq 0) \qquad (i = h + 1, \ldots, 3N), \end{aligned} \tag{2.4.12}$$

and $\chi_{3N+1} \equiv \phi_{3N+1} \equiv t$ $(\neq 0)$; where $\phi_d \equiv (\phi_1, \ldots, \phi_h)$ are the given constraints, and $\phi_i \equiv (\phi_{h+1}, \ldots, \phi_{3N})$ are n new and arbitrary functions, but such that when (2.4.12) are solved for the $3N + 1$ $(t; x, y, z)$, in terms of $(t; \chi_1, \ldots, \chi_{3N})$, and the results are substituted back into the constraints $\phi_d = 0$, they satisfy them identically in these variables. In terms of the latter, which are indeed a special case of q's, the constraints take the simple *equilibrium* forms:

$$\chi_d \equiv (\chi_1 = 0, \ldots, \chi_h = 0), \tag{2.4.12a}$$

and so (2.4.7), with $q \to \chi_i$, reduces to

$$\boldsymbol{r} = \boldsymbol{r}(t, \chi_{h+1}, \ldots, \chi_{3N}) \equiv \boldsymbol{r}(t, \chi_i). \tag{2.4.12b}$$

Clearly, the earlier choice (2.4.4) corresponds to the following special χ-case (assuming nonvanishing Jacobian of the transformation):

$$\chi_d = \chi_d(t, \xi) \equiv \xi_d - \Xi_d(t, \xi_i) = 0 \qquad (d = 1, \ldots, h),$$
$$\chi_i = \chi_i(t, \xi) \equiv \xi_i \neq 0 \qquad (i = h + 1, \ldots, 3N). \qquad (2.4.12c)$$

In practice, the transition from ξ to q, χ_i is frequently suggested "naturally" by the geometry of the particular problem. However, the general method described above [but in differential forms; i.e., as $d\chi_d \equiv d\phi_d$ $(= 0)$ and $d\chi_i \equiv d\phi_i$ $(\neq 0)$] will allow us, later (§2.11 ff.), to build in Pfaffian (possibly nonholonomic) constraints.

Finally, such equilibrium q, χ_i's extend to the case of the earlier described $n'(> 0)$ *additional* constraints. There we may choose the new equilibrium coordinates:

$$\chi'_{d'} \equiv \Phi_{d'} \quad (= 0) \qquad (d' = 1, \ldots, h'),$$
$$\chi'_{i'} \equiv \Phi_{i'} \quad (\neq 0) \qquad (i' = h' + 1, \ldots, n), \qquad (2.4.12d)$$

so that

$$\boldsymbol{r} = \boldsymbol{r}(t, q) \to \boldsymbol{r}(t, \chi'_{i'}). \qquad (2.4.12e)$$

Excess Coordinates

Sometimes, in a system possessing n minimal Lagrangean coordinates, $q = (q_1, \ldots, q_n)$, we introduce, say for mathematical convenience, e additional *excess*, or *surplus*, Lagrangean coordinates $q_E = (q_{n+1}, \ldots, q_{n+e})$. Since the $n + e$ positional coordinates q and q_E are nonminimal—that is, mutually dependent—they satisfy e constraints of the type

$$F_E(t; q_1, \ldots, q_n; q_{n+1}, \ldots, q_{n+e}) \equiv F_E(t; q, q_E) = 0 \qquad (E = 1, \ldots, e); \qquad (2.4.13)$$

and then we may have

$$\boldsymbol{r} = \boldsymbol{r}(t, q, q_E). \qquad (2.4.13a)$$

If we do not need the q_E's, we can easily get rid of them: solving the e equations (2.4.13) for them, we obtain $q_E = q_E(t; q)$, and substituting these expressions back into (2.4.13a) we recover (2.4.7). For this to be analytically possible we must have (see any book on advanced calculus)

$$|\partial F_E / \partial q_{E'}| \neq 0 \qquad (E = 1, \ldots, e;\ E' = n + 1, \ldots, n + e). \qquad (2.4.13b)$$

Example 2.4.2 Let us consider the planar three-bar mechanism shown in fig. 2.8. The O–xy coordinates of a generic point on bars OA_1 and A_2A_3 can be expressed in terms of the angles ϕ_1 and ϕ_3, respectively; similarly, for a generic point P on A_1A_2, such that $A_1P = l$, we have

$$x = l_1 \cos\phi_1 + l \cos\phi_2, \qquad y = l_1 \sin\phi_1 + l \sin\phi_2. \qquad (a)$$

So, ϕ_1, ϕ_2, ϕ_3 express the configurations of this system; but they are *not* minimal (i.e., independent). Indeed, taking the x, y components of the obvious vector equation

$$\boldsymbol{OA}_1 + \boldsymbol{A}_1\boldsymbol{A}_2 + \boldsymbol{A}_2\boldsymbol{A}_3 + \boldsymbol{A}_3\boldsymbol{O} = \boldsymbol{0},$$

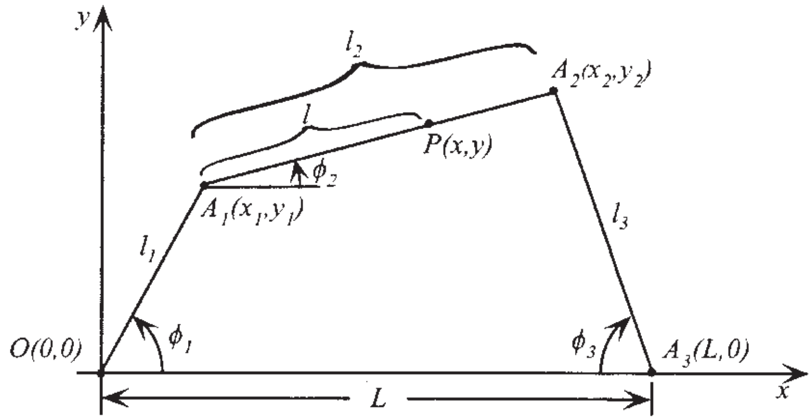

Figure 2.8 Excess coordinates in a planar three-bar mechanism.

we obtain the two constraints:

$$F_1 \equiv l_1 \cos\phi_1 + l_2 \cos\phi_2 + l_3 \cos\phi_3 - L = 0,$$
$$F_2 \equiv l_1 \sin\phi_1 + l_2 \sin\phi_2 - l_3 \sin\phi_3 = 0. \qquad \text{(b)}$$

Therefore, here, $n = 1$ and $e = 2$; knowledge of any *one* of these three angles determines the mechanism's configuration.

However, it is preferable to work with the representation (a), under (b), because if we tried to use the latter to express x and y in terms of either ϕ_1, or ϕ_2, or ϕ_3 only (wherever the corresponding Jacobian does not vanish), we would end up with fewer but *very* complicated looking equations of motion. It is preferable to have more but simpler equations (of motion and of constraint); that is, requiring minimality of coordinates, and thus embedding all holonomic constraints into the equations of motion, may be highly impractical. [See books on multibody dynamics; or Alishenas (1992). On the other hand, minimal formulations have numerical advantages (computational robustness).]

Another "excess representation" of this mechanism would be to use the *four* O–xy coordinates of A_1 and A_2, (x_1, y_1) and (x_2, y_2), respectively. Clearly, these latter are subject to the *three* constraints (so that, again, $n = 1$ but $e = 3$):

$$(x_1)^2 + (y_1)^2 = (l_1)^2; \qquad (x_2 - x_1)^2 + (y_2 - y_1)^2 = (l_2)^2;$$
$$(L - x_2)^2 + (0 - y_2)^2 = (l_3)^2. \qquad \text{(c)}$$

Example 2.4.3 Let us consider the planar double pendulum shown in fig. 2.9. The *four* bob coordinates x_1, y_1 and x_2, y_2 are constrained by the *two* equations

$$(x_1)^2 + (y_1)^2 = (l_1)^2, \qquad (x_2 - x_1)^2 + (y_2 - y_1)^2 = (l_2)^2; \qquad \text{(a)}$$

that is, here $N = 2 \Rightarrow 2N = 4$, and so the number of *holonomic constraints* $\equiv H = 2 \Rightarrow n = 2N - H = 2$. A convenient minimal representation of the pendulum's

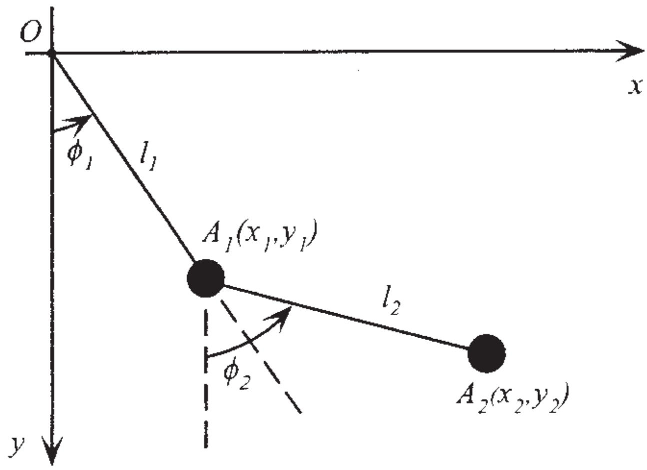

Figure 2.9 Excess coordinates in a planar double pendulum.

configurations is

$$x_1 = l_1 \cos\phi_1, \qquad y_1 = l_1 \sin\phi_1;$$
$$x_2 = l_1 \cos\phi_1 + l_2 \cos\phi_2, \qquad y_2 = l_1 \sin\phi_1 + l_2 \sin\phi_2. \tag{b}$$

2.5 VELOCITY, ACCELERATION, ADMISSIBLE AND VIRTUAL DISPLACEMENTS; IN SYSTEM VARIABLES

Velocity and Acceleration

We begin with the fundamental representation of the inertial position of a typical system particle P in Lagrangean variables (2.4.7):

$$\boldsymbol{r} = \boldsymbol{r}(t, q). \tag{2.5.1}$$

[Again, the inertialness of $\boldsymbol{r}$ is not essential, and is stated here just for concreteness. The methodology developed below applies to inertial and noninertial position vectors alike; and this, along with the possible curvilinearity (nonrectangular Cartesianness) and possible noninertialness of the coordinates, are the two key advantages of Lagrangean kinematics (and, later, kinetics) over that of Newton–Euler. This will become evident in the Lagrangean treatment of relative motion (§3.16).]

From this, it readily follows that the (inertial) *velocity* and *acceleration* of P, in these variables, are, respectively,

$$\boldsymbol{v} \equiv d\boldsymbol{r}/dt = \sum (\partial\boldsymbol{r}/\partial q_k)(dq_k/dt) + \partial\boldsymbol{r}/\partial t \equiv \sum v_k \boldsymbol{e}_k + \boldsymbol{e}_0, \tag{2.5.2}$$

$$\begin{aligned}\boldsymbol{a} \equiv d\boldsymbol{v}/dt &= \sum (\partial\boldsymbol{r}/\partial q_k)(d^2 q_k/dt^2) + \sum\sum (\partial^2\boldsymbol{r}/\partial q_k\,\partial q_l)(dq_k/dt)(dq_l/dt) \\ &\qquad + 2\sum (\partial^2\boldsymbol{r}/\partial q_k\,\partial t)(dq_k/dt) + \partial^2\boldsymbol{r}/\partial t^2 \\ &\equiv \sum w_k \boldsymbol{e}_k + \sum\sum v_k v_l\, \boldsymbol{e}_{k,l} + 2\sum v_k \boldsymbol{e}_{k,0} + \boldsymbol{e}_{0,0},\end{aligned} \tag{2.5.3}$$

where

$$dq_k/dt \equiv v_k, \qquad v = (v_1, \ldots, v_n) \equiv (v_k; k = 1, \ldots, n), \tag{2.5.2a}$$

$$d^2q_k/dt^2 \equiv dv_k/dt \equiv w_k, \qquad w = (w_1, \ldots, w_n) \equiv (w_k; k = 1, \ldots, n)$$

$$\text{[but, in general,} \quad \boldsymbol{a} \neq \sum w_k \boldsymbol{e}_k + w_0 \boldsymbol{e}_0; \qquad \text{see (2.5.4–6) below)]}, \tag{2.5.3a}$$

associated with these q's; and the fundamental (holonomic) basis vectors $\boldsymbol{e}_k$, $\boldsymbol{e}_0$, also associated with the q's, are defined by

$$\boldsymbol{e}_k = \boldsymbol{e}_k(t, q) \equiv \partial \boldsymbol{r}/\partial q_k, \qquad \boldsymbol{e}_0 = \boldsymbol{e}_0(t, q) \equiv \partial \boldsymbol{r}/\partial t \qquad \text{(or, sometimes, } \boldsymbol{e}_{n+1}, \text{ or } \boldsymbol{e}_t); \tag{2.5.4}$$

and the commas signify *partial derivatives* with respect to the q's, t:

$$\boldsymbol{e}_{k,l} \equiv \partial \boldsymbol{e}_k/\partial q_l = \partial \boldsymbol{e}_l/\partial q_k = \boldsymbol{e}_{l,k} \qquad [\text{i.e., } \partial/\partial q_l(\partial \boldsymbol{r}/\partial q_k) = \partial/\partial q_k(\partial \boldsymbol{r}/\partial q_l)], \tag{2.5.4a}$$

$$\boldsymbol{e}_{k,0} \equiv \partial \boldsymbol{e}_k/\partial t = \partial \boldsymbol{e}_0/\partial q_k = \boldsymbol{e}_{0,k} \qquad [\text{i.e., } \partial/\partial t(\partial \boldsymbol{r}/\partial q_k) = \partial/\partial q_k(\partial \boldsymbol{r}/\partial t)]; \tag{2.5.4b}$$

we reserve the notation a_k for the representation $\boldsymbol{a} = \sum a_k \boldsymbol{e}_k + a_0 \boldsymbol{e}_0$.

Also, note that with the help of the formal (nonrelativistic) notations:

$$t \equiv q_0 \equiv q_{n+1} \;\Rightarrow\; dt/dt \equiv dq_0/dt \equiv dq_{n+1}/dt \equiv v_0 \equiv v_{n+1} = 1, \tag{2.5.5a}$$

and

$$d^2t/dt^2 \equiv dv_0/dt \equiv dv_{n+1}/dt \equiv w_0 \equiv w_{n+1} = 0, \tag{2.5.5b}$$

we can rewrite (2.5.2, 3), respectively, in the "stationary" forms:

$$\boldsymbol{v} = \sum v_\alpha \boldsymbol{e}_\alpha, \qquad \boldsymbol{a} = \sum w_\alpha \boldsymbol{e}_\alpha + \sum\sum v_\alpha v_\beta \, \boldsymbol{e}_{\alpha,\beta}, \tag{2.5.6}$$

where, *here and throughout the rest of the book*, Greek subscripts range from 1 to $n + 1$ ($\equiv$ "0").

The $v_k \equiv dq_k/dt$ are the *holonomic* (and *contravariant*, in the sense of tensor algebra) *components*, in the q-coordinates, of the system *velocity* or, simply, *Lagrangean velocities* or, briefly, but not quite accurately, "generalized velocities." The key point here is that the velocity and acceleration of each *particle*, $\boldsymbol{v}$ and $\boldsymbol{a}$, respectively, are expressed in terms of *system* velocities $v \equiv dq/dt$ and their rates $w \equiv dv/dt \equiv d^2q/dt^2$, which are *common* to all particles, via the (generally, neither unit nor orthogonal) "mixed" = *particle and system*, basis vectors $\boldsymbol{e}_k$, $\boldsymbol{e}_0$. The latter, since they effect the *transition from particle to system quantities*, are fundamental to Lagrangean mechanics.

HISTORICAL

These vectors, most likely introduced by Somoff (1878, p. 155 ff.), were brought to prominence by Heun (in the early 1900s; e.g., Heun, 1906, p. 67 ff., 78 ff.), and were called by him *Begleitvektoren* ≈ accompanying, or attendant, vectors. Perhaps a better term would be "H(olonomic) mixed basis vectors" (see also Clifford, 1887, p. 81).

From the above, we readily deduce the following basic kinematical *identities*:

(i)

$$\partial \boldsymbol{r}/\partial q_k = \partial \boldsymbol{v}/\partial v_k = \partial \boldsymbol{a}/\partial w_k = \cdots \equiv \boldsymbol{e}_k, \tag{2.5.7}$$

that is, [with $(\ldots)^{\cdot} \equiv d(\ldots)/dt$],

$$\partial\boldsymbol{r}/\partial q_k = \partial\dot{\boldsymbol{r}}/\partial\dot{q}_k = \partial\ddot{\boldsymbol{r}}/\partial\ddot{q}_k = \cdots = \boldsymbol{e}_k \qquad \text{(“cancellation of the (over)dots”);} \tag{2.5.7a}$$

and

(ii) $$d/dt(\partial\boldsymbol{r}/\partial q_k) \equiv d/dt\,(\partial\boldsymbol{v}/\partial v_k) \equiv d\boldsymbol{e}_k/dt = \partial/\partial q_k\,(d\boldsymbol{r}/dt) \equiv \partial\boldsymbol{v}/\partial q_k,$$

or, with the help of the *Euler–Lagrange operator* in holonomic coordinates:

$$E_k(\ldots) \equiv d/dt(\ldots/\partial\dot{q}_k) - \partial\ldots/\partial q_k \equiv d/dt(\ldots/\partial v_k) - \partial\ldots/\partial q_k, \tag{2.5.9}$$

finally,

$$E_k(\boldsymbol{v}) \equiv d/dt(\partial\boldsymbol{v}/\partial v_k) - \partial\boldsymbol{v}/\partial q_k = \boldsymbol{0}. \tag{2.5.10}$$

In fact, for any well-behaved function $f = f(t, q)$, we have

$$\dot{f} \equiv df/dt \equiv \sum (\partial f/\partial q_k)(dq_k/dt) + \partial f/\partial t, \qquad \ddot{f} \equiv d^2 f/dt^2 = \cdots,$$

$$\Rightarrow\ \partial f/\partial q_k = \partial\dot{f}/\partial\dot{q}_k = \partial\ddot{f}/\partial\ddot{q}_k = \cdots; \tag{2.5.8}$$

and

$$E_k(f) \equiv d/dt\,(\partial f/\partial\dot{q}_k) - \partial f/\partial q_k \equiv d/dt\,(\partial f/\partial v_k) - \partial f/\partial q_k = 0. \tag{2.5.11}$$

The *integrability* conditions (2.5.7, 10) are crucial to Lagrangean kinetics (chap. 3); and, just like (2.5.2, 3), have nothing to do with constraints; that is, they hold the same, even if holonomic and/or nonholonomic constraints are later imposed on the system, as long as the q's are holonomic (genuine) coordinates (i.e., $q \neq$ nonholonomic or quasi coordinates; see §2.6, §2.9).

Admissible and Virtual Displacements

Proceeding as with the velocities, (2.5.2), we define the (first-order and inertial) *kinematically admissible*, or *possible*, and *virtual* displacements of a generic system particle P, respectively, by

$$d\boldsymbol{r} = \sum (\partial\boldsymbol{r}/\partial q_k)\,dq_k + (\partial\boldsymbol{r}/\partial t)\,dt \equiv \sum \boldsymbol{e}_k\,dq_k + \boldsymbol{e}_0\,dt, \tag{2.5.12a}$$

$$\delta\boldsymbol{r} = \sum (\partial\boldsymbol{r}/\partial q_k)\,\delta q_k \equiv \sum \boldsymbol{e}_k\,\delta q_k; \tag{2.5.12b}$$

whether the q-increments, or differentials, dq, δq, and dt are *independent or not* (say, by imposition of additional holonomic and nonholonomic constraints, later).

As the above show:

(i) if $dq_k = (dq_k/dt)\,dt \equiv v_k\,dt$, then $d\boldsymbol{r} = \boldsymbol{v}\,dt$;
(ii) if *all* the dq's and dt (δq's) vanish, then $d\boldsymbol{r} = \boldsymbol{0}$ ($\delta\boldsymbol{r} = \boldsymbol{0}$); and
(iii) $\partial(d\boldsymbol{r})/\partial(dq_k) = \partial(\delta\boldsymbol{r})/\partial(\delta q_k) = \boldsymbol{e}_k$.

These identities (in unorthodox but highly instructive notation) are useful in preparing the reader to understand, later, the nonholonomic coordinates.

REMARKS ON THE VIRTUAL DISPLACEMENT

Let us, now, pause to examine carefully this fundamental concept. First, we notice that $\delta\boldsymbol{r}$ is the *linear* (or *first-order*) and *homogeneous*, in the δq's, part of the "total virtual displacement" $\Delta\boldsymbol{r}$, which is defined by the following Taylor-like $\boldsymbol{r}$-expansion in the first-order increments δq, from a generic system configuration corresponding to the values q, but for *a fixed time t*:

$$\Delta\boldsymbol{r} \equiv \boldsymbol{r}(t, q + \delta q) - \boldsymbol{r}(t, q) \equiv \delta\boldsymbol{r} + (1/2)\,\delta^2\boldsymbol{r} + \cdots. \tag{2.5.13}$$

In other words, $\delta\boldsymbol{r}$ is a *special first position differential*, mathematically equivalent to $d\boldsymbol{r}$ with $t = constant \to dt = 0$ (i.e., completely equivalent to it for *stationary* constraints); hence, the special notation $\delta(\ldots)$:

$$d\boldsymbol{r} \to \delta\boldsymbol{r}, \qquad dq \to \delta q, \qquad \text{and} \qquad dt \to \delta t = 0 \text{ (isochrony, } always\text{)}. \tag{2.5.13a}$$

One could have denoted it as $d^*\boldsymbol{r}$, or $(d\boldsymbol{r})^*$, or $\boldsymbol{z}$, and so on; but since we do not see anything wrong with $\delta(\ldots)$, and to keep with the best traditions of analytical mechanics [originated by Lagrange himself and observed by all mechanics masters, such as Kirchhoff, Routh, Schell, Thomson and Tait, Gibbs, Appell, Volterra, Poincaré, Maggi, Webster, Heun, Hamel, Prange, Whittaker, Chetaev, Lur'e, Synge, Gantmacher, Pars et al.], we shall stick with it. Readers who feel uncomfortable with $\delta(\ldots)$ may devise their own suggestive notation; $d\boldsymbol{r}$ and dq won't do!

The above definitions also show the following:

(i) $\delta\boldsymbol{r}$ is mathematically equivalent to the *difference* between two possible/admissible displacements, say $d_1\boldsymbol{r}$ and $d_2\boldsymbol{r}$, taken along *different directions* but at the *same time* (and *same dt*); that is, skipping summation signs and subscripts, for simplicity,

$$\begin{aligned} d_2\boldsymbol{r} - d_1\boldsymbol{r} &= [(\partial\boldsymbol{r}/\partial q)\, d_2 q + (\partial\boldsymbol{r}/\partial t)\, dt] - [(\partial\boldsymbol{r}/\partial q)\, d_1 q + (\partial\boldsymbol{r}/\partial t)\, dt] \\ &= (\partial\boldsymbol{r}/\partial q)(d_2 q - d_1 q) \sim (\partial\boldsymbol{r}/\partial q)\, \delta q = \delta\boldsymbol{r}. \end{aligned} \tag{2.5.14}$$

(ii) For any well-behaved function $f = f(t)$: $\delta f = (\partial f/\partial t)\, \delta t = 0$; but if $f = f(t, q)$, then $\delta f = (\partial f/\partial q)\, \delta q \neq 0$ [even though, *after* the problem is solved, $q = q(t)$!].

(iii) The virtual displacements of mechanics do not always coincide with those of mathematics (i.e., calculus of variations). For example, even though, in general, $d\boldsymbol{r} \neq \delta\boldsymbol{r}$, for *catastatic* systems [i.e., $d\boldsymbol{r} = \sum \boldsymbol{e}_k(t, q)\, dq_k$, $\delta\boldsymbol{r} = \sum \boldsymbol{e}_k(t, q)\, \delta q_k$] the equality $dq_k = \delta q_k \Rightarrow d\boldsymbol{r} = \delta\boldsymbol{r}$ is kinematically possible [and in (q, t)-space $d\boldsymbol{r}$ and $\delta\boldsymbol{r}$ are "orthogonal" to the t-axis, even though $dt \neq 0$, $\delta t = 0$]; whereas, in variational calculus we are explicitly warned that dq (*parallel* to the t-axis) $\neq \delta q$ (*perpendicular* to it). These differences, rarely mentioned in mechanics and/or mathematics books, are very consequential, especially in *integral* variational principles for nonholonomic systems (chap. 7).

As definitions (2.5.12, 13), and so on, show, the (particle and/or system) virtual displacement is a simple, direct, and, as explained in chapter 3 and elsewhere, *indispensable* concept — without it Lagrangean mechanics would be impossible! Yet, since its inception (in the early 18th century), this concept has been surrounded with mysticism and confusion; and even today it is frequently misunderstood and/or ignorantly maligned. For instance, it has been called "too vague and cumbersome to be of practical use" by D. A. Levinson, in discussion in Borri et al. (1992); "ill-defined, nebulous, and hence objectionable" by T. R. Kane, in rebuttal to Desloge (1986); or, at best, has been given the impression that it has to be defined, or "chosen properly" (Kane and Levinson (1983)), in an ad hoc or a posteriori fashion to fit the facts, that is, to produce the correct equations of motion. For an extensive rebuttal of these false and misleading statements, from the viewpoint of kinetics, see chap. 3, appendix II. Others object to the arbitrariness of the δq's. But it is precisely in this arbitrariness that their strength and effectiveness lies: they do the job (e.g., yielding of the equations of motion) and then, modestly, retreat to the background leaving behind the mixed basis vectors $\boldsymbol{e}_k$. It is these latter [and their nonholonomic counterparts (§2.9)] that appear in the final equations of motion (chap. 3), just as in the derivation of differential ("field") equations in other areas of mathematical physics. For example, in continuum mechanics, for better visualization, we may employ a small spatial element (e.g., a "control volume"), of "infinitesimal" dimensions dx, dy, dz, to derive the local field equations of balance of mass, momentum, energy, and so on; but the ultimate differential equations never contain lone differentials—only combinations of finite limits of ratios among them; that is, *combinations of derivatives*. Moreover, differentials, actual/admissible/virtual, in addition to being easier to visualize than derivatives, are *invariant* under coordinate transformations; whereas derivatives are not. [Such invariance ideas led the Italian mathematicians G. Ricci and T. Levi-Civita to the development of *tensor* calculus (late 19th to early 20th century); see, for example, Papastavridis (1999).] For example, taking for simplicity, a one (global) *DOF* system, under the transformation $q \to q' = q'(t, q)$, we find, successively,

$$\delta \boldsymbol{r} = \boldsymbol{e}\, \delta q = (\partial \boldsymbol{r}/\partial q)\, \delta q = (\partial \boldsymbol{r}/\partial q)[(\partial q/\partial q')\, \delta q'] = [(\partial \boldsymbol{r}/\partial q)(\partial q/\partial q')]\, \delta q' \equiv \boldsymbol{e}'\, \delta q',$$

that is,

$$\boldsymbol{e}' \equiv \partial \boldsymbol{r}/\partial q' = (\partial q/\partial q')\boldsymbol{e} \;\Leftrightarrow\; \boldsymbol{e} \equiv \partial \boldsymbol{r}/\partial q = (\partial q'/\partial q)\boldsymbol{e}'. \tag{2.5.15}$$

But there is an additional, deeper, reason for the representation (2.5.12b): the position vectors $\boldsymbol{r}(t, q)$ and (possible) additional constraints, say $\psi_{H'}(t, \boldsymbol{r}) = 0 \to \psi_{H'}(t, q) = 0$, *cannot* be attached in these finite forms to the general kinetic principles of analytical mechanics, which are differential, and lead to the equations of motion (§3.2 ff.). Only virtual forms of $\boldsymbol{r}$ and $\psi_{H'} = 0$—special first differentials of them, linear and homogeneous in the δq's [like (2.5.12b)]—can be attached, or *adjoined*, to the Lagrangean variational equation of motion via the well-known method of *Lagrangean multipliers* (§3.5 ff.); and similarly for nonlinear (non-Pfaffian) velocity constraints, an area that shows clearly that nonvirtual schemes (as well as those based on the calculus of variations) break down (chap. 5)! Hence, the older admonition that the virtual displacements must be "small" or "infinitesimal." For example, to incorporate the *nonlinear* holonomic constraint $\phi(x, y) \equiv x^2 + y^2 = constant$ to the kinetic principles, we must attach to them its first virtual differential, $\delta\phi = 2(x\, \delta x + y\, \delta y) = 0$; which is the linear and homogeneous part of the total constraint change, between the system configurations (x, y) and $(x + \delta x,\ y + \delta y)$:

$$\Delta\phi \equiv \phi(x + \delta x,\ y + \delta y) - \phi(x, y) = [\delta\phi + (1/2)\, \delta^2\phi]_{\text{for small } \delta x,\, \delta y} \approx \delta\phi = 0.$$

But in the case of the *linear* holonomic constraint $\phi \equiv x + y = constant$, that total constraint change equals

$$\Delta\phi = \delta\phi = \delta x + \delta y = 0, \qquad \text{no matter what the size of } \delta x,\ \delta y;$$

and both equations, $\phi = 0$ and $\delta\phi = 0$, have the same coefficients ($\to$ slopes).

In sum: As long as we take the first virtual differentials of the constraints, the size of the δq's is inconsequential, whether they are one millimeter or ten million miles! It is the holonomic (or "gradient," or "natural") basis vectors $\{\boldsymbol{e}_k;\, k = 1, \ldots, n\}$, that matter.

As Coe puts it: "We often speak of displacements, both virtual and real, as being *arbitrarily small or infinitesimal*. This means that we are concerned only with the limiting directions of these displacements and the limiting values of the ratios of their lengths as they approach zero. Thus any two systems of virtual displacements are for our purposes identical if they have the same limiting directions and length ratios as they approach zero" (1938, p. 377). Coe's seems to be the earliest correct and vectorial exposition of these concepts in English; most likely, following the exposition of Burali-Forti and Boggio (1921, pp. 136 ff.). See also Lamb (1928, p. 113).

The earlier mentioned indispensability of the virtual displacements for kinetics will become clearer in chapter 3. Nevertheless, here is a preview: it is the *virtual* work of the forces maintaining the holonomic and/or nonholonomic constraints (i.e., the *constraint reactions*) that vanishes, and not just any work, admissible or actual; in fact, the latter would supply only *one* equation. This vanishing-of-the-virtual-work-of-constraint-reactions (principle of d'Alembert–Lagrange) is a physical postulate that generates not just one equation of motion (like the actual work/power equation does), but as many as the number of (local) *DOFs*; and, additionally, it allows us to eliminate/calculate these constraint forces. A more specialized virtual displacement $\rightarrow$ virtual work-based postulate is used to characterize the more general "servo/control" constraints (§3.17).

Example 2.5.1 *Differences Between Kinematically Admissible/Possible and Virtual Displacements.*

(i) Let us assume that we seek to determine the motion of a particle P capable of sliding along an ever straight line l rotating on the plane O–xy about O. The configurations of l and of P relative to that plane are determined, respectively, by ϕ and r, ϕ (fig. 2.10). Since $\boldsymbol{r} = \boldsymbol{r}(r, \phi)$: position of P in O–xy, we will have, in the most general case,

$$d\boldsymbol{r} = (\partial \boldsymbol{r}/\partial r)\, dr + (\partial \boldsymbol{r}/\partial \phi)\, d\phi\text{: kinematically admissible displacement of } P\text{, in } O\text{–}xy, \tag{a}$$

$$\delta \boldsymbol{r} = (\partial \boldsymbol{r}/\partial r)\, \delta r + (\partial \boldsymbol{r}/\partial \phi)\, \delta\phi\text{: virtual displacement of } P\text{, in } O\text{–}xy. \tag{b}$$

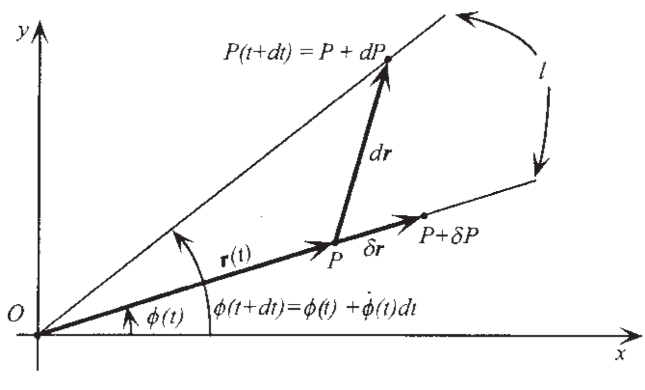

Figure 2.10 On the difference between possible/admissible and virtual displacements (ex. 2.5.1: a, b).

(a) If the rotation of l is influenced by the motion of P relative to it, then ϕ is another unknown Lagrangean coordinate, like r, waiting to be found from the equations of motion of the system P *and* l (i.e., $n = 2$). Then $d\boldsymbol{r}$ and $\delta\boldsymbol{r}$ are given by (a, b), respectively, and are mathematically equivalent. (b) If, however, the motion of l is known ahead of time (i.e., if it is constrained to rotate in a specified way, uninfluenced by the, yet unknown, motion of P), then

$$\phi = f(t)\text{: given function of time} \Rightarrow$$

$$d\phi = df(t) = [df(t)/dt]\, dt \equiv \omega(t)\, dt \neq 0, \qquad \text{but} \qquad \delta\phi = \delta f(t) = \omega(t)\, \delta t = 0.$$

As a result, (a, b) yield

$$d\boldsymbol{r} = (\partial\boldsymbol{r}/\partial r)\, dr + (\partial\boldsymbol{r}/\partial\phi)\, d\phi = (\partial\boldsymbol{r}/\partial r)\, dr + (\partial\boldsymbol{r}/\partial\phi)\, \omega(t)\, dt = d\boldsymbol{r}(t, r; dt, dr), \quad \text{(c)}$$

$$\delta\boldsymbol{r} = (\partial\boldsymbol{r}/\partial r)\, \delta r = \delta\boldsymbol{r}(t, r; \delta r). \quad \text{(d)}$$

(ii) Let us consider the motion of a particle P along the inclined side of a wedge W that moves with a *given* horizontal motion: $x = f(t)$ (fig. 2.11). Here, we have

$$\boldsymbol{MM}_1 = \boldsymbol{M}_3\boldsymbol{M}_2 = (\partial\boldsymbol{r}/\partial x)\, dx = (\partial\boldsymbol{r}/\partial x)[df(t)/dt]\, dt = (\partial\boldsymbol{r}/\partial t)\, dt \sim dt; \quad \text{(e)}$$

$$\boldsymbol{MM}_3 = \boldsymbol{M}_1\boldsymbol{M}_2 = \delta\boldsymbol{r} = (\partial\boldsymbol{r}/\partial q)\, \delta q \sim \delta q; \quad \text{(f)}$$

$$\boldsymbol{MM}_2 \sim d\boldsymbol{r} = (\partial\boldsymbol{r}/\partial q)\, dq + (\partial\boldsymbol{r}/\partial t)\, dt; \qquad \text{but} \;\; \delta x = 0. \quad \text{(g)}$$

(iii) Let us consider the motion of a particle P on the fixed and rigid surface $\phi(x, y, z) = 0$ or $z = z(x, y)$. Then, $\boldsymbol{r} = \boldsymbol{r}(x, y, z) = \boldsymbol{r}[x, y, z(x, y)] \equiv \boldsymbol{r}(x, y)$, and the classes of $d\boldsymbol{r}$ and $\delta\boldsymbol{r}$ are equivalent. But, on the moving and possibly deforming surface $\phi(t; x, y, z) = 0$ or $z = z(x, y; t)$, $\boldsymbol{r} = \cdots = \boldsymbol{r}(t; x, y)$, and so $d\boldsymbol{r} \neq \delta\boldsymbol{r}$: $\delta\boldsymbol{r}$ still lies on the instantaneous tangential plane of the surface at P, whereas $d\boldsymbol{r}$ does not.

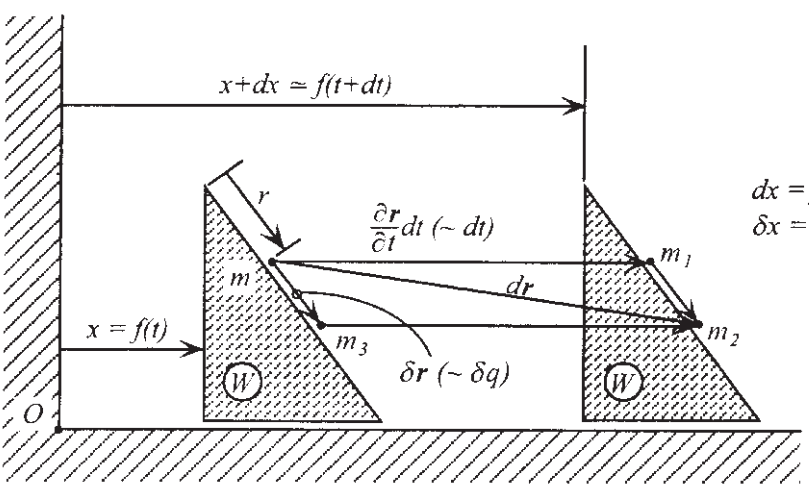

Figure 2.11 On the difference between possible/admissible and virtual displacements (ex. 2.5.1: b).

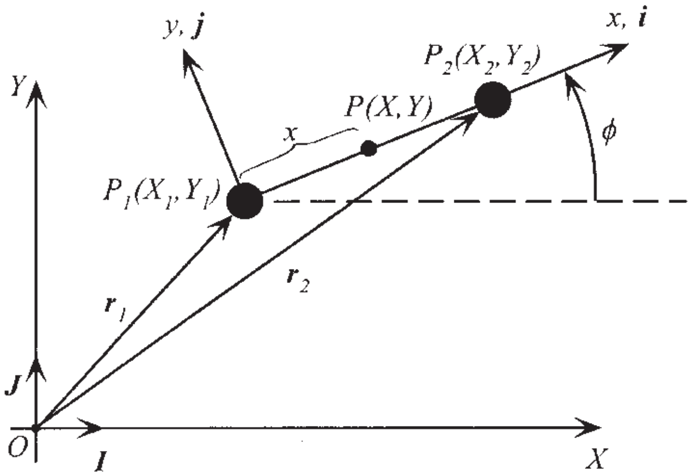

Figure 2.12 Two-particle system connected by a light rod.

Example 2.5.2 *Lagrangean Coordinates and Virtual Displacements.* Let us determine the Lagrangean description $\boldsymbol{r} = \boldsymbol{r}(\boldsymbol{r}_o; t, q)$ and corresponding virtual displacements $\delta\boldsymbol{r} = \cdots$ for the following systems:

(i) Two particles, P_1 and P_2, are connected by a massless rod of length l, in plane motion (fig. 2.12). For an arbitrary rod point $P(X, Y)$, including P_1 and P_2, we have

$$X = X_1 + x\cos\phi = X(x; X_1, \phi), \qquad Y = Y_1 + x\sin\phi = Y(x; Y_1, \phi), \tag{a}$$

or, vectorially,

$$\boldsymbol{r} = \boldsymbol{r}_1 + x\boldsymbol{i} = \boldsymbol{r}(x; X_1, Y_1, \phi), \qquad 0 \le x \le l. \tag{b}$$

Therefore, $\boldsymbol{r}_o = x\boldsymbol{i}$; while the (inertial) positions of P_1 and P_2 are given, respectively, by

$$\boldsymbol{r}_1 = \boldsymbol{r}(0; X_1, Y_1, \phi) = X_1\boldsymbol{I} + Y_1\boldsymbol{J}, \tag{c}$$

$$\begin{aligned}\boldsymbol{r}_2 = \boldsymbol{r}(l; X_1, Y_1, \phi) &= (X_1 + l\cos\phi)\boldsymbol{I} + (Y_1 + l\sin\phi)\boldsymbol{J}\\ &= (X_1\boldsymbol{I} + Y_1\boldsymbol{J}) + l(\cos\phi\boldsymbol{I} + \sin\phi\boldsymbol{J}) = \boldsymbol{r}_1 + l\boldsymbol{i}.\end{aligned} \tag{d}$$

Hence, this is a (holonomic) *three DOF* system: $q_1 = X_1$, $q_2 = Y_1$, $q_3 = \phi$. From (a) we obtain, for the virtual displacements,

$$\delta X = \delta X_1 + x(-\sin\phi)\,\delta\phi, \qquad \delta Y = \delta Y_1 + x(\cos\phi)\,\delta\phi; \tag{e}$$

or, vectorially,

$$\delta\boldsymbol{r} = \delta\boldsymbol{r}_1 + x\,\delta\boldsymbol{i} = \delta\boldsymbol{r}_1 + x[(\delta\phi\,\boldsymbol{k}) \times \boldsymbol{i}] = \delta\boldsymbol{r}_1 + (x\,\delta\phi)\boldsymbol{j}. \tag{f}$$

(ii) A rigid body in plane motion (fig. 2.13). For this *three DOF* system we have

$$\begin{aligned}X &= X_\blacklozenge + x\cos\phi - y\sin\phi = X(x, y; X_\blacklozenge, \phi),\\ Y &= Y_\blacklozenge + x\sin\phi + y\cos\phi = Y(x, y; Y_\blacklozenge, \phi),\end{aligned} \tag{g}$$

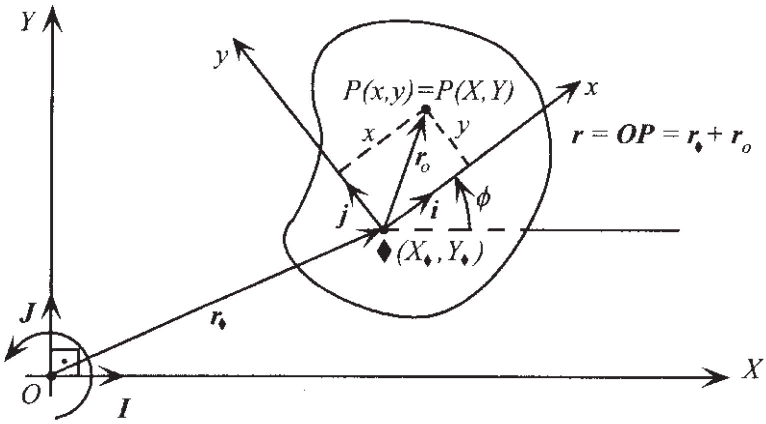

Figure 2.13 Rigid body in plane motion.

(and $Z = Z_\blacklozenge = 0$, say), or, vectorially,

$$\boldsymbol{r} = X\boldsymbol{I} + Y\boldsymbol{J} = \boldsymbol{r}(x, y; X_\blacklozenge, Y_\blacklozenge, \phi); \tag{h}$$

that is, $\boldsymbol{r}_o = x\boldsymbol{i} + y\boldsymbol{j}$ and $q_1 = X_\blacklozenge$, $q_2 = Y_\blacklozenge$, $q_3 = \phi$. Therefore, the virtual displacements are

$$\begin{aligned} \delta X &= \delta X_\blacklozenge - x \sin\phi\, \delta\phi - y\cos\phi\, \delta\phi = \delta X_\blacklozenge - \delta\phi(Y - Y_\blacklozenge), \\ \delta Y &= \delta Y_\blacklozenge + x\cos\phi\, \delta\phi - y \sin\phi\, \delta\phi = \delta Y_\blacklozenge + \delta\phi(X - X_\blacklozenge), \end{aligned} \tag{i}$$

(and $\delta Z = \delta Z_\blacklozenge = 0$), or, vectorially,

$$\delta\boldsymbol{r} = \delta\boldsymbol{r}_\blacklozenge + \delta\boldsymbol{\phi} \times (\boldsymbol{r} - \boldsymbol{r}_\blacklozenge), \qquad \delta\boldsymbol{\phi} = \delta\phi\, \boldsymbol{k}. \tag{j}$$

The extension to a rigid body in general *spatial* motion (with the help of the Eulerian angles, §1.12, and recalling discussion in § 1.8) is straightforward.

2.6 SYSTEM FORMS OF LINEAR VELOCITY (PFAFFIAN) CONSTRAINTS

Stationarity/Scleronomicity/Catastaticity for Positional/Geometrical ($\Rightarrow$ Holonomic) Constraints in System Variables

We begin by extending the discussion of §2.2 to general system variables, inertial or not. Positional constraints of the form $\phi(q) = 0$ ($\Rightarrow \partial\phi/\partial t = 0$) are called *stationary*; otherwise — that is, if $\phi(t, q) = 0$ ($\Rightarrow \partial\phi/\partial t \neq 0$) — they are called *nonstationary*; and if all constraints of a system are (or can be reduced to) such stationary (nonstationary) forms, the system is called *scleronomic* (*rheonomic*). Clearly, such a classification is *nonobjective*—that is, it depends on the particular mode and/or frame of reference used for the description of position/configuration: for example, substituting $\boldsymbol{r}(t, q)$ into the stationary constraint $\phi(\boldsymbol{r}) = 0$ turns it to a nonstationary constraint, $\phi[\boldsymbol{r}(t, q)] = \phi(t, q) = 0$ (and this is a reason that certain authors prefer to base this classification only for constraints expressed in system variables); or, a constraint that is stationary when expressed in terms of inertial coordinates (q) may very well become nonstationary when expressed in terms of noninertial coordinates (q'): under the frame of reference (i.e., explicitly time-dependent!) transformation $q \to q'(t, q) \Leftrightarrow q' \to q(t, q')$, the stationary constraint $\phi(q) = 0$ transforms to the nonstationary one $\phi(t, q') = 0$. Hence, a *scleronomic constraint* $\phi(q) = 0$ remains scleronomic under all coordinate (not frame of reference) transformations $q \to q'(q) \Leftrightarrow q' \to q(q')$; that is, its scleronomicity under such transformations is an objective property.

Stationarity/Scleronomicity/Catastaticity for Pfaffian Constraints in System Variables

Next, let us assume that the h holonomic constraints have been embedded into our system by the $n \equiv 3N - h$ Lagrangean coordinates q. To embed the *additional*, $m(< n)$ mutually independent and possibly nonholonomic Pfaffian constraints (2.2.9) into our Lagrangean kinematics and kinetics: first, we express them in system variables. Indeed, substituting $\boldsymbol{v}$ from (2.5.2) into (2.2.9), we obtain the Pfaffian constraints in system (holonomic) variables:

$$f_D \equiv \mathsf{S}\, (\boldsymbol{B}_D \cdot \boldsymbol{v}) + B_D = \cdots = \sum c_{Dk} v_k + c_D = 0 \quad (D = 1, \ldots, m), \tag{2.6.1}$$

where

$$c_{Dk} = c_{Dk}(t, q) \equiv \mathsf{S}\, \boldsymbol{B}_D \cdot (\partial \boldsymbol{r}/\partial q_k) \equiv \mathsf{S}\, \boldsymbol{B}_D \cdot \boldsymbol{e}_k, \tag{2.6.1a}$$

$$c_D \equiv c_{D,n+1} \equiv c_{D,0} = c_D(t, q) \equiv \mathsf{S}\, \boldsymbol{B}_D \cdot (\partial \boldsymbol{r}/\partial t) + B_D \equiv \mathsf{S}\, \boldsymbol{B}_D \cdot \boldsymbol{e}_0 + B_D; \tag{2.6.1b}$$

and $rank(c_{Dk}) = m$. Similarly, substituting $d\boldsymbol{r}$ from (2.5.12a) into the differential form of (2.2.9), $f_D\, dt = 0$, we obtain the *kinematically admissible*, or *possible*, form of these constraints in (holonomic) system variables:

$$d'\theta_D \equiv f_D\, dt = \sum c_{Dk}\, dq_k + c_D\, dt = 0; \tag{2.6.2}$$

with $d'\theta_D$: *not necessarily an exact differential*; that is, θ_D may not exist, it may be a "quasi variable" (§2.9) and, in view of what has already been said about virtualness, namely, $dt \to \delta t = 0$, the *virtual* form of these constraints in particle variables is

$$\delta'\theta_D \equiv \mathsf{S}\, \boldsymbol{B}_D \cdot \delta \boldsymbol{r} = 0, \tag{2.6.3}$$

and, accordingly, invoking (2.5.12b), in system variables,

$$\delta'\theta_D \equiv \sum c_{Dk}\, \delta q_k = 0. \tag{2.6.4}$$

The above show that, as in the particle variable case, the virtual displacements are mathematically equivalent to the difference between two systems of possible displacements, $d_1 q$ and $d_2 q$, occurring at the same position and for the same time, but in different directions: apply (2.6.2) at (t, q), for $d_1 q \neq d_2 q$, and subtract side by side and a (2.6.4)-like equation results.

And, as in (2.5.12a,b), once the constraints have been brought to these Pfaffian forms, the size of the δq's does not matter; it is the *constraint coefficients* c_{Dk} that do.

Now, if in (2.6.1–2),

(i) $$\partial c_{Dk}/\partial t = 0 \;\Rightarrow\; c_{Dk} = c_{Dk}(q) \tag{2.6.5a}$$

and

(ii) $$c_D \equiv c_{D,n+1} \equiv c_{D,0} = 0, \tag{2.6.5b}$$

$$\Rightarrow \text{constraint: } f_D = \sum c_{Dk}(q) v_k = 0,$$

for *all* $D = 1, \ldots, m$ and $k = 1, \ldots, n$, these constraints are called *stationary*; otherwise they are *nonstationary*; and a system with even one nonstationary constraint is called *rheonomic*; otherwise it is *scleronomic*. The inclusion of (2.6.5b) in the stationarity definition is made so that the velocity *form* of stationary *position* constraints coincides with that of the stationary *velocity* constraints:

$$\phi_D(q) = 0 \;\Rightarrow\; d\phi_D/dt = \sum (\partial\phi_D/\partial q_k) v_k \equiv \sum \phi_{Dk}(q) v_k = 0. \tag{2.6.5c}$$

If only $c_D \equiv c_{D,n+1} \equiv c_{D,0} = 0$, for *all* D, but $\partial c_{Dk}/\partial t \neq 0 \;\Rightarrow\; c_{Dk} = c_{Dk}(t, q)$ even for one value of D and k, the Pfaffian constraints are called *catastatic* [$\approx$ calm, orderly (Greek)]; otherwise they are called *acatastatic*. We notice that stationary constraints are catastatic, but catastatic constraints may not be stationary; we may still have $\partial c_{Dk}/\partial t \neq 0$ for some D and k. As mentioned earlier (2.2.11a ff.), it is the *castastatic/acatastatic classification*, having meaning only for Pfaffian constraints, that is the important one for analytical kinetics, not the stationary/nonstationary one.

Finally, as (2.6.1b) shows, the acatastatic coefficients c_D result from the nonstationary part of $\boldsymbol{v}$ (i.e., $\partial\boldsymbol{r}/\partial t$), and the acatastatic part of (2.2.9) (i.e., B_D). From this comes the search for frames of reference/Lagrangean coordinates where the Pfaffian constraint coefficients take their simplest possible form; a problem that, in turn, leads us to the investigation of the following.

Transformation Properties of c_{Dk} and c_D, under a General Frame-of-Reference Transformation

The latter is mathematically equivalent to an *explicitly* time-dependent coordinate transformation: $q \to q' = q'(t, q)$ and $t \to t' = t$. Then (2.6.1–1b) become

$$\begin{aligned} f_D &= \sum c_{Dk}\Big(\sum (\partial q_k/\partial q_{k'}) v_{k'} + \partial q_k/\partial t\Big) + c_D \\ &= \cdots = \sum c_{Dk'}\, v_{k'} + c'_D \quad (= 0) \qquad (k, k' = 1, \ldots, n;\; D = 1, \ldots, m); \end{aligned} \tag{2.6.6}$$

where

$$c_{Dk'} \equiv \sum (\partial q_k/\partial q_{k'}) c_{Dk} \qquad \text{(covariant vector-like transformation in } k\text{)}, \tag{2.6.6a}$$

$$c'_D \equiv \sum (\partial q_k/\partial t) c_{Dk} + c_D \qquad \text{(covariant vector-like transformation in } t \equiv n+1,$$

$$\text{with } q'_{n+1} \equiv t' = t \;\Rightarrow\; \partial t'/\partial t = 1). \tag{2.6.6b}$$

The above readily show that: (i) if $\partial q_k/\partial t = 0$ [i.e., $q = q(q')$] (= *coordinate transformation*; in the same frame of reference), then $c'_D = c_D$; and (ii) we *can* choose a frame of reference in which $c'_D = 0$; that is, catastaticity/acatastaticity (and stationarity/nonstationarity) are *frame-dependent properties*.

Holonomicity versus Nonholonomicity

The $m(< n)$ constraints (2.6.1) are *independent* if the $m \times n$ *constraint matrix* (c_{Dk}) has maximal rank (i.e., m) at each point in the region of definition of the q's and t.

Now, if these constraints are completely integrable $\equiv$ holonomic [i.e., either they are exact: $c_{Dk} = \partial h_D/\partial q_k$ and $c_D = \partial h_D/\partial t$, where $h_D = h_D(t, q)$ $(= 0)$; or they possess integrating factors, as explained in §2.2], then there exists a set of n "equilibrium," or "adapted (to the constraints)" system coordinates $\chi = (\chi_1, \ldots, \chi_n)$ in which these constraints take the simple *uncoupled* form:

$$\chi_1 \equiv h_1(t, q) = 0, \ldots, \chi_m \equiv h_m(t, q) = 0; \tag{2.6.7a}$$

$$\chi_{m+1} \equiv h_{m+1}(t, q) \neq 0, \ldots, \chi_n \equiv h_n(t, q) \neq 0; \tag{2.6.7b}$$

where, as in §2.4, the $n - m$ functions $h_{m+1}(t, q), \ldots, h_n(t, q)$ are arbitrary, except that when (2.6.7a, b) are solved for the n q's in terms of the $(n - m)$ $\chi_I \equiv (\chi_{m+1}, \ldots, \chi_n)$ and these expressions are inserted back into the m holonomic constraints $h_1(t, q) = 0, \ldots, h_m(t, q) = 0$, they satisfy them identically in the χ_I's and t. The χ_I's are the new positional system coordinates of this $3N - (h + m) = (3N - h) + m = n - m \equiv n'$ (both global and local) *DOF*:

$$q \to q' \equiv (\chi_{m+1}, \ldots, \chi_n) \equiv (q'_1, \ldots, q'_{n'}). \tag{2.6.7c}$$

This process of *adaptation to the constraints via new equilibrium coordinates* can be repeated if additional holonomic constraints are imposed on the system; and with some nontrivial modifications it carries over to the case of additional nonholonomic constraints (§2.11: essentially, by *expressing this adaptation* ... *idea in the small*; i.e., locally, via "equilibrium quasi coordinates"). The importance of this method to AM lies in its ability to *uncouple* constraints, and thus to simplify significantly the equations of motion (chap. 3).

If, on the other hand, the constraints (2.6.1) are *noncompletely integrable* $\equiv$ *nonholonomic*, then the number of independent Lagrangean coordinates (= number of *global* DOF) remains n, but the system has $n - m \equiv f$ *DOF* (in the *small*, or *local* case); that is, under the additional m nonholonomic constraints [(2.6.1), (2.6.2)], *the n q*'s *remain independent* (unlike the holonomic case!), *but the n* $v/dq/\delta q$'s *do not*—or, if the differential increments δq are *arbitrary* (if, for example, we let q_k become $q_k + \delta q_k$ while all the other q's *remain constant*), then they will *no longer be virtual*; that is, they will not be compatible with the virtual form of the constraints (2.6.4); and similarly for the v's, dq's. [Of course, if $m = 0$, then the n q's are independent *and* their arbitrary increments δq are *virtual*; that is, both q's and δq's satisfy the existing (initial) h holonomic constraints. For example, in the case of a sphere rolling on, say, a fixed plane: (a) if the plane is smooth (i.e., $m = 0$), both the arbitrary q's and the arbitrary $(q + dq)$'s, are kinematically possible; while (b) if the plane is sufficiently rough so that the sphere rolls on it (i.e., $m \neq 0$, and the additional (rolling) constraints are nonholonomic), only the q's are still arbitrary (independent), the $(q + dq)$'s are not — or, if they are, the sphere does not roll. For details, see exs. 2.13.4, 2.13.5, 2.13.6.]

To find the number of independent δq's under the additional m (holonomic or nonholonomic) constraints (2.6.1, 2, 4) we must now turn to the examination of the following.

Introduction to Virtual Displacements under Pfaffian Constraints (Introduction to Quasi Variables)

In this case, the particle virtual displacement is still represented by (2.5.12b):

$$\delta \boldsymbol{r} = \sum (\partial \boldsymbol{r}/\partial q_k)\, \delta q_k \equiv \sum \boldsymbol{e}_k\, \delta q_k, \tag{2.6.8}$$

but, due to the virtual constraints (2.6.4), out of the n δq's only $n - m$ are independent; that is, if, now, all n δq's vary arbitrarily, the resulting $\delta \boldsymbol{r}$, via (2.6.8), will *not* be virtual—denoting a differential increment of a system coordinate by δq does not necessarily make it virtual; it must also be constraint compatible. For example, solving (2.6.4) for the first m δq's,

$$\delta q_D \equiv (\delta q_1, \ldots, \delta q_m) = \textbf{\textit{Dependent}}\ \delta q\text{'s}, \tag{2.6.9a}$$

in terms of the last $n - m$ of them,

$$\delta q_I \equiv (\delta q_{m+1}, \ldots, \delta q_n) = \textbf{\textit{Independent}}\ \delta q\text{'s}, \tag{2.6.9b}$$

we obtain

$$\delta q_D = \sum b_{DI}\, \delta q_I \qquad (D = 1, \ldots, m;\ I = m+1, \ldots, n), \tag{2.6.9}$$

where $b_{DI} = b_{DI}(q, t) =$ known functions of (generally, all) the q's and t. Substituting (2.6.9) into (2.6.8), we obtain, successively,

$$\delta \boldsymbol{r} = \sum \boldsymbol{e}_k\, \delta q_k = \sum \boldsymbol{e}_D\, \delta q_D + \sum \boldsymbol{e}_I\, \delta q_I = \sum \boldsymbol{e}_D \Big(\sum b_{DI}\, \delta q_I\Big) + \sum \boldsymbol{e}_I\, \delta q_I;$$

finally

$$\text{either}\quad \delta \boldsymbol{r} = \sum \boldsymbol{e}_k\, \delta q_k,\ \text{under} \sum c_{Dk}\, \delta q_k = 0 \qquad (\delta q_k,\ \text{nonarbitrary}), \tag{2.6.10a}$$

$$\text{or}\quad \delta \boldsymbol{r} = \sum \boldsymbol{\beta}_I\, \delta q_I \qquad (\delta q_I,\ \text{arbitrary}), \tag{2.6.10b}$$

where

$$\boldsymbol{\beta}_I \equiv \boldsymbol{e}_I + \sum b_{DI} \boldsymbol{e}_D \equiv \partial \boldsymbol{r}/\partial q_I + \sum b_{DI}\, (\partial \boldsymbol{r}/\partial q_D)\ [\text{see also (2.11.13a ff.)}]; \tag{2.6.10c}$$

that is, the most general particle virtual displacement under (2.6.4) can be expressed as a *linear and homogeneous combination of the "narrower" basis* $\{\boldsymbol{\beta}_I;\ I = m+1, \ldots, n\}$, whose vectors are, *in general* [and unlike the $\boldsymbol{e}_k$'s—recalling (2.5.4a ff.)], *nongradient*, or *nonholonomic*:

$$\boldsymbol{\beta}_I \neq \partial \boldsymbol{r}/\partial q_I \ \Rightarrow\ \partial \boldsymbol{\beta}_I/\partial q_{I'} \neq \partial \boldsymbol{\beta}_{I'}/\partial q_I \qquad (I, I' = m+1, \ldots, n); \tag{2.6.11}$$

as can be verified directly by using (2.6.10c) in (2.6.11).

The number of independent δq's, here $n - m \equiv f$, equals the earlier defined number of local DOFs; and, inversely, we can redefine the number of DOFs in the small, henceforth called simply DOF, as the smallest number of independent parameters $\dot{q}_I \equiv v_I/dq_I/\delta q_I$ needed to determine $\boldsymbol{v}/d\boldsymbol{r}/\delta \boldsymbol{r}$, for all system particles and any admissible, and so on, local motion; that is, the number of DOFs (in the small) = minimum number of independent "local positional", or *motional*, parameters. Just as the number of DOFs in the large, $F = n$ (here), is the minimum number of independent *positional* parameters needed to determine the configurations of all system particles in any admissible, and so on, global motion.

REMARKS

(i) The f δq_I can, in turn, be expressed as linear and homogeneous combinations of another set of f-independent motional parameters, say η_I: $\delta q_I = \sum H_{II'}(t,q)\,\eta_{I'}$ $(I, I' = m+1, \ldots, n)$; in which case (2.6.10b) becomes

$$\delta \boldsymbol{r} = \sum \boldsymbol{\beta}_I\, \delta q_I = \sum \boldsymbol{\beta}_I \left(\sum H_{II'}\,\eta_{I'}\right) = \sum \left(\sum H_{II'}\boldsymbol{\beta}_I\right)\eta_{I'}$$
$$\equiv \sum \boldsymbol{h}_{I'}\eta_{I'} = \sum \boldsymbol{h}_I \eta_I. \qquad \text{(2.6.10d)}$$

(ii) As already mentioned, the importance of these considerations lies in kinetics (chap. 3), where it is shown that the number of *independent kinetic equations of motion* (= equations not containing forces of constraint) equals the number of *independent* δq's.

Problem 2.6.1 Show that due to the m Pfaffian constraints (2.6.1) (expressed in terms of the notation $dq_k/dt \equiv v_k$):

$$\sum c_{Dk} v_k + c_D = 0 \qquad (D = 1, \ldots, m;\ k = 1, \ldots, n), \qquad \text{(a)}$$

or, equivalently, in the (2.6.9)-like form, in the velocities,

$$v_D = \sum b_{DI} v_I + b_D \qquad (I = m+1, \ldots, n), \qquad \text{(b)}$$

the additional holonomic constraint $\phi(t, q) = 0$ satisfies the following $(n-m)+1$ conditions:

$$\partial\phi/\partial q_I + \sum b_{DI}(\partial\phi/\partial q_D) = 0 \qquad \text{and} \qquad \partial\phi/\partial t + \sum b_D(\partial\phi/\partial q_D) = 0; \qquad \text{(c)}$$

which, in terms of the notation $\phi(t, q_D, q_I) = \phi[t, q_D(t, q_I), q_I] \equiv \phi_o(t, q_I) = 0$, read simply

$$\partial\phi_o/\partial q_I = 0 \qquad \text{and} \qquad \partial\phi_o/\partial t = 0, \qquad \text{(d)}$$

respectively (compare with example 2.4.1.).

Before embarking into the detailed study of nonholonomic constraints and associated "coordinates" (to embed them), and the most general $\boldsymbol{v}/d\boldsymbol{r}/\delta\boldsymbol{r}$-representations in terms of $n-m$ arbitrary motional system parameters, of which the previous $v_I \equiv \dot{q}_I/dq_I/\delta q_I$ are a special case, let us pause to geometrize our analytical findings; and in the process dispel the incorrect impressions, held by many, that analytical mechanics is, somehow, only numbers (analysis), no pictures—an impression initiated, ironically, by Lagrange himself!

2.7 GEOMETRICAL INTERPRETATION OF CONSTRAINTS

Configuration Spaces

As explained in §2.2, *before* the imposition of any constraints, the configurations of a mechanical system S are described by the motion of its representative, or figurative, particle $P(S) \equiv P$ in a (clearly, nonunique) $3N$-dimensional Euclidean, or noncurved/

flat, space, E_{3N}, called *unconstrained*, or *free*, *configuration space*. [Briefly, *Euclidean*, or noncurved, or flat, means that, in it, the *Pythagorean theorem* ("distance squared = sum of squares of coordinate differences") *holds globally*; that is, between *any* two space points, no matter how far apart they may be; see, for example, Lur'e (1968, p. 807 ff.), Papastavridis (1999, §2.12.3).]

The position vector of P, in terms of its rectangular Cartesian coordinates/components relative to some orthonormal basis of fixed origin O, in there, is [recall (2.4.3 ff.)]

$$\boldsymbol{\xi} = [\xi_1 = \xi_1(t), \ldots, \xi_{3N} = \xi_{3N}(t)]. \tag{2.7.1}$$

However, as detailed in §2.4, upon imposition on S of h holonomic constraints and subsequent introduction of $n \equiv 3N - h$ Lagrangean coordinates $\boldsymbol{q} \equiv [q_1 = q_1(t), \ldots, q_n = q_n(t)]$, or simply $q = (q_1, \ldots, q_n)$, the above assumes the parametric representation

$$\boldsymbol{\xi} = \boldsymbol{\xi}(t, \boldsymbol{q}) = [\xi_1 = \xi_1(t; q), \ldots, \xi_{3N} = \xi_{3N}(t; q)], \tag{2.7.1a}$$

which, in geometrical terms, means that, as a result of these constraints, P can no longer roam throughout E_{3N}, but is forced to remain on its time-dependent *n-dimensional surface* defined by (2.7.1a), called *reduced*, or *constrained configuration space* of the system; actually the portion of that surface corresponding to the mathematically and physically allowable range of its curvilinear coordinates q. In differential–geometric/tensorial terms, that space, described by the *surface coordinates* q, when equipped with a physically motivated metric, becomes, at every instant t, a generally non-Euclidean (or curved, or nonflat) *metric manifold*, $M_n(t) \equiv M_n$, usually a Riemannian one, embedded in E_{3N}; and this explains the importance of Riemannian geometry to theoretical dynamics. [*Riemannian manifold* means one in which the square of the infinitesimal distance ("line element") is quadratic, homogeneous, and (usually) *positive–definite* in the coordinate differentials dq_k. In dynamics, the *manifold metric* is built from the system's *kinetic energy* (§3.9). See, for example, Lur'e (1968, pp. 810 ff.), Papastavridis (1999, §2.12, §5.6 ff.)] Schematically, we have

Configuration spaces
- *Unconstrained: E_{3N} (Euclidean manifold)*
- *Constrained: M_n (Non-Euclidean manifold)*

[N = number of particles, h = number of holonomic constraints, $n \equiv 3N - h$]

Now, as S moves in any continuous, or finite, way in the ordinary physical (three-dimensional and Euclidean) space, or some portion of it, P moves along a continuous M_n-curve, $q = q(t)$. The relevant analytical requirements on such q's (§2.4) are summarized as follows:

(i) The correspondence between the q *n-tuples* and some region of M_n must be *one-to-one and continuous* (additional holonomic constraints would exclude some parts of that region from the possible configurations).

(ii) If Δs = displacement, in M_n, corresponding to the q-increment Δq, we must have $\lim(\Delta s/\Delta q_k) \neq 0$, as $\Delta q_k \to 0$ $(k = 1, \ldots, n)$; or dq_k/ds (= "*direction cosines*" of unit tangent vector to system path in M_n) = finite. The q's are then called *regular*. (See also Langhaar, 1962, p. 16.)

Event Spaces

Instead of the "dynamical" spaces E_{3N} and M_n, we may use their (formal and nonrelativistic) "union" with time $t \equiv q_0 \equiv q_{n+1}$; symbolically,

$$E_{3N+1} \equiv E_{3N} \times T(ime) \qquad \text{and} \qquad M_{n+1} \equiv M_n \times T(ime). \tag{2.7.2}$$

These latter are called (unconstrained and constrained, respectively): *manifolds of configuration and time* (or *of extended configuration*), or "*geometrical*" *space-time manifolds*, or *film spaces*; or, simply, *event spaces*. $M_n(M_{n+1})$ is suitable for the study of scleronomic (rheonomic) systems. (One more such "generalized space," the *phase space* of Lagrangean coordinates and momenta, is examined in chap. 8.)

Constrained Configuration Spaces and their Tangent Planes

The *h stationary* and holonomic constraints define, in E_{3N}, a *stationary* (nonmoving) and *rigid* (nondeforming) *n-dimensional* surface M_n; while *h nonstationary* holonomic constraints define, in E_{3N}, a *nonstationary* (moving) and *nonrigid* (deforming) *n-dimensional* surface $M_n(t)$. However, these same *nonstationary* constraints also define, in E_{3N+1}, a stationary and rigid $(n+1)$-*dimensional* surface M_{n+1}; hence, the relativity of these terms! The equations $t = constant$ define ∞^1 privileged surfaces $M_n(t)$ in M_{n+1}. Thus, the motion of the system can be viewed either as (i) *a stationary curve in the geometrical space* M_{n+1}; or (ii) as *the motion of the representative system point in the deformable, or* "breathing," dynamical space $M_n(t)$. Further, through each M_n-point $q(t)$ there passes a $(n-1)$-ple infinity of kinematically possible system paths, on each of which the "rate of traverse" dq/dt is arbitrary; and through each M_{n+1}-point (q, t) there passes an n-ple infinity of such paths, but these latter, since there is no motion in M_{n+1}, are not traversed. The *kinetic* paths of a system in M_n and M_{n+1} are called its *trajectories/orbits* and *world lines*, respectively. Additional M_n/M_{n+1} differences are given below, in connection with nonholonomic constraints.

Next, and as differential geometry teaches, (i) the set of all $(n+1)$-ples (dq_α) make up the *tangent point space (hyperplane)* to M_{n+1} at P, $T_{n+1}(P)$; while (ii) the vectors $\{\boldsymbol{E}_\alpha \equiv \boldsymbol{E}_\alpha(P);\ \alpha = 1, \ldots, n;\ n+1\}$, defined by $d\boldsymbol{P} \equiv d\boldsymbol{\xi} \equiv d\boldsymbol{q} \equiv \sum \boldsymbol{E}_\alpha\, dq_\alpha$: vector of elementary system displacement determined by $P(q)$ and $P(q + dq)$ (each $\boldsymbol{E}_\alpha$ being tangent to the coordinate line q_α through P) constitute a "natural" basis for the *tangent vector space associated with, or corresponding to*, $T_{n+1}(P)$; and similarly for M_n. For simplicity, we shall denote both these point and vector spaces by $T_{n+1}(P)$, $T_n(P)$.

REMARKS

(i) Without a metric, these tangent spaces are *affine*. After they become equipped with one, they become Euclidean; *properly Euclidean* if the metric is positive definite, and *pseudo-Euclidean* if the metric is indefinite. As mentioned earlier, in mechanics the metric is based on the kinetic energy, and, therefore, it is either positive definite or positive semidefinite.

(ii) It is shown in differential geometry that the condition that $d\boldsymbol{E}_\alpha = \sum(\cdots)_{\alpha\beta}\boldsymbol{E}_\beta$ be an exact differential [i.e., $\partial/\partial q_\gamma(\partial\boldsymbol{E}_\alpha/\partial q_\beta) = \partial/\partial q_\beta(\partial\boldsymbol{E}_\alpha/\partial q_\gamma)$] leads to the requirement that M_{n+1}/M_n be a Riemannian manifold. For details, see, for example, Papastavridis (1999, p. 135).

Pfaffian Constraints

Let us begin with a system subjected to h holonomic constraints (2.4.2), and, therefore, described by the $n \equiv 3N - h$ holonomic coordinates q. Then, a motion of the system in the physical space E_3 corresponds to a certain curve in M_n(*trajectory or orbit*)/M_{n+1}(*world line*) traced by the figurative system particle P; and, conversely, admissible M_n/M_{n+1} curves represent some system motion. Now, let us impose on it the additional m Pfaffian constraints:

$$\textit{Kinematically admissible form}: \qquad d'\theta_D \equiv \sum c_{Dk}\, dq_k + c_D\, dt = 0, \tag{2.7.3}$$

$$\textit{Virtual form}: \qquad \delta'\theta_D \equiv \sum c_{Dk}\, \delta q_k = 0. \tag{2.7.4}$$

As a result of the above, we have the following geometrical picture:

(i) At each admissible M_{n+1}-point $P \equiv (q, t)$, the m constraints (2.7.3) define (or order, or map, or form), the $[(n+1) - m] = [(n-m)+1]$-dimensional "element" $T_{(n+1)-m}(P) \equiv T_{(n-m)+1}(P) \equiv T_{I+1}(P)$: *tangent space (plane) of kinematically admissible displacements (motions)*, of the earlier tangent plane $T_{n+1}(P)$, on which the kinematically admissible displacements of the system, dq, and dt lie. Therefore, at every P, only world lines with velocities $v_\alpha \equiv dq_\alpha/dt$ on that plane are possible—the system can only move along directions compatible with (2.7.3).

(ii) At each such point P, the m constraints (2.7.4) define the $(n-m)$-dimensional plane $T_{n-m}(P)$: *tangent space of virtual displacements (motions)*, or *virtual plane*, on which the virtual displacements of the system, δq, lie. Clearly, $T_{n-m}(P)$ is the intersection of $T_{(n-m)+1}(P)$ with the hyperplane $dt \to \delta t = 0$ there; symbolically, $T_{n-m}(P) = T_{(n-m)+1}|_{\delta t=0} \equiv V_{n-m}(P)$ (V for **v**irtual). $\{$And a manifold M_n/M_{n+1} whose *tangential bundle* (i.e., totality of its tangential spaces) is restricted by the m nonholonomic equations (2.7.3) [assuming that (2.7.3), (2.7.4) are nonholonomic] is called *nonholonomic manifold* $M_{n,n-m}/M_{n+1,n-m}$. Some authors call the so-restricted bundle, $T_{(n-m)+1}$ or T_{n-m}, *nonholonomic space embedded in* M_n, or M_{n+1}. See also Maißer (1983–1984), Papastavridis (1999, chap. 6), Prange (1935, pp. 557–560), Schouten (1954, p. 196).$\}$

(iii) The given constraint coefficients (c_{Dk}, c_D) define, at P, an $(m+1)$-dimensional *kinematically admissible constraint plane* (*element*) $C_{m+1}(P)$ perpendicular to $T_{m+1}(P)$ (with orthogonality defined in terms of the kinetic energy-based metric); while the (c_{Dk}) define an m-dimensional *virtual constraint plane* (i.e., of the virtual form of the constraints) $C_m(P)$ perpendicular to $V_{n-m}(P)$. Sometimes, $C_m(P)$ is referred to as the *orthogonal complement* of $V_{n-m}(P)$ relative to $T_n(P)$. The c_{Dk} can be viewed as the covariant (in the sense of tensor calculus) and holonomic components of the m *virtual constraint vectors* $\boldsymbol{c}_D = (c_{Dk})$, which, by (2.7.4), are *orthogonal to the virtual displacements* δq_k: $\boldsymbol{c}_D \cdot \delta\boldsymbol{q} = \sum c_{Dk}\, \delta q_k = 0$. Hence since the $\boldsymbol{c}_D$ are independent, they constitute a basis (span) for the earlier space $C_m(P)$. These two local planes are frequently called the *null*$[V_{n-m}(P)]$ and *range*$[C_n(P)]$ spaces of the $m \times n$ constraint matrix (c_{Dn}). These geometrical results are shown in fig. 2.14 (see also fig. 3.1).

Let us consolidate our findings:

(i) Under n *initial* holonomic constraints, a system can go from any admissible *initial* M_n/M_{n+1}-point, P_i, to any other *final* such point, P_f, along any chosen (M_n/M_{n+1})-lying path joining P_i and P_f.

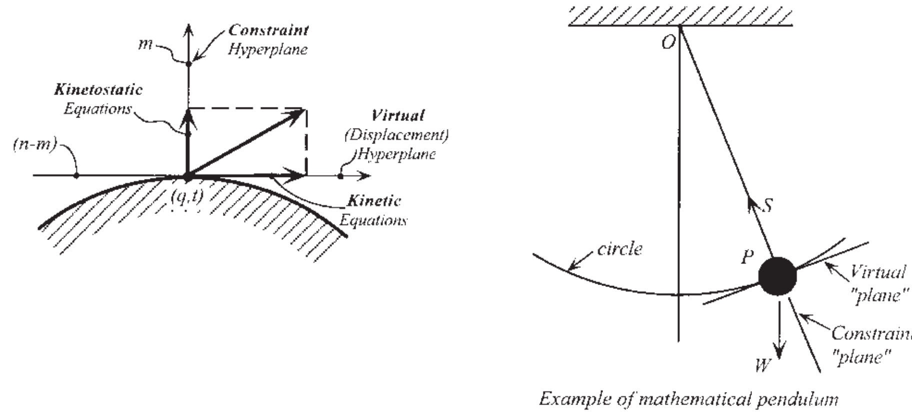

Figure 2.14 Virtual displacement (V_{n-m}) and constraint (C_m) hyperplanes in configuration space (see also fig. 3.1).

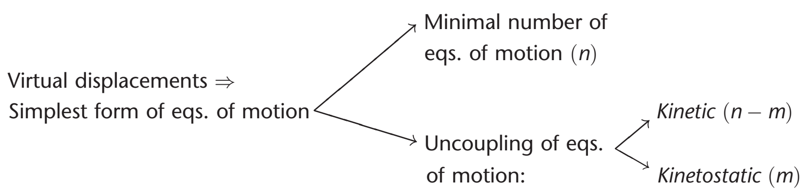
(ii) If the additional m Pfaffian constraints (2.7.3, 4) are holonomic, disguised in kinematical form, the local tangent planes become the earlier local tangent planes to reduced, or "smaller," configuration/event manifolds $M_{n-m}/M_{(n+1)-m}$, inside M_n/M_{n+1}. These reduced but finite surfaces contain all possible system motions through a given P_i — the system can go from any admissible *initial* $M_{n-m}/M_{(n+1)-m}$-point, P_i, to any other *final* such point, P_f, along any chosen (M_n/M_{n+1})-*lying path joining* P_i *and* P_f; that is, $DOF(local) = DOF(global) = n - m$.

(iii) On the other hand, if the additional m Pfaffian constraints are nonholonomic, we cannot construct these $M_{n-m}/M_{(n+1)-m}$. The global configuration/event manifolds of the system are still M_n/M_{n+1}, but these constraints have created, in there, a certain *path-dependence*: any (M_n/M_{n+1})-point P_f (in the admissible portions of M_n/M_{n+1}) is, again, accessible from any other (M_n/M_{n+1})-point P_i but only along a certain *kinematical family,* or "*network*," of tracks that is "narrower" than that of case (i); that is, the transition $P_i \rightarrow P_f$ is no longer arbitrary because of direction-of-motion constraints, at every point of those paths. Or, under such constraints, all configurations/events are still possible, *but not all velocities* (and, hence, *not all paths*); only certain M_n/M_{n+1}-curves correspond to physically realizable motions — the system is restricted locally, not globally; that is, $n = DOF(global) \neq DOF(local) = n - m$. We continue this geometrical interpretation of constrained systems in §2.11.

Kinetic Preview, Quasi Coordinates

The importance of these considerations, and especially of the concept of virtualness, to contrained system mechanics arises from the fact that most of the constraint forces dealt by AM (the so-called "passive," or contact, ones; i.e., those satisfying the d'Alembert–Lagrange principle, chap. 3) are perpendicular to the virtual displacement plane V_{n-m}, and so lie on the *virtual constraint plane* C_m. And this, as detailed in chapter 3, allows us to bring the system equations of motion into their *simplest* form; that is (i) to their smallest possible, or minimal, number (n), and (ii) to a complete *decoupling* of them into $(n - m)$ purely *kinetic* equations—that is, equations not containing constraint forces — by projecting them onto the *local virtual hyperplane*, and (m) *kinetostatic* equations — equations containing constraint forces — by projecting them onto the *local constraint hyperplane*, which is perpendicular to the virtual hyperplane there. This is the raison d'être of virtualness, and the essence of Lagrangean analytical mechanics. In all cases, under given initial/boundary conditions and forces, the system will follow a unique path (a trajectory, or orbit) determined, or singled out among the problem's kinematically admissible paths, by solving the full set of its kinetic and kinematic equations.

Schematically, our strategic plan is as the following:



Now, if the m Pfaffian constraints are holonomic, their uncoupling (and that of the corresponding equations of motion) is easily achieved by "adaptation to the constraints," as explained in §2.4 and §2.6; but, if they are nonholonomic this "adaptation" can be achieved only *locally*, via "equilibrium" *nonholonomic coordinates*, or *quasi coordinates*.

We begin the study of these fundamental kinematical concepts by first examining one of their important features: the possible *commutativity/noncommutativity* of the *virtual and possible operations*, $\delta(\ldots)$ *and* $d(\ldots)$, respectively, when applied to this new breed of "coordinates"; that is, we investigate the relation between $d[\delta(\textit{quasi coordinate})]$ and $\delta[d(\textit{quasi coordinate})]$.

2.8 NONCOMMUTATIVITY VERSUS NONHOLONOMICITY; INTRODUCTION TO THE THEOREM OF FROBENIUS

Let us recall the admissible (d) and virtual (δ) forms of the Pfaffian constraints (2.7.3, 4) (henceforth keeping possible non-exactness accents only when really necessary!):

$$d\theta_D \equiv \sum c_{Dk}\, dq_k + c_D\, dt = 0 \qquad \text{and} \qquad \delta\theta_D \equiv \sum c_{Dk}\, \delta q_k = 0, \tag{2.8.1}$$

where $D = 1, \ldots, m$; $I = m+1, \ldots, n$; k (*and all other small Latin indices*) $= 1, \ldots, n$. Now, $\delta(\ldots)$-varying the first of (2.8.1), and $d(\ldots)$-varying the second, and then subtracting them side by side, we find, after some straightforward differentiations and dummy index changes,

$$\begin{aligned} d(\delta\theta_D) - \delta(d\theta_D) = {} & \sum c_{Dk}[d(\delta q_k) - \delta(dq_k)] \\ & + \sum \Big(\sum (\partial c_{Dk}/\partial q_l - \partial c_{Dl}/\partial q_k)\, dq_l \\ & \qquad + (\partial c_{Dk}/\partial t - \partial c_D/\partial q_k)\, dt \Big)\, \delta q_k \\ & \qquad + c_D[d(\delta t) - \delta(dt)], \end{aligned} \tag{2.8.1a}$$

or, since the last term is zero [$\delta t = 0 \Rightarrow d(\delta t) = 0$, and, during $\delta(\ldots)$ time is kept constant $\Rightarrow \delta(dt) = 0$], and with the earlier notations $q_0 \equiv q_{n+1} \equiv t \Rightarrow \delta q_0 = \delta q_{n+1} = \delta t = 0, c_D \equiv c_{D0} \equiv c_{D,n+1}$, and *Greek subscripts* running from 1 to $n+1$ (or from 0 to n):

$$\begin{aligned} d(\delta\theta_D) - \delta(d\theta_D) = \sum c_{Dk}[d(\delta q_k) - \delta(dq_k)] \\ + \sum\sum (\partial c_{Dk}/\partial q_\alpha - \partial c_{D\alpha}/\partial q_k)\, dq_\alpha\, \delta q_k. \end{aligned} \tag{2.8.2}$$

A final simplification occurs with the useful notations $d(\delta\ldots) - \delta(d\ldots) \equiv D(\ldots)$, and

$$C^D{}_{\beta\alpha} \equiv \partial c_{D\beta}/\partial q_\alpha - \partial c_{D\alpha}/\partial q_\beta = -C^D{}_{\alpha\beta}, \tag{2.8.2a}$$

$$F_D \equiv \sum\sum C^D{}_{k\alpha}\, dq_\alpha\, \delta q_k : \text{Frobenius' } \textit{bilinear}, \text{ or } \textit{antisymmetric}, \textit{ covariant} \text{ of the Pfaffian forms (2.8.1).} \tag{2.8.2b}$$

Thus, (2.8.2) transforms to

$$D\theta_D = \sum c_{Dk}\, Dq_k + F_D. \tag{2.8.2c}$$

Problem 2.8.1 Starting with eqs. (2.5.12a,b):

$$d\boldsymbol{r} = \sum \boldsymbol{e}_k\, dq_k + \boldsymbol{e}_0\, dt, \qquad \delta\boldsymbol{r} = \sum \boldsymbol{e}_k\, \delta q_k, \tag{a}$$

and repeating the above process, show that

$$D\boldsymbol{r} = \sum Dq_k \boldsymbol{e}_k. \tag{b}$$

From the above basic kinematical identities, we draw the following conclusions:

(i) If $C^D{}_{k\alpha} = 0$, identically in the q's and t, and for all values of D, k, α then, since

$$Dq_k \equiv d(\delta q_k) - \delta(dq_k) = 0, \tag{2.8.3a}$$

the q_k being genuine = *holonomic* coordinates, it follows that

$$D\theta_D \equiv d(\delta\theta_D) - \delta(d\theta_D) = 0; \tag{2.8.3b}$$

that is, the θ_D are also holonomic coordinates, the $d\theta_D/\delta\theta_D$ are exact differentials. In this case (2.8.1) may be replaced by m holonomic constraints; which, in turn, may be embedded into the system via $n' = n - m$ new equilibrium coordinates, as explained in §2.4.

(ii) If $F_D \neq 0$, then $D\theta_D \neq 0$; or, more generally, we *cannot* assume that *both* $d(\delta q_k) = \delta(dq_k)$ *and* $d(\delta\theta_D) = \delta(d\theta_D)$ hold; it is *either the one or the other*. (As detailed in chap. 7, this realization helps one understand the fundamental differences that exist between variational *mathematics* and variational *mechanics*. See also pr. 2.12.5.) If we assume (2.8.3a) for all holonomic coordinates, *constrained or not*, then $D\theta_D \neq 0$; that is, the θ_D are nonholonomic coordinates; and, as Frobenius' theorem shows (see below), the constraints (2.8.1) are nonholonomic.

(iii) If, however, $F_D = 0$, since the $dq/\delta q$ are not independent, it does *not* necessarily follow that $C^D{}_{k\alpha} = 0$. To make further progress — that is, to establish *necessary and sufficient holonomicity/nonholonomicity conditions* in terms of the constraint coefficients, c_{Dk} and c_D, we need nontrivial help from differential equations/differential geometry; and this leads us directly to the following fundamental theorem of Frobenius (1877). First, let us formulate it in simple and general mathematical terms, and then we will tailor it to our kinematical context.

Theorem of Frobenius

The necessary and sufficient condition for the *complete* (or *unrestricted*) *integrability* $\equiv$ *holonomicity* of the Pfaffian system:

$$X_D \equiv \sum X_{DK}\,dx_K = 0 \qquad [D = 1, \ldots, m(<F);\; K, L = 1, \ldots, F], \tag{2.8.4}$$

where $X_{DK} = X_{DK}(x_1, \ldots, x_F) \equiv X_{Dk}(x) =$ given and well-behaved functions of their arguments, and $\operatorname{rank}(X_{DK}) = m(<F)$; that is, for it to have m independent integrals $f_D(x) = C_D =$ constants, is the vanishing of the corresponding m bilinear forms:

$$F_D \equiv \sum\sum (\partial X_{DK}/\partial x_L - \partial X_{DL}/\partial x_K) u_K v_L, \tag{2.8.5}$$

identically (in the x's) and simultaneously (for all D's), for any/all solutions $u = (u_1, \ldots, u_F)$, and $v = (v_1, \ldots, v_F)$ of the m constraints $\sum X_{DK}\eta_K = 0$; that is, for any/all $\eta_K \to u_K, v_K$ satisfying

$$\sum X_{DK}u_K = 0 \qquad \text{and} \qquad \sum X_{DK}v_K \equiv \sum X_{DL}v_L = 0. \tag{2.8.6}$$

[Also, recall comments following eqs. (2.3.11e).]

[If the system (2.8.4) is completely integrable, then, since its finite form depends on the integration constants C_D (i.e., ultimately, on the *initial values* of the x's), then it is *semiholonomic* (§2.3).]

Adapted to our kinematical problem — that is, with the identifications $F \to n+1$, $u_K \to \delta q_k$, $v_L \to dq_\alpha$, $x \to t$, q, and recalling that $q_{n+1} \equiv t$ satisfies the additional holonomic constraint $\delta q_{n+1} \equiv \delta t = 0$ — Frobenius theorem states that: If

$$\begin{aligned} F_D &\equiv d(\delta\theta_D) - \delta(d\theta_D) = d\Big(\sum c_{Dk}\,\delta q_k\Big) - \delta\Big(\sum c_{D\alpha}\,dq_\alpha\Big) \\ &= \sum\Big(\sum (\partial c_{Dk}/\partial q_\alpha - \partial c_{D\alpha}/\partial q_k)\,dq_\alpha\Big)\,\delta q_k \equiv \sum\sum C^D{}_{k\alpha}\,dq_\alpha\,\delta q_k = 0, \end{aligned} \tag{2.8.7}$$

for arbitrary $dq_\alpha = dq_k$, $dq_{n+1} \equiv dq_0 \equiv dt$ and δq_k, solutions of the constraints:

$$\sum c_{D\alpha}\,dq_\alpha = \sum c_{Dk}\,dq_k + c_D\,dt = 0 \qquad \text{and} \qquad \sum c_{Dk}\,\delta q_k = 0, \tag{2.8.1}$$

then these constraints are holonomic.

The above show that since our dq's and δq's are not independent, the vanishing of the F_D's does *not* necessarily lead to

$$C^D{}_{k\alpha} = 0, \tag{2.8.8}$$

as holonomicity conditions. For this to be the case, eqs. (2.8.8) are, clearly, *sufficient but not necessary*; they would be if the dq's and δq's were independent; namely, unconstrained.

This observation leads to the following implementation of Frobenius' theorem: we express each of the (n) nonindependent dq's and δq's as a linear and homogeneous combination of a new set of $n - m$ *independent* parameters (and dt, for the dq's), insert these representations in $F_D = 0$, and then, in each of the so resulting m bilinear covariants (in these new parameters), set its $n - m$ coefficients equal to zero. We shall see in §2.12 that, in the general case, this approach leads to a direct and usable form of Frobenius' theorem, due to Hamel. But before proceeding in that direction, we need to examine in sufficient detail the necessary tools: *nonholonomic coordinates,* or *quasi coordinates* (§2.9), and the associated *transitivity relations* (§2.10).

REFERENCES ON PFAFFIAN SYSTEMS AND FROBENIUS' THEOREM

(for proofs, and so on, in *decreasing* order of readability for nonmathematicians):

Klein (1926(a), pp. 207–214): introductory, quite insightful.

De la Vallée Poussin (1912, vol. 2, chap. 7): most readable classical exposition.

Guldberg (1927, pp. 573–576) and Pascal (1927, pp. 579–588): outstanding handbook summaries.

Forsyth (1890/1959, especially chaps. 2 and 11): detailed classical treatment.

Lovelock and Rund (1975/1989, chap. 5): excellent balance between classical and modern approaches.

Cartan (1922, chaps. 4–10): the foundation of modern treatments.

Weber [1900(a), (b)]: older encyclopedic treatise (a) and article (b, pp. 317–319).

Heil and Kitzka (1984, pp. 264–295): relatively readable modern summary.

Chetaev (1987/1989, pp. 319–326): happens to be in English (not particularly enlightening).

Frobenius (1877, pp. 267–287; also, in his *Collected Works*, pp. 249–334): the original exposition; not for beginners.

Hartman (1964, chap. 6): quite advanced; for ordinary differential equations specialists.

Outside of Lovelock et al., we are unaware of any contemporary *readable* exposition of these topics in English; i.e., without Cartanian exterior forms, and so on.

Example 2.8.1 *Necessary and Sufficient Condition(s) for the Holonomicity of the Single Pfaffian Constraint (2.3.1) via Frobenius' Theorem:*

$$d\theta \equiv a(x, y, z)\, dx + b(x, y, z)\, dy + c(x, y, z)\, dz \equiv a\, dx + b\, dy + c\, dz = 0, \tag{a}$$

or, since it is *catastatic*,

$$\delta\theta \equiv a\, \delta x + b\, \delta y + c\, \delta z = 0. \tag{b}$$

By d-varying (b), and δ-varying (a), and then subtracting side by side, we find, after some straightforward differentiations:

$$\begin{aligned} d(\delta\theta) - \delta(d\theta) &= a[d(\delta x) - \delta(dx)] + b[d(\delta y) - \delta(dy)] + c[d(\delta z) - \delta(dz)] \\ &\qquad + [(da\,\delta x - \delta a\,dx) + (db\,\delta y - \delta b\,dy) + (dc\,\delta z - \delta c\,dz)] \\ &= (\partial a/\partial y - \partial b/\partial x)(dy\,\delta x - \delta y\,dx) + (\partial a/\partial z - \partial c/\partial x)(dz\,\delta x - \delta z\,dx) \\ &\qquad + (\partial b/\partial z - \partial c/\partial y)(dz\,\delta y - \delta z\,dy) \end{aligned}$$

[substituting into this, $dz = (-a/c)\,dx + (-b/c)\,dy$ and $\delta z = (-a/c)\,\delta x + (-b/c)\,\delta y$, solutions of the constraints (a, b), respectively; since here $n - m = 3 - 1 = 2 =$ number of *independent differentials* (for each form of the constraint); we could, just as well, substitute $dx = \cdots dy + \cdots dz$ and $\delta x = \cdots \delta y + \cdots \delta z$, or $dy = \cdots$ and $\delta y = \cdots$]

$$\begin{aligned} &= \cdots = (\partial a/\partial y - \partial b/\partial x)(dy\,\delta x - \delta y\,dx) \\ &\qquad + (\partial a/\partial z - \partial c/\partial x)(-b/c)(dy\,\delta x - \delta y\,dx) \\ &\qquad + (\partial b/\partial z - \partial c/\partial y)(-a/c)(dx\,\delta y - \delta x\,dy) \\ &= [(\partial a/\partial y - \partial b/\partial x) + (b/c)(\partial c/\partial x - \partial a/\partial z) \\ &\qquad + (a/c)(\partial b/\partial z - \partial c/\partial y)](dy\,\delta x - \delta y\,dx). \end{aligned}$$

Setting $d(\delta\theta) - \delta(d\theta) = 0$, and since now the bilinear terms $dy\,\delta x$ and $\delta y\,dx$ are independent, we recover the earlier holonomicity condition (2.3.6).

Vectorial Considerations

Equations (a)/(b), in terms of the vector notation

$$\boldsymbol{h} = (a, b, c), \qquad d\boldsymbol{r} = (dx, dy, dz), \qquad \text{and} \qquad \delta\boldsymbol{r} = (\delta x, \delta y, \delta z), \tag{d}$$

state that

$$\boldsymbol{h} \cdot d\boldsymbol{r} = 0 \qquad \text{and} \qquad \boldsymbol{h} \cdot \delta\boldsymbol{r} = 0; \tag{e}$$

that is, $\boldsymbol{h}$ is *perpendicular* to the plane defined by the two (generally independent) directions $d\boldsymbol{r}$ and $\delta\boldsymbol{r}$, through $\boldsymbol{r} = (x, y, z)$. On the other hand, the second of (c) states that

$$d(\delta\theta) - \delta(d\theta) = \boldsymbol{curl\,h} \cdot (d\boldsymbol{r} \times \delta\boldsymbol{r}) = 0, \tag{f}$$

that is, ***curl h*** is perpendicular to the normal to that plane; and, hence, excluding the trivial case $d\boldsymbol{r} \times \delta\boldsymbol{r} = \boldsymbol{0}$, ***curl h*** lies on that plane. Accordingly, $\boldsymbol{h}$ and ***curl h*** are *perpendicular* to each other:

$$\boldsymbol{h} \cdot \boldsymbol{curl\ h} = 0. \qquad \text{i.e., (2.3.8a).} \tag{g}$$

Example 2.8.2 *The Two Independent and Catastatic Pfaffian Constraints:*

$$d\theta \equiv a(x, y, z)\,dx + b(x, y, z)\,dy + c(x, y, z)\,dz \equiv a\,dx + b\,dy + c\,dz = 0, \tag{a}$$

$$d\Theta \equiv A(x, y, z)\,dx + B(x, y, z)\,dy + C(x, y, z)\,dz \equiv A\,dx + B\,dy + C\,dz = 0, \tag{b}$$

when taken *together* (i.e., $n = 3$, $m = 2$) will always make up a *holonomic system*; even if each one of them separately (i.e., $n = 3$, $m = 1$) may be nonholonomic!

Solving (a) and (b) for any two of the dx, dy, dz in terms of the third, say dx and dy in terms of dz, we obtain

$$dx \equiv e(x, y, z)\, dz \qquad \text{and} \qquad dy \equiv f(x, y, z)\, dz; \tag{c}$$

and, similarly, since (a) and (b) are catastatic,

$$\delta x \equiv e(x, y, z)\, \delta z \qquad \text{and} \qquad \delta y \equiv f(x, y, z)\, \delta z. \tag{d}$$

Therefore, we find, successively,

$$\begin{aligned} d(\delta\theta) - \delta(d\theta) &= \\ &= \cdots = (\cdots)(dy\,\delta x - \delta y\,dx) + (\cdots)(dz\,\delta x - \delta z\,dx) + (\cdots)(dz\,\delta y - \delta z\,dy) \\ &= [\text{using (c) and (d)}] = \cdots = (\cdots)(dz\,\delta z - \delta z\,dz) = (\cdots)0 = 0; \end{aligned} \tag{e}$$

and, similarly,

$$d(\delta\Theta) - \delta(d\Theta) = \cdots = (\cdots)(dz\,\delta z - \delta z\,dz) = (\cdots)0 = 0; \quad \text{Q.E.D.} \tag{f}$$

Proceeding in a similar fashion, we can show that: *a system of* $n - 1$ *(or* n*) independent Pfaffian equations, in* n *variables [like* (2.8.1) *with* $m = n - 1$ *or* n*] is always holonomic*. This theorem illustrates the interesting kinematical fact that *additional constraints* may turn an originally (individually) nonholonomic constraint into a holonomic one (as part of a system of constraints); see also §2.12.

2.9 QUASI COORDINATES, AND THEIR CALCULUS

Let us, again, consider a holonomic system S described by the hitherto minimal, or independent, n Lagrangean coordinates $q = (q_1, \ldots, q_n)$, and hence having *kinematically admissible/possible* system displacements $(dq, dt) \equiv (dq_1, \ldots, dq_n; dt)$. Now, at a generic admissible point of S's configuration or event space (q, t), we can describe these local displacements via a new set of general differential positional and time parameters $(d\theta, dt) \equiv (d\theta_1, \ldots, d\theta_n; d\theta_{n+1} \equiv d\theta_0)$, defined by the $n + 1$ linear, homogeneous, and invertible transformations:

$$d\theta_k \equiv \sum a_{kl}\, dq_l + a_k\, dt, \quad d\theta_{n+1} \equiv d\theta_0 \equiv dq_{n+1} \equiv dq_0 \equiv dt, \tag{2.9.1}$$

$$rank(a_{kl}) = n \;\Rightarrow\; Det(a_{kl}) \neq 0, \qquad (k, l = 1, \ldots, n), \tag{2.9.1a}$$

where the coefficients a_{kl} and $a_k \equiv a_{k,n+1} \equiv a_{k0}$ are given functions of the q's and t (and as well-behaved as needed; say, continuous and once piecewise continuously differentiable, in some region of interest of their variables). Inverting (2.9.1), we obtain

$$dq_l = \sum A_{lk}\, d\theta_k + A_l\, dt, \qquad dq_{n+1} \equiv d\theta_{n+1} \equiv d\theta_0 \equiv dt, \tag{2.9.2}$$

$$rank(A_{lk}) = n \;\Rightarrow\; Det(A_{lk}) \neq 0, \qquad (k, l = 1, \ldots, n), \tag{2.9.2a}$$

where the "inverted coefficients" A_{lk} and $A_l \equiv A_{l,n+1} \equiv A_{l0}$ become known functions of the q's and t, and are also well-behaved. Clearly, since the transformations (2.9.1) and (2.9.2) are mutually inverse, their coefficients must satisfy certain consistency, or compatibility, conditions; so that, given the a's, one can determine the A's and vice versa. Indeed, substituting dq_l from (2.9.2) into (2.9.1), and $d\theta_k$ from (2.9.1) into (2.9.2), and with δ_{kl} = *Kronecker delta* (= 1 or 0, according as $k = l$, or $k \neq l$), we obtain the inverseness relations:

$$\sum a_{kr} A_{rl} \equiv \sum A_{rl} a_{kr} = \delta_{kl}, \qquad \sum a_{kr} A_r \equiv \sum A_r a_{kr} = -a_k, \tag{2.9.3a}$$

$$\sum A_{lr} a_{rk} \equiv \sum a_{rk} A_{lr} = \delta_{kl}, \qquad \sum A_{lr} a_r \equiv \sum a_r A_{lr} = -A_l. \tag{2.9.3b}$$

Further, with the help of the unifying notations $a_k \equiv a_{k,n+1}$ and $A_l \equiv A_{l,n+1}$, the definitions $a_{n+1,k} \equiv \delta_{n+1,k}$ $(= 0)$ and $A_{n+1,l} \equiv \delta_{n+1,l}$ $(= 0)$, and recalling that Greek subscripts have been agreed to run from 1 to $n+1$, the transformation coefficient matrices in (2.9.1) and (2.9.2) take the $(n+1) \times (n+1)$ "**S**patio-**T**emporal" forms:

$$\mathbf{a} = \left(\begin{array}{ccc|c} a_{11} & \cdots & a_{1n} & a_{1,n+1} \\ \cdots & \cdots & \cdots & \cdots \\ \cdots & \cdots & \cdots & \cdots \\ a_{n1} & \cdots & a_{nn} & a_{n,n+1} \\ \hline 0 & \cdots & 0 & 1 \end{array}\right) \equiv \left(\begin{array}{c|c} a_{kl} & a_k \\ \hline \mathbf{0} & 1 \end{array}\right) \equiv \left(\begin{array}{c|c} \mathbf{a}_\mathrm{S} & \mathbf{a}_\mathrm{T} \\ \hline \mathbf{0} & \mathbf{1} \end{array}\right) \equiv (a_{\beta\gamma}), \tag{2.9.4a}$$

$$\mathbf{A} = \left(\begin{array}{ccc|c} A_{11} & \cdots & A_{1n} & A_{1,n+1} \\ \cdots & \cdots & \cdots & \cdots \\ \cdots & \cdots & \cdots & \cdots \\ A_{n1} & \cdots & A_{nn} & A_{n,n+1} \\ \hline 0 & \cdots & 0 & 1 \end{array}\right) \equiv \left(\begin{array}{c|c} A_{kl} & A_k \\ \hline \mathbf{0} & 1 \end{array}\right) \equiv \left(\begin{array}{c|c} \mathbf{A}_\mathrm{S} & \mathbf{A}_\mathrm{T} \\ \hline \mathbf{0} & \mathbf{1} \end{array}\right) \equiv (A_{\beta\gamma}), \tag{2.9.4b}$$

Then (2.9.1, 2) assume the simpler (homogeneous) forms:

$$d\theta_\gamma = \sum a_{\gamma\beta}\, dq_\beta \;\Leftrightarrow\; dq_\beta = \sum A_{\beta\gamma}\, d\theta_\gamma, \tag{2.9.5}$$

while the consistency relations (2.9.3a) read simply

$$\mathbf{a}\,\mathbf{A} = \mathbf{1} \qquad \text{or} \qquad \sum a_{\beta\delta}\, A_{\delta\gamma} \equiv \sum A_{\delta\gamma}\, a_{\beta\delta} = \delta_{\beta\gamma}; \tag{2.9.6a}$$

and from this we obtain the "spatio-temporally partitioned" matrix multiplications:

$$\left(\begin{array}{c|c} \mathbf{a}_\mathrm{S} & \mathbf{a}_\mathrm{T} \\ \hline \mathbf{0} & \mathbf{1} \end{array}\right) \left(\begin{array}{c|c} \mathbf{A}_\mathrm{S} & \mathbf{A}_\mathrm{T} \\ \hline \mathbf{0} & \mathbf{1} \end{array}\right) = \left(\begin{array}{c|c} \mathbf{a}_\mathrm{S}\mathbf{A}_\mathrm{S} & \mathbf{a}_\mathrm{S}\mathbf{A}_\mathrm{T} + \mathbf{a}_\mathrm{T} \\ \hline \mathbf{0} & \mathbf{1} \end{array}\right) = \left(\begin{array}{c|c} \mathbf{1} & \mathbf{0} \\ \hline \mathbf{0} & \mathbf{1} \end{array}\right)$$

that is,

$$\mathbf{a}_\mathrm{S}\mathbf{A}_\mathrm{S} = \mathbf{1} \qquad \text{and} \qquad \mathbf{a}_\mathrm{S}\mathbf{A}_\mathrm{T} + \mathbf{a}_\mathrm{T} = \mathbf{0}; \tag{2.9.7a}$$

and, similarly, the consistency relations (2.9.3b) read

$$(\mathbf{a}\,\mathbf{A})^{\mathrm{T}} = \mathbf{A}^{\mathrm{T}}\mathbf{a}^{\mathrm{T}} = \mathbf{1} \qquad \text{or} \qquad \sum A_{\gamma\delta}\, a_{\delta\beta} = \sum a_{\delta\beta}\, A_{\gamma\delta} = \delta_{\beta\gamma}, \tag{2.9.6b}$$

from which

$$\left(\begin{array}{c|c} \mathbf{A}_{\mathrm{S}} & \mathbf{0} \\ \hline \mathbf{A}_{\mathrm{T}} & \mathbf{1} \end{array}\right)\left(\begin{array}{c|c} \mathbf{a}_{\mathrm{S}} & \mathbf{0} \\ \hline \mathbf{a}_{\mathrm{T}} & \mathbf{1} \end{array}\right) = \left(\begin{array}{c|c} \mathbf{A}_{\mathrm{S}}\mathbf{a}_{\mathrm{S}} & \mathbf{0} \\ \hline \mathbf{A}_{\mathrm{T}}\mathbf{a}_{\mathrm{S}} + \mathbf{a}_{\mathrm{T}} & \mathbf{1} \end{array}\right) = \left(\begin{array}{c|c} \mathbf{1} & \mathbf{0} \\ \hline \mathbf{0} & \mathbf{1} \end{array}\right)$$

that is,

$$\mathbf{A}_{\mathrm{S}}\mathbf{a}_{\mathrm{S}} = \mathbf{1} \qquad \text{and} \qquad \mathbf{A}_{\mathrm{T}}\mathbf{a}_{\mathrm{S}} + \mathbf{a}_{\mathrm{T}} = \mathbf{0}. \tag{2.9.7b}$$

Let us recapitulate the *notations* used here:

(i) Matrices are shown in roman and bold; vectors in italic and bold;
(ii) $(\ldots)^{\mathrm{T}} \equiv$ *transpose* of square matrix $(\ldots)$;
(iii) $\mathbf{a}_{\mathrm{S}}, \mathbf{A}_{\mathrm{S}} = (n \times n)$ *spatial*, or *catastatic*, submatrices of $\mathbf{a}$ and $\mathbf{A}$, respectively; and $\mathbf{a}_{\mathrm{T}}, \mathbf{A}_{\mathrm{T}} = (n \times 1)$ *temporal*, or *acatastatic*, submatrices of $\mathbf{a}$ and $\mathbf{A}$, respectively;
(iv) $\mathbf{1} =$ square *unit*, or *identity*, matrix (of appropriate dimensions);
(v) $\mathbf{0} =$ *zero* matrix (column or row vector of appropriate dimension); and
(vi) Here, *commas in subscripts* — for example, $a_{k,n+1}, A_l \equiv A_{l,n+1}$ — are used only to separate the spatial from the temporary of these subscripts, for better visualization; that is, no partial differentiations are implied, unless explicitly specified to that effect.

Thus, for example, for $\beta \to k$ and $\gamma \to l$ eqs. (2.9.6a) yield

$$\sum a_{kr}A_{rl} + a_{k,n+1}A_{n+1,l} = \delta_{kl} \to \sum a_{kr}A_{rl} = \delta_{kl}, \qquad \text{i.e., first of (2.9.3a);}$$

for $\beta \to n+1$ and $\gamma \to l$ they yield

$$\sum a_{n+1,\,r}\, A_{rl} + a_{n+1,\,n+1}\, A_{n+1,l} = \delta_{n+1,l}, \qquad \text{i.e., } 0 + 0 = 0;$$

while for $\beta \to k$ and $\gamma \to n+1$ they yield

$$\sum a_{kr}\, A_{r,\,n+1} + a_{k,\,n+1}\, A_{n+1,\,n+1} = \delta_{k,\,n+1} = 0, \qquad \text{i.e., second of (2.9.3a);}$$

and similarly with (2.9.6b).

Specializations, Remarks

(i) If (a_{kl}) is an *orthogonal* matrix — that is, if

$$a_{kl} = A_{lk} \qquad \text{and} \qquad \mathrm{Det}(a_{kl}) = \pm 1, \tag{2.9.8a}$$

then the spatial parts of (2.9.3a, 3b) are replaced, respectively, by

$$\sum a_{kr}\, a_{lr} \equiv \sum a_{lr}\, a_{kr} = \delta_{kl} \qquad \text{and} \qquad \sum a_{rl}\, a_{rk} \equiv \sum a_{rk}\, a_{rl} = \delta_{kl}; \tag{2.9.8b}$$

and, similarly, for the full $(n+1) \times (n+1)$ $\mathbf{a}$ and $\mathbf{A}$ matrices.

(ii) As shown in chap. 3, and foreshadowed below, it is the *spatial/catastatic submatrices* $\mathbf{a}_{\mathrm{S}}$ and $\mathbf{A}_{\mathrm{S}}$ that enter the equations of motion; not the *temporary/acatastatic submatrices* $\mathbf{a}_{\mathrm{T}}$ and $\mathbf{A}_{\mathrm{T}}$. The latter, however, enter the rate of energy, or power, equations (§3.9). In what follows, we shall have the opportunity to use all these, mutually equivalent and complementary notations; primarily the *indicial* and secondarily the matrix ones. All have relative advantages/drawbacks, depending on the task at hand.

Velocities and Virtual Displacements

Just as we defined new general kinematically admissible/possible system displacements via (2.9.1, 2), etc., we next define the following:

(i) The corresponding general system *velocities* ($d\theta \to \omega\, dt$);

$$\omega_k \equiv \sum a_{kl}(dq_l/dt) + a_k \equiv \sum a_{kl}\dot{q}_l + a_k \equiv \sum a_{kl}v_l + a_k,$$

$$\omega_{n+1} \equiv \omega_0 \equiv dq_{n+1}/dt \equiv dt/dt = 1 \qquad (\textit{isochrony}), \tag{2.9.9}$$

or, compactly,

$$\omega_\beta \equiv \sum a_{\beta\gamma}(dq_\gamma/dt) \equiv \sum a_{\beta\gamma}\, v_\gamma; \tag{2.9.9a}$$

and, inversely,

$$dq_l/dt \equiv \dot{q}_l \equiv v_l = \sum A_{lk}\,\omega_k + A_l, \qquad dq_{n+1}/dt \equiv \omega_{n+1} \equiv dt/dt = 1, \tag{2.9.10}$$

or, compactly,

$$dq_\gamma/dt \equiv \dot{q}_\gamma \equiv v_\gamma = \sum A_{\gamma\beta}\,\omega_\beta; \tag{2.9.10a}$$

and

(ii) The corresponding general system *virtual displacements* ($d\theta \to \delta\theta$, $d\theta_{n+1} \to \delta\theta_{n+1} = \delta t = 0$):

$$\delta\theta_k \equiv \sum a_{kl}\,\delta q_l, \qquad \delta\theta_{n+1} \equiv \delta q_{n+1} \equiv \delta t = 0; \tag{2.9.11}$$

and, inversely,

$$\delta q_l = \sum A_{lk}\,\delta\theta_k, \qquad \delta q_{n+1} \equiv \delta q_0 \equiv \delta\theta_{n+1} \equiv \delta\theta_0 \equiv \delta t = 0. \tag{2.9.12}$$

If the $d\theta$ and dt describe an *actual* motion, then $d\theta_k = \omega_k\, dt$. But it would be incorrect to set $\delta\theta_k = \omega_k\,\delta t$, because of the ever present (better, ever assumed) *virtual time constraint* $\delta t = 0$; whereas, in general, $\delta\theta_k \neq 0$!

Next, let us examine the integrability of these Pfaffian *forms* (not constraints!) (2.9.1, 11), of our hitherto n *DOF* system.

Bilinear Covariants, Integrability, Quasi Coordinates

Indeed, proceeding as in §2.8, and assuming that $d(\delta q_k) = \delta(dq_k)$, constraints or not, we find that the *Frobenius bilinear covariants* of (2.9.1, 11), $d(\delta\theta_k) - \delta(d\theta_k)$, equal

$$\begin{aligned} d(\delta\theta_k) - \delta(d\theta_k) &= \sum\sum (\partial a_{kl}/\partial q_s - \partial a_{ks}/\partial q_l)\, dq_s \delta q_l \\ &\quad + \sum (\partial a_{kl}/\partial t - \partial a_k/\partial q_l)\, dt\,\delta q_l \\ &\equiv \sum d\psi_{kl}\,\delta q_l. \end{aligned} \tag{2.9.13}$$

Now, with the help of these expressions, and since the dq's and δq's are (as yet) unconstrained (i.e., $m = 0$), like the q's, we can enunciate the following "obvious" theorems, in increasing order of specificity:

- The necessary and sufficient conditions for the *particular* Pfaffian *form* (not constraint!)

$$d\theta_k \equiv \sum a_{kl}\, dq_l + a_k\, dt, \qquad \text{or in virtual form} \qquad \delta\theta_k \equiv \sum a_{kl}\, \delta q_l, \quad (2.9.14)$$

  to be an *exact* differential—that is, for the hitherto shorthand symbols $d\theta_k$ and $\delta\theta_k$ to be the genuine (first and total) differentials of a bona fide function $\theta_k = \theta_k(q, t)$ ($\rightarrow$ *holonomic coordinate*)—is that its bilinear covariant (2.9.13), vanish.

- The necessary and sufficient condition for *a* Pfaffian form (2.9.14) to be the exact differential of θ_k [since its n δq's in (2.9.13) are arbitrary] is that its *associated n Pfaffian forms*

$$d\psi_{kl} \equiv \sum (\partial a_{kl}/\partial q_s - \partial a_{ks}/\partial q_l)\, dq_s + (\partial a_{kl}/\partial t - \partial a_k/\partial q_l)\, dt, \qquad (2.9.15)$$

  all vanish; that is, $d\psi_{kl} = 0$ for all $l\ (= 1, \ldots, n)$.

- The necessary and sufficient condition for *a* Pfaffian form (2.9.14) to be the exact differential of θ_k [since the n dq's and dt in (2.9.15) are arbitrary] is that the following $n(n+1)/2$ integrability (or exactness) conditions hold:

$$\partial a_{kl}/\partial q_s - \partial a_{ks}/\partial q_l = 0 \qquad \textit{and} \qquad \partial a_{kl}/\partial t - \partial a_k/\partial q_l = 0, \qquad (2.9.16)$$

  identically in the q's and t, and for *all* values of l, s $(= 1, \ldots, n)$. [For additional insights and details, see, for example, Hagihara (1970, pp. 42–46), Whittaker (1937, p. 296 ff.).]

Hence, if (2.9.16) hold for *all* $k = 1, \ldots, n$, the n θ's are just another minimal set of Lagrangean coordinates, like the q's: $\theta_k = \theta_k(q_1, \ldots, q_n; t)$; and $\omega_k \equiv d\theta_k/dt$ are the corresponding holonomic Lagrangean (generalized) velocities. But if, and this is the case of interest to AM,

$$\partial a_{kl}/\partial q_s - \partial a_{ks}/\partial q_l \neq 0 \qquad \text{or} \qquad \partial a_{kl}/\partial t - \partial a_k/\partial q_l \neq 0, \qquad (2.9.17)$$

even for one l, s, then ω_k is *not* a total time derivative, and $d\theta_k$ is *not* a genuine differential of a holonomic coordinate θ_k; *only* the $d\theta_k/\delta\theta_k/\omega_k$ are defined through (2.9.1, 9, 11). Such undefined quantities, θ_k, are called *pseudo- or quasi coordinates* [a term, most likely, due to Whittaker (1904)], or *nonholonomic coordinates*; and the ω_k, depicted by some authors by *symbolic* $(\ldots)^{\cdot}$-derivatives, like

$$\omega_k \equiv d'\theta_k/dt \equiv \overset{*}{\theta}_k \equiv \overset{o}{\theta}_k, \quad \text{etc.}, \qquad (2.9.18)$$

instead of $d\theta_k/dt$, are called quasi velocities. From now on we shall assume, with no loss in generality, that all (2.9.17) hold, and therefore all θ_k are quasi coordinates. {We notice that, the *isochrony* choice $d\theta_{n+1} \equiv dq_{n+1} \equiv dt$, resulting in [recalling (2.9.4a, b)]

$$a_{n+1,k} \equiv \delta_{n+1,k} = 0, \qquad a_{n+1,\,n+1} = \delta_{n+1,\,n+1} = 1, \qquad (2.9.19a)$$

and

$$A_{n+1,k} \equiv \delta_{n+1,k} = 0, \qquad A_{n+1,\,n+1} = \delta_{n+1,\,n+1} = 1, \qquad (2.9.19b)$$

guarantees that θ_{n+1} remains holonomic.}

REMARKS

(i) Let us consider, for simplicity, the catastatic version of (2.9.9),

$$\omega_k = \sum a_{kl}(t, q)v_l = \omega_k(t, q, \dot{q} \equiv v). \tag{2.9.20}$$

If the q's are *known/specified functions of time t*, then integrating (2.9.20) between an initial instant t_o and a current one t we obtain the line integral

$$\theta_k(t) - \theta_k(t_o) = \int_{t_o}^{t} \omega_k[\tau, q(\tau),\, v(\tau)]\, d\tau = \int_{t_o}^{t} \left(\sum a_{kl}[\tau, q(\tau)]v_l(\tau) \right) d\tau; \tag{2.9.20a}$$

similar to the work integral of general mechanics and thermodynamics. Since this is the integral of an inexact differential, as calculus/vector field theory teach, $\theta_k(t)$ depends on both t (current configuration) and the particular *path of integration/history* followed from t_o to t; it is *point- and path-dependent*. If it was a genuine global coordinate, it would be *point-dependent, but path-independent*. $\theta_k(t; t_o)$ is a *functional* of the particular curves/motion $\{q(\tau), t_o \le \tau \le t\}$!

(ii) As will be explained in §2.11, the satisfaction of (2.9.16) guarantees that θ_k, as defined by (2.9.14), is a holonomic coordinate; and that property will hold even if, at a later stage, the $dq_k/\delta q_k/v_k$ become *holonomically* and/or *nonholonomically constrained*. One the other hand, if θ_k is originally [i.e., as defined by (2.9.14)] *nonholonomic*, then upon imposition on the latter's right side of a sufficient number of additional *holonomic* and/or *nonholonomic* constraints, later, it will become holonomic; but that would be a different Pfaffian form.

In sum: once a holonomic coordinate, *always* a holonomic coordinate; but once a nonholonomic coordinate, *not always* a nonholonomic coordinate.

(iii) The local transformations $\boldsymbol{a}_\eta \equiv \sum A_{\beta\eta}\boldsymbol{E}_\beta \Leftrightarrow \boldsymbol{E}_\beta = \sum a_{\eta\beta}\boldsymbol{a}_\eta$, where [recalling discussion in (§2.7)] each $\boldsymbol{E}_\beta$ is tangent to the coordinate line dq_β at (q, t) and all together they constitute a holonomic basis for the local tangent space T_{n+1}, and the coefficients satisfy the earlier (2.9.3a, 3b), define a new but, generally nonholonomic basis there: that is, $\sum \boldsymbol{a}_\eta\, d\theta_\eta$: *nonexact differential* $\Rightarrow \partial\boldsymbol{a}_\eta/\partial\theta_\beta \ne \partial\boldsymbol{a}_\beta/\partial\theta_\eta$ [where the nonholonomic gradients, $\partial/\partial\theta_\beta$, are defined in (2.9.27 ff.)]. And, in view of

$$\sum \dot{q}_\beta \boldsymbol{E}_\beta \equiv \sum v_\beta \boldsymbol{E}_\beta = \sum v_\beta\Big(\sum a_{\eta\beta}\,\boldsymbol{a}_\eta\Big) = \sum\Big(\sum a_{\eta\beta}v_\beta\Big)\boldsymbol{a}_\eta = \sum \omega_\eta\,\boldsymbol{a}_\eta$$
$$= \sum \omega_\beta\, a_\beta,$$

the ω_β are simply the *nonholonomic components* of the system velocity vector, while the v_β are its *holonomic components*. [The system basis $\{\boldsymbol{a}_\eta\}$ plays a key role in the geometrical interpretation of Pfaffian constraints (§2.11.19a ff.)]

(iv) The precise term for the θ_k's is "nonholonomic (local) system coordinates," and for the ω_k's "nonholonomic system velocity parameters," or "(*contravariant*) *nonholonomic components of the system velocity*" (Schouten, 1954/1989, pp. 194–197). We shall call them collectively *quasi variables*; and their symbolic calculus, if proper precautions are taken, is quite useful. As Synge puts it: "In the theory of quasi-coordinates in dynamics, however, it pays to live dangerously and to use the notation $d\theta_k$ [in our notation]. Otherwise we shall be depriving ourselves of a very neat formal expression of the equations of motion" (1936, p. 29). On the symbolic calculus of quasi variables, see also Johnsen (1939).

Example 2.9.1 The most common example of quasi velocities in mechanics is the components of the (inertial) angular velocity of a rigid body moving, with no loss in generality here, about a fixed point O, resolved along either space-fixed (inertial) axes O–XYZ, $\omega_X, \omega_Y, \omega_Z$; or body-fixed (moving) axes O–$xyz, \omega_x, \omega_y, \omega_z$. If $\phi \to \theta \to \psi$ are the three Eulerian angles $3 \to 1 \to 3$, then for body-axes, and with the convenient notations $s(\ldots) \equiv \sin(\ldots)$ and $c(\ldots) \equiv \cos(\ldots)$, and $d\phi/dt \equiv \omega_\phi$, $d\theta/dt \equiv \omega_\theta$, $d\psi/dt \equiv \omega_\psi$, we have (§1.12)

$$\omega_x = (s\psi\, s\theta)\omega_\phi + (c\psi)\omega_\theta + (0)\omega_\psi, \tag{a}$$

$$\omega_y = (c\psi\, s\theta)\omega_\phi + (-s\psi)\omega_\theta + (0)\omega_\psi, \tag{b}$$

$$\omega_z = (c\theta)\omega_\phi + (0)\omega_\theta + (1)\omega_\psi; \tag{c}$$

that is, with $k = x \to 1,\ y \to 2,\ z \to 3$; and $l = \phi \to 1,\ \theta \to 2,\ \psi \to 3$, the nonvanishing elements of (a_{kl}) are

$$a_{11} = s\psi\, s\theta, \quad a_{12} = c\psi; \qquad a_{21} = c\psi\, s\theta, \quad a_{22} = -s\psi; \qquad a_{31} = c\theta, \quad a_{33} = 1. \tag{d}$$

Clearly, not all (2.9.16) hold identically here. For example,

$$\partial a_{12}/\partial q_3 \neq \partial a_{13}/\partial q_2 : \quad \partial(c\psi)/\partial\psi \neq \partial(0)/\partial\theta : \quad -s\psi \neq 0; \tag{e}$$

except in the *special* (*nonidentical!*) case: $\psi = 0,\ 2\pi$. If we set $\omega_x = d\theta_x/dt$, then

$$\theta_x(t) \equiv \int_{t_o}^{t} \omega_x\big[\theta(\tau), \psi(\tau); \omega_\phi(\tau), \omega_\theta(\tau)\big]\, d\tau + \theta_x\,(\textit{initial}) : \ \textit{path dependent}; \tag{f}$$

that is, θ_x is an (angular) quasi coordinate, and ω_x an (angular) quasi velocity; and similarly for $\theta_y, \theta_z; \omega_y, \omega_z$; that is, they are quasi variables (if the ϕ, θ, ψ *are unconstrained*). However, if we impose *additional* constraints, for example, $\phi = \textit{constant}$, $\theta = \textit{constant}$ (fixed-axis rotation), then (a–c) reduce to

$$\omega_x = 0, \quad \omega_y = 0, \quad \omega_z = d\psi/dt \ \Rightarrow\ \omega_x, \omega_y, \omega_z : \textit{holonomic velocities}; \tag{g}$$

$$\theta_z(t) - \theta_z\,(t_o\text{: } \textit{initial}) = \int_{t_o}^{t} [d\psi(\tau)/d\tau]\, d\tau = \psi(t) - \psi\,(t_o\text{: } \textit{initial})\text{: } \textit{path independent}. \tag{h}$$

Problem 2.9.1 Let the reader verify that the corresponding *space-fixed* components $\theta_X, \theta_Y, \theta_Z$ and $\omega_X, \omega_Y, \omega_Z$ (such that $\omega_X \equiv d\theta_X/dt$, etc.) are also, respectively, quasi coordinates and quasi velocities; and that under additional constraints they too may become holonomic variables.

Particle Kinematics in Quasi Variables

Due to the $\theta \leftrightarrow q$ transformation relations (2.9.1, 2, 9, 10, 11, 12), the (inertial) velocity, acceleration, kinematically admissible/possible displacement, and virtual displacement, of a typical system particle, obtained in §2.5 in holonomic variables, assume the following quasi-variable representations, respectively:

(i) Velocity:

$$\boldsymbol{v} = \sum \boldsymbol{e}_k \Big(\sum A_{kl}\, \omega_l + A_k \Big) + \boldsymbol{e}_0 = \cdots = \sum \boldsymbol{\varepsilon}_k \omega_k + \boldsymbol{\varepsilon}_{n+1} \equiv \sum \boldsymbol{\varepsilon}_k \omega_k + \boldsymbol{\varepsilon}_0; \quad (2.9.21)$$

(ii) Acceleration:

$$\begin{aligned} \boldsymbol{a} = \cdots &= \sum \boldsymbol{\varepsilon}_k (d\omega_k/dt) + \text{terms not containing } (d\omega/dt)\text{'s}; \\ &\equiv \sum \boldsymbol{\varepsilon}_k \dot{\omega}_k + \text{terms not containing } \dot{\omega}\text{'s}, \end{aligned} \quad (2.9.22)$$

(iii) Kinematically possible/admissible displacement:

$$d\boldsymbol{r} = \sum \boldsymbol{e}_k \Big(\sum A_{kl}\, d\theta_l + A_k\, dt \Big) + \boldsymbol{e}_0\, dt = \cdots = \sum \boldsymbol{\varepsilon}_k\, d\theta_k + \boldsymbol{\varepsilon}_0\, dt; \quad (2.9.23)$$

(iv) Virtual displacement:

$$\delta\boldsymbol{r} = \sum \boldsymbol{e}_k \Big(\sum A_{kl}\, \delta\theta_l \Big) = \cdots = \sum \boldsymbol{\varepsilon}_k\, \delta\theta_k; \quad (2.9.24)$$

where the fundamental, *generally nongradient*, $n+1$ *particle and system* vectors $\boldsymbol{\varepsilon}_k$ and $\boldsymbol{\varepsilon}_{n+1} \equiv \boldsymbol{\varepsilon}_0$, corresponding to the θ's, nonholonomic counterparts of the gradient vectors $\boldsymbol{e}_k$ and $\boldsymbol{e}_{n+1} \equiv \boldsymbol{e}_0$, which correspond to the q's [recalling (2.5.4–4b)], and *defined* naturally by (2.9.21–24), obey the following basic (covariant vector-like) transformation equations:

$$\boldsymbol{\varepsilon}_k \equiv \sum (\partial v_l/\partial \omega_k) \boldsymbol{e}_l = \sum A_{lk} \boldsymbol{e}_l, \quad (2.9.25a)$$

$$\boldsymbol{e}_k \equiv \sum (\partial \omega_l/\partial v_k) \boldsymbol{\varepsilon}_l = \sum a_{lk} \boldsymbol{\varepsilon}_l \qquad \text{[comparing with (2.9.11, 12)]}; \quad (2.9.25b)$$

$$\boldsymbol{\varepsilon}_0 \equiv \sum A_k \boldsymbol{e}_k + \boldsymbol{e}_0 = -\sum a_k \boldsymbol{\varepsilon}_k + \boldsymbol{e}_0, \quad (2.9.26a)$$

$$\boldsymbol{e}_0 \equiv \sum a_k \boldsymbol{\varepsilon}_k + \boldsymbol{\varepsilon}_0 = -\sum A_k \boldsymbol{e}_k + \boldsymbol{\varepsilon}_0 \qquad \text{[recalling (2.9.3a, 3b)]}. \quad (2.9.26b)$$

Clearly, if the $\boldsymbol{e}$ vectors are linearly independent (and $|a_{kl}|, |A_{kl}| \neq 0$), so are the $\boldsymbol{\varepsilon}$ vectors; even if the q's and/or $dq/dt \equiv v$'s get constrained later. And, as with the $\delta\boldsymbol{r}$-representation (2.5.12b), so with (2.9.24): *the size of the $\delta\theta$'s is unimportant; it is the $\boldsymbol{\varepsilon}$'s that matter, because they are the ones entering the equations of motion* (chap. 3)!

Quasi Chain Rule, Symbolic Notations

The above, especially (2.9.24), suggest the adoption of the following very useful symbolic *quasi-chain rule* for quasi variables:

$$\begin{aligned} \partial\boldsymbol{r}/\partial\theta_k &\equiv \sum (\partial\boldsymbol{r}/\partial q_l)(\partial v_l/\partial \omega_k) \equiv \sum (\partial\boldsymbol{r}/\partial q_l)\big[\partial(dq_l)/\partial(d\theta_k)\big] \\ &= \sum (\partial\boldsymbol{r}/\partial q_l)\big[\partial(\delta q_l)/\partial(\delta\theta_k)\big], \end{aligned}$$

or, simply,

$$\partial\mathbf{r}/\partial\theta_k \equiv \sum A_{lk}(\partial\mathbf{r}/\partial q_l): \quad \text{i.e., (2.9.25a);} \tag{2.9.27}$$

and, inversely,

$$\partial\mathbf{r}/\partial q_k = \sum(\partial\mathbf{r}/\partial\theta_l)(\partial\omega_l/\partial v_k) = \sum a_{lk}(\partial\mathbf{r}/\partial\theta_l): \quad \text{i.e., (2.9.25b).} \tag{2.9.28}$$

Similarly, for a general well-behaved function $f = f(q, t)$, and recalling (2.9.12), we obtain, successively, (i) for its *virtual variation* δf:

$$\delta f = \sum(\partial f/\partial q_k)\,\delta q_k = \sum(\partial f/\partial q_k)\Big(\sum(\partial v_k/\partial\omega_l)\,\delta\theta_l\Big) \equiv \sum(\partial f/\partial\theta_l)\,\delta\theta_l; \tag{2.9.29}$$

that is,

$$\partial f/\partial\theta_l \equiv \sum(\partial f/\partial q_k)(\partial v_k/\partial\omega_l) = \sum A_{kl}(\partial f/\partial q_k), \tag{2.9.30a}$$

and, inversely,

$$\partial f/\partial q_k = \sum(\partial f/\partial\theta_l)(\partial\omega_l/\partial v_k) = \sum a_{lk}(\partial f/\partial\theta_l); \tag{2.9.30b}$$

and (ii) for its *total differential* df [recalling (2.9.2)]:

$$\begin{aligned}
df &= \sum(\partial f/\partial q_\beta)\,dq_\beta = \sum(\partial f/\partial q_k)\,dq_k + (\partial f/\partial t)\,dt \\
&= \sum(\partial f/\partial q_k)\Big(\sum A_{kl}\,d\theta_l + A_k\,dt\Big) + (\partial f/\partial t)\,dt \\
&= \sum\Big(\sum A_{kl}(\partial f/\partial q_k)\Big)\,d\theta_l + \Big(\sum A_k(\partial f/\partial q_k) + \partial f/\partial t\Big)\,dt \\
&\equiv \sum(\partial f/\partial\theta_l)\,d\theta_l + (\partial f/\partial\theta_0)\,dt,
\end{aligned} \tag{2.9.31}$$

where we have introduced the additional symbolic notation [recalling that $\dot{\theta}_0 \equiv \dot{\theta}_{n+1} \equiv \omega_{n+1} = 1$]:

$$\begin{aligned}
\partial\ldots/\partial\theta_{n+1} &\equiv \sum(\partial\ldots/\partial q_\beta)(\partial v_\beta/\partial\omega_{n+1}) \\
&= \sum(\partial\ldots/\partial q_k)(\partial v_k/\partial\omega_{n+1}) + (\partial\ldots/\partial t)(\partial v_{n+1}/\partial\omega_{n+1}) \\
&= \sum A_k(\partial\ldots/\partial q_k) + \partial\ldots/\partial t;
\end{aligned} \tag{2.9.32}$$

instead of the formal extension of (2.9.30a) for $\theta_l \to \theta_{n+1}$. This latter we shall denote by $\partial\ldots/\partial(t)$:

$$\partial\ldots/\partial(t) \equiv \sum(\partial\ldots/\partial q_k)(\partial v_k/\partial\omega_{n+1}) = \sum A_k(\partial\ldots/\partial q_k); \tag{2.9.32a}$$

so that (2.9.32) assumes the final symbolic form

$$\partial\ldots/\partial\theta_{n+1} \equiv \partial\ldots/\partial\theta_0 \equiv \partial\ldots/\partial(t) + \partial\ldots/\partial t. \tag{2.9.32b}$$

Inversely, we have

$$\partial\ldots/\partial t = \sum(\partial\omega_\alpha/\partial v_{n+1})(\partial\ldots/\partial\theta_\alpha) = \partial\ldots/\partial\theta_{n+1} + \sum a_k(\partial\ldots/\partial\theta_k), \tag{2.9.32c}$$

and, comparing this with (2.9.30a, b), we readily conclude that

$$\partial\ldots/\partial(t) = \sum A_k(\partial\ldots/\partial q_k) = -\sum a_k(\partial\ldots/\partial\theta_k). \tag{2.9.32d}$$

Such (by no means uniform) symbolic notations are useful in *energy rate/power* theorems in nonholonomic variables (§3.9).

Some Fundamental Kinematical Identities

From the above (2.9.21 ff.), we readily obtain the following fundamental kinematical identities, nonholonomic counterparts of (2.5.7–10), and like them, holding independently of any subsequent holonomic and/or nonholonomic constraints.

(i) $$\partial\boldsymbol{r}/\partial\theta_k = \partial\dot{\boldsymbol{r}}/\partial\dot{\theta}_k = \partial\ddot{\boldsymbol{r}}/\partial\ddot{\theta}_k \equiv \partial\ddot{\boldsymbol{r}}/\partial\dot{\omega}_k = \cdots \equiv \boldsymbol{\varepsilon}_k,$$

or

$$\partial\boldsymbol{r}/\partial\theta_k = \partial\boldsymbol{v}/\partial\omega_k = \partial\boldsymbol{a}/\partial\dot{\omega}_k = \cdots \equiv \boldsymbol{\varepsilon}_k; \tag{2.9.33}$$

(ii) $$\partial q_k/\partial\theta_l \equiv \partial\dot{q}_k/\partial\dot{\theta}_l = \partial\ddot{q}_k/\partial\ddot{\theta}_l \equiv \partial\ddot{q}_k/\partial\dot{\omega}_l = \cdots \equiv A_{kl},$$

or

$$\partial q_k/\partial\theta_l = \partial v_k/\partial\omega_l = \partial w_k/\partial\dot{\omega}_l = \cdots \equiv A_{kl}; \qquad (\text{where } dv_k/dt \equiv w_k) \tag{2.9.34}$$

(iii) $$\partial\theta_k/\partial q_l = \partial\omega_k/\partial v_l = \partial\dot{\omega}_k/\partial w_l = \cdots \equiv a_{kl}, \tag{2.9.35}$$

with formal extensions for $\theta_{n+1} \equiv q_{n+1} \equiv t$. The $d\omega_k/dt \equiv d^2\theta_k/dt^2$ are called (not quite correctly) *quasi accelerations*; while the $\theta/\omega/\dot{\omega}/\ldots$ are referred to, collectively, as (system) *quasi variables*.
(iv) We have, successively,

$$\begin{aligned} d(\partial\boldsymbol{r}/\partial\theta_k)\big/dt &= d(\partial\boldsymbol{v}/\partial\omega_k)\big/dt = d\boldsymbol{\varepsilon}_k/dt \\ &= d\Big(\sum A_{lk}\boldsymbol{e}_l\Big)\Big/dt = \sum\big[(dA_{lk}/dt)\boldsymbol{e}_l + A_{lk}(d\boldsymbol{e}_l/dt)\big] \\ &= \sum(dA_{lk}/dt)\boldsymbol{e}_l + \sum A_{lk}(\partial\boldsymbol{v}/\partial q_l) \quad [\text{recalling (2.5.7, 10)}]. \end{aligned} \tag{2.9.36}$$

But by partial ∂q_l-differentiation of $\boldsymbol{v}(q, v, t) = \boldsymbol{v}[q, v(q, \omega, t), t] \equiv \boldsymbol{v}^*(q, \omega, t)$, we find

$$\partial\boldsymbol{v}^*/\partial q_l = \partial\boldsymbol{v}/\partial q_l + \sum(\partial\boldsymbol{v}/\partial v_r)(\partial v_r/\partial q_l) = \partial\boldsymbol{v}/\partial q_l + \sum(\partial v_r/\partial q_l)\boldsymbol{e}_r,$$

and so

$$\sum A_{lk}(\partial \boldsymbol{v}/\partial q_l) = \sum A_{lk}(\partial \boldsymbol{v}^*/\partial q_l) - \sum\sum A_{lk}(\partial v_r/\partial q_l)\boldsymbol{e}_r$$
$$= \partial \boldsymbol{v}^*/\partial \theta_k - \sum\sum A_{lk}(\partial v_r/\partial q_l)\boldsymbol{e}_r.$$

Therefore, returning to (2.9.36), we see that it yields

$$d\boldsymbol{\varepsilon}_k/dt - \partial \boldsymbol{v}^*/\partial \theta_k = \sum \Big[dA_{lk}/dt - \sum A_{rk}(\partial v_l/\partial q_r)\Big]\boldsymbol{e}_l \neq \mathbf{0}, \tag{2.9.36a}$$

that is, *unlike the H coordinate case* (2.5.10),

$$E_k{}^*(\boldsymbol{v}^*) \equiv (\partial \boldsymbol{v}^*/\partial \dot{\theta}_k)^{\cdot} - \partial \boldsymbol{v}^*/\partial \theta_k \equiv d/dt(\partial \boldsymbol{v}^*/\partial \omega_k) - \partial \boldsymbol{v}^*/\partial \theta_k \neq \mathbf{0}. \tag{2.9.37}$$

This *nonintegrability* relation is a first proof that, in general, the $\boldsymbol{\varepsilon}_k$ *basis vectors are nongradient*, or *nonholonomic*. More comprehensible and useful forms of $E_k{}^*(\boldsymbol{v}^*)$ are presented in the next section.

[Some authors call the $\boldsymbol{\varepsilon}_k$ vectors "partial velocities." However, in view of (2.9.33), they could just as well have been called *partial positions*, or *partial accelerations*, or even *partial jerks* (recall that $d\boldsymbol{a}/dt \equiv \boldsymbol{j} = jerk\ vector$, and therefore $\partial \boldsymbol{j}/\partial \ddot{\omega}_k = \boldsymbol{\varepsilon}_k$), etc. Perhaps a better term would be *nonholonomic mixed basis vectors* (i.e., nonholonomic counterpart of Heun's *Begleitvektoren*).]

A Useful Nonholonomic-Variable Notation

Frequently, for extra clarity, we will be using the following "(...)*-notation":

$$f = f(t, q, dq/dt \equiv v) = f[t, q, v(t, q, \omega)] \equiv f^*(t, q, \omega) \equiv f^*. \tag{2.9.38}$$

With its help:

(i) Equations (2.9.21), (2.9.22), (2.9.33) become, respectively,

$$\boldsymbol{v}(t, q, v) = \sum \boldsymbol{e}_k(t, q)v_k + \boldsymbol{e}_0(t, q) = \sum \boldsymbol{\varepsilon}_k(t, q)\omega_k + \boldsymbol{\varepsilon}_0(t, q) \equiv \boldsymbol{v}^*(t, q, \omega); \tag{2.9.39}$$

$$\boldsymbol{a}(t, q, v, w) = \sum \boldsymbol{e}_k(t, q)w_k + \text{no other } \ddot{q} \equiv w\text{-terms}$$
$$= \sum \boldsymbol{\varepsilon}_k(t, q)\dot{\omega}_k + \text{no other } \dot{\omega}\text{-terms} \equiv \boldsymbol{a}^*(t, q, \omega, \dot{\omega}); \tag{2.9.40}$$

$$\partial \boldsymbol{r}/\partial \theta_k = \partial \boldsymbol{v}^*/\partial \omega_k = \partial \boldsymbol{a}^*/\partial \dot{\omega}_k = \cdots \equiv \boldsymbol{\varepsilon}_k; \tag{2.9.41}$$

(ii) The quasi-chain rule (2.9.30a) and its inverse (2.9.30b) *generalize*, respectively, to

$$\partial f^*/\partial \theta_l \equiv \sum (\partial f^*/\partial q_k)(\partial v_k/\partial \omega_l) = \sum A_{kl}(\partial f^*/\partial q_k), \tag{2.9.42a}$$

and

$$\partial f^*/\partial q_k = \sum (\partial f^*/\partial \theta_l)(\partial \omega_l/\partial v_k) = \sum a_{lk}(\partial f^*/\partial \theta_l); \tag{2.9.42b}$$

also, we easily obtain the related chain rules [recall derivation of (2.9.37), and (2.9.42a)]

$$\partial f^*/\partial q_k = \partial f/\partial q_k + \sum (\partial f/\partial v_l)(\partial v_l/\partial q_k), \tag{2.9.43a}$$

$$\Rightarrow \ \partial f^*/\partial \theta_l = \sum A_{kl}(\partial f^*/\partial q_k) = \sum A_{kl}\Big[\partial f/\partial q_k + \sum (\partial f/\partial v_r)(\partial v_r/\partial q_k)\Big]. \tag{2.9.43b}$$

(iii) The following *genuine* (i.e., *ordinary calculus*) *chain rule*, and its inverse, hold:

$$\partial f^*/\partial \omega_l \equiv \sum (\partial f/\partial v_k)(\partial v_k/\partial \omega_l) = \sum A_{kl}(\partial f/\partial v_k), \tag{2.9.44a}$$

$$\partial f/\partial v_k = \sum (\partial f^*/\partial \omega_l)(\partial \omega_l/\partial v_k) = \sum a_{lk}(\partial f^*/\partial \omega_l). \tag{2.9.44b}$$

We notice the *difference* between (2.9.42a, b) and (2.9.44a, b); the former are *non-vectorial* transformations, just symbolic definitions; while (for those familiar with tensors) the latter are genuine *covariant vector* transformations.

(iv) Finally, invoking (2.9.11, 12, 42a, b), it is not hard to see that

$$\sum (\partial f^*/\partial \theta_k)\, \delta\theta_k = \sum (\partial f^*/\partial q_k)\, \delta q_k. \tag{2.9.45}$$

Some Closing Comments on Quasi Coordinates

The theory of nonholonomic coordinates and constraints is, by now, a well established and well understood part of differential geometry/tensor calculus and mechanics, with many fertile applications in those areas. Its long and successful history has been created by several famous mathematicians, such as (chronologically): Gibbs, Volterra, Poincaré, Heun, Hamel, Synge, Schouten, Struik, Vranceanu, Vagner, Kron, Kondo, Dobronravov et al. And yet, we encounter contemporary statements of appalling ignorance and confusion, like the following from an *advanced* "Tract in Natural Philosophy" devoted to rigid kinematics: "It appears that the reason why many a book on classical dynamics follows Kirchhoff's approach is a lack of understanding of the kinematics of rigid bodies. Thus, one finds extensive discussions on ill-defined — or, sometimes, totally undefined — esoteric quantities such as *quasi-coordinates* and *virtual displacements*," (Angeles, 1988, p. 2, the italics are that author's).

2.10 TRANSITIVITY, OR TRANSPOSITIONAL, RELATIONS; HAMEL COEFFICIENTS

So far, our system remains a holonomic (H) one, with $n \equiv 3N - h \;\; DOF$. Now, to be able to either (i) embed to it *additional Pfaffian* (*possibly nonholonomic*) *constraints* in their "simplest possible form" or, even if no such additional constraints are imposed, (ii) express the equations of the problem in quasi variables, or (iii) do both, we need to represent the right sides of the Frobenius bilinear covariants of the Pfaffian forms of its quasi variables, $(\ldots)\, dq\, \delta q$ [recall (2.9.13)], in terms of the latter's differentials, $(\ldots)\, d\theta\, \delta\theta$. [By simplest possible form we mean *uncoupled* from each other; and, as detailed in chap. 3, this leads to the simplest possible form of the equations of motion.] To this end, we insert expressions (2.9.2 and 12) into the right side of (2.9.13), and group the terms appropriately. The result is the following *generalized transitivity, or transpositional, equations* (Hamel's *Übergangs-,* or *Transitivitäts-gleichungen*):

$$
\begin{aligned}
d(\delta\theta_k) - \delta(d\theta_k) &= \sum a_{kl}[d(\delta q_l) - \delta(dq_l)] + \sum\sum \gamma^k{}_{\alpha\beta}\, d\theta_\beta\, \delta\theta_\alpha \\
&= \sum a_{kl}[d(\delta q_l) - \delta(dq_l)] + \sum\sum \gamma^k{}_{r\beta}\, d\theta_\beta\, \delta\theta_r \quad [\text{since } \delta\theta_{n+1} \equiv \delta t = 0] \\
&= \sum a_{kl}[d(\delta q_l) - \delta(dq_l)] + \sum\sum \gamma^k{}_{rs}\, d\theta_s\, \delta\theta_r + \sum \gamma^k{}_r\, dt\, \delta\theta_r,
\end{aligned} \tag{2.10.1}
$$

(again, we recall that all Latin (Greek) indices run from 1 to n (1 to $n+1$)) where the so-defined γ's, known as *Hamel* (*three-index*) *coefficients*, are explicitly given (and sometimes also defined) by

$$
\begin{aligned}
\gamma^k{}_{rs} &= \sum\sum (\partial a_{k\beta}/\partial q_\varepsilon - \partial a_{k\varepsilon}/\partial q_\beta) A_{\beta r} A_{\varepsilon s} \\
&= \sum\sum (\partial a_{kb}/\partial q_c - \partial a_{kc}/\partial q_b) A_{br} A_{cs} \\
&\quad + \sum (\partial a_{kb}/\partial t - \partial a_{k,n+1}/\partial q_b) A_{br} A_{n+1,s} \\
&\quad + \sum (\partial a_{k,n+1}/\partial q_c - \partial a_{kc}/\partial t) A_{n+1,r} A_{cs} \\
&\quad + (\partial a_{k,n+1}/\partial t - \partial a_{k,n+1}/\partial t) A_{n+1,r} A_{n+1,s},
\end{aligned} \tag{2.10.1a}
$$

or, due to $A_{n+1,r} = \delta_{n+1,r} = 0$ which leads to the *vanishing of the last three groups/sums of terms*, finally,

$$\gamma^k{}_{rs} = \sum\sum (\partial a_{kb}/\partial q_c - \partial a_{kc}/\partial q_b) A_{br} A_{cs}; \tag{2.10.2}$$

and

$$\gamma^k{}_{r,n+1} = -\gamma^k{}_{n+1,r} \equiv \gamma^k{}_r \equiv \sum\sum (\partial a_{k\beta}/\partial q_\varepsilon - \partial a_{k\varepsilon}/\partial q_\beta) A_{\beta r} A_{\varepsilon,n+1}, \tag{2.10.3}$$

or, with $a_{k,n+1} \equiv a_k$, $A_{k,n+1} \equiv A_k$, and since $A_{n+1,n+1} \equiv \delta_{n+1,n+1} = 1$, finally,

$$\gamma^k{}_r \equiv \sum\sum (\partial a_{kb}/\partial q_c - \partial a_{kc}/\partial q_b) A_{br} A_c + \sum (\partial a_{kb}/\partial t - \partial a_k/\partial q_b) A_{br}. \tag{2.10.4}$$

[The γ's are a significant generalization of coefficients introduced by Ricci (mid-1890s), Volterra (1898), Boltzmann (1902) et al.; and, hence, they are also referred as "Ricci/Boltzmann/Hamel (rotation) coefficients." See, for example, Papastavridis (1999, chaps. 3, 6).]

It is not hard to show [with the help of (2.9.3a, b)] that (2.10.1) inverts to

$$
\begin{aligned}
d(\delta q_k) - \delta(dq_k) = \sum A_{kl}\Big\{ &[d(\delta\theta_l) - \delta(d\theta_l)] \\
&- \sum\sum \gamma^l{}_{rs}\, d\theta_s\, \delta\theta_r - \sum \gamma^l{}_r\, dt\, \delta\theta_r \Big\}.
\end{aligned} \tag{2.10.5}
$$

For an actual motion, dividing both sides of (2.10.1) and (2.10.5) with dt [which does not interact with $\delta(\ldots)$], we obtain, respectively, the (system) *velocity transitivity equation* and its inverse:

$$(\delta\theta_k)^{\cdot} - \delta\omega_k = \sum a_{kl}[(\delta q_l)^{\cdot} - \delta v_l] + \sum\sum \gamma^k{}_{rs}\,\omega_s\,\delta\theta_r + \sum \gamma^k{}_r\,\delta\theta_r, \tag{2.10.6}$$

$$(\delta q_k)^{\cdot} - \delta v_k = \sum A_{kl}\Big\{[(\delta\theta_l)^{\cdot} - \delta\omega_l] - \sum\sum \gamma^l{}_{rs}\,\omega_s\,\delta\theta_r - \sum \gamma^l{}_r\,\delta\theta_r\Big\}. \tag{2.10.7}$$

Properties of the Hamel Coefficients

(i) Clearly, these coefficients depend, through the transformation coefficients $a_{\beta\varepsilon}$ and $A_{\beta\varepsilon}$, on the particular $v \leftrightarrow \omega$ choice; that is, *they do not depend on any particular system motion.*

(ii) The $\gamma^k{}_r$ contain the contributions of (a) the *acatastatic* terms a_k and A_k, and of (b) the *explicit time-dependence of the homogeneous coefficients* of the $v \Leftrightarrow \omega$ transformation. Hence, for *scleronomic* such transformations (i.e., $a_k = 0 \Rightarrow A_k = 0$, and $\partial a_{kl}/\partial t = 0 \Rightarrow \partial A_{kl}/\partial t = 0$) they vanish; but for *catastatic* ones, in general, they do not. In fact then, as (2.10.4) shows, they reduce to

$$\gamma^k{}_r = \sum (\partial a_{kb}/\partial t)A_{br} \qquad \text{(for catastatic Pfaffian transformations).} \tag{2.10.4a}$$

(iii) The matrix $\boldsymbol{\gamma}^k = (\gamma^k{}_{rs})$ is, obviously, *antisymmetric*; that is,

$$\gamma^k{}_{rs} = -\gamma^k{}_{sr} \Rightarrow \gamma^k{}_{rr}:\ \textit{diagonal elements} = 0 \qquad (k, r, s = 1, \ldots, n;\ \text{also } n+1). \tag{2.10.8}$$

To stress this antisymmetry in r and s, we chose to raise k; that is, we wrote $\gamma^k{}_{rs}$ instead of γ_{rks}, or γ_{krs}, or γ_{rsk}, and so on. [Nothing tensorial is implied here, although this happens to be the tensorially correct index positioning; see, for example, Papastavridis (1999, chaps. 3, 6).] Hence, each matrix $\boldsymbol{\gamma}^k$ can have at most $n(n-1)/2$ nonzero (nondiagonal) elements.

(iv) From the above, we readily conclude that

$$\gamma^{n+1}{}_{\varepsilon\beta} = 0 \Rightarrow \gamma^{n+1}{}_{kl} = 0, \qquad \gamma^{n+1}{}_{k,n+1} = -\gamma^{n+1}{}_{n+1,k} = 0, \qquad \gamma^{n+1}{}_{n+1,n+1} = 0$$

$$[k, l = 1, \ldots, n;\ \varepsilon, \beta = 1, \ldots, n; n+1], \tag{2.10.9}$$

and from this (recalling that $a_{n+1,k} = \delta_{n+1,k} = 0$), that

$$(\delta\theta_{n+1})^{\cdot} - \delta\omega_{n+1} \equiv d/dt(\delta q_{n+1}) - \delta(dq_{n+1}/dt) \equiv d/dt(\delta t) - \delta(dt/dt)$$
$$= \sum\sum \gamma^{n+1}{}_{rs}\,\omega_s\,\delta\theta_r + \sum \gamma^{n+1}{}_{r,n+1}\,\delta\theta_r = 0 + 0 = 0, \tag{2.10.10}$$

which, essentially, states that

$$d(\delta\theta_{n+1}) - \delta(d\theta_{n+1}) = d(\delta t) - \delta(dt) = d(0) - \delta(dt) = 0 - 0 = 0, \tag{2.10.10a}$$

as it should, and also shows that (2.10.1) and (2.10.2) also hold for $k = n+1$.

(v) In concrete problems, the analytical calculation of the nonvanishing γ's is best done, as Hamel et al. have pointed out, not by applying (2.10.1a–4), which are admittedly laborious and error prone, but by reading them off as *coefficients of the bilinear covariant* (2.10.1, 6), in terms of the general subindices: $o, \blacklozenge = 1, \ldots, n; n+1$:

$$d(\delta\theta_*) - \delta(d\theta_*) = \cdots + (\gamma^*{}_{o\blacklozenge})\, d\theta_\blacklozenge\, \delta\theta_o + \cdots. \tag{2.10.11}$$

Also, this task is independent of any particular assumptions about $d(\delta q) - \delta(dq)$; and, hence, assuming that for *all* holonomic coordinates $d(\delta q_k) = \delta(dq_k)$, or equivalently $(\delta q_k)^{\cdot} = \delta(\dot{q}_k) \equiv \delta v_k$ (Hamel viewpoint — see also pr. 2.12.5), *even if they* (*or their differentials*) *become constrained later*, we may safely and conveniently calculate all the nonvanishing γ's from the simplified, and henceforth definitive, transitivity equation:

$$d(\delta\theta_k) - \delta(d\theta_k) = \sum\sum \gamma^k{}_{rs}\, d\theta_s\, \delta\theta_r + \sum \gamma^k{}_r\, dt\, \delta\theta_r. \tag{2.10.12}$$

Finally, dividing the above with dt, and so on, we obtain its velocity form:

$$(\delta\theta_k)^{\cdot} - \delta\omega_k = \sum\sum \gamma^k{}_{rs}\omega_s\, \delta\theta_r + \sum \gamma^k{}_r\, \delta\theta_r; \tag{2.10.13}$$

a representation useful in Hamilton's time integral "principle" in quasi variables (chap. 7). Unfortunately, the transitivity equations, and their relations with the γ's, are nowhere to be found in the English language literature (with the exception of Neimark and Fufaev, 1967 and 1972, p. 126. ff.); although the definition of the γ's via (2.10.1a, 2) appears in a number of places. This unnatural situation produces an incomplete understanding of these basic quantities.

REMARK (A PREVIEW)

As will become clear in chapter 3, the expression for the system kinetic energy (and the Appellian "acceleration energy") are simpler in terms of quasi variables, such as the ω's and $d\omega/dt$'s, than in terms of holonomic variables like the v's and dv/dt's. And this leads to formally simpler equations of motion in the former variables than in the latter; for example, the well-known Eulerian rotational rigid-body equations (§1.17) are simpler in terms of such quasi variables than, say, in terms of Eulerian angles and their $(\ldots)^{\cdot}$-derivatives. But there is a catch: to obtain such simpler-looking Lagrange-type equations of motion — that is, equations based on the kinetic energy and its various gradients — we must calculate the corresponding γ's; something that, even with utilization of (2.10.11–13) and other practice-based short cuts, requires some labor and skill. On the positive side, however, the γ's supply an important "amount" of understanding into the kinematical structure of the particular problem; and Appellian-type equations in quasi variables may not contain the γ's, but they have other calculational difficulties. In sum, there is no painless way to obtain simple-looking equations of motion in quasi variables.

Problem 2.10.1 Verify that the transitivity equations, say (2.10.12), can be rewritten as

$$d(\delta\theta_k) - \delta(d\theta_k) = \sum\sum{}' \gamma^k{}_{rs}(d\theta_s\, \delta\theta_r - \delta\theta_s\, d\theta_r) + \sum \gamma^k{}_r\, dt\, \delta\theta_r, \tag{a}$$

where $\sum\sum{}'$ means that the summation extends over r and s only *once*; say, for $s < r$. [We point out the following interesting geometrical interpretation of (a): each of its double summation terms is proportional to a 2×2 determinant, which, in turn, equals the area of the infinitesimal parallelogram with sides two vectors on the local "$\theta_s\theta_r$-plane," at its origin (q, t) in configuration/event space, of respective rectangular Cartesian components $(d\theta_s, d\theta_r)$ and $(\delta\theta_s, \delta\theta_r)$ there; with the factor of proportionality being $\gamma^k{}_{rs}$. That parallelogram is the projection of the generalized parallelogram with sides $d\theta \equiv (d\theta_1, \ldots, d\theta_n)$ and $\delta\theta \equiv (\delta\theta_1, \ldots, \delta\theta_n)$, at (q, t), on the "$\theta_s\theta_r$-plane" (see, e.g., Boltzmann, 1904, pp. 104–107; Webster, 1912, pp. 84–87, 381–383; also Papastavridis, 1999, §3.14).]

Other Expressions for the γ's

By ∂q-differentiating (2.9.3a) and then rearranging so as to go from the $(\partial a/\partial q)$'s to the $(\partial A/\partial q)$'s, we obtain

$$\sum (\partial a_{kb}/\partial q_c) A_{br} = -\sum a_{kb}(\partial A_{br}/\partial q_c), \tag{2.10.14a}$$

$$\sum (\partial a_{kc}/\partial q_b) A_{cs} = -\sum a_{kc}(\partial A_{cs}/\partial q_b); \tag{2.10.14b}$$

then, substituting the above into (2.10.2), and renaming some dummy indices, we obtain the equivalent γ-expression:

$$\gamma^k{}_{rs} = \sum\sum a_{kb}\big[A_{cr}(\partial A_{bs}/\partial q_c) - A_{cs}(\partial A_{br}/\partial q_c)\big]. \tag{2.10.15}$$

For $s \to n+1$, the above yields an alternative to the (2.10.3), (2.10.4) expression for $\gamma^k{}_{r,n+1} \equiv \gamma^k{}_r$.

Problem 2.10.2 Show that yet another γ-expression is

$$\gamma^k{}_{rs} = \sum\sum (A_{br}A_{cs} - A_{cr}A_{bs})(\partial a_{kb}/\partial q_c), \tag{a}$$

and similarly for $\gamma^k{}_{r,n+1} \equiv \gamma^k{}_r$ (see also Stückler, 1955; Lobas, 1986, pp. 34–36).

Some Transformation Properties of the γ's

(i) With the help of the following useful notation:

$$a^k{}_{bc} \equiv \partial a_{kb}/\partial q_c - \partial a_{kc}/\partial q_b = -a^k{}_{cb}, \tag{2.10.16a}$$

$$a^k{}_{b,n+1} \equiv a^k{}_b \equiv \partial a_{kb}/\partial t - \partial a_k/\partial q_b \tag{2.10.16b}$$

[recalling (2.9.16); also similar notation in (2.8.2a)], the γ-definitions (2.10.2)–(2.10.4) are rewritten, respectively, as

$$\gamma^k{}_{rs} = \sum\sum a^k{}_{bc}A_{br}A_{cs}, \qquad \gamma^k{}_r = \sum\sum a^k{}_{bc}A_{br}A_c + \sum a^k{}_b A_{br}. \tag{2.10.17a, b}$$

With the help of the inverseness conditions (2.9.3a, 3b) and a number of dummy index changes, it is not too hard to show that (2.10.17a,b) invert, respectively, to

$$a^k{}_{bc} = \sum\sum \gamma^k{}_{rs}a_{rb}a_{sc}, \qquad a^k{}_b = \sum\sum \gamma^k{}_{rs}a_{rb}a_s + \sum \gamma^k{}_r a_{rb}. \tag{2.10.18a, b}$$

The above transformation equations show that if the $a^k{}_{bc}$ and $a^k{}_b$ vanish [recall conditions (2.9.16)], so do the $\gamma^k{}_{rs}$ and $\gamma^k{}_r$; and vice versa; that is, the vanishing of $\gamma^k \ldots$ constitutes the necessary and sufficient condition for $d\theta_k/\delta\theta_k$ to be an *exact differential*, and hence, for θ_k to be a *holonomic coordinate*. If the $dq/\delta q/v$ are *unconstrained*, as is the case so far (i.e., $m = 0$), this new set of exactness conditions in terms of the γ's does not offer any advantages over (2.9.16); the $a^k{}_{bc}$ and $a^k{}_b$ are easier to calculate than $\gamma^k{}_{rs}$ and $\gamma^k{}_r$. As shown in the next section, the real value of the γ's, in questions of holonomicity, appears whenever the $dq/\delta q/v$ are *constrained* $(m \neq 0)$.

REMARK

For those familiar with tensors, the transformation equations (2.10.17a, b) show that the $\gamma^k{}_{\ldots}$ and $a^k{}_{\ldots}$ transform as *covariant tensors* in their two subscripts; that is, both are components of the *same geometrical entity*: the a's, its holonomic components in the local "coordinates" $dq/\delta q$, and the γ's, its nonholonomic components in the local "coordinates" $d\theta/\delta\theta$, at (q, t). In precise tensor notation, using, for example, *accented* (*unaccented*) indices for *nonholonomic* (*holonomic*) *components*, summation convention over pairs of diagonal indices of the same kind (i.e., both holonomic, or both nonholonomic), and with the notational changes: $A_{br} \to A^b{}_{r'} \to A^r{}_{r'}$, $A_{cs} \to A^c{}_{s'} \to A^s{}_{s'}$, and $a^k{}_{bc} \to a^{k'}{}_{bc} \to a^{k'}{}_{rs} \to \gamma^{k'}{}_{rs}$ (= holonomic components), $\gamma^k{}_{rs} \to \gamma^{k'}{}_{r's'}$ (= nonholonomic components), the transformation equations (2.10.17a) read

$$\gamma^{k'}{}_{r's'} = A^r{}_{r'} A^s{}_{s'} \gamma^{k'}{}_{rs}; \tag{2.10.17c}$$

and similarly for (2.10.17b)–(2.10.18b). Such elaborate notation is a must in advanced differential-geometric investigations of nonholonomic systems. Fortunately, it will not be needed here.

(ii) The invariant definition of the γ's via the transitivity equations (2.10.1) and (2.10.12) readily shows that, contrary to what one might conclude by casually inspecting their derivative definition via (2.10.2–4), these *nontensorial* coefficients, known in tensor calculus as *geometrical objects of nonholonomicity* (or *anholonomicity*), are independent of the original holonomic coordinates q, and thus express geometric properties of the local/differential basis $d\theta/\delta\theta/\omega$. In particular, it follows that *if the γ's do (not) vanish, when based on some (q, t) frame of reference, they will (not) vanish in any other frame (q', t), obtainable from the original frame by an admissible transformation.*

(iii) However, under a *local* transformation $d\theta_k \Leftrightarrow d\theta_{k'}$, that is, at the same (q, t)-point, the γ's, *do* change, in the earlier mentioned nontensorial fashion.

[(a) For further details on tensorial nonholonomic dynamics see, for example, Dobronravov (1948, 1970, 1976), Kil'chevskii (1972, 1977), Maißer (1981, 1982, 1983–1984, 1991(b), 1997), Papastavridis (1999), Schouten (1954), Synge (1936), Vranceanu (1936); and references cited there. (b) For *transitivity* equation–based proofs of these statements, see, for (ii): ex. 2.12.2, and for (iii): ex. 2.10.1; and for a *derivative* definition–based proof, see, for example, Golab (1974, pp. 140–141).]

Noncommutativity of Mixed Partial Quasi Derivatives

Below we show that the second mixed partial symbolic quasi derivatives of an arbitrary well-behaved function $f = f(q, t, \ldots)$, in general, do *not* commute:

$$\partial/\partial\theta_k(\partial f/\partial\theta_l) \neq \partial/\partial\theta_l(\partial f/\partial\theta_k). \tag{2.10.19}$$

Invoking the basic quasi-derivative definition (2.9.30a, b), we obtain, successively,

$$\begin{aligned}\partial^2 f/\partial\theta_k\,\partial\theta_l &\equiv \partial/\partial\theta_k(\partial f/\partial\theta_l) \equiv \sum A_{rk}\Big\{\partial/\partial q_r\Big(\sum A_{sl}(\partial f/\partial q_s)\Big)\Big\}\\ &= \sum\sum\big[A_{rk}A_{sl}(\partial^2 f/\partial q_r\,\partial q_s) + A_{rk}(\partial A_{sl}/\partial q_r)(\partial f/\partial q_s)\big]\\ &= \sum\sum A_{rk}A_{sl}(\partial^2 f/\partial q_r\,\partial q_s) + \sum\Big(\sum\sum a_{bs}A_{rk}(\partial A_{sl}/\partial q_r)\Big)(\partial f/\partial\theta_b),\end{aligned}$$

and, analogously (with $k \to l$ and $l \to k$ in the above),

$$\begin{aligned}\partial^2 f/\partial\theta_l\,\partial\theta_k &\equiv \partial/\partial\theta_l(\partial f/\partial\theta_k) = \cdots\\ &= \sum\sum A_{rl}A_{sk}(\partial^2 f/\partial q_r\,\partial q_s) + \sum\Big(\sum\sum a_{bs}A_{rl}(\partial A_{sk}/\partial q_r)\Big)(\partial f/\partial\theta_b),\end{aligned}$$

and therefore subtracting these two side by side, and recalling the γ-definition (2.10.15), we obtain the following alternative *transitivity/noncommutativity* relation:

$$\begin{aligned}\partial^2 f/\partial\theta_k\,\partial\theta_l - \partial^2 f/\partial\theta_l\,\partial\theta_k &\equiv \partial/\partial\theta_k(\partial f/\partial\theta_l) - \partial/\partial\theta_l(\partial f/\partial\theta_k)\\ &= \sum\Big\{\sum\sum a_{bs}\big[A_{rk}(\partial A_{sl}/\partial q_r) - A_{rl}(\partial A_{sk}/\partial q_r)\big]\Big\}(\partial f/\partial\theta_b)\\ &= \sum \gamma^b{}_{kl}(\partial f/\partial\theta_b);\end{aligned}\tag{2.10.20}$$

which expresses noncommutativity in terms of $(\partial\ldots/\partial\theta)$-derivatives, rather than $(d\ldots/\delta\ldots)$-differentials, as (2.10.1) and (2.10.12) do.

REMARK

In the theory of continuous (or Lie) groups, it is customary to write $X_k f$ for our $\partial f/\partial\theta_k$, (2.9.30a); that is,

$$\partial\ldots/\partial\theta_k \equiv X_k\cdots \equiv \sum(\partial\ldots/\partial q_l)(\partial v_l/\partial\omega_k) = \sum A_{lk}(\partial\ldots/\partial q_l). \tag{2.10.21}$$

The differential operators X_k are called the *generators* of that group. In this notation, equation (2.10.20) is rewritten as

$$[X_k, X_l]f = \sum \gamma^b{}_{kl}(X_b f), \tag{2.10.22}$$

where $[X_k, X_l] \equiv X_k X_l - X_l X_k \equiv \sum \gamma^b{}_{kl}(X_b)$: *commutator of group*. For further details, see texts on Lie groups, and so on; also Hamel (1904(a), (b)), Hagihara (1970), McCauley (1997).

Problem 2.10.3 Extend (2.10.20) to the case where one or both of θ_k, θ_l are the (θ_{n+1})th "coordinate", that is, $\theta \to t$.

Problem 2.10.4 The choice $f \to q_r$ in (2.10.20), and then use of (2.9.34), yields the symbolic identity

$$\partial^2 q_r/\partial\theta_k\,\partial\theta_l - \partial^2 q_r/\partial\theta_l\,\partial\theta_k = \sum \gamma^b{}_{kl}(\partial q_r/\partial\theta_b) = \sum A_{rb}\gamma^b{}_{kl}. \tag{a}$$

Solving (a) for the γ's, derive the following alternative symbolic expression/definition for γ:

$$\gamma^b{}_{kl} = \sum a_{br}(\partial^2 q_r/\partial\theta_k\,\partial\theta_l - \partial^2 q_r/\partial\theta_l\,\partial\theta_k). \tag{b}$$

HINT

Multiply (a) with a_{sr} and sum over r, and so on.

Nonintegrability Conditions for a Nonholonomic Basis

Since (2.10.20) holds for an arbitrary f, let us apply it for $f \to \boldsymbol{r} = \boldsymbol{r}(t, q)$. In this case, $\partial f/\partial\theta_b \to \partial\boldsymbol{r}/\partial\theta_b \equiv \boldsymbol{\varepsilon}_b$, and thus we obtain the basic *nonintegrability* conditions for the nonholonomic basis $\{\boldsymbol{\varepsilon}_k; k = 1, \ldots, n\}$:

$$\partial\boldsymbol{\varepsilon}_l/\partial\theta_k - \partial\boldsymbol{\varepsilon}_k/\partial\theta_l = \sum \gamma^b{}_{kl}\,\boldsymbol{\varepsilon}_b, \tag{2.10.23}$$

or, compactly,

$$[\boldsymbol{\varepsilon}_k, \boldsymbol{\varepsilon}_l] \equiv \sum \gamma^b{}_{kl}\,\boldsymbol{\varepsilon}_b \equiv \textit{commutator of basis } \{\boldsymbol{\varepsilon}_k\}. \tag{2.10.23a}$$

In differential geometry, such bases are called *nonholonomic*, or *noncoordinate*, or *nongradient*; that is, they are *not* parts of a global coordinate system; like the $\{\boldsymbol{e}_k \equiv \partial\boldsymbol{r}/\partial q_k\}$ for which, clearly [recalling (2.5.4a)],

$$\partial\boldsymbol{e}_l/\partial q_k - \partial\boldsymbol{e}_k/\partial q_l \equiv [\boldsymbol{e}_k, \boldsymbol{e}_l] \equiv \boldsymbol{0}. \tag{2.10.23b}$$

In sum: the vanishing of the γ's is the necessary and sufficient condition for the corresponding basis to be *holonomic*; or *gradient*, or *coordinate*.

We leave it to the reader to show that (2.10.23) also hold for $k, l = n + 1$; that is, $\theta \to t$.

A Fundamental Kinematical Identity

Here, with the help of (2.10.23), we will complete the derivation of the basic identity (2.9.37). Indeed, since $\boldsymbol{\varepsilon}_k = \partial\boldsymbol{v}/\partial\omega_k \equiv \partial\boldsymbol{v}^*/\partial\omega_k = \boldsymbol{\varepsilon}_k(t, q)$, and [recalling (2.9.21)] $\boldsymbol{v} = \boldsymbol{v}^*(t, q, \omega) = \sum \boldsymbol{\varepsilon}_k\omega_k + \boldsymbol{\varepsilon}_{n+1} \equiv \sum \boldsymbol{\varepsilon}_k\omega_k + \boldsymbol{\varepsilon}_0$, we obtain, successively,

(i)
$$\begin{aligned} d/dt(\partial\boldsymbol{v}/\partial\omega_k) &\equiv d/dt(\partial\boldsymbol{v}^*/\partial\omega_k) \equiv d\boldsymbol{\varepsilon}_k/dt \\ &= \sum (\partial\boldsymbol{\varepsilon}_k/\partial q_l)v_l + \partial\boldsymbol{\varepsilon}_k/\partial t \\ &\qquad\qquad \text{[recalling the inverse quasi chain rule (2.9.30b)]} \\ &= \sum \Big(\sum a_{rl}(\partial\boldsymbol{\varepsilon}_k/\partial\theta_r)\Big)v_l + \partial\boldsymbol{\varepsilon}_k/\partial t \qquad \text{[recalling (2.9.9)]} \\ &= \sum (\partial\boldsymbol{\varepsilon}_k/\partial\theta_r)(\omega_r - a_r) + \partial\boldsymbol{\varepsilon}_k/\partial t \\ &= \sum (\partial\boldsymbol{\varepsilon}_k/\partial\theta_r)\omega_r - \sum (\partial\boldsymbol{\varepsilon}_k/\partial\theta_r)a_r + \partial\boldsymbol{\varepsilon}_k/\partial t. \end{aligned} \tag{2.10.24a}$$

(ii)
$$\partial\boldsymbol{v}/\partial\theta_k \equiv \partial\boldsymbol{v}^*/\partial\theta_k = \sum (\partial\boldsymbol{\varepsilon}_r/\partial\theta_k)\omega_r + \partial\boldsymbol{\varepsilon}_0/\partial\theta_k. \tag{2.10.24b}$$

Therefore, subtracting the above side by side, and recalling (2.9.32a, d), we obtain

$$
\begin{aligned}
d\boldsymbol{\varepsilon}_k/dt - \partial \boldsymbol{v}/\partial\theta_k &= \sum (\partial\boldsymbol{\varepsilon}_k/\partial\theta_r - \partial\boldsymbol{\varepsilon}_r/\partial\theta_k)\omega_r + (\partial\boldsymbol{\varepsilon}_k/\partial t - \partial\boldsymbol{\varepsilon}_0/\partial\theta_k) - \sum (\partial\boldsymbol{\varepsilon}_k/\partial\theta_r)a_r \\
&= \sum (\partial\boldsymbol{\varepsilon}_k/\partial\theta_r - \partial\boldsymbol{\varepsilon}_r/\partial\theta_k)\omega_r \\
&\qquad + \Big(\partial\boldsymbol{\varepsilon}_k/\partial\theta_0 - \sum A_s(\partial\boldsymbol{\varepsilon}_k/\partial q_s)\Big) \\
&\qquad - \Big(\partial\boldsymbol{\varepsilon}_0/\partial\theta_k - \sum (\partial\boldsymbol{\varepsilon}_k/\partial\theta_r)a_r\Big) \\
&= \sum (\partial\boldsymbol{\varepsilon}_k/\partial\theta_\beta - \partial\boldsymbol{\varepsilon}_\beta/\partial\theta_k)\omega_\beta \\
&\qquad - \sum A_s\Big(\sum a_{rs}(\partial\boldsymbol{\varepsilon}_k/\partial\theta_r)\Big) - \sum a_r(\partial\boldsymbol{\varepsilon}_k/\partial\theta_r)
\end{aligned}
$$

{for the first sum we use (2.10.23), with $l \to k$, $k \to \beta$, $b \to r$ [recalling (2.10.9)]; and by the second of (2.9.3a) the last two sums add up to zero}

$$
= \sum \Big(\sum \gamma^r{}_{\beta k}\boldsymbol{\varepsilon}_r\Big)\omega_\beta; \tag{2.10.24c}
$$

and so, finally,

$$
\begin{aligned}
&E_k{}^*(\boldsymbol{v}) \equiv E_k{}^*(\boldsymbol{v}^*):\ \text{Hamel vector of } \textit{nonholonomic deviation} \text{ of a particle} \\
&\quad \equiv d/dt(\partial\boldsymbol{v}/\partial\omega_k) - \partial\boldsymbol{v}/\partial\theta_k \equiv d/dt(\partial\boldsymbol{v}^*/\partial\omega_k) - \partial\boldsymbol{v}^*/\partial\theta_k \equiv d\boldsymbol{\varepsilon}_k/dt - \partial\boldsymbol{v}/\partial\theta_k \\
&\quad = \sum\sum \gamma^r{}_{\beta k}\boldsymbol{\varepsilon}_r\,\omega_\beta = \sum\sum \gamma^r{}_{lk}\,\omega_l\boldsymbol{\varepsilon}_r + \sum \gamma^r{}_{n+1,k}\,\omega_{n+1}\boldsymbol{\varepsilon}_r \quad \text{[swapping } k \text{ and } l\text{]} \\
&\quad = -\sum\sum \gamma^r{}_{kl}\,\omega_l\boldsymbol{\varepsilon}_r - \sum \gamma^r{}_k\boldsymbol{\varepsilon}_r \ = \ -\sum\Big(\sum \gamma^r{}_{kl}\,\omega_l + \gamma^r{}_k\Big)\boldsymbol{\varepsilon}_r \\
&\quad \equiv -\sum h^r{}_k\,\boldsymbol{\varepsilon}_r;
\end{aligned} \tag{2.10.25}
$$

where

$$
h^r{}_k \equiv \sum \gamma^r{}_{kl}\,\omega_l + \gamma^r{}_k = \sum \gamma^r{}_{k\beta}\,\omega_\beta:\ \textit{Two-index Hamel symbols.} \tag{2.10.25a}
$$

This fundamental kinematical identity, in its various equivalent forms, like the transitivity equations (2.10.1, etc.), shows clearly the difference between holonomic and nonholonomic *coordinates* (not constraints): for the former, $E_k(\boldsymbol{v}) = \mathbf{0}$; while for the latter, $E_k{}^*(\boldsymbol{v}) \equiv E_k{}^*(\boldsymbol{v}^*) \neq \mathbf{0}$. It is indispensable in the derivation of equations of motion in quasi variables (§3.3).

Problem 2.10.5 *Transitivity Relations for System Velocities.*

(i) Show that for the general nonstationary transformation (with $\dot{q}_l \equiv v_l$)

$$
\omega_k \equiv \sum a_{kl}v_l + a_k \ \Leftrightarrow\ v_l = \sum A_{lk}\omega_k + A_l, \tag{a}
$$

the following transitivity identities hold:

$$
\begin{aligned}
E_l(\omega_k) \equiv d/dt(\partial\omega_k/\partial v_l) - \partial\omega_k/\partial q_l &= \sum\Big(\sum \gamma^k{}_{r\beta}\,\omega_\beta\Big)a_{rl} \\
&= \sum\Big(\sum \gamma^k{}_{rs}\,\omega_s + \gamma^k{}_r\Big)a_{rl} \equiv \sum h^k{}_r\,a_{rl}.
\end{aligned} \tag{b}
$$

(ii) Then show that, in the *stationary* case, (b) specializes to

$$E_l(\omega_k) \equiv d/dt(\partial\omega_k/\partial v_l) - \partial\omega_k/\partial q_l = \sum\sum \gamma^k{}_{rs}\,\omega_s a_{rl}; \tag{c}$$

that is, the first line of (b) with $\beta \to s$.

(iii) Show that, as a result of the above, the transitivity equations (2.10.13), become

$$\begin{aligned}(\delta\theta_k)^{\cdot} - \delta\omega_k &= \sum\sum \gamma^k{}_{rs}\,\omega_s\,\delta\theta_r + \sum \gamma^k{}_r\,\delta\theta_r = \sum h^k{}_r\,\delta\theta_r \\ &= \sum\sum E_l(\omega_k)A_{lr}\,\delta\theta_r = \sum\sum (\partial v_l/\partial\omega_r)E_l(\omega_k)\delta\theta_r,\end{aligned} \tag{d}$$

where the $\sum (\partial v_l/\partial\omega_r)E_l(\omega_k)$ can be viewed as the *nonlinear* generalization of the $h^k{}_r$ (§5.2).

Problem 2.10.6 By direct d/δ-differentiations of $\delta\boldsymbol{r} = \sum \boldsymbol{\varepsilon}_k\,\delta\theta_k$ and $d\boldsymbol{r} = \sum \boldsymbol{\varepsilon}_k\,d\theta_k$, respectively (assume stationary systems, for algebraic simplicity but no loss in generality), and then use of

$$d\boldsymbol{\varepsilon}_k = d\Big(\sum A_{lk}\,\boldsymbol{e}_l\Big) = \sum (dA_{lk}\,\boldsymbol{e}_l + A_{lk}\,d\boldsymbol{e}_l), \tag{a}$$

and

$$d\boldsymbol{e}_l = \sum (\partial\boldsymbol{e}_l/\partial q_r)\,dq_r = \sum\sum (\partial\boldsymbol{e}_l/\partial q_r)A_{rs}\,d\theta_s,$$

$$dA_{lk} = \sum (\partial A_{lk}/\partial q_r)\,dq_r = \sum\sum (\partial A_{lk}/\partial q_r)A_{rs}\,d\theta_s, \tag{b}$$

and similarly for $\delta\boldsymbol{\varepsilon}_k = \delta(\sum A_{lk}\boldsymbol{e}_l) = \ldots$, and then recalling the γ-definitions, obtain the following basic *particle/vectorial transitivity equation*:

$$d(\delta\boldsymbol{r}) - \delta(d\boldsymbol{r}) = \sum \Big\{[d(\delta\theta_k) - \delta(d\theta_k)] + \sum\sum \gamma^k{}_{rs}\,d\theta_r\,\delta\theta_s\Big\}\boldsymbol{\varepsilon}_k; \tag{c}$$

or, dividing by dt, its equivalent velocity form

$$(\delta\boldsymbol{r})^{\cdot} - \delta\boldsymbol{v} = \sum \Big\{[(\delta\theta_k)^{\cdot} - \delta\omega_k] + \sum\sum \gamma^k{}_{rs}\,\omega_r\,\delta\theta_s\Big\}\;\boldsymbol{\varepsilon}_k. \tag{d}$$

Replacing in the above r with $\beta = 1, \ldots, n+1$, extends it to the *nonstationary/rheonomic* case.

[Note that (c) and (d) are independent of any $d(\delta q) - \delta(dq)$ assumptions. Therefore, since

$$d(\delta\boldsymbol{r}) - \delta(d\boldsymbol{r}) = \sum [d(\delta q_l) - \delta(dq_l)]\boldsymbol{e}_l = \sum\sum [d(\delta q_l) - \delta(dq_l)]a_{kl}\boldsymbol{\varepsilon}_k, \tag{e}$$

if we assume $d(\delta q_l) - \delta(dq_l) = 0$ (Hamel viewpoint), then $d(\delta\boldsymbol{r}) - \delta(d\boldsymbol{r}) = \boldsymbol{0}$, and this leads us back to the transitivity equations (2.10.12) and (2.10.13).]

Example 2.10.1 *Local Transformation Properties of the Hamel Coefficients*. Let us find how the γ's transform under the admissible (and, for simplicity, but with no loss in generality) stationary quasi-variable transformation $\theta \to \theta'$:

$$d\theta_{k'} = \sum a_{k'k}\,d\theta_k \;\Leftrightarrow\; d\theta_k = \sum A_{kk'}\,d\theta_{k'}, \tag{a}$$

where $a_{k'k} = a_{k'k}(q)$, $A_{kk'} = A_{kk'}(q)$, and all Latin indices run from 1 to n. We find, successively,

$$\begin{aligned}
d(\delta\theta_{k'}) - \delta(d\theta_{k'}) &= d\Big(\sum a_{k'k}\,\delta\theta_k\Big) - \delta\Big(\sum a_{k'k}\,d\theta_k\Big)\\
&= \sum \big[da_{k'k}\,\delta\theta_k + a_{k'k}\,d(\delta\theta_k) - \delta a_{k'k}\,d\theta_k - a_{k'k}\,\delta(d\theta_k)\big]\\
&= \sum \Big\{\Big(\sum (\partial a_{k'k}/\partial q_p)\,dq_p\Big)\,\delta\theta_k + a_{k'k}\,d(\delta\theta_k)\\
&\qquad - \Big(\sum (\partial a_{k'k}/\partial q_p)\,\delta q_p\Big)\,d\theta_k - a_{k'k}\,\delta(d\theta_k)\Big\}\\
&\qquad\qquad [\text{recalling that } dq_p = \sum A_{pr}\,d\theta_r\,,\ \text{etc.}]\\
&= \sum a_{k'k}[d(\delta\theta_k) - \delta(d\theta_k)]\\
&\quad + \sum\sum\sum \big[(\partial a_{k'k}/\partial q_p)A_{pr}\,d\theta_r\,\delta\theta_k - (\partial a_{k'k}/\partial q_p)A_{pr}\,d\theta_k\,\delta\theta_r\big]\\
&= \sum a_{k'k}\Big(\sum\sum \gamma^k{}_{bc}\,d\theta_c\,\delta\theta_b\Big)\\
&\quad + \sum\sum\sum \big[(\partial a_{k'k}/\partial q_p)A_{pr} - (\partial a_{k'r}/\partial q_p)A_{pk}\big]\,d\theta_r\,\delta\theta_k\\
&= \sum\sum\sum a_{k'k}\gamma^k{}_{bc}\Big(\sum A_{cc'}\,d\theta_{c'}\Big)\Big(\sum A_{bb'}\,\delta\theta_{b'}\Big)\\
&\quad + \sum\sum\sum \big[(\partial a_{k'k}/\partial q_p)A_{pr} - (\partial a_{k'r}/\partial q_p)A_{pk}\big]\Big(\sum A_{rr'}\,d\theta_{r'}\Big)\Big(\sum a_{kl'}\,\delta\theta_{l'}\Big)\\
&= \sum\sum\sum\sum\sum (a_{k'k}A_{rr'}A_{ll'}\gamma^k{}_{lr})\,d\theta_{r'}\,\delta\theta_{l'}\\
&\quad + \sum\sum\sum\sum (\partial a_{k'k}/\partial\theta_r - \partial a_{k'r}/\partial\theta_k)A_{rr'}A_{kl'}\,d\theta_{r'}\,\delta\theta_{l'}; \qquad \text{(b)}
\end{aligned}$$

and since, by definition,

$$d(\delta\theta_{k'}) - \delta(d\theta_{k'}) = \sum\sum \gamma^{k'}{}_{l'r'}\,d\theta_{r'}\,\delta\theta_{l'}, \qquad \text{(c)}$$

we conclude that

$$\gamma^{k'}{}_{l'r'} = \sum\sum\sum a_{k'k}A_{ll'}A_{rr'}\gamma^k{}_{lr} + \sum\sum (\partial a_{k'k}/\partial\theta_r - \partial a_{k'r}/\partial\theta_k)A_{kl'}A_{rr'}. \qquad \text{(d)}$$

In tensor calculus language, the transformation equation (d) shows that *the* $\gamma^k{}_{lr}$ *do not constitute a tensor*: if $\gamma^k{}_{lr} = 0$ (i.e., if the θ_k are holonomic coordinates), it does not necessarily follow that $\gamma^{k'}{}_{l'r'} = 0$; and that is why these quantities are called, instead, components of a *geometrical object*. However, if the *second* group of terms (double sum) in (d), which looks (symbolically) like a Hamel coefficient between the $d\theta_k$ and $d\theta_{k'}$, vanishes, the $\gamma^k{}_{lr}$ transform tensorially. In such a case, we call the $d\theta_k$ and $d\theta_{k'}$ *relatively holonomic*; that happens, for example, if the coefficients $a_{k'k}$ are constant.

For futher details, and the relation of the γ's to the *Christoffell symbols* (§3.10) and the *Ricci rotation coefficients*, both of which are also geometrical objects, see, for example (alphabetically): Papastavridis (1999), Schouten (1954), Synge (1936), Vranceanu (1936); also, for an alternative derivation of (d), see Golab (1974, pp. 141–142), Lynn (1963, pp. 201–203).

We have developed all the necessary analytical tools of Lagrangean kinematics. In the following sections, we will show how to apply them to the handling of *additional* Pfaffian (possibly nonholonomic) constraints.

For quick comparison, when working with other references, we present below the following, admittedly incomplete, but hopefully helpful, list of common γ-notations in the literature:

(i) *Our notation* (also in Papastavridis, 1999): $\gamma_{a\ c}^{\ b} \equiv \gamma^{b}_{\ ac}$ (sometimes, for extra clarity, a *subscript dot* is added between a and c, directly below b).

(ii) *Authors whose notation coincides with ours*: Dobronravov (1948, 1970, 1976), Golomb and Marx (1961), Gutowski (1971), Kil'chevskii (1972, 1977), Koiller (1992): $\gamma_{a\ c}^{\ b}$.

(iii) *Authors whose notation differs from ours*: Butenin (1971), Fischer and Stephan (1972), Neimark and Fufaev (1967/1972), Whittaker (1937; but his a_{kl} is our a_{lk}): γ_{abc}; Corben and Stehle (1960): γ_{acb}; Nordheim (1927): γ_{cba}; Rose (1938): γ_{bac}; Päsler (1968): $-\gamma_{bac}$; Djukic (1976), Funk (1962), Lur'e (1961/1968), Mei (1985), Prange (1935): $\gamma_{c\ a}^{\ b}$; Kilmister (1964, 1967): $\gamma^{a\ c}_{\ b}$; Maißer (1981): $A_{c\ a}^{\ b}$; Desloge (1982): α_{abc}; Stückler (1955): β_{abc}; Heun (1906): β_{acb}; Winkelmann and Grammel (1927): β_{cab}; Morgenstern and Szabó (1961): $\beta_{b,ac}$; Hamel (1904(a), (b)): $\beta_{a,c,b}$; Hamel (1949): $\beta_b^{\ a,c}$; Schaefer (1951): $\beta_{c\ a}^{\ b}$; Vranceanu (1936): $w_{a\ c}^{\ b}$; Wang (1979): $K_{A\ C}^{\ B}$; Schouten (1954): $2\Omega_{c\ a}^{\ b}$; Levi-Civita and Amaldi (1927): $\eta_{b|ca}$.

2.11 PFAFFIAN (VELOCITY) CONSTRAINTS VIA QUASI VARIABLES, AND THEIR GEOMETRICAL INTERPRETATION

Let us, now, assume that our hitherto holonomic $n\,(\equiv 3N - h)$-DOF system is subjected to the additional m independent Pfaffian constraints [recalling (2.7.3 and 2.7.4)]:

Kinematically admissible/possible form:

$$\sum c_{Dk}\, dq_k + c_D\, dt = 0, \tag{2.11.1a}$$

Virtual form:

$$\sum c_{Dk}\, \delta q_k = 0, \tag{2.11.1b}$$

Velocity form (with $dq_k/dt \equiv v_k$):

$$\sum c_{Dk} v_k + c_D = 0; \tag{2.11.1c}$$

where $D = 1, \ldots, m\,(<n), k = 1, \ldots, n$; and the constraint independence is expressed by the algebraic requirement $rank(c_{Dk}) = m$. Since additional holonomic constraints (in any form) can always be embedded, or built in, with a new set of fewer q's, we can, with no loss of generality, assume that all constraints (2.11.1) are nonholonomic.

Now, and in what constitutes a direct and natural extension of the method of holonomic equilibrium coordinates (§2.4) to the embedding Pfaffian constraints, we introduce the following *equilibrium quasi variables* (Hamel's choice):

Kinematically admissible/possible form:

$$d\theta_D \equiv \sum a_{Dk}\, dq_k + a_D\, dt \quad (= 0), \tag{2.11.2a}$$

$$d\theta_I \equiv \sum a_{Ik}\, dq_k + a_I\, dt \quad (\neq 0), \tag{2.11.2b}$$

$$d\theta_{n+1} \equiv d\theta_0 \equiv dq_{n+1} \equiv dq_0 \equiv dt \quad (\neq 0); \tag{2.11.2c}$$

Virtual form:

$$\delta\theta_D \equiv \sum a_{Dk}\, \delta q_k \quad (= 0), \tag{2.11.2d}$$

$$\delta\theta_I \equiv \sum a_{Ik}\, \delta q_k \quad (\neq 0), \tag{2.11.2e}$$

$$\delta\theta_{n+1} \equiv \delta q_{n+1} \equiv \delta t \quad (= 0); \tag{2.11.2f}$$

Velocity form:

$$\omega_D \equiv \sum a_{Dk} v_k + a_D \quad (= 0), \tag{2.11.2g}$$

$$\omega_I \equiv \sum a_{Ik} v_k + a_I \quad (\neq 0), \tag{2.11.2h}$$

$$\omega_{n+1} \equiv \omega_0 \equiv v_{n+1} \equiv v_0 \equiv dt/dt = 1 \quad (\neq 0); \tag{2.11.2i}$$

where (here and throughout the rest of the book): $D = 1, \ldots, m\ (< n) =$ *Dependent*, $I = m+1, \ldots, n =$ *Independent* [additional *dependent* (*independent*) indices will be denoted by D', $D'', \ldots (I', I'', \ldots)$]; and the coefficients a_{kl}, a_k are chosen as follows:

(i) $\quad a_{Dk} \equiv c_{Dk}$ and $a_D \equiv c_D$ [i.e., $\theta_D \equiv \chi_D$, recall (2.6.2–4; 2.8.1)], (2.11.3)

(ii) The a_{Ik} and a_I are *arbitrary*, except that when eqs. (2.11.2) are solved (inverted) for the $dq/\delta q/v$ in terms of the independent $d\theta/\delta\theta/\omega$, respectively; that is,

Kinematically admissible/possible form:

$$dq_k \equiv \sum A_{kI}\, d\theta_I + A_I\, dt \quad (\neq 0), \tag{2.11.4a}$$

$$dq_{n+1} \equiv dq_0 \equiv d\theta_{n+1} \equiv d\theta_0 \equiv dt \quad (\neq 0); \tag{2.11.4b}$$

Virtual form:

$$\delta q_k \equiv \sum A_{kI}\, \delta\theta_I \quad (\neq 0), \tag{2.11.4c}$$

$$\delta q_{n+1} \equiv \delta q_0 \equiv \delta\theta_{n+1} \equiv \delta\theta_0 \equiv \delta t = 0; \tag{2.11.4d}$$

Velocity form:

$$v_k \equiv \sum A_{kI}\omega_I + A_I \quad (\neq 0), \tag{2.11.4e}$$

$$v_{n+1} \equiv v_0 \equiv \omega_{n+1} \equiv \omega_0 \equiv dt/dt = 1 \quad (\neq 0); \tag{2.11.4f}$$

and then these results are substituted back into (2.11.1a–c) and (2.11.3), they *satisfy them identically*. Other choices of θ's and a's are, of course, possible (see special forms/choices, below), but Hamel's choice (2.11.2) is the simplest and most natural, because then our Pfaffian constraints assume the simple and *uncoupled* form:

Kinematically admissible/possible form:

$$d\theta_D = 0, \tag{2.11.5a}$$

Virtual form:

$$\delta\theta_D = 0, \tag{2.11.5b}$$

Velocity form:

$$\omega_D = 0; \tag{2.11.5c}$$

and, as a result (already described in § 2.7 and detailed in ch. 3), the equations of motion decouple into $n - m$ *kinetic* equations (no constraint forces) and m *kinetostatic* equations (constraint forces).

Constrained Particle Kinematics

In view of the constraints (2.11.5), the particle kinematical quantities (2.9.23–26) reduce to the following:

Kinematically admissible/possible displacement:

$$d\boldsymbol{r} = \sum \boldsymbol{\varepsilon}_I \, d\theta_I + \boldsymbol{\varepsilon}_{n+1} \, dt \equiv \sum \boldsymbol{\varepsilon}_I \, d\theta_I + \boldsymbol{\varepsilon}_0 \, dt; \tag{2.11.6a}$$

Virtual displacement:

$$\delta\boldsymbol{r} = \sum \boldsymbol{\varepsilon}_I \, \delta\theta_I ; \tag{2.11.6b}$$

Velocity:

$$\boldsymbol{v} = \sum \boldsymbol{\varepsilon}_I \, \omega_I + \boldsymbol{\varepsilon}_{n+1} \equiv \sum \boldsymbol{\varepsilon}_I \, \omega_I + \boldsymbol{\varepsilon}_0 ; \tag{2.11.6c}$$

Acceleration:

$$\boldsymbol{a} = \sum \boldsymbol{\varepsilon}_I \, \dot{\omega}_I + \text{terms not containing } \dot{\omega}. \tag{2.11.6d}$$

Special Forms/Choices of Quasi Variables

1. Once we have chosen the equilibrium quasi variables $d\theta/\delta\theta/\omega$, we can move to any other such set $d\theta'/\delta\theta'/\omega'$, defined via linear (invertible) transformations of the following type:

$$d\theta_{k'} \equiv \sum a_{k'k} \, d\theta_k + a_{k'} \, dt = \sum a_{k'I} \, d\theta_I + a_{k'} \, dt \quad (\neq 0), \tag{2.11.7a}$$

$$d\theta_{(n+1)'} \equiv d\theta_{n+1} \equiv dq_{n+1} \equiv dt \quad (\neq 0); \tag{2.11.7b}$$

and, inversely $[(a_{k'k}), (A_{kk'})$: nonsingular matrices$]$,

$$d\theta_k \equiv \sum A_{kk'} \, d\theta_{k'} + A_k \, dt \;\; \rightarrow \;\; d\theta_D = 0 \quad \text{and} \quad d\theta_I \neq 0; \tag{2.11.7c}$$

and similarly for $\delta\theta_{k'}$, $\omega_{k'}$.

2. If the Pfaffian nonholonomic *constraints* are given in the quasi-variable forms:

$$\sum a_{D'k}\, d\theta_k + a_{D'}\, dt = 0, \quad \text{or} \quad \sum a_{D'k}\, \delta\theta_k = 0, \quad \text{or} \quad \sum a_{D'k}\, \omega_k + a_{D'} = 0, \tag{2.11.8a}$$

then, proceeding à la Hamel again, we may introduce new quasi variables by

$$d\theta_{D'} \equiv \sum a_{D'k}\, d\theta_k + a_{D'}\, dt = 0, \qquad d\theta_{I'} \equiv \sum a_{I'k}\, d\theta_k + a_{I'}\, dt \neq 0; \tag{2.11.8b}$$

or

$$\delta\theta_{D'} \equiv \sum a_{D'k}\, \delta\theta_k = 0, \qquad \delta\theta_{I'} \equiv \sum a_{I'k}\, \delta\theta_k \neq 0; \tag{2.11.8c}$$

or

$$\omega_{D'} \equiv \sum a_{D'k}\omega_k + a_{D'} = 0, \qquad \omega_{I'} \equiv \sum a_{I'k}\, \omega_k + a_{I'} \neq 0; \tag{2.11.8d}$$

where, again, the coefficients $a_{I'k}$, $a_{I'}$ are arbitrary; but when (2.11.8b–d) are solved for the $d\theta/\delta\theta/\omega$ in terms of the $d\theta'/\delta\theta'/\omega'$, and the results are substituted back into (2.11.8a), they satisfy them identically (see also their specialization in item 4, below).

3. Frequently, the Pfaffian constraints (2.11.1) are given, or can be easily brought to, the special form [recalling (2.6.9–11), and, using the notation $dq_k/dt \equiv v_k$]:

$$dq_D = \sum b_{DI}\, dq_I + b_D\, dt, \quad \text{or} \quad \delta q_D = \sum b_{DI}\, \delta q_I, \quad \text{or} \quad v_D = \sum b_{DI} v_I + b_D, \tag{2.11.9}$$

where the coefficients b_{DI}, b_D are known functions of q and t; that is, the *first m* (or *dependent*) $dq_D/\delta q_D/v_D$ are expressed in terms of the *last* $n - m$ (*independent*) $dq_I/\delta q_I/v_I$. [In terms of the elements of the *original* $m \times n$ constraint matrix $(c_{Dk}) \equiv (a_{Dk})$, we, clearly, have $(b_{DI}) = -(a_{DD'})^{-1}(a_{DI})$, and so on. See also pr. 2.11.2.]

Now, the transformations (2.11.9) can be viewed as the following *special choice* of $d\theta/\delta\theta/\omega$:

$$d\theta_D = dq_D - \sum b_{DI}\, dq_I - b_D\, dt = 0, \quad d\theta_I \equiv dq_I \neq 0, \quad d\theta_{n+1} \equiv dq_{n+1} \equiv dt \neq 0; \tag{2.11.10a}$$

$$\delta\theta_D \equiv \delta q_D - \sum b_{DI}\, \delta q_I = 0, \qquad \delta\theta_I \equiv \delta q_I \neq 0, \qquad \delta\theta_{n+1} \equiv \delta q_{n+1} \equiv \delta t = 0; \tag{2.11.10b}$$

$$\omega_D \equiv v_D - \sum b_{DI} v_I - b_D = 0, \quad \omega_I \equiv v_I \neq 0, \quad \omega_{n+1} \equiv v_{n+1} \equiv dt/dt = 1 \neq 0. \tag{2.11.10c}$$

The above invert easily to

$$dq_D = d\theta_D + \sum b_{DI}\, d\theta_I + b_D\, dt = \sum b_{DI}\, d\theta_I + b_D\, dt,$$

$$dq_I = d\theta_I, \qquad dq_{n+1} \equiv d\theta_{n+1} \equiv dt; \tag{2.11.11a}$$

$$\delta q_D = \delta\theta_D + \sum b_{DI}\,\delta q_I = \sum b_{DI}\,\delta q_I,$$

$$\delta q_I = \delta\theta_I, \qquad \delta q_{n+1} \equiv \delta\theta_{n+1} \equiv \delta t = 0; \tag{2.11.11b}$$

$$v_D = \omega_D + \sum b_{DI}\omega_I + b_D = \sum b_{DI}\omega_I + b_D,$$

$$v_I = \omega_I, \qquad v_{n+1} \equiv v_0 = \omega_{n+1} \equiv \omega_0 = dt/dt = 1. \tag{2.11.11c}$$

Comparing (2.11.10, 11) with (2.11.2, 4) we readily conclude that, in this case, the (mutually inverse) transformation matrices **a** and **A** [recalling (2.9.4a ff.)] have the following special forms:

$$\mathbf{a} = \left(\begin{array}{cc|c} \mathbf{1} & -\mathbf{b} & -\mathbf{b}_{\mathrm{n+1}} \\ \mathbf{0} & \mathbf{1} & \mathbf{0} \\ \hline \mathbf{0} & \mathbf{0} & 1 \end{array}\right) \qquad \mathbf{A} = \left(\begin{array}{cc|c} \mathbf{1} & \mathbf{b} & \mathbf{b}_{\mathrm{n+1}} \\ \mathbf{0} & \mathbf{1} & \mathbf{0} \\ \hline \mathbf{0} & \mathbf{0} & 1 \end{array}\right), \tag{2.11.12}$$

that is,

$$\mathbf{a}_{\mathrm{S}} = \left(\begin{array}{c|c} \mathbf{1} & -\mathbf{b} \\ \hline \mathbf{0} & \mathbf{1} \end{array}\right) \qquad \mathbf{a}_{\mathrm{T}} = \left(\begin{array}{c} -\mathbf{b}_{\mathrm{n+1}} \\ \hline \mathbf{0} \end{array}\right), \tag{2.11.12a}$$

$$\mathbf{A}_{\mathrm{S}} = \left(\begin{array}{c|c} \mathbf{1} & \mathbf{b} \\ \hline \mathbf{0} & \mathbf{1} \end{array}\right) \qquad \mathbf{A}_{\mathrm{T}} = \left(\begin{array}{c} \mathbf{b}_{\mathrm{n+1}} \\ \hline \mathbf{0} \end{array}\right); \tag{2.11.12b}$$

where $\mathbf{b} = (b_{DI})$, $\mathbf{b}_{\mathrm{n+1}} = (b_{D,n+1} \equiv b_D)$; and, of course, satisfy the consistency relations (2.9.3a, b). For a slight generalization of the choice (2.11.10c), see pr. 2.11.2.

Particle Kinematics

In this case, the particle kinematical quantities [recalling (2.5.2 ff.) and (2.11.6a ff.), and that $\boldsymbol{e}_{n+1} \equiv \boldsymbol{e}_0 \equiv \partial\boldsymbol{r}/\partial t$] specialize to

$$\begin{aligned} d\boldsymbol{r} &= \sum \boldsymbol{e}_k\,dq_k + \boldsymbol{e}_{n+1}\,dt = \sum \boldsymbol{e}_D\,dq_D + \sum \boldsymbol{e}_I\,dq_I + \boldsymbol{e}_{n+1}\,dt \\ &= \sum \boldsymbol{e}_D\Big(\sum b_{DI}\,dq_I + b_D\,dt\Big) + \sum \boldsymbol{e}_I\,dq_I + \boldsymbol{e}_{n+1}\,dt \\ &\equiv \sum \boldsymbol{\beta}_I\,dq_I + \boldsymbol{\beta}_{n+1}\,dt \equiv \sum \boldsymbol{\beta}_I\,dq_I + \boldsymbol{\beta}_0\,dt, \end{aligned} \tag{2.11.13a}$$

$$\delta\boldsymbol{r} = \cdots = \sum \boldsymbol{\beta}_I\,\delta q_I, \tag{2.11.13b}$$

$$\boldsymbol{v} = \sum \boldsymbol{\beta}_I v_I + \boldsymbol{\beta}_{n+1} = \boldsymbol{v}(t, q, v_I) \equiv \boldsymbol{v}_o, \tag{2.11.13c}$$

$$\boldsymbol{a} = \sum \boldsymbol{\beta}_I \dot{v}_I + \text{terms not containing } \dot{v}_I = \boldsymbol{a}(t, q, v_I, \dot{v}_I) \ \equiv\ \boldsymbol{a}_o, \tag{2.11.13d}$$

where $(\boldsymbol{\varepsilon}_I \to \boldsymbol{\beta}_I)$:

$$\boldsymbol{\beta}_I \equiv \boldsymbol{e}_I + \sum b_{DI}\boldsymbol{e}_D, \qquad \boldsymbol{\beta}_{n+1} \equiv \boldsymbol{\beta}_0 \equiv \boldsymbol{e}_{n+1} + \sum b_D\boldsymbol{e}_D \equiv \boldsymbol{e}_0 + \sum b_D\boldsymbol{e}_D. \tag{2.11.13e}$$

REMARK

It should be pointed out that under the quasi-variable choice (2.11.9), and, according to an unorthodox yet internally consistent interpretation [advanced, mainly, by Ukrainian/Soviet/Russian authors, like Suslov, Voronets, Rumiantsev; and at odds with the earlier statement (§2.9) that the q's are always holonomic coordinates], the q_I, and hence also the q_D, are no longer genuine $\equiv$ holonomic coordinates, but have instead become quasi-, or nonholonomic coordinates; even though one could not tell that very well from their notation. To avoid errors in this slippery terrain, some authors have introduced the particular notation (q) (Johnsen, 1939); we shall use it occasionally, for extra clarity. Thus, specializing (2.9.27), while recalling the first of (2.11.12b), we can write

$$\begin{aligned}\partial\boldsymbol{r}/\partial(q_I) &\equiv \sum (\partial\boldsymbol{r}/\partial q_k)(\partial v_k/\partial v_I)\\ &= \sum (\partial\boldsymbol{r}/\partial q_D)(\partial v_D/\partial v_I) + \sum (\partial\boldsymbol{r}/\partial q_{I'})(\partial v_{I'}/\partial v_I)\\ &= \partial\boldsymbol{r}/\partial q_I + \sum b_{DI}(\partial\boldsymbol{r}/\partial q_D) = \sum A_{DI}\boldsymbol{e}_D + \sum A_{I'I}\boldsymbol{e}_{I'}\\ &= \sum b_{DI}\boldsymbol{e}_D + \sum \delta_{I'I}\boldsymbol{e}_{I'} = \sum b_{DI}\boldsymbol{e}_D + \boldsymbol{e}_I \equiv \boldsymbol{\beta}_I;\end{aligned} \tag{2.11.14a}$$

and analogously for $\boldsymbol{\beta}_{n+1} \equiv \boldsymbol{\beta}_0$. Similarly, with the helpful notation [(2.11.13c)]: $\boldsymbol{v} = \boldsymbol{v}(t, q, v) = \cdots = \boldsymbol{v}_o(t, q, v_I) \equiv \boldsymbol{v}_o$, chain rule, and recalling (2.11.9), we obtain

$$\partial\boldsymbol{v}_o/\partial v_I \equiv \partial\boldsymbol{v}/\partial v_I + \sum (\partial\boldsymbol{v}/\partial v_D)(\partial v_D/\partial v_I) = \boldsymbol{e}_I + \sum \boldsymbol{e}_D b_{DI} = \boldsymbol{\beta}_I; \tag{2.11.14b}$$

that is, the fundamental identities (2.9.33) specialize to

$$\partial\boldsymbol{r}/\partial(q_I) = \partial\boldsymbol{v}_o/\partial v_I = \partial\boldsymbol{a}_o/\partial\dot{v}_I = \cdots = \boldsymbol{\beta}_I = \boldsymbol{\beta}_I(t, q) \tag{2.11.14c}$$

[*not* to be confused with the analogous holonomic identities (2.5.7, 7a)].

Equation (2.11.14a) gives rise to the *special symbolic quasi chain rule* (see also chap. 5):

$$\begin{aligned}\partial\ldots/\partial(q_I) &\equiv \sum (\partial\ldots/\partial q_k)(\partial v_k/\partial v_I)\\ &= \sum (\partial\ldots/\partial q_D)(\partial v_D/\partial v_I) + \sum (\partial\ldots/\partial q_{I'})(\partial v_{I'}/\partial v_I)\\ &= \partial\ldots/\partial q_I + \sum b_{DI}(\partial\ldots/\partial q_D);\end{aligned} \tag{2.11.15a}$$

which, when applied to v_D, yields

$$\begin{aligned}\partial v_D/\partial(q_I) &\equiv \sum (\partial v_D/\partial q_{D'})(\partial v_{D'}/\partial v_I) + \sum (\partial v_D/\partial q_{I'})(\partial v_{I'}/\partial v_I)\\ &= \partial v_D/\partial q_I + \sum b_{D'I}(\partial v_D/\partial q_{D'}).\end{aligned} \tag{2.11.15b}$$

Generally, applying chain rule to

$$f = f(t, q, v) = f[t, q, v_D(t, q, v_I), v_I] \equiv f_o(t, q, v_I) = f_o, \tag{2.11.15c}$$

we obtain the useful formulae

$$\partial f_o/\partial v_I = \partial f/\partial v_I + \sum (\partial f/\partial v_D)(\partial v_D/\partial v_I) = \partial f/\partial v_I + \sum b_{DI}(\partial f/\partial v_D); \tag{2.11.15d}$$

and

$$\partial f_o/\partial q_I = \partial f/\partial q_I + \sum (\partial f/\partial v_D)(\partial v_D/\partial q_I); \tag{2.11.15e}$$

while (2.11.15a,b) are seen as specializations of

$$\begin{aligned}\partial f_o/\partial(q_I) &\equiv \partial f_o/\partial q_I + \sum (\partial f_o/\partial q_D)(\partial v_D/\partial v_I)\\ &\equiv \partial f_o/\partial q_I + \sum b_{DI}(\partial f_o/\partial q_D) \qquad [\textit{notation}, \text{ not chain rule!}].\end{aligned} \tag{2.11.15f}$$

Problem 2.11.1 With the help of the above symbolic identities [recall (2.11.12 ff.)] show that:

(i) $\partial q_k/\partial\theta_l \equiv \partial v_k/\partial\omega_l \to \partial q_k/\partial(q_l)$:

$$\partial q_D/\partial(q_{D'}) = A_{DD'} = \delta_{DD'}, \quad \partial q_D/\partial(q_I) = A_{DI} = b_{DI}, \quad \partial q_I/\partial(q_D) = A_{ID} = 0,$$
$$\partial q_I/\partial(q_{I'}) = A_{II'} = \delta_{II'}. \tag{a}$$

(ii) $\partial\theta_k/\partial q_l \equiv \partial\omega_k/\partial v_l \to \partial(q_k)/\partial q_l$:

$$\partial(q_D)/\partial q_{D'} = a_{DD'} = \delta_{DD'}, \quad \partial(q_D)/\partial q_I = a_{DI} = -b_{DI}, \quad \partial(q_I)/\partial q_D = a_{ID} = 0,$$
$$\partial(q_I)/\partial q_{I'} = a_{II'} = \delta_{II'}. \tag{b}$$

[Notice that $\partial q_D/\partial(q_I) = b_{DI} \neq \partial(q_D)/\partial q_I = -b_{DI}$.]

(iii) $\partial\ldots/\partial\theta_{n+1} \to \partial\ldots/\partial(q_{n+1})$ [recall (2.9.32 ff.), and since $A_{k,n+1} \equiv A_k$]

$$\begin{aligned}&= \sum A_k(\partial\ldots/\partial q_k) + \partial\ldots/\partial t\\ &= \sum A_D(\partial\ldots/\partial q_D) + \sum A_I(\partial\ldots/\partial q_I) + \partial\ldots/\partial t\\ &= \sum b_D(\partial\ldots/\partial q_D) + 0 + \partial\ldots/\partial t \;\equiv\; \partial\ldots/\partial(t) + \partial\ldots/\partial t;\end{aligned} \tag{c}$$

which for $\boldsymbol{r}$ yields the earlier (2.11.13e).

(iv) $\partial\boldsymbol{r}/\partial(q_D) \equiv \sum (\partial\boldsymbol{r}/\partial q_k)(\partial v_k/\partial v_D) = \sum \boldsymbol{e}_k A_{kD} = \cdots = \partial\boldsymbol{r}/\partial q_D$,

$$\text{i.e., } \boldsymbol{\beta}_D = \boldsymbol{e}_D. \tag{d}$$

(v) $$\partial\boldsymbol{\beta}_I/(q_{I'}) \neq \partial\boldsymbol{\beta}_{I'}/\partial(q_I); \tag{e}$$

which is a specialization of (2.10.23), and shows clearly that the basis $\{\boldsymbol{\beta}_I\}$ is non-gradient.

---

4. Occasionally, the constraints appear in the (2.11.9)-like form, but in the quasi variables $d\theta/\delta\theta/\omega$ [special case of (2.11.8a)]:

$$d\theta_D = \sum B_{DI}\, d\theta_I + B_D\, dt; \quad \text{or} \quad \delta\theta_D = \sum B_{DI}\, \delta\theta_I; \quad \text{or} \quad \omega_D = \sum B_{DI}\omega_I + B_D, \tag{2.11.16}$$

where the coefficients B_{DI}, B_D are known functions of q and t.

To uncouple them, proceeding as before, we introduce the following *new* equilibrium quasi variables $d\theta'/\delta\theta'/\omega'$ (to avoid accented indices, we accent the quasi variables themselves):

$$d\theta'_D \equiv d\theta_D - \sum B_{DI}\, d\theta_I - B_D\, dt = 0,\ d\theta'_I \equiv d\theta_I \neq 0,\ d\theta'_{n+1} \equiv d\theta_{n+1} \equiv dt \neq 0; \tag{2.11.17a}$$

$$\delta\theta'_D \equiv \delta\theta_D - \sum B_{DI}\, \delta\theta_I = 0, \quad \delta\theta'_I \equiv \delta\theta_I \neq 0, \quad \delta\theta'_{n+1} \equiv \delta\theta_{n+1} \equiv \delta t = 0; \tag{2.11.17b}$$

$$\omega'_D \equiv \omega_D - \sum B_{DI}\omega_I - B_D = 0, \quad \omega'_I \equiv \omega_I \neq 0, \quad \omega'_{n+1} \equiv \omega_{n+1} \equiv dt/dt = 1 \neq 0; \tag{2.11.17c}$$

which invert easily to

$$\begin{aligned}
&d\theta_D = d\theta'_D + \sum B_{DI}\, d\theta'_I + B_D\, dt = \sum B_{DI}\, d\theta'_I + B_D\, dt,\\
&d\theta_I = d\theta'_I, \qquad d\theta_{n+1} \equiv d\theta'_{n+1} \equiv dt; \qquad (2.11.18a)\\
&\delta\theta_D = \delta\theta'_D + \sum B_{DI}\, \delta\theta'_I = \sum B_{DI}\, \delta\theta'_I,\\
&\delta\theta_I = \delta\theta'_I, \qquad \delta\theta_{n+1} \equiv \delta\theta'_{n+1} \equiv \delta t = 0; \qquad (2.11.18b)\\
&\omega_D = \omega'_D + \sum B_{DI}\, \omega'_I + B_D = \sum B_{DI}\, \omega'_I + B_D,\\
&\omega_I = \omega'_I, \qquad \omega_{n+1} = \omega'_{n+1} = dt/dt = 1. \qquad (2.11.18c)
\end{aligned}$$

Clearly, (2.11.16)–(2.11.18) bear the same formal relation to (2.11.8a) that (2.11.9)–(2.11.11) bear to (2.11.2)–(2.11.4).

In sum, the possibilities are endless and, in practice, they are dictated by the specific features and needs of the problem at hand. The essential point in all these descriptions is that, ultimately, they express the n $dq/\delta q/v$ in terms of $n - m$ *independent* parameters $d\theta_I/\delta\theta_I/\omega_I$; and if the nonholonomic constraints are in coupled form, either among the $dq/\delta q/v$ or among another set of n quasi variables $d\theta/\delta\theta/\omega$ then, following Hamel, we introduce new *equilibrium* quasi variables $d\theta'/\delta\theta'/\omega'$ such that $d\theta'_D/\delta\theta'_D/\omega'_D = 0$ and $d\theta'_I/\delta\theta'_I/\omega'_I \neq 0$. And, as already stated, this *uncoupling* of the Pfaffian constraints is the main advantage of the method.

Problem 2.11.2 Consider the homogeneous Pfaffian constraints,

$$\omega_D = \sum a_{Dk} v_k = \sum a_{DD'} v_{D'} + \sum a_{DI'} v_{I'} \quad (= 0), \tag{a}$$

$$\omega_I = v_I = \sum \delta_{ID'} v_{D'} + \sum \delta_{II'} v_{I'} \quad \left(= \sum a_{Ik} v_k \neq 0\right), \tag{b}$$

where $D,\ D' = 1, \ldots, m; I,\ I' = m+1, \ldots, n$; that is, (with some easily understood notations)

$$\mathbf{a} \Rightarrow \mathbf{a}_{\mathrm{S}} = (a_{kl}) \equiv \begin{pmatrix} (a_{DD'}) & (a_{DI'}) \\ (a_{ID'}) & (a_{II'}) \end{pmatrix} = \begin{pmatrix} (a_{DD'}) & (a_{DI'}) \\ (0_{ID'}) & (\delta_{II'}) \end{pmatrix}. \tag{c}$$

(i) Verify that its inverse (assuming that $\mathbf{a}$ is nonsingular) equals

$$\mathbf{A} \Rightarrow \mathbf{A}_{\mathrm{S}} = (A_{kl}) \equiv \begin{pmatrix} (A_{DD'}) & (A_{DI'}) \\ (A_{ID'}) & (A_{II'}) \end{pmatrix} = \begin{pmatrix} (a_{DD'})^{-1} & -(a_{DD'})^{-1}(a_{D'I'}) \\ (0_{ID'}) & (\delta_{II'}) \end{pmatrix}. \tag{d}$$

(ii) Extend the above to the nonhomogeneous case; that is, $\omega_D = \sum a_{Dk} v_k + a_D\ (=0)$, $\omega_I = v_I\ (\neq 0)$.

(iii) Verify that the earlier particular choice (2.11.9 ff.) is a specialization of the above.

Geometrical Interpretation of Constraints

(May be omitted in a first reading.) We begin by partitioning the mutually inverse $n \times n$ matrices of the virtual transformation between $\delta q \leftrightarrow \delta\theta$, $\mathbf{a}_{\mathrm{S}} = (a_{kl})$ and $\mathbf{A}_{\mathrm{S}} = (A_{kl})$, into their *dependent* and *independent* parts:

$$\mathbf{a}_{\mathrm{S}} = \begin{pmatrix} \mathbf{a}_{\mathrm{D}} \\ \mathbf{a}_{\mathrm{I}} \end{pmatrix} = \begin{pmatrix} a_{Dk} \\ a_{Ik} \end{pmatrix}, \tag{2.11.19a}$$

$$\mathbf{A}_{\mathrm{S}} = (\mathbf{A}_{\mathrm{D}} \mid \mathbf{A}_{\mathrm{I}}) = (A_{kD} \mid A_{kI}). \tag{2.11.19b}$$

Clearly,

$$\mathbf{a}_{\mathrm{S}}\, \mathbf{A}_{\mathrm{S}} = \begin{pmatrix} \mathbf{a}_{\mathrm{D}}\mathbf{A}_{\mathrm{D}} & \mathbf{a}_{\mathrm{D}}\mathbf{A}_{\mathrm{I}} \\ \mathbf{a}_{\mathrm{I}}\mathbf{A}_{\mathrm{D}} & \mathbf{a}_{\mathrm{I}}\mathbf{A}_{\mathrm{I}} \end{pmatrix} = \begin{pmatrix} \mathbf{1} & \mathbf{0} \\ \mathbf{0} & \mathbf{1} \end{pmatrix}. \tag{2.11.19c}$$

Next, we partition these submatrices in terms of their *dependent* and *independent* (column) vectors as follows [with $(\ldots)^{\mathrm{T}} \equiv$ transpose of $(\ldots)$, and using strict matrix notation for vectors and their dot products, instead of the customary vector notation used before and after this subsection]:

$$\mathbf{a}_{\mathrm{D}} = \begin{pmatrix} \boldsymbol{a}_1{}^{\mathrm{T}} \\ \cdots \\ \boldsymbol{a}_m{}^{\mathrm{T}} \end{pmatrix}, \qquad \mathbf{a}_{\mathrm{D}}{}^{\mathrm{T}} = (\boldsymbol{a}_1, \ldots, \boldsymbol{a}_m), \qquad \boldsymbol{a}_D{}^{\mathrm{T}} = (a_{D1}, \ldots a_{Dn}), \tag{2.11.20a}$$

$$\mathbf{a}_{\mathrm{I}} = \begin{pmatrix} \boldsymbol{a}_{m+1}{}^{\mathrm{T}} \\ \cdots \\ \boldsymbol{a}_n{}^{\mathrm{T}} \end{pmatrix}, \qquad \mathbf{a}_{\mathrm{I}}{}^{\mathrm{T}} = (\boldsymbol{a}_{m+1}, \ldots, \boldsymbol{a}_n), \qquad \boldsymbol{a}_I{}^{\mathrm{T}} = (a_{I1}, \ldots a_{In}), \tag{2.11.20b}$$

$$\mathbf{A}_{\mathrm{D}} = (\boldsymbol{A}_1, \ldots, \boldsymbol{A}_m), \qquad \mathbf{A}_{\mathrm{D}}{}^{\mathrm{T}} = \begin{pmatrix} \boldsymbol{A}_1{}^{\mathrm{T}} \\ \cdots \\ \boldsymbol{A}_m{}^{\mathrm{T}} \end{pmatrix}, \qquad \boldsymbol{A}_D{}^{\mathrm{T}} = (A_{1D}, \ldots, A_{nD}), \quad (2.11.20c)$$

$$\mathbf{A}_{\mathrm{I}} = (\boldsymbol{A}_{m+1}, \ldots, \boldsymbol{A}_n), \qquad \mathbf{A}_{\mathrm{I}}{}^{\mathrm{T}} = \begin{pmatrix} \boldsymbol{A}_{m+1}{}^{\mathrm{T}} \\ \cdots \\ \boldsymbol{A}_n{}^{\mathrm{T}} \end{pmatrix}, \qquad \boldsymbol{A}_I{}^{\mathrm{T}} = (A_{1I}, \ldots, A_{nI}), \quad (2.11.20d)$$

Also, since $(\mathbf{a}_{\mathrm{D}} \cdot \mathbf{a}_{\mathrm{D}}{}^{\mathrm{T}})^{-1} \cdot (\mathbf{a}_{\mathrm{D}} \cdot \mathbf{a}_{\mathrm{D}}{}^{\mathrm{T}}) = \mathbf{1}$ and $\mathbf{A}_{\mathrm{D}}{}^{\mathrm{T}} \cdot \mathbf{a}_{\mathrm{D}}{}^{\mathrm{T}} = \mathbf{1}$, it follows that

$$\mathbf{A}_{\mathrm{D}}{}^{\mathrm{T}} = (\mathbf{a}_{\mathrm{D}} \cdot \mathbf{a}_{\mathrm{D}}{}^{\mathrm{T}})^{-1} \cdot \mathbf{a}_{\mathrm{D}}. \qquad (2.11.20e)$$

Now, in linear algebra terms, the virtual form of the constraint equations

$$\sum a_{Dk}\, \delta q_k = 0 \qquad [rank(a_{Dk}) = m\,(<n)], \qquad (2.11.21a)$$

[we note, in passing, that $rank(a_{Dk})_{m\times n} = rank(a_{Dk}|a_D)_{[m\times(n+1)]}$] or, in the above-introduced matrix notation,

$$\mathbf{a}_{\mathrm{D}} \cdot \delta\boldsymbol{q} = \mathbf{0}\,(\textit{one}\text{ matrix eq.}), \qquad \boldsymbol{a}_D{}^T \cdot \delta\boldsymbol{q} = 0\,[m\text{ vector (dot product) eqs.}], \qquad (2.11.21b)$$

state that *every virtual displacement* (*column*) *vector* $\delta\boldsymbol{q}^T = (\delta q_1, \ldots, \delta q_n)$, at the point (q, t), lies on the *local* $(n-m)$-*dimensional tangent/null/virtual plane of the* (*virtual form of the*) *constraint matrix* $\mathbf{a}_{\mathrm{D}} = (a_{Dk}), T_{n-m}(P) \equiv V_{n-m}(P) \equiv V_{n-m}$ (§2.7, suppressing the point dependence); or, equivalently, that $\delta\boldsymbol{q}$ is always *orthogonal* to the *local* m-*dimensional range space/constraint plane of* $\mathbf{a}_{\mathrm{D}}{}^{\mathrm{T}}, C_m(P) \equiv C_m$ (which is *orthogonally complementary to* V_{n-m}).

Next, in view of our quasi-variable choice, that is, $\delta\boldsymbol{q} = \mathbf{A}_{\mathrm{I}} \cdot \delta\boldsymbol{\theta}_I$, where $\delta\boldsymbol{\theta}_I{}^T = (\delta\theta_{m+1}, \ldots, \delta\theta_n)$, the $(n-m)$ vectors $(\boldsymbol{A}_{m+1}, \ldots, \boldsymbol{A}_n) \equiv \{\boldsymbol{A}_I\}$ constitute a basis for V_{n-m}; while the m constraint vectors $(\boldsymbol{a}_1, \ldots, \boldsymbol{a}_m) \equiv \{\boldsymbol{a}_D\}$ constitute a basis for C_m. Or, all (δq_k) satisfying (2.11.21a, b), at (q, t), form a local vector space V_{n-m}, which is orthogonal to the local vector space C_m built (spanned) by the m constraint vectors $\boldsymbol{a}_D{}^T = (a_{D1}, \ldots, a_{Dn})$.

More precisely, expressing (2.9.3a, b) in the above matrix/vector notation, we have

(i) $$\sum a_{Ik}A_{kI'} = \boldsymbol{a}_I{}^T \cdot \boldsymbol{A}_{I'} = \delta_{II'} \qquad (I, I' = m+1, \ldots, n), \qquad (2.11.22a)$$

$$\text{or} \qquad \mathbf{a}_{\mathrm{I}} \cdot \mathbf{A}_{\mathrm{I}} = \mathbf{1}, \qquad \text{or} \qquad \mathbf{A}_{\mathrm{I}}{}^{\mathrm{T}} \cdot \mathbf{a}_{\mathrm{I}}{}^{\mathrm{T}} = \mathbf{1}; \qquad (2.11.22b)$$

that is, the columns of $\mathbf{a}_{\mathrm{I}}{}^{\mathrm{T}}$ and $\mathbf{A}_{\mathrm{I}}$, or the rows of $\mathbf{a}_{\mathrm{I}}$ and $\mathbf{A}_{\mathrm{I}}{}^{\mathrm{T}}$, namely, the vectors $\{\boldsymbol{a}_I\}$ and $\{\boldsymbol{A}_I\}$, are mutually *dual*, or *reciprocal*, bases of V_{n-m}; and

(ii) $$\sum a_{Dk}A_{kD'} = \boldsymbol{a}_D{}^T \cdot \boldsymbol{A}_{D'} = \delta_{DD'} \qquad (D, D' = 1, \ldots, m), \qquad (2.11.22c)$$

$$\text{or} \qquad \mathbf{a}_{\mathrm{D}} \cdot \mathbf{A}_{\mathrm{D}} = \mathbf{1}, \qquad \text{or} \qquad \mathbf{A}_{\mathrm{D}}{}^{\mathrm{T}} \cdot \mathbf{a}_{\mathrm{D}}{}^{\mathrm{T}} = \mathbf{1}; \qquad (2.11.22d)$$

that is, the columns of $\mathbf{a_D}^{\mathrm{T}}$ and $\mathbf{A_D}$, or the rows of $\mathbf{a_D}$ and $\mathbf{A_D}^{\mathrm{T}}$, namely, the vectors $\{\boldsymbol{a}_D\}$ and $\{\boldsymbol{A}_D\}$, are mutually *dual* bases of C_m. Clearly, if the $\{\boldsymbol{a}_D\}$ are *orthonormal*, so are the $\{\boldsymbol{A}_D\}$, and the two bases coincide; and similarly for the bases $\{\boldsymbol{a}_I\}$, $\{\boldsymbol{A}_I\}$.

Likewise, from (2.9.3a, b) we obtain

$$\text{(iii)} \quad \sum a_{Dk} A_{kI} = \boldsymbol{a}_D{}^T \cdot \boldsymbol{A}_I = \delta_{DI} = 0 \qquad (D = 1, \ldots, m;\ I = m+1, \ldots, n), \tag{2.11.22e}$$

$$\text{or} \qquad \mathbf{a_D} \cdot \mathbf{A_I} = \mathbf{0}, \qquad \text{or} \qquad \mathbf{A_I}^{\mathrm{T}} \cdot \mathbf{a_D}^{\mathrm{T}} = \mathbf{0}; \tag{2.11.22f}$$

that is, the vectors $\{\boldsymbol{a}_D\}$ and $\{\boldsymbol{A}_I\}$ are mutually orthogonal.

$$\text{(iv)} \quad \sum a_{Ik} A_{kD} = \boldsymbol{a}_I{}^T \cdot \boldsymbol{A}_D = \delta_{ID} = 0 \qquad (I = m+1, \ldots, n;\ D = 1, \ldots, m), \tag{2.11.22g}$$

$$\text{or} \qquad \mathbf{a_I} \cdot \mathbf{A_D} = \mathbf{0}, \qquad \text{or} \qquad \mathbf{A_D}^{\mathrm{T}} \cdot \mathbf{a_I}^{\mathrm{T}} = \mathbf{0}. \tag{2.11.22h}$$

that is, the vectors $\{\boldsymbol{a}_I\}$ and $\{\boldsymbol{A}_D\}$ are mutually orthogonal. Equations (2.11.22f) and (2.11.22h) state, in linear algebra terms, that the "virtual displacement matrix" $\mathbf{A_I}$ is the *orthogonal complement* of the "constraint matrix" $\mathbf{a_D}$.

[Hence, the projections of an arbitrary system vector $\boldsymbol{M} = (M_1, \ldots, M_n)$ on the local mutually orthogonal (complementary) subspaces V_{n-m} and C_m, are, respectively,

Null/Virtual space projection $P\ldots(\cdots)$:

$$\sum A_{kI} M_k = (\mathbf{A_I}^{\mathrm{T}} \cdot \boldsymbol{M})_I = \boldsymbol{A}_I{}^T \cdot \boldsymbol{M} \equiv M_I \equiv P_{N(\text{Null})}(\boldsymbol{M}) \equiv P_{V(\text{Virtual})}(\boldsymbol{M}); \tag{2.11.23a}$$

Range/constraint space projection $P\ldots(\cdots)$:

$$\sum A_{kD} M_k = (\mathbf{A_D}^{\mathrm{T}} \cdot \boldsymbol{M})_D = \boldsymbol{A}_D{}^T \cdot \boldsymbol{M} \equiv M_D \equiv P_{R(\text{Range})}(\boldsymbol{M}) \equiv P_{C(\text{Constraint})}(\boldsymbol{M}).] \tag{2.11.23b}$$

The above hold, locally at least, for any velocity constraints, be they holonomic or nonholonomic. However: (a) If the constraints are nonholonomic, the corresponding null and range spaces are only local; at each admissible point of the system's constrained configuration (or event) space; but (b) If they are holonomic, then these spaces become global; that is, the hitherto n-dimensional configuration space is replaced by a new "smaller" such space described by $n - m$ Lagrangean coordinates, as detailed in §2.4 and §2.7.

Tensorial Hors d'Oeuvre

These *projection* ideas, originated by G. A. Maggi (1890s) and elaborated, via tensors, by J. L. Synge, G. Vranceanu, V. V. Vagner, G. Prange, G. Ferrarese, P. Maißer, N. N. Poliahov et al. (1920s–1980s), are very useful in interpreting the general problem of AM [i.e., of *decoupling* its equations of constrained motion into those *containing* the forces resulting from these constraints and those *not containing* these forces], in terms of simple geometrical pictures of the motion of a single "particle" in a generalized system space. They have become quite popular among multibody dynamicists, in recent decades; but, predominantly as exercises in linear algebra/matrix manipulations, that is, without the geometrical understanding and insight resulting from the full use of general tensors.

To show the advantages of the powerful tensorial indicial notation, over the *noncommutative* straightjacket of matrices, we summarize below some of the above results. With the help of the *summation convention* [over pairs of indices, one up and one down, from 1 to n; and where, here, capital indices (accented and/or unaccented), signify nonholonomic components], we have the following:

(a) Equations (2.11.21a, b), and their inverses:

$$\delta\theta^D \equiv a^D{}_k\,\delta q^k = 0, \qquad \delta q^k = A^k{}_I\,\delta\theta^I, \tag{2.11.24a}$$

(b) Equations (2.11.22a, b):

$$a^I{}_k A^k{}_{I'} = \delta^I{}_{I'}, \tag{2.11.24b}$$

(c) Equations (2.11.22c, d):

$$a^D{}_k A^k{}_{D'} = \delta^D{}_{D'}, \tag{2.11.24c}$$

(d) Equations (2.11.23a):

$$P_V(\boldsymbol{M}) \equiv A^k{}_I M_k = M_I, \tag{2.11.24d}$$

(e) Equations (2.11.23b):

$$P_C(\boldsymbol{M}) \equiv A^k{}_D M_k = M_D. \tag{2.11.24e}$$

The summation convention explains why, in order to project the (covariant) M_k, above, we dot them with $A^k{}_I$ and $A^k{}_D$, instead of $a^I{}_k$, $a^D{}_k$, respectively. [Briefly, the $\boldsymbol{a}^I(\boldsymbol{A}_I)$ build a nonholonomic contravariant (covariant) basis in V_{n-m}, while the $\boldsymbol{a}^D(\boldsymbol{A}_D)$ build a nonholonomic contravariant (covariant) basis in C_m.]

Last, a higher level of tensorial formalism may be achieved, if, as described briefly in (2.10.17c), we use accented (unaccented) indices to denote nonholonomic (holonomic) components; for example, successively: $a_{kl} \to a^k{}_l \to A^{k'}{}_k$, $A_{kl} \to A^k{}_l \to A^k{}_{k'}$; so that $\mathbf{a}\cdot\mathbf{A} = \mathbf{1}$ reads $A^{k'}{}_k A^k{}_{l'} = \delta^{k'}{}_{l'}$, and similarly for the other equations. For further details on tensorial nonholonomic dynamics, see, for example, Papastavridis (1999) and references cited therein.

2.12 CONSTRAINED TRANSITIVITY EQUATIONS, AND HAMEL'S FORM OF FROBENIUS' THEOREM

Constrained Transitivity Equations

Let us begin by examining the transitivity relations (2.10.1) under the Pfaffian constraints (2.11, 2a ff.), $d\theta_D = 0$, $\delta\theta_D = 0$, and their implications for the latter's holonomicity/nonholonomicity. Indeed, assuming $d(\delta q_k) = \delta(dq_k)$ for all $k = 1, \ldots, n$, whether the $dq/\delta q$ are constrained or not (what is known as the *Hamel viewpoint*, see pr. 2.12.5), the general transitivity equations (2.10.1) reduce to

$$d(\delta\theta_D) - \delta(d\theta_D) = \sum\sum \gamma^D{}_{II'}\, d\theta_{I'}\, \delta\theta_I + \sum \gamma^D{}_I\, dt\, \delta\theta_I, \tag{2.12.1a}$$

$$d(\delta\theta_I) - \delta(d\theta_I) = \sum\sum \gamma^I{}_{I'I''}\, d\theta_{I''}\, \delta\theta_{I'} + \sum \gamma^I{}_{I'}\, dt\, \delta\theta_{I'}. \tag{2.12.1b}$$

From the above we conclude that, even though $\omega_D(t) = 0$ (or a constant), or $d\theta_D(t) = 0$, or $\delta\theta_D(t) = 0$, from which it follows that $(\delta\theta_D)^{\cdot} = 0$ or $d(\delta\theta_D) = 0$, yet, in general, $d(\delta\theta_D) - \delta(d\theta_D) \neq 0 \;\Rightarrow\; -\delta(d\theta_D) \neq 0$! Specifically, as (2.12.1a) shows,

$$-\delta(d\theta_D) = \sum\sum \gamma^D{}_{II'}\, d\theta_{I'}\, \delta\theta_I + \sum \gamma^D{}_I\, dt\, \delta\theta_I \neq 0 \qquad \text{(in general);} \tag{2.12.1c}$$

that is, *we cannot assume that both $d(\delta q_k) = \delta(dq_k)$ and $d(\delta\theta_D) = \delta(d\theta_D)(= 0)$*! This is a delicate point that has important consequences in time-integral variational principles for nonholonomic systems (see Hamel, 1949, pp. 476–477; and this book, chapter 7; also pr. 2.12.5).

The Frobenius Theorem Revisited (and Made Easier to Implement)

We have already stated (§2.8) that the necessary and sufficient condition for the holonomicity of the system of m Pfaffian constraints

$$d\theta_D \equiv \sum a_{Dk}\, dq_k + a_D\, dt = 0, \qquad \delta\theta_D \equiv \sum a_{Dk}\, \delta q_k = 0 \qquad (D = 1, \ldots, m), \tag{2.12.2}$$

that is, for the existence of m linear combinations of the $d\theta_D = 0$, or $\delta\theta_D = 0$, that equal m independent exact differential equations $df_1 = 0, \ldots, df_m = 0 \Rightarrow f_1 = constant, \ldots, f_m = constant$, is the identical vanishing of their Frobenius bilinear covariants [recall (2.9.13)]

$$\begin{aligned} &d(\delta\theta_D) - \delta(d\theta_D) \\ &\quad = \sum\sum (\partial a_{Dk}/\partial q_l - \partial a_{Dl}/\partial q_k)\, dq_l\, \delta q_k + \sum (\partial a_{Dk}/\partial t - \partial a_D/\partial q_k)\, dt\, \delta q_k, \end{aligned} \tag{2.12.3}$$

for all dq_k, dt, δq_k solutions of (2.12.2). From this fundamental theorem we draw the following conclusions:

(i) If the dq_k, dt, δq_k are *unconstrained*, that is, if $m = 0$, then the identical satisfaction of the conditions

$$a^D{}_{kl} \equiv \partial a_{Dk}/\partial q_l - \partial a_{Dl}/\partial q_k = 0, \qquad a^D{}_k \equiv \partial a_{Dk}/\partial t - \partial a_D/\partial q_k = 0, \tag{2.12.3a}$$

for all k, $l = 1, \ldots, n$, is both *necessary* and *sufficient* for the holonomicity of θ_D (§2.9).

(ii) But, if the dq_k, dt, and δq_k are *constrained* by (2.12.2), then the vanishing of $d(\delta\theta_D) - \delta(d\theta_D)$ does not necessarily lead to (2.12.3a).

To obtain necessary conditions for the holonomicity of the system (2.12.2), we must express the dq_k, dt, δq_k, on the right side of (2.12.3), as linear and homogeneous combinations of $n - m$ *independent* parameters (Maggi's idea); that is, we must take the constraints (2.12.2) themselves into account. Indeed, substituting into (2.12.3) the general solutions of (2.12.2) [recalling (2.11.4)]:

$$dq_k \equiv \sum A_{kI}\, d\theta_I + A_I\, dt, \qquad \delta q_k \equiv \sum A_{kI}\, \delta\theta_I, \tag{2.12.4}$$

we obtain (2.12.1a). From this, it follows that (and this is the crux of this argument), since the $2(n-m)$ differentials $d\theta_I$, $\delta\theta_I$ are *independent/unconstrained*, the conditions

$$\gamma^D{}_{II'} = 0 \qquad \text{and} \qquad \gamma^D{}_{I,n+1} \equiv \gamma^D{}_I = 0, \tag{2.12.5}$$

for all $D = 1, \ldots, m$; $I, I' = m+1, \ldots, n$ {i.e. *maximum total number of distinct/independent such* $\gamma^D{}_{..}$*'s is* $[m(n-m)(n-m-1)/2] + m(n-m) = m(n-m)(n-m+1)/2 = mf(f+1)/2, f \equiv n-m$}, are both *sufficient* and *necessary* for the *holonomicity of the Pfaffian* system (2.12.2).

• Since [recalling the γ-definition (2.10.2 ff.)] (2.12.5) can be rewritten as

$$\gamma^D{}_{II'} = \sum\sum (\partial a_{Db}/\partial q_c - \partial a_{Dc}/\partial q_b) A_{bI} A_{cI'} \equiv \sum\sum a^D{}_{bc} A_{bI} A_{cI'} = 0, \tag{2.12.5a}$$

$$\begin{aligned}\gamma^D{}_I &\equiv \sum\sum (\partial a_{Db}/\partial q_c - \partial a_{Dc}/\partial q_b) A_{bI} A_c + \sum (\partial a_{Db}/\partial t - \partial a_D/\partial q_b) A_{bI} \\ &\equiv \sum\sum a^D{}_{bc} A_{bI} A_c + \sum a^D{}_b A_{bI} = 0,\end{aligned} \tag{2.12.5b}$$

we readily recognize that the (identical) vanishing of (all) the $\gamma^D{}_{..}$'s does not necessarily lead to the vanishing of (all) the $a^D{}_{bc}$, $a^D{}_b$, while the vanishing of all the latter leads to the vanishing of all the $\gamma^D{}_{..}$'s; that is, (2.12.3a) lead to (2.12.5, 5a, b) but not the other way around. Hence, (2.12.3a) are sufficient for holonomicity but not necessary, whereas (2.12.5, 5a, b) are both necessary and sufficient.

• Since, as (2.12.5a, b) make clear, each $\gamma^D{}_{..}$ $(\gamma^D{}_{.})$ depends, in general, on *all* the coefficients a_{Dk}, A_{kI} $(a_{Dk}, A_{kI}; a_D, A_k)$, the holonomicity/nonholonomicity of a(ny) particular constraint, of the given system (2.12.2), depends on all the others; that is, on the entire system of constraints. In other words: eqs. (2.12.5) check the holonomicity, or absence thereof, of each equation $d\theta_D, \delta\theta_D = 0$ against the entire system; that is, there is no such thing as testing an individual Pfaffian constraint, of a given system of such constraints, for holonomicity; doing that would be testing the new system consisting of that Pfaffian equation alone (i.e., $m = 1$) for holonomicity. In short, holonomicity/nonholonomicity is a *system* property.

As Neimark and Fufaev put it "the existence of a *single* nonintegrable constraint (in a system of constraints) does *not* necessarily mean a system is nonholonomic, since this constraint may prove to be integrable by virtue of the *remaining* constraint equations" (1972, p. 6, italics added). However [and recalling (2.10.16a–18b)], we can see that the identical vanishing of all coefficients $\gamma^k{}_{rs}$ and $\gamma^k{}_{r,n+1} \equiv \gamma^k{}_r$ (for *all* $r, s = 1, \ldots, n$) in

$$d(\delta\theta_k) - \delta(d\theta_k) = \cdots + (\gamma^k{}_{..})\, d\theta\, \delta\theta + (\gamma^k{}_{..})\, dt\, \delta\theta, \tag{2.12.5c}$$

independently of the constraints $d\theta_D, \delta\theta_D = 0$ (or, as if no constraints had been applied; and which is equivalent to $a^k{}_{rs} = 0$, $a^k{}_r = 0$, identically), is the necessary and sufficient condition for that particular θ_k to be a genuine/Lagrangean *coordinate*; that is, $a_{kr} = \partial\theta_k/\partial q_r$, $a_k = \partial\theta_k/\partial t$.

Let us recapitulate/summarize our findings:

(i) Pfaffian *forms* (not equations), like

$$d\theta_k \equiv \sum a_{kl}(q)\, dq_l \qquad (k = 1, \ldots, n';\ l = 1, \ldots, n;\ n \text{ and } n' \text{ unrelated}) \tag{2.12.6}$$

(for algebraic simplicity, but no loss in generality, we consider the stationary case), are either *exact* differentials, or *inexact* differentials.

If their dq's are *unconstrained*, then the necessary and sufficient conditions for $d\theta_k$ to be exact, and hence for θ_k to be a *holonomic coordinate*, are

$$a^k{}_{rs} = 0 \qquad (r, s = 1, \ldots, n). \tag{2.12.7}$$

In this case, each of the n' forms $d\theta_k$ is tested for *exactness* independently of the others; k, in (2.12.7), is a free index, uncoupled to both r and s. If $n = n'$, then, as already stated, conditions (2.12.7) can be replaced by

$$\gamma^k{}_{rs} = 0 \qquad (r, s = 1, \ldots, n); \tag{2.12.8}$$

but since calculating the γ's requires inverting (2.12.6) for the n dq's in terms of the n $d\theta$'s, eqs. (2.12.8) offer no advantage over eqs. (2.12.7).

If eqs. (2.12.7) hold, then $d\theta_k$ remains exact *no matter how many additional constraints may be imposed on its* dq*'s later*. For, then, we have

$$d(\delta\theta_k) - \delta(d\theta_k) = \sum\sum (\partial a_{kr}/\partial q_s - \partial a_{ks}/\partial q_r)\, dq_s\, \delta q_r = 0; \tag{2.12.9}$$

that is, if θ_k is a holonomic coordinate, it *remains holonomic* if additional constraints be imposed among its dq, δq's, later. This is the meaning of Hamel's rule: $d(\delta q_k) = \delta(dq_k)$, for all q's, constrained or not.

If eqs. (2.12.7) do not hold, $d\theta_k$ is inexact; but it can be made exact by additional constraints among its dq, δq's; that is, if θ_k is a quasi coordinate, it may *become a holonomic coordinate* by imposition of additional appropriate dq, δq constraints. For example, let us consider the Pfaffian form (not constraint)

$$d\theta \equiv a(x, y, z)\, dx + b(x, y, z)\, dy + c(x, y, z)\, dz.$$

Under the additional constraints $y = constant \Rightarrow dy = 0$ and $z = constant \Rightarrow dz = 0$, it becomes $d\theta \equiv a(x, y, z)\, dx \equiv f(x)\, dx = exact\ differential$, even if, originally, χ was a quasi coordinate.

(ii) Pfaffian *systems* of *constraints*

$$d\theta_D \equiv \sum a_{Dk}\, dq_k = 0, \qquad \delta\theta_D \equiv \sum a_{Dk}\, \delta q_k = 0, \tag{2.12.10a}$$

are either *holonomic* or they are nonholonomic. The necessary and sufficient conditions for holonomicity are

$$d(\delta\theta_D) - \delta(d\theta_D) = \sum\sum \gamma^D{}_{II'}\, d\theta_{I'}\, \delta\theta_I = 0, \tag{2.12.10b}$$

or, since the $d\theta_{I'}$, $\delta\theta_I$ are independent,

$$\gamma^D{}_{II'} = 0 \qquad (D = 1, \ldots, m;\ I, I' = m + 1, \ldots, n); \tag{2.12.10c}$$

that is, *the "dependent" γ's relative to their "independent" indices (subscripts) should vanish; or, the components of the dependent (constrained) Hamel coefficients along the independent (unconstrained) directions vanish.*

{This, more easily implementable, form of Frobenius' theorem seems to be due to Hamel (1904(a), 1935); also Cartan (1922, p. 105), Synge [1936, p. 19, eq. (4.16)], and Vranceanu [1929, p. 17, eq. (9′); 1936, p. 13].}

In closing this section, we repeat that Frobenius' theorem is about the integrability of *systems* of Pfaffian *equations*, like (2.12.2), not about the exactness of individual Pfaffian *forms*, like (2.12.6).

Example 2.12.1 *Special Case of the Hamel Coefficients, via Frobenius' Theorem.* Let us calculate the Hamel coefficients corresponding to the special constraint form

$$dq_D = \sum b_{DI}\, dq_I, \qquad \delta q_D = \sum b_{DI}\, \delta q_I, \tag{a}$$

where $b_{DI} = b_{DI}(q)$, and formulate the necessary/sufficient conditions for their holonomicity. We begin by viewing (a) as the following special Hamel choice [stationary version of (2.11.10a–12b)]:

$$d\theta_D = dq_D - \sum b_{DI}\, dq_I = 0, \qquad d\theta_I \equiv dq_I \neq 0, \qquad d\theta_{n+1} \equiv dq_{n+1} \equiv dt \neq 0; \tag{b}$$

$$\delta\theta_D \equiv \delta q_D - \sum b_{DI}\, \delta q_I = 0, \qquad \delta\theta_I \equiv \delta q_I \neq 0, \qquad \delta\theta_{n+1} \equiv \delta q_{n+1} \equiv \delta t = 0; \tag{c}$$

$$dq_D = d\theta_D + \sum b_{DI}\, d\theta_I = \sum b_{DI}\, d\theta_I, \quad dq_I = d\theta_I, \quad dq_{n+1} \equiv d\theta_{n+1} \equiv dt; \tag{d}$$

$$\delta q_D = \delta\theta_D + \sum b_{DI}\, \delta q_I = \sum b_{DI}\, \delta q_I, \quad \delta q_I = \delta\theta_I, \quad \delta q_{n+1} \equiv \delta\theta_{n+1} \equiv \delta t = 0; \tag{e}$$

also, since here $dq_I = d\theta_I$, we can rewrite the system (a) as

$$dq_k = \sum B_{kI}\, dq_I \equiv \sum A_{kI}\, d\theta_I,$$

where

$$(B_{kI}) = \begin{pmatrix} b_{1,m+1} & \cdots & b_{1n} \\ \cdots & \cdots & \cdots \\ b_{m,m+1} & \cdots & b_{mn} \\ \hline 1 & \cdots & 0 \\ \cdots & \cdots & \cdots \\ 0 & \cdots & 1 \end{pmatrix}. \tag{f}$$

Since $\theta_I = q_I$, we shall have $\gamma^I{}_{\alpha\beta} = 0$; while (2.12.9), with $k \to D$ and (f), becomes, successively,

$$\begin{aligned} d(\delta\theta_D) - \delta(d\theta_D) &= \sum\sum a^D{}_{rs}\, dq_s\, \delta q_r = \sum\sum a^D{}_{rs}\Big(\sum B_{sI}\, dq_I\Big)\Big(\sum B_{rI'}\, \delta q_{I'}\Big) \\ &= \cdots = \sum\sum\sum\sum (a^D{}_{rs}\, b_{sI}\, b_{rI'})\, dq_I\, \delta q_{I'} \\ &= \cdots = \sum\sum \gamma^D{}_{I'I}\, dq_I\, \delta q_{I'} \\ &\Big[= \sum\sum \gamma^D{}_{II'}\, dq_{I'}\, \delta q_I = \sum\sum \gamma^D{}_{II'}\, d\theta_{I'}\, \delta\theta_I\Big], \end{aligned} \tag{g}$$

where (expanding the sums in r and s, with $D, D', D'' = 1, \ldots, m$; $I, I' = m+1, \ldots, n$)

$$\gamma^D{}_{I'I} \equiv \sum\sum a^D{}_{D'D''}\, b_{D''I}\, b_{D'I'} + \sum a^D{}_{D'I}\, b_{D'I'} + \sum a^D{}_{I'D'}\, b_{D'I} + a^D{}_{I'I}; \tag{h}$$

or, since $a^D{}_{D'D''} \equiv a_{DD',D''} - a_{DD'',D'}$, where commas denote partial differentiations relative to the indicated q's and [by (2.11.12–12b)] $a_{DD'} \to \delta_{DD'}$, $a_{DI} \to -b_{DI}$, $a_{ID} \to 0$, $a_{II'} \to \delta_{II'}$:

$$\gamma^{D}{}_{I'I} = \sum\sum (0) b_{D''I} b_{D'I'} + \sum \big[0 - (-\partial b_{DI}/\partial q_{D'})\big] b_{D'I'} \\ + \sum \big[(-\partial b_{DI'}/\partial q_{D'}) - 0\big] b_{D'I} + \big[(-\partial b_{DI'}/\partial q_I) - (-\partial b_{DI}/\partial q_{I'})\big],$$

or finally,

$$\gamma^{D}{}_{I'I} = \big[\partial b_{DI}/\partial q_{I'} + \sum (\partial b_{DI}/\partial q_{D'}) b_{D'I'}\big] - \big[\partial b_{DI'}/\partial q_I + \sum (\partial b_{DI'}/\partial q_{D'}) b_{D'I}\big] \\ \equiv -w^{D}{}_{I'I} = w^{D}{}_{II'} = \textit{Voronets (or Woronetz) coefficients}; \tag{i}$$

clearly, a specialization of $\gamma^{D}{}_{I'I}$. Thus, (g) becomes

$$d(\delta\theta_D) - \delta(d\theta_D) = \sum\sum \gamma^{D}{}_{I'I}\, dq_I\, \delta q_{I'} = \sum\sum w^{D}{}_{II'}\, dq_I\, \delta q_{I'}, \tag{j}$$

and, since the dq_I and δq_I are independent, by Frobenius' theorem, the necessary and sufficient conditions for the holonomicity of the system (a) are

$$w^{D}{}_{II'} = 0, \tag{k}$$

which are none other than the earlier Deahna–Bouquet conditions (2.3.11b ff.).

REMARKS

(i) With the help of the symbolic notation (2.11.15a), we can rewrite (k) in the more memorable form,

$$\gamma^{D}{}_{I'I} = w^{D}{}_{II'} = \partial b_{DI}/\partial(q_{I'}) - \partial b_{DI'}/\partial(q_I). \tag{l}$$

(ii) In the special "Chaplygin (or Tchapligine) case" (§3.8), where $b_{DI} = b_{DI}(q_{m+1}, \ldots, q_n) \equiv b_{DI}(q_D)$, the above reduce to

$$\gamma^{D}{}_{I'I} = \partial b_{DI}/\partial q_{I'} - \partial b_{DI'}/\partial q_I \equiv t^{D}{}_{II'}. \tag{m}$$

Problem 2.12.1 Continuing from the previous example, show that eqs. (i) for the Voronets coefficients also result by direct application of the definition (2.10.2)

$$\gamma^{D}{}_{II'} = \sum\sum (\partial a_{Dk}/\partial q_r - \partial a_{Dr}/\partial q_k) A_{kI} A_{rI'} \tag{a}$$

to the constraints (ex. 2.12.1:a) in the equilibrium forms (ex. 2.12.1:b–e).

HINT

Here [recalling again (2.11.12–12b)]: $a_{DD'} = \delta_{DD'}$, $a_{DI} = -b_{DI}$, $a_{ID} = 0$, $a_{II'} = \delta_{II'}$; $A_{DD'} = \delta_{DD'}$, $A_{DI} = b_{DI}$, $A_{ID} = 0$, $A_{II'} = \delta_{II'}$.

Problem 2.12.2 Continuing from the above, show that in the general *nonstationary* case

$$dq_D = \sum b_{DI}\, dq_I + b_D\, dt, \qquad dq_I = \sum \delta_{II'}\, dq_{I'} = dq_I, \tag{a}$$

$$\delta q_D = \sum b_{DI}\, \delta q_I, \;\; \delta q_I = \sum \delta_{II'}\, \delta q_{I'} = \delta q_I; \quad b_{DI} = b_{DI}(t, q), \;\; b_D = b_D(t, q), \tag{b}$$

the ${\gamma^D}_{II'}$ *remain unchanged*, but we have, the additional *nonstationary Voronets* coefficients:

$$
\begin{aligned}
{\gamma^D}_{I,n+1} &\equiv {\gamma^D}_I = -{w^D}_{I,n+1} \equiv -{w^D}_I \\
&= \left[\partial b_D/\partial q_I + \sum (\partial b_D/\partial q_{D'}) b_{D'I}\right] - \left[\partial b_{DI}/\partial t + \sum (\partial b_{DI}/\partial q_{D'}) b_{D'}\right] \\
&= \partial b_D/\partial(q_I) - \partial b_{DI}/\partial(q_{n+1}) \qquad \text{(c)}
\end{aligned}
$$

[recalling the symbolic (2.9.32 ff.), (2.11.15): $A_k \to b_D$, and $\sum (\partial \ldots/\partial q_D) b_D = \partial \ldots/\partial(t)$].

REMARK

In concrete problems, use of the above definitions to calculate the w-coefficients is *not* recommended. Instead, the safest way to do this is to read them off directly as coefficients of the following bilinear difference/covariant:

$$
\begin{aligned}
d(\delta\theta_D) - \delta(d\theta_D) &= \cdots + {\gamma^D}_{II'}\, d\theta_{I'}\, \delta\theta_I + \cdots + {\gamma^D}_I\, dt\, \delta\theta_I + \cdots \\
&= \cdots - {w^D}_{II'}\, dq_{I'}\, \delta q_I + \cdots - {w^D}_I\, dt\, \delta q_I + \cdots . \qquad \text{(d)}
\end{aligned}
$$

Problem 2.12.3 Continuing from the preceding problem, verify that:

(i) in the *catastatic Voronets* case, the ${w^D}_{II'}$ remain unchanged, while ${w^D}_I = \partial b_{DI}/\partial t$; and

(ii) in the *stationary Voronets* case, the ${w^D}_{II'}$ remain unchanged, while ${w^D}_I = 0$.

Problem 2.12.4 Continuing from the above problems, verify that

(i) $$ {\gamma^I}_{\beta\varepsilon} = 0 \qquad (I = m+1, \ldots, n;\ \beta, \varepsilon = 1, \ldots, n;\ n+1); \qquad \text{(a)} $$

(ii) $$ {\gamma^D}_{D'\varepsilon} = 0 \qquad (D, D' = 1, \ldots, m;\ \varepsilon = 1, \ldots, n;\ n+1); \qquad \text{(b)} $$

(recall that $\theta_I = q_I$ is a holonomic coordinate).

Problem 2.12.5 Continuing from the above example and problems, consider again the nonstationary constraints in the special form (2.11.10a ff.):

$$ dq_D = \sum b_{DI}\, dq_I + b_D\, dt, \qquad \delta q_D = \sum b_{DI}\, \delta q_I, \qquad v_D = \sum b_{DI} v_I + b_D, \quad \text{(a)} $$

where $b_{DI} = b_{DI}(t, q)$, $b_D = b_D(t, q)$, and, as usual, $v_k \equiv dq_k/dt$.

Show by direct d/δ-differentiations of the above, and assuming that $d(\delta q_I) - \delta(dq_I) = 0$, that

$$ d(\delta q_D) - \delta(dq_D) = \sum\sum {w^D}_{II'}\, dq_{I'}\, \delta q_I + \sum {w^D}_I\, dt\, \delta q_I, \qquad \text{(b)} $$

or, dividing both sides by dt,

$$ (\delta q_D)^{\cdot} - \delta(\dot q_D) \equiv (\delta q_D)^{\cdot} - \delta v_D = \sum \left(\sum {w^D}_{II'}\, v_{I'} + {w^D}_I\right) \delta q_I \equiv \sum {v^D}_I\, \delta q_I; \quad \text{(c)} $$

that is, in general, and *contrary to the hitherto adopted Hamel viewpoint* (§2.12), $d(\delta q_D) \neq \delta\,(dq_D)$, as if the q_D are no longer holonomic coordinates!

REMARKS

The alternative (and, as shown below, internally consistent) viewpoint exhibited by (c) [originally advanced by Suslov (1901–1902), (1946, pp. 596–600), and continued by Levi-Civita (and Amaldi), Neimark and Fufaev, Rumiantsev, and others], is based on the following assumptions:

(i) If the n differentials/velocities $dq/\delta q/v$ are unconstrained, then we assume that the Hamel viewpoint holds for all of them; that is, $d(\delta q_k) = \delta\,(dq_k)$ $(k = 1, \ldots, n)$.

(ii) But, if these differentials/velocities are subject to m (a)-like constraints, then we assume that the Hamel viewpoint holds only for the *independent* of them, say the last $n-m$, but not for the *dependent* of them, that is for the remaining (first) m:

$$\text{Suslov viewpoint:} \qquad d(\delta q_I) - \delta(dq_I) = 0, \quad \text{but} \quad d(\delta q_D) - \delta(dq_D) \neq 0. \tag{d}$$

Let us examine this quantitatively, from the earlier generalized transitivity equations (2.10.1, 5):

$$d(\delta\theta_k) - \delta(d\theta_k) = \sum a_{kl}[d(\delta q_l) - \delta(dq_l)] + \sum\sum \gamma^k{}_{rs}\, d\theta_s\, \delta\theta_r + \sum \gamma^k{}_r\, dt\, \delta\theta_r, \tag{e}$$

$$d(\delta q_k) - \delta(dq_k) = \sum A_{kl}\Big\{[d(\delta\theta_l) - \delta(d\theta_l)] - \sum\sum \gamma^l{}_{rs}\, d\theta_s\, \delta\theta_r - \sum \gamma^l{}_r\, dt\, \delta\theta_r\Big\}. \tag{f}$$

(a) *Hamel viewpoint*: $d(\delta q_k) = \delta(dq_k)$, always. Then, since $d\theta_D$, $\delta\theta_D = 0$, (e) yields

$$d(\delta\theta_D) - \delta(d\theta_D) = \sum\sum \gamma^D{}_{II'}\, d\theta_{I'}\, \delta\theta_I + \sum \gamma^D{}_I\, dt\, \delta\theta_I \quad \text{[by (pr. 2.12.4: b)]} \tag{g}$$

$$= -\sum\sum w^D{}_{II'}\, dq_{I'}\, \delta q_I - \sum w^D{}_I\, dt\, \delta q_I \quad \text{[by (ex. 2.12.1: g, j)];} \tag{h}$$

$$d(\delta\theta_I) - \delta(d\theta_I) = \sum\sum \gamma^I{}_{I'I''}\, d\theta_{I''}\, \delta\theta_{I'} + \sum \gamma^I{}_{I'}\, dt\, \delta\theta_{I'} = 0 \quad \text{[by (pr. 2.12.4: a)].} \tag{i}$$

(b) *Suslov viewpoint* [for the Voronets-type constraints (a)]. Since here, $A_{DD'} = \delta_{DD'}$, $A_{ID} = 0$, $A_{II'} = \delta_{II'}$, eq. (f) yields, successively,

(1)
$$\begin{aligned} 0 &= d(\delta q_I) - \delta(dq_I) \\ &= \sum A_{II'}\Big\{[d(\delta\theta_{I'}) - \delta(d\theta_{I'})] - \sum\sum \gamma^I{}_{I'I''}\, d\theta_{I''}\, \delta\theta_{I'} - \sum \gamma^I{}_{I'}\, dt\, \delta\theta_{I'}\Big\} \\ &= [d(\delta\theta_I) - \delta(d\theta_I)] - \sum\sum \gamma^I{}_{I'I''}\, d\theta_{I''}\, \delta\theta_{I'} - \sum \gamma^I{}_{I'}\, dt\, \delta\theta_{I'} \\ &= d(\delta\theta_I) - \delta(d\theta_I) \qquad \text{[by (pr. 2.12.4: a)];} \end{aligned} \tag{j}$$

(2)
$$\begin{aligned} d(\delta q_D) &- \delta(dq_D) \\ &= \sum A_{DD'}\Big\{[d(\delta\theta_{D'}) - \delta(d\theta_{D'})] - \sum\sum \gamma^{D'}{}_{II'}\, d\theta_{I'}\, \delta\theta_I - \sum \gamma^{D'}{}_I\, dt\, \delta\theta_I\Big\} \\ &= [d(\delta\theta_D) - \delta(d\theta_D)] - \sum\sum \gamma^D{}_{II'}\, d\theta_{I'}\, \delta\theta_I - \sum \gamma^D{}_I\, dt\, \delta\theta_I \\ &= [d(\delta\theta_D) - \delta(d\theta_D)] + \sum\sum w^D{}_{II'}\, d\theta_{I'}\, \delta\theta_I + \sum w^D{}_I\, dt\, \delta\theta_I \\ &\qquad \text{[by (ex. 2.12.1: i), (pr. 2.12.2: c)]} \\ &= \sum\sum w^D{}_{II'}\, dq_{I'}\, \delta q_I + \sum w^D{}_I\, dt\, \delta q_I \quad \text{[by (b)],} \end{aligned}$$

and comparing the last two expressions of $d(\delta q_D) - \delta(dq_D)$, we immediately conclude that

$$d(\delta\theta_D) - \delta(d\theta_D) = 0. \tag{k}$$

Hence: In the Suslov viewpoint we must assume that $d(\delta\theta_k) = \delta\,(d\theta_k)$ $(k = 1, \ldots, n)$.

Both viewpoints are internally consistent; but, if applied improperly, they may give rise to contradictions/paradoxes. Hamel's viewpoint, however, has the advantage of being in agreement with variational calculus (more on this in §7.8).

Problem 2.12.6 Consider the special stationary $d\theta \;\Leftrightarrow\; dq$ transformation:

$$d\theta_D \equiv \sum a_{DD'}\, dq_{D'}\ (=0) \ \text{ and } \ d\theta_I \equiv dq_I\ (\neq 0;\ \text{the } \theta_I \text{ are } \textit{holonomic} \text{ coordinates}), \tag{a}$$

where $a_{DD'} = a_{DD'}(q_1, \ldots, q_m) \equiv a_{DD'}(q_D)$. Show that, in this case, the Hamel coefficients are

(i) $$\gamma^D{}_{D'D''} = \sum\sum (\partial a_{Dd'}/\partial q_{d''} - \partial a_{Dd''}/\partial q_{d'}) A_{d'D'} A_{d''D''}, \tag{b}$$

where D, D', D'', d', $d'' = 1, \ldots, m$ and $dq_{D'} = \sum A_{D'D}\, d\theta_D$; and

(ii) $$\gamma^k{}_{rs} = 0, \text{ for any one of } k, r, s \text{ greater than } m. \tag{c}$$

Example 2.12.2 *Transformation of the Hamel Coefficients under Frame of Reference Transformations.* Let us again consider, for algebraic simplicity but no loss in generality, the stationary Pfaffian constraint system:

$$d\theta_D \equiv \sum a_{Dk}\, dq_k = 0, \qquad \delta\theta_D \equiv \sum a_{Dk}\, \delta q_k = 0. \tag{a}$$

Further, let us assume that (a) is nonholonomic; that is, $\gamma^D{}_{II'} \neq 0$. Now we ask the question: Is it possible, by a frame of reference transformation $q \to q'(t, q)$, to make the constraints (a) holonomic? In other words, is it possible to find new Lagrangean coordinates $q_{k'} = q_{k'}(t, q_k)$, in which the corresponding $(dq_{k'} \;\Leftrightarrow\; d\theta_k)$ Hamel coefficients $\gamma(q')^D{}_{II'} \equiv \gamma'^D{}_{II'}$ vanish? Below we show that the answer to this is *no*; that is, if a system of constraints is nonholonomic in one frame of reference, it remains nonholonomic in all other frames of reference obtainable from the original via admissible frame of reference transformations.

Indeed, we find, successively [with $\gamma(q)^D{}_{II'} \equiv \gamma^D{}_{II'}$],

$$\begin{aligned}
0 \neq d(\delta\theta_D) - \delta(d\theta_D) &= \sum\sum \gamma^D{}_{I'I}\, d\theta_I\, \delta\theta_{I'} = \sum\sum a^D{}_{rs}\, dq_s\, \delta q_r \\
&= \sum\sum a^D{}_{rs}\Big(\sum (\partial q_s/\partial q_{s'})\, dq_{s'} + (\partial q_s/\partial t)\, dt\Big)\Big(\sum (\partial q_r/\partial q_{r'})\, \delta q_{r'}\Big) \\
&= \sum\sum\sum\sum \big[(\partial q_s/\partial q_{s'})(\partial q_r/\partial q_{r'}) a^D{}_{rs}\big] dq_{s'}\, \delta q_{r'} \\
&\quad + \sum\sum\sum \big[(\partial q_s/\partial t)(\partial q_r/\partial q_{r'}) a^D{}_{rs}\big] dt\, \delta q_{r'} \\
&\equiv \sum\sum a^D{}_{r's'}\, dq_{s'}\, \delta q_{r'} + \sum a^D{}_{r'}\, dt\, \delta q_{r'}
\end{aligned}$$

[where $a^D{}_{r's'} \equiv \partial a_{Dr'}/\partial q_{s'} - \partial a_{Ds'}/\partial q_{r'}$, etc.]

$$
\begin{aligned}
&= \sum\sum a^D{}_{r's'} \Big(\sum A_{s'I}\, d\theta_I + A_{s'}\, dt\Big)\Big(\sum A_{r'I'}\, \delta\theta_{I'}\Big) + \sum a^D{}_{r'} \Big(\sum A_{r'I'}\, \delta\theta_{I'}\Big)\, dt \\
&= \sum\sum\sum\sum (a^D{}_{r's'} A_{s'I} A_{r'I'})\, d\theta_I\, \delta\theta_{I'} + \sum\Big(\sum\sum a^D{}_{r's'} A_{r'I'} A_{s'} + \sum a^D{}_{r'} A_{r'I'}\Big)\, dt\, \delta\theta_{I'} \\
&= \sum\sum \gamma'^D{}_{I'I}\, d\theta_I\, \delta\theta_{I'} + \sum \gamma'^D{}_{I'}\, dt\, \delta\theta_{I'}, \qquad \text{(b)}
\end{aligned}
$$

from which, comparing with the first line of this equation, we readily conclude that

$$\gamma(q)^D{}_{I'I} = \gamma(q')^D{}_{I'I} \qquad \text{and} \qquad \gamma(q')^D{}_{I'} = 0; \qquad \text{(c)}$$

that is, *the Hamel coefficients remain invariant under frame of reference transformations*; or, these coefficients depend on the nonholonomic "coordinates" θ_k but they are independent of the particular holonomic coordinates frame used for their derivation.

Incidentally, this derivation also demonstrates that the γ-definition (2.10.1) is both practically and theoretically superior to the more common (2.10.2–4).

REMARKS

(i) We are reminded that the transformation properties of the γ's under *local* transformations: $d\theta_k \;\Leftrightarrow\; d\theta_{k'}$, at (q, t), have already been given in ex. 2.10.1.

(ii) The reader can easily verify that if, instead of (a), we had chosen a general *nonstationary* $d\theta \;\Leftrightarrow\; dq$ transformation, we would have found $\gamma(q')^D{}_{I'} = \gamma(q)^D{}_{I'}$, instead of the second of (c). Also, then,

$$
\begin{aligned}
d\theta_r = \sum a_{rs}\, dq_s + a_r\, dt &= \sum a_{rs}\Big(\sum (\partial q_s/\partial q_{s'})\, dq_{s'} + (\partial q_s/\partial t)\, dt\Big) + a_r\, dt \\
&\equiv \sum a_{rr'}\, dq_{r'} + a'_r\, dt,
\end{aligned}
$$

from which we can readily deduce the transformation relations among the coefficients $a(q)$, $a(q')$ [recall (2.6.6 ff.)].

Problem 2.12.7 (see Forsyth, 1890, p. 54.) Verify that a system of n independent Pfaffian constraints in the n (or even $n+1$) variables; that is,

$$d\theta_k \equiv \sum a_{kl}\, dq_l = 0 \qquad (k, l = 1, \ldots, n), \qquad \text{(a)}$$

is always holonomic.

Problem 2.12.8 *Alternative Formulation of Frobenius' Theorem*. It has been shown, by Frobenius and others (see, e.g., Pascal, 1927, p. 584), that the Pfaffian system:

$$d\theta_D \equiv \sum a_{Dk}(q)\, dq_k = 0 \qquad (D = 1, \ldots, m;\ k = 1, \ldots, n), \qquad \text{(a)}$$

is holonomic if, and only if, each of its m $(n+m)\times(n+m)$ antisymmetric "Frobenius matrices":

$$\mathbf{F}_{\mathrm{D}} \equiv \left(\begin{array}{ccccc|ccc} 0 & a^D{}_{12} & a^D{}_{13} & \cdots & a^D{}_{1n} & a_{11} & \cdots & a_{m1} \\ a^D{}_{21} & 0 & a^D{}_{23} & \cdots & a^D{}_{2n} & a_{12} & \cdots & a_{m2} \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ a^D{}_{n1} & a^D{}_{n2} & \cdots & \cdots & 0 & a_{1n} & \cdots & a_{mn} \\ \hline a_{11} & a_{12} & \cdots & \cdots & a_{1n} & 0 & \cdots & 0 \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ a_{m1} & a_{m2} & \cdots & \cdots & a_{mn} & 0 & \cdots & 0 \end{array}\right)$$

where $a^D{}_{kl} \equiv \partial a_{Dk}/\partial q_l - \partial a_{Dl}/\partial q_k \equiv a_{Dk,l} - a_{D,lk} = -a^D{}_{lk}$ (e.g., $a^D{}_{12} = -a^D{}_{21}$, $a^D{}_{11} = -a^D{}_{11} \Rightarrow a^D{}_{11} = 0$, etc.), has rank $2m$.

Apply this theorem for various simple cases: for example, $m = 0$ (i.e., dq_k unconstrained), $m = 1$ (one constraint), and $m = 2$ (two constraints).

Example 2.12.3 *Geometrical Interpretations of the Frobenius Conditions* (May be omitted in a first reading.) In terms of the earlier (2.11.20a ff.) *m constraint vectors* $\boldsymbol{a}_D = (a_{D1}, \ldots, a_{Dn})$ and $n - m$ *virtual vectors* $\boldsymbol{A}_I = (A_{I1}, \ldots, A_{In})$ (in ordinary vector, *nonmatrix* notation), Frobenius' conditions first of (2.12.5) assume the following forms:

(i) *First interpretation:* From the $\boldsymbol{a}_D$ we build the antisymmetric tensor:

$$(a^D{}_{kl}) = (-a^D{}_{lk}) \equiv (\partial a_{Dk}/\partial q_l - \partial a_{Dl}/\partial q_k). \tag{a}$$

These can be viewed as the holonomic (covariant) components of the "*rotation* or *curl(ing)* of $\boldsymbol{a}_D$": $a^D{}_{kl} = -(\boldsymbol{curl}\,\boldsymbol{a}_D)_{kl}$. Also, we recall that $A_{kl} \equiv \partial v_k/\partial \omega_l$. As a result of the above, (2.12.5):

$$\gamma^D{}_{II'} = \sum\sum (\partial a_{Dk}/\partial q_l - \partial a_{Dl}/\partial q_k) A_{kI} A_{lI'} \equiv \sum\sum a^D{}_{kl} A_{kI} A_{lI'} = 0, \tag{b}$$

assumes the (covariant) tensor transformation form, in k, l:

$$\begin{aligned}\gamma^D{}_{II'} &= \sum\sum (\partial v_k/\partial \omega_I)(\partial v_l/\partial \omega_{I'}) a^D{}_{kl} \\ &= \boldsymbol{A}_{I'} \cdot \boldsymbol{curl}\,\boldsymbol{a}_D \cdot \boldsymbol{A}_I = \sum\sum (\boldsymbol{A}_{I'})^l (\boldsymbol{curl}\,\boldsymbol{a}_D)_{lk} (\boldsymbol{A}_I)^k = 0;\end{aligned} \tag{c}$$

that is, *the (covariant) components of the* ***curl*** *of the dependent/constraint vectors* $\boldsymbol{a}_D$ *along the independent nonholonomic directions* $\boldsymbol{A}_I$ *should vanish.*

(ii) *Second interpretation:* The Frobenius conditions (first of 2.12.5), rewritten with the help of the alternative expression (2.10.15) and the quasi chain rule

(2.9.30a) as

$$\gamma^D{}_{II'} = \sum\sum \{a_{Db}[A_{cI}(\partial A_{bI'}/\partial q_c) - A_{cI'}(\partial A_{bI}/\partial q_c)]\}$$
$$\equiv \sum a_{Db}(\partial A_{bI'}/\partial\theta_I - \partial A_{bI}/\partial\theta_{I'}) = 0, \qquad \text{(d)}$$

state that the constraint vectors $\boldsymbol{a}_D$ should be *perpendicular* to the $(n-m)\ (n-m-1)/2$ vectors:

$$\boldsymbol{A}_{II'} = \left(\sum A_{cI}(\partial A_{bI'}/\partial q_c) - \sum A_{cI'}(\partial A_{bI}/\partial q_c)\right) \equiv (\partial A_{bI'}/\partial\theta_I - \partial A_{bI}/\partial\theta_{I'}) = -\boldsymbol{A}_{I'I},$$

that is,

$$\gamma^D{}_{II'} = \boldsymbol{a}_D \cdot \boldsymbol{A}_{II'} = 0. \qquad \text{(e)}$$

Similarly for the nonstationary/rheonomic Frobenius conditions (second of 2.12.5): $\gamma^D{}_I = 0$.

For further details, including the precise positioning of indices, as practiced in general tensor analysis (and not observed in the above discussion!), see, for example, Papastavridis (1999, §6.9).

2.13 GENERAL EXAMPLES AND PROBLEMS

Example 2.13.1 *Introduction to the Simplest Nonholonomic Problem: Knife, Sled, Scissors, and so on.* Let us consider the motion of a knife S, whose rigid blade remains perpendicular to the fixed plane $O\text{–}xy$, and in contact with it at the point $C(x, y)$, and whose mass center G lies a distance b $(\neq 0)$ from C along the blade (fig. 2.15). The instantaneous angular orientation of S is given by its blade's angle with the $+Ox$ axis ϕ.

Let us choose as Lagrangean coordinates: $q_1 = x$, $q_2 = y$, $q_3 = \phi$. If $\boldsymbol{v} = (dx/dt, dy/dt, dz/dt = 0) \equiv (v_x, v_y, 0) =$ (inertial) velocity of C, and $\boldsymbol{u} \equiv (\cos\phi, \sin\phi, 0)$: unit vector along the blade, then the velocity constraint is

$$\boldsymbol{v} \times \boldsymbol{u} = \boldsymbol{0} \Rightarrow (\sin\phi)v_x + (-\cos\phi)v_y = 0, \qquad \text{or} \qquad dy/dx = \tan\phi. \qquad \text{(a)}$$

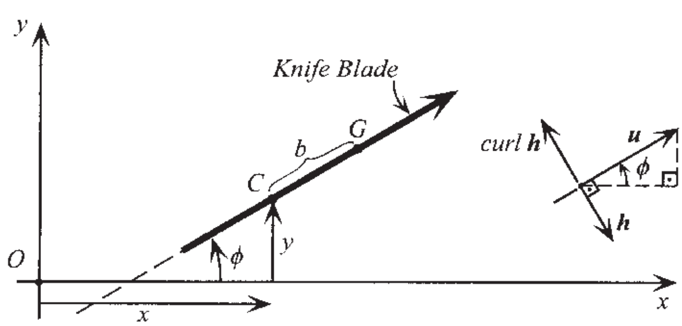


Figure 2.15 Knife in motion on fixed plane.

Since this is a *stationary* (and, of course, catastatic) constraint, we will also have, for its kinematically admissible/possible and virtual forms, respectively,

$$(\sin\phi)\,dx + (-\cos\phi)\,dy = 0 \qquad \text{and} \qquad (\sin\phi)\,\delta x + (-\cos\phi)\,\delta y = 0. \tag{b}$$

Other physical problems leading to such a constraint are:

(i) A racing boat with thin, deep, and wide keel, sailing on a still sea. Since the water resistance to the boat's longitudinal motion is *much larger* than the resistance to its transverse motion, the direction of the boat's instantaneous velocity must be always parallel to its keel's instantaneous heading;
(ii) a lamina moving on its plane, with a short and very stiff razor blade (or some similar rigid and very thin object: e.g., a small knife) embedded on its underside. Again, the lamina can move only along the instantaneous direction of its guiding blade;
(iii) a sled;
(iv) a pair of scissors cutting through a piece of paper;
(v) a pizza cutter, etc.

Application of the holonomicity criterion (2.3.6) or (2.3.8a) to (a), (b), with $\boldsymbol{h} = (\sin\phi, -\cos\phi, 0)$ and $d\boldsymbol{r} = (dx, dy, d\phi)$ [as if x, y, ϕ were rectangular Cartesian right-handed coordinates] yields

$$\begin{aligned} I \equiv \boldsymbol{h}\cdot\boldsymbol{curl}\,\boldsymbol{h} &= \boldsymbol{h}\cdot\big[(\partial/\partial x, \partial/\partial y, \partial/\partial\phi)\times(\sin\phi, -\cos\phi, 0)\big] \\ &= (\sin\phi, -\cos\phi, 0)\cdot(-\sin\phi, \cos\phi, 0) = -1 \neq 0; \end{aligned} \tag{c}$$

that is, the constraint (a), (b) is *nonholonomic*. This means that, although the general (global) configuration of S is specified completely by the *three* independent coordinates x, y, ϕ, *not all three of them* can be given, simultaneously, small arbitrary variations; that is, although there is no functional restriction of the type $f(x, y, \phi) = 0$, there is one of the type $g(dx, dy, d\phi; x, y, \phi) = 0$, namely the Pfaffian constraint (a), (b). Put geometrically: the blade has three *global* freedoms (x, y, ϕ), but only *two local* freedoms (any *two* of $dx, dy, d\phi$). Since $n = 3$ and $m = 1$, this is the *simplest* nonholonomic problem; and, accordingly, it has been studied extensively (by Bahar, Carathéodory, Chaplygin, et al.).

The independence of x, y, ϕ can be demonstrated as follows: we keep any two of them constant, and then show that varying the third results in a nontrivial (or nonempty) range of kinematically admissible positions:

(i) keep x and y fixed and vary ϕ continuously; the constraint (a), (b) is not violated [fig. 2.16(a)];
(ii) keep y and ϕ fixed. Varying x we can achieve other admissible configurations with different x's but the same y and ϕ;
but to go from one of them to another we have to vary all three coordinates [fig. 2.16(b)];
(iii) similarly when x and ϕ are fixed and y varies [fig. 2.16(c)].
The precise *kinetic* path followed in each case, among the kinematically possible/admissible ones, depends on the system's equations of (constrained) motion and on its initial conditions.

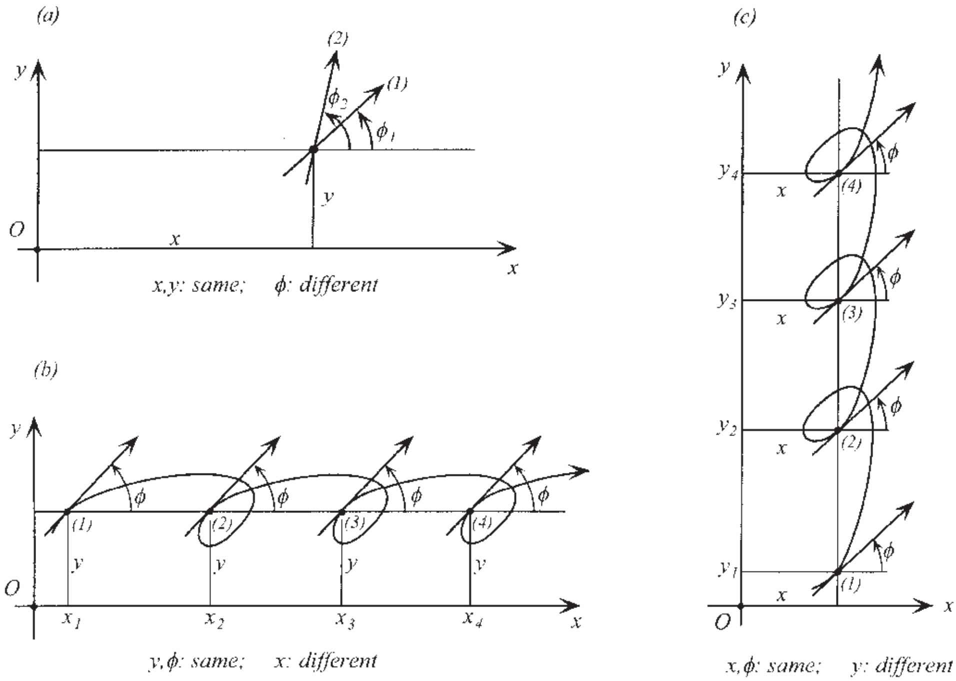

Figure 2.16 Global motions of a knife showing the independence of its three positional coordinates. We can always, through a suitable *finite* motion, bring the knife to a position and orientation as close as we want to any specified *original* position and orientation; that is, the relation among x, y, ϕ is nonunique.

An Ad Hoc Proof of the Impossibility of Obtaining a Relation $f(x, y, \phi) = 0$

Let us assume that such a constraint exists. Then d-varying it, and with subscripts for partial derivatives, yields

$$df = f_x\, dx + f_y\, dy + f_\phi\, d\phi = 0, \tag{d}$$

or, taking into account the constraint in the form: $dy = (\tan\phi)\, dx$,

$$df = (f_x + f_y \tan\phi)\, dx + (f_\phi)\, d\phi = 0, \tag{e}$$

where now dx and $d\phi$ are *independent*. Equation (e) leads immediately to

$$f_\phi = 0 \Rightarrow f = f(x, y) \qquad \text{and} \qquad f_x + f_y \tan\phi = 0. \tag{f}$$

By $(\partial/\partial\phi)$-differentiating the second of (f), while observing the first of (f), we obtain

$$f_y(1/\cos^2\phi) = 0, \tag{g}$$

from which, since in general $1/\cos^2\phi \neq 0$, it follows that $f_y = 0 \Rightarrow f = f(x)$. But then the second of (f) leads to $f_x = 0 \Rightarrow f = constant$ (*independent of* x, y, ϕ), and as such it cannot enforce the constraint $f(x, y, \phi) = 0$. Hence, no such f exists (with or without integrating factors).

However, if the knife was constrained to move along a *prescribed* path, on the $O\!-\!xy$ plane, the system would be holonomic! In that case, we would have in *advance* the path's equations, say in the parametric form:

$$x = x(s) \qquad \text{and} \qquad y = y(s) \qquad (s = \text{arc length}), \tag{h}$$

from which ϕ could be uniquely determined for every s [i.e., $\phi = \phi(s)$], via

$$dy/dx = dy/ds\Big/dx/ds \equiv y'(s)/x'(s) = \tan\phi(s). \tag{i}$$

This is somewhat analogous to the basic variables of Lagrangean mechanics q_k, $dq_k/dt \equiv v_k$, which, *before* the problem is solved, are considered as *independent*, and then, *after* the problem is completely solved, become dependent through time.

Example 2.13.2 *The Knife Problem: Hamel Coefficients.* Continuing from the preceding example: in view of the constraint (a), (b) there, and following Hamel's methodology ("equilibrium quasi velocities," §2.11), let us introduce the following three quasi velocities:

$$\begin{aligned}
\omega_1 &\equiv (-\sin\phi)v_x + (\cos\phi)v_y + (0)v_\phi \quad (= 0),\\
\omega_2 &\equiv (\cos\phi)v_x + (\sin\phi)v_y + (0)v_\phi = v \quad (\neq 0),\\
\omega_3 &\equiv (0)v_x + (0)v_y + (1)v_\phi = v_\phi \quad (\neq 0),
\end{aligned} \tag{a}$$

where $v =$ velocity component of the knife's contact point C; and hence $v_x = v\cos\phi$, $v_y = v\sin\phi$, and the constraint is simply $\omega_1 = 0$. Clearly, since

$$\partial(\cos\phi)/\partial\phi \neq \partial(0)/\partial x \qquad \text{and} \qquad \partial(\sin\phi)/\partial\phi \neq \partial(0)/\partial y, \tag{b}$$

$\omega_2 = v$ is a *quasi velocity*; that is, $v \neq$ total time derivative of a genuine position coordinate, or of any function of x, y, ϕ. Inverting (a), we obtain

$$\begin{aligned}
v_x &= (-\sin\phi)\omega_1 + (\cos\phi)\omega_2 + (0)\omega_3,\\
v_y &= (\cos\phi)\omega_1 + (\sin\phi)\omega_2 + (0)\omega_3,\\
v_\phi &= (0)\omega_1 + (0)\omega_2 + (1)\omega_3.
\end{aligned} \tag{c}$$

If $\mathbf{a}$ and $\mathbf{A}$ are the matrices of the transformations (a) and (c), respectively, then we easily verify that $\mathbf{a} = \mathbf{A}$, and $\operatorname{Det}\mathbf{a} = \operatorname{Det}\mathbf{A} = -\sin^2\phi - \cos^2\phi = -1$ (i.e., nonsingular transformations). Further, we notice that (a), (c) hold with $\omega_{1,2,3}$ and v_x, v_y, v_ϕ replaced, respectively, with $d\theta_{1,2,3} = \omega_{1,2,3}\,dt$ and $(dx, dy, d\phi) = (v_x, v_y, v_\phi)\,dt$; and, since they are *stationary*, also for $\delta\theta_{1,2,3}$ and $\delta x, \delta y, \delta\phi$.

Next, by direct d/δ-differentiations of $\delta\theta_1$, $d\theta_1$, and then subtraction, we find, successively,

$$\begin{aligned}
d(\delta\theta_1) - \delta(d\theta_1) &= d[(-\sin\phi)\,\delta x + (\cos\phi)\,\delta y + (0)\,\delta\phi]\\
&\quad - \delta[(-\sin\phi)\,dx + (\cos\phi)\,dy + (0)\,d\phi]\\
&= (-\sin\phi)(d\delta x - \delta dx) + (\cos\phi)(d\delta y - \delta dy)\\
&\quad - \cos\phi\,d\phi\,\delta x - \sin\phi\,d\phi\,\delta y + \cos\phi\,dx\,\delta\phi + \sin\phi\,dy\,\delta\phi\\
&= 0 + 0 - \cos\phi(1)\,d\theta_3[(-\sin\phi)\,\delta\theta_1 + (\cos\phi)\,\delta\theta_2 + (0)\,\delta\theta_3] - \cdots
\end{aligned}$$

[i.e., expressing dx, δx, dy, δy, $d\phi$, $\delta\phi$ from (c), with $\omega_{1,2,3}$ replaced with $d\theta_{1,2,3}$, $\delta\theta_{1,2,3}$] and so we, finally, obtain the differential transitivity equation:

$$d(\delta\theta_1) - \delta(d\theta_1) = d\theta_2\, \delta\theta_3 - d\theta_3\, \delta\theta_2, \tag{d}$$

[i.e., $d(\delta\theta_1) - \delta(d\theta_1) \neq 0$, even though $\delta\theta_1 = 0$ and $d\theta_1 = 0$]; and, also, dividing this by dt, which does not couple with $\delta(\ldots)$, we obtain its (equivalent) velocity transitivity equation:

$$(\delta\theta_1)^{\cdot} - \delta\omega_1 = (0)\,\delta\theta_1 + (-1)\omega_3\,\delta\theta_2 + (1)\omega_2\,\delta\theta_3 \quad (\neq 0). \tag{e}$$

Similarly, after some straightforward differentiations, we find

$$(\delta\theta_2)^{\cdot} - \delta\omega_2 = (1)\omega_3\,\delta\theta_1 + (0)\,\delta\theta_2 + (-1)\omega_1\,\delta\theta_3 \quad (= 0), \tag{f}$$

$$(\delta\theta_3)^{\cdot} - \delta\omega_3 = (0)\,\delta\theta_1 + (0)\,\delta\theta_2 + (0)\,\delta\theta_3 \quad (= 0). \tag{g}$$

From (e, f, g) we readily read off the *nonvanishing* Hamel's coefficients:

$$\gamma^D{}_{II'}\ (D = 1;\ I, I' = 2, 3): \qquad \gamma^1{}_{23} = -\gamma^1{}_{32} = -1; \tag{h}$$

$$\gamma^I{}_{kl}\ (I = 2;\ k, l = 1, 3): \qquad \gamma^2{}_{13} = -\gamma^2{}_{31} = 1. \tag{i}$$

REMARKS

(i) Since not all $\gamma^D{}_{II'} \to \gamma^1{}_{kl}$ $(k, l = 2, 3)$ vanish, we conclude, by Frobenius' theorem (§2.12), that our constraint, in any one of the following three forms:

Velocity:

$$\omega_1 \equiv (-\sin\phi)v_x + (\cos\phi)v_y + (0)v_\phi \quad (= 0), \tag{j}$$

Kinematically admissible:

$$d\theta_1 \equiv (-\sin\phi)\,dx + (\cos\phi)\,dy + (0)\,d\phi \quad (= 0), \tag{k}$$

Virtual:

$$\delta\theta_1 \equiv (-\sin\phi)\,\delta x + (\cos\phi)\,\delta y + (0)\,\delta\phi \quad (= 0), \tag{l}$$

is nonholonomic.

(ii) The fact that *upon imposition of the constraints* $\delta\theta_1 = 0$, $\omega_1 = 0$, the transitivity equation (f) yields $(\delta\theta_2)^{\cdot} - \delta\omega_2 = 0$ does *not* mean that

$$d\theta_2 \equiv (\cos\phi)\,dx + (\sin\phi)\,dy + (0)\,d\phi = v\,dt \quad (\neq 0), \tag{m}$$

or

$$\delta\theta_2 \equiv (\cos\phi)\,\delta x + (\sin\phi)\,\delta y + (0)\,\delta\phi \quad (\neq 0), \tag{n}$$

are exact; it does not mean that θ_2 is a genuine (Lagrangean) coordinate. For exactness, we should have $\gamma^2{}_{kl} = 0\ (k, l = 1, 2, 3) \Rightarrow (\delta\theta_2)^{\cdot} - \delta\omega_2 = 0$, *independently of the constraints* $\omega_1/d\theta_1/\delta\theta_1 = 0$. [We recall (§2.12) that Frobenius' theorem tests the holonomicity, or absence thereof, of a *system* of Pfaffian *equations of constraint*; whereas the *exactness*, or inexactness, of a particular Pfaffian *form*, like $d\theta_2$ and $d\theta_3 (\neq 0)$ is a property of that form; that is, it is ascertained by examination of that form alone, independently of other constraint equations. In sum: *constraint holonomicity is a system (coupled) property; while coordinate holonomicity is an individual (uncoupled) property*.]

(iii) Since $\omega_3 = d\phi/dt \equiv v_\phi$ is a genuine velocity, $\gamma^3{}_{kl} = 0$ $(k, l = 1, 2, 3)$; as expected.

Hamel Viewpoint versus Suslov Viewpoint

So far, we have assumed Hamel's viewpoint; that is,

$$d(\delta x) = \delta(dx), \qquad d(\delta y) = \delta(dy), \qquad d(\delta\phi) = \delta(d\phi); \tag{o}$$

and $d(\delta\theta_1) \neq \delta(d\theta_1)$, in spite of the constraint $\delta\theta_1 = 0$ and $d\theta_1 = 0$ [and that even if $d(\delta\theta_1) = 0$, still $-\delta(d\theta_1) \neq 0$!].

Let us now examine the Suslov viewpoint: with the analytically convenient choice, $q_D = y$ and $q_I = x, \phi$, we can rewrite the constraint as

$$d\theta_1 \equiv dy - (\tan\phi)\, dx = 0 \qquad \text{and} \qquad \delta\theta_1 \equiv \delta y - (\tan\phi)\, \delta x = 0 \qquad \text{[instead of (a)]},$$

or

$$dy = (\tan\phi)\, dx + (0)\, d\phi \qquad \text{and} \qquad \delta y = (\tan\phi)\, \delta x + (0)\, \delta\phi; \tag{p}$$

and, therefore, the corresponding transitivity equations become [instead of (d)–(g)]

$$\begin{aligned}
\text{Dependent:} \quad d(\delta y) - \delta(dy) &= d(\delta x \tan\phi) - \delta(dx \tan\phi) = \cdots \\
&= [d(\delta x) - \delta(dx)]\tan\phi + (1/\cos^2\phi)(d\phi\, \delta x - dx\, \delta\phi) \\
&= (1/\cos^2\phi)(d\phi\, \delta x - dx\, \delta\phi) \neq 0,
\end{aligned} \tag{q}$$

$$\text{Independent:} \quad d(\delta x) - \delta(dx) = 0, \qquad d(\delta\phi) - \delta(d\phi) = 0; \tag{r}$$

from which we readily read off the sole nonvanishing *Voronets* symbol:

$$w^y{}_{x\phi} = -w^y{}_{\phi x} = 1/\cos^2\phi. \tag{s}$$

Under Hamel's viewpoint, using the same variables, from $\delta y = (\tan\phi)\, \delta x$ (i.e., $\delta\theta_1 = 0$) it follows that $d(\delta y) = d(\delta x)\tan\phi + (1/\cos^2\phi)\, d\phi\, \delta x$ [i.e., $d(\delta\theta_1) = 0$]; but from $dy = (\tan\phi)\, dx$ (i.e., $d\theta_1 = 0$) it does *not* follow that $\delta(dy) = \delta(dx)\tan\phi - (1/\cos^2\phi)\, \delta\phi\, dx$ [i.e., $\delta(d\theta_1) \neq 0$].

Problem 2.13.1 Consider a knife (or sled, or scissors, etc.) moving on a *uniformly* rotating turntable T (fig. 2.17). In T-*fixed* (moving) coordinates $O{-}xy\phi$, its constraint is

$$(\sin\phi)v_x + (-\cos\phi)v_y = 0 \qquad [v_x \equiv dx/dt,\ v_y \equiv dy/dt]. \tag{a}$$

Show that in *inertial* (fixed) coordinates $O{-}XY\Phi$, where

$$\begin{aligned}
X &= (\cos\theta)x + (-\sin\theta)y + (0)\phi, \\
Y &= (\sin\theta)x + (\cos\theta)y + (0)\phi, \\
\Phi &= (0)x + (0)y + (1)\phi + \theta,
\end{aligned} \tag{b}$$

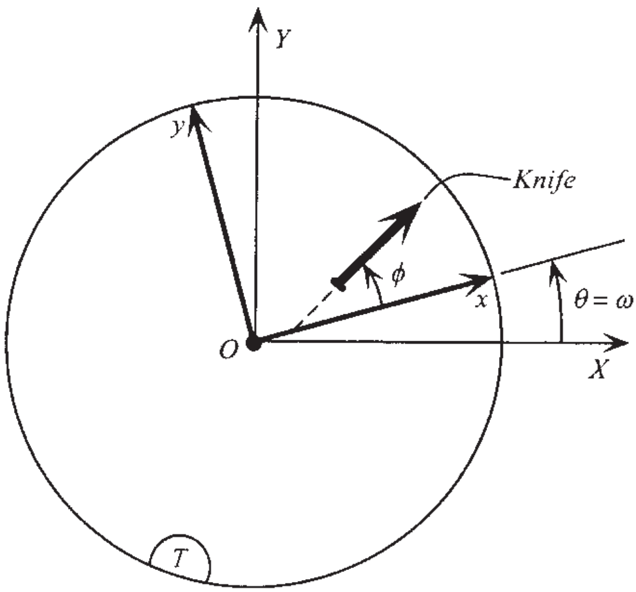

Figure 2.17 Knife moving on a uniformly rotating turntable.

and $\theta = \omega t, \omega$: constant angular velocity of $O\text{–}xy$ relative to $O\text{–}XY$ [i.e., say, $X = X(x, y, t)$, etc.], the constraint takes the (acatastatic) form (with $v_X \equiv dX/dt$, $v_Y \equiv dY/dt$),

$$(\sin \Phi) v_X + (-\cos \Phi) v_Y + \omega\big[(\cos \Phi) X + (\sin \Phi) Y\big] = 0. \tag{c}$$

Example 2.13.3 *Rolling Disk—Vertical Case*. Let us consider a circular thin disk D, of center G and radius r, rolling while remaining vertical on a fixed, rough, and horizontal plane P (fig. 2.18). (The general *nonvertical* case is presented later in ex. 2.13.7.) This system has *four* Lagrangean coordinates (or global DOF): the $(x, y, z = r)$ coordinates of G, and the Eulerian angles ϕ (precession) and ψ (spin). The constraints $z = r$ (contact) and $\theta = \pi/2$ are, clearly, holonomic (H). The velocity constraint is $\boldsymbol{v}_C = \boldsymbol{0}$ (where C is the contact point); or, since along the fixed axes $O\text{–}XYZ$ [with the notation $dx/dt \equiv v_x$, $dy/dt \equiv v_y$; $d\phi/dt \equiv \omega_\phi$, $d\psi/dt \equiv \omega_\psi$]:

$$\boldsymbol{v}_G = (v_x, v_y, 0), \qquad \boldsymbol{\omega} = (-\omega_\psi \sin\phi,\ \omega_\psi \cos\phi,\ \omega_\phi), \qquad \text{and} \qquad \boldsymbol{r}_{C/G} = (0, 0, -r),$$

$$\Rightarrow\ \boldsymbol{v}_C = \boldsymbol{v}_G + \boldsymbol{\omega} \times \boldsymbol{r}_{C/G} = \cdots = (v_x - r\,\omega_\psi \cos\phi,\ v_y - r\,\omega_\psi \sin\phi,\ 0) = \boldsymbol{0}, \tag{a}$$

or, in components, in the following equivalent forms:

$$\text{Velocity}: \qquad v_x = r\,\omega_\psi \cos\phi \qquad \text{and} \qquad v_y = r\,\omega_\psi \sin\phi, \tag{b}$$

$$\text{Kinematically admissible}: \quad dx = (r\cos\phi)\, d\psi \qquad \text{and} \qquad dy = (r\sin\phi)\, d\psi, \tag{c}$$

$$\text{Virtual}: \qquad \delta x = (r\cos\phi)\, \delta\psi \qquad \text{and} \qquad \delta y = (r\sin\phi)\, \delta\psi. \tag{d}$$

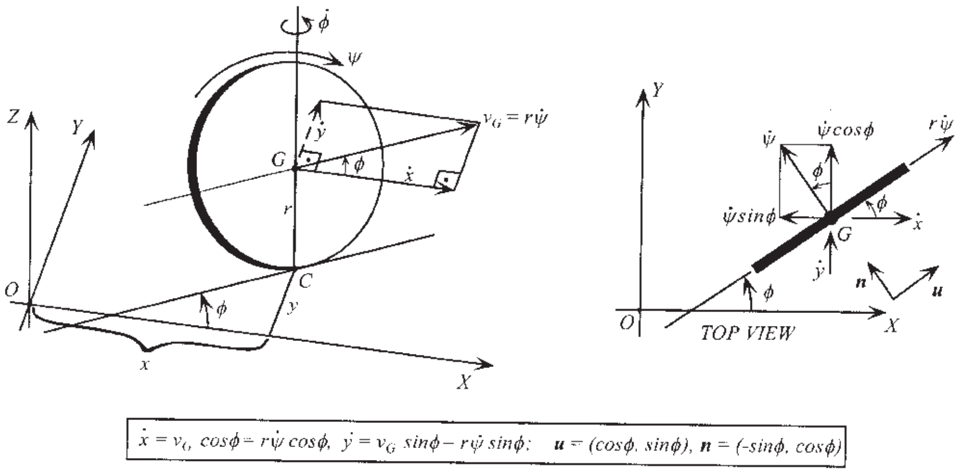

Figure 2.18 Rolling of vertical disk on a fixed plane.

As shown below, these constraints are nonholonomic (NH). Hence, the disk is a *scleronomic* NH system with $f \equiv n - m = 4 - 2 = 2$ *DOF in the small.*

It is not hard to see that imposition, on (b–d), of the *additional* H constraint $d\phi = 0 \ \Rightarrow\ \phi = constant$, say $\phi = 0$, would reduce them to the well-known H case of *plane rolling*: $dx = r\,d\psi \ \Rightarrow\ x = r\,\psi + constant$, and $dy = 0 \ \Rightarrow\ y = constant$. {Also, the problem would become H if the disk was forced to roll along a *prescribed* O–XY path. For, then, the rolling condition would be [with s: arc-length along (c)] $ds = r\,d\psi \ \Rightarrow\ s = r\,\psi + constant$, and (c) would yield the parametric equations $x = x(s)$ and $y = y(s)$; that is, for each s there would correspond a unique x, y, ψ, and ϕ [from (b–d)], and that would make the disk a *1* (*global*) *DOF H* system.}

Ad Hoc Proof of the Nonholonomicity of the Constraints (b–d)

Let us assume that we could find a finite relation $f(x, y, \phi, \psi) = 0$, compatible with (b–d). Then (with subscripts denoting partial derivatives), we would have

$$df = f_x\,dx + f_y\,dy + f_\phi\,d\phi + f_\psi\,d\psi = 0. \tag{e}$$

Substituting dx and dy from (c) into (e) — that is, *embedding* the constraints into it — yields

$$(r f_x \cos\phi + r f_y \sin\phi + f_\psi)\,d\psi + (f_\phi)\,d\phi = 0, \tag{f}$$

which, since now $d\psi$ and $d\phi$ are independent, gives

$$f_\phi = 0 \ \Rightarrow\ f = f(x, y, \psi) \qquad \text{and} \qquad r f_x \cos\phi + r f_y \sin\phi + f_\psi = 0. \tag{g}$$

Next, $(\partial/\partial\phi)$-differentiating the second of (g) once, while taking into account the first of (g), yields

$$-r f_x \sin\phi + r f_y \cos\phi = 0, \tag{h}$$

and repeating this procedure on (h), while again observing the first of (g), produces

$$-r f_x \cos\phi - r f_y \sin\phi = 0. \tag{i}$$

[Further $(\partial/\partial\phi)$-differentiations would not produce anything new.] The system (h), (i) has the unique solution,

$$f_x = 0 \qquad \text{and} \qquad f_y = 0, \tag{j}$$

due to which the second of (g) reduces to $f_\psi = 0$. It is clear that the above result in $f = constant$, and such a functional relation, obviously, *cannot* produce the constraints (b–d)— no $f(x, y, \phi, \psi)$ exists. Geometrically, this nonholonomicity has the following consequences: Starting from a certain *initial* configuration, we can roll the disk along two different paths to two *final* configurations with the same contact point—namely, same final (x, y), but *rotated relative to each other*; that is, with different final (ϕ, ψ). If the constraints were H, then ϕ and ψ would be functions of (x, y) and the two final positions of the disk would coincide completely.

Proof that the Constraints (b–d) are NH via Frobenius' Theorem

Let us rewrite the two constraints (c, d) in the equilibrium forms:

Kinematically admissible :

$$d\theta_1 \equiv dx - (r\cos\phi)\, d\psi = 0, \qquad d\theta_2 \equiv dy - (r\sin\phi)\, d\psi = 0, \tag{k}$$

Virtual :

$$\delta\theta_1 \equiv \delta x - (r\cos\phi)\, \delta\psi = 0, \qquad \delta\theta_2 \equiv \delta y - (r\sin\phi)\, \delta\psi = 0. \tag{l}$$

It follows that the corresponding bilinear covariants (2.8.2 ff.) are

$$d(\delta\theta_1) - \delta(d\theta_1) = \cdots = (r\sin\phi)(d\phi\, \delta\psi - d\psi\, \delta\phi), \tag{m}$$

$$d(\delta\theta_2) - \delta(d\theta_2) = \cdots = (-r\cos\phi)(d\phi\, \delta\psi - d\psi\, \delta\phi), \tag{n}$$

and, clearly, these vanish for arbitrary values of the *independent* differentials $d\phi, \delta\phi, d\psi, \delta\psi$, if $\sin\phi = 0$ and $\cos\phi = 0$. But then the constraints (c) reduce to $dx = 0 \Rightarrow x = constant$ and $dy = 0 \Rightarrow y = constant$, which is, in general, impossible. Hence, the constraints are NH [one can arrive at the same conclusion with the help of the γ's (§2.12), but that is more laborious].

Problem 2.13.2 Continuing from the previous problem (vertically rolling disk), show that its velocity constraints can be expressed in the equivalent form:

$$\boldsymbol{v}_G \cdot \boldsymbol{u} = v_x \cos\phi + v_y \sin\phi = r\,\omega_\psi, \tag{a}$$

$$\boldsymbol{v}_G \cdot \boldsymbol{n} = -v_x \sin\phi + v_y \cos\phi = 0, \tag{b}$$

where $\boldsymbol{u}$ and $\boldsymbol{n}$ are unit vectors on the disk plane (parallel to $O\text{–}XY$) and perpendicular to it, respectively (fig. 2.18). [Notice that (b) coincides, formally, with the *knife* problem constraint.]

Example 2.13.4 *Rolling Sphere — Introduction.* Let us consider a sphere of center G and radius r, rolling without slipping on a fixed, rough and, say, horizontal plane P (fig. 2.19). The complete specification of a generic sphere configuration requires *five* independent (minimal) Lagrangean coordinates. As such, we could take the (inertial)

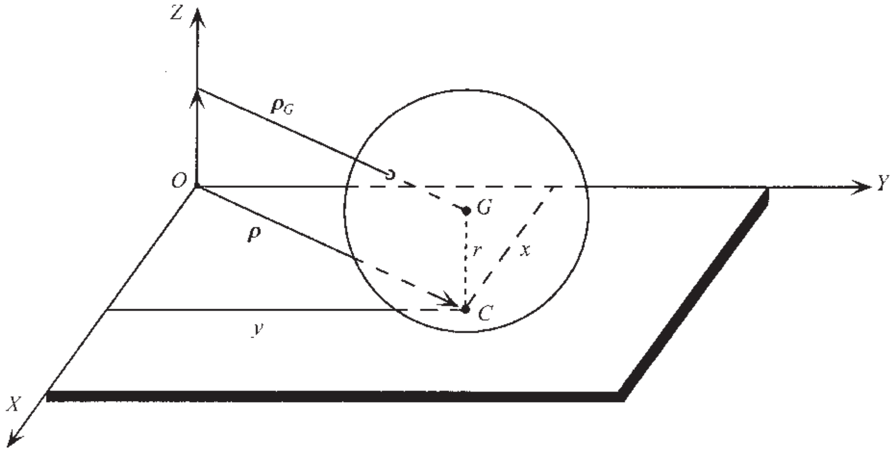

Figure 2.19 Rolling of a sphere on a fixed horizontal plane.

coordinates of G (X, Y), and the three Eulerian angles (ϕ, θ, ψ) of body-fixed axes G–xyz relative to translating (nonrotating) axes G–XYZ. The *contact* constraint is expressed by the holonomic (H) equation, $Z \equiv$ vertical coordinate of $G = r$. The *rolling* constraint is found by equating the (inertial) velocity of the contact point of the sphere C with that of its (instantaneously) adjacent plane point, which here is zero; $\boldsymbol{\omega} \equiv$ inertial angular velocity of sphere. Using components along O–XYZ axes throughout, we find

$$
\begin{aligned}
\boldsymbol{v}_C &= \boldsymbol{v}_G + \boldsymbol{\omega} \times \boldsymbol{r}_{C/G} = d\boldsymbol{\rho}_G/dt + \boldsymbol{\omega} \times (-r\boldsymbol{K}) \\
&= (v_X, v_Y, 0) + (\omega_X, \omega_Y, \omega_Z) \times (0, 0, -r) = \cdots = (v_X - r\,\omega_Y, v_Y + r\,\omega_X, 0) = \mathbf{0}.
\end{aligned}
$$

Hence, the rolling conditions are

$$v_X - r\,\omega_Y = 0, \qquad v_Y + r\,\omega_X = 0; \tag{a}$$

or, expressing the *space-fixed* components $\omega_{X,Y}$ in terms of their Eulerian angle rates (§1.12),

$$v_X - r(\sin\phi\,\omega_\theta - \sin\theta\cos\phi\,\omega_\psi) = 0, \qquad v_Y + r(\cos\phi\,\omega_\theta + \sin\theta\sin\phi\,\omega_\psi) = 0; \tag{b}$$

or, further, in *kinematically admissible* form,

$$dX - r(\sin\phi\,d\theta - \sin\theta\cos\phi\,d\psi) = 0, \qquad dY + r(\cos\phi\,d\theta + \sin\theta\sin\phi\,d\psi) = 0; \tag{c}$$

or, finally, since these constraints are catastatic, in *virtual* form,

$$\delta X - r(\sin\phi\,\delta\theta - \sin\theta\cos\phi\,\delta\psi) = 0, \qquad \delta Y + r(\cos\phi\,\delta\theta + \sin\theta\sin\phi\,\delta\psi) = 0. \tag{d}$$

[Absence of *pivoting* would have meant the following additional constraint:

$$(\boldsymbol{\omega})_{\text{normal to sphere at } C} = \omega_Z = \omega_\phi + \cos\theta\,\omega_\psi = 0,$$

or

$$d\phi + \cos\theta\,d\psi = 0 \;\Rightarrow\; d\phi/d\psi = -\cos\theta \equiv h(\theta)]. \tag{e}$$

As shown later, the constraints (a–d) are nonholonomic (NH). [We already notice that (c), for example, do *not* involve $d\phi$, and yet the constraints feature $\sin\phi$ and $\cos\phi$.] Mathematically, this means that it is impossible to obtain them by differentiating two finite constraint equations of the form $F(X, Y, \phi, \theta, \psi) = 0$ and $E(X, Y, \phi, \theta, \psi) = 0$; that is, the coordinates X, Y, ϕ, θ, ψ are independent. But their differentials $dX, dY, d\phi, d\theta, d\psi$, in view of (a–d), are not independent; that is, in general, only *three* of them can be varied simultaneously and arbitrarily. We say that *the sphere has five DOF in the large, but only three DOF in the small:* $f \equiv n - m = 5 - 2 = 3$. (Had we added pivoting, we would have $f = 2$.)

Kinematically, the above mean that the sphere may roll from an initial configuration, along two different routes, to two final configurations, which have both the same contact point and center location (i.e., same X, Y), but different angular orientations relative to each other (i.e., different ϕ, θ, ψ). If the constraints (a–d) were holonomic—for example, if the plane was *smooth*—it would be possible to vary all X, Y, ϕ, θ, ψ independently and arbitrarily without violating the (then) constraints; namely, the sphere's rigidity and the constancy of distance between G and C. Further, the sphere can roll from any *initial* configuration, with the sphere point C_i in contact with the plane point P_i, to any other *final* configuration, with the sphere point C_f in contact with the plane point P_f. To see this property, known as *accessibility* (§2.3), we draw on the plane a curve (γ) joining C_i and P_f, and another curve on the sphere (δ), of equal length to (γ), joining C_i and C_f. Now, a pivoting of the sphere can make the two arcs (γ) and (δ) tangent, at $C_i = P_i$. Then, we bring C_f to P_f by rolling (δ) on (γ). A final pivoting of the sphere brings it to its final configuration (see also Rutherford, 1960, pp. 161–162).

A Special Case

Assume, next, that the sphere rolls *without* pivoting, and also moves so that $\theta = constant \equiv \theta_o$. Let us find the path of G. With $\theta = constant \Rightarrow d\theta = 0$, the rolling constraints (c) reduce to

$$dX + r(\sin\theta_o)\cos\phi\, d\psi = 0, \qquad dY + r(\sin\theta_o)\sin\phi\, d\psi = 0; \tag{f}$$

and the no-pivoting constraint (e) to

$$d\phi/d\psi = -\cos\theta_o = constant. \tag{g}$$

This leaves only $n - m = 5 - 4 = 1\, DOF$ in the small. Taking ϕ as the independent coordinate and eliminating $d\psi$ between (f), with the help of (g), yields

$$dX = r(\tan\theta_o)\cos\phi\, d\phi, \qquad dY = r(\tan\theta_o)\sin\phi\, d\phi, \tag{h}$$

which integrates readily to the curve (with X_o and Y_o as integration constants):

$$X - X_0 = r(\tan\theta_o)\sin\phi, \qquad Y - Y_0 = -r(\tan\theta_o)\cos\phi; \tag{i}$$

that is, G describes, on the plane $Z = r$, a circle of radius $r\tan\theta_o$.

[These considerations also show how imposition of a sufficient number of additional holonomic and/or nonholonomic constraints turns an originally nonholonomic system into a holonomic one.]

Example 2.13.5 *Rolling Sphere on a Spinning Table—Introduction.* Let us extend the previous example to the case where the plane P is not fixed, but rotates about a fixed axis OZ perpendicular to it with, say, constant (inertial) angular velocity $\boldsymbol{\Omega}$. In this case, the rolling condition expresses the fact that the contact points of the sphere and the plane, C, have *equal inertial velocities*:

$$(\boldsymbol{v}_C)_{\text{sphere}} = (\boldsymbol{v}_C)_{\text{plane}}: \quad \boldsymbol{v}_G + \boldsymbol{\omega} \times \boldsymbol{r}_{C/G} = \boldsymbol{\Omega} \times \boldsymbol{r}_{C/O} \quad (= \boldsymbol{\Omega} \times \boldsymbol{\rho}); \tag{a}$$

or, in terms of their *components along inertial (background) axes O–XYZ/O–$\boldsymbol{IJK}$*:

$$(v_X, v_Y, 0) + (\omega_X, \omega_Y, \omega_Z) \times (0, 0, -r) = (0, 0, \Omega) \times (X, Y, 0), \tag{b}$$

from which we easily obtain the two rolling conditions:

$$v_X - r\,\omega_Y = -\Omega Y, \qquad v_Y + r\,\omega_X = \Omega X. \tag{c}$$

Next, expressing ω_X, ω_Y in terms of their Eulerian angles (between translating/nonrotating axes G–XYZ and sphere-fixed axes G–xyz) and their time rates, as in the preceding example, we transform (c) to

$$\begin{aligned} &v_X - r(\sin\phi\,\omega_\theta - \sin\theta\cos\phi\,\omega_\psi) + \Omega Y = 0,\\ &v_Y + r(\cos\phi\,\omega_\theta + \sin\theta\sin\phi\,\omega_\psi) - \Omega X = 0. \end{aligned} \tag{d}$$

The Ω-proportional terms in (d) are the *acatastatic* parts of these constraints, and arise out of our use of *inertial* coordinates to describe the kinematics in a *noninertial* frame; had we used *plane-fixed* (noninertial) coordinates, the constraints would have been catastatic in them. It is not hard to see that the *kinematically admissible/possible* and *virtual* forms of these constraints are, respectively (note differences between them resulting from constraint $\delta t = 0$),

$$\begin{aligned} &dX - r(\sin\phi\,d\theta - \sin\theta\cos\phi\,d\psi) + (\Omega Y)\,dt = 0,\\ &dY + r(\cos\phi\,d\theta + \sin\theta\sin\phi\,d\psi) - (\Omega X)\,dt = 0; \end{aligned} \tag{e}$$

$$\begin{aligned} &\delta X - r(\sin\phi\,\delta\theta - \sin\theta\cos\phi\,\delta\psi) = 0,\\ &\delta Y + r(\cos\phi\,\delta\theta + \sin\theta\sin\phi\,\delta\psi) = 0. \end{aligned} \tag{f}$$

Example 2.13.6 *Rolling Sphere on Spinning Table—the Transitivity Equations.* Continuing from the preceding example, let us show that its rolling constraints (c–f); as well as those of its previous, *stationary* table case) are nonholonomic; that is, the system has $n = 5$ *DOF in the large*, and $f \equiv n - m = 5 - 2 = 3$ *DOF in the small*.

In view of the structure of these constraints, we choose the following equilibrium quasi velocities (with the usual notations: $dX/dt \equiv v_X, \ldots, d\phi/dt \equiv \omega_\phi, \ldots$):

Dependent:

$$\omega_1 \equiv v_X - r\,\omega_Y + \Omega Y = v_X - r(\sin\phi\,\omega_\theta - \cos\phi\sin\theta\,\omega_\psi) + \Omega Y = v_X - r\,\omega_4 + \Omega Y\ (=0), \tag{a}$$

$$\omega_2 \equiv v_Y + r\,\omega_X - \Omega X = v_Y + r(\cos\phi\,\omega_\theta + \sin\phi\sin\theta\,\omega_\psi) - \Omega X = v_Y + r\,\omega_3 - \Omega X\ (=0), \tag{b}$$

Independent:

$$\omega_3 \equiv \omega_X = (\cos\phi)\omega_\theta + (\sin\phi\sin\theta)\omega_\psi \quad (\neq 0), \tag{c}$$

$$\omega_4 \equiv \omega_Y = (\sin\phi)\omega_\theta + (-\cos\phi\sin\theta)\omega_\psi \quad (\neq 0), \tag{d}$$

$$\omega_5 \equiv \omega_Z = (1)\omega_\phi + (\cos\theta)\omega_\psi \quad (\neq 0), \tag{e}$$

$$\omega_6 \equiv dt/dt = 1 \quad (\mathit{isochrony}). \tag{f}$$

Recalling results from §1.12, we readily see that these partially decoupled equations invert to

$$v_1 \equiv v_X = \omega_1 + r\,\omega_4 - \Omega Y \qquad \text{(without enforcement of constraints } \omega_{1,2} = 0), \tag{g1}$$

$$v_2 \equiv v_Y = \omega_2 - r\,\omega_3 + \Omega X \qquad \text{(without enforcement of constraints } \omega_{1,2} = 0), \tag{g2}$$

$$v_3 \equiv \omega_\phi = (-\cot\theta\sin\phi)\omega_3 + (\cot\theta\cos\phi)\omega_4 + \omega_5, \tag{g3}$$

$$v_4 \equiv \omega_\theta = (\cos\phi)\omega_3 + (\sin\phi)\omega_4, \tag{g4}$$

$$v_5 \equiv \omega_\psi = (\sin\phi/\sin\theta)\omega_3 + (-\cos\phi/\sin\theta)\omega_4, \tag{g5}$$

$$v_6 \equiv dt/dt = \omega_6 = 1. \tag{g6}$$

The *virtual* forms of (a–g6) are as follows [note absence of acatastatic terms in (h1, 2)]:

Dependent:

$$\delta\theta_1 \equiv \delta X - r\delta\theta_Y = \delta X + (-r\sin\phi)\,\delta\theta + (r\cos\phi\sin\theta)\,\delta\psi = \delta X - r\,\delta\theta_4 \quad (=0), \tag{h1}$$

$$\delta\theta_2 \equiv \delta Y + r\delta\theta_X = \delta Y + (r\cos\phi)\,\delta\theta + (r\sin\phi\sin\theta)\,\delta\psi = \delta Y + r\,\delta\theta_3 \quad (=0), \tag{h2}$$

Independent:

$$\delta\theta_3 \equiv \delta\theta_X = (\cos\phi)\,\delta\theta + (\sin\phi\sin\theta)\,\delta\psi \quad (\neq 0), \tag{h3}$$

$$\delta\theta_4 \equiv \delta\theta_Y = (\sin\phi)\,\delta\theta + (-\cos\phi\sin\theta)\,\delta\psi \quad (\neq 0), \tag{h4}$$

$$\delta\theta_5 \equiv \delta\theta_Z = (1)\,\delta\phi + (\cos\theta)\,\delta\psi \quad (\neq 0), \tag{h5}$$

$$\delta\theta_6 \equiv \delta q_6 \equiv \delta t = 0 \quad (\mathit{isochrony}); \tag{h6}$$

$$\delta q_1 \equiv \delta X = \delta\theta_1 + r\,\delta\theta_4, \tag{i1}$$

$$\delta q_2 \equiv \delta Y = \delta\theta_2 - r\,\delta\theta_3, \tag{i2}$$

$$\delta q_3 \equiv \delta\phi = (-\cot\theta\sin\phi)\,\delta\theta_3 + (\cot\theta\cos\phi)\,\delta\theta_4 + \delta\theta_5, \tag{i3}$$

$$\delta q_4 \equiv \delta\theta = (\cos\phi)\,\delta\theta_3 + (\sin\phi)\,\delta\theta_4, \tag{i4}$$

$$\delta q_5 \equiv \delta\psi = (\sin\phi/\sin\theta)\,\delta\theta_3 + (-\cos\phi/\sin\theta)\,\delta\theta_4, \tag{i5}$$

$$\delta q_6 \equiv \delta t = \delta\theta_6 = 0. \tag{i6}$$

Now we are ready to calculate Hamel's coefficients from the transitivity equations (§2.10):

$$(\delta\theta_k)^{\cdot} - \delta\omega_k = \sum\sum \gamma^k{}_{r\beta}\,\omega_\beta\,\delta\theta_r = \sum\sum \gamma^k{}_{rs}\,\omega_s\,\delta\theta_r + \sum \gamma^k{}_r\,\delta\theta_r, \tag{j}$$

where $k, r, s = 1, \ldots, 5$; $\beta = 1, \ldots, 6$; $\gamma^k{}_r \equiv \gamma^k{}_{r,n+1} = \gamma^k{}_{r6}$.

By direct differentiations, use of the above, and the indicated shortcuts [and noting that, even if $\Omega = \Omega(t) =$ given function of time, still $\delta\Omega = 0$], we obtain, successively,

$$\begin{aligned}(\delta\theta_1)^{\cdot} - \delta\omega_1 &= (\delta X - r\,\delta\theta_Y)^{\cdot} - \delta(v_X - r\,\omega_Y + \Omega Y)\\ &= [(\delta X)^{\cdot} - \delta v_X] - r[(\delta\theta_Y)^{\cdot} - \delta\omega_Y] - \Omega\,\delta Y\\ &= 0 - r[(\delta\theta_4)^{\cdot} - \delta\omega_4] - \Omega\,\delta Y\end{aligned}$$

[invoking the rotational transitivity equations (§1.14 and ex. 2.13.9), and (i2)]

$$\begin{aligned}&= -r(\omega_Z\,\delta\theta_X - \omega_X\,\delta\theta_Z) - \Omega(\delta\theta_2 - r\delta\theta_3)\\ &= -r(\omega_5\delta\theta_3 - \omega_3\delta\theta_5) - \Omega(\delta\theta_2 - r\delta\theta_3),\end{aligned}$$

or, finally,

$$(\delta\theta_1)^{\cdot} - \delta\omega_1 = (-r)\omega_5\,\delta\theta_3 + (r)\omega_3\,\delta\theta_5 + (-\Omega)\,\delta\theta_2 + (r\Omega)\,\delta\theta_3; \tag{k1}$$

$$\begin{aligned}(\delta\theta_2)^{\cdot} - \delta\omega_2 &= (\delta Y + r\,\delta\theta_X)^{\cdot} - \delta(v_Y + r\,\omega_X - \Omega X)\\ &= [(\delta Y)^{\cdot} - \delta v_Y] + r[(\delta\theta_X)^{\cdot} - \delta\omega_X] + \Omega\,\delta X\\ &= 0 + r[(\delta\theta_3)^{\cdot} - \delta\omega_3] + \Omega\,\delta X\end{aligned}$$

[invoking again the rotational transitivity equations and (i1)]

$$\begin{aligned}&= r(\omega_Y\delta\theta_Z - \omega_Z\delta\theta_Y) + \Omega(\delta\theta_1 + r\,\delta\theta_4)\\ &= r(\omega_4\delta\theta_5 - \omega_5\delta\theta_4) + \Omega(\delta\theta_1 + r\,\delta\theta_4),\end{aligned}$$

or, finally,

$$(\delta\theta_2)^{\cdot} - \delta\omega_2 = (-r)\omega_5\delta\theta_4 + (r)\omega_4\delta\theta_5 + (\Omega)\,\delta\theta_1 + (r\Omega)\,\delta\theta_4; \tag{k2}$$

and, again, the rotational transitivity equations (with $X \to 3,\ Y \to 4,\ Z \to 5$) give

$$(\delta\theta_3)^{\cdot} - \delta\omega_3 = \omega_4\,\delta\theta_5 - \omega_5\,\delta\theta_4, \tag{k3}$$

$$(\delta\theta_4)^{\cdot} - \delta\omega_4 = \omega_5\,\delta\theta_3 - \omega_3\,\delta\theta_5, \tag{k4}$$

$$(\delta\theta_5)^{\cdot} - \delta\omega_5 = \omega_3\,\delta\theta_4 - \omega_4\,\delta\theta_3. \tag{k5}$$

Comparing (j) with (k1–5) we readily find that the nonvanishing γ's are

$$\gamma^1{}_{35} = -\gamma^1{}_{53} = -r, \quad \gamma^1{}_{26} = -\gamma^1{}_{62} \equiv \gamma^1{}_2 = -\Omega, \quad \gamma^1{}_{36} = -\gamma^1{}_{63} \equiv \gamma^1{}_3 = r\,\Omega; \tag{11}$$

$$\gamma^2{}_{45} = -\gamma^2{}_{54} = -r, \quad \gamma^2{}_{16} = -\gamma^2{}_{61} \equiv \gamma^2{}_1 = \Omega, \quad \gamma^2{}_{46} = -\gamma^2{}_{64} \equiv \gamma^2{}_4 = r\,\Omega; \tag{12}$$

$$\gamma^3{}_{45} = -\gamma^3{}_{54} = \gamma^4{}_{53} = -\gamma^4{}_{35} = \gamma^5{}_{34} = -\gamma^5{}_{43} = -1 \quad [= -1\ (\textit{permutation symbol})]. \tag{13}$$

Here, $D(\textit{ependent}) = 1, 2$ and $I, I'(\textit{ndependent})) = 3, 4, 5$. Therefore,

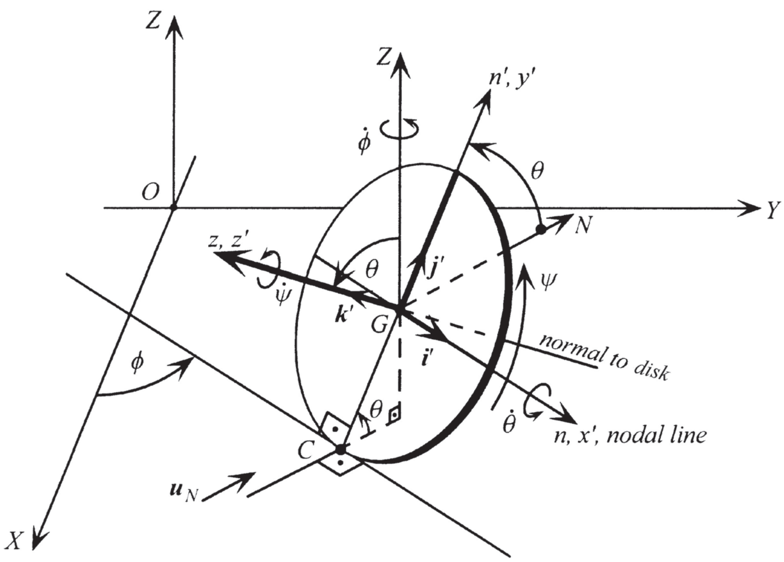
$$\gamma^D{}_{II'} : \gamma^1{}_{35} = -r \neq 0, \gamma^2{}_{45} = -r \neq 0; \qquad \gamma^D{}_I : \gamma^1{}_3 = \gamma^2{}_4 = r\,\Omega \neq 0; \tag{m}$$

and so, according to Frobenius' theorem (§2.12), the *system* of Pfaffian constraints $\omega_1 = 0$ and $\omega_2 = 0$ is *nonholonomic*, in both the catastatic (rolling on fixed plane) and acatastatic (rolling on rotating plane) cases; that is, for any given $\Omega = \Omega(t)$.

Example 2.13.7 *Rolling Disk on Fixed Plane.* Let us consider a thin circular disk (or coin, or ring, or hoop), of radius r and center G, rolling on a fixed horizontal and rough plane (fig. 2.20). A generic configuration of the disk is determined by the following *six* Lagrangean coordinates:

X, Y, Z: inertial coordinates of G;

ϕ, θ, ψ: Eulerian angles of *body-fixed* axes $G\text{–}xyz$ relative to the cotranslating but nonrotating axes $G\text{–}XYZ$ (similar to the rolling sphere case).



$$\boxed{\begin{aligned} &\boldsymbol{i}' = \cos\phi\, \boldsymbol{I} + \sin\phi\, \boldsymbol{J}, \ \ \boldsymbol{j}' = \cos\theta\, \boldsymbol{u}_N + \sin\theta\, \boldsymbol{K}, \ \ \boldsymbol{k}' = -\sin\theta\, \boldsymbol{u}_N + \cos\theta\, \boldsymbol{K}; \\ &\boldsymbol{u}_N = -\sin\phi\, \boldsymbol{I} + \cos\phi\, \boldsymbol{J}, \quad \boldsymbol{u}_n \equiv \boldsymbol{i}' \end{aligned}}$$

Figure 2.20 Geometry and kinematics of circular disk rolling on fixed rough plane. Axes: $G\text{–}nNZ \equiv G\text{–}x'NZ$: semifixed; $G\text{–}nn'z \equiv G\text{–}x'y'z'$: semimobile; $G\text{–}xyz$: body axes (not shown, but easily pictured); $G\text{–}XYZ$: space axes.

[In view of the complicated geometry, we avoid all ad hoc, possibly shorter, treatments, in favor of a fairly general and uniform approach. An alternative description is shown later.]

The vertical coordinate of G, clearly, satisfies the holonomic constraint

$$Z = r\sin\theta, \tag{a}$$

and this brings the number of independent Lagrangean coordinates down to *five*: X, Y, ϕ, θ, ψ; that is, $n = 5$.

The rolling constraint becomes, successively,

$$\begin{aligned}
\mathbf{0} = \boldsymbol{v}_C &= \boldsymbol{v}_G + \boldsymbol{\omega}\times\boldsymbol{r}_{C/G} \qquad (\boldsymbol{\omega}\text{: inertial angular velocity of disk})\\
&= \boldsymbol{v}_G - r\boldsymbol{\omega}\times\boldsymbol{j}'\\
&= \boldsymbol{v}_G - r(\omega_{x'}\boldsymbol{i}' + \omega_{y'}\boldsymbol{j}' + \omega_{z'}\boldsymbol{k}')\times\boldsymbol{j}' \qquad (\text{semimobile } \boldsymbol{\omega}\text{-decomposition})\\
&= \boldsymbol{v}_G - r\omega_{x'}(\boldsymbol{i}'\times\boldsymbol{j}') - r\omega_{z'}(\boldsymbol{k}'\times\boldsymbol{j}')\\
&= \boldsymbol{v}_G - r\omega_{x'}(\boldsymbol{k}') - r\omega_{z'}(-\boldsymbol{i}'),
\end{aligned} \tag{b}$$

from which we obtain the constraint components along the two "natural" (semifixed) directions $n(\boldsymbol{i}')$ and $N(\boldsymbol{u}_N)$:

(i) $$0 = \boldsymbol{v}_C\cdot\boldsymbol{i}' = \boldsymbol{v}_G\cdot\boldsymbol{i}' + r\,\omega_{z'} \qquad \text{or} \qquad v_{G,n} + r\,\omega_{z'} = 0; \tag{c1}$$

(ii) $$0 = \boldsymbol{v}_C\cdot\boldsymbol{u}_N = \boldsymbol{v}_G\cdot\boldsymbol{u}_N - r\,\omega_{x'}(\boldsymbol{k}'\cdot\boldsymbol{u}_N) + r\,\omega_{z'}(\boldsymbol{i}'\cdot\boldsymbol{u}_N) = \boldsymbol{v}_G\cdot\boldsymbol{u}_N - r\,\omega_{x'}(\boldsymbol{k}'\cdot\boldsymbol{u}_N),$$

or

$$v_{G,N} - r\,\omega_{x'}\cos(\pi/2 + \theta) = v_{G,N} + r\,\omega_{x'}\sin\theta = 0. \tag{c2}$$

The *third* semifixed direction component gives the earlier constraint (a):

$$0 = \boldsymbol{v}_C\cdot\boldsymbol{K} = \boldsymbol{v}_G\cdot\boldsymbol{K} - r\,\omega_{x'}(\boldsymbol{k}'\cdot\boldsymbol{K}) + r\,\omega_{z'}(\boldsymbol{i}'\cdot\boldsymbol{K}) = \boldsymbol{v}_G\cdot\boldsymbol{K} - r\,\omega_{x'}(\boldsymbol{k}'\cdot\boldsymbol{K}),$$

or, since $\omega_{x'} = \omega_\theta$,

$$0 = v_{G,Z} - r\,\omega_\theta\cos\theta \;\Rightarrow\; dZ - r\cos\theta\,d\theta = 0 \;\Rightarrow\; Z - r\sin\theta = \mathit{constant} \to 0.$$

Equations (c1, 2) contain nonholonomic velocities. Let us express them in terms of holonomic velocities exclusively. It is not hard to see that, with $\boldsymbol{v}_G = (\dot{X}, \dot{Y}, \dot{Z}) \equiv (v_X, v_Y, v_Z)$,

(i) $$\omega_{x'} = \omega_\theta, \qquad \omega_{y'} = (\sin\theta)\omega_\phi, \qquad \omega_{z'} = (\cos\theta)\omega_\phi + \omega_\psi; \tag{d1}$$

(ii) $$\begin{aligned} v_{G,n} &= \boldsymbol{v}_G\cdot\boldsymbol{i}' \equiv \boldsymbol{v}_G\cdot\boldsymbol{u}_n\\ &= (v_X\boldsymbol{I} + v_Y\boldsymbol{J} + v_Z\boldsymbol{K})\cdot(\cos\phi\,\boldsymbol{I} + \sin\phi\,\boldsymbol{J}) = (\cos\phi)v_X + (\sin\phi)v_Y; \end{aligned} \tag{d2}$$

(iii) $$\begin{aligned} v_{G,N} &= \boldsymbol{v}_G\cdot\boldsymbol{u}_N\\ &= (v_X\boldsymbol{I} + v_Y\boldsymbol{J} + v_Z\boldsymbol{K})\cdot(-\sin\phi\,\boldsymbol{I} + \cos\phi\,\boldsymbol{J}) = (-\sin\phi)v_X + (\cos\phi)v_Y. \end{aligned} \tag{d3}$$

With the help of (d1–3), the constraints (c1, 2) take, respectively, the holonomic velocities form:

(i) $$\boldsymbol{v}_C\cdot\boldsymbol{i}' \equiv v_{C,n} = (\cos\phi)v_X + (\sin\phi)v_Y + r(\omega_\psi + \cos\theta\,\omega_\phi) = 0, \tag{e1}$$

(ii) $$\boldsymbol{v}_C\cdot\boldsymbol{u}_N \equiv v_{C,N} = (-\sin\phi)v_X + (\cos\phi)v_Y + r\sin\theta\,\omega_\theta = 0. \tag{e2}$$

In view of (e1, 2), we introduce the following equilibrium quasi velocities:

Dependent:

$$\omega_1 \equiv v_{C,n} = v_{G,n} + r\,\omega_{z'} = (\cos\phi)v_X + (\sin\phi)v_Y + (r\cos\theta)\omega_\phi + (r)\omega_\psi \quad (=0), \quad \text{(f1)}$$

$$\omega_2 \equiv v_{C,N} = v_{G,N} + r\sin\theta\,\omega_{x'} = (-\sin\phi)v_X + (\cos\phi)v_Y + (r\sin\theta)\omega_\theta \quad (=0); \quad \text{(f2)}$$

Independent (semimobile components of $\boldsymbol{\omega}$):

$$\omega_3 \equiv \omega_n \equiv \omega_{x'} = \omega_\theta \quad (\neq 0), \quad \text{(f3)}$$

$$\omega_4 \equiv \omega_{n'} \equiv \omega_{y'} = (\sin\theta)\omega_\phi \quad (\neq 0), \quad \text{(f4)}$$

$$\omega_5 \equiv \omega_z \equiv \omega_{z'} = (\cos\theta)\omega_\phi + \omega_\psi \quad (\neq 0). \quad \text{(f5)}$$

These catastatic, and partially uncoupled, equations invert easily to

$$v_1 \equiv v_X = (\cos\phi)\omega_1 + (-\sin\phi)\omega_2 + (r\sin\theta\sin\phi)\omega_3 + (-r\cos\phi)\omega_5, \quad \text{(g1)}$$

$$v_2 \equiv v_Y = (\sin\phi)\omega_1 + (\cos\phi)\omega_2 + (-r\sin\theta\cos\phi)\omega_3 + (-r\sin\phi)\omega_5, \quad \text{(g2)}$$

$$v_3 \equiv \omega_\phi = (1/\sin\theta)\omega_4, \quad \text{(g3)}$$

$$v_4 \equiv \omega_\theta = \omega_3, \quad \text{(g4)}$$

$$v_5 \equiv \omega_\psi = \omega_5 - (\cot\theta)\omega_4. \quad \text{(g5)}$$

Below, we show that the constraints $\omega_1 = 0$ and $\omega_2 = 0$ are nonholonomic; that is, $n = 5$ *global DOF*, $m = 2 \to f \equiv n - m = 3$ *local DOF*.

Indeed, by direct d- and δ-operations on (f1–g5), and their virtual forms (which can be obtained from the above velocity forms in, by now, obvious ways), and combination of simple shortcuts with some straightforward algebra, we find, successively,

$$\begin{aligned}
(\delta\theta_1)^{\cdot} - \delta\omega_1 &= \left[(\delta p_{G,n})^{\cdot} - \delta v_{G,n}\right] + r[(\delta\theta_5)^{\cdot} - \delta\omega_5] \qquad [\text{where} \quad dp_{G,n} \equiv v_{G,n}\,dt] \\
&= \cdots = \{[(\cos\phi)\,\delta X + (\sin\phi)\,\delta Y]^{\cdot} - \delta[(\cos\phi)v_X + (\sin\phi)v_Y]\} \\
&\qquad + r(\omega_4\,\delta\theta_3 - \omega_3\,\delta\theta_4) \\
&= \cdots = \left\{\omega_\phi[(-\sin\phi)\,\delta X + (\cos\phi)\,\delta Y] - \delta\phi[(-\sin\phi)v_X + (\cos\phi)v_Y]\right\} \\
&\qquad + r(\omega_4\,\delta\theta_3 - \omega_3\,\delta\theta_4) \\
&= (\omega_\phi\,\delta p_{G,N} - v_{G,N}\,\delta\phi) + r(\omega_4\,\delta\theta_3 - \omega_3\,\delta\theta_4) \qquad [\text{where} \quad dp_{G,N} \equiv v_{G,N}\,dt] \\
&= [(\omega_4/\sin\theta)\,\delta p_{G,N} - v_{G,N}(\delta\theta_4/\sin\theta)] + r(\omega_4\,\delta\theta_3 - \omega_3\,\delta\theta_4) \\
&= (\omega_4/\sin\theta)(\delta p_{G,N} + r\sin\theta\,\delta\theta_3) - (\delta\theta_4/\sin\theta)(v_{G,N} + r\sin\theta\,\omega_3) \\
&= (1/\sin\theta)(\omega_4\,\delta p_{C,N} - v_{C,N}\,\delta\theta_4) \qquad [\text{where} \quad dp_{C,N} \equiv v_{C,N}\,dt] \\
&= (1/\sin\theta)(\omega_4\,\delta\theta_2 - \omega_2\,\delta\theta_4) = 0 \\
&\qquad (\text{after enforcing the constraints} \quad \delta\theta_2, \omega_2 = 0), \qquad \text{(h1)}
\end{aligned}$$

$$(\delta\theta_2)^{\cdot} - \delta\omega_2 = [(\delta p_{G,N})^{\cdot} - \delta v_{G,N}] + [(r \sin\theta\, \delta\theta_3)^{\cdot} - \delta(r \sin\theta\, \omega_3)]$$

[since $\omega_3 \sin\theta = \omega_\theta \sin\theta$ is integrable, the *second* bracket term vanishes]

$$= [(-\sin\phi)\, \delta X + (\cos\phi)\, \delta Y]^{\cdot} - \delta[(-\sin\phi)v_X + (\cos\phi)v_Y]$$
$$= -\omega_\phi(\cos\phi\, \delta X + \sin\phi\, \delta Y) + \delta\phi[(\cos\phi)v_X + (\sin\phi)v_Y]$$
$$= -\omega_\phi\, \delta p_{G,n} + \delta\phi\, v_{G,n}$$
$$= -(\omega_4/\sin\theta)(\delta\theta_1 - r\, \delta\theta_5) + (\delta\theta_4/\sin\theta)(\omega_1 - r\omega_5)$$
$$= -(1/\sin\theta)(\omega_4\, \delta\theta_1 - \omega_1\, \delta\theta_4) + (r/\sin\theta)(\omega_4\, \delta\theta_5 - \omega_5\, \delta\theta_4)$$
$$= (r/\sin\theta)(\omega_4\, \delta\theta_5 - \omega_5\, \delta\theta_4) \neq 0$$
$$\text{(even after enforcing the constraints } \delta\theta_1, \omega_1 = 0); \tag{h2}$$

$$(\delta\theta_3)^{\cdot} - \delta\omega_3 = 0 \text{ (independently of constraints)} \Rightarrow \theta_3 = \textit{holonomic coordinate}, \tag{h3}$$

$$(\delta\theta_4)^{\cdot} - \delta\omega_4 = (\sin\theta\, \delta\theta)^{\cdot} - \delta(\sin\theta\, \omega_\phi) = (\cos\theta)(\omega_\theta\, \delta\phi - \omega_\phi\, \delta\theta)$$
$$= (\cot\theta)(\omega_3\, \delta\theta_4 - \omega_4\, \delta\theta_3), \tag{h4}$$

$$(\delta\theta_5)^{\cdot} - \delta\omega_5 = (\delta\psi + \cos\theta\, \delta\phi)^{\cdot} - \delta(\omega_\psi + \cos\theta\, \omega_\phi) = (\sin\theta)(\omega_\phi\, \delta\theta - \omega_\theta\, \delta\phi)$$
$$= \omega_4\, \delta\theta_3 - \omega_3\, \delta\theta_4; \tag{h5}$$

and since $Z = r \sin\theta$, with $\omega_6 \equiv v_Z - r\cos\theta\, \omega_\theta \quad \Rightarrow \quad \delta\theta_6 = \delta Z - r\cos\theta\, \delta\theta$, we get

$$(\delta\theta_6)^{\cdot} - \delta\omega_6 = (\delta Z - r\cos\theta\, \delta\theta)^{\cdot} - \delta(v_Z - r\cos\theta\, \omega_\theta)$$
$$= (\delta Z)^{\cdot} - r(\cos\theta)^{\cdot}\delta\theta - r\cos\theta(\delta\theta)^{\cdot} - \delta v_Z + r(-\sin\theta)\, \delta\theta\, \omega_\theta + r\cos\theta\, \delta\omega_\theta = 0,$$

(independently of the other constraints) as expected.

From the above, we immediately read off the nonvanishing γ's:

$$\gamma^1{}_{24} = -\gamma^1{}_{42} = 1/\sin\theta;$$
$$\gamma^2{}_{41} = -\gamma^2{}_{14} = 1/\sin\theta, \qquad \gamma^2{}_{54} = -\gamma^2{}_{45} = r/\sin\theta;$$
$$\gamma^4{}_{43} = -\gamma^4{}_{34} = \cot\theta;$$
$$\gamma^5{}_{34} = -\gamma^5{}_{43} = 1. \tag{i}$$

Here, $D(\textit{ependent}) = 1, 2$ and $I, I'(\textit{ndependent}) = 3, 4, 5$. Therefore,

$$\gamma^D{}_{II'}: \quad \gamma^2{}_{54} = r/\sin\theta \neq 0; \tag{j}$$

and so, according to Frobenius' theorem (§2.12), the *system* of Pfaffian constraints $\omega_1 = 0$ and $\omega_2 = 0$ is *nonholonomic*. We also notice that to calculate all nonvanishing γ's, we must refrain from enforcing the constraints ω_1, $\delta\theta_1 = 0$ and ω_2, $\delta\theta_2 = 0$, in the earlier bilinear covariants.

Rolling Constraints via Components along Space Axes

With reference to fig. 2.20, we have, successively,

$$\boldsymbol{r}_{C/G} = -(r\cos\theta)\boldsymbol{u}_N - (r\sin\theta)\boldsymbol{K} = (-r\cos\theta)(-\sin\phi\, \boldsymbol{I} + \cos\phi\, \boldsymbol{J}) + (-r\sin\theta)\boldsymbol{K}$$
$$= (r\cos\theta\sin\phi)\boldsymbol{I} + (-r\cos\theta\cos\phi)\boldsymbol{J} + (-r\sin\theta)\boldsymbol{K}, \tag{k1}$$

$$\boldsymbol{\omega} = \omega_X \boldsymbol{I} + \omega_Y \boldsymbol{J} + \omega_Z \boldsymbol{K} \qquad \text{[recalling formulae in §1.12]}$$
$$= [(\cos\phi)\omega_\theta + (\sin\phi\sin\theta)\omega_\psi]\boldsymbol{I} + [(\sin\phi)\omega_\theta + (-\cos\phi\sin\theta)\omega_\psi]\boldsymbol{J}$$
$$+[\omega_\phi + (\cos\theta)\omega_\psi]\boldsymbol{K}, \tag{k2}$$

and, of course,

$$\boldsymbol{v}_G = v_X \boldsymbol{I} + v_Y \boldsymbol{J} + v_Z \boldsymbol{K}. \tag{k3}$$

Substituting these fixed-axes representations into the constraint (b): $\boldsymbol{0} = \boldsymbol{v}_C = \boldsymbol{v}_G + \boldsymbol{\omega} \times \boldsymbol{r}_{C/G}$, and setting its components along $\boldsymbol{I}, \boldsymbol{J}, \boldsymbol{K}$, equal to zero, we obtain the scalar conditions:

$$v_X + r(\cos\phi\cos\theta\,\omega_Z - \sin\theta\,\omega_Y)$$
$$= v_X + r[(\cos\phi\cos\theta)\omega_\phi - (\sin\phi\sin\theta)\omega_\theta + (\cos\phi)\omega_\psi] = 0,$$

$$v_Y + r(\sin\theta\,\omega_X + \sin\phi\cos\theta\,\omega_Z)$$
$$= v_Y + r[(\sin\phi\cos\theta)\omega_\phi + (\cos\phi\sin\theta)\omega_\theta + (\sin\phi)\omega_\psi] = 0,$$

$$v_Z - r\cos\theta(\cos\phi\,\omega_X + \sin\phi\,\omega_Y)$$
$$= v_Z - r\cos\theta\,\omega_\theta = 0 \;\Rightarrow\; Z = r\sin\theta \quad \text{(i.e., holonomic).} \tag{k4, 5, 6}$$

We leave it to the reader to verify that (k4, 5) are equivalent to the earlier (e1–f2); and, also, that they can be brought to the (perhaps simpler) form,

$$[(X/r) + \sin\phi\cos\theta]^{\cdot} + (\cos\phi)\omega_\psi = 0, \qquad [(Y/r) + \cos\phi\cos\theta]^{\cdot} + (\sin\phi)\omega_\psi = 0. \tag{k7}$$

Constraints and Transitivity Equations in Terms of the (Inertial) Coordinates of the Contact Point of the Disk (X_C, Y_C)

[This is a popular choice among mechanics authors (e.g., Hamel, 1949, pp. 470 ff., 478–479; Rosenberg, 1977, pp. 265 ff.) but our choice — that is, in terms of the coordinates of the disk center, G — shows more clearly the connection with the Eulerian angles.]

Taking the fixed-axes components of the obvious relation $\boldsymbol{r}_G = \boldsymbol{r}_C + \boldsymbol{r}_{G/C}$, and then $d/dt(\ldots)$-differentiating them, we obtain (consulting again fig. 2.20, and with $v_{C,X} \equiv dX_C/dt$, $v_{C,Y} \equiv dY_C/dt$)

(i) $X = X_C - (r\cos\theta)\sin\phi \;\Rightarrow\; v_X = v_{C,X} - (r\cos\phi\cos\theta)\omega_\phi + (r\sin\phi\sin\theta)\omega_\theta$, (l1)

(ii) $Y = Y_C + (r\cos\theta)\cos\phi \;\Rightarrow\; v_Y = v_{C,Y} - (r\sin\phi\cos\theta)\omega_\phi - (r\cos\phi\sin\theta)\omega_\theta$; (l2)

and substituting these v_X, v_Y expressions into (k4, 5), respectively, we eventually obtain the simpler forms

$$v_{C,X} + (r\cos\phi)\omega_\psi = 0 \qquad \text{and} \qquad v_{C,Y} + (r\sin\phi)\omega_\psi = 0. \tag{l3}$$

(The above can, also, be obtained by ad hoc knife problem–type considerations.)

In view of (13), we introduce the following *new* equilibrium quasi velocities:

Dependent:

$$\omega_1 \equiv v_{C,X} + (r\cos\phi)\omega_\psi \quad (= 0), \tag{m1}$$

$$\omega_2 \equiv v_{C,Y} + (r\sin\phi)\omega_\psi \quad (= 0); \tag{m2}$$

Independent:

$$\omega_3 \equiv \omega_\phi (\neq 0) \;\Rightarrow\; \gamma^3{}_{..} = 0, \tag{m3}$$

$$\omega_4 \equiv \omega_\theta (\neq 0) \;\Rightarrow\; \gamma^4{}_{..} = 0, \tag{m4}$$

$$\omega_5 \equiv (\cos\phi)v_{C,X} + (\sin\phi)v_{C,Y} \quad [= -r\,\omega_\psi, \text{ by (13)}]; \tag{m5}$$

or, instead, the equivalent but simpler, knife-type, quasi velocities:

Dependent:

$$\Omega_1 \equiv (-\sin\phi)v_{C,X} + (\cos\phi)v_{C,Y} \quad [= 0, \text{ by (13)}], \tag{n1}$$

$$\Omega_2 \equiv r\,\omega_\psi + (\cos\phi)v_{C,X} + (\sin\phi)v_{C,Y} = r\,\omega_\psi + \omega_5\,(= 0); \tag{n2}$$

Independent:

$$\Omega_3 \equiv \omega_3 \equiv \omega_\phi \quad (\neq 0), \tag{n3}$$

$$\Omega_4 \equiv \omega_4 \equiv \omega_\theta \quad (\neq 0), \tag{n4}$$

$$\Omega_5 \equiv \omega_5 \equiv (\cos\phi)v_{C,X} + (\sin\phi)v_{C,Y} \quad [= -r\,\omega_\psi + \Omega_2 = -r\,\omega_\psi]. \tag{n5}$$

Inverting the above yields

$$v_1 \equiv v_{C,X} = (-\sin\phi)\Omega_1 + (\cos\phi)\Omega_5, \tag{o1}$$

$$v_2 \equiv v_{C,Y} = (\cos\phi)\Omega_1 + (\sin\phi)\Omega_5, \tag{o2}$$

$$v_3 \equiv \omega_\phi = \Omega_3, \tag{o3}$$

$$v_4 \equiv \omega_\theta = \Omega_4, \tag{o4}$$

$$v_5 \equiv \omega_\psi = (1/r)(\Omega_2 - \Omega_5). \tag{o5}$$

By direct d/δ-differentiations of (n1–5), use of (o1–5), and the obvious notation $d\Theta_k \equiv \Omega_k dt$; $k = 1, \ldots, 5$, we obtain the corresponding transitivity equations as follows:

$$\begin{aligned}(\delta\Theta_1)^{\cdot} - \delta\Omega_1 &= [(-\sin\phi)\,\delta X_C + (\cos\phi)\,\delta Y_C]^{\cdot} - \delta[(-\sin\phi)v_{C,X} + (\cos\phi)v_{C,Y}] \\ &= \cdots = \cos\phi(v_{C,X}\,\delta\phi - \omega_\phi\,\delta X_C) + \sin\phi(v_{C,Y}\,\delta\phi - \omega_\phi\,\delta Y_C) \\ &= \cos\phi\big[(-\sin\phi\,\Omega_1 + \cos\phi\,\Omega_5)\,\delta\Theta_3 - \Omega_3(-\sin\phi\,\delta\Theta_1 + \cos\phi\,\delta\Theta_5)\big] \\ &\quad + \sin\phi\big[(\cos\phi\,\Omega_1 + \sin\phi\,\Omega_5)\,\delta\Theta_3 - \Omega_3(\cos\phi\,\delta\Theta_1 + \sin\phi\,\delta\Theta_5)\big] \\ &= \Omega_5\,\delta\Theta_3 - \Omega_3\,\delta\Theta_5,\end{aligned} \tag{p1}$$

$$
\begin{aligned}
(\delta\Theta_2)^{\cdot} - \delta\Omega_2 &= [r\,\delta\psi + (\cos\phi)\,\delta X_C + (\sin\phi)\,\delta Y_C]^{\cdot} - \delta[r\,\omega_\psi + (\cos\phi)v_{C,X} + (\sin\phi)v_{C,Y}] \\
&= \cdots = \sin\phi(v_{C,X}\,\delta\phi - \omega_\phi\,\delta X_C) + \cos\phi(\omega_\phi\,\delta Y_C - v_{C,Y}\,\delta\phi) \\
&= \sin\phi\big[(-\sin\phi\,\Omega_1 + \cos\phi\,\Omega_5)\,\delta\Theta_3 - \Omega_3(-\sin\phi\,\delta\Theta_1 + \cos\phi\,\delta\Theta_5)\big] \\
&\quad + \cos\phi\big[\Omega_3(\cos\phi\,\delta\Theta_1 + \sin\phi\,\delta\Theta_5) - (\cos\phi\,\Omega_1 + \sin\phi\,\Omega_5)\,\delta\Theta_3\big] \\
&= \Omega_3\,\delta\Theta_1 - \Omega_1\,\delta\Theta_3 \\
&\qquad (= 0, \text{upon imposition of the constraints } \delta\Theta_1, \Omega_1 = 0), \qquad \text{(p2)}
\end{aligned}
$$

$$(\delta\Theta_3)^{\cdot} - \delta\Omega_3 = (\delta\phi)^{\cdot} - \delta\omega_\phi = 0 \qquad (\Theta_3 = \textit{holonomic}), \tag{p3}$$

$$(\delta\Theta_4)^{\cdot} - \delta\Omega_4 = (\delta\theta)^{\cdot} - \delta\omega_\theta = 0 \qquad (\Theta_4 = \textit{holonomic}), \tag{p4}$$

$$
\begin{aligned}
(\delta\Theta_5)^{\cdot} - \delta\Omega_5 &= [(\cos\phi)\,\delta X_C + (\sin\phi)\,\delta Y_C]^{\cdot} - \delta[(\cos\phi)v_{C,X} + (\sin\phi)v_{C,Y}] \\
&= (-r\,\delta\psi)^{\cdot} - \delta(-r\,\omega_\psi) + (\delta\Theta_2)^{\cdot} - \delta\Omega_2 = 0 + \Omega_3\,\delta\Theta_1 - \Omega_1\delta\Theta_3 \\
&= \Omega_3\,\delta\Theta_1 - \Omega_1\,\delta\Theta_3 \\
&\qquad (= 0, \text{ upon imposition of the constraints } \delta\Theta_1, \Omega_1 = 0); \qquad \text{(p5)}
\end{aligned}
$$

that is, just like the knife problem (ex. 2.13.2), all the γ's are either ± 1 or 0.

Finally, here, $D(\textit{ependent}) = 1, 2$ and $I, I'(\textit{ndependent}) = 3, 4, 5$. Therefore,

$$\gamma^D{}_{II'}: \quad \gamma^1{}_{35} = -\gamma^1{}_{53} = 1 \neq 0; \tag{j}$$

and so, by Frobenius' theorem (§2.12), the constraint system $\Omega_1 = 0$ and $\Omega_2 = 0$ is nonholonomic.

Problem 2.13.3 *Rolling Disk in Accelerating Plane*. Continuing from the preceding example, show that if the plane *translates* (i.e., no rotation), relative to inertial space, with a *given* velocity $(v_X(t), v_Y(t), v_Z(t))$, and the new inertial axes $O\text{–}XYZ$ are chosen so that *OZ is always perpendicular to the translating plane*, and X, Y, Z are the new *inertial* coordinates of the center of the disk G, then the rolling constraints take the rheonomic form

$$(\cos\phi)[V_X - v_X(t)] + (\sin\phi)[V_Y - v_Y(t)] + (r\cos\theta)\omega_\phi + (r)\omega_\psi = 0, \tag{a}$$

$$(-\sin\phi)[V_X - v_X(t)] + (\cos\phi)[V_Y - v_Y(t)] + (r\sin\theta)\omega_\theta = 0, \tag{b}$$

where $V_X \equiv dX/dt$, $V_Y \equiv dY/dt$; $\omega_\phi \equiv d\phi/dt$, and so on; that is, they are the same as in the fixed plane case, but with $\boldsymbol{v}_G$ replaced with $\boldsymbol{v}_G - \boldsymbol{v}_C$ (where $\boldsymbol{v}_C$ is the inertial velocity of contact point of disk with plane).

Example 2.13.8 *Pair of Rolling Wheels on an Axle*. Let us discuss the kinematics of a pair of two thin identical wheels, each of radius r, connected by a light axle and able to turn freely about its ends (fig. 2.21), rolling on a fixed, horizontal, and rough plane. For its description, we choose the following (*six* $\rightarrow$) *five* Lagrangean coordinates:

$(X, Y, Z = r)$: inertial coordinates of midpoint of axle, G;

ϕ: angle between the $O\text{–}XY$ projection of the axle (say, from G'' toward G') and $+OX$;

ψ', ψ'': spin angles of the two wheels.

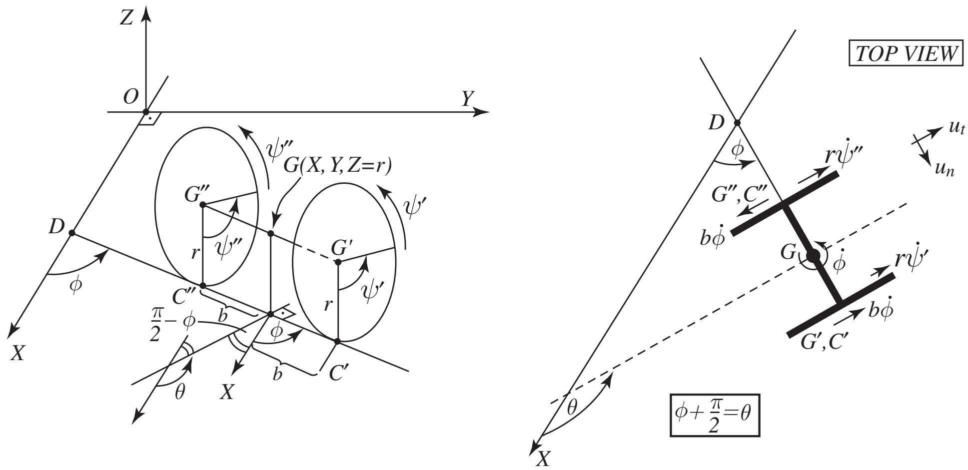


Figure 2.21 Rolling of two wheels on an axle, on fixed plane.

Here, the constraints are $\boldsymbol{v}_{C'} = \mathbf{0}$ and $\boldsymbol{v}_{C''} = \mathbf{0}$, where C' and C'' are the contact points of the two wheels. However, due to the constancy of $G''G'$ (and $C''C' = 2b$) and the continuous perpendicularity of the wheels to the axle, these conditions translate to *three* independent component equations, not four; say, the vanishing of $\boldsymbol{v}_{C'}$ and $\boldsymbol{v}_{C''}$ along and perpendicularly to the axle (the "natural" directions of the problem). Let us express this analytically: since

$$\boldsymbol{v}_{C'} = \boldsymbol{v}_{G'} + \boldsymbol{\omega}_{w'} \times \boldsymbol{r}_{C'/G'} = (\boldsymbol{v}_G + \boldsymbol{\omega}_A \times \boldsymbol{r}_{G'/G}) + \boldsymbol{\omega}_{w'} \times \boldsymbol{r}_{C'/G'}$$

[$\boldsymbol{\omega}_{w'}$ and $\boldsymbol{\omega}_A$: inertial angular velocities of first wheel and axle, respectively]

$$= (v_X, v_Y, 0) + (0, 0, \omega_\phi) \times (b\cos\phi, b\sin\phi, 0) + (\omega_{\psi'}\cos\phi, \omega_{\psi'}\sin\phi, \omega_\phi) \times (0, 0, -r)$$

$$= (v_X - b\,\omega_\phi \sin\phi - r\,\omega_{\psi'}\sin\phi,\ v_Y + b\,\omega_\phi\cos\phi + r\,\omega_{\psi'}\cos\phi,\ 0); \tag{a}$$

and similarly, for the second wheel [whose inertial angular velocity is $\boldsymbol{\omega}_{w''} = (\omega_{\psi''}\cos\phi,\ \omega_{\psi''}\sin\phi,\ \omega_\phi)$],

$$\boldsymbol{v}_{C''} = (v_X + b\,\omega_\phi\sin\phi - r\,\omega_{\psi''}\sin\phi,\ v_Y - b\,\omega_\phi\cos\phi + r\,\omega_{\psi''}\cos\phi,\ 0); \tag{b}$$

the constraints are (with $\boldsymbol{u}\ldots$ for *unit* vector):

$$0 = v_{C',n} \equiv \boldsymbol{v}_{C'} \cdot \boldsymbol{u}_n = \boldsymbol{v}_{C'} \cdot (\cos\phi, \sin\phi, 0) = v_{C'',n} \equiv \boldsymbol{v}_{C''} \cdot \boldsymbol{u}_n = \boldsymbol{v}_{C''} \cdot (\cos\phi, \sin\phi, 0),$$

or

$$v_{C',n} = v_{C'',n} = v_X\cos\phi + v_Y\sin\phi = 0; \tag{c1}$$

and

$$v_{C',t} \equiv \boldsymbol{v}_{C'} \cdot \boldsymbol{u}_t = \boldsymbol{v}_{C'} \cdot (-\sin\phi, \cos\phi, 0) = -v_X\sin\phi + v_Y\cos\phi + b\,\omega_\phi + r\,\omega_{\psi'} = 0, \tag{c2}$$

$$v_{C'',t} \equiv \boldsymbol{v}_{C''} \cdot \boldsymbol{u}_t = \boldsymbol{v}_{C''} \cdot (-\sin\phi, \cos\phi, 0) = -v_X\sin\phi + v_Y\cos\phi - b\,\omega_\phi + r\,\omega_{\psi''} = 0. \tag{c3}$$

[The above can also be obtained by simple geometrical considerations based on fig. 2.21.]

By inspection, we see that (c2, 3) yield the *integrable* combination

$$2b\,\omega_\phi + r(\omega_{\psi'} - \omega_{\psi''}) = 0 \;\Rightarrow\; 2b\,\phi = c - r(\psi' - \psi''),$$
$$[c = \textit{integration constant}, \text{ depending on the initial values of } \phi, \psi', \psi''].\tag{d}$$

Hence, we may take X, Y, ψ', ψ'', as the minimal Lagrangean coordinates of our system, subject to the two knife-like nonholonomic (to be shown below) constraints

$$v_{C',n} = v_{C'',n} = v_X \cos\phi + v_Y \sin\phi = 0;\tag{e1}$$
$$v_{C',t} = -v_X \sin\phi + v_Y \cos\phi + (r/2)(\omega_{\psi'} + \omega_{\psi''}) = 0;\tag{e2}$$

that is, $n = 4, m = 2 \;\Rightarrow\; f \equiv n - m = 4 - 2 = 2$ *DOF in the small*, and *4 DOF in the large*.

In view of (e1, 2), we introduce the following equilibrium quasi velocities:

$$\omega_1 \equiv (\cos\phi)v_X + (\sin\phi)v_Y \quad (= 0);\tag{f1}$$
$$\omega_2 \equiv (-\sin\phi)v_X + (\cos\phi)v_Y \quad (\neq 0);\tag{f2}$$
$$\omega_3 \equiv \omega_\phi \quad (\neq 0);\tag{f3}$$
$$\omega_4 \equiv 2(-v_X \sin\phi + v_Y \cos\phi) + r(\omega_{\psi'} + \omega_{\psi''}) \quad (= 0);\tag{f4}$$
$$\omega_5 \equiv 2b\,\omega_\phi + r(\omega_{\psi'} - \omega_{\psi''}) \quad (= 0;\ \omega_5 = \textit{holonomic}\text{ velocity});\tag{f5}$$

which invert easily to

$$v_X = (\cos\phi)\omega_1 + (-\sin\phi)\omega_2,\tag{f6}$$
$$v_Y = (\sin\phi)\omega_1 + (\cos\phi)\omega_2,\tag{f7}$$
$$\omega_\phi = (0)\omega_1 + (0)\omega_2 + (1)\omega_3,\tag{f8}$$
$$\omega_{\psi'} = (1/2r)(-2\omega_2 - 2r\,\omega_3 + \omega_4 + \omega_5),\tag{f9}$$
$$\omega_{\psi''} = (1/2r)(-2\omega_2 + 2r\,\omega_3 + \omega_4 - \omega_5).\tag{f10}$$

Comparing the above with the quasi velocities of the knife problem (ex. 2.13.2), to be denoted in this example by $\omega^K{}_{\dots}$, we readily see that we have the following correspondences:

$$\omega_1 \to \omega^K{}_2, \qquad \omega_2 \to \omega^K{}_1, \qquad \omega_3 \to \omega^K{}_3.\tag{f11}$$

Hence, and recalling the transitivity equations of that example, we find

$$(\delta\theta_1)^\cdot - \delta\omega_1 = (\delta\theta^K{}_2)^\cdot - \delta\omega^K{}_2 = \omega^K{}_3\,\delta\theta^K{}_1 - \omega^K{}_1\,\delta\theta^K{}_3 = \omega_3\,\delta\theta_2 - \omega_2\,\delta\theta_3 \quad (\neq 0),\tag{g1}$$
$$(\delta\theta_2)^\cdot - \delta\omega_2 = (\delta\theta^K{}_1)^\cdot - \delta\omega^K{}_1 = \omega^K{}_2\,\delta\theta^K{}_3 - \omega^K{}_3\,\delta\theta^K{}_2 = \omega_1\,\delta\theta_3 - \omega_3\,\delta\theta_1 \quad (\neq 0),$$
$$(= 0, \text{ after enforcement of the constraints } \delta\theta_1, \omega_1 = 0),\tag{g2}$$
$$(\delta\theta_3)^\cdot - \delta\omega_3 = 0 \qquad (\theta_3 = \phi = \textit{holonomic}\text{ coordinate}),\tag{g3}$$

$$(\delta\theta_4)^{\cdot} - \delta\omega_4 = 2[(\delta\theta_2)^{\cdot} - \delta\omega_2] + r[(\delta\psi' + \delta\psi'')^{\cdot} - \delta(\omega_{\psi'} + \omega_{\psi''})]$$
$$= 2(\omega_1\delta\theta_3 - \omega_3\,\delta\theta_1) + 0 \quad (= 0, \text{ after enforcing } \delta\theta_1, \omega_1 = 0), \tag{g4}$$
$$(\delta\theta_5)^{\cdot} - \delta\omega_5 = 2b[(\delta\phi)^{\cdot} - \delta\omega_\phi] + r[(\delta\psi' - \delta\omega'')^{\cdot} - \delta(\omega_{\psi'} - \omega_{\psi''})]$$
$$[= 0 \;\Rightarrow\; \theta_5 = 2b\phi + r(\psi' - \psi'') = \textit{holonomic}\text{ coordinate}]. \tag{g5}$$

The above immediately show that the nonvanishing γ's equal ± 1, as in the knife problem; and since here $D = 1, 4$; $I, I' = 2, 3$ and

$$\gamma^D{}_{II'}: \quad \gamma^1{}_{23} = -\gamma^1{}_{32} = 1 \neq 0, \tag{h}$$

the system of Pfaffian constraints $\omega_1 = 0$ and $\omega_4 = 0$ is *nonholonomic*.

For additional wheeled vehicle applications, see also Lobas (1986), Lur'e (1968, pp. 27–31), Mei (1985, pp. 35–36, 168–175, 437–439), Stückler (1955—excellent treatment).

Example 2.13.9 *Transitivity Equations for a Rigid Body in General (Uncontrained) Motion.* As explained in §1.8 ff., to describe the general spatial motion of a rigid body B we employ, among others, the following *two* sets of rectangular Cartesian axes [and associated *orthogonal–normalized–dextral (OND)* bases]: (i) a *body-fixed* set $\blacklozenge$–xyz/$\blacklozenge$–$\boldsymbol{ijk}$ (noninertial), where $\blacklozenge$ is a generic body point (pole); and (ii) a *space-fixed* one O–XYZ/O–$\boldsymbol{IJK}$ (inertial), where O is a generic fixed origin. Frequently (recalling §1.17, "A Comprehensive Example: The Rolling Coin"), we also use other "intermediate" axes/bases that are neither space- nor body-fixed: $\blacklozenge$–$x'y'z'$/$\blacklozenge$–$\boldsymbol{i'j'k'}$; for example, axes $\blacklozenge$–XYZ translating, or comoving, with B but nonrotating (i.e., ever parallel to O–XYZ).

Let us examine the transitivity equations associated with the translation of B with pole $\blacklozenge$, and its rotation about $\blacklozenge$ (earliest systematic treatment in Kirchhoff, 1883, pp. 56–59).

(i) *Rotation.* As shown in §1.12, the transformation relations among the spatial and body components of the inertial angular velocity of B, $\boldsymbol{\omega}$, and the Eulerian angles (and their rates) between $\blacklozenge$–xyz and O–XYZ (or $\blacklozenge$–XYZ) are [with $s\ldots \equiv \sin\ldots$, $c\ldots \equiv \cos\ldots$] as follows:

Body axes components (assuming $\sin\theta \neq 0$):

$$\omega_x = (s\theta\, s\psi)\omega_\phi + (c\psi)\omega_\theta, \quad \omega_y = (s\theta\, c\psi)\omega_\phi + (-s\psi)\omega_\theta, \quad \omega_z = (c\theta)\omega_\phi + \omega_\psi; \tag{a1}$$

$$\Rightarrow\; \omega_\phi = (s\psi/s\theta)\omega_x + (c\psi/s\theta)\omega_y, \qquad \omega_\theta = (c\psi)\omega_x + (-s\psi)\omega_y,$$
$$\omega_\psi = (-\cot\theta\, s\phi)\omega_x + (-\cot\theta\, c\psi)\omega_y + \omega_z. \tag{a2}$$

Space axes components (assuming $\sin\theta \neq 0$):

$$\omega_X = (c\phi)\omega_\theta + (s\phi\, s\theta)\omega_\psi, \quad \omega_Y = (s\phi)\omega_\theta + (-c\phi\, s\theta)\omega_\psi, \quad \omega_Z = \omega_\phi + (c\theta)\omega_\psi; \tag{b1}$$

$$\Rightarrow\; \omega_\phi = (-\cot\theta\, s\phi)\omega_X + (\cot\theta\, c\phi)\omega_Y + \omega_Z, \qquad \omega_\theta = (c\phi)\omega_X + (s\phi)\omega_Y,$$

$$\omega_\psi = (s\phi/s\theta)\omega_X + (-c\phi/s\theta)\omega_Y. \tag{b2}$$

Since these transformations are *stationary*, they also hold with the $\omega_{x,y,z;X,Y,Z}$ replaced by the $d\theta_{x,y,z;X,Y,Z}$ or $\delta\theta_{x,y,z;X,Y,Z}$ and the $\omega_{\phi,\theta,\psi}$ replaced by $d\phi, \ldots$, or $\delta\phi, \ldots$, respectively.

Transitivity Equations

(a) *Body axes:* Differentiating/varying the first of (a1), while invoking the "$d\delta = \delta d$" rule for ϕ, θ, ψ, we obtain, successively,

$$\begin{aligned}(\delta\theta_x)^{\cdot} - \delta\omega_x &= [(s\theta\, s\psi)\,\delta\phi + (c\psi)\,\delta\theta]^{\cdot} - \delta\big[(s\theta\, s\psi)\omega_\phi + (c\psi)\omega_\theta\big] \\ &= c\theta\, s\psi(\omega_\theta\,\delta\phi - \omega_\phi\,\delta\theta) + s\theta\, c\psi(\omega_\psi\,\delta\phi - \omega_\phi\,\delta\psi) + s\psi(\omega_\theta\,\delta\psi - \omega_\psi\,\delta\theta),\end{aligned}$$

and substituting $\omega_\phi, \ldots / \delta\phi, \ldots$ in terms of $\omega_x, \ldots / \delta\theta_x, \ldots$, from (a2), we eventually find

$$(\delta\theta_x)^{\cdot} - \delta\omega_x = \omega_z\,\delta\theta_y - \omega_y\,\delta\theta_z, \tag{c1}$$

and similarly, for the other two,

$$(\delta\theta_y)^{\cdot} - \delta\omega_y = \omega_x\,\delta\theta_z - \omega_z\,\delta\theta_x, \tag{c2}$$

$$(\delta\theta_z)^{\cdot} - \delta\omega_z = \omega_y\,\delta\theta_x - \omega_x\,\delta\theta_y. \tag{c3}$$

Hence, the nonvanishing γ's are

$$\gamma^x{}_{yz} = -\gamma^x{}_{zy} = 1, \qquad \gamma^y{}_{zx} = -\gamma^y{}_{xz} = 1, \qquad \gamma^z{}_{xy} = -\gamma^z{}_{yx} = 1; \tag{d1}$$

or, compactly [with $k, r, s \to x, y, z : 1, 2, 3$],

$$\begin{aligned}\gamma^k{}_{rs} &= \varepsilon_{krs} \equiv (k - r)(r - s)(s - k)/2 \\ &= \pm 1, \text{according as } k, r, s/x, y, z \text{ are an } \textit{even} \text{ or } \textit{odd} \text{ permutation of } 1, 2, 3; \\ &\qquad \text{and} = 0 \text{ in all other cases: } \textit{Levi-Civita permutation symbol} \text{ (1.1.6 ff.).}\end{aligned} \tag{d2}$$

(b) *Space axes:* Applying similar steps to (b1, 2), we eventually obtain

$$(\delta\theta_X)^{\cdot} - \delta\omega_X = \omega_Y\,\delta\theta_Z - \omega_Z\,\delta\theta_Y, \tag{e1}$$

and similarly, for the other two,

$$(\delta\theta_Y)^{\cdot} - \delta\omega_Y = \omega_Z\,\delta\theta_X - \omega_X\,\delta\theta_Z, \tag{e2}$$

$$(\delta\theta_Z)^{\cdot} - \delta\omega_Z = \omega_X\,\delta\theta_Y - \omega_Y\,\delta\theta_X. \tag{e3}$$

Hence, the nonvanishing γ's are

$$\gamma^X{}_{YZ} = -\gamma^X{}_{ZY} = -1, \qquad \gamma^Y{}_{ZX} = -\gamma^Y{}_{XZ} = -1, \qquad \gamma^Z{}_{XY} = -\gamma^Z{}_{YX} = -1; \tag{f1}$$

or, compactly (with $k, r, s \to X, Y, Z$: $1, 2, 3$),

$$\gamma^K{}_{RS} = -\varepsilon_{KRS} = \varepsilon_{RKS}. \tag{f2}$$

The above show clearly that the *orthogonal* components of $\boldsymbol{\omega}$, $\omega_{x,y,z}$ and $\omega_{X,Y,Z}$ are nonholonomic; while the *nonorthogonal* components $\omega_{\phi,\theta,\psi}$ are holonomic (and, again, this has nothing to do with constraints, but is a mathematical consequence of the *noncommutativity* of rigid rotations).

REMARK

These transitivity relations and γ-values, (c1–f2), are independent of the particular $\omega_{x,y,z;X,Y,Z} \Leftrightarrow \omega_{\phi,\theta,\psi}$ relationships (a1–b2); they express, in component form, invariant noncommutativity properties between the differentials of the vectors of infinitesimal rotation and angular velocity. A direct vectorial proof of these properties is presented in the next example.

(c) *Intermediate axes:* Such sets are the following axes of ex. 2.13.7: (i) $G\text{–}nn'z \equiv G\text{–}x'y'z'$, with OND basis $G\text{–}\boldsymbol{i}'\boldsymbol{j}'\boldsymbol{k}' \equiv G\text{–}\boldsymbol{u}_n\boldsymbol{u}_{n'}\boldsymbol{k}$; and (ii) $G\text{–}nNZ$, with OND basis $G\text{–}\boldsymbol{u}_n\boldsymbol{u}_N\boldsymbol{K}$ ($\boldsymbol{u}_n \equiv \boldsymbol{i}' =$ unit vector along $+$*nodal* line); and they are called by some authors *semimobile* (SM) and *semifixed* (SF), respectively.

Below, we collect some kinematical data pertinent to them. Since their inertial angular velocities are (consult fig. 2.20)

$$\begin{aligned}\boldsymbol{\omega}_{SM} \equiv \boldsymbol{\omega}' &= \omega_\phi\,\boldsymbol{K} + \omega_\theta\,\boldsymbol{i}' = \omega_\theta\,\boldsymbol{i}' + \omega_\phi(\sin\theta\,\boldsymbol{j}' + \cos\theta\,\boldsymbol{k}')\\ &= (\omega_\theta)\boldsymbol{i}' + (\omega_\phi\sin\theta)\boldsymbol{j}' + (\omega_\phi\cos\theta)\boldsymbol{k}'\\ &= \omega_\phi\,\boldsymbol{K} + \omega_\theta\,\boldsymbol{u}_n = \boldsymbol{\omega}_{SF} + \omega_\theta\,\boldsymbol{u}_n \equiv \boldsymbol{\omega}'' + \boldsymbol{\omega}_\theta\,\boldsymbol{u}_n,\end{aligned} \tag{g1}$$

$$\boldsymbol{\omega}_{SF} \equiv \boldsymbol{\omega}'' = \omega_\phi\,\boldsymbol{K}, \tag{g2}$$

we will have the following relations for the rates of change of their bases:

$$d\boldsymbol{u}_n/dt = \boldsymbol{\omega}' \times \boldsymbol{u}_n = \omega_\phi\,\boldsymbol{u}_N = \omega_\phi(\cos\theta\,\boldsymbol{u}_{n'} - \sin\theta\,\boldsymbol{k}'); \tag{g3}$$

$$d\boldsymbol{u}_{n'}/dt = \boldsymbol{\omega}' \times \boldsymbol{u}_{n'} = (-\omega_\phi\cos\theta)\boldsymbol{u}_n + \omega_\theta\,\boldsymbol{k}'; \tag{g4}$$

$$d\boldsymbol{k}'/dt = \boldsymbol{\omega}' \times \boldsymbol{k}' = (\omega_\phi\sin\theta)\boldsymbol{u}_n - \omega_\theta\,\boldsymbol{u}_{n'}; \tag{g5}$$

$$d\boldsymbol{u}_n/dt = \boldsymbol{\omega}'' \times \boldsymbol{u}_n = \omega_\phi\,\boldsymbol{u}_N; \tag{g6}$$

$$d\boldsymbol{u}_N/dt = \boldsymbol{\omega}'' \times \boldsymbol{u}_N = -\omega_\phi\,\boldsymbol{u}_n; \tag{g7}$$

$$d\boldsymbol{K}/dt = \boldsymbol{\omega}'' \times \boldsymbol{K} = \boldsymbol{0}. \tag{g8}$$

Finally, the body angular velocity along the SM axes, thanks to the second line of (g1), equals

$$\begin{aligned}\boldsymbol{\omega} = \boldsymbol{\omega}' + \omega_\psi\,\boldsymbol{k}' &= (\omega_\theta)\boldsymbol{i}' + (\omega_\phi\sin\theta)\boldsymbol{j}' + (\omega_\psi + \omega_\phi\cos\theta)\boldsymbol{k}'\\ &\equiv \omega_{x'}\,\boldsymbol{i}' + \omega_{y'}\,\boldsymbol{j}' + \omega_{z'}\,\boldsymbol{k}';\end{aligned} \tag{g9}$$

and since this is a scleronomic system, (g9) holds with $\omega_{x',y',z'}$, replaced with $d\theta_{x',y',z'}$ and $\delta\theta_{x',y',z'}$; and $\omega_{\phi,\theta,\psi}$ replaced with $d\phi, d\theta, d\psi$ and $\delta\phi, \delta\theta, \delta\psi$, respectively.

From the above, by straightforward differentiations, we obtain the *rotational transitivity equations* in terms of *semimobile components*:

$$(\delta\theta_{x'})^{\cdot} - \delta\omega_{x'} = 0 \qquad (\theta_{x'} \equiv \theta = \textit{holonomic}\ \text{coordinate} \Rightarrow \gamma^{x'}{}_{..} = 0), \tag{h1}$$

$$(\delta\theta_{y'})^{\cdot} - \delta\omega_{y'} = \cot\theta(\omega_{x'}\,\delta\theta_{y'} - \omega_{y'}\,\delta\theta_{x'}), \tag{h2}$$

$$(\delta\theta_{z'})^{\cdot} - \delta\omega_{z'} = (\omega_{y'}\,\delta\theta_{x'} - \omega_{x'}\,\delta\theta_{y'}); \tag{h3}$$

and hence the nonvanishing γ's are (assuming $\cot\theta = \mathit{finite}$)

$$\gamma^{y'}{}_{y'x'} = -\gamma^{y'}{}_{x'y'} = \cot\theta, \qquad \gamma^{z'}{}_{x'y'} = -\gamma^{z'}{}_{y'x'} = 1. \tag{h4}$$

Note that (h1–4) are none other than (h3–5) and (i) of ex. 2.13.7.

(ii) *Translation of pole (or basepoint)* ◆. Let us assume that ◆ has inertial position:

$$\boldsymbol{OP} = \boldsymbol{\rho} = \rho_X\,\boldsymbol{I} + \rho_Y\,\boldsymbol{J} + \rho_Z\,\boldsymbol{K}, \tag{h5}$$

and, therefore, inertial velocity:

$$\begin{aligned}
\boldsymbol{v} &\equiv d\boldsymbol{\rho}/dt\\
&= (d\rho_X/dt)\boldsymbol{I} + (d\rho_Y/dt)\boldsymbol{J} + (d\rho_Z/dt)\boldsymbol{K} \equiv v_X\,\boldsymbol{I} + v_Y\,\boldsymbol{J} + v_Z\,\boldsymbol{K}\\
&\qquad [\text{along } \textit{space}\text{-axes: } v_X \equiv d\rho_X/dt = \boldsymbol{v}\cdot\boldsymbol{I}, \text{etc.};\\
&\qquad\qquad \rho_{X,Y,Z}(v_{X,Y,Z})\text{: } \textit{holonomic} \text{ coordinates (velocities) of ◆.}]\\
&= v_x\,\boldsymbol{i} + v_y\boldsymbol{j} + v_z\,\boldsymbol{k} \equiv (dp_x/dt)\boldsymbol{i} + (dp_y/dt)\boldsymbol{j} + (dp_z/dt)\boldsymbol{k}\\
&\qquad [\text{along } \textit{body}\text{-axes: } v_x \equiv dp_x/dt \equiv \boldsymbol{v}\cdot\boldsymbol{i},\ \text{etc.};\\
&\qquad\qquad p_{x,y,z}(v_{x,y,z})\text{: } \textit{nonholonomic} \text{ coordinates (velocities) of ◆.}]
\end{aligned} \tag{h6}$$

Clearly, the above velocity components are related by the following vector transformations:

$$\begin{aligned}
v_x &= \cos(x,X)v_X + \cos(x,Y)v_Y + \cos(x,Z)v_Z, \quad \text{etc.}\\
v_X &= \cos(X,x)v_x + \cos(X,y)v_y + \cos(X,z)v_z, \quad \text{etc.},
\end{aligned} \tag{h7}$$

and, since this is a scleronomic system, their differentials are related by

$$\begin{aligned}
dp_x &\equiv v_x\,dt = (\boldsymbol{v}\cdot\boldsymbol{i})\,dt \equiv d\boldsymbol{\rho}\cdot\boldsymbol{i} = \cos(x,X)\,d\rho_X + \cos(x,Y)\,d\rho_Y + \cos(x,Z)\,d\rho_Z, \quad \text{etc.}\\
\delta p_x &\equiv \delta\boldsymbol{\rho}\cdot\boldsymbol{i} = \cos(x,X)\,\delta\rho_X + \cos(x,Y)\,\delta\rho_Y + \cos(x,Z)\,\delta\rho_Z, \quad \text{etc.}
\end{aligned} \tag{h8}$$

Next, since

$$d\boldsymbol{i} = d\boldsymbol{\theta}\times\boldsymbol{i}, \qquad \delta\boldsymbol{i} = \delta\boldsymbol{\theta}\times\boldsymbol{i} \quad \text{etc.}, \tag{i1}$$

where $d\boldsymbol{\theta} \equiv \boldsymbol{\omega}\,dt = d\theta_x\,\boldsymbol{i} + d\theta_y\boldsymbol{j} + d\theta_z\,\boldsymbol{k} = d\phi\,\boldsymbol{K} + d\theta\,\boldsymbol{u}_n + d\psi\,\boldsymbol{k}$ = elementary (*inertial*) *kinematically admissible/possible rotation vector*, hence $\delta\boldsymbol{\theta} = \delta\theta_x\,\boldsymbol{i} + \delta\theta_y\boldsymbol{j} + \delta\theta_z\,\boldsymbol{k} = \delta\phi\,\boldsymbol{K} + \delta\theta\,\boldsymbol{u}_n + \delta\psi\,\boldsymbol{k}$ = (*inertial*) *virtual rotation vector*, we find by direct calculation [with $(\ldots)^{\cdot}$ = *inertial rate of change*, for vectors]

$$\begin{aligned}
(\delta p_x)^{\cdot} &= (\delta\boldsymbol{\rho}\cdot\boldsymbol{i})^{\cdot} = (\delta\boldsymbol{\rho})^{\cdot}\cdot\boldsymbol{i} + \delta\boldsymbol{\rho}\cdot(\boldsymbol{i})^{\cdot} = (\delta\boldsymbol{\rho})^{\cdot}\cdot\boldsymbol{i} + \delta\boldsymbol{\rho}\cdot(\boldsymbol{\omega}\times\boldsymbol{i}),\\
\delta(dp_x/dt) &\equiv \delta v_x = \delta(\boldsymbol{v}\cdot\boldsymbol{i}) = \delta\boldsymbol{v}\cdot\boldsymbol{i} + \boldsymbol{v}\cdot\delta\boldsymbol{i} = \delta\boldsymbol{v}\cdot\boldsymbol{i} + \boldsymbol{v}\cdot(\delta\boldsymbol{\theta}\times\boldsymbol{i}),
\end{aligned} \tag{i2}$$

and subtracting the above side by side, while noting that $(\delta\boldsymbol{\rho})^{\cdot} - \delta\boldsymbol{v} = \delta(d\boldsymbol{\rho}/dt) - \delta\boldsymbol{v} = \delta\boldsymbol{v} - \delta\boldsymbol{v} = \boldsymbol{0}$, we obtain the x-component of the *pole velocity transitivity equation*:

$$\begin{aligned}
(\delta p_x)^{\cdot} - \delta v_x &= \delta\boldsymbol{\rho}\cdot(\boldsymbol{\omega}\times\boldsymbol{i}) - \boldsymbol{v}\cdot(\delta\boldsymbol{\theta}\times\boldsymbol{i}) = (\delta\boldsymbol{\rho}\times\boldsymbol{\omega})\cdot\boldsymbol{i} - (\boldsymbol{v}\times\delta\boldsymbol{\theta})\cdot\boldsymbol{i}\\
&= (\delta\boldsymbol{\rho}\times\boldsymbol{\omega} - \boldsymbol{v}\times\delta\boldsymbol{\theta})\cdot\boldsymbol{i};
\end{aligned} \tag{i3}$$

and similarly for its y and z components. Hence, our pole transitivity equation can be written in the following *vector* form [with $\partial(\ldots)$ and $\delta_{rel}(\ldots)$ denoting differentials of vectors, and so on, relative to the moving, here *body*-fixed, axes]:

$$\partial(\delta\boldsymbol{\rho})/\partial t - \delta_{rel}(d\boldsymbol{\rho}/dt) = \delta\boldsymbol{\rho} \times \boldsymbol{\omega} - \boldsymbol{v} \times \delta\boldsymbol{\theta}, \tag{i4a}$$

or

$$\delta_{rel}\boldsymbol{v} = \partial(\delta\boldsymbol{\rho})/\partial t + \boldsymbol{\omega} \times \delta\boldsymbol{\rho} + \boldsymbol{v} \times \delta\boldsymbol{\theta}. \tag{i4b}$$

In component form, along ◆–xyz, (i4a) reads

$$(\delta p_x)^{\cdot} - \delta v_x = (\omega_z\,\delta p_y - \omega_y\,\delta p_z) - (v_y\,\delta\theta_z - v_z\,\delta\theta_y), \tag{i5}$$

$$(\delta p_y)^{\cdot} - \delta v_y = (\omega_x\,\delta p_z - \omega_z\,\delta p_x) - (v_z\,\delta\theta_x - v_x\,\delta\theta_z), \tag{i6}$$

$$(\delta p_z)^{\cdot} - \delta v_z = (\omega_y\,\delta p_x - \omega_x\,\delta p_y) - (v_x\,\delta\theta_y - v_y\,\delta\theta_x); \tag{i7}$$

and, therefore, the nonvanishing γ's are [with accented (unaccented) indices for the components $\delta p_{x,y,z}(\delta\theta_{x,y,z})$]

$$\gamma^{x'}{}_{y'z} = -\gamma^{x'}{}_{zy'} = 1 \qquad \text{and} \qquad \gamma^{x'}{}_{yz'} = -\gamma^{x'}{}_{z'y} = 1, \tag{i8}$$

$$\gamma^{y'}{}_{z'x} = -\gamma^{y'}{}_{xz'} = 1 \qquad \text{and} \qquad \gamma^{y'}{}_{zx'} = -\gamma^{y'}{}_{x'z} = 1, \tag{i9}$$

$$\gamma^{z'}{}_{x'y} = -\gamma^{z'}{}_{yx'} = 1 \qquad \text{and} \qquad \gamma^{z'}{}_{xy'} = -\gamma^{z'}{}_{y'z} = 1. \tag{i10}$$

Semifixed axes ◆–$\boldsymbol{u}_n\boldsymbol{u}_N\boldsymbol{K}$. Here, we have

$$v_n \equiv (p_n)^{\cdot} = \boldsymbol{v}\cdot\boldsymbol{u}_n \equiv \boldsymbol{v}\cdot\boldsymbol{i}' = (\rho_X)^{\cdot}\cos\phi + (\rho_Y)^{\cdot}\sin\phi, \tag{j1}$$

$$v_N \equiv (p_N)^{\cdot} = \boldsymbol{v}\cdot\boldsymbol{u}_N = -(\rho_X)^{\cdot}\sin\phi + (\rho_Y)^{\cdot}\cos\phi, \tag{j2}$$

$$v_Z \equiv (p_Z)^{\cdot} = \boldsymbol{v}\cdot\boldsymbol{K} = (\rho_Z)^{\cdot} \;\Rightarrow\; \gamma^{Z}{}_{..} = 0 \quad (\text{i.e., } v_Z = \textit{holonomic} \text{ velocity}). \tag{j3}$$

We leave it to the reader to show that (recalling the earlier *semimobile* axes kinematics)

$$\begin{aligned}(\delta p_n)^{\cdot} - \delta v_n &= -[\omega_\phi\,\delta\rho_X - (\rho_X)^{\cdot}\,\delta\phi]\sin\phi + [\omega_\phi\,\delta\rho_Y - (\rho_Y)^{\cdot}\,\delta\phi]\cos\phi \\ &= \omega_\phi\,\delta p_N - v_N\,\delta\phi = (1/\sin\phi)(\omega_y\,\delta p_N - v_N\,\delta\theta_y),\end{aligned} \tag{j4}$$

$$\begin{aligned}(\delta p_N)^{\cdot} - \delta v_N &= -[\omega_\phi\,\delta\rho_X - (\rho_X)^{\cdot}\,\delta\phi]\cos\phi + [(\rho_Y)^{\cdot}\,\delta\phi - \omega_\phi\,\delta\rho_Y]\sin\phi \\ &= -\omega_\phi\,\delta p_n + (p_n)^{\cdot}\,\delta\phi = (1/\sin\phi)[(p_n)^{\cdot}\,\delta\theta_y - \omega_y\,\delta p_n];\end{aligned} \tag{j5}$$

and hence that the nonvanishing γ's are (with some, easily understood, ad hoc notation; and assuming that $\sin\theta \neq 0$)

$$\gamma^{n}{}_{Ny} = -\gamma^{n}{}_{yN} = 1/\sin\theta, \qquad \gamma^{N}{}_{yn} = -\gamma^{N}{}_{ny} = 1/\sin\theta. \tag{j6}$$

[Recalling ex. 2.13.7 (rolling disk problem), eqs. (d2, 3), (h1, 2), (i), etc.]

For related discussions of the rigid-body transitivity equations, see also Bremer (1988(b)) and Moiseyev and Rumyantsev (1968, pp. 7–8).

Example 2.13.10 *Cardanian Suspension of a Gyroscope*. Let us consider a gyroscope suspended à le Cardan (fig. 2.22). The rotation sequence

$$q_1 \equiv \phi(precession) \to q_2 \equiv \theta(nutation) \to q_3 \equiv \psi(spin)$$

(i.e., $3 \to 2 \to 1$, in the Eulerian angle sense of §1.12) brings the original axes $G\text{–}XYZ$, through the intermediate position $G\text{–}x'y'z'$ (outer gimbal), to the also intermediate position $G\text{–}xyz$ (inner gimbal).

Now: (i) The inertial angular velocity of the *outer* gimbal $\boldsymbol{\omega}_O$, *along outer gimbal–fixed axes*, is

$$\omega_{O,x'} = 0, \qquad \omega_{O,y'} = 0, \qquad \omega_{O,z'} = \omega_\phi; \tag{a}$$

(ii) the inertial angular velocity of the *inner* gimbal $\boldsymbol{\omega}_I$, *along inner gimbal–fixed axes*, is

$$\omega_{I,x} = -\omega_\phi \sin\theta, \qquad \omega_{I,y} = \omega_\theta, \qquad \omega_{I,z} = \omega_\phi \cos\theta; \tag{b}$$

and (iii) the inertial angular velocity of the *gyroscope* $\boldsymbol{\omega}$, *along inner gimbal–fixed axes*, is

$$\omega_x = \omega_\psi - \omega_\phi \sin\theta, \qquad \omega_y = \omega_\theta, \qquad \omega_z = \omega_\phi \cos\theta. \tag{c}$$

Let us find the transitivity equations corresponding to these quasi velocities. Equations (c) can be rewritten as

$$\omega_1 \equiv \omega_x \equiv (-\sin\theta)\omega_\phi + (0)\omega_\theta + (1)\omega_\psi \quad (\neq 0), \tag{d}$$

$$\omega_2 \equiv \omega_y \equiv (0)\omega_\phi + (1)\omega_\theta + (0)\omega_\psi \quad (\neq 0), \tag{e}$$

$$\omega_3 \equiv \omega_z \equiv (\cos\theta)\omega_\phi + (0)\omega_\theta + (0)\omega_\psi \quad (\neq 0); \tag{f}$$

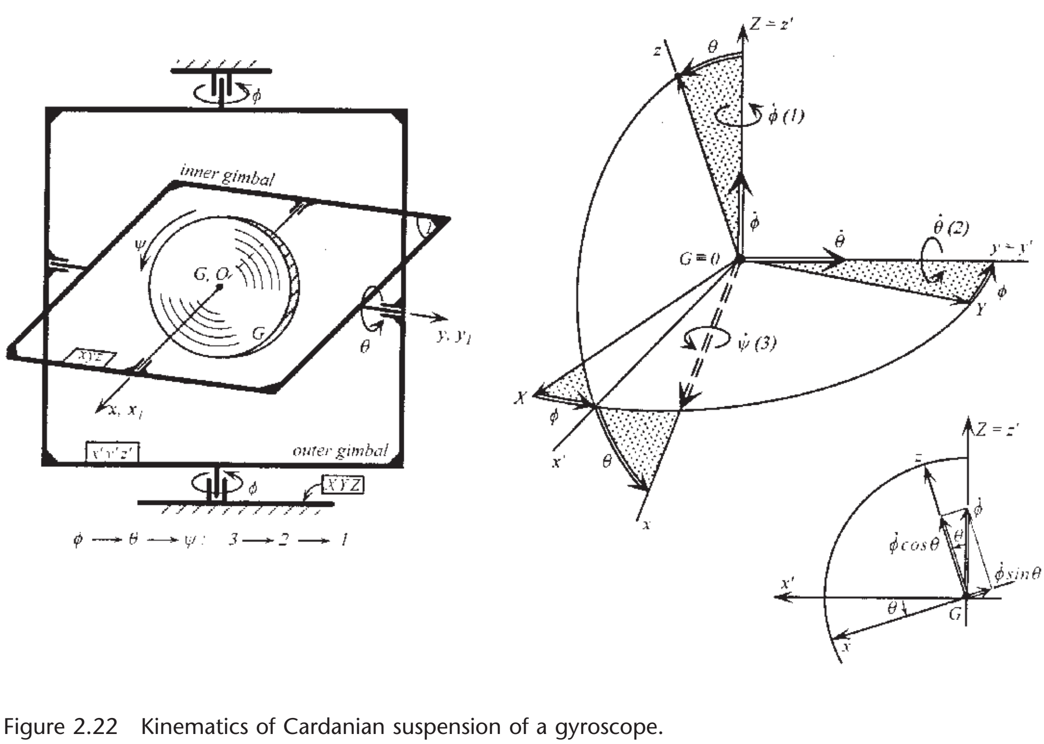

Figure 2.22 Kinematics of Cardanian suspension of a gyroscope.

and their inverses are readily found to be

$$v_1 \equiv \omega_\phi = (0)\omega_x + (0)\omega_y + (1/\cos\theta)\omega_z, \tag{g}$$

$$v_2 \equiv \omega_\theta = (0)\omega_x + (1)\omega_y + (0)\omega_z, \tag{h}$$

$$v_3 \equiv \omega_\psi = (1)\omega_x + (0)\omega_y + (\sin\theta/\cos\theta)\omega_z. \tag{i}$$

From these stationary relations, and assuming $d(\delta q_k) = \delta(dq_k)$ $(k = x, y, z)$, we obtain, successively,

(i) $d(\delta\theta_x) - \delta(d\theta_x) = d[(-\sin\theta)\,\delta\phi + \delta\psi] - \delta[(-\sin\theta)\,d\phi + d\psi]$

$$= \cdots = (\cos\theta)(d\phi\,\delta\theta - d\theta\,\delta\phi) = \cdots = d\theta_z\,\delta\theta_y - d\theta_y\,\delta\theta_z; \tag{j}$$

(ii) $d(\delta\theta_y) - \delta(d\theta_y) = 0 \quad (\Rightarrow \theta_y = \textit{holonomic}\text{ coordinate});$ (k)

(iii) $d(\delta\theta_z) - \delta(d\theta_z) = d[(\cos\theta)\,\delta\phi] - \delta[(\cos\theta)\,d\phi]$

$$= \cdots = (\sin\theta)(d\phi\,\delta\theta - d\theta\,\delta\phi) = \cdots = (\tan\theta)(d\theta_z\,\delta\theta_y - d\theta_y\,\delta\theta_z); \tag{l}$$

and so the nonvanishing γ's are (assuming $\theta \neq \pm\pi/2$)

$$\gamma^x{}_{yz} = -\gamma^x{}_{zy} \equiv \gamma^1{}_{23} = -\gamma^1{}_{32} = +1, \tag{m}$$

$$\gamma^z{}_{yz} = -\gamma^z{}_{zy} \equiv \gamma^3{}_{23} = -\gamma^3{}_{32} = \tan\theta. \tag{n}$$

Example 2.13.11 *An Elementary ad hoc Vectorial Derivation of the Rotational Rigid-Body Transitivity Equations*. Let us consider, with no loss of generality, a free rigid body B rotating with (inertial) angular velocity $\boldsymbol{\omega}$ about a fixed point O. Then, as is well known (§1.9 ff.), and since this is an internally scleronomic system, the (inertial) velocity/kinematically admissible displacements/virtual displacements of a typical B-particle of (inertial) position vector $\boldsymbol{r}$, are, respectively,

$$\boldsymbol{v} = \boldsymbol{\omega} \times \boldsymbol{r} \Rightarrow d\boldsymbol{r} = d\boldsymbol{\theta} \times \boldsymbol{r}, \qquad \delta\boldsymbol{r} = \delta\boldsymbol{\theta} \times \boldsymbol{r}, \tag{a}$$

where $d\boldsymbol{\theta} \equiv \boldsymbol{\omega}\,dt$, and $d(\ldots)/\delta(\ldots)$ are *kinematically admissible/virtual* (*inertial*) *variation operators*. Now, $d(\ldots)$-varying the last of (a), $\delta(\ldots)$-varying the second, and then subtracting the results side by side, while invoking (a) and the rule $d(\delta\boldsymbol{r}) - \delta(d\boldsymbol{r}) = \boldsymbol{0}$, we obtain, successively,

$$\boldsymbol{0} = d(\delta\boldsymbol{r}) - \delta(d\boldsymbol{r}) = [d(\delta\boldsymbol{\theta}) \times \boldsymbol{r} + \delta\boldsymbol{\theta} \times d\boldsymbol{r}] - [\delta(d\boldsymbol{\theta}) \times \boldsymbol{r} + d\boldsymbol{\theta} \times \delta\boldsymbol{r}]$$

$$= [d(\delta\boldsymbol{\theta}) \times \boldsymbol{r} + \delta\boldsymbol{\theta} \times (d\boldsymbol{\theta} \times \boldsymbol{r})] - [\delta(d\boldsymbol{\theta}) \times \boldsymbol{r} + d\boldsymbol{\theta} \times (\delta\boldsymbol{\theta} \times \boldsymbol{r})]$$

$$= [d(\delta\boldsymbol{\theta}) - \delta(d\boldsymbol{\theta})] \times \boldsymbol{r} + [\delta\boldsymbol{\theta} \times (d\boldsymbol{\theta} \times \boldsymbol{r}) - d\boldsymbol{\theta} \times (\delta\boldsymbol{\theta} \times \boldsymbol{r})]$$

[and applying to the second bracket (last two triple cross-products) the cyclic vector identity, holding for any three vectors $\boldsymbol{a}, \boldsymbol{b}, \boldsymbol{c}$: $\boldsymbol{a} \times (\boldsymbol{b} \times \boldsymbol{c}) + \boldsymbol{b} \times (\boldsymbol{c} \times \boldsymbol{a}) + \boldsymbol{c} \times (\boldsymbol{a} \times \boldsymbol{b}) = \boldsymbol{0}$, with the identifications: $\boldsymbol{a} \to \delta\boldsymbol{\theta}$, $\boldsymbol{b} \to d\boldsymbol{\theta}$, $\boldsymbol{c} \to \boldsymbol{r}$]

$$= [d(\delta\boldsymbol{\theta}) - \delta(d\boldsymbol{\theta})] \times \boldsymbol{r} + (\delta\boldsymbol{\theta} \times d\boldsymbol{\theta}) \times \boldsymbol{r},$$

from which, since $\boldsymbol{r}$ is arbitrary, we finally get the fundamental and general *inertial* rotational transitivity equation:

$$d(\delta\boldsymbol{\theta}) - \delta(d\boldsymbol{\theta}) = d\boldsymbol{\theta} \times \delta\boldsymbol{\theta}. \tag{b}$$

Dividing the above with dt, which does no interact with these differentials (and noting that, by Newtonian relativity, $dt = \partial t$), we also obtain the equivalent transitivity equation in terms of the angular velocities:

$$d(\delta\boldsymbol{\theta})/dt - \delta\boldsymbol{\omega} = \boldsymbol{\omega} \times \delta\boldsymbol{\theta}. \tag{c}$$

Next, let us find the counterparts of (b, c) in terms of *relative* differentials/variations, i.e. relative to moving (here body-fixed) axes, to be denoted by $\partial(\ldots)/\delta_{rel}(\ldots)$. Applying the well-known kinematical operator identities [(§1.7 ff.)]

$$d(\ldots) = \partial(\ldots) + d\boldsymbol{\theta} \times (\ldots), \qquad \delta(\ldots) = \delta_{rel}(\ldots) + \delta\boldsymbol{\theta} \times (\ldots), \tag{d}$$

(which immediately yield $\partial\boldsymbol{r} = \mathbf{0}$ and $\delta_{rel}\boldsymbol{r} = \mathbf{0}$, as expected) to $\delta\boldsymbol{\theta}$ and $d\boldsymbol{\theta}$, respectively, and then substracting side by side, we find, successively,

$$\begin{aligned} d(\delta\boldsymbol{\theta}) - \delta(d\boldsymbol{\theta}) &= \partial(\delta\boldsymbol{\theta}) - \delta_{rel}(d\boldsymbol{\theta}) + (d\boldsymbol{\theta} \times \delta\boldsymbol{\theta} - \delta\boldsymbol{\theta} \times d\boldsymbol{\theta}) \\ &= \partial(\delta\boldsymbol{\theta}) - \delta_{rel}(d\boldsymbol{\theta}) + 2(d\boldsymbol{\theta} \times \delta\boldsymbol{\theta}), \end{aligned} \tag{e}$$

or, invoking (b) for its left side and rearranging slightly, we get, finally,

$$\partial(\delta\boldsymbol{\theta}) - \delta_{rel}(d\boldsymbol{\theta}) = \delta\boldsymbol{\theta} \times d\boldsymbol{\theta}; \tag{f}$$

and dividing by dt, we also obtain its velocity equivalent,

$$\partial(\delta\boldsymbol{\theta})/dt - \delta_{rel}\boldsymbol{\omega} = \delta\boldsymbol{\theta} \times \boldsymbol{\omega}. \tag{g}$$

The kinematical identities (f, g) are the noninertial counterparts of (b, c).

The *difference* between (b, c) and (f, g) often goes unnoticed in the literature. To understand it better, let us write them down in component form, along *space-fixed* axes $\blacklozenge\text{–}XYZ$ and *body-fixed* axes $\blacklozenge\text{–}xyz$. Only the first equations are shown (i.e., X, x); the rest follow cyclically:

Space-fixed (inertial) axes:

$$d(\delta\theta_X) - \delta(d\theta_X) = d\theta_Y\,\delta\theta_Z - d\theta_Z\,\delta\theta_Y, \qquad \text{or} \qquad (\delta\theta_X)^{\cdot} - \delta\omega_X = \omega_Y\,\delta\theta_Z - \omega_Z\,\delta\theta_Y; \tag{h1}$$

Body-fixed (noninertial) axes:

$$d(\delta\theta_x) - \delta(d\theta_x) = d\theta_z\,\delta\theta_y - d\theta_y\,\delta\theta_z, \qquad \text{or} \qquad (\delta\theta_x)^{\cdot} - \delta\omega_x = \omega_z\,\delta\theta_y - \omega_y\,\delta\theta_z; \tag{h2}$$

which, naturally, coincide with equations (c1–f2) of ex. 2.13.9, and §1.14.

[When dealing with derivatives/differentials of *components*, we may safely use the same notation $(\ldots)^{\cdot}/d(\ldots)/\delta(\ldots)$ for both space and body such changes; here, the intended meaning is conveyed unambiguously].

Additional Special Results

(i) Applying the *second* of (d) for $\boldsymbol{\omega}$, and then equating the resulting $\delta\boldsymbol{\omega}$-expression with that obtained from (c), we get $d(\delta\boldsymbol{\theta})/dt - \boldsymbol{\omega} \times \delta\boldsymbol{\theta} = \delta_{rel}\boldsymbol{\omega} + \delta\boldsymbol{\theta} \times \boldsymbol{\omega}$, or, simplifying, $d(\delta\boldsymbol{\theta})/dt = \delta_{rel}\boldsymbol{\omega}$; or, equivalently (multiplying with dt),

$$d(\delta\boldsymbol{\theta}) = \delta_{rel}(d\boldsymbol{\theta}). \tag{i}$$

(ii) Starting from (c), and then invoking the first of (d), we obtain, successively,

$$\begin{aligned}\delta\boldsymbol{\omega} &= d(\delta\boldsymbol{\theta})/dt - \boldsymbol{\omega}\times\delta\boldsymbol{\theta} = [\partial(\delta\boldsymbol{\theta})/\partial t + \boldsymbol{\omega}\times\delta\boldsymbol{\theta}] - \boldsymbol{\omega}\times\delta\boldsymbol{\theta}\\ &= \partial(\delta\boldsymbol{\theta})/\partial t \qquad [= \delta_{rel}\boldsymbol{\omega} + \delta\boldsymbol{\theta}\times\boldsymbol{\omega}, \quad \text{by (g)}];\end{aligned}$$

that is,

$$\delta\boldsymbol{\omega} = \partial(\delta\boldsymbol{\theta})/\partial t, \qquad \text{or, equivalently,} \qquad \delta(d\boldsymbol{\theta}) = \partial(\delta\boldsymbol{\theta}); \tag{j}$$

which is "symmetrical" to (i).

(iii) Applying the *first* of (d) for $\boldsymbol{\omega}$ yields

$$d\boldsymbol{\omega} = \partial\boldsymbol{\omega}, \qquad \text{or, equivalently,} \qquad d(d\boldsymbol{\theta}) = \partial(d\boldsymbol{\theta}); \tag{k}$$

but the *second* of (d) shows that

$$\delta\boldsymbol{\omega} \neq \delta_{rel}\boldsymbol{\omega}, \qquad \text{or, equivalently,} \qquad \delta(d\boldsymbol{\theta}) \neq \delta_{rel}(d\boldsymbol{\theta}). \tag{l}$$

Problem 2.13.4 *Rigid-body Transitivity Equations*. Using the results of the preceding example and its notations, show that, for a rigid body rotating about a fixed point,

$$\partial(\delta\boldsymbol{r}) - \delta_{rel}(d\boldsymbol{r}) = (\delta\boldsymbol{\theta}\times d\boldsymbol{\theta})\times\boldsymbol{r} \neq \boldsymbol{0}, \tag{a}$$

or, equivalently (dividing by $dt = \partial t$),

$$\partial(\delta\boldsymbol{r})/\partial t - \delta_{rel}\boldsymbol{v} = (\delta\boldsymbol{\theta}\times\boldsymbol{\omega})\times\boldsymbol{r} \neq \boldsymbol{0}; \tag{b}$$

even though $d(\delta\boldsymbol{r}) - \delta(d\boldsymbol{r}) = \boldsymbol{0}$; that is, *the rule* $d(\delta\ldots) = \delta(d\ldots)$ *is not frame-invariant*!

Example 2.13.12 *A Special Rigid-Body Transitivity Equation — Holonomic Coordinates*. Continuing from the above examples, we show below that, for a rigid body rotating about a fixed point, the following transitivity/nonintegrability identity holds:

$$E_k(\boldsymbol{\omega}) \equiv d/dt(\partial\boldsymbol{\omega}/\partial v_k) - \partial\boldsymbol{\omega}/\partial q_k = \boldsymbol{\omega}\times(\partial\boldsymbol{\omega}/\partial v_k). \tag{a}$$

For such a system (with $k = 1, 2, 3$; and q_k = *angular Lagrangean coordinates*; e.g., Eulerian angles ϕ, θ, ψ) we will have

$$\begin{aligned}\boldsymbol{\omega} &= \boldsymbol{\omega}(q_k,\, dq_k/dt \equiv v_k) \equiv \boldsymbol{\omega}(q, v)\\ &= \textit{linear} \text{ and (for our system, also) } \textit{homogeneous} \text{ function of the } v_k\text{'s}\\ &= \sum (\partial\boldsymbol{\omega}/\partial v_k) v_k \text{ (by Euler's homogeneous function theorem)} \equiv \sum \boldsymbol{c}_k v_k,\end{aligned} \tag{b}$$

[definition of the $\boldsymbol{c}_k$'s; also, recalling (1.7.9a, b)] from which it follows that

$$d\boldsymbol{\theta} \equiv \boldsymbol{\omega}\, dt = \sum \boldsymbol{c}_k\, dq_k,$$

and since this is a scleronomic system

$$\delta\boldsymbol{\theta} = \sum \boldsymbol{c}_k\, \delta q_k; \tag{c}$$

and so the basis (quasi) vectors $\boldsymbol{c}_k \equiv \partial\boldsymbol{\omega}/\partial v_k$ (independent of the v_k's) can also be defined *symbolically* by

$$\boldsymbol{c}_k \equiv \partial\boldsymbol{\theta}/\partial q_k \equiv \partial(d\boldsymbol{\theta})/\partial(dq_k) \equiv \partial(\delta\boldsymbol{\theta})/\partial(\delta q_k). \tag{d}$$

Now, let us substitute the above representations into the earlier (inertial) transitivity equation

$$d(\delta\boldsymbol{\theta})/dt - \delta\boldsymbol{\omega} = \boldsymbol{\omega} \times \delta\boldsymbol{\theta}. \tag{e}$$

We find, successively,

(i) *Left* side [we assume that $(\delta q)^{\cdot} = \delta(dq/dt) \equiv \delta v$]:

$$\begin{aligned} d(\delta\boldsymbol{\theta})/dt - \delta\boldsymbol{\omega} &= d/dt\Big(\sum(\partial\boldsymbol{\omega}/\partial v_k)\delta q_k\Big) - \sum\,[(\partial\boldsymbol{\omega}/\partial q_k)\delta q_k + (\partial\boldsymbol{\omega}/\partial v_k)\delta v_k] \\ &= \cdots = \sum\,[d/dt(\partial\boldsymbol{\omega}/\partial v_k) - \partial\boldsymbol{\omega}/\partial q_k]\delta q_k = \sum\, E_k(\boldsymbol{\omega})\,\delta q_k. \end{aligned} \tag{f}$$

(ii) *Right* side:

$$\boldsymbol{\omega} \times \delta\boldsymbol{\theta} = \boldsymbol{\omega} \times \Big(\sum(\partial\boldsymbol{\omega}/\partial v_k)\delta q_k\Big) = \sum\,[\boldsymbol{\omega} \times (\partial\boldsymbol{\omega}/\partial v_k)]\delta q_k, \tag{g}$$

and therefore (since the δq_k are independent—but even if they were constrained that would only affect the equations of motion) equating the right sides of (f) and (g), the identity (a) follows.

In terms of the earlier $\boldsymbol{c}_k$ vectors, (a) reads

$$d\boldsymbol{c}_k/dt = \boldsymbol{\omega} \times \boldsymbol{c}_k + \partial\boldsymbol{\omega}/\partial q_k = \sum\,(\boldsymbol{c}_l \times \boldsymbol{c}_k + \partial\boldsymbol{c}_l/\partial q_k)v_l. \tag{h}$$

Finally, applying the first of (d) of ex. 2.13.11 to $\partial\boldsymbol{\omega}/\partial v_k$, and inserting the result into (a, h) produces the following interesting result:

$$E_{k,rel}(\boldsymbol{\omega}) \equiv \partial/\partial t(\partial\boldsymbol{\omega}/\partial v_k) - \partial\boldsymbol{\omega}/\partial q_k = \boldsymbol{0} \qquad \text{or} \qquad \partial\boldsymbol{c}_k/\partial t = \partial\boldsymbol{\omega}/\partial q_k. \tag{i}$$

Problem 2.13.5 Using the well-known kinematical result

$$d\boldsymbol{u}_k/dt = \boldsymbol{\omega} \times \boldsymbol{u}_k, \tag{a}$$

where $\{\boldsymbol{u}_k = \boldsymbol{u}_k(q)\}$ is, say, a *body-fixed* basis rotating with inertial angular velocity $\boldsymbol{\omega}$ (like the earlier $\boldsymbol{i}, \boldsymbol{j}, \boldsymbol{k}$), with the $\boldsymbol{\omega}$-representation (b) of the preceding example:

$$\boldsymbol{\omega} = \boldsymbol{\omega}(q_k, v_k) \equiv \boldsymbol{\omega}(q, v) = \sum\, \boldsymbol{c}_k v_k, \tag{b}$$

show that

$$\partial\boldsymbol{u}_k/\partial q_l = \boldsymbol{c}_l \times \boldsymbol{u}_k \qquad \text{[note subscript order]}, \tag{c}$$

i.e., (1.7.9c). Clearly, such a result holds for *any* vector $\boldsymbol{b} = \boldsymbol{b}(q)$ rotating with angular velocity $\boldsymbol{\omega}$: $\partial\boldsymbol{b}/\partial q_l = \boldsymbol{c}_l \times \boldsymbol{b} \equiv (\partial\boldsymbol{\omega}/\partial v_k) \times \boldsymbol{b}$. Also: (i) $d/dt(\partial\boldsymbol{b}/\partial q_l) = \partial/\partial q_l(d\boldsymbol{b}/dt)$, and (ii) $\partial\boldsymbol{b}/\partial v_l = \boldsymbol{0}$.

Problem 2.13.6 By direct substitution of the representations

$$d\boldsymbol{\theta} \equiv \boldsymbol{\omega}\, dt = \sum \boldsymbol{c}_k\, dq_k \qquad \text{and} \qquad \delta\boldsymbol{\theta} = \sum \boldsymbol{c}_k\, \delta q_k \tag{a}$$

into the earlier inertial rotational transitivity equation [ex. 2.13.11: eq. (b)].

$$d(\delta\boldsymbol{\theta}) - \delta(d\boldsymbol{\theta}) = d\boldsymbol{\theta} \times \delta\boldsymbol{\theta}, \tag{b}$$

and some simple differentiations, show that

$$\partial\boldsymbol{c}_k/\partial q_l - \partial\boldsymbol{c}_l/\partial q_k = \boldsymbol{c}_l \times \boldsymbol{c}_k. \tag{c}$$

This *nonintegrability* relation shows clearly that the basis $\{\boldsymbol{c}_k\}$ is nonholonomic (nongradient); whereas if $\boldsymbol{c}_k = \partial\boldsymbol{\theta}/\partial q_k$, then $d(\delta\boldsymbol{\theta}) = \delta(d\boldsymbol{\theta}) \Rightarrow \boldsymbol{\theta}$ = genuine angular coordinate. Simplify (c) if the $\{\boldsymbol{c}_k\}$ are an *orthogonal–unit–dextral* basis (see also Brunk, 1981).

Example 2.13.13 *A Special Rigid-Body Transitivity Equation—Nonholonomic Coordinates*. Continuing from ex. 2.13.11, let us substitute the (fully nonholonomic) representations

$$\boldsymbol{\omega} = \sum(\partial\boldsymbol{\omega}/\partial\omega_k)\omega_k \equiv \sum \boldsymbol{\varepsilon}_k\omega_k = \boldsymbol{\omega}(q,\omega), \qquad d\boldsymbol{\theta} = \sum \boldsymbol{\varepsilon}_k\, d\theta_k, \qquad \delta\boldsymbol{\theta} = \sum \boldsymbol{\varepsilon}_k\, \delta\theta_k, \tag{a}$$

where, as usual, θ_k = *quasi coordinates*, $\omega_k \equiv d\theta_k/dt$ = *quasi velocities*, and

$$\boldsymbol{\varepsilon}_k \equiv \partial\boldsymbol{\omega}/\partial\omega_k \equiv \partial(d\boldsymbol{\theta})/\partial(d\theta_k) \equiv \partial(\delta\boldsymbol{\theta})/\partial(\delta\theta_k) \equiv \partial\boldsymbol{\theta}/\partial\theta_k : \textit{nonholonomic}\ \text{basis}, \tag{b}$$

into the fundamental inertial rotational transitivity equation

$$d(\delta\boldsymbol{\theta})/dt - \delta\boldsymbol{\omega} = \boldsymbol{\omega} \times \delta\boldsymbol{\theta}. \tag{c}$$

We find, successively,

(i) *Left* side:

$$\begin{aligned} d(\delta\boldsymbol{\theta})/dt - \delta\boldsymbol{\omega} &= \sum \left[(\partial\boldsymbol{\omega}/\partial\omega_k)^{\cdot}\,\delta\theta_k + (\partial\boldsymbol{\omega}/\partial\omega_k)(\delta\theta_k)^{\cdot}\right] \\ &\quad - \sum \left[(\partial\boldsymbol{\omega}/\partial q_k)\,\delta q_k + (\partial\boldsymbol{\omega}/\partial\omega_k)\,\delta\omega_k\right] \end{aligned}$$

[and setting $\delta q_k = \sum A_{kl}\,\delta\theta_l \equiv \sum (\partial v_k/\partial\omega_l)\,\delta\theta_l$ (definition of the A_{kl})]

$$= \sum \left[(\partial\boldsymbol{\omega}/\partial\omega_k)^{\cdot} - \sum A_{lk}(\partial\boldsymbol{\omega}/\partial q_l)\right]\delta\theta_k + \sum (\partial\boldsymbol{\omega}/\partial\omega_l)[(\delta\theta_l)^{\cdot} - \delta\omega_l]$$

[recalling the $\partial\ldots/\partial\theta_k$ definition (2.9.30a); and setting (as in pr. 2.10.5)

$$(\delta\theta_l)^{\cdot} - \delta\omega_l = \sum h^l_{\ k}\,\delta\theta_k \qquad \text{(definition of the } h^l_{\ k})]$$

$$\begin{aligned} &\equiv \sum \left[(\partial\boldsymbol{\omega}/\partial\omega_k)^{\cdot} - \partial\boldsymbol{\omega}/\partial\theta_k\right]\delta\theta_k + \sum\sum (\partial\boldsymbol{\omega}/\partial\omega_l)h^l_{\ k}\,\delta\theta_k \\ &\equiv \sum \left[E_k{}^*(\boldsymbol{\omega}) + \sum h^l_{\ k}(\partial\boldsymbol{\omega}/\partial\omega_l)\right]\delta\theta_k. \end{aligned} \tag{d}$$

(ii) *Right* side:

$$\boldsymbol{\omega} \times \delta\boldsymbol{\theta} = \boldsymbol{\omega} \times \left(\sum (\partial\boldsymbol{\omega}/\partial\omega_k)\delta\theta_k\right) = \sum \left[\boldsymbol{\omega} \times (\partial\boldsymbol{\omega}/\partial\omega_k)\right] \delta\theta_k; \tag{e}$$

and, therefore, equating the right sides of (d) and (e), we obtain the identity

$$d/dt(\partial\boldsymbol{\omega}/\partial\omega_k) - \partial\boldsymbol{\omega}/\partial\theta_k + \sum h^l{}_k(\partial\boldsymbol{\omega}/\partial\omega_l) = \boldsymbol{\omega} \times (\partial\boldsymbol{\omega}/\partial\omega_k), \tag{f}$$

or, in terms of the quasi vectors $\boldsymbol{\varepsilon}_k = \boldsymbol{\varepsilon}_k(q)$,

$$d\boldsymbol{\varepsilon}_k/dt - \partial\boldsymbol{\omega}/\partial\theta_k = \boldsymbol{\omega} \times (\partial\boldsymbol{\omega}/\partial\omega_k) - \sum h^l{}_k\boldsymbol{\varepsilon}_l. \tag{g}$$

Finally, since $d\boldsymbol{\varepsilon}_k/dt = \partial\boldsymbol{\varepsilon}_k/\partial t + \boldsymbol{\omega} \times \boldsymbol{\varepsilon}_k$, (g) takes the *body-axes* form:

$$\partial\boldsymbol{\varepsilon}_k/\partial t - \partial\boldsymbol{\omega}/\partial\theta_k \equiv \partial/\partial t(\partial\boldsymbol{\omega}/\partial\dot{\theta}_k) - \partial\boldsymbol{\omega}/\partial\theta_k \equiv E^*_{k,rel}(\boldsymbol{\omega}) = -\sum h^l_k\boldsymbol{\varepsilon}_l, \tag{h}$$

which is a special case of the transitivity equation (2.10.25).

[Here too, we point out the differences between the *notation*:

$$\partial\boldsymbol{\omega}(q,\omega)/\partial\theta_l \equiv \sum \left[\partial\boldsymbol{\omega}(q,\omega)/\partial q_k\right](\partial v_k/\partial\omega_l), \tag{i}$$

and the vector *transformation* (by chain rule):

$$\partial\boldsymbol{\omega}(q,\omega)/\partial\omega_l = \sum \left[\partial\boldsymbol{\omega}(q,v)/\partial v_k\right](\partial v_k/\partial\omega_l) \qquad \text{or} \qquad \boldsymbol{\varepsilon}_l = \sum A_{kl}\,\boldsymbol{e}_k.] \tag{j}$$

See also Papastavridis, 1992.

Problem 2.13.7 By direct substitution of the representations

$$d\boldsymbol{\theta} \equiv \boldsymbol{\omega}\,dt = \sum \boldsymbol{\varepsilon}_k\,d\theta_k \qquad \text{and} \qquad \delta\boldsymbol{\theta} = \sum \boldsymbol{\varepsilon}_k\,\delta\theta_k \tag{a}$$

into the earlier inertial rotational transitivity equation [ex. 2.13.11, eq. (b)]

$$d(\delta\boldsymbol{\theta}) - \delta(d\boldsymbol{\theta}) = d\boldsymbol{\theta} \times \delta\boldsymbol{\theta} \tag{b}$$

and some simple differentiations, show that

$$\partial\boldsymbol{\varepsilon}_k/\partial\theta_l - \partial\boldsymbol{\varepsilon}_l/\partial\theta_k + \sum \eta^b{}_{kl}\,\boldsymbol{\varepsilon}_b = \boldsymbol{\varepsilon}_l \times \boldsymbol{\varepsilon}_k, \tag{c}$$

where these special Hamel coefficients $\eta^b{}_{kl}$ are defined by $d(\delta\theta_b) - \delta(d\theta_b) = \sum\sum \eta^b{}_{kl}\,d\theta_l\,\delta\theta_k$.

Example 2.13.14 *Angular Acceleration.* Let us consider *intermediate* axes $\blacklozenge\!-\!\boldsymbol{u}_k$ rotating with inertial angular velocity $\boldsymbol{\Omega} = \sum \Omega_k\,\boldsymbol{u}_k$. If the inertial angular velocity of a rigid body, resolved along these axes, is $\boldsymbol{\omega} = \sum \omega_k\,\boldsymbol{u}_k$ then its inertial angular *acceleration* equals

$$\boldsymbol{\alpha} \equiv d\boldsymbol{\omega}/dt = \partial\boldsymbol{\omega}/\partial t + \boldsymbol{\Omega} \times \boldsymbol{\omega} = \partial\boldsymbol{\omega}/\partial t - \boldsymbol{\omega}_o \times \boldsymbol{\omega}, \tag{a}$$

where $\partial\boldsymbol{\omega}/\partial t = \sum(d\omega_k/dt)\boldsymbol{u}_k$, and $\boldsymbol{\omega}_o \equiv \boldsymbol{\omega} - \boldsymbol{\Omega}$ = angular velocity of body relative to the *intermediate axes*.

Applying this result to the earlier case of *semimobile* axes $\blacklozenge\text{–}\boldsymbol{i}'\boldsymbol{j}'\boldsymbol{k}' \equiv \blacklozenge\text{–}\boldsymbol{u}_n\boldsymbol{u}_{n'}\boldsymbol{k}$ (ex. 2.13.9) where

$$\boldsymbol{\omega} = (\omega_\theta)\boldsymbol{u}_n + (\omega_\phi \sin\theta)\boldsymbol{u}_{n'} + (\omega_\psi + \omega_\phi \cos\theta)\boldsymbol{k} = \boldsymbol{\Omega} + \omega_\psi \boldsymbol{k} = \boldsymbol{\Omega} + \boldsymbol{\omega}_o, \tag{b}$$

[with the customary notations: $\omega_\phi \equiv d\phi/dt,\ \omega_\theta \equiv d\theta/dt,\ \omega_\psi \equiv d\psi/dt$]

that is, $\boldsymbol{\omega}_o = \omega_\psi \boldsymbol{k}$, we find, after some straightforward calculations,

$$\boldsymbol{\alpha} \equiv \alpha_n \boldsymbol{u}_n + \alpha_{n'}\boldsymbol{u}_{n'} + \alpha_k \boldsymbol{k}, \tag{c}$$

where

$$\begin{aligned}
\alpha_n &\equiv d\omega_\theta/dt + \omega_\phi\, \omega_\psi \sin\theta,\\
\alpha_{n'} &\equiv (d\omega_\phi/dt)\sin\theta + \omega_\phi\, \omega_\theta \cos\theta - \omega_\theta\, \omega_\psi,\\
\alpha_k &\equiv (d\omega_\phi/dt)\cos\theta + d\omega_\psi/dt - \omega_\phi\, \omega_\theta \sin\theta.
\end{aligned} \tag{d}$$

Let the reader repeat the above for the *semifixed* axes $\blacklozenge\text{–}\boldsymbol{u}_n\boldsymbol{u}_N\boldsymbol{K}$, where

$$\begin{aligned}
\boldsymbol{\omega} &= (\omega_\phi \boldsymbol{K} + \omega_\theta \boldsymbol{u}_n) + \omega_\psi \boldsymbol{k} = (\omega_\phi \boldsymbol{K} + \omega_\theta \boldsymbol{u}_n) + \omega_\psi(-\sin\theta\, \boldsymbol{u}_N + \cos\theta \boldsymbol{K})\\
&= (\omega_\theta)\boldsymbol{u}_n + (-\omega_\psi \sin\theta)\boldsymbol{u}_N + (\omega_\phi + \omega_\psi \cos\theta)\boldsymbol{K}\\
&\equiv \omega_\phi \boldsymbol{K} + \boldsymbol{\omega}_o \equiv \boldsymbol{\Omega} + \boldsymbol{\omega}_o.
\end{aligned} \tag{e}$$

[For *matrix* forms of rigid-body accelerations, see (1.11.9a ff.); also Lur'e (1968, pp. 68–72).]

3

Kinetics of Constrained Systems

(i.e., Lagrangean Kinetics)

Where we may appear to have rashly and needlessly interfered with methods and systems of proof in the present day generally accepted, we take the position of Restorers, and not of Innovators.

(Thomson and Tait, 1867–1912, Preface, p. vi)

[A] work of which the *unity of method* is one of the most striking characteristics. . . . That which most distinguishes the plan of this treatise from the usual type is the *direct application of the general principle* to each particular case.

(Gibbs, 1879, 3rd footnote, emphasis added; the work/treatise Gibbs refers to is Lagrange's *Mećanique Analytique*, and the "general principle" is *Lagrange's Principle* (§3.2))

[T]he author . . . again and again . . . experienced the extraordinary elation of mind which accompanies a preoccupation with the basic principles and methods of analytical mechanics.

(Lanczos, 1970, p. vii)

3.1 INTRODUCTION

This is the key chapter of the entire book; and since it is based on chapter 2, it should be read *after* the latter. We begin with a detailed coverage of the *two* fundamental principles, or pillars, of Lagrangean analytical mechanics:

(i) The *Principle of Lagrange* (and its *velocity* form known as *The Central Equation*); and
(ii) The *Principle of Relaxation of the Constraints*.

From these two, with the help of *virtual displacements*, and so on (§2.5 ff.), we, subsequently, obtain all possible *kinetic energy–based* (*Lagrangean*) and *acceleration energy–based* (*Appellian*) *equations of motion* of holonomic and/or Pfaffian (possibly nonholonomic) systems; in holonomic and/or nonholonomic variables, with/without constraint reactions; such as the equations of Routh–Voss, Maggi, Hamel, and Appell, to name the most important.

Next, applying standard mathematical transformations to these equations, we obtain the *theorem of work–energy* in its various forms; that is, in holonomic and/or nonholonomic variables, with/without constraint reactions, and so on. This concludes the first, general, part of the chapter (§3.1–12). The second and third parts apply the previous Lagrangean and Appellian methods/principles/equations, respectively, to the *rigid body* (§3.13–15) and to *noninertial frames of reference* (*or moving axes*) (§3.16). The chapter ends with (i) a concise discussion of the *servo*-, or *control*, constraints of Beghin–Appell (§3.17); and (ii) two Appendices on the historical evolution of (some of) the above principles/equations of motion, and their relations to virtual displacements and the confusion-laden principle of d'Alembert–Lagrange.

As with the previous chapters, a large number of completely solved examples and problems with their answers and/or helpful hints, many of them kinetic continuations of corresponding kinematical examples and problems of chapter 2, have been appropriately placed throughout this chapter.

For complementary reading, we recommend (alphabetically): Butenin (1971), Dobronravov (1970, 1976), Gantmacher (1966/1970), Hamel (1912/1922(b), 1949), Kilchevskii (1977), Lur'e (1961/1968/2002), Mei (1985, 1987(a), 1991), Mei and Liu (1987), Neimark and Fufaev (1967/1972), Nordheim (1927), Pars (1965), Poliahov et al. (1985), Prange (1935), Synge (1960). As with chapter 2, we are unaware of any other single exposition, in English, comparable to this one in the range of topics covered. Only Hamel (1949), Mei et al. (1991) and Neimark and Fufaev (1967/1972) cover major portions of the material treated here.

3.2 THE PRINCIPLE OF LAGRANGE (LP)

We begin with a finite mechanical system S consisting of particles $\{P\}$; each of mass dm, inertial acceleration $\boldsymbol{a} \equiv d\boldsymbol{v}/dt \equiv d^2\boldsymbol{r}/dt^2$, and each obeying the Newton–Euler equation of motion (§1.4):

$$dm\,\boldsymbol{a} = d\boldsymbol{f}, \tag{3.2.1}$$

where $d\boldsymbol{f}$ = *total force acting on P*. As explained in chapter 2, the *continuum* notation for particle quantities, employed here, simplifies matters, since it allows us to reserve all indices (to be introduced below) for *system* quantities.

The Force Classification

Now, and here we start parting company with the Newton–Euler mechanics, we decompose $d\boldsymbol{f}$ into *two* parts: (i) a total *physical*, or *impressed*, *force* $d\boldsymbol{F}$, and (ii) a total *constraint force*, or *constraint reaction*, $d\boldsymbol{R}$:

$$d\boldsymbol{f} = d\boldsymbol{F} + d\boldsymbol{R}. \tag{3.2.2}$$

Let us elaborate on these fundamental concepts:

(i) By constraint reactions, on our particle P, we shall understand (external and/or internal) forces, due solely to the (external and/or internal) geometrical and/or kinematical constitution of the system S; that is, forces caused exclusively by the prescribed (external and/or internal) constraints of S, and whose raison d'être is the preservation of these constraints. As a result, such forces are (a) *passive* (i.e., they appear only when absolutely needed; see below), and (b) expressible only through these constraints (since, by their definition, they contain neither physical constants nor material functions/coefficients). Therefore, these reactions become fully known only *after* the motion of S (under possible additional, nonconstraint forces and initial conditions) has been found. Examples of constraint reactions are: inextensible cable tensions, internal forces in a rigid body, normal forces among contacting (rolling/sliding/pivoting/nonpivoting) rigid bodies, and rolling (or static) friction.

(Generally, constraints and their reactions are classified, on the basis of the precise physical manner by which they are maintained, as *passive*, or as *active*. Except §3.17, where the latter are elaborated, this chapter deals only with *passive constraints/reactions*.)

(ii) By physical or impressed forces, on our particle P, we shall understand *all other* (*external and/or internal, nonconstraint*) *forces* acting on it, which means that [since the *total force on* P is determined through *variables describing the geometrical/kinematical and physical state of the rest of the matter surrounding that particle* (recalling §1.4)] the impressed forces depend, *at least partially*, on physical, or material, constants, unrelated to the constraints, and which can be determined only experimentally. Examples of such constants are: mass, gravitational constant, elastic moduli, viscous and/or dry friction coefficients, readings of the scale of a barometer or manometer; and examples of physical/impressed forces are gravity (weight), elastic (spring) forces, viscous damping forces, steam pressure, slipping (or sliding, or kinetic) friction [see remark (iii) below].

In other words, the impressed forces are forces expressed by material, or *constitutive*, equations, that contain those physical constants, and are assumed to be valid for any motion of the system; physical means *physically* (*functionally*) *given*—it does not mean that the values of these forces are necessarily known ahead of time!

In sum: *Impressed forces are given by constitutive equations, while reactions are not; but, in general, both these forces require, for their complete determination, knowledge of the subsequent motion of the system* (which, in turn, requires solution of an initial-value problem; namely, that of its equations of motion plus initial conditions).

Impressed forces are also, variously, referred to as (*directly*) *applied*, *active*, *acting*, *assigned*, *given*, *known* (where the last two terms have the meaning described above—see also remarks (iii) and (iv) below). In addition, the great physicist Planck (1928, pp. 101–103) calls our impressed forces "*treibende*" (driving, or propelling), while the highly instructive Langner (1997–1998, p. 49) proposes the rare but conceptually useful terms "*urgente*" (urging) for the impressed forces, and "*cogente*" (cogent, convincing) for the constraint forces. We follow Hamel (1949, pp. 65, 82, 517, 551), who calls impressed forces "*physikalisch gegebene*" (physically given) or "*eingeprägte*"; also Sommerfeld (1964, pp. 53–54), who calls them "forces of physical origin."

REMARKS

(i) From the viewpoint of continuum mechanics, practically all forces are physical (i.e., impressed); for example, an inextensible cable tension can be viewed as the limit of the tension of an elastic cable, or rubber band, whose modulus is getting higher and higher ($\rightarrow \infty$); and a rigid body can be viewed as a very stiff, practically strainless, deformable body. But there is also the exactly opposite viewpoint: kinetic and statistical theories of matter explain macroscopic phenomena, such as friction, viscosity, rust, by the motion of large numbers of smooth molecules, atoms, and so on. Their 19th century forerunners (Kelvin, Helmholtz, et al.) even tried to reduce the internal potential energy of bodies to the kinetic energy of a number of spinning "molecular gyrostats" strategically located inside them—see, for example, Gray (1918, chap. 8). And there is, of course, general relativity, which, continuing traditions of forceless mechanics, initiated by Hertz et al., set out to geometrize gravity completely; that is, *replace tactile mechanics by a visual mechanics*, albeit in a four-dimensional "space." For the modest purposes of macroscopic earthly mechanics, the impressed/constraint force division is both logically consistent and practically useful (economical), and so we uphold it throughout this book.

(ii) The decomposition (3.2.2), what Hamel (1949, p. 218) calls "d'Alembertsche Ansatz" ($\sim$ initial proposition), is the hallmark of analytical mechanics. Expressing system accelerations as partial/total derivatives of kinetic energies with respect to system coordinates, velocities, and time (§3.3) is a welcome but *secondary* characteristic of Lagrangean analytical mechanics; the primary one is the decomposition (3.2.2) and its consequences with regard to the equations of motion. By contrast, the Newton–Euler mechanics decomposes $d\boldsymbol{f}$ into (a) a total *external* force $d\boldsymbol{f}_e$ (= force originating, even partially, from *outside* of our system S), and (b) a total *internal*, or *mutual*, force $d\boldsymbol{f}_i$ (= force due *exclusively* to the rest of S, on its generic particle P):

$$d\boldsymbol{f} = d\boldsymbol{f}_e + d\boldsymbol{f}_i. \tag{3.2.3}$$

The connection between (3.2.2) and (3.2.3) is easily seen by decomposing $d\boldsymbol{F}(d\boldsymbol{R})$ into an external part $d\boldsymbol{F}_e(d\boldsymbol{R}_e)$ and an internal part $d\boldsymbol{F}_i(d\boldsymbol{R}_i)$, and then rearranging à la (3.2.3); that is, successively,

$$\begin{aligned} d\boldsymbol{f} &= d\boldsymbol{F} + d\boldsymbol{R} = (d\boldsymbol{F}_e + d\boldsymbol{F}_i) + (d\boldsymbol{R}_e + d\boldsymbol{R}_i) \\ &= (d\boldsymbol{F}_e + d\boldsymbol{R}_e) + (d\boldsymbol{F}_i + d\boldsymbol{R}_i) \equiv d\boldsymbol{f}_e + d\boldsymbol{f}_i, \end{aligned} \tag{3.2.4}$$

where

$$d\boldsymbol{f}_e \equiv d\boldsymbol{F}_e + d\boldsymbol{R}_e \qquad \text{and} \qquad d\boldsymbol{f}_i \equiv d\boldsymbol{F}_i + d\boldsymbol{R}_i. \tag{3.2.4a}$$

The decompositions (3.2.2) and (3.2.3), although physically different, may, for some special systems, coincide. For example, in a *free* (i.e., *externally unconstrained*) *rigid body* all *external forces* are *impressed* (i.e., *external reactions* = 0), and all *internal forces* are *reactions* (i.e., *internal impressed forces* = 0). The coincidence of external forces with impressed forces and of internal forces with reactions in this popular and well-known system is, probably, responsible for the frequent confusion and error accompanying d'Alembert's principle (detailed below), even in contemporary dynamics expositions.

(iii) *Rolling* friction should be counted as a *constraint reaction* because it is expressed by a geometrical/kinematical condition, not by a constitutive equation; while *slipping friction* should be counted as an *impressed force* because, according to the well-known Coulomb–Morin friction "law," it depends both on the contact condition (through the normal force, which is in both cases a constraint reaction) *and* on the physical properties of the contacting surfaces (through the kinetic friction coefficient). (That slipping friction is governed by a physical *inequality* does not affect our force classification.) The above apply to the (possible) rolling/slipping and pivoting/non-pivoting *couples*.

The difference between rolling and slipping friction, from the viewpoint of analytical mechanics (principle of virtual work, etc.), has been a source of considerable confusion and error, even among the better authors on the subject.

(iv) The force decomposition (3.2.2) is completely analogous to that occurring in continuum mechanics. For instance, in an incompressible (i.e., internally constrained) elastic solid, the total stress (force) consists of a "hydrostatic pressure" or "reaction stress" term (constraint reaction), plus an "elastic stress" term (impressed force) expressed by a constitutive equation/function of the elastic moduli (material constants) and the strains (motion → deformation), and it is assumed to be valid for any motion of that system. In general, the values of the stresses, both "incompressible/pressure" and "elastic" parts, for specific initial and boundary conditions, are found after solving that particular "initial- and boundary-value problem"; namely, the equations of motion of the solid plus its initial and boundary conditions.

HISTORICAL

The fundamental decomposition (3.2.2) seems to have been first given by Delaunay (1856); see, for example (alphabetically): Rumyantsev (1990, p. 268), Stäckel (1905, p. 450, footnote 11a); also Hamel (1912, pp. 81–82, 301–302, 457–458, 469–470), Heun [1902 (a, d)], Pars (1953, pp. 447–448), Webster (1912, pp. 41–42, 63–65).

Example 3.2.1 *Let us Find the Most Important Internal/External and Impressed/Constraint Forces in a Diesel-Powered Electric Locomotive, Rolling on Rails.* These are as follows:

(i) *Gravity* and *air resistance* (*drag*) are both *external* (their cause lies outside the system locomotive), and *impressed* (both depend partially on the physical constants: $g =$ *acceleration of gravity* and $\rho =$ *air density*, respectively).

(ii) *Pressure of burnt diesel fuel* is *internal* (it originates within the engine's cylinders) and *impressed* (depends on the gas temperature, density, etc.).

(iii) Forces on *connecting rods* and other moving parts of the engine:

(a) If these bodies are considered *rigid*, the forces are *internal reactions*;
(b) If they are considered *flexible*, say *elastic*, these forces are *internal* but *impressed* (and to calculate them we must know their elastic moduli).

(iv) Forces between *axles and their wheel bearings* are *internal* (for obvious reasons) and *impressed* (due to the relative motion among them — no constraints).

(v) Friction forces between *wheels and rail* are *external* (caused, partially, by an external body, the rail) and *reactions* (due to the slippingless rolling of wheels), and this holds for both their tangential (friction) and normal components; however, in the case of slipping (skidding), the friction changes to an *external impressed* force (it depends, partially, on the wheel–rail friction coefficient).

Example 3.2.2 *Let us Identify and Classify the Key Forces on a Person Walking up a Rough Hilly Road.* The external forces needed to overcome the (also external) forces of gravity and air resistance are those generated by the road friction. The latter are reactions, since there is no relative motion (i.e., constraint) between the walker's shoes and the road surface.

Arguments of the Forces

In classical (Newtonian) mechanics, the force $d\boldsymbol{f}$ on a particle P, of a system S, can depend, at most, on its position, velocity, and time; and on those of other particles of S, or even outside of S; and also, on material functions/coefficients. But, as an *independent constitutive equation* (i.e., not by some artificial control law), $d\boldsymbol{f}$ *cannot* depend on the acceleration $\boldsymbol{a}$ of P (and/or its higher time derivatives). This, however, does not preclude the occurrence of such a dependence by *elimination*: in the course of solving the equations of motion, and so on, of a problem, it is possible to relate functionally *a* force with *an* acceleration; but that is a *mathematical* coupling, not an independent physical one.

[Pars (1965, pp. 11–12; also 24–25) has shown that if df depended on $\boldsymbol{a}$, then the *initial state* of P, that is, its initial position and velocity, would not determine its future uniquely; see also Rosenberg (1977, pp. 10–17); and Hamel (1949, p. 49). But in other areas of classical physics, for instance electrodynamics (e.g., radiation damping), such a non-Newtonian explicit $\boldsymbol{a}$-dependence does not create inconsistencies.]

Lagrange's Principle

Dotting each of (3.2.1) and (3.2.2) with the corresponding particle's inertial virtual displacement $\delta\boldsymbol{r}$ (§2.5 ff.) and then summing the resulting equations over all system particles, for a fixed generic time, we obtain

$$\mathcal{S}\, dm\,\boldsymbol{a}\cdot\delta\boldsymbol{r} = \mathcal{S}\, d\boldsymbol{F}\cdot\delta\boldsymbol{r} + \mathcal{S}\, d\boldsymbol{R}\cdot\delta\boldsymbol{r}, \tag{3.2.5}$$

or, rearranging,

$$\mathcal{S}\,(dm\,\boldsymbol{a} - d\boldsymbol{F})\cdot\delta\boldsymbol{r} + \mathcal{S}\,(-d\boldsymbol{R})\cdot\delta\boldsymbol{r} = 0; \tag{3.2.6}$$

where [recall (§2.2.7 ff.)] the material sum $\mathcal{S}(\ldots)$ is to be understood as a Stieltjes' integral extending over all the *continuously and/or discretely* distributed system particles and their geometric/kinematic/inertial/kinetic variables.

Equations (3.2.5, 6) do not contain anything physically new; that is, they result from (3.2.1, 2) by purely mathematical transformations. To make further progress towards the derivation of reactionless equations of motion, one of the key objectives of analytical mechanics, we now *postulate* that (for bilateral, or equality, or reversible, constraints)

$$-\delta' W_R \equiv \mathcal{S}\,(-d\boldsymbol{R})\cdot\delta\boldsymbol{r} \equiv -\mathcal{S}\, d\boldsymbol{R}\cdot\delta\boldsymbol{r} = 0; \tag{3.2.7}$$

in words: at each instant, the (*first-order*) *total virtual work* of the system of (external and internal) "lost" (or forlorn, or accessory) forces $\{-d\boldsymbol{R}\}$, $-\delta' W_R$, *vanishes*. Then, equations (3.2.5, 6) immediately reduce to the new and nontrivial *principle of d'Alembert in Lagrange's form*, or, simply and more accurately, *principle of Lagrange* (*LP*) for such constraints:

$$\mathcal{S}\, dm\,\boldsymbol{a}\cdot\delta\boldsymbol{r} = \mathcal{S}\, d\boldsymbol{F}\cdot\delta\boldsymbol{r} \qquad \text{or} \qquad \mathcal{S}\,(dm\,\boldsymbol{a} - d\boldsymbol{F})\cdot\delta\boldsymbol{r} = 0; \tag{3.2.8}$$

what Lagrange calls "la formule générale de la Dynamique pour le mouvement d'un système quelconque de corps."

This fundamental differential variational equation states that *during the motion of a constrained system whose reactions, at each instant, satisfy the physical postulate* (*3.2.7*), *the total* (*first-order*) *virtual work of* (*the negative of*) *its "inertial forces"* $-\{-dm\,\boldsymbol{a}\} = \{dm\,\boldsymbol{a}\}$,

$$\delta I \equiv \mathcal{S}\, dm\,\boldsymbol{a}\cdot\delta\boldsymbol{r}, \tag{3.2.9}$$

equals the *similar virtual work of its* (*external and internal*) *impressed forces* $\{d\boldsymbol{F}\}$,

$$\delta' W \equiv \mathcal{S}\, d\boldsymbol{F}\cdot\delta\boldsymbol{r}; \tag{3.2.10}$$

that is,

$$\delta' W_R = 0 \;\Rightarrow\; \delta I = \delta' W. \tag{3.2.11}$$

The entire Lagrangean kinetics is based on LP, equations (3.2.7–11). Let us, therefore, examine them closely.

• Another, equivalent, formulation of the above is the following: during the motion, the totality of the lost forces $\{-d\boldsymbol{R} = d\boldsymbol{F} - dm\,\boldsymbol{a}\}$ are, at each instant, in *equilibrium*; not in the elementary sense of zero force and moment, but in that of the virtual work equation (3.2.7) (see also chap. 3, appendix 2).

• Here, we must stress that the above equations, and associated virtual work conception of equilibrium, are the *contemporary* formulation and interpretation of d'Alembert's principle; and they are due, primarily, to Heun and Hamel (early 20th century). As such, they bear practically zero resemblance to the original *workless* exposition of d'Alembert (1743). The latter postulated what, again in contemporary terms, amounts to equilibrium of the $\{-d\boldsymbol{R}\}$ in the elementary (i.e., Newton–Euler) sense of *zero resultant force and moment*:

$$\begin{aligned} S(-d\boldsymbol{R}) = \boldsymbol{0} \;&\Rightarrow\; S(dm\,\boldsymbol{a} - d\boldsymbol{F}) = \boldsymbol{0},\\ S\,\boldsymbol{r}\times(-d\boldsymbol{R}) = \boldsymbol{0} \;&\Rightarrow\; S\,\boldsymbol{r}\times(dm\,\boldsymbol{a} - d\boldsymbol{F}) = \boldsymbol{0}. \end{aligned}\tag{3.2.12}$$

It is not hard to see that for a *rigid* body (what d'Alembert dealt with) (3.2.7) specializes to (3.2.12). Indeed, substituting into (3.2.7) the most general rigid virtual displacement, $\delta\boldsymbol{r} = \delta\boldsymbol{r}_\blacklozenge + \delta\boldsymbol{\theta}\times(\boldsymbol{r} - \boldsymbol{r}_\blacklozenge)$ [where $\blacklozenge$ = *generic body point*, and $\delta\boldsymbol{\theta}$ = (first-order/elementary) *virtual rigid body rotation* (recalling §1.10 ff.)] and simple vector algebra, we obtain, successively,

$$\begin{aligned} -\delta' W_R &= S(-d\boldsymbol{R})\cdot[\delta\boldsymbol{r}_\blacklozenge + \delta\boldsymbol{\theta}\times(\boldsymbol{r} - \boldsymbol{r}_\blacklozenge)]\\ &= \Big[S(-d\boldsymbol{R})\Big]\cdot\delta\boldsymbol{r}_\blacklozenge + \Big[S(\boldsymbol{r} - \boldsymbol{r}_\blacklozenge)\times(-d\boldsymbol{R})\Big]\cdot\delta\boldsymbol{\theta}\\ &\equiv (-\boldsymbol{R})\cdot\delta\boldsymbol{r}_\blacklozenge + \boldsymbol{M}_\blacklozenge(-\boldsymbol{R})\cdot\delta\boldsymbol{\theta} = 0, \end{aligned}\tag{3.2.13}$$

from which, since $\delta\boldsymbol{r}_\blacklozenge$ and $\delta\boldsymbol{\theta}$ are arbitrary, (3.2.12) follows [and if $S(-d\boldsymbol{R}) = \boldsymbol{0}$, then $\boldsymbol{M}_\blacklozenge(-\boldsymbol{R}) = \boldsymbol{M}_{\text{origin}}(-\boldsymbol{R})$]. If, further, the rigid body is *free*, that is, unconstrained, then, as explained earlier, *all its external* (*internal*) *forces are impressed* (*reactions*) (i.e., $\{d\boldsymbol{f}_e\} = \{d\boldsymbol{F}\}$ and $\{d\boldsymbol{f}_i\} = \{d\boldsymbol{R}\}$), and the above lead to the Eulerian principles of linear and angular momentum (recall §1.8.18):

$$S\,d\boldsymbol{f}_e = S\,dm\,\boldsymbol{a} \qquad \text{and} \qquad S(\boldsymbol{r} - \boldsymbol{r}_\blacklozenge)\times d\boldsymbol{f}_e = S(\boldsymbol{r} - \boldsymbol{r}_\blacklozenge)\times dm\,\boldsymbol{a}. \tag{3.2.14}$$

It follows that, in studying the statics of free rigid bodies via virtual work, we only need include their external = impressed forces; and that is why here the methods of Newton–Euler and d'Alembert–Lagrange coincide and supply conditions that are both necessary and sufficient for equilibrium (see also Hamel, 1949, pp. 80–83).

This preoccupation of d'Alembert, and many others since him, with the special case of (systems of) rigid bodies and elementary *vector* equilibrium (3.2.12), has diverted attention from the far more general *scalar* virtual work equilibrium (3.2.7), which constitutes the essence of LP.

• In LP it is the *sum* $\delta' W_R \equiv S\,d\boldsymbol{R}\cdot\delta\boldsymbol{r}$ that vanishes, and not necessarily each of its terms $d\boldsymbol{R}\cdot\delta\boldsymbol{r}$ separately; although this latter may happen in special cases.

For example, as explained above, in a free rigid body (3.2.7) reduces to $\delta' W_R \to (\delta' W)_{\text{internal forces}} = 0$, although individually $d\boldsymbol{f}_i \cdot \delta\boldsymbol{r}$ may not vanish.

• While the $dm\,\boldsymbol{a}$ are present wherever a mass is accelerated, the $d\boldsymbol{F}$ may act only at a few system particles.

• In general, $\delta' W_R$ and $\delta' W$ are *not* the exact (or perfect, or total) virtual differentials of some system "work/force functions" W_R and W, respectively; that is, in general, they are *quasi variables*, and that is the purpose of the accented delta δ' (recall §2.9 ff.). The same holds for δI, but here, for convenience, we will make an exception and leave it unaccented.

• For *unilateral* (or *inequality*, or *irreversible*) constraints, LP is enlarged from (3.2.7–11) to

$$\mathsf{S}\, d\boldsymbol{R} \cdot \delta\boldsymbol{r} = \mathsf{S}\,(dm\,\boldsymbol{a} - d\boldsymbol{F}) \cdot \delta\boldsymbol{r} \geq 0 \;\;\Rightarrow\;\; \mathsf{S}\, dm\,\boldsymbol{a} \cdot \delta\boldsymbol{r} \geq \mathsf{S}\, d\boldsymbol{F} \cdot \delta\boldsymbol{r}, \quad (3.2.15)$$

or

$$\delta' W_R \geq 0 \;\;\Rightarrow\;\; \delta I \geq \delta' W. \quad (3.2.15a)$$

For example, in the case of a block resting under its own weight on a fixed horizontal table, the sole *impressed* force on the block, gravity, cannot perform *positive* virtual work; while the normal table *reaction* cannot perform *negative* virtual work: $\delta' W_R = -\delta' W \geq 0$.

Lagrange's Principle as a Constitutive Postulate

It must be stressed that LP, eqs. (3.2.7–11), is what is known in continuum mechanics as a *constitutive postulate* for the *nonphysical* part of the $d\boldsymbol{f}$'s, namely, the constraint reactions $\{d\boldsymbol{R}\}$; like Hooke's law in elasticity, or the Navier–Stokes law in fluid mechanics; hence, applying LP to a free (i.e., unconstrained) particle is like, say, applying the theory of elasticity to a rigid body! As such, LP is *not* a law of nature, like the Newton–Euler equation (3.2.1) (and its Cauchy form, in continuum mechanics), but subservient to them; if (3.2.1) can be likened to a constitution article, LP is a secondary law (say, a state law). Just as in continuum mechanics, where not all parts of the stress need be elastic, here in analytical mechanics too, *not all constraint reactions need satisfy (3.2.7)* (see §3.17). Those reactions that do, which is most of this book, we shall call *ideal* (or *perfect*, or *passive*, or *frictionless*).

In view of these facts, the frequently occurring expression "workless, or nonworking, constraints" must be replaced by the more precise one, *virtually workless constraints*. Indeed, under the most general kinematically admissible/possible particle displacement (§2.5)

$$d\boldsymbol{r} = \sum \boldsymbol{e}_k\, dq_k + \boldsymbol{e}_0\, dt, \qquad \text{where} \qquad \boldsymbol{e}_k \equiv \partial\boldsymbol{r}/\partial q_k, \quad \boldsymbol{e}_0 \equiv \partial\boldsymbol{r}/\partial t \;(\equiv \boldsymbol{e}_{n+1}), \quad (3.2.16)$$

the corresponding (first-order, or elementary) work of the constraint reactions is

$$d' W_R \equiv \mathsf{S}\, d\boldsymbol{R} \cdot d\boldsymbol{r} = \cdots = (d' W_R)_1 + (d' W_R)_2, \quad (3.2.16a)$$

where

$$(d'W_R)_1 \equiv \sum R_k\, dq_k, \qquad R_k \equiv \int dR \cdot e_k, \tag{3.2.16b}$$

$$(d'W_R)_2 \equiv R_0\, dt, \qquad R_0 \equiv \int dR \cdot e_0 \ (\equiv R_{n+1}); \tag{3.2.16c}$$

while, under an equally general virtual displacement $\delta r = \sum e_k\, \delta q_k$, the corresponding work is

$$\delta' W_R \equiv \int dR \cdot \delta r = \cdots = \sum R_k\, \delta q_k = 0; \tag{3.2.16d}$$

and therefore, since $(d'W_R)_1$ and $\delta' W_R$ are mathematically equivalent $(dq \sim \delta q)$,

$$(d'W_R)_1 = 0 \ \Rightarrow \ d'W_R = (d'W_R)_2 = \left[\int dR \cdot (\partial r/\partial t)\right] dt \neq 0. \tag{3.2.16e}$$

[In view of (3.2.16 ff.), it is, probably, better to think of *first-order* virtual work as *projection of the forces* in certain directions; and to forget all those traditional (and confusion-prone) definitions of it like "work of forces for a constraint compatible infinitesimal movement of the system."]

In sum: in general, the constraint reactions *are* working; even when virtually nonworking. *Actually, that is why the whole concept of virtualness was invented in analytical mechanics*. For example, let us consider a particle P constrained to remain on a rigid surface S, which undergoes a *given* motion. Then, the virtual work of the normal reaction exerted by S on P is zero, while the corresponding $d'W_R$ is not; but, if S is *stationary*, then both $\delta' W_R$ and $d'W_R$ vanish. From the viewpoint of continuum mechanics, the need for LP, or something equivalent, for the constraint reactions is relatively obvious.

Below, we present a simple such mathematical argument from the viewpoint of discrete mechanics. In an N-particle system with equations of motion [discrete counterparts of (3.2.1)],

$$m_P\, a_P = F_P + R_P \qquad (P = 1, \ldots, N), \tag{3.2.17a}$$

and assuming that the impressed F_P's are completely *known* functions of t, r, v (something that may not always be the case: e.g., sliding friction), we have $3N + 3N = 6N$ unknown scalar functions: (i) the $3N$ position vector components/coordinates $\{x_P(t), y_P(t), z_P(t)$: rectangular Cartesian components of $r_P\} \rightarrow \{d^2x_P/dt^2 = a_{P,x},\ d^2y_P/dt^2 = a_{P,y},\ d^2z_P/dt^2 = a_{P,z}$: rectangular Cartesian components of $a_P = d^2 r_P/dt^2\}$, plus (ii) the $3N$ reaction force components $\{R_{P,x}, R_{P,y}, R_{P,z}\}$. Against these unknowns, we have available: (i) the $3N$ scalar equations of motion (3.2.17a), and (ii) a total of $h + m$ scalar equations of constraint (recall §2.2 ff.):

$$h \textit{ geometric}:\ \phi_H(t, r_P) = 0 \qquad (H = 1, \ldots, h;\ P = 1, \ldots, N), \tag{3.2.17b}$$

$$m \textit{ velocity (possibly nonholonomic)}: f_D(t, r_P, v_P) = 0 \quad (D = 1, \ldots, m;\ P = 1, \ldots, N); \tag{3.2.17c}$$

that is, a total of $3N + h + m$ (differential) equations. Therefore, to make our problem determinate, we need $6N - (3N + h + m) = (3N - h) - m \equiv n - m \equiv f$ ($\equiv$ # *DOF in the small*) additional scalar equations. And here is where LP comes in: as shown later in this chapter, the *single energetic but variational equation*

$\delta' W_R = 0 \;\Rightarrow\; \delta I = \delta' W$ *produces precisely these* f *needed independent scalar equations* (unlike the single *actual, nonvariational*, work/energy theorem, which always produces only *one* such equation!); and the latter, along with initial/boundary conditions make the above constrained dynamical problem determinate, or closed.

This simple argument, *number of equations = number of unknowns* [probably originated by Lur'e (1968, pp. 245–248) and Gantmacher (1970, pp. 16–23)], shows clearly the *impossibility of building a general constrained system mechanics without additional physical postulates*, like LP, or something equivalent (it would be like trying to build a theory of elasticity without Hooke's law, or something similar relating stress to strain!), and thus lays to rest frequent but nevertheless erroneous claims that "analytical mechanics is nothing but a mathematically sophisticated rearrangement of Newton's laws."

In sum, analytical mechanics is both mathematically and physically different from the momentum mechanics of Newton–Euler. Schematically:

$$\text{Lagrangean analytical mechanics} = \text{Newton–Euler laws} \\ + \text{d'Alembert's physical postulate.}$$

As Lanczos puts it: "Those scientists who claim that analytical mechanics is nothing but a mathematically different formulation of the laws of Newton must assume that [LP] is deducible from the Newtonian laws of motion. The author is unable to see how this can be done. Certainly the third law of motion, "action equals reaction," is not wide enough to replace [LP]" (1970, p. 77).

The above also show clearly that trying to prove LP is meaningless; although, in the past, several scientists have tried to do that (like trying to prove Hooke's law in elasticity!). These considerations also indicate that if we choose to decompose the total force $d\boldsymbol{f}$ according to some other physical characteristic, then we must equip that mechanics with appropriate constitutive postulates for (some of) the forces involved, so as to make the corresponding dynamical problem determinate. Thus, in the Newton–Euler mechanics, where, as we have already seen, $d\boldsymbol{f}$ is decomposed into *external* and *internal* parts, the system equations of motion — that is, the principles of linear and angular momentum — thanks to the additional *constitutive* postulate of action–reaction, contain only the *external* forces (and couples); without that postulate, the equations of motion would involve *all* the forces, and the corresponding problem would be, in general, indeterminate. And in the case of matter–electromagnetic field interactions (e.g., electroelasticity, magneto-fluid-mechanics), we must, similarly, either know all forces involved, or supplement the equations of motion (of Newton–Euler and Maxwell) with special electromechanical constitutive equations, so that we end up again with a determinate system of equations.

More on Lagrange's Principle as a Constitutive Postulate

Here is what the noted mechanics historian E. Jouguet says about the *physical* nature of Lagrange's Principle (freely translated):

> In sum, therefore, Huygens and Jacob Bernoulli implicitly admit that the *forces developed by the constraints in the case of motion, are, like the forces developed by the constraints in the case of equilibrium,* forces that do no work in the virtual displacements

> compatible with the constraints. There is here a new *physical* postulate. It could be quite possible that *the property of not doing work be true for the constraint forces during equilibrium and not for the constraint forces during motion;* the reaction of a fixed surface on a point could be normal if the point was in equilibrium, and inclined if the point was moving; the reaction of a surface on a point could be normal if the surface was fixed and oblique if it was moving or deformable. This new postulate expresses, to use the language of Mr. P. Duhem [a French master (1861–1916), particularly famous for his contributions to continuum thermodynamics/energetics (in the tradition of Gibbs), and the history/axiomatics of theoretical mechanics], that the constraints, that have already been supposed [statically] frictionless, are also without *viscosity*. (1908, pp. 195–196),

and

> The dynamics of systems with constraints rests therefore on the property of forces generated, during the motion, by the constraints, of not doing work in the virtual displacements compatible with the given constraints. This is an *experimental* property, and at the same time an experimental property distinct from those that we have found for the forces developed by the constraints in the case of equilibrium, because it introduces the condition *that the constraints are without viscosity*. (1908, p. 202, emphasis added).

When Are the Methods of Newton–Euler (NE) and d'Alembert–Lagrange (AL) Equivalent?

Since there is only one mechanics, this is a natural question, but not an easy one. To begin with, since NE divides forces into external and internal (“apples”), while AL divides them into impressed and reactions (“oranges”), we should not be surprised if, for general mechanical systems and forces, no such equivalence exists, or should be expected, at all stages of the formulation and solution of a problem.

Equivalence at the highest level of the fundamental principles *may* exist only for special systems and problems: that is, those for which (i) the *internal forces* (NE) coincide with those of *constraint* (AL), and (ii) the *external forces* (NE) coincide with the *impressed ones* (AL). The only such system that we are aware of, satisfying both (i) and (ii), is the earlier-examined *free rigid body*; and there we saw that LP leads to the NE principles of linear and angular momentum. For other systems where the internal forces may be (wholly or partly) impressed, for example, an elastic body, the NE principles do not follow from LP; the latter, as an *independent axiom*, says nothing about *impressed forces*. However, for a given system and forces, both methods of NE and AL do the job pledged by all classical descriptions of motion, which is, given (i) the external (NE) and impressed (AL) forces, along with (ii) the system's state at an “initial” instant (i.e., initial configuration and velocities = initial conditions), and (iii) appropriate constitutive postulates for its internal forces (NE) and constraint reactions (AL), respectively (and possibly other additional geometrical/kinematical/physical facts intrinsic to that problem), then both NE and AL are theoretically equally capable in predicting the subsequent motion of the system and its remaining unknown forces (although both approaches may not be equivalent laborwise, or from the important Machian viewpoint of conceptual economy). On these fundamental issues, see also the masterful treatment of Hamel (1909; 1927, pp. 8–10, 14–18, 23–27, 38–39; 1949, chap. 4 and pp. 513–524).

The above can be summarized in the following:

(i) *Force decomposition:*

- Newton–Euler (NE)
  - *External*
    - External *impressed*
    - External *reactions*
  - *Internal*
    - Internal *impressed*
    - Internal *reactions*
- D'Alembert–Lagrange (AL)
  - *Impressed*
    - Impressed *external*
    - Impressed *internal*
  - *Reactions*
    - *External* reactions
    - *Internal* reactions

(ii) *Whence the need for d'Alembert's principle:*

Unknown forces

NE: Internal $\{d\boldsymbol{f}_i\}$ $\rightarrow$ Discrete: *action–reaction* $\quad S\, d\boldsymbol{f}_i = \mathbf{0}, \quad S\, \boldsymbol{r} \times d\boldsymbol{f}_i = \mathbf{0}$

[$\rightarrow$ Continuum: *Boltzmann's axiom*; i.e., symmetry of stress tensor]

AL: Reactions $\{d\boldsymbol{R}\}$ $\rightarrow$ *Lagrange's principle* $\quad S\, d\boldsymbol{R} \cdot \delta\boldsymbol{r} = 0$

(iii) *Consequences:*

NE: *Linear momentum*:
$$S\, d\boldsymbol{f}_i + S\, d\boldsymbol{f}_e = S\, dm\, \boldsymbol{a}$$
$$\Rightarrow S\, d\boldsymbol{f}_e = S\, dm\, \boldsymbol{a} \ \Rightarrow\ \boldsymbol{f}_e = m\, \boldsymbol{a}_G \quad (G = \text{mass center})$$

Angular momentum:
$$S\, [\boldsymbol{r} \times (d\boldsymbol{f}_i + d\boldsymbol{f}_e)] = S\, (\boldsymbol{r} \times dm\, \boldsymbol{a})$$
$$\Rightarrow\ S\, \boldsymbol{r} \times d\boldsymbol{f}_e = d/dt\Big[S\, (\boldsymbol{r} \times dm\, \boldsymbol{v})\Big]$$

AL: *Lagrange's principle*:
$$[-\delta' W_R \equiv S\, d\boldsymbol{R} \cdot \delta\boldsymbol{r} = 0] + [dm\, \boldsymbol{a} = d\boldsymbol{F} + d\boldsymbol{R}]$$
$$\Rightarrow S\, d\boldsymbol{F} \cdot \delta\boldsymbol{r} = S\, dm\, \boldsymbol{a} \cdot \delta\boldsymbol{r}$$

(iv) *Unknown force retrieval:*

NE: Principles of *rigidification* and *cut*
AL: Principle of *constraint relaxation* (Befreiungsprinzip, see below and §3.7)

(v) *Coincidence of NE with d'AL: free rigid body*

Free: External forces = Impressed forces; i.e., $\{d\boldsymbol{f}_e\} = \{d\boldsymbol{F}\}$ $\quad (\{d\boldsymbol{R}_e\} = \mathbf{0})$
Rigid: Internal forces = Constraint reactions; i.e., $\{d\boldsymbol{f}_i\} = \{d\boldsymbol{R}\}$ $\quad (\{d\boldsymbol{F}_i\} = \mathbf{0})$

[Briefly (a) *Rigidification principle*: If a system is in equilibrium under impressed and constraint forces, it will remain in equilibrium if additional constraints are imposed on it so as to render it partly or wholly rigid; that is, deformable bodies in equilibrium can be treated just like rigid ones — both satisfy the same (necessary) conditions; (b) *Cut principle*: We can replace the action of two contiguous parts of the body by corresponding force systems ($\Rightarrow$ free body diagrams). Both principles are due to Euler. For details, see books on statics; also Papastavridis (EM, in prep.).]

Example 3.2.3 *Plane Mathematical Pendulum: Comparison Between Principles of Moment (Original d'Alembert) and Virtual Work (Lagrange).* Let us consider the motion of a mathematical pendulum, of length l and mass m, about a fixed point O on a vertical plane.

(i) According to the *original formulation of the principle* (first by *Jakob Bernoulli* and then by *d'Alembert*), the string reaction $\boldsymbol{S}$ on the oscillating particle P must be in equilibrium; that is, its moment about O must vanish:

$$\boldsymbol{M}_O \equiv \boldsymbol{r} \times \boldsymbol{S} = \boldsymbol{0} \;\Rightarrow\; \boldsymbol{S} \text{ must be parallel to the string } OP \; (\boldsymbol{r} \equiv \boldsymbol{OP}). \tag{a}$$

As a result, the second part of the principle—that is, *impressed forces minus inertia forces must be in equilibrium*, yields (with $\boldsymbol{W}$ = *weight of* P)

$$\begin{aligned} \boldsymbol{r} \times \boldsymbol{W} = \boldsymbol{r} \times (m\,\boldsymbol{a}) \;&\Rightarrow\; -(W)(l \sin\phi) = \{m[l(d^2\phi/dt^2)]\}(l) \\ &\Rightarrow\; d^2\phi/dt^2 + (g/l)\sin\phi = 0. \end{aligned} \tag{b}$$

(ii) According to *Lagrange's formulation of the principle*, the virtual work of $\boldsymbol{S}$ must vanish:

$$\delta' W_R = \boldsymbol{S} \cdot \delta\boldsymbol{r} = 0 \;\Rightarrow\; \boldsymbol{S} \text{ must be perpendicular to the virtual displacement of } P, \tag{c}$$

and since the latter is along the instantaneous tangent to P's circular path about O, we conclude that $\boldsymbol{S}$ must be parallel to OP, as before.

Hence, the second part of the principle—that is, *virtual work of impressed forces minus that of inertia forces must vanish*, yields

$$\begin{aligned} \boldsymbol{W} \cdot \delta\boldsymbol{r} = (m\,\boldsymbol{a}) \cdot \delta\boldsymbol{r} \;&\Rightarrow\; -(W \sin\phi)(l\,\delta\phi) = \{m[l(d^2\phi/dt^2)]\}(l\,\delta\phi) \\ &\Rightarrow\; d^2\phi/dt^2 + (g/l)\sin\phi = 0; \end{aligned} \tag{d}$$

that is, the moment condition (b) and the virtual work condition (d) differ only by an inessential factor $\delta\phi$, and thus they produce the same reactionless equation of motion.

In view of the extreme similarity, almost identity, of these two approaches in this and other rigid-body problems, we can see how, over the 19th and 20th centuries, various scientists came to confuse the zero moment method of James (Jakob) Bernoulli-d'Alembert {i.e., $S\, \boldsymbol{r} \times (d\boldsymbol{F} - dm\,\boldsymbol{a}) = \boldsymbol{0}$, in our notation} with the zero virtual work method of Lagrange {i.e., $S\, \delta\boldsymbol{r} \cdot (d\boldsymbol{F} - dm\,\boldsymbol{a}) = 0$}, and to view the former as equivalent to the latter. (Also, the fact that the string tension $\boldsymbol{S}$ is not zero—that is, that the constraint reaction is in equilibrium, not in the elementary sense of *zero moment and force*, but in the sense of *zero virtual work*, demonstrates clearly one of the drawbacks of the original d'Alembertian formulation of the principle.)

Example 3.2.4 *Motion of an Unconstrained System Relative to its Mass Center G, via Lagrange's Principle* (Adapted from Williamson and Tarleton, 1900, pp. 242–293). Substituting $\boldsymbol{r} = \boldsymbol{r}_G + \boldsymbol{r}_{/G} \Rightarrow \boldsymbol{a} = \boldsymbol{a}_G + \boldsymbol{a}_{/G}$ into LP, (3.2.8), and regrouping, we obtain

$$0 = \delta\boldsymbol{r}_G \cdot \left[\mathcal{S}\,(dm\,\boldsymbol{a}_G - d\boldsymbol{F})\right] + \delta\boldsymbol{r}_G \cdot \left(\mathcal{S}\,dm\,\boldsymbol{a}_{/G}\right) \\ + \boldsymbol{a}_G \cdot \left(\mathcal{S}\,dm\,\delta\boldsymbol{r}_{/G}\right) + \mathcal{S}\,(dm\,\boldsymbol{a}_{/G} - d\boldsymbol{F}) \cdot \delta\boldsymbol{r}_{/G}, \tag{a}$$

from which, since $\mathcal{S}\,dm\,\boldsymbol{r}_{/G} = \boldsymbol{0} \Rightarrow \mathcal{S}\,dm\,\delta\boldsymbol{r}_{/G} = \boldsymbol{0}$ and $\mathcal{S}\,dm\,\boldsymbol{a}_{/G} = \boldsymbol{0}$, and the $\delta\boldsymbol{r}_G$, $\delta\boldsymbol{r}_{/G}$ are unrelated, we obtain

(i) $$\delta\boldsymbol{r}_G \cdot \left[\mathcal{S}\,(dm\,\boldsymbol{a}_G - d\boldsymbol{F})\right] = 0 \quad\Rightarrow\quad \mathcal{S}\,dm\,\boldsymbol{a}_G = \mathcal{S}\,d\boldsymbol{F},$$

that is,

$$m\,\boldsymbol{a}_G = \boldsymbol{F} \qquad (\textit{Principle of linear momentum}), \tag{b}$$

if $\delta\boldsymbol{r}_G$ is unconstrained, and

(ii) $$\mathcal{S}\,(dm\,\boldsymbol{a}_{/G} - d\boldsymbol{F}) \cdot \delta\boldsymbol{r}_{/G} = 0, \qquad \text{under the constraint} \quad \mathcal{S}\,dm\,\delta\boldsymbol{r}_{/G} = \boldsymbol{0}. \tag{c}$$

Combining, or adjoining, the second of (c) into the first of (c) with the vectorial Lagrangean multiplier $\boldsymbol{\lambda} = \boldsymbol{\lambda}(t)$ (see §3.5), we readily get

$$dm\,\boldsymbol{a}_{/G} = d\boldsymbol{F} + \boldsymbol{\lambda}\,dm, \tag{d}$$

and, summing this over the system, we obtain

$$\mathcal{S}\,dm\,\boldsymbol{a}_{/G} = \mathcal{S}\,d\boldsymbol{F} + \boldsymbol{\lambda}\left(\mathcal{S}\,dm\right) \quad\Rightarrow\quad \boldsymbol{0} = \boldsymbol{F} + \boldsymbol{\lambda}\,m \quad\Rightarrow\quad \boldsymbol{\lambda} = -\boldsymbol{F}/m, \tag{e}$$

so that, finally, (d) becomes

$$dm\,\boldsymbol{a}_{/G} = d\boldsymbol{F} - dm(\boldsymbol{F}/m) \qquad (= d\boldsymbol{F} - dm\,\boldsymbol{a}_G, \text{as expected}). \tag{f}$$

Example 3.2.5 *Sufficiency of the Statical Principle of Virtual Work (PVW) for the Equilibrium of Ideally Constrained Systems Deduced from LP.* In analytical statics (i.e., LP with $\boldsymbol{a} = \boldsymbol{0}$), the PVW states that *in a bilaterally constrained and originally motionless system (in an inertial frame), the vanishing of $\delta' W$ is a necessary and sufficient condition for it to remain in equilibrium in that frame*. In concrete applications, what we really employ is the *sufficiency* of the principle; that is, if $\delta' W = 0$, then the originally motionless system remains in equilibrium.

Here, we will start with LP as the basic axiom, set $\delta' W = 0$, and then derive sufficient conditions to maintain equilibrium; that is, go *from kinetics to statics*. Most authors proceed inversely—that is, go from statics to kinetics—and that makes the detection of the importance of the various constraints more difficult.

(i) *Necessary conditions*: If the system is in (inertial) equilibrium, then $\boldsymbol{a} = \boldsymbol{0}$, and therefore

$$\delta' W \equiv \mathcal{S}\,d\boldsymbol{F} \cdot \delta\boldsymbol{r} = 0 \qquad (\Rightarrow \delta' W_R \equiv \mathcal{S}\,d\boldsymbol{R} \cdot \delta\boldsymbol{r} = 0), \tag{a}$$

for $t_i \le t \le t_f$, where $t_i(t_f) = \textit{initial}\ (\textit{final})$ time and $t_f - t_i \equiv \tau$.

(ii) *Sufficiency conditions*: If $\delta' W = 0$, for $t_i \le t \le t_f$, then LP gives

$$\delta I \equiv \mathsf{S}\, dm\, \boldsymbol{a} \cdot \delta \boldsymbol{r} = 0, \qquad \text{for} \quad t_i \le t \le t_f. \tag{b}$$

Let us investigate the consequences of (a, b) for equilibrium. Substituting into (b) the particle displacement $d\boldsymbol{r} - \boldsymbol{e}_0\, dt = (\boldsymbol{v} - \boldsymbol{e}_0)\, dt \equiv [\boldsymbol{v} - (\partial \boldsymbol{r}/\partial t)]dt$, which is *mathematically equivalent to its virtual displacement*, and cancelling $dt (\neq 0)$, we obtain

$$\mathsf{S}\, dm\, \boldsymbol{a} \cdot \boldsymbol{v} = \mathsf{S}\, dm\, \boldsymbol{a} \cdot \boldsymbol{e}_0, \tag{c}$$

and since $2T \equiv \mathsf{S}\, dm\, \boldsymbol{v} \cdot \boldsymbol{v} \Rightarrow dT/dt = \mathsf{S}\, dm\, \boldsymbol{a} \cdot \boldsymbol{v}$, we are readily led to the following *rheonomic-type power equation*:

$$dT/dt = \mathsf{S}\, dm\, \boldsymbol{a} \cdot \boldsymbol{e}_0 = \mathsf{S}\, d\boldsymbol{F} \cdot \boldsymbol{e}_0 + \mathsf{S}\, d\boldsymbol{R} \cdot \boldsymbol{e}_0. \tag{d}$$

Integrating the above between t_i and $t (\le t_f)$, and setting $T_i \equiv T(t_i)$, $T \equiv T(t)$ yields

$$\Delta T \equiv T - T_i = \int_{t_i}^{t} \Big(\mathsf{S}\, dm\, \boldsymbol{a} \cdot \boldsymbol{e}_0 \Big)\, dt; \tag{e}$$

which also follows from $\int_{t_i}^{t} \delta' W\, dt = 0$. Equation (e) leads to the following conclusions:

(a) If $\boldsymbol{e}_0 = \boldsymbol{0}$, then $\Delta T = 0$, and since $\boldsymbol{v}_i \equiv \boldsymbol{v}(t_i) = \boldsymbol{0} \Rightarrow T_i = 0$, it follows that $T = 0$ for some time $t - t_i (\le t_f - t_i)$; and from this, since $T =$ *positive definite* in the $\boldsymbol{v} \cdot \boldsymbol{v} = v^2$, we conclude that then *all* the $\boldsymbol{v}$'s vanish for $t - t_i\, (\le t_f - t_i)$; that is, the system remains in equilibrium in that time interval.

Conversely, *if* $\Delta T = 0$ *for any* $t > t_i$, *then* (e) *leads, for arbitrary systems, to* $\boldsymbol{e}_0 = \boldsymbol{0}$. In this case, (c) gives $\boldsymbol{v} = \boldsymbol{0}$; that is, equilibrium [while (a) yields $\mathsf{S}\, d\boldsymbol{F} \cdot \boldsymbol{v} = \mathsf{S}\, d\boldsymbol{F} \cdot \boldsymbol{e}_0 = 0$]. The consequences of this in the presence of additional Pfaffian constraints are discussed below.

(b) If $\boldsymbol{e}_0 \neq \boldsymbol{0}$, then, in general, $\Delta T \neq 0$; that is, the system moves away from its original equilibrium configuration, even though $\delta' W = 0$, for $t_i \le t \le t_f$, and $\boldsymbol{v}_i = \boldsymbol{0}$.

Weaker special assumptions for equilibrium result for the following conditions:

(c) If $\boldsymbol{e}_0 \neq \boldsymbol{0}$, but $\int_{t_i}^{t} \big(\mathsf{S}\, dm\, \boldsymbol{a} \cdot \boldsymbol{e}_0 \big)\, dt = 0$; or

(d) If $\boldsymbol{e}_0 \neq \boldsymbol{0}$ but $\boldsymbol{a} \cdot \boldsymbol{e}_0 = 0$, for $t_i \le t \le t_f$.

Comparison with Gantmacher

Gantmacher's formulation of the PVW is as follows: "For some position (compatible with constraints) of a system to be an equilibrium position, it is necessary and sufficient that in this position the sum of the works of effective forces [our impressed forces] on any virtual displacements of the system be zero" and "If the constraints are nonstationary, then the term 'compatible with constraints' signifies that they are satisfied for any t if in them we put [our notation] $\boldsymbol{r} = \boldsymbol{r}_i$ and $\boldsymbol{v} = \boldsymbol{0}$" and "It is then assumed that [our] equation (a) holds for any value of t if in the expression for $d\boldsymbol{F}$ we put all $\boldsymbol{r} = \boldsymbol{r}_i$ and all $\boldsymbol{v} = \boldsymbol{0}$" (1970, p. 25). Let us relate this formulation with ours. By (2.5.2) $\boldsymbol{v} = \sum \boldsymbol{e}_k v_k + \boldsymbol{e}_0$. Hence, if $\boldsymbol{v} = \boldsymbol{0}$:

(i) If the v_k's are *unconstrained*, and since $\boldsymbol{e}_k \neq \boldsymbol{0}$, then $v_k = 0 \Rightarrow q_k = constant$ and $\boldsymbol{e}_0 = \boldsymbol{0}$—that is, the constraints are *stationary*—then the system *will* remain in equilibrium.

(ii) If, on the other hand, the v_k's are *constrained*, then, invoking the convenient representations (2.11.9, 13c, e), we have

$$\boldsymbol{v} \to \boldsymbol{v}_0 = \sum \boldsymbol{\beta}_I v_I + \boldsymbol{\beta}_0 = \boldsymbol{0} \Rightarrow v_i = 0 \quad \Rightarrow \quad q_I = constant, \quad \text{and} \quad \boldsymbol{\beta}_0 = \boldsymbol{0};$$

$$\boldsymbol{\beta}_0 = \boldsymbol{e}_0 + \sum b_D \boldsymbol{e}_D = \boldsymbol{0} \quad \Rightarrow \quad \boldsymbol{e}_0 = \boldsymbol{0}, \quad \text{and} \quad b_D = 0;$$

$$v_D = \sum b_{DI} v_I + b_D \quad \Rightarrow \quad v_D = 0 \quad \Rightarrow \quad q_D = constant \qquad (\Rightarrow q_k = constant).$$

In the light of the above, the PVW can be reformulated as follows: An originally motionless system remains in equilibrium if and only if (i) $\delta' W = 0$ and (ii) its *holonomic constraints* are *stationary* ($\boldsymbol{e}_0 \equiv \partial \boldsymbol{r}/\partial t = \boldsymbol{0}$) and its *Pfaffian constraints* are *catastatic* ($a_D = 0$ or $b_D = 0$). (The latter, however, may be nonstationary; and this explains Gantmacher's statement: "Note that in this case the virtual displacements ... may also be different for different t.")

REMARKS

(i) That "compatibility with constraints (during equilibrium)" leads to the above conclusions about them can be seen more clearly as follows. Let our system be subject to h holonomic constraints and m Pfaffian (holonomic and/or nonholonomic constraints):

$$\phi_H(t, \boldsymbol{r}) = 0, \qquad f_D \equiv \mathcal{S}\, \boldsymbol{B}_D(t, \boldsymbol{r}) \cdot \boldsymbol{v} + B_D(t, \boldsymbol{r}) = 0 \qquad (H = 1, \ldots, h;\ D = 1, \ldots, m). \tag{f}$$

By $d/dt(\ldots)$-differentiating the above, to make them explicit in both velocities and accelerations, we readily obtain [recalling *dot-product-of-tensor-definition* [(see 1.1.12d ff.)], in the first sum in (g2) below]:

$$\text{(a)} \quad d\phi_H/dt = \mathcal{S}\, (\partial \phi_H/\partial \boldsymbol{r}) \cdot \boldsymbol{v} \;+\; \partial \phi_H/\partial t \;=\; 0, \tag{g1}$$

$$\text{(b)} \quad d^2\phi_H/dt^2 = \mathcal{S}\, \big[(\partial^2 \phi_H/\partial \boldsymbol{r}\, \partial \boldsymbol{r}) : (\boldsymbol{v} \otimes \boldsymbol{v}) + (\partial \phi_H/\partial \boldsymbol{r}) \cdot \boldsymbol{a} + 2(\partial^2 \phi_H/\partial t\, \partial \boldsymbol{r}) \cdot \boldsymbol{v}\big] + \partial^2 \phi_H/\partial t^2 = 0, \tag{g2}$$

$$\text{(c)} \quad df_D/dt \equiv \mathcal{S}\, \{[(\partial \boldsymbol{B}_D/\partial \boldsymbol{r}) \cdot \boldsymbol{v} + (\partial \boldsymbol{B}_D/\partial t)] \cdot \boldsymbol{v} + \boldsymbol{B}_D \cdot \boldsymbol{a}\} + \mathcal{S}\, (\partial B_D/\partial \boldsymbol{r}) \cdot \boldsymbol{v} + \partial B_D/\partial t = 0. \tag{g3}$$

Now, since compatibility requires that, for $t_i \le t \le t_f$, eqs. (f–g3) should hold with $\boldsymbol{v} = \boldsymbol{0}$ *and* $\boldsymbol{a} = \boldsymbol{0}$ in them (just like the equations of motion), we readily obtain from the above the following conditions on these constraints:

$$\phi_H = 0, \tag{h1}$$

$$d\phi_H/dt = 0 \Rightarrow \partial \phi_H/\partial t = 0, \tag{h2}$$

$$d^2\phi_H/dt^2 = 0 \Rightarrow \partial^2 \phi_H/\partial t^2 = 0; \tag{h3}$$

$$f_D = 0 \Rightarrow B_D = 0, \tag{h4}$$

$$df_D/dt = 0 \Rightarrow \partial B_D/\partial t = 0; \tag{h5}$$

that is, for $t_i \le t \le t_f$, the holonomic constraints must be *stationary*, and the Pfaffian ones must be *catastatic*, as found earlier.

(ii) If we assume Earth to be *inertial*, then an *Earth-bound* system is scleronomic. But if we assume it to have a *given* motion, then our system is *rheonomic*. In both cases, the contact (nongravitational) forces from the Earth to that system are *external reactions*. If, finally, the Earth interacts with our system, then the two *taken together* constitute a *scleronomic* system whose internal forces are impressed (see also Nordheim, 1927, pp. 47–49).

Example 3.2.6 *Nonideal Constraints.* Let us consider a particle P of mass m, moving under an impressed force $\boldsymbol{F}$ and subject to the velocity constraint

$$f(t, \boldsymbol{r}, \boldsymbol{v}) = 0. \tag{a}$$

If the reaction created by (a) is $\boldsymbol{R}$, then the equation of motion of P is

$$m\,\boldsymbol{a} = \boldsymbol{F} + \boldsymbol{R}. \tag{b}$$

To relate the constraint equation to the reaction, so as to incorporate (a) into (b), we $d/dt(\ldots)$-differentiate the former:

$$f = 0 \Rightarrow df/dt = \partial f/\partial t + (\partial f/\partial \boldsymbol{r}) \cdot \boldsymbol{v} + (\partial f/\partial \boldsymbol{v}) \cdot \boldsymbol{a} = 0, \tag{c}$$

and, therefore,

$$m\,\boldsymbol{a} \cdot (\partial f/\partial \boldsymbol{v}) = -m[\partial f/\partial t + (\partial f/\partial \boldsymbol{r}) \cdot \boldsymbol{v}]; \tag{d}$$

but, also, from (b),

$$m\,\boldsymbol{a} \cdot (\partial f/\partial \boldsymbol{v}) = \boldsymbol{F} \cdot (\partial f/\partial \boldsymbol{v}) + \boldsymbol{R} \cdot (\partial f/\partial \boldsymbol{v}). \tag{e}$$

Equating the right sides of (d, e), thus eliminating the acceleration, and rearranging, we obtain

$$\boldsymbol{R} \cdot (\partial f/\partial \boldsymbol{v}) = -[m(\partial f/\partial t) + m(\partial f/\partial \boldsymbol{r}) \cdot \boldsymbol{v} + \boldsymbol{F} \cdot (\partial f/\partial \boldsymbol{v})]. \tag{f}$$

Now, the most general solution of (f), for $\boldsymbol{R}$, is

$$\boldsymbol{R} = -(\partial f/\partial \boldsymbol{v})\big[m(\partial f/\partial t) + m(\partial f/\partial \boldsymbol{r}) \cdot \boldsymbol{v} + \boldsymbol{F} \cdot (\partial f/\partial \boldsymbol{v})\big]\big/(\partial f/\partial \boldsymbol{v})^2 + \boldsymbol{T}, \tag{g}$$

where $\boldsymbol{T} =$ *arbitrary vector orthogonal to* $\partial f/\partial \boldsymbol{v}$. The above shows that, generally, the constraint reaction consists of *two* parts: (i) one *parallel* to $\partial f/\partial \boldsymbol{v}$:

$$\boldsymbol{N} = -(\partial f/\partial \boldsymbol{v})\big[m(\partial f/\partial t) + m(\partial f/\partial \boldsymbol{r}) \cdot \boldsymbol{v} + \boldsymbol{F} \cdot (\partial f/\partial \boldsymbol{v})\big]\big/(\partial f/\partial \boldsymbol{v})^2 \equiv \lambda(\partial f/\partial \boldsymbol{v}) \tag{h}$$

[where $\lambda =$ *Lagrangean multiplier*—see Lagrange's equations of the *first* kind, (§3.5)]; and (ii) one *normal* to it, $\boldsymbol{T}$.

If $\boldsymbol{T} = \boldsymbol{0}$, the constraint (a) is called *ideal*; and in that case, clearly, the equation of motion of the particle (b), under (a), becomes

$$m\,\boldsymbol{a} = \boldsymbol{F} - \big[\boldsymbol{F} \cdot (\partial f/\partial \boldsymbol{v}) + m(\partial f/\partial \boldsymbol{r}) \cdot \boldsymbol{v} + m(\partial f/\partial t)\big]\,\big[(\partial f/\partial \boldsymbol{v})/(\partial f/\partial \boldsymbol{v})^2\big]. \tag{i}$$

To make the problem determinate, we, usually, introduce a *constitutive* equation between $\boldsymbol{N}$ and $\boldsymbol{T}$. For example, in the common case of dry (solid/solid) *sliding* friction, we postulate the following relation between their magnitudes:

$$T = \mu N = \mu|\lambda(\partial f/\partial \boldsymbol{v})|, \qquad \mu = \textit{coefficient of kinetic friction}. \tag{j}$$

Then, and with (g, h), eq. (b) becomes

$$m\,\boldsymbol{a} = \boldsymbol{F} + \lambda(\partial f/\partial \boldsymbol{v}) - \mu|\lambda(\partial f/\partial \boldsymbol{v})|\boldsymbol{u}, \tag{k}$$

where $\boldsymbol{u} = \boldsymbol{v}/|\boldsymbol{v}|$.

For further details and applications of (k) see Poliahov et al. (1985, pp. 152–170).

Problem 3.2.1 Continuing from the preceding example, show that if the constraint (a) has the *holonomic* form

$$\phi(t, \boldsymbol{r}) = 0, \tag{a}$$

then (h) and (i) reduce, respectively, to

$$\boldsymbol{N} = -(\partial\phi/\partial\boldsymbol{r})\big[m(\partial\dot{\phi}/\partial t) + m(\partial\dot{\phi}/\partial\boldsymbol{r})\cdot\boldsymbol{v} + \boldsymbol{F}\cdot(\partial\phi/\partial\boldsymbol{r})\big]/(\partial\phi/\partial\boldsymbol{r})^{\,2} \equiv \lambda(\partial\phi/\partial\boldsymbol{r}) \tag{b}$$

and

$$m\,\boldsymbol{a} = \boldsymbol{F} - \big[\boldsymbol{F}\cdot(\partial\phi/\partial\boldsymbol{r}) + m(\partial\dot{\phi}/\partial\boldsymbol{r})\cdot\boldsymbol{v} + m(\partial\dot{\phi}/\partial t)\big]\big[(\partial\phi/\partial\boldsymbol{r})/(\partial\phi/\partial\boldsymbol{r})^2\big]. \tag{c}$$

(See also Lagrange's equations of the *first* kind, in §3.5.)

Introduction to the Principle of Relaxation of the Constraints (PRC)

Before we embark into a detailed quantitative discussion of Lagrange's Principle (LP) and its derivative equations of motion, let us discuss briefly the *second* pillar of analytical mechanics, the *principle of relaxation of the constraints* (*Befreiungsprinzip*; Hamel, 1917). LP allows us to get rid of the constraint forces and, eventually, obtain *reactionless* equations of motion; and, historically, this has been considered (and *is*) one of the advantages of the method, especially in physics. However, in many engineering problems we *do* need to calculate these reactions, and thus the question arises: How do we achieve this with such a reaction-eliminating Lagrangean formalism?

Here is where PRC comes in: to retrieve a(ny) particular, external and/or internal, "lost" reaction we, hypothetically, free, or relax, the system of its particular, external and/or internal, geometrical and/or motional, constraint(s) causing that reaction; that is, we, mentally, allow the formerly rigid, or unyielding, constraint(s) to deform, or become flexible, relaxed, so that the former reaction becomes an *impressed force* that depends on the *deformation of the violated constraint via some constitutive equation*. Then we calculate its virtual work, add it to $\delta' W$, and apply LP: $(\delta I = \delta' W)_{relaxed\ system}$; and so on and so forth, for as many reactions as needed (one, or more, or all, at a time). Last, since in our model the constraints are rigid, we enforce them in the *final* stage of the differential equations of motion. The mathematical expression of PRC is the very well-known and widely applied *method of "undetermined," or Lagrangean, multipliers* (§3.5).

REMARKS

(i) Another, *mixed*, method is, first, to use LP to calculate the *reactionless* equations (and from them the *motion*), and to then use the method of Newton–Euler (NE) to calculate the external and/or internal reactions. This may be practically expedient, but it is not logically/conceptually satisfactory; it makes Lagrangean mechanics look incomplete.

(ii) The counterpart of PRC in the NE method is the following: if, for example, we want to calculate an *internal* force — that is, one that, due to the action–reaction postulate, drops out of the force/moment side in the NE principles of linear/angular momentum — then, applying Euler's *cut principle*, we choose an appropriate *new free-body diagram* so that the former internal force(s)/moment(s) becomes *external*, and then apply to these *new subsystems*, the NE principles.

3.3 VIRTUAL WORK OF INERTIAL FORCES (δI), AND RELATED KINEMATICO-INERTIAL IDENTITIES

Here we transform (3.2.9), $\delta I \equiv S\, dm\, \boldsymbol{a} \cdot \delta \boldsymbol{r}$, from particle variables to *system* variables; both holonomic and nonholonomic. (Actually, δI is the *negative* of the virtual work of the "inertial forces" $\{-dm\,\boldsymbol{a}\}$. We hope that this slight deviation from traditional terminology will not cause any problems.) Understandably, this relies critically on the kinematical results of chapter 2 and, therefore knowledge of that material is *absolutely necessary*. To obtain the most general system equations of motion from LP, we must use the most general expressions for $\boldsymbol{a}$ and $\delta\boldsymbol{r}$. We recall (§2.5 ff.) that these are (with $k, l = 1, \ldots, n$)

$$\begin{aligned} \delta\boldsymbol{r} &= \sum \boldsymbol{e}_k \delta q_k = \textit{holonomic}\ \text{variable representation} \\ &= \sum \boldsymbol{\varepsilon}_l\, \delta\theta_l = \textit{nonholonomic}\ \text{variable representation}\ (\equiv \delta\boldsymbol{r}^*) \\ &\left(= \sum \boldsymbol{\varepsilon}_I\, \delta\theta_I,\ \text{under the constraints}\ \delta\theta_D = 0;\ D+1,\ldots,m;\ I = m+1,\ldots,n \right). \end{aligned} \tag{3.3.1}$$

where the fundamental *mixed basis vectors* $\{\boldsymbol{e}_k\}$ and $\{\boldsymbol{\varepsilon}_l\}$ are related by

$$\boldsymbol{e}_k \equiv \partial\boldsymbol{r}/\partial q_k = \sum a_{lk}\boldsymbol{\varepsilon}_l \quad \Leftrightarrow \quad \boldsymbol{\varepsilon}_l \equiv \partial\boldsymbol{r}/\partial\theta_l = \sum A_{kl}\boldsymbol{e}_k. \tag{3.3.1a}$$

1. Holonomic System Variables

Substituting the first of (3.3.1) into δI we obtain, successively,

$$\delta I \equiv S\, dm\, \boldsymbol{a} \cdot \delta\boldsymbol{r} = S\, dm\, \boldsymbol{a} \cdot \left(\sum \boldsymbol{e}_k\, \delta q_k \right) = \cdots = \sum E_k\, \delta q_k, \tag{3.3.2}$$

where $E_k \equiv S\, dm\, \boldsymbol{a} \cdot \boldsymbol{e}_k$: *holonomic* ($k$)th component of *system inertial "force"*

$$\begin{aligned} \Big[&\equiv S\, dm\, \boldsymbol{a} \cdot (\partial\boldsymbol{r}/\partial q_k) = S\, dm\, \boldsymbol{a} \cdot (\partial\mathbf{v}/\partial\dot{q}_k) = S\, dm\, \boldsymbol{a} \cdot (\partial\boldsymbol{a}/\partial\ddot{q}_k) \\ &\equiv S\, dm\, \boldsymbol{a} \cdot (\partial\boldsymbol{r}/\partial q_k) = S\, dm\, \boldsymbol{a} \cdot (\partial\mathbf{v}/\partial v_k) = S\, dm\, \boldsymbol{a} \cdot (\partial\boldsymbol{a}/\partial w_k) \Big]. \end{aligned} \tag{3.3.3}$$

Now, E_k transforms, successively, as follows:

$$\begin{aligned} E_k &\equiv \mathcal{S}\, dm\, \boldsymbol{a} \cdot \boldsymbol{e}_k = \mathcal{S}\, dm (d\boldsymbol{v}/dt) \cdot (\partial \boldsymbol{v}/\partial v_k) \\ &= d/dt\Big[\mathcal{S}\, dm\ \boldsymbol{v} \cdot (\partial \boldsymbol{v}/\partial v_k)\Big] - \mathcal{S}\,[dm\, \boldsymbol{v} \cdot (d/dt)(\partial \boldsymbol{v}/\partial v_k)] \\ &\quad [\text{recalling identity (2.5.10)}:\ E_k(\boldsymbol{v}) \equiv d/dt(\partial \boldsymbol{v}/\partial v_k) - \partial \boldsymbol{v}/\partial q_k = \boldsymbol{0}] \\ &= d/dt\Big[\mathcal{S}\, dm\, \boldsymbol{v} \cdot (\partial \boldsymbol{v}/\partial v_k)\Big] - \mathcal{S}\, dm\, \boldsymbol{v} \cdot (\partial \boldsymbol{v}/\partial q_k), \end{aligned} \tag{3.3.4}$$

or, finally, with the help of the (inertial) *kinetic energy*

$$T \equiv \mathcal{S}\,(1/2)(dm\, \boldsymbol{v} \cdot \boldsymbol{v}) = T(t, q, \dot{q}) \equiv T(t, q, v) \qquad [\text{since } \boldsymbol{v} = \boldsymbol{v}(t, q, v)], \tag{3.3.5}$$

we obtain

$$E_k = d/dt(\partial T/\partial v_k) - \partial T/\partial q_k \equiv d/dt(\partial T/\partial \dot{q}_k) - \partial T/\partial q_k \equiv E_k(T), \tag{3.3.6}$$

where

$$E_k(\ldots) = d/dt(\partial \ldots/\partial v_k) - \partial \ldots/\partial q_k \equiv d/dt(\partial \ldots/\partial \dot{q}_k) - \partial \ldots/\partial q_k: \quad (\text{holonomic Euler–Lagrange operator})_k. \tag{3.3.6a}$$

Equation (3.3.6) is a kinematico-inertial *identity*; that is, it holds always, independently of any possible additional constraints, as long as the q's are *holonomic coordinates*. Its cardinal importance to Lagrangean mechanics lies in the fact that it expresses system accelerations in terms of the *partial and total derivatives of a scalar energetic function of the system coordinates and velocities*, $T(t, q, v)$, *AS IF* the q's and $\dot{q}$'s $\equiv$ v's (and t) were *independent variables*. That is why we have reserved the *special notation* $E_k(T) \equiv E_k$ when that operator is applied to the *kinetic energy*; even though $E_k(\ldots)$ can be applied to any function of the q's, v's, and t. Also, (3.3.1–6a) clearly show the *indispensability of virtual displacements* (i.e., the $\boldsymbol{e}_k$ vectors) to Lagrangean mechanics/equations of motion [i.e., the particular T-based expression for the system inertia/acceleration given by (3.3.6)], whether the constraint reactions are ideal or not.

In sum: no $\boldsymbol{e}_k$'s, no Lagrangean equations, that is, for an arbitrary particle/system vector $\boldsymbol{z}_k \neq \boldsymbol{e}_k$,

$$\mathcal{S}\, dm\, \boldsymbol{a} \cdot \boldsymbol{z}_k \neq (d/dt)(\partial T/\partial v_k) - \partial T/\partial q_k. \tag{3.3.6b}$$

This should put to rest once and for all false claims that "one can build Lagrangean mechanics without virtual displacements." The $\delta(\ldots)$ is not the issue; the $\boldsymbol{e}_k$ ($\rightarrow$ *projections*) are!

Let us collect the key kinematico-inertial identities involved here:

(a) $$\mathcal{S}\, dm\, \boldsymbol{v} \cdot \boldsymbol{e}_k = \mathcal{S}\, dm\, \boldsymbol{v} \cdot (\partial \boldsymbol{v}/\partial v_k) = \partial T/\partial v_k \equiv \partial T/\partial \dot{q}_k \equiv p_k(t, q, v) = p_k:$$

Holonomic (k)th component of system *momentum*; (3.3.7a)

(b) $$\mathcal{S}\, dm\, \boldsymbol{v} \cdot (d\boldsymbol{e}_k/dt) = \mathcal{S}\, dm\, \boldsymbol{v} \cdot (\partial \boldsymbol{v}/\partial q_k) = \partial T/\partial q_k \equiv r_k(t, q, v) = r_k:$$

Holonomic (k)th component of "associated, or momental, inertial force"; (3.3.7b)

(c) $$E_k \equiv dp_k/dt - r_k. \tag{3.3.7c}$$

[$p_k \equiv \partial T/\partial \dot{q}_k$ is the only kind of momentum that there is in analytical (Lagrangean and Hamiltonian) mechanics; and, as shown later, it comprises both the linear and angular momentum of the Newton–Euler mechanics.]

2. Nonholonomic System Variables

Substituting the second of (3.3.1) into δI, we obtain, successively with $\boldsymbol{a} = \boldsymbol{a}^* =$ *particle acceleration in nonholonomic variables* (and similarly for other quantities):

$$\delta I \equiv S\, dm\, \boldsymbol{a} \cdot \delta \boldsymbol{r} = S\, dm\, \boldsymbol{a}^* \cdot \left(\sum \boldsymbol{\varepsilon}_k\, \delta\theta_k\right) = \cdots = \sum I_k\, \delta\theta_k, \tag{3.3.8}$$

where $I_k \equiv S\, dm\, \boldsymbol{a}^* \cdot \boldsymbol{\varepsilon}_k =$ *nonholonomic* (k)th component of *system inertial force*

$$\left[\equiv S\, dm\, \boldsymbol{a}^* \cdot (\partial \boldsymbol{v}^*/\partial\omega_k) = S\, dm\, \boldsymbol{a}^* \cdot (\partial \boldsymbol{a}^*/\partial\dot{\omega}_k),\ \text{recalling (2.9.35, 43)}\right]$$
$$= I_k(t, q, \omega, \dot{\omega}) \qquad [\text{since } \boldsymbol{a}^* = \boldsymbol{a}^*(t, q, \omega, \dot{\omega}) \text{ and } \boldsymbol{\varepsilon}_k = \boldsymbol{\varepsilon}_k(t, q)]. \tag{3.3.9}$$

From the invariance of δI: $\sum E_k\, \delta q_k = \sum I_k\, \delta\theta_k$, and [recalling (2.9.11, 12)] $\delta q_k = \sum A_{kl}\, \delta\theta_l \Leftrightarrow \delta\theta_l = \sum a_{lk}\delta q_k$, we readily obtain the basic (covariant vector-like) transformation equations:

$$I_k = \sum A_{lk} E_l \quad \Leftrightarrow \quad E_k = \sum a_{lk} I_l. \tag{3.3.10}$$

The above expresses the nonholonomic inertial components in *holonomic* variables. To express them in terms of *nonholonomic* variables, we transform (3.3.9), successively, as follows:

$$I_k \equiv S\, dm\, \boldsymbol{a}^* \cdot \boldsymbol{\varepsilon}_k = S\, dm(d\boldsymbol{v}^*/dt) \cdot (\partial \boldsymbol{v}^*/\partial\omega_k)$$
$$= d/dt\left(S\, dm\, \boldsymbol{v}^* \cdot (\partial \boldsymbol{v}^*/\partial\omega_k)\right) - S\,[dm\, \boldsymbol{v}^* \cdot d/dt(\partial \boldsymbol{v}^*/\partial\omega_k)]$$
$$[\text{adding and subtracting } S\, dm\, \boldsymbol{v}^* \cdot (\partial \boldsymbol{v}^*/\partial\theta_k),\ \text{and regrouping}]$$
$$= d/dt\left(S\, dm\, \boldsymbol{v}^* \cdot (\partial \boldsymbol{v}^*/\partial\omega_k)\right) - S\, dm\, \boldsymbol{v}^* \cdot (\partial \boldsymbol{v}^*/\partial\theta_k)$$
$$- S\, dm\, \boldsymbol{v}^* \cdot [(d/dt)(\partial \boldsymbol{v}^*/\partial\omega_k) - \partial \boldsymbol{v}^*/\partial\theta_k]; \tag{3.3.11a}$$

or, invoking the nonintegrability identity (2.10.24, 25) [Greek subscripts run from 1 to $n+1$ (time)],

$$E_k{}^*(\boldsymbol{v}^*) \equiv d/dt(\partial \boldsymbol{v}^*/\partial\omega_k) - \partial \boldsymbol{v}^*/\partial\theta_k \equiv d\boldsymbol{\varepsilon}_k/dt - \partial \boldsymbol{v}^*/\partial\theta_k$$
$$= -\sum\sum \gamma^r{}_{kl}\, \omega_l \boldsymbol{\varepsilon}_r - \sum \gamma^r{}_k\, \boldsymbol{\varepsilon}_r \qquad [\text{since } \omega_{n+1} \equiv \omega_0 \equiv dt/dt = 1]$$
$$= -\sum\sum \gamma^r{}_{k\alpha}\, \omega_\alpha \boldsymbol{\varepsilon}_r = -\sum\sum \gamma^r{}_{k\alpha}\, \omega_\alpha (\partial \boldsymbol{v}^*/\partial\omega_r), \tag{3.3.11b}$$

introducing the (inertial) *kinetic energy in quasi variables*

$$T \equiv S\, 1/2(dm\, \boldsymbol{v}^* \cdot \boldsymbol{v}^*) = T(t, q, \omega) \equiv T^* \qquad [\text{since } \boldsymbol{v}^* = \boldsymbol{v}^*(t, q, \omega)] \tag{3.3.11c}$$

and recalling the *symbolic quasi chain rule* (2.9.32a, 44a)

$$\partial T^*/\partial\theta_k \equiv \sum (\partial T^*/\partial q_l)(\partial v_l/\partial\omega_k) = \sum A_{lk}(\partial T^*/\partial q_l), \tag{3.3.11d}$$

and the (*nonholonomic Euler–Lagrange operator*)$_k$

$$E_k{}^*(\ldots) \equiv d/dt(\partial \ldots/\partial\omega_k) - \partial \ldots/\partial\theta_k, \tag{3.3.11e}$$

we finally obtain the nonholonomic (system) variable counterpart of E_k:

$$\begin{aligned} I_k &= d/dt(\partial T^*/\partial\omega_k) - \partial T^*/\partial\theta_k + \sum\sum \gamma^r{}_{kl}(\partial T^*/\partial\omega_r)\omega_l + \sum \gamma^r{}_k(\partial T^*/\partial\omega_r) \\ &= d/dt(\partial T^*/\partial\omega_k) - \partial T^*/\partial\theta_k + \sum\sum \gamma^r{}_{k\alpha}(\partial T^*/\partial\omega_r)\omega_\alpha \\ &\equiv E_k{}^*(T^*) - \Gamma_k \equiv E_k{}^* - \Gamma_k \qquad \text{[note difference from (3.3.6)]}, \end{aligned} \tag{3.3.12}$$

where [recalling (2.10.25a)]

$$\begin{aligned} -\Gamma_k &\equiv -S\, dm\, \boldsymbol{v}^* \cdot E_k{}^*(\boldsymbol{v}^*) = \sum\sum \gamma^r{}_{k\alpha}(\partial T^*/\partial\omega_r)\omega_\alpha \equiv \sum h^r{}_k(\partial T^*/\partial\omega_r) \\ &= -(\text{System } \textit{nonholonomic deviation}, \text{ or correction, term})_k. \end{aligned} \tag{3.3.12a}$$

We summarize the key kinematico-inertial identities below:

(a) $$S\, dm\, \boldsymbol{v}^* \cdot \boldsymbol{\varepsilon}_k = S\, dm\, \boldsymbol{v}^* \cdot (\partial\boldsymbol{v}^*/\partial\omega_k) = \partial T^*/\partial\omega_k \equiv P_k(t, q, \omega) = P_k:$$
Nonholonomic (k)th component of system *momentum*, (3.3.13a)

(b) $$\boldsymbol{\gamma}_k \equiv E_k{}^*(\boldsymbol{v}^*) \equiv d\boldsymbol{\varepsilon}_k/dt - \partial\boldsymbol{v}^*/\partial\theta_k = \cdots = \sum\sum \gamma^r{}_{\alpha k}\,\omega_\alpha \boldsymbol{\varepsilon}_r$$
$= -$(Particle *nonholonomic deviation*, or correction, term)$_k$, (3.3.13b)

$$\begin{aligned} S\, dm\, \boldsymbol{v}^* \cdot (d\boldsymbol{\varepsilon}_k/dt) &\equiv S\, dm\, \boldsymbol{v}^* \cdot (\partial\boldsymbol{v}^*/\partial\theta_k) + S\, dm\, \boldsymbol{v}^* \cdot \boldsymbol{\gamma}_k \\ &= \partial T^*/\partial\theta_k + \sum\sum \gamma^r{}_{\alpha k}(\partial T^*/\partial\omega_r)\omega_\alpha = \partial T^*/\partial\theta_k - \sum\sum \gamma^r{}_{k\alpha}(\partial T^*/\partial\omega_r)\omega_\alpha \\ &= \partial T^*/\partial\theta_k + \Gamma_k \qquad \text{[note difference from (3.3.7b)]}, \end{aligned} \tag{3.3.13c}$$

$$-\Gamma_k = \sum\sum \gamma^r{}_{k\alpha}(\partial T^*/\partial\omega_r)\omega_\alpha = -\Gamma_{k,n} - \Gamma_{k,0}, \tag{3.3.13d}$$

where

$$-\Gamma_{k,n} \equiv \sum\sum \gamma^r{}_{kl}(\partial T^*/\partial\omega_r)\omega_l, \tag{3.3.13e}$$

$$-\Gamma_{k,0} \equiv -\Gamma_{k,n+1} \equiv \sum \gamma^r{}_k(\partial T^*/\partial\omega_r):$$
"nonholonomic rheonomic force". (3.3.13f)

With the help of the above, I_k, (3.3.12), can be rewritten in the *momentum* form:

$$I_k = dP_k/dt - \partial T^*/\partial\theta_k + \sum\sum \gamma^r{}_{k\alpha} P_r\,\omega_\alpha. \tag{3.3.14}$$

[Originally due to Hamel [1904(a),(b)], but for *stationary/scleronomic* transformations; that is, with α replaced by, say, $l = 1, \ldots, n$.]

(c) $$\delta I \equiv S\, dm\, \boldsymbol{a} \cdot \delta\boldsymbol{r} = \sum E_k\,\delta q_k = \sum I_k\,\delta\theta_k, \tag{3.3.15}$$

where

$$E_k \equiv S\, dm\, \boldsymbol{a} \cdot \boldsymbol{e}_k = d/dt(\partial T/\partial v_k) - \partial T/\partial q_k \equiv E_k(T) = \sum a_{lk} I_l, \qquad (3.3.15a)$$

$$I_k \equiv S\, dm\, \boldsymbol{a}^* \cdot \boldsymbol{\varepsilon}_k = d/dt(\partial T^*/\partial \omega_k) - \partial T^*/\partial \theta_k + \sum\sum \gamma^r_{k\alpha}(\partial T^*/\partial \omega_r)\omega_\alpha$$
$$\equiv E_k{}^*(T^*) - \Gamma_k \equiv E_k{}^* - \Gamma_k = \sum A_{lk} E_l; \qquad (3.3.15b)$$

that is, it is $E_k \equiv E_k(T)$ and I_k that transform like covariant vectors; the $E_k{}^* \equiv E_k{}^*(T^*)$ do *not* (or, the terms $E_k{}^*$ and Γ_k, considered separately, do not transform as covariant vectors; but taken *together*, as $E_k{}^* - \Gamma_k \equiv I_k$, *they do!*).

3. Acceleration, or Appellian, Forms

The above expressions for the inertia vector E_k (or I_k) are based on the kinetic energy T (*or* T^*), because for their derivation we used the *velocity* identities $\boldsymbol{e}_k = \partial \boldsymbol{v}/\partial v_k$ (or $\boldsymbol{\varepsilon}_k = \partial \boldsymbol{v}^*/\partial \omega_k$). Let us now find expressions for these vectors using the *acceleration* identities $\boldsymbol{e}_k = \partial \boldsymbol{a}/\partial \ddot{q}_k \equiv \partial \boldsymbol{a}/\partial w_k$ (or $\boldsymbol{\varepsilon}_k = \partial \boldsymbol{a}^*/\partial \dot{\omega}_k$). The results will turn out to be based on a scalar function that depends on the accelerations in a similar way that T (*or* T^*) depend on the velocities. [The choice $\boldsymbol{e}_k = \partial \boldsymbol{r}/\partial q_k$ does not seem to lead to any useful expression for E_k; while the choice $\boldsymbol{\varepsilon}_k = \partial \boldsymbol{r}^*/\partial \theta_k \equiv \sum A_{lk} \boldsymbol{e}_l \equiv \sum A_{lk}(\partial \boldsymbol{v}/\partial v_l)$ will be examined later.]

(i) Holonomic variables

We have, successively,

$$E_k \equiv S\, dm\, \boldsymbol{a} \cdot \boldsymbol{e}_k = S\, dm\, \boldsymbol{a} \cdot (\partial \boldsymbol{a}/\partial \ddot{q}_k) = \partial S/\partial \ddot{q}_k \equiv \partial S/\partial w_k, \qquad (3.3.16a)$$

where

$$S \equiv S\,(1/2)(dm\, \boldsymbol{a} \cdot \boldsymbol{a}) = S\,(1/2)(dm\, a^2) = S(t, q, \dot{q}, \ddot{q}) \equiv S(t, q, v, w):$$

"Gibbs–Appell function," or simply *Appellian*, in holonomic variables [or "acceleration energy" (Saint-Germain, 1901)]. (3.3.16b)

(ii) Nonholonomic variables

Similarly, we obtain

$$I_k \equiv S\, dm\, \boldsymbol{a}^* \cdot \boldsymbol{\varepsilon}_k = S\, dm\, \boldsymbol{a}^* \cdot (\partial \boldsymbol{a}^*/\partial \dot{\omega}_k) = \partial S^*/\partial \dot{\omega}_k, \qquad (3.3.17a)$$

where

$$S^* \equiv S\,(1/2)(dm\, \boldsymbol{a}^* \cdot \boldsymbol{a}^*) = S\,(1/2)[dm(a^*)^2] = S^*(t, q, \omega, \dot{\omega}):$$

Appellian, in nonholonomic variables. (3.3.17b)

To relate the above, we apply chain rule to $S = S^*$. We obtain, successively,

$$\partial S/\partial \ddot{q}_k \equiv \partial S/\partial w_k = \sum (\partial S^*/\partial \dot{\omega}_l)(\partial \dot{\omega}_l/\partial \ddot{q}_k) = \sum a_{lk}(\partial S^*/\partial \dot{\omega}_l), \qquad (3.3.17c)$$

and, inversely,

$$\partial S^*/\partial\dot{\omega}_k = \sum (\partial S/\partial\ddot{q}_l)(\partial\ddot{q}_l/\partial\dot{w}_k) = \sum A_{lk}(\partial S/\partial\ddot{q}_l) \equiv \sum A_{lk}(\partial S/\partial w_l); \tag{3.3.17d}$$

which are none other than the transformation equations (3.3.10).

In sum, we have the following theoretically equivalent expressions for E_k and I_k:

(i) $$\begin{aligned} E_k &\equiv S\, dm\, \boldsymbol{a}\cdot\boldsymbol{e}_k \Big(= \sum a_{lk} I_l\Big) \\ &= d/dt(\partial T/\partial v_k) - \partial T/\partial q_k && \text{[Lagrange (1780)]} \\ &= \sum a_{lk}[E_l{}^*(T^*) - \Gamma_l] \\ &= \sum a_{lk}(\partial S^*/\partial\dot{\omega}_l) = \partial S/\partial\ddot{q}_k \equiv \partial S/\partial w_k && \text{[Appell (1899)];} \end{aligned} \tag{3.3.18a}$$

(ii) $$\begin{aligned} I_k &\equiv S\, dm\, \boldsymbol{a}^*\cdot\boldsymbol{\varepsilon}_k \qquad \Big(= \sum A_{lk} E_l\Big) \\ &= d/dt(\partial T^*/\partial\omega_k) - \partial T^*/\partial\theta_k + \sum\sum \gamma^r{}_{k\alpha}(\partial T^*/\partial\omega_r)\omega_\alpha \\ &\equiv E_k{}^*(T^*) - \Gamma_k && \text{[Volterra (1898), Hamel (1903/1904)]} \\ &= \sum A_{lk}\big[d/dt(\partial T/\partial v_l) - \partial T/\partial q_l\big] && \text{[Maggi (1896, 1901, 1903)]} \\ &= \sum A_{lk}(\partial S/\partial\ddot{q}_l) = \partial S^*/\partial\dot{\omega}_k && \text{[Gibbs (1879)].} \end{aligned} \tag{3.3.18b}$$

REMARKS

(i) We can define $(n+1)$th, or (0)th, "temporal" holonomic and nonholonomic components of the system inertia vector by (with $dq_{n+1}/dt \equiv dq_0/dt \equiv dt/dt \equiv v_{n+1} \equiv v_0 = 1$)

$$\begin{aligned} E_{n+1} \equiv E_0 &\equiv S\, dm\, \boldsymbol{a}\cdot\boldsymbol{e}_{n+1} = S\, dm\, \boldsymbol{a}\cdot\boldsymbol{e}_0 = S\, dm\, \boldsymbol{a}\cdot(\partial\boldsymbol{r}/\partial t) \\ &= \cdots = d/dt(\partial T/\partial v_0) - \partial T/\partial q_0 = d/dt(\partial T/\partial\dot{t}) - \partial T/\partial t, \end{aligned} \tag{3.3.19a}$$

$$I_{n+1} \equiv I_0 \equiv S\, dm\, \boldsymbol{a}^*\cdot\boldsymbol{\varepsilon}_{n+1} = S\, dm\, \boldsymbol{a}^*\cdot\boldsymbol{\varepsilon}_0 = S\, dm\, \boldsymbol{a}^*\cdot(\partial\boldsymbol{r}^*/\partial\theta_0) = \cdots. \tag{3.3.19b}$$

However, such *nonvirtual* components will not be needed in the equations of motion; they could play a role in the formulation of "partial work/energy rate" equations (§3.9).

(ii) Here, as throughout this book [e.g. (2.9.38ff.), ch. 5], superstars $(\ldots)^*$ denote functions of $t, q, \omega, \dot{\omega}, \ldots$:

$$f(t, q, \dot{q}, \ddot{q}, \ldots) = f[t, q, \dot{q}(t, q, \omega), \ddot{q}(t, q, \omega, \dot{\omega}), \ldots] \equiv f^*(t, q, \omega, \dot{\omega}, \ldots).$$

A Special Case

Let us find E_k and I_k for the following special quasi-velocity choice (recalling 2.11.9 ff.)

$$v_D = \sum b_{DI}(t, q) v_I + b_D(t, q), \qquad v_I = \sum \delta_{II'} v_{I'} = v_I, \tag{3.3.20a}$$

and its inverse

$$\omega_D = \sum b_{DI}(t,q)v_I + b_D(t,q), \qquad \omega_I = v_I. \tag{3.3.20b}$$

Here, clearly [recalling (2.11.12b), and with $\delta_{..} =$ *Kronecker delta*];

$$A_{DD'} = \delta_{DD'}, \qquad A_{DI} = b_{DI}, \qquad A_{ID} = 0, \qquad A_{II'} = \delta_{II'}, \tag{3.3.20c}$$

and so the *Maggi form* $I_k = \sum A_{lk}E_l$ specializes to $I_k = \sum A_{Dk}E_D + \sum A_{Ik}E_I$

$$\Rightarrow I_{D'} = \sum \delta_{DD'}E_D + \sum (0)E_I = E_{D'}, \tag{3.3.20d}$$

$$I_{I'} = \sum b_{DI'}E_D + \sum \delta_{II'}E_I = E_{I'} + \sum b_{DI'}E_D. \tag{3.3.20e}$$

In sum, for the special choice (3.3.20a, b) I_k takes the following form, in terms of *holonomic* Lagrangean (T) and Appellian (S) variables (with $D = 1, \ldots, m$; $I = m+1, \ldots, n$ as usual):

$$I_D = E_D \equiv (\partial T/\partial v_D)^{\cdot} - \partial T/\partial q_D = \partial S/\partial \dot{v}_D \equiv \partial S/\partial w_D; \tag{3.3.20f}$$

$$I_I = E_I + \sum b_{DI}E_D \equiv [(\partial T/\partial v_I)^{\cdot} - \partial T/\partial q_I] + \sum b_{DI}[(\partial T/\partial v_D)^{\cdot} - \partial T/\partial q_D]$$

[Chaplygin (1895, publ. 1897), Hadamard (1895)] (3.3.20g)

$$= \partial S/\partial \ddot{q}_I + \sum b_{DI}(\partial S/\partial \ddot{q}_D) \equiv \partial S/\partial w_I + \sum b_{DI}(\partial S/\partial w_D). \tag{3.3.20h}$$

The specialization of I_k, for (3.3.20a, b), to *nonholonomic* variables [due to Chaplygin (1895/1897), *in addition to* his equations (3.3.20g); and Voronets (1901)] and other related results, are given in §3.8.

We have expressed the (*total, first order*) *virtual work of the* (*negative of the*) *inertial* "*forces*," δI, in system variables. The kinematico-inertial identities obtained are central to analytical mechanics, and that is why they were deliberately presented before any discussion of system forces and constraints; because, indeed, they are independent of the latter. These identities also show clearly the importance of the *kinetic energy* (primarily) and the *Appellian* (secondarily) to our subject, and so these quantities are examined in detail later (§3.9.11, 13–16).

Now, let us proceed to express the virtual works of the real forces, namely, $\delta' W$ and $\delta' W_R$, in system variables. This will be considerably easier than the task just completed.

3.4 VIRTUAL WORKS OF FORCES: IMPRESSED ($\delta' W$) AND CONSTRAINT REACTIONS ($\delta' W_R$)

1. Holonomic Variables

Substituting $\delta \boldsymbol{r} = \sum \boldsymbol{e}_k\, \delta q_k$ into the earlier expressions for $\delta' W$ and $\delta' W_R$ (3.2.7, 10), we readily obtain

$$\delta' W \equiv \mathsf{S}\, d\boldsymbol{F} \cdot \delta \boldsymbol{r} = \mathsf{S}\, d\boldsymbol{F} \cdot \left(\sum \boldsymbol{e}_k\, \delta q_k\right) = \cdots = \sum Q_k\, \delta q_k, \tag{3.4.1a}$$

$$\delta' W_R \equiv \mathsf{S}\, d\boldsymbol{R} \cdot \delta \boldsymbol{r} = \mathsf{S}\, d\boldsymbol{R} \cdot \left(\sum \boldsymbol{e}_k\, \delta q_k\right) = \cdots = \sum R_k\, \delta q_k, \tag{3.4.1b}$$

where

$$Q_k \equiv \int dF \cdot e_k\text{: Holonomic }(k)\text{th component of system } \textit{impressed} \text{ force,} \tag{3.4.1c}$$

$$R_k \equiv \int dR \cdot e_k\text{: Holonomic }(k)\text{th component of system } \textit{constraint reaction}. \tag{3.4.1d}$$

2. Nonholonomic Variables

Substituting $\delta \boldsymbol{r} = \sum \boldsymbol{\varepsilon}_k \, \delta\theta_k$ ($\equiv \delta \boldsymbol{r}^*$) into $\delta' W$ and $\delta' W_R$, we, similarly, obtain

$$\delta' W \equiv \int d\boldsymbol{F} \cdot \delta \boldsymbol{r}^* = \int d\boldsymbol{F} \cdot \left(\sum \boldsymbol{\varepsilon}_k \, \delta\theta_k\right) = \cdots = \sum \Theta_k \, \delta\theta_k, \tag{3.4.2a}$$

$$\delta' W_R \equiv \int d\boldsymbol{R} \cdot \delta \boldsymbol{r}^* = \int d\boldsymbol{R} \cdot \left(\sum \boldsymbol{\varepsilon}_k \, \delta\theta_k\right) = \cdots = \sum \Lambda_k \, \delta\theta_k, \tag{3.4.2b}$$

where

$$\Theta_k \equiv \int d\boldsymbol{F} \cdot \boldsymbol{\varepsilon}_k\text{: Nonholonomic }(k)\text{th component of system } \textit{impressed} \text{ force,} \tag{3.4.2c}$$

$$\Lambda_k \equiv \int d\boldsymbol{R} \cdot \boldsymbol{\varepsilon}_k\text{: Nonholonomic }(k)\text{th component of system } \textit{constraint} \text{ force.} \tag{3.4.2d}$$

Here too, these are ever valid definitions/results, no matter how many constraints may be imposed on the system later.

3. Transformation Relations

From the invariance of the virtual differentials $\delta' W$ and $\delta' W_R$, we obtain the following transformation formulae for the various system forces; that is, from

$$\begin{aligned}\delta' W = \sum Q_k \, \delta q_k = \sum Q_k \left(\sum A_{kl} \, \delta\theta_l\right) = \sum \Theta_l \, \delta\theta_l = \sum \Theta_l \left(\sum a_{lk} \, \delta q_k\right) \\ = \sum Q_k \, \delta q_k,\end{aligned} \tag{3.4.3a}$$

we conclude

$$\Theta_l = \sum A_{kl} Q_k \qquad \left[= \sum Q_k (\partial v_k / \partial \omega_l)\right] \tag{3.4.3b}$$

and, inversely,

$$Q_k = \sum a_{lk} \Theta_l \qquad \left[= \sum (\partial \omega_l / \partial v_k) \Theta_l\right]; \tag{3.4.3c}$$

and, similarly, from $\delta' W_R = \cdots$, we conclude

$$\Lambda_l = \sum A_{kl} R_k \qquad \left[= \sum R_k (\partial v_k / \partial \omega_l)\right] \tag{3.4.3d}$$

and, inversely,

$$R_k = \sum a_{lk} \Lambda_l \qquad \left[= \sum (\partial \omega_l / \partial v_k) \Lambda_l\right]. \tag{3.4.3e}$$

[These formulae can also be obtained from the $\boldsymbol{e}_k \Leftrightarrow \boldsymbol{\varepsilon}_k$ transformation equations (2.9.25a, b) as follows:

$$\Theta_l \equiv S\, d\boldsymbol{F}\cdot\boldsymbol{\varepsilon}_l = S\, d\boldsymbol{F}\cdot\Big(\sum A_{kl}\boldsymbol{\varepsilon}_k\Big) = \sum A_{kl}\Big(S\, d\boldsymbol{F}\cdot\boldsymbol{e}_k\Big) = \sum A_{kl}Q_k,$$

$$Q_k \equiv S\, d\boldsymbol{F}\cdot\boldsymbol{e}_k = S\, d\boldsymbol{F}\cdot\Big(\sum a_{lk}\boldsymbol{\varepsilon}_l\Big) = \sum a_{lk}\Big(S\, d\boldsymbol{F}\cdot\boldsymbol{\varepsilon}_l\Big) = \sum a_{lk}\Theta_l.]$$

Rheonomic, or "temporal," $(n+1)$th *nonvirtual* force components can also be defined by

$$Q_{n+1} \equiv Q_0 \equiv S\, d\boldsymbol{F}\cdot\boldsymbol{e}_{n+1} \equiv S\, d\boldsymbol{F}\cdot\boldsymbol{e}_0 \equiv S\, d\boldsymbol{F}\cdot(\partial\boldsymbol{r}/\partial t) \qquad \text{(holonomic impressed)}, \tag{3.4.4a}$$

$$R_{n+1} \equiv R_0 \equiv S\, d\boldsymbol{R}\cdot\boldsymbol{e}_{n+1} \equiv S\, d\boldsymbol{R}\cdot\boldsymbol{e}_0 \equiv S\, d\boldsymbol{R}\cdot(\partial\boldsymbol{r}/\partial t) \qquad \text{(holonomic reaction)}; \tag{3.4.4b}$$

$$\Theta_{n+1} \equiv \Theta_0 \equiv S\, d\boldsymbol{F}\cdot\boldsymbol{\varepsilon}_{n+1} \equiv S\, d\boldsymbol{F}\cdot\boldsymbol{\varepsilon}_0 \equiv S\, d\boldsymbol{F}\cdot(\partial\boldsymbol{r}^*/\partial\theta_{n+1}) \qquad \text{(nonholonomic impressed)}, \tag{3.4.4c}$$

$$\Lambda_{n+1} \equiv \Lambda_0 \equiv S\, d\boldsymbol{R}\cdot\boldsymbol{\varepsilon}_{n+1} \equiv S\, d\boldsymbol{R}\cdot\boldsymbol{\varepsilon}_0 \equiv S\, d\boldsymbol{R}\cdot(\partial\boldsymbol{r}^*/\partial\theta_{n+1}) \qquad \text{(nonholonomic reaction)}; \tag{3.4.4d}$$

and, recalling (2.9.26a, b), we can easily deduce the following transformation equations among these components:

$$\begin{aligned} Q_{n+1} \equiv Q_0 &\equiv S\, d\boldsymbol{F}\cdot\boldsymbol{e}_{n+1} = S\, d\boldsymbol{F}\cdot\Big(\sum a_{k,n+1}\boldsymbol{\varepsilon}_k + \boldsymbol{\varepsilon}_{n+1}\Big) \\ &= \sum a_{k,n+1}\Big(S\, d\boldsymbol{F}\cdot\boldsymbol{\varepsilon}_k\Big) + S\, d\boldsymbol{F}\cdot\boldsymbol{\varepsilon}_{n+1} = \sum a_{k,n+1}\Theta_k + \Theta_{n+1}, \end{aligned} \tag{3.4.4e}$$

$$\begin{aligned} R_{n+1} \equiv R_0 &\equiv S\, d\boldsymbol{R}\cdot\boldsymbol{e}_{n+1} = S\, d\boldsymbol{R}\cdot\Big(\sum a_{k,n+1}\boldsymbol{\varepsilon}_k + \boldsymbol{\varepsilon}_{n+1}\Big) \\ &= \sum a_{k,n+1}\Big(S\, d\boldsymbol{R}\cdot\boldsymbol{\varepsilon}_k\Big) + S\, d\boldsymbol{R}\cdot\boldsymbol{\varepsilon}_{n+1} = \sum a_{k,n+1}\Lambda_k + \Lambda_{n+1}; \end{aligned} \tag{3.4.4f}$$

and, conversely,

$$\begin{aligned} \Theta_0 &\equiv S\, d\boldsymbol{F}\cdot\boldsymbol{\varepsilon}_0 = S\, d\boldsymbol{F}\cdot\Big(\sum A_k\boldsymbol{e}_k + \boldsymbol{e}_0\Big) \\ &= \sum A_k\Big(S\, d\boldsymbol{F}\cdot\boldsymbol{e}_k\Big) + S\, d\boldsymbol{F}\cdot\boldsymbol{e}_0 = \sum A_kQ_k + Q_0, \end{aligned} \tag{3.4.4g}$$

$$\begin{aligned} \Lambda_0 &\equiv S\, d\boldsymbol{R}\cdot\boldsymbol{\varepsilon}_0 = S\, d\boldsymbol{R}\cdot\Big(\sum A_k\boldsymbol{e}_k + \boldsymbol{e}_0\Big) \\ &= \sum A_k\Big(S\, d\boldsymbol{R}\cdot\boldsymbol{e}_k\Big) + S\, d\boldsymbol{R}\cdot\boldsymbol{e}_0 = \sum A_kR_k + R_0. \end{aligned} \tag{3.4.4h}$$

Problem 3.4.1 With the help of the second of each of (2.9.3a, b), prove the additional forms of the above transformation equations:

$$\Theta_{n+1} = -\sum a_{k,n+1}\Theta_k + Q_{n+1}, \qquad \text{or, simply,} \qquad \Theta_0 = -\sum a_k\Theta_k + Q_0, \tag{a}$$

$$\Lambda_{n+1} = -\sum a_{k,n+1}\Lambda_k + R_{n+1}, \qquad \text{or, simply,} \qquad \Lambda_0 = -\sum a_k\Lambda_k + R_0. \tag{b}$$

REMARK

A little analytical reflection will show that all these transformations can be condensed in the formulae [with Greek subscripts running from 1 to $n+1$, recall (2.9.6a, b)]:

$$\Theta_\alpha = \sum A_{\beta\alpha} Q_\beta \;\Leftrightarrow\; Q_\beta = \sum a_{\alpha\beta}\Theta_\alpha, \tag{3.4.5a}$$

$$\Lambda_\alpha = \sum A_{\beta\alpha} R_\beta \;\Leftrightarrow\; R_\beta = \sum a_{\alpha\beta}\Lambda_\alpha. \tag{3.4.5b}$$

A Special Case

For the earlier particular case (3.3.20a ff.: $A_{DD'} = \delta_{DD'}$, $A_{DI} = b_{DI}$, $A_{ID} = 0$, $A_{II'} = \delta_{II'}$), the above transformation equations specialize to

$$\Theta_{D'} = \sum A_{kD'} Q_k = \sum \delta_{DD'} Q_D + \sum (0) Q_I = Q_{D'}, \quad \text{i.e.,} \quad \Theta_D = Q_D, \tag{3.4.6a}$$

$$\Theta_{I'} = \sum A_{kI'} Q_k = \sum b_{DI'} Q_D + \sum \delta_{II'} Q_I = Q_{I'} + \sum b_{DI'} Q_D,$$

$$\text{i.e.,} \qquad \Theta_I = Q_I + \sum b_{DI} Q_D \equiv Q_{I,o} \equiv Q_{Io}; \tag{3.4.6b}$$

and, similarly,

$$\Theta_0 = \cdots = \sum b_D Q_D + Q_0 \equiv Q_{0,o}. \tag{3.4.6c}$$

Example 3.4.1 *Virtually Workless Forces.* The following are examples of forces that do zero virtual work:

(i) Forces among the particles of a rigid body; generally, the forces among rigidly connected particles and/or bodies.
(ii) Forces on particles that are either at rest (e.g., a fixed pivot, or hinge, about which a system body may turn, or a joint between two system bodies), or are constrained to move in *prescribed* ways; that is, their (inertial) motion is known in advance as a function of time.
(iii) Forces from completely *smooth* curves and/or surfaces that are either at (inertial) rest or have *prescribed* (inertial) motions.
(iv) Forces from perfectly *rough* curves and/or surfaces, either at rest or having prescribed motions. See also Pars (1965, pp. 24–25), Whittaker (1937, pp. 31–32).

Example 3.4.2 If z is a virtual displacement, then $S\, d\boldsymbol{R}\cdot\boldsymbol{z} = 0$. Let us show the *converse*: If for a kinematically admissible/possible vector $\boldsymbol{z}$ we have $S\, d\boldsymbol{R}\cdot\boldsymbol{z} = 0$, then $\boldsymbol{z}$ is a virtual displacement; that is,

$$\boldsymbol{z} = \sum \boldsymbol{\varepsilon}_I\, \delta\theta_I \qquad (I = m+1, \ldots, n). \tag{a}$$

The proof is by contradiction: Let $\boldsymbol{z} = \delta\boldsymbol{r} + \boldsymbol{y}$ ($\neq \delta\boldsymbol{r}$), where the *relaxed* part $\boldsymbol{y}$ may be, at most,

$$\boldsymbol{y} = \sum \boldsymbol{\varepsilon}_D\, \delta'\theta_D + \boldsymbol{\varepsilon}_0\, \delta' t \qquad (D = 1, \ldots, m; \quad \delta'\theta_D, \delta' t\text{: components of } \boldsymbol{y}). \tag{b}$$

Substituting (b) into LP we get, successively,

$$0 = S\, d\boldsymbol{R}\cdot\boldsymbol{z} = S\, d\boldsymbol{R}\cdot\delta\boldsymbol{r} + S\, d\boldsymbol{R}\cdot\boldsymbol{y} = \cdots = 0 + \sum \Lambda_D\, \delta'\theta_D + \Lambda_0\, \delta' t,$$

from which, since the $m+1$ $\delta'\theta_D$ and $\delta' t$ are *independent*, we obtain $\Lambda_D, \Lambda_0 = 0$. But, clearly, due to the constraints $\delta\theta_D = 0$ and $\delta t = 0$, this is impossible. Thus, if we assume that $\boldsymbol{y} \neq \boldsymbol{0}$, we are led to a contradiction. Hence, $\boldsymbol{y} = \boldsymbol{0}$, and $\boldsymbol{z}$ is a virtual displacement expressible by (a).

3.5 EQUATIONS OF MOTION VIA LAGRANGE'S PRINCIPLE: GENERAL FORMS

Let us now proceed to the final synthesis; that is, the formulation of equations of motion in general system variables. We begin with the "constraint reaction part" of LP, eq. (3.2.7), and so on:

$$\delta' W_R \equiv \mathsf{S}\, d\boldsymbol{R} \cdot \delta\boldsymbol{r} = \sum R_k\, \delta q_k = \sum \Lambda_k\, \delta\theta_k = 0. \tag{3.5.1}$$

If the n δq's are *unconstrained* (or *independent*, or *free*), so are the n $\delta\theta$'s. Then, (3.5.1) leads to

$$R_k = 0, \qquad \Lambda_k = 0. \tag{3.5.2}$$

If, however, the n δq's are *constrained* by the m $(< n)$ Pfaffian, holonomic and/or nonholonomic, constraints

$$\delta\theta_D \equiv \sum a_{Dk}\, \delta q_k = 0 \qquad (D = 1, \ldots, m), \tag{3.5.3}$$

then, introducing m *Lagrangean* (hitherto) *undetermined multipliers* $-\lambda_D = -\lambda_D(t)$ (the minus sign is only for algebraic convenience—see multiplier rule, below), and invoking (3.5.3), we can replace (3.5.1) with

$$\begin{aligned} \delta' W_R + \sum (-\lambda_D)\, \delta\theta_D &= \sum \Lambda_k\, \delta\theta_k + \sum (-\lambda_D)\, \delta\theta_D \\ &= \sum R_k\, \delta q_k + \sum\sum (-\lambda_D) a_{Dk}\, \delta q_k = 0, \end{aligned} \tag{3.5.4}$$

where, now, the n δq's and $\delta\theta$'s (can be treated as if they) are free. Therefore, (3.5.4) leads immediately to the following:

(i) in *holonomic* variables,

$$\sum \Big(R_k - \sum \lambda_D\, a_{Dk} \Big)\, \delta q_k = 0 \;\Rightarrow\; R_k = \sum \lambda_D a_{Dk} \qquad [= R_k(q, t)]; \tag{3.5.5}$$

(ii) in *nonholonomic* variables (with $I = m+1, \ldots, n$),

$$\sum \Lambda_k\, \delta\theta_k - \sum \lambda_D\, \delta\theta_D = \sum (\Lambda_D - \lambda_D)\, \delta\theta_D + \sum (\Lambda_I - 0)\, \delta\theta_I = 0, \tag{3.5.6}$$

and from this to the nonholonomic counterpart of (3.5.5),

$$\Lambda_D = \lambda_D \quad (1 \cdot \delta\theta_D = 0) \qquad \text{and} \qquad \Lambda_I = 0 \quad (0 \cdot \delta\theta_I = 0); \tag{3.5.7}$$

that is, the m Lagrangean multipliers associated with the m "equilibrium" constraints $\omega_D = 0$ or $\delta\theta_D = 0$ are, in effect, the first m nonholonomic (covariant) components of the system reaction vector in configuration space. We also notice that whenever $\delta\theta_k = 0$, $\Lambda_k \neq 0$, and vice versa ($k = 1, \ldots, n$; and even $n+1$), that is,

$\Lambda_D\,\delta\theta_D = (\Lambda_D)(0) = 0$ and $\Lambda_I\,\delta\theta_I = (0)(\delta\theta_I) = 0$, so that

$$\delta' W_R = \sum \Lambda_D\,\delta\theta_D + \sum \Lambda_I\,\delta\theta_I = 0 + 0 = 0, \tag{3.5.8}$$

in accordance with LP.

The advantage of the nonholonomic (3.5.7, 8) over the holonomic (3.5.5) is that, in the former, constraints and reactions *decouple* naturally; whereas in the latter they are coupled; that is, in general,

$$\delta q_k \neq 0, \quad R_k \neq 0 \;\;\Rightarrow\;\; R_k\,\delta q_k \neq 0, \qquad \textit{but} \qquad \sum R_k\,\delta q_k = 0. \tag{3.5.9}$$

Finally, substituting the first of (3.5.7) into (3.5.5), we recover the earlier transformation equations (3.4.3e): $R_k = \sum \Lambda_D a_{Dk} = \sum \Lambda_I a_{Ik}$, as expected.

REMARK

In the case of *unilateral* constraints $\delta\theta_D \geq 0$ (if, originally, they have the form $\delta\theta_D \leq 0$, we replace $\delta\theta_D$ with $-\delta\theta_D$), from the "unilateral LP" $\delta' W_R \geq 0$ and (3.5.4) we conclude that $\sum \lambda_D\,\delta\theta_D \geq 0$; and since the $\delta\theta_D$ are positive or zero, the λ_D must also be positive or zero.

In sum: If the unilateral constraints are chosen so that $\delta\theta_* > 0$ is possible/admissible, then the corresponding reaction λ_* is positive or zero (see also §3.7).

The Lagrangean Multiplier Rule, or Adjoining of Constraints

This fundamental mathematical theorem [one of the most useful mathematical results of the 18th century, initiated by Euler, but brought to prominence by Lagrange—see Hoppe (1926(a), p. 62)] states that:

The single (differential) variational equation

$$\delta' M \equiv \sum M_k\,\delta q_k = 0, \tag{3.5.10a}$$

where $M_k = M_k(q, \dot q, \ddot q, \ldots, t)$ and the n δq's are restricted by the m ($<n$) independent Pfaffian constraints

$$\delta\theta_D \equiv \sum a_{Dk}\,\delta q_k = 0 \qquad [\textit{rank}\ (a_{Dk}) = m], \tag{3.5.10b}$$

is completely equivalent to the new variational equation

$$\delta' M + \sum (-\lambda_D)\,\delta\theta_D = \delta' M + \sum\sum (-\lambda_D a_{Dk})\,\delta q_k = 0,$$

or

$$\sum \Big(M_k - \sum \lambda_D a_{Dk} \Big)\,\delta q_k = 0, \tag{3.5.10c}$$

where the n δq's are (better, can be viewed as) unconstrained; that is, (3.5.10a, b) are equivalent to the n equations

$$M_k = \sum \lambda_D a_{Dk} \tag{3.5.10d}$$

which, along with the m constraints (3.5.10b), in velocity form

$$\omega_D \equiv \sum a_{Dk}\dot{q}_k + a_D = 0, \tag{3.5.10e}$$

make up a system of $n+m$ equations for the $n+m$ unknown functions $q(t)$ and $\lambda(t)$.

INFORMAL PROOF

Let us define the $m\,\lambda_D$'s by the m nonsingular equations

$$M_{D'} = \sum \lambda_D a_{DD'} \qquad (D, D' = 1, \ldots, m), \tag{3.5.10f}$$

that is, eqs. (3.5.10d) with $k \to D'$. For such λ's eq. (3.5.10c) reduces to

$$\sum \Big(M_I - \sum \lambda_D a_{DI}\Big)\,\delta q_I = 0, \tag{3.5.10g}$$

where the $(n-m)\,\delta q_I$'s are now free. From the above, we immediately conclude that

$$M_I = \sum \lambda_D a_{DI}; \tag{3.5.10h}$$

that is, eqs. (3.5.10d) with $k \to I$.

Example 3.5.1 *Lagrange's Equations of the First Kind.* The multiplier rule applied to

$$\delta' W_R \equiv S\, d\boldsymbol{R}\cdot\delta\boldsymbol{r} = 0, \tag{a}$$

where the $\delta\boldsymbol{r}$ are restricted by (i) the h holonomic constraints $(H = 1, \ldots, h)$

$$\phi_H(t, \boldsymbol{r}) = 0 \;\Rightarrow\; \delta\phi_H = S\,(\partial\phi_H/\partial\boldsymbol{r})\cdot\delta\boldsymbol{r} = 0, \tag{b1}$$

and (ii) the m Pfaffian (possibly nonholonomic) constraints $[D = 1, \ldots, m$ $(< n \equiv 3N - h)$ and $\boldsymbol{B}_D = \boldsymbol{B}_D(t, \boldsymbol{r})]$

$$S\,\boldsymbol{B}_D\cdot\boldsymbol{v} + B_D = 0 \;\Rightarrow\; S\,\boldsymbol{B}_D\cdot\delta\boldsymbol{r} = 0, \tag{b2}$$

leads, with the help of the $h+m$ Lagrangean multipliers $\mu_H = \mu_H(t)$ and $\lambda_D = \lambda_D(t)$, to

$$S\Big(d\boldsymbol{R} - \sum \mu_H(\partial\phi_H/\partial\boldsymbol{r}) - \sum \lambda_D\boldsymbol{B}_D\Big)\cdot\delta\boldsymbol{r} = 0, \tag{c1}$$

from which, since the $\delta\boldsymbol{r}$ can now be treated as free, we obtain the *constitutive equation for the total constraint reaction* on the typical particle P due to all system constraints:

$$d\boldsymbol{R} = \sum \mu_H(\partial\phi_H/\partial\boldsymbol{r}) + \sum \lambda_D\boldsymbol{B}_D. \tag{c2}$$

Then, the *Newton–Euler/d'Alembert* particle equation $dm\,\boldsymbol{a} = d\boldsymbol{F} + d\boldsymbol{R}$ becomes the famous *Lagrange's equation of the first kind*:

$$dm\,\boldsymbol{a} = d\boldsymbol{F} + \sum \mu_H(\partial\phi_H/\partial\boldsymbol{r}) + \sum \lambda_D\boldsymbol{B}_D. \tag{c3}$$

In the more common *discrete* notation, the constraints (b1, 2) become (with $P = 1, \ldots, N \equiv$ *number of system particles*)

$$\delta\phi_H = \sum (\partial\phi_H/\partial \boldsymbol{r}_P) \cdot \delta\boldsymbol{r}_P = 0 \qquad \text{and} \qquad \sum \boldsymbol{B}_{DP} \cdot \delta\boldsymbol{r}_P = 0, \tag{c4}$$

respectively, while the equation of constrainted motion (c3) assumes the form

$$m_P \boldsymbol{a}_P = \boldsymbol{F}_P + \boldsymbol{R}_P = \boldsymbol{F}_P + \sum \mu_H (\partial\phi_H/\partial\boldsymbol{r}_P) + \sum \lambda_D \boldsymbol{B}_{DP}. \tag{c5}$$

To understand the relation between the *particle* reactions $d\boldsymbol{R}$, $\boldsymbol{R}_P$ and their *system* counterparts R_k, Λ_k, we insert (c2) into their corresponding definitions (3.4.1d, 2d). We find, successively,

(i)

$$\begin{aligned} R_k &\equiv S\, d\boldsymbol{R} \cdot \boldsymbol{e}_k = S\Big(\sum \mu_H(\partial\phi_H/\partial\boldsymbol{r}) + \sum \lambda_D \boldsymbol{B}_D\Big) \cdot \boldsymbol{e}_k \\ &= \sum \mu_H \Big(S\, (\partial\phi_H/\partial\boldsymbol{r}) \cdot (\partial\boldsymbol{r}/\partial q_k)\Big) + \sum \lambda_D \Big(S\, \boldsymbol{B}_D \cdot \boldsymbol{e}_k\Big) \\ &\equiv \sum \mu_H (\partial\phi_H/\partial q_k) + \sum \lambda_D B_{Dk}, \end{aligned} \tag{d1}$$

and, comparing with the second of (3.5.5), $R_k = \sum \lambda_D a_{Dk}$, we readily conclude that

$$\partial\phi_H(t, q)/\partial q_k \equiv S\, [\partial\phi_H(t, \boldsymbol{r})/\partial\boldsymbol{r}] \cdot [\partial\boldsymbol{r}(t, q)/\partial q_k] = 0, \tag{d2}$$

and

$$B_{Dk} \equiv S\, \boldsymbol{B}_D \cdot \boldsymbol{e}_k = a_{Dk}; \tag{d3}$$

recall ex. 2.4.1 and (2.6.1ff.).

REMARK

The above also show that, as long as the quasi variables are chosen so that

$$0 = S\, \boldsymbol{B}_D \cdot \delta\boldsymbol{r} \equiv \delta\theta_D = \sum a_{Dk}\, \delta q_k \;\; \Rightarrow \;\; S\, \boldsymbol{B}_D \cdot \boldsymbol{e}_k = a_{Dk}, \tag{e1}$$

the multipliers λ_D in (c2, 3) coincide with those in the second of (3.5.5). Indeed, $\boldsymbol{e}_k$ – dotting (c3) and then S-summing, we obtain the "Routh–Voss" equations [see (3.5.15) below]:

$$S\, dm\, \boldsymbol{a} \cdot \boldsymbol{e}_k = S\, d\boldsymbol{F} \cdot \boldsymbol{e}_k + \sum \mu_H \Big(S\, (\partial\phi_H/\partial\boldsymbol{r}) \cdot \boldsymbol{e}_k\Big) + \sum \lambda_D \Big(S\, \boldsymbol{B}_D \cdot \boldsymbol{e}_k\Big), \tag{e2}$$

or

$$E_k = Q_k + 0 + \sum \lambda_D a_{Dk}. \tag{e3}$$

(ii)

$$\begin{aligned} \Lambda_k &\equiv S\, d\boldsymbol{R} \cdot \boldsymbol{\varepsilon}_k = S\Big(\sum \mu_H(\partial\phi_H/\partial\boldsymbol{r}) + \sum \lambda_D \boldsymbol{B}_D\Big) \cdot \boldsymbol{\varepsilon}_k \\ &= \sum \mu_H \Big(S\, (\partial\phi_H/\partial\boldsymbol{r}) \cdot (\partial\boldsymbol{r}/\partial\theta_k)\Big) + \sum \lambda_D \Big(S\, \boldsymbol{B}_D \cdot \boldsymbol{\varepsilon}_k\Big) \\ &\equiv \sum \mu_H (\partial\phi_H/\partial\phi_k) + \sum \lambda_D {B'}_{Dk}, \end{aligned} \tag{f1}$$

and, comparing with (3.5.7), $\Lambda_D = \lambda_D$ and $\Lambda_I = 0$, we readily conclude that

$$\partial\phi_H/\partial\theta_k \equiv \mathcal{S}\,(\partial\phi_H/\partial\boldsymbol{r})\cdot\boldsymbol{\varepsilon}_k = \mathcal{S}\,(\partial\phi_H/\partial\boldsymbol{r})\cdot\left(\sum A_{lk}\boldsymbol{e}_l\right)$$
$$= \cdots = \sum A_{lk}(\partial\phi_H/\partial q_l) = 0, \tag{f2}$$

and (with $k = 1, \ldots, n$; $D, D' = 1, \ldots, m$; $I = m+1, \ldots, n$)

$$B'_{Dk} \equiv \mathcal{S}\,\boldsymbol{B}_D\cdot\boldsymbol{\varepsilon}_k = \mathcal{S}\,\boldsymbol{B}_D\cdot\left(\sum A_{lk}\boldsymbol{e}_l\right) = \sum A_{lk}\left(\mathcal{S}\,\boldsymbol{B}_D\cdot\boldsymbol{e}_l\right) = \sum A_{lk}a_{Dl} = \delta_{kD};$$

that is,

$$B'_{DD'} \equiv \mathcal{S}\,\boldsymbol{B}_D\cdot\boldsymbol{\varepsilon}_{D'} = \delta_{DD'}, \qquad B'_{DI} \equiv \mathcal{S}\,\boldsymbol{B}_D\cdot\boldsymbol{\varepsilon}_I = \delta_{DI} = 0. \tag{f3}$$

Some of the above can also be obtained from the virtual forms of the constraints. Thus, we find, successively,

(a)
$$0 = \delta\phi_H = \mathcal{S}\,(\partial\phi_H/\partial\boldsymbol{r})\cdot\delta\boldsymbol{r} = \mathcal{S}\,(\partial\phi_H/\partial\boldsymbol{r})\cdot\left(\sum \boldsymbol{\varepsilon}_k\,\delta\theta_k\right) = \cdots = \sum(\partial\phi_H/\partial\theta_k)\,\delta\theta_k$$
$$= \sum(\partial\phi_H/\partial\theta_D)\,\delta\theta_D + \sum(\partial\phi_H/\partial\theta_I)\,\delta\theta_I = 0 + \sum(\partial\phi_H/\partial\theta_I)\,\delta\theta_I \Rightarrow \partial\phi_H/\partial\theta_I = 0. \tag{g1}$$

(b) $$0 = \delta\theta_D \equiv \mathcal{S}\,\boldsymbol{B}_D\cdot\delta\boldsymbol{r} = \mathcal{S}\,\boldsymbol{B}_D\cdot\left(\sum \boldsymbol{\varepsilon}_k\,\delta\theta_k\right) = \cdots = \sum B'_{Dk}\,\delta\theta_k$$
$$= \sum B'_{DD'}\,\delta\theta_{D'} + \sum B'_{DI}\,\delta\theta_I = 0 + \sum B'_{DI}\,\delta\theta_I \;\Rightarrow\; B'_{DI} = 0. \tag{g2}$$

HISTORICAL

The terms *Lagrange's equations of the first kind* (and *second* kind—see below) seem to have originated in Jacobi's famous *Lectures on Dynamics* (winter 1842/1843, publ. 1866), and have been widely used in the German and Russian literature. They are not too well known among English and French authors (see, e.g., Voss, 1901, p. 81, footnote #220).

Example 3.5.2 *Lagrange's Principle and Multipliers: Particle on a Surface* (Kraft, 1885, vol. 2, pp. 194–195). Let us consider a particle P of mass m moving on a smooth surface $\phi(x, y, z, t) = 0$, where x, y, z are inertial rectangular Cartesian coordinates of P, under a total impressed force with rectangular Cartesian components (X, Y, Z). According to LP, the motion is given by (with the customary notations $dx/dt \equiv v_x$, $d^2x/dt^2 \equiv dv_x/dt \equiv a_x, \ldots$)

$$(m\,a_x - X)\,\delta x + (m\,a_y - Y)\,\delta y + (m\,a_z - Z)\,\delta z = 0, \tag{a}$$

under the (virtual form of the surface) constraint

$$\delta\phi = 0: \quad (\partial\phi/\partial x)\,\delta x + (\partial\phi/\partial y)\,\delta y + (\partial\phi/\partial z)\,\delta z = 0. \tag{b}$$

By Lagrange's multipliers, (a) and (b) combine to the *unconstrained* variational equation,

$$[m\,a_x - X - \lambda(\partial\phi/\partial x)]\,\delta x + [m\,a_y - Y - \lambda(\partial\phi/\partial y)]\,\delta y$$
$$+ [m\,a_z - Z - \lambda(\partial\phi/\partial z)]\,\delta z = 0, \tag{c}$$

and this leads directly to the three Lagrangean (Routh–Voss) equations of the first kind:

$$m\,a_x = X + \lambda(\partial\phi/\partial x), \qquad m\,a_y = Y + \lambda(\partial\phi/\partial y), \qquad m\,a_z = Z + \lambda(\partial\phi/\partial z). \quad \text{(d)}$$

Eliminating the multiplier λ among (d) we obtain the *two* reactionless equations (with subscripts denoting partial derivatives):

$$(m\,a_x - X)/\phi_x = (m\,a_y - Y)/\phi_y = (m\,a_z - Z)/\phi_z \qquad (= \lambda). \quad \text{(e)}$$

Next:

(i) either we solve the system consisting of any two of (e), plus the constraint $\phi = 0$, for the three unknown functions $x(t)$, $y(t)$, $z(t)$, and then calculate $\lambda \to \lambda(t)$ from (d), or (e), if needed;
(ii) or we solve the system consisting of (d) and $\phi = 0$ for the four unknown functions $x(t)$, $y(t)$, $z(t)$, and $\lambda(t)$.

Equations (e) can also be obtained as follows: in view of (b), *only two out of the three virtual displacements are independent*; here $n = 3$ and $m = 1$. Taking δx as the *dependent* virtual displacement, and solving (b) for it in terms of the other two (assuming that $\phi_x \neq 0$), we obtain

$$\delta x = -(\phi_y/\phi_x)\delta y - (\phi_z/\phi_x)\delta z, \quad \text{(f)}$$

and substituting this into (a), and regrouping terms, we get the new *unconstrained* variational equation of motion

$$[m\,a_y - Y - (m\,a_x - X)(\phi_y/\phi_x)]\,\delta y + [m\,a_z - Z - (m\,a_x - X)(\phi_z/\phi_x)]\,\delta z = 0. \quad \text{(g)}$$

The above, *since δy and δz are now free*, leads immediately to the two *reactionless* $\equiv$ *kinetic* equations,

$$m\,a_y = Y + (m\,a_x - X)(\phi_y/\phi_x), \qquad m\,a_z = Z + (m\,a_x - X)(\phi_z/\phi_x), \quad \text{(h)}$$

which are none other than the earlier eqs. (e).

REMARKS

(i) Equations (h) can be, fairly, called "Maggi $\to$ Hadamard equations of the first kind"; and the extension of this idea to holonomic system variables and corresponding Pfaffian constraints yields "Hadamard's equations (of the second kind)" (§3.8).

(ii) Equations (b–d = "*adjoining* of constraints") and equations (f–h = "*embedding* of constraints") embody the two available ways of handling constrained stationary problems in differential calculus; although, there, the former is discussed much more frequently than the latter!

Specialization

Let the reader verify that if the surface constraint has the special form $z = f(x, y)$, then:

(i) eqs. (d, e) reduce, respectively, to

Routh–Voss equations:

$$m\,a_x = X + \lambda(\partial f/\partial x), \qquad m\,a_y = Y + \lambda(\partial f/\partial y), \qquad m\,a_z = Z - \lambda, \tag{i}$$

Kinetic Maggi → Hadamard equations (of the first kind):

$$(m\,a_x - X)/f_x = (m\,a_y - Y)/f_y = (m\,a_z - Z)/(-1) \qquad (= \lambda), \tag{j}$$

$$\Rightarrow (m\,a_x - X) + (m\,a_z - Z)f_x = 0, \qquad (m\,a_y - Y) + (m\,a_z - Z)f_y = 0. \tag{k}$$

(ii) Substituting into (k): $a_z \equiv \ddot{z} = \cdots = \ddot{x}f_x + \ddot{y}f_y + (\dot{x})^2 f_{xx} + (\dot{y})^2 f_{yy} + 2\dot{x}\,\dot{y}\,f_{xy}$; that is, using the constraint and its $(\ldots)^{\cdot}$-derivatives to eliminate z and its derivatives from them, we obtain the two kinetic equations in x, y and their derivatives alone:

$$\ddot{x}(1 + {f_x}^2) + \ddot{y}f_x f_y + (\dot{x})^2 f_x f_{xx} + 2\dot{x}\,\dot{y}\,f_x f_{xy} + (\dot{y})^2 f_x f_{yy} = (X + f_x Z)/m, \tag{l}$$

$$\ddot{y}(1 + {f_y}^2) + \ddot{x}f_x f_y + (\dot{y})^2 f_y f_{yy} + 2\dot{x}\,\dot{y}\,f_y f_{xy} + (\dot{x})^2 f_y f_{xx} = (Y + f_y Z)/m, \tag{m}$$

[which are the "Chaplygin–Voronets"-type equations of the problem (see §3.8)].

(iii) Solving the last of (j) for λ, and then using into it the earlier expression $\ddot{z} = \cdots$, we obtain the following (kinetostatic) expression:

$$\begin{aligned}\lambda &= Z - m\ddot{z}\\ &= Z - m\Big[\ddot{x}f_x + \ddot{y}f_y + (\dot{x})^2 f_{xx} + (\dot{y})^2 f_{yy} + \dot{x}\,\dot{y}\,f_{xy}\Big];\end{aligned} \tag{n}$$

which, once the motion has been found: $x = x(t)$, $y = y(t)$, yields the constraint reaction $\lambda = \lambda(t)$.

(iv) Finally, substituting (n) into the first and second of (i), we recover (k, l), respectively.

Example 3.5.3 Let us apply the results of the preceding example to a particle P of mass m moving under gravity on a smooth vertical plane that spins about a vertical of its straight lines, Oz (positive upward), with *constant* angular velocity $\boldsymbol{\omega}$ (Kraft, 1885, vol. 2, pp. 194–195). Choosing inertial axes $O\text{–}xyz$ so that Ox coincides with the original intersection of the spinning plane and the horizontal plane $O\text{–}xy$ through the origin, we have, for the impressed forces,

$$X = 0, \qquad Y = 0, \qquad Z = +mg; \tag{a}$$

and, for the constraint,

$$y/x = \sin(\omega t)/\cos(\omega t) \quad \Rightarrow \quad \phi(t, x, y, z) = y\cos(\omega t) - x\sin(\omega t) = 0. \tag{b}$$

Therefore, equations (e) of the preceding example yield

$$(m\,\ddot{x} - 0)/[-\sin(\omega t)] = (m\,\ddot{y} - 0)/\cos(\omega t) = (m\,\ddot{z} - mg)/0 \quad (= -\lambda),$$

or, rearranging (to *avoid the singularity* caused by $f_z = 0$),

$$(m\,\ddot{x} - 0)\cos(\omega t) = (m\,\ddot{y} - 0)[-\sin(\omega t)] \quad \Rightarrow \quad \ddot{x}\cos(\omega t) + \ddot{y}\sin(\omega t) = 0, \tag{c}$$

$$(m\,\ddot{x} - 0)(0) = (m\,\ddot{z} - mg)[-\sin(\omega t)] \quad \Rightarrow \quad \ddot{z} = g, \tag{d}$$

$$(m\,\ddot{y} - 0)(0) = (m\,\ddot{z} - mg)\cos(\omega t) \quad \Rightarrow \quad \ddot{z} = g. \tag{e}$$

Let us, now, solve (c–e). Using plane polar coordinates (r, ϕ): $x = r\cos(\omega t) \Rightarrow \dot{x} = \cdots \Rightarrow \ddot{x} = \cdots$ and $y = r\sin(\omega t) \Rightarrow \dot{y} = \cdots \Rightarrow \ddot{y} = \cdots$, we can rewrite (c) in the simpler form

$$\ddot{r} - \omega^2 r = 0. \tag{f}$$

The solution of (d) = (e), with initial conditions $z(0) \equiv z_o$ and $\dot{z}(0) \equiv v_o$, is

$$z = (1/2)gt^2 + v_o t + z_o, \tag{g}$$

while that of (f), with initial conditions $r(0) = r_o$ and $\dot{r}(0) = v_{r,o}$, is

$$2\omega r = (\omega r_o + v_{r,o})e^{\omega t} + (\omega r_o - v_{r,o})e^{-\omega t}. \tag{h}$$

Equations (g, h) locate P on the spinning plane at time t, and, with the help of (b), specify its inertial position at the same time. (See also Walton, 1876, pp. 398–411.)

Example 3.5.4 *Lagrange's Equations of the First Kind; Particle on Two Surfaces.* Let us calculate the reactions on a particle P moving in space under the two constraints (where x, y, z are the inertial rectangular Cartesian coordinates of P)

$$\phi_1 \equiv x^2 + y^2 + z^2 - l^2 = 0 \qquad \text{and} \qquad \phi_2 \equiv z - y\tan\theta = 0; \tag{a}$$

that is, $n = 3 - 2 = 1$: for example, the bob of spherical pendulum of (constant) length l, forced to remain on the plane $\phi_2 = 0$, that makes an angle θ with the plane $z = 0$. Using commas followed by subscripts to denote partial (coordinate) derivatives, we find, from (a),

$$\delta\phi_1 = \phi_{1,x}\,\delta x + \phi_{1,y}\,\delta y + \phi_{1,z}\,\delta z = 0, \qquad \delta\phi_2 = \phi_{2,x}\,\delta x + \phi_{2,y}\,\delta y + \phi_{2,z}\,\delta z = 0. \tag{b}$$

Solving (b) for the two excess virtual displacements in terms of the third, say δy and δz in terms of δx, we obtain

$$\delta y = -(2x/J)\,\delta x \qquad \text{and} \qquad \delta z = -(2x\tan\theta/J)\,\delta x, \tag{c}$$

where

$$J \equiv \begin{vmatrix} \phi_{1,y} & \phi_{1,z} \\ \phi_{2,y} & \phi_{2,z} \end{vmatrix} = 2(y + z\tan\theta) \qquad (\neq 0,\ \text{assumed}). \tag{d}$$

Substituting δy and δz from (c) into the principle of d'Alembert–Lagrange for the particle reaction — that is,

$$R_x\,\delta x + R_y\,\delta y + R_z\,\delta z = 0, \tag{e}$$

results in

$$\left[R_x - (2x/J)R_y - (2x\tan\theta/J)R_z\right]\delta x \equiv R'_x\,\delta x = 0, \tag{f}$$

from which, since δx is independent, we obtain $R'_x = 0$; that is,

$$R_x/(R_y + \tan\theta R_z) = x/(y + z\tan\theta). \tag{g}$$

Further, the ideal reaction postulate for $\boldsymbol{R}$:

$$\boldsymbol{R} = \lambda_1(\partial\phi_1/\partial\boldsymbol{r}) + \lambda_2(\partial\phi_2/\partial\boldsymbol{r}), \tag{h}$$

with (a) and in components, yields

$$R_x = \lambda_1 \phi_{1,x} + \lambda_2 \phi_{2,x} = \cdots = 2\lambda_1 x, \tag{i}$$

$$R_y = \lambda_1 \phi_{1,y} + \lambda_2 \phi_{2,y} = \cdots = 2\lambda_1 y - \lambda_2 \tan\theta, \tag{j}$$

$$R_z = \lambda_1 \phi_{1,z} + \lambda_2 \phi_{2,z} = \cdots = 2\lambda_1 z + \lambda_2; \tag{k}$$

which, of course, are consistent with (g). Finally, since $J \neq 0$, we can use any two of (i–k) to express $\lambda_{1,2}$ uniquely, in terms of $R_{x,y,z}$; for instance, solve (j, k) for $\lambda_{1,2}$ in terms of $R_{y,z}$. (See also Routh, 1891, p. 35.)

Example 3.5.5 *Lagrange's Equations of the First Kind; and Elimination of Reactions.* Let us consider a system of N particles, moving under the $h + m \equiv M$ (possibly nonholonomic but ideal) constraints

$$f_D(t, \boldsymbol{r}, \boldsymbol{v}) = 0 \qquad (D = 1, \ldots, M < 3N), \tag{a}$$

and, therefore (recalling ex. 3.2.6), having Lagrangean equations of motion of the first kind (we revert to continuum notation for convenience),

$$dm\, \boldsymbol{a} = d\boldsymbol{F} + \sum \lambda_D (\partial f_D / \partial \boldsymbol{v}). \tag{b}$$

Now, to obtain *reactionless* = *kinetic* equations of motion, we will combine (b) with the *acceleration form* of (a). To this end, we $(\ldots)^{\cdot}$-differentiate (a) once, thus obtaining

$$df_D/dt = \partial f_D/\partial t + S\left[(\partial f_D/\partial \boldsymbol{r}) \cdot \boldsymbol{v} + (\partial f_D/\partial \boldsymbol{v}) \cdot \boldsymbol{a}\right] = 0, \tag{c}$$

and from this, rearranging, we get

$$S(\partial f_D/\partial \boldsymbol{v}) \cdot \boldsymbol{a} = -S(\partial f_D/\partial \boldsymbol{r}) \cdot \boldsymbol{v} - \partial f_D/\partial t. \tag{d}$$

Now, to be able to use (d) in (b), so as to eliminate $\boldsymbol{a}$, we dot the latter with $\partial f_D/\partial \boldsymbol{v}$ and sum over the particles (with $D, D' = 1, \ldots, M$):

$$S(\partial f_D/\partial \boldsymbol{v}) \cdot \boldsymbol{a} = S[(d\boldsymbol{F}/dm) \cdot (\partial f_D/\partial \boldsymbol{v})] + \sum \lambda_{D'} \Big(S(\partial f_{D'}/\partial \boldsymbol{v}) \cdot (\partial f_D/\partial \boldsymbol{v})/dm \Big), \tag{e}$$

and, comparing the right sides of the above with (d), we readily conclude that

$$\sum \lambda_{D'} \Big\{ S[\partial f_{D'}/\partial(dm\boldsymbol{v})] \cdot (\partial f_D/\partial \boldsymbol{v}) \Big\}$$
$$= -S\{d\boldsymbol{F} \cdot [\partial f_D/\partial(dm\boldsymbol{v})]\} - S(\partial f_D/\partial \boldsymbol{r}) \cdot \boldsymbol{v} - \partial f_D/\partial t. \tag{f}$$

Since $rank[\partial f_D/\partial(dm\boldsymbol{v})] = rank(\partial f_D/\partial \boldsymbol{v}) = M$, and therefore

$$Det\Big\{ S[\partial f_{D'}/\partial(dm\boldsymbol{v})] \cdot (\partial f_D/\partial \boldsymbol{v}) \Big\} \neq 0, \tag{g}$$

the M linear nonhomogeneous equations (f) can supply uniquely (locally, at least) the λ_D's as functions of the $\boldsymbol{r}$'s, $\boldsymbol{v}$'s, and t. Finally, substituting the so-calculated λ_D's back into (b), we obtain N second-order equations for the $\boldsymbol{r} = \boldsymbol{r}(t)$. (See also exs. 3.10.2, 5.3.5, and 5.3.6; and Voss, 1885.)

Problem 3.5.1 Continuing from the preceding example, find the form that (f) takes if the constraints (a) have the *holonomic* form

$$\phi_H(t, \boldsymbol{r}) = 0. \tag{a}$$

HINT

Calculate $f_D \equiv d\phi_D/dt = 0$, and then show that $\partial f_D/\partial \boldsymbol{v} = \partial \phi_D/\partial \boldsymbol{r}$.

Let us now turn to the second, and more important, "reactionless part" of LP, (eqs. 3.2.8, 11), and express it in system variables.

1. Holonomic Variables

In this case LP, $\delta I = \delta' W$, assumes the form

$$\sum E_k\, \delta q_k = \sum Q_k\, \delta q_k,$$

or, explicitly,

$$\sum \{[d/dt(\partial T/\partial \dot{q}_k) - \partial T/\partial q_k] - Q_k\}\, \delta q_k$$
$$\equiv \sum \{[d/dt(\partial T/\partial v_k) - \partial T/\partial q_k] - Q_k\}\, \delta q_k = 0. \tag{3.5.11}$$

This *differential variational equation* is fundamental to Lagrangean analytical mechanics; all conceivable/possible Lagrangean equations of motion are based on it and flow from it.

(a) Now, if the n δq's are independent (i.e., $m = 0 \Rightarrow f = n$ *DOF*), (3.5.11) leads immediately to *Lagrange's equations of the second kind*: $E_k = Q_k$; or explicitly (recalling the kinematico-inertial results of §3.3 in holonomic variables),

$$E_k \equiv d/dt(\partial T/\partial \dot{q}_k) - \partial T/\partial q_k$$
$$\equiv d/dt(\partial T/\partial v_k) - \partial T/\partial q_k = Q_k \qquad \text{[Lagrange (1780)]}, \tag{3.5.12}$$
$$\equiv \partial S/\partial \ddot{q}_k \equiv \partial S/\partial \dot{v}_k \equiv \partial S/\partial w_k = Q_k \qquad \text{[Appell (1899)]}. \tag{3.5.13}$$

Further, substituting $\delta q_k = \sum A_{kl}\, \delta\theta_l$ $(k, l = 1, \ldots, n)$ into (3.5.11) readily yields

$$\sum A_{kl} E_k = \sum A_{kl} Q_k \qquad (\textit{i.e., } I_l = \Theta_l, \textit{ but in holonomic variables})$$
$$\text{[Maggi (1896, 1901, 1903)]}. \tag{3.5.14}$$

However, in this unconstrained case, neither Appell's equations, (3.5.13), nor Maggi's equations, (3.5.14), offer any particular advantages over those of Lagrange, (3.5.12); their real usefulness/advantages over eqs. (3.5.12) lie in the constrained case (see below). Equations (3.5.12) are rightfully considered among the most important ones of the entire mathematical physics and engineering; we shall call them simply *Lagrange's equations*.

(b) If the n δq's are *constrained* by (3.5.3): $\sum a_{Dk}\, \delta q_k = 0$ $(D = 1, \ldots, m;$ $k = 1, \ldots, n)$, that is, $f \equiv n - m =$ number of *DOF*, then application of the multiplier rule, between these constraints and (3.5.11), leads immediately to the *Routh–Voss equations*

$$E_k = Q_k + \sum \lambda_D a_{Dk} \ (\equiv Q_k + R_k); \tag{3.5.15}$$

or, explicitly, as in (3.5.12, 13),

$$E_k \equiv d/dt(\partial T/\partial \dot{q}_k) - \partial T/\partial q_k = Q_k + \sum \lambda_D a_{Dk}$$
[Routh (1877), Voss (1885)], (3.5.16)

$$\equiv \partial S/\partial \ddot{q}_k = Q_k + \sum \lambda_D a_{Dk} \text{ (Appellian form of the Routh–Voss eqs.).} \tag{3.5.17}$$

The corresponding Maggi form is presented below.

[Equations (3.5.15) are not to be confused with the other, more famous, equations of Routh of *steady motion*, etc. (§8.3 ff.)]

CAUTION

Some authors (e.g., Haug, 1992, pp. 169–170) state, falsely, that if the n q's are independent, the n δq's are arbitrary, and then (3.5.12, 13) follow from (3.5.11). But as we have seen (§2.3, §2.8, and §2.12), if the additional constraints (3.5.3, 10b) are nonholonomic the q's remain independent, whereas, obviously, the δq's are no longer arbitrary, that is, (3.5.12, 13) do *not* always hold for independent q's.

2. Holonomic → Nonholonomic Variables

In this case LP, $\delta I = \delta' W$, assumes the form

$$\sum I_k \, \delta\theta_k = \sum \Theta_k \, \delta\theta_k. \tag{3.5.18}$$

(a) If the n $\delta\theta$'s are *unconstrained* (i.e., if $m = 0 \Rightarrow f \equiv n - m = n = \# \ DOF$), then (3.5.18) leads to $I_k = \Theta_k$, or, due to the kinematico-inertial identities (3.3.10 ff.) for I_k, to the following *three* general forms:

$$I_k \equiv \sum A_{lk} E_l = \sum A_{lk} Q_l,$$

or, in extenso,

$$\sum [d/dt(\partial T/\partial \dot{q}_l) - \partial T/\partial q_l] A_{lk} = \sum A_{lk} Q_l$$
(*Maggi form:* holonomic variables), (3.5.19a)

$$\equiv \sum A_{lk} (\partial S/\partial \ddot{q}_l) = \sum A_{lk} Q_l$$
(*Appellian form of Maggi form:* holonomic variables), (3.5.19b)

$$\equiv \partial S^*/\partial \dot{\omega}_k = \Theta_k$$
[Gibbs (1879): nonholonomic variables, but no constraints!], (3.5.19c)

$$\equiv d/dt(\partial T^*/\partial \omega_k) - \partial T^*/\partial \theta_k + \sum\sum \gamma^r{}_{k\alpha} (\partial T^*/\partial \omega_r) \omega_\alpha = \Theta_k$$
$$\equiv E_k{}^*(T^*) - \Gamma_k = \Theta_k$$
[Volterra (1898), Hamel (1903–1904)]. (3.5.19d)

Equations (3.5.19a, b) have no advantages over Lagrange's equations (3.5.12); but equations (3.5.19c, d) may be truly useful for unconstrained systems in quasi variables, for example, a rigid body moving about a fixed point [→ Eulerian rotational equations (§1.17)].

(b) If the $\delta\theta$'s are *constrained* by $\delta\theta_D = 0$, but $\delta\theta_I \neq 0$ (i.e., if $f \equiv n - m = \#\ DOF$), then the multiplier rule applied to (3.5.18) yields the following *two* groups of equations:

Kinetostatic (i.e., reaction containing) equations:

$$I_D = \Theta_D + \Lambda_D \qquad [= \Theta_D + \lambda_D \quad (D = 1, \ldots, m)], \tag{3.5.20a}$$

Kinetic (i.e., reactionless) equations:

$$I_I = \Theta_I \qquad (I = m+1, \ldots, n); \tag{3.5.20b}$$

[and in view of the constraint $1 \cdot \delta\theta_{n+1} = 1 \cdot \delta t = 0$, we also have $I_{n+1} = \Theta_{n+1} + \Lambda_{n+1}$, but that nonvirtual relation is more of an *energy rate*–like equation (as in §3.9)].

Alternative Derivation of Equations (3.5.20a, b)

First, with the help of the Kronecker delta (hopefully, not to be confused with the virtual variation symbol $\delta \ldots$), we rewrite the constraints $\delta\theta_D = 0$ as

$$0 = \delta\theta_D = \sum \delta_{DD'}\, \delta\theta_{D'} = \sum \delta_{DD'}\, \delta\theta_{D'} + \sum \delta_{DI}\, \delta\theta_I = \sum \delta_{Dk}\, \delta\theta_k. \tag{3.5.20c}$$

Then, using the method of Lagrangean multipliers, we combine them with (3.5.18): (1) we multiply each constraint $\delta\theta_D (= 0)$ with $-\lambda_D (\neq 0)$ and sum over D; (2) we multiply each "nonconstraint" $\delta\theta_I (\neq 0)$ with $-\lambda_I (= 0)$ and sum over I; and, (3), we add the so-resulting two zeros to (3.5.18), thus obtaining

$$\sum \left(I_k - \Theta_k - \sum \lambda_D\, \delta_{Dk} \right) \delta\theta_k = 0. \tag{3.5.20d}$$

Since the $\delta\theta_k$ can now be viewed as unconstrained, (3.5.20d) decouples to the two sets of equations:

$$k = D': \qquad I_{D'} - \Theta_{D'} = \sum \lambda_D\, \delta_{DD'} = \lambda_{D'} \qquad (\textit{Kinetic equations}), \tag{3.5.20e}$$

$$k = I: \qquad I_I - \Theta_I = \sum \lambda_D\, \delta_{DI} = \lambda_I = 0 \qquad (\textit{Kinetostatic equations}). \tag{3.5.20f}$$

Here, too, as with the unconstrained case (3.5.19a–d), we have the following *three* general forms for (3.5.20a) and (3.5.20b):

- Kinetic equations (with $I, I' = m+1, \ldots, n$; $k = 1, \ldots, n$; $\gamma^r{}_I \equiv \gamma^r{}_{I,n+1}$):

$$I_I \equiv \sum A_{kI} E_k = \sum A_{kI} Q_k,$$

or, in extenso,

$$\sum [d/dt(\partial T/\partial \dot{q}_k) - \partial T/\partial q_k] A_{kI} = \sum A_{kI} Q_k$$

[Maggi (1896, 1901, 1903): holonomic variables], (3.5.21a)

$$\equiv \sum A_{kI}(\partial S/\partial \ddot{q}_k) = \sum A_{kI} Q_k$$

(Appellian form of Maggi form: holonomic variables), (3.5.21b)

$$\equiv \partial S^*/\partial \dot{\omega}_I = \Theta_I$$

[Appell (1899–1925): special cases of nonholonomic variables], (3.5.21c)

$$\equiv d/dt(\partial T^*/\partial \omega_I) - \partial T^*/\partial \theta_I + \sum\sum \gamma^k{}_{II'}(\partial T^*/\partial \omega_k)\omega_{I'} + \sum \gamma^k{}_I(\partial T^*/\partial \omega_k) = \Theta_I$$

[Hamel (1903–1904): "Lagrange–Euler equations"]; (3.5.21d)

- Kinetostatic equations (with $D = 1, \ldots, m$; $I = m+1, \ldots, n$; $k = 1, \ldots n$; $\gamma^r{}_D \equiv \gamma^r{}_{D,n+1}$) :

$$I_D \equiv \sum A_{kD} E_k = \sum A_{kD} Q_k + \Lambda_D,$$

or, in extenso,

$$\sum [d/dt(\partial T/\partial \dot{q}_k) - \partial T/\partial q_k] A_{kD} = \sum A_{kD} Q_k + \Lambda_D, \quad (3.5.22a)$$

$$\equiv \sum A_{kD}(\partial S/\partial \ddot{q}_k) = \sum A_{kD} Q_k + \Lambda_D, \quad (3.5.22b)$$

$$\equiv \partial S^*/\partial \dot{\omega}_D = \Theta_D + \Lambda_D$$

[Cotton (1907): special variables] (3.5.22c)

$$\equiv d/dt(\partial T^*/\partial \omega_D) - \partial T^*/\partial \theta_D + \sum\sum \gamma^k{}_{DI}(\partial T^*/\partial \omega_k)\omega_I + \sum \gamma^k{}_D(\partial T^*/\partial \omega_k) = \Theta_D + \Lambda_D$$

[Stückler (1955); special case by Schouten (late 1920s, 1954)]. (3.5.22d)

REMARKS

(i) In the absence of constraints, the above n equations in the ω's, plus the n transformation equations $\dot{q}_k = \sum A_{kl}\omega_l + A_k$, constitute a system of $2n$ *first-order* equations in the $2n$ unknown functions $\omega_k = \omega_k(t)$ and $q_k = q_k(t)$. [Or, after using the $\omega \leftrightarrow \dot{q}$ equations in them, thus expressing the ω_k's in terms of the $\dot{q}_k$'s, they constitute a set of n *second-order* equations for the n unknowns $q_k(t)$.] In the presence of m constraints $\omega_D = 0$, the $n - m$ kinetic equations plus the n transformation equations $\dot{q}_k = \sum A_{kI}\omega_I + A_k$ constitute a system of $2n - m$ *first-order* equations in the $2n - m$ functions $\omega_I = \omega_I(t)$ and $q_k = q_k(t)$. Or, equivalently, substituting $\omega_I = \sum a_{Ik}\dot{q}_k + a_I$ $(\neq 0)$ into the $n - m$ kinetic equations, we obtain a system of $n - m$ *second-order* equations for the $q_k = q_k(t)$; and then, pairing them with the m constraints $\sum a_{Dk}\dot{q}_k + a_D = 0$, we finally obtain a system of $(n - m) + m = n$ *second-order* reactionless equations for the $q_k = q_k(t)$. Further, it can be shown that there exists a nonsingular linear transformation $\dot{q}_k = \sum A_{kl}\omega_l + A_k$, or

$\dot{q}_\alpha = \sum A_{\alpha\beta}\,\omega_\beta$ (recalling that $dq_{n+1}/dt = \omega_{n+1} = dt/dt = 1$) that brings the *non-negative* kinetic energy $2T = \sum\sum M_{\alpha\beta}\,\dot{q}_\alpha \dot{q}_\beta$ to the following *sum of squares* form:

$$2T \to 2T^* = \sum {\omega_\alpha}^2 = \sum {\omega_k}^2 + {\omega_{n+1}}^2; \tag{3.5.23a}$$

in which case, since $P_k \equiv \partial T^*/\partial\omega_k = \omega_k$ and $P_{n+1} \equiv \partial T^*/\partial\omega_{n+1} = \omega_{n+1} = 1$, $\partial T^*/\partial\theta_k \equiv \sum (\partial T^*/\partial q_l) A_{lk} = 0$, the nonholonomic system inertia assumes the *Eulerian form* (recall inertia side of Eulerian rigid-body rotational equations, §1.17):

$$I_k = d\omega_k/dt + \sum\sum \gamma^r{}_{k\alpha}\,\omega_r\,\omega_\alpha; \tag{3.5.23b}$$

and that is why Hamel called *his* equations "Lagrange–Euler equations." (However, by choosing the ω_k's so as to nullify the $\partial T^*/\partial\theta_k$'s, we probably end up complicating the $\gamma^r{}_{k\alpha}$'s.)

(ii) The advantage of nonholonomic *variables* in the Hamel "equilibrium form" $\omega_D = 0$ is that then both constraints and equations of motion *decouple* naturally into $n - m$ *purely kinetic* (i.e., *reactionless*) *equations* ($\delta\theta_I \neq 0$; $\Lambda_I = 0 \Rightarrow I_I = \Theta_I$) *and m reaction-containing, or kinetostatic, equations* ($\delta\theta_D = 0$; $\Lambda_D \neq 0 \Rightarrow I_D = \Theta_D + \Lambda_D$). In holonomic variables, by contrast, both (Pfaffian) constraints and (Routh–Voss and Appell) equations of motion are coupled. Solving the $n - m$ *kinetic* equations (plus constraints, etc.) constitutes the lion's share of the difficulty of the problem. Once this has been achieved, then the reactions Λ_D follow immediately from the (now) *algebraic* equations: $\Lambda_D = \Lambda_D(t) = I_D(t) - \Theta_D(t)$.

(iii) When using Hamel's equations under the constraints $\omega_D = 0$, we must enforce the latter *after* all partial differentiations have been carried out, not before; otherwise, we would not, in general, calculate correctly the key nonholonomic terms ($k, r = 1, \ldots, n$; $\alpha = 1, \ldots, n+1$; $I' = m+1, \ldots, n$)

$$-\Gamma_k = \sum\sum \gamma^r{}_{k\alpha}(\partial T^*/\partial\omega_r)\omega_\alpha = \sum\sum \gamma^r{}_{kI'}(\partial T^*/\partial\omega_r)\omega_{I'} + \sum \gamma^r{}_k(\partial T^*/\partial\omega_r); \tag{3.5.24a}$$

and, unfortunately, this drawback holds for both kinetic and kinetostatic equations. Let us see why. Expanding T^* à la Taylor around $\omega_D = 0$, we obtain

$$T^* = T^*{}_o + \sum (\partial T^*/\partial\omega_D)_o\,\omega_D + \text{quadratic terms in } \omega_D, \tag{3.5.24b}$$

where

$$T^*{}_o = T^*(q, \omega_D = 0, \omega_I, t) = T^*{}_o(q, \omega_I, t); \tag{3.5.24c}$$

and, generally, $(\ldots)_o \equiv (\ldots, \omega_D = 0, \ldots)$ (a useful notation, to be utilized *frequently*, for extra clarity); and, therefore,

$$(\partial T^*/\partial\omega_D)_o \neq \partial T^*{}_o/\partial\omega_D = 0, \tag{3.5.24d}$$

$$(\partial T^*/\partial\omega_I)_o = \partial T^*{}_o/\partial\omega_I \;\Rightarrow\; d/dt[(\partial T^*/\partial\omega_I)_o] = d/dt(\partial T^*{}_o/\partial\omega_I), \tag{3.5.24e}$$

$$(\partial T^*/\partial\theta_k)_o \equiv \sum A_{rk}(\partial T^*/\partial q_r)_o = \sum A_{rk}(\partial T^*{}_o/\partial q_r). \tag{3.5.24f}$$

In view of these results, $-\Gamma_k$, (3.5.24a), transforms to

$$-\Gamma_k = \sum\sum \gamma^D{}_{kI'}(\partial T^*/\partial\omega_D)_o\,\omega_{I'} + \sum\sum \gamma^{I''}{}_{kI'}(\partial T^*{}_o/\partial\omega_{I''})\omega_{I'}$$
$$+ \sum \gamma^D{}_k(\partial T^*/\partial\omega_D)_o + \sum \gamma^I{}_k(\partial T^*{}_o/\partial\omega_I); \tag{3.5.24g}$$

an expression that shows clearly that the presence of the *first* (*double*) *and third* (*single*) *sums* generally necessitates the use of T^*, instead of $T^*{}_o$.

However, with the help of the above expression we can obtain conditions that tell us when we can use the constrained kinetic energy $T^*{}_o$ in Hamel's equations right from the start. Let us do this, for simplicity, for the common case of the *kinetic* such equations of a *scleronomic* system. Then,

$$-\Gamma_k \to -\Gamma_I = \sum\sum \gamma^D{}_{II'}(\partial T^*/\partial\omega_D)_o\,\omega_{I'} + \sum\sum \gamma^{I''}{}_{II'}(\partial T^*{}_o/\partial\omega_{I''})\omega_{I'}; \tag{3.5.24h}$$

and (3.5.24d, e) make it clear that the sought conditions will result from the (identical) vanishing of the *first* sum in (3.5.24h); that is,

$$\sum\sum \gamma^D{}_{II'}(\partial T^*/\partial\omega_D)_o\,\omega_{I'} = 0. \tag{3.5.24i}$$

But (as made clear in §3.9),

$$2T^* = \sum\sum M^*{}_{kl}(q)\omega_k\,\omega_l = \sum\sum (\partial^2 T^*/\partial\omega_k\,\partial\omega_l)\omega_k\,\omega_l$$
$$\Rightarrow\ (\partial T^*/\partial\omega_D)_o = \sum (\partial^2 T^*/\partial\omega_D\,\partial\omega_I)\omega_I, \tag{3.5.24j}$$

and so (3.5.24i) reduces to

$$\sum\sum\sum \gamma^D{}_{II'}(\partial^2 T^*/\partial\omega_D\,\partial\omega_{I''})\,\omega_{I''}\,\omega_{I'} = 0; \tag{3.5.24k}$$

and from this we easily conclude that the *necessary and sufficient conditions for the use of* $T^*{}_o$ *in Hamel's equations* are

$$\sum \gamma^D{}_{II'}(\partial^2 T^*/\partial\omega_D\,\partial\omega_{I''}) = 0. \tag{3.5.24l}$$

For example, in the case of a *single* Pfaffian constraint, $\omega_1 = 0$ (i.e., $m = 1$), (3.5.24l) yields

$$\gamma^1{}_{II'}(\partial^2 T^*/\partial\omega_1\,\partial\omega_{I''}) = 0 \qquad (I, I', I'' = 2, \ldots, n), \tag{3.5.24m}$$

which means that either all "nonholonomic inertial coefficients" $\partial^2 T^*/\partial\omega_1\,\partial\omega_{I''} \equiv M^*{}_{1I''}$ vanish [i.e., T^* consists of an ω_1-free part and an $\omega_1{}^2$-proportional part; or $\gamma^1{}_{II'} = 0$, which means that constraint is holonomic (by Frobenius' theorem, §2.12)]. The consequences of (3.5.24l) are detailed in Hamel (1904(a), pp. 22–29); see also Hadamard (1895).

In sum, in using the Hamel equations, even if we are not interested in constraint reactions, we must begin with the unconstrained kinetic energy $T^* = T^*(q, \omega_D, \omega_I, t)$, carry out all required differentiations, and then enforce the constraints $\omega_D = 0$, at the end; and, a constraint $\omega_D = 0$ can be enforced ahead of time in T^*-terms that are *quadratic* in that ω_D; namely, in $(\ldots)\omega_D{}^2$ terms.

This inconvenience is a small price to pay for such powerful and conceptually insightful equations. Similarly, a detailed analysis of (3.5.24g) shows that *it is possible to have* $\Gamma_k = 0$ (i.e., Hamel equations $\to$ Lagrange's equations) *even though not all* γ*'s are zero*. An analogous situation occurs in the Maggi equations, even in the kinetic case—that is,

$$I_I \equiv \sum A_{kI} E_k \equiv \sum [d/dt(\partial T/\partial \dot{q}_k) - \partial T/\partial q_k] A_{kI} = \sum A_{kI} Q_k, \qquad (3.5.24n)$$

since $k = 1, \ldots, n$, we have to calculate $T = T(t, q, \dot{q}_D, \dot{q}_I)$; the "reduced," or constrained, kinetic energy

$$T_o \equiv T(t, q, \dot{q}_D = \sum b_{DI}\dot{q}_I + b_D, \dot{q}_I) \equiv T_o(t, q, \dot{q}_I), \qquad (3.5.24o)$$

obviously will not do. This seems to be a drawback of all T-based (i.e., Lagrangean) equations. No such problems appear for the kinetic *Appellian* equations: there, with the convenient notation

$$\begin{aligned} S^* = S^*(t, q, \omega_D, \omega_I, \dot{\omega}_D, \dot{\omega}_I) &= \textit{original, or unconstrained, or relaxed, Appellian} \\ \to S^*(t, q, \omega_D = 0, \omega_I, \dot{\omega}_D = 0, \dot{\omega}_I) &\equiv S^*{}_o(t, q, \omega_I, \dot{\omega}_I) \\ &\equiv S^*{}_o = \textit{constrained Appellian}, \qquad (3.5.25a) \end{aligned}$$

and the help of the Taylor expansion (with some obvious calculus notations)

$$S^* = S^*{}_o + \sum \left[(\partial S^*/\partial \omega_D)_o \, \omega_D + (\partial S^*/\partial \dot{\omega}_D)_o \, \dot{\omega}_D \right] + \textit{quadratic terms in } \omega_D, \dot{\omega}_D, \qquad (3.5.25b)$$

we get the general results [similar to (3.5.24c, e)]

$$(\partial S^*/\partial \dot{\omega}_I)_o = \partial S^*{}_o/\partial \dot{\omega}_I \qquad \text{and} \qquad (\partial S^*/\partial \dot{\omega}_D)_o \neq \partial S^*{}_o/\partial \dot{\omega}_D = 0. \qquad (3.5.25c)$$

Therefore, if we are not interested in finding constraint reactions, we *can* enforce the constraints $\omega_D = 0$ and $\dot{\omega}_D = 0$ into S^* right from the beginning; that is, start working with $S^*{}_o$, and thus save a considerable amount of labor. This property, due to the first of (3.5.25c), marks a key difference between the equations of Appell and Hamel, and their corresponding special cases.

Special Case

If all constraints on the q's are *holonomic* and have the *equilibrium* form $\theta_D \to q_D = constant \equiv q_{Do}$, then

$$(\partial S^*/\partial \dot{\omega}_I)_o \to E_I(T)|_o \to E_I(T_o),$$

where $T_o \equiv T(t, q_D = constant, q_I, \dot{q}_D = 0, \dot{q}_I) \equiv T_o(t, q_I, \dot{q}_I)$, and, similarly for the impressed forces, $Q_I = Q_I(t, q, \dot{q}) \to Q_I(t, q_I, \dot{q}_I) \equiv Q_{Io}$, and so the kinetic equations become $E_I \equiv E_I(T_o) \equiv \partial S_o/\partial \ddot{q}_I = Q_{Io}$.

(iv) *Comparison between Lagrange's equations of the first and second kind, and their respective constraints*. Those of the *first* kind, eq. (ex. 3.5.1: c3), constitute a set of

$$3N + (h + m) = [(3N - h) + m] + 2h \equiv (n + m) + 2h$$

scalar equations, for the $3N + (h + m)$ unknown functions:

$$\{x_P, y_P, z_P;\ P = 1, \ldots, N\}, \qquad \{\mu_H;\ H = 1, \ldots, h\} \qquad \text{and} \qquad \{\lambda_D;\ D = 1, \ldots, m\}.$$

Once the *positions* (and hence accelerations) and *multipliers* become known functions of time, (ex. 3.5.1: c2) supply the reactions.

Those of the *second* kind, actually the Routh–Voss equations (3.5.15, 16), constitute a set of

$$n + m \equiv (3N - h) + m$$

equations for the $n + m$ unknowns:

$$\{q_k;\ k = 1, \ldots, n\} \qquad \text{and} \qquad \{\lambda_D;\ D = 1, \ldots, m\}.$$

Once the q's and λ's have been found as functions of time, then $\boldsymbol{r}_P = \boldsymbol{r}_P(t, q) \to \boldsymbol{r}_P(t)$ $[\to \boldsymbol{a}_P = \boldsymbol{a}_P(t)]$, and, again, (ex. 3.5.1: c2) supply the reactions. From the latter and the (now) known λ's, we can calculate the μ's.

In sum, in the *second-kind case* we have $2h$ *fewer equations*, which is the result of having absorbed the h holonomic constraints into that description with the $n \equiv 3N - h$ q's [see remark (v) below]. Also, even in the presence of additional holonomic and/or nonholonomic constraints, we still work with the *unconstrained* kinetic energy T.

However, and this is a general comment, the ultimate judgement regarding the relative merits of various types of equations of motion must be shaped by several, frequently intangible/nonquantifiable considerations (in the sense of the famous Machian principle of *Denkökonomie*), in addition to the mere tallying of their number of equations, and so on ("bean counting").

(v) *Purpose for appearance of the multipliers.* That the multipliers μ_H, of the h holonomic constraints $\phi_H(t, \boldsymbol{r}) = 0$, are not present in Lagrange's equations of the second kind (and in the Routh–Voss equations) is no accident: the m λ_D's (and this is a general remark) express the reactions of whatever constraints have not been taken care of by our chosen q's; that is, *they are due to the additional holonomic and/or nonholonomic constraints not yet built in* (*or embedded, or absorbed*) *into our particular q's description.* Then, the multipliers appear as coefficients in the virtual work of the reactions of these additional constraints.

(vi) *Apparent indeterminacy of Lagrange's equations.* Let us consider a system with equations of motion

$$E_k \equiv d/dt(\partial T/\partial \dot{q}_k) - \partial T/\partial q_k = Q_k. \tag{3.5.26a}$$

Since, as explained earlier, all possible constraints are already built in into the chosen q-description, the corresponding system constraint reactions R_k have been eliminated from the right side of (3.5.26a); the Q_k are wholly impressed. However, occasionally, the latter depend on constraint reactions: for example, the *sliding* Coulomb–Morin friction F on a particle sliding on a rough surface — according to our definition, an impressed force — is given by

$$-\mu N(\boldsymbol{v}/|\boldsymbol{v}|), \tag{3.5.26b}$$

where $N =$ *normal* force from surface to particle (clearly, a contact constraint *reaction*), $\mu =$ *sliding friction coefficient*, and $\boldsymbol{v} =$ particle *velocity relative to the surface*. In such a case, if we embed *all* holonomic constraints into our q's, and hence into our T

and Q_k's, the resulting Lagrangean equations (3.5.26a) will, in general, constitute an *indeterminate* system; that is, the total number of equations, including constitutive ones like (3.5.26b), will be smaller than the number of unknowns involved. Such an indeterminacy [what Kilmister and Reeve (1966, p. 215) call "failure" of Lagrange's equations] can be easily removed by *relaxing* the system's constraints, and thus generating the hitherto missing equations (see also "principle of relaxation" in §3.7). Similar "failures" would appear if one used minimal quasi velocities to embed all nonholonomic constraints (see also Rosenberg, 1977, pp. 152–157).

(vii) We have presented the *four* basic types of equations of motion: *Routh–Voss, Maggi, Hamel,* and *Appell*. They can be classified as follows:

Kinetic energy-based equations of motion

Holonomic variables: Routh-Voss (coupled)
Maggi (uncoupled: kinetic, kinetostatic)

Nonholonomic variables: Hamel (uncoupled: kinetic, kinetostatic)

Acceleration-based equations of motion

Holonomic variables: Appell (coupled)

Nonholonomic variables: Appell (uncoupled: kinetic, kinetostatic)

Additional special cases and/or combinations of the above—for example, equations of Ferrers, Hadamard, Chaplygin, Voronets, et al.—are presented in §3.8.

• From all the equations of constrained motion given earlier, *only those by Hamel* (and their special cases—see §3.8), through their γ-proportional terms (recall Hamel's formulation of Frobenius' theorem, §2.12), can distinguish between genuinely nonholonomic Pfaffian constraints and holonomic ones disguised in Pfaffian/velocity form. All other types, that is the equations of Routh–Voss, Maggi, Appell (and their special cases—see §3.8), hold *unchanged* in form whether their Pfaffian constraints are holonomic or nonholonomic; that is, *those equations cannot detect nonholonomicity, only Hamel's equations can do that*.

• On the other hand, only Appell's equations preserve their form in *both holonomic and nonholonomic variables*; and, in the kinetic ones, the nonholonomic constraints can be enforced in the Appellian function right from the start.

(viii) The terms *kinetic* and *kinetostatic*, in the particular sense used here (brought to mainstream dynamics by Heun and his students, in the early 20th century), and observed by some of the best contemporary textbooks on engineering dynamics, for example, Butenin et al. (1985, vol. 2, chap. 16, pp. 330–339), Loitsianskii and Lur'e (1983, vol. 2, chap. 28, pp. 345–384), Ziegler (1965, vol. 2, pp. 146–152), are not well known among English language authors, and so one should be careful in comparing various references.

(ix) Finally, we would like to state that we are not partial to any particular set of equations of motion; all have advantages and disadvantages; all are worth learning!

All such conceivable equations (whose combinations and special cases are practically endless; see also §3.8) flow out of the differential variational principles of analytical mechanics; that is, the principles of *Lagrange* and of *relaxation of the constraints*, in their various forms (see also §3.6 and §3.7). These principles, being *invariant*, constitute the sole physical and mathematical glue that holds all these (coordinate and constraint-dependent) equations of motion together—and they keep reminding us that, in spite of appearances, *there is only one* (*classical*) *mechanics!*

Geometrical Interpretation of the Uncoupling of the Equations of Motion into Kinetic and Kinetostatic

The Routh–Voss equations,

$$E_k \equiv d/dt(\partial T/\partial \dot{q}_k) - \partial T/\partial q_k = Q_k + \sum \lambda_D a_{Dk}, \tag{3.5.27a}$$

represent an equation among (covariant) components of vectors at a point (q) in configuration space, or a point (t, q) in event space. Now, we recall from §2.11, eq. (2.11.19a ff.), that the $n - m$ vectors $\boldsymbol{A}_I{}^T = (A_{1I}, \ldots, A_{nI})$ span, at that point, the *null*, or *virtual*, hyperplane (or affine space) $N_I \equiv V$, of the *constraint matrix* $\mathbf{A}_\mathrm{D} = (a_{Dk})$; while the m vectors $\boldsymbol{A}_D{}^T = (A_{1D}, \ldots, A_{nD})$ span its orthogonal complement, the *range*, or *constraint*, hyperplane (or affine space) C_m. Therefore, multiplying (3.5.27a) with $A_{kI}(A_{kD})$ and then summing over k, from 1 to n, means projecting that equation onto the local *virtual* (*constraint*) space; and since the constraint reactions $R_k = \sum \lambda_D a_{Dk}$ are perpendicular to the virtual space, they disappear from the kinetic Maggi equations. Indeed, we have, successively,

(i)
$$\begin{aligned}\sum A_{kI} E_k &= \sum A_{kI} Q_k + \sum\sum \lambda_D a_{Dk} A_{kI} \\ &= \sum A_{kI} Q_k + \sum \lambda_D\, \delta_{DI} = \sum A_{kI} Q_k + 0,\end{aligned}$$

that is,

$$\sum A_{kI} E_k = \sum A_{kI} Q_k \qquad \text{or} \qquad I_I = \Theta_I; \tag{3.5.27b}$$

(ii)
$$\begin{aligned}\sum A_{kD'} E_k &= \sum A_{kD'} Q_k + \sum\sum \lambda_D a_{Dk} A_{kD'} \\ &= \sum A_{kD'} Q_k + \sum \lambda_D\, \delta_{DD'} = \sum A_{kD'} Q_k + \lambda_{D'},\end{aligned}$$

that is,

$$\sum A_{kD} E_k = \sum A_{kD} Q_k + \lambda_D \qquad \text{or} \qquad I_D = \Theta_D + \lambda_D. \tag{3.5.27c}$$

Tensorial Treatment

(Kinetic complement of comments made at the end of §2.11; may be omitted in a first reading.) In the language of tensors (whose general indicial notation begins to show its true simplicity and power here), the I_I, Θ_I, $\Lambda_I = 0$ $(I_D, \Theta_D, \Lambda_D = \lambda_D)$ are *covariant* components of the corresponding system vectors along the *contravariant* basis $\boldsymbol{A}^I(\boldsymbol{A}^D)$, which is *dual* to the earlier basis $\boldsymbol{A}_I(\boldsymbol{A}_D)$. Dotting the vectorial Routh–Voss equations [fig. 3.1(a)]

$$\boldsymbol{E} = \boldsymbol{Q} + \boldsymbol{R}, \tag{3.5.28a}$$

where (with summation convention) $\boldsymbol{R} = R_k \boldsymbol{E}^k = (\lambda_D\, a^D{}_k)\boldsymbol{E}^k = \lambda_D \boldsymbol{A}^D$ (i.e., $\boldsymbol{R}$ is perpendicular to the virtual local plane) with $\boldsymbol{A}_I = A^k{}_I \boldsymbol{E}_k$—that is, projecting it onto the virtual local plane — yields

$$\boldsymbol{E} \cdot \boldsymbol{A}_I = \boldsymbol{Q} \cdot \boldsymbol{A}_I + \boldsymbol{R} \cdot \boldsymbol{A}_I, \tag{3.5.28b}$$

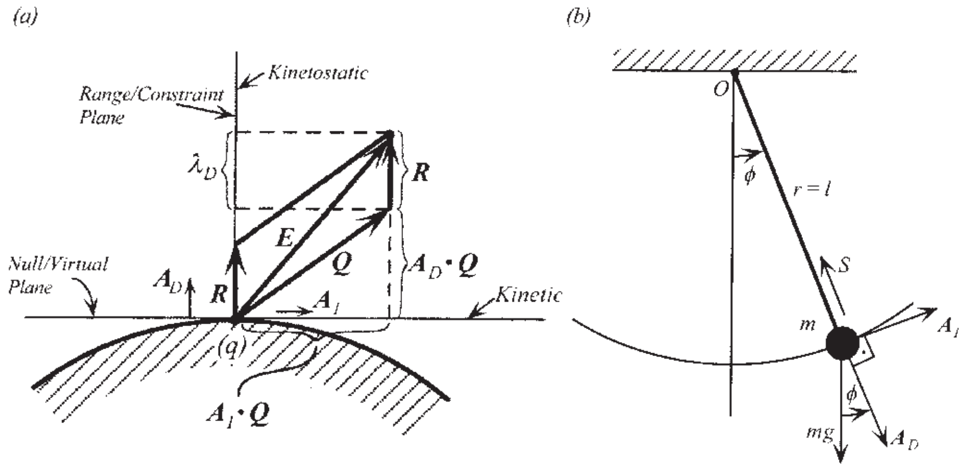

Figure 3.1 (a) Geometrical interpretation of uncoupling of equations of motion (''Method of projections'' of Maggi); and (b) its application to the planar mathematical pendulum.

or, since $\boldsymbol{R} \cdot \boldsymbol{A}_I = \lambda_D(\boldsymbol{A}^D \cdot \boldsymbol{A}_I) = \lambda_D \, \delta^D{}_I = 0$, finally $\boldsymbol{E} \cdot \boldsymbol{A}_I = \boldsymbol{Q} \cdot \boldsymbol{A}_I$,

$$\text{i.e., } A^k{}_I E_k = A^k{}_I Q_k \text{ (kinetic Maggi)}, \qquad \text{or} \qquad I_I = \Theta_I; \tag{3.5.28c}$$

while dotting them with $\boldsymbol{A}_D = A^k{}_D \boldsymbol{E}_k$—that is, projecting it onto the constraint local plane—yields

$$\boldsymbol{E} \cdot \boldsymbol{A}_D = \boldsymbol{Q} \cdot \boldsymbol{A}_D + \boldsymbol{R} \cdot \boldsymbol{A}_D, \tag{3.5.28d}$$

or, since $\boldsymbol{R} \cdot \boldsymbol{A}_D = \lambda_{D'}(\boldsymbol{A}^{D'} \cdot \boldsymbol{A}_D) = \lambda_{D'} \, \delta^{D'}{}_D = \lambda_D$, finally

$$A^k{}_D E_k = A^k{}_D Q_k + \lambda_D \text{ (kinetostatic Maggi)}, \qquad \text{or} \qquad I_D = \Theta_D + \lambda_D. \tag{3.5.28e}$$

For the planar mathematical pendulum of length l, mass m, and string tension S [fig. 3.1(b)], $\boldsymbol{A}_I = \partial \boldsymbol{r}/\partial \phi = \textit{along tangent}$, $\boldsymbol{A}_D = \partial \boldsymbol{r}/\partial r = \textit{along normal}$, and so (3.5.28b, d) become

$$\boldsymbol{E} \cdot \boldsymbol{A}_I = \boldsymbol{Q} \cdot \boldsymbol{A}_I: \qquad ml(d^2\phi/dt^2) = -mg \sin \phi \qquad (\textit{kinetic Maggi eq.}), \tag{3.5.28f}$$

$$\boldsymbol{E} \cdot \boldsymbol{A}_D = \boldsymbol{Q} \cdot \boldsymbol{A}_D + \boldsymbol{R} \cdot \boldsymbol{A}_D: \quad ml(d\phi/dt)^2 = -mg \cos \phi + S \quad (\textit{kinetostatic Maggi eq.}). \tag{3.5.28g}$$

These geometrical considerations demonstrate the importance of the *method* of projections of Maggi, over and above that of the Maggi *equations*. His method can be applied to any kind of multiplier-containing (mixed) equations.

Example 3.5.6 *Lagrange's Equations* (Williamson and Tarleton, 1900, pp. 437–438). Let us consider a scleronomic system described by the Lagrangean equations

$$d/dt(\partial T/\partial v_k) - \partial T/\partial q_k = Q_k \qquad (k = 1, \ldots, n). \tag{a}$$

Now, the change of the system momentum $p_k \equiv \partial T/\partial v_k$ during an elementary time interval dt is $(dp_k/dt)dt$, and this, according to (a), equals $Q_k\, dt + (\partial T/\partial q_k)\, dt$. Since the system is scleronomic, $\partial T/\partial q_k =$ quadratic homogeneous function of the v_k's (see also §3.9), and therefore if the system is at rest, it vanishes. Hence, the result: *The elementary change of a typical component of the system momentum consists of two parts: one due to the corresponding impressed force, and one due to the (possible) previous motion.*

Problem 3.5.2 *Lagrange's Equations: 1 DOF.* Let us consider the most general holonomic and rheonomic 1 DOF system; that is, $n = 1$ and $m = 0$, with inertial (double) kinetic energy

$$2T = A(t, q)\dot{q}^2 + 2B(t, q)\dot{q} + C(t, q), \quad (A, C \geq 0, \text{ always}) \tag{a}$$

and hence Lagrangean (negative) inertial force

$$\begin{aligned} E_q(T) &\equiv (\partial T/\partial \dot{q})^{\cdot} - \partial T/\partial q \\ &= (1/2)\big[2A\,\ddot{q} + (\partial A/\partial q)\dot{q}^2 + 2(\partial A/\partial t)\dot{q} + 2(\partial B/\partial t) - \partial C/\partial q\big]. \end{aligned} \tag{b}$$

(i) Show that the *new* Lagrangean coordinate x, defined by

$$x \equiv \int [A(t, q)]^{1/2}\, dq = x(t, q) \;\Leftrightarrow\; q = q(t, x), \tag{c}$$

reduces $2T$ to

$$2T = \dot{x}^2 + 2b(x, t)\dot{x} + c(x, t), \tag{d}$$

where

$$b(t, x) \equiv \Big\{A^{1/2}(B/A + \partial q/\partial t)\Big\}_{\text{evaluated at } q=q(t,x)}, \tag{e}$$

$$c(t, x) \equiv \Big\{A(\partial q/\partial t)^2 + 2B(\partial q/\partial t) + C\Big\}_{\text{evaluated at } q=q(t,x)}, \tag{f}$$

and generates the following (negative) Lagrangean inertial force:

$$E_x(T) \equiv (\partial T/\partial \dot{x})^{\cdot} - \partial T/\partial x = d^2x/dt^2 + \partial b/\partial t - (1/2)(\partial c/\partial x); \tag{g}$$

that is, *no* (dx/dt)*-proportional* (*i.e., damping/friction*) *terms*. Such coordinate transformations may prove useful in nonlinear oscillation problems.

(ii) Show that in the *scleronomic* case, i.e., when $B, C \equiv 0$ and hence $2T = A(q)\dot{q}^2$, the inertia forces (b) and (g) reduce, respectively, to

$$A(d^2q/dt^2) + (1/2)(dA/dq)(dq/dt)^2 \qquad \text{and} \qquad d^2x/dt^2. \tag{h}$$

Problem 3.5.3 *Lagrange's Equations: 1 DOF.* Let us consider a 1 DOF system with kinetic and potential energies

$$2T = A(q)(dq/dt)^2 \qquad \text{and} \qquad V = V(q), \tag{a}$$

respectively, capable of oscillating about its equilibrium position $q = 0$. Show that the *period* of its *small amplitude* (i.e., *linearized*, or *harmonic*) vibration equals [with $(\ldots)' \equiv d(\ldots)/dq$]

$$2\pi[A(0)/V''(0)]^{1/2}. \tag{b}$$

HINT

Here, $A(0) > 0$, $V(0) = 0$, $V'(0) = 0$, $V''(0) > 0$; and, as shown in §3.9 ff.,

$$Q = -\partial V/\partial q = -dV/dq \equiv -V'.$$

Expand T and V à la Taylor about $q = 0$, and keep only up to *quadratic* terms in q and $\dot{q}$, etc.

Problem 3.5.4 *Lagrange's Equation: 1 DOF.* Continuing from the preceding problem, show that if $q = q_o$ is an equilibrium position, instead of $q = 0$, then (b) is replaced by

$$2\pi[A(q_o)/V''(q_o)]^{1/2}. \tag{a}$$

Problem 3.5.5 *Lagrange's Equations: Pendulum of Varying Length.* Show that the planar oscillations of a mathematical pendulum of varying, or variable, length $l = l(t) =$ *given function of time*, on a vertical plane, are governed by the (variable coefficient) equation

$$(l^2\dot{\phi})^{\cdot} + g\,l \sin\phi = 0 \;\Rightarrow\; d^2\phi/dt^2 + 2(\dot{l}/l)(d\phi/dt) + (g/l)\sin\phi = 0, \tag{a}$$

where $\phi =$ angle of pendulum string with vertical.

For the treatment of special cases, see for example, Lamb (1943, pp. 198–199).

Example 3.5.7 *Lagrange's Equations: Planar Double Pendulum; Work of Impressed Forces.* Let us consider a double mathematical pendulum in vertical plane motion, under gravity [fig. 3.2(a)]. Below we calculate the components of the system impressed force by several methods.

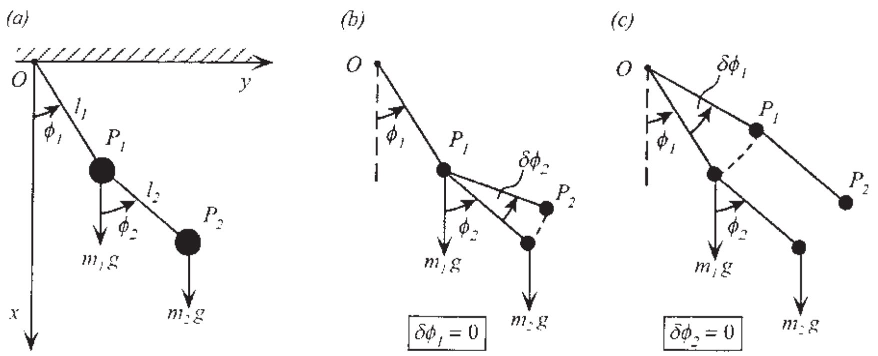

Figure 3.2 (a–c) Double planar mathematical pendulum, under gravity; calculation of impressed system forces.

(i) *From the Q_k-definitions* (§3.4). Here, with $q_1 = \phi_1$, $q_2 = \phi_2$ and some obvious notations, we have

$$\boldsymbol{r}_1 = (l_1 \cos\phi_1, l_1 \sin\phi_1, 0), \qquad \boldsymbol{r}_2 = (l_1 \cos\phi_1 + l_2 \cos\phi_2, l_1 \sin\phi_1 + l_2 \sin\phi_2, 0), \quad \text{(a)}$$

$$\boldsymbol{F}_1 = (m_1 g, 0, 0), \qquad \boldsymbol{F}_2 = (m_2 g, 0, 0), \quad \text{(b)}$$

and, therefore, we obtain

$$Q_1 \equiv \mathsf{S}\, d\boldsymbol{F} \cdot (\partial \boldsymbol{r}/\partial q_1) = \boldsymbol{F}_1 \cdot (\partial \boldsymbol{r}_1/\partial q_1) + \boldsymbol{F}_2 \cdot (\partial \boldsymbol{r}_2/\partial q_1)$$
$$= \cdots = -m_1 g l_1 \sin\phi_1 - m_2 g\, l_1 \sin\phi_1 = -(m_1 + m_2) g l_1 \sin\phi_1, \quad \text{(c)}$$

$$Q_2 \equiv \mathsf{S}\, d\boldsymbol{F} \cdot (\partial \boldsymbol{r}/\partial q_2) = \boldsymbol{F}_1 \cdot (\partial \boldsymbol{r}_1/\partial q_2) + \boldsymbol{F}_2 \cdot (\partial \boldsymbol{r}_2/\partial q_2)$$
$$= \cdots = -m_2 g\, l_2 \sin\phi_2. \quad \text{(d)}$$

(ii) *Directly from virtual work*. Let us find Q_2; that is, $\delta' W$ for $\delta\phi_1 = 0$ and $\delta\phi_2 \neq 0$: $(\delta' W)_2 \equiv Q_2\, \delta\phi_2$. Referring to fig. 3.2(b), we have

$$(\delta' W)_2 = (m_2 g)\, \delta(l_2 \cos\phi_2) = -m_2 g\, l_2 \sin\phi_2\, \delta\phi_2 \;\Rightarrow\; Q_2 = -m_2 g\, l_2 \sin\phi_2. \quad \text{(e)}$$

Similarly, to find Q_1—that is, $\delta' W$ for $\delta\phi_1 \neq 0$ and $\delta\phi_2 = 0$: $(\delta' W)_1 \equiv Q_1\, \delta\phi_1$, referring to fig. 3.2(c), we find

$$(\delta' W)_1 = (m_1 g)\, \delta(l_1 \cos\phi_1) + (m_2 g)\, \delta(l_1 \cos\phi_1) = (m_1 + m_2) g\, \delta(l_1 \cos\phi_1)$$
$$= -(m_1 + m_2) g\, l_1 \sin\phi_1\, \delta\phi_1 \;\Rightarrow\; Q_1 = -(m_1 + m_2) g\, l_1 \sin\phi_1. \quad \text{(f)}$$

(iii) *From potential energy (see also §3.9)*. Here, the total potential energy of gravity ($\rightarrow$ impressed forces), $V = V(\phi_1, \phi_2)$, is

$$V = -(m_1 g)(l_1 \cos\phi_1) - (m_2 g)(l_1 \cos\phi_1 + l_2 \cos\phi_2)$$
$$= -(m_1 + m_2) g\, l_1 \cos\phi_1 - m_2 g\, l_2 \cos\phi_2, \quad \text{(g)}$$

and since $\delta' W = -\delta V$, we obtain

$$Q_1 = -\partial V/\partial\phi_1 = -(m_1 + m_2) g\, l_1 \sin\phi_1, \qquad Q_2 = -\partial V/\partial\phi_2 = -m_2 g\, l_2 \sin\phi_2. \quad \text{(h, i)}$$

REMARK

Had we chosen as system positional coordinates (fig. 3.3)

$$q_1 = \theta_1 \equiv \phi_1 \qquad \text{and} \qquad q_2 = \theta_2 \equiv \phi_2 - \phi_1 = \phi_2 - \theta_1, \quad \text{(j)}$$

then (g) would assume the form

$$V = V(\theta_1, \theta_2) = -(m_1 + m_2) g\, l_1 \cos\theta_1 - m_2 g\, l_2 \cos(\theta_1 + \theta_2), \quad \text{(k)}$$

and the corresponding Lagrangean forces would be

$$Q_1 = -\partial V/\partial\theta_1 = -(m_1 + m_2) g\, l_1 \sin\theta_1 - m_2 g\, l_2 \sin(\theta_1 + \theta_2), \quad \text{(l)}$$

$$Q_2 = -\partial V/\partial\theta_2 = -m_2 g\, l_2 \sin(\theta_1 + \theta_2). \quad \text{(m)}$$

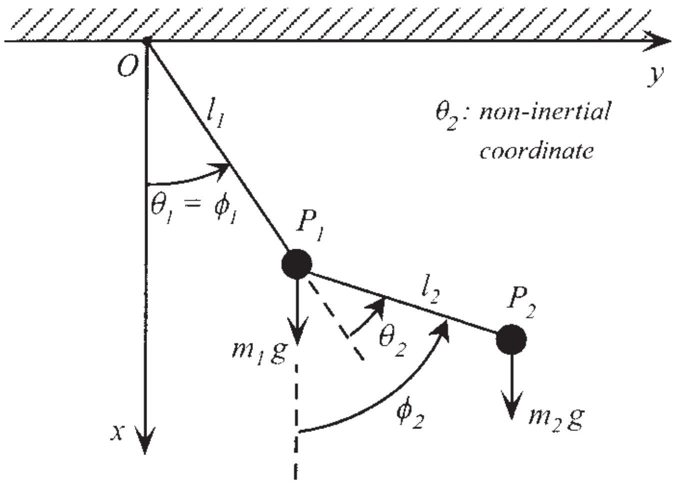

Figure 3.3 Double planar mathematical pendulum under gravity; alternative coordinates.

Example 3.5.8 *Lagrange's Equations: Planar Double Pendulum; Derivation of Equations of Motion.* Continuing from the preceding example (and its figures), let us first calculate the kinetic energy of the pendulum. We find, successively,

$$x_1 = l_1 \cos\phi_1 \Rightarrow \dot{x}_1 = -l_1\dot{\phi}_1 \sin\phi_1, \tag{a}$$

$$y_1 = l_1 \sin\phi_1 \Rightarrow \dot{y}_1 = l_1\dot{\phi}_1 \cos\phi_1, \tag{b}$$

$$x_2 = l_1 \cos\phi_1 + l_2\cos\phi_2 \Rightarrow \dot{x}_2 = -l_1\dot{\phi}_1 \sin\phi_1 - l_2\dot{\phi}_2\sin\phi_2, \tag{c}$$

$$y_2 = l_1 \sin\phi_1 + l_2\sin\phi_2 \Rightarrow \dot{y}_2 = l_1\dot{\phi}_1 \cos\phi_1 + l_2\dot{\phi}_2\cos\phi_2; \tag{d}$$

$$v_1{}^2 = (\dot{x}_1)^2 + (\dot{y}_1)^2 = \cdots = l_1{}^2(\dot{\phi}_1)^2, \tag{e}$$

$$v_2{}^2 = (\dot{x}_2)^2 + (\dot{y}_2)^2 = \cdots = l_1{}^2(\dot{\phi}_1)^2 + 2l_1l_2\cos(\phi_2-\phi_1)\dot{\phi}_1\dot{\phi}_2 + l_2{}^2(\dot{\phi}_2)^2; \tag{f}$$

$$\begin{aligned} 2T &= m_1v_1{}^2 + m_2v_2{}^2 \\ &= \cdots = (m_1+m_2)l_1{}^2(\dot{\phi}_1)^2 + 2m_2l_1l_2\cos(\phi_2-\phi_1)\dot{\phi}_1\dot{\phi}_2 + m_2l_2{}^2(\dot{\phi}_2)^2; \end{aligned} \tag{g}$$

and by the preceding example,

$$Q_1 = -(m_1+m_2)g\,l_1\sin\phi_1, \qquad Q_2 = -m_2g\,l_2\sin\phi_2. \tag{h}$$

From the above, we obtain

$$\begin{aligned} \partial T/\partial\dot{\phi}_1 &= (m_1+m_2)l_1{}^2\dot{\phi}_1 + m_2l_1l_2\cos(\phi_2-\phi_1)\dot{\phi}_2, \\ (\partial T/\partial\dot{\phi}_1)^{\cdot} &= (m_1+m_2)l_1{}^2\ddot{\phi}_1 \\ &\quad + m_2l_1l_2\cos(\phi_2-\phi_1)\ddot{\phi}_2 - m_2l_1l_2\sin(\phi_2-\phi_1)(\dot{\phi}_2-\dot{\phi}_1)\dot{\phi}_2, \end{aligned} \tag{i}$$

$$\partial T/\partial\phi_1 = m_2l_1l_2\sin(\phi_2-\phi_1)\dot{\phi}_1\dot{\phi}_2. \tag{j}$$

Therefore, Lagrange's equation for $q_1 = \phi_1$: $(\partial T/\partial\dot{\phi}_1)^{\cdot} - \partial T/\partial\phi_1 = Q_1$, becomes after some simple algebra,

$$(m_1 + m_2){l_1}^2(d^2\phi_1/dt^2) + m_2 l_1 l_2 \cos(\phi_2 - \phi_1)(d^2\phi_2/dt^2) \\ - m_2 l_1 l_2 \sin(\phi_2 - \phi_1)(d\phi_2/dt)^2 + (m_1 + m_2) g\, l_1 \sin\phi_1 = 0. \quad \text{(k)}$$

Similarly, we find Lagrange's equation for $q_2 = \phi_2$:

$$m_2{l_2}^2(d^2\phi_2/dt^2) + m_2 l_1 l_2 \cos(\phi_2 - \phi_1)(d^2\phi_1/dt^2) \\ + m_2 l_1 l_2 \sin(\phi_2 - \phi_1)(d\phi_1/dt)^2 + m_2 g\, l_2 \sin\phi_2 = 0. \quad \text{(l)}$$

The above constitute a set of two *coupled* nonlinear second-order equations for $\phi_1(t)$ and $\phi_2(t)$.

Constraints

(i) Assume, next, that we impose on our system the constraint

$$f_1 \equiv y_1 = l_1 \sin\phi_1 = 0 \qquad [\Rightarrow \phi_1(t) = 0 \Rightarrow \delta\phi_1 = 0]; \quad \text{(m)}$$

that is, we restrict the *upper half* OP_1 to remain vertical, so that the double pendulum reduces to a simple pendulum P_1P_2 oscillating about the fixed point P_1.

Since $\partial f_1/\partial\phi_1 = l_1 \cos\phi_1 = l_1$ and $\partial f_1/\partial\phi_2 = 0$ $[\Rightarrow \delta f_1 = (l_1\cos\phi_1)\delta\phi_1 + (0)\delta\phi_2 = (l_1)\delta\phi_1 + (0)\delta\phi_2]$, the equations of motion in this case are (k) and (l), but with the terms $\lambda_1 l_1 \cos\phi_1 = \lambda_1 l_1$ and and $\lambda_1 \cdot 0 = 0$ (where λ_1 = multiplier corresponding to the constraint $\delta f_1 = 0$) *added*, respectively, to their right sides; that is, in general, it is *not enough* to simply set in these two equations $\phi_1 = 0$ $(\Rightarrow \dot{\phi}_1 = 0, \ddot{\phi}_1 = 0)$! Indeed, then the equations of the (m)-constrained pendulum motion decouple to the Routh–Voss equations:

$$\phi_1: \quad \lambda_1 = m_2 l_2\big[\cos\phi_2(d^2\phi_2/dt^2) - \sin\phi_2(d\phi_2/dt)^2\big] \qquad (\textit{kinetostatic}), \quad \text{(n)}$$

$$\phi_2: \quad d^2\phi_2/dt^2 + (g/l_2)\sin\phi_2 = 0 \qquad (\textit{kinetic}). \quad \text{(o)}$$

With the initial conditions at, say, $t = 0$: $\phi_2(0) \equiv \phi_o = 0$ and $\dot{\phi}_2(0) \equiv \dot{\phi}_o$, equation (o) readily integrates, in well-known elementary ways, to (the energy equation)

$$(\dot{\phi}_2)^2 = (\dot{\phi}_o)^2 - (2g/l_2)(1 - \cos\phi_2), \quad \text{(p)}$$

in which case, (n) yields the *constraint reaction* in terms of the angle $\phi_2 = \phi_2(t)$ and its *initial conditions*

$$\lambda_1 = \cdots = m_2[(2 - 3\cos\phi_2)g - l_2(\dot{\phi}_o)^2]\sin\phi_2 = \lambda_1(t; \phi_o, \dot{\phi}_o). \quad \text{(q)}$$

Finally, since

$$\delta' W_R = [\lambda_1(\partial f_1/\partial\phi_1)]\,\delta\phi_1 \equiv R_1\,\delta\phi_1 \\ = (\lambda_1 l_1 \cos\phi_1)\,\delta\phi_1 = \lambda_1\,\delta(l_1\sin\phi_1) = \lambda_1\,\delta y_1\,(= 0), \quad \text{(r)}$$

the multiplier represents the (variable) *horizontal force of reaction needed to preserve the constraint (m)*. [Other forms of (m) will result in different, but physically equivalent, forms of the multiplier. See also §3.7: Relaxation of Constraints.]

(ii) Similarly, if ϕ_2 acquires a prescribed motion, say $\phi_2 = f(t) =$ *known function of time*, then, since in that case $\delta\phi_2 = \delta f(t) = 0$ [$= (0)\,\delta\phi_1 + (1)\,\delta\phi_2$], we must add a term $\lambda_2 \cdot 0 = 0$ to the right side of the ϕ_1-equation, and a term $\lambda_2 \cdot 1$ to the right side of the ϕ_2-equation [where $\lambda_2 =$ multiplier corresponding to the constraint $f_2 \equiv \phi_2 - f(t) = 0 \Rightarrow \delta f_2 = 0$]. The rest of the calculations are left to the reader.

Problem 3.5.6 *Constrained Double Pendulum.* Continuing from the preceding example, assume that we impose on our pendulum the constraint

$$f_2 \equiv y_2 = l_1 \sin\phi_1 + l_2 \sin\phi_2 = 0. \tag{a}$$

(i) Show that in this case, and for the special simplifying choice $l_1 = l_2 \equiv l$ [$\Rightarrow \sin\phi_1 + \sin\phi_2 = 0 \Rightarrow \phi_1 + \phi_2 = 0$], the equations of motion reduce to

$$\begin{aligned}(m_1 + m_2)l^2(d^2\phi_1/dt^2) - m_2 l^2 \cos(2\phi_1)(d^2\phi_1/dt^2) + m_2 l^2 \sin(2\phi_1)(d\phi_1/dt)^2 \\ + (m_1 + m_2)g\,l \sin\phi_1 = \lambda_1 l \cos\phi_1,\end{aligned} \tag{b}$$

$$\begin{aligned}- m_2 l^2(d^2\phi_1/dt^2) + m_2 l^2 \cos(2\phi_1)(d^2\phi_1/dt^2) - m_2 l^2 \sin(2\phi_1)(d\phi_1/dt)^2 \\ - m_2 g\,l \sin\phi_1 = \lambda_1 l \cos\phi_1.\end{aligned} \tag{c}$$

(ii) From the above, deduce that [e.g. by *adding* (b) and (c) etc.]:

$$\lambda_1 = (m_1 l/2)(1/\cos\phi_1)(d^2\phi_1/dt^2) + (m_1 g/2)\tan\phi_1. \tag{d}$$

Interpret the multiplier λ_1 physically.

(iii) From the above, deduce that [e.g. by *subtracting* (b) and (c) from each other etc.]:

$$(m_1 + 4m_2 \sin^2\phi_1)(d^2\phi_1/dt^2) + 2m_2 \sin(2\phi_1)(d\phi_1/dt)^2 + (m_1 + 2m_2)(g/l)\sin\phi_1 = 0; \tag{e}$$

i.e., a single pendulum-like, reactionless (kinetic) and nonliner equation.

Example 3.5.9 *Small (Linearized) Oscillations of Double Pendulum.* Continuing from the preceding example, let us study the small (linearized) amplitude/velocity/acceleration oscillatory motions of our planar double mathematical pendulum about its equilibrium configuration $\phi_1 = 0,\ \phi_2 = 0$.

There are two ways to proceed. Either (i) we keep up to *quadratic* terms in $\phi_1,\ \phi_2$ and their derivatives in T and V (or up to *linear* ones in the Q's) so that the corresponding Lagrangean equations end up *linear* in these functions; or (ii) we directly linearize the earlier-found equations of motion (for a more general treatment of linearized motions, see §3.10).

Let us begin with the first way; it is not hard to show that the earlier $T,\ V\ (Q_{1,2})$ approximate to the homogeneous *quadratic* (*linear*) forms:

$$2T = (m_1 + m_2){l_1}^2(\dot\phi_1)^2 + 2m_2 l_1 l_2 \dot\phi_1 \dot\phi_2 + m_2 {l_2}^2(\dot\phi_2)^2; \tag{a}$$

$$2V = (m_1 + m_2)g\,l_1 {\phi_1}^2 + m_2 g\,l_2 {\phi_2}^2 + \textit{constant terms}, \tag{b}$$

$$Q_1 = -(m_1 + m_2)g\,l_1\phi_1, \qquad Q_2 = -m_2 g\,l_2 \phi_2. \tag{c}$$

Then, with $L \equiv T - V = \textit{Lagrangean of the system}$, we easily obtain

$$\partial L/\partial\dot{\phi}_1 = (m_1 + m_2){l_1}^2\dot{\phi}_1 + m_2 l_1 l_2\dot{\phi}_2, \tag{d}$$

$$(\partial L/\partial\dot{\phi}_1)^{\cdot} = (m_1 + m_2){l_1}^2\ddot{\phi}_1 + m_2 l_1 l_2\ddot{\phi}_2, \tag{e}$$

$$\partial L/\partial\phi_1 = -(m_1 + m_2)g\, l_1\phi_1 \quad (= Q_1); \tag{f}$$

$$\partial L/\partial\dot{\phi}_2 = m_2 l_1 l_2\dot{\phi}_1 + m_2{l_2}^2\dot{\phi}_2, \tag{g}$$

$$(\partial L/\partial\dot{\phi}_2)^{\cdot} = m_2 l_1 l_2\ddot{\phi}_1 + m_2{l_2}^2\ddot{\phi}_2, \tag{h}$$

$$\partial L/\partial\phi_2 = -m_2 g\, l_2\phi_2 \quad (= Q_1). \tag{i}$$

Therefore, Lagrange's linearized (but still coupled!) equations are

$$(m_1 + m_2)l_1(d^2\phi_1/dt^2) + m_2 l_2(d^2\phi_2/dt^2) + (m_1 + m_2)g\,\phi_1 = 0, \tag{j}$$

$$l_1(d^2\phi_1/dt^2) + l_2(d^2\phi_2/dt^2) + g\,\phi_2 = 0. \tag{k}$$

The reader can verify that (j, k) result by direct linearization of (k, l) of the preceding example, respectively.

Solution of System of Equations (j, k)

As the theory of differential equations/linear vibration teaches us, the general solution of this *homogeneous* system is a linear combination, or superposition, of the following *harmonic motions* (*or modes*):

$$\phi_1 = A\sin(\omega t + \varepsilon) \qquad \text{and} \qquad \phi_2 = B\sin(\omega t + \varepsilon), \tag{l}$$

where $A, B = \textit{mode amplitudes}$, $\omega = \textit{mode frequency}$, and $\varepsilon = \textit{mode phase}$. Substituting (l) into (j, k), we are readily led to the algebraic system for the mode amplitudes:

$$[(m_1 + m_2)(g - l_1\omega^2)]A + (-m_2 l_2\omega^2)B = 0, \tag{m}$$

$$(-l_1\omega^2)A + (g - l_2\omega^2)B = 0. \tag{n}$$

The requirement for *nontrivial* A and B leads, in well-known ways, to the determinantal (secular) equation

$$\begin{vmatrix} (m_1 + m_2)(g - l_1\omega^2) & -m_2 l_2\omega^2 \\ -l_1\omega^2 & g - l_2\omega^2 \end{vmatrix} = 0, \tag{o}$$

which, when expanded, becomes

$$(m_1 l_1 l_2)\omega^4 - [(m_1 + m_2)(l_1 + l_2)g]\omega^2 + (m_1 + m_2)g^2 = 0. \tag{p}$$

To simplify the algebra we, henceforth, assume that $m_1 = m_2 \equiv m$ and $l_1 = l_2 \equiv l$. Then (p) reduces to

$$\omega^4 - 4(g/l)\omega^2 + 2(g/l)^2 = 0, \tag{q}$$

and its positive roots can be easily shown to be

$$\omega_1 = \{[2 - (2)^{1/2}](g/l)\}^{1/2} \qquad (\textit{lower frequency}), \tag{r1}$$

$$\omega_2 = \{[2 + (2)^{1/2}](g/l)\}^{1/2} \qquad (> \omega_1,\ \textit{higher frequency}). \tag{r2}$$

For $\omega = \omega_1, \omega_2$, the *amplitude ratios*

$$\mu \equiv B/A = [l_1\omega^2/(g - l_2\omega^2)] = \omega^2/[(g/l) - \omega^2] \quad [= \mu(\omega^2)] \tag{s}$$

[obtained from (n), for $l_1 = l_2$] are found to be

$$\mu_1 = B_1/A_1 = [2 - (2)^{1/2}]/[(2)^{1/2} - 1] = (2)^{1/2}, \tag{s1}$$

$$\mu_2 = B_2/A_2 = -[2 + (2)^{1/2}]/[1 + (2)^{1/2}] = -(2)^{1/2}, \tag{s2}$$

that is, $B_1 = (2)^{1/2}A_1$ and $B_2 = -(2)^{1/2}A_2$, for *any initial conditions*, and therefore the general solution of (j, k) is

$$\phi_1 = \phi_{1,1} + \phi_{1,2}, \qquad \phi_2 = \phi_{2,1} + \phi_{2,2}, \tag{t}$$

where

$$\phi_{1,1} = A_1 \sin(\omega_1 t + \varepsilon_1), \qquad \phi_{2,1} = \mu_1 A_1 \sin(\omega_1 t + \varepsilon_1), \tag{t1}$$

$$\phi_{1,2} = A_2 \sin(\omega_2 t + \varepsilon_2), \qquad \phi_{2,2} = \mu_2 A_2 \sin(\omega_2 t + \varepsilon_2). \tag{t2}$$

The above show that, for each frequency $\omega_k (k = 1, 2)$, the ratio of the corresponding mode amplitudes $\phi_{1,k}$ and $\phi_{2,k}$ is *constant*; that is, *independent of the initial conditions*

$$\phi_{2,1}/\phi_{1,1} = \mu_1 = (2)^{1/2} \qquad \text{and} \qquad \phi_{2,2}/\phi_{1,2} = \mu_2 = -(2)^{1/2}. \tag{t3}$$

The remaining *four* constants A_1, ε_1, and A_2, ε_2 are determined from the initial conditions.

For example, if at $t = 0$ we choose $\phi_1 = 0$, $\dot{\phi}_1 = 0$, and $\phi_2 = \phi_o$, $\dot{\phi}_2 = 0$, then, since

$$\dot{\phi}_1 = A_1\omega_1 \cos(\omega_1 t + \varepsilon_1) + A_2\omega_2 \cos(\omega_2 t + \varepsilon_2), \tag{u1}$$

$$\dot{\phi}_2 = (2)^{1/2} A_1\omega_1 \cos(\omega_1 t + \varepsilon_1) - (2)^{1/2} A_2\omega_2 \cos(\omega_2 t + \varepsilon_2), \tag{u2}$$

eqs. (t–t2), the above, and the initial conditions lead to the following algebraic system:

$$\phi_1: \qquad 0 = A_1 \sin\varepsilon_1 + A_2 \sin\varepsilon_2, \tag{v1}$$

$$\phi_2: \qquad \phi_o = (2)^{1/2} A_1 \sin\varepsilon_1 - (2)^{1/2} A_2 \sin\varepsilon_2, \tag{v2}$$

$$\dot{\phi}_1: \qquad 0 = A_1\omega_1 \cos\varepsilon_1 + A_2\omega_2 \cos\varepsilon_2, \tag{v3}$$

$$\dot{\phi}_2: \qquad 0 = (2)^{1/2} A_1\omega_1 \cos\varepsilon_1 - (2)^{1/2} A_2\omega_2 \cos\varepsilon_2. \tag{v4}$$

From the last two equations, we readily conclude that $\cos\varepsilon_1 = \cos\varepsilon_2 = 0 \Rightarrow \varepsilon_1 = \varepsilon_2 = \pi/2$; and so the first two reduce to $A_1 + A_2 = 0$ and $A_1 - A_2 = [(2)^{1/2}/2]\phi_o$, and from these we easily find $A_1 = [(2)^{1/2}/4]\phi_o$ and $A_2 =$

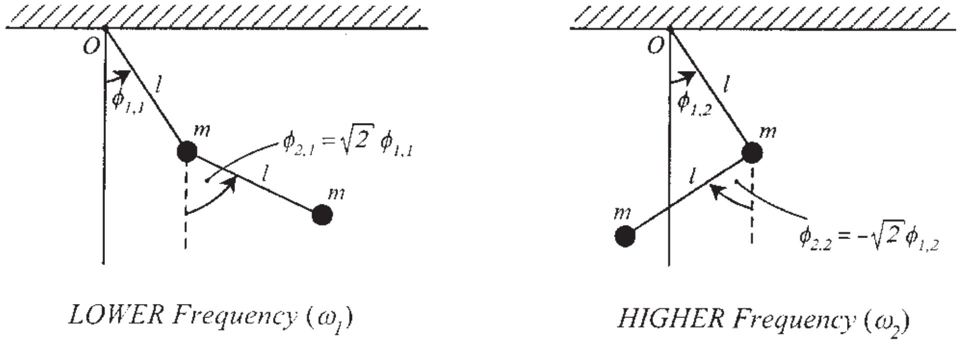

Figure 3.4 Angular modes of planar double pendulum, for its two frequencies: (a) lower frequency, (b) higher frequency. The amplitudes of $\phi_{1,1}$, $\phi_{1,2}$ depend on the initial conditions.

$-[(2)^{1/2}/4]\phi_o$. Hence, the particular solution of our system (j, k), satisfying the earlier chosen initial conditions, is

$$\phi_1 = [\phi_o(2)^{1/2}/4][\cos(\omega_1 t) - \cos(\omega_2 t)], \tag{w1}$$

$$\phi_2 = (\phi_o/2)[\cos(\omega_1 t) + \cos(\omega_2 t)]; \tag{w2}$$

where ω_1, ω_2 are given by (r1, 2).

The relative modal contributions for each frequency are shown in fig. 3.4(a, b).

Problem 3.5.7 *Double Pendulum; Noninertial Coordinates.* Consider the double pendulum of fig. 3.3.

(i) Show that its (Lagrangean) equations of motion in the angles $\theta_1 (\equiv \phi_1)$ and θ_2, under gravity, are

$$\begin{aligned}&[m_1 l_1{}^2 + m_2(l_1{}^2 + 2l_1 l_2\cos\theta_2 + l_2{}^2)](d^2\theta_1/dt^2) + m_2 l_2(l_1\cos\theta_2 + l_2)(d^2\theta_2/dt^2)\\&\quad - (m_2 l_1 l_2 \sin\theta_2)(d\theta_2/dt)^2 - (2m_2 l_1 l_2\sin\theta_2)(d\theta_1/dt)(d\theta_2/dt)\\&\quad + (m_1+m_2)l_1 g\sin\theta_1 + m_2 l_2 g\sin(\theta_1+\theta_2) = 0,\end{aligned} \tag{a}$$

$$\begin{aligned}&(m_2 l_2{}^2)(d^2\theta_2/dt^2) + m_2 l_2(l_1\cos\theta_2 + l_2)(d^2\theta_1/dt^2)\\&\quad + (m_2 l_1 l_2\sin\theta_2)(d\theta_1/dt)^2 + m_2 l_2 g\sin(\theta_1+\theta_2) = 0.\end{aligned} \tag{b}$$

(ii) Obtain its equations of small motion; that is, linearize (a, b).

(iii) What do (a, b) reduce to for $l_1 = 0$, or $l_2 = 0$, before and after their linearization?

Problem 3.5.8 *Double Physical Pendulum.* A rigid body I of mass M can rotate freely about a fixed and smooth *vertical* axis. A second rigid body II of mass m can rotate freely about a second smooth and also vertical axis that is fixed on body I (fig. 3.5).

(i) Show that the (double) kinetic energy of this double planar "physical" pendulum is

$$2T = A\dot{\phi}^2 + 2\Gamma\dot{\phi}\,\dot{\psi} + B\dot{\psi}^2, \tag{a}$$

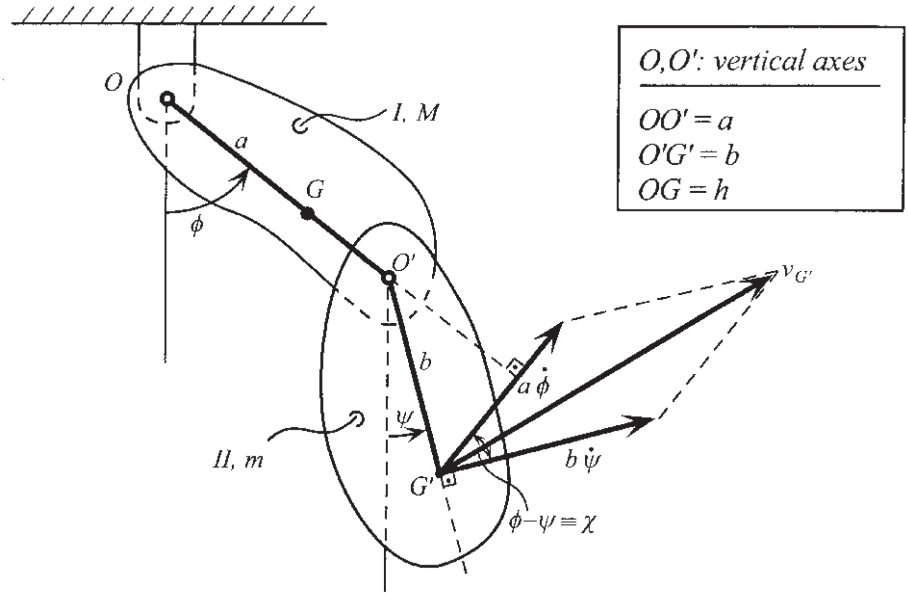

Figure 3.5 Double and planar physical pendulum, moving on horizontal plane.

where $A \equiv MK^2 + ma^2$, $B \equiv m(k^2 + b^2)$, $\Gamma \equiv m\,a\,b\cos(\phi - \psi) = m\,a\,b\cos(\psi - \phi) \equiv m\,a\,b\cos\chi$ (definition of angle χ); $K(k) =$ *radius of gyration of* $I(II)$ *about* O (G').

(ii) Show that, in this (force-free) case,

$$\partial T/\partial\dot{\phi} + \partial T/\partial\dot{\psi} \equiv p_\phi + p_\psi \equiv \text{total angular momentum about } O\text{-axis} = constant \equiv c, \tag{b}$$

or

$$(A + \Gamma)(d\phi/dt) + (B + \Gamma)(d\psi/dt) = c; \tag{b1}$$

and

$$2T = E\ (another\ constant). \tag{c}$$

(iii) Show that, with the help of $\chi \equiv \phi - \psi$, eq. (b1) can be further transformed to

$$(A + 2\Gamma + B)(d\psi/dt) = c - (A + \Gamma)(d\chi/dt),$$

or

$$(A + 2\Gamma + B)[A(d\phi/dt) + \Gamma(d\psi/dt)] = (A + \Gamma)c + (AB - \Gamma^2)(d\chi/dt). \tag{d}$$

(iv) With the help of this integral, show that the energy integral (c) can be rewritten as

$$(d\chi/dt)[A(d\phi/dt) + \Gamma(d\psi/dt)] + c(d\psi/dt) = E,$$

or

$$(d\chi/dt)^2(AB - \Gamma^2) + c^2 = (A + 2\Gamma + B)E. \tag{e}$$

(v) Finally, and recalling the Γ-definition, show that (e) transforms to

$$(d\chi/dt)^2 = [(A + B + 2m\,a\,b\cos\chi)E - c^2]/[AB - (m\,a\,b)^2\cos^2\chi] \equiv f(\chi), \quad \text{(f)}$$

that is, the problem has been led to a quadrature.

For further discussion of this famous problem, and of its many variations, see, for example (alphabetically): Marcolongo (1912, pp. 213–216), Schell (1880, pp. 549–551), Thomson and Tait (1912, pp. 310, 324–325), Timoshenko and Young (1948, pp. 209–211, 215–216, 249–250, 276–278, 312–314).

Problem 3.5.9 *Double Physical Pendulum: Vertical Axes.* Continuing from the preceding problem (penduli axes through O and O' *vertical*), obtain its Lagrangean equations of motion. What happens to these equations if the center of mass of the entire system $I + II$ is at its *maximum/minimum* distance from O? Assume that O, G, O' are collinear, and $OG = h$.

HINT

Introduce the new angular variables $q_1 = \phi$ and $q_2 = \theta \equiv \psi - \phi\ (= -\chi) =$ inclination of body II relative to I (positive counterclockwise). Then, $T \to T(\theta; \dot{\phi}, \dot{\theta})$, and so on.

Problem 3.5.10 *Double Physical Pendulum: Horizontal Axes.* Consider the preceding double pendulum problem, but now with both axes through O and O' *horizontal*. In addition, assume that the mass center of body I, G, lies in the plane of the axes O and O', and $OG = h$. Show that here T is the same, *in form*, as in the previous vertical axes case, but the *potential* of gravity forces, V, equals (exactly)

$$V = -M\,g\,h\cos\phi - m\,g(a\cos\phi + b\cos\psi) + constant, \quad \text{(a)}$$

and therefore the corresponding Lagrangean impressed forces are

$$Q_\phi = -\partial V/\partial\phi = \cdots \qquad \text{and} \qquad Q_\psi = -\partial V/\partial\psi = \cdots. \quad \text{(b)}$$

Then write down Lagrange's equations for $q_1 = \phi$ and $q_2 = \psi$.

Problem 3.5.11 *Double Physical Pendulum: Horizontal Axes; Small Oscillations.* Continuing from the preceding problem (O and O' horizontal), show that for *small* oscillations about the vertical equilibrium position ϕ, $\psi = 0$, *linearization* of the exact equations leads to the coupled system

$$(Mh + ma)[L(d^2\phi/dt^2) + g\phi] + m\,a\,b(d^2\psi/dt^2) = 0,$$
$$a(d^2\phi/dt^2) + L'(d^2\psi/dt^2) + g\,\psi = 0, \quad \text{(a)}$$

where

$$L \equiv (MK^2 + ma^2)/(Mh + ma) \qquad \text{and} \qquad L' \equiv (k^2 + b^2)/b. \quad \text{(b)}$$

Interpret L and L' in terms of single pendulum quantities. Then, assume as solutions of (a)

$$\phi = \phi_o\sin(\omega t + \varepsilon) \qquad \text{and} \qquad \psi = \psi_o\sin(\omega t + \varepsilon), \quad \text{(c)}$$

where $\phi_o, \psi_o = \textit{angular amplitudes}$, $\varepsilon = \textit{initial phase}$, and $\omega = \textit{frequency}$, and show that the ω^2 are real, positive, and unequal, and are the roots of

$$(\Omega - L)(\Omega - L') = (ma^2 b)/(Mh + ma), \qquad \text{where } \Omega \equiv g/\omega^2; \tag{d}$$

say $\Omega_1 < \Omega_2$; and thus conclude that

$$\Omega_1 < \min(L, L') \leq \max(L, L') < \Omega_2. \tag{e}$$

Finally, show that

$$\psi_o/\phi_o = a/(\Omega - L') = \cdots, \tag{f}$$

and, therefore, (i) for the *smaller* ω ($\rightarrow$ *larger* $\Omega = \Omega_2$), $\phi \cdot \psi > 0$ (i.e., in the slower mode, the angles have the same sign); while (ii) for the *larger* ω ($\rightarrow$ *smaller* $\Omega = \Omega_1$), $\phi \cdot \psi < 0$ (i.e., in the faster mode, the angles have opposite signs).

[For a discussion of the historically famous case of the *nonringing, or "silent"*, bell of Köln (Cologne), Germany (1876; bell + clapper = double pendulum), based on (a), see, for example, Hamel ([1922(b)] 1912, 1st ed., pp. 514 ff.), Szabó (1977, pp. 89–90), Timoshenko and Young (1948, p. 278).]

Problem 3.5.12 *General Form of Lagrange's Equations for a 2 DOF System.* Consider a *2 DOF* holonomic and scleronomic system; for example, a particle on a fixed surface, or the previous double pendulum, with (double) kinetic energy

$$2T = A(dx/dt)^2 + 2\Gamma(dx/dt)(dy/dt) + B(dy/dt)^2, \tag{a}$$

and such that $\delta' W = X\delta x + Y\delta y$, where $A, B, \Gamma; X, Y$, are functions of x, y.

(i) Show that its Lagrangean equations of motion in $q_1 = x$ and $q_2 = y$ are

$$A(d^2x/dt^2) + \Gamma(d^2y/dt^2) + (1/2)(\partial A/\partial x)(dx/dt)^2 + (\partial A/\partial y)(dx/dt)(dy/dt)$$
$$+ [\partial\Gamma/\partial y - (1/2)(\partial B/\partial x)](dy/dt)^2 = X, \tag{b}$$

$$B(d^2y/dt^2) + \Gamma(d^2x/dt^2) + (1/2)(\partial B/\partial y)(dy/dt)^2 + (\partial B/\partial x)(dx/dt)(dy/dt)$$
$$+ [\partial\Gamma/\partial x - (1/2)(\partial A/\partial y)](dx/dt)^2 = Y, \tag{c}$$

and ponder over the geometrical/kinematical/inertial meaning and origin of each of these terms.

(ii) Show that these equations *linearize* to the (still coupled) system:

$$A_o(d^2x/dt^2) + \Gamma_o(d^2y/dt^2) = (\partial X/\partial x)_o\, x + (\partial X/\partial y)_o\, y, \tag{d}$$

$$B_o(d^2y/dt^2) + \Gamma_o(d^2x/dt^2) = (\partial Y/\partial x)_o\, x + (\partial Y/\partial y)_o\, y, \tag{e}$$

where $(\ldots)_o \equiv (\ldots)$ *evaluated at* $x, y = 0$.

Example 3.5.10 *Lagrange's Equations, 2 DOF: Elastic Pendulum, or Swinging Spring.* Let us derive and discuss the equations of plane motion, under gravity, of a pendulum consisting of a heavy particle (or bob) of mass m suspended by a linearly elastic and massless spring of stiffness k (a positive constant) and unstretched (or natural) length b (fig. 3.6). This is a holonomic and scleronomic

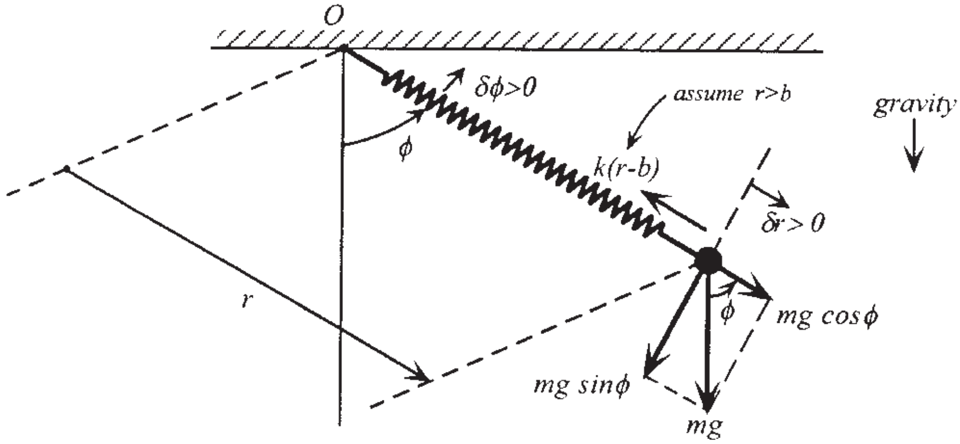

Figure 3.6 Geometry and forces on plane elastic pendulum.

two DOF system; that is, $n = 2$, $m = 0$. With Lagrangean coordinates as the polar coordinates of the bob: $q_1 = r$, $q_1 = \phi$, its (double) kinetic energy is

$$2T = m\,v^2 = m(ds/dt)^2 = m[(\dot{r})^2 + r^2(\dot{\phi})^2], \tag{a}$$

while the virtual work of its impressed forces, gravity and spring force, equals

$$\delta' W = -k(r - b)\,\delta r + (m\,g\cos\phi)\,\delta r - (m\,g\sin\phi)(r\,\delta\phi) \equiv Q_r\,\delta r + Q_\phi\,\delta\phi, \tag{b}$$

that is,

$$Q_r = -k(r - b) + m\,g\cos\phi, \qquad Q_\phi = -m\,g\,r\sin\phi. \tag{c}$$

Alternatively, the potential energy of the system is

$$V = (1/2)k(r - b)^2 - m\,g\,r\cos\phi = V(r, \phi), \tag{d}$$

and so the corresponding Lagrangean forces are $Q_r = -\partial V/\partial r = \cdots$, $Q_\phi = -\partial V/\partial\phi = \cdots$, equations (c). We also notice that for $r > b$: $Q_{r,\text{spring}} \equiv -k(r - b) < 0$, as it should; and analogously for $r < b$. Lagrange's equations, then, are

$$E_r(T) \equiv E_r = Q_r: \qquad (m\dot{r})^{\cdot} - mr(\dot{\phi})^2 = -k(r - b) + m\,g\cos\phi, \tag{e}$$

$$E_\phi(T) \equiv E_\phi = Q_\phi: \qquad (mr^2\dot{\phi})^{\cdot} = -m\,g\,r\sin\phi; \tag{f}$$

or, after some simplifications (since $r \neq 0$),

$$d^2r/dt^2 - r(d\phi/dt)^2 = -(k/m)(r - b) + g\cos\phi, \tag{g}$$

$$r(d^2\phi/dt^2) + 2(dr/dt)(d\phi/dt) = -g\sin\phi. \tag{h}$$

The general solution of this *nonlinear and coupled system* is unknown, and so we will limit ourselves to some simple and physically motivated special solutions of it.

(i) *Equilibrium solution*: Setting all $(\ldots)^{\cdot}$-derivatives in (g, h) equal to zero, we find [with $(\ldots)_o \equiv$ *equilibrium value of* $(\ldots)$]

$$0 = -(k/m)(r_o - b) + g\cos\phi_o, \qquad 0 = -g\sin\phi_o, \tag{i}$$

and, from these algebraic equations, we readily obtain the equilibrium values

$$\phi_o = 0, \qquad r_o - b = mg/k \equiv \rho. \tag{j}$$

Thus, in terms of the new variable

$$x \equiv r - r_o = r - (b + \rho) = r - [b + (mg/k)] = \textit{deviation from vertical equilibrium},$$

and with $\omega_r{}^2 \equiv k/m$, eqs. (g, h) can be, finally, rewritten as

$$\ddot{x} - (r_o + x)(\dot{\phi})^2 + g(1 - \cos\phi) + \omega_r{}^2 x = 0, \tag{k}$$

$$(r_o + x)\ddot{\phi} + 2\dot{x}\,\dot{\phi} + g\sin\phi = 0. \tag{l}$$

(ii) *Ordinary (or mathematical) pendulum solution*; that is, $r = constant \equiv R$. In this case, (g, h) become [since all forces here are impressed; and, contrary to (ex. 3.5.8: m ff.), no multipliers are involved]:

$$-R(\dot{\phi})^2 = -(k/m)(R - b) + g\cos\phi, \tag{m}$$

$$\ddot{\phi} + \omega_\phi{}^2 \sin\phi = 0, \qquad \omega_\phi{}^2 \equiv g/R, \tag{n}$$

and, from these, we get $\phi(t) = \phi_o = 0$ and $R = r_o = b + (mg/k)$; that is, the previous equilibrium case.

(iii) *Linearization of equations (g, h), (k, l)*. We readily obtain the *uncoupled* system:

$$\ddot{r} + \omega_r{}^2 r = (k/m)b + g$$

$$\Rightarrow \ddot{x} + \omega_r{}^2 x = 0 \;\Rightarrow\; x = A\sin(\omega_r t) + B\cos(\omega_r t), \tag{o}$$

$$g\sin\phi = 0 \;\Rightarrow\; \phi(t) = 0 \qquad (A, B\text{: } \textit{integration constants}); \tag{p}$$

that is, a small oscillation of frequency ω_r about the vertical equilibrium $r = r_o$, or $x = 0$.

(iv) *Nearly vertical oscillation*; that is, ϕ small. Then (g, h)/(k, l) reduce to the *coupled* system:

$$\ddot{r} + \omega_r{}^2 r = (k/m)b + g$$

$$\Rightarrow \ddot{x} + \omega_r{}^2 x = 0 \;\Rightarrow\; x = A\sin(\omega_r t) + B\cos(\omega_r t), \tag{q = o}$$

$$r\ddot{\phi} + 2\dot{r}\dot{\phi} + g\phi = 0$$

$$\Rightarrow (r_o + x)\ddot{\phi} + 2\dot{x}\dot{\phi} + g\phi = 0 \;\Rightarrow\; (1 + \varepsilon)\ddot{\phi} + 2\dot{\varepsilon}\,\dot{\phi} + \omega_\phi{}^2\phi = 0, \tag{r}$$

where $\varepsilon = \varepsilon(t) \equiv x/r_o$ (and $\omega_\phi{}^2 \equiv g/r_o$).

Now, since $x =$ *harmonic in time*, equation (r) is a linear differential equation with harmonically varying coefficients; or, as it is generally called, a *parametrically* excited one [or *rheo-linear* $=$ *rheonomic* $+$ *linear*]. As the theory of these important "Hill/

Floquet/Mathieu" equations shows, the solutions of (r) are stable; that is, $\phi =$ *oscillatory and bounded*, or not, depending on the values of

$$\omega_\phi/\omega_r \equiv \omega, \qquad \text{or} \qquad \omega^2 = (g/r_o)/(k/m) = mg/r_o k = gravity/elasticity. \tag{s}$$

Specifically, it can be shown that:

(i) If $\omega \neq N/2$, or $\omega^2 \neq N^2/4$ $(N = 1, 2, 3, \ldots)$, then both x and ϕ remain small as required by the linearization; but,

(ii) If $\omega \approx N/2$, or $\omega^2 \approx N^2/4$ $(= 1/4, 1, 9/4, \ldots)$, then $\phi \to \infty$, in spite of the absence of external excitation; that is, then, the vertical x-oscillation, acting as *internal forcing*, causes ever larger (nonlinear) angular oscillations; and since the *total energy of the system remains constant*, this phenomenon [commonly known as *parametric, or internal, resonance*] comes at the expense of the x-oscillation; that is, energy flows from the vertical oscillation to the angular one, and (as shown by experiments) *back*. But here, contrary to constant coefficient linearized coupled systems (e.g., the earlier double pendulum), we do need to examine some *nonlinear* version of the problem: either the exact equations (g, h)/(k, l), or some weakly nonlinear system of them, and the linear but parametric equations (q, r).

[The case $N = 1 \Rightarrow \omega_r \approx \omega_\phi$, or $mg \approx kr_o/4$, is the most dangerous one, because, as the "stability chart" of equation (r) shows, that is where *the instability region is at its widest*; and that width is proportional to the amplitude of the "fundamental x-solution," (q = o).]

For further details, see, for example, Nayfeh (1973, pp. 185–189, 214–216, 262–264; and references cited there), Nayfeh and Mook (1979, pp. 369–370, 431–432), Pfeiffer (1989, pp. 209–210); also Dysthe and Gudmestad (1975). For an extensive treatment, see Starzhinskii (1977/1980, pp. 50–55; also pp. 59–75, 79–83, 95–98, 133–135).

Problem 3.5.13 *Elastic Pendulum.* Continuing from the preceding example, let us consider the "fundamental" solution, equations (q = o)

$$\begin{aligned} x &= A\sin(\omega_r t) + B\cos(\omega_r t) = x_o\cos(\omega_r t + \chi), \\ \varepsilon &= \varepsilon(t) \equiv x/r_o = \varepsilon_o\cos(\omega_r t + \chi), \end{aligned} \tag{a}$$

where $A, B, x_o, \chi =$ *integration constants*. Next, and following standard methods of perturbation theory, assume a solution of (r) in the form

$$\phi = \phi_o\cos(\omega_\phi t + \psi) + \Phi_1 \equiv \Phi_o + \Phi_1, \tag{b}$$

where $\Phi_1 =$ *small* relative to Φ_o. Then, insert these ε and ϕ solutions in (r) and, after neglecting all terms containing products of $\varepsilon, \varepsilon_o$ with Φ_1, and its $(\ldots)^{\cdot}$-derivatives, bring it to the ordinary (i.e., constant coefficient) undamped and forced oscillation form

$$\begin{aligned} \ddot{\Phi}_1 + {\omega_\phi}^2\Phi_1 &= -[(1+\varepsilon)\ddot{\Phi}_o + 2\varepsilon\,\dot{\Phi}_o + {\omega_\phi}^2\Phi_o] \\ &= -[\varepsilon\,\ddot{\Phi}_o + 2\varepsilon\,\dot{\Phi}_o] \qquad\qquad \text{[explain why]} \\ &= \cdots = f(t;\ \omega_r, \omega_f;\ \chi, \psi;\ \varepsilon_o, \phi_o) \\ &\text{(known function; linear superposition of two harmonic excitations of} \\ &\text{frequencies } \omega_r + \omega_\phi \text{ and } \omega_r - \omega_\phi) \end{aligned} \tag{c}$$

Find the particular solution of this equation (nonhomogeneous part), and then establish that:

(i) If $\omega_\phi/\omega_r \neq 1/2$, then both x and ϕ remain small; but
(ii) If $\omega_\phi/\omega_r \approx 1/2$, then Φ_1 (and therefore ϕ) $\to \infty$ [as in the (nonlinear) problem of "small denominators," or "combination tones"—see, e.g., Stoker (1950, pp. 112–114); also §8.16, this volume].

Problem 3.5.14 *Elastic Pendulum.* Continuing from the last example, let us substitute into its exact equations (k, l) [instead of the preceding problem's assumed solution (b)]

$$x = X + \Delta X, \qquad \phi = \Phi + \Delta\Phi, \tag{a}$$

where X and Φ are its following *fundamental* motion/solutions,

$$X = X(t) = x_o \cos(\omega_r t + \chi), \qquad \Phi = \Phi(t) = 0, \tag{b}$$

and $\Delta X(t)$, $\Delta\Phi(t)$ are the *small perturbations* about that state, and keep only up to linear terms in this small (neighboring) motion. Show that, then, we obtain the *uncoupled* linear system:

$$(\Delta X)^{\cdot\cdot} + \omega_r{}^2\,\Delta X = 0 \qquad \text{and} \qquad (1+\varepsilon)(\Delta\Phi)^{\cdot\cdot} + 2\dot{\varepsilon}\,(\Delta\Phi)^{\cdot} + \omega_\phi{}^2\,\Delta\Phi = 0, \tag{c}$$

where $\varepsilon \equiv X/r_o$; or, since $|\varepsilon| =$ *much smaller than* 1,

$$(\Delta\Phi)^{\cdot\cdot} + 2\dot{\varepsilon}\,(\Delta\Phi)^{\cdot} + \omega_\phi{}^2(1-\varepsilon)\Delta\Phi = 0, \tag{d}$$

that is, the neighboring motion $\Delta\Phi(t)$ depends on the fundamental one through $X(t)$, or $\varepsilon(t)$. Solve the first of (c), insert its solution into (d), and then show that, since the coefficients of both $\Delta\Phi$ and $(\Delta\Phi)^{\cdot}$ have the same (parametric) frequency ω_r, the resulting equation (d) can be led to a standard Mathieu equation; that is,

$$\ddot{y} + P(t)y = 0, \tag{e}$$

where $P(t + 2\pi/\omega_r) = P(t)$, $\Delta\phi \sim y\exp(-\varepsilon)$, and $P = \omega_\phi{}^2(1-\varepsilon) - \ddot{\varepsilon} - \dot{\varepsilon}^2$.

Problem 3.5.15 *Lagrange's Equations: Cylindrical and Spherical Coordinates.* Show that the equations of motion of, say, a free particle P in cylindrical and spherical coordinates, are (fig. 3.7) as follows:

(i) *Cylindrical* ($x = r\cos\phi$, $y = r\sin\phi$, $z = z$; $v_r{}' = \dot{r}$, $v_\phi{}' = r\dot{\phi}$, $v_z{}' = \dot{z}$):

$$\text{Radial:} \quad m[\ddot{r} - r(\dot{\phi})^2] = Q_r \qquad (= F_r;\ m\,a_r{}' = F_r), \tag{a}$$

$$\text{Transverse:} \quad m(r^2\dot{\phi})^{\cdot} = Q_\phi \qquad (= rF_\phi;\ m\,a_\phi{}' = F_\phi), \tag{b}$$

$$\text{Vertical:} \quad m\,\ddot{z} = Q_z \qquad (= F_z;\ m\,a_z{}' = F_z); \tag{c}$$

where

$$\begin{aligned}\delta' W = (F_r, F_\phi, F_z)\cdot(\delta r, r\,\delta\phi,\ \delta z) &= F_r\,\delta r + (rF_\phi)\,\delta\phi + F_z\,\delta z \\ &= Q_r\,\delta r + Q_\phi\,\delta\phi + Q_z\,\delta z;\end{aligned} \tag{d}$$

$\boldsymbol{F} = (F_r, F_\phi, F_z) =$ *total force on P*.

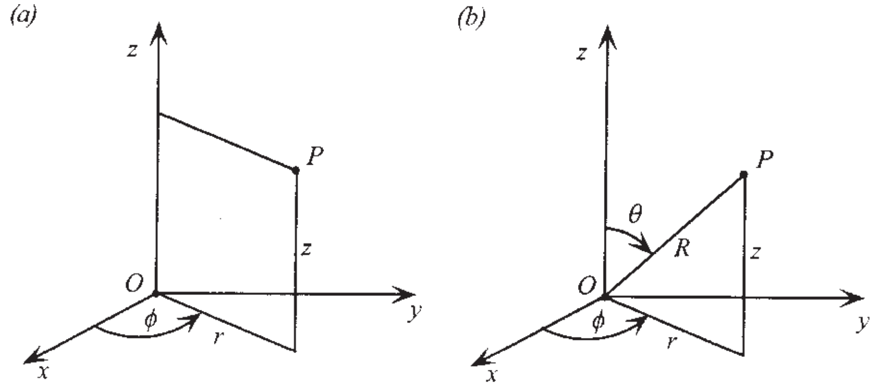

Figure 3.7 Particle in space: (a) cylindrical and (b) spherical coordinates.

(ii) *Spherical* $[x = (R\sin\theta)\cos\phi, \quad y = (R\sin\theta)\sin\phi, \quad z = R\cos\theta; \quad v_R{}' = \dot{R}, v_\theta{}' = R\dot{\theta},\ v_\phi{}' = (R\sin\theta)\dot{\phi}]$:

$$\text{Radial:} \qquad m[\ddot{R} - R(\dot{\theta})^2 - R\sin^2\theta(\dot{\phi})^2] = Q_R \ \ (= F_R;\ m\,a_R{}' = F_R), \quad \text{(e)}$$

$$\text{Transverse } (\theta\text{-plane}): \ m[(R^2\dot{\theta})^{\cdot} - R^2\sin\theta\cos\theta(\dot{\phi})^2] = Q_\theta \ (= R\,F_\theta;\ m\,a_\theta{}' = F_\theta), \quad \text{(f)}$$

$$\text{Normal (to } \theta\text{-plane)}: \ m(R^2\sin^2\theta\,\dot{\phi})^{\cdot} = Q_\phi \qquad (= R\sin\theta\,F_\phi;\ m\,a_\phi{}' = F_\phi); \quad \text{(g)}$$

where

$$\begin{aligned} \delta' W &= (F_R,\ F_\theta,\ F_\phi)\cdot(\delta R,\ R\,\delta\theta,\ R\ \sin\theta\,\delta\phi) \\ &= (F_R)\,\delta R + (RF_\theta)\,\delta\theta + (R\sin\theta F_\phi)\,\delta\phi = Q_R\,\delta R + Q_\theta\,\delta\theta + Q_\phi\,\delta\phi; \end{aligned} \qquad \text{(h)}$$

$\boldsymbol{F} = (F_R,\ F_\theta,\ F_\phi) = \textit{total force on } P.$

HINT

$2T = m[(\dot{x})^2 + (\dot{y})^2 + (\dot{z})^2]$; $\dot{x} = \cdots$, $\dot{y} = \cdots$, $\dot{z} = \cdots$, and so on.

Problem 3.5.16 *Lagrange's Equations: Particle on Sphere, or Spherical Pendulum.* Consider the motion of a heavy particle P of mass m on the inner part of a smooth and stationary spherical surface of radius l, under (constant) gravity (fig. 3.8).

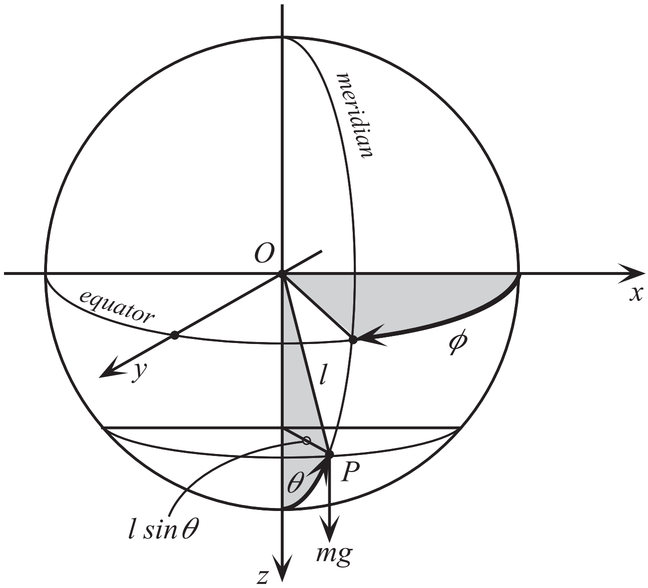
Show that the Routh–Voss equations of this constrained system [constraint: $f_1 \equiv R - l\ (= 0)$; $q_1 = R$, $q_2 = \theta$, $q_3 = \phi$; $n = 3$, $m = 1$], with $+Oz$ taken vertically downwards, are

$$R\!: \qquad (\dot{\theta})^2 + \sin^2\theta\,(\dot{\phi})^2 = -(1/l)[g\cos\theta + (\lambda/m)(\partial f_1/\partial R)_o], \qquad \text{(a)}$$

$$\theta\!: \qquad \ddot{\theta} - \sin\theta\cos\theta\,(\dot{\phi})^2 = -(g/l)\sin\theta, \qquad \text{(b)}$$

$$\phi\!: \qquad (\sin^2\theta)\,\dot{\phi} = \textit{constant} \equiv p, \qquad \text{(c)}$$

$[\Rightarrow (l\sin\theta)^2\dot{\phi} = l^2 p \equiv C$; i.e., the horizontal projection of the motion follows Kepler's second law].



$x = (l \sin\theta)\cos\phi$

$y = (l \sin\theta)\sin\phi$

$z = l\cos\theta$

Figure 3.8 Geometry of spherical pendulum.

Solving (b, c) we find the *motion*, and then substituting the results into (a) we obtain the *multiplier* $\lambda = \lambda(t;\ \textit{initial conditions})$. Show that $\lambda = -S/l$, where $S =$ *sphere reaction on P* (or string tension, in the pendulum case), and $(\ldots)_o \equiv (\ldots)_{R=l}$.

On the analytical treatment of these nonlinear equations (including the stability of special motions), there exists a large literature; see, for example (alphabetically): Hamel (1949, pp. 262–264, 285, 691–692, 710–712), Lamb (1923, pp. 305–307), Landau and Lifshitz (1960, pp. 33–34), MacMillan (1927, pp. 337–344), Müller and Prange (1923, pp. 163–184), Pöschl (1949, pp. 46–49, 141–143), Synge and Griffith (1959, pp. 335–342), Webster (1912, pp. 42–45, 48–55, 124–125); also Corben and Stehle (1960, pp. 105–107), for an application of the perturbation method.

Problem 3.5.17 *Lagrange's Equations: Particle on Sphere, or Spherical Pendulum.* Continuing from the preceding problem:

(i) Show that its integrals of *energy* and *angular momentum* (about the *Oz* axis) can be written, respectively, as

$$(1/2)ml^2[(\dot\theta)^2 + \sin^2\theta(\dot\phi)^2] - m\,g\,l\cos\theta = \textit{constant} \equiv E, \tag{a}$$

$$(\sin^2\theta)\dot\phi = \textit{constant} \equiv p. \tag{b}$$

(ii) Show that eliminating $\dot\phi$ between (a, b) and then $(\ldots)^{\cdot}$-differentiating the resulting equation, and so on, we recover the θ-equation of the last problem.

Problem 3.5.18 *Lagrange's Equations: Particle on Sphere, or Spherical Pendulum; Integration of the θ-Equation.* Continuing from the preceding problem:

(i) Show that its θ- and ϕ-equations combine to the θ-*only* equation:

$$d^2\theta/dt^2 - (C^2/l^4)(\cos\theta/\sin^3\theta) + (g/l)\sin\theta = 0, \tag{a}$$

where $C = (l \sin\theta)^2 \dot{\phi} = constant$. What is the physical meaning of the singularity, in (a), for $\theta = 0$?

(ii) By integrating (a), show that

$$t = \int_{\theta_o}^{\theta} \sin\theta \,[2h \sin^2\theta - (C^2/l^4) + 2(g/l)\cos\theta \sin^2\theta]^{-1/2}\, d\theta. \tag{b}$$

HINT

The first integral of the differential equation $\ddot{x} = f(x)$ is

$$(1/2)(dx/dt)^2 + V(x) = constant \equiv h, \qquad \text{where } V(x) = -\int f(x)\, dx; \tag{c}$$

and from this we readily obtain

$$t = \int_{x_o = x(0)}^{x} [2h - 2V(x)]^{-1/2}\, dx. \tag{d}$$

Here, $x = \theta$, and

$$f(x) \to f(\theta) = (C^2/l^4)(\cos\theta / \sin^3\theta) - (g/l)\sin\theta, \tag{e}$$

so that $V(\theta) = -\int f(\theta) d\theta = \cdots$.

(iii) Setting $\cos\theta = z$, and with the abbreviations

$$2h - (C^2/l^4) \equiv \alpha, \qquad -2(g/l) \equiv \beta, \qquad -2h \equiv \gamma, \tag{f}$$

reduces (b) to the *elliptic* integral

$$t = -\int_{z_o}^{z} [\alpha - \beta z + \gamma z^2 + \beta z^3]^{-1/2}\, dz, \tag{g}$$

which *cannot* be integrated by a combination of elementary functions. For further details, see books on the *asymptotic* integration of ordinary differential equations, elliptic functions, and so on.

Problem 3.5.19 *Lagrange's Equations: Particle on Sphere, or Spherical Pendulum; Steady Motion.* Continuing from the preceding problems, show that the particular solution $\theta = \theta_o$ (i.e., particle describes a horizontal circle), requires that

$$d\phi/dt = C/r^2 = (g/l)^{1/2}(\cos\theta_o)^{-1/2} = constant \equiv \omega_o, \tag{a}$$

where $C^2 = (gl^3 \sin^4\theta_o)/\cos\theta_o$; that is, for every θ_o there exists a particular such "steady motion" of constant angular velocity ω_o; and, hence, a period

$$\begin{aligned} \tau_o &\equiv 2\pi/\omega_o = 2\pi(l/g)^{1/2}(\cos\theta_o)^{1/2} \\ &\approx 2\pi(l/g)^{1/2}, \text{ for small } \theta_o \text{ (as for the \textit{plane} pendulum).} \end{aligned} \tag{b}$$

Problem 3.5.20 *Lagrange's Equations: Particle on Sphere, or Spherical Pendulum; Stability of Steady Motion.* Continuing from the preceding problems:

(i) By setting in the exact θ-equation of the pendulum

$$\theta(t) = \theta_o + \Delta\theta(t) \equiv \theta_o + x(t), \qquad d\phi(t)/dt = \omega_o + \Delta[d\phi(t)/dt] \equiv \omega_o + y(t), \tag{a}$$

expanding à la Taylor, and keeping only up to first-degree terms in x, y and their $(\ldots)^{\cdot}$-derivatives (i.e., considering small disturbances), and taking into account the equations of the fundamental state θ_o, obtain the *linear perturbation* equations from that state:

$$d^2x/dt^2 + \{[(1 + 2\cos^2\theta_o)/\sin^4\theta_o](C^2/l^4) + (g/l)\cos\theta_o\}x = 0. \tag{b}$$

Then, taking into account the C versus θ_o relation for that state (see preceding problem), show that (b) simplifies to

$$d^2x/dt^2 + k^2x = 0, \qquad \text{where } k^2 \equiv [(g/l)(1 + 3\cos^2\theta_o)]/\sin^4\theta_o, \tag{c}$$

that is, a harmonic oscillation around the constant value θ_o with a period [recall (b) of preceding problem]

$$\begin{aligned}\tau' = 2\pi/k &= \left[2\pi(l/g)^{1/2}(\cos\theta_o)^{1/2}\right]\Big/(1 + 3\cos^2\theta_o)^{1/2}\\ &\equiv \tau_o/(1 + 3\cos^2\theta_o)^{1/2}.\end{aligned} \tag{d}$$

Notice that, since $\theta_o = 0, \pi/2$ are excluded, we will have $\tau_o/2 < \tau' < \tau_o$.

Such motions, where the *linear perturbation equations* around them are *equations with constant coefficients*, we call, after Routh *steady* (for an extensive treatment, see §8.5).

(ii) By carrying out a similar linearization of the exact ϕ-equation, $\dot{\phi} = C/(l\sin\theta)^2$, around θ_o, show that (to the first degree in x)

$$y = -[(2C\cos\theta_o)/(l^2\sin^3\theta_o)]x = -2[(g/l)(\cos\theta_o)/\sin^2\theta_o]^{1/2}x, \tag{e}$$

that is, $\dot{\phi}$ oscillates just like x, but the presence of the minus sign shows that as θ increases $\dot{\phi}$ decreases, and vice versa.

For further details on the integration of the above equations, and the behavior of the perturbed motion, for various values of θ_o, see, for example, Hamel ([1922(b)] 1912, 1st ed., pp. 106–108).

Example 3.5.11 *Constrained Lagrange's Equations → Routh–Voss Equations.* Let us consider the spatial, and initially unconstrained, motion of a particle of mass m in cylindrical coordinates $q_1 = r$, $q_2 = \phi$, $q_3 = z$ (vertical, positive upward), under the action of (constant) gravity (fig. 3.9).

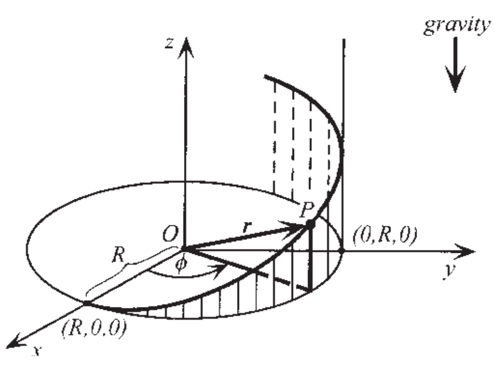


Figure 3.9 Particle on a helical path.

Here, clearly, the (double) kinetic energy and impressed forces are, respectively,

$$2T = m\,v^2 = m(ds/dt)^2 = m[(\dot{r})^2 + r^2(\dot{\phi})^2 + (\dot{z})^2], \tag{a}$$

$$Q_r = 0, \qquad Q_\phi = 0, \qquad Q_z = -m\,g, \tag{b}$$

and therefore, Lagrange's equations are (recall prob. 3.5.15)

$$E_r \equiv (\partial T/\partial \dot{r})^{\cdot} - \partial T/\partial r = m[\ddot{r} - r(\dot{\phi})^2] = 0, \tag{c}$$

$$E_\phi \equiv (\partial T/\partial \dot{\phi})^{\cdot} - \partial T/\partial \phi = m(r^2\dot{\phi})^{\cdot} = 0, \tag{d}$$

$$E_z \equiv (\partial T/\partial \dot{z})^{\cdot} - \partial T/\partial z = m\,\ddot{z} = -m\,g. \tag{e}$$

Next, assume that the particle is constrained to move on a smooth circular helix with axis z, radius R, and pitch p. Analytically, this means that now r, ϕ, z are coupled by the *two* constraints (assume that for $\phi = 0$, $z = 0$):

$$f_1 \equiv r - R = 0, \qquad f_2 \equiv z - p\,\phi = 0 \qquad (R, p\text{: } \textit{positive constants}). \tag{f}$$

In this case, the kinetic energy (a) assumes the constrained form

$$T \to T_o = \cdots = (m/2)(R^2 + p^2)(\dot{\phi})^2 \equiv T_o(\dot{\phi}) = (m/2)[1 + (R/p)^2](\dot{z})^2 \equiv T_o(\dot{z}), \tag{g}$$

and, from $\delta' W = -m\,g\,\delta z = -m\,g\,\delta(p\,\phi) = -m\,g\,p\,\delta\phi$, we readily conclude that, contrary to (b),

$$Q_{z,o} = -m\,g, \qquad Q_{\phi,o} = -m\,g\,p. \tag{h}$$

Therefore, the *kinetic* = *reactionless* equations are either of the following:

(i) $$(\partial T_o/\partial \dot{\phi})^{\cdot} - \partial T_o/\partial \phi = Q_{\phi,o}\text{:} \quad m(R^2 + p^2)\ddot{\phi} = -m\,g\,p, \tag{i}$$

$$\Rightarrow \phi = -[(g\,p)/(R^2 + p^2)](t^2/2) + \dot{\phi}(0)t + \phi(0); \tag{j}$$

(ii) $$(\partial T_o/\partial \dot{z})^{\cdot} - \partial T_o/\partial z = Q_{z,o}\text{:} \quad m[1 + (R/p)^2]\ddot{z} = -m\,g, \tag{k}$$

$$\Rightarrow z = -[(g\,p^2)/(R^2 + p^2)](t^2/2) + \dot{z}(0)t + z(0) \quad (= p\,\phi). \tag{l}$$

To calculate the *constraint reactions*, we use the Routh–Voss equations

$$E_k(T) = Q_k + \sum \lambda_D(\partial f_D/\partial q_k) \equiv Q_k + R_k$$
$$(k = 1, 2, 3 \to r, \phi, z;\ D = 1, 2;\ \text{i.e., } n = 3,\ m = 2). \tag{m}$$

These latter here give [using (a), (b) and (f), *not* (g); and *then* enforcing (f)]

$$E_r = \lambda_1(\partial f_1/\partial r) + \lambda_2(\partial f_2/\partial r)\text{:} \quad m[\ddot{r} - r(\dot{\phi})^2] = \lambda_1(1) + \lambda_2(0) \quad \text{or} \quad -m\,R(\dot{\phi})^2 = \lambda_1, \tag{n}$$

$$E_\phi = \lambda_1(\partial f_1/\partial \phi) + \lambda_2(\partial f_2/\partial \phi)\text{:} \quad m(r^2\dot{\phi})^{\cdot} = \lambda_1(0) + \lambda_2(-p) \quad \text{or} \quad m\,R^2\ddot{\phi} = -p\,\lambda_2, \tag{o}$$

$$E_z = Q_z + \lambda_1(\partial f_1/\partial z) + \lambda_2(\partial f_2/\partial z)\text{:} \quad m\,\ddot{z} = -m\,g + \lambda_1(0) + \lambda_2(1) \quad \text{or} \quad m\,\ddot{z} = -m\,g + \lambda_2. \tag{p}$$

If $(F_r,\ F_\phi,\ F_z)$ = *vector of constraint reaction on particle, from wire (in polar coordinates)*, then from the reaction virtual work invariance

$$\delta' W = F_r\,\delta r + F_\phi(R\,\delta\phi) + F_z\,\delta z = R_r\,\delta r + R_\phi\,\delta\phi + R_z\,\delta z \quad (=0),$$

we readily obtain

$$R_r = \lambda_1 = F_r, \qquad R_\phi = -p\,\lambda_2 = R\,F_\phi, \qquad R_z = \lambda_2 = F_z, \tag{q}$$

and so (n–p) transform to

$$m\,R(\dot\phi)^2 = -F_r, \qquad m\,R^2\ddot\phi = R\,F_\phi, \qquad m\,\ddot z = -m\,g + F_z, \tag{r}$$

and, from these [since $\lambda_2 = -(R/p)F_\phi = F_z \ \Rightarrow\ -R\,F_\phi = p\,F_z$] and the second of (f), we get

$$-m\,R^2\ddot\phi = p(m\,\ddot z + m\,g) \ \Rightarrow\ m(R^2 + p^2)\ddot\phi = -m\,g\,p; \quad \text{i.e., eq. (i).} \tag{s}$$

Solving (i = s), we find $\phi(t)$, and then inserting it into (r) we obtain $(F_r,\ F_\phi,\ F_z)$ and λ_1, λ_2 as functions of time and the initial conditions. The reader may wish to discuss the limiting cases:

$$p \to 0 \ (\text{i.e., } \textit{helix} \to \textit{circle of radius } R) \ \text{ and } \ p \to \infty.$$

Problem 3.5.21 *Routh–Voss Equations: Plane Rolling*. Consider two right circular and rough cylinders, C and C', with corresponding masses M and m, radii R and r, and horizontal (mutually parallel) axes O and O', in plane and slippingless rolling on each other. Assume, for simplicity, that C' is stationary (fig. 3.10; initially, P and P' coincide). Here, the constraints are

$$f_1 \equiv \rho - (R + r) \equiv \rho - b = 0\ (\textit{contact}), \qquad f_2 \equiv b\,\phi - r\,\theta = 0\ (\textit{rolling}). \tag{a}$$

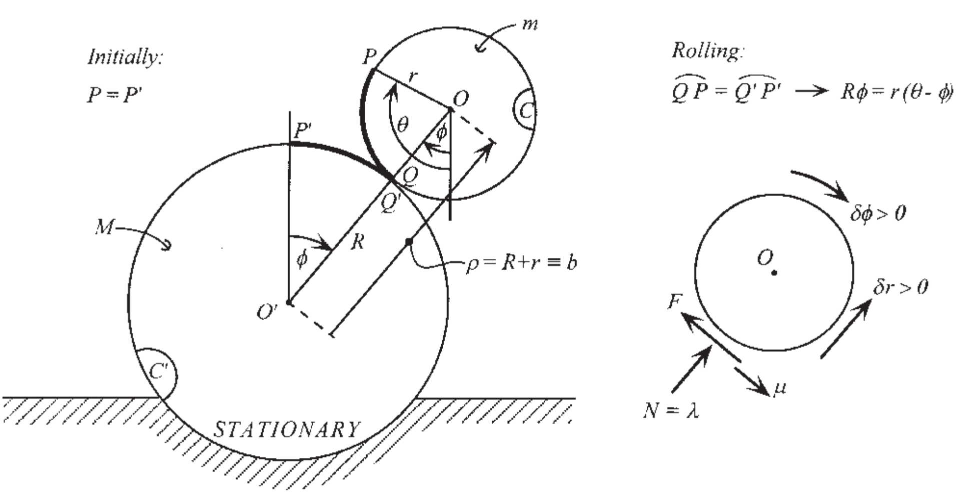

Figure 3.10 Cylinder C in a plane rolling over the fixed cylinder C'. [Initially, $P = P'$; rolling condition: $arc(PQ) = arc(Q'P') \Rightarrow R\phi = r(\theta - \phi) \Rightarrow (R + r)\phi = r\theta$.]

(i) Show that the Routh–Voss equations, in $q_1 = \rho$, $q_2 = \phi$, $q_3 = \theta$, and with $\lambda_1 \equiv \lambda$, $\lambda_2 \equiv \mu$ [i.e., $n = 3$ and $m = 2$, as long as C and C' are in contact], are

$$m\,\ddot{\rho} = -m\,g\cos\phi + m\,\rho(\dot{\phi})^2 + \lambda(1)\big|_{\text{eqs.(a)}} \Rightarrow \lambda = m\,g\cos\phi - m\,b(\dot{\phi})^2, \quad \text{(b)}$$

$$(m\,\rho^2\dot{\phi})^{\cdot} = m\,g\rho\sin\phi + \mu(b)\big|_{\text{eqs.(a)}} \;\Rightarrow\; \mu = m\,g\ddot{\phi} - m\,g\sin\phi, \quad \text{(c)}$$

$$(mr^2/2)\ddot{\theta} = \mu(-r)\big|_{\text{eqs.(a)}} \Rightarrow \mu = -(m\,b/2)\ddot{\phi} = -(m\,r/2)\ddot{\theta}. \quad \text{(d)}$$

(ii) Eliminating μ between (c, d), obtain the kinetic equation

$$\ddot{\phi} = (2g/3b)\sin\phi. \quad \text{(e)}$$

(iii) Show that (a) $\lambda = N =$ *normal* force from C' to C [> 0, for $g\cos\phi > b(\dot{\phi})^2$, from eq. (b); if not, then $\lambda = 0$]; and (b) $\mu = -F \Rightarrow F = -\mu =$ *tangential* (*frictional*) force from C' to C [$\mu = -(mb/2)\ddot{\phi} = -(mg/3)\sin\phi < 0$, by (e)].

(iv) Finally, find the critical angle at which C loses contact with C'. (See also Fetter and Walecka, 1980, pp. 74–77.)

Example 3.5.12 *Invariance of the Routh–Voss Equations under Frame of Reference Transformations.* Let us consider a system subject to the Pfaffian (holonomic and/or nonholonomic) constraints

$$f_D \equiv \sum a_{Dk}\,\dot{q}_k + a_D = 0 \qquad [D = 1,\ldots,m(<n);\; k = 1,\ldots,n], \quad \text{(a)}$$

and, hence, having the Routh–Voss equations of motion

$$E_k(L) = Q_k + \sum \lambda_D\,a_{Dk} \equiv Q_k + R_k, \quad \text{(b)}$$

where $L \equiv T - V =$ *Lagrangean* of system [$= -(V - T) = -$(*kinetic potential*) of system, in 19th century terminology], and $Q_k =$ *nonpotential impressed forces*.

Now, let us subject its Lagrangean coordinates $q \equiv (q_1,\ldots,q_n)$ to the following general *explicitly time-dependent and nonsingular* (i.e., *uniquely invertible*) *point transformation*:

$$q_k = q_k(t; q_{1'},\ldots,q_{n'}) \Leftrightarrow q'_{k'} \equiv q_{k'} = q_{k'}(t; q_1,\ldots,q_n), \quad \text{(c)}$$

or, compactly, $q = q(t, q') \Leftrightarrow q' = q'(t, q)$. Let us express eqs. (b) in terms of the $q_{k'}$s. From (c), we readily find

$$dq_s/dt = \sum(\partial q_s/\partial q_{s'})(dq_{s'}/dt) + \partial q_s/\partial t \quad \text{and} \quad \delta q_s = \sum(\partial q_s/\partial q_{s'})\,\delta q_{s'}, \quad \text{(d)}$$

and so the constraints (a) transform to

$$\begin{aligned} f_D &\equiv \sum a_{Dk}\Big(\sum(\partial q_k/\partial q_{k'})(dq_{k'}/dt) + \partial q_k/\partial t\Big) + a_D = \cdots \\ &= \sum a_{Dk'}(dq_{k'}/dt) + a'_D = 0, \end{aligned} \quad \text{(e)}$$

where [recalling (2.6.6–6b)]

$$a_{Dk'} \equiv \sum(\partial q_k/\partial q_{k'})a_{Dk}, \qquad a'_D \equiv \sum(\partial q_s/\partial t)a_{Ds} + a_D. \quad \text{(f)}$$

Next, to the left side of (b). Applying the chain rule to $L(t, q, dq/dt) = L'(t, q', dq'/dt)$: *$q'$-Lagrangean*, and, with the helpful notations $dq_k/dt \equiv v_k$, $dq_{k'}/dt \equiv v_{k'}$, we obtain

$$\partial L'/\partial v_{s'} = \sum (\partial L/\partial v_s)(\partial v_s/\partial v_{s'}) = \sum (\partial L/\partial v_s)(\partial q_s/\partial q_{s'}), \tag{g1}$$

$$\partial L'/\partial q_{s'} = \sum (\partial L/\partial q_s)(\partial q_s/\partial q_{s'}) + \sum (\partial L/\partial v_s)(\partial v_s/\partial q_{s'}). \tag{g2}$$

But, from (c, d), and in addition to $\partial v_s/\partial v_{s'} = \partial q_s/\partial q_{s'}$ [utilized in (g1)], we also have

$$\begin{aligned}\partial v_s/\partial q_{s'} &= (\partial/\partial q_{s'})\Big(\sum (\partial q_s/\partial q_{k'}) v_{k'} + \partial q_s/\partial t\Big)\\ &= \sum (\partial^2 q_s/\partial q_{s'}\partial q_{k'}) v_{k'} + \partial^2 q_s/\partial q_{s'}\partial t = (\partial q_s/\partial q_{s'})^{\cdot},\end{aligned}$$

that is,

$$E_{s'}(v_s) \equiv d/dt(\partial v_s/\partial v_{s'}) - \partial v_s/\partial q_{s'} = 0 \qquad \text{[recalling (2.5.7–10)]}. \tag{h}$$

Thanks to these identities and (g1, 2) we find, successively,

$$\begin{aligned}(\partial L'/\partial v_{s'})^{\cdot} - \partial L'/\partial q_{s'} &= \Big(\sum (\partial L/\partial v_s)^{\cdot}(\partial q_s/\partial q_{s'}) + \sum (\partial L/\partial v_s)(\partial q_s/\partial q_{s'})^{\cdot}\Big)\\ &\quad - \Big(\sum (\partial L/\partial q_s)(\partial q_s/\partial q_{s'}) + \sum (\partial L/\partial v_s)(\partial q_s/\partial q_{s'})^{\cdot}\Big)\\ &= \sum [(\partial L/\partial \dot{q}_s)^{\cdot} - \partial L/\partial q_s](\partial q_s/\partial q_{s'}) \text{ [invoking (b, a) and (f)]}\\ &= \sum \Big(Q_s + \sum \lambda_D a_{Ds}\Big)(\partial q_s/\partial q_{s'}) \equiv Q_{s'} + \sum \lambda_D a_{Ds'},\end{aligned} \tag{i}$$

or, compactly,

$$E_{s'}(L') = Q_{s'} + \sum \lambda_D a_{Ds'} \equiv Q_{s'} + R_{s'}, \tag{j}$$

where $Q_{s'} \equiv \sum (\partial q_s/\partial q_{s'}) Q_s$. [The latter can also be established from the virtual work invariance: $\delta' W \equiv \sum Q_k\, \delta q_k = \sum Q_{k'}\, \delta q_{k'}$ and the second of eq. (d).]

Notice that (j) amounts to $\lambda'_{D'} \to \lambda_{D'} = \lambda_D$; that is, the multipliers are *invariant*, or *objective*, under the *frame of reference* transformation (c). Equations (j) express the following fundamental theorem.

THEOREM

The Routh–Voss equations transform like a covariant vector under general frame of reference transformations $q \to q'(t, q)$; that is, these equations are form invariant not only under arbitrary Lagrangean coordinate transformations in a given frame, but also under arbitrary frame of reference transformations (whereas the Newton–Euler equations are not!).

As already stated on several occasions, this twofold form invariance of the equations of motion constitutes the major advantage of "Lagrange" over "Newton–Euler."

Example 3.5.13 *Uniqueness of the Lagrangean, Introduction to Gyroscopicity, etc.* Let us consider two distinct Lagrangeans, L and L', which, however, produce the same (Lagrangean) equations of motion; that is,

$$E_k(L) = E_k(L') \quad (= 0, \text{ or } \ Q_k, \quad \text{or} \quad Q_k + R_k). \tag{a}$$

We ask the questions: By what amount can L and L' differ at most (so that we work with the simplest of them)? or, How unique is a system Lagrangean? To answer these, we assume that

$$L' - L = f(t, q, dq/dt \equiv v), \tag{b}$$

and then try to find as much as possible about f.

Indeed, since $E_k(\ldots)$ is a *linear* operator, (a) and (b) lead to

$$\begin{aligned} 0 = E_k(L' - L) = E_k(L') - E_k(L) = E_k(f) &\equiv d/dt(\partial f/\partial v_k) - \partial f/\partial q_k \\ = \sum [(\partial/\partial q_s)(\partial f/\partial v_k)]v_s &+ \sum [(\partial/\partial v_s)(\partial f/\partial v_k)](dv_s/dt) \\ &+ (\partial/\partial t)(\partial f/\partial v_k) - \partial f/\partial q_k. \end{aligned} \tag{c}$$

However, since L *and* L' must produce the *same accelerations* (i.e., the same $\sim dv/dt \equiv d^2q/dt^2$ terms), the *corresponding coefficients in (c) must vanish*: $\partial^2 f/\partial v_s \partial v_k = 0$. This leads readily to

$$f = \sum C_s v_s + C, \tag{d}$$

where $C_s = C_s(t, q)$ and $C = C(t, q)$ are arbitrary but sufficiently differentiable functions of the q's and t. Substituting (d) into (c), we obtain

$$E_r(f) = \sum (\partial C_r/\partial q_s - \partial C_s/\partial q_r)(dq_s/dt) + (\partial C_r/\partial t - \partial C/\partial q_r) = 0, \tag{e}$$

and, since this must hold for arbitrary (dq/dt)'s we conclude that

$$\partial C_r/\partial q_s - \partial C_s/\partial q_r = 0 \qquad \text{and} \qquad \partial C_r/\partial t - \partial C/\partial q_r = 0, \quad \text{for all } r, s = 1, \ldots, n. \tag{f}$$

These *exactness* conditions (recalling §2.3), in turn, imply the existence of a *gauge* function $F(t, q)$, such that

$$C_r = \partial F/\partial q_r \qquad \text{and} \qquad C = \partial F/\partial t; \tag{g}$$

and so, (d) reduces to

$$f = \cdots = dF(t, q)/dt; \tag{h}$$

that is, L and $L' = L + dF/dt$ will produce the same equations of motion.

In sum: *The Lagrangean function is defined only to within the total time-derivative of an arbitrary function of the Lagrangean coordinates and time*. It follows that *constant terms*, or terms of the form $f(t)$, can be immediately neglected from a Lagrangean with no consequences on the equations of motion.

Generalized Potential, Gyroscopic Forces

A similar argument shows that if some (or all) of the Q_k's are expressible in terms of a *generalized potential* $V = V(t, q, \dot{q} \equiv v)$ as

$$Q_k = d/dt(\partial V/\partial v_k) - \partial V/\partial q_k, \tag{i}$$

then the most general such V must be *linear* in the v's:

$$V = \sum V_s(t, q)\, v_s + V^{(0)}(t, q). \tag{j}$$

Indeed, by (i), $Q_k = \cdots = \sum (\partial^2 V/\partial v_k \partial v_s)(dv_s/dt) + (t, q, v)$-*terms*. But, in classical mechanics, $Q_k = Q_k(t, q, v)$, and therefore $\partial^2 V/\partial v_k \partial v_s = 0$, from which (j) follows. So substituting (j) into (i), we see that such forces take the explicit form

$$Q_k = \cdots = -\partial V^{(0)}/\partial q_k + \sum (\partial V_k/\partial q_l - \partial V_l/\partial q_k)\dot{q}_l + \partial V_k/\partial t. \tag{k}$$

Here, we introduce a new definition.

DEFINITION

The *(non-constraint) forces with vanishing power*—that is, $\sum Q_k \dot{q}_k \equiv \sum Q_k v_k = 0$ — are called *gyroscopic*. Then, since $\sum\sum (\partial V_k/\partial q_l - \partial V_l/\partial q_k) v_l\, v_k = 0$ [due to the antisymmetry of the $(\ldots)$ terms in k, l], it follows that if

$$\sum (\partial V_k/\partial t) v_k = 0 \qquad \text{and} \qquad \sum (\partial V^{(0)}/\partial q_k) v_k = dV^{(0)}/dt - \partial V^{(0)}/\partial t = 0, \tag{l}$$

then the generalized potential forces (i, k) are gyroscopic. (Gyroscopicity is detailed in §3.9 ff.)

Next, let us illustrate the theorem of the uniqueness of the Lagrangean by a few simple examples.

(i) Consider a particle P of mass m free to slide along a massless smooth and rigid rod OA, which rotates, say clockwise, about a horizontal axis through O (i.e., on a vertical plane) with a *given* motion $\phi = \phi(t) =$ *known function of time* (fig. 3.11).

It is not hard to show that *a* Lagrangean for this system is

$$L' = (m/2)[(r_o + r)^2(\dot{\phi})^2 + (\dot{r})^2] - [-m\,g(r_o + r)\sin\phi], \tag{m}$$

where B is *any* "origin" on OA [$r_o = constant$, $q = r = r(t)$]. By the foregoing theory, the Lagrangean $L = L' - m\,g\,r_o \sin\phi(t)$ will result in the same equation of motion for $q_1 = r$ as L':

$$E_r(L) = E_r(L'): \quad \ddot{r} - (\dot{\phi})^2 r = g \sin\phi + r_o(\dot{\phi})^2. \tag{n}$$

That, however, would not be the case if OA was *unconstrained*; then, $q_2 = \phi$.

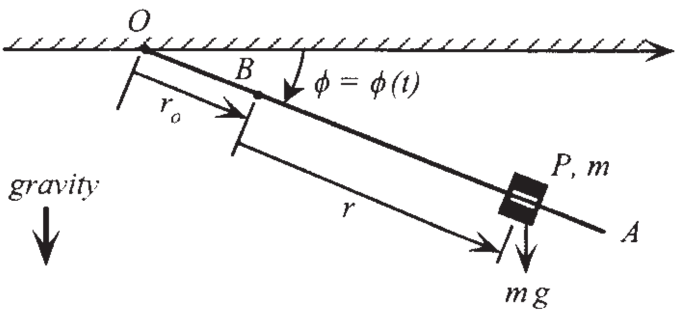

Figure 3.11 Particle P sliding over a rotating rod OA, which rotates in a prescribed way about a horizontal axis through O.

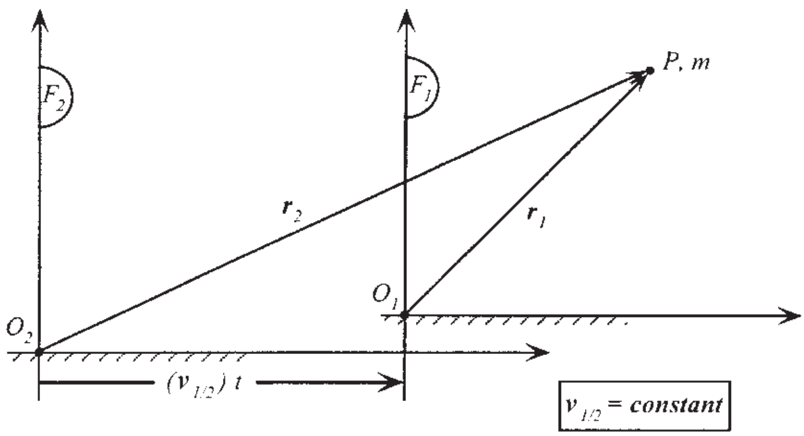

Figure 3.12 Two inertial frames in relative motion, assuming that at time $t = 0$ their origins, O_1 and O_2, coincide.

(ii) Consider the motion of a particle P of mass m in two inertial frames of reference, F_1 and F_2, in relative motion; say, F_1 moving with (vectorially) *constant* velocity $\boldsymbol{v}_{1/2}$ relative to F_2 (fig. 3.12). If we assume, for simplicity, but no loss of generality, that $V = 0$ and/or $Q_k = 0$, then the Lagrangean of P in F_2, which is L_2, equals

$$\begin{aligned} L_2 &= (m/2)\boldsymbol{v}_2 \cdot \boldsymbol{v}_2 = (m/2)(\boldsymbol{v}_1 + \boldsymbol{v}_{1/2}) \cdot (\boldsymbol{v}_1 + \boldsymbol{v}_{1/2}) \\ &= (m/2)\boldsymbol{v}_1 \cdot \boldsymbol{v}_1 + m\,\boldsymbol{v}_1 \cdot \boldsymbol{v}_{1/2} + (m/2)\boldsymbol{v}_{1/2} \cdot \boldsymbol{v}_{1/2} \\ &= L_1 + df/dt \equiv L_1 + F, \end{aligned} \tag{o}$$

where

$$L_1 = (m/2)\boldsymbol{v}_1 \cdot \boldsymbol{v}_1, \qquad f = m\,\boldsymbol{r}_1 \cdot \boldsymbol{v}_{1/2} + (m/2)(\boldsymbol{v}_{1/2} \cdot \boldsymbol{v}_{1/2})t. \tag{o1}$$

Clearly, both Lagrangeans produce the same (i.e., equivalent) equations of motion (*"principle" of Galilean relativity*):

$$(\partial L_2/\partial \boldsymbol{v}_2)^{\cdot} - \partial L_2/\partial \boldsymbol{r}_2 = \mathbf{0}: \qquad d(m\boldsymbol{v}_2)/dt = \mathbf{0}, \tag{p1}$$

$$(\partial L_1/\partial \boldsymbol{v}_1)^{\cdot} - \partial L_1/\partial \boldsymbol{r}_1 = \mathbf{0}: \qquad d(m\boldsymbol{v}_1)/dt = \mathbf{0}. \tag{p2}$$

(iii) Let us extend the preceding example to the case of *general translation*; that is,

$$\boldsymbol{v}_{1/2} = \boldsymbol{v}_{1/2}(t). \tag{q}$$

Here, we have, successively,

$$\begin{aligned} L_2 &= (m/2)\boldsymbol{v}_2 \cdot \boldsymbol{v}_2 = (m/2)(\boldsymbol{v}_1 + \boldsymbol{v}_{1/2}) \cdot (\boldsymbol{v}_1 + \boldsymbol{v}_{1/2}) \\ &= (m/2)\boldsymbol{v}_1 \cdot \boldsymbol{v}_1 + m\,\boldsymbol{v}_1 \cdot \boldsymbol{v}_{1/2} + (m/2)\boldsymbol{v}_{1/2} \cdot \boldsymbol{v}_{1/2} \\ &= (m/2)\boldsymbol{v}_1 \cdot \boldsymbol{v}_1 + (m/2)\boldsymbol{v}_{1/2} \cdot \boldsymbol{v}_{1/2} + [(m\,\boldsymbol{r}_1 \cdot \boldsymbol{v}_{1/2})^{\cdot} - m\,\boldsymbol{r}_1 \cdot (d\boldsymbol{v}_{1/2}/dt)] \\ &= L_1 + \textit{given function of time} \text{ (i.e., omittable)} \\ &\qquad + \textit{total derivative of function of position and time} \text{ (i.e., omittable)} \\ &\qquad - m\,\boldsymbol{r}_1 \cdot (d\boldsymbol{v}_{1/2}/dt) \end{aligned}$$

and so, to within "L-important" terms,

$$L_2 = L_1 - m\boldsymbol{r}_1 \cdot (d\boldsymbol{v}_{1/2}/dt) \equiv L_1 - m\boldsymbol{r}_1 \cdot \boldsymbol{a}_{1/2}. \tag{r}$$

[In the earlier, Galilean case, clearly, $\boldsymbol{a}_{1/2} = \boldsymbol{0}$.] The corresponding Lagrangean equations are

$$(\partial L_2/\partial \boldsymbol{v}_2)^{\cdot} - \partial L_2/\partial \boldsymbol{r}_2 = \boldsymbol{0}: \qquad d(m\boldsymbol{v}_2)/dt = \boldsymbol{0} \Rightarrow m\boldsymbol{a}_2 = \boldsymbol{0}, \tag{s1}$$

$$(\partial L_1/\partial \boldsymbol{v}_1)^{\cdot} - \partial L_1/\partial \boldsymbol{r}_1 = \boldsymbol{0}: \qquad d(m\boldsymbol{v}_1)/dt - (-m\boldsymbol{a}_{1/2}) = \boldsymbol{0}$$
$$\Rightarrow m\boldsymbol{a}_1 = -m\boldsymbol{a}_{1/2} (= \text{"}\textit{transport force}\text{"}); \tag{s2}$$

that is, F_2 is *noninertial*.

Example 3.5.14 *On the Physical Significance of the Lagrangean Multipliers* [May be omitted in a first reading]. Let us consider an n *DOF* system with kinetic and potential energies T and V, respectively, no nonpotential impressed forces, but subject to the holonomic constraints

$$f_D = f_D(q_1, \ldots, q_n) \equiv f_D(q) = 0 \qquad [D = 1, \ldots, m(< n)]. \tag{a}$$

Its Routh–Voss equations of motion (with $k = 1, \ldots, n$)

$$(\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k = -(\partial V/\partial q_k) + \sum \lambda_D(\partial f_D/\partial q_k) \equiv Q_k + R_k, \tag{b}$$

can, clearly, be rewritten in the multiplierless/kinetic form

$$(\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k = -(\partial V_T/\partial q_k), \tag{c}$$

where

$$V_T \equiv V + V_C = V - \sum \lambda_D(t) f_D(q);$$

in words:

$$\text{Total potential} = \text{Ordinary potential} + \text{"Constraint potential"}; \tag{d}$$

that is, the holonomic constraint reactions can be brought to the potential (impressed) force form

$$R_k = -\partial V_C/\partial q_k = -(\partial/\partial q_k)\Big(-\sum \lambda_D f_D\Big) = \sum \lambda_D(\partial f_D/\partial q_k) = R_k(t, q). \tag{e}$$

The apparent contradiction of a *conservative* system [since $\partial V/\partial t = 0$ and $\partial f_D/\partial t = 0$ (more in §3.9)] containing *explicitly time-dependent* forces [i.e., $\partial R_k/\partial t = \sum (d\lambda_D/dt)(\partial f_D/\partial q_K) \neq 0$] is explained by the fact that the constraint potential $V_C = -\sum \lambda_D f_D$ *is known only along the trajectory curve of the figurative system point, in configuration space*; and not throughout the allowable domain of the q's there, like $V(q)$. Below, elaborating the above, we interpret the *constraint reactions* as limiting cases of elastic (potential) forces whose stiffnesses tend to infinity, something which is in agreement with the *principle of relaxation of the constraints* (§3.7); and in the process we obtain an interesting physical interpretation of the Lagrangean multipliers.

Let us consider, for simplicity, but no loss of generality, the case of a single constraint (i.e., $m = 1$)

$$f = f(q_1, \ldots, q_n) \equiv f(q) = 0. \tag{f}$$

Now, since this constraint is maintained by strong forces, *during actual system motions* equation (f) cannot be violated by a large amount. Therefore, the potential of the (reaction turned impressed) forces maintaining (f), $\Pi(f)$, can be written with sufficient accuracy as the following finite Taylor series around $f = 0$ [with $(\ldots)' \equiv d(\ldots)/df$]:

$$\Pi = \Pi(f) = \Pi(0) + \Pi'(0)f + (1/2)\Pi''(0)f^2; \tag{g}$$

and since these forces can be likened, for small f, to very stiff elastic forces, we must also have

$$\Pi'(0) = 0 \qquad \text{and} \qquad \Pi''(0) \equiv 1/\varepsilon > 0, \tag{h}$$

where $\varepsilon =$ *small positive constant*; so that the constraint (f) is maintained by strong forces (theoretically, $\varepsilon \to 0$). Hence, and neglecting the immaterial constant $\Pi(0)$, we have for small f's,

$$\Pi(f) = f^2/2\varepsilon, \tag{i}$$

in which case the corresponding spring-like force equals

$$-\partial\Pi/\partial q_k = -(f/\varepsilon)(\partial f/\partial q_k); \tag{j}$$

and since this must equal the Lagrangean constraint reaction (e), that is,

$$R_k = -\partial V_C/\partial q_k = -(\partial/\partial q_k)(-\lambda f) = \lambda(\partial f/\partial q_k), \tag{k}$$

comparing (j, k), we immediately conclude that

$$\lambda = -f/\varepsilon \equiv \lambda(f; \varepsilon), \tag{l}$$

that is, λ is a measure of the *(time-dependent) violation of the constraint* $f = 0$; and in the theoretical limit of analytical mechanics, $\varepsilon \to 0$ and $f \to 0$,

$$\lambda = -\lim(f/\varepsilon) = \textit{force caused by a linear elastic spring of infinite stiffness}\ (1/\varepsilon). \tag{m}$$

Application of these ideas to the plane motion of a particle of, say, unit mass under the constraint $f(x, y) = 0$ (plane curve, in rectangular Cartesian coordinates x, y), and, for simplicity, no impressed forces, yields the equations

Constrained Lagrangean eqs: $\quad \ddot{x} = \lambda(\partial f/\partial x), \quad \ddot{y} = \lambda(\partial f/\partial y),$ (n)

Unconstrained Newton–Euler eqs: $\quad \ddot{x} = -(1/\varepsilon)(\partial w/\partial x), \quad \ddot{y} = -(1/\varepsilon)(\partial w/\partial y),$ (o)

where (fig. 3.13)

$$\Pi \approx V_C = V_C(f; \varepsilon) = w/\varepsilon = (1/\varepsilon)f^2 = (f/\varepsilon)f = -\lambda f; \tag{p}$$

that is, for small ε, V_C represents a steep potential gully whose bottom coincides with the constraint curve $f = 0$.

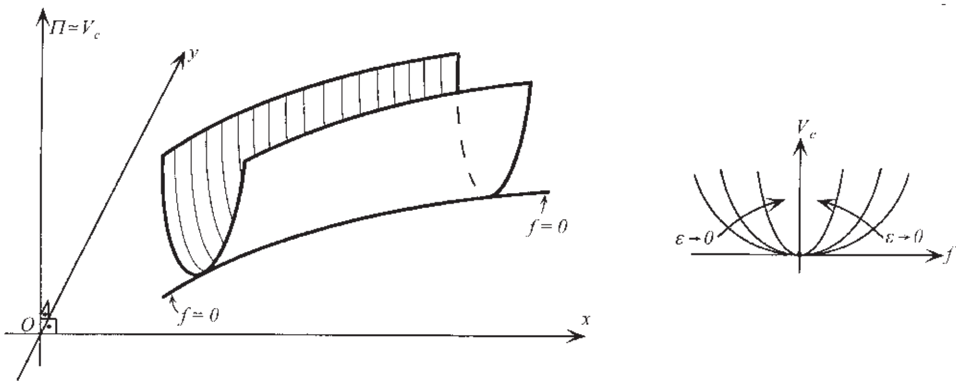

Figure 3.13 Constraint potential as a steep potential gully whose bottom coincides with the constraint curve $f = 0$.

A detailed analysis of whether and how, as $\varepsilon \to 0$ (limit of infinite stiffness), the solutions of (o) tend to those of (n), carried out by Kampen and Lodder, shows that for this to happen

> [T]he applied forces [must] vary smoothly compared with the periods of the internal elastic vibrations in the rods and bodies responsible for the constraints. If that is not satisfied one cannot treat these bodies as rigid, but must include their internal vibrations as additional degrees of freedom in the description of the system. *Lagrange's equations apply to a pendulum that I have set in motion with my hand, but not when I have hit it with a hammer ... or when it is set in motion by an escapement*. (Kampen and Lodder, 1984, pp. 420–421, emphasis added)

For further details and insights, see, for example, Arnold (1974, §17), Kampen and Lodder (1984; and references cited therein); also Gallavotti (1983, p. 168 ff.), Lanczos (1962, chap. 24, pp. 11–12; 1970, pp. 141–145), and Park (1990, pp. 60–61).

Example 3.5.15 *Maggi Equations (Holonomic Constraints).* Let us formulate the kinetic and kinetostatic rotational Maggi equations for a thin homogeneous bar AB [of length $|\boldsymbol{AB}| = 2$, and moment of inertia about a(ny) axis through its mass center G, perpendicular to its length, I], in arbitrary spatial motion, under gravity, in terms of the direction cosines of the bar α, β, γ relative to fixed (inertial) axes $O\text{–}xyz$; or, equivalently, relative to comoving/translating but nonrotating axes $G\text{–}xyz$ (fig. 3.14) (Ramsey, 1937, p. 234).

Here, only the *rotational* part of the kinetic energy of the bar is needed. Choosing as Lagrangean rotational coordinates $q_1 = \alpha,\ q_2 = \beta,\ q_2 = \gamma$, we readily obtain from geometry

$$\alpha = \sin\theta\cos\phi, \quad \beta = \sin\theta\sin\phi, \quad \gamma = \cos\theta, \quad \text{and} \quad \alpha^2 + \beta^2 + \gamma^2 = 1 \quad \text{(constraint)}, \tag{a}$$

that is, $n = 3$, $m = 1$. Hence, using König's theorem, the Eulerian angle kinematics (§1.12), and with the usual notations [$(\omega_1, \omega_2, \omega_3) =$ inertial angular velocity of bar, along its principal axes $G\text{–}123$ ($G\text{–}1$: along bar, $G\text{–}2, 3$: perpendicular to it), and

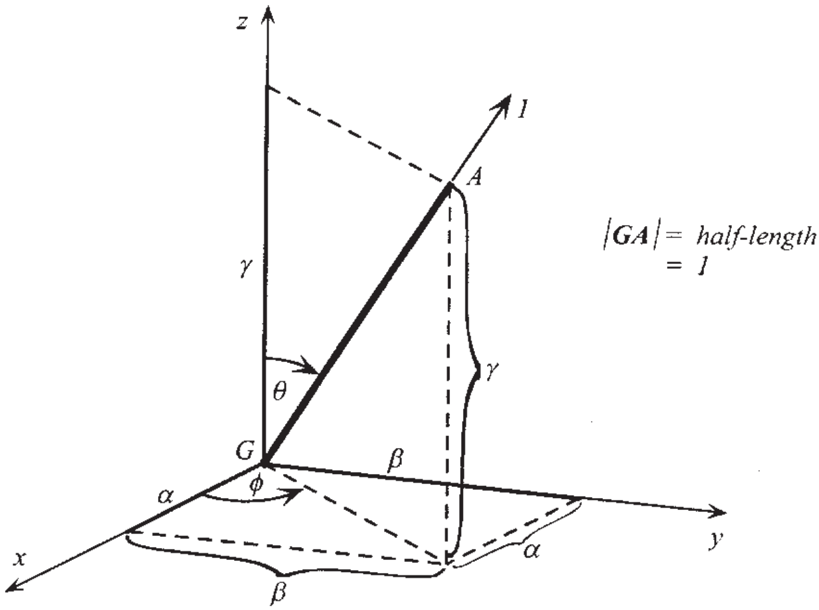

Figure 3.14 Geometry of homogeneous bar in arbitrary spatial motion.

$I_{1,2,3}$ = principal moments of inertia there], we find for the (double) rotational kinetic energy of the bar

$$\begin{aligned}2T &= I_1\,{\omega_1}^2 + I_2\,{\omega_2}^2 + I_3\,{\omega_3}^2\\ &= (0)(\dot\psi + \dot\phi\cos\theta)^2 + (I)(\dot\theta)^2 + (I)(\dot\phi\sin\theta)^2 = I\,[(\dot\theta)^2 + \sin^2\theta(\dot\phi)^2]. \qquad \text{(b)}\end{aligned}$$

To implement Maggi's equations, we need to express T in terms of α, β, γ and their $(\ldots)^{\cdot}$-derivatives. Indeed, using (a) we find, successively,

(i) $$\sin^2\theta = 1 - \cos^2\theta = 1 - \gamma^2 = \alpha^2 + \beta^2; \qquad \text{(c)}$$

(ii) $$(\dot\gamma)^2 = (-\sin\theta\,\dot\theta)^2 = \sin^2\theta(\dot\theta)^2 = (\alpha^2 + \beta^2)(\dot\theta)^2; \qquad \text{(d)}$$

(iii) $$\begin{aligned}(\alpha\,\dot\beta - \dot\alpha\,\beta) &= (\sin\theta\cos\phi)[(\cos\theta\sin\phi)\dot\theta + \alpha\,\dot\phi]\\ &\quad - (\sin\theta\sin\phi)[(\cos\theta\cos\phi)\dot\theta - \beta\,\dot\phi]\\ &= \cdots = (\alpha^2 + \beta^2)\dot\phi; \qquad \text{(e)}\end{aligned}$$

(iv) $$\chi \equiv (\alpha\,\dot\beta - \dot\alpha\,\beta)^2 + (\alpha\,\dot\alpha + \beta\,\dot\beta)^2 = \cdots = (\alpha^2 + \beta^2)[(\dot\alpha)^2 + (\dot\beta)^2], \qquad \text{(f)}$$

but, also [invoking the fourth of eq. (a)]

$$\chi = (\alpha\,\dot\beta - \dot\alpha\,\beta)^2 + \gamma^2(\dot\gamma)^2, \qquad \text{(g)}$$

and so equating the right sides of (f) and (g), adding $(\dot{\gamma})^2$ to both, and rearranging, we get

$$(\alpha\dot{\beta} - \dot{\alpha}\beta)^2 + (\dot{\gamma})^2 = (\alpha^2 + \beta^2)[(\dot{\alpha})^2 + (\dot{\beta})^2] + (\dot{\gamma})^2(1 - \gamma^2)$$
$$= \cdots = (\alpha^2 + \beta^2)[(\dot{\alpha})^2 + (\dot{\beta})^2 + (\dot{\gamma})^2]. \qquad \text{(h)}$$

As a result of the above [(d) $\to$ (c) $\to$ (e) $\to$ (h)], the kinetic energy (b) becomes, successively,

$$2T = I\Big\{(\dot{\gamma})^2/(\alpha^2 + \beta^2) + (\alpha^2 + \beta^2)[(\alpha\dot{\beta} - \dot{\alpha}\beta)^2/(\alpha^2 + \beta^2)^2]\Big\}$$
$$= I\Big\{[(\alpha\dot{\beta} - \dot{\alpha}\beta)^2 + (\dot{\gamma})^2]/(\alpha^2 + \beta^2)\Big\}$$
$$= I\Big[(\dot{\alpha})^2 + (\dot{\beta})^2 + (\dot{\gamma})^2\Big]. \qquad \text{(i)}$$

Next, we introduce the new (holonomic) coordinates:

$$f_1 \equiv \alpha^2 + \beta^2 + \gamma^2 - 1 \quad (= 0), \qquad f_2 \equiv \beta \quad (\neq 0), \qquad f_3 \equiv \gamma \quad (\neq 0), \qquad \text{(j)}$$

which invert easily to (no constraint enforcement yet!)

$$\alpha^2 = 1 + f_1 - (f_2)^2 - (f_3)^2, \qquad \beta = f_2, \qquad \gamma = f_3. \qquad \text{(k)}$$

Now, with the useful notation $M_k \equiv [(\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k] - Q_k \equiv E_k - Q_k = E_k + \partial V/\partial q_k$, where $V = V(q_k\colon \alpha, \beta, \gamma) =$ *potential energy*, Maggi's equations yield

Kinetostatic:

$$f_1\colon \quad (\partial\alpha/\partial f_1)M_\alpha + (\partial\beta/\partial f_1)M_\beta + (\partial\gamma/\partial f_1)M_\gamma = \lambda_1,$$
$$\Rightarrow (1/2\alpha)M_\alpha = \lambda_1 \;\Rightarrow\; (1/\alpha)(I\ddot{\alpha} + \partial V/\partial\alpha) = 2\lambda_1; \qquad \text{(l)}$$

Kinetic:

$$f_2\colon \quad (\partial\alpha/\partial f_2)M_\alpha + (\partial\beta/\partial f_2)M_\beta + (\partial\gamma/\partial f_2)M_\gamma = 0,$$
$$\Rightarrow (-\beta/\alpha)M_\alpha + M_\beta = 0 \Rightarrow (1/\alpha)(I\ddot{\alpha} + \partial V/\partial\alpha)$$
$$= (1/\beta)(I\ddot{\beta} + \partial V/\partial\beta); \qquad \text{(m)}$$

$$f_3\colon \quad (\partial\alpha/\partial f_3)M_\alpha + (\partial\beta/\partial f_3)M_\beta + (\partial\gamma/\partial f_3)M_\gamma = 0,$$
$$\Rightarrow (-\gamma/\alpha)M_\alpha + M_\gamma = 0 \Rightarrow (1/\alpha)(I\ddot{\alpha} + \partial V/\partial\alpha)$$
$$= (1/\gamma)(I\ddot{\gamma} + \partial V/\partial\gamma); \qquad \text{(n)}$$

and from these we immediately obtain the more symmetric form

$$(1/\alpha)(I\ddot{\alpha} + \partial V/\partial\alpha) = (1/\beta)(I\ddot{\beta} + \partial V/\partial\beta) = (1/\gamma)(I\ddot{\gamma} + \partial V/\partial\gamma) = 2\lambda_1. \qquad \text{(o)}$$

If only the motion is sought, we combine (k, l) with the constraint (a); then, if the reaction $\lambda_1(t)$ is needed, it can be found from (j).

It is not hard to see that the Routh–Voss equations of this problem are

$$M_\alpha = \lambda_1(2\alpha), \qquad M_\beta = \lambda_1(2\beta), \qquad M_\gamma = \lambda_1(2\gamma), \qquad \text{i.e., eqs. (m).} \qquad \text{(p)}$$

Other f-coordinate choices would have led to different, but equivalent, λ's and equations of motion.

Problem 3.5.22 *Maggi Equations.* Formulate both kinetic and kinetostatic Maggi equations for a particle constrained to move on a smooth circular helix (ex. 3.5.11), for the following choice of coordinates:

$$f_1 \equiv r - R \ (= 0), \qquad f_2 \equiv z - p\,\phi \ (= 0), \qquad f_3 \equiv z \ (\neq 0). \tag{a}$$

HINT

After $(\ldots)^{\cdot}$-differentiating (a), we easily conclude that here the nonvanishing elements of (a_{kl}) are $a_{11} = a_{23} = a_{33} = 1$, $a_{22} = -p$; and, therefore, the nonvanishing elements of its inverse matrix [(i.e., the Maggi equation coefficients) = (A_{kl})], are $A_{11} = A_{33} = 1$, $A_{22} = -A_{23} = -1/p$.

Problem 3.5.23 *Maggi Equations.* Repeat the preceding problem, but for the following choice of coordinates:

$$f_1 \equiv r - R \ (= 0), \qquad f_2 \equiv z - p\,\phi \ (= 0), \qquad f_3 \equiv \phi \ (\neq 0). \tag{a}$$

Problem 3.5.24 *Euler's Equations via Lagrange's Equations.* Consider, for simplicity, but no real loss in generality, the force-free motion of a rigid body B rotating about a fixed point O. With the help of the $\omega_{1,2,3} \Leftrightarrow \dot{\phi}, \dot{\theta}, \dot{\psi}$ relationships (§1.12), where O–123 are principal axes of B at O, show that the Lagrangean equations for ϕ, θ, ψ, lead to Euler's equations (§1.17).

HINT

Since $2T = I_1\omega_1{}^2 + I_2\omega_2{}^2 + I_3\omega_3{}^2 = 2T(\omega_{1,2,3}) = 2T^*$, we find, successively,

$$\begin{aligned} \partial T/\partial\dot{\psi} &= (\partial T^*/\partial\omega_1)(\partial\omega_1/\partial\dot{\psi}) + (\partial T^*/\partial\omega_2)(\partial\omega_2/\partial\dot{\psi}) + (\partial T^*/\partial\omega_3)(\partial\omega_3/\partial\dot{\psi}) \\ &= (I_1\omega_1)(0) + (I_2\omega_2)(0) + (I_3\omega_3)(1) = I_3\omega_3, \end{aligned} \tag{a}$$

$$\begin{aligned} \partial T/\partial\psi &= (\partial T^*/\partial\omega_1)(\partial\omega_1/\partial\psi) + (\partial T^*/\partial\omega_2)(\partial\omega_2/\partial\psi) + (\partial T^*/\partial\omega_3)(\partial\omega_3/\partial\psi) \\ &= (I_1\omega_1)[(s\theta\, c\psi)\dot{\phi} + (-s\psi)\dot{\theta}] + (I_2\omega_2)[(-s\theta\, s\psi)\dot{\phi} + (-c\psi)\dot{\theta}] + (I_3\omega_3)(0) \\ &= (I_1\omega_1)(\omega_2) + (I_2\omega_2)(-\omega_1), \end{aligned} \tag{b}$$

and, therefore,

$$E_\psi(T) \equiv (\partial T/\partial\dot{\psi})^{\cdot} - \partial T/\partial\psi = I_3(d\omega_3/dt) - (I_1 - I_2)\omega_1\omega_2 = 0; \tag{c}$$

and similarly for $E_\theta(T) = 0$ and $E_\phi(T) = 0$. Let the reader ponder about the possible drawbacks of this derivation of *Euler's equations*.

3.6 THE CENTRAL EQUATION (THE *ZENTRALGLEICHUNG* OF HEUN AND HAMEL)

Thus far, the transition from the particle *accelerations* that appear explicitly in Lagrange's principle (LP),

$$\delta I = \delta' W, \qquad \text{or, in extenso,} \qquad \mathcal{S}\, dm\, \boldsymbol{a} \cdot \delta\boldsymbol{r} = \mathcal{S}\, d\boldsymbol{F} \cdot \delta\boldsymbol{r}, \tag{3.6.1}$$

to system velocities/kinetic energy derivatives, and so on, that appear in the equations of motion deriving from it, is carried out in the components of the (negative of the) system inertial "forces": for example, $E_k \equiv \mathcal{S}\, dm\, \boldsymbol{a}\cdot\boldsymbol{e}_k = \cdots = (\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k$, and similarly for $I_k \equiv \mathcal{S}\, dm\, \boldsymbol{a}\cdot\boldsymbol{\varepsilon}_k = \cdots$. However, a transition from particle accelerations to particle velocities (i.e., from $\boldsymbol{a}$'s to $\boldsymbol{v}$'s), and from there to system velocities, can also be effected by proceeding directly from the variational equation (3.6.1).

Indeed, in view of the purely *kinematic* identity

$$d(\boldsymbol{v}\cdot\delta\boldsymbol{r})/dt = \boldsymbol{a}\cdot\delta\boldsymbol{r} + \delta(\boldsymbol{v}\cdot\boldsymbol{v}/2) + \boldsymbol{v}\cdot[d(\delta\boldsymbol{r})/dt - \delta(d\boldsymbol{r}/dt)], \tag{3.6.2}$$

δI transforms readily to

$$\begin{aligned}\delta I &\equiv \mathcal{S}\, dm\, \boldsymbol{a}\cdot\delta\boldsymbol{r}\\ &= d/dt\Big(\mathcal{S}\, dm\, \boldsymbol{v}\cdot\delta\boldsymbol{r}\Big) - \mathcal{S}\, dm\, \boldsymbol{v}\cdot\delta\boldsymbol{v} - \mathcal{S}\, dm\, \boldsymbol{v}\cdot[d(\delta\boldsymbol{r})/dt - \delta(d\boldsymbol{r}/dt)],\end{aligned}$$

or

$$\delta I \equiv d(\delta P)/dt - \delta T - \delta D, \tag{3.6.3}$$

where

$$\begin{aligned}\delta T &\equiv \delta\Big(\mathcal{S}\,(1/2) dm\, \boldsymbol{v}\cdot\boldsymbol{v}\Big) = \mathcal{S}\, dm\, \boldsymbol{v}\cdot\delta\boldsymbol{v} = \mathcal{S}\, dm\, \boldsymbol{v}\cdot\delta(d\boldsymbol{r}/dt)\\ &= \textit{First virtual variation of (inertial) kinetic energy},\end{aligned} \tag{3.6.3a}$$

$$\delta P \equiv \mathcal{S}\, dm\, \boldsymbol{v}\cdot\delta\boldsymbol{r} = \textit{Total virtual work of (linear) momenta of system particles}, \tag{3.6.3b}$$

$$\begin{aligned}\delta D &\equiv \mathcal{S}\, dm\, \boldsymbol{v}\cdot[d(\delta\boldsymbol{r})/dt - \delta(d\boldsymbol{r}/dt)] \equiv \mathcal{S}\, dm\, \boldsymbol{v}\cdot[(\delta\boldsymbol{r})^{\cdot} - \delta\boldsymbol{v}]\\ &= \textit{Total ``virtual (work of) nonholonomic deviation.''}\end{aligned} \tag{3.6.3c}$$

Hence LP, (3.6.1), takes the *velocity* form:

$$\delta T + \delta' W + \delta D = d(\delta P)/dt. \tag{3.6.4}$$

This fundamental *differential* variational equation, on a par with LP, was originally obtained by Lagrange himself (in the course of the derivation of his equations from LP), but its importance was fully appreciated much later by Heun (early 1900s), who dubbed it the *central equation* of AM (*Zentralgleichung*, CE). Specifically, its importance lies in that it replaces a *second*-order invariant, $\delta I \equiv \mathcal{S}\, dm\, \boldsymbol{a}\cdot\delta\boldsymbol{r}$, with its *first*-order invariants δT, δP, δD.

We should, also, point out the following:

(i) Multiplying (3.6.4) with dt and then integrating the result over the arbitrary time interval (t_1, t_2), we obtain the following *time integral variational equation:*

$$\int_{t_1}^{t_2} (\delta T + \delta' W + \delta D)\, dt = \Big\{\delta P\Big\}_{t_1}^{t_2} \equiv \Big\{\mathcal{S}\, dm\, \boldsymbol{v}\cdot\delta\boldsymbol{r}\Big\}_{t_1}^{t_2}; \tag{3.6.5}$$

commonly known as *Hamilton's principle* (HP—detailed in chap. 7).

(ii) It is not necessary to assume, in CE, that $(\delta \boldsymbol{r})^{\cdot} = \delta \boldsymbol{v}$, or equivalently $d(\delta \boldsymbol{r}) = \delta(d\boldsymbol{r})$. As Hamel has stressed, and as will become clear below, the equations of motion derived from the above are *independent of any such commutation rules*. Thus, assuming in (3.6.4), (3.6.5) $(\delta \boldsymbol{r})^{\cdot} = \delta \boldsymbol{v}$, that is, $\delta D = 0$, reduces them, respectively, to

$$\delta T + \delta' W = d(\delta P)/dt \qquad (\textit{ordinary}\ \text{CE}) \tag{3.6.6}$$

$$\int_{t_1}^{t_2} (\delta T + \delta' W)\, dt = \Big\{\delta P\Big\}_{t_1}^{t_2} \equiv \Big\{ \mathcal{S}\, dm\ \boldsymbol{v} \cdot \delta \boldsymbol{r}\Big\}_{t_1}^{t_2} \qquad (\textit{ordinary}\ \text{HP}). \tag{3.6.6a}$$

[Heun called (3.6.6) the *central equation*; while Hamel (1949, pp. 233–235) called (3.6.4) the *generalized*, or *general, central equation*. Also, Rosenberg (1977, pp. 167–168), virtually alone in the entire English language literature to handle this matter properly, chose to translate (3.6.4, 6) as the *central principle*.]

Now, the differential variational equation (3.6.4) is expressed in *particle* vectors/variables; and in that form it may be quite useful in, say, rigid-body applications. For the purposes of the general theory, however, we need to express it in general *system* variables. Indeed, proceeding from the invariant definitions (3.6.3a–c) we find, successively,

(a)
$$T = T(t, q, \dot{q}) = T^* = T^*(t, q, \omega) \Rightarrow \delta T = \delta T^*$$

$$\delta T = \delta T(t, q, \dot{q}) = \sum [(\partial T/\partial q_k)\, \delta q_k + (\partial T/\partial \dot{q}_k)\, \delta(\dot{q}_k)], \tag{3.6.7a}$$

$$\begin{aligned} \delta T^* = \delta T^*(t, q, \omega) &= \sum [(\partial T^*/\partial \omega_k)\, \delta \omega_k + (\partial T^*/\partial q_k)\, \delta q_k] \\ &= \sum (\partial T^*/\partial \omega_k)\, \delta \omega_k + \sum \Big[(\partial T^*/\partial q_k)\Big(\sum A_{kl}\, \delta \theta_l\Big)\Big] \\ &= \cdots \equiv \sum P_k\, \delta \omega_k + \sum (\partial T^*/\partial \theta_k)\, \delta \theta_k; \end{aligned} \tag{3.6.7b}$$

(b)
$$\delta' W \equiv \mathcal{S}\, d\boldsymbol{F} \cdot \delta \boldsymbol{r} = \sum Q_k\ \delta q_k = \sum \Theta_k\ \delta \theta_k; \tag{3.6.7c}$$

(c)
$$\delta P = \cdots = \sum P_k\, \delta \theta_k = \sum p_k\ \delta q_k\ \Big[\text{since}\ \mathcal{S}\, dm\ \boldsymbol{v} \cdot \boldsymbol{e}_k \equiv p_k,\ \mathcal{S}\, dm\ \boldsymbol{v} \cdot \boldsymbol{\varepsilon}_k \equiv P_k\Big] \tag{3.6.7d}$$

$$\Rightarrow p_l = \sum a_{kl} P_k, \quad \text{i.e., } \partial T/\partial \dot{q}_l = \sum (\partial T^*/\partial \omega_k)(\partial \omega_k/\partial \dot{q}_l), \tag{3.6.7e}$$

$$P_k = \sum A_{lk} p_l, \quad \text{i.e., } \partial T^*/\partial \omega_k = \sum (\partial T/\partial \dot{q}_l)(\partial \dot{q}_l/\partial \omega_k); \tag{3.6.7f}$$

$$\Rightarrow (\delta P)^{\cdot} \equiv \Big(\mathcal{S}\, dm\ \boldsymbol{v} \cdot \delta \boldsymbol{r}\Big)^{\cdot}$$

$$= \Big(\sum p_k\ \delta q_k\Big)^{\cdot} = \sum \dot{p}_k\ \delta q_k + \sum p_k (\delta q_k)^{\cdot}, \tag{3.6.7g}$$

$$= \Big(\sum P_k\ \delta \theta_k\Big)^{\cdot} = \sum \dot{P}_k\ \delta \theta_k + \sum P_k (\delta \theta_k)^{\cdot}; \tag{3.6.7h}$$

(d) Recalling the general *particle transitivity equation* (prob. 2.10.6; with Greek indices running from 1 to $n + 1$), which holds independently of any $d(\delta q) - \delta(dq)$ rules,

$$\begin{aligned} (\delta \boldsymbol{r})^{\cdot} - \delta \boldsymbol{v} &= \sum [(\delta q_k)^{\cdot} - \delta(\dot{q}_k)] \boldsymbol{e}_k \\ &= \sum [(\delta \theta_k)^{\cdot} - \delta \omega_k] \boldsymbol{\varepsilon}_k - \sum \Big(\sum \sum \gamma^k{}_{r\alpha}\ \omega_\alpha\ \delta \theta_r\Big) \boldsymbol{\varepsilon}_k, \end{aligned} \tag{3.6.7i}$$

we obtain (invoking the above definitions of p_k, P_k)

$$\begin{aligned}\delta D &\equiv S\, dm\ \boldsymbol{v}\cdot[(\delta\boldsymbol{r})^{\cdot} - \delta\boldsymbol{v}] \\ &= \cdots = \sum p_k[(\delta q_k)^{\cdot} - \delta(\dot{q}_k)] = \sum P_k[(\delta\theta_k)^{\cdot} - \delta\omega_k] - \sum\sum\sum \gamma^k{}_{r\alpha} P_k \omega_\alpha\, \delta\theta_r.\end{aligned} \tag{3.6.7j}$$

Next, substituting the above system expressions into the general CE, (3.6.4), re-arranged à la LP as $(\delta P)^{\cdot} - \delta T - \delta D = \delta' W$, we obtain its following system forms.

1. Holonomic System Variables

$$\left(\sum p_k\, \delta q_k\right)^{\cdot} - \delta T - \sum p_k[(\delta q_k)^{\cdot} - \delta(\dot{q}_k)] = \sum Q_k\, \delta q_k \quad (\equiv \delta' W), \tag{3.6.8}$$

or (after expanding and collecting terms, and factoring out δq_k)

$$\sum (dp_k/dt - \partial T/\partial q_k)\, \delta q_k = \sum Q_k\, \delta q_k \quad \text{[LP in holonomic variables (3.5.11 ff.)]} \tag{3.6.8a}$$

We notice that (3.6.8a) results always from (3.6.8), *regardless of any assumptions about* $(\delta q_k)^{\cdot} - \delta(\dot{q}_k)$. However, (3.6.8) is more general than (3.6.8a); for example, if we express some of its terms in θ-variables (see below, and ex. 3.8.1), or if we assume that $(\delta q_k)^{\cdot} \neq \delta(\dot{q}_k)$, for some δq, $\dot{q}$'s [see Voronets equations (3.8.14a ff.)].

2. Nonholonomic System Variables

$$\left(\sum P_k\, \delta\theta_k\right)^{\cdot} - \delta T - \left\{\sum P_k[(\delta\theta_k)^{\cdot} - \delta\omega_k] - \sum\sum\sum \gamma^k{}_{r\alpha} P_k\, \omega_\alpha\, \delta\theta_r\right\} = \sum \Theta_k\, \delta\theta_k,$$

or, after expanding and collecting terms, etc.,

$$\sum \dot{P}_k\, \delta\theta_k - \sum (\partial T^*/\partial\theta_k)\, \delta\theta_k + \sum\sum\sum \gamma^k{}_{r\alpha} P_k\, \omega_\alpha\, \delta\theta_r = \sum \Theta_k\, \delta\theta_k, \tag{3.6.9}$$

or (factoring out $\delta\theta_k$, and performing some index changes in the γ-term)

$$\sum \left(dP_k/dt - \partial T^*/\partial\theta_k + \sum\sum \gamma^r{}_{k\alpha} P_r\, \omega_\alpha\right) \delta\theta_k = \sum \Theta_k\, \delta\theta_k, \tag{3.6.9a}$$

which is none other than LP in quasi variables (3.5.18 ff.).

3. Mixed Variable Forms

(i) With the help of (3.6.7a–j) [also, recalling the *general system transitivity equations* (2.10.6, 7)], we can rewrite (3.6.9) as follows:

$$\begin{aligned}&\sum \dot{P}_k\, \delta\theta_k - \sum (\partial T^*/\partial\theta_k)\, \delta\theta_k \\ &\qquad + \sum P_k\left\{[(\delta\theta_k)^{\cdot} - \delta\omega_k] - \sum a_{kl}[(\delta q_l)^{\cdot} - \delta(\dot{q}_l)]\right\} = \sum \Theta_k\, \delta\theta_k.\end{aligned} \tag{3.6.10}$$

From the above we readily see the following.

(ii) If we assume that $(\delta q_k)^{\cdot} - \delta(\dot{q}_k) = 0$ [$\Rightarrow d(\delta \boldsymbol{r}) - \delta(d\boldsymbol{r}) = \sum [d(\delta q_k) - \delta(dq_k)]\boldsymbol{e}_k = \boldsymbol{0} \Rightarrow \delta D = 0$ (ordinary CE, (3.6.6)) — *Hamel viewpoint*], then (3.6.10) becomes

$$\sum \dot{P}_k \, \delta\theta_k - \sum (\partial T^*/\partial\theta_k) \, \delta\theta_k + \sum P_k[(\delta\theta_k)^{\cdot} - \delta\omega_k] = \sum \Theta_k \, \delta\theta_k; \tag{3.6.11}$$

which, since in this case $(\delta\theta_k)^{\cdot} - \delta\omega_k = \sum\sum \gamma^k{}_{r\alpha} \, \omega_\alpha \, \delta\theta_r$, is none other than (3.6.9). Hence, even if we had started with (3.6.6), rearranged as $(\delta P)^{\cdot} - \delta T = \delta' W$, with δT, $\delta' W$, $(\delta P)^{\cdot}$ given by (3.6.7b, c, h), respectively, we would *still have arrived at (3.6.11)*. Also, recalling (3.3.12a), and comparing (3.6.11) with (3.6.9), we readily conclude that, then,

$$\sum P_k[(\delta\theta_k)^{\cdot} - \delta\omega_k] = -\sum \Gamma_k \, \delta\theta_k. \tag{3.6.11a}$$

(iii) However, if we assume that $(\delta\theta_k)^{\cdot} - \delta\omega_k = 0$ (*Suslov viewpoint*), and invoke (3.6.7e), eq. (3.6.10) becomes

$$\begin{aligned} &\sum \dot{P}_k \, \delta\theta_k - \sum (\partial T^*/\partial\theta_k) \, \delta\theta_k - \sum P_k\Big\{\sum a_{kl}[(\delta q_l)^{\cdot} - \delta(\dot{q}_l)]\Big\} \\ &\quad = \sum \dot{P}_k \, \delta\theta_k - \sum (\partial T^*/\partial\theta_k) \, \delta\theta_k - \sum p_k[(\delta q_k)^{\cdot} - \delta(\dot{q}_k)] = \sum \Theta_k \, \delta\theta_k. \end{aligned} \tag{3.6.12}$$

Equations (3.6.4, 6; 8; 9; 10, 11, 12) are mutually equivalent; but, unless properly understood and applied, they may lead to (apparently) contradictory results. [These variational equations are useful in integral variational "principles": chap. 7; also ex. 3.8.1.] Hence, whenever needed, we may safely assume that $d(\delta q_k) = \delta(dq_k)$ for *all* holonomic coordinates, constrained or not. Indeed, in applications to concrete problems, the CE in the form (3.6.11) seems to be the single most useful equation of analytical mechanics. Its implementation requires knowledge of $T \to T^*$, the Θ's, and the $\dot{q} \leftrightarrow \omega$ transformation; the $\gamma^k_{\bullet\blacklozenge}$'s, as already pointed out in § 2.10, are simply read off as the coefficients of

$$(\delta\theta_k)^{\cdot} - \delta\omega_k = \cdots + (\ldots)^k_{\bullet\blacklozenge} \, \omega_\blacklozenge \, \delta\theta_\bullet + \cdots . \tag{3.6.12a}$$

WHICH ARE THE BEST EQUATIONS OF MOTION ?

Over the past couple of decades or so, a debate has been brewing, in applied engineering (multibody) dynamics circles, as to which of all available equations of motion are the best, or "more efficient." We believe that such questions, and attempted answers, are at best counterproductive and myopic; and, at worst, self-serving and wasteful. Fortunately, for dynamics, there is no cure-all set of equations that works best under all circumstances; theoretical and applied, exact and approximate (including computational). Different equations (see also special forms in §3.8) have different uses, advantages and disadvantages, like the various tools in a mechanic's toolbox. Some are more conceptually efficient (a classification almost never heard of by applied dynamicists) and less computationally efficient, and vice versa; some are more fertile and/or beautiful (!) than others. Such a healthy pluralism testifies to the vitality and diversity of the human intellect, keeps our science alive and should be welcome, indeed treasured, by all—*we learn more by solving one problem with several methods than by solving several problems with one method. We must learn them all, especially today!*

It seems to us, however, that one of the best such tools *is not any particular set of equations of motion*, but instead, the *central (variational) equation* in the form (3.6.11) $\Rightarrow$

$$\sum (\ldots)_D \, \delta\theta_D + \sum (\ldots)_I \, \delta\theta_I = 0. \tag{3.6.12b}$$

The vanishing of its $(\ldots)_D$ terms (appropriately modified, according to the method of Lagrangean multipliers) yields the *m kinetostatic* equations, while the vanishing of its $(\ldots)_I$ terms yields the $n - m$ *kinetic* equations; and these, plus constraints and initial/boundary temporal conditions, constitute a mathematically *determinate* system. [Also, the *differential* variational principles (chap. 6), of which LP, eqs. (3.6.8a) and (3.6.9a), constitute the foundation, seem especially promising, for both finite and impulsive motion, and for both linear (Pfaffian) and nonlinear velocity constraints.] Such a *unifying* approach, acting like a conceptual centripetal force and countering the centrifugal ones of the various equations of motion, should be welcome and psychologically satisfying. After all, *there is only one mechanics*; although the average observer of the contemporary (tower of Babel-like) dynamics literature would not get that impression!

Example 3.6.1 *Holonomic System in Nonholonomic Coordinates: Plane Motion of a Free Particle* (Appell, 1925, pp. 6–7, 17–18; Lur'e, 1968, pp. 401–402). Let us consider a particle P of mass m moving along the plane curve C, on the $O\text{–}xy$ plane, under known/given forces (fig. 3.15). The instantaneous position and velocity of this *two DOF* system ($n = 2$, $m = 0$) can be defined in several equivalent ways. Thus, we may choose the following descriptions:

(i) *Holonomic variables*: a convenient such choice are the polar coordinates of P

$$q_1 = r, \quad q_2 = \phi \quad (\text{angle from } Ox) \;\Rightarrow\; \dot{q}_1 = \dot{r}, \quad \dot{q}_2 = \dot{\phi}. \tag{a}$$

(ii) *Nonholonomic variables*: following Appell, we choose as such: (a) $\theta_1 = q_1 = r$; that is, the magnitude of the *position* vector $\boldsymbol{r} = \boldsymbol{OP}$, and (b) $\theta_2 = \sigma$ (a quasi coordinate, as shown below), such that $\dot{\theta}_2 \equiv \omega_2 = \dot{\sigma} = r^2\dot{\phi}$, or $d\sigma = r^2 d\phi =$ *twice the area of the elementary sector swept by the radius vector OP between the time instants* $t(\rightarrow r)$

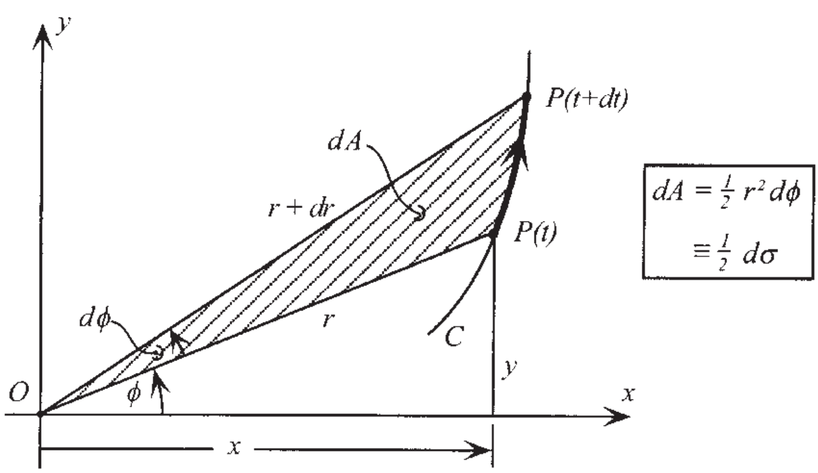

Figure 3.15 Plane motion of a particle under given forces ($2\,dA = r^2\,d\phi \equiv d\sigma$).

and $t + dt\,(\to r + dr)$; that is, approximately, twice the area of a circular sector of radius r and central angle $d\phi$ — a well-known calculus result. Hence, the following transformation equations, and their inverses:

$$\omega_1 = (1)\dot{q}_1 + (0)\dot{q}_2, \qquad \omega_2(0)\dot{q}_1 + (r^2)\dot{q}_2; \tag{b}$$

$$\dot{q}_1 = (1)\omega_1 + (0)\omega_2, \qquad \dot{q}_2 = (0)\omega_1 + (r^{-2})\omega_2. \tag{c}$$

Transitivity Equations

From (b, c), and since this is a scleronomic system, that is, $\delta q_1 = \delta\theta_1 = \delta r$, $dq_1 = d\theta_1 = dr$; $\delta\theta_2 = \delta\sigma = r^2\,\delta\phi = r^2\,\delta q_2$, $d\theta_2 = d\sigma = r^2\,d\phi = r^2\,dq_2$, and so on, we find

$$(\delta\theta_1)^{\cdot} - \delta\omega_1 = (\delta r)^{\cdot} - \delta(\dot{r}) = 0 \qquad (r = \textit{holonomic coordinate}), \tag{d}$$

$$\begin{aligned}(\delta\theta_2)^{\cdot} - \delta\omega_2 &= (r^2\,\delta\phi)^{\cdot} - \delta(r^2\dot{\phi}) = \cdots = 2r\,\dot{r}\,\delta\phi - 2r\,\dot{\phi}\,\delta r \\ &= 2r\,\omega_1\,\delta\phi - 2r(\omega_2/r^2)\,\delta r = 2r\,\omega_1(r^{-2}\,\delta\theta_2) - (2r^{-1}\omega_2)\,\delta\theta_1 \\ &= 2r^{-1}(\omega_1\,\delta\theta_2 - \omega_2\,\delta\theta_1).\end{aligned} \tag{e}$$

Kinetic Energy

From $x = r\cos\phi$, $y = r\sin\phi \;\Rightarrow\; \dot{x} = \ldots, \dot{y} = \ldots$, and the above, we find

$$\begin{aligned}2T = m[(\dot{x})^2 + (\dot{y})^2] &= \cdots = m[(\dot{r})^2 + r^2(\dot{\phi})^2] \\ &= \cdots = m[(\omega_1)^2 + r^{-2}(\omega_2)^2] = T^*.\end{aligned} \tag{f}$$

Appellian

From $\ddot{x} = \ldots, \ddot{y} = \ldots$, we find, successively,

$$\begin{aligned}2S &= m[(\ddot{x})^2 + (\ddot{y})^2] = \cdots = m[(a_r)^2 + (a_\phi)^2] \qquad \text{(physical components)} \\ &= m\Big\{[\ddot{r} - r(\dot{\phi})^2]^2 + [r^{-1}(r^2\dot{\phi})^{\cdot}]^2\Big\} \\ &= m\Big\{[\ddot{r} - r^{-3}(\dot{\sigma})^2]^2 + (r^{-1}\ddot{\sigma})^2\Big\},\end{aligned}$$

or, to within "Appell-important" terms $\equiv \cdots$,

$$\begin{aligned}2S \to 2S^* &= m[(\ddot{r})^2 - 2r^{-3}\ddot{r}(\dot{\sigma})^2 + r^{-2}(\ddot{\sigma})^2] + \cdots \\ &= m[(\dot{\omega}_1)^2 - 2r^{-3}(\omega_2)^2\dot{\omega}_1 + r^{-2}(\dot{\omega}_2)^2] + \cdots.\end{aligned} \tag{g}$$

Virtual Works

Let the physical (polar) components of the total impressed force on P, that is, $\boldsymbol{F}$, be (F_r, F_ϕ). Then,

$$\begin{aligned}\delta' W &= F_r\,\delta r + F_\phi(r\,\delta\phi) \equiv Q_r\,\delta r + Q_\phi\,\delta\phi \\ &= F_r\,\delta\theta_1 + F_\phi(r^{-1}\,\delta\theta_2) = \Theta_1\,\delta\theta_1 + \Theta_2\,\delta\theta_2,\end{aligned} \tag{h}$$

that is,

$$Q_1 \equiv Q_r = F_r, \qquad Q_2 \equiv Q_\phi = rF_\phi \qquad \text{(holonomic components)} \tag{i}$$
$$\Theta_1 = F_r, \qquad \Theta_2 = r^{-1}F_\phi \qquad \text{(nonholonomic components).} \tag{j}$$

Equations of Motion

(i) *Holonomic variables*: The Lagrange and Appell equations are

$$q_1 \equiv r: \quad (\partial T/\partial \dot{r})^{\cdot} - \partial T/\partial r \equiv \partial S/\partial \ddot{r} = Q_r: \quad m[\ddot{r} - r(\dot{\phi})^2] = F_r, \tag{k}$$
$$q_2 \equiv \phi: \quad (\partial T/\partial \dot{\phi})^{\cdot} - \partial T/\partial \phi \equiv \partial S/\partial \ddot{\phi} = Q_\phi: \quad m(r^2\dot{\phi})^{\cdot} = rF_\phi. \tag{l}$$

(ii) *Nonholonomic variables*: Since

$$P_1 \equiv \partial T^*/\partial \omega_1 = m\,\omega_1 \qquad (= m\dot{r}) \;\Rightarrow\; \dot{P}_1 = m\,\dot{\omega}_1 \quad (= m\,\ddot{r}), \tag{m}$$
$$P_2 \equiv \partial T^*/\partial \omega_2 = mr^{-2}\omega_2 \quad (= mr^{-2}\dot{\sigma}) \;\Rightarrow\; \dot{P}_2 = (m\,r^{-2}\omega_2)^{\cdot}\,; \tag{n}$$

and

$$\begin{aligned}\partial T^*/\partial \theta_1 \equiv \partial T^*/\partial r &= A_{11}(\partial T^*/\partial q_1) + A_{21}(\partial T^*/\partial q_2)\\ &= (1)(\partial T^*/\partial r) + (0)(\partial T^*/\partial \phi) = \partial T^*/\partial r\\ &= (m/2)(-2)[r^{-3}(\omega_2)^2] = -m\,r^{-3}(\omega_2)^2,\end{aligned} \tag{o}$$

$$\begin{aligned}\partial T^*/\partial \theta_2 \equiv \partial T^*/\partial \sigma &= A_{12}(\partial T^*/\partial q_1) + A_{22}(\partial T^*/\partial q_2)\\ &= (0)(\partial T^*/\partial r) + (r^2)(\partial T^*/\partial \phi) = 0,\end{aligned} \tag{p}$$

the central equation (3.6.11)

$$\sum \dot{P}_k\,\delta\theta_k - \sum (\partial T^*/\partial \theta_k)\,\delta\theta_k + \sum P_k[(\delta\theta_k)^{\cdot} - \delta\omega_k] = \sum \Theta_k\,\delta\theta_k \tag{q}$$

yields

$$\begin{aligned}&\dot{P}_1\,\delta\theta_1 + \dot{P}_2\,\delta\theta_2 - (\partial T^*/\partial \theta_1)\,\delta\theta_1 - (\partial T^*/\partial \theta_2)\,\delta\theta_2\\ &\qquad + P_1[(\delta\theta_1)^{\cdot} - \delta\omega_1] + P_2[(\delta\theta_2)^{\cdot} - \delta\omega_2] = \Theta_1\,\delta\theta_1 + \Theta_2\,\delta\theta_2,\end{aligned} \tag{r}$$

or collecting $(\ldots)\,\delta\theta_k$ terms,

$$[\dot{P}_1 - \partial T^*/\partial \theta_1 + (-2\omega_2/r)P_2 - \Theta_1]\,\delta\theta_1 + [\dot{P}_2 + (2\omega_1/r)P_2 - \Theta_2]\,\delta\theta_2 = 0, \tag{s}$$

from which, since $\delta\theta_1$ and $\delta\theta_2$ are unconstrained, we obtain the Hamel equations:

$$\theta_1: \qquad \dot{P}_1 - \partial T^*/\partial \theta_1 - (2\omega_2/r)P_2 = \Theta_1, \tag{t1}$$

or

$$m\,\dot{\omega}_1 + m\,r^{-3}(\omega_2)^2 - (2r^{-1}\omega_2)(m\,r^{-2}\omega_2) = \Theta_1,$$

or, finally,

$$m[\ddot{r} - r^{-3}(\dot{\sigma})^2] = F_r, \quad \text{i.e., equation (k);} \tag{t2}$$

and

$$\theta_2: \qquad \dot{P}_2 + (2\omega_1/r)P_2 = \Theta_2, \tag{t3}$$

or

$$(m\,r^{-2}\omega_2)^{\cdot} + (2r^{-1}\omega_1)(m\,r^{-2}\omega_2) = \Theta_2,$$

or, finally,

$$m\,r^{-2}\ddot{\sigma} - r^{-3}(2m\,\dot{r}\,\dot{\sigma}) + r^{-3}(2m\,\dot{r}\,\dot{\sigma}) = \Theta_2 \Rightarrow m\,\ddot{\sigma} = rF_\phi, \tag{t4}$$

that is, (l); from which, if $F_\phi = 0$, we obtain Kepler's second "law": $\dot{\sigma} = r^2\dot{\phi} =$ *constant*.

REMARKS

(i) The above Hamel equations coincide with those of Appell, but in nonholonomic variables:

$$\partial S^*/\partial \ddot{r} = \Theta_r \qquad [\partial S^*/\partial \dot{\omega}_1 = \Theta_1], \tag{u1}$$

$$\partial S^*/\partial \ddot{\sigma} = \Theta_\sigma \qquad [\partial S^*/\partial \dot{\omega}_2 = \Theta_2]. \tag{u2}$$

(ii) We also notice that, since

$$[(\partial T^*/\partial \dot{r})^{\cdot} - \partial T^*/\partial r] - \partial S^*/\partial \ddot{r} \equiv \Gamma_r \qquad [= (2\omega_2/r)P_2] \neq 0, \tag{v1}$$

$$[(\partial T^*/\partial \dot{\sigma})^{\cdot} - \partial T^*/\partial \sigma] - \partial S^*/\partial \ddot{\sigma} \equiv \Gamma_\sigma \qquad [= -(2\omega_1/r)P_2] \neq 0, \tag{v2}$$

the Lagrange-type equations in quasi variables

$$E_r(T^*) \equiv (\partial T^*/\partial \dot{r})^{\cdot} - \partial T^*/\partial r = \Theta_r, \qquad E_\sigma(T^*) \equiv (\partial T^*/\partial \dot{\sigma})^{\cdot} - \partial T^*/\partial \sigma = \Theta_\sigma, \tag{v3}$$

would have been incorrect.

3.7 THE PRINCIPLE OF RELAXATION OF THE CONSTRAINTS (THE LAGRANGE–HAMEL *BEFREIUNGSPRINZIP*)

We have already seen (§3.5) how to (i) eliminate the constraint reactions (kinetic equations), and (ii) how to retrieve them, if needed (kinetostatic equations). For the first task, we postulated *Lagrange's principle (LP)*; while for the second, we have utilized the method of Lagrangean multipliers. This latter (recall last part of §3.2) is the mathematical expression of the *principle of relaxation, or freeing, or liberation, of the constraints (PRC)*—the second pillar of analytical mechanics, and its logical counterpart to the Eulerian *cut* principle ("free-body diagram") for calculating internal forces, of the stereomechanical approach.

It was Hamel who, around 1916 (publ. 1917), recognized the cardinal importance of this principle and introduced the term *Befreiungsprinzip* for it. Up until then, it had not been stated explicitly anywhere. Lagrange, in his admirably informal style, had simply said about it, "*Car c'est en quoi consiste l'esprit de la méthode de cette section.* … Notre méthode donne, comme l'on voit, le moyen de déterminer ces forces et ces résistances; ce qui n'est pas un des moindres avantages de cette méthode". [Lagrange, 1965 (reprint of 4th ed.), vol. 1, p. 73, emphasis added]. Even today, it is rarely stated explicitly in the English language literature: for example, Lawden (1972, p. 54; who (seems to have) coined our term "method of relaxation of constraints"), Leipholz (1978, 1983; who calls it "relaxation principle of Lagrange"), Serrin (1959, pp. 146–147; who refers to it as "Lagrange's Freeing Principle"); and Bahar (1970–1980; who describes it, instructively, as "the rubber-band approach"). Such a method was long known and routinely applied in analytical statics; although it was not sufficiently acknowledged, explicitly. That is why its extension to kinetics, a nontrivial matter, was aptly called by Heun (early 1900s) *kinetostatics = the determination of internal and external reactions in moving rigid systems* — an important mechanical engineering problem (see also Stäckel, 1905, pp. 667–670). Let us examine it more closely. Following Hamel (1927, p. 26; 1949, pp. 74, 173, 522):

• In addition to the constrained system, we form (mentally) a relaxed, or freed one, in which a particular, or all, constraints have been eliminated. The equations of motion remain formally the same, except that now the former reactions are *impressed* forces whose virtual work is

$$\sum \lambda_D \,\delta\theta_D = \sum \Big(\sum \lambda_D \, a_{Dk} \Big) \, \delta q_k; \tag{3.7.1}$$

for a particular $\lambda_D = \Lambda_D$, the corresponding "relaxed virtual work" is

$$(\delta' W_R)_D \equiv \lambda_D \; \delta\theta_D = \Lambda_D \; \delta\theta_D, \tag{3.7.1a}$$

as if the constraint $\delta\theta_D = 0$ *did not exist*.

• The former reactions have now become impressed forces that depend on the previously forbidden deformation/motion, i.e., *on those geometrical/kinematical variables that were not allowed to vary in the non-relaxed system* (and, possibly, on other non-mechanical variables — see below).

• A word of caution: When applying this principle to cases where the freed system requires more than mechanics (M) for its description — that is, wherever the additional, relaxed, deformation/motion introduces *additional*, say thermodynamical (T) and/or electrodynamical (E) variables, mutually coupled — we should expect such a dependence to be reflected in the multipliers; that is, symbolically, $\lambda = \lambda(M, T, E)$. As long as we stay within pure mechanics (this book), however, no such problems seem to arise. See for instance Serrin (1959, pp. 146–147), who warns against the blind generalization of the principle from simple mechanics [e.g., the compressible perfect, or ideal, fluid viewed as a freed incompressible perfect fluid, whose stress (pressure), according to the PRC, depends on the formerly forbidden compressibility; i.e., on the density which, before, was not allowed to vary], to more physically complex cases (e.g., a gas where the pressure is a definite thermodynamical variable).

Example 3.7.1 *Applications of PRC.*

(i) In pure (or slippingless) *rolling*, the friction is a *reaction* force. It follows that in *slipping*, the friction depends on the previous constraint; that is, on the *relative velocity* of the two contacting surfaces, and on other material coefficients; and, hence, it has become an impressed force.

(ii) The *tension* in an extensible cable depends on the latter's *stretch*, and other material coefficients.

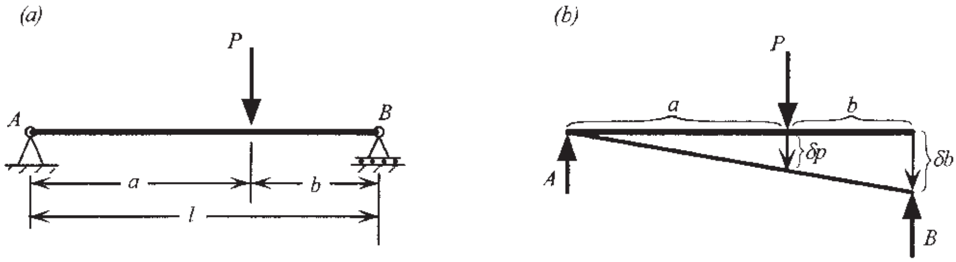

Figure 3.16 Principle of relaxation in statics: reactions on a simply supported beam.

(iii) *Statics*: Let us calculate the reaction B of the simply supported (statically determinate) beam of fig. 3.16(a). We allow, mentally, the formerly unyielding support B to move down (or up) and then calculate the virtual works of all impressed forces on the so relaxed beam, i.e., of the ever impressed P and of the former reaction B, and set it equal to zero [fig. 3.16(b)]:

$$\delta' W = P\,\delta p - B\,\delta b = 0 \;\Rightarrow\; B = (\delta p/\delta b)P = (a/l)P; \tag{a1}$$

(since $\delta p/\delta b = \textit{finite}$, and independent of the δp, δb magnitudes); and, similarly, $A = (b/l)P$. Because of the linearity of $\delta' W$, we can calculate one or more reactions at a time, or even all of them simultaneously.

(iv) *Dynamics*: Let us calculate the string tension S in the planar mathematical pendulum of mass m and length l (fig. 3.17).

(a) *Relaxed LP version*. Here, we allow the inextensible string to become a rubber band, compute the virtual works of all (old and new) impressed and inertial forces (i.e., apply LP to the relaxed system), and then enforce on the result the old constraint, $r = l$:

$$\begin{aligned}\delta' W|_{r=l} &= (W\cos\phi - S)\,\delta r - (W\sin\phi)(r\,\delta\phi)\big|_{r=l} = (W\cos\phi - S)\,\delta r - (W\,l\sin\phi)\,\delta\phi \\ &= Q_r\,\delta r + Q_\phi\,\delta\phi \;\Rightarrow\; Q_r = W\cos\phi - S, \qquad Q_\phi = -W\,l\sin\phi;\end{aligned} \tag{a2}$$

and similarly for $\delta I = E_r\,\delta r + E_\phi\,\delta\phi$, where the relaxed (double) kinetic energy is $2T = m[(\dot r)^2 + r^2(\dot\phi)^2]$, and therefore:

$$E_r \equiv (\partial T/\partial \dot r)^{\cdot} - \partial T/\partial r = (m\,\dot r)^{\cdot} - m\,r(\dot\phi)^2\big|_{r=l} = -m\,l(\dot\phi)^2, \tag{b}$$

$$E_\phi \equiv (\partial T/\partial \dot\phi)^{\cdot} - \partial T/\partial \phi = (m\,r^2\dot\phi)^{\cdot}\big|_{r=l} = m\,l^2\ddot\phi. \tag{c}$$

Hence, the relaxed $\rightarrow$ constrained LP, $(\delta I = \delta' W)\big|_{r=l}$, yields

$$m\,l(\dot\phi)^2 = S - W\cos\phi \quad \text{(kinetostatic)}, \qquad m\,l^2\ddot\phi = -W\,l\sin\phi \quad \text{(kinetic)}. \tag{d}$$

First, we solve the kinetic equation, the second of (d) (plus initial conditions), and obtain the motion $\phi = \phi(t)$; and then, substituting the latter into the kinetostatic equation, the first of (d), we get the tension $S = ml(\dot\phi)^2 + W\cos\phi = S(t)$. Had we started with the constrained (double) kinetic energy $ml^2(\dot\phi)^2$, we would not have been able to obtain the kinetostatic equation, just the kinetic one.

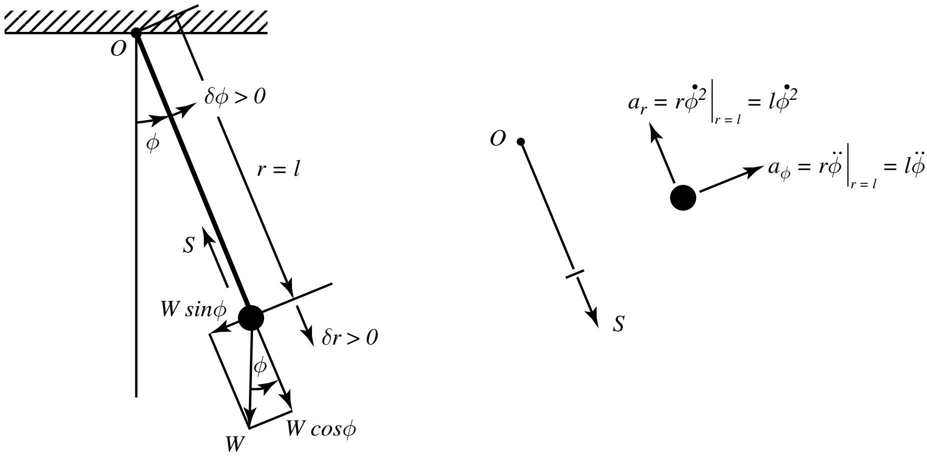

Figure 3.17 Principle of constraint relaxation applied in the calculation of the tension of the inextensible string of a planar pendulum.

(b) *Lagrangean multipliers*. In this version of LP/PRC, we have

$$Q_r = W\cos\phi, \qquad Q_\phi = (Wr\sin\phi)\big|_{r=l} = W\,l\sin\phi, \tag{e}$$

since S is a reaction, while $q_1 = r$ and $q_2 = \phi$ are subject to the constraint

$$f \equiv r - l = 0 \;\Rightarrow\; \delta f = (\partial f/\partial r)\,\delta r = (1)\,\delta r = 0; \tag{f}$$

that is, $n = 2$, $m = 1$. Hence, the Routh–Voss equations yield

$$E_r = Q_r + \lambda(\partial f/\partial r): \qquad -ml(\dot{\phi})^2 = W\cos\phi + \lambda(1), \tag{g1}$$

$$E_\phi = Q_\phi + \lambda(\partial f/\partial \phi): \qquad ml^2\ddot{\phi} = -W\,l\sin\phi; \tag{g2}$$

while from $\delta' W_R = -S\,\delta r = R_r\,\delta r = \lambda(1)\,\delta r$, we conclude that $\lambda = -S$, thus recovering (d). Had we written the constraint as $f \equiv l - r = 0 \Rightarrow (-1)\cdot\delta r = 0$, we would have $R_r = \lambda(\partial f/\partial r) = \lambda(-1) = -\lambda$, and, accordingly, $\delta' W_R = -S\,\delta r = R_r\,\delta r = \lambda(-1)\,\delta r \Rightarrow \lambda = S$, so that the final equations of motion would be unchanged. Also, since $\delta' W_R \geq 0$ for $\delta r \leq 0$ (§3.2.15, 15a), it follows that $S > 0$, as expected.

Example 3.7.2 *Relaxation of Constraints, External Reactions: Pendulum with Horizontally Moving Support* (Butenin, 1971, pp. 73–74). A block A of mass M, capable of translating along the smooth horizontal axis/floor Ox, is smoothly hinged to a massless rod AB of length l. The latter carries at its other end a particle B of mass m [fig. 3.18(a)]. Let us find the floor reaction on A and its motion on the O–xy plane.

Equations of Motion

For the relaxed system [fig. 3.18(b)], we introduce the following equilibrium coordinates:

$$q_1 = y_A \equiv y, \qquad q_2 = x_A \equiv x, \qquad q_3 = \phi, \tag{a}$$

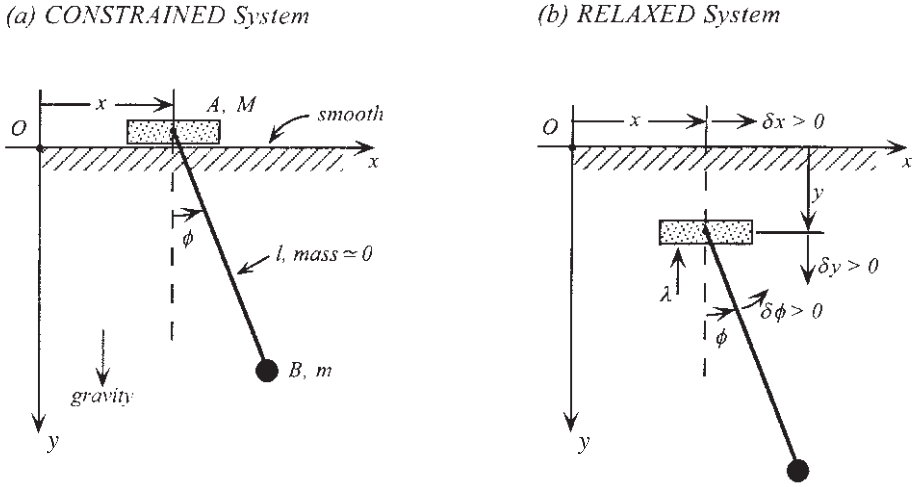

Figure 3.18 Principle of relaxation applied to a two DOF pendulum: (a) constrained, and (b) relaxed.

so that the floor constraint is simply $q_1 = 0$; that is, here $f \equiv n - m = 3 - 1 = 2$ DOF. Since the (inertial) coordinates of A and B are, respectively,

$$(x_A, y_A) = (x, y), \qquad (x_B, y_B) = (x + l\sin\phi, y + l\cos\phi), \tag{b}$$

the (double) kinetic energy of the system becomes, successively,

$$\begin{aligned} 2T &= M[(\dot{x}_A)^2 + (\dot{y}_A)^2] + m[(\dot{x}_B)^2 + (\dot{y}_B)^2] \\ &= \cdots = (M + m)(\dot{x})^2 + (M + m)(\dot{y})^2 + (ml^2)(\dot{\phi})^2 \\ &\quad + 2(ml\cos\phi)\dot{x}\dot{\phi} - 2(ml\sin\phi)\dot{y}\dot{\phi}, \end{aligned} \tag{c}$$

and so the *constrained* (double) kinetic energy is

$$2T\big|_{y=0} \equiv 2T_o = (M + m)(\dot{x})^2 + (m\,l^2)(\dot{\phi})^2 + 2(m\,l\cos\phi)\dot{x}\,\dot{\phi}. \tag{d}$$

Next, the relaxed virtual work $\delta' W$ equals, successively,

$$\begin{aligned} \delta' W &= (M\,g)\,\delta y + (m\,g)\,\delta y_B = (M\,g)\,\delta y + (m\,g)\,\delta(y + l\cos\phi) \\ &= [(M + m)g]\,\delta y + (-m\,g\,l\sin\phi)\,\delta\phi = Q_x\,\delta x + Q_y\,\delta y + Q_\phi\,\delta\phi, \end{aligned}$$

from which it follows that

$$Q_x = 0, \qquad Q_y = (M + m)g, \qquad Q_\phi = -m\,g\,l\sin\phi; \tag{e}$$

that is, Q_y could not have been obtained from the constrained virtual work

$$\delta' W\big|_{y=0} = (\delta' W)_o = (-m\,g\,l\sin\phi)\,\delta\phi. \tag{f}$$

Therefore, the Routh–Voss equations [which, due to the chosen special equilibrium relaxed coordinates (a), *decouple*] are

(i) $E_y(T) = Q_y + \lambda_y\big|_o$:

$$[(M+m)\ddot{y} - m\,l\sin\phi\,\ddot{\phi} - m\,l(\dot{\phi})^2\cos\phi]\big|_{y=0} = (M+m)g + \lambda_y, \tag{g}$$

or, finally,

$$\lambda_y \equiv \lambda = -m\,l[\sin\phi\,\ddot{\phi} + \cos\phi(\dot{\phi})^2] - (M+m)g; \tag{h}$$

(ii) $E_x(T) = Q_x\big|_o$: $[(M+m)\dot{x} + m\,l\cos\phi\,\dot{\phi}]^{\cdot}\big|_{y=0} = 0$

$$\Rightarrow (M+m)\dot{x} + (m\,l\,\dot{\phi})\cos\phi = \textit{constant} \tag{i}$$

(i.e., conservation of total linear momentum of system in the x-direction, since the total horizontal *external* force on the system vanishes).

(iii) $E_\phi(T) = Q_\phi\big|_o$: $(m\,l^2\dot{\phi} + m\,l\cos\phi\,\dot{x})^{\cdot} + m\,l\sin\phi\,\dot{x}\,\dot{\phi} = -m\,g\,l\sin\phi$,

or, after some simple manipulations,

$$\ddot{\phi} + (\cos\phi/l)\ddot{x} = -(g/l)\sin\phi; \tag{j}$$

and for *small* ϕ's, linearizing in ϕ, we obtain the *forced pendulum-type* equation:

$$\ddot{\phi} + (g/l)\phi = -(1/l)\ddot{x}. \tag{k}$$

SOLUTION

First, we solve the two kinetic (= reactionless) equations (i, j/k), plus *initial* conditions: $\{x_o, \phi_o, \dot{x}_o, \dot{\phi}_o\} \equiv IC$, and thus find $x = x(t, IC)$, $\phi = \phi(t, IC)$; and then we substitute these solutions into the kinetostatic equation (h) and obtain $\lambda = \lambda(t, IC)$. Clearly, thanks to the uncoupling of the equations, all difficulty lies in the first (kinetic) part.

REMARK

Use of the initial conditions, say $\phi(0) = 0$, $\dot{\phi}(0) = \omega_o$, $\dot{x}(0) = v_o$, in the constrained (i.e., actual) energy conservation equation $T_o + V_o = (T_o + V_o)_i$ (i for *initial*) where, as found earlier,

$$2T_o = (M+m)(\dot{x})^2 + (ml^2)(\dot{\phi})^2 + 2(ml\cos\phi)\dot{x}\dot{\phi}, \tag{l}$$

$$\Rightarrow 2T_{o,i} = (M+m)(v_o)^2 + (ml^2)(\omega_o)^2 + 2m\,l\,v_o\,\omega_o, \tag{m}$$

and

$$V_o = m\,g\,l(1-\cos\phi) = -m\,g\,l\cos\phi + \textit{constant}, \tag{n}$$

$$\Rightarrow V_{o,i} = -m\,g\,l + \textit{constant}, \tag{o}$$

yields the additional [to (i)] integral:

$$T_o - m\,g\,l\cos\phi = T_{o,i} - m\,g\,l = (\textit{another})\ \textit{constant}. \tag{p}$$

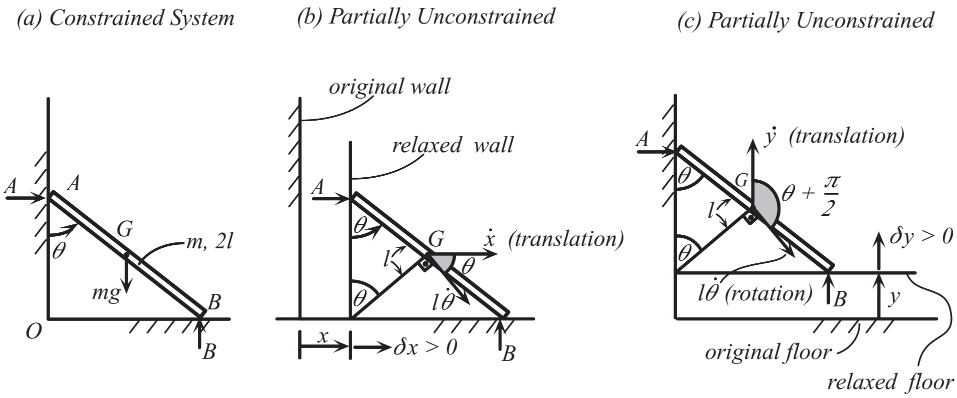

Figure 3.19 Plane motion of homogeneous ladder on smooth wall and floor: (a) constrained, and (b, c) partially constrained.

Example 3.7.3 *Relaxation of Constraints, External Reactions: Ladder* (Lawden, 1972, pp. 16–17, 54; also Osgood, 1937, pp. 322–325). A homogeneous bar (ladder) of length $2l$ and mass m, with one of its ends, A, constrained to move on a smooth vertical wall and the other, B, on a smooth horizontal floor [fig. 3.19(a)], is released, say with initial conditions (IC) $\theta(0) = \theta_o$, $\dot{\theta}(0) = 0$, and slides on the vertical plane $O{-}xy$. Let us find its equations of motion and external reactions: A from the wall and B from the floor, on the ladder. For algebraic simplicity, first, we relax only the wall and find A [fig. 3.19(b)]; then, we relax only the floor and find B [fig. 3.19(c)].

(i) *Wall relaxation*: Assume that the wall can translate horizontally, and let $x = x(t)$ be its generic distance/coordinate from the original wall (or from another fixed wall to its right, or left). With $q_1 = x$, $q_2 = \theta$, the wall constraint is $x = 0$, or $x = constant$; that is, $f \equiv n - m = 2 - 1 = 1$. Next, the (double) relaxed kinetic energy, by König's theorem ($G = center\ of\ mass$), is

$$
\begin{aligned}
2T &= (ml^2/3)(\dot{\theta})^2 + m\,{v_G}^2 \qquad \text{(invoking the law of cosines)} \\
&= (ml^2/3)(\dot{\theta})^2 + m[(\dot{x})^2 + l^2(\dot{\theta})^2 + 2l\,\dot{x}\,\dot{\theta}\cos\theta], \qquad \text{(a)}
\end{aligned}
$$

$$
\Rightarrow 2T\big|_{x=o} \equiv 2T_o = (4m\,l^2/3)(\dot{\theta})^2 = \textit{constrained (double) kinetic energy}; \qquad \text{(b)}
$$

and the total relaxed virtual work (to the first order in $\delta\theta$, and with A as an impressed force) is

$$
\begin{aligned}
\delta' W &= A\,\delta x + m\,g\,l[\cos\theta - \cos(\theta + \delta\theta)] \\
&= A\,\delta x + m\,g\,l[\cos\theta - (\cos\theta - \sin\theta\,\delta\theta + \cdots)] \\
&= A\,\delta x + (m\,g\,l\sin\theta)\,\delta\theta \;\Rightarrow\; Q_x = A,\; Q_\theta = m\,g\,l\sin\theta; \qquad \text{(c)}
\end{aligned}
$$

Q_θ can also be found from the constrained system potential $V_o = mgl\cos\theta$:

$$
Q_\theta = -\partial V_o/\partial\theta = -\partial(mgl\cos\theta)/\partial\theta = mgl\sin\theta. \qquad \text{(d)}
$$

In view of the above, the equations of motion are

(a) $\quad E_\theta(T)\big|_o = E_\theta(T_o) = Q_\theta\big|_o$:

$$
[(4l\ddot{\theta}/3) + \cos\theta\,\ddot{x})]\big|_o = (4l/3)\ddot{\theta} = g\sin\theta, \qquad \text{(e)}
$$

(b) $$E_x(T) = Q_x\big|_o:$$
$$m[\ddot{x} + (l\cos\theta)\ddot{\theta} - l\sin\theta(\dot{\theta})^2]\big|_o = m\,l[(\cos\theta)\ddot{\theta} - \sin\theta(\dot{\theta})^2] = A. \tag{f}$$

SOLUTION

First, we solve the kinetic equation (e) for $\theta = \theta(t, IC)$, and then insert that value into the kinetostatic equation (f), thus obtaining $A = A(t, IC)$, or $A = A(\theta, IC)$. Indeed, due to the well-known energetic identity $\dot{\theta}\ddot{\theta} = (d/dt)[(\dot{\theta})^2/2]$, (e) integrates to (ladder in contact with wall)

$$2l(\dot{\theta})^2/3 = g(\cos\theta_o - \cos\theta) \;\Rightarrow\; \dot{\theta} = \cdots, \ddot{\theta} = \cdots, \tag{g}$$

and substituting into (f) yields the wall reaction as a function of the angle θ (and the initial condition θ_o as parameter):

$$A = 3mg(3\cos\theta - 2\cos\theta_o)\sin\theta/4; \tag{h}$$

an expression that shows that the ladder loses contact with the wall when $\cos\theta = 2\cos\theta_o/3$; that is, when the end A has descended by $2/3$ of its initial height above the floor.

REMARK

Equation (g) also results from energy conservation (*i* for *initial*):

$$T_o + V_o = (T_o + V_o)_i \;\Rightarrow\; 2m\,l^2(\dot{\theta})^2/3 + m\,g\,l\cos\theta = 0 + m\,g\,l\cos\theta_o. \tag{i}$$

(ii) *Floor relaxation* [fig. 3.19(c)]: By König's theorem (and the theorem of cosines), we find

$$\begin{aligned} 2T &= (ml^2/3)(\dot{\theta})^2 + m{v_G}^2 \\ &= (ml^2/3)(\dot{\theta})^2 + m[(\dot{y})^2 + l^2(\dot{\theta})^2 - 2l\,\dot{y}\,\dot{\theta}\sin\theta] \\ &= (4ml^2/3)(\dot{\theta})^2 + m(\dot{y})^2 - (2m\,l\sin\theta)\dot{y}\,\dot{\theta}, \end{aligned} \tag{j}$$

$$\Rightarrow 2T\big|_{y=o} \equiv 2T_o = (4ml^2/3)(\dot{\theta})^2 = \textit{constrained (double) kinetic energy}; \tag{k}$$

and the total relaxed virtual work (to the first order in $\delta\theta$, and with B as an impressed force) is

$$\begin{aligned} \delta' W = B\,\delta y - mg\,\delta y - mg\,\delta(l\cos\theta) = (B - mg)\,\delta y + (mgl\sin\theta)\,\delta\theta \\ \Rightarrow Q_y = B - mg, \qquad Q_\theta = m\,g\,l\sin\theta. \end{aligned} \tag{l}$$

Hence, the equations of motion are

(a) $$E_\theta(T)\big|_o = E_\theta(T_o) = Q_\theta\big|_o:$$
$$[(ml^2\ddot{\theta}/3) + (ml^2\dot{\theta} - ml\dot{y}\sin\theta)^{\cdot} + ml\dot{\theta}\dot{y}\cos\theta]\big|_o = mgl\sin\theta,$$
$$\Rightarrow (4l/3)\ddot{\theta} = g\sin\theta \qquad \text{(as before)}, \tag{m}$$

(b) $$E_y(T) = Q_y\big|_o \quad [= Q_y\big|_o + \lambda, \text{ if we set } Q_y = -mg, \lambda = B]:$$
$$[m(\dot{y} - l\sin\theta\,\dot{\theta})^{\cdot}]\big|_o = B - mg$$
$$\Rightarrow -ml[(\sin\theta)\ddot{\theta} + \cos\theta(\dot{\theta})^2] = B - mg, \tag{n}$$

from which [and invoking (g, m)]

$$\begin{aligned} B &= -ml(3g\sin\theta/4\lambda)\sin\theta - ml\cos\theta[(3g\cos\theta_o/2l) - (3g\cos\theta/2l)] + mg \\ &= (mg/4)[-3(1-\cos^2\theta) + 6\cos^2\theta - 6\cos\theta\cos\theta_o] + mg \\ &= (mg/4)[1 - 6\cos\theta\cos\theta_o + 9\cos^2\theta] = \textit{function of } \theta \textit{ and } \theta_o(>0). \end{aligned} \tag{o}$$

For $\cos\theta = 2\cos\theta_o/3$ [loss of contact with the wall, from (h)], the above yields $B = mg/4$.

Example 3.7.4 *Relaxation of Constraints, Internal Reactions: Atwood's Machine.* Two particles, P_1 and P_2, of respective masses m and M, are connected by a light and inextensible string of negligible mass, that passes over a light, smooth, and fixed pulley [fig. 3.20(a)]. Let us find the accelerations of P_1 and P_2 and the (approximately constant) string tension S.

(i) *Original (constrained) system.* This well-known apparatus is subject to the holonomic and stationary constraint

$$x + (h - X) = constant \;\Rightarrow\; x = X \pm constant \;\Rightarrow\; \dot{x} = \dot{X} \quad and \quad \delta x = \delta X; \tag{a}$$

that is, $n = 1$. Choosing as Lagrangean coordinate $q_1 = q = x$, and with the earlier notation $(\ldots)_o \equiv (\ldots)\big|_{\text{constrained system}}$, we find

$$\begin{aligned} &2T_o = (m+M)(\dot{x})^2, \\ &\delta' W \Rightarrow (\delta' W)_o = (mg)\,\delta x - (Mg)\,\delta x = (m-M)g\,\delta x \;\Rightarrow\; Q_{x,o} = (m-M)g \\ &[= (mg - S)\,\delta x - (Mg - S)\,\delta x, \text{ had we included the constraint reaction}], \end{aligned} \tag{b}$$

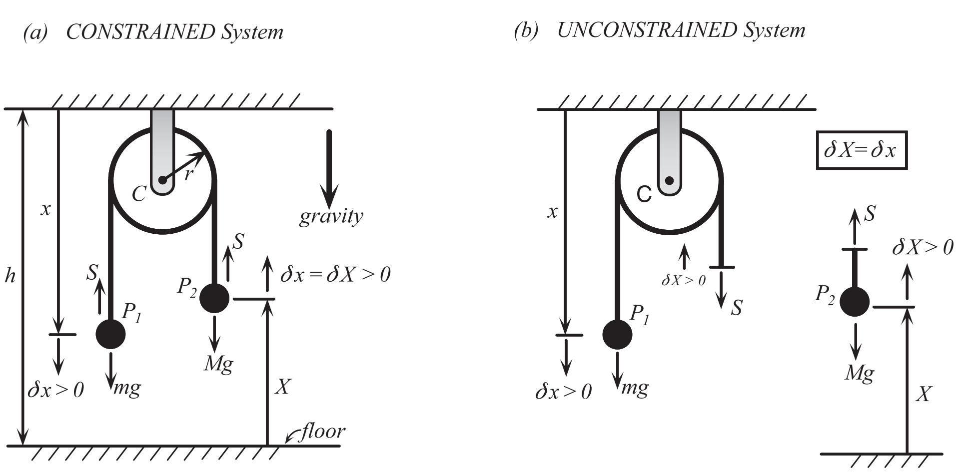

Figure 3.20 Atwood's machine: (a) original (constrained), and (b) relaxed.

and therefore Lagrange's sole (kinetic) equation is

$$(\partial T_o/\partial \dot{x})^{\cdot} - \partial T_o/\partial x = Q_{x,o}: \quad (m + M)\ddot{x} = (m - M)g, \tag{c}$$

from which [plus initial conditions $x(t_o) = x_o$, $\dot{x}(t_o) = v_o$] we obtain the motion $\ddot{x} = \cdots \Rightarrow x = x(t) = \cdots$. Finally, the constraint yields the P_2 motion $X = X(t) = \cdots$.

(ii) *Relaxed (unconstrained) system; calculation of string tension.*

(a) *Rubber-band version*. Since the constraint is the string's *inextensibility*, let us relax it by cutting it into *two separate inextensible substrings* [fig. 3.20(b)], in a manner reminiscent of the "free-body diagram" method ("cut principle"), so that $n = 2$. Choosing as Lagrangean coordinates $q_1 = x$ and $q_2 = X$, we have (now with S considered an impressed force)

$$2T = m(\dot{x})^2 + M(\dot{X})^2,$$
$$\delta' W = (mg - S)\,\delta x + (S - Mg)\,\delta X \;\Rightarrow\; Q_x = mg - S, \quad Q_X = S - Mg, \tag{d}$$

and therefore Lagrange's equations are

$$(\partial T/\partial \dot{x})^{\cdot} - \partial T/\partial x = Q_x: \qquad m\ddot{x} = mg - S, \tag{e}$$

$$(\partial T/\partial \dot{X})^{\cdot} - \partial T/\partial X = Q_X: \qquad m\ddot{X} = S - Mg. \tag{f}$$

These two, plus the constraint (a) (i.e., we return to the original, constrained, system), allow us to find $x(t) = \cdots, X(t)\cdots, S(t) = \cdots$. Eliminating S between (e, f), and then enforcing the constraint (a) $\rightarrow \ddot{x} = \ddot{X}$, produces the earlier equation (c); while utilizing the solution of the latter into either (e) or (f) [or eliminating $\ddot{x} = \ddot{X}$ between (e, f)] yields the sought reaction $S = [2mM/(m + M)]g$.

(b) *Lagrange's multiplier version*. Since the constraint is $f(x, X) \equiv x - X \pm$ *constant* $= 0$, and now, with x and X treated as independent (and S no longer considered an impressed force, but a reaction!), and taking $\delta x,\ \delta X > 0$,

$$\delta' W = (m\,g)\,\delta x - (M\,g)\,\delta X \;\Rightarrow\; Q_x = m\,g, \qquad Q_X = -M\,g, \tag{g}$$

the Routh–Voss equations, with multiplier λ, are

$$(\partial T/\partial \dot{x})^{\cdot} - \partial T/\partial x = Q_x + \lambda(\partial f/\partial x): \qquad m\ddot{x} = mg + \lambda(1), \tag{h}$$

$$(\partial T/\partial \dot{X})^{\cdot} - \partial T/\partial X = Q_X + \lambda(\partial f/\partial X): \qquad M\ddot{X} = -Mg + \lambda(-1). \tag{i}$$

From the above, clearly, $\delta' W_R \equiv R_x\,\delta x + R_X\,\delta X = \lambda(\delta x - \delta X)$ ($= 0$, upon enforcing the constraint $f = 0$; as LP requires). But also, by direct calculation [from fig. 3.20(b)], $\delta' W_R = -S\,\delta x + S\,\delta X = -S(\delta x - \delta X)$. Hence, it follows that $\lambda = -S(< 0)$, and so (h, i) coincide with (e, f), respectively.

REMARKS

(a) Had we written the above constraint as $f(x, X) \equiv X - x \pm$ *constant* $= 0$, the Routh–Voss equations would be

$$(\partial T/\partial \dot{x})^{\cdot} - \partial T/\partial x = Q_x + \lambda(\partial f/\partial x): \qquad m\ddot{x} = mg + \lambda(-1), \tag{j}$$

$$(\partial T/\partial \dot{X})^{\cdot} - \partial T/\partial X = Q_X + \lambda(\partial f/\partial X): \qquad M\ddot{X} = -Mg + \lambda(+1), \tag{k}$$

but since, now,

$$\delta' W_R \equiv R_x\,\delta x + R_X\,\delta X = (-\lambda)\,\delta x + (\lambda)\,\delta X = -\lambda(\delta x - \delta X) = -S(\delta x - \delta X),$$

we conclude that $\lambda = S(>0)$, and so (h, i) coincide with (j, k), respectively.

The lesson of this is that the multiplier adjusts its sign [and/or value, under *mathematically different but physically equivalent* forms of the constraint $f(x, X) = 0$], so that the final equations of motion retain their invariant physical content; and, of course, $\delta' W_R = 0$.

(b) In terms of the equilibrium coordinates $q_1 = x - X \pm constant$ and $q_2 = x(\Rightarrow dq_1 = 0,\ \dot{q}_1 = 0,\ \delta q_1 = 0)$, the constraint is simply $f \equiv q_1 = 0$ (*or a constant*). For such a choice, since now $x = q_2$ and $X = q_2 - q_1 \pm constant$ (no constraint enforcement yet!),

$$2T = m(\dot{x})^2 + M(\dot{X})^2 = \cdots = M(\dot{q}_1)^2 + (m+M)(\dot{q}_2)^2 - 2M\dot{q}_1\dot{q}_2, \tag{l}$$

$$\delta' W = (mg)\,\delta x - (Mg)\,\delta X = \cdots = (Mg)\,\delta q_1 + (m-M)g\,\delta q_2$$

$$\Rightarrow\ Q_1 = Mg, \qquad Q_2 = (m-M)g, \tag{m}$$

and so, in these coordinates, the Routh–Voss equations *decouple* naturally (upon enforcement of the constraint $q_1 = 0,\ \dot{q}_1 = 0, \ldots$ at the end) to a *kinetostatic* equation:

$$(\partial T/\partial \dot{q}_1)^{\cdot} - \partial T/\partial q_1 = Q_1 + \lambda(\partial f/\partial q_1):$$

$$-M\ddot{q}_2 = Mg + \lambda(+1), \qquad \text{or} \qquad M\ddot{x} = -Mg - \lambda, \tag{n}$$

and a *kinetic* one:

$$(\partial T/\partial \dot{q}_2)^{\cdot} - \partial T/\partial q_2 = Q_2 + \lambda(\partial f/\partial q_2):$$

$$(M+m)\ddot{q}_2 = (m-M)g + \lambda(0), \qquad \text{or} \qquad (M+m)\ddot{x} = (m-M)g, \tag{o}$$

($R_2 = 0$, since q_2 is unconstrained); and since

$$\delta' W_R \equiv R_1\,\delta q_1 + R_2\,\delta q_2 = \lambda\,\delta q_1 = -S(\delta x - \delta X), \tag{p}$$

it follows that now $\lambda = -S$, as observed earlier; that is, (n, o) coincide with (i, c), respectively.

Finally, we notice that $E_2(T_o) = E_2(T)\big|_o = (M+m)\ddot{q}_2 = (M+m)\ddot{x}$; while by (l), $2T\big|_o = 2T_o = (m+M)(\dot{q}_2)^2$, and therefore $E_1(T_o) = 0 \neq E_1(T)\big|_o = -M\ddot{q}_2$.

(iii) *Inclusion of rotary inertia of pulley*. If the pulley is assumed circular and homogeneous with radius r, mass μ, and radius of gyration k about its pin C, then it is not hard to show that the earlier results modify slightly to

$$\ddot{x} = (m-M)g/[(m+M) + \mu(k/r)^2], \quad \text{Left cable} = m(g - \ddot{x}),$$

$$\text{Right cable} = M(g + \ddot{x}). \tag{q}$$

Example 3.7.5 *PRC and the Determinacy versus Indeterminacy of Lagrange's Equations*. Let us consider a homogeneous sphere (or cylinder, or disk) of mass m and radius r, in plane motion (rolling or slipping) down a fixed inclined plane of slope with the horizontal θ (fig. 3.21). In terms of the "natural" Lagrangean coordinates of the problem $q_1 = y$ and $q_2 = x$ (coordinates of center of mass G)

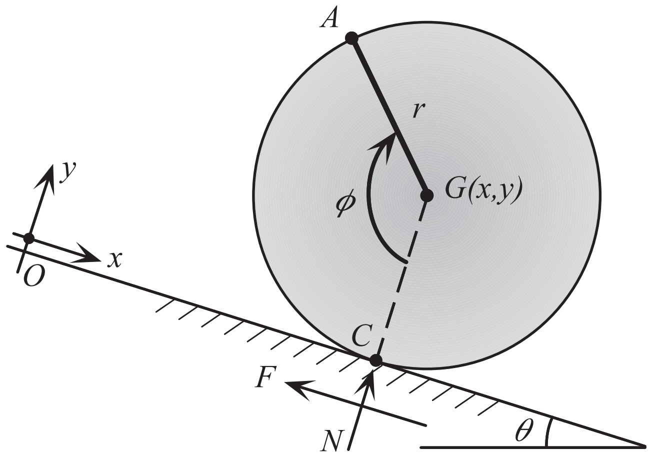

Figure 3.21 Plane motion (rolling/slipping) of a sphere down a fixed incline to illustrate the apparent indeterminacy of the Lagrangean equations. $O(rigin)$ chosen so that $arc(AC) = OC$; that is, during rolling $OC = r\phi$.

and $q_3 = \phi$, the constraints are

$$f_1 \equiv y - r = 0 \;\Rightarrow\; \delta f_1 = \delta y = 0 \qquad \text{(contact)}, \tag{a}$$

$$f_2 \equiv x - r\phi = 0 \;\Rightarrow\; \delta f_2 = \delta x - r\,\delta\phi = 0 \qquad \text{(if the sphere rolls)}. \tag{b}$$

By König's theorem, the (double) relaxed kinetic energy of the sphere, rolling or slipping, is

$$2T = m[(\dot{x})^2 + (\dot{y})^2] + I(\dot{\phi})^2 \tag{c}$$

(I = moment of inertia of sphere about axis through G, normal to plane of motion $= 2mr^2/5$). Now, and as is well known from the undergraduate dynamics treatment of this problem, we distinguish the following two cases.

(i) *The sphere rolls* $[|F/N| < \mu = \textit{coefficient of (static) friction}]$.

(a) *Relaxation of constraints; rubber-band approach.* Here, $f \equiv n - m = 3 - 2 = 1$. The virtual work of all forces is (no constraint enforcement!)

$$\begin{aligned}\delta' W &= m\,g\sin\theta\,\delta x - m\,g\cos\theta\,\delta y + N\delta y - F(\delta x - r\,\delta\phi)\\ &= Q_x\,\delta x + Q_y\,\delta y + Q_\phi\,\delta\phi\\ \Rightarrow Q_x &= m\,g\sin\theta - F, \qquad Q_y = N - m\,g\cos\theta, \qquad Q_\phi = rF.\end{aligned} \tag{d}$$

With eqs. (c, d) Lagrange's equations yield

$$(\partial T/\partial\dot{x})^{\cdot} - \partial T/\partial x = Q_x: \qquad m\ddot{x} = mg\sin\theta - F, \tag{e1}$$

$$(\partial T/\partial\dot{y})^{\cdot} - \partial T/\partial y = Q_y: \qquad m\ddot{y} = N - mg\cos\theta, \tag{e2}$$

$$(\partial T/\partial\dot{\phi})^{\cdot} - \partial T/\partial\phi = Q_\phi: \qquad I\ddot{\phi} = rF, \tag{e3}$$

and along with the constraints (a, b) they constitute a *determinate* system of five equations in the five unknown functions of time: x, y, ϕ, N, F.

(b) *Relaxation of constraints; Lagrangean multiplier approach.* Here, too, $f \equiv n - m = 3 - 2 = 1$. Now the virtual work of *all* forces is [recall eqs. (a, b); the work of the *reactions* F and N appears indirectly as virtual work of the multipliers]

$$\begin{aligned}\delta' W &= mg\sin\theta\,\delta x - mg\cos\theta\,\delta y + \lambda_1\,\delta f_1 + \lambda_2\,\delta f_2\\ &= (mg\sin\theta + \lambda_2)\,\delta x + (-mg\cos\theta + \lambda_1)\,\delta y + (-r\,\lambda_2)\,\delta\phi\\ &= (Q_x + R_x)\,\delta x + (Q_y + R_y)\,\delta y + (Q_\phi + R_\phi)\,\delta\phi \qquad \text{(f1)}\end{aligned}$$

$$\begin{aligned}\Rightarrow Q_x &= mg\sin\theta, & R_x &= \lambda_1(\partial f_1/\partial x) + \lambda_2(\partial f_2/\partial x) = \lambda_1(0) + \lambda_2(1) = \lambda_2,\\ Q_y &= -mg\cos\theta, & R_y &= \lambda_1(\partial f_1/\partial y) + \lambda_2(\partial f_2/\partial y) = \lambda_1(1) + \lambda_2(0) = \lambda_1,\\ Q_\phi &= 0, & R_\phi &= \lambda_1(\partial f_1/\partial\phi) + \lambda_2(\partial f_2/\partial\phi) = \lambda_1(0) + \lambda_2(-r) = -\lambda_2 r.\end{aligned} \qquad \text{(f2)}$$

With eqs. (c, h, i) the Routh–Voss equations yield

$$(\partial T/\partial\dot{x})^{\cdot} - \partial T/\partial x = Q_x + R_x: \qquad m\,\ddot{x} = mg\sin\theta + \lambda_2, \qquad \text{(g1)}$$

$$(\partial T/\partial\dot{y})^{\cdot} - \partial T/\partial y = Q_y + R_y: \qquad m\,\ddot{y} = -m\,g\cos\theta + \lambda_1, \qquad \text{(g2)}$$

$$(\partial T/\partial\dot{\phi})^{\cdot} - \partial T/\partial\phi = Q_\phi + R_\phi: \qquad I\ddot{\phi} = -\lambda_2 r, \qquad \text{(g3)}$$

and along with eqs. (a, b) they constitute a *determinate* system of five equations in the five unknowns: $x, y, \phi, \lambda_1, \lambda_2$. Upon calculating $\delta' W_R \equiv \lambda_1\,\delta f_1 + \lambda_2\,\delta f_2 = \lambda_1\,\delta y + \lambda_2(\delta x - r\,\delta\phi)$ and equating it with $\delta' W_R = (-F)\,\delta x + (N)\,\delta y + (F\,r)\,\delta\phi$, calculated from the relaxed free-body diagram of the sphere, we immediately conclude that $\lambda_1 = N$ and $\lambda_2 = -F$. [Also, a "mixed" relaxation approach; i.e., part rubber band (e.g., including the virtual work of N directly) and part multiplier (e.g., including the virtual work of F via a $\lambda_2\,\delta f_2$ term) would have resulted in completely equivalent results.]

(c) *Embedding of all constraints.* Enforcing both eqs. (a, b) into T and $\delta' W$ and keeping ϕ as the sole Lagrangean coordinate (i.e., $n = 1$, $m = 0$), we obtain

$$2T_o = m(r\dot{\phi})^2 + I(\dot{\phi})^2 = I_C(\dot{\phi})^2 \qquad \text{(h)}$$

($I_C \equiv I + mr^2$ = moment of inertia of sphere about axis through contact point C, normal to plane of motion $= 7mr^2/5$),

$$\delta' W_o = m\,g\sin\theta\,\delta x = Q_{\phi,o}\,\delta\phi \;\Rightarrow\; Q_{\phi,o} = mgr\sin\theta. \qquad \text{(i)}$$

With eqs. (h, i), the sole (kinetic) Lagrangean equation yields

$$I_C\,\ddot{\phi} = m\,g\,r\sin\theta, \qquad \text{or, explicitly,} \qquad \ddot{\phi} - (5g/7r)\sin\theta = 0, \qquad \text{(j)}$$

and with the initial conditions, say $\phi(0) = \phi_o$ and $\dot{\phi}(0) = \omega_o$, readily yields $\phi = \phi(t)$. Then, using the constraints (a, b), we obtain $x = x(t)$ and $y = y(t)$. However, to find the reactions N and F, we either have to apply relaxation [as in parts (i.a) and (i.b) of this example], or go *outside* Lagrangean mechanics and apply the Newton–Euler momentum principles to the sphere. If we *embed only some of the constraints* into

T and $\delta' W$, say eq. (a) but not eq. (b) (i.e., $n = 2$, $m = 1$), then

$$2T = m(\dot{x})^2 + I(\dot{\phi})^2, \tag{k}$$

$$\delta' W = (m g \sin\theta - F)\,\delta x + (F\,r)\,\delta\phi = Q_x\,\delta x + Q_\phi\,\delta\phi$$

$$\Rightarrow\; Q_x = m g \sin\theta - F, \qquad Q_\phi = rF, \tag{l}$$

and so Lagrange's equations yield

$$(\partial T/\partial\dot{x})^{\cdot} - \partial T/\partial x = Q_x: \qquad m\ddot{x} = m g \sin\theta - F, \tag{m1}$$

$$(\partial T/\partial\dot{\phi})^{\cdot} - \partial T/\partial\phi = Q_\phi: \qquad I\ddot{\phi} = r\,F, \tag{m2}$$

and along with the constraint (b) constitute a *determinate* system of three equations in the three unknowns: x, ϕ, F. To find y and N we can either use relaxation, as before, or resort to the Newton–Euler momentum principles.

In sum: as long as the sphere rolls, all Lagrangean approaches (zero, partial, or complete embedding of the holonomic constraints) result in determinate systems of equations for their variables.

(ii) *The sphere slips*. In this case, the sole constraint is eq. (a):

$$f_1 \equiv y - r = 0 \;\Rightarrow\; \delta f_1 = \delta y = 0 \qquad \text{(contact)}, \tag{a}$$

while eq. (b) is replaced by the *constitutive* equation

$$|F/N| = \mu, \qquad \text{or} \qquad |F| = \mu\,|N| \qquad [\mu = \textit{coefficient of (kinetic) friction}]. \tag{n}$$

(a) *Relaxation of constraints; rubber-band approach*. Here, $f \equiv n - m = 3 - 1 = 2$, and so T and $\delta' W$ are given by eqs. (c, d), respectively. Therefore, Lagrange's equations are again eqs. (e–g); and along with eqs. (a), (r) constitute a *determinate* system of five equations in the five unknowns: x, y, ϕ, N, F.

(b) *Relaxation of constraints; Lagrange's multiplier approach*. Here, too, $f \equiv n - m = 3 - 1 = 2$, T is given by eq. (c), while [in the spirit of eq. (f1), the normal *reaction* appears through a *multiplier*]

$$\begin{aligned}\delta' W &= m g \sin\theta\,\delta x - m g \cos\theta\,\delta y - F\,\delta x + (F\,r)\,\delta\phi + \lambda_1\,\delta f_1\\ &= (m g \sin\theta - F)\,\delta x + (\lambda_1 - m g \cos\theta)\,\delta y + (F\,r)\,\delta\phi,\end{aligned} \tag{o1}$$

that is,

$$\begin{aligned} Q_x &= m g \sin\theta - F, & R_x &= \lambda_1(\partial f_1/\partial x) = 0,\\ Q_y &= -m g \cos\theta, & R_y &= \lambda_1(\partial f_1/\partial y) = \lambda_1,\\ Q_\phi &= Fr, & R_\phi &= \lambda_1(\partial f_1/\partial\phi) = 0.\end{aligned} \tag{o2}$$

Hence, the Routh–Voss equations yield

$$(\partial T/\partial\dot{x})^{\cdot} - \partial T/\partial x = Q_x + R_x: \qquad m\,\ddot{x} = m g \sin\theta - F, \tag{p1}$$

$$(\partial T/\partial\dot{y})^{\cdot} - \partial T/\partial y = Q_y + R_y: \qquad m\ddot{y} = -m g \cos\theta + \lambda_1, \tag{p2}$$

$$(\partial T/\partial\dot{\phi})^{\cdot} - \partial T/\partial\phi = Q_\phi + R_\phi: \qquad I\ddot{\phi} = F\,r, \tag{p3}$$

and along with eqs. (a, n) constitute a *determinate* system of five equations in the five unknowns: x, y, ϕ, N, F. Here too we can easily show that $\lambda_1 = N$.

(c) *Embedding of all constraints*. Here, $f \equiv n - m = 2 - 1 = 1$. Enforcing eq. (a) into T and $\delta' W$ (= virtual work of all impressed forces), we have

$$2T = m(\dot{x})^2 + I(\dot{\phi})^2, \tag{q}$$

$$\delta' W = (m g \sin\theta - F)\,\delta x + (F\,r)\,\delta\phi = Q_x\,\delta x + Q_\phi\,\delta\phi \tag{r1}$$

$$\Rightarrow Q_x = m g \sin\theta - F, \qquad Q_\phi = r\,F, \tag{r2}$$

and so Lagrange's equations yield

$$(\partial T/\partial\dot{x})^{\cdot} - \partial T/\partial x = Q_x: \qquad m\,\ddot{x} = m g \sin\theta - F, \tag{s1}$$

$$(\partial T/\partial\dot{\phi})^{\cdot} - \partial T/\partial\phi = Q_\phi: \qquad I\ddot{\phi} = r\,F. \tag{s2}$$

But this is an *indeterminate* system, since we have generated *two* equations for our three unknowns: x, ϕ, F; and adding eq. (n) would introduce the extra unknown N.

As the handling of the previous cases has shown, such an apparent failure of the Lagrangean method to produce a "well-posed" problem is, generally, due to (i) our embedding of *all* (here holonomic) constraints into T and $\delta' W$, and (ii) the existence of *impressed forces that depend explicitly on (some or all of) the constraint reactions*. (Similar indeterminacy will result if we embed all *nonholonomic* constraints into T and $\delta' W$ via quasi variables.) To achieve determinacy, either we apply the principle of relaxation of the constraints; or we go outside of Lagrangean mechanics, usually applying the Newton–Euler principles of linear/angular momentum.

REMARK

Similar "indeterminacies" appear often in the Newton–Euler method; for example, by application of the momentum principles to an inappropriate free-body diagram. Here, determinacy is attained through the use of additional judiciously chosen *sub–free-body diagrams*, and subsequent application of the momentum principles to the resulting subbodies; for example, the well-known method of *sections*, of A. Ritter, in the statics of trusses.

Problem 3.7.1 *Determinacy versus Indeterminacy of Lagrange's Equations*. Consider a thin homogeneous bar AB of mass m and length $2l$, in plane motion, sliding on a fixed horizontal rough floor and a fixed vertical rough wall; in both, contacts with the same friction coefficient μ (fig. 3.22).

(i) Show that if we embed *all* (holonomic) constraints into T and $\delta' W$, and keep θ as the sole positional coordinate, then

$$2T_o = (4/3)ml^2(\dot{\theta})^2, \tag{a}$$

$$\delta' W_o = \left[m g l \sin\theta - 2l \sin\theta(\mu A) - 2l\cos\theta(\mu B)\right]\delta\theta, \tag{b}$$

and therefore the (kinetic) Lagrangean equation for θ is

$$4ml(d^2\theta/dt^2) = 3\left[mg\sin\theta - 2\sin\theta(\mu A) - 2\cos\theta(\mu B)\right]. \tag{c}$$

Is this a determinate problem for the equations and unknowns involved?

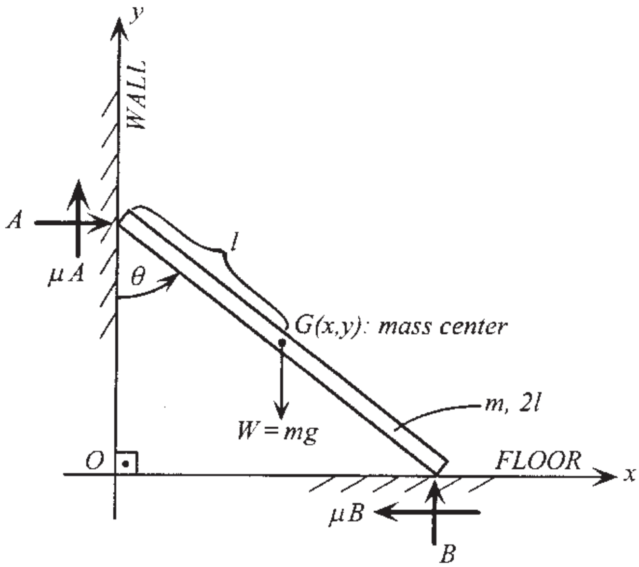

Figure 3.22 Plane sliding of homogeneous bar on rough wall and floor.

(ii) Show that if we apply the principle of relaxation, then (with positional coordinates $x, y =$ *Cartesian coordinates of bar's center of mass*, and θ)

$$2T = m[\dot{x}^2 + \dot{y}^2 + (1/3)l^2\dot{\theta}^2], \tag{d}$$

$$\begin{aligned}\delta' W &= (A - \mu B)\,\delta x + (B + \mu A - mg)\,\delta y \\ &\quad + l(B\sin\theta - A\cos\theta - \mu A\sin\theta - \mu B\cos\theta)\,\delta\theta,\end{aligned} \tag{e}$$

and therefore Routh–Voss equations yield

$$m\,\ddot{x} = A - \mu B, \tag{f}$$

$$m\,\ddot{y} = B + \mu A - m\,g, \tag{g}$$

$$(ml/3)\ddot{\theta} = B(\sin\theta - \mu\cos\theta) - A(\cos\theta + \mu\sin\theta). \tag{h}$$

Is this system of equations (plus constraints) determinate in its unknowns?

(iii) Show that by eliminating A and B from eq. (h), via eqs. (f, g), and the x, y, θ constraints, we obtain the kinetic θ-equation

$$2l(\mu^2 - 2)(d^2\theta/dt^2) + 6\mu l(d\theta/dt)^2 + 3g[(1 - \mu^2)\sin\theta - 2\mu\cos\theta] = 0. \tag{i}$$

Example 3.7.6 *Motion under Frictionless Unilateral Constraints.* Let us consider a holonomic n *DOF* system under the single unilateral constraint $f(t, q) \geq 0$. Then, two types of motion are possible:

(i) $f > 0$: The system escapes the constraint, and its equations of motion $E_k = Q_k$ $(k = 1, \ldots, n)$ hold until $f = 0$ vanishes.

(ii) $f = 0$: The system obeys the constraint, and its motion is governed by, say its Routh–Voss equations $E_k = Q_k + \lambda(\partial f/\partial q_k)$, to which we must also append $f(t, q) = 0$. As long as $f = 0$, we must also have

$$df/dt = \sum (\partial f/\partial q_k)(dq_k/dt) + \partial f/\partial t = 0 \qquad (\textit{velocity compatibility}), \tag{a}$$

$$\begin{aligned} d^2f/dt^2 = \sum (\partial f/\partial q_k)(d^2q_k/dt^2) + \sum\sum (\partial^2 f/\partial q_l \partial q_k)(dq_l/dt)(dq_k/dt) \\ + 2\sum (\partial^2 f/\partial t\,\partial q_k)(dq_k/dt) + \partial^2 f/\partial t^2 = 0 \\ (\textit{acceleration compatibility}). \end{aligned} \tag{b}$$

The $n + 1$ equations [Routh–Voss + eq. (b)] determine, at every instant for which $f = 0$, the n (d^2q/dt^2)'s and t. Further, in such a case, the n δq's may satisfy (a) $\delta f = 0$, or (b) $\delta f > 0$. In the former case, $\delta' W_R \equiv \lambda\,\delta f = 0$; in the latter, $\delta' W_R > 0$ (for every δq compatible with $\delta f > 0$) $\Rightarrow \lambda > 0$ (i.e., these (normal) reactions have a definite sense; for example, when a body B contacts an obstacle, the reaction from the latter to B must be directed *toward* B).

In sum: an $(f = 0)$-type of motion is physically meaningful as long as λ remains positive.

Finally, let us examine the following three possible cases (at a given instant):

(i) $f = 0$ *and* $df/dt \leq 0$: then we have impact ($\rightarrow$ chap. 4); the velocities at the end of it will be such that $df/dt \geq 0$.

(ii) $f = 0$ *and* $df/dt > 0$: then f *will* take positive values, and we are back to the case $f > 0$.

(iii) $f = 0$ *and* $df/dt = 0$: then we have one of the following two possibilities: (a) *constraint-preserving* motion $(f = 0)$, or (b) *escaping from it* $(f > 0)$. In the first case, we can calculate the (d^2q/dt^2)'s and $\lambda(> 0)$ from the Routh–Voss equations and eq. (b); while in the second, the (d^2q/dt^2)'s are found from $E_k = Q_k$, and then $d^2f/dt^2 \equiv a \geq 0$ (f, after being zero, will become later *positive*). Denoting by $\Delta(d^2q/dt^2)$ the (d^2q/dt^2)-difference in the above two cases, and since the Q's, q's, and (dq/dt)'s are the same for both, we obtain [with kinetic energy: $2T = \sum\sum M_{kl}(dq_k/dt)(dq_l/dt) = \textit{positive definite} \geq 0$]

$$\sum M_{kl}\Delta(d^2q_l/dt^2) = \lambda(\partial f/\partial q_k); \tag{c}$$

and similarly from eq. (b)

$$\sum (\partial f/\partial q_k)\Delta(d^2q_k/dt^2) = -a. \tag{d}$$

Combining the above we obtain

$$-a\lambda = \sum\sum M_{kl}\,\Delta(dq_k/dt)\Delta(dq_l/dt) = \textit{positive definite} \geq 0,$$

that is, since $\lambda > 0$, it follows that $a \leq 0$. Hence, cases (iii.a, b) are complementary to each other, and thus only *one of them will be physically acceptable*. For example, in a *constraint-preserving* motion $(f = 0)$, as long as $\lambda > 0$, an escape from it is impossible; such an escape will happen if λ, in going from $+$ to $-$, vanishes.

So, basically, the study of the escape from a unilateral constraint can be made equally well either (i) by looking at the sign of the multiplier λ in the constraint-preserving motion, or (ii) by examining if the escaping assumption leads to $f > 0$.

The general theory of unilateral constraints has been developed by the "French school" of Appell, Delassus, Pérès, Beghin, Bouligand, et al.; see, for example, Pérès (1953, pp. 301–328); also (alphabetically): Glocker (1995), Hamel (1949, pp. 219–220) for a(n implicitly applied) postulate of *continuous transition* from the state where a unilateral constraint holds to the one where that constraint is abandoned (moment of loss of contact, or separation), Zhuravlev et al. (1993).

3.8 EQUATIONS OF MOTION: SPECIAL FORMS

We have established the *four* basic types of equations of motion (§3.5); namely, the equations of

(i) *Lagrange* and *Routh–Voss* (holonomic variables, motion and reactions coupled);
(ii) *Maggi* (holonomic variables, motion and reactions uncoupled);
(iii) *Hamel* (nonholonomic variables, motion and reactions uncoupled); and
(iv) *Appell* (holonomic and/or nonholonomic variables, motion and reactions coupled and/or uncoupled).

Let us now see the various *special* forms that these equations assume, for special choices of the coordinates and forms of the constraints.

3.8.1 Holonomic Constraints

Holonomic Coordinates

If the (additional) constraints are

$$f_D \equiv f_D(t, q) = 0 \qquad \text{(in finite form)} \qquad [D = 1, \dots, m(< n)], \tag{3.8.1a}$$

or

$$\delta f_D \equiv \sum (\partial f_D/\partial q_k)\,\delta q_k \equiv \sum a_{Dk}\,\delta q_k = 0 \qquad \text{[in virtual (Pfaffian) form]}, \tag{3.8.1b}$$

then
(A) The *Routh–Voss* and *Appell* equations specialize, respectively, to

$$E_k \equiv d/dt(\partial T/\partial \dot{q}_k) - \partial T/\partial q_k = Q_k + \sum \lambda_D(\partial f_D/\partial q_k), \tag{3.8.2a}$$

$$E_k \equiv \partial S/\partial \ddot{q}_k = Q_k + \sum \lambda_D(\partial f_D/\partial q_k); \tag{3.8.2b}$$

or, compactly, with the convenient notation

$$M_k \equiv E_k - Q_k, \tag{3.8.2c}$$

$$M_k = \sum \lambda_D(\partial f_D/\partial q_k). \tag{3.8.2d}$$

(B) Let us find the corresponding *Maggi* equations. To embed (or absorb) equations (3.8.1a) into Lagrange's principle (LP), and following Hamel's choice of quasi variables, we introduce *n new "equilibrium" holonomic coordinates* $e \equiv \{e_k;\ k = 1, \dots, n\}$ by

$$e_D \equiv f_D(t, q) = 0, \qquad e_I \equiv f_I(t, q) \neq 0, \qquad e_{n+1} \equiv q_{n+1} = t,$$
$$(D = 1, \dots, m;\ I = m+1, \dots, n), \tag{3.8.3a}$$

where the $f_I(t,q)$ are *arbitrary*, but such that when the system (3.8.3a) is solved for the q's in terms of the e's, for each t (assuming this can be done uniquely), and the result is substituted back into the constraints $f_D(t,q)=0$, it *satisfies them identically*. Clearly, the $\partial e_k/\partial q_l$ $(\partial q_k/\partial e_l)$ are the holonomic counterparts of the Pfaffian coefficients $a_{kl}(A_{kl})$. We also notice that since

$$q_k = q_k(t,e) \Rightarrow \dot{q}_k = \sum (\partial q_k/\partial e_l)\dot{e}_l + \partial q_k/\partial t,$$

$$\ddot{q}_k = \sum (\partial q_k/\partial e_l)\ddot{e}_l + \textit{function of } e,\ \dot{e},\ t, \tag{3.8.3b}$$

we have [as expected, recalling (2.9.35 ff.)]

$$\partial q_k/\partial e_l = \partial \dot{q}_k/\partial \dot{e}_l = \partial \ddot{q}_k/\partial \ddot{e}_l = \cdots \equiv A_{kl}; \tag{3.8.3c}$$

and, similarly, we can show that

$$\partial e_k/\partial q_l = \partial \dot{e}_k/\partial \dot{q}_l = \partial \ddot{e}_k/\partial \ddot{q}_l = \cdots \equiv a_{kl}. \tag{3.8.3d}$$

Inverting (3.8.3a) results in $q_k = q_k(t,e)$ [$\Rightarrow q_k(t,e_I)$, upon enforcing $e_D=0$], from which we obtain the virtual system displacement representation [holonomic specialization of (2.11.4a ff.)]:

$$\delta q_k = \sum (\partial q_k/\partial e_l)\,\delta e_l \equiv \sum A_{kl}\,\delta e_l$$

$$\Big[= \sum (\partial q_k/\partial e_I)\,\delta e_I \equiv \sum A_{kI}\,\delta e_I,\ \text{upon enforcing } e_D=0 \Rightarrow \delta e_D = 0\Big]. \tag{3.8.3e}$$

Now, combining LP, in terms of these new coordinates; that is,

$$\begin{aligned}\sum M_k\,\delta q_k &= \sum M_k\Big(\sum (\partial q_k/\partial e_l)\,\delta e_l\Big) = \sum \Big(\sum (\partial q_k/\partial e_l) M_k\Big)\,\delta e_l \\ &= \sum \Big(\sum (\partial q_k/\partial e_D) M_k\Big)\,\delta e_D + \sum\Big(\sum (\partial q_k/\partial e_I) M_k\Big)\,\delta e_I = 0,\end{aligned} \tag{3.8.4a}$$

with the method of Lagrangean multipliers [in effect, rewriting the constraints $\delta e_D = 0$ as $1\cdot\delta e_D = 0$ (and $1\cdot\delta e_{n+1} = 1\cdot\delta q_{n+1} = 1\cdot\delta t = 0$), and viewing the $\delta e_I \neq 0$ as satisfying the constraints $0\cdot\delta e_I = 0$], yields

$$\sum\Big(\sum (\partial q_k/\partial e_D) M_k - \lambda_D\Big)\,\delta e_D + \sum\Big(\sum (\partial q_k/\partial e_I) M_k - 0\Big)\,\delta e_I = 0, \tag{3.8.4b}$$

from which, since now the δe_D and δe_I can be viewed as unconstrained, we obtain the following *holonomic* Maggi-type of equations:

$$\sum (\partial q_k/\partial e_D) M_k = \lambda_D \qquad (m\ \textit{kinetostatic}\ \text{equations}), \tag{3.8.4c}$$

$$\sum (\partial q_k/\partial e_I) M_k = 0 \qquad (n-m\ \textit{kinetic}\ \text{equationsno multipliers}); \tag{3.8.4d}$$

or, in extenso [recalling the notation (3.8.2c)],

$$\sum \big[(\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k\big](\partial q_k/\partial e_D) = \sum (\partial q_k/\partial e_D) Q_k + \lambda_D, \tag{3.8.4e}$$

$$\sum \big[(\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k\big](\partial q_k/\partial e_I) = \sum (\partial q_k/\partial e_I) Q_k. \tag{3.8.4f}$$

The kinetic equations (3.8.4d, f) can also be obtained as follows: substituting $\delta q_k = \sum (\partial q_k/\partial e_I)\,\delta e_I$ (i.e., constraints enforced) into LP we obtain, successively,

$$\sum M_k \delta q_k = \sum M_k \Big(\sum (\partial q_k/\partial e_I)\,\delta e_I\Big) = \sum \Big(\sum (\partial q_k/\partial e_I) M_k\Big)\,\delta e_I = 0,$$

from which, since the δe_I are arbitrary, (3.8.4d, f) result.

REMARKS

(i) In forming the expressions appearing in (3.8.4c–f) we start with the *unconstrained* T and Q_k's (i.e., as functions of both the e_D's and e_I's, etc.), then carry out all relevant differentiations, and then, at the end, set $e_D = 0$ (just as in the nonholonomic variable case); otherwise the $\partial/\partial e_D$-differentiations would be impossible.

Also, using (3.8.3a), we can express these holonomic Maggi equations, exclusively, either in terms of q, $\dot{q}$, t, or in terms of e, $\dot{e}$, t; whichever is more helpful/desirable.

(ii) In view of the kinematico-inertial identity $(\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k \equiv \partial S/\partial \ddot{q}_k$, eqs. (3.8.4c, d) can also be written, respectively, in the Appellian forms

$$\sum (\partial S/\partial \ddot{q}_k)(\partial q_k/\partial e_D) = \sum (\partial q_k/\partial e_D) Q_k + \lambda_D, \tag{3.8.4g}$$

$$\sum (\partial S/\partial \ddot{q}_k)(\partial q_k/\partial e_I) = \sum (\partial q_k/\partial e_I) Q_k. \tag{3.8.4h}$$

Special Case of Coordinates

An interesting special choice of e's, in (3.8.3e), is the following:

$$e_D \equiv f_D(t, q) = 0, \qquad e_I \equiv q_I \neq 0, \qquad e_{n+1} \equiv q_{n+1} = t,$$
$$(D = 1, \ldots, m; \quad I = m+1, \ldots, n); \tag{3.8.5a}$$

that is, the last $n - m$ $\dot{q}$'s are taken as the new *independent* Lagrangean coordinates. The above invert readily to $q_D = q_D(t, e_I) = q_D(t, q_I)$, $q_I = q_I$, and hence [recalling (2.11.9) ff., with $b_{DI} \to \partial q_D/\partial q_I$; also, by (3.8.6a) ff. and (3.8.11a) ff.] (3.8.4c, d) specialize, respectively, to

$$\sum (\partial q_k/\partial e_D) M_k = \sum (\partial q_{D'}/\partial e_D) M_{D'} + \sum (\partial q_I/\partial e_D) M_I$$
$$= \sum (\delta_{D'D}) M_{D'} + \sum (0) M_I = \lambda_D,$$

or, finally,

$$M_D = \lambda_D \qquad (m \ \ \textit{kinetostatic} \text{ equations}); \tag{3.8.5b}$$

and

$$\sum (\partial q_k/\partial e_I) M_k = \sum (\partial q_D/\partial e_I) M_D + \sum (\partial q_{I'}/\partial e_I) M_{I'}$$
$$= \sum (\partial q_D/\partial q_I) M_D + \sum (\delta_{I'I}) M_{I'} = 0,$$

or, finally,

$$M_I + \sum (\partial q_D/\partial q_I) M_D = 0 \qquad (n - m \ \ \textit{kinetic} \text{ equations}). \tag{3.8.5c}$$

In extenso, eqs. (3.8.5b, c) read, respectively,

$$E_D \equiv (\partial T/\partial \dot{q}_D)^{\cdot} - \partial T/\partial q_D = Q_D + \lambda_D, \tag{3.8.5d}$$

$$\begin{aligned} E_I + \sum (\partial q_D/\partial q_I) E_D \\ &\equiv [(\partial T/\partial \dot{q}_I)^{\cdot} - \partial T/\partial q_I] + \sum [(\partial T/\partial \dot{q}_D)^{\cdot} - \partial T/\partial q_D](\partial q_D/\partial q_I) \\ &= Q_I + \sum (\partial q_D/\partial q_I) Q_D. \end{aligned} \tag{3.8.5e}$$

Appellian forms of (3.8.5b, c) can be immediately written down [$E_D \equiv \partial S/\partial \ddot{q}_D$, $E_I \equiv \partial S/\partial \ddot{q}_I$]. We notice the following

(i) From $q_D = q_D(t, q_I)$, it follows that

$$\dot{q}_D = \sum (\partial q_D/\partial q_I)\dot{q}_I + \partial q_D/\partial t, \qquad \ddot{q}_D = \sum (\partial q_D/\partial q_I)\ddot{q}_I + \textit{function of } t,\ q_I,\ \dot{q}_I, \tag{3.8.6a}$$

and therefore [specialization of (3.8.3c)]

$$\partial q_D/\partial q_I = \partial \dot{q}_D/\partial \dot{q}_I = \partial \ddot{q}_D/\partial \ddot{q}_I = \cdots \equiv b_{DI}(t, q_I). \tag{3.8.6b}$$

Equations (3.8.5b–e) are the holonomic counterparts of *Hadamard*'s equations (see below); and to obtain the latter we simply replace in the above $\partial q_D/\partial q_I$ with $\partial \dot{q}_D/\partial \dot{q}_I \equiv b_{DI}$.

(ii) As hinted earlier, equations (3.8.5b, c) also result if we view the choice (3.8.5a) as the following special case of (3.8.3a):

$$\begin{aligned} &e_D \equiv f_D = q_D - q_D(t, q_I) = 0, \qquad e_I \equiv f_I = q_I \neq 0, \\ &\Rightarrow q_D = e_D + q_D(t, e_I), \qquad q_I = e_I. \end{aligned} \tag{3.8.7a}$$

Because then we have [recalling (2.11.9–12b), and with $D,\ D' = 1, \ldots, m$; $I,\ I' = m+1, \ldots, n$]

$(a_{kl}) \to (\partial e_k/\partial q_l) \equiv (\partial f_k/\partial q_l)$:

$$a_{DD'} = \delta_{DD'}, \qquad a_{DI} = -\partial q_D/\partial q_I, \qquad a_{ID} = 0, \qquad a_{II'} = \delta_{II'}; \tag{3.8.7b}$$

$(A_{kl}) \to (\partial q_k/\partial e_l)$:

$$A_{DD'} = \delta_{DD'}, \qquad A_{DI} = \partial q_D/\partial q_I, \qquad A_{ID} = 0, \qquad A_{II'} = \delta_{II'}; \tag{3.8.7c}$$

and so (3.8.4c, d) specialize to (3.8.5b, c), as shown there. For additional derivations, see (3.8.11a) ff. (Chaplygin-Hadamard eq's, a specialization of the Routh–Voss equations).

Special Case of Constraints

If the constraints (3.8.1a), $f_D = 0$, have the special "equilibrium" (or "adapted to the constraints") form $q_D = \textit{constant} \equiv q_{Do}$, then rewriting them as $f_D \equiv q_D - q_{Do} = 0$, we readily find

$$a_{Dk} \equiv \partial f_D/\partial q_k: \qquad a_{DD'} = \partial f_D/\partial q_{D'} = \delta_{DD'}, \qquad a_{DI} = \partial f_D/\partial q_I = 0, \tag{3.8.8a}$$

and so the Routh–Voss equations (3.8.2a, b) readily decouple to

$$E_D = Q_D + \lambda_D \quad (\textit{kinetostatic}), \qquad E_I = Q_I \quad (\textit{kinetic}). \tag{3.8.8b}$$

These are also the corresponding Maggi equations: for, in this case, we have (3.8.8a) and

$$a_{ID} = 0, \quad a_{II'} = \delta_{II'}; \qquad A_{DD'} = \delta_{DD'}, \quad A_{DI} = 0, \quad A_{ID} = 0, \quad A_{II'} = \delta_{II'}; \tag{3.8.8c}$$

and therefore [recalling (3.3.10)]

$$I_D = \sum A_{kD} E_k = \sum A_{D'D} E_{D'} + \sum A_{ID} E_I = \sum \delta_{D'D} E_{D'} + 0 = E_D, \tag{3.8.8d}$$

$$I_I = \sum A_{kI} E_k = \sum A_{DI} E_D + \sum A_{I'I} E_{I'} = 0 + \sum \delta_{I'I} E_{I'} = E_I; \tag{3.8.8e}$$

and similarly for the impressed forces [recalling (3.4.3b ff.)].

Equations (3.8.8b) are sometimes taken as the analytical expression of the principle of relaxation of the constraints; see, for example, Butenin (1971, pp. 70–71), Symon (1971, pp. 370–372).

Further, if we are not interested in calculating the reactions λ_D, then with

$$T = T(t, q, \dot{q}) = T(t, q_D = q_{Do}, q_I, \dot{q}_D = 0, \dot{q}_I) \equiv T_o(t, q_I, \dot{q}_I)$$
$$\equiv T_o\text{: } \textit{constrained} \text{ (or reduced) kinetic energy,}$$

and since (expanding à la Taylor, and with some obvious calculus notations)

$$T = T_o + \sum (\partial T/\partial q_D)_o q_D + \sum (\partial T/\partial \dot{q}_D)_o \dot{q}_D + \cdots, \tag{3.8.9a}$$

from which

$$(\partial T/\partial q_I)_o = \partial T_o/\partial q_I \qquad [(\partial T/\partial q_D)_o \neq \partial T_o/\partial q_D = 0], \tag{3.8.9b}$$

$$(\partial T/\partial \dot{q}_I)_o = \partial T_o/\partial \dot{q}_I \qquad [(\partial T/\partial \dot{q}_D)_o \neq \partial T_o/\partial \dot{q}_D = 0], \tag{3.8.9c}$$

we obtain the following rule: *In the case of holonomic variables and constraints, if we are only interested in the motion (kinetic problem), we may embed/enforce the constraints q_D = constant into $T \to T_o$ right from the start*; that is, the second of (3.8.8b) can be replaced by $E_I(T_o) \equiv (\partial T_o/\partial \dot{q}_I)^{\cdot} - \partial T_o/\partial q_I = Q_I$; and this saves considerable labor (see also the holonomic Hamel equations below).

(C) Let us find the corresponding *Hamel* equations. In this case (recalling 2.9–2.12), $\theta_k \to e_k$ (*holonomic coordinates*), $\omega_D \equiv \dot{e}_D \equiv \dot{f}_D = 0$, $\omega_I \equiv \dot{e}_I \equiv \dot{f}_I \neq 0$, *the corresponding Hamel coefficients* $\gamma^k{}_{..}$ *vanish* [$\Rightarrow I_k = E_k{}^*(T^*)$], and so Hamel's equations (3.5.19a ff.) reduce to

$$d/dt(\partial T^*/\partial \dot{e}_D) - \partial T^*/\partial e_D = \sum (\partial q_k/\partial e_D) Q_k + \lambda_D \qquad (\textit{kinetostatic} \text{ eqs.}), \tag{3.8.10a}$$

$$d/dt(\partial T^*/\partial \dot{e}_I) - \partial T^*/\partial e_I = \sum (\partial q_k/\partial e_I) Q_k \qquad (\textit{kinetic} \text{ eqs.}), \tag{3.8.10b}$$

where $T^* = T[t, q(t, e), \dot{q}(t, e, \dot{e})] \equiv T^*(t, e, \dot{e})$; that is, these equations are none other than *Maggi's equations* (3.8.4e, f), respectively, *but expressed in the e-variables.*

We also notice that, here, too, we can replace the $n - m$ kinetic equations (3.8.10b) with

$$d/dt(\partial T^*{}_o/\partial \dot{e}_I) - \partial T^*{}_o/\partial e_I = \sum (\partial q_k/\partial e_I) Q_k \qquad (\textit{kinetic} \text{ eqs.}), \tag{3.8.10c}$$

or, compactly, $E_I(T^*{}_o) = \Theta_I$, where

$$T^*{}_o = T^*[t, e_D = 0,\ e_I \neq 0,\ \dot{e}_D = 0,\ \dot{e}_I \neq 0] \equiv T^*{}_o(t, e_I, \dot{e}_I):$$
constrained kinetic energy T^*.

Thus, for the earlier special choice $q_D = q_D(t, q_I),\ q_I = q_I$, eqs. (3.8.10c) reduce to

$$E_I(T_o) \equiv d/dt(\partial T_o/\partial \dot{q}_I) - \partial T_o/\partial q_I = Q_{Io}, \tag{3.8.10d}$$

where

$$T_o \equiv T[t, q_D(t, q_I), q_I;\ \dot{q}_D(t, q_I, \dot{q}_I), \dot{q}_I] \equiv T_o(t, q_I, \dot{q}_I):\ \text{constrained kinetic energy } T,$$

$$Q_{Io} \equiv Q_I + \sum b_{DI} Q_D:\ \textit{constrained impressed force}$$
[a special case of $\Theta_I$recall (3.8.6b)].

Equations (3.8.10d) are none other than the earlier equations (3.8.5e), but expressed in the q_I's only.

Unfortunately, if the constraints $\dot{q}_D = \dot{q}_D(t, q_I, \dot{q}_I)$ are nonholonomic, then eqs. (3.8.10d) do *not* hold; that is, $E_I(T_o) \neq Q_{Io}$ (or even Q_I). It is shown later that, in such a case, if we use the velocity constraints to eliminate the $m\ \dot{q}_D$'s from the kinetic energy and impressed forces, and then apply these constrained, or reduced, quantities to multiplierless Lagrangean equations, like (3.8.10d), we will get *incorrect* equations of motion; other equations apply there (special cases of Hamel equations: equations of *Chaplygin* and *Voronets*) — equations that, if the velocity constraints are holonomic, reduce to (3.8.10d).

3.8.2 Nonholonomic Constraints

Holonomic Variables

(A) *Equations of Chaplygin–Hadamard.* Let us find the equations of motion corresponding to the additional, possibly nonholonomic, special Pfaffian constraints (2.11.9 ff.)

$$\dot{q}_D = \sum b_{DI}\dot{q}_I + b_D \ \Rightarrow\ \delta q_D = \sum b_{DI}\,\delta q_I. \tag{3.8.11a}$$

In view of the importance of this topic for the entire Lagrangean kinetics, we present *four* derivations.

(i) *Via Lagrange's principle (LP)*. With the help of the earlier notation (3.8.2c), $M_k \equiv E_k - Q_k$, LP specializes, successively, to

$$0 = \sum M_k\,\delta q_k = \sum M_D\,\delta q_D + \sum M_I\,\delta q_I = \sum M_D\Big(\sum b_{DI}\,\delta q_I\Big) + \sum M_I\,\delta q_I$$
$$= \sum \Big(M_I + \sum b_{DI} M_D\Big)\,\delta q_I, \tag{3.8.11b}$$

from which, since the $n - m\ \delta q_I$'s are independent, we obtain the $n - m$ kinetic equations (Chaplygin, 1895, publ. 1897; Hadamard, 1895)

$$M_I + \sum b_{DI} M_D = 0, \qquad \text{or} \qquad E_I + \sum b_{DI} E_D = Q_I + \sum b_{DI} Q_D \quad (\equiv Q_{Io}), \tag{3.8.11c}$$

or, in extenso, (a) in the (more common) *Lagrangean* form:

$$[(\partial T/\partial \dot{q}_I)^{\cdot} - \partial T/\partial q_I] + \sum [(\partial T/\partial \dot{q}_D)^{\cdot} - \partial T/\partial q_D] b_{DI} \\ = Q_I + \sum b_{DI} Q_D \equiv Q_{Io}; \tag{3.8.11d}$$

and, in view of the kinematico-inertial identity $(\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k \equiv \partial S/\partial \ddot{q}_k$, (b) in the *Appellian* form:

$$\partial S/\partial \ddot{q}_I + \sum b_{DI}(\partial S/\partial \ddot{q}_D) = Q_I + \sum b_{DI} Q_D \equiv Q_{Io}. \tag{3.8.11e}$$

(ii) *Via Lagrangean multipliers*. Multiplying each constraint (3.8.11a), $\delta q_D - \sum b_{DI}\delta q_I = 0$, with the multiplier $-\lambda_D$ and adding them to LP, we obtain, successively,

$$0 = \sum M_k\, \delta q_k = \sum M_k\, \delta q_k + \sum (-\lambda_D)\Big(\delta q_D - \sum b_{DI}\, \delta q_I\Big) \\ = \cdots = \sum (M_D - \lambda_D)\, \delta q_D + \sum \Big(M_I + \sum \lambda_D b_{DI}\Big)\, \delta q_I, \tag{3.8.11f}$$

from which, since now the δq_D's and δq_I's *can* be treated as independent, we obtain the two groups of equations

$$M_D = \lambda_D \qquad \text{or} \qquad E_D = Q_D + \lambda_D, \tag{3.8.11g}$$

$$M_I = -\sum \lambda_D b_{DI} \qquad \text{or} \qquad E_I = Q_I - \sum b_{DI}\lambda_D; \tag{3.8.11h}$$

and eliminating the m λ_D's among them [solving (3.8.11g) for λ_D and substituting in (3.8.11h), etc.], we recover the Hadamard equations (3.8.11c). Equations (3.8.11g) can be considered as the *kinetostatic complement of the kinetic equations* (3.8.11c).

(iii) *As a specialization of the Routh–Voss equations*. We recall [(2.11.9) ff.] that the special constraint form (3.8.11a) [(2.11.9)ff.] can be viewed as a Pfaffian system with the following coefficients:

$$a_{DD'} = \delta_{DD'}, \qquad a_{DI} = \partial\omega_D/\partial \dot{q}_I = -b_{DI} \qquad (\text{and } a_{ID} = 0,\ a_{II'} = \delta_{II'}). \tag{3.8.11i}$$

In view of these values, the general Routh–Voss equations

$$E_k \equiv (\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k = Q_k + \sum \lambda_D a_{Dk} \tag{3.8.11j}$$

specialize to the two groups:

$$\text{(a)} \quad E_D = Q_D + \sum \lambda_{D'} a_{D'D} = Q_D + \sum \lambda_{D'}\delta_{DD'} = Q_D + \lambda_D, \\ \Rightarrow R_D = \sum a_{D'D}\lambda_{D'} = \sum \lambda_{D'}\delta_{DD'} = \lambda_D, \tag{3.8.11k}$$

$$\text{(b)} \quad E_I = Q_I + \sum \lambda_D a_{DI} = Q_I + \sum \lambda_D(-b_{DI}) = Q_I - \sum \lambda_D b_{DI} \\ = Q_I - \sum b_{DI}(E_D - Q_D)$$

$$\Rightarrow E_I + \sum b_{DI} E_D = Q_I + \sum b_{DI} Q_D \quad (\equiv Q_{Io}), \tag{3.8.11c}$$

$$\Rightarrow R_I = \sum a_{DI}\lambda_D = -\sum b_{DI}\lambda_D \quad \Big[= -\sum b_{DI}(E_D - Q_D)\Big]. \tag{3.8.11l}$$

Here, too, note that *the multipliers and their interpretation depend on the particular form of the constraints*; that is, if the constraints of a problem are written in two physically equivalent but analytically different forms, the associated multipliers (and, hence, kinetic and kinetostatic equations) will be equivalent but different; although, for theoretical purposes (and because both are components of the same constraint reaction vector, in configuration space), we may designate them both by λ_D. We repeat (§ 3.5), what holds all these descriptions together is the variational equation of Lagrange (LP), plus his method of multipliers (relaxation principle). It is these fundamental *invariant* tools that allow us to interrelate and compare the particular multiplier/constraint representation and equations of motion of the same problem.

(iv) *As a specialization of the Maggi equations.* In this case [recalling (3.8.7c)]

$$A_{DD'} = \delta_{DD'}, \qquad A_{DI} = \partial\dot{q}_D/\partial\dot{q}_I = b_{DI}, \qquad A_{ID} = 0, \qquad A_{II'} = \delta_{II'}. \quad (3.8.11\text{m})$$

Therefore, (a) Maggi's *kinetostatic* equations, $I_D - \Theta_D \equiv \sum A_{kD}M_k = \Lambda_D(= \lambda_D)$, specialize to

$$I_D - \Theta_D = \sum A_{D'D}M_{D'} + \sum A_{ID}M_I = \cdots = M_D + 0 = \lambda_D, \quad \text{i.e., } E_D = Q_D + \lambda_D, \tag{3.8.11n}$$

while (b) Maggi's *kinetic* equations, $I_I - \Theta_I \equiv \sum A_{kI}M_k = 0$, specialize to

$$I_I - \Theta_I = \sum A_{DI}M_D + \sum A_{I'I}M_{I'} = \sum b_{DI}M_D + M_I = 0,$$
$$\text{i.e., } E_I + \sum b_{DI}E_D = Q_I + \sum b_{DI}Q_D.$$

REMARKS

(i) In these equations, T and the Q's (and S) are functions of all n $\dot{q}$'s ($\dot{q}$'s and $\ddot{q}$'s); that is, *no constraints are to be enforced in them yet*. That has to wait until all differentiations have been carried out. The $n - m$ equations (3.8.11o) plus the m constraints (3.8.11a) constitute a system of n equations for the n $q_k(t)$. Had we enforced the constraints in the Appellian

$$S = S(t, q, \dot{q}_D, \dot{q}_I, \ddot{q}_D, \ddot{q}_I) = S[t, q, \dot{q}_D(t, q, \dot{q}_I), \dot{q}_I, \ddot{q}_D(t, q, \dot{q}_I, \ddot{q}_I), \ddot{q}_I]$$
$$\equiv S_o(t, q, \dot{q}_I, \ddot{q}_I) = S_o\text{: \textit{constrained Appellian}}, \tag{3.8.12a}$$

then LP would have given us, not (3.8.11e), but since

$$\delta I = \sum (\partial S/\partial\ddot{q}_k)\, \delta q_k = \sum (\partial S_o/\partial\ddot{q}_I)\, \delta q_I, \tag{3.8.12b}$$

even though $\partial S/\partial\ddot{q}_I \neq \partial S_o/\partial\ddot{q}_I$ and

$$\delta' W = \sum Q_k \delta q_k = \sum \Big(Q_I + \sum b_{DI}Q_D\Big)\, \delta q_I \equiv \sum Q_{Io}\, \delta q_I, \tag{3.8.12c}$$

finally [and this is *Appell's original form of 1899* (scleronomic case), 1900 (rheonomic case)],

$$\partial S_o/\partial\ddot{q}_I = Q_{Io}. \tag{3.8.12d}$$

As stressed earlier, no such simplification (and preservation of form of the equations of motion) holds for $T \to T_o$-based equations.

(ii) Here, too, we first solve the kinetic equations (+ constraints + initial conditions) and obtain the motion $q_k(t)$. Then, the kinetostatic equations immediately yield

$$\begin{aligned}\lambda_D &= E_D(t, q, \dot{q}, \ddot{q}) - Q_D(t, q, \dot{q}) \\ &= \cdots = \textit{known function of time (and initial conditions)}.\end{aligned} \tag{3.8.12e}$$

(iii) What is important here is not so much Hadamard's equations themselves, but the *method(s)* for obtaining them. These latter can be applied even for nonholonomic variable constraints: for example,

$$\omega_D = \sum f_{DI}(t, q)\omega_I + f_D(t, q) \;\Rightarrow\; \delta\theta_D = \sum f_{DI}(t, q)\,\delta\theta_I, \tag{3.8.12f}$$

(i.e., $\delta\theta_D, \delta\theta_I \neq 0$), and for both Hamel- and Appell-type equations of motion.

(iv) Finally, we point out (what is probably amply clear by now) that if the constraints (3.8.11a) are holonomic ($b_{DI} = \partial q_D/\partial q_I$), then the Hadamard equations reduce to the earlier equations (3.8.5c, e).

Problem 3.8.1 *The Korteweg Equations.* Consider a system subject to the m, possibly nonholonomic, Pfaffian constraints

$$\sum a_{Dk}\,\delta q_k = 0 \qquad [k = 1, \ldots, n;\; D = 1, \ldots, m(< n);\; \textit{rank}\ (a_{Dk}) = m], \tag{a}$$

and hence, assuming, as usual, *ideal* constraints, that is,

$$\sum R_k\,\delta q_k = 0, \tag{b}$$

having the Routh–Voss equations of motion

$$M_k \equiv E_k - Q_k \equiv (\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k - Q_k = \sum \lambda_D a_{Dk} \quad (= R_k). \tag{c}$$

Show that the above imply that the following $(m+1) \times (m+1)$ determinant

$$\begin{vmatrix} R_1 & \ldots & R_m & \vdots & R_{m+1}\,\delta q_{m+1} + \cdots + R_n\,\delta q_n \\ \cdots & \cdots & \cdots & \vdots & \cdots\cdots \\ a_{11} & \ldots & a_{1m} & \vdots & a_{1,m+1}\,\delta q_{m+1} + \cdots + a_{1n}\,\delta q_n \\ \cdots & \cdots & \cdots & \vdots & \cdots\cdots \\ a_{m1} & \ldots & a_{mm} & \vdots & a_{m,m+1}\,\delta q_{m+1} + \cdots + a_{mm}\,\delta q_n \end{vmatrix} \tag{d}$$

vanishes, *identically*—that is, for arbitrary $\delta q_I \equiv (\delta q_{m+1}, \ldots, \delta q_n)$; and that this, in turn, thanks to well-known determinant properties, leads to the following $n - m$ determinantal equations:

$$\begin{vmatrix} R_1 & \ldots & R_m & \vdots & R_{m+1} \\ a_{11} & \ldots & a_{1m} & \vdots & a_{1,m+1} \\ \cdots & \cdots & \cdots & \vdots & \cdots \\ a_{m1} & \ldots & a_{mm} & \vdots & a_{m,m+1} \end{vmatrix} = 0, \ldots, \begin{vmatrix} R_1 & \ldots & R_m & \vdots & R_n \\ a_{11} & \ldots & a_{1m} & \vdots & a_{1n} \\ \cdots & \cdots & \cdots & \vdots & \cdots \\ a_{m1} & \ldots & a_{mm} & \vdots & a_{mn} \end{vmatrix} = 0; \tag{e}$$

and, conversely, (e) lead to the vanishing of (d).

REMARKS

(i) In view of (c), eqs. (e) constitute a set of $n - m$ *kinetic* equations, which, along with the m constraints (a) [in velocity form; i.e., $\sum a_{Dk}\dot{q}_k + a_D = 0$], make up a determinate system for the n $q_k(t)$.

(ii) Equations (d, e) seem to be due to Korteweg (1899, pp. 135–136, eqs. (8)]; and also Quanjel (1906, pp. 268–269, eqs. (16)). See also Routh (1891, vol. I, pp. 34–35).

HINT

The m $\delta q_D \equiv (\delta q_1, \ldots, \delta q_m)$, obtained from (a) as functions of the $n - m$ $\delta q_I \equiv (\delta q_{m+1}, \ldots, \delta q_n)$, must satisfy (b) for *arbitrary* δq_I.

Nonholonomic variables

(A) *Equations of Chaplygin (or Tschaplygine)*. Let us find the form that Hamel's equations assume when the, generally nonholonomic, Pfaffian constraints have the special scleronomic/stationary form

$$\dot{q}_D = \sum b_{DI}\dot{q}_I \;\Rightarrow\; \delta q_D = \sum b_{DI}\,\delta q_I, \tag{3.8.13a}$$

where (a) $b_{DI} = b_{DI}(q_{m+1}, \ldots, q_n)$ [a specialization of (3.8.11a)], and (b) $\partial T/\partial q_D = 0 \;\Rightarrow\; T = T(t, q_I, \dot{q}_D, \dot{q}_I)$; that is, *the m* q_D's *do not appear either in the constraint coefficients or in the original (unconstrained) kinetic energy*.

Such "Chaplygin systems" can be viewed as the following special Hamel case:

$$\omega_D \equiv \dot{q}_D - \sum b_{DI}\dot{q}_I = 0, \qquad \omega_I \equiv \dot{q}_I \neq 0, \tag{3.8.13b}$$

which invert immediately to

$$\dot{q}_D = \omega_D + \sum b_{DI}\omega_I, \qquad \dot{q}_I = \omega_I. \tag{3.8.13c}$$

Equations (3.8.13b, c) readily show that here (a_{kl}) and (A_{kl}) have their earlier special forms:

$$a_{DD'} = \delta_{DD'}, \quad a_{DI} = \partial\omega_D/\partial\dot{q}_I = -b_{DI}, \quad a_{ID} = 0, \quad a_{II'} = \delta_{II'}; \tag{3.8.13d}$$

$$A_{DD'} = \delta_{DD'}, \qquad A_{DI} = \partial\dot{q}_D/\partial\omega_I = b_{DI}, \qquad A_{ID} = 0, \qquad A_{II'} = \delta_{II'}. \tag{3.8.13e}$$

From the above we find, successively, the following specializations for the various Hamel equation terms ($D, D', D'', \ldots = 1, \ldots, m$; $I, I', I'', \ldots = m+1, \ldots, n$):

(i) $\quad \gamma^I{}_{I'I''} = 0$ (notice that $\theta_I \equiv q_I$; i.e., θ_I is a holonomic coordinate), (3.8.13f)

(ii) $$\gamma^D{}_{II'} = \sum\sum (\partial a_{Dk}/\partial q_r - \partial a_{Dr}/\partial q_k) A_{kI} A_{rI'}$$
$$= \sum\sum [\partial(-b_{DI''})/\partial q_{I'''} - \partial(-b_{DI'''})/\partial q_{I''}]\delta_{I''I}\,\delta_{I'''I'}$$
$$= \sum\sum (\partial b_{DI'''}/\partial q_{I''} - \partial b_{DI''}/\partial q_{I'''})\,\delta_{I''I}\,\delta_{I'''I'}$$
$$= \sum (\partial b_{DI'}/\partial q_{I''} - \partial b_{DI''}/\partial q_{I'})\,\delta_{I''I} \;=\; \partial b_{DI'}/\partial q_I - \partial b_{DI}/\partial q_{I'}$$
$$\equiv -t^D{}_{II'} = t^D{}_{I'I}: \textit{Chaplygin coefficients} \text{ (ex. 2.12.1, Remarks).} \tag{3.8.13g}$$

(iii) By chain rule (and recalling that $\partial\dot{q}_k/\partial\omega_r = A_{kr}$),

$$\partial T^*/\partial\omega_D = \sum (\partial T/\partial\dot{q}_k)(\partial\dot{q}_k/\partial\omega_D) = \sum (\partial T/\partial\dot{q}_k) A_{kD}$$
$$= \sum (\partial T/\partial\dot{q}_{D'}) A_{D'D} + \sum (\partial T/\partial\dot{q}_I) A_{ID}$$
$$= \sum (\partial T/\partial\dot{q}_{D'})(\delta_{D'D}) + \sum (\partial T/\partial\dot{q}_I)(0)$$
$$= (\partial T/\partial\dot{q}_D)\big|_{\text{enforcing of constraints}} \equiv (\partial T/\partial\dot{q}_D)_o = \textit{function of } t, q_I, \dot{q}_I. \tag{3.8.13h}$$

(iv) Substituting the above into the correction term $-\Gamma_I$, (3.3.12a), we find, successively,

$$-\Gamma_I \equiv \sum\sum \gamma^k{}_{I\alpha}(\partial T^*/\partial\omega_k)\omega_\alpha \rightarrow \sum\sum \gamma^D{}_{II'}(\partial T^*/\partial\omega_D)\omega_{I'},$$

or, finally,

$$-\Gamma_I \rightarrow -\Gamma_{Io} \equiv \sum\sum t^D{}_{I'I}(\partial T/\partial\dot{q}_D)_o\,\dot{q}_{I'}$$
$$= \sum\sum (\partial b_{DI'}/\partial q_I - \partial b_{DI}/\partial q_{I'})(\partial T/\partial\dot{q}_D)_o\,\dot{q}_{I'}$$
$$= \textit{function of } t, q_I, \dot{q}_I \; (\textit{quadratic in the } \dot{q}_I). \tag{3.8.13i}$$

(v) With

$$T = T(t, q_I, \dot{q}_D, \dot{q}_I) = T[t, q_I, \dot{q}_D(t, q_I, \dot{q}_I), \dot{q}_I]$$
$$= T_o(t, q_I, \dot{q}_I) \equiv T_o = \textit{Chaplygin constrained kinetic energy}, \tag{3.8.13j}$$

we have

$$\partial T^*/\partial\omega_I \rightarrow \partial T_o/\partial\dot{q}_I; \tag{3.8.13k}$$

$$\partial T^*/\partial\theta_I \equiv \sum(\partial T^*/\partial q_k)(\partial\dot{q}_k/\partial\omega_I) = \sum (\partial T^*/\partial q_k) A_{kI}$$
$$= \sum (\partial T^*/\partial q_D) A_{DI} + \sum (\partial T^*/\partial q_{I'}) A_{I'I}$$
$$= \sum (\partial T^*/\partial q_D) b_{DI} + \sum (\partial T^*/\partial q_{I'})\,\delta_{I'I}$$
$$= \sum (0) b_{DI} + \sum (\partial T^*/\partial q_{I'})\,\delta_{I'I} = \partial T^*/\partial q_I \rightarrow \partial T_o/\partial q_I. \tag{3.8.13l}$$

(vi) Recalling (3.8.12c) and (3.8.13b)

$$\delta' W = \sum \Theta_k\,\delta\theta_k = \sum \Theta_I\,\delta\theta_I = \sum Q_{Io}\,\delta q_I. \tag{3.8.13m}$$

(vii) And so,

$$E_I{}^*(T^*) \to E_I(T_o) \equiv (\partial T_o/\partial \dot{q}_I)^{\cdot} - \partial T_o/\partial q_I \quad [\neq E_I(T)]. \tag{3.8.13n}$$

Substituting all these findings into the kinetic Hamel equations (3.5.21d) [or into the central equation (3.6.8 ff.)], we obtain the $n - m$ (kinetic) equations of *Chaplygin*, in the following equivalent forms:

$$\begin{aligned}
(\partial T_o/\partial \dot{q}_I)^{\cdot} - \partial T_o/\partial q_I + \sum\sum (\partial b_{DI'}/\partial q_I - \partial b_{DI}/\partial q_{I'})(\partial T/\partial \dot{q}_D)_o\, \dot{q}_{I'} \\
\equiv (\partial T_o/\partial v_I)^{\cdot} - \partial T_o/\partial q_I + \sum\sum t^D{}_{I'I}(\partial T/\partial v_D)_o\, v_{I'} \\
\equiv (\partial T_o/\partial v_I)^{\cdot} - \partial T_o/\partial q_I - \sum\sum t^D{}_{II'}(\partial T/\partial v_D)_o\, v_{I'} \\
\equiv E_I(T_o) - \Gamma_{Io} = Q_I + \sum b_{DI} Q_D \equiv Q_{Io}.
\end{aligned} \tag{3.8.13o}$$

REMARKS

(i) Chaplygin's equations (1895, publ. 1897) are the earliest (special Hamel-type) equations of motion of nonholonomic systems in terms of T_o (and T) and in special nonholonomic *system* variables. Chaplygin obtained these equations by expressing the T-gradients appearing in his earlier Chaplygin–Hadamard equations (3.8.11c, d) in terms of T_o-gradients [by applying chain rule to (3.8.13j)—an instructive exercise in partial differentiations that the readers are urged to reproduce for themselves]. The importance of (3.8.13o) is primarily theoretical and conceptual, not so much practical: these equations, presented at a time when nonholonomic dynamics was at its infancy, clearly demonstrated that, in general, $E_I(T_o) \neq Q_{Io}$ (or even Q_I); that is, *unless the constraints are holonomic* ($t^D{}_{I'I} = 0$), *or some other special case in which* $\Gamma_{Io} = 0$ *(for some or all* $I = m+1, \ldots, n$), *the ordinary Lagrangean equations do not hold for the constrained, or reduced, system*. [To the best of our knowledge, the first proof of this basic fact, for the special case of a *convex body rolling, under gravity, on a rough plane*, is due to C. Neumann (1885). But Chaplygin's treatment was, simultaneously, more general and easier to follow. See also appendix 3.A1.] Failure to observe this rule led, in the 1890s, to a number of erroneous equations of motion, even by some of the better mathematicians/mechanicians of that epoch (see examples below).

(ii) By their very structure, Chaplygin's equations are only *kinetic*; that is, since $\partial T_o/\partial \dot{q}_D = 0$, they do *not* allow for constraint reaction calculations. However, these $n - m$ equations, when solved, allow us to determine the $n - m$ functions $q_I = q_I(t)$ without recourse to the constraints (3.8.13a); the latter are then used to calculate the m $q_D = q_D(t)$.

(iii) Contrary to Hamel's equations, Chaplygin's equations involve *both* T and T_o, an apparent formal drawback; but, in return, they do not require a(ny) constraint matrix inversion [i.e., $(a_{kl}) \to (A_{kl})$], just the given *nonsquare* matrix (b_{DI}), instead of two.

For ad hoc chain-rule derivations of Chaplygin's equations, see, for example, Butenin (1971, pp. 196–212), Dobronravov (1970, pp. 87–106), Lur'e (1968, pp. 397 ff.), Neimark and Fufaev (1972, pp. 106–108, 110–112); also Kil'chevskii (1977, pp. 162–166).

Problem 3.8.2 *Generalized Chaplygin Equations*. Show that in terms of the *general independent quasi velocities* ω_I defined by (in terms of the helpful notation $\dot{q}_k \equiv v_k$)

$$v_I = \sum B_{II'}\omega_{I'}, \qquad B_{II'} = B_{II'}(q_{m+1}, \ldots, q_n) \equiv B_{II'}(q_I), \tag{a}$$

Chaplygin's equations take the [slightly more general than (3.8.13o)] form

$$(\partial T^*{}_o/\partial\omega_I)^{\cdot} - \partial T^*{}_o/\partial\theta_I + \sum\sum(\partial B_{kI'}/\partial\theta_I - \partial B_{kI}/\partial\theta_{I'})(\partial T/\partial\dot{q}_k)_o\,\omega_{I'} = Q^*{}_{Io}, \quad \text{(b)}$$

where:

(i) $$v_k = \sum l_{kI}\omega_I, \qquad l_{kI} = l_{kI}(q_{m+1},\ldots,q_n) \equiv l_{kI}(q_I),$$
$$v_D = \sum\sum(b_{DI}B_{II'})\omega_{I'} \equiv \sum l_{DI}\omega_I, \qquad v_I = \sum B_{II'}\omega_{I'} \equiv \sum l_{II'}\omega_{I'}; \quad \text{(c)}$$

(ii) $$T = T(t, q_I, v_k) = T\Big(t, q_I, v_k = \sum l_{kI}\omega_I\Big) \equiv T^*{}_o(t, q_I, \omega_I) \equiv T^*{}_o; \quad \text{(d)}$$

(iii) $$\partial T^*{}_o/\partial\theta_I \equiv \sum(\partial T^*{}_o/\partial q_{I'})(\partial v_{I'}/\partial\omega_I) = \sum(\partial T^*{}_o/\partial q_{I'})B_{I'I}, \quad \text{(e)}$$
$$\partial l_{kI'}/\partial\theta_I \equiv \sum(\partial l_{kI'}/\partial q_{I''})(\partial v_{I''}/\partial\omega_I) = \sum(\partial l_{kI'}/\partial q_{I''})B_{I''I}; \quad \text{(f)}$$

(iv) $$\delta' W \equiv \sum Q_k\,\delta q_k = \cdots = \sum Q^*{}_{Io}\,\delta\theta_I \qquad (\text{definition of } Q^*{}_{Io}); \quad \text{(g)}$$
$$\Rightarrow Q^*{}_{Io} = \sum B_{I'I}\Big(Q_{I'} + \sum b_{DI'}Q_D\Big) \equiv \sum B_{I'I}\,Q_{I'o}. \quad \text{(h)}$$

[See also Neimark and Fufaev (1972, pp. 110–112). In there, on pp. 106–108, eqs. (3.16, 17, 19), it seems that a *tilde* ($\sim$) should be placed on the impressed force Q_I.]

Equations of Voronets (or *Woronetz*). Let us find the form that Hamel's equations assume when the, generally nonholonomic, Pfaffian constraints have the special rheonomic/nonstationary form (again, with $v_k \equiv \dot{q}_k$)

$$v_D = \sum b_{DI}v_I + b_D \;\Rightarrow\; \delta q_D = \sum b_{DI}\,\delta q_I, \quad (3.8.14a)$$

where $b_{DI} = b_{DI}(t, q_1,\ldots,q_n) \equiv b_{DI}(t, q)$, $b_D = b_D(t, q_1,\ldots,q_n) \equiv b_D(t, q)$; or the Hamel form

$$\omega_D \equiv v_D - \sum b_{DI}v_I - b_D = 0, \qquad \omega_I \equiv v_I \neq 0; \quad (3.8.14b)$$

with its (easy to obtain) inverse

$$v_D = \omega_D + \sum b_{DI}\omega_I + b_D, \qquad v_I = \omega_I. \quad (3.8.14c)$$

Clearly, since (3.8.14a–c) are a generalization of the Chaplygin constraints (3.8.13a–c), the associated equations of Voronets, derived below, will constitute a generalization of those of Chaplygin (3.8.13o); but a special case of those of Hamel.

Equations (3.8.14b, c) readily show that, here, the transformation matrices (a_{kl}) and (A_{kl}) have their earlier special forms:

$$a_{DD'} = \delta_{DD'}, \quad a_{DI} = \partial\omega_D/\partial v_I = -b_{DI}, \quad a_{ID} = 0, \quad a_{II'} = \delta_{II'}; \quad (3.8.14d)$$
$$A_{DD'} = \delta_{DD'}, \quad A_{DI} = \partial v_D/\partial\omega_I = b_{DI}, \quad A_{ID} = 0, \quad A_{II'} = \delta_{II'}. \quad (3.8.14e)$$

From the above, and the results of ex. 2.12.1 and prob. 2.12.1 ff., we find, successively, the following specializations for the various Hamel equation terms (D, D', D'', $\ldots = 1, \ldots, m; I, I', I'', \ldots = m+1, \ldots, n$):

(i) $$\gamma^I{}_{I'I''} = 0 \qquad (\theta_I \equiv q_I;\ \text{i.e., } \theta_I \text{ is a holonomic coordinate!}). \tag{3.8.14f}$$

(ii)
$$\begin{aligned}
\gamma^D{}_{II'} &= \sum\sum (\partial a_{Dk}/\partial q_r - \partial a_{Dr}/\partial q_k) A_{kI} A_{rI'} \\
&= \cdots = \Big[\partial b_{DI'}/\partial q_I + \sum b_{D'I}(\partial b_{DI'}/\partial q_{D'})\Big] \\
&\qquad - \Big[\partial b_{DI}/\partial q_{I'} + \sum b_{D'I'}(\partial b_{DI}/\partial q_{D'})\Big] \\
&\equiv \partial b_{DI'}/\partial(q_I) - \partial b_{DI}/\partial(q_{I'}) \\
&= t^D{}_{I'I} + \sum [b_{D'I}(\partial b_{DI'}/\partial q_{D'}) - b_{D'I'}(\partial b_{DI}/\partial q_{D'})] \\
&\equiv w^D{}_{I'I} = -w^D{}_{II'} \qquad \text{(recalling ex. 2.12.1),}
\end{aligned} \tag{3.8.14g}$$

$$\begin{aligned}
\gamma^D{}_{I,n+1} \equiv \gamma^D{}_I &= \cdots = \Big[\partial b_D/\partial q_I + \sum b_{D'I}(\partial b_D/\partial q_{D'})\Big] \\
&\qquad - \Big[\partial b_{DI}/\partial t + \sum b_{D'}(\partial b_{DI}/\partial q_{D'})\Big] \\
&\equiv \partial b_D/\partial(q_I) - \partial b_{DI}/\partial(q_{n+1}) \\
&= -t^D{}_{I,n+1} + \sum [b_{D'I}(\partial b_D/\partial q_{D'}) - b_{D'}(\partial b_{DI}/\partial q_{D'})] \\
&\equiv -w^D{}_{I,n+1} \equiv -w^D{}_I \qquad \text{(recalling prob. 2.12.2);}
\end{aligned} \tag{3.8.14h}$$

or they can be read off from the transitivity equations below (which, incidentally, show clearly that the only surviving γ's are the $\gamma^D{}_{II'}$ and $\gamma^D{}_I$)

$$\begin{aligned}
d(\delta\theta_D) - \delta(d\theta_D) &= \sum\sum \gamma^D{}_{II'}\, d\theta_{I'}\, \delta\theta_I + \sum \gamma^D{}_I\, \delta\theta_I \\
&= -\sum\sum w^D{}_{II'}\, dq_{I'}\, \delta q_I - \sum w^D{}_I\, \delta q_I.
\end{aligned} \tag{3.8.14i}$$

(iii) With

$$\begin{aligned}
T &= T(t, q, v_D, v_I) = T[t, q, v_D(t, q, v_I), v_I] \\
&= T_o(t, q, v_I) \equiv T_o = \textit{Voronets constrained kinetic energy} \\
&\quad \text{[a generalization of Chaplygin's (3.8.13j), and a special case of } T^*(t, q, \omega)],
\end{aligned} \tag{3.8.14j}$$

we find, successively,

$$\partial T^*/\partial\omega_I \to \partial T_o/\partial v_I \quad [\neq (\partial T/\partial v_I)_o \equiv p_{Io} = \textit{function of } t, q, v_I]; \tag{3.8.14k}$$

$$\partial T^*/\partial\omega_D = \text{[repeating steps as in (3.8.13h)]} = (\partial T/\partial v_D)_o = \textit{function of } t, q, v_I; \tag{3.8.14l}$$

$$\begin{aligned}
\partial T^*/\partial\theta_I &\equiv \sum (\partial T^*/\partial q_k)(\partial v_k/\partial\omega_I) = \sum (\partial T^*/\partial q_k) A_{kI} \\
&= \sum (\partial T^*/\partial q_D) A_{DI} + \sum (\partial T^*/\partial q_{I'}) A_{I'I} \\
&= \sum (\partial T^*/\partial q_D) b_{DI} + \sum (\partial T^*/\partial q_{I'})\, \delta_{I'I} \\
&= \partial T^*/\partial q_I + \sum b_{DI}(\partial T^*/\partial q_D),
\end{aligned} \tag{3.8.14m}$$

that is,

$$\partial T^*/\partial\theta_I \to \partial T_o/\partial q_I + \sum b_{DI}(\partial T_o/\partial q_D) \equiv \partial T_o/\partial(q_I) \qquad \text{(symbolic derivative).} \tag{3.8.14n}$$

(iv) Substituting the above into the correction term $-\Gamma_I$, (3.3.12a), we find, successively,

$$\begin{aligned}-\Gamma_I &\equiv \sum\sum \gamma^b{}_{I\alpha}(\partial T^*/\partial\omega_b)\omega_\alpha \to \sum\sum \gamma^D{}_{II'}(\partial T^*/\partial\omega_D)\omega_{I'} + \sum \gamma^D{}_I(\partial T^*/\partial\omega_D)\\ &= \cdots = -\sum\sum w^D{}_{II'}(\partial T/\partial v_D)_o\, v_{I'} - \sum w^D{}_I(\partial T/\partial v_D)_o \equiv -\Gamma_{Io}.\end{aligned} \tag{3.8.14o}$$

(v) Proceeding as in (3.8.13m),

$$\delta' W = \sum \Theta_k\, \delta\theta_k = \sum \Theta_I\, \delta\theta_I = \sum \left(Q_I + \sum b_{DI} Q_D\right) \delta q_I \equiv \sum Q_{Io}\, \delta q_I. \tag{3.8.14p}$$

Substituting all these findings into the kinetic Hamel equations (3.5.21d) [or into the central equation (3.6.9 or 11), with (3.8.14i); namely, the Hamel approach; *or* into (3.6.8 or 12), but with $d(\delta q_D) - \delta(dq_D) = \sum\sum w^D{}_{II'}\, dq_{I'}\, \delta q_I + \sum w^D{}_I\, \delta q_I$, $d(\delta q_I) - \delta(dq_I) = 0$; namely the Suslov approach (see also ex. 3.8.1, below)], we obtain the $n - m$ (kinetic) equations of *Voronets*, in the following equivalent forms [recalling (3.8.13o)]:

$$\begin{aligned}&(\partial T_o/\partial \dot q_I)^{\cdot} - \partial T_o/\partial q_I - \sum b_{DI}(\partial T_o/\partial q_D)\\ &\qquad - \sum\sum w^D{}_{II'}(\partial T/\partial \dot q_D)_o \dot q_{I'} - \sum w^D{}_I(\partial T/\partial \dot q_D)_o\\ &\qquad \equiv (\partial T_o/\partial v_I)^{\cdot} - \partial T_o/\partial(q_I) - \sum\sum w^D{}_{II'} p_{Do}\, v_{I'} - \sum w^D{}_I p_{Do}, \text{[since } v_{n+1} = 1]\\ &\qquad \equiv E_I(T_o) - \sum b_{DI}(\partial T_o/\partial q_D) - \Gamma_{Io}\\ &\qquad \equiv E_{(I)}(T_o) - \Gamma_{Io} = Q_I + \sum b_{DI} Q_D \equiv Q_{Io}.\end{aligned} \tag{3.8.14q}$$

SPECIALIZATIONS, REMARKS

(i) If the constraints are *catastatic* (i.e., $b_D = 0$), then, as (3.8.14h) readily shows, the $w^D{}_I$ reduce to $\partial b_{DI}/\partial t$; and if they are *stationary*, or scleronomic, they vanish.

(ii) If the Voronets constraints reduce to those of Chaplygin, then (3.8.14q) reduce to (3.8.13o).

(iii) We believe that the above derivation of the Voronets equations (i.e., deductively from those of Hamel) is their clearest presentation in the entire dynamics literature in English; and one of the few anywhere.

(iv) By looking at the constraint forms (3.8.11a), (3.8.14a), we can state that the *Voronets equations bear the same relation to those of Hamel that the Hadamard equations bear relative to those of Maggi* [although it took about 20 years for that to be recognized: Hamel (1924)]. Schematically:

Maggi (1896, 1901, 1903) → Hadamard (1895)
Hamel (1903, 1904) → Voronets (1901).

Problem 3.8.3 *Generalized Voronets' Equations.* Formulate Voronets' equations in the *general quasi velocities* ω_I defined by

$$v_I = \sum B_{II'}\,\omega_{I'} + B_I, \tag{a}$$

where the coefficients $B_{II'}$ and B_I are assumed functions of *all* the q's and t; and the ν_k are constrained, as in (3.8.14a):

$$v_D = \sum b_{DI}\,v_I + b_D. \tag{b}$$

(2C) *Equations in General Nonholonomic Variables; when the nonholonomic constraints have the general form* $[D' = 1, \ldots, m\ (< n), k = 1, \ldots, n]$:

$$\sum a_{D'k}\omega_k + a_{D'} = 0 \ \Rightarrow\ \sum a_{D'k}\,\delta\theta_k = 0, \tag{3.8.15a}$$

where (i) the coefficients $a_{D'k}$ and $a_{D'}$ are functions of all the q's and t [and *rank* $(a_{D'k}) = m$], and (ii) the v's and ω's are related by

$$\omega_k \equiv \sum a_{kl}v_l + a_k \neq 0 \ \Leftrightarrow\ v_l = \sum A_{lk}\omega_k + A_l \neq 0, \tag{3.8.15b}$$

instead of the earlier holonomic variable forms $\omega_D \equiv \sum a_{Dk}\nu_k + a_D = 0$, etc..

Applying the general methods expounded in §3.5, we may proceed in one of the following two ways: either we

(i) *Adjoin* the constraints (3.8.15a) to LP in the ω variables (3.5.18),

$$\sum I_k\,\delta\theta_k = \sum \Theta_k\,\delta\theta_k, \tag{3.8.15c}$$

with m Lagrangean multipliers $\lambda_{D'}$, and thus obtain the n *coupled* Routh–Voss type of equations:

$$I_k = \Theta_k + \sum \lambda_{D'}a_{D'k}, \tag{3.8.15d}$$

where the inertia terms I_k have one of the following basic forms:

$$I_k = \sum (\partial v_l/\partial\omega_k)E_l \equiv \sum A_{lk}[(\partial T/\partial\dot{q}_l)^{\cdot} - \partial T/\partial q_l] \qquad \text{(Maggi)}, \tag{3.8.15e}$$

$$= (\partial T^*/\partial\omega_k)^{\cdot} - \partial T^*/\partial\theta_k + \sum\sum \gamma^b{}_{k\alpha}(\partial T^*/\partial\omega_b)\omega_\alpha \qquad \text{(Hamel)}, \tag{3.8.15f}$$

$$= \partial S^*/\partial\dot{\omega}_k \equiv \sum A_{lk}(\partial S/\partial\ddot{q}_l) \qquad \text{(Appell)}; \tag{3.8.15g}$$

and which, along with the m constraints (3.8.15a) and the n transformation equations (3.8.15b), constitute a system of $n + m + n = 2n + m$ equations for the $2n + m$ unknown functions $q_k(t)$, $\omega_k(t)$, $\lambda_{D'}(t)$; or we

(ii) *Introduce new quasi variables* θ', $\omega' \equiv d\theta'/dt$ by

$$\omega_{D'} \equiv \sum a_{D'k}\,\omega_k + a_{D'} \quad (= 0) \ \Rightarrow\ \delta\theta_{D'} \equiv \sum a_{D'k}\,\delta\theta_k \quad (= 0), \tag{3.8.15h}$$

$$\omega_{I'} \equiv \sum a_{I'k}\,\omega_k + a_{I'} \quad (\neq 0) \ \Rightarrow\ \delta\theta_{I'} \equiv \sum a_{I'k}\,\delta\theta_k \quad (\neq 0), \tag{3.8.15i}$$

and, inversely,

$$\omega_k \equiv \sum A_{kk'}\omega_{k'} + A_k = \sum A_{kI'}\omega_{I'} + A_k \;\Rightarrow\; \delta\theta_k \equiv \sum A_{kI'}\,\delta\theta_{I'} = 0, \quad (3.8.15j)$$

[where, as in §2.11, the $n-m$ $\omega_{I'} \equiv \cdots$ are arbitrary, except that when the system (3.8.15h, i) is solved for the ω in terms of the ω' (and time) and the results are inserted in (3.8.15a), they satisfy them identically], and then, with the help of these Maggi-like representations, apply LP in the ω' variables

$$\sum I_{k'}\,\delta\theta_{k'} = \sum \Theta_{k'}\,\delta\theta_{k'} \;\Rightarrow\; \sum I_{I'}\,\delta\theta_{I'} = \sum \Theta_{I'}\,\delta\theta_{I'}, \quad (3.8.15k)$$

where

$$I_{k'} = \sum (\partial\omega_k/\partial\omega_{k'})I_k \equiv \sum A_{kk'}I_k$$
$$\Leftrightarrow\; I_k = \sum (\partial\omega_{k'}/\partial\omega_k)I_{k'} \equiv \sum a_{k'k}I_{k'}, \quad (3.8.15l)$$
$$\Theta_{k'} = \sum A_{kk'}\Theta_k \Leftrightarrow \Theta_k = \sum a_{k'k}\Theta_{k'}; \quad (3.8.15m)$$

from which, applying the method of Lagrangean multipliers [by now, in well-understood ways; i.e., with the constraints (3.8.15a, h) written as $1\cdot\delta\theta_{D'} = 0$, and the $\delta\theta_{I'} \neq 0$ viewed as satisfying the constraints $0\cdot\delta\theta_{I'} = 0$], we readily obtain the following two groups of equations:

$$I_{D'} = \Theta_{D'} + \lambda_{D'} \qquad (n-m \;\textit{kinetostatic}\text{ equations}), \quad (3.8.15n)$$
$$I_{I'} = \Theta_{I'} \qquad (m \;\textit{kinetic}\text{ equations}); \quad (3.8.15o)$$

where the inertia terms $I_{k'}$ have one of the following basic forms:

$$I_{k'} = \sum (\partial\omega_k/\partial\omega_{k'})I_k \equiv \sum A_{kk'}I_k \qquad \text{(Maggi-type)}, \quad (3.8.15p)$$
$$= (\partial T^{*\prime}/\partial\omega_{k'})^{\cdot} - \partial T^{*\prime}/\partial\theta_{k'} + \sum\sum \gamma^{b'}{}_{k'\alpha'}(\partial T^{*\prime}/\partial\omega_{b'})\omega_{\alpha'}$$
$$(\alpha' = m+1,\ldots,n; n+1) \qquad \text{(Hamel-type)}, \quad (3.8.15q)$$
$$= \partial S^{*\prime}/\partial\dot{\omega}_{k'} \equiv \sum A_{kk'}(\partial S^*/\partial\dot{\omega}_k) \qquad \text{(Appell-type)}. \quad (3.8.15r)$$

In these equations:

(i) $T^{*\prime} \equiv T^*(t, q, \omega_k \equiv \sum A_{kk'}\omega_{k'} + A_k) \equiv T^*(t, q, \omega_{D'}, \omega_{I'})$; and the constraints $\omega_{D'} = 0$ are to be enforced *after* all differentiations, not before; otherwise we could not calculate terms like $\gamma^{D'}{}_{k'\alpha'}(\partial T^{*\prime}/\partial\omega_{D'})\omega_{\alpha'}$.

(ii) The $\gamma^{D'}{}_{k'\alpha'}$ can be calculated either from the *transitivity* equations

$$d(\delta\theta_{k'}) - \delta(d\theta_{k'}) = \sum\sum \gamma^{k'}{}_{l'\alpha'}\,d\theta_{\alpha'}\,\delta\theta_{l'} = \sum\sum \gamma^{k'}{}_{l'r'}\,d\theta_{r'}\,\delta\theta_{l'} + \sum \gamma^{k'}{}_{l'}\,\delta\theta_{l'}, \quad (3.8.15s)$$

(which is, usually, the easier way), or from the *transformation* equations (ex. 2.10.1: d)

$$\gamma^{k'}{}_{l'r'} = \sum\sum\sum a_{k'k}A_{ll'}A_{rr'}\gamma^{k}{}_{lr} + \sum\sum (\partial a_{k'k}/\partial\theta_r - \partial a_{k'r}/\partial\theta_k)A_{kl'}A_{rr'}, \quad (3.8.15t)$$

where

$$\partial a_{k'k}/\partial\theta_r \equiv \sum (\partial a_{k'k}/\partial q_b)(\partial\dot{q}_b/\partial\omega_r) = \sum A_{br}(\partial a_{k'k}/\partial q_b); \tag{3.8.15u}$$

and similarly for the $\gamma^{k'}{}_{l'} \equiv \gamma^{k'}{}_{l',(n+1)'}$.

(iii) $$S^{*\prime} \equiv S^*[t, q, \omega(t, q, \omega'), \dot{\omega}(t, q, \omega', \dot{\omega}')] \equiv S^{*\prime}(t, q, \omega', \dot{\omega}') \text{ and}$$
$$S^{*\prime}{}_o \equiv S^{*\prime}(t, q, \omega_{D'} = 0, \omega_{I'} \neq 0, \dot{\omega}_{D'} = 0, \dot{\omega}_{I'}) \equiv S^{*\prime}_o(t, q, \omega_{I'}, \dot{\omega}_{I'});$$

and in (3.8.15r) $S^{*\prime}$ can be replaced by $S^{*\prime}{}_o$ for $k' \to I = m+1, \ldots, n$, but not for $k' \to D = 1, \ldots, m$. Let the reader adapt the above to the case where the θ/ω variables are already constrained by, say, the m_1 constraints $\omega_D = 0/\delta\theta_D = 0$ $(D = 1, \ldots, m_1)$, and then are subjected to the *additional* m_2 (3.8.15a)-like constraints

$$\sum a_{D'k}\,\omega_k + a_{D'} = 0 \qquad [D' = 1, \ldots, m_2;\ n - (m_1 + m_2) > 0]. \tag{3.8.15v}$$

Problem 3.8.4 *Hadamard Form of the Hamel Equations.* Let the m Pfaffian constraints have the special Voronets form

$$\omega_D \equiv \sum B_{DI}\omega_I + B_D, \tag{a}$$

with the B_{DI} and B_D assumed known functions of all the q's and t. By viewing (a) as the following special case of the Hamel-type constraints (3.8.15a)

$$\Omega_D \equiv \omega_D - \sum B_{DI}\omega_I - B_D \quad (= 0), \qquad \Omega_I \equiv \omega_I \quad (\neq 0), \tag{b, c}$$

with inverse

$$\omega_D \equiv \Omega_D + \sum B_{DI}\Omega_I + B_D \quad \Big(= \sum B_{DI}\Omega_I + B_D\Big), \tag{d}$$

$$\omega_I \equiv \Omega_I, \tag{e}$$

and applying any one of the above methods used in the derivation of the Hadamard equations, show that, in this case, the equations of motion (in the t, q, ω variables) may take the decoupled Hadamard form as follows:

Kinetostatic: $$I_D = \Theta_D + \lambda_D, \tag{f}$$

Kinetic: $$I_I + \sum B_{DI} I_D = \Theta_I + \sum B_{DI}\Theta_D, \tag{g}$$

where, with our usual notations,

$$I_k = (\partial T^*/\partial\omega_k)^{\cdot} - \partial T^*/\partial\theta_k + \sum\sum \gamma^b{}_{k\alpha}(\partial T^*/\partial\omega_b)\,\omega_\alpha, \tag{h}$$

$$= \partial S^*/\partial\dot{\omega}_k \quad (= \partial S^*{}_o/\partial\dot{\omega}_I, \quad \text{for} \quad I = m+1, \ldots, n). \tag{i}$$

For an application of these equations, see Nikitina (1976).

Problem 3.8.5 *Special Hamel Equations.* Show that if the Pfaffian constraints have the special Hamel form [but slightly more general than Voronets' form (3.8.14a)]

$$\omega_D \equiv \sum a_{Dk} v_k + a_D \quad (= 0), \qquad \omega_I \equiv v_I \quad (\neq 0), \tag{a}$$

where the a_{Dk}, a_D are functions of all the q's and t; that is,

$$a_{Dk} = a_{Dk}, \quad a_{D,n+1} = a_D, \quad a_{ID} = \delta_{ID} = 0, \quad a_{II'} = \delta_{II'}, \quad a_{I,n+1} = 0,$$
$$a_{n+1,k} = 0, \quad a_{n+1,n+1} = 1, \tag{b}$$

and, therefore (recalling prob. 2.11.2),

$$(A_{DD'}) = (a_{DD'})^{-1}, \qquad (A_{DI}) = -(a_{DD'})^{-1}(a_{D'I}), \qquad A_{ID} = \delta_{ID} = 0, \qquad A_{II'} = \delta_{II'}, \tag{c}$$

then (i) the Maggi *kinetic* and *kinetostatic* equations specialize, respectively, to

$$M_I + \sum A_{DI} M_D = 0, \qquad \sum A_{D'D} M_{D'} = \lambda_D, \tag{d}$$

where $M_k \equiv E_k - Q_k \equiv [(\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k] - Q_k$ (and for $A_{DI} = b_{DI}$, $A_{D'D} = \delta_{D'D}$, they specialize to the corresponding Hadamard equations), and (ii) the Hamel *kinetic* equations specialize to

$$(\partial T^*/\partial \omega_I)^{\cdot} - \partial T^*/\partial \theta_I + \sum\sum \gamma^D{}_{II'}(\partial T^*/\partial \omega_D)\omega_{I'} + \sum \gamma^D{}_I(\partial T^*/\partial \omega_D) = \Theta_I, \tag{e}$$

where after all differentiations we set $\omega_D = 0$ and $\omega_I \equiv \dot{q}_I$ (Schouten, 1954, pp. 196–197); and similarly for the kinetostatic equations.

HINT

Since $\theta_I \equiv q_I$ (i.e., holonomic coordinates), we will have

$$d(\delta\theta_I) - \delta(d\theta_I) = 0 \;\Rightarrow\; \gamma^I{}_{kl}, \gamma^I{}_{k,n+1} \equiv \gamma^I{}_k = 0; \tag{f}$$

and, of course, $\gamma^{n+1}{}_{kl}$, $\gamma^{n+1}{}_k = 0$; and, due to (d, e), the remaining $\gamma^D{}_{II'}$, $\gamma^D{}_I$ simplify further.

Problem 3.8.6 *Special Hamel Equations (continued).* Show that eqs. (e) of the preceding problem can be further simplified to

$$(\partial T^*{}_o/\partial \dot{q}_I)^{\cdot} - \partial T^*{}_o/\partial \theta_I + \sum\sum \gamma^D{}_{II'}(\partial T^*/\partial \omega_D)\dot{q}_{I'} + \sum \gamma^D{}_I(\partial T^*/\partial \omega_D) = \Theta_I, \tag{a}$$

where $T^*{}_o = T^*(t, q, \omega_D = 0,\ \omega_I = \dot{q}_I) \equiv T^*{}_o(t, q, \dot{q}_I)$; that is, the constraints have been enforced in T^* right from the start (as in the Voronets case) in the *first* and *second* terms, and *after* the differentiations in the *third* and *fourth* terms (sums); or, we replace $\partial T^*/\partial \omega_D$ with its equal:

$$\sum A_{kD}(\partial T/\partial \dot{q}_k) = \sum A_{D'D}(\partial T/\partial \dot{q}_{D'}) + \sum A_{ID}(\partial T/\partial \dot{q}_I) = \sum A_{D'D}(\partial T/\partial \dot{q}_{D'}).$$

REMARKS

(i) The $n - m$ equations (a), plus the m constraints $\sum a_{Dk}\dot{q}_k + a_D = 0$, constitute a determinate system of n equations in the n functions $q_k(t)$.

(ii) Clearly, if the constraints (a) of the preceding problem assume the Voronets form (3.8.14a) (i.e., $A_{DD'} = \delta_{DD'}$, $A_{ID} = \delta_{ID} = 0$, $\gamma^D{}_{II'} \to -w^D{}_{II'}$, etc.) then (a) must reduce to the Voronets equations (3.8.14q). [See also Hamel, 1904(a), pp. 20–21; Prange, 1935, pp. 537–539; Schouten, 1954, pp. 196–197.]

Problem 3.8.7 *Special Hamel Equations (continued)*. Write down the *kineto-static* Hamel equations of the preceding problem.

Example 3.8.1 *A Mixed Hamel–Voronets Type of Equations* [May be omitted in a first reading. Adapted from Neimark and Fufaev (1972, pp. 141–143)]. Let us consider a system subject to the Voronets-like Pfaffian constraints (with $\dot{q}_k \equiv v_k$):

$$v_D \equiv \sum b_{DI}\, v_I + b_D \qquad [D = 1, \ldots, m\ (< n);\ I = m+1, \ldots, n]. \tag{a}$$

To handle these constraints, we make the following quasi-velocity choice: (i) We express the *first* M $(\leq m)$ of the m v_D's à la Hamel:

$$\omega_d \equiv v_d - \sum b_{dI}\, v_I - b_d \equiv \sum a_{dI}\, v_I + a_I \quad (= 0), \tag{b1}$$

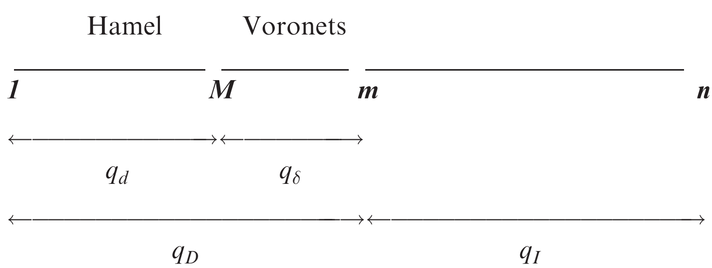
and also

$$\omega_I \equiv \sum a_{II'}\, v_{I'} + a_I \qquad\qquad (\neq 0), \tag{b2}$$

where $d = 1, \ldots, M$; $I, I' = m+1, \ldots, n$ [and the *new* coefficients $a_{II'}$, a_I are such that upon inversion of (b2) and substitution of the v's in (a), the latter is satisfied identically]; and (ii) express the remaining $m - M$ of the v_D's à la Voronets:

$$v_\delta \equiv \sum b_{\delta I}\, v_I + b_\delta \qquad [\delta = M+1, \ldots, m\ (< n)]. \tag{c}$$

The range of these indices, so important to the understanding of this example, is shown below for quick reference:



q_i : *union of* q_d *and* q_I

$$\begin{aligned}
&D, D', D'', \ldots = 1, \ldots, m\ (< n);\ I, I', I'', \ldots = m+1, \ldots, n;\\
&d, d', d'', \ldots = 1, \ldots, M\ (< m);\ \delta, \delta', \delta'', \ldots = M+1, \ldots, m;\\
&i, i', i'', \ldots = 1, \ldots, M \quad \textit{and} \quad m+1, \ldots, n;
\end{aligned} \tag{d}$$

and, these indices may be used to characterize either a *particular* v or ω of a group, or the *entire* group. Hence, they can be rewritten compactly as $\omega_i \equiv \sum a_{ii'} v_{i'} + a_i$.

Now, let us establish the *transitivity equations*. Recalling the results of prob. 2.12.5, we have the following:

(i) For the Hamel group, eqs. (b):

$$\textit{Hamel viewpoint}: (\delta\theta_i)^{\cdot} - \delta\omega_i = \sum\sum \gamma^i{}_{i'i''}\, \omega_{i''}\, \delta\theta_{i'} + \sum \gamma^i{}_{i'}\, \delta\theta_{i'}, \tag{e}$$

where

$$\sum A_{ii'} a_{i'i''} = \delta_{ii''} \ \Rightarrow \ \gamma^i{}_{i'i''} \equiv \sum\sum (\partial a_{ii'''}/\partial q_{i''''} - \partial a_{ii''''}/\partial q_{i'''}) A_{i'''i'} A_{i''''i''}, \quad \text{(e1)}$$

and analogously for $\gamma^i{}_{i'} \equiv \gamma^i{}_{i',n+1}$; that is, the $\gamma^i{}_{..}$'s are based on eqs. (b), and $d(\delta q_i) = \delta(dq_i)$.

(ii) For the Voronets group, eq. (c):

Suslov viewpoint: $(\delta q_I)^{\cdot} - \delta(\dot{q}_I) = 0,$

$$(\delta q_\delta)^{\cdot} - \delta(\dot{q}_\delta) = \sum\sum w^\delta{}_{II'} \dot{q}_{I'}\, \delta q_I + \sum w^\delta{}_I\, \delta q_I \quad \text{(f)}$$

[i.e., here, too, we may assume $d(\delta q_d) = \delta(dq_d) \ \Rightarrow \ d(\delta q_i) = \delta(dq_i)$].

In addition, to implement the central equation (CE), and thus derive the equations of motion:

(i) We invert the virtual form of eqs. (b), thus obtaining [no enforcement of constraints (b1) yet]

$$\delta q_i = \sum A_{ii'}\, \delta\theta_{i'} \quad \Big[= \sum A_{iI}\, \delta\theta_I;\ \text{since, by (b1)},\ \delta\theta_d = 0\Big], \quad \text{(g)}$$

where $\dot{\theta}_i \equiv \omega_i$.

(ii) From the virtual form of (c), and then use of (g) for $i \to I$, we get

$$\delta q_\delta = \sum b_{\delta I}\, \delta q_I = \sum \Big(\sum b_{\delta I} A_{Ii}\Big)\, \delta\theta_i \equiv \sum F_{\delta i}\, \delta\theta_i \quad \Big[= \sum F_{\delta I}\, \delta\theta_I\Big]. \quad \text{(h)}$$

Equations (g, h) express the n δq's in terms of the $M + (n-m)$ $\delta\theta_i$'s [$\Rightarrow (n-m)$ $\delta\theta_I$'s] introduced by the virtual form of (b).

(iii) Finally, we employ the notation

$$T = T(t, q, \dot{q}_i, \dot{q}_\delta) = \cdots = T^*(t, q, \omega_i) = T^* \quad \text{(no constraint enforcement yet)}, \quad \text{(i)}$$

meaning that T^* is what becomes of T after expressing all its $\dot{q}$'s in terms of the ω_i's [*velocity* forms of (g, h)]; that is, after substituting into it

$$\dot{q}_i = \sum A_{ii'} \omega_{i'} + A_i \qquad \text{[obtained after solving (b) for the } \dot{q}_i \equiv v_i],$$

and

$$\dot{q}_\delta = \sum b_{\delta I} \dot{q}_I + b_\delta = \sum b_{\delta I}\Big(\sum A_{Ii}\, \omega_i + A_I\Big) + b_\delta \equiv \sum F_{\delta i}\, \omega_i + F_\delta. \quad \text{(j)}$$

Next, to obtain the equations of motion, we will utilize the central equation (3.6.8 ff.)

$$\Big(\sum p_k\, \delta q_k\Big)^{\cdot} - \delta T - \sum p_k[(\delta q_k)^{\cdot} - \delta(\dot{q}_k)] = \sum Q_k\, \delta q_k \quad (\equiv \delta' W). \quad \text{(k)}$$

Indeed, substituting into it the two expressions (f) for $(\delta q)^{\cdot} - \delta(\dot{q})$, we obtain

$$\Big(\sum p_k\, \delta q_k\Big)^{\cdot} - \delta T - \sum p_\delta[(\delta q_\delta)^{\cdot} - \delta(\dot{q}_\delta)]$$
$$= \Big(\sum p_k\, \delta q_k\Big)^{\cdot} - \delta T - \sum p_\delta\Big(\sum\sum w^\delta{}_{II'}\, v_{I'}\, \delta q_I + \sum w^\delta{}_I\, \delta q_I\Big) = \delta' W. \quad \text{(l)}$$

Next, due to (i, j) (and this is the important step here)

$$\delta P \equiv \mathsf{S}\, dm\, \boldsymbol{v} \cdot \delta \boldsymbol{r} = \sum p_k\, \delta q_k = \sum P_k\, \delta\theta_k = \sum P_i\, \delta\theta_i, \quad P_k \equiv \partial T^*/\partial\omega_k,$$

$$\delta T = \delta T^* = \sum [(\partial T^*/\partial\omega_i)\, \delta\omega_i + (\partial T^*/\partial\theta_i)\, \delta\theta_i], \quad \text{and} \quad \delta' W = \sum \Theta_i\, \delta\theta_i, \tag{m}$$

and so, with the help of (g), the variational equation (l) can be rewritten as

$$\Big(\sum P_i\, \delta\theta_i\Big)^{\boldsymbol{\cdot}} - \delta T^* - \sum\sum\sum\sum w^{\delta}{}_{II'} p_\delta\, v_{I'} (A_{Ii}\, \delta\theta_i) - \sum\sum\sum w^{\delta}{}_{I}\, p_\delta (A_{Ii}\, \delta\theta_i)$$
$$= \sum \Theta_i\, \delta\theta_i. \tag{n}$$

Finally, transforming the *first two* terms of the above via (m) [or (3.6.7a ff., with $k \to i$)], then applying the transitivity equations (e), and, finally, factoring out the common $\delta\theta_i$, we get

$$\sum (I_i - \Theta_i)\, \delta\theta_i = 0, \tag{o}$$

where

$$\begin{aligned} I_i \equiv{}& (\partial T^*/\partial\omega_i)^{\boldsymbol{\cdot}} - \partial T^*/\partial\theta_i \\ &+ \Big(\sum\sum \gamma^{i'}{}_{ii''} (\partial T^*/\partial\omega_{i'})\omega_{i''} + \sum \gamma^{i'}{}_{i} (\partial T^*/\partial\omega_{i'})\Big) \\ &- \Big(\sum\sum\sum w^{\delta}{}_{II'} (\partial T/\partial v_\delta) v_{I'} A_{Ii} + \sum\sum w^{\delta}{}_{I} (\partial T/\partial v_\delta) A_{Ii}\Big), \end{aligned} \tag{p}$$

and

$$\begin{aligned} \partial T^*/\partial\theta_i \equiv{}& \sum (\partial T^*/\partial q_k)(\partial v_k/\partial\omega_i) \\ ={}& \sum (\partial T^*/\partial q_{i'})(\partial v_{i'}/\partial\omega_i) + \sum (\partial T^*/\partial q_\delta)(\partial v_\delta/\partial\omega_i) \qquad \text{[invoking (j)]} \\ ={}& \sum (\partial T^*/\partial q_{i'}) A_{i'i} + \sum\sum (\partial T^*/\partial q_\delta)(b_{\delta I} A_{Ii}). \end{aligned} \tag{q}$$

From the above we obtain, in by now well-understood ways (i.e., $\delta\theta_d = 0 \Rightarrow$ *multipliers*, Λ_d), the two uncoupled groups of "*mixed*" (or "*intermediate*") *Hamel–Voronets equations*:

$$I_d = \Theta_d + \Lambda_d \ (\textit{kinetostatic}\ \text{equations}), \qquad I_I = \Theta_I \ (\textit{kinetic}\ \text{equations}). \tag{r1, 2}$$

In particular, the *kinetic* equations (r2) are, in extenso,

$$(\partial T^*/\partial\omega_I)^{\boldsymbol{\cdot}} - \partial T^*/\partial\theta_I + \Big(\sum\sum \gamma^{i}{}_{Ii'} (\partial T^*/\partial\omega_i)\omega_{i'} + \sum \gamma^{i}{}_{I} (\partial T^*/\partial\omega_i)\Big)$$
$$- \Big(\sum\sum\sum w^{\delta}{}_{I'I''} A_{I'I} (\partial T/\partial v_\delta) v_{I''} + \sum\sum w^{\delta}{}_{I'} A_{I'I} (\partial T/\partial v_\delta)\Big) = \Theta_I. \tag{s}$$

These are, indeed, mixed Hamel–Voronets equations, because:

(i) If $M = m$ (i.e., $\delta = 0$), the Voronets terms (*fourth* group of terms: $-[\ldots]$) disappear and (s) reduce to the kinetic Hamel equations; whereas

(ii) If $M = 0$ (i.e., $d = 0$, $\delta = D$, and $i = I$), and we restrict ourselves to *holonomic* coordinates and the Voronets constraints (a) = (c), then $A_{II'} = \delta_{II'}$ [= Kronecker delta in (g)], all the Hamel symbols $\gamma^{i}{}_{Ii'}$, $\gamma^{i}{}_{I}$ vanish, T^* becomes $T_o(t, q, v_I)$, and (from $\delta' W = \sum \Theta_I \, \delta\theta_I = \sum Q_{Io} \, \delta q_I$) $\Theta_I \to Q_{Io}$; and, as a result, (s) reduce to the familiar Voronets equations (3.8.14q):

$$(\partial T_o/\partial v_I)^{\cdot} - \partial T_o/\partial q_I - \sum (\partial T_o/\partial q_D) b_{DI} - \Big(\sum\sum w^D{}_{II'} (\partial T/\partial v_D) v_{I'} + \sum w^D{}_I (\partial T/\partial v_D) \Big) = \Theta_I; \qquad \text{(t)}$$

and for Chaplygin systems, they reduce to the Chaplygin equations (3.8.13o).

Finally, if $M = 0$ and we choose *nonholonomic* coordinates, (s) lead to the Voronets and Chaplygin equations in quasi variables. The details are left to the reader [recall probs. 3.8.2 and 3.8.3; see also Fradlin (1961)].

Example 3.8.2 *Transformation of the Correction Terms $-\Gamma_k$ that Appear in the Hamel Equations.* From the invariance of LP, under local quasi-coordinate differential/velocity transformations

$$\delta\theta_{k'} = \sum (\partial\omega_{k'}/\partial\omega_k) \, \delta\theta_k \equiv \sum a_{k'k} \, \delta\theta_k \;\Leftrightarrow\; \delta\theta_k = \sum (\partial\omega_k/\partial\omega_{k'}) \, \delta\theta_{k'} \equiv A_{kk'} \, \delta\theta_{k'},$$

that is,

$$\sum I_k \, \delta\theta_k = \sum \Theta_k \, \delta\theta_k \;\Leftrightarrow\; \sum I_{k'} \, \delta\theta_{k'} = \sum \Theta_{k'} \, \delta\theta_{k'}, \qquad \text{(a1)}$$

we readily conclude that the I_k and Θ_k transform as (covariant) vectors, that is,

$$I_{k'} = \sum A_{kk'} I_k \;\Leftrightarrow\; I_k = \sum a_{k'k} I_{k'}, \quad \text{etc.} \qquad \text{(a2)}$$

However, this does *not* imply that the constituents of $I_k \equiv E_k{}^*(T^*) - \Gamma_k \equiv E_k{}^* - \Gamma_k$, taken individually, transform as such vectors. In fact, as shown below, *neither* $E_k{}^*$ (=nonholonomic Euler–Lagrange part of inertia) nor $-\Gamma_k$ (or $\Gamma_k =$ nonholonomic deviation/correction) transform vectorially; that is, à la (a2); although their *combination* $E_k{}^* - \Gamma_k$ does!

We begin by examining the transformation properties of the $-\Gamma_k$'s under $\omega_{k'} = \sum a_{k'k} \, \omega_k$, $\omega_k = \sum A_{kk'} \, \omega_{k'}$ (assumed *stationary* for algebraic simplicity, but no loss in generality); that is, relate

$$-\Gamma_{l'} \equiv \sum\sum \gamma^{k'}{}_{l'r'} (\partial T^{*\prime}/\partial\omega_{k'}) \omega_{r'} \equiv -\Gamma_{l'}(t, q, \omega'), \qquad \text{(b)}$$

and $-\Gamma_l = -\Gamma_l(t, q, \omega)$. Below, we present two such derivations; one in *system variables* and one in terms of *particle vectors*.

(i) *System variable derivation*. Substituting the γ-transformation equations (3.8.15t)

$$\gamma^{k'}{}_{l'r'} = \sum\sum\sum a_{k'k} A_{ll'} A_{rr'} \gamma^k{}_{lr} + \sum\sum (\partial a_{k'k}/\partial\theta_r - \partial a_{k'r}/\partial\theta_k) A_{kl'} A_{rr'},$$

where

$$\partial a_{k'k}/\partial\theta_r \equiv \sum (\partial a_{k'k}/\partial q_b)(\partial \dot{q}_b/\partial\omega_r) \equiv \sum A_{br} (\partial a_{k'k}/\partial q_b);$$

into (b), we find, successively,

$$
\begin{aligned}
-\Gamma_{l'} &\equiv \sum\sum\Big\{\Big(\sum\sum\sum a_{k'k}A_{ll'}A_{rr'}\gamma^{k}{}_{lr}+\cdots\Big)\Big(\sum A_{sk'}(\partial T^*/\partial\omega_s)\Big)\Big(\sum a_{r'b}\,\omega_b\Big)\Big\}\\
&=\cdots=\sum\sum\sum A_{ll'}\big(\gamma^{s}{}_{lb}(\partial T^*/\partial\omega_s)\omega_b\big)\\
&\qquad+\sum\sum\sum\sum[A_{ll'}A_{kk'}(\partial a_{k'l}/\partial\theta_r-\partial a_{k'r}/\partial\theta_l)\,\omega_r](\partial T^*/\partial\omega_k)\\
&=\sum A_{ll'}(-\Gamma_l)+\sum\sum\sum\sum[A_{ll'}A_{kk'}(\partial a_{k'l}/\partial\theta_r-\partial a_{k'r}/\partial\theta_l)\,\omega_r](\partial T^*/\partial\omega_k),
\end{aligned}
\tag{c}
$$

which is the sought *nonvectorial* transformation equation.

(ii) *Particle variable derivation*. We begin with the definition of $\Gamma_{k'}$ in terms of the transformed particle variables (3.3.12a):

$$
\begin{aligned}
\Gamma_{l'} &\equiv S\,dm\,\boldsymbol{v}^{*\prime}\cdot\big[(\partial\boldsymbol{v}^{*\prime}/\partial\omega_{l'})^{\cdot}-\partial\boldsymbol{v}^{*\prime}/\partial\theta_{l'}\big]\\
&=S\,dm\,\boldsymbol{v}^{*\prime}\cdot(d\boldsymbol{\varepsilon}_{l'}/dt-\partial\boldsymbol{v}^{*\prime}/\partial\theta_{l'});
\end{aligned}
\tag{d}
$$

where (again, assuming, for algebraic simplicity, stationary constraints and a *stationary* $\omega\Leftrightarrow\omega'$ transformation)

$$\boldsymbol{v}=\boldsymbol{v}^*\equiv\sum\omega_l\,\boldsymbol{\varepsilon}_l=\sum(\partial\boldsymbol{v}^*/\partial\omega_l)\omega_l=\boldsymbol{v}^{*\prime}\equiv\sum\omega_{l'}\,\boldsymbol{\varepsilon}_{l'}=\sum(\partial\boldsymbol{v}^{*\prime}/\partial\omega_{l'})\,\omega_{l'}. \tag{e}$$

From the representations (e), we readily deduce the basic $\boldsymbol{\varepsilon}\leftrightarrow\boldsymbol{\varepsilon}'$ transformation equations

$$\boldsymbol{\varepsilon}_{l'}=\sum(\partial\omega_l/\partial\omega_{l'})\boldsymbol{\varepsilon}_l\ \Leftrightarrow\ \boldsymbol{\varepsilon}_l=\sum(\partial\omega_{l'}/\partial\omega_l)\boldsymbol{\varepsilon}_{l'}\qquad\text{[like (a2)].}\tag{f}$$

From the above, and with an eye toward (d), we obtain, successively,

(a) $$d\boldsymbol{\varepsilon}_{l'}/dt=\sum[(\partial\omega_l/\partial\omega_{l'})^{\cdot}\boldsymbol{\varepsilon}_l+(\partial\omega_l/\partial\omega_{l'})(d\boldsymbol{\varepsilon}_l/dt)];\tag{g}$$

(b)
$$
\begin{aligned}
\partial\boldsymbol{v}^{*\prime}/\partial\theta_{l'} &\equiv\sum(\partial\boldsymbol{v}^{*\prime}/\partial q_l)(\partial\dot q_l/\partial\omega_{l'})\qquad\text{(by definition)}\\
&=\sum\Big((\partial\boldsymbol{v}^*/\partial q_l)+\sum(\partial\boldsymbol{v}^*/\partial\omega_s)(\partial\omega_s/\partial q_l)\Big)(\partial\dot q_l/\partial\omega_{l'})\qquad\text{[by chain rule on (e)]}\\
&=\sum(\partial\boldsymbol{v}^*/\partial q_l)(\partial\dot q_l/\partial\omega_{l'})+\sum(\partial\boldsymbol{v}^*/\partial\omega_s)\Big(\sum(\partial\omega_s/\partial q_l)(\partial\dot q_l/\partial\omega_{l'})\Big)\\
&=\sum\Big(\sum(\partial\boldsymbol{v}^*/\partial\theta_s)(\partial\omega_s/\partial\dot q_l)\Big)(\partial\dot q_l/\partial\omega_{l'})+\sum(\partial\boldsymbol{v}^*/\partial\omega_s)(\partial\omega_s/\partial\theta_{l'})\\
&=\sum(\partial\boldsymbol{v}^*/\partial\theta_l)(\partial\omega_l/\partial\omega_{l'})+\sum(\partial\omega_l/\partial\theta_{l'})\boldsymbol{\varepsilon}_l.
\end{aligned}
\tag{h}
$$

Inserting the expressions (g, h) into (d), and regrouping, we find

$$
\begin{aligned}
\Gamma_{l'} &=\cdots=S\,dm\,\boldsymbol{v}^{*\prime}\cdot\Big(\sum[(\partial\omega_l/\partial\omega_{l'})^{\cdot}-\partial\omega_l/\partial\theta_{l'}]\boldsymbol{\varepsilon}_l\Big)\\
&\qquad+\sum\Big(S\,dm\,\boldsymbol{v}^{*\prime}\cdot(d\boldsymbol{\varepsilon}_l/dt-\partial\boldsymbol{v}^*/\partial\theta_l)\Big)(\partial\omega_l/\partial\omega_{l'})\\
&=\sum\Big\{S\,dm\,\boldsymbol{v}^{*\prime}\cdot[\partial\boldsymbol{v}^*/\partial\omega_l-\partial\boldsymbol{v}^*/\partial\theta_l]\Big\}(\partial\omega_l/\partial\omega_{l'})\\
&\qquad+\sum[(\partial\omega_l/\partial\omega_{l'})^{\cdot}-\partial\omega_l/\partial\theta_{l'}]\Big(S\,dm\,\boldsymbol{v}^{*\prime}\cdot\boldsymbol{\varepsilon}_l\Big),
\end{aligned}
$$

or, finally (and recalling that $\boldsymbol{\nu}^{*\prime} = \boldsymbol{\nu}^* = \boldsymbol{\nu}$),

$$\Gamma_{l'} = \sum (\partial\omega_l/\partial\omega_{l'})\Gamma_l + \sum \left[(\partial\omega_l/\partial\omega_{l'})^{\cdot} - \partial\omega_l/\partial\theta_{l'}\right](\partial T^*/\partial\omega_l)', \tag{i}$$

where

$$(\partial T^*/\partial\omega_l)' \equiv (\partial T^*/\partial\omega_l)\big|_{\text{after the differentiations we insert } \omega=\omega(t,q,\omega')} = \textit{function of } t, q, \omega'.$$

We leave it to the reader to show that (i) [which, actually, holds for a general (*nonlinear* and nonstationary) transformation $\omega = \omega(t, q, \omega')$ (see chap. 5)], in our linear and homogeneous case, coincides with (c).

Now, from the transformation law (a2), for the $I_k \equiv E_k{}^* - \Gamma_k$, and (i) for the Γ_l [or following steps entirely similar to those taken in obtaining (g, h), but for $T^* = T^{*\prime}$], it is not hard to see that the nonholonomic Euler–Lagrange terms $E_k{}^* = I_k + \Gamma_k$ must transform as follows:

$$\begin{aligned} E_{k'}{}^* &\equiv (\partial T^{*\prime}/\partial\omega_{k'})^{\cdot} - \partial T^{*\prime}/\partial\theta_{k'} \quad (= I_{k'} + \Gamma_{k'}) \\ &= \sum (\partial\omega_k/\partial\omega_{k'})E_k{}^* + \sum [(\partial\omega_k/\partial\omega_{k'})^{\cdot} - \partial\omega_k/\partial\theta_{k'}](\partial T^*/\partial\omega_k)'; \end{aligned} \tag{j}$$

indeed, subtracting (i) from (j), side by side, yields (a2).

Clearly: (i) if $(\partial\omega_k/\partial\omega_{k'})^{\cdot} - \partial\omega_k/\partial\theta_{k'} = 0$ (in which case, ω and ω' are referred to as "relatively holonomic"), both Γ_k and $E_k{}^*$ transform as vectors; and (ii) if Γ_k, $\Gamma_{k'}, \ldots = 0$ (i.e., holonomic coordinates), then $E_k{}^*$ ($\rightarrow E_k = \textit{holonomic inertia}$) transforms as a vector.

Problem 3.8.8 Show that (assuming a linear and stationary $\dot{q} \leftrightarrow \omega$ relationship)

$$\begin{aligned} -\Gamma_k &= \sum \left[(\partial\dot{q}_l/\partial\omega_k)^{\cdot} - \partial\dot{q}_l/\partial\theta_k\right](\partial T/\partial\dot{q}_l)^* \\ &= \sum\sum \gamma^b{}_{ks}\,\omega_s\Big(\sum (\partial\dot{q}_l/\partial\omega_b)(\partial T/\partial\dot{q}_l)^*\Big) = \sum\sum \gamma^b{}_{ks}(\partial T^*/\partial\omega_b)\,\omega_s; \end{aligned} \tag{a}$$

[for *rheonomic* systems s runs from 1 to $n + 1$] and, therefore, also

$$-\Gamma_{k'} = \sum \left[(\partial\dot{q}_l/\partial\omega_{k'})^{\cdot} - \partial\dot{q}_l/\partial\theta_{k'}\right](\partial T/\partial\dot{q}_l)' = \cdots = \sum\sum \gamma^{b'}{}_{k's'}(\partial T^{*\prime}/\partial\omega_{b'})\,\omega_{s'}, \tag{b}$$

where

$$(\partial T/\partial\dot{q}_l)' \equiv (\partial T/\partial\dot{q}_l)\big|_{\text{after the differentiations we insert } \dot{q}=\dot{q}(t,q,\omega')} = \textit{function of } t, q, \omega'.$$

Below, we summarize the most prevalent quasi-velocity/constraint choices in equations of motion:

Hamel (general):	$\omega_D \equiv \sum a_{Dk}\dot{q}_k + a_D = 0,$	ω_I: arbitrary $\neq 0$;
Hamel (special):	$\omega_D \equiv \sum a_{Dk}\dot{q}_k + a_D = 0,$	$\omega_I \equiv \dot{q}_I \neq 0$;
Voronets (special):	$\omega_D \equiv \dot{q}_D - \sum b_{DI}\dot{q}_I - b_D = 0,$	$\omega_I \equiv \dot{q}_I \neq 0$;
Voronets (general):	$\omega_D \equiv \dot{q}_D - \sum b_{DI}\dot{q}_I - b_D = 0,$	ω_I: arbitrary $\neq 0$;
Maggi:	$\dot{q}_k = \sum A_{kl}\omega_l + A_k \neq 0,$	$\omega_D = 0,\quad \omega_I$: arbitrary $\neq 0$.

3.9 KINETIC AND POTENTIAL ENERGIES; ENERGY RATE, OR POWER, THEOREMS

The foregoing theory has shown the importance of kinetic energy, $T \equiv S\,(dm\,\boldsymbol{v}\cdot\boldsymbol{v})/2$, to analytical mechanics and its equations of motion. Let us, therefore, examine in some detail the following topics.

3.9.1 Kinetic Energy in Holonomic (System) Variables

Substituting into it the particle (inertial) velocity representation in holonomic variables (§2.5)

$$\boldsymbol{v} = \sum \boldsymbol{e}_k \dot{q}_k + \boldsymbol{e}_0 \qquad (\boldsymbol{e}_k \equiv \partial\boldsymbol{r}/\partial q_k,\ \ \boldsymbol{e}_0 \equiv \boldsymbol{e}_{n+1} \equiv \partial\boldsymbol{r}/\partial q_{n+1} \equiv \partial\boldsymbol{r}/\partial t), \tag{3.9.1}$$

and grouping terms, we obtain the following basic kinetic energy representation:

$$T = T(t, q, \dot{q}) = T_2 + T_1 + T_0, \tag{3.9.2}$$

where

$$T_2 = T_2(t, q, \dot{q}) \equiv (1/2)\sum\sum M_{kl}\dot{q}_k\dot{q}_l \ (\geqslant 0, \textit{quadratic} \text{ and homogeneous in the } \dot{q}\text{s}),$$

$$M_{kl} = M_{kl}(t, q) \equiv S\, dm\, \boldsymbol{e}_k\cdot\boldsymbol{e}_l \equiv S\, dm\,(\partial\boldsymbol{r}/\partial q_k)\cdot(\partial\boldsymbol{r}/\partial q_l) \quad (= M_{lk}), \tag{3.9.2a}$$

$$T_1 = T_1(t, q, \dot{q}) \equiv \sum M_k\,\dot{q}_k \qquad\qquad (\textit{linear} \text{ and homogeneous in the } \dot{q}\text{s}),$$

$$M_k = M_k(t, q) \equiv S\, dm\, \boldsymbol{e}_k\cdot\boldsymbol{e}_0 \equiv S\, dm(\partial\boldsymbol{r}/\partial q_k)\cdot(\partial\boldsymbol{r}/\partial t)$$
$$(= M_{k0} = M_{0k} \equiv M_{k,n+1} = M_{n+1,k}), \tag{3.9.2b}$$

$$T_0 = T_0(t, q) \equiv M_0/2 \qquad\qquad (\geq 0, \textit{zeroth} \text{ degree in the } \dot{q}\text{s}),$$

$$M_0 = M_0(t, q) \equiv S\, dm\, \boldsymbol{e}_0\cdot\boldsymbol{e}_0 \equiv S\, dm(\partial\boldsymbol{r}/\partial t)\cdot(\partial\boldsymbol{r}/\partial t)$$
$$(= M_{00} \equiv M_{n+1,n+1} \geq 0), \tag{3.9.2c}$$

that is,

$$\begin{aligned} 2T = {} & M_{11}\dot{q}_1{}^2 + 2M_{12}\,\dot{q}_1\dot{q}_2 + M_{22}\,\dot{q}_2{}^2 + \cdots + M_{nn}\,\dot{q}_n{}^2 \\ & + 2M_1\dot{q}_1 + \cdots + 2M_n\,\dot{q}_n \\ & + M_0; \end{aligned}$$

or, compactly (with $\alpha, \beta = 1, \ldots, n, n+1$; and noting that $\dot{q}_{n+1} = \dot{t} = 1$),

$$2T = \sum\sum M_{\alpha\beta}\,\dot{q}_\alpha\dot{q}_\beta, \qquad M_{\alpha\beta} = M_{\beta\alpha} \equiv S\, dm\,(\partial\boldsymbol{r}/\partial q_\alpha)\cdot(\partial\boldsymbol{r}/\partial q_\beta). \tag{3.9.2d}$$

Clearly, the *holonomic coefficients of inertia* $M_{\alpha\beta} = M_{\alpha\beta}(t, q)$ vary with the system configuration and time, and, of course, the particular q-representation (in some q's, they might even be constant, like the particles' masses).

Some Analytical Considerations

(i) If $\boldsymbol{r} = \boldsymbol{r}(q)$ (i.e., *stationary* holonomic constraints in the q's) $\Rightarrow \boldsymbol{e}_0 \equiv \partial\boldsymbol{r}/\partial t = \boldsymbol{0} \Rightarrow$ *all* the M_k and M_0 vanish, and

$$2T \to 2T_2 = \sum\sum M_{kl}\dot{q}_k\dot{q}_l \quad [= 2(\text{kinetic energy for "frozen constraints"})]; \tag{3.9.2e}$$

and the vanishing of the $\boldsymbol{v}$'s implies that of the $\dot{q}$'s and of T. Also, since, in general,

$$2T_2 = \mathbf{S}\, dm(\boldsymbol{v} - \boldsymbol{e}_0)^2 = \mathbf{S}\, dm\Big(\sum \boldsymbol{e}_k\dot{q}_k\Big)^2,$$

T_2 represents the kinetic energy of the "virtual velocities" $\boldsymbol{v} - \boldsymbol{e}_0$ (Lur'e, 1968, pp. 10, 135).

(ii) In the general *nonstationary* case ($\partial\mathbf{r}/\partial t \neq \mathbf{0}$), it can be shown that, as long as the $3N$ coordinates of the system's particles $\boldsymbol{\xi} \equiv \{\xi_*; * = 1, \ldots, 3N\}$ can be expressed in terms of n minimal positional coordinates $q \equiv \{q_k; k = 1, \ldots, n\}$—that is, as long as $rank(\partial\xi_*/\partial q_k) = n$ [recall (2.4.8 ff.)], except possibly at a number of individual singular points where $rank(\partial\xi_*/\partial q_k) < n$ (a situation we shall exclude)—T_2 is *always nondegenerate*, or *nonsingular*; that is, $Det(M_{kl}) \neq 0$; and since $T_2 \geq 0$ it follows that

$$T_2 = \textit{positive definite} \text{ in the } \dot{q}\text{'s} \quad (\text{i.e., } \textit{always nonnegative}, \text{ and } \textit{zero only if all } \dot{q}\text{'s} = 0). \tag{3.9.2f}$$

As is well known, the necessary and sufficient conditions for this are

$$|M_{11}| = M_{11} > 0, \qquad \begin{vmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{vmatrix} > 0, \qquad \begin{vmatrix} M_{11} & \cdots & M_{1n} \\ \vdots & \ldots & \vdots \\ M_{n1} & \cdots & M_{nn} \end{vmatrix} > 0, \tag{3.9.2g}$$

for all q's and t in their domain of definition. The last of the above n inequalities states that the *inertia matrix* $\mathbf{M} = (M_{kl})$ *is nonsingular*; while the one before it states the same for the corresponding matrix of the new system obtained from the given by adding to it the constraint $q_n = constant$. [For proofs, see, for example, Gantmacher (1970, pp. 46–47), Lamb (1929, pp. 182–183), Langhaar (1962, pp. 308–313).]

As for the *total* kinetic energy T, it is clear from its definition that it is always *nonnegative*, but it vanishes for a single set of (not necessarily zero) values of the $\dot{q}$'s.

(iii) The terms T_1 and T_0 are called, respectively, *gyroscopic* and *centrifugal* parts of T (§3.16, §8.3 ff.). Clearly, $T_0 \geq 0$; and also $|T_1| < T_2 + T_0$, otherwise we might have $T < 0$.

(iv) If $T_1 = T_0 = 0$, the system is also called *natural*, eq. (3.9.2e).

(v) We notice that T can always be represented as

$$T = T'_2 + T'_0, \tag{3.9.2h}$$

where $2T'_2 \equiv \sum\sum M_{kl}(\dot{q}_k - x_k)(\dot{q}_l - x_l) = \textit{positive definite in the } \dot{q}_k - x_k,$ the $x_k = x_k(t)$ have units of Lagrangean velocities; that is, $\dot{q}_k$, and $T'_0 = T'_0(t, q)$. Clearly, if $T'_0 > 0$, then $T > 0$.

Some Useful Identities

Invoking the *homogeneous function theorem* of Euler [according to which, if $f = f(x_1, \ldots, x_n) = \textit{homogeneous of degree } H \textit{ in its variables } x_1, \ldots, x_n$, then

$$\sum (\partial f/\partial x_k)x_k = H \cdot f\,],$$

we obtain the following useful kinematico-inertial T-*identities*:

$$\text{(a)}\quad \sum (\partial T/\partial \dot{q}_k)\dot{q}_k = \sum [\partial(T_2 + T_1 + T_0)/\partial \dot{q}_k]\dot{q}_k$$
$$= (2)T_2 + (1)T_1 + (0)T_0 = 2T_2 + T_1 = T + (T_2 - T_0)$$
$$[= 2T,\ \text{if}\ \partial \boldsymbol{r}/\partial t = \boldsymbol{0}]; \tag{3.9.3a}$$

$$\text{(b)}\quad \sum E_k(T)\dot{q}_k \equiv \sum [(\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k]\dot{q}_k$$
$$= \left(\sum (\partial T/\partial \dot{q}_k)\dot{q}_k\right)^{\cdot} - \sum [(\partial T/\partial \dot{q}_k)\ddot{q}_k + (\partial T/\partial q_k)\dot{q}_k]$$
$$= [T + (T_2 - T_0)]^{\cdot} - (dT/dt - \partial T/\partial t),$$

or, finally, a form that will prove useful in the energy rate theorem below [with $E_k(T) \equiv E_k$],

$$\sum E_k \dot{q}_k = \left(\sum (\partial T/\partial \dot{q}_k)\dot{q}_k - T\right)^{\cdot} + \partial T/\partial t = (T_2 - T_0)^{\cdot} + \partial T/\partial t. \tag{3.9.3b}$$

3.9.2 Kinetic Energy in Nonholonomic (System) Variables

Substituting into T the particle (inertial) velocity representation in nonholonomic variables (2.9.23 ff.)

$$\boldsymbol{v} \to \boldsymbol{v}^* = \sum \boldsymbol{\varepsilon}_k\, \omega_k + \boldsymbol{\varepsilon}_0, \tag{3.9.4}$$

where

$$\boldsymbol{\varepsilon}_k \equiv \partial \boldsymbol{r}/\partial \theta_k,$$
$$\boldsymbol{\varepsilon}_0 \equiv \boldsymbol{\varepsilon}_{n+1} \equiv \partial \boldsymbol{r}/\partial \theta_{n+1} \equiv \sum (\partial \boldsymbol{r}/\partial q_\alpha)(\partial \dot{q}_\alpha/\partial \omega_{n+1})$$
$$= \partial \boldsymbol{r}/\partial t + \sum A_k(\partial \boldsymbol{r}/\partial q_k) \equiv \partial \boldsymbol{r}/\partial t + \partial \boldsymbol{r}/\partial(t) \equiv \boldsymbol{e}_0 + \sum A_k \boldsymbol{e}_k, \tag{3.9.4a}$$

and grouping terms, we obtain the following basic kinetic energy representation:

$$T \to T^* = T^*(t, q, \omega) = T^*{}_2 + T^*{}_1 + T^*{}_0, \tag{3.9.4b}$$

where

$$2T^*{}_2 = 2T^*{}_2(t, q, \omega) \equiv \sum\sum M^*{}_{kl}\, \omega_k\, \omega_l \quad (\textit{quadratic}\ \text{and homogeneous in the}\ \omega\text{'s}),$$
$$M^*{}_{kl} = M^*{}_{kl}(t, q) \equiv S\, dm\, \boldsymbol{\varepsilon}_k \cdot \boldsymbol{\varepsilon}_l \equiv S\, dm(\partial \boldsymbol{r}/\partial \theta_k) \cdot (\partial \boldsymbol{r}/\partial \theta_l) \quad (= M^*{}_{lk}), \tag{3.9.4c}$$
$$T^*{}_1 = T^*{}_1(t, q, \omega) \equiv \sum M^*{}_k\, \omega_k \qquad (\textit{linear}\ \text{and homogeneous in the}\ \omega\text{'s}),$$
$$M^*{}_k = M^*{}_k(t, q) \equiv S\, dm\, \boldsymbol{\varepsilon}_k \cdot \boldsymbol{\varepsilon}_0 \equiv S\, dm(\partial \boldsymbol{r}/\partial \theta_k) \cdot (\partial \boldsymbol{r}/\partial \theta_{n+1})$$
$$(= M^*{}_{k,n+1} = M^*{}_{n+1,k}), \tag{3.9.4d}$$
$$T^*{}_0 = T^*{}_0(t, q) \equiv M^*{}_0/2 \qquad (\textit{zeroth}\ \text{degree in the}\ \omega\text{'s}),$$
$$M^*{}_0 = M^*{}_0(t, q) \equiv S\, dm\, \boldsymbol{\varepsilon}_{n+1} \cdot \boldsymbol{\varepsilon}_{n+1}$$
$$\equiv S\, dm\, \boldsymbol{\varepsilon}_0 \cdot \boldsymbol{\varepsilon}_0 \equiv S\, dm\, (\partial \boldsymbol{r}/\partial \theta_{n+1}) \cdot (\partial \boldsymbol{r}/\partial \theta_{n+1}) \quad (= M^*{}_{n+1,n+1}/2); \tag{3.9.4e}$$

or, compactly (with $\alpha, \beta = 1, \ldots, n, n+1$; and noting that $\dot{\theta}_{n+1} = \dot{t} = 1$),

$$2T^* = \sum\sum M^*_{\alpha\beta}\,\omega_\alpha\,\omega_\beta, \qquad M^*_{\alpha\beta} = M^*_{\beta\alpha} \equiv S\, dm\,(\partial\mathbf{r}/\partial\theta_\alpha)\cdot(\partial\mathbf{r}/\partial\theta_\beta). \tag{3.9.4f}$$

The *nonholonomic coefficients of inertia* $M^*_{\alpha\beta} = M^*_{\alpha\beta}(t, q)$ satisfy similar analytical conditions as the holonomic ones $M_{\alpha\beta}$. Let us relate them; recalling (2.9.25a ff.) we find the following:

(a) $$M^*_{kl} \equiv S\, dm\,\boldsymbol{\varepsilon}_k\cdot\boldsymbol{\varepsilon}_l = S\, dm\Big(\sum A_{rk}\,\boldsymbol{e}_r\Big)\cdot\Big(\sum A_{sl}\,\boldsymbol{e}_s\Big)$$
$$= \sum\sum A_{rk}A_{sl}\Big(S\, dm\,\boldsymbol{e}_r\cdot\boldsymbol{e}_s\Big);\ \text{ i.e., } M^*_{kl} = \sum\sum A_{rk}A_{sl}M_{rs}; \tag{3.9.4g}$$

and, inversely,

$$M_{rs} = \cdots = \sum\sum a_{kr}a_{ls}\,M^*_{kl}; \tag{3.9.4h}$$

(b) $$M^*_k \equiv S\, dm\,\boldsymbol{\varepsilon}_k\cdot\boldsymbol{\varepsilon}_0 = S\, dm\Big(\sum A_{rk}\,\boldsymbol{e}_r\Big)\cdot\Big(\sum A_s\boldsymbol{e}_s + \boldsymbol{e}_0\Big)$$
$$= \sum\sum A_{rk}A_s\Big(S\, dm\,\boldsymbol{e}_r\cdot\boldsymbol{e}_s\Big) + \sum A_{rk}\Big(S\, dm\,\boldsymbol{e}_r\cdot\boldsymbol{e}_0\Big), \tag{3.9.4i}$$

that is,

$$M^*_k = \sum\sum A_{rk}\,A_s\,M_{rs} + \sum A_{rk}\,M_r; \tag{3.9.4j}$$

and, inversely,

$$M_r = \cdots = \sum\sum a_{kr}\,a_l\,M^*_{kl} + \sum a_{kr}\,M^*_k; \tag{3.9.4k}$$

(c) $$M^*_0 \equiv S\, dm\,\boldsymbol{\varepsilon}_0\cdot\boldsymbol{\varepsilon}_0 = S\, dm\Big(\sum A_r\boldsymbol{e}_r + \boldsymbol{e}_0\Big)\cdot\Big(\sum A_s\boldsymbol{e}_s + \boldsymbol{e}_0\Big)$$
$$= \sum\sum A_r\,A_s\Big(S\, dm\,\boldsymbol{e}_r\cdot\boldsymbol{e}_s\Big) + \sum A_r\Big(S\, dm\,\boldsymbol{e}_r\cdot\boldsymbol{e}_0\Big)$$
$$+ \sum A_s\Big(S\, dm\,\boldsymbol{e}_s\cdot\boldsymbol{e}_0\Big) + S\, dm\,\boldsymbol{e}_0\cdot\boldsymbol{e}_0,$$

that is,

$$M^*_0 = \sum\sum A_r\,A_s\,M_{rs} + 2\sum A_r\,M_r + M_0; \tag{3.9.4l}$$

and, inversely,

$$M_0 = \sum\sum a_k\,a_l\,M^*_{kl} + 2\sum a_k\,M^*_k + M^*_0. \tag{3.9.4m}$$

The above show clearly that even if we start with a *homogeneous* (*quadratic*) T, still we may end up with a *nonhomogeneous* (quadratic) T^*, and vice versa. Also, a little reflection (and recollection of the results of §2.9) shows that (3.9.4g–m) can be consolidated into the compact formulae

$$M^*_{\alpha\beta} = \sum\sum A_{\gamma\alpha}\,A_{\delta\beta}\,M_{\gamma\delta} \Leftrightarrow M_{\gamma\delta} = \sum\sum a_{\alpha\gamma}\,a_{\beta\delta}\,M^*_{\alpha\beta}. \tag{3.9.4n}$$

[In tensor language, these are the transformation equations between the holonomic ($M_{\alpha\beta}$) and nonholonomic ($M^*_{\alpha\beta}$) *covariant* components of the *metric tensor* in the system *event* space (§2.7), whose arc-length element (squared) is

$$(ds)^2 = 2T(dt)^2 = \sum\sum M_{\alpha\beta}\, dq_\alpha\, dq_\beta = \sum\sum M^*_{\alpha\beta}\, d\theta_\alpha\, d\theta_\beta; \tag{3.9.4o}$$

and similarly in configuration space; see, for example, Lur'e (1968), Papastavridis (1998, 1999), Synge (1936).]

Some Useful Identities

Again, applying Euler's homogeneous function theorem to T^* we easily obtain the following identities:

(a)

$$\begin{aligned}\sum (\partial T^*/\partial\omega_k)\,\omega_k &= \sum [\partial(T^*_2 + T^*_1 + T^*_0)/\partial\omega_k]\,\omega_k\\ &= (2)T^*_2 + (1)T^*_1 + (0)T^*_0 = 2T^*_2 + T^*_1 = T^* + (T^*_2 - T^*_0);\end{aligned} \tag{3.9.5a}$$

(b)

$$\begin{aligned}\sum E_k{}^*\,\omega_k &\equiv \sum [(\partial T^*/\partial\omega_k)^{\cdot} - \partial T^*/\partial\theta_k]\omega_k\\ &= \left\{\left(\sum (\partial T^*/\partial\omega_k)\omega_k\right)^{\cdot} - \sum (\partial T^*/\partial\omega_k)\dot{\omega}_k\right\} - \sum (\partial T^*/\partial q_l)\left(\sum A_{lk}\omega_k\right)\\ &\qquad \text{[replacing, in the last term, } \textstyle\sum A_{lk}\,\omega_k \text{ with } \dot{q}_l - A_l]\\ &= \left(\sum (\partial T^*/\partial\omega_k)\omega_k - T^*\right)^{\cdot} + \left(\partial T^*/\partial t + \sum A_l(\partial T^*/\partial q_l)\right),\end{aligned}$$

or, finally [recalling (2.9.33 ff.) and (3.9.5a)],

$$\sum E_k{}^*\,\omega_k = \left(\sum (\partial T^*/\partial\omega_k)\,\omega_k - T^*\right)^{\cdot} + \partial T^*/\partial\theta_{n+1} = (T^*_2 - T^*_0)^{\cdot} + \partial T^*/\partial\theta_{n+1},$$

where

$$\partial T^*/\partial\theta_{n+1} \equiv \partial T^*/\partial t + \sum A_l(\partial T^*/\partial q_l); \tag{3.9.5b}$$

a form that will prove useful in the energy rate theorem below.

3.9.3 Potential Energy

It is frequently possible to express the virtual work of the *impressed* forces, $\delta' W \equiv S\, d\boldsymbol{F}\cdot\delta\boldsymbol{r}$, as

$$\begin{aligned}\delta' W &= -\,\delta V + \delta' W_{NP} = \sum [-\partial V/\partial q_k + Q_{k,NP}]\,\delta q_k \equiv \sum Q_k\,\delta q_k\\ &= \sum [-\partial V^*/\partial\theta_k + \Theta_{k,NP}]\,\delta\theta_k \equiv \sum \Theta_k\,\delta\theta_k,\end{aligned} \tag{3.9.6a}$$

where

$$V = V(q,t) = V^*(q,t) = \textit{potential (}\text{or } \textit{potential energy}\text{), in system variables;} \tag{3.9.6b}$$

$$\partial V^*/\partial\theta_k \equiv \sum (\partial V^*/\partial q_l)(\partial\dot{q}_l/\partial\omega_k) = \sum A_{lk}(\partial V^*/\partial q_l), \tag{3.9.6c}$$

$$\partial V^*/\partial q_k \equiv \sum (\partial V^*/\partial\theta_l)(\partial\omega_l/\partial\dot{q}_k) = \sum a_{lk}(\partial V^*/\partial\theta_l); \tag{3.9.6d}$$

$$-\partial V/\partial q_k = \textit{holonomic potential} \text{ part of } Q_k, \tag{3.9.6e}$$

$$Q_{k,NP} = \textit{holonomic nonpotential} \text{ part of } Q_k; \tag{3.9.6f}$$

$$-\partial V^*/\partial\theta_k = \textit{nonholonomic potential} \text{ part of } \Theta_k, \tag{3.9.6g}$$

$$\Theta_{k,NP} = \textit{nonholonomic nonpotential} \text{ part of } \Theta_k. \tag{3.9.6h}$$

The connection between δV in particle and system variables is given by

$$\begin{aligned}\delta V &= S\,(\partial V/\partial\boldsymbol{r})\cdot\delta\boldsymbol{r} = S\,(\partial V/\partial\boldsymbol{r})\cdot\Big(\sum \boldsymbol{e}_k\,\delta q_k\Big)\\ &= \sum\Big(S\,(\partial V/\partial\boldsymbol{r})\cdot\boldsymbol{e}_k\Big)\,\delta q_k = \sum(\partial V/\partial q_k)\,\delta q_k,\end{aligned} \tag{3.9.6i}$$

$$\begin{aligned}&= S\,(\partial V/\partial\boldsymbol{r})\cdot\Big(\sum \boldsymbol{\varepsilon}_k\,\delta\theta_k\Big)\\ &= \sum\Big(S\,(\partial V/\partial\boldsymbol{r})\cdot\boldsymbol{\varepsilon}_k\Big)\,\delta\theta_k = \sum(\partial V^*/\partial\theta_k)\,\delta\theta_k.\end{aligned} \tag{3.9.6j}$$

REMARK ON THE POTENTIAL OF CONSTRAINT REACTIONS

Since, in general,

$$d'W_R \equiv S\,d\boldsymbol{R}\cdot d\boldsymbol{r} \neq 0 \qquad \Big(\text{whereas } \ \delta'W_R \equiv S\,d\boldsymbol{R}\cdot\delta\boldsymbol{r} = 0\Big),$$

it is conceivable that $d'W_R = -dV$, namely, that constraint reactions are, *partly or wholly, potential*. Thus, we may have

$$R_0 \equiv R_{n+1} \equiv S\,d\boldsymbol{R}\cdot\boldsymbol{e}_0 = -\partial V/\partial t = -\sum(\partial V/\partial c_k)(dc_k/dt), \tag{3.9.6k}$$

where the c_k $(k = 1, 2, 3, \ldots)$ are certain time-dependent system *parameters*; for example, mass, length, area, and so on. Such "parameteric reactions" appear in areas like *parametric excitation* (*Mathieu–Floquet theory*) and *adiabatic invariance* (§7.9 examples/problems; §8.15).

From now on, generally, we will omit the subscripts NP in the Q's and Θ's. If potential parts exist, they will usually be absorbed into the system's *kinetic potential*, or *Lagrangean function* $L \equiv T - V = L^* \equiv T^* - V^*$; explicitly,

$$L = L(t, q, \dot{q}) \equiv T(t, q, \dot{q}) - V(t, q) \qquad \text{(holonomic variables)}, \tag{3.9.7a}$$

$$L^* = L^*(t, q, \omega) \equiv T^*(t, q, \omega) - V^*(t, q) \qquad \text{(nonholonomic variables)}. \tag{3.9.7b}$$

The only change in the earlier equations of motion is that $T(T^*)$ is replaced, wherever it appears, by $L(L^*)$; then, and unless explicitly stated to the contrary, $Q_k(\Theta_k)$ will stand for the *nonpotential* parts of the corresponding forces.

Generalized Potential

(Recall ex. 3.5.12.) Occasionally, the potential part of Q_k is given by the [slightly more general than (3.9.6e)] expression

$$Q_{k,\,\text{generalized potential}} \equiv Q_{k,GP} \equiv (\partial V/\partial\dot{q}_k)^{\cdot} - \partial V/\partial q_k \equiv E_k(V), \tag{3.9.8a}$$

where

$$V = V(t, q, \dot{q}) = \textit{generalized (holonomic) potential};$$

or, in extenso,

$$\begin{aligned} Q_{k,GP} &= \sum \left[(\partial^2 V/\partial q_l\, \partial \dot{q}_k)\dot{q}_l + (\partial^2 V/\partial \dot{q}_l\, \partial \dot{q}_k)\ddot{q}_l\right] + \partial^2 V/\partial t\, \partial \dot{q}_k - \partial V/\partial q_k \\ &= \sum (\partial^2 V/\partial \dot{q}_l\, \partial \dot{q}_k)\ddot{q}_l + \text{terms not containing accelerations } \ddot{q}. \end{aligned} \tag{3.9.8b}$$

However, since in *classical mechanics* $\partial Q_k/\partial \ddot{q}_l = 0$ (Pars, 1965, pp. 11–12), we conclude from the above that $\partial^2 V/\partial \dot{q}_l\, \partial \dot{q}_k = 0 \;\Rightarrow\; V$ can be, at most, *linear* in the $\dot{q}$'s; that is,

$$V = \sum \gamma_k(t, q)\dot{q}_k + V_0(t, q) \equiv V_1(t, q, \dot{q}) + V_0(t, q). \tag{3.9.8c}$$

Substituting (3.9.8c) into (3.9.8a, b), we obtain

$$Q_{k,GP} = d\gamma_k/dt - \partial/\partial q_k\left(\sum \gamma_l \dot{q}_l + V_0\right) = \cdots = \sum \gamma_{kl}\, \dot{q}_l + \partial\gamma_k/\partial t - \partial V_0/\partial q_k,$$

where

$$\gamma_{kl} = \gamma_{kl}(t, q) \equiv \partial\gamma_k/\partial q_l - \partial\gamma_l/\partial q_k \quad (= -\,\gamma_{lk}); \tag{3.9.8d}$$

that is, $\gamma_{11} = -\gamma_{11} \;\Rightarrow\; \gamma_{11} = 0$, $\gamma_{12} = -\gamma_{21}$, and so on.

Gyroscopicity

Now we introduce the following important concept.

DEFINITION

Impressed (i.e., nonconstraint) forces Q_k that satisfy the "power" condition

$$\sum Q_k\, \dot{q}_k = 0 \tag{3.9.8e}$$

are called *gyroscopic*. In view of the antisymmetry of the *gyroscopic coefficients* γ_{kl}, it is not hard to see that

$$\sum\left(\sum \gamma_{kl}\, \dot{q}_l\right)\dot{q}_k \equiv \sum\sum \gamma_{kl}\, \dot{q}_k\dot{q}_l = \sum\sum [(\gamma_{kl} + \gamma_{lk})/2]\dot{q}_k\, \dot{q}_l = 0. \tag{3.9.8f}$$

Hence, the representation/decomposition (3.9.8d) states that a *generalized potential force* consists, at most, of three parts: a *gyroscopic* $\sum \gamma_{kl}\dot{q}_l$, a *nonstationary* $\partial\gamma_k/\partial t$, and a *purely potential* $-\partial V_0/\partial q_k$. If, further, $\sum (\partial\gamma_k/\partial t)\dot{q}_k = 0$ and $\sum (\partial V_0/\partial q_k)\dot{q}_k = dV_0/dt - \partial V_0/\partial t = 0$, then $Q_{k,GP}$ is (purely) gyroscopic.

REMARKS ON GYROSCOPIC FORCES/TERMS

(i) Typically, but not exclusively, gyroscopic forces appear in problems of *relative motion/moving axes* (§3.16); for example, Coriolis force [see also Gantmacher (1970, pp. 68–69), Goldstein (1980, pp. 21–23), for applications of generalized, or "velocity-dependent," potentials to electrodynamics].

(ii) Let us assume that $dq_k = \dot{q}_k\, dt$ (actual motion). Then, due to (3.9.8e), we have

$$d'W_g \equiv \sum \Big(\sum \gamma_{kl}\, \dot{q}_l\Big) dq_k = \Big(\sum\sum \gamma_{kl}\, \dot{q}_k\, \dot{q}_l\Big) dt = 0; \tag{3.9.9a}$$

but, in general,

$$\delta' W_g \equiv \sum \Big(\sum \gamma_{kl}\, \dot{q}_l\Big)\, \delta q_k = \sum\sum \gamma_{kl}\, \dot{q}_l\, \delta q_k \neq 0; \tag{3.9.9b}$$

that is, the *actual elementary work of gyroscopic forces vanishes*; but their *virtual work*, *in general*, *does not* (if it did, such forces would not have the opportunity to appear in Lagrangean equations!).

(iii) *Gyroscopicity of particle variables*: Let us call the force system $\{d\boldsymbol{F}\}$ gyroscopic, if it satisfies $S\, d\boldsymbol{F}\cdot\boldsymbol{v} = 0$. Substituting into this the particle velocity representation (3.9.1), we obtain, successively,

$$\begin{aligned} 0 &= S\, d\boldsymbol{F}\cdot\Big(\sum \boldsymbol{e}_k\, \dot{q}_k + \boldsymbol{e}_0\Big) = \sum \Big(S\, d\boldsymbol{F}\cdot\boldsymbol{e}_k\Big)\dot{q}_k + S\, d\boldsymbol{F}\cdot\boldsymbol{e}_0 \\ &= \sum Q_k \dot{q}_k + Q_0 \;\Rightarrow\; \sum Q_k\dot{q}_k \neq 0; \end{aligned} \tag{3.9.9c}$$

that is, in general, the corresponding *system* forces Q_k are not gyroscopic; and, conversely, even if the Q_k are gyroscopic (i.e., $\sum Q_k\dot{q}_k = 0$), the $d\boldsymbol{F}$ may not be $\big(S\, d\boldsymbol{F}\cdot\boldsymbol{v} \neq 0\big)$. However, if $\boldsymbol{e}_0 \equiv \partial\boldsymbol{r}/\partial t = \boldsymbol{0}$ (stationary holonomic constraints), then the Q_k and $d\boldsymbol{F}$ are gyroscopic simultaneously.

(iv) More generally, let us examine how gyroscopicity is affected by a general *frame of reference* transformation:

$$q \to q' :\; q_k = q_k(t, q_{k'}) \;\Rightarrow\; \dot{q}_k = \sum (\partial q_k/\partial q_{k'})\dot{q}_{k'} + \partial q_k/\partial t. \tag{3.9.9d}$$

Indeed, substituting (3.9.9d) into (3.9.8e), and recalling that the q'-frame impressed forces $Q_{k'}$ are defined by the frame invariant virtual work relation:

$$\delta' W = \sum Q_k\, \delta q_k = \sum Q_k \Big(\sum (\partial q_k/\partial q_{k'})\, \delta q_{k'}\Big) \equiv \sum Q_{k'}\, \delta q_{k'}, \tag{3.9.9e}$$

that is,

$$Q_{k'} = \sum (\partial q_k/\partial q_{k'}) Q_k \;\Leftrightarrow\; Q_k = \sum (\partial q_{k'}/\partial q_k) Q_{k'}, \tag{3.9.9f}$$

we obtain

$$\begin{aligned} 0 &= \sum Q_k\, \dot{q}_k = \sum Q_k \Big(\sum (\partial q_k/\partial q_{k'})\dot{q}_{k'}\Big) + \sum Q_k(\partial q_k/\partial t) \\ &= \sum Q_{k'}\, \dot{q}_{k'} + \sum Q_k(\partial q_k/\partial t) \;\Rightarrow\; \sum Q_{k'}\dot{q}_{k'} \neq 0; \end{aligned} \tag{3.9.9g}$$

that is, in general, the $Q_{k'}$ are nongyroscopic. If, however, $\partial q_k/\partial t = 0$ [in which case (3.9.9d) expresses a *coordinate* (*not a frame of reference*) transformation], the $Q_{k'}$ are also gyroscopic. In sum: *force gyroscopicity is a frame-dependent property*.

Finally, similar results hold for the generalized potential and corresponding forces in *nonholonomic* coordinates; that is,

$$V^* = V^*(t, q, \omega) = \sum \gamma^*{}_k(t, q)\, \omega_k + V^*{}_0(t, q) \equiv V^*{}_1(t, q, \omega) + V^*{}_0(t, q)$$
$$= generalized\ (nonholonomic)\ potential, \tag{3.9.9h}$$

$$\Rightarrow\ \Theta_{k,\,\text{generalized potential}} \equiv \Theta_{k,GP} \equiv (\partial V^*/\partial \omega_k)^{\cdot} - \partial V^*/\partial \theta_k$$
$$= \cdots = \sum \gamma^*{}_{kl}\, \omega_l + \partial \gamma^*{}_k/\partial t - \partial V^*{}_0/\partial \theta_k, \tag{3.9.9i}$$

where

$$\gamma^*{}_{kl} = \gamma^*{}_{kl}(t, q) \equiv \partial \gamma^*{}_k/\partial \theta_l - \partial \gamma^*{}_l/\partial \theta_k \quad (= -\gamma^*{}_{lk}). \tag{3.9.9j}$$

Rayleigh's Dissipation Function

Let us consider the linear viscous friction on a particle; that is, the impressed force given by the constitutive equation

$$d\boldsymbol{F} = -f\,\boldsymbol{v}, \qquad f = positive\ constant. \tag{3.9.10a}$$

Recalling (3.9.1), the corresponding system force $Q_{k,D} \equiv S\, d\boldsymbol{F}\cdot\boldsymbol{e}_k = \cdots$ can be expressed as

$$Q_{k,D} = -\partial F/\partial \dot{q}_k = -\sum f_{kl}\,\dot{q}_l - f_k, \tag{3.9.10b}$$

where the *Rayleigh dissipation function*, or *dissipativity* (Kelvin), F, is defined by

$$F \equiv S\,(f/2)\,\boldsymbol{v}\cdot\boldsymbol{v} = \cdots = F_2 + F_1 + F_0 \quad [= F(t, q, \dot{q})], \tag{3.9.10c}$$
$$F_2 \equiv (1/2)\sum f_{kl}\,\dot{q}_k\,\dot{q}_l\ (\geq 0), \qquad f_{kl} \equiv S f\,\boldsymbol{e}_k\cdot\boldsymbol{e}_l \quad (= f_{lk}), \tag{3.9.10d}$$
$$F_1 \equiv \sum f_k\,\dot{q}_k, \qquad f_k \equiv S f\,\boldsymbol{e}_k\cdot\boldsymbol{e}_0 \quad (= f_{k,n+1} \equiv f_{k,0}), \tag{3.9.10e}$$
$$F_0 \equiv (1/2) S f\,\boldsymbol{e}_0\cdot\boldsymbol{e}_0 \quad (= f_{n+1,n+1}/2 \equiv f_{0,0}/2); \tag{3.9.10f}$$

and has similar analytical properties with the kinetic energy (in the latter, replace dm with f).

Stationary Case

If $\boldsymbol{e}_0 \equiv \partial \boldsymbol{r}/\partial t = \boldsymbol{0}$ (case dealt by Rayleigh, in 1873), then

$$F = F_2 = (1/2)\sum f_{kl}\,\dot{q}_k\,\dot{q}_l, \tag{3.9.10g}$$

and the power of the corresponding dissipative forces, by Euler's homogeneous function theorem, equals

$$\sum Q_{k,D}\,\dot{q}_k = -\sum (\partial F/\partial \dot{q}_k)\dot{q}_k = -2F_2 \quad (= -2F); \tag{3.9.10h}$$

that is (as detailed below, or may be already known from general mechanics), $2F_2$ *measures the rate of decrease of the system's energy due to such friction*. For more general forms of dissipation functions, see Lur'e (1968, pp. 227–238).

Finally, if we use the nonholonomic particle velocity representation (3.9.4) in F, (3.9.10c), we will obtain the dissipation function in quasi variables: $F \to F^*(t, q, \omega) = \cdots$. The details are left to the reader.

Energy Rate, or Power (or Activity) Theorems

As a rule, such theorems are obtained by, first, multiplying (dotting) the equations of motion by the corresponding velocities and then summing over the entire system (or pairs of indices), for a fixed generic time. The result is a *single scalar equation* whose *inertia side* is (roughly) the rate of change of the kinetic energy of the system, and whose *force side* is the rate of working, or power, of whatever forces appear in the equations of motion.

Contrary to LP, which is a single energetic but *variational* equation (and, as such, can generate as many independent equations of motion as the number of the system's DOF), the energy rate relation is also a *single* energetic but *actual* equation (and, as such, it *cannot*, in general, be used to produce correct equations of motion)—and this is a *fundamental difference between energy and variational theorems/principles of mechanics!* [On this "insidious fallacy," see Pars (1965, pp. 86–87), also ex. 3.9.3.]

Below we derive these theorems (better, theorem in its various forms) in both holonomic and nonholonomic variables.

Holonomic Variables

Multiplying each Routh–Voss equation (3.5.15), say, with free index k, with $\dot{q}_k$ and summing over k, from 1 to n, and then invoking the earlier identity (3.9.3b) and the $m(< n)$ Pfaffian constraints $\sum a_{Dk}\,\dot{q}_k + a_D = 0$ [from which it follows that

$$\sum\Big(\sum \lambda_D\, a_{Dk}\Big)\dot{q}_k = \sum \lambda_D\Big(\sum a_{Dk}\,\dot{q}_k\Big) = -\sum \lambda_D\, a_D\Big], \tag{3.9.11a}$$

we obtain the *holonomic power equation*

$$\Big(\sum (\partial T/\partial \dot{q}_k)\dot{q}_k - T\Big)^{\cdot} = (T_2 - T_0)^{\cdot} = -\partial T/\partial t + \sum Q_k\,\dot{q}_k - \sum \lambda_D\, a_D. \tag{3.9.11b}$$

If some (or all) of the Q_k's are derived partly (or wholly) from a potential function V, then (3.9.3b) is replaced by

$$\sum E_k(L)\dot{q}_k \equiv \sum [(\partial L/\partial \dot{q}_k)^{\cdot} - \partial L/\partial q_k]\dot{q}_k = \partial L/\partial t + dh/dt, \tag{3.9.11c}$$

and, accordingly, (3.9.11b) is replaced by the simpler looking form

$$dh/dt = -\partial L/\partial t + \sum Q_k\,\dot{q}_k - \sum \lambda_D\, a_D, \tag{3.9.11d}$$

where

$$h = h(t, q, \dot{q}) \equiv \sum (\partial L/\partial \dot{q}_k)\dot{q}_k - L$$
$$= L_2 - L_0 = T_2 - (T_0 - V_0):$$

Generalized energy of the system in holonomic variables

(= *Hamiltonian function*, when expressed in terms of $t, q,$ and $p \equiv \partial T/\partial \dot{q}$; instead of the $\dot{q}$'s — see chap. 8), (3.9.11e)

and

$$L = L_2 + L_1 + L_0; \qquad L_2 \equiv T_2, \quad L_1 \equiv T_1 - V_1, \quad L_0 \equiv T_0 - V_0, \tag{3.9.11f}$$

Q_k = *nonpotential* part of virtual work term $(\ldots)\,\delta q_k$. (3.9.11g)

An additional useful form of the power theorem results if, instead of h, we use the ordinary (or classical) *total energy* of the system E:

$$E \equiv T + V_0 \quad (= T + V, \quad \text{if} \quad V_1 = 0). \tag{3.9.11h}$$

Then, since

$$h = T_2 - (T_0 - V_0) = (T - T_1 - T_0) - (T_0 - V_0) = (T + V_0) - (T_1 + 2T_0)$$

or

$$h = E - (T_1 + 2T_0) \qquad \text{or} \qquad E - h = T_1 + 2T_0, \tag{3.9.11i}$$

the power equations (3.9.11b, d) assume the equivalent *classical energy rate* form (analytical mechanics form of Leibniz's "law of vis viva")

$$dE/dt = -\partial L/\partial t + (T_1 + 2T_0)^{\cdot} + \sum Q_k\,\dot{q}_k - \sum \lambda_D\,a_D\,. \tag{3.9.11j}$$

If, in the above, all forces are *nonpotential*, then E and L must be replaced by T [$\rightarrow$ (3.9.11b)].

Problem 3.9.1 Show that in terms of the more general total energy

$$E' \equiv E + V_1 = T + V = T + (V_1 + V_0) \quad (\Rightarrow \dot{E} = \dot{E}' - \dot{V}_1), \tag{a}$$

the power equation (3.9.11j) becomes

$$dE'/dt = -\partial L/\partial t + (T_1 + 2T_0)^{\cdot} + \dot{V}_1 + \sum Q_k\,\dot{q}_k - \sum \lambda_D\,a_D. \tag{b}$$

Specializations

(i) If the (initial) holonomic constraints of the system are stationary/scleronomic, then $T_1, T_0 = 0, \partial T/\partial t = 0 \;\Rightarrow\; T = T_2, h = E = T_2 + V_0$, and (3.9.11d, j) reduce to

$$dE/dt = \partial V_0/\partial t + \sum Q_k\,\dot{q}_k - \sum \lambda_D\,a_D\,. \tag{3.9.11k}$$

(ii) If, further, $\partial V/\partial t = 0$ and all additional Pfaffian constraints are *catastatic*—that is, $a_D = 0$ $(D = 1, \ldots, m)$—then the above simplifies to

$$dE/dt = \sum Q_k \dot{q}_k, \tag{3.9.11l}$$

[or $dT/dt = \sum Q_k \dot{q}_k$, if *all* forces are *nonpotential*].

(iii) Finally, if all impressed forces are either *potential* $(Q_k = 0)$, or *gyroscopic*, then (3.9.11l) yields the *theorem of conservation of* (*classical*) *energy*:

$$dE/dt = 0 \ \Rightarrow \ E = T + V_0 = constant. \tag{3.9.11m}$$

Systems that satisfy all the above: namely, (a) *all* their constraints are *stationary* [slightly stronger than just catastatic—in view of (ii), condition (a) is sufficient but nonnecessary], (b) all their forces are either potential or gyroscopic, and (c) their (ordinary or generalized) potential does not depend explicitly on time; are called (classically) *conservative*. Hence, (3.9.11m) expresses the following theorem.

THEOREM

During any actual motion of a conservative system, its (*classical*) *energy*, evaluated at any point of its trajectory (or orbit), remains *constant*.

Equation (3.9.11m) is a *first* integral of the system's equations of motion; that is, it does *not* contain any accelerations; it is called the (classical) *energy integral*. [Equation (3.9.11m) is the reason for the *minus* sign in the potential force definitions (3.9.6a ff.). In the older literature (roughly, until the early 1900s), we frequently encounter the term "force function" for $U \equiv -V_0$: $Q_{k,\text{potential}} \equiv \partial U/\partial q_k$; then (3.9.11m) would read $T = U + constant$. Some authors have, *erroneously*, taken this to mean some kind of a scalar function from which we can, by taking its gradients, obtain *all* system forces!]

A slightly more general conservation theorem than (3.9.11m) can be obtained from (3.9.11d) wherever the following conditions apply: (a) $\partial L/\partial t = 0$ (which does *not* necessitate that T_1, T_0 vanish, and/or that $\partial T/\partial t$ or $\partial V/\partial t$ vanish individually), (b) all forces are either potential or gyroscopic, and (c) $a_D = 0$ (catastatic Pfaffian constraints). Then, (3.9.11d) yields the (holonomic) *Jacobi–Painlevé generalized energy integral*:

$$dh/dt = 0 \ \Rightarrow \ h = T_2 - (T_0 - V_0) = T_2 + (V_0 - T_0) = constant, \tag{3.9.11n}$$

even though in this case, as (3.9.11i) shows, $E \neq constant$; if, in addition, $T_0 = 0$, then (3.9.11n) reduces to (3.9.11m). Of course, the preceding are *sufficient* conditions, i.e. other combinations of physical circumstances can nullify the right side of (3.9.11d), and thus reproduce (3.9.11n).

Nonholonomic Variables

The power equations (3.9.11b, d, j), just like the equations of motion they came from, have two drawbacks: (i) they contain multipliers (reactions)—that is, they are "mixed power equations," and (ii) they cannot distinguish between nonholonomic Pfaffian constraints and holonomic ones disguised as Pfaffian. Hence the need for nonholonomic power equations. To obtain them, we begin by multiplying the *kinetic*

Hamel equations (3.5.19d, 20b, 21d) with $T^* \to L^* \equiv T^* - V^*$ (to include possible potential forces)

$$I_I \equiv (\partial L^*/\partial\omega_I)^{\cdot} - \partial L^*/\partial\theta_I + \sum\sum \gamma^r{}_{II'}(\partial L^*/\partial\omega_r)\omega_{I'} + \sum \gamma^r{}_I(\partial L^*/\partial\omega_r)$$
$$= \Theta_I \qquad (r = 1, \ldots, n;\ I, I' = m+1, \ldots, n), \tag{3.9.12a}$$

with ω_I and sum over I.

(i) Then notice that by (3.9.5b), with $T^* \to L^*$,

$$\sum E_I{}^*(L^*)\,\omega_I \equiv \sum E^*{}_I\,\omega_I \equiv \sum [(\partial L^*/\partial\omega_I)^{\cdot} - \partial L^*/\partial\theta_I]\omega_I$$
$$= dh^*/dt + \partial L^*/\partial\theta_{n+1}, \tag{3.9.12b}$$

where

$$h^* \equiv \sum (\partial L^*/\partial\omega_I)\,\omega_I - L^* = L^*{}_2 - L^*{}_0 = T^*{}_2 + (V^*{}_0 - T^*{}_0)$$
$$= h^*(t, q, \omega)\text{: \textit{generalized energy of the system,}}$$
$$\text{\textit{in nonholonomic variables}}\ (\neq h,\ \text{in general}), \tag{3.9.12c}$$

and

$$L^* = L^*(t, q, \omega) \equiv L^*{}_2 + L^*{}_1 + L^*{}_0;$$
$$L^*{}_2 \equiv T^*{}_2, \qquad L^*{}_1 \equiv T^*{}_1 - V^*{}_1, \qquad L^*{}_0 \equiv T^*{}_0 - V^*{}_0, \tag{3.9.12d}$$

$$\Theta_I = \text{\textit{nonpotential} part of virtual work term } (\ldots)\,\delta\theta_I, \tag{3.9.12e}$$

and

$$\partial L^*/\partial\theta_{n+1} \equiv \partial L^*/\partial t + \sum A_k(\partial L^*/\partial q_k) \tag{3.9.12f}$$

[Note the differences between (3.9.12b) and (3.9.11c); and absence of *linear* $\omega(\dot{q})$ terms in $h^*(h)$, even though $T^*{}_1(T_1)$ appear in $E^*{}_I(E_k)$].

(ii) Since $\gamma^r{}_{II'} = -\gamma^r{}_{I'I}$ (i.e., antisymmetry, or *gyroscopicity*, of Hamel's coefficients),

$$\sum\Big(\sum\sum \gamma^r{}_{II'}(\partial L^*/\partial\omega_r)\omega_{I'}\Big)\omega_I = \sum\Big(\sum\sum \gamma^r{}_{II'}\omega_{I'}\omega_I\Big)(\partial L^*/\partial\omega_r) = 0. \tag{3.9.12g}$$

Collecting these results, we obtain the *nonholonomic* (*multiplierless, or kinetic*) *power equation*

$$\sum I_I\,\omega_I = \sum E_I{}^*(L^*)\,\omega_I + \sum\Big(\sum \gamma^r{}_I(\partial L^*/\partial\omega_r)\Big)\omega_I = \sum \Theta_I\,\omega_I, \tag{3.9.12h}$$

or, finally,

$$dh^*/dt = -\partial L^*/\partial\theta_{n+1} + \sum \Theta_I\,\omega_I - R, \tag{3.9.12i}$$

where

$$R \equiv \sum\sum \gamma^r{}_I(\partial L^*/\partial\omega_r)\,\omega_I\text{: \textit{rheonomic nonholonomic power.}} \tag{3.9.12j}$$

From this important equation, we draw the following special conclusions: by (2.10.4),

$$\gamma^r{}_I = \sum\sum (\partial a_{rk}/\partial q_l - \partial a_{rl}/\partial q_k) A_{kI}\, A_l + \sum (\partial a_{rk}/\partial t - \partial a_r/\partial q_k) A_{kI}, \quad (3.9.12\text{k})$$

and, therefore, if $a_r \equiv a_{r,n+1} = 0 \Rightarrow A_r \equiv A_{r,n+1} = 0$, then $\partial L^*/\partial \theta_{n+1} = \partial L^*/\partial t$ and

$$R = \cdots = \sum\sum\sum [(\partial a_{rk}/\partial t) A_{kI}](\partial L^*/\partial \omega_r)\, \omega_I = \sum\sum (\partial a_{rk}/\partial t)(\partial L^*/\partial \omega_r)\dot{q}_k; \quad (3.9.12\text{l})$$

if, further, $a_{rk} = a_{rk}(q)$, then $R = 0$, and (3.9.12i) reduces to

$$dh^*/dt = -\partial L^*/\partial t + \sum \Theta_I \omega_I \quad (3.9.12\text{m})$$

(R also vanishes *if all Pfaffian constraints are holonomic*; then $\gamma^r{}_I = 0$); and, if, in addition, $\partial L^*/\partial t = 0$ and $\sum \Theta_I \omega_I = \sum \Theta_k \omega_k = 0$ (all impressed forces are potential; i.e., $\Theta_I = 0$, or gyroscopic), then (3.9.12m) leads immediately to the *nonholonomic Jacobi–Painlevé energy integral*

$$dh^*/dt = 0 \;\Rightarrow\; h^* = T^*{}_2 + (V^*{}_0 - T^*{}_0) = \textit{constant}. \quad (3.9.12\text{n})$$

[However, other combinations can create the same result—see example of rolling sphere on spinning plane (ex. 3.18.4).]

Finally, as with the Hamel-type equations of motion, the constraints $\omega_D = 0$ should be enforced *after* all pertinent differentiations have been carried out; otherwise we would miss the $\sum\sum \gamma^D{}_I(\partial L^*/\partial \omega_D)\, \omega_I$ terms in R.

REMARKS

(i) As (3.9.12f) shows, the term $\partial L^*/\partial \theta_{n+1}$ derives from the *nonstationarity* of L^* [through $\partial L^*/\partial t$, as in the *holonomic* case (3.9.11d)] and also from the acatastaticity of the Pfaffian constraints [through $\sum A_k(\partial L^*/\partial q_k)$], whether these latter are nonholonomic or not.

(ii) The R term should be expected on analytical and physical grounds: Hamel's equations, through their γ-terms, do distinguish between genuine nonholonomic constraints and holonomic ones disguised in velocity/differential form; and this *unique characteristic* of theirs is carried over to the *corresponding power equation* (3.9.12i).

(iii) The above make clear that the *nonholonomic and kinetic equation* (3.9.12i) can be written down *without knowledge of the solution of the equations of motion* [unlike its holonomic counterpart (3.9.11d, j), which require knowledge of the multipliers].

(iv) Had we used the following definition:

$$d^*L^*/dt \equiv \sum [(\partial L^*/\partial \theta_I)\, \omega_I + (\partial L^*/\partial \omega_I)\, \dot{\omega}_I] + \partial L^*/\partial t, \quad (3.9.12\text{o})$$

instead of the one made here [in view of $L^* = L^*(t, q, \omega)$]:

$$dL^*/dt \equiv \sum [(\partial L^*/\partial q_k)\dot{q}_k + (\partial L^*/\partial \omega_k)\dot{\omega}_k] + \partial L^*/\partial t, \quad (3.9.12\text{p})$$

then

$$
\begin{aligned}
dL^*/dt - d^*L^*/dt &= \sum (\partial L^*/\partial q_k)\dot{q}_k - \sum (\partial L^*/\partial \theta_I)\,\omega_I \\
&= \sum (\partial L^*/\partial q_k)\Big(\sum A_{kI}\,\omega_I + A_k\Big) - \sum (\partial L^*/\partial \theta_I)\,\omega_I \\
&= \cdots = \sum (\partial L^*/\partial q_k)A_k = \partial L^*/\partial \theta_{n+1} - \partial L^*/\partial t \qquad (3.9.12\text{q})
\end{aligned}
$$

[and for a general function $f^*(t, q, \omega)$: $df^*/dt = d^*L^*/dt + \sum (\partial f^*/\partial q_k)A_k$]; and the power equation would be

$$d^*h^*/dt = -\partial L^*/\partial t + \sum \Theta_I\,\omega_I - R, \tag{3.9.12r}$$

where

$$d^*h^*/dt \equiv \Big(\sum (\partial L^*/\partial \omega_I)\,\omega_I\Big)^{\cdot} - d^*L^*/dt. \tag{3.9.12s}$$

(v) Since $\omega_D = 0$, no power equations can result by multiplying Hamel's equations (kinetic and/or kinetostatic) with ω_D.

(vi) A power theorem in terms of the classical *total energy*, *but in nonholonomic variables*

$$E = E^* \equiv T^* + V^*_0 = \cdots = h^* + (T^*_1 + 2T^*_0) \quad [= T^* + V^*, \quad \text{if} \quad V^*_1 = 0], \tag{3.9.12t}$$

can also be formulated. The details are left to the reader.

(vii) About the possibility of formulating power equations using the remaining two general forms of the equations of motion—namely, those by Appell and Maggi—we note the following:

(a) The equations of Appell *contain accelerations explicitly*, and therefore are pretty inconvenient as a starting point for power equations.

(b) Multiplying each of Maggi's kinetic equations (3.5.19a, 20b, 21a) with ω_I and then summing over I, we obtain, successively,

$$\sum \Big(\sum A_{kI}\,E_k\Big)\omega_I = \sum \Big(\sum A_{kI}\,Q_k\Big)\omega_I, \tag{3.9.12u}$$

or, since $\dot{q}_k = \sum A_{kI}\,\omega_I + A_k$,

$$\sum E_k(\dot{q}_k - A_k) = \sum Q_k(\dot{q}_k - A_k),$$

or, rearranging,

$$\sum (E_k - Q_k)A_k = \sum (E_k - Q_k)\dot{q}_k. \tag{3.9.12v}$$

It is not hard to show that, since $E_k - Q_k = \sum \lambda_D\,a_{Dk}$ and [recalling the second of (2.9.3a)] $\sum a_{Dk}\,A_k = -a_D$, both sides of the above equal $-\sum \lambda_D\,a_D$, and so no really new power theorem has emerged here.

(viii) The *methodology* of this section can be carried intact to the case of *nonlinear* constraints/coordinates, $\omega = \omega(t, q, \dot{q})$ — see chap. 5.

Example 3.9.1 *Energy Rate Equations in Particle Variables via LP or the Central Equation.* Let us consider a *stationary* system; that is, one whose constraints are all *scleronomic*. Then, $\delta\boldsymbol{r}$ and $d\boldsymbol{r}$ are mathematically equivalent. Hence:

(i) Substituting $d\boldsymbol{r} = \boldsymbol{v}\,dt$ for $\delta\boldsymbol{r}$ in LP yields

$$\mathcal{S}\, dm\, \boldsymbol{a} \cdot d\boldsymbol{r} = \mathcal{S}\, d\boldsymbol{F} \cdot d\boldsymbol{r} \;\Rightarrow\; dT = d'W; \tag{a}$$

(ii) Similarly, with $\delta\boldsymbol{r} \to d\boldsymbol{r} = \boldsymbol{v}\,dt$ and $\delta\boldsymbol{v} \to d\boldsymbol{v}$, the central equation (3.6.6) yields

$$\mathcal{S}\, dm\, \boldsymbol{v} \cdot d\boldsymbol{v} + \mathcal{S}\, d\boldsymbol{F} \cdot d\boldsymbol{r} = d/dt\Big(\mathcal{S}\, dm\, \boldsymbol{v} \cdot d\boldsymbol{r}\Big)$$
$$\Rightarrow\; dT + d'W = d(2T) \;\Rightarrow\; dT = d'W; \tag{b}$$

that is, in both cases we obtain, as a special case, the differential form (in time) of the work–energy theorem.

Problem 3.9.2 Consider a system of N particles, under the ideal constraints

$$\begin{aligned} &\phi_H(\boldsymbol{r}_P, t) = 0 && (H = 1, \ldots, h), \\ &\sum \boldsymbol{B}_{DP}(\boldsymbol{r}_P, t) \cdot \boldsymbol{v}_P + B_D(\boldsymbol{r}_P, t) = 0 && (D = 1, \ldots, m), \end{aligned} \tag{a}$$

and, therefore (recall ex. 3.5.1) having Lagrangean equations of the first kind

$$m_P\, \boldsymbol{a}_P = \boldsymbol{F}_P + \boldsymbol{R}_P, \qquad \boldsymbol{R}_P = \sum \mu_H (\partial\phi_H/\partial\boldsymbol{r}_P) + \sum \lambda_D\, \boldsymbol{B}_{DP}, \tag{b}$$

where $\boldsymbol{F}_P$ ($\boldsymbol{R}_P$): *total impressed* (*reaction*) *force on a system particle* $P = 1, \ldots, N$ ($=$ # *particles*), and $3N - (h + m) > 0$. Show that its corresponding *power* equation is

$$dT/dt = \sum \boldsymbol{F}_P \cdot \boldsymbol{v}_P - \sum \mu_H (\partial\phi_H/\partial t) - \sum \lambda_D\, B_D; \tag{c}$$

and then interpret it physically.

Problem 3.9.3 Continuing from the preceding problem, show that for *stationary* constraints (i.e., scleronomic system) and *potential* impressed forces (i.e., $\boldsymbol{F}_P = -\partial V_0(\boldsymbol{r}_P, t)/\partial\boldsymbol{r}_P$), the power equation (c) reduces to the nonstationary energy rate equation

$$dE/dt = -\partial V_0/\partial t, \qquad E \equiv T + V_0. \tag{a}$$

Example 3.9.2 *Power Equations from Particle Variable Considerations.* Dotting the Newton–Euler equation of particle motion (in continuum form) $dm\,\boldsymbol{a} = d\boldsymbol{F} + d\boldsymbol{R}$ with the inertial particle velocity $\boldsymbol{v}$, and then summing over the system particles, we obtain the "D'Alembert–Lagrange form of the power theorem"

$$\mathcal{S}\, dm\, \boldsymbol{a} \cdot \boldsymbol{v} = \mathcal{S}\, d\boldsymbol{F} \cdot \boldsymbol{v} + \mathcal{S}\, d\boldsymbol{R} \cdot \boldsymbol{v}. \tag{a}$$

[That, in general, $\mathcal{S}\, d\boldsymbol{R} \cdot \boldsymbol{v} \neq 0$ points to another big difference between power theorems and LP]. Next, substituting into (a) the *holonomic* representation (3.9.1),

$\boldsymbol{v} = \sum \boldsymbol{e}_k \dot{q}_k + \boldsymbol{e}_0$, we get

$$\sum \left(S\, dm\, \boldsymbol{a} \cdot \boldsymbol{e}_k \right) \dot{q}_k + S\, dm\, \boldsymbol{a} \cdot \boldsymbol{e}_0 = \sum \left(S\, d\boldsymbol{F} \cdot \boldsymbol{e}_k \right) \dot{q}_k + \sum \left(S\, d\boldsymbol{R} \cdot \boldsymbol{e}_k \right) \dot{q}_k + S\, (d\boldsymbol{F} + d\boldsymbol{R}) \cdot \boldsymbol{e}_0, \tag{b}$$

and, from this, we immediately obtain the *two* holonomic power equations:

(i)
$$\sum E_k \dot{q}_k = \sum Q_k \dot{q}_k + \sum R_k \dot{q}_k, \tag{c}$$

and, since $R_k = \sum \lambda_D a_{Dk} \;\Rightarrow\; \sum R_k \dot{q}_k = \cdots = -\sum \lambda_D a_D$,

$$\sum E_k \dot{q}_k = \sum Q_k \dot{q}_k - \sum \lambda_D a_D, \tag{d}$$

that is, eq. (3.9.11c, d); and the "rheonomic power equation"

(ii)
$$S\, dm\, \boldsymbol{a} \cdot \boldsymbol{e}_0 = S\, (d\boldsymbol{F} + d\boldsymbol{R}) \cdot \boldsymbol{e}_0,$$

that is,

$$S\, dm\, \boldsymbol{a} \cdot (\partial \boldsymbol{r}/\partial t) = S\, (d\boldsymbol{F} + d\boldsymbol{R}) \cdot (\partial \boldsymbol{r}/\partial t). \tag{e}$$

Similarly, inserting in (a) the *nonholonomic* representation (3.9.4), $\boldsymbol{v}^* = \sum \boldsymbol{\varepsilon}_I \omega_I + \boldsymbol{\varepsilon}_0$, we obtain the two power equations

$$\sum I_I \omega_I = \sum \Theta_I \omega_I, \tag{f}$$

that is, eq. (3.9.12h); and

$$S\, dm\, \boldsymbol{a} \cdot (\partial \boldsymbol{r}/\partial \theta_{n+1}) = S\, (d\boldsymbol{F} + d\boldsymbol{R}) \cdot (\partial \boldsymbol{r}/\partial \theta_{n+1}) \quad \text{or} \quad I_{n+1} = \Theta_{n+1} + \Lambda_{n+1}. \tag{g}$$

Example 3.9.3 *On the Derivation of Lagrangean Equations of Motion from the Single Power Equation* (Pars' "insidious fallacy"). It is frequently claimed [especially in engineering books on vibration, but also in more theoretical and classy expositions; e.g., Birkhoff (1927, p. 17), Corben and Stehle (1960 and 1994, pp. 78–79)] that the *Lagrangean equations of motion*, say for concreteness, the Routh–Voss equations

$$E_k = Q_k + R_k, \qquad R_k = \sum \lambda_D a_{Dk}, \tag{a}$$

can be derived, not only from Lagrange's principle (LP), which is variational, but also from a *single power equation*, like (c) of the preceding example:

$$\sum E_k \dot{q}_k = \sum Q_k \dot{q}_k + \sum R_k \dot{q}_k, \tag{b}$$

and, therefore, one does not need all those strange and annoying concepts like virtual displacements/work, LP, and so on.

Well, such claims are false for the following reasons:

(i) Clearly, the forces in eq. (a) whose power is zero will not appear in eq. (b). How, then, are such forces going to be retrieved in the reverse reasoning from (b) to (a)? Such equations of motion would be "correct to within zero power terms" [just like Lagrangean equations are "correct to within zero *virtual* work terms"; or contain multiplier-proportional terms, like (a)]. The most important such "zero power forces" are the following two: (a) constraint reactions of *catastatic* Pfaffian constraints, and (b) (impressed) *gyroscopic* forces; like the γ-proportional terms of the Hamel-type equations. So the claim that if the Q_k are wholly potential (i.e., $Q_k = -\partial V_0(q,t)/\partial t$), then the equations of motion are $E_k(L) = Q_k + \sum \lambda_D a_{Dk}$, may be correct (for a nongyroscopic system), or it may not (for a gyroscopic system). (See also Ziegler, 1968, pp. 34–35.)

(ii) But there is a more serious objection to a reasoning that "leads" from the *single* equation (b) to the n equations (a), even for catastatic and nongyroscopic systems. We can deduce eq. (a) from LP—that is, $\sum (E_k - Q_k)\,\delta q_k = 0$, under $\sum a_{Dk}\,\delta q_k = 0$ — because of the *arbitrariness* of the δq's. On the other hand, eq. (b), rewritten as $\sum (E_k - Q_k - R_k)\,dq_k = 0$, holds for $dq_k = (\dot{q}_k)dt =$ *actual motion differentials/velocities*.

(iii) We have seen (§3.6) that LP is equivalent to the central equation

$$\delta T + \delta' W = \left(\sum (\partial T/\partial_k)\,\delta q_k\right)^{\cdot}. \tag{c}$$

On the other hand, as we know from general mechanics, the power equation (b) is equivalent to

$$dT = d'W, \tag{d}$$

where $d'W$ is *actual elementary work*, *in time*, *of all forces*; that is, *impressed plus reactions*. Hence, eqs. (c) and (d) are, in general, very different equations; eq. (c) represents much more than eq. (d).

HISTORICAL REMARK

A fair number of (unsuccessful) attempts to derive all the equations of motion from a single energy equation were made in the late 1800s to early 1900s by the so-called school of "Energetics." Specifically, its followers sought to obtain the equations of motion from the energy conservation equation (3.9.11m)

$$E \equiv T + V_0 = constant, \qquad V_0 = V_0(\boldsymbol{r}). \tag{e}$$

If the system is *unconstrained*, then $(\ldots)^{\cdot}$-differentiating (e) we obtain

$$\mathcal{S}\,[dm\,\boldsymbol{a} + (\partial V_0/\partial \boldsymbol{r})]\cdot \boldsymbol{v} = 0, \tag{f}$$

and further, if this holds for each and every value of $\boldsymbol{v}$, then we are led to the correct equation

$$dm\,\boldsymbol{a} + (\partial V_0/\partial \boldsymbol{r}) = \boldsymbol{0}. \tag{g}$$

If, however, the system if *constrained* then, as Lipschitz remarked, this argument does *not* apply. To circumvent this difficulty, Helm, a leading "energeticist," proposed that, instead of introducing the usual virtual considerations, give the energy "principle" the following form: *the total energy change along any kinematically possible translational and/or rotational direction should vanish*. But, under such an arbitrary variation [assuming $\delta(d\boldsymbol{r}) = d(\delta\boldsymbol{r})$],

$$V_0 \;\rightarrow\; V_0 + \delta V_0 = V_0 + \mathcal{S}\,(\partial V_0/\partial \boldsymbol{r})\cdot\delta\boldsymbol{r},$$

$$\begin{aligned} T + \delta T &= T + \mathcal{S}\, dm\,\boldsymbol{v}\cdot\delta\boldsymbol{v} \\ &= T + d/dt\left(\mathcal{S}\, dm\,\boldsymbol{v}\cdot\delta\boldsymbol{r}\right) - \mathcal{S}\, dm\,\boldsymbol{a}\cdot\delta\boldsymbol{v}, \end{aligned}$$

that is,

$$\delta T = d/dt\Big(\mathcal{S}\, dm\, \boldsymbol{v} \cdot \delta \boldsymbol{r}\Big) - \delta I \quad (\Rightarrow \delta T \neq \delta I).$$

Combining the above with $\delta E \equiv \delta T + \delta V_0 = 0$, we obtain

$$\delta I - \delta V_0 = d/dt\Big(\mathcal{S}\, dm\, \boldsymbol{v} \cdot \delta \boldsymbol{r}\Big),$$

instead of the correct $\delta I + \delta V_0 = 0$. Hence, such a variation of the energy equation does *not* produce the correct equations even for a conservative system; again, the stumbling block is the difference between (c) and (d). If, on the other hand, we had *defined*, a priori,

$$\delta T \equiv \mathcal{S}\, dm\, \boldsymbol{a} \cdot \delta \boldsymbol{r} \quad (= \delta I),$$

then $\delta T + \delta V_0 = 0$ would indeed lead to the correct equations of motion, but that would be an *arbitrary formalism* with the sole purpose to show the *equivalence between the energy rate equation and LP*. [At the time, that was a hotly debated issue among some of the best physicists of the day; and it makes us, today, appreciate better the simple and correct formulations of Heun and Hamel.] However, such ideas of *invariance of a certain differential* (*or integral*) *variational energetic expression under translations/rotations* proved useful later in supplying classical and nonclassical conservation theorems; for example, integral invariants (§8.12), Noetherian theory (§8.13), and so on; see also Dobronravov (1976, pp. 139–186, 209–249).

Example 3.9.4 Let us consider a homogeneous bar AB of mass m and length l pinned to the vertical shaft S of negligible mass (fig. 3.23). The system is constrained to spin about S with the *constant* angular velocity $\boldsymbol{\Omega}$. Let us discuss its power equation.

We will present two solutions: one with $q_1 = \theta$ as the sole unconstrained Lagrangean coordinate, and one with the *two* Lagrangean coordinates, $q_1 = \phi$ (angle of precession of shaft) and $q_2 = \theta$, but under the holonomic constraint

$$f_1 \equiv \phi - \Omega t \pm constant = 0 \quad \text{(finite form)} \tag{a1}$$

$$\Rightarrow \delta f_1 = \delta\phi = 0 \quad \text{(virtual form, since } \delta t = 0\text{)}, \tag{a2}$$

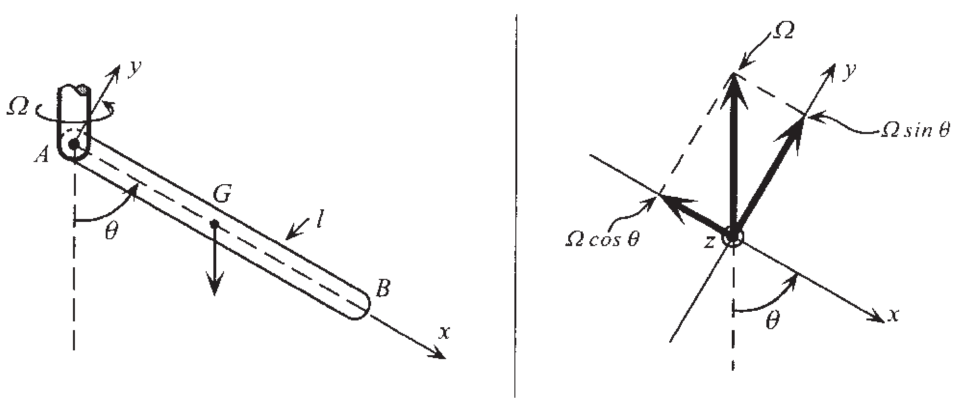


Figure 3.23 Geometry and kinematics of spinning bar *AB*.

or

$$\dot{\phi} + (-\Omega) = 0 \quad \text{(velocity form, acatastatic).} \tag{a3}$$

(i) *First solution* ($n = 1, m = 0$ — constraints embedded, no multipliers): Here $\boldsymbol{\omega}$ = *inertial angular velocity of AB* $= (-\Omega\cos\theta, \Omega\sin\theta, \dot{\theta})$, along the *body-fixed* (*and principal*) axes A–xyz, and $\boldsymbol{I}$ is the *moment of inertia tensor of AB at A*: *diagonal*($I_x = 0$, $I_y = ml^2/3, I_z = ml^2/3$). Hence, by König's theorem, and with $(\ldots)_o$ denoting constrained system quantities, we have

$$\begin{aligned} 2T_o &= I_x{\omega_x}^2 + I_y{\omega_y}^2 + I_z{\omega_z}^2 \\ &= (ml^2/3)[\Omega^2\sin^2\theta + (\dot{\theta})^2] = 2T_{o,2} + 2T_{o,1} + 2T_{o,0}, \end{aligned} \tag{b1}$$

where

$$2T_{o,2} = (ml^2/3)(\dot{\theta})^2, \qquad 2T_{o,1} = 0, \qquad 2T_{o,0} = (ml^2/3)(\sin^2\theta)\Omega^2, \tag{b2}$$

$$V_o \equiv V = -(mgl/2)\cos\theta \quad (= 0 \text{ at horizontal level through } A); \tag{b3}$$

that is, $\partial L_o/\partial t \equiv \partial(T_o - V)/\partial t = 0$; also, $Q_{\theta,\text{nonpotential}} \equiv Q_\theta = 0$, $a_D = 0$ (no constraints $\Rightarrow$ no multipliers). As a result of the above, the power equation (3.9.11d) reduces to the Jacobi–Painlevé integral (3.9.11n):

$$h \to h_o \equiv T_{o,2} + (V - T_{o,0}) = \textit{constant}$$

(evaluated at some initial time instant, and hence function of the initial conditions $\neq E_o \equiv T_o + V$)

or

$$l(\dot{\theta})^2 - 3g\cos\theta - (l\sin^2\theta)\Omega^2 = \textit{constant}; \tag{c}$$

an equation which, for given initial conditions, relates θ and $\dot{\theta}$; but, being a kinetic power equation, cannot supply the reactive couple M enforcing the constraint $\Omega = \textit{constant}$. To find the latter, either we apply the elementary "Newton–Euler" power equation to this constrained system, in which case M appears as an *external* moment; or we apply the generalized power equation to the relaxed system (second solution), in which case M appears either as a Lagrangean multiplier or as an impressed moment. Indeed, we have:

(ii) *Elementary power equation* [corresponding to (i)]: here, eq. (3.9.11j)

$$dE/dt = -\partial L/\partial t + (T_1 + 2T_0)^{\bullet} + \sum Q_k\,\dot{q}_k - \sum \lambda_D a_D, \tag{d1}$$

reduces to

$$dE_o/dt \equiv (T_o + V)^{\bullet} = (2T_{o,0})^{\bullet}, \tag{d2}$$

and therefore the elementary ("Newton–Euler") power equation, dE/dt = power of *external* forces and couples, yields

$$(2T_{o,0})^{\bullet} = M\Omega \quad \Rightarrow \quad M = (2T_{o,0})^{\bullet}/\Omega = (2ml^2\Omega/3)\sin\theta\cos\theta\,\dot{\theta}; \tag{d3}$$

that is, $M = \textit{variable}$, even though $\Omega = \textit{constant}$.

Without the benefit of (d1, 2) [or (3.9.11i): $\dot{E}_o - \dot{h}_o = (T_{o,1} + 2T_{o,0})^{\cdot} = (2T_{o,0})^{\cdot}$], the elementary power theorem, $(T_o + V)^{\cdot} = M\Omega$, would have given

$$\left\{(ml^2/6)\left[\Omega^2 \sin^2\theta + (\dot{\theta})^2\right] - (mgl/2)\cos\theta\right\}^{\cdot} = M\Omega, \tag{d4}$$

and this, to eliminate $\ddot{\theta}$ and thus reproduce (d3), would have to be combined with the kinetic θ-equation, or with the $(\ldots)^{\cdot}$ version of (c).

(iii) *Second solution* ($n = 2, m = 1$ — constraints adjoined, multipliers): Here, we have

$$2T = (ml^2/3)(\dot{\theta})^2 + (ml^2/3)(\dot{\phi}\sin\theta)^2 = 2T_2 + 2T_1 + 2T_0, \tag{e1}$$

where

$$2T_2 = (ml^2/3)(\sin^2\theta)(\dot{\phi})^2 + (ml^2/3)(\dot{\theta})^2, \qquad 2T_1 = 0, \qquad 2T_0 = 0, \tag{e2}$$

$$V = -(mgl/2)\cos\theta \quad (= 0 \text{ at horizontal level through } A); \tag{e3}$$

that is, $\partial L/\partial t \equiv \partial(T - V)/\partial t = 0$.

Next, and in the sense of the relaxation principle, either we take $Q_{k,\text{nonpotential}} \equiv Q_k = 0$, but [recalling (a1–3), and since now $n = 2, m = 1$] *add* the term $-\sum \lambda_D a_D = -\lambda_1 a_1 = -\lambda_1(-\Omega) \equiv \lambda\,\Omega$; or, using the "rubber-band" approach, we take $\lambda_D = 0$, but keep the term $\sum Q_k \dot{q}_k = Q_\phi \dot{\phi}$, where $(\delta' W)_\phi \equiv Q_\phi\,\delta\phi = M\,\delta\phi$, since now M has become an impressed force (moment) and $\delta\phi \neq 0$. Following the first of these two equivalent alternatives, we obtain $\dot{h} = \lambda\,\Omega$, or since [recall (3.9.11i)] $h = E - (T_1 + 2T_0) = E$, we find $(\dot{E})_o = \lambda\,\Omega$, that is, (d3); and similarly for the second approach.

In this problem, the first solution (constrained system) is simpler; but to find the constraint reaction, we had to go *outside* of Lagrangean mechanics, to the Newton–Euler power equation (3.9.11j) [$\Rightarrow$ line following (d2)]. The second solution (relaxed system) could prove more useful in complicated situations, where the application of (d1, 2) might not be so simple.

Problem 3.9.4 Continuing from the preceding example, discuss the power equations if ϕ and θ are connected by the acatastatic Pfaffian constraint $\dot{\phi} + (-c)\theta = 0$, $c = constant$; that is, $\Omega \equiv \dot{\phi} = c\theta$ (variable rate of shaft spinning).

Problem 3.9.5 Consider a particle of mass m moving on a smooth circular tube of radius r (fig. 3.24).

(i) Show that if the tube is *free to rotate* about a vertical diameter, the Lagrangean equations of motion of the particle + tube system, for $q_1 = \phi$ and $q_2 = \theta$, are

$$E_\phi = \left[(I + mr^2\sin^2\theta)\dot{\phi}\right]^{\cdot} = Q_\phi, \qquad E_\theta = mr^2[\ddot{\theta} - \sin\theta\cos\theta(\dot{\phi})^2] = Q_\theta, \tag{a}$$

where I = *moment of inertia of tube about its vertical diameter*. Calculate and interpret Q_ϕ, Q_θ.

(ii) Show that if the tube is constrained to rotate with *constant* angular velocity, $\dot{\phi} \equiv \Omega = constant$, then the driving moment needed to enforce this constraint, M, equals

$$M = 2mr^2\Omega\sin\theta\cos\theta\,\dot{\theta} = mr^2\Omega\sin(2\theta)\,\dot{\theta}:$$
$$\textit{variable}, \text{ even though } \Omega \text{ is } \textit{constant}. \tag{b}$$

Relate M with Q_ϕ, and interpret the second of (a).

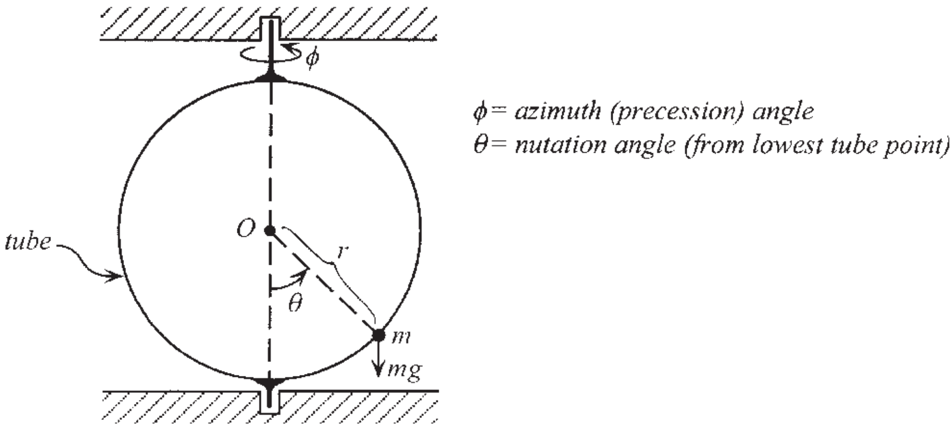

Figure 3.24 Particle moving on a smooth circular spinning tube.

HINT

$m\Omega^2(r\sin\theta) = $ *centrifugal force on particle*.

(iii) Discuss the power theorem in case (ii), and, with its help, calculate M.

[See also Greenwood (1977, pp. 74–77) for a discussion of the stability of the equilibrium of the particle relative to the tube, in case (ii).]

Problem 3.9.6 (Berezkin, 1968, vol. II, pp. 67–68). Consider a homogeneous bar AB of mass m and length $2l$, whose ends A and B are constrained to slide on the perpendicular and smooth sides of the rigid, plane, and rectangular frame *abcd* [fig. 3.25(a)]. The whole assembly is constrained to rotate about the vertical axis (v) with constant (inertial) angular velocity $\boldsymbol{\omega}$.

(i) Show that the kinetic Lagrangean equation of the (relative) angular motion of the bar is

$$\ddot{\theta} + \omega^2 \sin\theta\cos\theta = -(3g/4l)\cos\theta. \qquad \text{(a)}$$

(ii) Then show that the corresponding *Jacobi–Painlevé* integral—that is, $(T_2 - T_0) + V_0 = constant$ — is

$$(2l/3)\left[(\dot{\theta})^2 - \omega^2\cos^2\theta\right] + g\sin\theta = constant \equiv h. \qquad \text{(b)}$$

(iii) By applying the *principle of relaxation* (§3.7), show that the kinetostatic equation that yields the normal reaction at A, N, is

$$ml\left[\ddot{\theta}\cos\theta - (\dot{\theta})^2\sin\theta\right] = -mg + N. \qquad \text{(c)}$$

HINT

Introduce the relaxed coordinate y (fig. 3.25); and, at the end, set $y = 0$.

(iv) Finally, show that, substituting into (c): $\ddot{\theta}$ from the kinetic equation (a), and $(\dot{\theta})^2$ from the energy integral (b), we obtain

$$\begin{aligned} N &= mg - ml\left[2\omega^2\sin\theta\cos^2\theta + (3g/4l)(\cos^2\theta - 2\sin^2\theta) + (3h/2m)\sin\theta\right] \\ &= \text{function of } \theta, \omega, \text{ and the initial conditions (through } h). \qquad \text{(d)} \end{aligned}$$

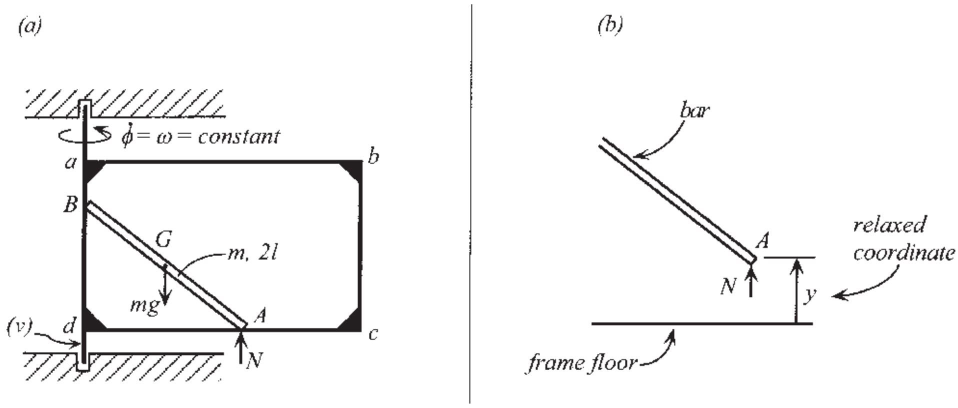

Figure 3.25 (a) Bar *AB* sliding on a uniformly rotating, plane, rigid, and rectangular frame *abcd*; (b) relaxed end *A*, with corresponding coordinate *y* and reaction *N*.

Example 3.9.5 *Introduction to Relative Motion* (for an extensive coverage see §3.16). Let us consider a particle P of mass m constrained to move on, say, the outer surface of a vertical circular and smooth cylinder of radius r (fig. 3.26). We will examine the energy equation of the particle when the cylinder is stationary, and when it spins about OZ with constant angular velocity $\boldsymbol{\omega}$. Then we will examine the case when P moves relative to the cylinder–fixed axes O–xyz.

(i) *Stationary cylinder*. With $q_1 = \Phi$ and $q_2 = Z$ (here, $r = constant \Rightarrow \dot{r} = 0$) and the plane $Z = 0$ for zero potential energy, we have

$$2T = m[r^2(\dot{\Phi})^2 + (\dot{Z})^2], \qquad V = mgZ, \qquad L = T - V, \tag{a}$$

and, therefore,

$$\begin{aligned} h &= (\partial L/\partial\dot{\Phi})\dot{\Phi} + (\partial L/\partial\dot{Z})\dot{Z} - L = \cdots = (m/2)[r^2(\dot{\Phi})^2 + (\dot{Z})^2] + mgZ \\ &= E \equiv T + V = constant, \text{ since } Q_{k,\,\text{nonpotential}} \equiv Q_k = 0,\ \partial L/\partial t = 0,\ a_D = 0. \end{aligned} \tag{b}$$

(ii) *Spinning cylinder*. In terms of the *noninertial* coordinates $r = constant$, ϕ such that $\dot{\phi} = \dot{\Phi} - \omega$, $z = Z$, we readily find

$$\begin{aligned} &2T = m[r^2(\dot{\phi} + \omega)^2 + (\dot{z})^2] \equiv 2T_2 + 2T_1 + 2T_0, \qquad V = m\,g\,z, \qquad L = T - V, \\ &2T_2 = m[r^2(\dot{\phi})^2 + (\dot{z})^2], \qquad T_1 = m\,r^2\omega\,\dot{\phi}, \qquad 2T_0 = m\,r^2\omega^2, \end{aligned} \tag{c}$$

and, therefore,

$$\begin{aligned} h &= (\partial L/\partial\dot{\phi})\dot{\phi} + (\partial L/\partial\dot{z})\dot{z} - L \\ &= \cdots = (m/2)[r^2(\dot{\phi})^2 + (\dot{z})^2] - (m/2)(r^2\omega^2) + mgz \\ &= T_2 - T_0 + V = constant, \text{ since } Q_{k,\text{nonpotential}} \equiv Q_k = 0,\ \partial L/\partial t = 0,\ a_D = 0. \end{aligned} \tag{d}$$

Clearly, $h \neq E \equiv T + V = (m/2)[r^2(\dot{\phi} + \omega)^2 + (\dot{z})^2] + mgz$.

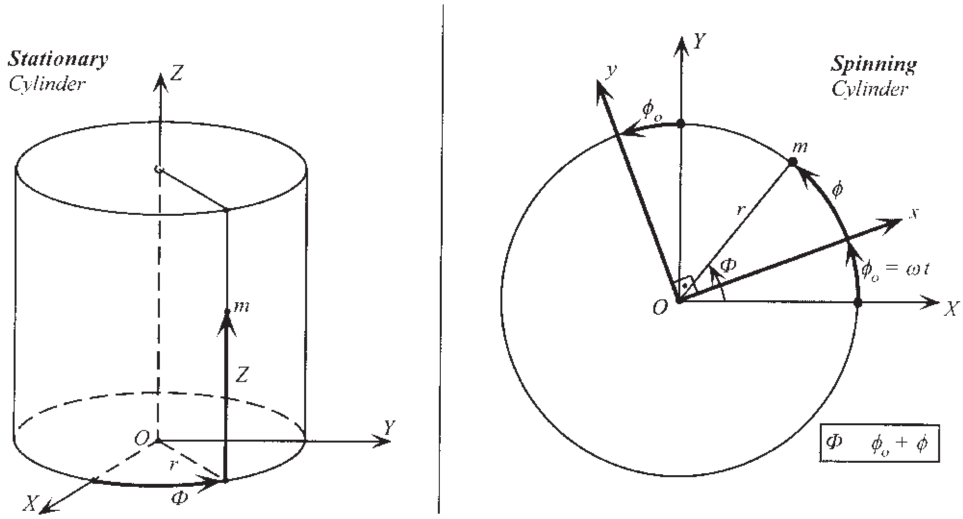

Figure 3.26 Particle moving on the outer surface of (a) a fixed and (b) a moving cylinder.

(iii) *(Introduction to) Relative Motion*. Let us generalize the above for an *arbitrary system moving relative to the uniformly rotating frame Oxyz*; that is, $r = r(t) \neq constant$. Since, in this case,

$$X = r\cos(\phi + \omega t), \qquad Y = r\sin(\phi + \omega t), \qquad Z = z, \tag{e}$$

we obtain, successively,

$$2T = \mathbf{S}\, dm[(\dot{X})^2 + (\dot{Y})^2 + (\dot{Z})^2] = \cdots = 2(T_{(2)} + \omega T_{(1)} + \omega^2 T_{(0)}), \tag{f}$$

where

$$2T_{(2)} \equiv \mathbf{S}\, dm\, [(\dot{r})^2 + r^2(\dot{\phi})^2 + (\dot{z})^2] \qquad (\equiv 2T_2), \tag{g1}$$

$$T_{(1)} \equiv \mathbf{S}\, dm\, r^2\dot{\phi} \qquad (\omega T_{(1)} \equiv T_1), \tag{g2}$$

$$2T_{(0)} \equiv \mathbf{S}\, dm\, r^2 \qquad (\omega^2 T_{(0)} \equiv T_0). \tag{g3}$$

Now, if $r, \phi, z =$ *stationary functions of n (noninertial) Lagrangean coordinates* $q \equiv (q_1, \ldots, q_n)$, and the system is further unconstrained, but under a potential $V_0 = V_0(q)$, then (since the Euler–Lagrange operator is linear) the Lagrangean equations of the system in the q's become

$$[(\partial T_{(2)}/\partial \dot{q}_k)^{\cdot} - \partial T_{(2)}/\partial q_k] + \omega[(\partial T_{(1)}/\partial \dot{q}_k)^{\cdot} - \partial T_{(1)}/\partial q_k] = -\partial V_R/\partial q_k, \tag{h}$$

where

$$V_R \equiv V_0 - \omega^2 T_{(0)} = V_0 - T_0 = \textit{relative potential}. \tag{i}$$

For reasons that will become clearer in §3.16, the $\sim \omega$ *(second)* group of terms, in (h), are called *gyroscopic*. If they vanish, the relative motion of the system is the same as if the cylinder was at rest but the system's potential energy was diminished by the "centrifugal potential" $\omega^2 T_{(0)}$. These terms vanish if every $\dot{q}_k$ vanishes; that is, if $q_k = constant$ (*relative equilibrium*). For a general rigid body in relative motion this cannot happen, unless the body *translates parallelly to the* $OZ = Oz$ *axis*; but it may happen for special systems of particles, or if $T_{(1)}$ is an *exact* differential, say

$$T_{(1)} = df(q, \dot{q})/dt, \qquad \text{where } f = \textit{arbitrary function of its arguments}, \tag{j}$$

because then it is not hard to see that

$$(\partial T_{(1)}/\partial \dot{q}_k)^{\cdot} = (\partial \dot{f}/\partial \dot{q}_k)^{\cdot} = (\partial f/\partial q_k)^{\cdot} = \partial/\partial q_k(df/dt) = \partial T_{(1)}/\partial q_k. \tag{k}$$

If $k = 1$, this holds always; then $T_{(1)} = F(q_1)\dot{q}_1$, where $F(q_1) =$ *arbitrary function of* q_1*; that is, there are no gyroscopic terms in one DOF systems!* We shall return to this important topic in the examples of §3.16, where it will be shown that (h) has the generalized energy integral

$$h \equiv T_{(2)} + V_R \equiv T_{(2)} + (V - \omega^2 T_{(0)}) = constant. \tag{l}$$

Problem 3.9.7 Consider a particle P of mass m constrained to slide inside a smooth and straight tube of negligible mass, and also under the action of a linear spring of constant k and unstretched length r_o (fig. 3.27). The tube spins about a vertical axis OZ with *constant* angular velocity ω.

With $\rho \equiv r - r_o$, show that the system has the following Jacobi–Painlevé integral:

$$\begin{aligned} h &\equiv T_2 - T_0 + V_0 \\ &= (m/2)(\dot{\rho})^2 - (m\omega^2/2)(\rho + r_o)^2 + (k/2)(\rho^2) = constant. \end{aligned} \tag{a}$$

Example 3.9.6 *Lagrangean Equations for* q_{n+1}. Let us find the "temporal Lagrangean equation"; that is, (assuming the n δq's are unconstrained)

$$d/dt(\partial T/\partial \dot{q}_0) - \partial T/\partial q_0 = Q_0 + R_0, \tag{a}$$

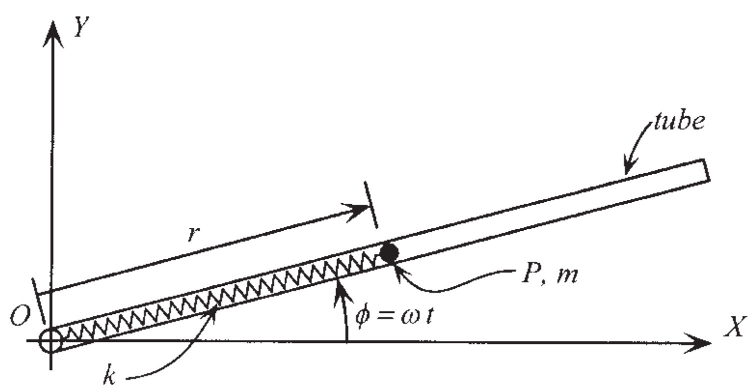

Figure 3.27 Particle on uniformly rotating horizontal tube.

where $q_{n+1} \equiv q_0 \equiv t \;\Rightarrow\; \dot{q}_0 = 1$, and [recalling (3.4.4a ff.)]

$$Q_{n+1} \equiv Q_0 \equiv \textstyle\int d\boldsymbol{F} \cdot \boldsymbol{e}_0 \equiv \int d\boldsymbol{F} \cdot (\partial \mathbf{r}/\partial t),$$
$$R_{n+1} \equiv R_0 \equiv \textstyle\int d\boldsymbol{R} \cdot \boldsymbol{e}_0 \equiv \int d\boldsymbol{R} \cdot (\partial \mathbf{r}/\partial t) \quad (\neq 0, \text{ in general}). \tag{b}$$

Since (recalling that $\alpha, \beta = 1, \ldots, n+1$)

$$\begin{aligned} 2T &= \sum\sum M_{\alpha\beta}\, \dot{q}_\alpha \dot{q}_\beta \\ &= \sum\sum M_{kl}\, \dot{q}_k \dot{q}_l + 2\sum M_{k,n+1} \dot{q}_k \dot{q}_{n+1} + M_{n+1,\,n+1} \dot{q}_{n+1} \dot{q}_{n+1} \\ &\equiv \sum\sum M_{kl}\, \dot{q}_k \dot{q}_l + 2\sum M_{k0} \dot{q}_k \dot{q}_0 + M_{00} \dot{q}_0 \dot{q}_0 \\ &\equiv \sum\sum M_{kl}\, \dot{q}_k \dot{q}_l + 2\sum M_k \dot{q}_k + M_0, \end{aligned} \tag{c}$$

eq. (a) becomes

$$\left(\sum M_k \dot{q}_k + M_0 q_0\right)^{\cdot} - \partial T/\partial q_0 = Q_0 + R_0, \tag{d}$$

or, finally,

$$\begin{aligned} &\left(\sum M_k \dot{q}_k + M_0\right)^{\cdot} - (1/2) \sum\sum (\partial M_{\alpha\beta}/\partial t) \dot{q}_\alpha \dot{q}_\beta = Q_0 + R_0 \\ &\Big[\text{or, if } M_k = 0 \text{ and } M_0 = 0; \text{ i.e., if } 2T = \sum\sum M_{kl}(t, q) \dot{q}_k \dot{q}_l, \\ &\qquad\qquad \text{then } -\partial T/\partial t = Q_0 + R_0\Big]; \end{aligned} \tag{e}$$

which is none other than the rheonomic power identity (e) of example 3.9.2, but in system variables.

Extensions to quasi variables (i.e., the $(n+1)$th *Hamel equation*) are easily obtainable. These equations, since they contain the unknown R_0, do not seem to offer any particular advantage and so they will not be pursued any further. [See, e.g., Mattioli (1931–1932), Pastori (1960); also Nadile (1950) for the quasi-variable case, and an alternative derivation of (3.9.12i).] However, the above considerations may prove helpful in understanding better the connection between scleronomic and rheonomic systems. Following Lamb (1910, p. 758), we may consider time as an *additional* $(n+1)$th coordinate of an originally scleronomic system—that is, $q_{n+1} \equiv q_0 \equiv t$; or, start with a *scleronomic* system in the $n+1$ coordinates $(q, q_0) \equiv (q_1, \ldots q_n;\; q_{n+1} \equiv q_0)$ and then let $q_0 = \phi(t) =$ *known function of time*:

$$\begin{aligned} 2T &= \sum\sum M_{\alpha\beta}\, \dot{q}_\alpha \dot{q}_\beta \qquad [\text{where } M_{\alpha\beta} = M_{\alpha\beta}(q, q_0)] \\ &= \sum\sum M_{kl}\, \dot{q}_k \dot{q}_l + 2\sum M_{k0}\, \dot{q}_k \dot{q}_0 + M_{00}\, \dot{q}_0 \dot{q}_0 \\ &\equiv \sum\sum M_{kl}\, \dot{q}_k \dot{q}_l + 2\sum M_k \dot{q}_k \dot{\phi} + M_0 \dot{\phi}\, \dot{\phi} \\ &\equiv \sum\sum M_{kl}\, \dot{q}_k \dot{q}_l + 2\sum M'_k\, \dot{q}_k + M'_0 \\ &= 2T_2 + 2T_1 + 2T_0 = (\textit{double}) \textit{ kinetic energy of an n DOF rheonomic system}, \end{aligned} \tag{f}$$

where $M_{kl} = M_{kl}(q, t),\; M'_k = M'_k(q, t),\; M'_0 = M'_0(q, t)$.

Finally, since the constraint $\dot{q}_0 = 1 (\Rightarrow \delta q_0 = 0)$ — or, generally, $\Phi[q_0, \phi(t)] = 0$ $(\Rightarrow \delta\Phi = 0)$ — is holonomic it can be enforced in T right from start; that is, before any differentiations (recall remarks in §3.5); and that constraint is maintained by the force $Q_0 + R_0$.

REMARK

The above and ex. 3.9.2 show that, even if we dotted the Newton–Euler particle equation of motion with $d\boldsymbol{r} = \sum \boldsymbol{e}_k \, dq_k + \boldsymbol{e}_0 \, dt$ (instead of with $\delta\boldsymbol{r} = \sum \boldsymbol{e}_k \, \delta q_k$) and then summed over the system particles, (i.e., $S\, dm\, \boldsymbol{a} \cdot d\boldsymbol{r} = S\, d\boldsymbol{F} \cdot d\boldsymbol{r} + S\, d\boldsymbol{R} \cdot d\boldsymbol{r}$), and thus ended up, in system variables, with $\sum (E_k - Q_k - R_k) dq_k + (E_0 - Q_0 - R_0)\, dt = 0$, (i) we would still need an additional postulate for $\sum R_k \, dq_k$ (like the d'Alembert–Lagrange principle), and (ii) the $(\ldots)dt$-terms would not have produced anything new; that is, no additional Lagrangean equation of motion. In sum [and contrary to what some Lagrangean derivations seem to, falsely, imply; e.g., Corben and Stehle (1960, pp. 78–79)]: *there is no way getting around virtual displacements and an independent physical postulate for the constraint reactions!*

Problem 3.9.8 (i) Show that in the Voronets equations case, eqs. (3.8.14a ff.), (a) [recall (3.9.12f)]

$$\partial L^*/\partial\theta_{n+1} = \partial L^*/\partial t + \sum b_D (\partial L^*/\partial q_D), \tag{a}$$

where (by partial differentiation):

$$\partial L^*/\partial q_D = \partial L/\partial q_D + \sum (\partial L/\partial \dot{q}_{D'})(\partial \dot{q}_{D'}/\partial q_D); \tag{b}$$

and (b) the rheonomic nonholonomic power term R, (3.9.12j), reduces to

$$R = \sum\sum w^D{}_I (\partial L/\partial \dot{q}_D)_o \, \dot{q}_I, \tag{c}$$

where [recall (3.8.14h)] $-w^D{}_I = \partial b_D/\partial(q_I) - \partial b_{DI}/\partial(q_{n+1})$.

(ii) Then formulate the "Voronets power equation"; and, finally, specialize the latter to the "Chaplygin power equation."

3.10 LAGRANGE'S EQUATIONS: EXPLICIT FORMS; AND LINEAR VARIATIONAL EQUATIONS (OR METHOD OF SMALL OSCILLATIONS)

Explicit Forms of Lagrange's Equations

We have already seen (§3.9) that the most general expression for T in holonomic system (Lagrangean) variables is

$$2T = \sum\sum M_{kl} \dot{q}_k \dot{q}_l + 2\sum M_k \dot{q}_k + M_0 \; \equiv \; 2T_2 + 2T_1 + 2T_0. \tag{3.10.1a}$$

Let us find the explicit forms of the corresponding (and, hence, most general) inertia, or Lagrangean acceleration, terms $E_k \equiv E_k(T) \equiv (\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k$. Since $E_k(\ldots)$ is a *linear* operator, we have

$$E_k(T) = E_k(T_2) + E_k(T_1) + E_k(T_0). \tag{3.10.1b}$$

Recalling that $M_{kl} = M_{lk}$, we obtain, successively,

$$
\begin{aligned}
\text{(i)}\quad E_k(T_2) &= [(\partial/\partial\dot{q}_k)^{\cdot} - \partial/\partial q_k]\Big[(1/2)\sum\sum M_{kl}\,\dot{q}_k\,\dot{q}_l\Big] \\
&= \Big(\sum M_{kr}\,\dot{q}_r\Big)^{\cdot} - (1/2)\sum\sum(\partial M_{rs}/\partial q_k)\dot{q}_r\,\dot{q}_s \\
&= \sum M_{kr}\,\ddot{q}_r + \sum\sum[\partial M_{kr}/\partial q_s - (1/2)(\partial M_{rs}/\partial q_k)]\dot{q}_r\,\dot{q}_s \\
&\qquad + \sum(\partial M_{kr}/\partial t)\dot{q}_r.
\end{aligned} \tag{3.10.1c}
$$

But

$$\sum\sum(\partial M_{kr}/\partial q_s)\dot{q}_r\dot{q}_s = (1/2)\sum\sum(\partial M_{kr}/\partial q_s + \partial M_{ks}/\partial q_r)\dot{q}_r\,\dot{q}_s,$$

and so the middle (double sum) term of (3.10.1c) can be rewritten as

$$\sum\sum(1/2)(\partial M_{kr}/\partial q_s + \partial M_{ks}/\partial q_r - \partial M_{rs}/\partial q_k)\dot{q}_r\,\dot{q}_s \equiv \sum\sum \Gamma_{k,rs}\,\dot{q}_r\,\dot{q}_s,$$

where the just introduced quantities ("geometrical objects," in tensorial language)

$$\Gamma_{k,rs} = \Gamma_{k,sr} \equiv (1/2)(\partial M_{kr}/\partial q_s + \partial M_{ks}/\partial q_r - \partial M_{rs}/\partial q_k) \tag{3.10.1d}$$

are the famous (holonomic) *Christoffel symbols of the first kind*. So, finally, (3.10.1c) becomes

$$E_k(T_2) = \sum M_{kr}\,\ddot{q}_r + \sum\sum \Gamma_{k,rs}\,\dot{q}_r\,\dot{q}_s + \sum(\partial M_{kr}/\partial t)\dot{q}_r. \tag{3.10.1e}$$

$$
\begin{aligned}
\text{(ii)}\quad E_k(T_1) &= \Big[(\partial/\partial\dot{q}_k)\Big(\sum M_r\,\dot{q}_r\Big)\Big]^{\cdot} - (\partial/\partial q_k)\Big(\sum M_r\,\dot{q}_r\Big) \\
&= \partial M_k/\partial t - \sum(\partial M_r/\partial q_k - \partial M_k/\partial q_r)\dot{q}_r \equiv \partial M_k/\partial t - G_k,
\end{aligned} \tag{3.10.1f}
$$

where

$$G_k \equiv \sum g_{kr}\,\dot{q}_r, \qquad g_{kr} = -g_{rk} \equiv \partial M_r/\partial q_k - \partial M_k/\partial q_r; \tag{3.10.1g}$$

that is, $g_{12} = -g_{21},\ g_{11} = -g_{11}\ \Rightarrow\ g_{11} = 0$, and so on.

$$\text{(iii)}\qquad E_k(T_0) = (\partial T_0/\partial\dot{q}_k)^{\cdot} - \partial T_0/\partial q_k = 0 - \partial T_0/\partial q_k = -(1/2)(\partial M_0/\partial q_k). \tag{3.10.1h}$$

In view of (3.10.1e, f, h), the Lagrangean acceleration (3.10.1b) assumes the definitive form

$$
\begin{aligned}
E_k \equiv E_k(T) &= \sum M_{kr}\,\ddot{q}_r + \sum\sum \Gamma_{k,rs}\,\dot{q}_r\dot{q}_s + \sum(\partial M_{kr}/\partial t)\dot{q}_r \\
&\qquad + \partial M_k/\partial t - G_k - (1/2)(\partial M_0/\partial q_k).
\end{aligned} \tag{3.10.1i}
$$

In the theory of *relative motion* (§3.16) where (3.10.1i) primarily applies, it is customary to rearrange and rename the above as follows:

$$E_k = E_{k,R} + E_{k,T} + E_{k,C}, \tag{3.10.2}$$

where

$$E_{k,R} \equiv E_k(T_2) \equiv (\partial T_2/\partial \dot{q}_k)^{\cdot} - \partial T_2/\partial q_k: \qquad \textit{Relative acceleration}, \tag{3.10.2a}$$

$$E_{k,T} \equiv \partial M_k/\partial t - \partial T_0/\partial q_k: \qquad \textit{Transport acceleration}, \tag{3.10.2b}$$

$$E_{k,C} \equiv \sum (\partial M_k/\partial q_r - \partial M_r/\partial q_k)\dot{q}_r \equiv -\sum g_{kr}\, \dot{q}_r \equiv -G_k: \qquad \textit{Coriolis (or gyroscopic) acceleration}. \tag{3.10.2c}$$

This *three-part decomposition* of the Lagrangean acceleration E_k, and the recognition of its importance (especially of the Coriolis/gyroscopic part $E_{k,C}$), are due to Thomson and Tait (1867–1912, §319, pp. 318–327).

In view of the above kinematico-inertial identities, the Lagrangean equations of motion in the fairly general case of a holonomic n *DOF* system, with potential $V = V_0(q)$ and under nonpotential forces Q_k (i.e., $E_k = Q_k - \partial V_0/\partial q_k$), assume the explicit form

$$\sum M_{kr}\, \ddot{q}_r + \sum\sum \Gamma_{k,rs}\, \dot{q}_r \dot{q}_s + \sum (\partial M_{kr}/\partial t)\dot{q}_r = Q_k + G_k - \partial(V_0 - T_0)/\partial q_k - \partial M_k/\partial t; \tag{3.10.3}$$

and similarly for other T-based equations.

In the common case $\partial T/\partial t = 0$ ("stationary/scleronomic" kinetic energy), (3.10.3) specializes to

$$\sum M_{kr}\ddot{q}_r + \sum\sum \Gamma_{k,rs}\dot{q}_r\, \dot{q}_s = Q_k + G_k - \partial(V_0 - T_0)/\partial q_k; \tag{3.10.3a}$$

while if $\partial \mathbf{r}/\partial t = \mathbf{0}$ (stationary holonomic constraints), then $T \to T_2$ and the above reduces to

$$\sum M_{kr}\ddot{q}_r + \sum\sum \Gamma_{k,rs}\, \dot{q}_r\, \dot{q}_s = Q_k - \partial V_0/\partial q_k. \tag{3.10.3b}$$

Inertial Coupling

In general, *all* the above equations are inertially (or dynamically) coupled; that is, each E_k contains all the system accelerations $\ddot{q}$. To decouple them, we introduce the symmetric inertial quantities $m_{kl} = m_{lk}$, "conjugate" to the $M_{kl} = M_{lk}$, via the definition

$$\sum m_{kl} M_{lr} = \delta_{kr} \quad (= 1,\ \text{if}\ \ k = r;\ = 0,\ \text{if}\ \ k = r). \tag{3.10.4}$$

Multiplying each of (3.10.3) with m_{sk} and adding over k, invoking (3.10.4), and renaming some dummy indices, we obtain the *inertially decoupled* Lagrangean equations

$$\ddot{q}_k + \sum\sum \Gamma^k{}_{rs}\, \dot{q}_r\, \dot{q}_s + \sum\sum m_{ks}(\partial M_{sr}/\partial t)\dot{q}_r = \sum m_{ks}[Q_s + G_s - \partial(V_0 - T_0)/\partial q_s - \partial M_s/\partial t], \tag{3.10.5}$$

where we have introduced the following, similar to (3.10.1d), quantities:

$$\Gamma^k{}_{rs} = \Gamma^k{}_{sr} \equiv \sum m_{kl}\Gamma_{l,rs}:$$

$$(holonomic)\ \textit{Christoffel symbols of the second kind} \tag{3.10.5a}$$

$$\left(\Leftrightarrow\ \Gamma_{l,rs} = \sum M_{lk}\Gamma^k{}_{rs}\right). \tag{3.10.5b}$$

Velocity-Proportional Terms of (3.10.3, 5)

In general, there are two kinds of such terms: linear ($\sim \dot{q}_r$) and nonlinear ($\sim \dot{q}_r\,\dot{q}_s$). Let us examine the latter first.

(i) *Nonlinear terms* like $\Gamma_{k,rs}\,\dot{q}_r\dot{q}_s$ or $\Gamma^k{}_{rs}\,\dot{q}_r\dot{q}_s$ occur because their coefficients, the Christoffels, are intimately related to the *curvilinearity*; that is, the *nonlinearity*, of the coordinates q. Let us see this: recalling the definitions (3.9.2a) and (3.10.1d), we have, successively,

$$\begin{aligned}
\Gamma_{k,rs} &= (1/2)(\partial M_{kr}/\partial q_s + \partial M_{ks}/\partial q_r - \partial M_{rs}/\partial q_k)\\
&= (1/2)\Big\{(\partial/\partial q_s)\Big[\textstyle\int dm(\partial\mathbf{r}/\partial q_k)\cdot(\partial\mathbf{r}/\partial q_r)\Big] + \cdots\Big\}\\
&= (1/2)\Big\{\textstyle\int dm\big[(\partial^2\mathbf{r}/\partial q_s\partial q_k)\cdot(\partial\mathbf{r}/\partial q_r) + (\partial\mathbf{r}/\partial q_k)\cdot(\partial^2\mathbf{r}/\partial q_s\partial q_r)\\
&\quad + (\partial^2\mathbf{r}/\partial q_r\partial q_k)\cdot(\partial\mathbf{r}/\partial q_s) + (\partial\mathbf{r}/\partial q_k)\cdot(\partial^2\mathbf{r}/\partial q_r\partial q_s)\\
&\quad - (\partial^2\mathbf{r}/\partial q_k\partial q_r)\cdot(\partial\mathbf{r}/\partial q_s) - (\partial\mathbf{r}/\partial q_r)\cdot(\partial^2\mathbf{r}/\partial q_k\partial q_s)\big]\Big\}\\
&= \textstyle\int dm(\partial^2\mathbf{r}/\partial q_r\partial q_s)\cdot(\partial\mathbf{r}/\partial q_k) \equiv \int dm(\partial\boldsymbol{e}_r/\partial q_s)\cdot\boldsymbol{e}_k\\
&= \textstyle\int dm(\partial\boldsymbol{e}_s/\partial q_r)\cdot\boldsymbol{e}_k = \Gamma_{k,sr} \quad \text{[recalling (2.5.4a, b)]},
\end{aligned} \tag{3.10.6}$$

from which we conclude that if $\partial\boldsymbol{e}_r/\partial q_s \equiv \partial^2\mathbf{r}/\partial q_r\partial q_s = \mathbf{0}$ (e.g., rectilinear coordinates), then $\Gamma_{k,rs} = 0 \ \Rightarrow\ \Gamma^k{}_{rs} = 0$. Hence, the following theorem.

THEOREM

In general, *Lagrange's equations are nonlinear*; this is part of the price we pay for using *"generalized"* (i.e., *curvilinear) coordinates.*

(ii) *Linear terms* like:

(a) $(\partial M_{kr}/\partial t)\dot{q}_r$ clearly result from the *nonstationarity of the inertia coefficients;*

(b) $g_{kr}\,\dot{q}_r$ result from the *nonstationarity of the holonomic (built-in) constraints*

$$(\partial\mathbf{r}/\partial t \neq \mathbf{0} \Rightarrow T_1 \neq 0,\ M_k \neq 0);$$

(c) $\gamma_{kr}\,\dot{q}_r$ [recall *generalized (holonomic) potential* (3.9.8a ff.)] result from the part of the potential that is *linear* in the $\dot{q}$'s.

We notice that both forces corresponding to (b) and (c) type of terms — namely, the inertial $G_k = \sum g_{kr}\,\dot{q}_r$ and the potential $Q_{k,GP} - \partial\gamma_k/\partial t = \sum \gamma_{kr}\,\dot{q}_r$ (part of Q_k) — are *gyroscopic*; that is, they have zero power. And this explains the disappearance of T_1 and V_1 from the generalized energy integral $h \equiv T_2 + (V_0 - T_0) = \textit{constant}$.

Both forces can be combined as follows: with

$$L_1 \equiv T_1 - V_1 = \sum (M_k - \gamma_k)\dot{q}_k \equiv \sum l_k \dot{q}_k, \tag{3.10.7a}$$

[recalling (3.9.8c)] we obtain, successively,

$$-E_k(L_1) = \cdots = -(\partial M_k/\partial t) + G_k + Q_{k,GP} = -(\partial l_k/\partial t) + \sum l_{kr}\dot{q}_r, \tag{3.10.7b}$$

where the *gyroscopic coefficients* of L_1, l_{kr}, are defined by

$$l_{kr} \equiv g_{kr} + \gamma_{kr} \equiv \partial(M_r - \gamma_r)/\partial q_k - \partial(M_k - \gamma_k)/\partial q_r = \partial l_r/\partial q_k - \partial l_k/\partial q_r. \tag{3.10.7c}$$

We also notice that, whenever such terms appear, since $g_{kk} = 0$ and $\gamma_{kk} = 0$, $\dot{q}_k$ *does not appear in the (k)*th *Lagrangean equation*, say $E_k = Q_k$. Instead, for each such term that appears as $g_{rk}\dot{q}_r$ in the (k)th equation $(r \neq k)$, another term, like $g_{kr}\dot{q}_k = -g_{rk}\dot{q}_k$ appears in the (r)th equation $E_r = Q_r$. For example, for $n = 3$, eq. (3.10.2c), $E_{k,C} = -\sum g_{kr}\dot{q}_r$, yields

$$\begin{aligned} E_{1,C} &= (0)\dot{q}_1 + g_{21}\dot{q}_2 + g_{31}\dot{q}_3, \\ E_{2,C} &= -g_{21}\dot{q}_1 + (0)\dot{q}_2 + g_{32}\dot{q}_3, \\ E_{3,C} &= -g_{31}\dot{q}_1 - g_{32}\dot{q}_2 + (0)\dot{q}_3. \end{aligned} \tag{3.10.7d}$$

This property also appears in the theory of *cyclic* systems (§8.4 ff.).

(d) $-f_{kr}\dot{q}_r$ [recall Rayleigh's dissipation function (3.9.10b ff.)] result from linear viscous friction.

A Compact Notation

Since $q_0 \equiv t \Rightarrow \dot{q} \equiv \dot{t} = 1 \Rightarrow \ddot{q}_0 \equiv \ddot{t} = 0$, and with all Greek indices running from 1 to $n+1$, we may rewrite E_k, (3.10.1i), as follows

$$E_k = \sum M_{k\alpha}\ddot{q}_\alpha + \sum\sum \Gamma_{k,\alpha\beta}\dot{q}_\alpha\dot{q}_\beta, \tag{3.10.8a}$$

where

$$\begin{aligned} 2\Gamma_{k,\alpha\beta} = 2\Gamma_{k,\beta\alpha} &\equiv \partial M_{k\alpha}/\partial q_\beta + \partial M_{k\beta}/\partial q_\alpha - \partial M_{\alpha\beta}/\partial q_k \\ &\left[= 2\int dm(\partial \boldsymbol{e}_\alpha/\partial q_\beta)\cdot \boldsymbol{e}_k\right]; \end{aligned} \tag{3.10.8b}$$

a form, most likely, due to T. Levi-Civita (1895), one of the founders of *tensor calculus*. If the index positioning (i.e., sub-/superscripts) appears arbitrary, it is because we have been trying to avoid tensor calculus and its associated simple and helpful conventions. [For an extensive treatment of these topics via this remarkable and beautiful geometrico-analytical tool, see, e.g., Papastavridis (1999) and references cited therein.]

Indeed, expanding the above, we obtain

$$\begin{aligned} E_k &= \sum M_{kr}\ddot{q}_r + \sum\sum \Gamma_{k,rs}\dot{q}_r\dot{q}_s + 2\sum \Gamma_{k,r,n+1}\dot{q}_r + \Gamma_{k,n+1,n+1} \\ &\equiv \sum M_{kr}\ddot{q}_r + \sum\sum \Gamma_{k,rs}\dot{q}_r\dot{q}_s + 2\sum \Gamma_{k,r}\dot{q}_r + \Gamma_k, \end{aligned} \tag{3.10.8c}$$

where

$$\text{(a)} \qquad 2\Gamma_{k,r,n+1} = 2\Gamma_{k,n+1,r} \equiv 2\Gamma_{k,r} \quad \left[= 2 \textstyle\int dm(\partial \boldsymbol{e}_r/\partial t) \cdot \boldsymbol{e}_k\right]$$
$$\equiv \partial M_{kr}/\partial q_{n+1} + \partial M_{k,n+1}/\partial q_r - \partial M_{r,n+1}/\partial q_k$$
$$= \partial M_{kr}/\partial t + (\partial M_k/\partial q_r - \partial M_r/\partial q_k) \equiv \partial M_{kr}/\partial t + g_{rk}, \qquad (3.10.8d)$$

so that the corresponding E_k-term becomes

$$2\sum \Gamma_{k,r}\, \dot{q}_r = \sum (\partial M_{kr}/\partial t)\dot{q}_r - \sum g_{kr}\, \dot{q}_r = \sum (\partial M_{kr}/\partial t)\dot{q}_r - G_k:$$
$$\textit{nonstationary} \text{ and } \textit{gyroscopic/Coriolis} \text{ terms } (\sim \dot{q}); \qquad (3.10.8e)$$

and

$$\text{(b)} \qquad 2\Gamma_{k,n+1,n+1} \equiv 2\Gamma_k \quad \left[= 2 \textstyle\int dm(\partial \boldsymbol{e}_{n+1}/\partial q_{n+1}) \cdot \boldsymbol{e}_k = 2 \textstyle\int dm(\partial \boldsymbol{e}_0/\partial t) \cdot \boldsymbol{e}_k\right]$$
$$\equiv \partial M_{k,n+1}/\partial q_{n+1} + \partial M_{k,n+1}/\partial q_{n+1} - \partial M_{n+1,n+1}/\partial q_k$$
$$= 2(\partial M_k/\partial t) - \partial M_0/\partial q_k \equiv 2(\partial M_k/\partial t - \partial T_0/\partial q_k):$$
$$\textit{nonstationary} \text{ and } \textit{centrifugal} \text{ terms (no } \dot{q}\text{'s)}. \qquad (3.10.8f)$$

In this compact notation, the earlier equations (3.10.3) and (3.10.5) can be written, respectively, as

$$\sum M_{kr}\, \ddot{q}_r + \sum\sum \Gamma_{k,\alpha\beta}\, \dot{q}_\alpha \dot{q}_\beta = Q_k - \partial V_0/\partial q_k, \qquad (3.10.8g)$$

and

$$\ddot{q}_k + \sum\sum \Gamma^k{}_{\alpha\beta}\, \dot{q}_\alpha\, \dot{q}_\beta$$
$$\left[= \ddot{q}_k + \sum\sum \Gamma^k{}_{rs}\, \dot{q}_r\, \dot{q}_s + 2\sum \Gamma^k{}_{r,n+1}\, \dot{q}_r + \Gamma^k{}_{n+1,n+1}\right.$$
$$\left.\equiv \ddot{q}_k + \sum\sum \Gamma^k{}_{rs}\, \dot{q}_r\, \dot{q}_s + 2\sum \Gamma^k{}_r\, \dot{q}_r + \Gamma^k\right]$$
$$= \sum m_{kr}(Q_r - \partial V_0/\partial q_r), \qquad (3.10.8h)$$

where

$$\Gamma^k{}_{\alpha\beta} \equiv \sum m_{ks} \Gamma_{s,\alpha\beta}$$
$$\Rightarrow \Gamma^k{}_{r,n+1} \equiv \sum m_{ks}\, \Gamma_{s,r,n+1} \equiv \Gamma^k{}_{r0} \equiv \Gamma^k{}_r,$$
$$\Gamma^k{}_{n+1,n+1} \equiv \sum m_{ks}\, \Gamma_{s,n+1,n+1} \equiv \Gamma^k{}_{00} \equiv \Gamma^k. \qquad (3.10.8i)$$

We notice that $\Gamma_{n+1,n+1,n+1} \equiv \Gamma_{0,00} \equiv \Gamma_0 = \cdots = (1/2)(\partial M_0/\partial t) = \partial T_0/\partial t$ does not appear in the equations of motion; but it might appear in special forms of power equations.

Explicit Forms of Hamel's Equations

Let us, next, extend the above to *nonholonomic* variables; that is, find the explicit form of the Hamel acceleration (and equations)

$$I_k \equiv (\partial T^*/\partial \omega_k)^{\cdot} - \partial T^*/\partial \theta_k + \sum\sum \gamma^r{}_{k\alpha}(\partial T^*/\partial \omega_r)\omega_\alpha, \qquad (3.10.9a)$$

where

$$2T = \sum\sum M^*{}_{\alpha\beta}\,\omega_\alpha\omega_\beta. \tag{3.10.9b}$$

Nonholonomic Christoffel-Like Symbols

For algebraic simplicity, but no loss in generality, we restrict ourselves to the *stationary* case. By $\partial\ldots/\partial\theta_k$-differentiating the nonholonomic inertia coefficients

$$M^*{}_{kl} = M^*{}_{lk} \equiv S\, dm\,\boldsymbol{\varepsilon}_k \cdot \boldsymbol{\varepsilon}_l \equiv S\, dm(\partial\mathbf{r}/\partial\theta_k)\cdot(\partial\mathbf{r}/\partial\theta_l), \tag{3.10.9c}$$

an operation that we shall also denote here by a subscript comma [i.e., $\partial(\ldots)/\partial\theta_k \equiv (\ldots)_{,k}$], we obtain

$$\partial M^*{}_{kl}/\partial\theta_r = S\, dm(\boldsymbol{\varepsilon}_{k,r}\cdot\boldsymbol{\varepsilon}_l + \boldsymbol{\varepsilon}_k\cdot\boldsymbol{\varepsilon}_{l,r}),$$

and, therefore, the *nonholonomic Christoffel symbol-like* quantities, defined in complete analogy with their holonomic counterparts (3.10.1d) as

$$2\Gamma^*{}_{k,rs} \equiv \partial M^*{}_{ks}/\partial\theta_r + \partial M^*{}_{kr}/\partial\theta_s - \partial M^*{}_{rs}/\partial\theta_k, \tag{3.10.9d}$$

transform, successively, to

$$\begin{aligned} 2\Gamma^*{}_{k,rs} &\equiv S\, dm\big[(\boldsymbol{\varepsilon}_k\cdot\boldsymbol{\varepsilon}_{s,r} + \boldsymbol{\varepsilon}_s\cdot\boldsymbol{\varepsilon}_{k,r}) + (\boldsymbol{\varepsilon}_k\cdot\boldsymbol{\varepsilon}_{r,s} + \boldsymbol{\varepsilon}_r\cdot\boldsymbol{\varepsilon}_{k,s}) - (\boldsymbol{\varepsilon}_r\cdot\boldsymbol{\varepsilon}_{s,k} + \boldsymbol{\varepsilon}_s\cdot\boldsymbol{\varepsilon}_{r,k})\big] \\ &= S\, dm\big[\boldsymbol{\varepsilon}_k\cdot(\boldsymbol{\varepsilon}_{s,r} + \boldsymbol{\varepsilon}_{r,s}) + \boldsymbol{\varepsilon}_r\cdot(\boldsymbol{\varepsilon}_{k,s} - \boldsymbol{\varepsilon}_{s,k}) + \boldsymbol{\varepsilon}_s\cdot(\boldsymbol{\varepsilon}_{k,r} - \boldsymbol{\varepsilon}_{r,k})\big]; \end{aligned}$$

and recalling the fundamental *noncommutativity/nonintegrability* relations (2.10.23), rewritten here as

$$\begin{aligned} \partial^2\mathbf{r}/\partial\theta_s\partial\theta_k - \partial^2\mathbf{r}/\partial\theta_k\partial\theta_s &\equiv \partial\boldsymbol{\varepsilon}_k/\partial\theta_s - \partial\boldsymbol{\varepsilon}_s/\partial\theta_k \equiv \boldsymbol{\varepsilon}_{k,s} - \boldsymbol{\varepsilon}_{s,k} \\ &= \sum \gamma^l{}_{sk}(\partial\mathbf{r}/\partial\theta_l) \equiv \sum \gamma^l{}_{sk}\,\boldsymbol{\varepsilon}_l, \end{aligned} \tag{3.10.9e}$$

we obtain, finally,

$$\begin{aligned} 2\Gamma^*{}_{k,rs} &= S\, dm\Big[\boldsymbol{\varepsilon}_k\cdot(\boldsymbol{\varepsilon}_{s,r} + \boldsymbol{\varepsilon}_{r,s}) + \boldsymbol{\varepsilon}_r\cdot\Big(\sum \gamma^l{}_{sk}\boldsymbol{\varepsilon}_l\Big) + \boldsymbol{\varepsilon}_s\cdot\Big(\sum \gamma^l{}_{rk}\,\boldsymbol{\varepsilon}_l\Big)\Big] \\ &= S\, dm\,\boldsymbol{\varepsilon}_k\cdot(\boldsymbol{\varepsilon}_{s,r} + \boldsymbol{\varepsilon}_{r,s}) + \sum(\gamma^l{}_{sk}M^*{}_{rl} + \gamma^l{}_{rk}M^*{}_{sl}). \end{aligned} \tag{3.10.9f}$$

Nonholonomic Euler–Lagrange Terms

Next, differentiating the stationary version of (3.10.9b)

$$2T = \sum\sum M^*{}_{kl}\,\omega_k\,\omega_l, \tag{3.10.9g}$$

we obtain $\partial T^*/\partial\omega_k = \sum M^*{}_{kl}\,\omega_l$ and, therefore,

$$(\partial T^*/\partial\omega_k)^{\cdot} = \sum M^*{}_{kl}\,\dot{\omega}_l + \sum (dM^*{}_{kl}/dt)\,\dot{\omega}_l,$$

or, since

$$dM^*{}_{kl}/dt = \sum (\partial M^*{}_{kl}/\partial q_r)\dot{q}_r = \sum (\partial M^*{}_{kl}/\partial q_r)\Big(\sum A_{rs}\omega_s\Big)$$
$$= \sum \Big(\sum A_{rs}(\partial M^*{}_{kl}/\partial q_r)\Big)\omega_s \equiv \sum (\partial M^*{}_{kl}/\partial \theta_s)\omega_s,$$

we get,

$$(\partial T^*/\partial \omega_k)^{\cdot} = \sum M^*{}_{kl}\dot{\omega}_l + \sum\sum (\partial M^*{}_{kl}/\partial \theta_s)\omega_s\omega_l. \tag{3.10.9h}$$

Introducing the above into the stationary version of (3.10.9a) results in

$$I_k \equiv d/dt(\partial T^*/\partial \omega_k) - \partial T^*/\partial \theta_k + \sum\sum \gamma^r{}_{kl}(\partial T^*/\partial \omega_r)\,\omega_l,$$
$$= \sum M^*{}_{kl}(d\omega_l/dt) + \sum\sum\sum \gamma^r{}_{kl}\,M^*{}_{rs}\,\omega_s\omega_l$$
$$+ \sum\sum [\partial M^*{}_{kl}/\partial \theta_s - (1/2)(\partial M^*{}_{sl}/\partial \theta_k)]\,\omega_s\omega_l, \tag{3.10.9i}$$

or, since the third (double sum) term equals

$$(1/2)\sum\sum (\partial M^*{}_{ks}/\partial \theta_l + \partial M^*{}_{kl}/\partial \theta_s - \partial M^*{}_{sl}/\partial \theta_k)\omega_s\omega_l$$
$$\equiv \sum\sum \Gamma^*{}_{k,ls}\,\omega_s\omega_l, \tag{3.10.9j}$$

we finally obtain the (3.10.3b)-like form

$$I_k = \sum M^*{}_{kl}(d\omega_l/dt) + \sum\sum \Lambda_{k,ls}\,\omega_s\omega_l, \tag{3.10.9k}$$

where

$$\Lambda_{k,ls} \equiv \Gamma^*{}_{k,ls} + \sum \gamma^r{}_{kl}M^*{}_{rs}; \tag{3.10.9l}$$

that is, it is the just introduced quantities $\Lambda_{k,ls}$ that deserve to be called *nonholonomic Christoffel symbols of the first kind*, rather than the formally similar to the holonomic ones $\Gamma^*{}_{k,ls}$, eqs. (3.10.9d). Finally, it is not hard to see that we can replace in (3.10.9k) the $\Lambda_{k,ls}$ with their *symmetric* parts (1/2) $(\Lambda_{k,ls} + \Lambda_{k,sl})$. Let the reader extend these results to the nonstationary case. [For a detailed tensorial treatment of these topics, see, for example, Papastavridis (1999, chaps. 6, 7).]

Problem 3.10.1 *Explicit Form of Chaplygin's Equations* [recall (3.8.13a ff.)]. Consider a Chaplygin system; that is, one with constraints:

$$\dot{q}_D = \sum b_{DI}\dot{q}_I, \qquad (D, D', D'' \ldots = 1, \ldots, m;\ I, I', I'' \ldots = m+1, \ldots, n), \tag{a}$$

where

$$b_{DI} = b_{DI}(q_1, \ldots, q_m) \equiv b_{DI}(q_I).$$

(i) Show that its (double) kinetic energy becomes

$$2T \equiv \sum\sum M_{kl}\,\dot{q}_k\,\dot{q}_l$$
$$= \cdots = \sum\sum M_{II'o}\,\dot{q}_I\,\dot{q}_{I'} = \sum\sum m_{II'}\,\dot{q}_I\,\dot{q}_{I'} \equiv 2T_o(q_I, \dot{q}_I) = 2T_o, \tag{b}$$

where

$$M_{kl} = M_{kl}(q_I) \qquad (k, l = 1, \ldots, n), \tag{c1}$$

$$M_{II'o} \equiv M_{II'} + 2\sum b_{DI'} M_{DI} + \sum b_{DI} b_{D'I'} M_{DD'} \quad (\neq M_{I'Io}), \tag{c2}$$

$$2m_{II'} = 2m_{I'I} \equiv M_{II'o} + M_{I'Io} \qquad (\textit{functions of the } q_I\text{'s}). \tag{c3}$$

(ii) Then show, by differentiating (b), that Chaplygin's equations [recall (3.8.13o)]

$$(\partial T_o/\partial \dot{q}_I)^{\cdot} - \partial T_o/\partial q_I - \sum\sum t^D{}_{II'} (\partial T/\partial \dot{q}_D)_o \, \dot{q}_{I'} = Q_{Io}, \tag{d}$$

where

$$-t^D{}_{II'} \equiv \partial b_{DI'}/\partial q_I - \partial b_{DI}/\partial q_{I'} = \textit{Chaplygin coefficients} \quad (= t^D{}_{I'I}), \tag{d1}$$

$$Q_{Io} \equiv Q_I + \sum b_{DI} Q_D, \tag{d2}$$

assume the explicit, (3.10.9k)-like, form

$$\sum m_{II'} \ddot{q}_{I'} + \sum\sum \lambda_{I,I'I''} \, \dot{q}_{I'} \dot{q}_{I''} = Q_{Io}, \tag{e}$$

where

$$\lambda_{I,I'I''} \equiv \Gamma'_{I,I'I''} + \sum \Big(M_{DI''} + \sum b_{D'I''} M_{DD'} \Big) t^D{}_{II'} \quad (\neq \lambda_{I,I''I'}), \tag{e1}$$

$$\begin{aligned} 2\Gamma'_{I,I'I''} &\equiv 2\Gamma'_{I,I''I'} = \partial m_{II''}/\partial q_{I'} + \partial m_{II'}/\partial q_{I''} - \partial m_{I'I''}/\partial q_I \\ &= (\textit{double}) \textit{ first-kind Christoffels, based on the } \{m_{II'}\}. \end{aligned} \tag{e2}$$

Note that: (i) in (e), the $\lambda_{I,I'I''}$ may be replaced by their *symmetric* parts in their last two subscripts: $(\lambda_{I,I'I''} + \lambda_{I,I''I'})/2$; and (ii) equations (e) look like the Lagrangean equations of a scleronomic and holonomic system with $n - m$ Lagrangean coordinates q_I, kinetic energy given by (b), first-kind Christoffels = the symmetric parts of the $\lambda_{I,I'I''}$, and under the impressed forces Q_{Io}.

Linear Variational Equations; or Method of Small Oscillations (Routh, Poincaré et al.)

Let us consider, with no real loss of generality, a *scleronomic* and *holonomic* system S with equations of motion

$$(\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k = Q_k, \qquad \text{where} \quad 2T = \sum\sum M_{kl}(q) \dot{q}_k \, \dot{q}_l \quad (k, l = 1, \ldots, n), \tag{3.10.10}$$

in a completely known state of motion (or equilibrium), henceforth referred to as the *fundamental*, or *undisturbed*, state I; and given by the known particular solution(s) to (3.10.10) $q_k = f_k(t)$. Below, we examine the continuous motions of S in the *neighborhood* of $I, I + \Delta(I) \equiv II$, resulting from *small disturbances* (in some sense) applied to I. Such a study has a twofold usefulness: (i) it informs us about the stability/instability of the original state I; and/or (ii) helps us to understand, approximately, the general motion of S whenever the exact solution of (3.10.10) is beyond our reach. Since this is an approximate method, with no error analysis available, its results should be applied with caution; for example, in the case of *finite* disturbances on I, described by *nonlinear* perturbation equations, it may lead to completely false results.

Linear Perturbation Equations

Let the solution(s) of (3.10.10) for the perturbed state II be $q_k = f_k(t) + x_k(t)$, where $x_k = x_k(t)$ is the small perturbation describing the temporal evolution of $II - I \equiv \Delta(I) \approx \delta(I)$. [Generally, we use $\delta(\ldots)$ for *first*-order changes and $\Delta(\ldots)$ for *total* changes, from I.] Then, with

$$T(II) \equiv T(q, \dot{q}) \equiv T(f + x, \dot{f} + \dot{x}) \equiv T, \qquad T(I) \equiv T(f, \dot{f}\,) \equiv T_o, \tag{3.10.10a}$$

and *all* M_{kl}*-derivatives evaluated at* I, we obtain, to the *second* $x, \dot{x}$-order,

$$\begin{aligned} 2T &= \sum\sum \Big\{M_{kl} + \Big(\sum (\partial M_{kl}/\partial q_r)x_r \\ &\qquad + (1/2)\sum\sum (\partial^2 M_{kl}/\partial q_r \partial q_s)x_r x_s\Big)\Big\}(\dot{f}_k + \dot{x}_k)(\dot{f}_l + \dot{x}_l) \\ &= \cdots = 2(T_o + \Delta T) = 2(T_o + \Delta T_1 + \Delta T_2), \end{aligned} \tag{3.10.10b}$$

where

$$2T_o \equiv \sum\sum M_{kl}\dot{f}_k \dot{f}_l, \tag{3.10.10c}$$

$$\Delta T_1 \equiv \sum (\alpha_k x_k + \beta_k \dot{x}_k), \tag{3.10.10d}$$

$$2\alpha_k \equiv \sum\sum (\partial M_{rl}/\partial q_k)\dot{f}_r \dot{f}_l \equiv \sum \varepsilon_{lk}\dot{f}_l, \qquad \beta_k \equiv \sum M_{kl}\dot{f}_l; \tag{3.10.10e}$$

$$\begin{aligned} 2\Delta T_2 &\equiv \sum\sum \mu_{kl}\dot{x}_k\dot{x}_l + 2\sum\sum \varepsilon_{kl}\dot{x}_k x_l + \sum\sum \zeta_{kl} x_k x_l \\ &\quad (\equiv 2\Delta T_{2,2} + 2\Delta T_{2,1} + 2\Delta T_{2,0}), \end{aligned} \tag{3.10.10f}$$

$$\mu_{kl} \equiv M_{kl} \quad (= \mu_{lk}), \tag{3.10.10.g}$$

$$\varepsilon_{kl} \equiv \sum (\partial M_{kr}/\partial q_l)\,\dot{f}_r = \sum (\partial M_{rk}/\partial q_l)\dot{f}_r \quad (\neq \varepsilon_{lk}, \text{ in general}), \tag{3.10.10h}$$

$$2\zeta_{kl} \equiv \sum\sum (\partial^2 M_{rs}/\partial q_k \partial q_l)\,\dot{f}_r \dot{f}_s \quad (= 2\zeta_{lk}). \tag{3.10.10i}$$

Similarly, with

$$\begin{aligned} &Q_k(II) \equiv Q_k(t, q, \dot{q}) = Q_k(t, f + x, \dot{f} + \dot{x}) \equiv Q_k, \\ &Q_k(I) \equiv Q_k(t, f, \dot{f}\,) \equiv Q_{k,o}, \end{aligned} \tag{3.10.10j}$$

and *all* Q_k*-derivatives evaluated at* I, we obtain, to the *first* $x, \dot{x}$-order,

$$Q_k = Q_{k,o} + \sum (\eta_{kl} x_l + \theta_{kl}\dot{x}_l), \tag{3.10.10k}$$

$$\eta_{kl} \equiv \partial Q_k/\partial q_l \quad (\neq \eta_{lk}, \text{ in general}), \qquad \theta_{kl} \equiv \partial Q_k/\partial \dot{q}_l \quad (\neq \theta_{lk}, \text{ in general}). \tag{3.10.10l}$$

Now, since the f_k and $\dot{f}_k$ (i.e., the fundamental state I), are *known functions of time* (equal to constants or zero in the case of equilibrium), T can be viewed as the *(approximate) kinetic energy of a rheonomic system with hitherto unknown and uncon-*

strained Lagrangean coordinates x_k recalling ex. 3.9.6). Therefore, the *equations of motion of the adjacent state II* are the *Lagrangean equations for the* x_k:

$$(\partial T/\partial \dot{x}_k)^{\cdot} - \partial T/\partial x_k = Q_k. \tag{3.10.11}$$

But, by (3.10.10a–l),

$$\partial T/\partial x_k = \alpha_k + \sum (\zeta_{kl}\, x_l + \varepsilon_{lk}\, \dot{x}_l), \tag{3.10.11a}$$

$$\partial T/\partial \dot{x}_k = \beta_k + \sum (\varepsilon_{kl}\, x_l + \mu_{kl}\, \dot{x}_l), \tag{3.10.11b}$$

and the undisturbed state I satisfies the equations

$$(\partial T_o/\partial \dot{f}_k)^{\cdot} - \partial T_o/\partial f_k = Q_{k,o},$$

$$\Big(\sum M_{kl}\dot{f}_l\Big)^{\cdot} - (1/2)\sum\sum(\partial M_{rl}/\partial q_k)\dot{f}_r\dot{f}_l \equiv d\beta_k/dt - \alpha_k = Q_{k,o}, \tag{3.10.11c}$$

i.e., (3.10.10) with $x = 0,\ \dot{x} = 0$. Therefore, eqs. (3.10.11), finally, assume the following form of *linear(ized) and homogeneous perturbation equations:*

$$\sum \left\{\mu_{kl}\ddot{x}_l + [(\varepsilon_{kl} - \varepsilon_{lk}) + \dot{\mu}_{kl}]\dot{x}_l + (\dot{\varepsilon}_{kl} - \zeta_{kl})x_l\right\}$$
$$= \sum(\eta_{kl}x_l + \theta_{kl}\dot{x}_l). \tag{3.10.12}$$

REMARKS

(i) These equations can also be obtained by substituting $q_k = f_k + x_k,\ \dot{q}_k = \dot{f}_k + \dot{x}_k$ in $\partial T/\partial \dot{q}_k$ and $\partial T/\partial q_k$, expanding à la Taylor around I, and keeping only up to *linear* terms in the $x, \dot{x}$:

(a) $$\partial T/\partial \dot{q}_k = \sum(M_{kl}\dot{f}_l + M_{kl}\dot{x}_l) + \sum\sum\ [(\partial M_{kl}/\partial q_r)\dot{f}_l]x_r,$$

$$\Rightarrow (\partial T/\partial \dot{q}_k)^{\cdot} = \sum\ (M_{kl}\ddot{f}_l + \dot{M}_{kl}\dot{f}_l + M_{kl}\,\ddot{x}_l + \dot{M}_{kl}\,\dot{x}_l)$$
$$+ \sum\sum\left\{(\partial M_{kl}/\partial q_r)\dot{f}_l\,\dot{x}_r + [(\partial M_{kl}/\partial q_r)\dot{f}_l]^{\cdot}\ x_r\right\}, \tag{3.10.11d}$$

(b) $$\partial T/\partial q_k = (1/2)\sum\sum(\partial M_{rl}/\partial q_k)\dot{f}_r\,\dot{f}_l + \sum\sum(\partial M_{rl}/\partial q_k)\dot{f}_r\ \dot{x}_l$$
$$+ (1/2)\sum\sum\sum\ [(\partial^2 M_{rs}/\partial q_l\partial q_k)\dot{f}_r\ \dot{f}_s]x_l, \tag{3.10.11e}$$

and similarly for Q_k [as in (3.10.10j–l)]; and then inserting these values in (3.10.10) while noting that, since the $f_k(t)$ describe the fundamental state, (3.10.11c) holds:

$$\sum(M_{kl}\ddot{f}_l + \dot{M}_{kl}\dot{f}_l) - (1/2)\sum\sum(\partial M_{rl}/\partial q_k)\dot{f}_r\dot{f}_l = Q_{k,o}. \tag{3.10.11f}$$

Again, the result is eqs. (3.10.12).

(ii) If, during the perturbed motion $\Delta(I)$, an *additional* force X_k, *not provided by the expansion* (3.10.10k) occurs, then such a term should be added to the right side of (3.10.12). Here, we shall assume that $X_k = 0$.

Since $f_r = f_r(t) =$ *known function of time*, so are the coefficients $\mu, \varepsilon, \zeta, \eta, \theta$ in (3.10.12). However, from the mathematical viewpoint, even such a *linear but variable coefficient system* is (or can be) quite complicated. Therefore, to make some headway, from now on we shall restrict ourselves to the special case where all *these* *coefficients are constant in time*. Then, (3.10.12) reduces to the constant coefficient system:

$$\sum \left[\mu_{kl}\ddot{x}_l + (\varepsilon_{kl} - \varepsilon_{lk})\dot{x}_l - \zeta_{kl}x_l\right] = \sum (\eta_{kl}x_l + \theta_{kl}\dot{x}_l); \tag{3.10.13}$$

whose mathematical theory is well known (see below).

Steady Motion

A fundamental state whose *linear perturbational equations* have *constant coefficients*, like (3.10.13), is called a *state of steady motion* (Routh, 1877), or, sometimes (but not quite correctly), *stationary* motion. Common examples of such a state are (i) absolute or relative *equilibrium* (in which case, the f_k are constant or zero); (ii) *cyclic* systems undergoing "isocyclic" motions [i.e., certain of their coordinates (the "nonignorable" ones) and certain of their velocities (the "ignorable" ones) remain constant (§ 8.5)].

We begin our study of steady motion by noting that, in such a state, since the $\mu, \varepsilon, \zeta, \eta, \theta$ are constant, the perturbed motion $x_k(t)$ is *independent* of the particular instant at which the disturbance is applied to that state.

Next, let us examine closely the right (perturbed force) side of (3.10.13). Following Kelvin and Tait, we call the x-proportional terms *positional* forces, and the $\dot{x}$-proportional terms *motional* forces. Each of these terms can be further subdivided into its *symmetric* and *antisymmetric* parts; the latter are defined, respectively, by the following unique decompositions:

$$\eta_{kl} = \eta'_{kl} + \eta''_{kl}, \qquad \theta_{kl} = \theta'_{kl} + \theta''_{kl}, \tag{3.10.14}$$

where the symmetric parts (single accents) are defined by

$$\eta'_{kl} = \eta'_{lk} \equiv (1/2)(\eta_{kl} + \eta_{lk}), \qquad \theta'_{kl} = \theta'_{lk} \equiv (1/2)(\theta_{kl} + \theta_{lk}), \tag{3.10.14a}$$

and the antisymmetric ones (double accents) by

$$\eta''_{kl} = -\eta''_{lk} \equiv (1/2)(\eta_{kl} - \eta_{lk}), \qquad \theta''_{kl} = -\theta''_{lk} \equiv (1/2)(\theta_{kl} - \theta_{lk}); \tag{3.10.14b}$$

that is, $\eta'_{kk} = \eta_{kk}$, $\eta''_{kk} = 0$ and $\theta'_{kk} = \theta_{kk}$, $\theta''_{kk} = 0$. The so-resulting *four* types of forces we classify as follows:

(i)
$$\sum \eta'_{kl}x_l \equiv \eta'_k = \textit{potential positional forces}, \tag{3.10.14c}$$

derivable from the potential:

$$V' = -(1/2)\sum\sum \eta'_{kl}x_k x_l \;\Rightarrow\; -(\partial V'/\partial x_k) = \eta'_k; \tag{3.10.14d}$$

and whose inertial counterparts are the $-\zeta_{kl}x_l$ terms in (3.10.13).

(ii)
$$\sum \eta''_{kl}x_l \equiv \eta''_k = \textit{nonpotential } (\Rightarrow \textit{nonconservative}), \textit{ or circulatory},$$
$$\textit{positional forces} = (1/2)\sum (\partial\eta''_k/\partial x_l - \partial\eta''_l/\partial x_k)x_l, \tag{3.10.14e}$$

where the η''_{kl} are referred to as *vorticity* coefficients. [Such forces are also called *artificial* (Thomson and Tait), since their work over a closed route of configurations is nonzero; and so, upon repetition of that cycle, they can produce unbounded amounts of energy].

(iii) $$\sum \theta'_{kl}\,\dot{x}_l \equiv \theta'_k = \textit{damping motional forces}, \tag{3.10.14f}$$

derivable from the *Rayleigh dissipation function* (3.9.10a ff.; with $F \to D'$)

$$D' \equiv -(1/2)\sum\sum \theta'_{kl}\dot{x}_k\dot{x}_l \Rightarrow -(\partial D'/\partial \dot{x}_k) = \theta'_k. \tag{3.10.14g}$$

If the (perturbational) power of these forces:

$$\sum \theta'_k \dot{x}_k = \sum\sum \theta'_{kl}\dot{x}_k\dot{x}_l = -2D',$$

is *negative definite* (*in the* $\dot{x}$), then damping is called *complete*; if it is only *negative semidefinite* (i.e., it may vanish for some $\dot{x} \neq 0$), then it is called *pervasive*. (This difference does matter in stability questions.)

(iv) $$\sum \theta''_{kl}\,\dot{x}_l \equiv \theta''_k = \textit{gyroscopic motional forces}, \tag{3.10.14h}$$

derivable from the gyroscopic *function*

$$\Theta'' = -\sum\sum \theta''_{kl}\,x_k\,\dot{x}_l \;\Rightarrow\; -(\partial\Theta''/\partial x_k) = \theta''_k, \tag{3.10.14i}$$

and whose inertial counterparts are the $(\varepsilon_{kl} - \varepsilon_{lk})\dot{x}_l$ terms in (3.10.13).

To understand these forces and their effects on the disturbance $x_k(t)$ better, let us form the *power equation of the perturbed motion*: multiplying (3.10.13) with $\dot{x}_k$ and summing over k, while noting that the gyroscopic contributions from both sides vanish, we obtain

$$d(\Delta h)/dt = C - 2D', \tag{3.10.15}$$

where [recalling (3.10.10f)]

$$\begin{aligned} 2\Delta h &\equiv \sum\sum (\mu_{kl}\,\dot{x}_k\,\dot{x}_l - \zeta_{kl}\,x_k\,x_l) + 2V' \\ &\equiv 2[\Delta T_{2,2} + (V' - \Delta T_{2,0})] = 2\ (\textit{generalized})\ \textit{energy of disturbance}, \end{aligned} \tag{3.10.15a}$$

$$C \equiv \sum \eta''_k\,\dot{x}_k = \sum\sum \eta''_{kl}\,x_l\,\dot{x}_k = \textit{circulatory power}. \tag{3.10.15b}$$

Hence, if $C = 0$, then $2D'$ represents the *rate of decrease of the perturbational energy* Δh.

For *stability* investigations (see below), it is convenient to bring all terms of (3.10.13) on the same side and group them appropriately as follows (with some renaming, to conform with standard contemporary practices):

$$\sum [M_{kl}\,\ddot{x}_l + (D_{kl} + G_{kl})\dot{x}_l + (K_{kl} + N_{kl})\,x_l] = 0, \tag{3.10.16}$$

where

$$M_{kl} = M_{lk} \equiv \mu_{kl} = \textit{coefficients of inertia/mass}$$
$$[\mathbf{M} = (M_{kl})\text{: symmetric and positive definite matrix}], \tag{3.10.16a}$$
$$D_{kl} = D_{lk} \equiv -\theta'_{kl} = \textit{damping coefficients}$$
$$[\mathbf{D} = (D_{kl})\text{: symmetric matrix; if positive definite: complete damping,}$$
$$\text{if positive semidefinite: pervasive damping}], \tag{3.10.16b}$$
$$G_{kl} = -G_{lk} \equiv (\varepsilon_{kl} - \varepsilon_{lk}) - \theta''{}_{kl} = \textit{gyroscopic coefficients}$$
$$[\mathbf{G} = (G_{kl})\text{: antisymmetric matrix, no general sign properties}], \tag{3.10.16c}$$
$$K_{kl} = K_{lk} \equiv -(\zeta_{kl} + \eta'{}_{kl}) = \textit{conservative positional coefficients}$$
$$[\mathbf{K} = (K_{kl})\text{: symmetric matrix; if positive definite, then static stability}], \tag{3.10.16d}$$
$$N_{kl} = -N_{lk} \equiv -\eta''{}_{kl} = \textit{nonconservative positional, or circulatory, coefficients}$$
$$[\mathbf{N} = (N_{kl})\text{: antisymmetric matrix, no general sign properties}]. \tag{3.10.16e}$$

Stability of Steady Motion (see also § 8.6)

Substituting into (3.10.16) $x_k = x_k(t) = X_k \exp(\lambda t)$ ($X_k =$ constant amplitude, depending on the initial conditions, and λ an exponent to be determined), and requiring nontrivial solutions, we are led in well-known ways to the system's *secular* or *characteristic* equation

$$\Delta(\lambda) \equiv \left| M_{kl}\,\lambda^2 + (D_{kl} + G_{kl})\,\lambda + (K_{kl} + N_{kl}) \right| = 0, \tag{3.10.17}$$

or, if expanded,

$$\Delta(\lambda) \equiv a_0\lambda^m + a_1\lambda^{m-1} + a_2\lambda^{m-2} + \cdots + a_{m-1}\lambda + a_m = 0, \tag{3.10.18}$$

where $m = 2n$, all coefficients are *real*, and (by Viète's rules, or by induction)

$$a_0 = \left| M_{kl} \right| > 0 \qquad \text{and} \qquad a_m = \left| K_{kl} + N_{kl} \right|. \tag{3.10.18a}$$

Brief Detour/Summary of Relevant Fundamentals of the Theory of Stability of Motion

DEFINITION

A (fundamental) state of motion I is called stable, relative to bounded initial disturbances (i.e., initial condition changes), if the resulting perturbation from it, $\Delta(I)$, also remains bounded for all subsequent time. More precisely, let $y = y(t) \equiv (x, \dot{x})$ and $t_{\text{initial}} \equiv t_i$. Then, I is stable if, for any constant $\varepsilon > 0$, another constant $\delta = \delta(\varepsilon) > 0$ can be found such that, from $|y_i \equiv y(t_i)| < \delta$, it follows that $|y(t)| < \varepsilon$ for all $t > t_i$; that is, I is stable if it is possible to keep y as small as we wish by appropriately restricting its initial value y_i. The intuitive/popular understanding of a stable state of motion (or equilibrium) as one in which "the smaller the initial disturbance, the smaller the subsequent perturbation from it'' corresponds, clearly, to the special case where $\delta(\ldots)$ is a *monotonically decreasing* function of ε. (Outside of the absolute value $|\ldots|$, other ''norms'' $\|\ldots\|$ can be selected.) In many applications, however, such boundedness of $\Delta(I)$ is not enough; there, for stability, the disturbance must also diminish in time, and eventually die away, that is, all so perturbed motions must tend toward I as time increases indefinitely; mathematically: $|y| \to 0$, as $t \to \infty$. This, sharper, type of stability is called *asymptotic stability*, while the earlier one requiring only $\Delta(I)$-boundedness is referred to as *stability in the sense of Lagrange*. If I is stable for any size initial disturbance, then I is called *totally* or *globally* stable; while if it is stable only for ''small'' initial disturbances, then it is called, simply, stable (e.g., a ship safe for ocean voyages vs. a ship safe only for Mediterranean sea voyages). Clearly, in practice, only the latter type of stability is serviceable. For nonlinear systems in particular, the initial disturbances must be small enough so that the perturbed motions are still controlled by the fundamental motion I. (We should remark that, since, out of nonlinear equations of motion, qualitatively new and unexpected phenomena may emerge, no single definition of stability of motion, that is uniformly physically meaningful and technically useful, is possible or desirable — stability is a human-made *condition*, not an ever valid and exceptionless physical law, like the equations of motion. As the distinguished applied mathematician R. Bellman put it, ''stability is a much overburdened word with an unstabilized definition.'' Below, only the practically important asymptotic stability is examined.)

Usually, the exact equations of a perturbation $\Delta(I)$, from I, consist of a linear part [which here is assumed to (exist and) be the *constant coefficient*, or *autonomous*, system (3.10.16)] and of a nonlinear part. Now, it is shown in the theory of stability [A. M. Lyapounov's ''first approximation'' (early 1890s); also H. Poincaré's ''équations aux variations'' (1892)] that for such a system:

1. If the real parts of all roots of its characteristic equation (3.10.17, 18) are negative, then the fundamental state I is asymptotically stable, irrespectively of the nonlinear terms of $\Delta(I)$; that is, our linearized analysis suffices to establish the asymptotic stability of I.
2. If even one of the roots of (3.10.17, 18) has a positive real part, then I is unstable, irrespectively of the nonlinear terms of $\Delta(I)$; again, the linearized analysis suffices.
3. Critical (or neutral, or marginally stable) case: If even one of the roots of (3.10.17, 18) has zero real part while its remaining roots, if any, have negative real parts [i.e., if the linearized perturbations are stable but not asymptotically stable — provided that those zero-real-part roots are *distinct*, so that their contributions to the general solution of (3.10.16) have no t-proportional (*secular*) terms, otherwise I is unstable as in the second case], the stability of I cannot be decided from the first approximation (3.10.16), we must also examine the nonlinear part of the exact perturbation equations; the linearized analysis does not suffice! Physically, the presence of a root with zero real part indicates an exact balance among certain of the system's physical properties/parameters and associated forces. Such systems *may* be *structurally unstable*, that is, they may be such that, if their parameters and forces are subjected to small variations, the nature of their motions changes completely, for example, from oscillatory to nonoscillatory. So, in practical terms (i.e., unavoidable imperfections/irregularities/impurities, etc.), the critical case should be classified as (nonlinearly) unstable!

For these reasons, the behavior of the linearized system (3.10.16) in cases 1 and 2 is called *significant* (i.e., conclusive), while that in case 3 is called *nonsignificant* (i.e. inconclusive). Obviously: (i) If the linear part of $\Delta(I)$ is absent, the above results do not apply; while (ii) if its nonlinear part is absent, then we can safely conclude that the state I is: case 1, asymptotically stable; case 2, unstable; and case 3, stable/not asymptotically stable.]

From the above it follows that, since the imaginary parts of the roots of (3.10.18) do not affect the stability of I, both ordinary and/or asymptotic, it is not necessary to actually solve (3.10.18), just check the sign of the real part of its roots. This is achieved by several (necessary and/or sufficient) criteria of various degrees of generality and ease of application. Below we describe two of the most well-known such criteria: those of *Routh* (1876–1877) and *Hurwitz* (1895) [also *Clifford* (1868) and *Hermite* (1850)].

(i) *Criterion of Routh*. Let us build the following array of *Routh coefficients*:

$$\begin{array}{llll}
a_0 & a_2 & a_4 & \cdots \\
a_1 & a_3 & a_5 & \cdots \\
b_1 \equiv (a_1 a_2 - a_0 a_3)/a_1 & b_2 \equiv (a_1 a_4 - a_0 a_5)/a_1 & b_3 \equiv (a_1 a_6 - a_0 a_7)/a_1 & \cdots \\
c_1 \equiv (b_1 a_3 - a_1 b_2)/b_1 & c_2 \equiv (b_1 a_5 - a_1 b_3)/b_1 & c_3 \equiv (b_1 a_7 - a_1 b_4)/b_1 & \cdots \\
d_1 \equiv (c_1 b_2 - b_1 c_2)/c_1 & d_2 \equiv (c_1 b_3 - b_1 c_3)/c_1 & d_3 \equiv (c_1 b_4 - b_1 c_4)/c_1 & \cdots \\
\cdots\cdots & \cdots\cdots & \cdots\cdots & \cdots
\end{array}$$

that is, its first (second) row consists of the *even* (*odd*) coefficients of (3.10.18); also, $a_\bullet = 0$, for $\bullet > m$. Now, all the roots of the characteristic equation have *negative real parts* ($\Rightarrow$ the fundamental state I is *asymptotically stable*) if and only if *all the elements of the first column of the above table are positive*; that is, if and only if

$$a_0 > 0, \qquad a_1 > 0, \qquad b_1 > 0, \qquad c_1 > 0, \qquad d_1 > 0, \ldots; \tag{3.10.18b}$$

or, more generally, *if they have the same sign*—it can be shown that the number of roots with positive real parts ($\Rightarrow$ instability) equals the number of sign changes.

(ii) *Criterion of Hurwitz*. Let us build the following m *Hurwitz determinants*:

$$H_h \equiv \begin{vmatrix} a_1 & a_3 & a_5 & \cdots & a_{2h-1} \\ a_0 & a_2 & a_4 & \cdots & a_{2h-2} \\ 0 & a_1 & a_3 & \cdots & a_{2h-3} \\ 0 & a_0 & a_2 & \cdots & a_{2h-4} \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ 0 & 0 & 0 & \cdots & a_h \end{vmatrix} \qquad (h = 1, 2, \ldots, m), \tag{3.10.18c}$$

that is, we build H_m and its $m - 1$ principal minors, while taking $a_\bullet = 0$ for all $\bullet > m$ or < 0:

$$H_1 = a_1, \qquad H_2 = \begin{vmatrix} a_1 & a_3 \\ a_0 & a_2 \end{vmatrix}, \qquad H_3 = \begin{vmatrix} a_1 & a_3 & a_5 \\ a_0 & a_2 & a_4 \\ 0 & a_1 & a_3 \end{vmatrix}, \ldots. \tag{3.10.18d}$$

Now, assuming that $a_0 > 0$ [if it is not, we multiply (3.10.18) with -1], all the roots of the characteristic equation have *negative real parts* ($\Rightarrow$ the fundamental state I is *asymptotic stability*) if and only if *all m determinants H_h are positive*, that is,

$$a_0 > 0, \qquad \text{and} \qquad H_1 > 0, \ldots, H_{m-1} > 0, \qquad H_m > 0. \tag{3.10.18e}$$

- Since $H_m = a_m H_{m-1}$ (verify this!), these inequalities can be replaced by

$$a_0 > 0, \qquad \text{and} \qquad H_1 > 0, \ldots, H_{m-1} > 0, \qquad a_m > 0; \tag{3.10.18f}$$

that is, there is no need to calculate H_m, just check the signs of the first $m-1$ Hurwitz determinants and a_m (and a_0).

- Further, it can be shown that from (3.10.18e, f) it follows that

$$a_0 > 0, \qquad \text{and} \qquad a_1 > 0, \ldots, a_{m-1} > 0, \qquad a_m > 0, \tag{3.10.18g}$$

and therefore *negativity of even one of the coefficients of (3.10.18) indicates instability*.

REMARKS

(i) For detailed discussions and proofs of these two criteria, see the original works of Routh and Hurwitz; also Bellman and Kalaba (1964: collection of original papers), Chetayev (1961, chap. 4), Di Stefano et al. (1990, chap. 5), Gantmacher (1970, pp. 197–201), Leipholz (1970, §1.3, pp. 21–59), Mansour (1999, pp. R11–R15), McCuskey (1959, pp. 185–187), Synge (1960, pp. 185–188).

(ii) The criteria are theoretically equivalent (as can be verified by, say, the method of induction), but Hurwitz's criterion has the slight advantage over that of Routh of avoiding the calculation of fractions; hence the common term *Routh–Hurwitz criterion*.

(iii) The Routh–Hurwitz criteria are most suitable if all the coefficients of (3.10.18), $a_0, a_1, \ldots, a_{m-1}, a_m$ are *given numbers*. If, however, these coefficients contain parameters, then the implementation of the criteria becomes complicated. For this reason, throughout the 20th century, a number of alternative stability criteria have been formulated, especially criteria that are based directly on the sign properties of the coefficient matrices of (3.10.16); that is, (3.10.16a–e); and thus avoid the calculation of the coefficients of (3.10.18) and associated Routh coefficients (3.10.18b)/Hurwitz determinants (3.10.18c); e.g. criteria of *Liénard–Chipart, Mikhailov* et al.

(iv) On this technically important topic there exists, understandably, a large body of excellent literature; for example, (alphabetically): Bremer (1988, chap. 6), Hiller (1983, chap. 8), Hughes (1986, appendix A, pp. 480–521), Huseyin (1978), Magnus (1970), Merkin (1987), Müller (1977), Müller and Schiehlen (1976/1985), and Pfeiffer (1989).

EXAMPLE

Let us verify the Hurwitz criterion for the simple case of the *linearly damped and undriven oscillator*

$$M\ddot{x} + D\dot{x} + Kx = 0, \tag{3.10.19}$$

where $M = \textit{mass}\ (> 0)$, $D = \textit{damping}\ (> 0)$, $K = \textit{elasticity}\ (> 0)$. It is not hard to see that, here ($m = 2$), the characteristic equation is

$$M\lambda^2 + D\lambda + K = 0, \tag{3.10.19a}$$

and, therefore, the Hurwitz determinants are

$$H_1 = a_1 = D, \qquad H_2 = a_1 a_2 - a_0 a_3 = DK - M0 = DK. \tag{3.10.19b}$$

For asymptotic stability, we must have $H_1 = D > 0$ and $H_2 = DK > 0 \Rightarrow D$, $K > 0$, and hence all solutions of (3.10.19) are asymptotically stable, as is already well known.

Next, let us see some less trivial applications of these criteria.

Example 3.10.1 *Rotating Shaft; Gyroscopic versus Circulatory Forces.* Here, we study a simplified version of the problem of critical speed of rotation of an originally straight shaft (axis OZ), of noncircular cross-section, rotating with constant (inertial) angular velocity $\boldsymbol{\omega}$ about OZ, by examining the *equilibrium or small linearized motion* of a particle P of mass m, representing the concentrated mass of a disk (of negligible rotary inertia) mounted on the shaft, *relative to both inertial axes O–XYZ and corotational (shaft-fixed) ones $Oxyz$* $(OZ \equiv Oz)$ of angular velocity $\boldsymbol{\omega}$ [fig. 3.28 (recall fig. 1.8); see also fig. 3.37].

(i) Let us begin with the *moving axes O–xyz*. The disk/particle P is subjected to the following forces (the $OZ \equiv Oz$ components are omitted if not needed):

(a) *centrifugal* (an *inertial* force):

$$m\,\omega^2(x, y), \tag{a1}$$

(b) *gyroscopic/Coriolis* (an *inertial* force):

$$-2m\,\boldsymbol{\omega} \times \boldsymbol{v}_{\text{relative}} = -2m(0, 0, \omega) \times (\dot{x}, \dot{y}, 0) = 2m\,\omega(\dot{y}, -\dot{x}), \tag{a2}$$

(c) *elastic* (assuming the shaft has a *single* flexural rigidity and acts like a linear spring of known constant *stiffness* $k > 0$; a *physical* positional conservative force):

$$-k\,\boldsymbol{r} = -k(x, y), \tag{a3}$$

(d) *external damping* [e.g., aerodynamic forces (drag), bearing forces; a *physical* force]:

$$-(2d_e)m\,\boldsymbol{v}_{\text{relative}} = -2m\,d_e(\dot{x}, \dot{y}) \qquad (d_e\text{: known positive constant}), \tag{a4}$$

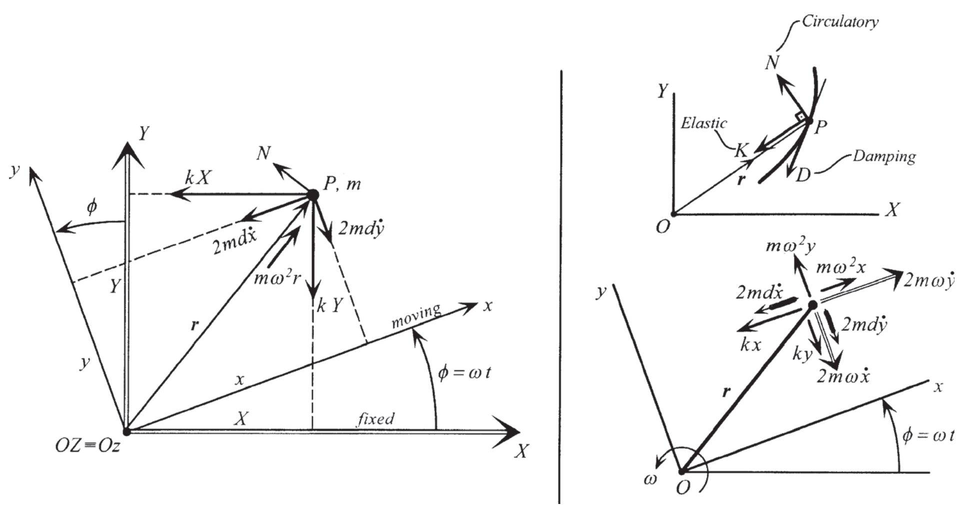

Figure 3.28 Particle model for study of stability of a rotating shaft.

(e) *internal damping* (due to the shaft properties; a *physical* force):

$$-(2d_i)m\,\boldsymbol{v}_{\text{relative}} = -2m\,d_i(\dot{x}, \dot{y}) \qquad (d_i\text{: known positive constant}). \tag{a5}$$

Applying the principle of linear momentum for relative motion to P (§1.7 ff.), we obtain

$$m\,\ddot{x} = -kx + m\,\omega^2 x + 2m\,\omega\,\dot{y} - 2m(d_e + d_i)\dot{x}, \tag{b1}$$

$$m\,\ddot{y} = -ky + m\,\omega^2 y - 2m\,\omega\,\dot{x} - 2m(d_e + d_i)\dot{y}, \tag{b2}$$

or, rearranging (and with $d \equiv d_e + d_i$),

$$\ddot{x} + 2d\dot{x} - 2\omega\dot{y} + (k/m - \omega^2)x = 0, \tag{b3}$$

$$\ddot{y} + 2d\dot{y} + 2\omega\dot{x} + (k/m - \omega^2)y = 0. \tag{b4}$$

These (relative motion) equations contain all types of terms/forces, except *circulatory* ones.

Power Equation

Multiplying (b3) with $\dot{x}$ and (b4) with $\dot{y}$, and adding together, and then transforming à la §3.9, we obtain the *noninertial* power equation

$$dh/dt = -2D_r, \tag{c}$$

where

$$h \equiv T_2 + (V - T_0) = \textit{generalized energy}, \tag{c1}$$

$$2T_2 = m[(\dot{x})^2 + (\dot{y})^2], \qquad 2T_0 = m\,\omega^2(x^2 + y^2), \qquad 2V = k(x^2 + y^2), \tag{c2}$$

$$2D_r \equiv (2m\,d)[(\dot{x})^2 + (\dot{y})^2] = m\,d[(\dot{x})^2 + (\dot{y})^2]\text{:}$$
$$\textit{relative dissipation (damping) function}. \tag{c3}$$

(ii) Now, let us examine the *fixed axes O–XYZ* description (see also Bahar and Kwatny, 1992). Since the constitutive equations and associated material constants are *objective* = *frame-invariant*, and by a simple moving → fixed axes transformation (§1.7):

$$\begin{aligned} -2m\,d_i\boldsymbol{v}_{\text{relative}} &= -2m\,d_i[\boldsymbol{v}_{\text{absolute}} - (\boldsymbol{\omega} \times \boldsymbol{r})] \\ &= -2m\,d_i[(\dot{X}, \dot{Y}, 0) - (0, 0, \omega) \times (X, Y, 0)] \\ &= -2m\,d_i(\dot{X} + \omega Y, \dot{Y} - \omega X, 0), \end{aligned} \tag{d}$$

(i.e., $\dot{x} = \dot{X} + \omega Y$ and $\dot{y} = \dot{Y} - \omega X$, if O–XYZ and O–xyz coincide *instantaneously*), the inertial equations of motion of P are

$$m\ddot{X} = -kX - 2m\,d_e\dot{X} - 2m\,d_i(\dot{X} + \omega Y), \tag{e1}$$

$$m\ddot{Y} = -kY - 2m\,d_e\dot{Y} - 2m\,d_i(\dot{Y} - \omega X), \tag{e2}$$

or, rearranging (and with $d \equiv d_e + d_i$, $k/m \equiv \omega_o{}^2$),

$$\ddot{X} + 2d\dot{X} + \omega_o{}^2 X + 2d_i\omega Y = 0, \tag{e3}$$

$$\ddot{Y} + 2d\dot{Y} + \omega_o{}^2 Y - 2d_i\omega X = 0. \tag{e4}$$

Comparing the above with (b3, 4) we see that, here, instead of a gyroscopic force ($\sim \omega$ terms), we have a circulatory one:

$$\boldsymbol{N} \equiv -2m\, d_i\, \omega\, (Y, -X) = 2m\, d_i\, \omega\, (-Y, X), \tag{e5}$$

which, clearly, is perpendicular/transverse to the position vector $\boldsymbol{OP} \equiv \boldsymbol{r}$ (i.e., $\boldsymbol{N} \cdot \boldsymbol{r} = 0$) and rotates, or *circulates*, with it with angular velocity $\boldsymbol{\omega}$; hence its name.

REMARK

Equations (e1, 2) can also be derived in an ad hoc fashion as follows: referring to fig. 3.28, we can write

$$m\ddot{X} = -kX - 2m\, d_e\dot{X} + [-(2m\, d_i\, \dot{x})\cos\phi + (2m\, d_i\, \dot{y})\sin\phi], \tag{e6}$$

$$m\ddot{Y} = -kY - 2m\, d_e\dot{Y} + [-(2m\, d_i\, \dot{x})\sin\phi - (2m\, d_i\, \dot{y})\cos\phi]. \tag{e7}$$

But, as is well known from analytic geometry,

$$x = X\cos\phi + Y\sin\phi, \qquad y = -X\sin\phi + Y\cos\phi,$$

and, therefore (since $\phi = \omega\, t$),

$$\dot{x} = \dot{X}\cos\phi + \dot{Y}\sin\phi - X\omega\sin\phi + Y\omega\cos\phi, \tag{e8}$$

$$\dot{y} = -\dot{X}\sin\phi + \dot{Y}\cos\phi - X\omega\cos\phi - Y\omega\sin\phi. \tag{e9}$$

Substituting (e8, 9) into (e6, 7), we readily recover (e1, 2).

Power Equation

Multiplying (e3) with $\dot{X}$ and (e4) with $\dot{Y}$, and adding together, and so on, we obtain the *inertial* power equation

$$dE/dt = -2D_a + C, \tag{f}$$

where

$$E \equiv T + V = \textit{ total (inertial) energy}, \tag{f1}$$

$$2T = m[(\dot{X})^2 + (\dot{Y})^2], \qquad 2V = k(X^2 + Y^2), \tag{f2}$$

$$2D_a \equiv (2m\, d)[(\dot{X})^2 + (\dot{Y})^2]:$$

$$\textit{absolute dissipation (damping) function.} \tag{f3}$$

$C \equiv \boldsymbol{N} \cdot \boldsymbol{v} = 2m\, d_i\, \omega(X\dot{Y} - Y\dot{X})$: *circulatory power* ($\boldsymbol{v} \equiv \boldsymbol{v}_{\text{absolute}}$).

Further, since the quantity

$$X\dot{Y} - Y\dot{X} \equiv 2(dA_Z/dt)$$
$$= 2\ (\textit{areal velocity},\ OZ\textit{-component})\ \textit{swept in inertial space}$$
$$\textit{by the radius } OP \textit{ in } dt, \tag{f5}$$

is a *quasi velocity* $[2dA_Z = X\,dY + (-Y)dX \;\Rightarrow\; \partial(-Y)/\partial Y = -1 \neq \partial(X)/\partial X = +1]$, it follows that

$$C = 4m\,d_i\,\omega\ (dA_Z/dt) \neq \textit{total time derivative of a scalar energetic function}; \tag{f6}$$

that is, C is a *path-dependent* quantity, like D_a. Indeed, integrating (f) between two arbitrary instants, from an "initial" t_i to a "final" t_f, we obtain

$$\Delta E \equiv E_f - E_i = \int_{t_i}^{t_f} (-2D_a + C)\,dt = -\int_{t_i}^{t_f} (2D_a)\,dt + (4m\,d_i\,\omega)\Delta A_Z, \tag{g}$$

where

$$\Delta A_Z = \textit{ area swept by } OP \textit{ from } \ t_i \ \text{ to } \ t_f. \tag{g1}$$

[The total inertial power equation (f) holds unchanged even in the presence of *gyroscopic* forces; since these latter are *normal* to P's inertial velocity, we would then have an additional $\sim -\dot{Y}$ term on the right side of (e1) and a $\sim +\dot{X}$ term on that of (e2): two terms whose combined inertial power, clearly, vanishes.]

Stability Investigation

Substituting $X,\ Y \sim \exp(\lambda t)$ in (e3, 4) and requiring nontrivial solutions, we arrive, in well-known ways, at the corresponding characteristic equation

$$a_0\lambda^4 + a_1\lambda^3 + a_2\lambda^2 + a_3\lambda + a_4 = 0, \tag{h}$$

where

$$\begin{aligned}
a_0 &\equiv 1,\\
a_1 &\equiv 4(d_e + d_i) \equiv 4d,\\
a_2 &\equiv 4(d_e + d_i)^2 + 2(k/m) \equiv 4d^2 + 2{\omega_o}^2,\\
a_3 &\equiv 4(d_e + d_i)(k/m) \equiv 4d\ {\omega_o}^2,\\
a_4 &\equiv (k/m)^2 + 4{d_i}^2\omega^2 \equiv {\omega_o}^4 + 4{d_i}^2\omega^2.
\end{aligned} \tag{h1}$$

Hence, the Routh–Hurwitz asymptotic stability conditions (here $m = 4$ — not to be confused with the mass of P)

$$a_0 > 0, \quad a_1 > 0, \quad a_1a_2 - a_0a_3 > 0, \quad (a_1a_2 - a_0a_3)a_3 - {a_1}^2a_4 > 0, \quad a_4 > 0,$$

yield

$$d > 0, \qquad d(4d^2 + {\omega_o}^2), \qquad d^2(d^2{\omega_o}^2 - {d_i}^2\omega^2) > 0, \qquad {\omega_o}^4 + 4{d_i}^2\omega^2 > 0. \tag{h2}$$

Clearly, since d_e, d_i ($\Rightarrow d > 0$) and k ($= m\,\omega_o{}^2 > 0$) are positive, the *first, second, and fourth (last)* of conditions (h2) are satisfied; while the *third* of them furnishes the upper ω-bound:

$$\omega^2 < [1 + (d_e/d_i)]^2 (k/m). \tag{h3}$$

This shows that as $d_i \to 0$,

$$\omega_{\text{critical}} \equiv [1 + (d_e/d_i)](k/m)^{1/2} \equiv [1 + (d_e/d_i)]\,\omega_o \to \infty; \tag{h4}$$

and as $d_i \to \infty$, $\omega_{\text{critical}} \to 0$: that is, d_i has a *destabilizing* effect; hence, in rotor design, we should aim at *more* d_e and *less* d_i.

For further details and insights, and discussion of stability using the rotating axes equations (b3, 4), see, for example (alphabetically): Bolotin (1963, chap. 3), Dimentberg (1961, chap. 2), Ziegler (1968, pp. 94–96, 101); and for additional, more realistic, circulatory force examples, see Bremer [1988(a), pp. 144–149]. For further applications of the Routh–Hurwitz criterion to the stability of mechanical systems, see texts on linear and nonlinear vibrations and controls.

Problem 3.10.2 Show that if the fundamental state I of a scleronomic system is one of *equilibrium* in the q_k — that is, if $f_k = constant$, *or* 0 [recall (3.10.10a ff.)]— the equations of small motion around I are

$$\sum M_{kl}\ddot{x}_l = \sum [(\partial Q_k/\partial q_l)x_l + (\partial Q_k/\partial \dot{q}_l)\dot{x}_l] \tag{a}$$

$$\left[= -\sum (\partial^2 V/\partial q_l \partial q_k) x_l, \quad \text{if } Q_k = -\partial V(q)/\partial q_k \right], \tag{b}$$

where all the $x/\dot{x}/\ddot{x}$-coefficients are evaluated on I and, therefore, are *constant* [something that makes the systems (a, b) always solvable].

Notice that in case (b), or in case (a) with $\partial Q_k/\partial \dot{q}_l = \partial Q_l/\partial \dot{q}_k$, *no gyroscopic terms appear*.

Problem 3.10.3 With the help of the following quadratic and bilinear forms:

$$2T'_2 \equiv \sum\sum M_{kl}\dot{x}_k\dot{x}_l \qquad (\equiv 2\Delta T_{2,2}\text{: “\textit{contracted}” \textit{kinetic energy}}), \tag{a}$$

$$2D \equiv \sum\sum D_{kl}\dot{x}_k\dot{x}_l \qquad (\equiv -2D'\text{: \textit{damping function}}), \tag{b}$$

$$G \equiv \sum\sum G_{kl}x_k\dot{x}_l \qquad (\equiv -2\Delta T_{2,1} + \Theta''\text{: \textit{gyroscopic function}}), \tag{c}$$

$$2V \equiv \sum\sum K_{kl}x_k x_l \qquad (\equiv 2V' - 2\Delta T_{2,0}\text{: \textit{potential function}}), \tag{d}$$

and

$$N_k \equiv -\sum N_{kl}x_l \qquad (\equiv \eta'_k\text{: \textit{circulatory force}}), \tag{e}$$

show that the linear variational equations of small motion about a fundamental state of steady motion can be rewritten in the Lagrangean (linear vibration) form

$$(\partial T'_2/\partial \dot{x}_k)^{\cdot} + \partial D/\partial \dot{x}_k + \partial(G + V)/\partial x_k = N_k. \tag{f}$$

Problem 3.10.4 Show that if the fundamental state I is one of *equilibrium* — that is, $f_k(t) \equiv 0$, and $\partial Q_k/\partial \dot{q}_l = \partial Q_l/\partial \dot{q}_k$ (e.g., positional forces only) there — then

$$\varepsilon_{kl} = 0, \qquad \zeta_{kl} = 0, \qquad \theta_{kl} = 0 \ (\Rightarrow G_{kl} = 0, \quad K_{kl} = -\eta'_{kl}), \tag{a}$$

and therefore the equations of small motion about such an I reduce to

$$\sum [M_{kl}\ddot{x}_l + D_{kl}\dot{x}_l + (K_{kl} + N_{kl})x_l] = 0. \tag{b}$$

We notice that the *absence of gyroscopic terms* is the key difference between small motion about *absolute* and *relative* equilibrium (and, of course, general motion).

Problem 3.10.5 Consider the *cubic* characteristic equation

$$\lambda^3 + A_2\lambda^2 + A_1\lambda + A_0 = 0, \tag{a}$$

with roots $\lambda_1, \lambda_2, \lambda_3$.

(i) Show that

$$A_2 = -(\lambda_1 + \lambda_2 + \lambda_3), \qquad A_1 = \lambda_1\lambda_2 + \lambda_1\lambda_3 + \lambda_2\lambda_3, \qquad A_0 = -(\lambda_1\lambda_2\lambda_3). \tag{b}$$

(ii) Since one of these roots must be *real* and the other two either *real* or *complex conjugate*, we write

$$\lambda_1 = \rho_1, \qquad \lambda_2 = \rho_2 + i\sigma_2, \qquad \lambda_3 = \rho_2 - i\sigma_2, \tag{c}$$

where $i^2 \equiv -1$, and ρ_1, ρ_2, σ_2 are *real*. Show that

$$A_2 = -(\rho_1 + 2\rho_2), \qquad A_1 = 2\rho_1\rho_2 + {\rho_2}^2 + {\sigma_2}^2, \qquad A_0 = -\rho_1({\rho_2}^2 + {\sigma_2}^2). \tag{d}$$

Problem 3.10.6 Continuing from the preceding problem, show that the (necessary and sufficient) asymptotic stability conditions for a system with the cubic characteristic equation

$$\lambda^3 + A_2\lambda^2 + A_1\lambda + A_0 = 0, \tag{a}$$

are

$$\text{(i)}\ A_2, A_1, A_0 > 0 \qquad \text{(positive coefficients)}, \qquad \text{and} \qquad \text{(ii)}\ A_2A_1 > A_0. \tag{b}$$

Problem 3.10.7 Consider the *quartic* characteristic equation

$$\lambda^4 + A_3\lambda^3 + A_2\lambda^2 + A_1\lambda + A_0 = 0, \tag{a}$$

with roots

$$\lambda_1 = \rho_1 + i\sigma_1, \qquad \lambda_2 = \rho_1 - i\sigma_1, \qquad \lambda_3 = \rho_2 + i\sigma_2, \qquad \lambda_4 = \rho_2 - i\sigma_2. \tag{b}$$

Show that

$$\begin{aligned} A_3 &= -2(\rho_1 + \rho_2), \\ A_2 &= {\rho_1}^2 + {\rho_2}^2 + {\sigma_1}^2 + {\sigma_2}^2 + 4\rho_1\rho_2, \\ A_1 &= -2\rho_1({\rho_2}^2 + {\sigma_2}^2) - 2\rho_2({\rho_1}^2 + {\sigma_1}^2), \\ A_0 &= ({\rho_1}^2 + {\sigma_1}^2)({\rho_2}^2 + {\sigma_2}^2). \end{aligned} \tag{c}$$

Problem 3.10.8 Consider again the *quartic* characteristic equation

$$\lambda^4 + A_3\lambda^3 + A_2\lambda^2 + A_1\lambda + A_0 = 0. \tag{a}$$

Show that the Routh–Hurwitz criteria applied to (a) produce the following (necessary and sufficient) asymptotic stability conditions:

(i) $$A_3,\ A_2,\ A_1,\ A_0 > 0 \qquad \text{(positive coefficients)}, \tag{b}$$

(ii) $$A_3 A_2 A_1 > {A_1}^2 + {A_3}^2 A_0. \tag{c}$$

Problem 3.10.9 Deduce the Routh–Hurwitz asymptotic stability conditions for the indicated special cases:

(i) $m = 2$, i.e., $a_0\lambda^2 + a_1\lambda + a_2 = 0$:

$$a_0,\ a_1,\ a_2 > 0; \tag{a}$$

(ii) $m = 3$, i.e., $a_0\lambda^3 + a_1\lambda^2 + a_2\lambda + a_3 = 0$:

- $$a_0,\ a_1,\ a_2,\ a_3 > 0, \tag{b1}$$
- $$a_1 a_2 - a_0 a_3 > 0; \tag{b2}$$

(iii) $m = 4$, i.e., $a_0\lambda^4 + a_1\lambda^3 + a_2\lambda^2 + a_3\lambda + a_4 = 0$:

- $$a_0,\ a_1 > 0, \tag{c1}$$
- $$A \equiv a_1 a_2 - a_0 a_3 > 0, \tag{c2}$$
- $$B \equiv a_3 A - {a_1}^2 a_4 > 0, \tag{c3}$$
- $$a_4 > 0. \tag{c4}$$

Due to eqs. (c3, 4), condition (c2) can be replaced by the simpler $a_3 > 0$; then, it follows that $a_2 > 0$.

(iv) $m = 5$, i.e., $a_0\lambda^5 + a_1\lambda^4 + a_2\lambda^3 + a_3\lambda^2 + a_4\lambda + a_5 = 0$.

With the abbreviations $A \equiv a_1 a_2 - a_0 a_3$, $C \equiv a_1 a_4 - a_0 a_5$, and $D \equiv a_3 a_4 - a_2 a_5$, they are

- $$a_0,\ a_1,\ A > 0, \tag{d1}$$
- $$a_3 A - a_1 C > 0, \tag{d2}$$
- $$AD - C^2 > 0, \tag{d3}$$
- $$a_5 > 0. \tag{d4}$$

But, since $a_1(AD - C^2) \equiv C(a_3 A - a_1 C) - a_5 A^2$, and due to (d3, 4), condition (d2) can be replaced by the simpler $C > 0$; also, we must have $a_4 > 0$ and $D > 0$.

Notice that, in *all* cases, we must have satisfaction of the *essential conditions*: $a_0 = |M_{kl}| > 0$ and $a_m = |K_{kl} + N_{kl} > 0|$.

Problem 3.10.10 Consider the two-DOF undamped and gyroscopic system with perturbation equations

$$M_1\ddot{x}_1 + G\dot{x}_2 + K_1 x_1 = 0, \qquad M_2\ddot{x}_2 - G\dot{x}_1 + K_2 x_2 = 0, \tag{a}$$

where $M_{1,2} = \textit{inertia/mass}$ (> 0), $K_{1,2} = \textit{positional noncirculatory coefficients}$, and $G = \textit{gyroscopicity}$.

(i) Show that its characteristic equation is

$$a_0\lambda^4 + a_2\lambda^2 + a_4 = 0, \tag{b}$$

where

$$\begin{aligned} a_0 &\equiv M_1 M_2 \ (> 0 - \text{always, on physical grounds}), \\ a_2 &\equiv M_1 K_2 + M_2 K_1 + G^2, \\ a_4 &\equiv K_1 K_2. \end{aligned} \tag{c}$$

(ii) Show that the Routh–Hurwitz criteria applied to this problem ($m = 4$, and $a_1, a_3 = 0$) produce the three asymptotic stability conditions

$$a_0 > 0, \qquad a_2 > 0, \qquad a_4 > 0. \tag{d}$$

(iii) Show that the *second* of (d) can be satisfied for *sufficiently high values of the "spin term"* G^2, no matter what the signs of K_1 and K_2 are. [This is a special case of the famous *gyroscopic stabilization theorem* of Kelvin and Tait. For a more extensive treatment, see §8.6.]

REMARK

The presence of light damping ($\sim \dot{x}$) changes this stability picture considerably. For details and technical applications, for example, see Grammel (1950, vol. 1, pp. 261–262; vol. 2, pp. 230–247).

Problem 3.10.11 Consider a smooth surface S spinning with constant inertial angular velocity $\boldsymbol{\omega}$ about a vertical axis OZ (positive upward), where O is a surface point with horizontal tangential plane to it there. Let the equation of S in *corotating* (*surface-fixed*) coordinates O–xyz, where Ox, Oy are tangent to the lines of principal curvature of S at O and $Oz \equiv OZ$, be, to the *second* order in x, y,

$$2z = x^2/\rho_1 + y^2/\rho_2, \qquad \rho_{1,2} = \textit{principal radii of curvature of } S \text{ at } O. \tag{a}$$

In addition, consider a particle P of mass $m = 1$, moving under gravity on S, in the neighborhood of O.

(i) Show that, *to the second order*, the (double) Lagrangean of P is

$$2L = \left\{(\dot{x})^2 + (\dot{y})^2 + 2\omega(x\dot{y} - y\dot{x}) + [\omega^2 - (g/\rho_1)]x^2 + [\omega^2 - (g/\rho_2)]y^2\right\}, \tag{b}$$

and therefore its equations of (relative) motion in the neighborhood of O are

$$\ddot{x} - \gamma\dot{y} + k_1 x = 0, \qquad \ddot{y} + \gamma\dot{x} + k_2 y = 0, \tag{c}$$

where

$$\gamma \equiv 2\omega, \qquad k_1 \equiv (g/\rho_1) - \omega^2, \qquad k_2 \equiv (g/\rho_2) - \omega^2. \tag{d}$$

(ii) The system (c) has the form of eqs. (a) of the preceding problem; with $x_1 = x$, $x_2 = y$, $M_1 = M_2 = 1\,(> 0)$, $G = -\gamma$, $K_1 = k_1$, $K_2 = k_2$. Specialize the asymptotic stability conditions (d) established there to this problem.

[See also Whittaker (1937, pp. 207–208); and for the case of small ($\sim \dot{x}, \dot{y}$) friction, see Lamb (1943, pp. 253–254).]

Problem 3.10.12 Using the Routh–Hurwitz criterion, show that in an asymptotically *stable* (linear) system *all the coefficients of the characteristic equation (3.10.18), $a_0, a_1, a_2, \ldots, a_{m-1}, a_m$, have the same sign* ($> 0$)*; that is, none of them vanishes*. (This is a *necessary*, but not sufficient, condition for such stability!)

HINT

Let the roots of that equation be

$$-\varepsilon_1, \ldots, -\varepsilon_* \qquad \text{and} \qquad -\rho_1 \pm i\sigma_1, \ldots, -\rho_\bullet \pm i\sigma_\bullet,$$

where $* + \bullet = m$ (# possible multiple roots being counted individually), and all ε, ρ, σ are real and *positive* (asymptotically stable system). Then, by well-known theorems of the theory of equations,

$$\begin{aligned}\Delta(\lambda) &= a_0\big[(\lambda + \varepsilon_1)\cdots(\lambda + \varepsilon_*)\big]\big[(\lambda^2 + 2\rho_1\lambda + {\rho_1}^2 + {\sigma_1}^2)\cdots(\lambda^2 + 2\rho_\bullet\lambda + {\rho_\bullet}^2 + {\sigma_\bullet}^2)\big]\\ &= a_0(\lambda^m + \cdots) = 0. \end{aligned} \tag{a}$$

Example 3.10.2 *The Jacobi–Synge Equations.* The preceding equations show that the Lagrangean equations of motion, under say, the holonomic constraints

$$\phi_H(t, q) = 0 \;\Rightarrow\; \sum (\partial\phi_H/\partial q_k)\dot{q}_k + \partial\phi_H/\partial t = 0 \qquad (H = 1, \ldots, m), \tag{a}$$

have the general form

$$\sum M_{kr}(t, q)\ddot{q}_r = f_k(t, q, \dot{q}) + \sum \lambda_H(\partial\phi_H/\partial q_k), \tag{b}$$

where $f_k(t, q, \dot{q})$ is a known function of its arguments. [If the constraints are given in the general Pfaffian (possibly nonholonomic) form $\sum a_{Hk}\dot{q}_k + a_H = 0$, then we replace the gradients $\partial\phi_H/\partial q_k$ with the constraint coefficients $a_{Hk}(t, q)$.]

It was Jacobi's idea (Jacobi, 1866, p. 55) to $(\ldots)^{\cdot}$-differentiate the velocity constraints (a) once more, thus bring them into their acceleration form (i.e., $\sim \ddot{q}$ terms), and then combine them, *like additional equations of motion*, with (b). [We are indebted to Dr. F. Pfister for pointing this out to us; see Pfister (1995). This idea was also carried out, independently and slightly differently, by Synge (in 1926) via general tensor calculus, in his pioneering and influential memoir (Synge, 1926–1927, pp. 53–55).] This fusion of constraints, in acceleration form, with the equations of motion in Routh–Voss (multiplier) form, something very popular among applied dynamicistes today, is carried out below in matrix form.

Indeed, first we $(\ldots)^{\cdot}$-differentiate (a) once more, thus obtaining

$$\sum (\partial\phi_H/\partial q_k)\ddot{q}_k = g_H(t, q, \dot{q}) \qquad (H = 1, \ldots, m), \tag{c}$$

where $g_H(t, q, \dot{q})$ is a known function of its arguments, like $f_k(t, q, \dot{q})$. Next we introduce some simple matrix notation:

$$\mathbf{M} = (M_{kr})\text{: } \textit{nonsingular} \text{ and positive definite}, \qquad \mathbf{q}^{\mathrm{T}} = (q_1, \ldots, q_n),$$
$$\boldsymbol{\Phi}_{\mathbf{q}} = (\partial \phi_H / \partial q_k)\text{: } \textit{nonsingular}, \qquad \boldsymbol{\lambda}^{\mathrm{T}} = (\lambda_1, \ldots, \lambda_m),$$
$$\mathbf{f}^{\mathrm{T}} = (f_1, \ldots, f_n), \qquad \mathbf{g}^{\mathrm{T}} = (g_1, \ldots, g_n), \quad \text{where} \quad (\ldots)^{\mathrm{T}} \equiv \textit{transpose} \text{ of } (\ldots); \tag{d}$$

so that, with its help, we can rewrite eqs. (b, c) as

$$\mathbf{M}\,\ddot{\mathbf{q}} = \mathbf{f} + \boldsymbol{\Phi}_{\mathbf{q}}{}^{\mathrm{T}}\,\boldsymbol{\lambda}, \qquad \boldsymbol{\Phi}_{\mathbf{q}}\,\ddot{\mathbf{q}} = \mathbf{g}, \tag{e}$$

respectively; and finally, we combine eqs. (e) into the following matrix form:

$$\begin{pmatrix} \mathbf{M} & \boldsymbol{\Phi}_{\mathbf{q}}{}^{\mathrm{T}} \\ \boldsymbol{\Phi}_{\mathbf{q}} & \mathbf{0} \end{pmatrix} \begin{pmatrix} \ddot{\mathbf{q}} \\ -\boldsymbol{\lambda} \end{pmatrix} = \begin{pmatrix} \mathbf{f} \\ \mathbf{g} \end{pmatrix}, \tag{f}$$

where $\mathbf{0}$ is the $m \times n$ zero matrix.

Equations (f) can be justifiably called the *Jacobi form of the Routh–Voss equations*; and, at any instant for which $\mathbf{q}$ and $\dot{\mathbf{q}}$ are known, these constitute a system of $n + m$ algebraic equations that (since $\mathbf{M}$ and $\boldsymbol{\Phi}_{\mathbf{q}}$ are nonsingular) *can* be solved (numerically) for their linearly appearing $n + m$ unknowns $\ddot{\mathbf{q}}$ and $\boldsymbol{\lambda}$. For further details, see books on computational/multibody dynamics; for example, Nikravesh (1988), Udwadia and Kalaba (1996); while, for a tensorial derivation, see Papastavridis (1998; 1999, pp. 324–325) and Synge (1926–1927).

3.11 APPELL'S EQUATIONS: EXPLICIT FORMS

Holonomic Variables

Let us begin with *holonomic* variables and, for algebraic simplicity, but no loss of generality, *stationary* constraints. Then [recalling (2.5.2 ff.)]

$$\begin{aligned} \boldsymbol{v} &= \sum \boldsymbol{e}_k \dot{q}_k \\ \Rightarrow \boldsymbol{a} \equiv d\boldsymbol{v}/dt &= \sum \boldsymbol{e}_k \ddot{q}_k + \sum (d\boldsymbol{e}_k/dt)\dot{q}_k \\ &= \sum \boldsymbol{e}_k \ddot{q}_k + \sum\sum (\partial \boldsymbol{e}_k/\partial q_l)\dot{q}_l\,\dot{q}_k\,, \end{aligned} \tag{3.11.1}$$

and, accordingly (and using subscript commas for partial q-derivatives), the system Appellian becomes

$$\begin{aligned} S \equiv \mathsf{S}\,(1/2)\,dm\,\boldsymbol{a}\cdot\boldsymbol{a} = (1/2)\mathsf{S}\,dm\Big[&\Big(\sum \boldsymbol{e}_k \ddot{q}_k + \sum\sum \boldsymbol{e}_{k,l}\,\dot{q}_l\,\dot{q}_k\Big) \\ &\cdot \Big(\sum \boldsymbol{e}_r \ddot{q}_r + \sum\sum \boldsymbol{e}_{r,s}\,\dot{q}_r\,\dot{q}_s\Big)\Big], \end{aligned} \tag{3.11.2}$$

or, with some dummy index changes, and recalling that $M_{kl} \equiv \mathsf{S}\, dm\, \boldsymbol{e}_k \cdot \boldsymbol{e}_l$ and

$$\begin{aligned} \Gamma_{k,lp} = \Gamma_{k,pl} &\equiv \mathsf{S}\, dm\, \boldsymbol{e}_k \cdot \boldsymbol{e}_{l,p} = \mathsf{S}\, dm\, \boldsymbol{e}_k \cdot \boldsymbol{e}_{p,l} \\ &= (1/2)(\partial M_{kl}/\partial q_p + \partial M_{kp}/\partial q_l - \partial M_{lp}/\partial q_k) \end{aligned} \tag{3.11.3}$$

(§3.9, §3.10), we finally obtain, *to within Appell important terms* (i.e., $\sim \ddot{q}$),

$$S = (1/2) \sum\sum M_{kl}\, \ddot{q}_k\, \ddot{q}_l + \sum\sum\sum \Gamma_{k,lp}\, \ddot{q}_k\, \dot{q}_l\, \dot{q}_p. \tag{3.11.4}$$

The above shows how to find the Appellian function for *nonstationary* constraints: (i) since $\ddot{q}_{n+1} = \ddot{t} = \dot{1} = 0$, the *first* group of terms (double sum) remains unchanged; while (ii) in the *second* group of terms (triple sum), k still runs from 1 to n, but l and p must now run from 1 to $n+1$; hence, we replace them, respectively, with the Greek subscripts α and β. The result is

$$\begin{aligned} S &= (1/2) \sum\sum M_{kl}\, \ddot{q}_k\, \ddot{q}_l + \sum\sum\sum \Gamma_{k,\alpha\beta}\, \ddot{q}_k\, \dot{q}_\alpha\, \dot{q}_\beta \\ &= (1/2) \sum\sum M_{kl}\, \ddot{q}_k\, \ddot{q}_l + \sum\sum\sum \Gamma_{k,lp}\, \ddot{q}_k\, \dot{q}_l\, \dot{q}_p \\ &\quad + 2 \sum\sum \Gamma_{k,l,n+1}\, \ddot{q}_k\, \dot{q}_l + \sum \Gamma_{k,n+1,n+1}\, \ddot{q}_k\, ; \end{aligned} \tag{3.11.5}$$

where $\Gamma_{k,l,n+1} (\Gamma_{k,n+1,n+1})$ is what results from $\Gamma_{k,lp}$ by formally replacing p (p and l) with $n+1$; that is, $q_{n+1} \to t$ [recalling (3.10.8d–f)].

Expressions (3.11.4) and (3.11.5) show clearly how to build S if we know T; that is, if we know its inertial coefficients $M_{\alpha\beta}$: M_{kl}, $M_{k,n+1} \equiv M_k$, $M_{n+1,n+1} \equiv M_0 = 2T_0$; they also reconfirm the kinematico-inertial identity $\partial S/\partial \ddot{q}_k = (\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k$.

Nonholonomic Variables

Next, let us repeat the above, but for quasi variables (i.e., $S \to S^*(q, \omega, \dot{\omega}, t) = S^*$); first, again, for the *stationary* case. Substituting

$$\boldsymbol{a} = \boldsymbol{a}^* \equiv d\boldsymbol{v}^*/dt = \sum \boldsymbol{\varepsilon}_k\, \dot{\omega}_k + \sum (d\boldsymbol{\varepsilon}_k/dt)\, \omega_k$$

(and using here subscript commas for partial θ-derivatives)

$$= \sum \boldsymbol{\varepsilon}_k\, \dot{\omega}_k + \sum\sum \boldsymbol{\varepsilon}_{k,l}\, \omega_l\, \omega_k\, , \tag{3.11.6}$$

into $S^* \equiv \mathsf{S}\, (1/2) dm\, \boldsymbol{a}^* \cdot \boldsymbol{a}^*$, we obtain, *to within Appell important terms* (i.e., $\sim \dot{\omega}$)

$$\begin{aligned} 2S^* &= \sum\sum \Big(\mathsf{S}\, dm\, \boldsymbol{\varepsilon}_k \cdot \boldsymbol{\varepsilon}_l \Big) \dot{\omega}_k\, \dot{\omega}_l \\ &\quad + \sum\sum\sum \Big(\mathsf{S}\, dm\, \boldsymbol{\varepsilon}_k \cdot (\boldsymbol{\varepsilon}_{l,p} + \boldsymbol{\varepsilon}_{p,l}) \Big) \dot{\omega}_k\, \omega_l\, \omega_p\, , \end{aligned}$$

or, since [recalling (3.10.9f)]

$$\begin{aligned} \mathsf{S}\, dm\, \boldsymbol{\varepsilon}_k \cdot (\boldsymbol{\varepsilon}_{l,p} + \boldsymbol{\varepsilon}_{p,l}) &= 2\Gamma^*_{k,lp} - \sum \big(\gamma^r{}_{lk} M^*{}_{pr} + \gamma^r{}_{pk} M^*{}_{lr} \big) \\ &= 2\Gamma^*_{k,lp} + \sum \big(\gamma^r{}_{kl} M^*{}_{pr} + \gamma^r{}_{kp} M^*{}_{lr} \big), \end{aligned}$$

finally,

$$S^* = (1/2) \sum\sum M^*{}_{kl}\, \dot{\omega}_k\, \dot{\omega}_l + \sum\sum\sum \Lambda_{k,lp}\, \dot{\omega}_k\, \omega_l\, \omega_p\, , \tag{3.11.7}$$

where [recalling (3.10.9l)]

$$\Lambda_{k,lp} \equiv \Gamma^*{}_{k,lp} + \sum \gamma^r{}_{kl} M^*{}_{pr}. \tag{3.11.7a}$$

from the above we easily see that:

(i) To find S^* we need not just the $M^*{}_{kl}$ (like T^*), but also the $\gamma^r{}_{kl}$ (like I_k); and [recall (3.10.9k)]

(ii) $$\partial S^*/\partial \dot{\omega}_k = \sum M^*{}_{kl}\, \dot{\omega}_l + \sum\sum \Lambda_{k,lp}\, \omega_l\, \omega_p = I_k. \tag{3.11.7b}$$

Let the reader extend the above, eqs. (3.11.6–7a), to the *nonstationary* case.

REMARKS

(i) In general, both kinetic energy and Appellian are more simply expressed in nonholonomic rather than holonomic variables; that is, for the same problem, T^* and S^* are simpler *in form* than T and S, respectively. As a result, for *holonomic systems in holonomic variables*, Appell's equations are trivial; that is, not worth the effort. But for *holonomic systems in nonholonomic variables*, they may offer definite advantages: for example, the Eulerian rigid-body equations (Gibbs, 1879; see example below, and §3.13 ff.); then, the resulting equations of motion are of the *first order* in the ω's.

(ii) For *nonholonomic systems in nonholonomic variables*, the equations of Hamel and Appell, although theoretically equivalent, have the following differences:

(a) In the Hamel case, even if no reactions are sought, we still need the unconstrained (relaxed) kinetic energy T^*; and the coefficients $\gamma^r{}_{II'}$, $\gamma^r{}_{I,n+1}$.
(b) In the Appell case, if no reactions are sought, we may work with the *constrained* Appellian $S^*{}_o$ right from the start, and thus save a considerable amount of labor; otherwise we must calculate the unconstrained Appellian S^*; and, in all cases, the Appellian can be calculated only to within Appell-important (i.e., acceleration-containing) terms.

Also, Appell's equations are *simpler looking* than Hamel's, and *form-invariant in both holonomic and nonholonomic variables*. But calculating the Appellian requires more labor than calculating the kinetic energy. In both cases, as in other areas of science, with constant practice we learn special short cuts, or use ready-made expressions for particular systems.

Example 3.11.1 *Let us Find the Appellian of a Rigid Body Moving about a Fixed Point O.* Using body-fixed principal inertia axes $O\text{–}xyz \equiv O\text{–}123$, we find

$$(M^*{}_{kl}) = \textit{diagonal}\ (I_1, I_2, I_3) = \textit{constant components}, \tag{a}$$

and therefore all Γ^*'s vanish. Also, we recall from ex. 2.13.9 that for such axes $\gamma^r{}_{kl} = \varepsilon_{rkl} \equiv \pm 1$, according as r, k, l are an even or odd permutation of 1, 2, 3; and zero in all other cases. Accordingly, the expression (3.11.7), with (3.11.7a), and $\boldsymbol{\omega} = (\omega_1, \omega_2, \omega_3) = \textit{inertial angular velocity of body}$, specializes to

$$\begin{aligned} S^* = (1/2)\Big[I_1(\dot{\omega}_1)^2 + I_2(\dot{\omega}_2)^2 + I_3(\dot{\omega}_3)^2\Big] \\ + (I_3 - I_2)\,\dot{\omega}_1\,\omega_2\,\omega_3 + (I_1 - I_3)\,\dot{\omega}_2\,\omega_3\,\omega_1 + (I_2 - I_1)\,\dot{\omega}_3\,\omega_1\,\omega_2, \end{aligned} \tag{b}$$

and from this we immediately obtain the well-known (body-fixed + principal axes) Eulerian expressions for the body inertia (§1.17)

$$\partial S^*/\partial\dot{\omega}_1 = I_1\dot{\omega}_1 + (I_3 - I_2)\,\omega_2\,\omega_3, \quad \text{etc., cyclically.}$$

3.12 EQUATIONS OF MOTION: INTEGRATION AND CONSERVATION THEOREMS

Integrals of the Equations of Motion

Let us consider, without much loss in generality and understanding, a, say, potential and holonomic system S with Lagrangean equations of motion

$$E_k(L) \equiv (\partial L/\partial\dot{q}_k)^{\cdot} - \partial L/\partial q_k = 0 \qquad (k = 1, \ldots, n),$$

or, in extenso, since $L = L(q, \dot{q}, t)$ (and with $l = 1, \ldots, n$)

$$\sum(\partial^2 L/\partial\dot{q}_k\partial\dot{q}_l)\ddot{q}_l + \sum(\partial^2 L/\partial\dot{q}_k\partial q_l)\dot{q}_l + \partial^2 L/\partial\dot{q}_k\partial t - \partial L/\partial q_k = 0$$

or (recalling §3.10), with some easily understood ad hoc notations,

$$\sum a_{kl}(q,t)\ddot{q}_l + \sum\sum b_{klm}(q,t)\dot{q}_l\dot{q}_m + \sum c_{kl}(q,t)\dot{q}_l + d_k(q,\dot{q},t) = 0$$

This is a system of n *second*-order equations in the qs, *linear* in the
lently, a system of *total-order* $2n$ (= sum of orders of highest derivatives of dependent variables). As the theory of differential equations teaches, its general analytical solution (if and when known) will contain (at most) $2n$ *arbitrary constants of integration* $c \equiv (c_1, \ldots, c_{2n})$:

$$q_k = q_k(t, c) = \textit{general solution of } (3.12.1\text{-}2a).$$

Next, and for the purposes of our discussion below, it is helpful to introduce the following transformation of variables $q, \dot{q} \to (x_1, \ldots, x_{2n}) \equiv x$:

$$q_1 = x_1, \ldots, q_n = x_n; \qquad \dot{q}_1 = x_{n+1}, \ldots, \dot{q}_n = x_{2n}.$$

In terms of them, eqs. (3.12.1, 2), or, equivalently [assuming nonsingular Hessian $|\partial^2 L/\partial\dot{q}_k\,\partial\dot{q}_l|$],

$\ddot{q}_l = \cdots = Q_l(q, \dot{q}, t)$ ("forces", known functions of their arguments — *normal*

(and, generally, any given differential system of total order $2n$) reduce to the 2
system of equations

$$\dot{x}_1 = x_{n+1} \equiv X_1(x,t), \ldots, \qquad \dot{x}_n = x_{2n} \equiv X_n(x,t);$$

$$\dot{x}_{n+1} = Q_1(x,t) \equiv X_{n+1}(x,t), \ldots, \qquad \dot{x}_{2n} = Q_n(x,t) \equiv X_{2n}(x,t);$$

or, compactly,

$$dx_*/dt = X_*(x,t) \qquad (* = 1, \ldots, 2n).$$

[Alternatively, in terms of the Lagrangean *momenta*, conjugate to the q_k,

$$\partial T/\partial\dot{q}_k = \partial L/\partial\dot{q}_k \equiv p_k = p_k(q, \dot{q}, t),$$

(assuming $\partial V/\partial\dot{q}_k = 0$), the n *second-order* Lagrangean equations (3.12.1-2a) can be rewritten as the $2n$ *first-order* equations

$$p_k = \partial L/\partial\dot{q}_k \equiv p_k(q, \dot{q}, t)$$

and

$$\dot{p}_k = \partial L/\partial q_k = \dot{p}_k(q, \dot{q}, t) = P_k(q, p, t), \tag{3.12.4e}$$

where, in the last step, we inverted (3.12.4d) to obtain $\dot{q}_k = \dot{q}_k(q, p, t)$ (see §8.2 on *Hamiltonian/canonical* equations of motion). Such first-order formulations are quite useful in both theoretical and numerical situations.]

Some Mathematical Background

[See also, e.g. Destouches (1948, ch. III: pp. 106–121; extensive classical discussion) and Nielsen (1935, pp. 216–232; outstanding elementary treatment).]

Consider a $(2n)$th $\equiv (*)$th order differential system, in any of the following equivalent forms:

$$F_*(x, dx/dt, t) = 0 \qquad [\textit{implicit} \text{ form}], \tag{3.12.5a}$$

$$dx_*/dt = X_*(x_\bullet, t) \quad [\textit{explicit/typical} \text{ form } (*, \bullet = 1, \ldots, 2n)], \quad (3.12.4c) = (3.12.5b)$$

$$dx_1/X_1 = dx_2/X_2 = \cdots = dx_{2n}/X_{2n} = dt, \tag{3.12.5c}$$

where the F_*, X_* are known functions of their arguments. A *solution* of (3.12.5a, b, c), in an open time interval of interest, $\tau \equiv (t_0, t_1)$, is the set of $2n$ (continuously differentiable) functions $x_*(t)$ that satisfies them. Next, we recall from the theory of ordinary differential equations, the following fundamental

THEOREM OF INITIAL CONDITIONS (UNIQUENESS OF SOLUTIONS, LIPSCHITZ CONDITIONS)

If $x(t_{\text{initial}} \equiv t_o) = \textit{given}$, and if, at every point of τ, all X_* as well as $\partial X_*/\partial x_\bullet$ are continuous, then the system (3.12.5a, b, c) has a *unique* solution in τ. [These conditions are restrictive, so, in practice, we frequently find cases where they do not hold. If the existence conditions hold, but not those of uniqueness, several motions are possible (indeterminate motion). For example, the nonlinear system [plus initial conditions (IC)] $\ddot{q} = 6q^{1/3}$, $q(0)$, $\dot{q}(0) = 0$ (e.g. rectilinear motion of a particle), is analytic everywhere except in the neighborhood of $q = 0$ (a singular point) — the uniqueness conditions are not satisfied there. The problem yields the following *three* (3) motions: $q(t) = 0$ (equilibrium), $q(t) = -t^3$ and $q(t) = +t^3$ — the IC do *not* determine the ultimate motion uniquely. If not even the *existence* conditions hold, worse things may happen.]

In *mechanics* terms, the theorem states that: If the n positions q and n velocities dq/dt are specified/prescribed at an "initial" instant t_o, and if the n forces Q satisfy the above Lipschitz conditions in τ, the subsequent system motion during that time interval is determined uniquely.

The first step in the integration of the system (3.12.5a, b, c) is the search for *integrals*.

DEFINITION

We call *first integral* of the system (3.12.5a, b, c) any function $f(x, t)$ that, for every one of its solutions $x_* = x_*(t)$, remains constant, for arbitrary t: $f(x, t) = \textit{constant} \equiv c$, where the constant may change when the particular solution (i.e. motion) changes; that is, a first integral is, in general, a function depending on time both explicitly and implicitly, through the x's, that stays constant on account of the equations of motion, independently of initial conditions; i.e., it is *an integral that depends on only one constant*, a constant whose value depends (or, is determined by) the *initial conditions*, that is, on the particular system solution/motion and stays the same throughout it. [A system integral that depends on $p(\leqslant 2n)$ distinct such constants leads to p first integrals — see (3.12.5f) ff.]

In mechanics terms, a numerical/scalar function $f(q, \dot{q}, t)$ is called first integral of (the equations of) motion of a system S, e.g. eqs (3.12.1, 2, 2a, 4a), if and only if it remains constant for every solution of those equations:

$$f(q, \dot{q}, t) = f[q(t), \dot{q}(t), t] = \textit{constant during S's motion}$$
$$\textit{(depends on initial conditions of that particular motion)}, \tag{3.12.5d}$$
$$\Rightarrow df/dt = \sum (\partial f/\partial x_*)(dx_*/dt) + \partial f/\partial t = \sum (\partial f/\partial x_*)X_* + \partial f/\partial t = 0,$$
identically, for any $q(t)$, $\dot{q}(t)$, and t satisfying S's equations of motion. (3.12.5e)

Hence, every such integral lowers the degree of the differential system by 1; and therein lies their principal usefulness to mechanics. [Also, since first integrals are defined relative to the equations of motion, possible *constraint* equations may also be viewed as first integrals of them (e.g. §6.1)]. In particular, we may show the following

THEOREM

Under broad analytical conditions, we can replace one, or more, of S's equations of motion, say of (3.12.4a), with an equal number of first integrals of them, i.e. with (3.12.5d, 6a)-like equations (e.g. an energy integral). [However, for certain values of the initial conditions, such a replacement may introduce "parasitic" (i.e. extraneous to our problem) solutions.]

Classification of first integrals: (i) *First integrals explicitly independent of time*; that is, $\partial f/\partial t = 0 \Rightarrow f(x) = f(q, dq/dt) = \textit{constant}$. (ii) *First integrals depending explicitly on time*; that is, $f(x, t) = f(q, dq/dt, t) = \textit{constant}$. [In certain areas of physics (e.g., statistical mechanics), other first integral classifications are important.]

Distinct (*or Independent*) *first integrals*. If $f = a$ (constant) is a first integral, so is $F(f) = b$ (another constant), where $F(f)$ is an arbitrary function of f. More generally, let $f_1 = a_1, \ldots, f_p = a_p$ be $p(\leqslant 2n)$ distinct first integrals, that is, none of them is expressible as a(-n algebraic) function of the other $p - 1$, i.e. as

$$f_i = \phi(f_1, \ldots, f_{i-1}, f_{i+1}, \ldots, f_p), \tag{3.12.5f}$$

then $F(f_1, \ldots, f_p) = b$ is also an integral ($\Rightarrow \dot{F} = \sum (\partial F/\partial f_\alpha)\dot{f}_\alpha = 0$, $\alpha = 1, \ldots, p$), though not a distinct one.

Now, it is shown in the theory of ordinary differential equations that *the complete, or general, analytical solution* of the $(2n)$th order system (3.12.4a, c–d, 5a–c) contains, or depends on, *at most* $2n$ *independent, or distinct, constants of integration*; and, conversely, a $2n$-order system is considered completely integrated (i.e. its motion completely known) if $2n$ distinct first integrals of it are known (non-distinct integrals do *not* lower, further, the system order, hence they are of no interest to mechanics). One way of expressing such a solution is in the form of $2n$ distinct *first integrals*:

$$f_*(x, t) = c_* = \textit{arbitrary constants (of integration)} \qquad (* = 1, \ldots 2n). \tag{3.12.5g}$$

A second way is obtained, in principle by solving (3.12.5g) for the x:

$$x_* = \phi_*(t; c_1, \ldots, c_{2n}) \equiv \phi_*(t; c), \tag{3.12.5h}$$

or, simply,

$$x_* = x_*(t; c_1, \ldots, c_{2n}) \equiv x_*(t; c). \tag{3.12.5i}$$

The constants are usually evaluated by applying the *initial conditions* to (3.12.5g) or (3.12.5h, i). Indeed, applying them to the latter yields $x_{*o} = \phi_*(t_o; c_1, \ldots, c_{2n})$, from which, solving for the c_*, we get

$$c_* = c_*(t_o; x_{1o}, \ldots, x_{2n,o}), \tag{3.12.5j}$$

and, inserting these expressions back into (3.12.5h), we obtain the particular solution

$$x_* = \phi_*(t; t_o, x_{1o}, \ldots, x_{2n,o}) \equiv \phi_*(t; t_o, x_o). \tag{3.12.5k}$$

Finally, evaluating this for $t = t_o$, or swapping the roles of t, t_o and x, x_o, readily leads to

$$x_{*o} = \phi_*(t_o, t; x_1, \ldots, x_{2n}) \equiv \phi_*(t_o, t; x) \qquad [\text{solution of (3.12.5k) for the } x_o]; \tag{3.12.5l}$$

that is, the (3.12.5k) are $2n$ first integrals, whose values are the initial values of the dependent variables.

Back to Mechanics

In terms of the variables of Lagrangean mechanics q and $\dot{q}$, eq's (3.12.5g) translate to the $2n$ independent *first integrals* of the equations of motion, or simply *constants of the motion* (each one depending on only one constant):

$$f_*(q, \dot{q}, t) = c_* \qquad (* = 1, \ldots, 2n), \tag{3.12.6a}$$

$$[\text{or, in Hamiltonian variables(ch. 8)}, \ \psi_*(q, p, t) = c_*] \tag{3.12.6b}$$

which is a system of total order $2n$.

The *energy integral*, whenever it exists [usually, not an explicit function of time, and not always equal to the sum of the system's kinetic and potential energies ($\equiv$ total energy of system)] is one such (first) integral (details in §3.9). Similarly, (3.12.5h, i) translate to the customary mechanics form (*motion*):

$$q_k = q_k(t; c_1, \ldots, c_{2n}) \equiv q_k(t; c), \qquad \dot{q}_k = \dot{q}_k(t; c_1, \ldots, c_{2n}) \equiv \dot{q}_k(t; c). \tag{3.12.6c}$$

$$[\text{compatible with } \dot{q}_k = \partial q_k(t; c)/\partial t = \cdots]$$

Each choice of constants c constitutes a different $q_k \leftrightarrow t$ relation and, therefore, a *particular solution/motion*. And, conversely, inverting (3.12.6c) [assuming that their Jacobian $|\partial(q, \dot{q})/\partial c| \neq 0$], we obtain the earlier $2n$ distinct integrals

$$c_* = f_*(q, \dot{q}, t) \qquad (* = 1, \ldots, 2n). \tag{3.12.6d}$$

Each c_* is a constant of the motion [and, therefore, along the latter each $f_*(q, \dot{q}, t)$ is conserved] but its value depends on the particular $q_k \leftrightarrow t$; that is, on the particular motion. Further, due to (3.12.6c, d), an integral of motion $F = F(q, \dot{q}, t) = constant$ becomes

$$F(q, \dot{q}, t) = F[q(t, c), \dot{q}(t, c), t] \equiv F'(t, c). \tag{3.12.6e}$$

But $0 = \dot{F} = dF'/dt = \partial F/\partial t$, and therefore F' *does not depend explicitly on time*; that is, finally,

$$F(q, \dot{q}, t) = F'(c) = \textit{function of the independent } c\text{'s}; \tag{3.12.6f}$$

and every other constant of the motion depends on them.

Example: The second order differential equation/system $\ddot{q} + q = 0$ (linear oscillator) has the two distinct first integrals $f_1(q, \dot{q}) = q^2 + \dot{q}^2 = c_1, f_2(q, \dot{q}, t) = \tan^{-1}(q/\dot{q}) - t = c_2$, which, when solved for q, $\dot{q}$ yield $q(t; c_1, c_2) = c_1^{1/2}\sin(t + c_2)$, $\dot{q}(t; c_1, c_2) = c_1^{1/2}\cos(t + c_2)[= \partial q/\partial t]$; the $c_{1,2}$ are evaluated from the initial conditions $q(0) \equiv q_o = c_1^{1/2}\sin c_2$, $\dot{q}(0) \equiv \dot{q}_o = c_1^{1/2}\cos c_2$ (see below).

Usually, we apply (3.12.6d) for some "initial" time t_o, say $t_o = 0$, and thus express the c's for all time in terms of the initial values of the qs and $\dot{q}$s (or, in terms of the *initial state* of the system) $q_k(0) = q_{k,o}$ and $\dot{q}_k(0) = \dot{q}_{k,o}$; i.e., compactly

$$c_* = c_*(q_o, \dot{q}_o) \quad [= f_*(q_o, \dot{q}_o, 0)]. \tag{3.12.7a}$$

Then, (3.12.6c) can be rewritten, respectively, à la (3.12.5k), as

$$q_k = q_k(t; q_o, \dot{q}_o), \qquad \dot{q}_k = \dot{q}_k(t; q_o, \dot{q}_o); \tag{3.12.7b}$$

a fact that shows that the number of arbitrarily prescribable conditions (data) at our disposal is $2n$.

In sum:

- The determination of the most general motion of an n DOF (holonomic and potential) mechanical system is mathematically equivalent to the determination of the $2n$ distinct/independent integrals, or constants of motion, of its n second-order Lagrangean equations. [Clearly, the more independent integrals we know—up to the (very rarely achievable) theoretical maximum/full set $2n$—the better we understand/characterize the system's motion; hence the keen interest in finding the greatest possible number of such integrals. However, as Landau and Lifshitz (1960, p. 13) point out, not all such integrals are equally important to mechanics. The most significant ones derive from "the fundamental homogeneity and isotropy of space and time"; and the physical quantities represented by them are said to be *conserved*. Further, such integrals of motion are *additive*; that is, for systems with negligible mutual interaction of their parts (see closed/open systems, below), *their values for the whole system equal the sum of their values for its individual parts*; and therein lies their importance to mechanics; see ex. 3.12.3, below.]
- An initial state of a system — that is, a particular choice of the $2n$ q_os (positions) and $\dot{q}_o$s (velocities) — determines a particular motion; and every constant of motion is determined by that initial state, via (3.12.7a, b). [For a detailed discussion of the geometrical interpretation of the above in generalized spaces, and more, see, for example, Prange (1935, pp. 547—564).]

These fundamental results allow us to express, in principle, the solution of any dynamical problem as the following time power series around $t = 0$:

$$\begin{aligned} q_k(t) &= q_k(0) + \dot{q}_k(0)t + (1/2)\ddot{q}_k(0)t^2 + \cdots \\ &\equiv q_{k,o} + \dot{q}_{k,o}t + (1/2)\ddot{q}_{k,o}t^2 + \cdots. \end{aligned} \tag{3.12.8}$$

To calculate $\ddot{q}_k(0) \equiv \ddot{q}_{k,o}$ we evaluate (3.12.1, 2) at $t = 0$, use the given $q_{k,o}$ and $\dot{q}_{k,o}$, and then solve it for $\ddot{q}_{k,o}$. To calculate $\dddot{q}_k(0) \equiv \dddot{q}_{k,o}$ we $(\ldots)^{\cdot}$-differentiate (3.12.1, 2), evaluate it at $t = 0$, and then solve for $\dddot{q}_{k,o}$ while using $q_{k,o}$, $\dot{q}_{k,o}$, $\ddot{q}_{k,o}$ in it. Continuing this well-known process, we can determine *all* $(\ldots)^{\cdot}$-derivatives of the q_k at $t = 0$ in terms of the $2n$ q_o, $\dot{q}_o$. It can be shown that, for a large number of useful mechanics problems, the conditions of *convergence* of the series (3.12.8) are satisfied, for some time after $t = 0$, and therefore that representation is meaningful. [Also, such series are quite useful in problems of *initial motions*; see, e.g., Whittaker, 1937, pp. 45–46.]

Determinism

The preceding constitute a quantitative version of the doctrine of classical *determinism* (advanced, especially in connection with problems of *celestial* mechanics, by Laplace et al.). According to this doctrine, if we knew the present state of the universe—that is, the positions and velocities of all its particles, and the forces acting on them, and were able to solve its equations of motion (and exclude internal collisions)—then, we would be able to *predict its entire future* (*and past!*) *uniquely*. However, such *strict causality* = *determinism* is illusory for the following theoretical and practical reasons:

(i) In general, the equations of motion cannot be solved via finite combinations of the known elementary functions (see elementary vs. advanced problems below), and the errors of approximate solutions, due either to truncations of series or to iterations, do not remain small (bounded) for long time intervals.

(ii) The initial state of a system can never be known with infinite accuracy/precision. Therefore, the long-term predictions of *systems that are sensitive to such initial conditions*, due to the cumulative effect of the unavoidable errors in these latter, will be quite erroneous; for example, *chaotic* behavior of nonlinear (deterministic) systems. As McCauley puts it: "*Because* of errors that were made by the computer's roundoff/truncation algorithm, he (E. Lorenz, 1963) discovered what is now called *sensitivity with respect to small changes in initial conditions*: big changes in trajectory patterns occurred at later times owing to shifts in the last digits of the starting conditions" (1993, p. 3, last emphasis added). [The literature on chaotic, or stochastic, motion/dynamics is enormous and growing . . . regularly; we recommend Lichtenberg and Lieberman (1992), Tabor (1989).]

(iii) Clearly, our classical (i.e., nonrelativistic, nonquantum, nonprobabilistic, etc.) mathematical model neglects certain factors, or causes, that may prove quite significant in the long (and, sometimes, even short) run; for example, very *high speeds* and *electromagnetic fields* (relativity) and/or very *small spatial regions* (atomic phenomena: Heisenberg's indeterminacy principle, and Born's probabilistic/statistical interpretation of quantum mechanics).

Hence, since, even within classical mechanics, long-term predictions are practically unreliable, and depending on the system at hand and the accuracy sought, we must update our exact or approximate solutions at the end of an(y) appropriate time interval, using data obtained experimentally at that time.

Elementary versus Advanced Problems

On the basis of the principles used for their integration, we divide mechanical problems into *two* kinds: *elementary* and *advanced*; not a clear-cut and/or uniform terminology, by any means.

- *Elementary* are those problems soluble completely by *quadratures*; namely, those whose solutions are expressible either in terms of known *elementary* functions (solution in "closed form"), or as *indefinite integrals* of such functions.
- *Advanced* are those problems that *cannot* be solved by quadratures.

Unfortunately, as one might have anticipated, most mechanics problems are *not* elementary; and, whenever they are, it is always *because their Lagrangeans possess some special* (*symmetry*) *properties*. Below we summarize some of these special properties that are frequently associated with the elementary problems and account for their solvability via quadratures. This ability to predict properties of the solution(s) of a problem by examining its Lagrangean—that is, without acutally solving its equations of motion—is one of the key advantages of the Lagrangean (and Hamiltonian) method over that of Newton–Euler. [For a general treatment of the relation between Lagrangean properties and conservation theorems, see, for example, §8.13 and McCauley (1997, pp. 63–72), Saletan and Cromer (1971, chap. 3); while, for a discussion of *integrability* in Hamiltonian/canonical systems see §8.10, §8.14.]

Closed Systems

We begin with an *isolated*, or *closed*, system; that is, a finite system S consisting of a number of rigid bodies and/or particles that interact only with each other; and as such, one *without* time-varying parameters; namely, a system uninfluenced by sources outside itself. If S is also conservative, or reversible, and can be described by a Lagrangean, then the latter must have the general (inertial) form

$$L \equiv T - V = (1/2) \textstyle\int dm\, \boldsymbol{v} \cdot \boldsymbol{v} - V(\boldsymbol{r}), \tag{3.12.9}$$

where $\boldsymbol{r}/\boldsymbol{v}$ = inertial *position/velocity* of a generic particle of S. The "force function" $-V(\boldsymbol{r})$ represents the contribution of the mutual *interaction* (forces) to the Lagrangean; if the bodies/particles of S are noninteracting, then $V = 0$.

That V depends only on the $\boldsymbol{r}$'s means that a change in the position of any of the particles of S affects *instantaneously* all its other particles; otherwise, if interactions spread with *finite* velocity, then, due to the law of velocity addition among any two Galilean frames (= inertial frames in relative accelerationless translation), that velocity of propagation would be different in any two such frames. As a result, the equations of motion of these interacting particles in two inertial frames would be *different*; in clear violation of the classical principle of Galilean relativity, which requires form invariance of the equations of motion among inertial frames [recalling §1.4–1.6; see also Landau and Lifshitz (1960, p. 8)].

Now, the equations of motion of a typical particle of S are

$$(\partial L/\partial \boldsymbol{v})^{\cdot} - \partial L/\partial \boldsymbol{r} = \mathbf{0}: \quad dm(d\boldsymbol{v}/dt) = -\partial V/\partial \boldsymbol{r}. \tag{3.12.9a}$$

From the above, and since $d\boldsymbol{v}/dt \equiv d^2\boldsymbol{r}/dt^2 \equiv \boldsymbol{a}$, both L and the equations of motion remain unchanged (invariant) under a $t \to -t$ transformation; and, hence, also under $dt \to -dt$. This expresses the *reversibility* of motion of such systems, and the *isotropy* of time (i.e., identical properties in both future and past "directions"), in addition to its *homogeneity*.

In terms of (inertial) Lagrangean coordinates $q = (q_1, \ldots, q_n)$, equations (3.12.9) and (3.12.9a) assume, respectively, the system forms

$$L \equiv T - V = \sum\sum (1/2) M_{kl}(q) \dot{q}_k \dot{q}_l - V(q), \qquad (\partial L/\partial \dot{q}_k)^{\cdot} - \partial L/\partial q_k = 0. \tag{3.12.9b}$$

Open Systems

Next, let us consider a system S_1 that is *not* closed, and interacts with another system S_2 that has a *given* motion; that is, it is unaffected by its interaction with S_1. Then we say that S_1 is *open*, or that it moves in the given *external* field of S_2. If we know the Lagrangean of the combined system $S_1 + S_2 \equiv S$, L, then we can find the Lagrangean of S_1, L_1, by replacing in L the coordinates and velocities of S_2, $q_{(2)}$ and $\dot{q}_{(2)}$ by their given functions of time. In particular, if S is closed, then, since in this case [with $q_{(1)}$ and $\dot{q}_{(1)}$ = *coordinates* and *velocities* of S_1, and corresponding notations for its kinetic and potential energies]

$$L = T_{(1)}\left[q_{(1)}, \dot{q}_{(1)}\right] + T_{(2)}\left[q_{(2)}, \dot{q}_{(2)}\right] - V\left[q_{(1)}, q_{(2)}\right], \tag{3.12.10a}$$

from which (recalling ex. 3.5.13)

$$T_{(2)}\left[q_{(2)}(t), \dot{q}_{(2)}(t)\right] = \textit{given} \text{ function of time, and hence omittable from } L, \tag{3.12.10b}$$

we finally obtain

$$\begin{aligned} L_1 &= T_{(1)}\left[q_{(1)}, \dot{q}_{(1)}\right] - V\left[q_{(1)}, q_{(2)}(t)\right] \\ &\equiv T_{(1)}\left[q_{(1)}, \dot{q}_{(1)}\right] - V\left[q_{(1)}, t\right] \;\Rightarrow\; \partial L_1/\partial t = -\partial V/\partial t \neq 0. \end{aligned} \tag{3.12.10c}$$

Integrals of Closed Systems

Here, we prove that *a closed mechanical system with n positional coordinates has* $2n - 1$ *independent integrals*. Indeed, since [as the second of eqs. (3.12.9b) shows] the equations of motion for such a system do *not* contain the time explicitly, the time origin is completely arbitrary and we can take as one of the $2n$ arbitrary constants of integration of the general solution $q_k(t; c_1, \ldots, c_n)$ the *additive* time constant τ. Eliminating $t + \tau$ from the $2n$ functions $q_k = q_k(t + \tau; c_1, \ldots, c_{2n-1})$ and $\dot{q}_k = \dot{q}_k(t + \tau; c_1, \ldots, c_{2n-1})$, we can express the remaining $2n - 1$ constants $c_1, \ldots, c_{2n-1}$ in terms of the $2n$ q's and $\dot{q}$'s:

$$c_l = c_l(q, \dot{q}), \qquad (l = 1, \ldots, n - 1); \tag{3.12.11}$$

that is, our system has $2n - 1$ independent integrals, Q.E.D.

Ignorable Coordinates and Momentum Conservation

We have seen the power theorem and Jacobi–Painlevé generalized energy integral (§3.9). Let us now see some generalized, or Lagrangean, *momentum* integrals. We consider, again, a system with Lagrangean $L = L(t, q, \dot{q})$ and equations of motion

$$(\partial L/\partial \dot{q}_k)^{\cdot} - \partial L/\partial q_k = 0 \qquad (k = 1, \ldots, n). \tag{3.12.12a}$$

If some of the system *coordinates*, say $q_1, \ldots, q_M$ $(M \leq n)$, do not appear explicitly in L (although the corresponding velocities $\dot{q}_1, \ldots, \dot{q}_M$ do) — that is, if

$$L = L(t; q_{M+1}, \ldots, q_n; \dot{q}_1, \ldots, \dot{q}_n), \tag{3.12.12b}$$

then, as (3.12.12a) immediately show, the corresponding (holonomic) Lagrangean *momenta* $p_i \equiv \partial L/\partial \dot{q}_i$ $(i = 1, \ldots, M)$ are conserved:

$$(\partial L/\partial \dot{q}_i)^{\cdot} = 0 \;\Rightarrow\; \partial L/\partial \dot{q}_i \equiv p_i = \textit{constant} \equiv c_i; \tag{3.12.12c}$$

where the constants of integration c_i are to be evaluated from the initial conditions. Coordinates like $q_1, \ldots, q_M$ are called *ignorable*, or *cyclic* (after Thomson and Tait, Helmholtz, Routh et al.—see §8.3, 4); whereas the rest of the q's that do appear in L, and hence satisfy eqs. (3.12.12a) but with $k = M + 1, \ldots, n$, are called *palpable*. The presence (or, rather, absence!) of ignorable coordinates is one of the most common reasons for the solubility of problems by quadratures. We show in §8.3, 4 how to utilize the M "cyclic integrals" (3.12.12c) to reduce the number of Lagrangean equations (3.12.12a) by the number of ignorable coordinates present in L (method of "ignoration of coordinates" of Routh and Helmholtz).

Example 3.12.1 Consider a system with Lagrangean

$$L = (m/2)\left[(\dot{r})^2 + r^2(\dot{\phi})^2\right] - V(r), \tag{a}$$

[particle of mass m in plane motion ($r, \phi =$ polar coordinates) in potential field $V = V(r)$]. Here, clearly, $\partial L/\partial\phi = 0$; that is, ϕ is ignorable. Therefore, the system possesses the cyclic integral

$$p_\phi \equiv \partial L/\partial\dot{\phi} = mr^2\dot{\phi} = constant, \tag{b}$$

which expresses the conservation of the component of the angular momentum of the particle, about the origin, along an axis perpendicular to the plane of the motion.

Example 3.12.2 *First-Order Form of the Routh–Voss Equations.* Let us find the first-order forms of a system subject to the m Pfaffian constraints

$$\omega_D \equiv \sum a_{Dk}\,\dot{q}_k + a_D = 0 \qquad [k = 1, \dots, n;\ D = 1, \dots, m\ (<n)], \tag{a}$$

and, hence, having the Routh–Voss equations of motion

$$E_k(L) = Q_k + \sum \lambda_D\, a_{Dk} \qquad \left[Q_k = nonpotential \text{ part of } (\dots)\,\delta q_k \text{ in } \delta' W\right]. \tag{b}$$

With the variable change (3.12.4)

$$q_1 = x_1, \dots, q_n = x_n; \qquad \dot{q}_1 = x_{n+1} = \dot{x}_1, \dots, \dot{q}_n = x_{2n} = \dot{x}_n\,, \tag{c}$$

L becomes $L(t; x_1, \dots, x_n; x_{n+1}, \dots, x_{2n})$ and therefore the m first-order equations (a) and n second-order equations (b) in the q's transform, respectively, to the m *finite* equations

$$\sum a_{Dk} x_{n+k} + a_D = 0, \tag{d}$$

and the n *first-order* equations

$$(\partial L/\partial x_{n+k})^{\cdot} - \partial L/\partial x_k = Q_k + \sum \lambda_D\, a_{Dk}\,, \tag{e}$$

since $\partial L/\partial x_{n+k} = linear$ in the x_{n+k} ($k = 1, \dots, n$). Equations (d, e) and the second half of (c) constitute a system of $2n + m$ first-order equations for the $2n$ x's and m λ_D's.

Example 3.12.3 *Integrals of a Closed System.* Let us find the integrals of a closed system with (inertial) Lagrangean

$$L = (1/2)\mathsf{S}\, dm\, \boldsymbol{v}\cdot\boldsymbol{v} - V(\boldsymbol{r}) = T(q, \dot{q}) - V(q); \tag{a}$$

or, of a closed system in a *constant* (time-independent) external field.

(i) *Energy integral*. Here, $\partial L/\partial t = 0$, $Q_{k,\text{nonpotential}} = 0$, and $a_D = 0$. Hence, the holonomic power equation (3.9.11d ff.) immediately yields

$$h \equiv \sum (\partial L/\partial \dot{q}_k)\dot{q}_k - L = (2T) - (T - V) = T(q, \dot{q}) + V(q) \equiv E = \textit{constant}. \quad \text{(b)}$$

The condition $\partial L/\partial t = 0$ is a consequence of the *homogeneity of time* for closed systems. The energy integral (b) is *additive*: the energy of a closed system consisting of several closed subsystems *with negligible mutual interaction* equals the sum of the individual subenergies of these subsystems. This also results from the linearity of $h = E$ in L in (b).

[Whittaker (in 1900) has shown how to use the energy equation (b) to reduce a closed *n-DOF* system into another with $(n-1)$ *DOF* (and a quadrature); see, for example, Whittaker (1937, pp. 64–67); also Butenin (1971, pp. 103–110), MacMillan (1936, pp. 320–322).]

(ii) *Linear momentum integral*. The *homogeneity of space* for such systems leads to the requirement that the first-order change of their Lagrangeans under $\boldsymbol{r} \to \boldsymbol{r} + \Delta\boldsymbol{r}$, where $\Delta\boldsymbol{r}$ = arbitrary elementary *rigid translation*, i.e. common to all system particles, and $\boldsymbol{v} \to \boldsymbol{v}$ (i.e., no velocity change), should vanish.

Since, here, $L = L(\boldsymbol{r}, \boldsymbol{v})$, the condition $\Delta L = 0$, under such changes, translates to

$$\Delta L = \mathsf{S}\, (\partial L/\partial \boldsymbol{r}) \cdot \Delta\boldsymbol{r} = \Delta\boldsymbol{r} \cdot \mathsf{S}\, (\partial L/\partial \boldsymbol{r}) = 0 \;\Rightarrow\; \partial L/\partial \boldsymbol{r} = \boldsymbol{0}. \quad \text{(c)}$$

As a result, Lagrange's equations reduce to

$$\mathsf{S}\, d/dt(\partial L/\partial \boldsymbol{v}) = d/dt\Big(\mathsf{S}\, \partial L/\partial \boldsymbol{v}\Big) = \boldsymbol{0}, \quad \text{(d)}$$

or

$$\boldsymbol{p} \equiv \mathsf{S}\, \partial L/\partial \boldsymbol{v} = \mathsf{S}\, dm\, \boldsymbol{v} \equiv \mathsf{S}\, d\boldsymbol{p}: \;\textit{system linear momentum} = \textit{constant}. \quad \text{(e)}$$

Clearly, $\boldsymbol{p}$ is additive even for nonnegligible interactions of the constituent subsystems.

Next, the linear momentum $\boldsymbol{p}$/(total) energy E/Lagrangean L of a system in an inertial frame F are related to those in another frame F', translating relative to F with velocity $\boldsymbol{v}_o = d\boldsymbol{r}_o/dt$ (fig. 3.29), $\boldsymbol{p}'/E'/L'$, respectively, as follows: since $\boldsymbol{v} = \boldsymbol{v}_o + \boldsymbol{v}'$ ($\boldsymbol{v}'$ = particle velocities relative to F'), we find, successively,

$$\text{(a)} \qquad \boldsymbol{p} = \mathsf{S}\, dm\, \boldsymbol{v} = \mathsf{S}\, dm(\boldsymbol{v}_o + \boldsymbol{v}') = \boldsymbol{v}_o\Big(\mathsf{S}\, dm\Big) + \mathsf{S}\, dm\, \boldsymbol{v}' \equiv \boldsymbol{p}' + m\,\boldsymbol{v}_o. \quad \text{(f)}$$

If $\boldsymbol{p}' = \boldsymbol{0}$ (i.e., if the system is *at rest* relative to F'), then (f) yields the *velocity of the system as a whole* relative to F, or *velocity of its mass center* G relative to F:

$$\boldsymbol{v}_o = \boldsymbol{p}/m = \mathsf{S}\, dm\, \boldsymbol{v} \Big/ \mathsf{S}\, dm$$
$$\Rightarrow \mathsf{S}\, dm\, \boldsymbol{r} - \boldsymbol{p}t = m\,\boldsymbol{r}_{Go} \;\Rightarrow\; \boldsymbol{r}_G = \boldsymbol{r}_{Go} + (\boldsymbol{p}/m)t; \quad \text{(g)}$$

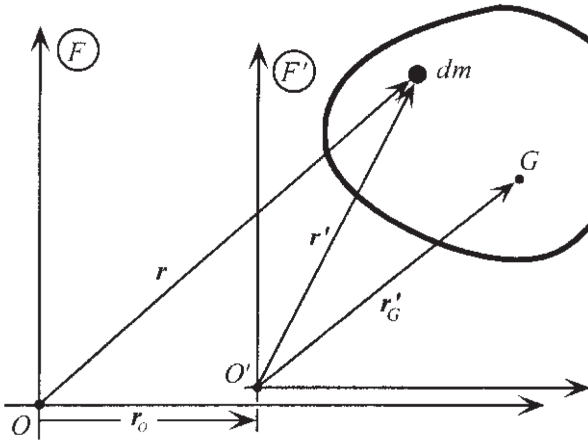

Figure 3.29 Frames F and F' in mutual translation.

that is, the center of mass of a closed system *moves uniformly in a straight line*.

(b)

$$\begin{aligned} E &\equiv (1/2)\mathsf{S}\, dm\, \boldsymbol{v}\cdot\boldsymbol{v} + V \\ &= (1/2)\mathsf{S}\, dm\big[(\boldsymbol{v}_o + \boldsymbol{v}')\cdot(\boldsymbol{v}_o + \boldsymbol{v}')\big] + V \\ &= E' + \boldsymbol{p}'\cdot\boldsymbol{v}_o + (1/2)m\, {v_o}^2, \end{aligned} \tag{h1}$$

where

$$E' \equiv (1/2)\mathsf{S}\, dm\, \boldsymbol{v}'\cdot\boldsymbol{v}' + V. \tag{h2}$$

If $\boldsymbol{p}' = \boldsymbol{0}$, as earlier (i.e., if G is at rest in F'), then (h1) and (h2) reduce, respectively, to

$$E = (1/2)m\, {v_o}^2 + E_{\text{internal}}, \tag{h3}$$

and

$$\begin{aligned} E' &= E_{\text{internal}} = \textit{internal} \text{ energy of system} \\ &= \text{kinetic energy of motion of system particles } \textit{relative} \text{ to mass center,} \\ &\qquad \text{plus potential energy of their mutual } \textit{interactions} \\ &= \text{energy of system when at rest as a whole.} \end{aligned} \tag{h4}$$

(c)

$$\begin{aligned} L &\equiv (1/2)\mathsf{S}\, dm\, \boldsymbol{v}\cdot\boldsymbol{v} - V \\ &= (1/2)\mathsf{S}\, dm\big[(\boldsymbol{v}_o + \boldsymbol{v}')\cdot(\boldsymbol{v}_o + \boldsymbol{v}')\big] - V \\ &= L' + \boldsymbol{p}'\cdot\boldsymbol{v}_o + (1/2)m\, {v_o}^2, \end{aligned} \tag{i1}$$

where

$$L' \equiv T' - V = (1/2)\mathsf{S}\, dm\, \boldsymbol{v}'\cdot\boldsymbol{v}' - V. \tag{i2}$$

Finally, integrating the above from an "initial" time up to a generic one, t, we obtain (to within inessential constants) the law of transformation of the *Hamiltonian action* of the system (chaps. 7 and 8) between the frames $F(A_H)$ and $F'(A_{H'})$:

$$A_H \equiv \int L\,dt = \cdots = A_{H'} + m\,\boldsymbol{v}_o \cdot \boldsymbol{r}_{G'} + (1/2)m\,v_o{}^2 t, \tag{i3}$$

where

$$A_{H'} \equiv \int L'\,dt, \quad \boldsymbol{r}_{G'} = \textit{position vector of } G \textit{ in } F'. \tag{i4}$$

(iii) *Angular momentum integral.* The *isotropy of space* for such systems leads to the requirement that the first-order change of their Lagrangeans under

$$\boldsymbol{r} \to \boldsymbol{r} + \varDelta\boldsymbol{r} = \boldsymbol{r} + \varDelta\boldsymbol{\theta} \times \boldsymbol{r}, \qquad \boldsymbol{v} \to \boldsymbol{v} + \varDelta\boldsymbol{v} = \boldsymbol{v} + \varDelta\boldsymbol{\theta} \times \boldsymbol{v}, \tag{j1, 2}$$

where $\varDelta\boldsymbol{\theta}$ = arbitrary *elementary rigid rotation* (i.e. common to all system particles), should vanish.

Since, by Lagrange's equations $\partial L/\partial\boldsymbol{r} = d/dt(\partial L/\partial\boldsymbol{v}) = d/dt(d\boldsymbol{p})$, the condition $\varDelta L = 0$ under (j1, 2), yields, successively,

$$\begin{aligned}\varDelta L &= \mathsf{S}\,[(\partial L/\partial\boldsymbol{r})\cdot\varDelta\boldsymbol{r} + (\partial L/\partial\boldsymbol{v})\cdot\varDelta\boldsymbol{v}] \\ &= \mathsf{S}\,[(d\boldsymbol{p})^{\cdot}\cdot(\varDelta\boldsymbol{\theta}\times\boldsymbol{r}) + d\boldsymbol{p}\cdot(\varDelta\boldsymbol{\theta}\times\boldsymbol{v})] \\ &= \varDelta\boldsymbol{\theta}\cdot\mathsf{S}\,[\boldsymbol{r}\times(d\boldsymbol{p})^{\cdot} + \boldsymbol{v}\times d\boldsymbol{p}] \\ &= \varDelta\boldsymbol{\theta}\cdot\left(\mathsf{S}\,\boldsymbol{r}\times d\boldsymbol{p}\right)^{\cdot} = 0,\end{aligned} \tag{j3}$$

from which, since $\varDelta\boldsymbol{\theta}$ is arbitrary, we obtain the principle of *conservation of angular momentum*

$$\begin{aligned}\boldsymbol{H}_O &\equiv \mathsf{S}\,\boldsymbol{r}\times d\boldsymbol{p} \equiv \mathsf{S}\,\boldsymbol{r}\times(dm\,\boldsymbol{v}): \\ &\qquad (\textit{inertial})\ \textit{absolute angular momentum}\ (\textit{or moment of momentum})\ \textit{about an} \\ &\qquad F\textit{-fixed point } O \\ &= \textit{constant}.\end{aligned} \tag{j4}$$

Clearly, $\boldsymbol{H}_O$, like $\boldsymbol{p}$, is additive even for nonnegligible interactions.

Thus, a closed system has *ten* additive (scalar) integrals:

- Homogeneity of *time*: conservation of *energy* (one),
- Homogeneity of *space*: conservation of *linear* momentum (three),
- Center of mass moves with constant velocity (three), and
- Isotropy of *space*: conservation of *angular* momentum (three).

Finally, let us relate the absolute angular momenta of the system in the two earlier frames $F(\boldsymbol{H}_O)$ and $F'(\boldsymbol{H}_{O'})$. With $\boldsymbol{r}_o$ = position of origin O' of F' relative to origin O of F, and $\boldsymbol{r}'$ = position of typical system particle relative to O', we have

$$\begin{aligned}\boldsymbol{H}_O &\equiv \mathsf{S}\,\boldsymbol{r}\times(dm\,\boldsymbol{v}) = \mathsf{S}\left[(\boldsymbol{r}_o + \boldsymbol{r}')\times dm(\boldsymbol{v}_o + \boldsymbol{v}')\right] \\ &= \boldsymbol{r}_o\times(m\boldsymbol{v}_o) + \boldsymbol{r}_o\times(m\boldsymbol{v}'_G) + m\boldsymbol{r}'_G\times\boldsymbol{v}_o + \boldsymbol{H}_{O'},\end{aligned} \tag{j5}$$

where

$$\boldsymbol{H}_{O'} \equiv \mathbf{S}\, \boldsymbol{r}' \times (dm\, \boldsymbol{v}') = \textit{absolute angular momentum about } O', \tag{j6}$$

and

$$\boldsymbol{r}'_G\ (\boldsymbol{v}'_G) = \textit{position (velocity) of system mass center, } G, \textit{ relative to } O'. \tag{j7}$$

In particular, if the origins of F and F' instantaneously coincide ($\boldsymbol{r}_o = \mathbf{0} \Rightarrow \boldsymbol{r}'_G = \boldsymbol{r}_G$), and the system is at rest in F' as a whole ($\boldsymbol{v}_o = \boldsymbol{v}_G \ \Rightarrow\ m\boldsymbol{v}_o = m\boldsymbol{v}_G = \boldsymbol{p}$), then (j5, 6) reduce, respectively, to

$$\boldsymbol{H}_O = \boldsymbol{H}_{O,\text{intrinsic}} + \boldsymbol{r}_G \times \boldsymbol{p}, \tag{j8}$$

$$\boldsymbol{H}_{O'} = \boldsymbol{H}_{O,\text{intrinsic}} \equiv \mathbf{S}\, \boldsymbol{r} \times (dm\, \boldsymbol{v}'):$$

$$\textit{intrinsic angular momentum of system in } F' \textit{about } O', \tag{j9}$$

$$\boldsymbol{r}_G \times \boldsymbol{p} = \textit{angular momentum of system due to its motion as a whole.} \tag{j10}$$

For additional special cases see, for example, Landau and Lifshitz (1960, pp. 20–22); also Whittaker (1937, pp. 59–62), and our ex. 8.13.1.

Example 3.12.4 *Separable Systems of Liouville, Stäckel et al.* (see also §8.10). As eqs. (3.12.1, 2) readily show, Lagrange's equations are *coupled* in the q's; that is, in general, the (k)th such equation ($1 \le k \le n$) contains q_k, $\dot{q}_k$, $\ddot{q}_k$, and all the other q's and $\dot{q}$'s. Below we examine some special systems in which *each of their equations of motion contains only one such variable* and its $(\ldots)^{\cdot}$-derivatives. Such *uncoupled*, or *separable*, systems can be solved by quadratures.

(i) Let us consider a system completely describable by

$$2T = v_1(q_1)(\dot{q}_1)^2 + \cdots + v_n(q_n)(\dot{q}_n)^2, \tag{a1}$$

$$V = w_1(q_1) + \cdots + w_n(q_n), \tag{a2}$$

where each $v_k(\ldots)$ (> 0, assumed) and $w_k(\ldots)$ is an arbitrary function of q_k only. Its Lagrangean equations [with $(\ldots)' \equiv d(\ldots)/dq_k$; $k = 1, \ldots, n$]

$$d[v_k(q_k)\dot{q}_k]/dt - (1/2)v_k{}'(q_k)(\dot{q}_k)^2 = -w_k{}'(q_k),$$

or

$$v_k(q_k)\ddot{q}_k + (1/2)v_k{}'(q_k)(\dot{q}_k)^2 = -w_k{}'(q_k), \tag{b}$$

are clearly *uncoupled*. Integrating (b) once, we readily obtain the energy integrals

$$(1/2)v_k(q_k)(\dot{q}_k)^2 + w_k(q_k) = c_k \qquad (c_k\textit{: constants of integration}), \tag{c}$$

and integrating this once more, since q_k and t are separable, we finally obtain the quadrature

$$t = \int \{v_k(q_k)/[2c_k - 2w_k(q_k)]\}^{1/2}\, dq_k + \beta_k \qquad (\beta_k\textit{: new integration constants}). \tag{d}$$

(ii) Let us consider the *Liouville* systems (1849)

$$2T = u\,[v_1(q_1)(\dot{q}_1)^2 + \cdots + v_n(q_n)(\dot{q}_n)^2], \tag{e1}$$

$$V = [w_1(q_1) + \cdots + w_n(q_n)]/u, \tag{e2}$$

where $u \equiv u_1(q_1) + \cdots + u_n(q_n)$ (> 0). Below we show that systems that are, or can be put, in this form can be solved by quadratures, like (d).

Indeed, with the help of the (assumed invertible) transformation of variables $q_k \to x_k$:

$$x_k = \int [v_k(q_k)]^{1/2}\, dq_k \;\Rightarrow\; dx_k = [v_k(q_k)]^{1/2}\, dq_k\,, \tag{f}$$

we can reduce T (to within u) to a sum of squares in the new velocities:

$$2T = u\,[(\dot{x}_1)^2 + \cdots + (\dot{x}_n)^2], \tag{g1}$$

$$u \equiv u_1[q_1(x_1)] + \cdots + u_n[q_n(x_n)] = u_1(x_1) + \cdots + u_n(x_n); \tag{g2}$$

similarly V, (e2), transforms to

$$V = \{w_1[q_1(x_1)] + \cdots + w_n[q_n(x_n)]\}/u \equiv [w_1(x_1) + \cdots + w_n(x_n)]/u. \tag{g3}$$

Hence, *renaming the* x's *as* q's, we can rewrite (g1, 3) as

$$2T = u\,[(\dot{q}_1)^2 + \cdots + (\dot{q}_n)^2], \tag{h1}$$

$$V = [w_1(q_1) + \cdots + w_n(q_n)]/u. \tag{h2}$$

Now, the typical Lagrangean equation of the above system is

$$(u\,\dot{q}_k)^{\cdot} - (1/2)(\partial u/\partial q_k)[(\dot{q}_1)^2 + \cdots + (\dot{q}_n)^2] = -\partial V/\partial q_k\,. \tag{i1}$$

To find the corresponding energy equation, we multiply (i1) by $2u\,\dot{q}_k$, and notice that

$$\begin{aligned}[u^2(\dot{q}_k)^2]^{\cdot} = 2u\,\dot{u}\,(\dot{q}_k)^2 + u^2(2\dot{q}_k\,\ddot{q}_k) &= 2u\,\dot{q}_k(\dot{u}\,\dot{q}_k + u\,\ddot{q}_k)\\ &= 2u\,\dot{q}_k(u\,\dot{q}_k)^{\cdot}.\end{aligned}$$

The result is

$$[u^2(\dot{q}_k)^2]^{\cdot} - u\,\dot{q}_k(\partial u/\partial q_k)[(\dot{q}_1)^2 + \cdots + (\dot{q}_n)^2] = -2u\,\dot{q}_k(\partial V/\partial q_k). \tag{i2}$$

But from the energy integral (of this conservative system), we have

$$T + V \equiv E = h = constant \;\Rightarrow\; u[(\dot{q}_1)^2 + \cdots + (\dot{q}_n)^2] = 2(h - V), \tag{j1}$$

and so (i2) can be rewritten, successively, as

$$\begin{aligned}[u^2(\dot{q}_k)^2]^{\cdot} &= 2(h - V)\dot{q}_k(\partial u/\partial q_k) - 2u\,\dot{q}_k(\partial V/\partial q_k)\\ &= 2\dot{q}_k\{\partial/\partial q_k[u(h - V)]\}\\ &= 2\dot{q}_k\big\{\partial/\partial q_k\big(hu - [w_1(q_1) + \cdots + w_n(q_n)]\big)\big\}\\ &= 2\dot{q}_k\{d/dq_k[h\,u_k(q_k) - w_k(q_k)]\}\\ &= 2[h\,u_k(q_k) - w_k(q_k)]^{\cdot}.\end{aligned} \tag{j2}$$

Integrating (j2), we immediately obtain

$$(1/2)u^2(\dot{q}_k)^2 = h\,u_k(q_k) - w_k(q_k) + \gamma_k \ (\gamma_k\text{: } \textit{integration constants}). \tag{j3}$$

But the n γ_k are *not* independent: summing the n integrals (j3) over all k, and then dividing by u, we obtain

$$\begin{aligned}(1/2)u\,[(\dot{q}_1)^2 + \cdots + (\dot{q}_n)^2] + [w_1(q_1) + \cdots + w_n(q_n)]\big/u \\ = h + (\gamma_1 + \cdots + \gamma_n)/u,\end{aligned}$$

and comparing this with the energy equation (j1), we easily conclude that

$$\gamma_1 + \cdots + \gamma_n = 0. \tag{j4}$$

Hence, the first integration of our system, (j3), has produced n constants, say $\gamma_1, \ldots, \gamma_{n-1}, h$; *not* $n+1$.

Finally, from (j3), we readily obtain the n (separable variable) equations

$$\begin{aligned}[h\,u_1(q_1) - w_1(q_1) + \gamma_1]^{-1/2}\,dq_1 = \cdots = [h\,u_n(q_n) - w_n(q_n) + \gamma_n]^{-1/2}\,dq_n \\ = (2)^{1/2}\,dt/u,\end{aligned} \tag{j5}$$

and from these, with the notation $2[h\,u_k(q_k) - w_k(q_k) + \gamma_k] \equiv f_k(q_k)$, we conclude that

(a) $$\sum u_k\Big(dq_k\Big/\Big[f_k(q_k)^{1/2}\Big]\Big) = \Big(\sum u_k\Big)dt\Big/u = dt,$$

or, integrating,

$$\sum \int \frac{u_k\,dq_k}{\sqrt{f_k(q_k)}} = t + \eta_1 \qquad (\eta_1\text{: } \textit{integration constant}); \tag{k1}$$

and

(b) $$\int \frac{dq_1}{\sqrt{f_1(q_1)}} - \int \frac{dq_l}{\sqrt{f_l(q_l)}} = \eta_l \qquad (l = 2, \ldots, n). \tag{k2}$$

Equation (k1) and the $n-1$ equations (k2) supply the n independent constants of integration $\eta_1, \ldots, \eta_n$, which along with the earlier $n-1$ independent γ's and the energy constant h (i.e., $\gamma_1, \ldots, \gamma_{n-1}, h$), constitute the $2n$ expected independent constants of integration of the system (h1, 2) [we also note that, by (j5), and since $u > 0$, it follows that in (k1, 2) $f_k(q_k)^{1/2}$ has the same sign as dq_k; a fact that becomes important whenever one or more of the q's oscillates between fixed limits (*libration*—see §8.14)]. Lastly, the original variables of (e1, 2) can be recovered from (f) with another integration. For extensive discussions of these systems, including Hamilton–Jacobi methods, see, e.g., Hamel (1949, pp. 302–303, 358–361, 669–688), Lur'e (1968, pp. 538–548), Pars (1965, pp. 291–348); also Whittaker (1937, p. 60, and references therein).

3.13 THE RIGID BODY: LAGRANGEAN–EULERIAN KINEMATICO-INERTIAL IDENTITIES

Kinematical Preliminaries

As we have seen in §1.7 ff. (fig. 3.30), the inertial velocity of a typical body point P equals

$$\begin{aligned} \boldsymbol{v} &\equiv d\boldsymbol{r}/dt \equiv d\boldsymbol{r}_\blacklozenge/dt \; + \; d(\boldsymbol{r} - \boldsymbol{r}_\blacklozenge)/dt \equiv d\boldsymbol{r}_\blacklozenge/dt + d\boldsymbol{r}_{/\blacklozenge}/dt \\ &\equiv \boldsymbol{v}_\blacklozenge + \boldsymbol{v}_{/\blacklozenge} = \boldsymbol{v}_\blacklozenge + \boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge}, \end{aligned} \tag{3.13.1}$$

or, in components, with some easily understood notation,

(a) Along the *space-fixed* (inertial) axes/basis $O\text{–}XYZ/\boldsymbol{IJK}$:

$$\boldsymbol{r} = X\boldsymbol{I} + Y\boldsymbol{J} + Z\boldsymbol{K}, \qquad \boldsymbol{r}_{/\blacklozenge} = (X - X_\blacklozenge)\boldsymbol{I} + (Y - Y_\blacklozenge)\boldsymbol{J} + (Z - Z_\blacklozenge)\boldsymbol{K}, \tag{3.13.1a}$$

and, therefore,

$$v_X = v_{\blacklozenge,X} + \omega_Y(Z - Z_\blacklozenge) - \omega_Z(Y - Y_\blacklozenge), \quad \text{etc., cyclically;} \tag{3.13.1b}$$

(b) Along the *body-fixed* (noninertial) axes/basis $\blacklozenge\text{–}xyz/\boldsymbol{ijk}$:

$$\boldsymbol{r}_{/\blacklozenge} = x_{/\blacklozenge}\boldsymbol{i} + y_{/\blacklozenge}\boldsymbol{j} + z_{/\blacklozenge}\boldsymbol{k}, \tag{3.13.1c}$$

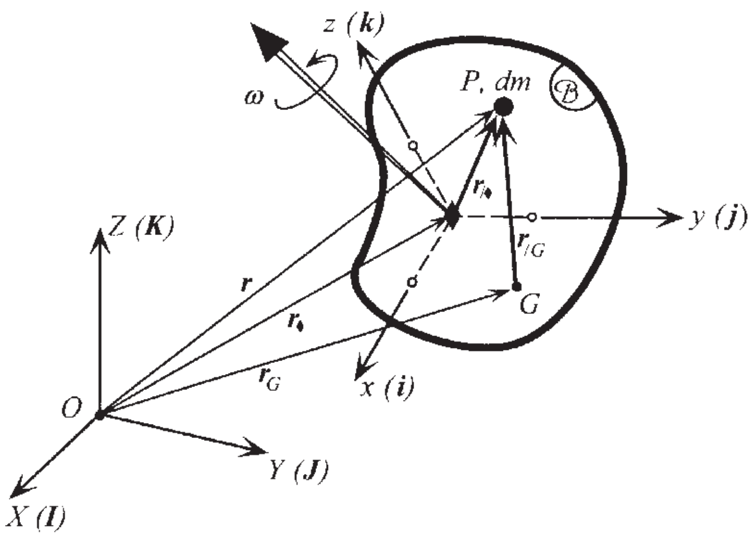

Figure 3.30 Basic notation for general rigid-body motion:
O–XYZ = *space-fixed* (inertial) axes; *O–**IJK*** = associated basis;
◆–*xyz* = *body-fixed* (noninertial) axes; ◆–***ijk*** = associated basis;
G = center of mass of body *B*;
$\boldsymbol{r}_{/\blacklozenge}$ = position of representative body particle *P* relative to arbitrary body point ◆;
$\boldsymbol{r}_{/G}$ = position of representative body particle *P* relative to *G*;
ω = inertial angular velocity of body *B*.

and therefore,

$$v_x = v_{\blacklozenge,x} + \omega_y\, z_{/\blacklozenge} - \omega_z\, y_{/\blacklozenge}, \quad \text{etc., cyclically.} \tag{3.13.1d}$$

We point out that since $v_{\blacklozenge,X} = \dot{X}$, etc., cyclically, the inertial components $v_{\blacklozenge;X,Y,Z}$ are *holonomic*; whereas, since

$$v_{\blacklozenge,x} = \cos(x, X)\dot{X} + \cos(x, Y)\dot{Y} + \cos(x, Z)\dot{Z}, \quad \text{etc., cyclically,} \tag{3.13.1e}$$

the noninertial components $v_{\blacklozenge;x,y,z}$ are *nonholonomic*, or *quasi velocities*; and so are the $\omega_{x,y,z}$.

Kinetic Energy

Substituting (3.13.1) into $2T \equiv \mathcal{S}\, dm\, \boldsymbol{v}\cdot\boldsymbol{v}$, we obtain, successively,

$$\begin{aligned} 2T &\equiv \mathcal{S}\, dm(\boldsymbol{v}_\blacklozenge + \boldsymbol{\omega}\times\boldsymbol{r}_{/\blacklozenge})\cdot(\boldsymbol{v}_\blacklozenge + \boldsymbol{\omega}\times\boldsymbol{r}_{/\blacklozenge}) \\ &= \cdots = 2T_{\text{translation}} + 2T_{\text{rotation}} + 2T_{\text{coupling}}, \end{aligned} \tag{3.13.2}$$

where

$$\begin{aligned} 2T_{\text{translation}} &\equiv 2T_T \equiv \mathcal{S}\, dm\, \boldsymbol{v}_\blacklozenge\cdot\boldsymbol{v}_\blacklozenge = m\,\boldsymbol{v}_\blacklozenge\cdot\boldsymbol{v}_\blacklozenge = m\,{\boldsymbol{v}_\blacklozenge}^2 \\ &= m\left({v_{\blacklozenge,X}}^2 + {v_{\blacklozenge,Y}}^2 + {v_{\blacklozenge,Z}}^2\right) = m\left({v_{\blacklozenge,x}}^2 + {v_{\blacklozenge,y}}^2 + {v_{\blacklozenge,z}}^2\right) \\ &= 2(\textit{kinetic energy of translation}), \end{aligned} \tag{3.13.2a}$$

$$\begin{aligned} 2T_{\text{rotation}} &\equiv 2T_R \equiv \mathcal{S}\, dm(\boldsymbol{\omega}\times\boldsymbol{r}_{/\blacklozenge})\cdot(\boldsymbol{\omega}\times\boldsymbol{r}_{/\blacklozenge}) \\ &= \cdots = \mathcal{S}\, dm\,\boldsymbol{\omega}\cdot[\boldsymbol{r}_{/\blacklozenge}\times(\boldsymbol{\omega}\times\boldsymbol{r}_{/\blacklozenge})] \equiv \boldsymbol{\omega}\cdot\boldsymbol{h}_\blacklozenge \\ &= 2(\textit{kinetic energy of rotation}), \end{aligned} \tag{3.13.2b}$$

$$\begin{aligned} \boldsymbol{h}_\blacklozenge &\equiv \mathcal{S}\, dm[\boldsymbol{r}_{/\blacklozenge}\times(\boldsymbol{\omega}\times\boldsymbol{r}_{/\blacklozenge})] \\ &= (\textit{inertial})\ \textit{relative angular momentum of the body } B \textit{ about } \blacklozenge;\ \textit{a system vector}, \end{aligned} \tag{3.13.2c}$$

$$\begin{aligned} T_{\text{coupling}} &\equiv T_C \equiv \mathcal{S}\, dm[\boldsymbol{v}_\blacklozenge\cdot(\boldsymbol{\omega}\times\boldsymbol{r}_{/\blacklozenge})] = \boldsymbol{\omega}\cdot\mathcal{S}\, dm(\boldsymbol{r}_{/\blacklozenge}\times\boldsymbol{v}_\blacklozenge) \\ &= \boldsymbol{\omega}\cdot\left[\left(\mathcal{S}\, dm\,\boldsymbol{r}_{/\blacklozenge}\right)\times\boldsymbol{v}_\blacklozenge\right] = \boldsymbol{\omega}\cdot(m\,\boldsymbol{r}_{G/\blacklozenge}\times\boldsymbol{v}_\blacklozenge) \\ &= m\,\boldsymbol{v}_\blacklozenge\cdot(\boldsymbol{\omega}\times\boldsymbol{r}_{G/\blacklozenge}) \equiv m\,\boldsymbol{v}_\blacklozenge\cdot\boldsymbol{v}_{G/\blacklozenge} \\ &= \textit{kinetic energy of coupling (of translation of } \blacklozenge \textit{ with rotation of } B). \end{aligned} \tag{3.13.2d}$$

[Clearly,

$$\mathcal{S}\, dm\,\boldsymbol{r}_{/\blacklozenge} = \mathcal{S}\, dm(\boldsymbol{r}_{G/\blacklozenge} + \boldsymbol{r}_{/G}) = \mathcal{S}\, dm\,\boldsymbol{r}_{G/\blacklozenge} + \mathcal{S}\, dm\,\boldsymbol{r}_{/G} = m\,\boldsymbol{r}_{G/\blacklozenge} + \boldsymbol{0}.]$$

Further, since (using simple vector algebra identities; recalling §1.16 ff.)

$$\boldsymbol{h}_\blacklozenge \equiv \mathcal{S}\, dm\left[(\boldsymbol{r}_{/\blacklozenge}\cdot\boldsymbol{r}_{/\blacklozenge})\boldsymbol{\omega} - (\boldsymbol{\omega}\cdot\boldsymbol{r}_{/\blacklozenge})\boldsymbol{r}_{/\blacklozenge}\right] \equiv \boldsymbol{I}_\blacklozenge\cdot\boldsymbol{\omega}, \tag{3.13.3}$$

where $\boldsymbol{I}_\blacklozenge$ = *inertia tensor* of B at $\blacklozenge$; or, in components along, say, $\blacklozenge$–*xyz*,

$$h_{\blacklozenge,x} = I_{\blacklozenge,xx}\,\omega_x + I_{\blacklozenge,xy}\,\omega_y + I_{\blacklozenge,xz}\,\omega_z\,, \quad \text{etc., cyclically,} \tag{3.13.3a}$$

the expression (3.13.2b) assumes the form

$$2T_R = \boldsymbol{\omega}\cdot\boldsymbol{I}_\blacklozenge\cdot\boldsymbol{\omega} = I_{\blacklozenge,xx}\,\omega_x{}^2 + I_{\blacklozenge,yy}\,\omega_y{}^2 + I_{\blacklozenge,zz}\,\omega_z{}^2 + 2\big(I_{\blacklozenge,xy}\,\omega_x\,\omega_y + I_{\blacklozenge,xz}\,\omega_x\,\omega_z + I_{\blacklozenge,yz}\,\omega_y\,\omega_z\big). \tag{3.13.3b}$$

Hence, finally [and with $\omega_x = \omega\, l_x$, etc., where $\boldsymbol{l} = (l_x, l_y, l_z)$ = *unit vector along* $\boldsymbol{\omega}$], $2T$ becomes

$$\begin{aligned} 2T &= m\,v_\blacklozenge{}^2 + I_{\blacklozenge,l}\,\omega^2 + 2\boldsymbol{\omega}\cdot(m\boldsymbol{r}_{G/\blacklozenge}\times\boldsymbol{v}_\blacklozenge) \\ &= m\,v_\blacklozenge{}^2 + I_{\blacklozenge,l}\,\omega^2 + 2m\boldsymbol{v}_\blacklozenge\cdot(\boldsymbol{\omega}\times\boldsymbol{r}_{G/\blacklozenge}) \\ &\equiv m\,v_\blacklozenge{}^2 + I_{\blacklozenge,l}\,\omega^2 + 2m\boldsymbol{v}_\blacklozenge\cdot\boldsymbol{v}_{G/\blacklozenge}, \end{aligned} \tag{3.13.3c}$$

(= function of the *six* quasi velocities: $v_{\blacklozenge;x,y,z}$ and $\omega_{x,y,z}$, if *body-fixed* axes are used), where

$$\begin{aligned} I_{\blacklozenge,l} &\equiv l_x{}^2 I_{\blacklozenge,xx} + \cdots + 2l_x\,l_y\,I_{\blacklozenge,xy} + \cdots \\ &= \textit{moment of inertia of B about axis of instantaneous rotation through } \blacklozenge. \end{aligned} \tag{3.13.3d}$$

Special Cases of (3.13.3c)

- If we choose our body-fixed axes to be also *principal* axes: $\blacklozenge$–*xyz* → $\blacklozenge$–123, then, with some obvious notations,

$$\begin{aligned} I_{\blacklozenge,l} &= l_x{}^2 I_{\blacklozenge,x} + l_y{}^2 I_{\blacklozenge,y} + l_z{}^2 I_{\blacklozenge,z} \\ &\equiv l_1{}^2 I_{\blacklozenge,1} + l_2{}^2 I_{\blacklozenge,2} + l_3{}^2 I_{\blacklozenge,3} \quad (\equiv l_1{}^2 A + l_2{}^2 B + l_3{}^2 C), \end{aligned} \tag{3.13.4a}$$

and so the rotational kinetic energy (3.13.3b) reduces to

$$2T_R = I_{\blacklozenge,1}\,\omega_1{}^2 + I_{\blacklozenge,2}\,\omega_2{}^2 + I_{\blacklozenge,3}\,\omega_3{}^3. \tag{3.13.4b}$$

- If, *further*, $\blacklozenge = G$ then, clearly, $T_C = 0$ and (3.13.3c) assumes the (König) form

$$2T = m\,v_G{}^2 + I_{G,l}\,\omega^2 = m\,v_G{}^2 + (I_{G,1}\,\omega_1{}^2 + I_{G,2}\,\omega_2{}^2 + I_{G,3}\,\omega_3{}^2); \tag{3.13.4c}$$

in words: the kinetic energy of a moving rigid body consists of two independent (uncoupled) parts: one depending on the motion of the body's center of mass (G) and another equal to the kinetic energy of motion relative to that center. [This is the kinetic energy analog of the familiar Newton–Euler (momentum) proposition that: (i) the motion of G is indistinguishable from that of a fictitious particle of equal mass placed there and acted on by a force equal to the total external force on the body, through G; and (ii) the motion (rotation) of the body about G is the same as if G were fixed and the body is acted on by the same forces (and/or couples) as in the actual case. These results, clearly, also hold for *impulsive* motion (chap. 4).]

It is also possible to express T in terms of *holonomic* (instead of quasi-) coordinates: specifically, with $\boldsymbol{r}_G = X_G \boldsymbol{I} + Y_G \boldsymbol{J} + Z_G \boldsymbol{K}$ and ϕ, θ, $\psi =$ Eulerian angles of G–xyz relative to O–XYZ (or G–XYZ), the (double) kinetic energy transforms to

$$\begin{aligned} 2T &= m v_G{}^2 + \boldsymbol{\omega} \cdot \textstyle\int dm[\boldsymbol{r}_{/G} \times (\boldsymbol{\omega} \times \boldsymbol{r}_{/G})] \\ &= m\Big[(\dot{X}_G)^2 + (\dot{Y}_G)^2 + (\dot{Z}_G)^2\Big] + 2T_R\big(\phi, \theta, \psi; \dot{\phi}, \dot{\theta}, \dot{\psi}\big), \end{aligned} \tag{3.13.4d}$$

[where, since the $\boldsymbol{r}_{/G}$, in the second term of (3.13.4d), depend only on the Eulerian angles, and (recalling results of §1.12): $\boldsymbol{\omega} = \boldsymbol{u}_\phi(\phi, \theta, \psi)\dot{\phi} + \boldsymbol{u}_\theta(\phi, \theta, \psi)\dot{\theta} + \boldsymbol{u}_\psi(\phi, \theta, \psi)\dot{\psi}$; $\boldsymbol{u}_{\phi,\theta,\psi}(\equiv \boldsymbol{K i' k''})$: *nonorthogonal unit vectors*, that term, $2T_R$, becomes a *quadratic homogeneous* function of the Eulerian rates $\dot{\phi}$, $\dot{\theta}$, $\dot{\psi}$, with coefficients functions of the Eulerian angles ϕ, θ, ψ] and, accordingly, the Lagrangean inertial forces (or system accelerations) corresponding to the so-chosen Lagrangean coordinates $q_1 = X_G, \ldots, q_6 = \psi$ are

Motion of G: $\quad E_1 \equiv E_X = m\ddot{X}_G, \quad E_2 \equiv E_Y = m\ddot{Y}_G, \quad E_3 \equiv E_Z = m\ddot{Z}_G,$ (3.13.4e)

Motion around G:

$$\begin{aligned} E_4 &\equiv E_\phi = (\partial T_R/\partial\dot{\phi})^{\cdot} - \partial T_R/\partial\phi, \\ E_5 &\equiv E_\theta = (\partial T_R/\partial\dot{\theta})^{\cdot} - \partial T_R/\partial\theta, \\ E_6 &\equiv E_\psi = (\partial T_R/\partial\dot{\psi})^{\cdot} - \partial T_R/\partial\psi. \end{aligned} \tag{3.13.4f}$$

However, upon explicit calculation, eqs. (3.13.4f) turn out to be less simple than their quasi-variable counterparts based on eqs. (3.13.2a–4c).

• If B is a *body of revolution* about, say, the $\blacklozenge$–z axis, then, since $\blacklozenge$–xyz are principal axes and $I_{\blacklozenge,x} = I_{\blacklozenge,y} =$ *perpendicular* (or *transverse*, or *equatorial*) moment of inertia, then

$$\begin{aligned} 2T_R &= I_{\blacklozenge,x}\,\omega_x{}^2 + I_{\blacklozenge,y}\,\omega_y{}^2 + I_{\blacklozenge,z}\,\omega_z{}^2 = I_{\blacklozenge,x}(\omega_x{}^2 + \omega_y{}^2) + I_{\blacklozenge,z}\,\omega_z{}^2 \\ &= I_{\blacklozenge,x}(\omega^2 - \omega_z{}^2) + I_{\blacklozenge,z}\,\omega_z{}^2 = I_{\blacklozenge,x}\,\omega^2 + (I_{\blacklozenge,z} - I_{\blacklozenge,x})\,\omega_z{}^2, \end{aligned} \tag{3.13.4g}$$

or, generally, with the helpful notations $I_{\blacklozenge,x} \equiv I_{\blacklozenge,\text{transverse}} \equiv I_{\blacklozenge,T}$, $I_{\blacklozenge,z} \equiv I_{\blacklozenge,\text{axial}} \equiv I_{\blacklozenge,A}$, and $\boldsymbol{k} \equiv \boldsymbol{u}$: *unit* vector along axis of revolution,

$$2T_R \;=\; I_{\blacklozenge,T}\,\omega^2 + (I_{\blacklozenge,A} - I_{\blacklozenge,T})(\boldsymbol{\omega} \cdot \boldsymbol{u})^2. \tag{3.13.4h}$$

The System Momentum Vectors

[We begin by pointing out that, by (1.10.29a)ff., if $\boldsymbol{n}$ = constant (*fixed axis*), then $\boldsymbol{\omega}\,dt = d(\chi\boldsymbol{n}) \equiv d\chi = d$ (*ordinary/holonomic vector*); while, if $\boldsymbol{n}$ = variable (*mobile axis*), then $\boldsymbol{\omega}\,dt = d$(*quasi-vector*) $\equiv d\boldsymbol{\theta}$.] Now, since the rigid body is an internally scleronomic system, $\delta\boldsymbol{r} = \delta\boldsymbol{r}_\blacklozenge + \delta\boldsymbol{\theta} \times \boldsymbol{r}_{/\blacklozenge}$, and, as a result, the total (inertial and first-order) virtual "work" of its linear momenta, δP [recalling (3.6.3b)], specializes to

$$\begin{aligned} \delta P &\equiv \textstyle\int dm\,\boldsymbol{v} \cdot \delta\boldsymbol{r} = \int dm\,\boldsymbol{v} \cdot (\delta\boldsymbol{r}_\blacklozenge + \delta\boldsymbol{\theta} \times \boldsymbol{r}_{/\blacklozenge}) \\ &= \cdots = \boldsymbol{p} \cdot \delta\boldsymbol{r}_\blacklozenge + \boldsymbol{H}_\blacklozenge \cdot \delta\boldsymbol{\theta}, \end{aligned} \tag{3.13.5}$$

where

$$\boldsymbol{p} \equiv \int dm\, \boldsymbol{v} = m\,\boldsymbol{v}_G = (inertial)\ linear\ momentum\ of\ body\ B, \tag{3.13.5a}$$

$$\boldsymbol{H}_\blacklozenge \equiv \int \boldsymbol{r}_{/\blacklozenge} \times (dm\, \boldsymbol{v}) = (inertial)\ absolute\ angular\ momentum\ of\ B\ about\ \blacklozenge. \tag{3.13.5b}$$

These two momenta are the fundamental *system* vectors of Eulerian rigid-body mechanics. They transform, further, as follows:

$$\boldsymbol{p} \equiv \int dm(\boldsymbol{v}_\blacklozenge + \boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge}) = m\boldsymbol{v}_\blacklozenge + \boldsymbol{\omega} \times (m\boldsymbol{r}_{G/\blacklozenge}), \tag{3.13.5c}$$

$$\boldsymbol{H}_\blacklozenge \equiv \int dm\, \boldsymbol{r}_{/\blacklozenge} \times (\boldsymbol{v}_\blacklozenge + \boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge}) = \boldsymbol{h}_\blacklozenge + m(\boldsymbol{r}_{G/\blacklozenge} \times \boldsymbol{v}_\blacklozenge). \tag{3.13.5d}$$

- If $\blacklozenge = G$, then $\boldsymbol{r}_{G/\blacklozenge} = \boldsymbol{0}$, and (3.13.5c, d) reduce, respectively, to

$$\boldsymbol{p} = m\,\boldsymbol{v}_G \qquad \text{and} \qquad \boldsymbol{H}_G = \boldsymbol{h}_G = \int dm\, \boldsymbol{r}_{/\blacklozenge} \times (\boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge}). \tag{3.13.5e}$$

Next, let us relate the above to the (inertial) *absolute angular momentum of B about the origin O*, $\boldsymbol{H}_O$ (recalling §1.6). Since $\boldsymbol{r} = \boldsymbol{r}_\blacklozenge + \boldsymbol{r}_{/\blacklozenge}$, we find, successively,

$$\begin{aligned}
\boldsymbol{H}_O &\equiv \int \boldsymbol{r} \times (dm\, \boldsymbol{v}) = \int dm(\boldsymbol{r}_\blacklozenge \times \boldsymbol{v}) + \int dm(\boldsymbol{r}_{/\blacklozenge} \times \boldsymbol{v}) \\
&= \boldsymbol{r}_\blacklozenge \times \left(\int dm\, \boldsymbol{v}\right) + \boldsymbol{H}_\blacklozenge \ = \ \boldsymbol{r}_\blacklozenge \times \boldsymbol{p} + [\boldsymbol{h}_\blacklozenge + m(\boldsymbol{r}_{G/\blacklozenge} \times \boldsymbol{v}_\blacklozenge)] \qquad \text{[recalling (3.13.5d)]} \\
&= \boldsymbol{I}_\blacklozenge \cdot \boldsymbol{\omega} + m(\boldsymbol{r}_{G/\blacklozenge} \times \boldsymbol{v}_\blacklozenge) + \boldsymbol{r}_\blacklozenge \times \boldsymbol{p};
\end{aligned} \tag{3.13.6}$$

and, therefore

- If $\blacklozenge = G$, then

$$\boldsymbol{H}_O = \boldsymbol{I}_G \cdot \boldsymbol{\omega} + \boldsymbol{r}_G \times \boldsymbol{p} = \boldsymbol{I}_G \cdot \boldsymbol{\omega} + \boldsymbol{r}_G \times (m\boldsymbol{v}_G); \tag{3.13.6a}$$

- If $\blacklozenge = O$ (i.e., motion about a *fixed* point — rotation), then $\boldsymbol{r}_\blacklozenge = \boldsymbol{0}$, $\boldsymbol{v}_\blacklozenge = \boldsymbol{0}$, and the above reduce to

$$\boldsymbol{p} = m\boldsymbol{v}_G = m(\boldsymbol{\omega} \times \boldsymbol{r}_G) \qquad \text{and} \qquad \boldsymbol{H}_O = \boldsymbol{h}_O = \boldsymbol{I}_O \cdot \boldsymbol{\omega}. \tag{3.13.6b}$$

More general $\boldsymbol{H}/\boldsymbol{h}/\boldsymbol{p}$ definitions appear in §3.16, in connection with the problem of *relative motion*; that is, when $\blacklozenge$ is *not* a body point but has its own (known or unknown) motion relative to both $O\text{–}XYZ$ and the body.

Kinetic Energy via Momentum Vectors

Now we are ready to relate the system quantities $T/\boldsymbol{p}/\boldsymbol{H}_\blacklozenge$. Indeed, since the free (i.e. *externally* unconstrained) rigid body is (an *internally*) *scleronomic* system, we can replace in (3.13.5) $\delta\boldsymbol{r}/\delta\boldsymbol{r}_\blacklozenge/\delta\boldsymbol{\theta}$ with $d\boldsymbol{r} = \boldsymbol{v}\,dt/d\boldsymbol{r}_\blacklozenge = \boldsymbol{v}_\blacklozenge\,dt/d\boldsymbol{\theta} = \boldsymbol{\omega}\,dt$, respectively, and then divide by dt; thus resulting in

$$2T = \boldsymbol{p} \cdot \boldsymbol{v}_\blacklozenge + \boldsymbol{H}_\blacklozenge \cdot \boldsymbol{\omega}. \tag{3.13.7}$$

Let us examine T more closely. From the earlier representations—that is,

$$2T = m\boldsymbol{v}_\blacklozenge \cdot \boldsymbol{v}_\blacklozenge + \boldsymbol{\omega} \cdot \left\{\int dm[\boldsymbol{r}_{/\blacklozenge} \times (\boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge})]\right\} + \boldsymbol{\omega} \cdot (m\boldsymbol{r}_{G/\blacklozenge} \times \boldsymbol{v}_\blacklozenge),$$

we realize that

$$2T = 2T(\boldsymbol{v}_\blacklozenge, \boldsymbol{\omega}) = \textit{function of the velocity variables, or velocity state, of the body}, \tag{3.13.7a}$$

and, therefore, *differentiating T with respect to these variables*, we obtain

$$\begin{aligned} dT &= m\boldsymbol{v}_\blacklozenge \cdot d\boldsymbol{v}_\blacklozenge + (1/2)\Big\{d\boldsymbol{\omega}\cdot\boldsymbol{h}_\blacklozenge + \boldsymbol{\omega}\cdot \mathsf{S}\, dm\big[\boldsymbol{r}_{/\blacklozenge} \times (d\boldsymbol{\omega}\times\boldsymbol{r}_{/\blacklozenge})\big]\Big\} \\ &\quad + \boldsymbol{\omega}\cdot(m\boldsymbol{r}_{G/\blacklozenge}\times d\boldsymbol{v}_\blacklozenge) + d\boldsymbol{\omega}\cdot(m\boldsymbol{r}_{G/\blacklozenge}\times\boldsymbol{v}_\blacklozenge); \end{aligned} \tag{3.13.7b}$$

or, since $\boldsymbol{\omega}\cdot[\boldsymbol{r}_{/\blacklozenge}\times(d\boldsymbol{\omega}\times\boldsymbol{r}_{/\blacklozenge})] = (\boldsymbol{r}_{/\blacklozenge})^2(\boldsymbol{\omega}\cdot d\boldsymbol{\omega}) - (\boldsymbol{r}_{/\blacklozenge}\cdot d\boldsymbol{\omega})(\boldsymbol{r}_{/\blacklozenge}\cdot\boldsymbol{\omega})$, from which

$$\begin{aligned} \boldsymbol{\omega}\cdot \mathsf{S}\, dm[\boldsymbol{r}_{/\blacklozenge}\times(d\boldsymbol{\omega}\times\boldsymbol{r}_{/\blacklozenge})] &= d\boldsymbol{\omega}\cdot \mathsf{S}\, dm[(\boldsymbol{r}_{/\blacklozenge})^2\boldsymbol{\omega} - (\boldsymbol{r}_{/\blacklozenge}\cdot\boldsymbol{\omega})\,\boldsymbol{r}_{/\blacklozenge}] \\ &= d\boldsymbol{\omega}\cdot\boldsymbol{h}_\blacklozenge, \end{aligned} \tag{3.13.7c}$$

we finally establish that

$$dT = [m\boldsymbol{v}_\blacklozenge + m(\boldsymbol{\omega}\times\boldsymbol{r}_{G/\blacklozenge})]\cdot d\boldsymbol{v}_\blacklozenge + [\boldsymbol{h}_\blacklozenge + m(\boldsymbol{r}_{G/\blacklozenge}\times\boldsymbol{v}_\blacklozenge)]\cdot d\boldsymbol{\omega}. \tag{3.13.7d}$$

But from (3.13.7a) and the invariant differential definition, we must also have

$$dT = (\partial T/\partial\boldsymbol{v}_\blacklozenge)\cdot d\boldsymbol{v}_\blacklozenge + (\partial T/\partial\boldsymbol{\omega})\cdot d\boldsymbol{\omega}. \tag{3.13.7e}$$

The representations (3.13.7d) and (3.13.7e), since the $d\boldsymbol{v}_\blacklozenge$ and $d\boldsymbol{\omega}$ are independent, immediately lead to the following basic kinematico-inertial identities:

$$\boldsymbol{p} = \partial T/\partial\boldsymbol{v}_\blacklozenge \quad [= m(\boldsymbol{v}_\blacklozenge + \boldsymbol{\omega}\times\boldsymbol{r}_{G/\blacklozenge}) = m\boldsymbol{v}_G], \tag{3.13.7f}$$

$$\boldsymbol{H}_\blacklozenge = \partial T/\partial\boldsymbol{\omega} \quad [= \boldsymbol{h}_\blacklozenge + (m\boldsymbol{r}_{G/\blacklozenge}\times\boldsymbol{v}_\blacklozenge)]. \tag{3.13.7g}$$

[We notice that $\partial T(\boldsymbol{v}_\blacklozenge,\boldsymbol{\omega})/\partial\boldsymbol{v}_\blacklozenge = \partial T(\boldsymbol{v}_G,\boldsymbol{\omega})/\partial\boldsymbol{v}_G = \boldsymbol{p}$.] The above translate readily to the following *six* scalar/component equations:

- Along the *body-fixed* axes $\blacklozenge - xyz$:

$$p_x = m(v_{\blacklozenge,x} + \omega_y z_{G/\blacklozenge} - \omega_z y_{G/\blacklozenge}) = \partial T/\partial v_{\blacklozenge,x}, \quad \text{etc., cyclically}, \tag{3.13.7h}$$

$$H_{\blacklozenge,x} = h_{\blacklozenge,x} + m(y_{G/\blacklozenge}v_{\blacklozenge,z} - z_{G/\blacklozenge}v_{\blacklozenge,y}) = \partial T/\partial\omega_x, \quad \text{etc., cyclically}, \tag{3.13.7i}$$

where

$$h_{\blacklozenge,x} = I_{\blacklozenge,xx}\omega_x + I_{\blacklozenge,xy}\omega_y + I_{\blacklozenge,xz}\omega_z = \partial T_R/\partial\omega_x, \quad \text{etc., cyclically}, \tag{3.13.7j}$$

- Along the *space-fixed* axes $\blacklozenge - XYZ$:

$$\begin{aligned} p_X &= m\,[v_{\blacklozenge,X} + \omega_Y(Z_G - Z_\blacklozenge) - \omega_Z(Y_G - Y_\blacklozenge)] \\ &\equiv m\,(v_{\blacklozenge,X} + \omega_Y Z_{G/\blacklozenge} - \omega_Z Y_{G/\blacklozenge}) = \partial T/\partial v_{\blacklozenge,X}, \quad \text{etc., cyclically}, \end{aligned} \tag{3.13.7k}$$

$$H_{\blacklozenge,X} = h_{\blacklozenge,X} + m\,(Y_{G/\blacklozenge}v_{\blacklozenge,Z} - Z_{G/\blacklozenge}v_{\blacklozenge,Y}) = \partial T/\partial\omega_X, \quad \text{etc., cyclically}, \tag{3.13.7l}$$

where the $h_{\blacklozenge;X,Y,Z}$ can be found from the vector transformations

$$h_{\blacklozenge,X} = \cos(X,x)\,h_{\blacklozenge,x} + \cos(X,y)\,h_{\blacklozenge,y} + \cos(X,z)\,h_{\blacklozenge,z}, \quad \text{etc., cyclically}. \tag{3.13.7m}$$

Acceleration Vectors

Let us now calculate the total (inertial and first-order) virtual "work" of the inertial forces of the particles of the body [recall (3.2.9, 3.3.2 ff.)]. We find, successively,

$$\delta I \equiv S\, dm\, \boldsymbol{a} \cdot \delta \boldsymbol{r} = S\, dm\, \boldsymbol{a} \cdot (\delta \boldsymbol{r}_{\blacklozenge} + \delta \boldsymbol{\theta} \times \boldsymbol{r}_{/\blacklozenge}) \\ = \cdots = \boldsymbol{I} \cdot \delta \boldsymbol{r}_{\blacklozenge} + \boldsymbol{A}_{\blacklozenge} \cdot \delta \boldsymbol{\theta}, \tag{3.13.8}$$

where

$$\boldsymbol{I} \equiv S\, dm\, \boldsymbol{a} = m\, \boldsymbol{a}_G = (\textit{inertial}) \textit{ linear inertia of body } B, \tag{3.13.8a}$$

$$\boldsymbol{A}_{\blacklozenge} \equiv S\, \boldsymbol{r}_{/\blacklozenge} \times (dm\, \boldsymbol{a}) = (\textit{inertial}) \textit{ relative angular inertia of } B \textit{ about } \blacklozenge. \tag{3.13.8b}$$

Our next task is to relate these two Eulerian system vectors to their *momentum* counterparts, $\boldsymbol{p}$ and $\boldsymbol{H}_{\blacklozenge}$:

(i) Clearly,
$$\boldsymbol{I} = d\boldsymbol{p}/dt; \tag{3.13.8c}$$

(ii) By $(\ldots)^{\cdot}$-differentiating $\boldsymbol{H}_{\blacklozenge}$ we obtain, successively,

$$d\boldsymbol{H}_{\blacklozenge}/dt = d/dt\Big[S\, \boldsymbol{r}_{/\blacklozenge} \times (dm\, \boldsymbol{v})\Big] = S\, dm(\boldsymbol{v}_{/\blacklozenge} \times \boldsymbol{v}) + S\, dm(\boldsymbol{r}_{/\blacklozenge} \times \boldsymbol{a}) \\ = S\, dm(\boldsymbol{v} - \boldsymbol{v}_{\blacklozenge}) \times \boldsymbol{v} + S\, dm(\boldsymbol{r}_{/\blacklozenge} \times \boldsymbol{a}) \\ = -S\, dm(\boldsymbol{v}_{\blacklozenge} \times \boldsymbol{v}) + S\, dm(\boldsymbol{r}_{/\blacklozenge} \times \boldsymbol{a}), \tag{3.13.8d}$$

or, finally,

$$\boldsymbol{A}_{\blacklozenge} = d\boldsymbol{H}_{\blacklozenge}/dt + \boldsymbol{v}_{\blacklozenge} \times \boldsymbol{p}. \tag{3.13.8e}$$

For $\blacklozenge = G$ the above specialize, respectively, to

$$\boldsymbol{I} = m\, \boldsymbol{a}_G \qquad \text{and} \qquad \boldsymbol{A}_G = d\boldsymbol{H}_G/dt = d\boldsymbol{h}_G/dt, \tag{3.13.8f 1}$$

where

$$\boldsymbol{H}_G \equiv S\, \boldsymbol{r}_{/\blacklozenge} \times (dm\, \boldsymbol{v}) = \boldsymbol{h}_G \equiv S\, \boldsymbol{r}_{/G} \times (dm\, \boldsymbol{v}_{/G}). \tag{3.13.8f 2}$$

REMARK

It is not hard to show that (3.13.8e) also holds with $\blacklozenge$ replaced by *any other* (not necessarily body-) point $\bullet$ moving with arbitrary inertial velocity $\boldsymbol{v}_{\bullet} \equiv \boldsymbol{v}_{\bullet/O}$. Indeed, with

$$\boldsymbol{H}_{\bullet} \equiv S\, \boldsymbol{r}_{/\bullet} \times (dm\, \boldsymbol{v}),$$

we readily find

$$d\boldsymbol{H}_{\bullet}/dt = S\, \boldsymbol{v}_{/\bullet} \times (dm\, \boldsymbol{v}) + S\, \boldsymbol{r}_{/\bullet} \times (dm\, \boldsymbol{a}) \\ = S\, (\boldsymbol{v} - \boldsymbol{v}_{\bullet}) \times (dm\, \boldsymbol{v}) + S\, \boldsymbol{r}_{/\bullet} \times (dm\, \boldsymbol{a}) \\ = -S\, \boldsymbol{v}_{\bullet} \times (dm\, \boldsymbol{v}) + S\, \boldsymbol{r}_{/\bullet} \times (dm\, \boldsymbol{a}), \tag{3.13.8g}$$

or, finally,

$$\boldsymbol{A}_\bullet = d\boldsymbol{H}_\bullet/dt + \boldsymbol{v}_\bullet \times \boldsymbol{p}, \quad \text{Q.E.D.} \quad \text{(see also §1.6, and appendix 3.A2).} \tag{3.13.8h}$$

Moving Axes

To express the above inertia vectors in terms of the more useful rates relative to (noninertial) axes, either *body-fixed* or *intermediate* (*neither body- nor space-fixed*—chosen so that the inertia tensor components along them remain constant), we simply replace in the right sides of their representations, such as (3.13.8c, e, f), $d(\ldots)/dt$ with $\partial(\ldots)/\partial t + \boldsymbol{\Omega} \times (\ldots)$, where $\partial(\ldots)/\partial t$ = *rate of change of vector … relative to axes that are rotating with (inertial) angular velocity* $\boldsymbol{\Omega}$ (recalling §1.7 ff.). Thus, expressions (3.13.8c, h) become, respectively,

$$\boldsymbol{I} = \partial\boldsymbol{p}/\partial t + \boldsymbol{\Omega} \times \boldsymbol{p} \qquad \text{and} \qquad \boldsymbol{A}_\bullet = \partial\boldsymbol{H}_\bullet/\partial t + \boldsymbol{\Omega} \times \boldsymbol{H}_\bullet + \boldsymbol{v}_\bullet \times \boldsymbol{p}. \tag{3.13.9}$$

Special Cases

- If $\bullet = \blacklozenge = G$, then $\boldsymbol{v}_\bullet = \boldsymbol{v}_G$ (or, if $\boldsymbol{v}_\bullet = \boldsymbol{0}$), and so (3.13.9) specialize to

$$\boldsymbol{I} = \partial\boldsymbol{p}/\partial t + \boldsymbol{\Omega} \times \boldsymbol{p} \qquad \text{and} \qquad \boldsymbol{A}_G = \partial\boldsymbol{H}_G/\partial t + \boldsymbol{\Omega} \times \boldsymbol{H}_G \qquad (\text{with } \boldsymbol{H}_G = \boldsymbol{h}_G). \tag{3.13.9a}$$

- If $\boldsymbol{\Omega} = \boldsymbol{\omega}$ and $\bullet = \blacklozenge$ (i.e., for *body-fixed* axes $\blacklozenge$–xyz), then $\partial\boldsymbol{r}_{G/\blacklozenge}/\partial t = \boldsymbol{0}$ and $\partial\boldsymbol{\omega}/\partial t = d\boldsymbol{\omega}/dt \equiv \boldsymbol{\alpha}$ = *inertial angular acceleration of* B, and so (3.13.9), with (3.13.7f, g), reduce to

$$\begin{aligned} \boldsymbol{I} &= \partial\boldsymbol{p}/\partial t + \boldsymbol{\omega} \times \boldsymbol{p} \\ &= m\big[\partial\boldsymbol{v}_\blacklozenge/\partial t + \boldsymbol{\omega} \times \boldsymbol{v}_\blacklozenge + \boldsymbol{\omega} \times (\boldsymbol{\omega} \times \boldsymbol{r}_{G/\blacklozenge}) + \boldsymbol{\alpha} \times \boldsymbol{r}_{G/\blacklozenge}\big], \end{aligned} \tag{3.13.9b}$$

$$\begin{aligned} \boldsymbol{A}_\blacklozenge &= \partial\boldsymbol{H}_\blacklozenge/\partial t + \boldsymbol{\omega} \times \boldsymbol{H}_\blacklozenge + \boldsymbol{v}_\blacklozenge \times \boldsymbol{p} \\ &= \partial\boldsymbol{h}_\blacklozenge/\partial t + \boldsymbol{\omega} \times \boldsymbol{h}_\blacklozenge + m\boldsymbol{r}_{G/\blacklozenge} \times [\partial\boldsymbol{v}_\blacklozenge/\partial t + (\boldsymbol{\omega} \times \boldsymbol{v}_\blacklozenge)]. \end{aligned} \tag{3.13.9c}$$

- If $\boldsymbol{\Omega} = \boldsymbol{\omega}$ and $\bullet = \blacklozenge = G$, the last two terms in (3.13.9b) and the last two (of the four) terms of (3.13.9c) vanish, and so these equations reduce, respectively, to

$$\boldsymbol{I} = m(\partial\boldsymbol{v}_G/\partial t + \boldsymbol{\omega} \times \boldsymbol{v}_G), \qquad \boldsymbol{A}_G = \partial\boldsymbol{h}_G/\partial t + \boldsymbol{\omega} \times \boldsymbol{h}_G. \tag{3.13.9d}$$

The above show clearly the *decoupling* of the two motions: the *translatory* ($\boldsymbol{v}_G$) from the *rotatory* ($\boldsymbol{\omega}$) in the system inertia vectors: for the rotatory motion, G can be viewed as stationary (Euler, 1749). Indeed, if $\boldsymbol{v}_G = \boldsymbol{0}$, we are left with the *sole* system vector

$$\boldsymbol{A}_G = \partial\boldsymbol{h}_G/\partial t + \boldsymbol{\omega} \times \boldsymbol{h}_G = \partial/\partial t(\partial T_R/\partial\boldsymbol{\omega}) + \boldsymbol{\omega} \times (\partial T_R/\partial\boldsymbol{\omega}). \tag{3.13.9e}$$

Component Representations

A better understanding of the (difficulties involved in the) preceding equations may be achieved if we express them in components. Thus, along *body-fixed* axes $\blacklozenge$–xyz, eqs. (3.13.9b, c) translate to the following system of *six* coupled expressions for the six quasi velocities $v_{\blacklozenge;x,y,z}$ and $\omega_{x,y,z}$:

$$\begin{aligned} I_x = m\Big\{ & \dot{v}_{\blacklozenge,x} + (\omega_y v_{\blacklozenge,z} - \omega_z v_{\blacklozenge,y}) \\ & + \big[\omega_y(\omega_x y_{G/\blacklozenge} - \omega_y x_{G/\blacklozenge}) - \omega_z(\omega_z x_{G/\blacklozenge} - \omega_x z_{G/\blacklozenge})\big] \\ & + (\dot{\omega}_y z_{G/\blacklozenge} - \dot{\omega}_z y_{G/\blacklozenge})\Big\}, \quad \text{etc., cyclically,} \end{aligned} \tag{3.13.10a}$$

$$\begin{aligned} A_{\blacklozenge,x} = {} & I_{\blacklozenge,xx}\dot{\omega}_x + I_{\blacklozenge,xy}\dot{\omega}_y + I_{\blacklozenge,xz}\dot{\omega}_z \\ & + \big[-(I_{\blacklozenge,yy} - I_{\blacklozenge,zz})\omega_y\omega_z + I_{\blacklozenge,xy}\omega_x\omega_z + I_{\blacklozenge,xz}\omega_x\omega_y + I_{\blacklozenge,yz}({\omega_y}^2 + {\omega_z}^2)\big] \\ & + m\Big\{(y_{G/\blacklozenge}\,\dot{v}_{\blacklozenge,z} - z_{G/\blacklozenge}\,\dot{v}_{\blacklozenge,y}) \\ & + \big[y_{G/\blacklozenge}(\omega_x v_{\blacklozenge,y} - \omega_y v_{\blacklozenge,x}) - z_{G/\blacklozenge}(\omega_y v_{\blacklozenge,z} - \omega_z v_{\blacklozenge,y})\big]\Big\}, \quad \text{etc., cyclically;} \end{aligned} \tag{3.13.10b}$$

while (3.13.9d), if the corresponding body-axes $G-xyz$ are also *principal*, $G-123$, take the well-known (decoupled!) Eulerian form as follows:

$$\begin{aligned} I_x &= m[\dot{v}_{G,x} + (\omega_y v_{G,z} - \omega_z v_{G,y})] \\ &\equiv m[\dot{v}_{G,1} + (\omega_2 v_{G,3} - \omega_3 v_{G,2})] = I_1, \quad \text{etc., cyclically,} \end{aligned} \tag{3.13.10c}$$

$$\begin{aligned} A_{\blacklozenge,x} &= I_{\blacklozenge,x}\,\dot{\omega}_x - (I_{\blacklozenge,y} - I_{\blacklozenge,z})\omega_y\omega_z \\ &\equiv I_{\blacklozenge,1}\,\dot{\omega}_1 - (I_{\blacklozenge,2} - I_{\blacklozenge,3})\omega_2\omega_3 = A_{\blacklozenge,1}, \quad \text{etc., cyclically.} \end{aligned} \tag{3.13.10d}$$

As (3.13.9c) shows, the expressions (3.13.10d) also hold with G replaced by *any body- and space-fixed point*; if one exists.

Lagrangean Forms

Let us now see the connection of the above with analytical mechanics. In terms of the T-gradients (3.13.7f, g), eqs. (3.13.9 ff.) take the following Lagrangean forms:

(i) $$\boldsymbol{I} = \partial/\partial t(\partial T/\partial \boldsymbol{v}_\blacklozenge) + \boldsymbol{\Omega} \times (\partial T/\partial \boldsymbol{v}_\blacklozenge) \tag{3.13.11a}$$

[recalling that $\partial T(\boldsymbol{v}_\blacklozenge, \boldsymbol{\omega})/\partial \boldsymbol{v}_\blacklozenge = \partial T(\boldsymbol{v}_G, \boldsymbol{\omega})/\partial \boldsymbol{v}_G = \boldsymbol{p}$],

$$\boldsymbol{A}_\bullet = \partial/\partial t(\partial T/\partial \boldsymbol{\omega}) + \boldsymbol{\Omega} \times (\partial T/\partial \boldsymbol{\omega}) + \boldsymbol{v}_\bullet \times (\partial T/\partial \boldsymbol{v}_\blacklozenge), \tag{3.13.11b}$$

and, in components (intermediate axes),

$$I_x = (\partial T/\partial v_{\blacklozenge,x})^{\cdot} + \Omega_y(\partial T/\partial v_{\blacklozenge,z}) - \Omega_z(\partial T/\partial v_{\blacklozenge,y}) \quad \text{etc., cyclically,} \tag{3.13.11c}$$

$$\begin{aligned} A_{\bullet,x} = {} & (\partial T/\partial \omega_x)^{\cdot} + \Omega_y(\partial T/\partial \omega_z) - \Omega_z(\partial T/\partial \omega_y) \\ & + v_{\bullet,y}(\partial T/\partial v_{\blacklozenge,z}) - v_{\bullet,z}(\partial T/\partial v_{\blacklozenge,y}), \quad \text{etc., cyclically;} \end{aligned} \tag{3.13.11d}$$

(ii) $$\boldsymbol{I} = \partial/\partial t(\partial T/\partial \boldsymbol{v}_\blacklozenge) + \boldsymbol{\omega} \times (\partial T/\partial \boldsymbol{v}_\blacklozenge), \tag{3.13.11e}$$

$$\boldsymbol{A}_\bullet = \partial/\partial t(\partial T/\partial \boldsymbol{\omega}) + \boldsymbol{\omega} \times (\partial T/\partial \boldsymbol{\omega}) + \boldsymbol{v}_\blacklozenge \times (\partial T/\partial \boldsymbol{v}_\blacklozenge), \tag{3.13.11f}$$

and, in components (body-fixed axes),

$$I_x = (\partial T/\partial v_{\blacklozenge,x})^{\cdot} + \omega_y(\partial T/\partial v_{\blacklozenge,z}) - \omega_z(\partial T/\partial v_{\blacklozenge,y}), \quad \text{etc., cyclically,} \tag{3.13.11g}$$

$$A_{\blacklozenge,x} = (\partial T/\partial \omega_x)^{\cdot} + \omega_y(\partial T/\partial \omega_z) - \omega_z(\partial T/\partial \omega_y) + v_{\blacklozenge,y}(\partial T/\partial v_{\blacklozenge,z}) - v_{\blacklozenge,z}(\partial T/\partial v_{\blacklozenge,y}), \quad \text{etc., cyclically;} \tag{3.13.11h}$$

(iii)

$$\boldsymbol{I} = \partial/\partial t(\partial T/\partial \boldsymbol{v}_G) + \boldsymbol{\Omega} \times (\partial T/\partial \boldsymbol{v}_G), \tag{3.13.11i}$$

$$\boldsymbol{A}_G = \partial/\partial t(\partial T/\partial \boldsymbol{\omega}) + \boldsymbol{\Omega} \times (\partial T/\partial \boldsymbol{\omega}), \tag{3.13.11j}$$

and, in components (intermediate axes),

$$I_x = (\partial T/\partial v_{G,x})^{\cdot} + \Omega_y(\partial T/\partial v_{G,z}) - \Omega_z(\partial T/\partial v_{G,y}), \quad \text{etc., cyclically,} \tag{3.13.11k}$$

$$A_{G,x} = (\partial T/\partial \omega_x)^{\cdot} + \Omega_y(\partial T/\partial \omega_z) - \Omega_z(\partial T/\partial \omega_y), \quad \text{etc., cyclically.} \tag{3.13.11l}$$

For additional forms, see, for example, Heun (1906, pp. 269–271; 1913, pp. 397–401), Suslov (1946, pp. 490–521), Winkelmann and Grammel [1927, pp. 446–449, via the (not very popular) *motor calculus* of R. von Mises (1924)], Winkelmann [1929(b), pp. 14–27]; also Hölder (1939), and §3.16, this volume.

Example 3.13.1 *Kinetic Energy of a Rigid Body.* A thin homogeneous disk D, of mass m and radius r, with fixed center O, rolls without slipping on a fixed rough plane P; its plane thus makes a constant angle (of nutation) θ with P. Let us calculate its kinetic energy if the disk/plane contact point C rotates with a constant angular velocity $\boldsymbol{\omega}_o$ on the circular projection of D on P (fig. 3.31).

Since $\boldsymbol{v}_C = \boldsymbol{0}$ and $\boldsymbol{v}_O = \boldsymbol{0}$, the basic velocity equation $\boldsymbol{v}_C = \boldsymbol{v}_O + \boldsymbol{\omega} \times \boldsymbol{r}_{C/O}$ yields $\boldsymbol{\omega}$: *parallel to the diameter COA*; alternatively, since the velocities of two of its points, C and O, vanish, the disk can only turn about the axis CO. As fig. 3.31(b) shows, $\omega = \omega_o \sin\theta$. [Or, we consider a point B along the disk axis, at distance l from O. During the motion: (i) B traces a circle of radius $l\sin\theta$ (on a plane parallel to P) with angular velocity ω_o, and hence velocity $v_B = \omega_o(l\sin\theta)$; and, simultaneously, (ii) as part of the rotating disk, B turns (instantaneously) about CA with angular velocity

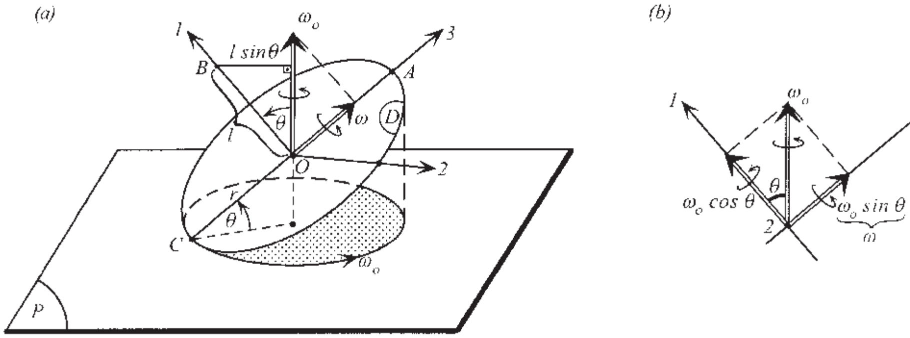

Figure 3.31 (a) Circular disk D rolling at an angle θ (nutation) on a fixed plane P; (b) details of decomposition of $\boldsymbol{\omega}_o$ along axes 123.

$\boldsymbol{\omega}$, and therefore has velocity $v_B = \omega l$, Q.E.D.] By König's theorem, and principal central axes O–123 [i.e., $\boldsymbol{\omega} = (0, 0, \omega)$], we readily find

$$\begin{aligned}2T &= I_{O,1}\omega_1{}^2 + I_{O,2}\omega_2{}^2 + I_{O,3}\omega_3{}^2\\ &= (mr^2/2)(0) + (mr^2/4)(0) + (mr^2/4)(\omega_o \sin\theta)^2\\ &= (mr^2 \sin^2\theta/4)\omega_o{}^2 = I_{COA}\,\omega^2. \qquad \text{(a)}\end{aligned}$$

Example 3.13.2 *Kinetic Energy of a Rigid Body*. Let us calculate the kinetic energy of a homogeneous and right circular cone, of radius r, height h, and half angle θ, rolling without slipping on a fixed rough plane P (fig. 3.32), with $\boldsymbol{v}_O = \mathbf{0}$.

Reasoning as in the preceding example—that is, since $\boldsymbol{v}_O = \mathbf{0}$ and $\boldsymbol{v}_B = \mathbf{0}$—we conclude that $\boldsymbol{\omega}$ is parallel to the cone generator OB. If the angular velocity of turning of OB around the perpendicular to the plane is $\boldsymbol{\omega}_o$, then, as fig. 3.32(b) shows,

$$(r\cos\theta)\omega = (h\sin\theta)\omega = (h\cos\theta)\omega_o \;\Rightarrow\; \omega = \omega_o \cot\theta, \qquad \text{(a)}$$

and so along the (intermediate) principal axes O–123,

$$\boldsymbol{\omega} = (-\omega\cos\theta,\ \omega\sin\theta,\ 0) = [-(\omega_o\cot\theta)\cos\theta,\ (\omega_o\cot\theta)\sin\theta, 0]; \qquad \text{(b)}$$

also, from tables,

$$I_{O,1} = (3/10)m\,r^2, \qquad I_{O,2} = I_{O,3} = (3m/5)[h^2 + (r^2/4)].$$

Therefore, König's theorem yields (dropping the subscript O from the I's)

$$\begin{aligned}2T &= I_1\,\omega_1{}^2 + I_2\,\omega_2{}^2 + I_3\,\omega_3{}^2\\ &= [(3/10)mr^2](-\omega_o\cos^2\theta/\sin\theta)^2\\ &\quad + \{(3m/5)[h^2 + (r^2/4)]\}(\omega_o\cos\theta)^2 + \{(3m/5)[h^2 + (r^2/4)]\}(0)\\ &= \{[(3m/20)(r^2 + 6h^2)]\cos^2\theta\}\omega_o{}^2\\ &= \{[(3m/20)(r^2 + 6h^2)]\sin^2\theta\}\omega^2\\ &= I_1(-\omega\cos\theta)^2 + I_2(\omega\sin\theta)^2 = (I_1\cos^2\theta + I_2\sin^2\theta)\,\omega^2 = I_{OB}\,\omega^2. \qquad \text{(c)}\end{aligned}$$

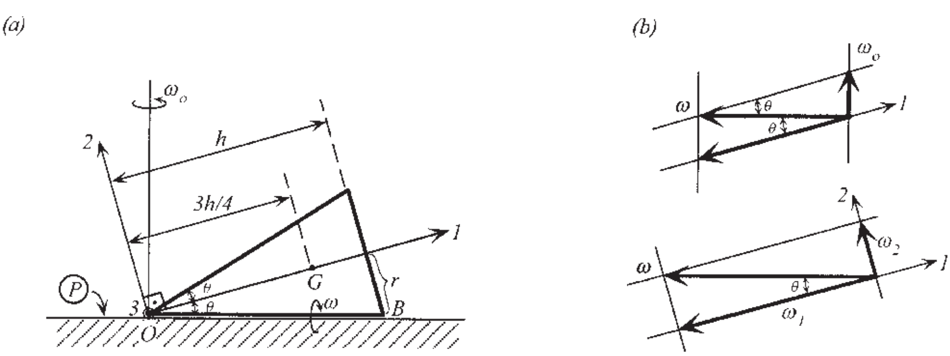

Figure 3.32 (a) Rolling of a right and circular cone with one point fixed, on a rough and fixed plane P; (b) decompositions of ω along ω_o and 1, and along 1 and 2.

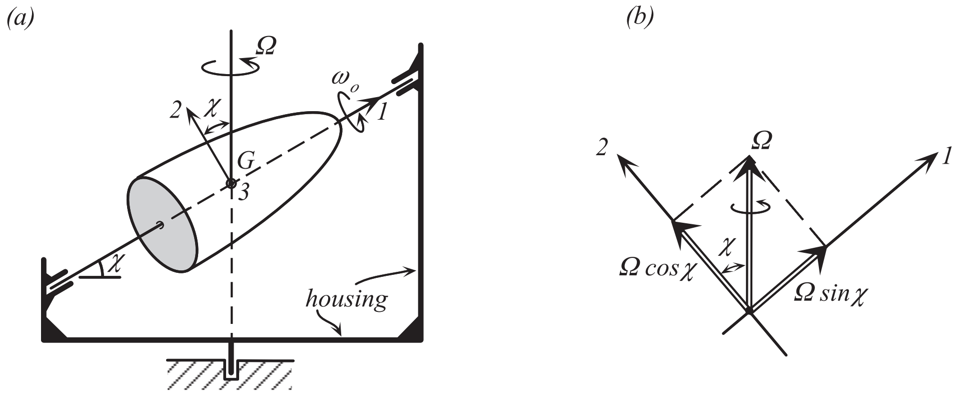

Figure 3.33 (a) Gyrostat spinning inside a housing; (b) details of decomposition of $\boldsymbol{\Omega}$ along 123.

Example 3.13.3 *Kinetic Energy of a Rigid Body*. We consider here a homogeneous rigid body of revolution with central principal moments of inertia $I_1 \equiv A$, $I_2 = I_3 \equiv B$ (fig. 3.33; $G =$ *center of mass*), spinning about its axis of symmetry $G1$ with angular velocity $\boldsymbol{\omega}_o$. This axis is fixed at a constant angle χ in a housing, as shown, and this latter turns about a fixed vertical axis with angular velocity $\boldsymbol{\Omega}$.

Let us calculate the kinetic energy of this body (gyrostat). Here, clearly,

$$\boldsymbol{\omega} = (\omega_1, \omega_2, \omega_3) = (\omega_o + \Omega \sin\chi,\ \Omega\cos\chi,\ 0), \tag{a}$$

and, therefore, by König's theorem ($\boldsymbol{v}_C = \mathbf{0}$)

$$2T = I_1\,\omega_1{}^2 + I_2\,\omega_2{}^2 + I_3\,\omega_3{}^2 = A(\omega_o + \Omega\sin\chi)^2 + B(\Omega\cos\chi)^2 + B(0)^2. \tag{b}$$

Example 3.13.4 *Rigid Body: System Force and Kinematico-Inertial Identities*. We consider here a rigid body B in general spatial motion. Let us calculate the components of its Lagrangean (holonomic) forces $\boldsymbol{Q} = \{Q_k;\ k = 1, \ldots, 6\}$ in terms of the corresponding elementary vectorial quantities.

With reference to fig. 3.34, and recalling the results of § 3.4, we find, successively,

$$\begin{aligned} Q_k &\equiv \mathcal{S}\, d\boldsymbol{F}\cdot\boldsymbol{e}_k = \mathcal{S}\, d\boldsymbol{F}\cdot(\partial\boldsymbol{r}/\partial q_k) = \mathcal{S}\, d\boldsymbol{F}\cdot(\partial\boldsymbol{v}/\partial\dot{q}_k) \\ &= \mathcal{S}\, d\boldsymbol{F}\cdot(\partial/\partial\dot{q}_k)(\boldsymbol{v}_G + \boldsymbol{\omega}\times\boldsymbol{r}_{/G}) \end{aligned}$$

[but $(\partial/\partial\dot{q}_k)(\boldsymbol{\omega}\times\boldsymbol{r}_{/G}) = (\partial\boldsymbol{\omega}/\partial\dot{q}_k)\times\boldsymbol{r}_{/G} + \boldsymbol{\omega}\times(\partial\boldsymbol{r}_{/G}/\partial\dot{q}_k) = (\partial\boldsymbol{\omega}/\partial\dot{q}_k)\times\boldsymbol{r}_{/G}$ (explain)]

$$\begin{aligned} &= \mathcal{S}\, d\boldsymbol{F}\cdot(\partial\boldsymbol{v}_G/\partial\dot{q}_k) + \mathcal{S}\, d\boldsymbol{F}\cdot[(\partial\boldsymbol{\omega}/\partial\dot{q}_k)\times\boldsymbol{r}_{/G}] \\ &= (\partial\boldsymbol{v}_G/\partial\dot{q}_k)\cdot\mathcal{S}\, d\boldsymbol{F} + (\partial\boldsymbol{\omega}/\partial\dot{q}_k)\cdot\mathcal{S}\,(\boldsymbol{r}_{/G}\times d\boldsymbol{F}) \\ &\equiv \boldsymbol{F}\cdot(\partial\boldsymbol{v}_G/\partial\dot{q}_k) + \boldsymbol{M}_G\cdot(\partial\boldsymbol{\omega}/\partial\dot{q}_k), \end{aligned} \tag{a}$$

where $\boldsymbol{F}(\boldsymbol{M}_G) =$ *resultant force* (*moment*) *of all* $d\boldsymbol{F}$, acting at G (about G). Actually, this identity holds for any other chosen *body-fixed* point (pole) ◆.

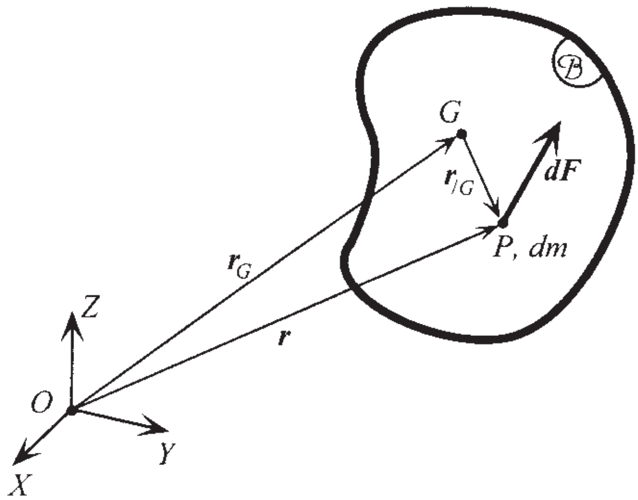

Figure 3.34 Impressed force $d\boldsymbol{F}$ applied to a typical particle P of a rigid body B.

Further, if the body is *unconstrained*, then, by Euler's principles, $\boldsymbol{F} = m\,\boldsymbol{a}_G \equiv d\boldsymbol{p}/dt$ and $\boldsymbol{M}_G = d\boldsymbol{H}_G/dt$, where $\boldsymbol{H}_G = \mathbf{S}\, \boldsymbol{r}_{/G} \times (dm\, \boldsymbol{v})$ [(16.5a ff.)], and so we can rewrite (a) in the kinetic form

$$Q_k = (m\,\boldsymbol{a}_G)\cdot(\partial \boldsymbol{v}_G/\partial \dot{q}_k) + (d\boldsymbol{H}_G/dt)\cdot(\partial \boldsymbol{\omega}/\partial \dot{q}_k). \tag{b}$$

[We can also replace in the above $\partial \boldsymbol{v}_G/\partial \dot{q}_k$ with $\partial \boldsymbol{a}_G/\partial \ddot{q}_k$. Then,

$$2[m\,\boldsymbol{a}_G\cdot(\partial \boldsymbol{v}_G/\partial \dot{q}_k)] = \partial(m\,\boldsymbol{a}_G\cdot\boldsymbol{a}_G)/\partial \ddot{q}_k, \text{ etc. (à la Appell)}] \tag{c}$$

Hence, we finally obtain (rather effortlessly!) the following important kinematico-inertial identities:

$$E_k \equiv (\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k = (d\boldsymbol{p}/dt)\cdot(\partial \boldsymbol{v}_G/\partial \dot{q}_k) + (d\boldsymbol{H}_G/dt)\cdot(\partial \boldsymbol{\omega}/\partial \dot{q}_k); \tag{d}$$

which hold even under additional constraints, as long as the q's are *holonomic coordinates*.

Example 3.13.5 *Rigid Body: System Force and Kinematico-Inertial Identities.* Let us prove eq. (d) of the preceding example directly, from general Lagrangean identities. We have, successively,

$$\begin{aligned} E_k &\equiv \mathbf{S}\, dm\, \boldsymbol{a}\cdot(\partial \boldsymbol{v}/\partial \dot{q}_k) \\ &= \mathbf{S}\, dm\, \boldsymbol{a}\cdot[(\partial \boldsymbol{v}_G/\partial \dot{q}_k) + (\partial \boldsymbol{\omega}/\partial \dot{q}_k)\times \boldsymbol{r}_{/G}] \\ &= \cdots = m\,\boldsymbol{a}_G\cdot(\partial \boldsymbol{v}_G/\partial \dot{q}_k) + \left[\mathbf{S}\, \boldsymbol{r}_{/G}\times(dm\,\boldsymbol{a})\right]\cdot(\partial \boldsymbol{\omega}/\partial \dot{q}_k) \end{aligned}$$

$$\Big[\text{but } d\boldsymbol{H}_G/dt = \Big[\mathcal{S}\, \boldsymbol{r}_{/G} \times (dm\ \boldsymbol{v})\Big]^{\cdot} = \mathcal{S}\,[\boldsymbol{v}_{/G} \times (dm\,\boldsymbol{v}) + \boldsymbol{r}_{/G} \times (dm\,\boldsymbol{a})]$$
$$= \mathcal{S}\,(\boldsymbol{v} - \boldsymbol{v}_G) \times (dm\ \boldsymbol{v}) + \mathcal{S}\,\boldsymbol{r}_{/G} \times (dm\ \boldsymbol{a})$$
$$= \boldsymbol{0} + \mathcal{S}\,\boldsymbol{r}_{/G} \times (dm\ \boldsymbol{a}) \quad \text{(explain)}\Big],$$

and so, finally,

$$E_k = (d\boldsymbol{p}/dt) \cdot (\partial \boldsymbol{v}_G/\partial \dot{q}_k) + (d\boldsymbol{H}_G/dt) \cdot (\partial \boldsymbol{\omega}/\partial \dot{q}_k), \quad \text{Q.E.D.} \tag{a}$$

3.14 THE RIGID BODY: APPELLIAN KINEMATICO-INERTIAL IDENTITIES

Here, we develop *explicit* expressions for the Appellian $S \equiv \mathcal{S}\,(1/2)dm\,\boldsymbol{a} \cdot \boldsymbol{a}$ of a *single* rigid body. (The Appellian of a system of rigid bodies is the sum of the Appellians of its parts; just like the mass and kinetic energy.)

Fixed-Point Rotation

We begin with a rigid body B moving (rotating) about a *fixed point* $\blacklozenge$. Since, then, the inertial acceleration of a typical body particle is

$$\boldsymbol{a} = d\boldsymbol{v}/dt = d\boldsymbol{v}_{/\blacklozenge}/dt = d/dt(\boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge}) = \boldsymbol{\alpha} \times \boldsymbol{r}_{/\blacklozenge} + \boldsymbol{\omega} \times (\boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge}), \tag{3.14.1a}$$

the Appellian of B, *to within acceleration terms* $\equiv$ *Appell-important terms,* becomes

$$S = \mathcal{S}\,(1/2)\,dm[(\boldsymbol{\alpha} \times \boldsymbol{r}_{/\blacklozenge}) \cdot (\boldsymbol{\alpha} \times \boldsymbol{r}_{/\blacklozenge})] + \mathcal{S}\,dm\{(\boldsymbol{\alpha} \times \boldsymbol{r}_{/\blacklozenge}) \cdot [\boldsymbol{\omega} \times (\boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge})]\}. \tag{3.14.1b}$$

Now: (i) The *first* integral in (3.14.1b) equals T_R, eq. (3.13.2b), *but with* $\boldsymbol{\omega}$ *replaced with* $\boldsymbol{\alpha}$. Therefore, reasoning as there, we find

$$\mathcal{S}\,(1/2)dm[(\boldsymbol{\alpha} \times \boldsymbol{r}_{/\blacklozenge}) \cdot (\boldsymbol{\alpha} \times \boldsymbol{r}_{/\blacklozenge})] = (1/2)\boldsymbol{\alpha} \cdot \boldsymbol{I}_{\blacklozenge} \cdot \boldsymbol{\alpha}. \tag{3.14.1c}$$

(ii) The *second* integral, in view of the transformations [recalling the identities: $\boldsymbol{a} \cdot (\boldsymbol{b} \times \boldsymbol{c}) = \boldsymbol{b} \cdot (\boldsymbol{c} \times \boldsymbol{a}) = \boldsymbol{c} \cdot (\boldsymbol{a} \times \boldsymbol{b})$ and $\boldsymbol{a} \times (\boldsymbol{b} \times \boldsymbol{c}) = (\boldsymbol{a} \cdot \boldsymbol{c})\boldsymbol{b} - (\boldsymbol{a} \cdot \boldsymbol{b})\boldsymbol{c}$, holding for any three vectors $\boldsymbol{a}$, $\boldsymbol{b}$, $\boldsymbol{c}$]:

$$(\boldsymbol{\alpha} \times \boldsymbol{r}_{/\blacklozenge}) \cdot [\boldsymbol{\omega} \times (\boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge})] = (\boldsymbol{\alpha} \times \boldsymbol{r}_{/\blacklozenge}) \cdot [(\boldsymbol{\omega} \cdot \boldsymbol{r}_{/\blacklozenge})\,\boldsymbol{\omega} - \omega^2\,\boldsymbol{r}_{/\blacklozenge}]$$
$$= (\boldsymbol{\omega} \times \boldsymbol{\alpha}) \cdot [(\boldsymbol{\omega} \cdot \boldsymbol{r}_{/\blacklozenge})\,\boldsymbol{r}_{/\blacklozenge}]$$
$$[\text{since } (\boldsymbol{\alpha} \times \boldsymbol{r}_{/\blacklozenge}) \cdot \boldsymbol{r}_{/\blacklozenge} = 0 \ \text{ and } \ (\boldsymbol{\alpha} \times \boldsymbol{r}_{/\blacklozenge}) \cdot \boldsymbol{\omega} = (\boldsymbol{\omega} \times \boldsymbol{\alpha}) \cdot \boldsymbol{r}_{/\blacklozenge}]$$
$$= (\boldsymbol{\alpha} \times \boldsymbol{\omega}) \cdot [\boldsymbol{r}_{/\blacklozenge} \times (\boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge})]$$
$$[\text{since} \quad (\boldsymbol{\omega} \times \boldsymbol{\alpha}) \cdot \boldsymbol{\omega} = 0], \tag{3.14.1d}$$

reduces to [recalling the definition of $\boldsymbol{h}_{\blacklozenge}$, (3.13.2c)]

$$(\boldsymbol{\alpha} \times \boldsymbol{\omega}) \cdot \mathcal{S}\,dm\,[\boldsymbol{r}_{/\blacklozenge} \times (\boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge})] = (\boldsymbol{\alpha} \times \boldsymbol{\omega}) \cdot \boldsymbol{h}_{\blacklozenge}. \tag{3.14.1e}$$

The above results allow us to rewrite (3.14.1b) in the following equivalent forms:

$$\begin{aligned} S &= (1/2)\boldsymbol{\alpha}\cdot\boldsymbol{I}_\blacklozenge\cdot\boldsymbol{\alpha} + \boldsymbol{\alpha}\cdot(\boldsymbol{\omega}\times\boldsymbol{h}_\blacklozenge) \\ &= (1/2)\boldsymbol{\alpha}\cdot\boldsymbol{I}_\blacklozenge\cdot\boldsymbol{\alpha} + \boldsymbol{\alpha}\cdot[\boldsymbol{\omega}\times(\boldsymbol{I}_\blacklozenge\cdot\boldsymbol{\omega})] \\ &= (1/2)\boldsymbol{\alpha}\cdot\boldsymbol{I}_\blacklozenge\cdot\boldsymbol{\alpha} + (\boldsymbol{\alpha}\times\boldsymbol{\omega})\cdot(\boldsymbol{I}_\blacklozenge\cdot\boldsymbol{\omega}); \end{aligned} \tag{3.14.1f}$$

the second term/sum being a *bilinear* form in the components of $\boldsymbol{\alpha}\times\boldsymbol{\omega}$ and $\boldsymbol{\omega}$, with coefficients the components of the inertia tensor $\boldsymbol{I}_\blacklozenge$.

Component Forms

It is not hard to see that in terms of the components of $\boldsymbol{\omega}$, $\boldsymbol{\alpha}$, $\boldsymbol{I}_\blacklozenge$ along *body-fixed* axes, $\blacklozenge$-xyz ($\Rightarrow \alpha_x = \dot{\omega}_x$, etc.), the expression (3.14.1f) assumes the explicit form

$$\begin{aligned} S = (1/2)&(I_{\blacklozenge,xx}\,\alpha_x{}^2 + I_{\blacklozenge,yy}\,\alpha_y{}^2 + I_{\blacklozenge,zz}\,\alpha_z{}^2 \\ &+ 2\,I_{\blacklozenge,xy}\,\alpha_x\alpha_y + 2\,I_{\blacklozenge,xz}\,\alpha_x\alpha_z + 2\,I_{\blacklozenge,yz}\,\alpha_y\alpha_z) \\ &+ [(\alpha_y\,\omega_z - \alpha_z\,\omega_y)(I_{\blacklozenge,xx}\,\omega_x + I_{\blacklozenge,xy}\,\omega_y + I_{\blacklozenge,xz}\,\omega_z) \\ &+ (\alpha_z\,\omega_x - \alpha_x\,\omega_z)(I_{\blacklozenge,yx}\,\omega_x + I_{\blacklozenge,yy}\,\omega_y + I_{\blacklozenge,yz}\,\omega_z) \\ &+ (\alpha_x\,\omega_y - \alpha_y\,\omega_x)(I_{\blacklozenge,zx}\,\omega_x + I_{\blacklozenge,zy}\,\omega_y + I_{\blacklozenge,zz}\,\omega_z)]; \end{aligned} \tag{3.14.2a}$$

or, if $\blacklozenge$–xyz are also *principal axes* [i.e., $\boldsymbol{I}_\blacklozenge$ = *diagonal* $(I_{\blacklozenge,x}, I_{\blacklozenge,y}, I_{\blacklozenge,z})$],

$$\begin{aligned} S &= (1/2)(I_{\blacklozenge,x}\,\alpha_x{}^2 + I_{\blacklozenge,y}\,\alpha_y{}^2 + I_{\blacklozenge,z}\,\alpha_z{}^2) \\ &\quad + [(\alpha_y\,\omega_z - \alpha_z\,\omega_y)(I_{\blacklozenge,x}\,\omega_x) + (\alpha_z\,\omega_x - \alpha_x\,\omega_z)(I_{\blacklozenge,y}\,\omega_y) \\ &\quad + (\alpha_x\,\omega_y - \alpha_y\,\omega_x)(I_{\blacklozenge,z}\,\omega_z)] \\ &= (1/2)(I_{\blacklozenge,x}\,\alpha_x{}^2 + I_{\blacklozenge,y}\,\alpha_y{}^2 + I_{\blacklozenge,z}\,\alpha_z{}^2) \\ &\quad - \alpha_x[(I_{\blacklozenge,y} - I_{\blacklozenge,z})\omega_y\,\omega_z] - \alpha_y[(I_{\blacklozenge,z} - I_{\blacklozenge,x})\omega_z\,\omega_x] \\ &\quad - \alpha_z[(I_{\blacklozenge,x} - I_{\blacklozenge,y})\omega_x\,\omega_y]. \end{aligned} \tag{3.14.2b}$$

From the latter we immediately obtain the well-known Eulerian angular inertia components (Gibbs, 1879)

$$\begin{aligned} A_x &= \partial S/\partial\alpha_x = I_{\blacklozenge,x}\,\alpha_x - (I_{\blacklozenge,y} - I_{\blacklozenge,z})\omega_y\,\omega_z \\ &\quad [= I_{\blacklozenge,x}\,\dot{\omega}_x - (I_{\blacklozenge,y} - I_{\blacklozenge,z})\omega_y\,\omega_z = \partial S/\partial\dot{\omega}_x], \quad \text{etc., cyclically.} \end{aligned} \tag{3.14.2c}$$

REMARKS

(i) If the axes $\blacklozenge$-xyz are still principal but *non–body-fixed*, rotating with inertial angular velocity $\boldsymbol{\Omega} = (\Omega_x, \Omega_y, \Omega_z)$, then $\boldsymbol{\alpha} = \partial\boldsymbol{\omega}/\partial t + \boldsymbol{\Omega}\times\boldsymbol{\omega}$, or, in components,

$$\alpha_x = \dot{\omega}_x + (\Omega_y\,\omega_z - \Omega_z\,\omega_y), \quad \text{etc., cyclically,}$$

and so (3.14.2b) is replaced by

$$\begin{aligned} S &= (1/2)[I_{\blacklozenge,x}(\dot{\omega}_x)^2 + I_{\blacklozenge,y}(\dot{\omega}_y)^2 + I_{\blacklozenge,z}(\dot{\omega}_z)^2] \\ &\quad - \dot{\omega}_x[(I_{\blacklozenge,y} - I_{\blacklozenge,z})\omega_y\,\omega_z + I_{\blacklozenge,x}(\omega_y\,\Omega_z - \omega_z\,\Omega_y)] - \dot{\omega}_y[\ldots] - \dot{\omega}_z[\ldots]. \end{aligned} \tag{3.14.2d}$$

(ii) If the axes $\blacklozenge$–xyz are *nonprincipal* and non–body-fixed, then it can be shown (verify it!) that we must add the following terms to the right side of (3.14.2d):

$$-I_{\blacklozenge,yz}\{-\dot{\omega}_y\,\dot{\omega}_z-\dot{\omega}_x({\omega_y}^2-{\omega_z}^2)+\dot{\omega}_y[\omega_y(\omega_x-\Omega_x)+\omega_x\,\Omega_y]$$
$$-\dot{\omega}_z[\omega_z(\omega_x-\Omega_x)+\omega_x\,\Omega_z]\}-I_{\blacklozenge,zx}\{\ldots\}-I_{\blacklozenge,xy}\{\ldots\}. \tag{3.14.2e}$$

For detailed scalar derivations of the above see, for example, Appell [1900(a), (b)].

General Motion

In this case, the inertial acceleration of a typical body particle is

$$\boldsymbol{a}=d\boldsymbol{v}/dt=\boldsymbol{a}_{\blacklozenge}+\boldsymbol{a}_{/\blacklozenge}=\boldsymbol{a}_{\blacklozenge}+\boldsymbol{\alpha}\times\boldsymbol{r}_{/\blacklozenge}+\boldsymbol{\omega}\times(\boldsymbol{\omega}\times\boldsymbol{r}_{/\blacklozenge}). \tag{3.14.3a}$$

Now, to avoid long calculations, we make the following observations:

(i) The difference between the corresponding *velocity* formula and the first *two* terms in (3.14.3a) is that, there, $\boldsymbol{a}_{\blacklozenge}$ and $\boldsymbol{\alpha}$ are replaced, respectively, by $\boldsymbol{v}_{\blacklozenge}$ and $\boldsymbol{\omega}$. Therefore, we will obtain the corresponding terms in S if, in the earlier T-expressions (3.13.2 ff.); that is,

$$2T=m\,{v_{\blacklozenge}}^2+2m(\boldsymbol{v}_{\blacklozenge}\times\boldsymbol{\omega})\cdot\boldsymbol{r}_{/\blacklozenge}+\boldsymbol{\omega}\cdot\boldsymbol{I}_{\blacklozenge}\cdot\boldsymbol{\omega}, \tag{3.14.3b}$$

we replace $\boldsymbol{v}_{\blacklozenge}$ and ω with $\boldsymbol{a}_{\blacklozenge}$ and $\boldsymbol{\alpha}$, respectively.

(ii) But the product $\boldsymbol{a}\cdot\boldsymbol{a}$ results in *two* additional *Appell-important* terms in S [the square of $\boldsymbol{\omega}\times(\boldsymbol{\omega}\times\boldsymbol{r}_{/\blacklozenge})$ does *not* produce any $(d\boldsymbol{\omega}/dt)$-proportional terms]:

- One from $(\boldsymbol{\alpha}\times\boldsymbol{r}_{/\blacklozenge})\cdot[\boldsymbol{\omega}\times(\boldsymbol{\omega}\times\boldsymbol{r}_{/\blacklozenge})]$, and hence given by (3.14.1d, e) [also (3.14.1f)]; and
- Another that transforms, successively, as follows:

$$\int dm\boldsymbol{a}_{\blacklozenge}\cdot[\boldsymbol{\omega}\times(\boldsymbol{\omega}\times\boldsymbol{r}_{/\blacklozenge})]=m\boldsymbol{a}_{\blacklozenge}\cdot[\boldsymbol{\omega}\times(\boldsymbol{\omega}\times\boldsymbol{r}_{G/\blacklozenge})]$$
$$=m(\boldsymbol{a}_{\blacklozenge}\times\boldsymbol{\omega})\cdot(\boldsymbol{\omega}\times\boldsymbol{r}_{G/\blacklozenge}). \tag{3.14.3c}$$

Collecting all these results, we conclude that in the case of *general motion*, and *to within* $\sim\boldsymbol{\alpha}$ *terms*,

$$2S=m{a_{\blacklozenge}}^2+2m(\boldsymbol{a}_{\blacklozenge}\times\boldsymbol{\alpha})\cdot\boldsymbol{r}_{G/\blacklozenge}+2m(\boldsymbol{a}_{\blacklozenge}\times\boldsymbol{\omega})\cdot(\boldsymbol{\omega}\times\boldsymbol{r}_{G/\blacklozenge})$$
$$+\boldsymbol{\alpha}\cdot\boldsymbol{I}_{\blacklozenge}\cdot\boldsymbol{\alpha}+2(\boldsymbol{\alpha}\times\boldsymbol{\omega})\cdot(\boldsymbol{I}_{\blacklozenge}\cdot\boldsymbol{\omega}). \tag{3.14.3d}$$

Specializations

(i) If $\blacklozenge=G$, the *second* and *third* terms in the above vanish, and so (3.14.3d) reduces to the Appellian counterpart of the well-known König's theorem (for T, with $\blacklozenge=G$)

$$2S=m{a_G}^2+\boldsymbol{\alpha}\cdot\boldsymbol{I}_G\cdot\boldsymbol{\alpha}+2(\boldsymbol{\alpha}\times\boldsymbol{\omega})\cdot(\boldsymbol{I}_G\cdot\boldsymbol{\omega})$$
$$=2\ (\textit{Appellian of translation of } G+\textit{rotation about } G$$
$$+\textit{coupling of } \boldsymbol{\omega} \textit{ and } \boldsymbol{\alpha}). \tag{3.14.4a}$$

However, there is no T-counterpart to the last term of (3.14.4a).

(ii) If $\blacklozenge$–xyz (G–xyz) are *body-fixed* [in which case, $\boldsymbol{\Omega} = \boldsymbol{\omega} \Rightarrow \alpha_{x,y,z} = \dot{\omega}_{x,y,z}$], the expressions (3.14.3d), (3.14.4a) can be simplified further. Since, in this case,

$$\boldsymbol{a}_\blacklozenge \equiv d\boldsymbol{v}_\blacklozenge/dt = \partial\boldsymbol{v}_\blacklozenge/\partial t + \boldsymbol{\omega} \times \boldsymbol{v}_\blacklozenge, \tag{3.14.4b}$$

to within Appell-important terms, $a_\blacklozenge{}^2$ can be replaced by

$$(\partial\boldsymbol{v}_\blacklozenge/\partial t)^2 + 2(\partial\boldsymbol{v}_\blacklozenge/\partial t)\cdot(\boldsymbol{\omega} \times \boldsymbol{v}_\blacklozenge), \tag{3.14.4c}$$

and $\boldsymbol{a}_\blacklozenge \times \boldsymbol{\omega}$ by $(\partial\boldsymbol{v}_\blacklozenge/\partial t) \times \boldsymbol{\omega}$ [where, we recall, $(\partial\boldsymbol{v}_\blacklozenge/\partial t)_{x,y,z} = (\dot{v}_{\blacklozenge;x,y,z})$]; and so, to within $\sim (\partial\boldsymbol{v}_\blacklozenge/\partial t)$ $[(\partial\boldsymbol{v}_G/\partial t)]$ and $\sim \boldsymbol{\alpha}$ terms, and after some simple vectorial rearrangement, (3.14.3d) and (3.14.4a) read, respectively,

$$\begin{aligned} 2S = {} & m(\partial\boldsymbol{v}_\blacklozenge/\partial t)^2 + 2m(\partial\boldsymbol{v}_\blacklozenge/\partial t + \boldsymbol{\omega} \times \boldsymbol{v}_\blacklozenge)\cdot(\boldsymbol{\alpha} \times \boldsymbol{r}_{G/\blacklozenge}) \\ & + 2m[(\partial\boldsymbol{v}_\blacklozenge/\partial t) \times \boldsymbol{\omega}]\cdot(\boldsymbol{v}_\blacklozenge) + \boldsymbol{\omega} \times \boldsymbol{r}_{G/\blacklozenge}) \\ & + \boldsymbol{\alpha}\cdot\boldsymbol{I}_\blacklozenge\cdot\boldsymbol{\alpha} + 2(\boldsymbol{\alpha} \times \boldsymbol{\omega})\cdot(\boldsymbol{I}_\blacklozenge\cdot\boldsymbol{\omega}); \end{aligned} \tag{3.14.4d}$$

and

$$2S = m(\partial\boldsymbol{v}_G/\partial t)^2 + 2m[(\partial\boldsymbol{v}_G/\partial t) \times \boldsymbol{\omega}]\cdot\boldsymbol{v}_G + \boldsymbol{\alpha}\cdot\boldsymbol{I}_G\cdot\boldsymbol{\alpha} + 2(\boldsymbol{\alpha} \times \boldsymbol{\omega})\cdot(\boldsymbol{I}_G\cdot\boldsymbol{\omega}). \tag{3.14.4e}$$

Problem 3.14.1 *Appellian Counterpart of the "British Theorem."* Show that, to within "Appell-important terms," the Appellian of a uniform rod AB, of mass m, equals

$$S = (m/6)(\boldsymbol{a}_A{}^2 + \boldsymbol{a}_A\cdot\boldsymbol{a}_B + \boldsymbol{a}_B{}^2), \tag{a}$$

where $\boldsymbol{a}_A$ and $\boldsymbol{a}_B$ are the *accelerations of the endpoints A and B* (see also Bahar, 1994, pp. 1685–1686).

3.15 THE RIGID BODY: VIRTUAL WORK OF FORCES

Introduction, General Results

In the last two sections, we discussed the explicit forms of the virtual work of the *inertia* forces, δI, for a rigid body B, in both Lagrangean and Appellian variables. Here, we present the corresponding forms of the [total (first-order) and inertial] *virtual work of the impressed forces*,

$$\delta' W \equiv \textstyle\int d\boldsymbol{F}\cdot\delta\boldsymbol{r}, \tag{3.15.1a}$$

[recall (3.2.8 ff.) and §3.4], and thus complete the specialization of *Lagrange's principle*, $\delta I = \delta' W$, to the rigid body.

Using the notations, and so on, of the preceding sections, we obtain, successively,

$$\delta' W = \textstyle\int d\boldsymbol{F}\cdot(\delta\boldsymbol{r}_\blacklozenge + \delta\boldsymbol{\theta} \times \boldsymbol{r}_{/\blacklozenge}) = \cdots = \boldsymbol{F}\cdot\delta\boldsymbol{r}_\blacklozenge + \boldsymbol{M}_\blacklozenge\cdot\delta\boldsymbol{\theta}, \tag{3.15.1b}$$

where

$$\boldsymbol{F} = \mathcal{S}\, d\boldsymbol{F} = \textit{total impressed force on } B \; (\textit{acting through } \blacklozenge),$$

$$\boldsymbol{M}_{\blacklozenge} = \mathcal{S}\, \boldsymbol{r}_{/\blacklozenge} \times d\boldsymbol{F} = \textit{total impressed moment on } B \textit{ about } \blacklozenge. \tag{3.15.1c}$$

Component Representations

Let us, next, express (3.15.1b) in terms of the components of its vectors along the following useful axes/coordinates:

(i) If the coordinates/components of $\blacklozenge$ relative to the *fixed axes/basis* $O\text{–}XYZ/\boldsymbol{IJK}$ are $X_{\blacklozenge}$, $Y_{\blacklozenge}$, $Z_{\blacklozenge}$, and the Eulerian angles of a *body-fixed* axes/basis $\blacklozenge\text{–}xyz/\boldsymbol{ijk}$ relative to the *cotranslating (nonrotating)* axes/basis $\blacklozenge\text{–}XYZ/\boldsymbol{IJK}$ are ϕ, θ, ψ [recalling §1.12] — that is, if the Lagrangean coordinates of B are $q_{1,2,3} = X_{\blacklozenge},\ Y_{\blacklozenge},\ Z_{\blacklozenge}$, and $q_{4,5,6} = \phi,\ \theta,\ \psi$ — then

$$\delta\boldsymbol{r}_{\blacklozenge} = \delta X_{\blacklozenge}\boldsymbol{I} + \delta Y_{\blacklozenge}\boldsymbol{J} + \delta Z_{\blacklozenge}\boldsymbol{K}, \qquad \delta\boldsymbol{\theta} = \delta\phi\,\boldsymbol{K} + \delta\theta\,\boldsymbol{u}_n + \delta\psi\,\boldsymbol{k} \tag{3.15.1d}$$

[$\boldsymbol{u}_n$: *unit vector along nodal line*] and, substituting them into (3.15.1b), we obtain

$$\delta' W = Q_X\,\delta X_{\blacklozenge} + Q_Y\,\delta Y_{\blacklozenge} + Q_Z\,\delta Z_{\blacklozenge} + M_{\blacklozenge,\phi}\,\delta\phi + M_{\blacklozenge,\theta}\,\delta\theta + M_{\blacklozenge,\psi}\,\delta\psi, \tag{3.15.1e}$$

where

$$\begin{aligned} Q_X &\equiv \boldsymbol{F}\cdot\boldsymbol{I} && (\equiv Q_1), \quad \text{etc., cyclically,}\\ M_{\blacklozenge,\phi} &\equiv \boldsymbol{M}_{\blacklozenge}\cdot\boldsymbol{K} && (\equiv Q_4 \equiv Q_\phi),\\ M_{\blacklozenge,\theta} &\equiv \boldsymbol{M}_{\blacklozenge}\cdot\boldsymbol{u}_n && (\equiv Q_5 \equiv Q_\theta),\\ M_{\blacklozenge,\psi} &\equiv \boldsymbol{M}_{\blacklozenge}\cdot\boldsymbol{k} && (\equiv Q_6 \equiv Q_\psi); \end{aligned} \tag{3.15.1f}$$

that is, $\boldsymbol{M}_{\blacklozenge;\phi,\theta,\psi}$ are the *components* of $\boldsymbol{M}_{\blacklozenge}$ along this "natural" unit but *nonorthogonal* axes/basis $\blacklozenge$–$Znz/\boldsymbol{Ku}_n\boldsymbol{k}$.

(ii) Similarly, using *body-fixed axes/basis*, $\blacklozenge$–$xyz/\boldsymbol{ijk}$, we can write

$$\delta' W = Q_x\delta x_{\blacklozenge} + Q_y\delta y_{\blacklozenge} + Q_z\delta z_{\blacklozenge} + M_{\blacklozenge,x}\delta\theta_x + M_{\blacklozenge,y}\delta\theta_y + M_{\blacklozenge,z}\delta\theta_z, \tag{3.15.1g}$$

but, here, both the $(\delta x_{\blacklozenge},\ \delta y_{\blacklozenge},\ \delta z_{\blacklozenge})$ and $(\delta\theta_x,\ \delta\theta_y,\ \delta\theta_z)$ are *virtual variations of quasi coordinates* [whose $(\ldots)^{\cdot}$-derivatives are the earlier quasi velocities $v_{\blacklozenge;x,y,z}$ and $\omega_{x,y,z}$, respectively; i.e., $dx_{\blacklozenge} = v_{\blacklozenge,x}\,dt$, $d\theta_x = \omega_x\,dt$, etc.].

(iii) Finally, using *cotranslating axes/basis*, $\blacklozenge$–$XYZ/\boldsymbol{IJK}$, we have

$$\delta' W = Q_X\delta X_{\blacklozenge} + Q_Y\delta Y_{\blacklozenge} + Q_Z\delta Z_{\blacklozenge} + M_{\blacklozenge,X}\delta\theta_X + M_{\blacklozenge,Y}\delta\theta_Y + M_{\blacklozenge,Z}\delta\theta_Z, \tag{3.15.1h}$$

where the $(X_{\blacklozenge},\ Y_{\blacklozenge},\ Z_{\blacklozenge})$ are genuine (holonomic) coordinates, but the $(\theta_X,\ \theta_Y,\ \theta_Z)$ are *quasi coordinates* [i.e., $dX_{\blacklozenge} = (dX_{\blacklozenge}/dt)dt \equiv v_{\blacklozenge,X}dt,\ d\theta_X \equiv \omega_X dt$, etc.].

Component Transformations

To relate these various $\boldsymbol{M}_{\blacklozenge}$ components with each other we shall use (i) *basis vector transformations* and, equivalently, (ii) the $\delta' W$ invariance.

(i) Basis Vector Transformations

(a) *Eulerian versus Inertial Components*. With reference to fig. 3.35, we find, successively,

$$M_{\blacklozenge,\phi}(\equiv M_{\blacklozenge,Z}) \equiv \boldsymbol{M}_{\blacklozenge} \cdot \boldsymbol{K} \quad [= (0)M_{\blacklozenge,X} + (0)M_{\blacklozenge,Y} + (1)M_{\blacklozenge,Z}], \tag{3.15.2a}$$

$$\begin{aligned} M_{\blacklozenge,\theta}(\equiv M_{\blacklozenge,n}) &\equiv \boldsymbol{M}_{\blacklozenge} \cdot \boldsymbol{u}_n \\ &= (M_{\blacklozenge,X}\boldsymbol{I} + M_{\blacklozenge,Y}\boldsymbol{J} + M_{\blacklozenge,Z}\boldsymbol{K}) \cdot (\cos\phi\,\boldsymbol{I} + \sin\phi\,\boldsymbol{J}) \\ &= (\cos\phi)M_{\blacklozenge,X} + (\sin\phi)M_{\blacklozenge,Y} + (0)M_{\blacklozenge,Z}, \end{aligned} \tag{3.15.2b}$$

$$\begin{aligned} M_{\blacklozenge,\psi}(\equiv M_{\blacklozenge,z}) &\equiv \boldsymbol{M}_{\blacklozenge} \cdot \boldsymbol{k} = \boldsymbol{M}_{\blacklozenge} \cdot (-\sin\theta\,\boldsymbol{u}_N + \cos\theta\,\boldsymbol{K}) \\ &= \boldsymbol{M}_{\blacklozenge} \cdot [-\sin\theta(-\sin\phi\,\boldsymbol{I} + \cos\phi\,\boldsymbol{J}) + \cos\theta\,\boldsymbol{K}] \\ &= (M_{\blacklozenge,X}\boldsymbol{I} + M_{\blacklozenge,Y}\boldsymbol{J} + M_{\blacklozenge,Z}\boldsymbol{K}) \cdot (\sin\phi\sin\theta\,\boldsymbol{I} - \cos\phi\sin\theta\,\boldsymbol{J} + \cos\theta\,\boldsymbol{K}) \\ &= (\sin\phi\sin\theta)M_{\blacklozenge,X} + (-\cos\phi\sin\theta)M_{\blacklozenge,Y} + (\cos\theta)M_{\blacklozenge,Z}. \end{aligned} \tag{3.15.2c}$$

Inverting the above, we obtain, after some simple algebra,

$$M_{\blacklozenge,X} = (-\cot\theta\sin\phi)M_{\blacklozenge,\phi} + (\cos\phi)M_{\blacklozenge,\theta} + (\sin\phi/\sin\theta)M_{\blacklozenge,\psi}, \tag{3.15.2d}$$

$$M_{\blacklozenge,Y} = (\cot\theta\cos\phi)M_{\blacklozenge,\phi} + (\sin\phi)M_{\blacklozenge,\theta} + (-\cos\phi/\sin\theta)M_{\blacklozenge,\psi}, \tag{3.15.2e}$$

$$M_{\blacklozenge,Z} = (1)M_{\blacklozenge,\phi} + (0)M_{\blacklozenge,\theta} + (0)M_{\blacklozenge,\psi}. \tag{3.15.2f}$$

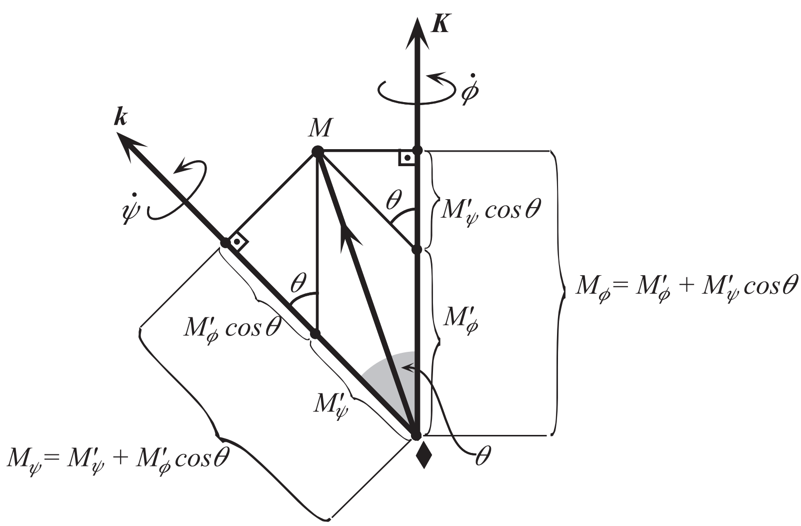

Figure 3.35 Geometrical demonstration of difference between *orthogonal* projections (in nonorthogonal axes) ($M_{\phi,\theta,\psi}$) and *parallel* ($M'_{\phi,\theta,\psi}$) projections (components); $\boldsymbol{M}_{\blacklozenge} \equiv \boldsymbol{M}$.

(b) *Eulerian versus Body-Fixed Components*. Again, with reference to fig. 3.35, we find, successively,

$$\begin{aligned} M_{\blacklozenge,\phi}(\equiv M_{\blacklozenge,Z}) &\equiv \boldsymbol{M}_\blacklozenge \cdot \boldsymbol{K} = \boldsymbol{M}_\blacklozenge \cdot (\sin\theta\, \boldsymbol{j}' + \cos\theta\, \boldsymbol{k}) \\ &= \boldsymbol{M}_\blacklozenge \cdot [\sin\theta(\sin\psi\, \boldsymbol{i} + \cos\psi\, \boldsymbol{j}) + \cos\theta\, \boldsymbol{k}] \\ &= (M_{\blacklozenge,x}\, \boldsymbol{i} + M_{\blacklozenge,y}\, \boldsymbol{j} + M_{\blacklozenge,z}\, \boldsymbol{k}) \cdot (\sin\theta\sin\psi\, \boldsymbol{i} + \sin\theta\cos\psi\, \boldsymbol{j} + \cos\theta\, \boldsymbol{k}) \\ &= (\sin\theta\sin\psi) M_{\blacklozenge,x} + (\sin\theta\cos\psi) M_{\blacklozenge,y} + (\cos\theta) M_{\blacklozenge z,}, \end{aligned} \tag{3.15.2g}$$

$$\begin{aligned} M_{\blacklozenge,\theta}\,(\equiv M_{\blacklozenge,n}) &\equiv \boldsymbol{M}_\blacklozenge \cdot \boldsymbol{u}_n = \boldsymbol{M}_\blacklozenge \cdot (\cos\psi\, \boldsymbol{i} - \sin\psi\, \boldsymbol{j}) \\ &= (\cos\psi) M_{\blacklozenge,x} + (-\sin\psi) M_{\blacklozenge,y} + (0) M_{\blacklozenge,z}, \end{aligned} \tag{3.15.2h}$$

$$M_{\blacklozenge,\psi}\,(\equiv M_{\blacklozenge,z}) \equiv \boldsymbol{M}_\blacklozenge \cdot \boldsymbol{k} = (0) M_{\blacklozenge,x} + (0) M_{\blacklozenge,y} + (1) M_{\blacklozenge,z}. \tag{3.15.2i}$$

Inverting the above, we obtain

$$M_{\blacklozenge,x} = (\sin\psi/\sin\theta) M_{\blacklozenge,\phi} + (\cos\psi) M_{\blacklozenge,\theta} + (-\cot\theta\sin\psi) M_{\blacklozenge,\psi}, \tag{3.15.2j}$$

$$M_{\blacklozenge,y} = (\cos\psi/\sin\theta) M_{\blacklozenge,\phi} + (\sin\psi) M_{\blacklozenge,\theta} + (-\cot\theta\cos\psi) M_{\blacklozenge,\psi}, \tag{3.15.2k}$$

$$M_{\blacklozenge,z} = (0) M_{\blacklozenge,\phi} + (0) M_{\blacklozenge,\theta} + (1) M_{\blacklozenge,\psi}. \tag{3.15.2l}$$

Similarly, we can relate the *Eulerian* axes/basis components with, say, those along the *semimobile* axes/basis $\blacklozenge\text{–}x'y'z'/\boldsymbol{i}'\boldsymbol{j}'\boldsymbol{k}' \equiv \blacklozenge\text{–}nn'z/\boldsymbol{u}_n\,\boldsymbol{j}'\boldsymbol{k}$, or the *semifixed* $\blacklozenge\text{–}x'NZ/\boldsymbol{i}'\boldsymbol{u}_N\boldsymbol{K} \equiv \blacklozenge\text{–}nNZ/\boldsymbol{u}_n\boldsymbol{u}_N\boldsymbol{K}$ ones; and, from (3.15.2a–c) and (3.15.2g–i), we can relate the $M_{\blacklozenge;x,y,z}$ with the $M_{\blacklozenge;X,Y,Z}$. The details are left to the reader.

(ii) $\delta' W$ Invariance

Such derivations are based on the following earlier found kinematic relations (§1.12):

- *Eulerian versus inertial axes*:

$$\begin{aligned} \delta\theta_X &= (0)\,\delta\phi + (\cos\phi)\,\delta\theta + (\sin\phi\sin\theta)\,\delta\psi, \\ \delta\theta_Y &= (0)\,\delta\phi + (\sin\phi)\,\delta\theta + (-\cos\phi\sin\theta)\,\delta\psi, \\ \delta\theta_Z &= (1)\,\delta\phi + (0)\,\delta\theta + (\cos\theta)\,\delta\psi; \end{aligned} \tag{3.15.3a}$$

$$\begin{aligned} \delta\phi &= (-\cot\theta\sin\phi)\,\delta\theta_X + (\cot\theta\cos\phi)\,\delta\theta_Y + (1)\,\delta\theta_Z, \\ \delta\theta &= (\cos\phi)\,\delta\theta_X + (\sin\phi)\,\delta\theta_Y + (0)\,\delta\theta_Z, \\ \delta\psi &= (\sin\phi/\sin\theta)\,\delta\theta_X + (-\cos\phi/\sin\theta)\,\delta\theta_Y + (0)\,\delta\theta_Z. \end{aligned} \tag{3.15.3b}$$

- *Eulerian versus body-fixed axes*:

$$\begin{aligned} \delta\theta_x &= (\sin\psi\,\sin\theta)\,\delta\phi + (\cos\psi)\,\delta\theta + (0)\,\delta\psi, \\ \delta\theta_y &= (\cos\psi\,\sin\theta)\,\delta\phi + (-\sin\psi)\,\delta\theta + (0)\,\delta\psi, \\ \delta\theta_z &= (\cos\theta)\,\delta\phi + (0)\,\delta\theta + (1)\,\delta\psi; \end{aligned} \tag{3.15.3c}$$

$$\begin{aligned} \delta\phi &= (\sin\psi/\sin\theta)\,\delta\theta_x + (\cos\psi/\sin\theta)\,\delta\theta_y + (0)\,\delta\theta_z, \\ \delta\theta &= (\cos\psi)\,\delta\theta_x + (-\sin\psi)\,\delta\theta_y + (0)\,\delta\theta_z, \\ \delta\psi &= (-\cot\theta\,\sin\phi)\,\delta\theta_x + (-\cot\theta\,\cos\psi)\,\delta\theta_y + (1)\,\delta\theta_z. \end{aligned} \tag{3.15.3d}$$

From the above, we can also find the relations $\delta\theta_{x,y,z} = (\ldots)\,\delta\theta_{X,Y,Z}$ and its inverse $\delta\theta_{X,Y,Z} = (\ldots)\,\delta\theta_{x,y,z}$.

For obvious reasons, we need consider only the "moment part" of $\delta' W$; that is,

$$\delta' W_M \equiv \boldsymbol{M}_{\blacklozenge,\phi}\,\delta\phi + \boldsymbol{M}_{\blacklozenge,\theta}\,\delta\theta + \boldsymbol{M}_{\blacklozenge,\psi}\,\delta\psi.$$

(a) *Eulerian versus Inertial Components*. With the help of (3.15.3b), we find, successively,

$$\begin{aligned}
\delta' W_M &= \boldsymbol{M}_{\blacklozenge,\phi}[(-\cot\theta\sin\phi)\,\delta\theta_X + (\cot\theta\cos\phi)\,\delta\theta_Y + (1)\,\delta\theta_Z]\\
&\quad + \boldsymbol{M}_{\blacklozenge,\theta}[(\cos\phi)\,\delta\theta_X + (\sin\phi)\,\delta\theta_Y + (0)\,\delta\theta_Z]\\
&\quad + \boldsymbol{M}_{\blacklozenge,\psi}[(\sin\phi/\sin\theta)\,\delta\theta_X + (-\cos\phi/\sin\theta)\,\delta\theta_Y + (0)\,\delta\theta_Z]\\
&= [(-\cot\theta\sin\phi)\boldsymbol{M}_{\blacklozenge,\phi} + (\cos\phi)\boldsymbol{M}_{\blacklozenge,\theta} + (\sin\phi/\sin\theta)\boldsymbol{M}_{\blacklozenge,\psi}]\,\delta\theta_X\\
&\quad + [(\cot\theta\cos\phi)\boldsymbol{M}_{\blacklozenge,\phi} + (\sin\phi)\boldsymbol{M}_{\blacklozenge,\theta} + (-\cos\phi/\sin\theta)\boldsymbol{M}_{\blacklozenge,\psi}]\,\delta\theta_Y\\
&\quad + [(1)\boldsymbol{M}_{\blacklozenge,\phi} + (0)\boldsymbol{M}_{\blacklozenge,\theta} + (0)\boldsymbol{M}_{\blacklozenge,\psi}]\,\delta\theta_Z\\
&= \boldsymbol{M}_{\blacklozenge,X}\,\delta\theta_X + \boldsymbol{M}_{\blacklozenge,Y}\,\delta\theta_Y + \boldsymbol{M}_{\blacklozenge,Z}\,\delta\theta_Z; \qquad \text{that is, eqs. (3.15.2d–f).} \qquad (3.15.4a)
\end{aligned}$$

(b) *Eulerian versus Body-Fixed Components*. With the help of (3.15.3c) we find, successively,

$$\begin{aligned}
\delta' W_M &= \boldsymbol{M}_{\blacklozenge,X}[(0)\,\delta\phi + (\cos\phi)\,\delta\theta + (\sin\phi\sin\theta)\,\delta\psi]\\
&\quad + \boldsymbol{M}_{\blacklozenge,Y}[(0)\,\delta\phi + (\sin\phi)\,\delta\theta + (-\cos\phi\sin\theta)\,\delta\psi]\\
&\quad + \boldsymbol{M}_{\blacklozenge,Z}[(1)\,\delta\phi + (0)\,\delta\theta + (\cos\phi)\,\delta\psi]\\
&= [(0)\boldsymbol{M}_{\blacklozenge,X} + (0)\boldsymbol{M}_{\blacklozenge,Y} + (1)\boldsymbol{M}_{\blacklozenge,Z}]\,\delta\phi\\
&\quad + [(\cos\phi)\boldsymbol{M}_{\blacklozenge,X} + (\sin\phi)\boldsymbol{M}_{\blacklozenge,Y} + (0)\boldsymbol{M}_{\blacklozenge,Z}]\,\delta\theta\\
&\quad + [(\sin\phi\sin\theta)\boldsymbol{M}_{\blacklozenge,X} + (-\cos\phi\sin\theta)\boldsymbol{M}_{\blacklozenge,Y} + (\cos\theta)\boldsymbol{M}_{\blacklozenge,Z}]\,\delta\psi\\
&= \boldsymbol{M}_{\blacklozenge,\phi}\,\delta\phi + \boldsymbol{M}_{\blacklozenge,\theta}\,\delta\theta + \boldsymbol{M}_{\blacklozenge,\psi}\,\delta\psi; \qquad (3.15.4b)
\end{aligned}$$

that is, eqs. (3.15.2a–c), without inverting eqs. (3.15.2d–f).

Similarly, using the transformations (3.15.3c, d), we can recover the earlier equations (3.15.2g–l).

We hope that the above have demonstrated the simplicity and superiority of the "*$\delta' W$ invariance*" approach. It, clearly, allows us to find the Lagrangean forces in any other "new" system of holonomic/nonholonomic variables—if we know them in an "old" one—plus the differential geometrical equations relating these two systems.

Example 3.15.1 *Eulerian Components versus Projections* [recall (1.2.7a ff.)]. As already known, the Eulerian axes/basis $\blacklozenge$–$Znz/\boldsymbol{K}\boldsymbol{u}_n\boldsymbol{k}$ is *nonorthogonal*. Therefore (and *omitting all subscripts* $\blacklozenge$ for simplicity),

$$\boldsymbol{M} \neq M_\phi\,\boldsymbol{K} + M_\theta\,\boldsymbol{u}_n + M_\psi\,\boldsymbol{k}, \qquad \text{(a)}$$

even though, as (3.15.1f) remind us,

$$M_\phi = \boldsymbol{M}\cdot\boldsymbol{K}, \qquad M_\theta = \boldsymbol{M}\cdot\boldsymbol{u}_n, \qquad M_\psi = \boldsymbol{M}\cdot\boldsymbol{k} \tag{b}$$

(components entering virtual work, just like the system momenta $p_{\phi,\theta,\psi}$); that is, in the case of *nonorthogonal axes*, the *(orthogonal) projections of (a vector)* $\boldsymbol{M}$, $M_{\phi,\theta,\psi}$, are *not equal to its components* (i.e., *parallel projections*), *say* $M'_{\phi,\theta,\psi}$ (fig. 3.35).

To find these latter (referred in tensor calculus as *contravariant* components), we set

$$\boldsymbol{M} = M'_\phi\,\boldsymbol{K} + M'_\theta\,\boldsymbol{u}_n + M'_\psi\,\boldsymbol{k}, \tag{c}$$

dot it in succession with $\boldsymbol{K}$, $\boldsymbol{u}_n$, $\boldsymbol{k}$, and then invoke (b) and fig. 3.35.

The results are

$$\begin{aligned} M_\phi &= M'_\phi(\boldsymbol{K}\cdot\boldsymbol{K}) + M'_\theta(\boldsymbol{u}_n\cdot\boldsymbol{K}) + M'_\psi(\boldsymbol{k}\cdot\boldsymbol{K}) \\ &= M'_\phi(1) + M'_\theta(0) + M'_\psi(\cos\theta) = M'_\phi + (\cos\theta)M'_\psi, \end{aligned} \tag{d}$$

$$\begin{aligned} M_\theta &= M'_\phi(\boldsymbol{K}\cdot\boldsymbol{u}_n) + M'_\theta(\boldsymbol{u}_n\cdot\boldsymbol{u}_n) + M'_\psi(\boldsymbol{k}\cdot\boldsymbol{u}_n) \\ &= M'_\phi(0) + M'_\theta(1) + M'_\psi(0) = M'_\theta, \end{aligned} \tag{e}$$

$$\begin{aligned} M_\psi &= M'_\phi(\boldsymbol{K}\cdot\boldsymbol{k}) + M'_\theta(\boldsymbol{u}_n\cdot\boldsymbol{k}) + M'_\psi(\boldsymbol{k}\cdot\boldsymbol{k}) \\ &= M'_\phi(\cos\theta) + M'_\theta(0) + M'_\psi(1) = (\cos\theta)M'_\phi + M'_\psi. \end{aligned} \tag{f}$$

Inverting the above, we easily obtain (see also fig. 3.35)

$$M'_\phi = (1/\sin^2\theta)(M_\phi - \cos\theta M_\psi), \tag{g}$$

$$M'_\theta = M_\theta, \tag{h}$$

$$M'_\psi = (1/\sin^2\theta)(M_\psi - \cos\theta M_\phi). \tag{i}$$

Example 3.15.2 *Equilibrium Conditions; and Accelerationless Rigid-Body Motion.*

(i) *Equilibrium conditions of forces via virtual work*. Let us consider these forces as acting on the various material particles of a rigid body/system, and let us calculate the corresponding (total, first-order, and inertial) virtual work. Reasoning as in (3.15.1b, c), we obtain

$$\begin{aligned} \delta' W_{\text{all forces}} &\equiv \delta' W_f \equiv \mathsf{S}\, d\boldsymbol{f}\cdot\delta\boldsymbol{r} \\ &= \mathsf{S}\, d\boldsymbol{f}\cdot(\delta\boldsymbol{r}_\blacklozenge + \delta\boldsymbol{\theta}\times\boldsymbol{r}_{/\blacklozenge}) = \cdots = \boldsymbol{f}\cdot\delta\boldsymbol{r}_\blacklozenge + \boldsymbol{M}_\blacklozenge\cdot\delta\boldsymbol{\theta}, \end{aligned} \tag{a}$$

where

$$\boldsymbol{f} = \mathsf{S}\, d\boldsymbol{f} = \textit{total force on B (acting through } \blacklozenge),$$

$$\boldsymbol{M}_\blacklozenge = \mathsf{S}\, \boldsymbol{r}_{/\blacklozenge}\times d\boldsymbol{f} = \textit{total moment on B about } \blacklozenge. \tag{b}$$

Since the virtual displacements $\delta\boldsymbol{r}_\blacklozenge$, $\delta\boldsymbol{\theta}$ are independent/arbitrary, the condition $\delta' W_f = 0$ leads to the well-known force equilibrium equations

$$\boldsymbol{f} = \boldsymbol{0} \qquad \text{and} \qquad \boldsymbol{M}_\blacklozenge = \boldsymbol{0}. \tag{c}$$

In sum: if $\delta' W_f = 0$, for *every rigid virtual displacement*, the forces are in equilibrium; and, conversely, if the forces are in equilibrium in the sense of (c), then $\delta' W_f = 0$.

Finally, if we invoke the *action–reaction* principle for the internal forces (§ 1.6), eqs. (c) can be replaced by

$$\boldsymbol{f}_{\text{external}} = \boldsymbol{0} \qquad \text{and} \qquad \boldsymbol{M}_{\blacklozenge,\text{external}} = \boldsymbol{0}. \tag{d}$$

[See also Marcolongo, 1911, pp. 266–269; and Heun, 1902(b)].

If $\delta' W \equiv \int d\boldsymbol{F} \cdot \delta\boldsymbol{r} = \int d\boldsymbol{F} \cdot (\delta\boldsymbol{r}_\blacklozenge + \delta\boldsymbol{\theta} \times \boldsymbol{r}_{/\blacklozenge}) = 0$, then we are led to the following.

(ii) *Accelerationless motion of a rigid body*. The latter is defined as that for which

$$\delta I \equiv \int dm\boldsymbol{a} \cdot \delta\boldsymbol{r} = 0, \qquad \text{for } every \quad \delta\boldsymbol{r} = \delta\boldsymbol{r}_\blacklozenge + \delta\boldsymbol{\theta} \times \boldsymbol{r}_{/\blacklozenge}. \tag{e}$$

Then, since [recall (3.13.8 ff.)]

$$\delta I \equiv \int dm\boldsymbol{a} \cdot (\delta\boldsymbol{r}_\blacklozenge + \delta\boldsymbol{\theta} \times \boldsymbol{r}_{/\blacklozenge}) = \cdots = \boldsymbol{I} \cdot \delta\boldsymbol{r}_\blacklozenge + \boldsymbol{A}_\blacklozenge \cdot \delta\boldsymbol{\theta}, \tag{f}$$

where

$$\boldsymbol{I} \equiv \int dm\, \boldsymbol{a} = m\, \boldsymbol{a}_G = (inertial)\ linear\ inertia\ of\ body\ B, \tag{g}$$

$$\boldsymbol{A}_\blacklozenge \equiv \int \boldsymbol{r}_{/\blacklozenge} \times (dm\, \boldsymbol{a}) = (inertial)\ relative\ angular\ inertia\ of\ B\ about\ \blacklozenge, \tag{h}$$

it follows that

$$\boldsymbol{I} = \boldsymbol{0} \qquad \text{and} \qquad \boldsymbol{A}_\blacklozenge = \boldsymbol{0}; \tag{i}$$

and, therefore, that [choosing in (f) $\delta\boldsymbol{r} \to \boldsymbol{v} = \boldsymbol{v}_\blacklozenge + \boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge}$]

$$\begin{aligned} \delta I \to dT/dt &\equiv \int dm\, \boldsymbol{a} \cdot \boldsymbol{v} = \int dm\, \boldsymbol{a} \cdot (\boldsymbol{v}_\blacklozenge + \boldsymbol{\omega} \times \boldsymbol{r}_{/\blacklozenge}) \\ &= \cdots = \boldsymbol{I} \cdot \boldsymbol{v}_\blacklozenge + \boldsymbol{A}_\blacklozenge \cdot \boldsymbol{\omega} = 0 \ \Rightarrow\ T = constant, \end{aligned} \tag{j}$$

that is, *if the body was initially at (inertial) rest, it remains at rest (equilibrium)*.

Clearly, the choice of $\blacklozenge$ has no effect on such a motion. In particular, if we select $\blacklozenge = G$, the equations of motion yield

$$m(d\boldsymbol{v}_G/dt) = \boldsymbol{0} \ \Rightarrow\ \boldsymbol{v}_G = constant \qquad \text{and} \qquad d\boldsymbol{h}_G/dt = \boldsymbol{0} \ \Rightarrow\ \boldsymbol{h}_G = constant, \tag{k}$$

from which, since $\boldsymbol{v}_G$ and $\boldsymbol{h}_G$ are mutually independent, we conclude that G can be taken as still.

Example 3.15.3 *Analytical Statics: Equilibrium Conditions via Virtual Work*. With the help of the concept of virtual work, and so on, we can summarize statics into the following results/propositions:

THEOREM

Two equivalent force (and/or couple) systems acting on a rigid body produce equal virtual works.

THEOREM

In every *reversible* rigid virtual displacement, the total virtual work of the constraint reactions vanishes (statical principle of Lagrange).

On Irreversible, or Unilateral, Constraints. Consider a particle P and a stationary rigid surface S with equation $f(x, y, z) = 0$. If P moves on S, then its coordinates satisfy the equation $f = 0$. The function f is positive on one side of S and negative on the other. Therefore, if P moves on the positive side of S, and cannot penetrate it or move except on that side, then its constraint is $f \geq 0$. In such cases, we distinguish: (i) *ordinary* positions of P, if $f > 0$, and (ii) *limiting*, or *boundary*, positions, if $f = 0$. Now we can state the general principle of virtual work, as follows.

LEMMA

The total virtual work of the (ideal) constraint reactions of a system in equilibrium (or motion), in every unilateral virtual displacement, is *either positive or zero*:

$$\delta' W_R \equiv \mathcal{S}\, d\boldsymbol{R} \cdot \delta\boldsymbol{r} \geq 0. \tag{a}$$

PRINCIPLE OF VIRTUAL WORK

For equilibrium at a *boundary* configuration of a scleronomic and originally motionless system, it is necessary and sufficient that the total *impressed* virtual work, $\delta' W \equiv \mathcal{S}\, d\boldsymbol{F} \cdot \delta\boldsymbol{r}$, be *zero* for all *reversible* virtual displacements; and *zero* or *negative* for all *nonreversible* virtual displacements (Fourier, 1798).

Problem 3.15.1 *Virtual Work-Like Characterization of Astatic Equilibrium*. Show that the vanishing of the (total, first-order, and inertial) *vector virtual work of all forces*

$$\delta' \boldsymbol{W}_V \equiv \mathcal{S}\, d\boldsymbol{f} \times \delta\boldsymbol{r}, \tag{a}$$

for *every* $\delta\boldsymbol{r} = \delta\boldsymbol{r}_\blacklozenge + \delta\boldsymbol{\theta} \times \boldsymbol{r}_{/\blacklozenge}$, leads to the *astaticity* conditions for these forces (recalling the *tensor product* definition, §1.1)

$$\boldsymbol{f} = \mathcal{S}\, d\boldsymbol{f} = \boldsymbol{0} \quad \text{(vector)}, \qquad \mathcal{S}\, \boldsymbol{r} \otimes d\boldsymbol{f} = \boldsymbol{0} \quad \text{(tensor)}; \tag{b}$$

and, conversely, if (the twelve scalar conditions) (b) hold, then $\delta' \boldsymbol{W}_V = \boldsymbol{0}$.

[This result seems to be due to Heun, 1902(a), p. 69; see also Biezeno, 1927, pp. 253–254.]

Example 3.15.4 *Eulerian Equations of Motion of a Rigid Body B Moving about a Fixed Point* $\blacklozenge$ *via the Central Equation* (recall §3.6):

$$\delta T + \delta' W = d/dt(\delta P). \tag{a}$$

For this special system (with $O = \blacklozenge$; i.e., $\boldsymbol{r}_{/\blacklozenge} = \boldsymbol{r}$, and using *body-fixed* axes at $\blacklozenge$), we have

(i)
$$\delta' W \equiv \mathcal{S}\, d\boldsymbol{F} \cdot \delta\boldsymbol{r} = \mathcal{S}\, d\boldsymbol{F} \cdot (\delta\boldsymbol{\theta} \times \boldsymbol{r}) = \boldsymbol{M} \cdot \delta\boldsymbol{\theta}, \tag{b}$$

$$\boldsymbol{M} \equiv \boldsymbol{M}_\blacklozenge \equiv \mathcal{S}\, \boldsymbol{r} \times d\boldsymbol{F} = \textit{total impressed moment on } B, \textit{ about origin } \blacklozenge; \tag{c}$$

(ii)
$$2T = \mathsf{S}\, dm\, \boldsymbol{v}^2 = \mathsf{S}\, dm(\boldsymbol{\omega}\times\boldsymbol{r})^2 = \mathsf{S}\, dm\{[\boldsymbol{r}\times(\boldsymbol{\omega}\times\boldsymbol{r})]\cdot\boldsymbol{\omega}\}$$
$$= \boldsymbol{H}\cdot\boldsymbol{\omega} = \sum H_k\,\omega_k = (\partial T/\partial\boldsymbol{\omega})\cdot\boldsymbol{\omega} = \sum(\partial T/\partial\omega_k)\,\omega_k, \tag{d}$$
where
$$\boldsymbol{H} \equiv \boldsymbol{H}_\blacklozenge \equiv \mathsf{S}\, dm\,[\boldsymbol{r}\times(\boldsymbol{\omega}\times\boldsymbol{r})] = \mathsf{S}\,\boldsymbol{r}\times(dm\,\boldsymbol{v}) = \partial T/\partial\boldsymbol{\omega}$$
$$= (H_x, H_y, H_z) = (\partial T/\partial\omega_x, \partial T/\partial\omega_y, \partial T/\partial\omega_z)$$
$$= (\textit{inertial})\ \textit{absolute angular momentum of } B \textit{ about } \blacklozenge; \tag{e}$$

and $k = 1, 2, 3 \equiv x, y, z$. From the above, and since, here, the *independent kinematical variable* is $\boldsymbol{\omega}$, we obtain
$$\delta T = \mathsf{S}\, dm\boldsymbol{v}\cdot\delta\boldsymbol{v} = \mathsf{S}\, dm(\boldsymbol{\omega}\times\boldsymbol{r})\cdot(\delta\boldsymbol{\omega}\times\boldsymbol{r})$$
$$= \Big\{\mathsf{S}\, dm[\boldsymbol{r}\times(\boldsymbol{\omega}\times\boldsymbol{r})]\Big\}\cdot\delta\boldsymbol{\omega}$$
$$= \boldsymbol{H}\cdot\delta\boldsymbol{\omega} = (\partial T/\partial\boldsymbol{\omega})\cdot\delta\boldsymbol{\omega} = \sum H_k\delta\omega_k = \sum(\partial T/\partial\omega_k)\delta\omega_k$$
$$= \boldsymbol{H}\cdot\delta_{\mathrm{rel}}\boldsymbol{\omega} \quad [\delta_{\mathrm{rel}}(\cdots) = \textit{virtual variation of}\,(\cdots)\ \textit{relative to}\ \blacklozenge - xyz]. \tag{f}$$

(iii)
$$d/dt(\delta P) = d/dt\Big(\mathsf{S}\, dm\boldsymbol{v}\cdot\delta\boldsymbol{r}\Big) = d/dt\Big[\mathsf{S}\, dm\boldsymbol{v}\cdot(\delta\boldsymbol{\theta}\times\boldsymbol{r})\Big]$$
$$= d/dt(\boldsymbol{H}\cdot\delta\boldsymbol{\theta}) = d/dt\Big(\sum H_k\,\delta\theta_k\Big) = (\partial/\partial t)(\boldsymbol{H}\cdot\delta\boldsymbol{\theta})$$
$$= (\partial\boldsymbol{H}/\partial t)\cdot\delta\boldsymbol{\theta} + \boldsymbol{H}\cdot[\partial(\delta\boldsymbol{\theta})/\partial t] \qquad [\text{where } \partial\boldsymbol{H}/\partial t = (dH_k/dt)]$$
$$= (\partial\boldsymbol{H}/\partial t)\cdot\delta\boldsymbol{\theta} + \boldsymbol{H}\cdot(\delta_{\mathrm{rel}}\boldsymbol{\omega} + \delta\boldsymbol{\theta}\times\boldsymbol{\omega}) \qquad [\text{recalling ex. 2.3.11: (g)}]$$
$$= (\partial\boldsymbol{H}/\partial t + \boldsymbol{\omega}\times\boldsymbol{H})\cdot\delta\boldsymbol{\theta} + \boldsymbol{H}\cdot\delta_{\mathrm{rel}}\boldsymbol{\omega}. \tag{g}$$

In view of (b–g), the central equation (a) reduces to
$$(\partial\boldsymbol{H}/\partial t + \boldsymbol{\omega}\times\boldsymbol{H})\cdot\delta\boldsymbol{\theta} = \boldsymbol{M}\cdot\delta\boldsymbol{\theta}, \tag{h}$$

that is, $\delta I = \delta' W$. Now: (a) If $\delta\boldsymbol{\theta}$ is *unconstrained*, the variational equation (h) leads immediately to the equation of motion
$$\partial\boldsymbol{H}/\partial t + \boldsymbol{\omega}\times\boldsymbol{H} = \boldsymbol{M}; \tag{i}$$

(b) If, on the other hand, $\delta\boldsymbol{\theta}$ is *constrained*, say by the Pfaffian equation $\boldsymbol{B}\cdot\delta\boldsymbol{\theta} = 0$ [where $\boldsymbol{B} = \boldsymbol{B}(t, \boldsymbol{r})$], then the multiplier rule applied to (i) yields the "Routh–Voss-type" equation [with $\lambda = \lambda(t) = $ *multiplier*]:
$$\partial\boldsymbol{H}/\partial t + \boldsymbol{\omega}\times\boldsymbol{H} = \boldsymbol{M} + \lambda\boldsymbol{B}. \tag{j}$$

Clearly, the *reaction moment* $\lambda\boldsymbol{B}$ has zero virtual work: $(\lambda\boldsymbol{B})\cdot\delta\boldsymbol{\theta} = 0$.

If the body-fixed axes $\blacklozenge{-}xyz$ are also *principal*, then $H_k = I_k\,\omega_k$ ($I_k =$ *principal moments of inertia at* $\blacklozenge$), and equations (i) readily reduce to the famous Eulerian rotational equations. [The more general forms (i, j) seem to be due to Lagrange. See also Heun (1906, pp. 276–280), and Papastavridis (1992) for alternative derivations and additional insights.]

Problem 3.15.2 Consider a rigid body moving about a fixed point ◆. Relate its Lagrangean and Eulerian momentum and inertia/acceleration vectors.

HINT

With ◆$-xyz$ principal axes at ◆, and Lagrangean coordinates their Eulerian angles relative to fixed axes (ϕ, θ, ψ), we have

$$\delta P \equiv \int dm\, \boldsymbol{v} \cdot \delta \boldsymbol{r} = p_\phi\, \delta\phi + p_\theta\, \delta\theta + p_\psi\, \delta\psi \qquad \text{(Lagrangean momenta)},$$

$$\delta I \equiv \int dm\, \boldsymbol{a} \cdot \delta \boldsymbol{r} = A_\phi\, \delta\phi + A_\theta\, \delta\theta + A_\psi\, \delta\psi \qquad \text{(Lagrangean inertia/accelerations)},$$

$$2T = 2T^* = I_x {\omega_x}^2 + I_y {\omega_y}^2 + I_z {\omega_z}^2, \tag{a}$$

where

$$A_\phi \equiv I_\phi \equiv (\partial T/\partial \dot{\phi})^{\cdot} - \partial T/\partial \phi = dp_\phi/dt - \partial T/\partial \phi, \quad \text{etc.} \tag{b}$$

But also, using some of the earlier kinematics [eqs. (3.15.3d)],

$$\begin{aligned} \delta P &= p_\phi[(\ldots)\, \delta\theta_x + (\ldots)\, \delta\theta_y + (\ldots)\, \delta\theta_z] + \cdots \\ &\equiv H_x\, \delta\theta_x + \cdots \quad \text{(Eulerian momenta)}, \end{aligned} \tag{c}$$

from which

$$\begin{aligned} H_x &= (\ldots)p_\phi + (\ldots)p_\theta + (\ldots)p_\psi, \qquad H_y = \cdots, \qquad H_z = \cdots; \\ p_\phi &= (\ldots)H_x + (\ldots)H_y + (\ldots)H_z, \qquad p_\theta = \cdots,\ p_\psi = \cdots; \end{aligned} \tag{d}$$

and by chain rule

$$\begin{aligned} \partial T/\partial \phi &= \sum (\partial T^*/\partial \omega_k)(\partial \omega_k/\partial \phi) = \sum (I_k \omega_k)(\partial \omega_k/\partial \phi) = \sum H_k (\partial \omega_k/\partial \phi) \\ &= \cdots, \quad \partial T/\partial \theta = \cdots, \quad \partial T/\partial \psi = \cdots, \text{ etc.} \end{aligned} \tag{e}$$

Hence, using the above, we obtain the sought relations

$$\begin{aligned} A_\phi &= dp_\phi/dt - \partial T/\partial \phi = \cdots = (\ldots)A_x + (\ldots)A_y + (\ldots)A_z, \quad \text{etc.} \\ A_x &= (\ldots)A_\phi + (\ldots)A_\theta + (\ldots)A_\psi = dH_x/dt + \omega_y H_z - \omega_z H_y, \quad \text{etc.} \\ &\qquad \text{(Eulerian inertia/accelerations).} \end{aligned} \tag{f}$$

3.16 RELATIVE MOTION (OR MOVING AXES/FRAMES) VIA LAGRANGE'S METHOD

In this section, following the rare and masterful treatment of Lur'e (1968, chap. 9, pp. 423–493), we derive the Lagrangean type of equations of motion of a system S relative to a noninertial frame of reference (with associated *moving axes* $O-xyz$), in general known or unknown rigid motion relative to an inertial frame (with associated *fixed axes* $I-XYZ$), or relative to its comoving nonrotating frame (with associated *translating axes* $O-XYZ$)—see fig. 3.36, depicting a convenient two-dimensional such case.

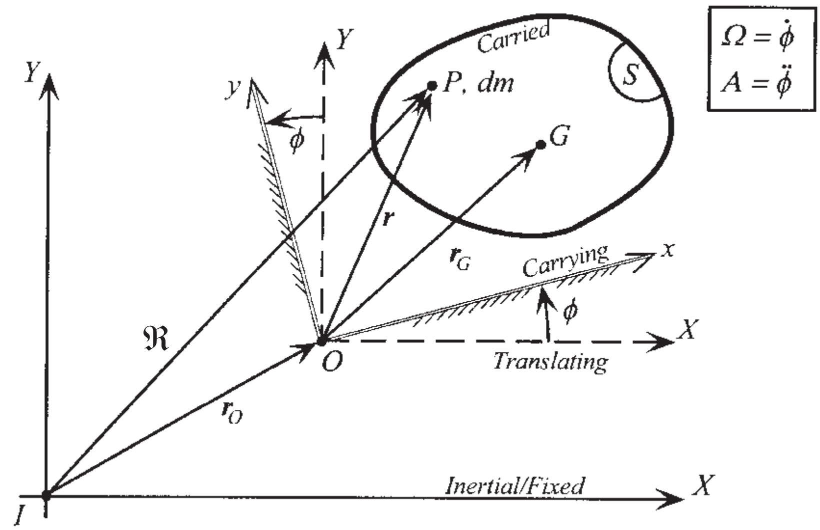

Figure 3.36 Two-dimensional case of system *S* in general motion relative to the arbitrarily moving axes *O–xyz*.

Here, we shall use the following terminology and notation:

O–xyz: *carrying* (or *supporting*, or *transporting*, or *intermediate*, or *housing*) body, or frame; e.g., an airplane. Its origin *O* is referred to as *moving pole*, or *basis*.
$\boldsymbol{\Omega}$ = (*inertial*) *angular velocity* vector of *O–xyz*; i.e., relative to *I–XYZ*/*O–XYZ*;
$d\boldsymbol{\Omega}/dt \equiv \boldsymbol{A}$ = corresponding *angular acceleration* vector.
$d(\ldots)/dt$ = *inertial rate of change* of $(\ldots)$; i.e., relative to *I–XYZ*/*O–XYZ*;
$\partial(\ldots)/\partial t$ = *noninertial rate of change* of $(\ldots)$; i.e., relative to *O–xyz*.

As shown in §1.1 and §1.7:

For an arbitrary *vector* $\boldsymbol{b}$,

$$d\boldsymbol{b}/dt = \partial\boldsymbol{b}/\partial t + \boldsymbol{\Omega} \times \boldsymbol{b}; \tag{3.16.1a}$$

For an arbitrary *second-order tensor* $\boldsymbol{T}$,

$$d\boldsymbol{T}/dt = \partial\boldsymbol{T}/\partial t + \boldsymbol{\Omega} \times \boldsymbol{T} - \boldsymbol{T} \times \boldsymbol{\Omega}. \tag{3.16.1b}$$

Also, as shown there (or, most easily, using Cartesian components), for any two vectors $\boldsymbol{a}$ and $\boldsymbol{b}$,

$$(\boldsymbol{a} \times \boldsymbol{T}) \cdot \boldsymbol{b} = \boldsymbol{a} \times (\boldsymbol{T} \cdot \boldsymbol{b}) \qquad \text{and} \qquad (\boldsymbol{T} \times \boldsymbol{a}) \cdot \boldsymbol{b} = \boldsymbol{T} \cdot (\boldsymbol{a} \times \boldsymbol{b}). \tag{3.16.1c}$$

S: *carried* body/system; e.g., a spinning gyroscope inside the (earlier) carrying airplane.

Geometry

We begin with the obvious geometrical relations:

$$\boldsymbol{r}_{/I} = \boldsymbol{r}_{O/I} + \boldsymbol{r}_{/O} \qquad \text{or, simply,} \qquad \boldsymbol{\Re} = \boldsymbol{r}_O + \boldsymbol{r}. \tag{3.16.2a}$$

Now: (i) Let

$$\boldsymbol{r} = \boldsymbol{r}(q_1, \ldots, q_n) \equiv \boldsymbol{r}(q), \tag{3.16.2b}$$

where $n \equiv 3N - h$, $N =$ number of particles of S (*if* we choose to adopt the particle model for it), $h \equiv$ number of holonomic constraints on S. The $q \equiv (q_1, \ldots, q_n)$ are *noninertial* Lagrangean coordinates; that is, they specify the configurations of the carried body S relative to the carrying one $O\text{–}xyz$; and, as explained in §2.4, they guarantee the satisfaction of the above holonomic constraints.

(ii) If the motion of $O\text{–}xyz$ is *known*, or *prescribed*, and hence unaffected by the motion of S, then $\boldsymbol{r}_O = \boldsymbol{r}_O(t)$; S is *rheonomic*.

(iii) If, on the other hand, the motion of $O\text{–}xyz$ is *unknown* [e.g., if the motion of the earlier gyroscope (S) does affect the motion of the airplane ($O\text{–}xyz$)!], then $\boldsymbol{r}_O = \boldsymbol{r}_O$ (*inertial coordinates of pole* O), and hence, not an explicit function of t; S is *scleronomic*.

Kinematics → Kinetic Energy

Since the inertial velocity of a typical S-particle is (recalling §1.7)

$$\begin{aligned} \boldsymbol{v} &\equiv d\boldsymbol{\Re}/dt = d\boldsymbol{r}_O/dt + d\boldsymbol{r}/dt = \boldsymbol{v}_O + (\partial\boldsymbol{r}/\partial t + \boldsymbol{\Omega} \times \boldsymbol{r}) \\ &\equiv \boldsymbol{v}_O + \boldsymbol{v}_{\text{rel}} + \boldsymbol{\Omega} \times \boldsymbol{r}, \end{aligned} \tag{3.16.3a}$$

where

$$\boldsymbol{v}_O = d\boldsymbol{r}_O/dt = \textit{inertial velocity of } \text{pole } O, \tag{3.16.3b}$$

$$\begin{aligned} \boldsymbol{v}_{\text{rel}} &= \partial\boldsymbol{r}/\partial t = \textit{relative velocity} \text{ of typical } S\text{-particle} \\ &= \sum (\partial\boldsymbol{r}/\partial q_k)(dq_k/dt) \equiv \sum \boldsymbol{e}_k\, \dot{q}_k \qquad [\text{by (3.16.2b)}], \end{aligned} \tag{3.16.3c}$$

the (inertial) kinetic energy of S, $T \equiv (1/2)\int dm\, \boldsymbol{v} \cdot \boldsymbol{v}$, becomes

$$T = T_{\text{trnspt}} + T_{\text{rel}} + T_{\text{cpl}}, \tag{3.16.3d}$$

where

$$\begin{aligned} 2T_{\text{trnspt}} &\equiv m\, v_O{}^2 + \int dm(\boldsymbol{\Omega} \times \boldsymbol{r})^2 + 2m\, \boldsymbol{v}_O \cdot (\boldsymbol{\Omega} \times \boldsymbol{r}_G) \\ &= m\, v_O{}^2 + 2m\, \boldsymbol{v}_O \cdot (\boldsymbol{\Omega} \times \boldsymbol{r}_G) + \boldsymbol{\Omega} \cdot \boldsymbol{I}_O \cdot \boldsymbol{\Omega} \\ &= 2\ (\textit{kinetic energy of transport}), \end{aligned} \tag{3.16.3e}$$

[recall, $T_{\text{rotation}} \equiv T_R$, expressions (3.13.2b, 3b), and see fig. 3.36],

$$\begin{aligned} 2T_{\text{rel}} &\equiv \int dm\, \boldsymbol{v}_{\text{rel}}{}^2 = \int dm\, (\partial\boldsymbol{r}/\partial t)^2 \\ &= \int dm\Big[\sum (\partial\boldsymbol{r}/\partial q_k)\dot{q}_k\Big] \cdot \Big[\sum (\partial\boldsymbol{r}/\partial q_l)\dot{q}_l\Big] \\ &= \sum\sum \Big[\int dm\, (\partial\boldsymbol{r}/\partial q_k) \cdot (\partial\boldsymbol{r}/\partial q_l)\Big]\dot{q}_k\, \dot{q}_l \equiv \sum\sum \Big(\int dm\, \boldsymbol{e}_k \cdot \boldsymbol{e}_l\Big)\dot{q}_k\, \dot{q}_l \\ &= 2\ (\textit{relative kinetic energy}), \end{aligned} \tag{3.16.3f}$$

$$
\begin{aligned}
T_{\text{cpl}} &\equiv \boldsymbol{p}_{\text{rel}} \cdot \boldsymbol{v}_O + \boldsymbol{H}_{O,\text{rel}} \cdot \boldsymbol{\Omega} \\
&= \textit{kinetic energy of coupling (of carrying and carried motions;} \\
&\quad \textit{or ``Coriolis kinetic energy''}), \qquad (3.16.3g)
\end{aligned}
$$

$$
\begin{aligned}
\boldsymbol{p}_{\text{rel}} &\equiv \int dm\, \boldsymbol{v}_{\text{rel}} = \int dm(\partial \boldsymbol{r}/\partial t) = m\, \boldsymbol{v}_{G,\text{rel}} \equiv m(\partial \boldsymbol{r}_G/\partial t) \\
&= \int dm\Big[\sum (\partial \boldsymbol{r}/\partial q_k)\dot{q}_k\Big] = \sum \Big[\int dm\, (\partial \boldsymbol{r}/\partial q_k)\Big]\dot{q}_k \\
&= \textit{(noninertial) linear momentum of body } S, \qquad (3.16.3h)
\end{aligned}
$$

$$
\begin{aligned}
\boldsymbol{H}_{O,\text{rel}} &\equiv \int \boldsymbol{r} \times (dm\, \boldsymbol{v}_{\text{rel}}) = \int \boldsymbol{r} \times [dm(\partial \boldsymbol{r}/\partial t)] \\
&= \cdots = \sum \Big[\int dm\, \boldsymbol{r} \times (\partial \boldsymbol{r}/\partial q_k)\Big]\dot{q}_k \\
&= \textit{noninertial (absolute) angular momentum of } S \textit{ about } O. \qquad (3.16.3i)
\end{aligned}
$$

Before applying the Lagrangean formalism to the above, let us reduce them further to system forms, in the sense of §3.9:

(a) T_{trnspt} is *independent* of the $\dot{q}$'s. It would be the kinetic energy of S if the latter was frozen relative to O–xyz; that is, *if these axes were fixed in* S. In accordance with (3.9.2, 2c), we shall rename it T_0 $[\sim (\dot{q})^0]$.

(b) With the notations

$$
\begin{aligned}
M_k &\equiv \boldsymbol{v}_O \cdot \Big[\int dm\, (\partial \boldsymbol{r}/\partial q_k)\Big] + \boldsymbol{\Omega} \cdot \Big[\int dm \boldsymbol{r} \times (\partial \boldsymbol{r}/\partial q_k)\Big] \\
&= \boldsymbol{v}_O \cdot \Big(\int dm\, \boldsymbol{e}_k\Big) + \boldsymbol{\Omega} \cdot \Big[\int (dm\, \boldsymbol{r} \times \boldsymbol{e}_k)\Big], \qquad (3.16.4a)
\end{aligned}
$$

$$
M_{kl} \equiv \int dm\, (\partial \boldsymbol{r}/\partial q_k) \cdot (\partial \boldsymbol{r}/\partial q_l) = \int dm\, \boldsymbol{e}_k \cdot \boldsymbol{e}_l, \qquad (3.16.4b)
$$

and recalling (3.9.2a, b), we can rewrite T_{cpl} and T_{rel} as

$$
\begin{aligned}
T_{\text{cpl}} &= \sum M_k\, \dot{q}_k \equiv T_1 \quad (\sim \dot{q}), \\
2T_{\text{rel}} &= \sum\sum M_{kl}\, \dot{q}_k\, \dot{q}_l \equiv 2T_2 \quad [\sim (\dot{q})^2]. \qquad (3.16.4c)
\end{aligned}
$$

So, finally, the total kinetic energy, (3.16.3d), assumes the following general Lagrangean notation:

$$
T = T_{\text{rel}} + T_{\text{cpl}} + T_{\text{trnspt}} \equiv T_2 + T_1 + T_0. \qquad (3.16.4d)
$$

Now, as the above expressions show, T depends on the following:

(a) The *six carrying quasi velocities* $\boldsymbol{v}_O = (v_{O,x,y,z})$ and $\boldsymbol{\Omega} = (\Omega_{x,y,z})$, along O–xyz [Along I–XYZ/O–XYZ, we would have $\boldsymbol{r}_O = (X_O, Y_O, Z_O)$, and, therefore, $\boldsymbol{v}_O = (v_{O;X,Y,Z}) \equiv (\dot{X}_O, \dot{Y}_O, \dot{Z}_O) =$ *holonomic* components]; and

(b) The *n carried holonomic velocities* $\dot{q} \equiv (\dot{q}_1, \ldots, \dot{q}_n)$.

Therefore, in the general case, we will obtain *two* groups of equations:

(a) *six* Hamel-type (or Lagrange–Euler) equations for the quasi velocities, *coupled* with
(b) n Lagrange-type equations for the $q/\dot{q}$'s.

The right, or *force*, sides of these equations will contain the corresponding six nonholonomic and n holonomic forces (and/or moments). Indeed, recalling (3.16.2a), we have

$$\begin{aligned}\delta\mathfrak{R} &= \delta \boldsymbol{r}_O + \delta\boldsymbol{r} = \delta\boldsymbol{r}_O + (\delta_{\mathrm{rel}}\boldsymbol{r} + \delta\boldsymbol{\Theta}\times\boldsymbol{r}) \qquad [\text{where } d\boldsymbol{\Theta}/dt \equiv \boldsymbol{\Omega}]\\ &= \delta\boldsymbol{r}_O + \delta\boldsymbol{\Theta}\times\boldsymbol{r} + \sum(\partial\boldsymbol{r}/\partial q_k)\delta q_k; \end{aligned} \tag{3.16.5a}$$

if $\boldsymbol{r}_O = \boldsymbol{r}_O(t)$ then, clearly, $\delta\boldsymbol{r}_O = \boldsymbol{0}$. Hence, in general, the total (inertial and first-order) impressed virtual work equals

$$\delta' W = \int d\boldsymbol{F}\cdot\delta\mathfrak{R} = \cdots = \boldsymbol{F}\cdot\delta\boldsymbol{r}_O + \boldsymbol{M}_O\cdot\delta\boldsymbol{\Theta} + \sum Q_k\,\delta q_k, \tag{3.16.5b}$$

where

$$\boldsymbol{F} \equiv \int d\boldsymbol{F} = \textit{total impressed force (acting at } O), \tag{3.16.5c}$$

$$\boldsymbol{M}_O \equiv \int \boldsymbol{r}\times d\boldsymbol{F} = \textit{total impressed moment about } O. \tag{3.16.5d}$$

Let us now find the $6+n$ equations of motion.

Hamel-Type (or Lagrange–Euler) Carrying Body Equations

(A review of §3.13 is highly recommended.) Since $T_{\mathrm{rel}} = T_2$ is independent of the quasi velocities $v_{O;x,y,z}$ and $\Omega_{x,y,z}$, we can write

$$\partial T/\partial v_{O,k} = \partial T_0/\partial v_{O,k} + \partial T_1/\partial v_{O,k}, \qquad \partial T/\partial\Omega_k = \partial T_0/\partial\Omega_k + \partial T_1/\partial\Omega_k, \tag{3.16.5e}$$

where $k = x, y, z$. Now, recalling the expressions for T, $\partial T/\partial\boldsymbol{v}_\blacklozenge$, $\partial T/\partial\boldsymbol{\omega}$ from §3.13 (and setting in those formulae $T\to T_O$, $\blacklozenge\to O$, $\boldsymbol{\omega}\to\boldsymbol{\Omega}$, we readily conclude that

$$\partial T_0/\partial v_{O,x} = m(v_{O,x} + \Omega_y z_G - \Omega_z y_G), \quad \text{etc., cyclically,} \tag{3.16.5f}$$

$$\partial T_0/\partial\Omega_x = m(y_G v_{O,z} - z_G v_{O,y}) + (I_{O,xx}\Omega_x + I_{O,xy}\Omega_y + I_{O,xz}\Omega_z), \quad \text{etc., cyclically,} \tag{3.16.5g}$$

where $(I_{O,kl};\ k, l = x, y, z)$ are the components of the inertia tensor of the system S about O, along $O{-}xyz$; and

$$\partial T_1/\partial v_{O,x} = m(dx_G/dt) = (\boldsymbol{p}_{\mathrm{rel}})_x, \quad \text{etc., cyclically,} \tag{3.16.5h}$$

$$\partial T_1/\partial\Omega_x = (\boldsymbol{H}_{O,\mathrm{rel}})_x, \quad \text{etc., cyclically.} \tag{3.16.5i}$$

A moment's reflection will show that the left (inertia/acceleration) sides of the equations for $\boldsymbol{v}_O$ and $\boldsymbol{\Omega}$ are none other than the former expressions (3.13.11a, b) with $\blacklozenge, \bullet \to O$. Hence, for an unconstrained rigid body, we have [since all (symbolic) partial derivatives of T relative to the quasi coordinates vanish]

$$\boldsymbol{I} = d/dt(\partial T/\partial\boldsymbol{v}_O) \equiv \partial/\partial t(\partial T/\partial\boldsymbol{v}_\blacklozenge) + \boldsymbol{\Omega}\times(\partial T/\partial\boldsymbol{v}_\blacklozenge) = \boldsymbol{F}, \tag{3.16.6a}$$

or, in components,

$$I_x = (\partial T/\partial v_{O,x})^{\cdot} + \Omega_y(\partial T/\partial v_{O,z}) - \Omega_z(\partial T/\partial v_{O,y}) = F_x, \quad \text{etc., cyclically,} \tag{3.16.6b}$$

and

$$\begin{aligned} \boldsymbol{A}_O &= d/dt(\partial T/\partial \boldsymbol{\Omega}) + \boldsymbol{v}_O \times (\partial T/\partial \boldsymbol{v}_O) \\ &\equiv \partial/\partial t(\partial T/\partial \boldsymbol{\Omega}) + \boldsymbol{\Omega} \times (\partial T/\partial \boldsymbol{\Omega}) + \boldsymbol{v}_O \times (\partial T/\partial \boldsymbol{v}_O) = \boldsymbol{M}_O, \end{aligned} \tag{3.16.6c}$$

or, in components,

$$\begin{aligned} A_{O,x} &= (\partial T/\partial \Omega_x)^{\cdot} + \Omega_y(\partial T/\partial \Omega_z) - \Omega_z(\partial T/\partial \Omega_y) \\ &\quad + v_{O,y}(\partial T/\partial v_{O,z}) - v_{O,z}(\partial T/\partial v_{O,y}) = M_{O,x}, \quad \text{etc., cyclically.} \end{aligned} \tag{3.16.6d}$$

To obtain explicit Euler-type equations from the above, we introduce in (3.16.6a–d) the earlier found expressions for T. In this way:

(i) Equations (3.16.6b) yield

$$\begin{aligned} m\Big\{ & \dot{v}_{O,x} + (\dot{\Omega}_y z_G - \dot{\Omega}_z y_G) + (\Omega_y \dot{z}_G - \Omega_z \dot{y}_G) + (\Omega_y v_{O,z} - \Omega_z v_{O,y}) \\ & + [\Omega_y(\Omega_x y_G - \Omega_y x_G) - \Omega_z(\Omega_z x_G - \Omega_x z_G)] \\ & + (\ddot{x}_G + \Omega_y \dot{z}_G - \Omega_z \dot{y}_G)\Big\} = F_x, \quad \text{etc., cyclically;} \end{aligned} \tag{3.16.6e}$$

or, in vector form (appropriately grouped),

$$\begin{aligned} & m[\partial \boldsymbol{v}_O/\partial t + \boldsymbol{\Omega} \times \boldsymbol{v}_O) + (d\boldsymbol{\Omega}/dt) \times \boldsymbol{r}_G + \boldsymbol{\Omega} \times (\boldsymbol{\Omega} \times \boldsymbol{r}_G) + 2\boldsymbol{\Omega} \times (\partial \boldsymbol{r}_G/\partial t) + \partial^2 \boldsymbol{r}_G/\partial t^2] \\ & \quad \equiv m\big\{[\boldsymbol{a}_O + (d\boldsymbol{\Omega}/dt) \times \boldsymbol{r}_G + \boldsymbol{\Omega} \times (\boldsymbol{\Omega} \times \boldsymbol{r}_G)] + 2\boldsymbol{\Omega} \times \boldsymbol{v}_{G,\mathrm{rel}} + \boldsymbol{a}_{G,\mathrm{rel}}\big\} \\ & \quad \equiv m(\boldsymbol{a}_{G,\mathrm{transport}} + \boldsymbol{a}_{G,\mathrm{Coriolis}} + \boldsymbol{a}_{G,\mathrm{relative}}) \equiv m\,\boldsymbol{a}_{G,\mathrm{inertial}} \equiv m\,\boldsymbol{a}_G = \boldsymbol{F}; \end{aligned} \tag{3.16.6f}$$

which is the well-known equation of motion of the "inertial center" of the carried system G.

[Also, the above equations and the earlier kinematic relations

$$\begin{aligned} \boldsymbol{v}_{G,\mathrm{rel}} &= \partial \boldsymbol{r}_G/\partial t = \sum (\partial \boldsymbol{r}_G/\partial q_k)\dot{q}_k, \\ \boldsymbol{a}_{G,\mathrm{rel}} &= \partial \boldsymbol{v}_G/\partial t = \sum (\partial \boldsymbol{r}_G/\partial q_k)\ddot{q}_k + \sum\sum (\partial^2 \boldsymbol{r}_G/\partial q_k \partial q_l)\dot{q}_k \dot{q}_l, \end{aligned} \tag{3.16.6g}$$

demonstrate clearly the *coupling* of the holonomic velocities $\dot{q}$ with the nonholonomic ones $v_{O;x,y,z}$ and $\Omega_{x,y,z}$.]

(ii) Equations (3.16.6d) yield

$$\begin{aligned} & m(y_G\,\dot{v}_{O,z} - z_G\,\dot{v}_{O,y}) + (I_{O,xx}\,\dot{\Omega}_x + I_{O,yy}\,\dot{\Omega}_y + I_{O,zz}\,\dot{\Omega}_z \\ & \quad + \dot{I}_{O,xx}\,\Omega_x + \dot{I}_{O,xy}\,\Omega_y + \dot{I}_{O,xz}\,\Omega_z) \\ & \quad + (\boldsymbol{H}_{O,\mathrm{rel}})_x^{\cdot} + m[\Omega_y(v_{O,y}\,x_G - v_{O,x}\,y_G) - \Omega_z(v_{O,x}\,z_G - v_{O,z}\,x_G)] \\ & \quad + \Omega_y(I_{O,zx}\,\Omega_x + I_{O,zy}\,\Omega_y + I_{O,zz}\,\Omega_z) - \Omega_z(I_{O,yx}\,\Omega_x + I_{O,yy}\,\Omega_y + I_{O,yz}\,\Omega_z) \\ & \quad + \Omega_y(\boldsymbol{H}_{O,\mathrm{rel}})_z - \Omega_z(\boldsymbol{H}_{O,\mathrm{rel}})_y \\ & \quad + m[v_{O,y}(\Omega_x\,y_G - \Omega_y\,x_G) - v_{O,z}(\Omega_z\,x_G - \Omega_x\,z_G)] = M_{O,x}, \quad \text{etc., cyclically;} \end{aligned} \tag{3.16.6h}$$

or, vectorially,

$$\boldsymbol{I}_O \cdot (d\boldsymbol{\Omega}/dt) + (\partial \boldsymbol{I}_O/\partial t) \cdot \boldsymbol{\Omega} + \boldsymbol{\Omega} \times (\boldsymbol{I}_O \cdot \boldsymbol{\Omega}) + (\partial \boldsymbol{H}_{O,\mathrm{rel}}/\partial t + \boldsymbol{\Omega} \times \boldsymbol{H}_{O,\mathrm{rel}}) + m r_G \times \boldsymbol{a}_O = \boldsymbol{M}_O. \quad (3.16.6\mathrm{i})$$

This equation can be transformed further. Recalling the inertia tensor definition [§1.15, and with $\boldsymbol{1} = (\delta_{kl}) = 3 \times 3$ *unit* (*Cartesian*) *tensor*, where $k, l = x, y, z$; and $\otimes$ = *tensor product* (§1.1)], $\boldsymbol{I}_O = S\, dm[(\boldsymbol{r}\cdot\boldsymbol{r})\boldsymbol{1} - \boldsymbol{r}\otimes\boldsymbol{r}]$, we obtain

$$\partial \boldsymbol{I}_O/\partial t = 2\sum \Big\{ S\, dm\big[\{\boldsymbol{r}\cdot(\partial\boldsymbol{r}/\partial q_k)\}\boldsymbol{1} - (1/2)\boldsymbol{r}\otimes(\partial\boldsymbol{r}/\partial q_k) - (1/2)(\partial\boldsymbol{r}/\partial q_k)\otimes\boldsymbol{r}\big]\Big\}\dot{q}_k, \quad (3.16.7\mathrm{a})$$

and, therefore, we find, successively,

$$\begin{aligned}
(\partial \boldsymbol{I}_O/\partial t)\cdot\boldsymbol{\Omega} + \boldsymbol{\Omega}\times\boldsymbol{H}_{O,\mathrm{rel}}
&= 2\sum \Big\{ S\, dm\big[\{\boldsymbol{r}\cdot(\partial\boldsymbol{r}/\partial q_k)\}\boldsymbol{\Omega} - (1/2)\{(\partial\boldsymbol{r}/\partial q_k)\otimes\boldsymbol{r}\}\cdot\boldsymbol{\Omega} - (1/2)\{\boldsymbol{r}\otimes(\partial\boldsymbol{r}/\partial q_k)\}\cdot\boldsymbol{\Omega} \\
&\qquad + (1/2)\boldsymbol{\Omega}\times\{\boldsymbol{r}\times(\partial\boldsymbol{r}/\partial q_k)\}\big]\Big\}\dot{q}_k \\
&= 2\sum \Big\{ S\, dm\, \boldsymbol{r}\times[\boldsymbol{\Omega}\times(\partial\boldsymbol{r}/\partial q_k)]\Big\}\dot{q}_k \\
&= 2 S\, dm\, \boldsymbol{r}\times(\boldsymbol{\Omega}\times\boldsymbol{v}_{\mathrm{rel}}) = S\, \boldsymbol{r}\times(2dm\,\boldsymbol{\Omega}\times\boldsymbol{v}_{\mathrm{rel}}): \\
&\quad - (\textit{Total moment of Coriolis forces, on the carrying body, about } O, \\
&\qquad \textit{due to the motion of the carried body relative to it}) \equiv -\boldsymbol{M}_{O,\mathrm{Coriolis}}.
\end{aligned} \quad (3.16.7\mathrm{b})$$

In view of this result, and using (3.16.6f) to eliminate $\boldsymbol{a}_O$, we can rewrite (3.16.6h) (after some judicious regrouping) in the following Euler-like form:

$$\boldsymbol{I}_G \cdot (d\boldsymbol{\Omega}/dt) + \boldsymbol{\Omega}\times(\boldsymbol{I}_G\cdot\boldsymbol{\Omega}) = \boldsymbol{M}_G + \boldsymbol{M}_{G,\mathrm{Coriolis}} - \partial\boldsymbol{H}_{G,\mathrm{rel}}/\partial t, \quad (3.16.7\mathrm{c})$$

where

$$\boldsymbol{I}_G = \boldsymbol{I}_O - m\big[(\boldsymbol{r}_G\cdot\boldsymbol{r}_G)\boldsymbol{1} - r_G\otimes\boldsymbol{r}_G\big]: \textit{Moment of inertia of S about G}$$
$$(\textit{direct tensorial form of parallel axis theorem; recall §1.15}), \quad (3.16.7\mathrm{d})$$

$$\boldsymbol{H}_{G,\mathrm{rel}} = \boldsymbol{H}_{O,\mathrm{rel}} - m\,\boldsymbol{r}_G\times(\partial\boldsymbol{r}_G/\partial t), \quad (3.16.7\mathrm{e})$$

$$\begin{aligned}
\boldsymbol{M}_{G,\mathrm{Coriolis}} &\equiv -[(\partial\boldsymbol{I}_G/\partial t)\cdot\boldsymbol{\Omega} + \boldsymbol{\Omega}\times\boldsymbol{H}_{G,\mathrm{rel}}] \\
&= \boldsymbol{M}_{O,\mathrm{Coriolis}} - \boldsymbol{r}_G\times(2m\boldsymbol{\Omega}\times\boldsymbol{v}_{G,\mathrm{rel}}) \qquad [\text{i.e., same as (3.16.7b), but about } G],
\end{aligned} \quad (3.16.7\mathrm{f})$$

$$\boldsymbol{M}_G = \boldsymbol{M}_O - \boldsymbol{r}_G\times\boldsymbol{F} \qquad [\text{with } \boldsymbol{F} \text{ assumed applied at } O]. \quad (3.16.7\mathrm{g})$$

REMARKS, SPECIALIZATIONS

(i) Equations (3.16.7c) result immediately from (3.16.6h) with the choice $O \to G$.

(ii) If S is a rigid body and the O–xyz are *body-fixed* axes on it, then the relative rates $\partial(\ldots)/\partial t$ vanish, $\boldsymbol{\Omega} \to \boldsymbol{\omega}$, $d\boldsymbol{\Omega}/dt \to \boldsymbol{\alpha}$, and (3.16.6f, e) reduce,

$$m[(\partial \boldsymbol{v}_O/\partial t + \boldsymbol{\omega} \times \boldsymbol{v}_O) + \boldsymbol{\alpha} \times \boldsymbol{r}_G + \boldsymbol{\omega} \times (\boldsymbol{\omega} \times \boldsymbol{r}_G)] = \boldsymbol{F}, \tag{3.16.8a}$$

$$\begin{aligned} m\big\{&(\dot{v}_{O,x} + \omega_y v_{O,z} - \omega_z v_{O,y}) + (\dot{\omega}_y z_G - \dot{\omega}_z y_G) \\ &- [({\omega_y}^2 + {\omega_z}^2)x_G - \omega_x(\omega_y y_G + \omega_z z_G)]\big\} = F_x, \quad \text{etc., cyclically;} \end{aligned} \tag{3.16.8b}$$

and, of course, (its left side) coincides with (3.13.10a), with $\blacklozenge \to O$.

If, further, we choose, for algebraic simplicity, (body-fixed) *principal* axes of S at O, eqs. (3.16.6h–7b) reduce to

$$\boldsymbol{I}_O \cdot \boldsymbol{\alpha} + \boldsymbol{\omega} \times (\boldsymbol{I}_O \cdot \boldsymbol{\omega}) + m\boldsymbol{r}_G \times \boldsymbol{a}_O = \boldsymbol{M}_O, \tag{3.16.8c}$$

$$\begin{aligned} I_{O,xx}\,\dot{\omega}_x &+ (I_{O,zz} - I_{O,yy})\omega_y\,\omega_z \\ &+ m[y_G(\dot{v}_{O,z} + \omega_z v_{O,y} - \omega_y v_{O,z}) \\ &- z_G(\dot{v}_{O,y} + \omega_z v_{O,x} - \omega_x v_{O,z})] = M_{O,x}, \quad \text{etc., cyclically.} \end{aligned} \tag{3.16.8d}$$

If, finally, $O \to G$ then (3.16.8a, c) reduce, respectively, to the well-known

$$m(\partial \boldsymbol{v}_G/\partial t + \boldsymbol{\omega} \times \boldsymbol{v}_G) = \boldsymbol{F} \qquad \text{and} \qquad \boldsymbol{I}_G \cdot \boldsymbol{\alpha} + \boldsymbol{\omega} \times (\boldsymbol{I}_G \cdot \boldsymbol{\omega}) = \boldsymbol{M}_O. \tag{3.16.8e}$$

All these equations express the Eulerian principles of *linear* and *angular* momentum, for the rigid body S about various points, O, G, and so on.

(iii) We hope that the above lengthy and tedious calculations (especially those in components) have begun to convince the reader that, in this case at least, *the Lagrangean approach (L) is superior to the Eulerian approach (E)*; even though both are, roughly, theoretically equivalent. As Lur'e (1968, pp. 412–413) points out: In E, in order to derive rotational equations we begin with the principle of angular momentum about a fixed point in I–XYZ and then transfer both angular momenta and moments of forces to an arbitrary, say, body-fixed point; and in the process we utilize certain kinematico-inertial results. In L, on the other hand, the calculations (of the various partial and total derivatives of the kinetic energy) are almost automatic (… mechanical!); although their final results need "translating" back to the more geometrical Newtonian–Eulerian language. However, as already stressed (Introduction and this chapter), a far more important advantage of L over E, for theoretical work anyway, is that, even in complex problems, *the former (L) preserves the structure/form of the equations of motion, whereas in the latter (E) these equations appear structureless/formless* ("a bunch of terms"), and hence hard to remember, understand, and interpret.

(iv) The preceding equations of motion can, of course, be derived via *Appell's method*. Indeed, from equation (3.14.4d), with $\blacklozenge \to O$ and slight rearrangement, we obtain

$$\begin{aligned} 2S = m[&(\dot{v}_{O,x})^2 + (\dot{v}_{O,y})^2 + (\dot{v}_{O,z})^2] \\ &+ 2(\partial \boldsymbol{v}_O/\partial t) \cdot [\boldsymbol{\omega} \times m(\boldsymbol{v}_O + \boldsymbol{\omega} \times \boldsymbol{r}_G)] \\ &+ 2m\boldsymbol{\alpha} \cdot [\boldsymbol{r}_G \times (\partial \boldsymbol{v}_O/\partial t + \boldsymbol{\omega} \times \boldsymbol{v}_O)] \\ &+ \boldsymbol{\alpha} \cdot \boldsymbol{I}_O \cdot \boldsymbol{\alpha} + 2\boldsymbol{\alpha} \cdot [\boldsymbol{\omega} \times (\boldsymbol{I}_O \cdot \boldsymbol{\omega})]; \end{aligned} \tag{3.16.9a}$$

and from this, using the following simple identities ($\boldsymbol{a}, \boldsymbol{b}$: arbitrary vectors, and $k = x, y, z$):

$$\partial(\boldsymbol{a} \cdot \boldsymbol{b})/\partial a_k = b_k, \qquad \partial(\boldsymbol{a} \cdot \boldsymbol{b})/\partial b_k = a_k, \tag{3.16.9b}$$

and

$$\partial(\boldsymbol{a} \times \boldsymbol{b})/\partial a_x = \boldsymbol{i} \times \boldsymbol{b} = \boldsymbol{k} b_y - \boldsymbol{j} b_z, \quad \text{etc., cyclically,} \tag{3.16.9c}$$

we find

$$\partial S/\partial \dot{v}_{O,k} = m\{\dot{v}_{O,k} + (\boldsymbol{\omega} \times \boldsymbol{v}_O)_k + (\boldsymbol{\alpha} \times \boldsymbol{r}_G)_k + [\boldsymbol{\omega} \times (\boldsymbol{\omega} \times \boldsymbol{r}_G)]_k\} = F_k, \tag{3.16.10a}$$

$$\partial S/\partial \dot{\omega}_k = m\big[\boldsymbol{r}_G \times (\partial \boldsymbol{v}_O/\partial t + \boldsymbol{\omega} \times \boldsymbol{v}_O)\big]_k + \big[\boldsymbol{I}_O \cdot \boldsymbol{\alpha} + \boldsymbol{\omega} \times (\boldsymbol{I}_O \cdot \boldsymbol{\omega})\big]_k = M_{O,k}, \tag{3.16.10b}$$

that is, equations (3.16.8a, c), respectively. This completes the discussion of the quasi-velocity equations of the carrying body. Let us now turn to the q-equations of the carried system S.

Lagrange-Type Carried System Equations

(This is an application of §3.10, and so we recommend a rereading of that section.) First, we notice that, in view of the linearity of the holonomic Euler–Lagrange operator,

$$E_k(T) = E_k(T_0) + E_k(T_1) + E_k(T_2). \tag{3.16.11a}$$

Next, invoking the earlier $T_{0,1,2}$ expressions (3.16.3d–4c), we find, successively,

(i) $$E_k(T_0) = \cdots = -\partial T_0/\partial q_k$$
$$= -m(\boldsymbol{v}_O \times \boldsymbol{\Omega}) \cdot (\partial \boldsymbol{r}_G/\partial q_k) - (1/2)\boldsymbol{\Omega} \cdot (\partial \boldsymbol{I}_O/\partial q_k) \cdot \boldsymbol{\Omega}, \tag{3.16.11b}$$

(ii) $$E_k(T_1) = E_k(\boldsymbol{v}_O \cdot \boldsymbol{p}_{\text{rel}}) + E_k(\boldsymbol{\Omega} \cdot \boldsymbol{H}_{O,\text{rel}}). \tag{3.16.11c}$$

But:

(a) $$E_k(\boldsymbol{v}_O \cdot \boldsymbol{p}_{\text{rel}}) = (d\boldsymbol{v}_O/dt) \cdot (\partial \boldsymbol{p}_{\text{rel}}/\partial \dot{q}_k) + \boldsymbol{v}_O \cdot E_k(\boldsymbol{p}_{\text{rel}})$$
$$= m(d\boldsymbol{v}_O/dt) \cdot [\partial/\partial \dot{q}_k(\partial \boldsymbol{r}_G/\partial t)] + m\, \boldsymbol{v}_O \cdot E_k(\partial \boldsymbol{r}_G/\partial t), \tag{3.16.11d}$$

or, in view of the kinematical identities,

$$\partial/\partial \dot{q}_k(\partial \boldsymbol{r}_G/\partial t) = \partial \boldsymbol{r}_G/\partial q_k, \tag{3.16.11e}$$

$$d/dt(\partial \boldsymbol{r}_G/\partial q_k) = \partial/\partial q_k(d\boldsymbol{r}_G/dt) = \partial/\partial q_k(\partial \boldsymbol{r}_G/\partial t) + \partial/\partial q_k(\boldsymbol{\Omega} \times \boldsymbol{r}_G)$$
$$= \partial/\partial q_k(\partial \boldsymbol{r}_G/\partial t) + \boldsymbol{\Omega} \times (\partial \boldsymbol{r}_G/\partial q_k), \tag{3.16.11f}$$

from which

$$E_k(\partial \boldsymbol{r}_G/\partial t) \equiv \big[\partial/\partial \dot{q}_k(\partial \boldsymbol{r}_G/\partial t)\big]^{\cdot} - \partial/\partial q_k(\partial \boldsymbol{r}_G/\partial t)$$
$$= d/dt(\partial \boldsymbol{r}_G/\partial q_k) - \partial/\partial q_k(\partial \boldsymbol{r}_G/\partial t) = \boldsymbol{\Omega} \times (\partial \boldsymbol{r}_G/\partial q_k), \tag{3.16.11g}$$

so that (3.16.11d) becomes

$$E_k(\boldsymbol{v}_O \cdot \boldsymbol{p}_{\text{rel}}) = m\,\boldsymbol{a}_O \cdot (\partial \boldsymbol{r}_G/\partial q_k) + m(\boldsymbol{v}_O \times \boldsymbol{\Omega}) \cdot (\partial \boldsymbol{r}_G/\partial q_k)$$
$$= m\big[(\partial \boldsymbol{v}_O/\partial t + \boldsymbol{\Omega} \times \boldsymbol{v}_O) + \boldsymbol{v}_O \times \boldsymbol{\Omega}\big] \cdot (\partial \boldsymbol{r}_G/\partial q_k);$$

that is, finally,

$$E_k(\boldsymbol{v}_O \cdot \boldsymbol{p}_{\text{rel}}) = m(\partial \boldsymbol{v}_O/\partial t) \cdot (\partial \boldsymbol{r}_G/\partial q_k). \tag{3.16.11h}$$

(b) $$E_k(\boldsymbol{\Omega} \cdot \boldsymbol{H}_{O,\text{rel}}) = (d\boldsymbol{\Omega}/dt) \cdot (\partial \boldsymbol{H}_{O,\text{rel}}/\partial \dot{q}_k) + \boldsymbol{\Omega} \cdot E_k(\boldsymbol{H}_{O,\text{rel}})$$
$$\equiv (d\boldsymbol{\Omega}/dt) \cdot (\partial \boldsymbol{H}_{O,\text{rel}}/\partial \dot{q}_k) + \boldsymbol{\Omega} \cdot [(\partial \boldsymbol{H}_{O,\text{rel}}/\partial \dot{q}_k)^{\cdot} - \partial \boldsymbol{H}_{O,\text{rel}}/\partial q_k]$$
$$= (d\boldsymbol{\Omega}/dt) \cdot (\partial \boldsymbol{H}_{O,\text{rel}}/\partial \dot{q}_k)$$
$$+ \boldsymbol{\Omega} \cdot [\partial/\partial t(\partial \boldsymbol{H}_{O,\text{rel}}/\partial \dot{q}_k) + \boldsymbol{\Omega} \times (\partial \boldsymbol{H}_{O,\text{rel}}/\partial \dot{q}_k) - \partial \boldsymbol{H}_{O,\text{rel}}/\partial q_k];$$

that is, finally,

$$E_k(\boldsymbol{\Omega} \cdot \boldsymbol{H}_{O,\text{rel}}) = (d\boldsymbol{\Omega}/dt) \cdot (\partial \boldsymbol{H}_{O,\text{rel}}/\partial \dot{q}_k) + \boldsymbol{\Omega} \cdot [\partial/\partial t(\partial \boldsymbol{H}_{O,\text{rel}}/\partial \dot{q}_k) - \partial \boldsymbol{H}_{O,\text{rel}}/\partial q_k]$$
$$\equiv (d\boldsymbol{\Omega}/dt) \cdot (\partial \boldsymbol{H}_{O,\text{rel}}/\partial \dot{q}_k) + \boldsymbol{\Omega} \cdot E_{k,\text{rel}}(\boldsymbol{H}_{O,\text{rel}}), \tag{3.16.11i}$$

where

$$E_{k,\text{rel}}(\ldots) \equiv \partial/\partial t(\partial \ldots/\partial \dot{q}_k) - \partial \ldots/\partial q_k :$$
Relative Euler–Lagrange operator (for the carrying body). (3.16.11j)

Introducing all these partial results into the Lagrangean equations of motion, say $E_k(T) = Q_k$, or

$$E_k(T_2) = Q_k - E_k(T_1) - E_k(T_0), \tag{3.16.12a}$$

we obtain the equations of relative motion for the q's:

$$E_k(T_2) = Q_k - m(\partial \boldsymbol{v}_O/\partial t + \boldsymbol{\Omega} \times \boldsymbol{v}_O) \cdot (\partial \boldsymbol{r}_G/\partial q_k) + (1/2)\boldsymbol{\Omega} \cdot (\partial \boldsymbol{I}_O/\partial q_k) \cdot \boldsymbol{\Omega}$$
$$- (d\boldsymbol{\Omega}/dt) \cdot (\partial \boldsymbol{H}_{O,\text{rel}}/\partial \dot{q}_k) - \boldsymbol{\Omega} \cdot E_{k,\text{rel}}(\boldsymbol{H}_{O,\text{rel}}). \tag{3.16.12b}$$

However, the inertial, or fictitious (= frame dependent) "forces" on the right side of (3.16.12b) can be further transformed as follows:

(i) $$Q_{k,\text{translation}} \equiv Q_{k,T} \equiv -m(\partial \boldsymbol{v}_O/\partial t + \boldsymbol{\Omega} \times \boldsymbol{v}_O) \cdot (\partial \boldsymbol{r}_G/\partial q_k)$$
$$= -m\,\boldsymbol{a}_O \cdot (\partial \boldsymbol{r}_G/\partial q_k) = -\partial V_T/\partial q_k:$$
Lagrangean inertial force of translation, (3.16.12c)

where the corresponding potential of the *homogeneous* field of these "forces" is defined by

$$V_T \equiv m\,\boldsymbol{a}_O \cdot \boldsymbol{r}_G = S\,\boldsymbol{a}_O \cdot (dm\,\boldsymbol{r}) = S\,dm(\partial \boldsymbol{v}_O/\partial t + \boldsymbol{\Omega} \times \boldsymbol{v}_O) \cdot \boldsymbol{r}$$
$$= S\,dm\big[(\partial \boldsymbol{v}_O/\partial t) \cdot \boldsymbol{r} + \boldsymbol{r} \cdot (\boldsymbol{\Omega} \times \boldsymbol{v}_O)\big]. \tag{3.16.12d}$$

(ii)
$$Q_{k,\text{centrifugal}} \equiv Q_{k,CF} \equiv (1/2)[\boldsymbol{\Omega} \cdot (\partial \boldsymbol{I}_O/\partial q_k) \cdot \boldsymbol{\Omega}]$$
$$= \int dm\, (\boldsymbol{\Omega} \times \boldsymbol{r}) \cdot [\boldsymbol{\Omega} \times (\partial \boldsymbol{r}/\partial q_k)] = -\,\partial V_{CF}/\partial q_k : \quad \textit{Lagrangean centrifugal inertial force}, \tag{3.16.12e}$$

where the corresponding *centrifugal* potential of these "forces" is defined by

$$V_{CF} \equiv -(1/2)\boldsymbol{\Omega} \cdot \boldsymbol{I}_O \cdot \boldsymbol{\Omega} = -(1/2)\int dm(\boldsymbol{\Omega} \times \boldsymbol{r})^2. \tag{3.16.12f}$$

(iii) Since

$$\boldsymbol{H}_{O,\text{rel}} \equiv \int \boldsymbol{r} \times dm(\partial \boldsymbol{v}_O/\partial t) = \sum \left(\int dm\, \boldsymbol{r} \times (\partial \boldsymbol{r}/\partial q_k)\right)\dot{q}_k, \tag{3.16.12g}$$

we have

$$(d\boldsymbol{\Omega}/dt) \cdot (\partial \boldsymbol{H}_{O,\text{rel}}/\partial \dot{q}_k) = (d\boldsymbol{\Omega}/dt) \cdot \left(\int dm\, \boldsymbol{r} \times (\partial \boldsymbol{r}/\partial q_k)\right)$$
$$= \int dm\, \big((d\boldsymbol{\Omega}/dt) \times \boldsymbol{r}\big) \cdot (\partial \boldsymbol{r}/\partial q_k), \tag{3.16.12h}$$

and, therefore,

$$Q_{k,\text{rotation}} \equiv Q_{k,R} \equiv -(d\boldsymbol{\Omega}/dt) \cdot (\partial \boldsymbol{H}_{O,\text{rel}}/\partial \dot{q}_k)$$
$$= -\int [(d\boldsymbol{\Omega}/dt) \times (dm\, \boldsymbol{r})] \cdot (\partial \boldsymbol{r}/\partial q_k) = \int dm\, (d\boldsymbol{\Omega}/dt) \cdot [(\partial \boldsymbol{r}/\partial q_k) \times \boldsymbol{r}]$$
$$\equiv \int d\boldsymbol{I}_R \cdot \boldsymbol{e}_k\text{: } \textit{Lagrangean rotational inertial force}; \tag{3.16.12i}$$

where

$$d\boldsymbol{I}_{\text{rotation}} \equiv d\boldsymbol{I}_R \equiv -dm\,\big((d\boldsymbol{\Omega}/dt) \times \boldsymbol{r}\big)\text{: } \textit{Rotational inertial force, on a typical particle.} \tag{3.16.12j}$$

(iv) Finally, from (3.16.12g) we obtain

$$\partial \boldsymbol{H}_{O,\text{rel}}/\partial \dot{q}_k = \int dm\, \boldsymbol{r} \times (\partial \boldsymbol{r}/\partial q_k),$$

and from this, further,

$$\partial/\partial t(\partial \boldsymbol{H}_{O,\text{rel}}/\partial \dot{q}_k) = \sum \left\{\int dm\big[(\partial \boldsymbol{r}/\partial q_l) \times (\partial \boldsymbol{r}/\partial q_k) + \boldsymbol{r} \times (\partial^2/\partial q_l \partial q_k)\big]\right\}\dot{q}_l,$$

and

$$\partial \boldsymbol{H}_{O,\text{rel}}/\partial q_k = \sum \left\{\int dm\big[(\partial \boldsymbol{r}/\partial q_k) \times (\partial \boldsymbol{r}/\partial q_l) + \boldsymbol{r} \times (\partial^2 \boldsymbol{r}/\partial q_k \partial q_l)\big]\right\}\dot{q}_l.$$

Therefore, recalling (3.16.11j), we find, successively,

$$-\boldsymbol{\Omega} \cdot E_{k,\text{rel}}(\boldsymbol{H}_{O,\text{rel}}) = -2\boldsymbol{\Omega} \cdot \left(\sum \left\{\int dm\big[(\partial \boldsymbol{r}/\partial q_l) \times (\partial \boldsymbol{r}/\partial q_k)\big]\right\}\right)\dot{q}_l$$
$$= -2\boldsymbol{\Omega} \cdot \int dm[(\partial \boldsymbol{r}/\partial t) \times (\partial \boldsymbol{r}/\partial q_k)] \qquad \text{[recalling (3.16.3c)]},$$
$$= -\int [2(\boldsymbol{\Omega} \times dm\, \boldsymbol{v}_{\text{rel}})] \cdot (\partial \boldsymbol{r}/\partial q_k)$$
$$\equiv \sum (\boldsymbol{\Omega} \cdot \boldsymbol{G}_{kl})\, \dot{q}_l \equiv \sum g_{kl}\dot{q}_l, \tag{3.16.12k}$$

where

$$\boldsymbol{G}_{kl} \equiv 2 \mathsf{S}\, dm\, [(\partial \boldsymbol{r}/\partial q_k) \times (\partial \boldsymbol{r}/\partial q_l)] \equiv 2 \mathsf{S}\, dm(\boldsymbol{e}_k \times \boldsymbol{e}_l) \quad (= -\boldsymbol{G}_{lk}), \tag{3.16.12l}$$

$$g_{kl} \equiv \boldsymbol{\Omega} \cdot \boldsymbol{G}_{kl} = 2 \mathsf{S}\, dm[\boldsymbol{\Omega} \cdot (\boldsymbol{e}_k \times \boldsymbol{e}_l)]\text{: } \textit{Gyroscopic coefficients} \quad (= -g_{lk}), \tag{3.16.12m}$$

or, finally [recalling (3.10.1f, g)],

$$-\boldsymbol{\Omega} \cdot E_{k,\mathrm{rel}}(\boldsymbol{H}_{O,\mathrm{rel}}) = \sum g_{kl}\, \dot{q}_l$$
$$\equiv Q_{k,\mathrm{gyroscopic}} \equiv Q_{k,\mathrm{Coriolis}} \equiv -E_{k,C} \equiv G_k. \tag{3.16.12n}$$

[Also, recall mathematically similar terms arising out of the coefficients of the $\sim \dot{q}$ terms of the generalized potential, equations (3.9.8a ff.).]

In view of all these partial results, eqs. (3.16.12c–n), and recalling that $T_{\mathrm{relative}} \equiv T_{\mathrm{rel}} \equiv T_2$, we can rewrite (3.16.12b) as

$$E_k(T_{\mathrm{rel}}) = Q_k + Q_{k,R} + G_k - \partial(V_{CF} + V_T)/\partial q_k \equiv Q_k + Q_{k,inertial}. \tag{3.16.13}$$

This completes the discussion of the Lagrange-type carried system equations.

REMARKS

The *left* side of (3.16.13) clearly depends only on quantities describing the configuration and motions of the carried body (bodies) relative to the carrying one; the *four* parts of $Q_{k,inertial}$ are "correction terms," since $O\text{–}xyz$ is noninertial. Hence:

(i) If the motion of $O\text{–}xyz$ is known, or prescribed, *only eqs.* (*3.16.13*) *need be considered;* not the earlier Hamel-type carrying equations. Actually, since we have indeed proved that, in the case of relative motion, LP, for the carried system, takes the form

$$\sum \left[E_k(T_{\mathrm{rel}}) - Q_k - Q_{k,inertial}\right] \delta q_k = 0, \tag{3.16.14}$$

any other set of Lagrangean, or Appellian, equations can be employed with the replacements:

$$T \to T_{\mathrm{rel}} \qquad \text{and} \qquad Q_k \to Q_k + Q_{k,inertial}; \tag{3.16.14a}$$

for example, it is not hard to see that $E_k(T_{\mathrm{rel}}) \equiv \partial S_{\mathrm{rel}}/\partial \ddot{q}_k$, where $S_{\mathrm{rel}} =$ part of S that depends solely on $t, q, \dot{q}, \ddot{q}$.

Additional Pfaffian constraints and/or nonholonomic coordinates can be easily handled using the methods described in §3.2–3.8.

(ii) If, on the other hand, the motion of $O\text{–}xyz$ is *not* known, then these equations should be solved together with the earlier ones of the carrying body. Then, we would have a system of $n + 6$ coupled equations of the *second order* in the n q's and of the *first order* in the 6 $v_{O;x,y,z}$ and $\omega_{x,y,z}$. To these we should also add the (linear and homogeneous) relations between the *holonomic* velocity components of $O\text{–}xyz$ relative to $I\text{–}XYZ$, say $\dot{q}_{1,\ldots,6}$ (*not* the q's of S relative to $O\text{–}xyz$), and their *nonholonomic* counterparts $\omega_{1,\ldots,6} \equiv v_{O;x,y,z}/\omega_{x,y,z}$.

(iii) Finally, if we had chosen *inertial (I)* Lagrangean coordinates, say $q_I = q_I(q_{NI}, t)$, where the *noninertial* (*NI*) coordinates are the earlier q's, then eqs. (3.16.2a) would become

$$\Re = \boldsymbol{r}_O + \boldsymbol{r}(q_{NI}) = \boldsymbol{r}_O + \boldsymbol{r}(t, q_I), \tag{3.16.14b}$$

that is, $\boldsymbol{r}$ would be *nonstationary*! In this case, the relative motion equations (3.16.13) would still hold, but with $T_{\text{rel}} \equiv T_2$ replaced by $T_{2,2} + T_{2,1} + T_{2,0}$, where

$$2T_{2,2} \equiv \sum\sum M_{2,kl}\,\dot{q}_k\,\dot{q}_l, \qquad T_{2,1} \equiv \sum M_{2,k}\,\dot{q}_k, \qquad 2T_{2,0} \equiv M_{2,0}, \tag{3.16.14c}$$

$$M_{2,kl} \equiv S\, dm(\partial\boldsymbol{r}/\partial q_k)\cdot(\partial\boldsymbol{r}/\partial q_l), \qquad M_{2,k} \equiv S\, dm(\partial\boldsymbol{r}/\partial q_k)\cdot(\partial\boldsymbol{r}/\partial t),$$
$$M_{2,0} \equiv S\, dm(\partial\boldsymbol{r}/\partial t)\cdot(\partial\boldsymbol{r}/\partial t). \tag{3.16.14d}$$

Example 3.16.1 *Direct Derivation of the Lagrangean Equations of the Carried Body via LP.* Let us assume, for concreteness, that $O{-}xyz$ has a *prescribed* motion. Now, the Newton–Euler equation of motion of a typical particle P, of the carried system S, of mass dm and acted upon by a total *impressed* (*reaction*) force $d\boldsymbol{F}(d\boldsymbol{R})$ is (recalling §1.7)

$$dm\,\boldsymbol{a}_{\text{rel}} = (d\boldsymbol{F} + d\boldsymbol{R}) + (d\boldsymbol{f}_O + d\boldsymbol{f}_T + d\boldsymbol{f}_C), \tag{a}$$

where

$d\boldsymbol{f} = d\boldsymbol{F} + d\boldsymbol{R}$: *Real (i.e., non–frame-dependent) force,*

$d\boldsymbol{f}_O \equiv -dm\,\boldsymbol{a}_O$: *Transport translational "force"*
(due to the inertial acceleration of the pole O),

$$d\boldsymbol{f}_T \equiv -dm[(d\boldsymbol{\Omega}/dt)\times\boldsymbol{r} + \boldsymbol{\Omega}\times(\boldsymbol{\Omega}\times\boldsymbol{r})]$$
$$= -dm((d\boldsymbol{\Omega}/dt)\times\boldsymbol{r}) - dm[(\boldsymbol{\Omega}\cdot\boldsymbol{r})\boldsymbol{\Omega} - \Omega^2\boldsymbol{r}]:$$

Transport rotational + centrifugal "force" (= purely centrifugal, if $\boldsymbol{\Omega}$ = constant; due to the inertial angular motion of $O{-}xyz$),

$d\boldsymbol{f}_C = -2\,dm\,(\boldsymbol{\Omega}\times\boldsymbol{v}_{\text{rel}})$:

Coriolis "force" (due to the coupling of the relative motion of S with the inertial angular motion of $O{-}xyz$). (b)

[Incidentally, the above show that, in the most general case of motion,

$$dm(\partial^2\boldsymbol{r}/\partial t^2) = d\boldsymbol{f} + (d\boldsymbol{f}_O + d\boldsymbol{f}_T + d\boldsymbol{f}_C) = \textit{function of } t, \boldsymbol{r}, \boldsymbol{v}_{\text{rel}} \equiv \partial\boldsymbol{r}/\partial t.]$$

Dotting (a) with $\delta\mathfrak{R} = \delta\boldsymbol{r}_O(t) + \delta\boldsymbol{r} = \delta\boldsymbol{r}$, and then summing over the system particles, yields LP for the carried body:

$$S\, dm\,\boldsymbol{a}_{\text{rel}}\cdot\delta\boldsymbol{r} = S\,(d\boldsymbol{F} + d\boldsymbol{R})\cdot\delta\boldsymbol{r} + S\,(d\boldsymbol{f}_O + d\boldsymbol{f}_T + d\boldsymbol{f}_C)\cdot\delta\boldsymbol{r}. \tag{c}$$

Now:

(i) Since $\boldsymbol{a}_{\text{rel}} = \partial\boldsymbol{v}_{\text{rel}}/\partial t = \partial/\partial t(\partial\boldsymbol{r}/\partial t)$, and during the above virtual variations the axes O–xyz are held fixed—that is, $\delta\boldsymbol{r} = \delta_{\text{rel}}\,\boldsymbol{r} = \sum(\partial\boldsymbol{r}/\partial q_k)\,\delta q_k$—and the q_k are *noninertial* coordinates of S relative to $O{-}xyz$, reasoning as in (3.3.3 ff.), we readily conclude that

$$S\, dm\,\boldsymbol{a}_{\text{rel}}\cdot\delta\boldsymbol{r} = \sum E_k(T_{\text{rel}})\,\delta q_k \equiv \sum\left[(\partial T_{\text{rel}}/\partial\dot{q}_k)^{\cdot} - \partial T_{\text{rel}}/\partial q_k\right]\delta q_k, \tag{d}$$

where

$$2T_{\text{rel}} = 2T_{\text{rel}}(q, \dot{q}) = \mathbf{S}\, dm\, \boldsymbol{v}_{\text{rel}} \cdot \boldsymbol{v}_{\text{rel}}. \tag{e}$$

(ii) The Q_k are defined, as usual, by (recalling §3.4)

$$\mathbf{S}\, d\boldsymbol{F} \cdot \delta\boldsymbol{r} = \sum Q_k\, \delta q_k. \tag{f}$$

(iii) The (relative = inertial) virtual work of the constraint reactions vanishes:

$$\mathbf{S}\, d\boldsymbol{R} \cdot \delta\boldsymbol{r} = \mathbf{S}\, d\boldsymbol{R} \cdot \delta_{\text{rel}}\boldsymbol{r} = \sum R_k\, \delta q_k = 0. \tag{g}$$

(iv) We define the following fictitious Lagrangean forces:

$$\mathbf{S}\, d\boldsymbol{f}_O \cdot \delta\boldsymbol{r} \equiv -\mathbf{S}\, dm\, \boldsymbol{a}_O \cdot \delta\boldsymbol{r}$$
$$\equiv \sum Q_{k,translational\ \text{transport}}\, \delta q_k \equiv \sum Q_{k,T}\, \delta q_k, \tag{h}$$

$$\mathbf{S}\, d\boldsymbol{f}_T \cdot \delta\boldsymbol{r} \equiv -\mathbf{S}\, dm\big((d\boldsymbol{\Omega}/dt) \times \boldsymbol{r}\big) \cdot \delta\boldsymbol{r} - \boldsymbol{\Omega} \cdot \Big(\mathbf{S}\, dm(\boldsymbol{\Omega} \cdot \boldsymbol{r})\, \delta\boldsymbol{r}\Big) + \Omega^2 \Big(\mathbf{S}\, dm\, \boldsymbol{r} \cdot \delta\boldsymbol{r}\Big)$$
$$\equiv \sum Q_{k,rotational+centrifugal\ \text{transport}}\, \delta q_k \equiv \sum (Q_{k,R} + Q_{k,CF})\, \delta q_k, \tag{i}$$

$$\mathbf{S}\, d\boldsymbol{f}_C \cdot \delta\boldsymbol{r} \equiv -2\mathbf{S}\, dm(\boldsymbol{\Omega} \times \boldsymbol{v}_{\text{rel}}) \cdot \delta\boldsymbol{r}$$
$$\equiv \sum Q_{k,\text{Coriolis/gyroscopic}}\, \delta q_k \equiv \sum Q_{k,C}\, \delta q_k. \tag{j}$$

Now, since the motion of $O{-}xyz$ is prescribed, $\boldsymbol{a}_O$, $\boldsymbol{\Omega}$, and $d\boldsymbol{\Omega}/dt$ are given functions of time, and, therefore, the "forces" $Q_{k;T,R,CF}$ will be functions of t and the q's, while the $Q_{k,C}$ will be functions of t, q's, and $\dot{q}$'s. If the δq's are independent—that is, if S is *unconstrained relative to* (*the constrained*) $O{-}xyz$—then (c), with (d–j), yield the earlier equations (3.16.13):

$$E_k(T_{\text{rel}}) = Q_k + Q_{k,T} + Q_{k,R} + Q_{k,CF} + Q_{k,C}, \tag{k}$$

where $Q_{k,T} = -\partial V_T/\partial q_k$, $Q_{k,CF} = -\partial V_{CF}/\partial q_k$, $Q_{k,C} = G_k$.

If the δq are *constrained*, then we proceed in, by now, well-known ways; that is, either we *adjoin* the constraints to (c ff.) via *multipliers*, or *embed* them via relative *quasi variables*. Let the reader work out the details of this direct approach if the motion of $O{-}xyz$ is also unknown.

Example 3.16.2 *Cartesian Tensor Derivation of the Lagrangean Equations of the Carried Body*. Let us consider, without much loss in generality, two frames/axes with common origin: an inertial/fixed $O{-}x_{k'}$, and a noninertial/moving (rotating) $O{-}x_k$ ($k = 1, 2, 3$; $k' = 1', 2', 3'$). As is well known (§1.1), these two sets of axes are related by the following *orthogonal* transformation:

$$x_{k'} = \sum A_{k'k} x_k \;\Leftrightarrow\; x_k = \sum A_{kk'} x_{k'}, \tag{a}$$

where $\{A_{k'k} \equiv \cos(x_{k'}, x_k) = \cos(x_k, x_{k'}) \equiv A_{kk'} = \textit{pure function of time}\}$ is a *proper orthogonal* tensor/matrix. The inertial Lagrangean function and corresponding equations of motion of a particle P of unit mass (i.e., m = 1, for analytical simplicity) and under ordinary potential forces only (here we are interested in kinematical/frame of reference effects—nonpotential forces can always be added later) are, respectively,

$$L = (1/2)\left(\sum \dot{x}_{k'}\,\dot{x}_{k'}\right) - V(x_{k'}, t) = L(t, x_{k'}, \dot{x}_{k'}), \tag{b}$$

$$(\partial L/\partial \dot{x}_{k'})^{\cdot} - \partial L/\partial x_{k'} = 0: \quad (\dot{x}_{k'})^{\cdot} + \partial V/\partial x_{k'} = 0. \tag{c}$$

Next, using (a), we will express L in terms of $\{t, x_k, \dot{x}_k, A_{k'k}, \dot{A}_{k'k}\}$ and then, using the frame invariance of the Lagrangean operator/equations *in these new variables*, we will obtain the equations of relative motion of P: $(\partial L/\partial \dot{x}_k)^{\cdot} - \partial L/\partial x_k = 0$. Indeed, $(\ldots)^{\cdot}$-differentiating (a), we obtain

$$\dot{x}_{k'} = \sum (\dot{A}_{k'k} x_k + A_{k'k}\dot{x}_k), \tag{d}$$

and, therefore, successively,

$$\begin{aligned}\sum \dot{x}_{k'}\dot{x}_{k'} &= \sum \left(\sum (\dot{A}_{k'k} x_k + A_{k'k}\,\dot{x}_k)\right)\left(\sum (\dot{A}_{k'l}\,x_l + A_{k'l}\,\dot{x}_l)\right)\\ &= \sum\sum\sum (A_{k'k}A_{k'l}\dot{x}_k\dot{x}_l + \dot{A}_{k'k}\dot{A}_{k'l}x_k x_l + 2\dot{A}_{k'k}A_{k'l}x_k\dot{x}_l),\end{aligned} \tag{e}$$

or, since [(1.7.22a ff.)], $\sum A_{k'k}A_{k'l} = \delta_{kl}$ and $\dot{A}_{k'k} = \sum A_{k'l}\Omega_{lk}$, where

$\sum \dot{A}_{k'k}A_{k'l} = \sum \dot{A}_{kk'}A_{lk'} \equiv \Omega_{lk} = -\Omega_{kl}$:

(inertial) angular velocity tensor of moving axes relative to fixed axes, but resolved along the moving axes, (f)

equation (e) transforms further to

$$\begin{aligned}\sum \dot{x}_{k'}\dot{x}_{k'} = \sum\sum \delta_{kl}\dot{x}_k\dot{x}_l + \sum\sum\sum \left(\sum A_{k'r}\Omega_{rk}\right)\left(\sum A_{k's}\Omega_{sl}\right)x_k x_l\\ + 2\sum\sum \Omega_{lk}\dot{x}_l x_k,\end{aligned} \tag{g}$$

and so, finally, the moving axes Lagrangean becomes

$$L = \sum (1/2)\dot{x}_k\dot{x}_k + \sum\sum\sum (1/2)\Omega_{sk}\Omega_{sl}\,x_k\,x_l + \sum\sum \Omega_{lk}\,\dot{x}_l\,x_k - V(t, x_k). \tag{h}$$

Now:

- The first term $\sum (1/2)\dot{x}_k\dot{x}_k$, will give rise to the *relative* acceleration;
- The second term $\sum\sum\sum (1/2)\Omega_{sk}\Omega_{sl}x_k x_l$: *centrifugal potential*, will give rise to the acceleration of *transport*; and
- The third term $\sum\sum \Omega_{lk}\dot{x}_l x_k$: *Schering potential*, will give rise to the *Coriolis* acceleration.

Indeed, from (h) we obtain

$$\partial L/\partial \dot{x}_k = \dot{x}_k + \sum\sum \Omega_{lr}\delta_{lk}x_r = \dot{x}_k + \sum \Omega_{kr}x_r, \tag{i}$$

$$\Rightarrow (\partial L/\partial \dot{x}_k)^{\cdot} = \ddot{x}_k + \sum (\dot{\Omega}_{kr}x_r + \Omega_{kr}\dot{x}_r), \tag{j}$$

$$\begin{aligned}\partial L/\partial x_k &= \sum\sum \Omega_{sk}\Omega_{sl}x_l + \sum \Omega_{rk}\dot{x}_r - \partial V/\partial x_k\\ &= \sum\sum \Omega_{sk}\Omega_{sl}x_l - \sum \Omega_{kr}\dot{x}_r - \partial V/\partial x_k,\end{aligned} \tag{k}$$

and, therefore, the Lagrangean equations of relative motion, $(\partial L/\partial \dot{x}_k)^{\cdot} - \partial L/\partial x_k = 0$, become

$$\ddot{x}_k - \sum\sum \Omega_{sk}\Omega_{sl}x_l + \sum \dot{\Omega}_{kl}x_l + 2\sum \Omega_{kl}\dot{x}_l = -\partial V/\partial x_k. \tag{l}$$

Let the reader show that (l) is none other than [with $\boldsymbol{\omega} = (\omega_k)$, $\boldsymbol{\alpha} = (\dot{\omega}_k)$, $\boldsymbol{r} = (x_k)$, $\boldsymbol{v}_{\rm rel} = (\dot{x}_k)$]

$$\ddot{x}_k + [\boldsymbol{\omega} \times (\boldsymbol{\omega} \times \boldsymbol{r})]_k + (\boldsymbol{\alpha} \times \boldsymbol{r})_k + (2\boldsymbol{\omega} \times \boldsymbol{v}_{\rm rel})_k = -\partial V/\partial x_k. \tag{m}$$

HINT

Recall that (1.1.16a ff.) $(\boldsymbol{\Omega} \cdot \boldsymbol{r})_k = (\boldsymbol{\omega} \times \boldsymbol{r})_k$: $\sum \Omega_{kl}x_l = \sum\sum \varepsilon_{ksl}\,\omega_s\,x_l$; that is, $\boldsymbol{\Omega} = (\Omega_{kl} = -\Omega_{lk} = \sum \varepsilon_{ksl}\,\omega_s)$. See also Morgenstern and Szabó (1961, pp. 7–9).

Problem 3.16.1 Extend the tensorial method of the preceding example to the most general case of relative motion (i.e., no common origin of relatively moving frames):

$$x_{k'} = \sum A_{k'k}x_k + b_{k'} \;\Leftrightarrow\; x_k = \sum A_{kk'}x_{k'} + b_k, \tag{a}$$

where $b_{k'} = -\sum A_{k'k}b_k$ = components of position vector of moving origin O relative to fixed origin, along the *fixed* axes; $b_k = -\sum A_{kk'}\,b_{k'}$; and $\{A_{k'k},\, b_{k'},\, b_k\}$ = *pure functions of time*. This will give rise to "forces" due to the inertial motion ("transport") of the origin O.

Example 3.16.3 *Direct Lagrangean Treatment of Gyroscopic Couple.* Let us consider an axisymmetric (carried) body, spinning with angular velocity $\boldsymbol{\omega}_o$ about its axis of symmetry. The latter is fixed relative to the body's "housing" (carrying body). It is shown in gyrodynamics that $\boldsymbol{\omega}_o$ gives rise to an additional moment, or "gyroscopic couple," *on the housing + fixed (nonspinning) gyro* system equal to $(C\boldsymbol{\omega}_o) \times \boldsymbol{\Omega}$, where C = *moment of inertia of carried body about its spinning axis*, and $\boldsymbol{\Omega}$ = vector of *inertial angular velocity of housing*. Let us find the Lagrangean expression of that couple.

Here

$$\boldsymbol{\Omega} = \sum(\partial\boldsymbol{\Omega}/\partial\dot{q}_k)\dot{q}_k + \partial\boldsymbol{\Omega}/\partial t \Rightarrow \delta\boldsymbol{\Theta} = \sum(\partial\boldsymbol{\Omega}/\partial\dot{q}_k)\delta q_k, \tag{a}$$

where $d\boldsymbol{\Theta}/dt \equiv \boldsymbol{\Omega}$. Therefore, the virtual work of the gyro-couple equals, successively,

$$\begin{aligned}
\delta' W_G &\equiv [(C\boldsymbol{\omega}_o) \times \boldsymbol{\Omega}] \cdot \delta\boldsymbol{\Theta} \\
&= \Big\{(C\boldsymbol{\omega}_o) \times \Big(\sum (\partial\boldsymbol{\Omega}/\partial\dot{q}_l)\dot{q}_l + \partial\boldsymbol{\Omega}/\partial t\Big)\Big\} \cdot \Big(\sum (\partial\boldsymbol{\Omega}/\partial\dot{q}_k)\,\delta q_k\Big) \\
&\equiv \sum\Big(\sum g_{kl}\dot{q}_l + g_k\Big)\delta q_k \equiv \sum (G_k + g_k)\,\delta q_k,
\end{aligned} \tag{b}$$

where

$$\begin{aligned} g_{kl} &\equiv [(C\boldsymbol{\omega}_o) \times (\partial\boldsymbol{\Omega}/\partial\dot{q}_l)] \cdot (\partial\boldsymbol{\Omega}/\partial\dot{q}_k) \\ &= (C\boldsymbol{\omega}_o) \cdot [(\partial\boldsymbol{\Omega}/\partial\dot{q}_l) \times (\partial\boldsymbol{\Omega}/\partial\dot{q}_k)] \equiv (C\boldsymbol{\omega}_o) \cdot \boldsymbol{G}_{kl} = -g_{lk}, \end{aligned} \tag{c}$$

$$\begin{aligned} g_k &\equiv [(C\boldsymbol{\omega}_o) \times (\partial\boldsymbol{\Omega}/\partial t)] \cdot (\partial\boldsymbol{\Omega}/\partial\dot{q}_k) \\ &= (C\boldsymbol{\omega}_o) \cdot [(\partial\boldsymbol{\Omega}/\partial t) \times (\partial\boldsymbol{\Omega}/\partial\dot{q}_k)] \equiv (C\boldsymbol{\omega}_o) \cdot \boldsymbol{G}_k \quad (\equiv g_{k,n+1} \equiv g_{k,t}). \end{aligned} \tag{d}$$

Clearly, $\sum G_k\dot{q}_k = \sum\sum g_{kl}\dot{q}_l\dot{q}_k = 0$; that is, the G_k are gyroscopic. From the above, it follows that, if there are no further constraints, the equations of motion of the system *housing* + *gyro* are

$$(\partial T_A/\partial\dot{q}_k)^{\cdot} - \partial T_A/\partial q_k = Q_k + G_k + g_k, \tag{e}$$

where T_A = (*inertial*) *kinetic energy of system housing + gyro if* $\boldsymbol{\omega}_o = \mathbf{0}$ (i.e., with the gyro held fixed in its housing) ≡ *apparent kinetic energy*. The above can be easily extended to a system consisting of several housings and gyros. [See Cabannes, 1965, pp. 201–203, 274–277; Roseau, 1987, pp. 49–53; also §8.4 ff., and Papastavridis (*Elementary Mechanics* (under production), examples on gyrodynamics).]

Example 3.16.4 *Rotating Frames: The Free Particle.* Here, using Lagrangean methods, we derive the equations of plane motion of a particle P of mass m on a frame $O\text{–}xyz$ rotating with (inertial) angular velocity $\boldsymbol{\Omega} = (0, 0, \Omega)$ relative to an inertial one $O\text{–}XYZ$; and such that $OZ \equiv Oz$ (fig. 3.37). By $(\ldots)^{\cdot}$-differentiating the well-known transformation equations between these two frames

$$X = x\cos\phi - y\sin\phi, \qquad Y = x\sin\phi + y\cos\phi, \tag{a}$$

and recalling that $\Omega = \dot{\phi}$, we obtain

$$\begin{aligned} \dot{X} &= (\dot{x}\cos\phi - \dot{y}\sin\phi) - (x\sin\phi + y\cos\phi)\Omega, \\ \dot{Y} &= (\dot{x}\sin\phi + \dot{y}\cos\phi) + (x\cos\phi - y\sin\phi)\Omega. \end{aligned} \tag{b}$$

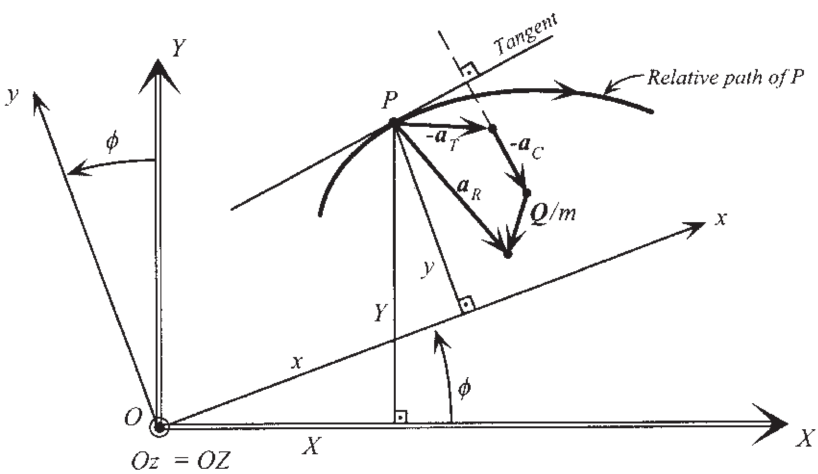

Figure 3.37 Particle P moving on a rotating frame $O\text{–}xy\,(z)$.

To understand better the meaning of (b), we consider the special instant at which the axes of these two frames coincide; that is, for $\phi = 0$. Then, (b) yields

$$\dot{X} = \dot{x} - y\,\Omega, \qquad \dot{Y} = \dot{y} + x\,\Omega, \tag{c}$$

that is, $\dot{X} \neq \dot{x}$ and $\dot{Y} \neq \dot{y}$, even though, then, $X = x$ and $Y = y$; eq. (c) is the $O\text{–}xy/XY$ component form of the well-known vector equation (§1.7)

$$d\boldsymbol{r}/dt = \partial\boldsymbol{r}/\partial t + \boldsymbol{\Omega} \times \boldsymbol{r}, \qquad \text{where } \boldsymbol{r} = (x, y, 0),\ \boldsymbol{\Omega} = (0, 0, \Omega). \tag{d}$$

Thanks to (c), the inertial (double) kinetic energy of P becomes

$$2T = m[(\dot{X})^2 + (\dot{Y})^2] \equiv 2(T_2 + T_1 + T_0), \tag{e}$$

where

$$\begin{aligned} 2T_2 &\equiv m[(\dot{x})^2 + (\dot{y})^2], \\ T_1 &\equiv m(x\dot{y} - \dot{x}y)\Omega, \\ 2T_0 &\equiv m(x^2 + y^2)\Omega^2 = m(X^2 + Y^2)\Omega^2 = m\,r^2\Omega^2, \end{aligned} \tag{f}$$

and, therefore, if $\delta' W = Q_x\,\delta x + Q_y\,\delta y$, Lagrange's equations here are

$$[m(\dot{x} - y\,\Omega)]^{\cdot} - m(\dot{y} + x\,\Omega)\Omega = m(\ddot{x} - 2\dot{y}\,\Omega - x\,\Omega^2 - y\,\dot{\Omega}) = Q_x, \tag{g}$$

$$[m(\dot{y} + x\,\Omega)]^{\cdot} - m(\dot{x} - y\,\Omega)\Omega = m(\ddot{y} + 2\dot{x}\,\Omega - y\,\Omega^2 + x\,\dot{\Omega}) = Q_y; \tag{h}$$

and, from these, the following Newton–Euler (*O–xy-centric*) forms result:

$$m\,\ddot{x} = Q_x - m(-x\,\Omega^2 - y\,\dot{\Omega}) - (-2m\,\dot{y}\,\Omega), \tag{i}$$

$$m\,\ddot{y} = Q_y - m(-y\,\Omega^2 + x\,\dot{\Omega}) - (+2m\,\dot{x}\,\Omega), \tag{j}$$

where (in two dimensions)

$$\boldsymbol{a}_T = (-x\,\Omega^2 - y\,\dot{\Omega}, -y\,\Omega^2 + x\,\dot{\Omega}) = \textit{Transport acceleration (normal + tangent)}, \tag{k}$$

$$\boldsymbol{a}_C = (-2\dot{y}\,\Omega, +2\dot{x}\,\Omega) = \textit{Coriolis acceleration.} \tag{l}$$

Since $\boldsymbol{a}_C$ is perpendicular to $\boldsymbol{v}_{\mathrm{rel}} = (\dot{x}, \dot{y})$, if (i) $\dot{\Omega} = 0$ and (ii) $\delta' W = -\delta V(x, y)$, eqs. (g, h/i, j) readily combine to produce the *relative power equation*

$$m(\dot{x}\,\ddot{x} + \dot{y}\,\ddot{y}) - m(x\,\dot{x} + y\,\dot{y})\Omega^2 = -\dot{V}; \tag{m}$$

and the latter integrates easily to the *generalized energy (Jacobi–Painlevé) integral* [recalling (3.9.11n)]

$$T_2 + (V - T_0) \equiv h = \textit{constant}\ (\neq E \equiv T + V). \tag{n}$$

Example 3.16.5 *Rotating Frames: General System.* Here, we extend the preceding example to a general system. (Although the general theory of such systems in moving axes has already been studied in this section, nevertheless, we think that the ad hoc treatment of this special but important case, presented below, is quite instructive.) Summing (e, f) over the entire system, we readily find

$$2T = S\left[(\dot{X})^2 + (\dot{Y})^2\right]dm \equiv 2(T_2 + T_1 + T_0)$$
$$\equiv 2\left[T_{\text{rel}} + \Omega\, H_{O,\text{rel}} + (1/2)\Omega^2 I_O\right] = 2\left[T_{\text{rel}} + \Omega\, H_O - (1/2)\Omega^2 I_O\right], \qquad \text{(a)}$$

where

$$2T_2 \equiv 2T_{\text{rel}} \equiv S\left[(\dot{x})^2 + (\dot{y})^2\right]dm$$
$$= 2(\textit{kinetic energy relative to rotating frame}) \qquad (\text{i.e., } T \text{ for } \Omega = 0), \quad \text{(b)}$$
$$T_1 \equiv \Omega\, S\,(x\,\dot{y} - y\,\dot{x})\,dm \equiv \Omega\, H_{O,\text{rel}}, \qquad \text{(c)}$$
$$2T_0 \equiv \Omega^2 S\,(x^2 + y^2)\,dm = \Omega^2 S\,(X^2 + Y^2)dm = \Omega^2 I_O$$
$$= 2(\textit{centrifugal energy}); \qquad \text{(d)}$$
$$H_{O,\text{rel}} \equiv S\,(x\,\dot{y} - y\,\dot{x})\,dm = \textit{angular momentum} \text{ about } OZ \equiv Oz \text{ and relative to the } \textit{rotating} \text{ frame}, \qquad \text{(e)}$$
$$H_O \equiv S\,(X\dot{Y} - Y\dot{X})\,dm = S\,[x(\dot{y} + x\,\Omega) - y(\dot{x} - y\,\Omega)]\,dm$$
$$= \cdots = H_{O,\text{rel}} + \Omega\, I_O = \textit{angular momentum} \text{ about } OZ \equiv Oz \text{ and relative to the } \textit{fixed} \text{ frame}, \qquad \text{(f)}$$
$$I_O \equiv S\,(X^2 + Y^2)\,dm = S\,(x^2 + y^2)\,dm = S\,r^2\,dm$$
$$= \textit{moment of inertia about } OZ \equiv Oz\ (\textit{frame independent}); \qquad \text{(g)}$$
$$(\Rightarrow\ \Omega\, H_O = \Omega\, H_{O,\text{rel}} + \Omega^2 I_O \ = \ T_1 + 2T_0).$$

[In the general three-dimensional case, since $\dot{Z} = \dot{z}$, a $(1/2)(\dot{z})^2 dm$ term must be added to the integrand of T and T_{rel}.]

Now, if the system is completely describable, relative to the rotating frame, by n Lagrangean coordinates $q = (q_1, \ldots, q_n)$ [i.e., if $x = x(q)$, $y = y(q)$, $z = z(q)$], then $T_{\text{rel}} =$ *quadratic* and *homogeneous* in the $\dot{q}$'s, with coefficients functions of the q's. If, further, $T = T(q, \dot{\phi} \equiv \Omega)$—that is, $q_{n+1} = \phi =$ additional "*azimuthal*" cyclic coordinate (§ 8.4), for the complete *inertial description* of the system—and $Q_k = -\partial V/\partial q_k$, $Q_{n+1} \equiv M_O =$ *total impressed moment about* $OZ \equiv Oz$, and no further constraints are present, then the $n+1$ Lagrangean equations for these q's are

$$(\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k = -\partial V/\partial q_k, \qquad \text{(h)}$$

and [by (a), and noting that, equivalently,

$$\partial T/\partial\Omega = H_{O,\text{rel}} + \Omega I_O = H_O + \Omega(\partial H_O/\partial\Omega) - \Omega I_O = H_O + \Omega(I_O) - \Omega I_O = H_O]$$
$$(\partial T/\partial\Omega)^{\cdot} - \partial T/\partial\phi = \dot{H}_O = M_O. \qquad \text{(i)}$$

If $M_O = 0$ (*free* rotating system), then by eq. (i), $H_O = 0$ and $\Omega \neq \textit{constant}$; whereas if $\Omega = \textit{constant}$ (*constrained* rotation), then $M_O = \textit{constraint reaction}$ (*a Lagrangean multiplier*) $\neq 0$, and therefore $H_O \neq \textit{constant}$.

Special Case

If $\Omega = constant$ (e.g., $O{-}xyz \rightarrow$ Earth), substituting eq. (a ff.) into eq. (h), we obtain

$$(\partial T_{\mathrm{rel}}/\partial \dot{q}_k)^{\cdot} - \partial T_{\mathrm{rel}}/\partial q_k + \Omega\,[(\partial H_{O,\mathrm{rel}}/\partial \dot{q}_k)^{\cdot} - \partial H_{O,\mathrm{rel}}/\partial q_k] \\ - (1/2)\Omega^2(\partial I_O/\partial q_k) = -\partial V/\partial q_k. \qquad \text{(j)}$$

But, since $\partial \dot{x}/\partial \dot{q}_k = \partial x/\partial q_k$ and $\partial \dot{x}/\partial q_k = (\partial x/\partial q_k)^{\cdot}$ [i.e., $E_k(\dot{x}) = 0$, etc.], we have

(i) $\partial H_{O,\mathrm{rel}}/\partial \dot{q}_k = \displaystyle\mathcal{S}\,[x(\partial \dot{y}/\partial \dot{q}_k) - y(\partial \dot{x}/\partial \dot{q}_k)]\,dm = \mathcal{S}\,[x(\partial y/\partial q_k) - y(\partial x/\partial q_k)]\,dm,$

and, from this,

$$(\partial H_{O,\mathrm{rel}}/\partial \dot{q}_k)^{\cdot} = \mathcal{S}\,[\dot{x}(\partial y/\partial q_k) - \dot{y}(\partial x/\partial q_k)]\,dm + \mathcal{S}\,[x(\partial \dot{y}/\partial q_k) - y(\partial \dot{x}/\partial q_k)]\,dm;$$

(ii) $\partial H_{O,\mathrm{rel}}/\partial q_k = \displaystyle\mathcal{S}\,[\dot{y}(\partial x/\partial q_k) - \dot{x}(\partial y/\partial q_k)]\,dm + \mathcal{S}\,[x(\partial \dot{y}/\partial q_k) - y(\partial \dot{x}/\partial q_k)]\,dm.$

Therefore, subtracting these two expressions side by side, we find

$$\begin{aligned}(\partial H_{O,\mathrm{rel}}/\partial \dot{q}_k)^{\cdot} &- \partial H_{O,\mathrm{rel}}/\partial q_k \\ &= 2\mathcal{S}\,[\dot{x}\,(\partial y/\partial q_k) - \dot{y}\,(\partial x/\partial q_k)]\,dm \\ &= 2\mathcal{S}\left\{\left(\sum (\partial x/\partial q_l)\dot{q}_l\right)(\partial y/\partial q_k) - \left(\sum (\partial y/\partial q_l)\dot{q}_l\right)(\partial x/\partial q_k)\right\} dm \\ &\equiv \sum G_{lk}\,\dot{q}_l, \qquad \text{(k)}\end{aligned}$$

where

$$\begin{aligned}G_{lk} &\equiv 2\mathcal{S}\,[(\partial x/\partial q_l)(\partial y/\partial q_k) - (\partial x/\partial q_k)(\partial y/\partial q_l)]\,dm \\ &\equiv 2\mathcal{S}\,[(\partial(x, y)/\partial(q_l, \partial q_k)]\,dm = -G_{kl} \\ &\quad \text{(analytically known, once the } q\text{'s are chosen).} \qquad \text{(l)}\end{aligned}$$

In view of (k, l), eq. (j) can be rewritten in the definitive form

$$E_k(T_{\mathrm{rel}}) + \Omega \sum G_{lk}\dot{q}_l = -\partial V_{\mathrm{rel}}/\partial q_k; \qquad \text{(m)}$$

where

$$V_{\mathrm{rel}} \equiv V - (1/2)\Omega^2 I_O = \textit{total relative potential} \quad (= V - T_0). \qquad \text{(m1)}$$

Other possible *nonpotential* and *noninertial* forces, such as friction and/or constraints, can be added to the *right* side of (m) as Q's and/or multiplier-proportional terms.

The Lagrangean form (m) brings out clearly the *differences* between uniformly rotating axes ($\Omega = constant \neq 0$) and inertial ones ($\Omega = 0$). These are:

- The additional *centrifugal potential* $V_{CF} = -\Omega^2 I_O/2$ [recalling (3.16.12f)], which gives rise to the *centrifugal "force"* $-\partial V_{CF}/\partial q_k = (1/2)\Omega^2(\partial I_O/\partial q_k)$; and
- The additional *gyroscopic* (or *compounded centrifugal*, or *Coriolis*), and generally *nonpotential, "forces"* $-\Omega \sum G_{lk}\dot{q}_l = \Omega \sum G_{kl}\dot{q}_l$.

It is not hard to see that, in the absence of nonpotential forces, the equations of motion of the particle in ex. 3.16.4, eqs. (i, j), can be rewritten, respectively, in the (m)–like form

$$m\,\ddot{x} = -\partial V_{\mathrm{rel}}/\partial x + 2m\,\Omega\,\dot{y}, \qquad m\,\ddot{y} = -\partial V_{\mathrm{rel}}/\partial y - 2m\,\Omega\,\dot{x}, \tag{n}$$

(also $m\,\ddot{z} = -\partial V_{\mathrm{rel}}/\partial z$), $V_{\mathrm{rel}} \equiv V - (1/2)m\,\Omega^2(x^2 + y^2)$; or, vectorially (2 dimensions),

$$m(\partial^2\boldsymbol{r}/\partial t^2) = -\boldsymbol{grad}\,V_{\mathrm{rel}} + 2m(\partial\boldsymbol{r}/\partial t) \times \boldsymbol{\Omega}. \tag{n1}$$

Equations (n, n1) are useful in atmospheric physics ($\Omega =$ *rotation of Earth*).]

Relative Equilibrium

This is defined as the special motion for which

$$T_{\mathrm{rel}} = 0 \qquad \text{and all} \qquad \dot{q}_k = 0. \tag{o}$$

Then, eqs. (m) yield the following *conditions for relative equilibrium*:

$$\partial V_{\mathrm{rel}}/\partial q_k \equiv \partial\big(V - \tfrac{1}{2}\Omega^2 I_O\big)/\partial q_k = 0; \tag{p}$$

namely, that V_{rel} be stationary.

For further discussion, especially the case of (small) motion around such equilibria, and their stability, and applications, see, for example (alphabetically): Appell (vol. 4, 1932, 1937), Duhem (1911, pp. 422-499), Lamb (1932, pp. 195–199, 307–310, 427–428, 713–714; 1943, pp. 244–255), Ledoux (1958, pp. 616–620), Lyttleton (1953, pp. 19–30); also §8.6 in this volume.

Problem 3.16.2 *Rotating Frames.* Continuing from the preceding example, show that:

(i) In terms of *corotating* (i.e., noninertial) polar coordinates $(r,\ \theta)$, for each particle,

$$\begin{aligned} 2T &= \mathsf{S}\left[(\dot{r})^2 + r^2(\Omega + \dot{\theta})^2\right] dm \\ &= \mathsf{S}\left[(\dot{r})^2 + r^2(\dot{\theta})^2\right] dm + 2\Omega\Big(\mathsf{S}\, r^2\dot{\theta}\,dm\Big) + \Omega^2\Big(\mathsf{S}\, r^2\,dm\Big); \end{aligned} \tag{a}$$

(ii)
$$H_{O,\mathrm{rel}} \equiv \mathsf{S}\,(x\dot{y} - y\dot{x})\,dm = \mathsf{S}\,(r^2\dot{\theta})\,dm = \cdots = \sum \beta_k\,\dot{q}_k, \tag{b}$$

where

$$\beta_k \equiv \mathsf{S}\,[x(\partial y/\partial q_k) - y(\partial x/\partial q_k)]\,dm = \beta_k(q);$$

then show that

$$G_{lk} \equiv \partial\beta_k/\partial q_l - \partial\beta_l/\partial q_k = -G_{kl} \qquad (k, l = 1, \ldots, n). \tag{c}$$

Problem 3.16.3 *Rotating Frames: Special Cases.* Continuing from the preceding problem, show that (i) if $\dot{\theta} = 0$, or (ii) if $n = 1$ (i.e., if the system is described on the uniformly rotating frame by only *one* coordinate q), then the $\omega/\dot{q}$-proportional (gyroscopic) terms, in the corresponding equations of motion, vanish; that is, then, the effect of the rotation Ω there is only the centrifugal force $(1/2)\Omega^2(\partial I_O/\partial q)$.

HINT

In (ii) $H_{O,\mathrm{rel}} =$ *(some function of q)* $\dot{q}$; then $E(H_{O,\mathrm{rel}}) = \cdots$.

Problem 3.16.4 *Rotating Frames: A Special Power Equation.* Continuing from the preceding example, and employing its notations, show that the power equation of a system moving on a *uniformly* rotating frame is

$$d/dt(T_{\mathrm{rel}} + V - \Omega^2 I_O/2) \equiv (T_{\mathrm{rel}} + V_{\mathrm{rel}})^{\cdot} = \sum Q_k\dot{q}_k, \tag{a}$$

where Q_k = *nonpotential* and *noninertial* forces; and, therefore, if all $Q_k = 0$, eq. (a) leads to the *Jacobi–Painlevé* integral

$$T_{\mathrm{rel}} + V - \Omega^2 I_O/2 = 0. \tag{b}$$

HINTS

We have

$$dT/dt = (T_2 + T_0)^{\cdot} + \Omega\Big[\mathbf{S}\,(x\ddot{y} - y\ddot{x})\,dm\Big]$$

[by the results of ex. 3.16.4 and ex. 3.16.5]

$$= (T_2 - T_0)^{\cdot} + \Omega\Big[\mathbf{S}\,(x\,dF_y - y\,dF_x)\Big]$$

[by eqs. (g, h / i, j) of ex. 3.16.4, summed over the entire system, with $\Omega = constant$ and $(Q_x, Q_y) \to d\boldsymbol{F} = (dF_x, dF_y) =$ *total impressed force* on particle of mass *dm*]. (c)

But, also, by the "elementary" power theorem (since, here, *impressed forces* = *external forces*), $dT/dt =$ *Total externally supplied power*

$$= \Omega\Big[\mathbf{S}\,(x\,dF_y - y\,dF_x)\Big] + \sum Q_k\dot{q}_k. \tag{d}$$

Problem 3.16.5 *Rotating Frames: A Special Power Equation (continued).* Continuing from the preceding example, and employing its notations, show that:

(i) If $M_O = 0$, then $H_O = constant$; and
(ii) If, further, we choose Ω so that (always) $H_{O,\mathrm{rel}} = 0$, then

$$H_O = \Omega\, I_O \qquad \text{and} \qquad T = \cdots = T_{\mathrm{rel}} + {H_O}^2/2I_O; \tag{a}$$

and thus deduce that if all the (nonpotential) Q_k's vanish, the (inertial) energy equation $E \equiv T + V = constant$ specializes to

$$T_{\mathrm{rel}} + V + {H_O}^2/2I_O = constant; \tag{b}$$

that is, eq. (b) of the preceding problem but with $\Omega \to H_O$ and $-\Omega^2 I_O/2 \to {H_O}^2/2I_O$.

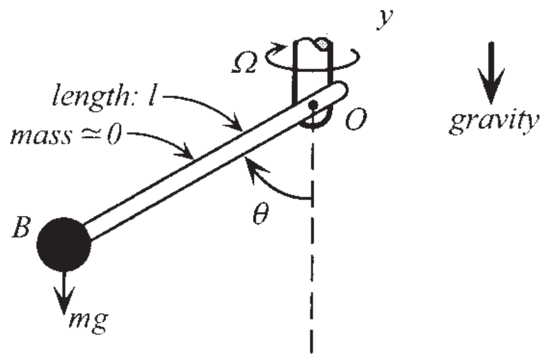

Figure 3.38 Uniformly rotating plane pendulum.

Problem 3.16.6 *Rotating Pendulum.* Consider a mathematical pendulum, of length l and mass m, whose plane of oscillation is constrained to rotate with constant inertial angular velocity Ω about its vertical axis (fig. 3.38).

(i) Show that its equations of (relative angular) motion and energy are, respectively,

$$\ddot{\theta} + (g/l)\sin\theta - (1/2)\Omega^2\sin(2\theta) = 0, \tag{a}$$

$$(ml^2/2)\left[(\dot{\theta})^2 - 2(g/l)\cos\theta - \Omega^2\sin^2\theta\right] \equiv h = constant. \tag{b}$$

Explain the absence of gyroscopic terms in both (a) and (b).

(ii) Linearize (a) in θ and then show that if $\Omega^2 < g/l$, the pendulum performs harmonic oscillations about the vertical with period $\tau = 2\pi[(g/l) - \Omega^2]^{-1/2}$; that is, the configuration of relative equilibrium $\theta = 0$ is *stable*; whereas, if $\Omega^2 \geq g/l$, it is *unstable* (i.e., we need the nonlinear equation).

(iii) Next, add $\dot{\theta}$-proportional (small) friction $-f\dot{\theta}$ *(f = constant friction coefficient)*. Does this affect the stability/instability of $\theta = 0$? Explain.

For an alternative discussion, see Kauderer (1958, pp. 239–242); and for discussions of the stability of the equilibrium configurations of (a), based on (b), and more see e.g. (alphabetically): Babakov (1968, pp. 463–467), Greenwood (1977, pp. 62, 74–77), Pars (1965, pp. 85–86).

Problem 3.16.7 *Rotating Frames: Carrying Body Effect.* Consider a particle P of mass m in unconstrained motion relative to a carrying rigid body B. The latter can spin freely about the fixed vertical axis Oz.

(i) Show that the inertial kinetic energy of the entire system "$B + P$," expressed in terms of components along B-fixed axes $O{-}xyz$, is

$$\begin{aligned} 2T = m[(\dot{x})^2 + (\dot{y})^2 + (\dot{z})^2] + 2m(x\dot{y} - y\dot{x})\dot{\phi} \\ + [I + m(x^2 + y^2)](\dot{\phi})^2, \end{aligned} \tag{a}$$

where I = *moment of inertia of B about Oz*, ϕ = *inertial angular coordinate of B*; and, therefore, its four Lagrangean equations of motion are (with some obvious notations)

$$x: \quad m[\ddot{x} - 2\dot{\phi}\,\dot{y} - x(\dot{\phi})^2 - y\,\ddot{\phi}] = Q_x, \tag{b}$$

$$y: \quad m[\ddot{y} + 2\dot{\phi}\,\dot{x} - y(\dot{\phi})^2 + x\,\ddot{\phi}] = Q_y, \tag{c}$$

$$z: \quad m\,\ddot{z} = Q_z, \tag{d}$$

$$\phi: \quad \{[I + m(x^2 + y^2)]\dot{\phi} + m(x\,\dot{y} - y\,\dot{x})\}^{\cdot} = \Phi. \tag{e}$$

(ii) Specialize the above to the case where B spins at a *constant* rate: $\dot{\phi}$ = *constant*; that is, adjust the torque Φ so as to maintain $\ddot{\phi} = 0$, or $\delta\phi = 0$; or, equivalently, assume that $I \to \infty$.

(iii) Show that the above special case equations result by application of Lagrange's method to

$$2T = m[(\dot{x})^2 + (\dot{y})^2 + (\dot{z})^2] + 2m\,\Omega(x\dot{y} - y\dot{x}) + m\,\Omega^2(x^2 + y^2)$$

$=$ *inertial (double) kinetic energy of P referred to axes spinning with constant inertial angular velocity* $\dot{\phi} = \Omega$. (f)

Problem 3.16.8 *Rotating Frames: 3-D Case.* Extend the results of the preceding examples and problems to the general case of two frames with common origin: (i) a *fixed* $O{-}XYZ$ (*inertial*), and (ii) a *moving* $O{-}xyz$ (*noninertial*) rotating relative to the first with constant angular velocity Ω (fig. 3.39).

Specifically, show that the (inertial) kinetic energy of a particle P of mass m equals

$$T = T_2 + T_1 + T_0, \tag{a}$$

where

$$2T_2 = m\,[(\dot{x})^2 + (\dot{y})^2 + (\dot{z})^2], \tag{b}$$

$$T_1 = m\,[\dot{x}(z\,\omega_y - y\,\omega_z) + \dot{y}(x\,\omega_z - z\,\omega_x) + \dot{z}(y\,\omega_x - x\,\omega_y)], \tag{c}$$

$$2T_0 = m\,[(z\,\omega_y - y\,\omega_z)^2 + (x\,\omega_z - z\,\omega_x)^2 + (y\,\omega_x - x\,\omega_y)^2]; \tag{d}$$

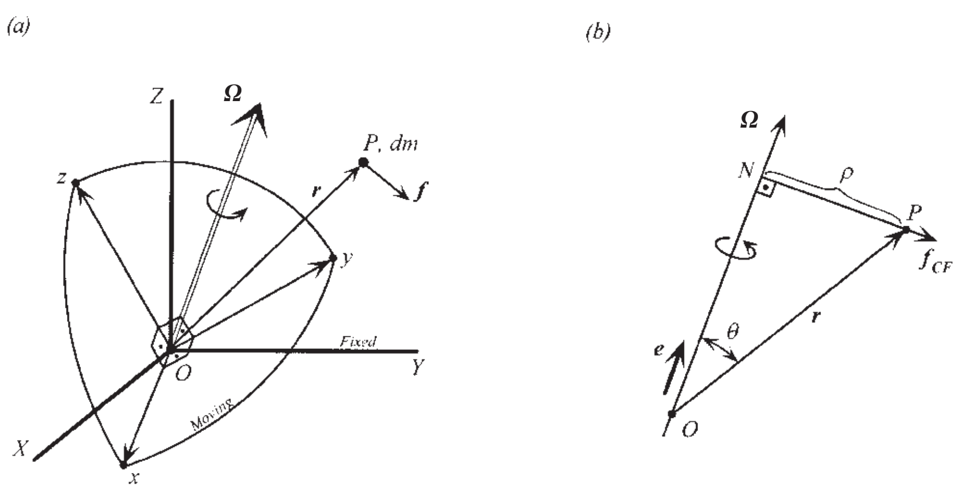

Figure 3.39 (a) Particle P in general relative motion in a rotating frame O–xyz; (b) details of centrifugal "force" $\boldsymbol{f}_{CF}$.

and, therefore, by the method of Lagrange, the equations of (unconstrained) motion of P in $O\text{–}xyz$, under a total impressed force $\boldsymbol{F} = (F_x, F_y, F_z)$, are

$$m(\partial^2\boldsymbol{r}/\partial t^2) = \boldsymbol{F} + \partial T_0/\partial\boldsymbol{r} + \boldsymbol{f}_C, \tag{e}$$

where

$$\begin{aligned} \boldsymbol{f}_C &= -2m\boldsymbol{\Omega} \times (\ \ \boldsymbol{r}\ \ \ \ t) = -2m\boldsymbol{\Omega} \times \boldsymbol{v}_{\mathrm{rel}} \equiv -2m\mathbf{\Omega} \cdot \boldsymbol{v}_{\mathrm{rel}} \\ &\qquad [\text{definition of } \textit{antisymmetric} \text{ angular velocity } \textit{tensor}\ \mathbf{\Omega}\ (\S1.1,\ \S1.7)] \\ &= \textit{Gyroscopic (Coriolis) ``force''} \\ &= -2m(\Omega_x, \Omega_y, \Omega_z) \times (\dot{x}, \dot{y}, \dot{z}) \\ &= (2m\,\Omega_z\,\dot{y} - 2m\,\Omega_y\,\dot{z},\ 2m\,\Omega_x\,\dot{z} - 2m\,\Omega_z\,\dot{x},\ 2m\,\Omega_y\,\dot{x} - 2m\,\Omega_x\,\dot{y}), \end{aligned} \tag{f}$$

and

$$\mathbf{\Omega} = \begin{pmatrix} \Omega_{xx} = 0 & \Omega_{xy} = -\Omega_z & \Omega_{xz} = \Omega_y \\ \Omega_{yx} = \Omega_z & \Omega_{yy} = 0 & \Omega_{yz} = -\Omega_x \\ \Omega_{zx} = -\Omega_y & \Omega_{zy} = \Omega_x & \Omega_{zz} = 0 \end{pmatrix}. \tag{g}$$

Problem 3.16.9 *Rotating Frames: 3-D Case (continued).* Continuing from the preceding problem, show that

$$\partial T_0/\partial x = \cdots = m[\Omega^2 x - (\boldsymbol{\Omega} \cdot \boldsymbol{r})\Omega_x], \quad \text{etc., cyclically,} \tag{a}$$

and, further, with $\boldsymbol{\Omega} = \Omega\,\boldsymbol{e}$ [fig. 3.39(b)], that

$$\begin{aligned} \boldsymbol{f}_{CF} &= \boldsymbol{grad}\ T_0 \equiv \partial T_0/\partial\boldsymbol{r} = \cdots = m\,\Omega^2[\boldsymbol{r} - (\boldsymbol{e} \cdot \boldsymbol{r})\boldsymbol{e}] \\ &= m\,\Omega^2(\boldsymbol{r} - \boldsymbol{ON}) = (m\,\Omega^2)\boldsymbol{NP} \\ &= \textit{Centrifugal ``force''} \qquad (\text{i.e., } |\boldsymbol{f}_{CF}| = m\,\Omega^2\rho). \end{aligned} \tag{b}$$

Problem 3.16.10 *Lagrangean of a Particle in General Relative Motion.* Consider a particle P of mass m in unconstrained motion relative to a *noninertial* frame $O\text{–}xyz$ that has given motion, under a total force $\boldsymbol{f} = -\partial V(\boldsymbol{r})/\partial\boldsymbol{r}$, $V(\boldsymbol{r}) =$ *potential*. Show that:

(i) To within terms equal to the *total time derivative of a given function of the coordinates and time* (i.e., to within "Lagrange-important" terms), the (double) Lagrangean of P is

$$2L\ =\ m\boldsymbol{v}_{\mathrm{rel}} \cdot \boldsymbol{v}_{\mathrm{rel}} + 2m\,\boldsymbol{v}_{\mathrm{rel}}(\boldsymbol{\Omega} \times \boldsymbol{r}) + m(\boldsymbol{\Omega} \times \boldsymbol{r})^2 - 2m(\boldsymbol{a}_O \cdot \boldsymbol{r}) - 2V(\boldsymbol{r}). \tag{a}$$

(ii) $$\begin{aligned} &\partial L/\partial\boldsymbol{v}_{\mathrm{rel}} = m(\boldsymbol{v}_{\mathrm{rel}} + \boldsymbol{\Omega} \times \boldsymbol{r}) \equiv \boldsymbol{p}_{\mathrm{rel}} + m(\boldsymbol{\Omega} \times \boldsymbol{r}) = m\,\boldsymbol{v} \equiv \boldsymbol{p} \\ &(\boldsymbol{v} = \textit{inertial velocity of } P \textit{ relative to the moving axes origin } O), \end{aligned} \tag{b}$$

$$\partial L/\partial\boldsymbol{r} = m(\boldsymbol{v}_{\mathrm{rel}} \times \boldsymbol{\Omega}) + m(\boldsymbol{\Omega} \times \boldsymbol{r}) \times \boldsymbol{\Omega} - m\,\boldsymbol{a}_O - \partial V/\partial\boldsymbol{r}. \tag{c}$$

Hence, obtain the Lagrangean equations of P: $(\partial L/\partial\boldsymbol{v}_{\mathrm{rel}})^{\boldsymbol{\cdot}} - \partial L/\partial\boldsymbol{r} = \boldsymbol{0}$.

Notice that in the Lagrangean formalism, the equations of motion have the same *form* in both inertial and noninertial axes; but the corresponding Lagrangeans *are* different.

Problem 3.16.11 *Energetics of a Particle in Relative Motion.* Specialize the results of the preceding problem to the case where $O\text{–}xyz$ rotates *uniformly* about a fixed axis through O.

(i) Show that, in this case, the *generalized energy* of a particle,

$$h \equiv h_{\text{rel}} \equiv (\partial L/\partial \boldsymbol{v}_{\text{rel}}) \cdot \boldsymbol{v}_{\text{rel}} - L \equiv \boldsymbol{p} \cdot \boldsymbol{v}_{\text{rel}} - L, \tag{a}$$

reduces to (notice absence of terms *linear* in $\boldsymbol{v}_{\text{rel}}$)

$$h = (1/2)m{v_{\text{rel}}}^2 + [V - (1/2)m(\boldsymbol{\Omega} \times \boldsymbol{r})^2]. \tag{b}$$

(ii) Interpret the *centrifugal potential*

$$V_{CF} \equiv -(1/2)m(\boldsymbol{\Omega} \times \boldsymbol{r})^2 = (m/2)[(\boldsymbol{\Omega} \cdot \boldsymbol{r})^2 - \Omega^2 r^2].$$

[Alternatively, we can show that the corresponding *centrifugal "force"*

$$\boldsymbol{f}_{CF} \equiv -m\,\boldsymbol{a}_{CF} = -m[\boldsymbol{\Omega} \times (\boldsymbol{\Omega} \times \boldsymbol{r})] \tag{c}$$

is *irrotational*; that is, show that $\boldsymbol{curl}\, \boldsymbol{f}_{CF} = -m\, \boldsymbol{curl}\, [\boldsymbol{\Omega} \times (\boldsymbol{\Omega} \times \boldsymbol{r})] = \boldsymbol{0} \Rightarrow \boldsymbol{f}_{CF} = -\boldsymbol{grad}\, V_{CF}$.]

Problem 3.16.12 *Energetics of a Particle in Relative Motion (continued).* Continuing from the preceding problem (of uniform fixed-axis rotation), show that the generalized energy h can be expressed as

$$h_{\text{rel}} \equiv h = h_{\text{inertial}} - \boldsymbol{H}_O \cdot \boldsymbol{\Omega}, \tag{a}$$

where

$$h_{\text{inertial}} \equiv (1/2)m\, v^2 + V = T + V \quad (\equiv E), \tag{b}$$

$$v^2 = \boldsymbol{v} \cdot \boldsymbol{v} = \textit{inertial velocity of } P, \qquad \boldsymbol{H}_O \equiv \boldsymbol{r} \times (m\boldsymbol{v}) = \boldsymbol{r} \times (\partial L/\partial \boldsymbol{v}_{\text{rel}}). \tag{c}$$

Equation (a) expresses the *law of transformation of (generalized) energy* between an inertial frame and a uniformly rotating/nontranslating one. However, both linear and angular momentum of P in the noninertial frame $O\text{–}xyz$ are equal to their inertial counterparts in the inertial $O\text{–}XYZ$:

$$\boldsymbol{p} \equiv \partial L/\partial \boldsymbol{v}_{\text{rel}} = m\,\boldsymbol{v} \equiv \boldsymbol{p}_{\text{inertial}} \quad \text{and} \quad \boldsymbol{H}_O \equiv \boldsymbol{r} \times (\partial L/\partial \boldsymbol{v}_{\text{rel}}) = \boldsymbol{r} \times \boldsymbol{p} = \boldsymbol{r} \times \boldsymbol{p}_{\text{inertial}} \equiv \boldsymbol{H}_{O,\text{rel}}.$$

For a scalar derivation, see also Born (1927, p. 23).

Example 3.16.6 *Motion of a Particle Near the Surface of Earth.* Let us obtain the equations of motion of a particle P of mass m near the surface of Earth (fig. 3.40). Referring to fig. 3.40, and employing the usual notations, we readily find

$$\boldsymbol{\Omega} = (\Omega_x, \Omega_y, \Omega_z) = (-\Omega \cos\theta, 0, \Omega \sin\theta), \tag{a}$$

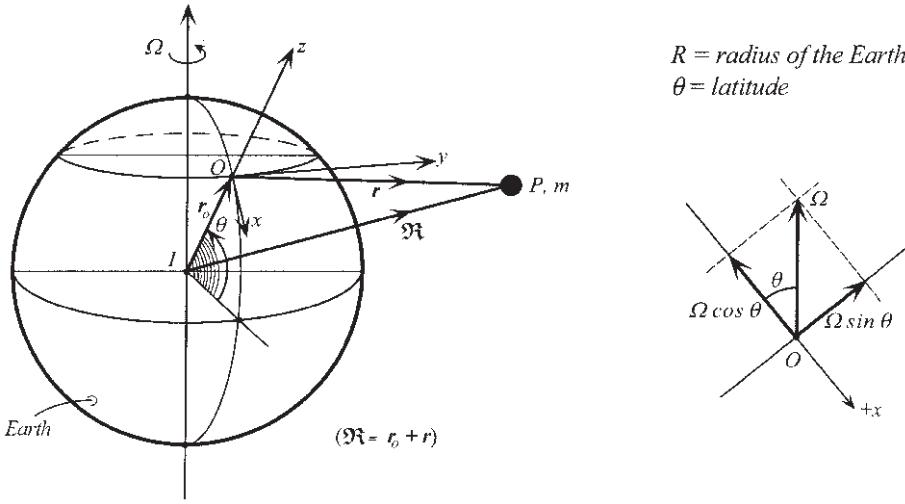

Figure 3.40 Motion of a particle P near Earth's surface, using Earth-bound axes O–xyz. $\boldsymbol{r_o} \to \boldsymbol{R}$, R = radius of the Earth; θ = latitude.

$$\begin{aligned} \boldsymbol{v}_P \equiv \boldsymbol{v} = \boldsymbol{v}_O + \boldsymbol{v}_{P/O} &= \boldsymbol{\Omega} \times \boldsymbol{R} + (\boldsymbol{v}_{P,rel} + \boldsymbol{\Omega} \times \boldsymbol{r}) = \boldsymbol{v}_{P,rel} + \boldsymbol{\Omega} \times (\boldsymbol{R} + \boldsymbol{r}) \quad \{\text{with } \boldsymbol{r}_o \to \boldsymbol{R} = R\boldsymbol{k}\} \\ &= (\dot{x}, \dot{y}, \dot{z}) + (-\Omega \cos\theta,\ 0,\ \Omega \sin\theta) \times (x, y, R + z) \\ &= (\dot{x} - \Omega\, y \sin\theta,\ \dot{y} + \Omega\, x \sin\theta + \Omega(R+z)\cos\theta,\ \dot{z} - \Omega\, y\cos\theta), \end{aligned} \tag{b}$$

and, therefore,

$$2T = mv^2 = \left[(\dot{x} - \Omega y \sin\theta)^2 + \big(\dot{y} + \Omega x \sin\theta + \Omega(R+z)\cos\theta\big)^2 + (\dot{z} - \Omega y \cos\theta)^2\right]; \tag{c}$$

also, in the neighborhood of Earth's surface, $V = mgz$.

From the above, it follows that Lagrange's equations for x, y, z are

$$\ddot{x} = 2\Omega\, \dot{y} \sin\theta + \Omega^2[\sin\theta(x \sin\theta + z\cos\theta) + R \sin\theta\cos\theta], \tag{d}$$

$$\ddot{y} = -2\Omega\, \dot{x} \sin\theta - 2\Omega\, \dot{z}\cos\theta + \Omega^2 y, \tag{e}$$

$$\ddot{z} = 2\Omega\, \dot{y}\cos\theta + \Omega^2[\cos\theta(x\sin\theta + z\cos\theta) + R\cos^2\theta] - g. \tag{f}$$

The terms proportional to Ω are the components of the *Coriolis (gyroscopic)* "force" per unit mass, and those proportional to Ω^2 are those of the centrifugal "force."

APPROXIMATE SOLUTION

Since $\Omega = 2\pi/(24)\,(60)\,(60) \approx 7.27 \times 10^{-5}$ rad/s, to a *first* Ω-approximation, we may neglect in (d–f) the Ω^2-terms, and rewrite the rest so that we can easily identify the gyroscopic terms ($\sim \Omega$) in there more easily:

$$\ddot{x} = (0)\dot{x} + (2\Omega\sin\theta)\dot{y} + (0)\dot{z}, \tag{g}$$

$$\ddot{y} = (-2\Omega\sin\theta)\dot{x} + (0)\dot{y} + (-2\Omega\cos\theta)\dot{z}, \tag{h}$$

$$\ddot{z} = (0)\dot{x} + (2\Omega\cos\theta)\dot{y} + (0)\dot{z} - g. \tag{i}$$

To solve the linear system (g–i) we choose, for algebraic simplicity, the *free-fall initial conditions* at $t = 0$:

$$x = 0, \quad y = 0, \quad z = H\ (> 0); \qquad \dot{x} = 0, \quad \dot{y} = 0, \quad \dot{z} = 0. \tag{j}$$

Then (we recall that, here, $\theta = constant$), eqs. (g) and (i) integrate once, respectively, to

$$\dot{x} = (2\Omega \sin\theta)y, \qquad \dot{z} = (2\Omega\cos\theta)y - g\,t. \tag{k}$$

Substituting (k) into (h), neglecting $\sim \Omega^2$ terms, for consistency, and integrating the resulting equation while enforcing (j), we obtain

$$\ddot{y} = -4\Omega^2 y + (2\Omega g\cos\theta)t \;\approx\; (2\Omega g\cos\theta)t \;\Rightarrow\; y = (\Omega g\cos\theta/3)t^3\ (> 0); \tag{l}$$

that is, in both the *north* ($0 \le \theta \le \pi/2$) and *south* ($-\pi/2 \le \theta \le 0$) hemispheres, the particle deviates *eastwards*. Thanks to (l), and (j), and to within $\sim \Omega$ terms, eqs. (k) finally integrate, respectively, to

$$x = 0 \qquad \text{and} \qquad z = H - (1/2)gt^2. \tag{m}$$

Clearly, for $t = (2H/g)^{1/2} \;\Rightarrow\; z = 0$; that is, P hits the ground. Then, its eastward deviation is

$$y_{\text{eastward}} = (2\Omega H/3)(2H/g)^{1/2}\cos\theta. \tag{n}$$

The above derivation of the equations of motion (d–f) clearly shows the superiority and simplicity of the Lagrangean method over that of Newton–Euler.

For an alternative solution of (g–i) see, for example, Spiegel (1967, pp. 152–154); and, for an instructive treatment of the effect of the $\sim \Omega^2$ terms, see, for example, Bahar (1991).

Problem 3.16.13 Consider the gyroscope shown in fig. 3.41. With the usual notations [and A/C = *transverse/axial* (principal) moments of inertia at G], show that:

(i)
$$2T = A(\dot{\theta})^2 + A(\dot{\phi}\sin\theta)^2 + C(\dot{\psi} + \dot{\phi}\cos\theta)^2. \tag{a}$$

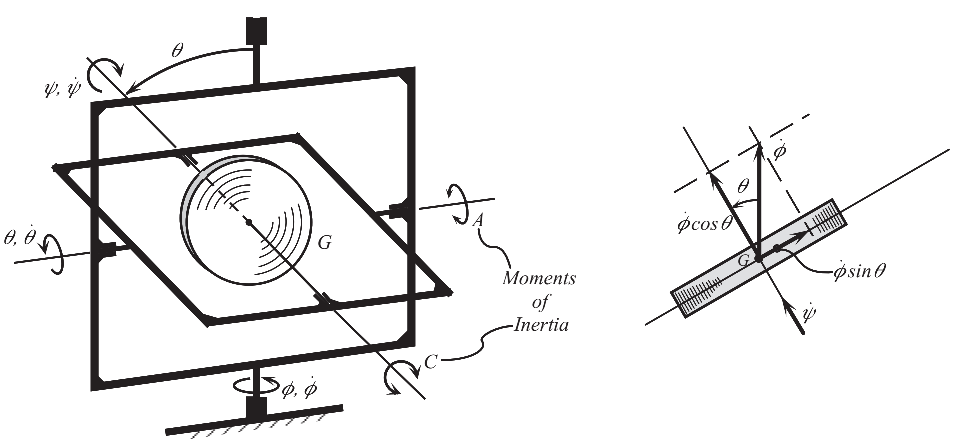

Figure 3.41 A gyroscope (and its Eulerian angles), supported in a light housing.

(ii) The equations of motion are

$$\theta: \qquad A\ddot{\theta} - A(\dot{\phi})^2 \sin\theta\cos\theta + C(\dot{\psi} + \dot{\phi}\cos\theta)\dot{\phi}\sin\theta = Q_\theta, \tag{b}$$

$$\phi: \qquad A\ddot{\phi}\sin^2\theta + 2A\dot{\phi}\dot{\theta}\sin\theta\cos\theta - C(\dot{\psi} + \dot{\phi}\cos\theta)\dot{\theta}\sin\theta + C\cos\theta(\dot{\psi} + \dot{\phi}\cos\theta)^{\cdot} = Q_\phi, \tag{c}$$

$$\psi: \qquad C(\dot{\psi} + \dot{\phi}\cos\theta)^{\cdot} = Q_\psi. \tag{d}$$

(iii) If $Q_\psi = 0$, then $\dot{\psi} + \dot{\phi}\cos\theta \equiv$ *total spin* $=$ *constant* $\equiv n$, and the ϕ, θ equations become

$$\theta: \qquad A\,\ddot{\theta} - A(\dot{\phi})^2 \sin\theta\cos\theta + (C\,n\sin\theta)\dot{\phi} = Q_\theta, \tag{e}$$

$$\phi: \qquad A\,\ddot{\phi}\sin^2\theta + 2A\,\dot{\phi}\,\dot{\theta}\sin\theta\cos\theta - (C\,n\sin\theta)\dot{\theta} = Q_\phi. \tag{f}$$

Identify the gyroscopic terms in the above equations of motion.

Problem 3.16.14 *Gyroscopic Effects in a Pendulum of Varying Length.* A block B, of mass M, translates along the smooth horizontal floor/axis Ox. Block B is also connected to a linear spring of stiffness k whose other end is joined to the vertical wall Oy. A massless rod BP of variable length $l = l(t) = l_o + v\,t$ [$l_o =$ *constant* (*initial*) *length*, $v =$ *constant rate of change of* l] carries at its end P a particle P of mass m (fig. 3.42).

Choosing axes O–xy so that $(CO) =$ *stress-free length* of spring, show that, with the usual notations, the Lagrangean equations of motion of this system can be written as

$$(\partial T_2/\partial\dot{x})^{\cdot} - \partial T_2/\partial x = -k\,x - m\,v\cos\phi\,\dot{\phi}, \tag{a}$$

$$(\partial T_2/\partial\dot{\phi})^{\cdot} - \partial T_2/\partial\phi = -m\,g\,l\sin\phi + m\,v\cos\phi\,\dot{x}. \tag{b}$$

Identify the *gyroscopic (Coriolis)* forces in the above equations, and indicate their directions on fig. 3.42. What happens if $l =$ *constant*.

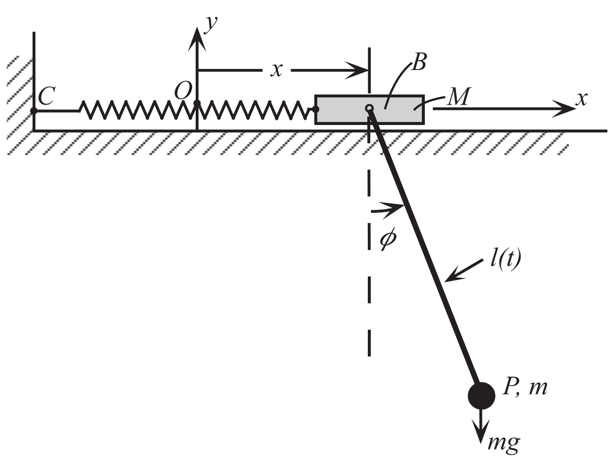

Figure 3.42 Pendulum of uniformly varying length and horizontally moving support.

Example 3.16.7 *An Additional Power Theorem for Relative Motion.* (Thomson and Tait, 1867–1912, §319, p. 319; see also Winkelmann and Grammel, 1927, pp. 463–465). Let us consider, with no loss of generality, a system with Lagrangean equations of motion

$$E_k = Q_k, \tag{a}$$

where [recalling (3.10.1a ff.)] the left side decomposes into the following *three* parts:

$$E_k = E_{k,R} + E_{k,T} + E_{k,C}, \tag{b}$$

$$E_{k,R} \equiv E_k(T_2) \equiv (\partial T_2/\partial \dot{q}_k)^{\cdot} - \partial T_2/\partial q_k \qquad (\textit{relative inertia}), \tag{c}$$

$$E_{k,T} \equiv \partial M_k/\partial t - \partial T_0/\partial q_k \qquad (\textit{transport inertia}), \tag{d}$$

$$E_{k,C} \equiv \sum (\partial M_k/\partial q_r - \partial M_r/\partial q_k)\dot{q}_r \qquad (\textit{Coriolis inertia}). \tag{e}$$

From (a), we immediately obtain the power equation

$$\sum E_k \dot{q}_k = \sum Q_k \dot{q}_k \equiv P(\textit{-ower of impressed forces}). \tag{f}$$

Let us transform the *left* side of (f). We find successively [recalling (3.9.3b) with $T_0 = 0,\ T_1 = 0,\ T_2 = T$]

(i) $$\sum E_{k,R}\, \dot{q}_k \equiv \sum \left[(\partial T_2/\partial \dot{q}_k)^{\cdot} - \partial T_2/\partial q_k\right] \dot{q}_k = dT_2/dt + \partial T_2/\partial t; \tag{g}$$

(ii) $$\sum E_{k,T}\, \dot{q}_k \equiv \sum (\partial M_k/\partial t)\dot{q}_k - \sum (\partial T_0/\partial q_k)\dot{q}_k \equiv \partial T_1/\partial t - d_q T_0/dt, \tag{h}$$

where

$$d_q(\ldots)/dt \equiv \sum [\partial(\ldots)/\partial q_k]\dot{q}_k \qquad \text{(i.e., } t \text{ and the } \dot{q}\text{'s remain fixed);} \tag{i}$$

(iii) $$\begin{aligned}\sum E_{k,C}\, \dot{q}_k &\equiv \sum \Big(\sum (\partial M_k/\partial q_r - \partial M_r/\partial q_k)\dot{q}_r\Big)\dot{q}_k \\ &\equiv \sum \Big(-\sum g_{kr}\dot{q}_r\Big)\dot{q}_k = 0.\end{aligned} \tag{j}$$

[Incidentally, eq. (j) shows the error committed when one tries to obtain Lagrange's equations for gyroscopic systems, eqs. (a), from a single *power* equation like (f), instead of a single but *virtual work* equation, like LP.]

In view of (g–j), we can rewrite (f) as

$$dT_2/dt = P + d_q T_0/dt - \partial(T_2 + T_1)/\partial t. \tag{k}$$

But, further, we have

$$dT_0/dt = \partial T_0/\partial t + \sum (\partial T_0/\partial q_k)\dot{q}_k = \partial T_0/\partial t + d_q T_0/dt, \tag{l}$$

and

$$\begin{aligned} dT_1/dt &= \partial T_1/\partial t + \sum [(\partial T_1/\partial q_k)\dot{q}_k + (\partial T_1/\partial \dot{q}_k)\ddot{q}_k] \\ &= \partial T_1/\partial t + d_q T_1/dt + \sum M_k\, \ddot{q}_k; \end{aligned} \tag{m}$$

and, therefore, the power equation (k) is finally transformed to

$$dT/dt = (T_2 + T_1 + T_0)^{\cdot}$$
$$= P + dT_0/dt + d_q(T_0 + T_1)/dt - \partial T_2/\partial t + \sum M_k \ddot{q}_k. \qquad \text{(n)}$$

The last *four* terms on (the right side of) the above represent the *rate of supply of kinetic energy to the carried system from the carrying body* (i.e., from its "tracks").

3.17 SERVO (OR CONTROL) CONSTRAINTS

The constraints examined so far, both holonomic and nonholonomic, are realized through mechanical *contact* of the system parts with foreign objects or obstacles (directly or indirectly, through auxiliary massless bodies; e.g., light inextensible cables). These latter are either *at rest*, or, generally, *they move in ways known in advance*; and, hence, they are unaffected by the motion and forces of the system. The associated reactions are *passive*; that is, without the aforementioned contacts, they cease to exist; and, for *bilateral* constraints, are assumed to satisfy LP (§3.2):

$$\delta' W_R \equiv \textstyle\int d\boldsymbol{R} \cdot \delta \boldsymbol{r} = \sum R_k \delta q_k = 0. \qquad (3.17.1)$$

Such constraints are the simplest ones to be found in mechanical systems; and analytical mechanics (AM) has, since its inception, been preoccupied with their study to such an extent that, in the minds of many, the subject is almost synonymous with their study. However, such constraints/reactions (C/R) are only one out of many logical and physical possibilities. Just as in continuum mechanics, not all parts of the total stress need obey Hooke's law, or even be elastic, so in AM, there exist constrained systems whose total reactions do *not* satisfy LP (3.17.1). Here, we summarize the basics of that particular and technically important non-LP type of C/R known as *servo(motoric)*, or *control*, or *control systems*, or C/Rs of the *second* kind: $(C/R)_2$; with the designation C/Rs of the *first* kind, $(C/R)_1$, reserved for the earlier passive ones.

The $(C/R)_2$s are realized through auxiliary sources of energy that go into action automatically, and are automatically adjusted (or turned off) so that, at every moment, a particular such constraint is realized, that is, at least one of the obstacles that interacts physically with our system, either through direct contact or via action at a distance (e.g. electromagnetic forces), regulates its motion so that certain holonomic and/or nonholonomic constraints, specified ahead of time, are enforced continuously. Therefore, the motion of the controlling object(s) is not known in advance as a function of time [as in the $(C/R)_1$ cases], but as the system moves, it continuously adjusts itself so as to satisfy all prescribed constraints.

The associated *servoreactions* are not known in advance but are calculated after the motion of the system has been determined; that is, as with $(C/R)_1$, first we solve the kinetic problem, and then the kinetostatic one.

HISTORICAL

These servoconstraints were introduced and examined in the early 1920s by P. Appell and his distinguished student H. Beghin ("*Liaisons comportant un Asservissement*," since the term *control* did not exist then), in their investigations of the Sperry-Anschütz gyrocompass and related navigation devices. Non-$(C/R)_1$ cases were also studied earlier (≈ 1910–1916) by the Russian–Ukrainian J. I. Grdina (1871–1931) in his studies of the dynamics of living organisms; but we have not been able to access them; see, for example, Fradlin, B. N., *J. Appl. Mechanics* (Ukrainian), **8** (6), 581–591, 1962 (in Russian); also, Arczewski and Pietrucha (1993, pp. 74–75).

Here, too, our treatment is based on a judicious modification of LP, with guiding goal to make the servoproblem *determinate*; that is, generate as many equations as the unknowns introduced by that model, say coordinates and multipliers (reactions). We begin with the Newton–Euler equation of motion of a generic system particle P of mass dm, which, in this case, has the following form:

$$dm\,\boldsymbol{a} = d\boldsymbol{F} + d\boldsymbol{R} + d\boldsymbol{R}', \tag{3.17.2}$$

where

$$d\boldsymbol{F} = \textit{total impressed force on } P, \tag{3.17.2a}$$

$$d\boldsymbol{R} = \textit{total passive reaction force (1st kind) on } P, \tag{3.17.2b}$$

$$d\boldsymbol{R}' = \textit{total servoreaction force (2nd kind) on } P. \tag{3.17.2c}$$

From (3.17.2), carrying out some obvious mathematical operations, we obtain

$$\begin{aligned} 0 &= \mathcal{S}\,(dm\,\boldsymbol{a} - d\boldsymbol{F} - d\boldsymbol{R} - d\boldsymbol{R}')\cdot\delta\boldsymbol{r} \\ &= \mathcal{S}\,(dm\,\boldsymbol{a} - d\boldsymbol{F} - d\boldsymbol{R}')\cdot\delta\boldsymbol{r} + \mathcal{S}\,d\boldsymbol{R}\cdot\delta\boldsymbol{r}, \end{aligned} \tag{3.17.3}$$

and, invoking (3.17.1), we finally obtain

$$\mathcal{S}\,(dm\,\boldsymbol{a} - d\boldsymbol{F})\cdot\delta\boldsymbol{r} = \mathcal{S}\,d\boldsymbol{R}'\cdot\delta\boldsymbol{r} \neq 0. \tag{3.17.4}$$

From the above, it follows that to obtain completely reactionless equations in both the $\{d\boldsymbol{R}\}$ and $\{d\boldsymbol{R}'\}$, *we must modify the* $\{\delta\boldsymbol{r}\}$ (*and* δq's), *if possible, by imposing on them additional restrictions* (*constraints in virtual form*) *so that not only* $\delta' W_R = 0$, *but also*

$$\delta' W_{R'} \equiv \mathcal{S}\,d\boldsymbol{R}'\cdot\delta\boldsymbol{r} = 0 \qquad \left[\Rightarrow \mathcal{S}\,(dm\,\boldsymbol{a} - d\boldsymbol{F})\cdot\delta\boldsymbol{r} = 0\right]. \tag{3.17.5}$$

This is the "*Servo–Lagrange (D'Alembert) principle" (SLP)*. In words: among the virtual displacements nullifying the virtual work of whatever ordinary contact/passive reactions are present, we seek if there may exist a *narrower class* that, simultaneously, nullifies the virtual work of the additional servo/control constraint reactions. That narrower class of δq's, if it exists, is determined by eq. (3.17.5), which, accordingly, becomes the key constitutive, namely, *physical*, tool for the Lagrangean solution of servoproblems. Indeed, we show below that *such problems are determinate if the number of servoconstraints equals the number of additional restrictive virtual conditions (= number of servoreactions) generated by (3.17.5)*.

An Example: The Servopendulum

Before we express these ideas in general system variables, let us discuss in some detail the following simple but instructive example: the (vertical) plane motion of a mathematical pendulum of mass m and variable (controlled) length l (fig. 3.43). Let us choose here $q_1 = l$ and $q_2 = \phi$, and study the case where an external agency, say, an

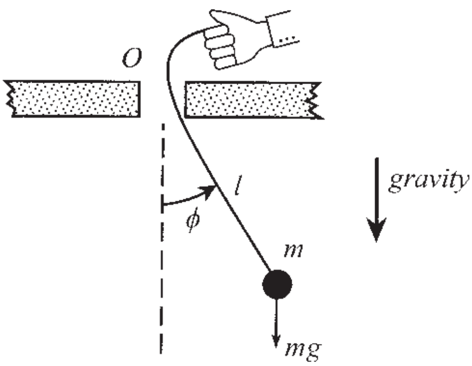

Figure 3.43 Geometry and physics of plane servopendulum.

agile hand, pulls the pendulum at O so that at every instant the following holonomic servoconstraint holds:

$$f(l, \phi) = 0 \;\Rightarrow\; l = l(\phi) = \textit{known functional relation}. \tag{3.17.6}$$

Since (3.17.6) is maintained by the hand at O, the virtual work of the corresponding servoreaction vanishes, à la (3.17.5), if

$$\delta l = 0. \tag{3.17.7}$$

In general, and this is important, *the holonomic servoconstraint (3.17.6) and the corresponding virtual servoconstraint (3.17.7) are unrelated to each other; that is, the latter does not follow from the former by differentiation (variation)*.

Rewriting (3.17.7) as $(1)\,\delta l = 0$, or as $(1)\,\delta l + (0)\,\delta\phi = 0$, and combining it via Lagrangean multipliers to LP:

$$M_l\,\delta l + M_\phi\,\delta\phi = 0, \tag{3.17.8}$$

where

$$M_l \equiv E_l - Q_l \equiv [(\partial T/\partial \dot{l})^{\cdot} - \partial T/\partial l] - Q_l, \tag{3.17.8a}$$

$$M_\phi \equiv E_\phi - Q_\phi \equiv [(\partial T/\partial \dot{\phi})^{\cdot} - \partial T/\partial \phi] - Q_\phi, \tag{3.17.8b}$$

$$2T = m[(\dot{l})^2 + l^2(\dot{\phi})^2], \tag{3.17.8c}$$

$$V = -m\,g\,l\cos\phi$$
$$\Rightarrow\; Q_l = -\partial V/\partial l = +m\,g\,\cos\phi, \qquad Q_\phi = -\partial V/\partial\phi = -m\,g\,l\,\sin\phi, \tag{3.17.8d}$$

we immediately obtain the two Routh–Voss type equations of servomotion (λ = multiplier)

$$(\partial T/\partial \dot{l})^{\cdot} - \partial T/\partial l = Q_l + \lambda(1): \quad (m\,\dot{l})^{\cdot} - m\,l(\dot{\phi})^2 = m\,g\,\cos\phi + \lambda, \tag{3.17.9a}$$

$$(\partial T/\partial \dot{\phi})^{\cdot} - \partial T/\partial \phi = Q_\phi + \lambda(0): \quad (m\,l^2\dot{\phi})^{\cdot} = -m\,g\,l\,\sin\phi; \tag{3.17.9b}$$

which, along with the servoconstraint (3.17.6), constitute a determinate system for $l(t),\ \phi(t),\ \lambda(t)$. Indeed, substituting (3.17.6) into the reactionless equation (3.17.9b), and since $dl/dt = (dl/d\phi)\,\dot{\phi}$, results in [assuming $l(t) \neq 0$]

$$d^2\phi/dt^2 + A(\phi)(d\phi/dt)^2 + B(\phi)\sin\phi = 0, \tag{3.17.10}$$

where

$$A(\phi) \equiv 2[dl(\phi)/d\phi]/l(\phi), \qquad B(\phi) \equiv g/l(\phi): \quad \textit{known functions of } \phi. \tag{3.17.10a}$$

Next, solving the nonlinear ϕ-equation (3.17.10) (plus initial conditions), we obtain $\phi = \phi(t)$; then (3.17.6) yields $l = l[\phi(t)] = l(t)$; and, finally, substituting the so-found $\phi(t)$ and $l(t)$ into the multiplier-containing equation (3.17.9a) we get the servoreaction $\lambda = \lambda(t)$. In sum:

$$\delta' W_{R'} = 0 \ \Rightarrow\ \delta l = 0 \ \Rightarrow\ M_\phi = 0 \ \Rightarrow\ \phi(t) \ \Rightarrow\ l = l[\phi(t)] = l(t) \ \Rightarrow\ \lambda(t).$$

To understand this servoconstraint problem better, let us also discuss the following related *nonservo* versions of it:

(i) If the constraint (3.17.6) was an ordinary (i.e., passive) one, *even though of the exact same finite form as in the servo case*, then we would have,

$$\begin{aligned}&\delta f = (\partial f/\partial l)\,\delta l + (\partial f/\partial\phi)\,\delta\phi = 0\\ &\Rightarrow\ \delta l = -\big[(\partial f/\partial\phi)/(\partial f/\partial l)\big]\,\delta\phi \equiv [dl(\phi)/d\phi]\,\delta\phi,\end{aligned} \tag{3.17.11}$$

instead of (3.17.7); that is, in general, $\delta l \neq 0$ and $\delta\phi \neq 0$; and this combined with LP, eq. (3.17.8), would have produced the two Routh–Voss-type equations

$$M_l = \lambda(\partial f/\partial l) \qquad \text{and} \qquad M_\phi = \lambda(\partial f/\partial\phi); \tag{3.17.12}$$

or, equivalently, the kinetic (Hadamard-type) equation

$$(\partial f/\partial l)M_\phi - (\partial f/\partial\phi)M_l = 0 \ \Rightarrow\ M_\phi + [dl(\phi)/d\phi]M_l = 0, \tag{3.17.13}$$

resulting by eliminating λ between eqs. (3.17.12). These latter plus the (now assumed) passive constraint (3.17.6) would constitute a determinate system for $l(t),\ \phi(t),\ \lambda(t)$.

(ii) Next, if, unlike the servo case, the *temporal variation of l was known in advance*, that is, if $l = l(t) =$ *known (i.e., prescribed) function of time* (e.g., parametric excitation), but no constraint $f(l,\phi) = 0$ existed, then we would have $\delta l = 0$ but $\delta\phi \neq 0$, i.e., $(1)\,\delta l + (0)\,\delta\phi = 0$, and so the equations of motion would be

$$M_l = \lambda(1) \qquad \text{and} \qquad M_\phi = \lambda(0) = 0, \tag{3.17.14}$$

as in the servo case; but without (3.17.6) to connect them. Clearly, this case is also determinate.

(iii) Finally, if l and ϕ were completely unrelated, and neither of the two was known in advance, then

$$\delta l \neq 0 \qquad \text{and} \qquad \delta\phi \neq 0; \qquad \text{i.e., } (0)\,\delta l + (0)\,\delta\phi = 0, \tag{3.17.15a}$$

and this combined with (3.17.8) would produce the two equations

$$M_l = \lambda(0) = 0 \qquad \text{and} \qquad M_\phi = \lambda(0) = 0, \tag{3.17.15b}$$

from which $l(t)$ and $\phi(t)$ could be determined.

The above cases are summarized below [with *accents (subscripts)* denoting *ordinary (partial)* derivatives]:

	Finite constraints		*Virtual constraints*	*Equations of motion*	
0.	$f(l, \phi) = 0 \Rightarrow l = l(\phi)$	(servo)	But: $\delta l = 0,\ \delta\phi \neq 0$	$M_l = \lambda$,	$M_\phi = 0$
1.	$f(l, \phi) = 0$	(passive)	$\Rightarrow\ \delta f = 0$: $\delta l = l'(\phi)\delta\phi \neq 0$, $\delta\phi \neq 0$	$M_l = \lambda f_l$,	$M_\phi = \lambda f_\phi$
2.	No $f(l, \phi) = 0$ but $l = l(t)$	(prescribed)	$\delta l = 0, \delta\phi \neq 0$	$M_l = \lambda$,	$M_\phi = 0$
3.	No $f(l, \phi) = 0$		$\delta l \neq 0, \delta\phi \neq 0$	$M_l = 0$,	$M_\phi = 0$

This simple but sort of prototypical example helps us understand some of the fundamental features of constrained system mechanics:

- Even though, in both cases 0 (servo) and 1 (passive), the constraint has the same finite form, yet the virtual displacement restrictions in each case are not the same, but depend on exactly how the corresponding constraint is realized, that is, on how the controls are applied. And these differences in virtual displacements lead, in turn, to different equations of motion, and, of course, different equations of power. Indeed, for these four cases, we have, respectively:

$$\begin{aligned} M_l \dot{l} + M_\phi \dot{\phi} &= (\lambda)\ (\dot{l}) + (0)\ (\dot{\phi}) = \lambda \dot{l} \neq 0 && [\textit{servo problem}] \\ &= (\lambda f_l)\ (\dot{l}) + (\lambda f_\phi)\ (\dot{\phi}) = \lambda \dot{f} = 0 && [\textit{passive problem}] \\ &= (\lambda)\ (\dot{l}) + (0)\ (\dot{\phi}) = \lambda \dot{l} \neq 0 && [l(t)\ \textit{prescribed, no}\ f(l, \phi) = 0] \\ &= (0)\ (\dot{l}) + (0)\ (\dot{\phi}) = 0 && [l\ \textit{and}\ \phi\ \textit{independent, no}\ f(l, \phi) = 0]; \end{aligned} \tag{3.17.16}$$

  even though, in *all* cases, $\delta I - \delta' W = M_l\, \delta l + M_\phi\, \delta\phi = 0$.
- Conversely, cases 0 and 2 may have the same virtual constraints ($\Rightarrow$ same form of equations of motion), but since they are physically different ($\Rightarrow$ different finite constraints) they will have different ultimate solutions $l = l(t$; initial conditions), $\phi = \phi(t$; initial conditions).

The example also demonstrates that servoproblems can be treated competently and clearly by Lagrangean mechanics; that is, contrary to certain authors' claims (that, somehow, Lagrange's method is restricted to "ideal" constraints), these problems do not fall outside the classical methods, and, hence, do not need new "principles" for their solution. However, they *do* need a proper understanding of the underlying physics, and subsequent *correct application of the dynamical principle of virtual work*, but viewed as a constitutive postulate, like (3.17.1) and (3.17.5), and not as some mysterious "law of nature." This is far safer than manipulating the equations of motion, even the Lagrangean ones.

General Considerations

One Holonomic Servoconstraint

Now, let us resume our general considerations in system variables. For simplicity, but no real loss of generality, we begin our discussion with an *n-DOF* system under *holonomic servoconstraints*. We introduce the following basic definition.

DEFINITION

The holonomic equation

$$f(t, q_1, \ldots, q_n) \equiv f(t, q) = 0 \tag{3.17.17}$$

represents a servoconstraint, say, *relative to* q_1, if after substituting into it $q_2 = q_2(t), \ldots, q_n = q_n(t)$, which are not known in advance, it takes the form

$$q_1 = q_1(t, q_2, \ldots, q_n) = q_1\big[t, q_2 = q_2(t), \ldots, q_n = q_n(t)\big] \equiv q_{1o}(t). \tag{3.17.17a}$$

Now, the virtual variations of the system—that is, the virtual form of (3.17.17, 17a), follow from the constitutive requirement of the *vanishing of the total virtual work of the corresponding servoreactions*; that is, from the *constitutive variational equation* (3.17.5). The latter yields

$$\delta q_1 = (\partial q_{1o}/\partial t)\,\delta t = 0, \qquad \delta q_2 \neq 0, \ldots, \delta q_n \neq 0, \tag{3.17.17b}$$

or, equivalently,

$$(1)\,\delta q_1 + (0)\,\delta q_2 + \cdots + (0)\,\delta q_n = 0; \tag{3.17.17c}$$

and when this is combined with ("adjoined" to) SLP, eq. (3.17.4), it leads to the following "servo-Routh–Voss" equations [with $E_k - Q_k \equiv M_k$ $(k = 1, \ldots, n)$, $\lambda_1 \equiv \lambda$]:

$$\textit{Kinetostatic}: \qquad M_1 = \lambda(1) \qquad \text{or} \qquad M_1 = \lambda, \tag{3.17.17d}$$

$$\textit{Kinetic}: \qquad M_2 = \cdots = M_n = \lambda(0) = 0. \tag{3.17.17e}$$

Here, too, the *finite* holonomic control constraint (3.17.17) is, generally, unrelated to the *virtual* control constraints (3.17.17b, c) resulting from $\delta' W_{R'} = 0$. Next, solving the n equations (3.17.17e) and (3.17.17), or (3.17.17a), with $dq_1/dt = \sum (\partial q_1/\partial q_\bullet)\,(dq_\bullet/dt) + \partial q_1/\partial t$ $\ (\bullet = 2, \ldots, n)$, we obtain $q_2 = q_2(t), \ldots, q_n = q_n(t)$; and then, substituting these time functions in (3.17.17d), we find $\lambda = M_1(t) = \lambda(t)$.

If the constraint (3.17.17, 17a) was passive, we would have

$$q_1 = q_1(t, q_2, \ldots, q_n) \ \Rightarrow\ \delta q_1 = \sum (\partial q_1/\partial q_\bullet)\,\delta q_\bullet \neq 0 \qquad (\bullet = 2, \ldots, n), \tag{3.17.18a}$$

or, equivalently,

$$(1)\,\delta q_1 + (-\partial q_1/\partial q_2)\,\delta q_2 + \cdots + (-\partial q_1/\partial q_n)\,\delta q_n = 0, \tag{3.17.18b}$$

instead of (3.17.17b, c), and so the corresponding equations of motion would be, in the Routh–Voss form

$$M_1 = \lambda(1); \qquad M_2 = \lambda(-\partial q_1/\partial q_2), \ldots,\ M_n = \lambda(-\partial q_1/\partial q_n); \tag{3.17.18c}$$

or, in the Hadamard form,

$$\textit{Kinetostatic}: \qquad M_1 = \lambda; \tag{3.17.18d}$$

$$\textit{Kinetic}: \qquad M_2 + (\partial q_1/\partial q_2)\,M_1 = 0, \ldots,\ M_n + (\partial q_1/\partial q_n)\,M_1 = 0; \tag{3.17.18e}$$

and since the constraint (3.17.17) is holonomic, we can enforce it directly into the kinetic energy; that is,

$$\begin{aligned} T &= T[t,\, q_1(t,\, q_2, \ldots, q_n),\, \dot{q}_1(t,\, q_2, \ldots, q_n),\, q_2, \ldots, q_n,\, \dot{q}_2, \ldots, \dot{q}_n] \\ &\equiv T_o(t,\, q_\bullet,\, \dot{q}_\bullet) \equiv T_o, \end{aligned} \tag{3.17.18f}$$

and $E_\bullet + (\partial q_1/\partial q_\bullet)\, E_1 = (\partial T_o/\partial \dot{q}_\bullet)^{\cdot} - \partial T_o/\partial q_\bullet \equiv E_\bullet(T_o)$, so that (3.17.18e) can be rewritten as

$$E_\bullet(T_o) = Q_\bullet + (\partial q_1/\partial q_\bullet)\, Q_1 \quad (\equiv Q_{\bullet,o}). \tag{3.17.18g}$$

Two Holonomic Servoconstraints

Next, if we have *two* servoconstraints *relative to q_1 and q_2*:

$$f_1(t, q_1, \ldots, q_n) \equiv f_1(t, q) = 0 \qquad \text{and} \qquad f_2(t, q_1, \ldots, q_n) \equiv f_2(t, q) = 0, \tag{3.17.19a}$$

or, equivalently,

$$\begin{aligned} q_1 &= q_1(t, q_3, \ldots, q_n) \;\Rightarrow\; q_1[t, q_3 = q_3(t), \ldots, q_n = q_n(t)] \equiv q_{1o}(t), \\ q_2 &= q_2(t, q_3, \ldots, q_n) \;\Rightarrow\; q_2[t, q_3 = q_3(t), \ldots, q_n = q_n(t)] \equiv q_{2o}(t), \end{aligned} \tag{3.17.19b}$$

then, by repeating the earlier reasoning, we deduce that, for the fundamental equation (3.17.5) to hold, the virtual variations of the system must satisfy

$$\delta q_1 = 0, \qquad \delta q_2 = 0; \qquad \delta q_3 \neq 0, \ldots, \delta q_n \neq 0, \tag{3.17.19c}$$

or, equivalently,

$$(1)\,\delta q_1 + (0)\,\delta q_2 + \cdots + (0)\,\delta q_n = 0, \qquad (0)\,\delta q_1 + (1)\,\delta q_2 + \cdots + (0)\,\delta q_n = 0; \tag{3.17.19d}$$

and when these expressions are combined with LP,

$$M_1\,\delta q_1 + M_2\,\delta q_2 + M_3\,\delta q_3 + \cdots + M_n\,\delta q_n = 0, \tag{3.17.19e}$$

via the multipliers λ_1 and λ_2, they produce the following two groups of equations of servomotion:

$$\textit{Kinetostatic}: \quad M_1 = \lambda_1\,(1) + \lambda_2\,(0) = \lambda_1, \qquad M_2 = \lambda_1\,(0) + \lambda_2\,(1) = \lambda_2; \tag{3.17.19f}$$

$$\textit{Kinetic}: \qquad M_3 = \lambda_1\,(0) + \lambda_2\,(0) = 0, \ldots,\ M_n = \lambda_1\,(0) + \lambda_2\,(0) = 0. \tag{3.17.19g}$$

Solving the n equations (3.17.19g) and (3.17.19a, b) yields $q_1(t), \ldots, q_n(t)$; and then substituting these time functions in (3.17.19f) gives the two servoreactions

$$\lambda_1 = M_1(t) = \lambda_1(t) \qquad \text{and} \qquad \lambda_2 = M_2(t) = \lambda_2(t). \tag{3.17.19h}$$

General Case: Holonomic and/or Pfaffian Servoconstraints

The extension to $m'(<n)$ holonomic servoconstraints relative to $q_1, \ldots, q_{m'}$ is obvious. However, in all cases:

- In order to have a determinate problem, the number of nonvirtual servoconstraints [like (3.17.17), (3.17.19a)], m', must equal the number of virtual servoconstraints resulting from (3.17.5): $\delta' W_{R'} = 0$ [like (3.17.17b, c), (3.17.19c, d)], say s; since this also equals the number of unknown servoreactions/multipliers); that is, we must have

$$\begin{aligned} &\boldsymbol{m}'\,(\equiv \textit{number of nonvirtual servoconstraints}) \\ &\quad = \boldsymbol{s}\,(\equiv \textit{number of virtual servoconstraints} \equiv \textit{number of servoreactions}). \end{aligned}$$

- If $\boldsymbol{m'} > \boldsymbol{s}$ [i.e., more (nonvirtual) servoconstraints than servoreactions], the problem is, in general, *impossible (overdeterminate)*—we cannot have more servoconstraints than the number of virtual conditions on the Lagrangean coordinates resulting from the nullification of the virtual work of the associated servoreactions; that is, $\delta' W_{R'} = 0$; while
- If $\boldsymbol{m'} < \boldsymbol{s}$ [i.e., fewer (nonvirtual) servoconstraints than servoreactions], the problem is *indeterminate*, unless we are given additional physical facts (constitutive equations) about the behavior of these servoreactions.

The above methodology is extended intact to the case where *some (or all)* of the m' servoconstraints are *holonomic* and *the rest (or all)* are *Pfaffian, holonomic or not*. Specifically, let our system be subject to the following additional constraints:

(i) *m passive (1st kind)* (with no loss in generality) Pfaffian constraints

$$\sum a_{dk}\dot{q}_k + a_d = 0 \qquad (d = 1, \ldots, m) \tag{3.17.20a}$$

whose *virtual* form is, therefore [recalling (2.9.11)],

$$\sum a_{dk}\,\delta q_k = 0, \tag{3.17.20b}$$

and

(ii) m' *servo (2nd kind)* (again, with no loss in generality) Pfaffian constraints

$$\sum a'_{d'k}\,\dot{q}_k + a'_{d'} = 0 \qquad (d' = 1, \ldots, m') \tag{3.17.20c}$$

with virtual form

$$\sum A_{Dk}\,\delta q_k = 0 \qquad (D = 1, \ldots, s); \tag{3.17.20d}$$

where, as already stressed, the (coefficients of the) "servovirtual" forms (3.17.20d) follow from the *vanishing of the virtual work of the servoreactions*, eq. (3.17.5); *that is*, they are *unrelated* to (the coefficients of) their velocity "counterparts" (3.17.20c), and so are, in general, their numbers m' and s [unlike the coefficients/number of (3.17.20b), which are directly related with those of (3.17.20a), as detailed in § 2.9]. Combination of the virtual forms (3.17.20b) and (3.17.20d) with LP readily yields the n Routh–Voss-type equations of motion

$$(\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k = Q_k + \sum \lambda_d\, a_{dk} + \sum \lambda'_D\, A_{Dk}, \tag{3.17.20e}$$

where the λ's (λ''s) are the $m(s)$ passive (servo) reactions; and along with (3.17.20a) and (3.17.20c) constitute a system of $n + m + m'$ *equations* for the $n + m + s$ *unknowns* (created by these "narrower" δq's): $\{q_1(t), \ldots, q_n(t);\ \lambda_1(t), \ldots, \lambda_m(t);\ \lambda'_1(t), \ldots, \lambda'_s(t)\}$; hence the requirement $m' = s$, for determinacy. [For a Maggi–like approach, the *number of independent δq's = number of independent equations*, equals $n - (m + s)$.]

This is an area in rapid evolution, and one with great potential for significant additional theoretical and practical results; for example, formulation in terms of quasi variables, application of differential and integral variational principles (chaps. 6, 7), extension to varying mass, impulsive motion of servocontrolled systems (chap. 4).

So far, all the relevant work in English seems to consist of translations of French and Soviet/Russian works. Among these, we recommend for complementary reading (alphabetically): Appell (1953, pp. 402–416), Apykhtin and Iakovlev (1980), Azizov (1986), Beghin (1967, pp. 440–443, 523–525), Cabannes (1965, pp. 188–191; summary of Appell/Beghin's work), Castoldi (1949), Kirgetov [1964(a),(b); 1967], Levi-Civita and Amaldi (1927, pp. 377–380, Mei (1987, pp. 243–248; excellent summary), Rumiantsev (1976, and references cited therein).

Problem 3.17.1 Consider a circular homogeneous disk D of negligible mass and radius R, free to rotate about a fixed horizontal axis through its center (pin) O (fig. 3.44). A plate P, of mass m and mass center G, is smoothly pin-joined on D at a point A. A motor *acting on the disk* D (or, perhaps, being located at A) at every instant realizes the servoconstraint

$$\text{angle}(OA,\, AG) \equiv \phi - \theta = \pi/2. \tag{a}$$

(i) Show that the (double) kinetic and potential energies of P are, respectively,

$$2T = m\big[R^2(\dot{\phi})^2 + (l^2 + k_G{}^2)\,(\dot{\theta})^2 + 2Rl\cos(\phi - \theta)\dot{\phi}\,\dot{\theta}\big], \tag{b}$$

$$(k_G = \textit{radius of gyration of } P \textit{ about } G)$$

$$V = -mg(R\cos\phi + l\cos\theta),$$

$$\Rightarrow\ \delta' W = -mg(R\sin\phi\,\delta\phi + l\sin\theta\,\delta\theta) = \textit{virtual work of weight}. \tag{c}$$

An additional term $(1/2)I_O(\dot{\phi})^2$, in T, would have accounted for the inertia of D (I_O = moment of inertia of disk about O).

(ii) Show that, here, the condition $\delta' W_{R'} = 0$ (recall that the servomotor is acting on D) leads to

$$\delta\phi = 0 \qquad \text{or} \qquad (1)\,\delta\phi + (0)\,\delta\theta = 0; \tag{d}$$

and, hence, to the equations of motion

$$M_\phi = \lambda \qquad \text{and} \qquad M_\theta = 0, \tag{e}$$

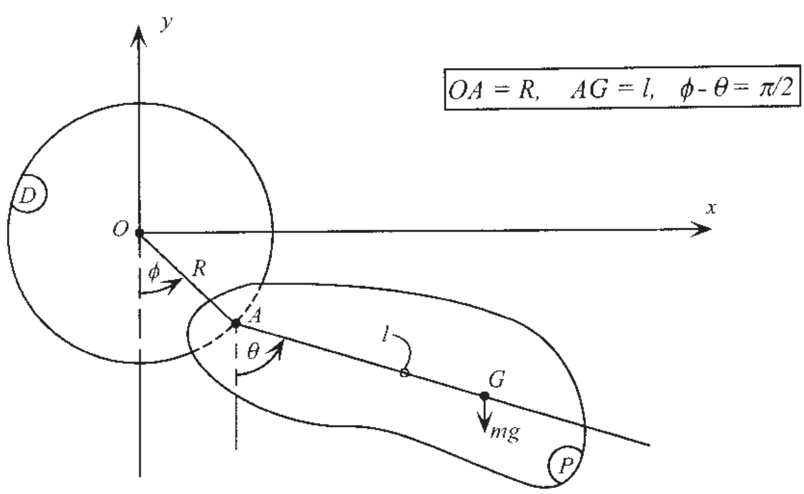

Figure 3.44 "Double" pendulum under the servoconstraint $\phi - \theta = \pi/2$ on disk D; $OA = R$, $AG = l$.

where

$$M_\phi \equiv E_\phi - Q_\phi \equiv [(\partial T/\partial\dot{\phi})^{\cdot} - \partial T/\partial\phi] - (-mg\,R\,\sin\phi) = \cdots, \tag{f}$$

$$M_\theta \equiv E_\theta - Q_\theta \equiv [(\partial T/\partial\dot{\theta})^{\cdot} - \partial T/\partial\theta] - (-mgl\,\sin\theta) = \cdots. \tag{g}$$

(iii) Show that (e, f, g), in extenso, after taking into account the servoconstraint (a) and with ${k_A}^2 \equiv {k_G}^2 + l^2$, are

$$m\big[R^2\ddot{\phi} + R\,l(\dot{\theta})^2 + gR\,\sin\phi\big] = \lambda, \tag{h}$$

or

$$\lambda(t) = m\big[R^2\ddot{\theta} + Rl(\dot{\theta})^2 + gR\,\cos\theta\big], \tag{i}$$

and

$${k_A}^2\,\ddot{\theta} - Rl(\dot{\theta})^2 + g\,l\,\sin\theta = 0. \tag{j}$$

[Hence solving the kinetic equation (j), we obtain $\theta(t)$, and then substituting that function of time into the kinetostatic equation (i), we obtain the servoreaction $\lambda(t)$.]

(iv) Extend the above to include the inertia of the disk D.

For additional details and insights, see Appell (1953, pp. 411–412), Cabannes (1968, pp. 189–191), Kirgetov (1967, pp. 473–474).

Problem 3.17.2 Continuing from the preceding problem, show that if the constraint (a), $\phi - \theta = \pi/2$, is an ordinary passive one, say by contact between D and P [$\Rightarrow \delta\phi = \delta\theta \neq 0$, or $(1)\,\delta\phi + (-1)\,\delta\theta = 0$], then the corresponding equations of motion are

$$M_\phi = \lambda \qquad \text{and} \qquad M_\theta = -\lambda. \tag{a}$$

Then show that combination of (a) ($\Rightarrow M_\phi + M_\theta = 0$) with the above constraint results in the physical pendulum-like kinetic equation

$$(R^2 + {k_A}^2)\ddot{\theta} + g(R\,\cos\theta + l\,\sin\theta) = 0, \tag{b}$$

from which $\theta(t)$ [and $\phi = \pi/2 + \theta(t) \equiv \phi(t)$] can be determined.

[The multiplier (passive reaction) can then be easily found from either of the (now algebraic) equations (a): $\lambda = M_\phi[\phi(t), \theta(t)] = M_\phi(t) = -M_\theta[\phi(t), \theta(t)] = -M_\theta(t) = \lambda(t)$.]

Finally, extend these results to include the inertia of the disk D.

Problem 3.17.3 Continuing from the preceding problems, show that if $\phi = \phi(t) = \textit{prescribed}$, but no $f(\phi, \theta) = 0$ exists [i.e., $\delta\phi = 0$ but $\delta\theta \neq 0$], then the equations of motion are

$$M_\phi = \lambda \qquad \text{and} \qquad M_\theta = 0; \tag{a}$$

and constitute a determinate system for $\theta = \theta(t)$, $\lambda = \lambda(t)$.

What happens if ϕ and θ and their virtual variations are *completely independent* [i.e., no $f(\phi, \theta) = 0$, and $\delta\phi = 0$, $\delta\theta = 0$]?

Finally, extend these results to include the inertia of the disk D.

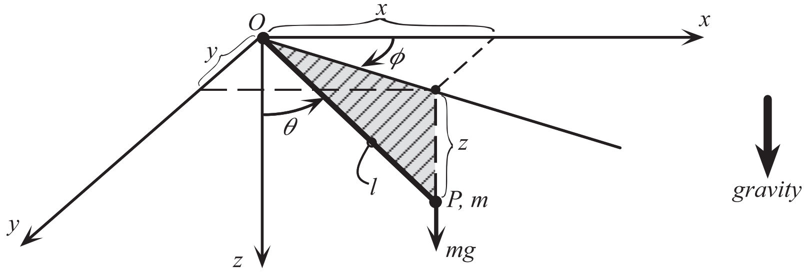

Figure 3.45 Spherical mathematical pendulum under a servoconstraint at O. Spherical coordinates: $x = (l \sin\theta)\cos\phi$; $y = (l \sin\theta)\sin\phi$; $z = l\cos\theta$.

Problem 3.17.4 (Castoldi, 1949). Consider the motion of the spherical (mathematical) pendulum P, of mass m and length l (fig. 3.45).

(i) Show that under the servoconstraint at O,

$$f(l, \theta) = 0 \;\Rightarrow\; l = l(\theta)\,\{= \cdots = l[\theta(t)];\quad \delta l = 0,\ \delta\phi \neq 0,\ \delta\theta \neq 0\}, \tag{a}$$

its ϕ and θ equations of motion are

$$E_\phi = Q_\phi: \qquad (l^2 \sin^2\theta)\ddot{\phi} + 2[l\,\sin^2\theta(dl/d\theta) + l^2\,\sin\theta\,\cos\theta]\,\dot{\phi}\,\dot{\theta} = 0, \tag{b}$$

$$E_\theta = Q_\theta: \qquad l^2\ddot{\theta} + 2\,l(dl/d\theta)(\dot{\theta})^2 - (l^2\,\sin\theta\,\cos\theta)(\dot{\phi})^2 = -g\,l\,\sin\theta. \tag{c}$$

[Three equations for $l(t)$, $\phi(t)$, $\theta(t)$.]

(ii) Show that if eq. (a) represents an ordinary passive constraint [$\Rightarrow \delta l = (dl/d\theta)\,\delta\theta \neq 0$, $\delta\phi \neq 0$, $\delta\theta \neq 0$], then the reactionless (Hadamard-type) equations for ϕ and θ are

$$E_\phi = Q_\phi: \qquad (l^2\sin^2\theta)\ddot{\phi} + 2\big[l\sin^2\theta(dl/d\theta) + l^2\sin\theta\,\cos\theta\big]\dot{\phi}\,\dot{\theta} = 0, \tag{d}$$

$$E_\theta + (dl/d\theta)E_l = Q_\theta + (dl/d\theta)Q_l:$$

$$\big[(dl/d\theta)^2 + l^2\big]\ddot{\theta} + (dl/d\theta)\big[(d^2l/d\theta^2) + l\big](\dot{\theta})^2$$
$$- \,l\big[l\cos\theta + (dl/d\theta)\sin\theta\big]\sin\theta(\dot{\phi})^2 = g\,l\big[(dl/d\theta)l^{-1}\cos\theta - \sin\theta\big].$$

[Again three equations for $l(t)$, $\phi(t)$, $\theta(t)$.] (e)

(iii) Show that (e) can be rewritten as

$$(\partial T_o/\partial\dot{\theta})^{\cdot} - \partial T_o/\partial\theta = Q_\theta + (dl/d\theta)Q_l \quad (\equiv Q_{\theta o}), \tag{f}$$

where

$$2T_o = m\big[(dl/d\theta)^2(\dot{\theta})^2 + l^2(\dot{\theta})^2 + l^2\sin^2\theta(\dot{\phi})^2\big]$$

$$Q_\phi = 0, \qquad Q_\theta = -mgl\,\sin\theta, \qquad Q_l = mg\,\cos\theta. \tag{g}$$

(iv) Find the general functional expressions for the reaction $\lambda = \lambda(t)$ in cases (i) and (ii).

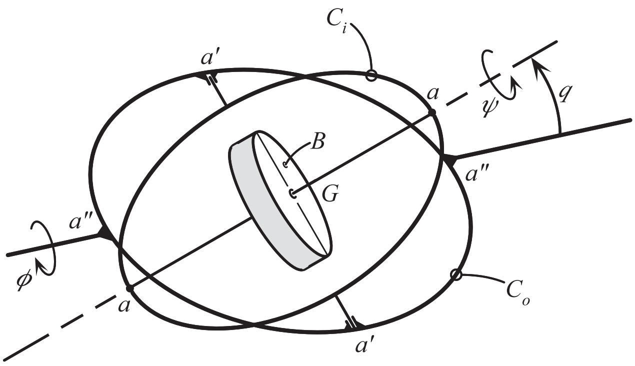

Figure 3.46 Servoconstraints on a Cardan-suspended gyro [ϕ = angle of rotation of C_o; θ = angle of planes of C_i and C_o; ψ = angle of rotation of B about "articulation axis" a–a, fixed in C_i (spin axis)].

Example 3.17.1 Let us consider a gyro B (axisymmetric body of revolution), supported by two Cardan-like massless circular rings $C_{i(\text{inner})}$ and $C_{o(\text{outer})}$, with its center of mass G at the intersection of the three axes a–a, a'–a', a''–a'' (fig. 3.46).

(i) Now, let us assume that a motor, *acting on* C_o, realizes, at every instant, the servoconstraint

$$\phi = \theta. \tag{a}$$

To nullify the virtual work of the corresponding reactions, from the motor to C_o, we choose the *restricted* virtual displacement

$$\delta\phi = 0; \tag{b}$$

which, we notice, does *not* coincide with the formal mathematical virtual version of (a): $\delta\phi = \delta\theta$. Equation (b) can be rewritten, equivalently, as

$$(1)\,\delta\phi + (0)\,\delta\theta + (0)\,\delta\psi = 0, \tag{c}$$

and, therefore, combined with the principle of Lagrange

$$M_\phi\,\delta\phi + M_\theta\,\delta\theta + M_\psi\,\delta\psi = 0, \tag{d}$$

leads, with the help of the multiplier λ to the Routh–Voss equations

$$M_\phi = \lambda(1): \qquad E_\phi = Q_\phi + \lambda, \tag{e}$$

$$M_\theta = \lambda(0): \qquad E_\theta = Q_\theta$$

$$(\text{e.g.}, Q_\theta = -k\,\theta,\ k = \textit{torsional spring constant}), \tag{f}$$

$$M_\psi = \lambda(0): \qquad E_\psi = Q_\psi, \tag{g}$$

where [applying, by now, well-known steps, and with A/C = *transverse*/*axial* principal moments of inertia of B at G]

$$2T = A\big[(\dot{\theta})^2 + (\dot{\phi})^2 \sin^2\theta\big] + C(\dot{\psi} + \dot{\phi}\cos\theta)^2. \tag{h}$$

The solution of this servoproblem proceeds as follows: solving (f, g) *and* (a), we obtain $\phi(t)$, $\theta(t)$, $\psi(t)$; and then substituting these time expressions into (e), we get the servoreaction $\lambda(t)$.

(ii) If (a) was an ordinary passive constraint, then (b, c) would be replaced by

$$\delta\phi = \delta\theta, \quad \delta\psi \neq 0 \;\Rightarrow\; (1)\,\delta\phi + (-1)\,\delta\theta + (0)\,\delta\psi = 0, \tag{i}$$

and the equations of motion (e–g) by

$$M_\phi = \lambda(1) = \lambda, \qquad M_\theta = \lambda(-1) = -\lambda, \qquad M_\psi = \lambda(0) = 0; \tag{j}$$

and, along with (a), would constitute a determinate system for $\phi(t)$, $\theta(t)$, $\psi(t)$, $\lambda(t)$.

Here, too, we notice that *analytically identical constraints, (a)*, depending on *how* and *where* they are applied, *lead to different equations of motion and reactions*. In the case of gyrocompasses, such servoconstraints allow us to increase or diminish the resulting oscillations; that is, to control them.

Example 3.17.2 A plane P translates sliding over another fixed horizontal plane O–XY. A homogeneous sphere Σ, of radius R and mass m, rolls on P with inertial angular velocity $\boldsymbol{\omega}$. The motion of P is regulated automatically so that the center of mass G of Σ rotates uniformly around OZ with constant inertial angular velocity $\boldsymbol{\Omega}$ (fig. 3.47). Let us study the motion of the sphere. Here we have the following two constraints:

(i) *rolling of Σ on P* (ordinary passive kind),

$$\boldsymbol{v}_C(\Sigma) = \boldsymbol{v}_C(P) \;\Rightarrow\; \boldsymbol{v}_G + \boldsymbol{\omega} \times \boldsymbol{r}_{C/G} = \boldsymbol{v}_C(P) = \boldsymbol{v}_A(P), \tag{a}$$

where A = *arbitrary plane point* = $(u, \nu, 0)$, or, in components,

$$(\dot{\xi},\, \dot{\eta},\, \dot{R} = 0) + (\omega_X,\, \omega_Y,\, \omega_Z) \times (0,\, 0,\, -R) = (\dot{u},\, \dot{v},\, 0), \tag{b}$$

from which we readily obtain the two rolling constraints

$$\dot{\xi} - \omega_Y R = \dot{u} \qquad \text{and} \qquad \dot{\eta} + \omega_X R = \dot{v}; \tag{c1, 2}$$

and (ii) uniform *rotation* of G around OZ (servoconstraint),

$$\boldsymbol{v}_G = \boldsymbol{\Omega} \times \boldsymbol{r}_{G/O} = \boldsymbol{\Omega} \times \boldsymbol{r}_{G/O'}, \tag{d}$$

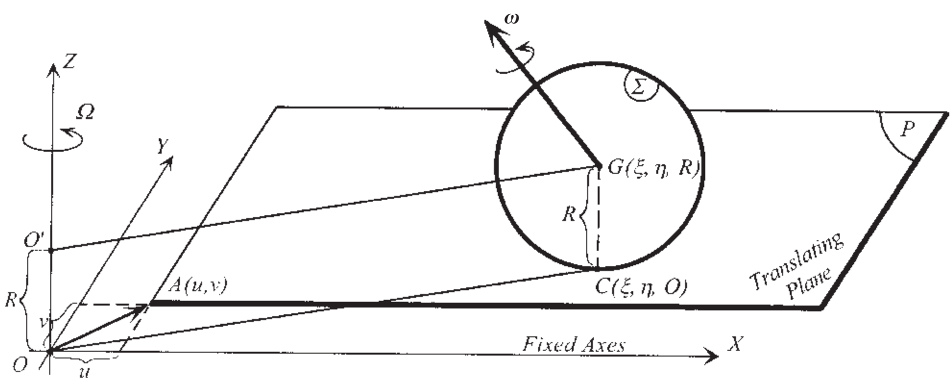

Figure 3.47 Controlled rolling of a sphere on a translating plane.

or, in components,

$$(\dot{\xi}, \dot{\eta}, 0) = (0, 0, \Omega) \times (\xi, \eta, 0), \tag{e}$$

from which we readily obtain the two Pfaffian servoconstraints

$$\dot{\xi} + \Omega\,\eta = 0 \qquad \text{and} \qquad \dot{\eta} - \Omega\,\xi = 0. \tag{f}$$

The servoconstraint on the sphere is expressed by the dependence of (c) on the $(\ldots)^{\cdot}$-derivatives of the two control parameters u and v; that is, $\dot{u}$ and $\dot{v}$.

Now, the servoreactions are the reaction forces from the plane to the sphere. Therefore, their virtual work $\delta' W_{R'} = (\ldots)\,\delta u + (\ldots)\,\delta v$ vanishes for the virtual displacements

$$\delta u = 0 \qquad \text{and} \qquad \delta v = 0, \tag{g}$$

or, equivalently,

$$(1)\,\delta u + (0)\,\delta v = 0 \qquad \text{and} \qquad (0)\,\delta u + (1)\,\delta v = 0; \tag{h}$$

which bear no formal mathematical relation to (f).

Next, to the equations of motion. To be able to enforce the *nonholonomic* Pfaffian constraints (c) right from the start, it is best not to use the kinetic energy ($\rightarrow$ Hamel equations), but the Appellian. Indeed, to within "Appell-important" terms (§3.14), the (double) Appellian of the sphere equals

$$\begin{aligned}
2S &= m[(\ddot{\xi})^2 + (\ddot{\eta})^2] + (2mR^2/5)\big[(\dot{\omega}_X)^2 + (\dot{\omega}_Y)^2 + (\dot{\omega}_Z)^2\big] \\
&\qquad [\text{or, eliminating } \dot{\omega}_X \text{ and } \dot{\omega}_Y \text{ via the passive constraints (c):} \\
&\qquad \omega_Y = R^{-1}(\dot{\xi} - \dot{u}) \quad \text{and} \quad \omega_X = R^{-1}(\dot{v} - \dot{\eta}) \;\Rightarrow\; \dot{\omega}_X = \cdots, \dot{\omega}_Y = \cdots] \\
&= m\big[(\ddot{\xi})^2 + (\ddot{\eta})^2\big] + (2m/5)\big[(\ddot{v} - \ddot{\eta})^2 + (\ddot{\xi} - \ddot{u})^2 + R^2(\dot{\omega}_Z)^2\big] \\
&\equiv 2S(\ddot{\xi}, \ddot{\eta}; \ddot{u}, \ddot{v}, \dot{\omega}_Z),
\end{aligned} \tag{i}$$

and, therefore, combining the principle of virtual work [with $d\theta_X \equiv \omega_X\,dt$, and noticing that the virtual work of all impressed forces (here, gravity) vanishes]

$$(\partial S/\partial \ddot{\xi})\,\delta\xi + (\partial S/\partial \ddot{\eta})\,\delta\eta + (\partial S/\partial \ddot{u})\,\delta u + (\partial S/\partial \ddot{v})\,\delta v + (\partial S/\partial \dot{\omega}_Z)\,\delta\theta_Z = 0, \tag{j}$$

with the two virtual servoconstraints (g, h) via the two multipliers (servoreactions) λ and μ, yields the following Routh–Voss equations (in Appellian form):

Kinetic:

$$\partial S/\partial \ddot{\xi} = 0: \qquad \ddot{\xi} - (2/7)\ddot{u} = 0, \tag{k}$$

$$\partial S/\partial \ddot{\eta} = 0: \qquad \ddot{\eta} - (2/7)\ddot{v} = 0, \tag{l}$$

$$\partial S/\partial \dot{\omega}_Z = 0: \qquad \dot{\omega}_Z = 0 \;\Rightarrow\; \omega_Z \equiv \dot{\theta}_Z = \textit{constant}; \tag{m}$$

Kinetostatic:

$$\partial S/\partial \ddot{u} = \lambda(1) + \mu(0): \qquad (2m/5)\,(\ddot{u} - \ddot{\xi}) = \lambda,$$

$$\text{or, invoking (c1),} \qquad 2mR\,\dot{\omega}_Y + 5\lambda = 0, \tag{n}$$

$$\partial S/\partial \ddot{v} = \lambda(0) + \mu(1): \qquad (2m/5)\,(\ddot{v} - \ddot{\eta}) = \mu,$$

$$\text{or, invoking (c2),} \qquad 2mR\,\dot{\omega}_X - 5\mu = 0. \tag{o}$$

These *five* equations plus the *two* servo equations (f) constitute a determinate system for the seven unknowns: $\xi(t)$, $\eta(t)$, $\omega_Z(t)$, $u(t), v(t)$, $\lambda(t)$, $\mu(t)$; then, $\omega_X(t)$ and $\omega_Y(t)$ can be found from (c). For additional details and insights, see, for example, Appell (1953, pp. 415–416), Beghin (1967, pp. 523–525), Kirgetov (1967, pp. 475–476).

Problem 3.17.5 Continuing from the preceding example,

(i) Show that the servoconstraints (f) integrate to

$$\xi = a\cos(\Omega t) \qquad \text{and} \qquad \eta = a\sin(\Omega t) \qquad (a = constant), \tag{a}$$

and, therefore, equations (k, l) yield, for a(ny) typical point A or C of the translating plane, the "cycloidal" translatory motion

$$u = (7/2)a\cos(\Omega t) + c_1 t + c_2, \qquad v = (7/2)a\sin(\Omega t) + c_3 t + c_4, \tag{b}$$

where the $c_{1,2,3,4}$ are integration constants.

(ii) After calculating $\omega_X(t), \omega_Y(t), \omega_Z(t)$ [via equations (c), (m) and the above], show that $\boldsymbol{\omega} = (\omega_X, \omega_Y, \omega_Z)$, emanating from G, describes an oblique cone of circular horizontal base, of radius $(5/2)(a/R)\Omega$, and is traversed at the uniform rate $\boldsymbol{\Omega}$.

3.18 GENERAL EXAMPLES AND PROBLEMS

Example 3.18.1 *Dynamics of a Sled (or Knife, or Scissors, etc.)* Let us determine the forces and equations of motion of the sled shown in fig. 3.48.

The sled kinematics have already been discussed in ex. 2.13.1 and ex. 2.13.2. We recall that $q_1 = x$, $q_2 = y$, $q_3 = \phi$, and that the nonholonomic (scleronomic) constraint is

$$v_{C,y}/v_{C,x} = \dot{y}/\dot{x} = dy/\,dx = \tan\phi \;\Rightarrow\; dy = (\tan\phi)\,dx, \tag{a}$$

or

$$(1)\,dx + (-1/\tan\phi)\,dy + (0)\,d\phi = 0. \tag{b}$$

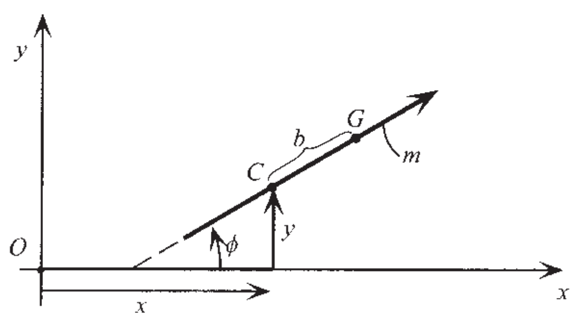

Figure 3.48 Sled in plane motion (on a fixed plane); geometry and forces. G = mass center; C = contact point; $I \equiv I_C \equiv mk_c{}^2$ = moment of inertia about $C = I_G + mb^2$ (k_c = radius of gyration about C).

Kinetic Energy

Applying König's theorem about C, we find (no constraint enforcement yet!), in *holonomic* variables,

$$2T = m[(\dot{x})^2 + (\dot{y})^2] + 2m\,\dot{\phi}\big[\dot{y}(x_G - x) - \dot{x}(y_G - y)\big] + I_C(\dot{\phi})^2$$
$$= m[(\dot{x})^2 + (\dot{y})^2] + 2m\,b\,\dot{\phi}(\dot{y}\,\cos\phi - \dot{x}\,\sin\phi) + I_C(\dot{\phi})^2, \qquad \text{(c)}$$

and since [recalling (ex. 2.13.2: a–c)]

$$(\dot{x})^2 + (\dot{y})^2 = (-\omega_1\,\sin\phi + \omega_2\,\cos\phi)^2 + (\omega_1\,\cos\phi + \omega_2\,\sin\phi)^2 = \cdots = \omega_1{}^2 + \omega_2{}^2, \qquad \text{(d1)}$$

$$(\cos\phi)\dot{x} + (\sin\phi)\dot{y} \equiv v \equiv \omega_2 = \textit{velocity of contact point along sled} \quad (\neq 0)$$

$$\dot{y}\,\cos\phi - \dot{x}\,\sin\phi = \omega_1 \quad (= 0,\ \text{to be enforced later}) \qquad \text{and} \qquad \dot{\phi} = \omega_3, \qquad \text{(d2, 3, 4)}$$

in *nonholonomic* variables:

$$2T = 2T^* = m(\omega_1{}^2 + \omega_2{}^2) + 2m\,b\,\omega_1\,\omega_2 + I_C\,\omega_3{}^2. \qquad \text{(e)}$$

We point out that the *quadratic* term $m\,\omega_1{}^2$ can be safely omitted from $2T^*$ right at this stage; but *not* the term $2m\,b\,\omega_1\,\omega_2$ (why?). From (c) and (e), and the constraint, we readily conclude that the corresponding *constrained* (double) kinetic energies are

$$2T \rightarrow 2T_{oo} = m[(\dot{x})^2 + (\dot{y})^2] + I_C(\dot{\phi})^2$$
$$(\text{"partially constrained," i.e., still a function of } \dot{x}, \dot{y}, \dot{\phi}), \qquad \text{(f)}$$

$$2T^* \rightarrow 2T^*{}_o = m\,\omega_2{}^2 + I_C\,\omega_3{}^2. \qquad \text{(g)}$$

Appellian

Applying the Appellian counterpart of König's theorem (recalling §3.14); that is,

$$S = S_G + S_{/G}, \qquad \text{(h)}$$

$$2S_G \equiv m\,\boldsymbol{a}_G \cdot \boldsymbol{a}_G = m\,a_G{}^2 = 2\ (\text{Appellian of } \textit{translation} \text{ of mass center}), \qquad \text{(i)}$$

$$2S_{/G} \equiv \mathsf{S}\, dm\,\boldsymbol{a}_{/G} \cdot \boldsymbol{a}_{/G} = \mathsf{S}\, dm\, a_{/G}{}^2$$
$$= 2\,[\text{Appellian of motion (rotation) about the mass center}], \qquad \text{(j)}$$

for the relaxed (unconstrained) system and in *holonomic* variables, we find

$$a_G{}^2 = (\ddot{x}_G)^2 + (\ddot{y}_G)^2 = [(x + b\,\cos\phi)^{\cdot\cdot}]^2 + [(y + b\,\sin\phi)^{\cdot\cdot}]^2$$
$$= [\ddot{x} - b\,\ddot{\phi}\,\sin\phi - b(\dot{\phi})^2\,\cos\phi]^2 + [\ddot{y} + b\,\ddot{\phi}\,\cos\phi - b(\dot{\phi})^2\,\sin\phi]^2$$
$$= (\ddot{x})^2 + (\ddot{y})^2 + b^2(\ddot{\phi})^2 + 2b\,\ddot{\phi}(\ddot{y}\,\cos\phi - \ddot{x}\,\sin\phi)$$
$$- 2b(\dot{\phi})^2(\ddot{x}\,\cos\phi + \ddot{y}\,\sin\phi) + \textit{terms not containing } \ddot{x}, \ddot{y}, \ddot{\phi}, \qquad \text{(k)}$$

and (with r = distance of a typical sled particle, of mass dm, from G)

$$2S_{/G} \equiv \mathsf{S}\, dm\big[(r\ddot{\phi})^2 + (r\dot{\phi}^2)^2\big] = I_G(\ddot{\phi})^2 + I_G(\dot{\phi})^4, \qquad \text{(l)}$$

or, *to within "Appell-important terms,"*

$$\begin{aligned}2S &= m[(\ddot{x})^2 + (\ddot{y})^2 + b^2(\ddot{\phi})^2 + 2b\,\ddot{\phi}(\ddot{y}\cos\phi - \ddot{x}\sin\phi) \\ &\qquad - 2b(\dot{\phi})^2(\ddot{x}\cos\phi + \ddot{y}\sin\phi)] + I_G(\ddot{\phi})^2 \\ &= 2S(\phi, \dot{\phi}, \ddot{x}, \ddot{y}, \ddot{\phi}).\end{aligned} \tag{m}$$

To express S in the $\dot{\omega}$ variables — that is, $S \to S^*(t, q, \omega, \dot{\omega}) \equiv S^*$ — we need the $\ddot{q}$'s; that is, $\ddot{x}, \ddot{y}, \ddot{\phi}$, in terms of $t, q, \omega, \dot{\omega}$. Indeed, $(\ldots)^{\cdot}$-differentiating $\dot{q}_k = \sum A_{kl}\,\omega_l$, we find

$$\ddot{q}_1 \equiv \ddot{x} = (-\sin\phi)\dot{\omega}_1 + (\cos\phi)\dot{\omega}_2 + (-\cos\phi)\omega_1\omega_3 + (-\sin\phi)\omega_2\omega_3, \tag{n1}$$

$$\ddot{q}_2 \equiv \ddot{y} = (\cos\phi)\dot{\omega}_1 + (\sin\phi)\dot{\omega}_2 + (-\sin\phi)\omega_1\omega_3 + (\cos\phi)\omega_2\omega_3, \tag{n2}$$

$$\ddot{q}_3 \equiv \ddot{\phi} = (1)\dot{\omega}_3. \tag{n3}$$

However, and this is a very useful and labor-saving remark, since only $\partial S^*/\partial\dot{\omega}_k$ $(k = 1, 2, 3)$ enter the equations of motion, and because of the analytical identities:

$$S\,(t, q, \dot{q}, \ddot{q}) = S^*(t, q, \omega, \dot{\omega}) \quad \text{and} \quad \partial\ddot{q}_k/\partial\dot{\omega}_l = \partial\dot{q}_k/\partial\omega_l \equiv A_{kl}(t, q)$$

($k = 1, 2, 3$ — although, obviously, this is a general result), from which, by chain rule,

$$\partial S^*/\partial\dot{\omega}_k = \sum (\partial S/\partial\ddot{q}_l)(\partial\ddot{q}_l/\partial\dot{\omega}_k) = \cdots = \sum A_{lk}(\partial S/\partial\ddot{q}_l), \tag{m1}$$

it follows that it is *not* necessary to square the $\ddot{q}$'s and then insert them into (m); that is, there is no need to calculate $S^*(\ldots, \dot{\omega})$; but, as (m1) shows, we *do* need to use the *linear* $\ddot{q} \Leftrightarrow \dot{\omega}$ relations (n1–3). From (m1) it also follows that

$$(\partial S^*/\partial\dot{\omega}_k)_o = \sum A_{lk}(\partial S/\partial\ddot{q}_l)_o, \tag{m2}$$

where $(\partial S/\partial\ddot{q}_l)_o$ means that *after* we differentiate S of (m) in the $\ddot{q}$'s, we insert there the *contrained* $\ddot{q} \to (\ddot{q})_o \equiv \ddot{q}_o \Leftrightarrow \omega$ relations and not the relaxed (n1–3); that is,

$$\ddot{q}_{1o} \equiv \ddot{x} = (\cos\phi)\dot{\omega}_2 + (-\sin\phi)\,\omega_2\,\omega_3, \tag{n4}$$

$$\ddot{q}_{2o} \equiv \ddot{y} = (\sin\phi)\dot{\omega}_2 + (\cos\phi)\,\omega_2\,\omega_3, \tag{n5}$$

$$\ddot{q}_{3o} \equiv \ddot{\phi} = (1)\,\dot{\omega}_3. \tag{n6}$$

The above can also be found by $(\ldots)^{\cdot}$-differentiation of the "natural" (constrained) variables $\dot{x} = v\cos\phi$, $\dot{y} = v\sin\phi$, where v = *velocity in sled's direction*. The result is

$$\ddot{x} = \dot{v}\cos\phi - v\,\dot{\phi}\sin\phi, \qquad \ddot{y} = \dot{v}\sin\phi + v\dot{\phi}\cos\phi; \tag{n7}$$

and inverts readily to

$$\dot{v} = \ddot{x}\cos\phi + \ddot{y}\sin\phi \qquad (= \textit{acceleration along sled}), \tag{n8}$$

$$v\,\dot{\phi} = \ddot{y}\cos\phi - \ddot{x}\sin\phi \qquad (= \textit{acceleration normal to sled}); \tag{n9}$$

[from which it also follows that $(\ddot{x})^2 + (\ddot{y})^2 = (\dot{v})^2 + v^2(\dot{\phi})^2$]. Clearly, (n7) and (n4–6) are identical. As a result of (n7–9), the Appellian expression (m) transforms to

$$2S_o = m\left[(\dot{v})^2 + v^2(\dot{\phi})^2 + b^2(\ddot{\phi})^2 + 2b\, v\,\dot{\phi}\,\ddot{\phi} - 2b(\dot{\phi})^2\dot{v}\right] + I_G(\ddot{\phi})^2,$$

or

$$2S^*{}_o = m\left[(\dot{\omega}_2)^2 + {\omega_2}^2{\omega_3}^2 + b^2(\dot{\omega}_3)^2 + 2b\,\omega_2\,\omega_3\,\dot{\omega}_3 - 2b\,{\omega_3}^2\,\dot{\omega}_2\right] + I_G(\dot{\omega}_3)^2, \qquad \text{(m3)}$$

or, finally, to within "Appell-important" terms (and recalling that, by the parallel axis theorem, $I_C = I_G + m\,b^2$)

$$2S^*{}_o = m\left[(\dot{\omega}_2)^2 + 2b\,\omega_3(\omega_2\,\dot{\omega}_3 - \omega_3\,\dot{\omega}_2\right] + I_C(\dot{\omega}_3)^2. \qquad \text{(m4)}$$

Virtual Work

With reference to fig. 3.49 and §3.4 and §3.15, we find, successively,

$$\delta' W = X\,\delta x + Y\,\delta y + M_C\,\delta\phi = Q_1\,\delta q_1 + Q_2\,\delta q_2 + Q_3\,\delta q_3$$
$$\Rightarrow Q_1 = X, \quad Q_2 = Y, \quad Q_3 = M_C \qquad (\textit{holonomic components}), \qquad \text{(n10)}$$

and (from the invariance of $\delta' W$)

$$\delta' W = \sum Q_k\,\delta q_k = \sum Q_k\Big(\sum A_{kl}\,\delta\theta_l\Big) = \sum \Theta_l\,\delta\theta_l$$
$$\Rightarrow \Theta_l = \sum A_{kl} Q_k \quad (\textit{holonomic components}), \text{ and, inversely, } Q_k = \sum a_{lk}\Theta_l, \qquad \text{(n11)}$$

and, therefore, here [recalling (ex. 2.13.2: a, c)],

$$\Theta_1 = -X\,\cos\phi + Y\,\sin\phi \equiv N = \textit{impressed system force perpendicular to sled}, \qquad \text{(n12)}$$

$$\Theta_2 = X\,\cos\phi + Y\,\sin\phi \equiv K = \textit{impressed system force along sled}, \qquad \text{(n13)}$$

$$\Theta_3 = M_C \equiv M = \textit{impressed system moment about } C\ (\textit{perpendicular to } O\text{–}XY); \qquad \text{(n14)}$$

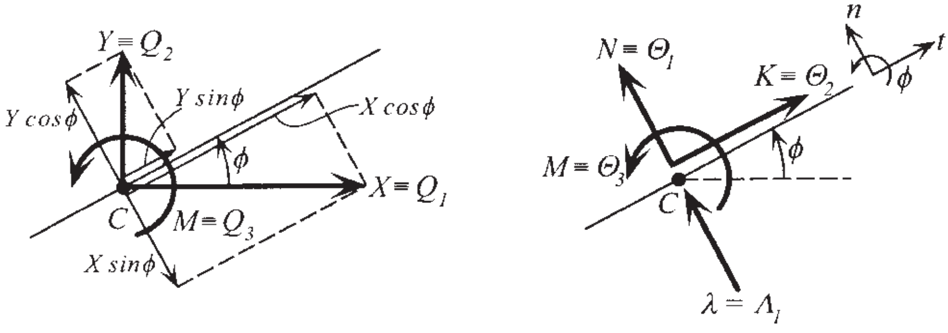

Figure 3.49 Holonomic and nonholonomic components of impressed forces and reactions on sled. Impressed forces on sled: *holonomic*: $Q_1 \equiv X, Q_2 \equiv Y, Q_3 \equiv M$; *nonholonomic*: $\Theta_1 \equiv N, \Theta_2 \equiv K, \Theta_3 \equiv M$.

and similarly for the reactions (here, only $\Lambda_1 \neq 0$)

$$\delta' W_R = \lambda_1\,\delta\theta_1 = \Lambda_1\,\delta\theta_1 = \sum R_k\,\delta q_k \qquad (\lambda_1 = \textit{Lagrangean multiplier})$$

$$\Rightarrow \lambda_1 = \Lambda_1 = \sum A_{k1} R_k, \text{ and, inversely, } R_k = a_{1k}\Lambda_1 = a_{1k}\lambda_1. \tag{n15}$$

The Routh–Voss Equations

Invoking the above results, we find, successively,

$$E_1(T) = Q_1 + \lambda_1 a_{11}: \qquad (m\,\dot{x} - m\,b\,\dot{\phi}\,\sin\phi)^{\cdot} = X + \lambda(-\sin\phi),$$

$$\text{or} \quad m[\ddot{x} - b\,\ddot{\phi}\,\sin\phi - b(\dot{\phi})^2\,\cos\phi] = X - \lambda\,\sin\phi; \tag{o1}$$

$$E_2(T) = Q_2 + \lambda_1 a_{12}: \qquad (m\,\dot{y} + m\,b\,\dot{\phi}\,\cos\phi)^{\cdot} = Y + \lambda(\cos\phi),$$

$$\text{or} \quad m[\ddot{y} + b\,\ddot{\phi}\,\cos\phi - b(\dot{\phi})^2\,\sin\phi] = Y + \lambda\,\cos\phi; \tag{o2}$$

$$E_3(T) = Q_3 + \lambda_1 a_{13}:$$

$$[I_C\dot{\phi} + m\,b(-\dot{x}\,\sin\phi + \dot{y}\,\cos\phi)]^{\cdot} + m\,b\,\dot{\phi}(\dot{x}\,\cos\phi + \dot{y}\,\sin\phi) = M + \lambda(0),$$

$$\text{or} \quad I_C\,\ddot{\phi} + m\,b(\ddot{y}\,\cos\phi - \ddot{x}\,\sin\phi) = M. \tag{o3}$$

These three coupled equations, plus the constraint (a, b), constitute a system of four equations for the four functions: $x(t), y(t), \phi(t), \lambda(t)$.

- Clearly, equations (o1, 2) express the principle of *linear* momentum for the sled along O–XY, respectively; while (o3) expresses that of *angular* momentum about C.
- The derivation of the ϕ-equation, (o3), shows clearly why we should *not* enforce the constraint (a, b) in T. Had we done so — that is, $T \to T_{oo}$ [eq. (f)], *since that constraint is nonholonomic* — we would have obtained the *incorrect* Routh–Voss equations

$$E_1(T_{oo}) = Q_1 + \lambda_1 a_{11}: \qquad (m\dot{x})^{\cdot} = X - \lambda\,\sin\phi, \tag{o4}$$

$$E_2(T_{oo}) = Q_2 + \lambda_1 a_{12}: \qquad (m\dot{y})^{\cdot} = Y + \lambda\,\cos\phi, \tag{o5}$$

$$E_3(T_{oo}) = Q_3 + \lambda_1 a_{13}: \qquad I_C(\dot{\phi})^{\cdot} = M. \tag{o6}$$

Elimination of the Reaction λ among Equations (n7–9)

Multiplying (o1) with $\cos\phi$ and (o2) with $\sin\phi$, and adding side by side, yields

$$\cos\phi(m\,\dot{x} - m\,b\,\dot{\phi}\,\sin\phi)^{\cdot} + \sin\phi(m\,\dot{y} + m\,b\,\dot{\phi}\,\cos\phi)^{\cdot} = X\,\cos\phi + Y\,\sin\phi,$$

or, simplifying, and so on,

$$m[\ddot{x}\,\cos\phi + \ddot{y}\,\sin\phi - b(\dot{\phi})^2] = K. \tag{o7}$$

Equations (o7) and (o3) are, essentially, the (kinetic) Maggi–Hadamard equations of our problem (see below) and, along with the constraint (a), they constitute a determinate system for $x(t), y(t), \phi(t)$. Once this has been accomplished, then, to isolate λ, we multiply (o1) with $-\sin\phi$ and (o2) with $\cos\phi$, and add, and thus obtain (the kinetostatic Maggi equation)

$$\lambda = m(-\ddot{x}\,\sin\phi + \ddot{y}\,\cos\phi + b\,\ddot{\phi}) - (-X\,\sin\phi + Y\,\cos\phi)$$
$$= \textit{inertia ``force'' perpendicular to sled} - \textit{impressed force perpendicular to sled}$$
$$\equiv m a_{G,n} - N \quad (= \textit{constraint reaction perpendicular to sled}). \tag{o8}$$

In terms of the "natural" (or "intrinsic") variables v and ϕ, defined by

$$\dot{x} = v\,\cos\phi \qquad \text{and} \qquad \dot{y} = v\,\sin\phi, \qquad \text{where } \ v = \textit{velocity in direction of sled},$$

the kinetic equations (o7) and (o3) assume, respectively, the simpler Hamel forms (see below)

$$m[\dot{v} - b(\dot{\phi})^2] = K \qquad \text{and} \qquad I_C\,\ddot{\phi} + m\,b\,\dot{\phi}\,v = M, \tag{p1, 2}$$

while the kinetostatic (o8) becomes

$$m(b\,\ddot{\phi} + v\,\dot{\phi}) = N + \lambda. \tag{p3}$$

If $K, M = 0$ (force-free case), eqs. (p1, 2) reduce to

$$m[\dot{v} - b(\dot{\phi})^2] = 0 \qquad \text{and} \qquad I_C\,\ddot{\phi} + m\,b\,\dot{\phi}\,v = 0, \tag{p4, 5}$$

and yield, readily, the (first) integral of *energy*:

$$2T = m\,v^2 + 2m\,b\,\dot{\phi}(-\dot{x}\,\sin\phi + \dot{y}\,\cos\phi) + I_C(\dot{\phi})^2 = \textit{constant} \equiv 2h,$$

or, after enforcing the constraint (a),

$$m\,v^2 + I_C(\dot{\phi})^2 = 2h. \tag{p6}$$

(See also Carathéodory, 1933; and Hamel, 1949, pp. 467–470.)

The Maggi Equations

With $M_k \equiv E_k(T) - Q_k$ $(k = 1, 2, 3 \to x, y, \phi)$, and (A_{kl}) from (n1–3), Maggi's equations become

$$A_{xx}M_x + A_{yx}M_y + A_{\phi x}M_\phi = \lambda: \quad (-\sin\phi)M_x + (\cos\phi)M_y + (0)M_\phi = \lambda, \tag{q1}$$
$$A_{xy}M_x + A_{yy}M_y + A_{\phi y}M_\phi = 0: \quad (\cos\phi)M_x + (\sin\phi)M_y + (0)M_\phi = 0, \tag{q2}$$
$$A_{x\phi}M_x + A_{y\phi}M_y + A_{\phi\phi}M_\phi = 0: \quad (0)M_x + (0)M_y + (1)M_\phi = 0; \tag{q3}$$

or, explicitly,

$$m(\ddot{y}\cos\phi - \ddot{x}\sin\phi) + m\,b\,\ddot{\phi} = (\cos\phi\,Y - \sin\phi\,X) + \lambda\,, \tag{q4}$$
$$m(\ddot{x}\cos\phi + \ddot{y}\sin\phi) - m\,b(\dot{\phi})^2 = \cos\phi\,X + \sin\phi\,Y\,, \tag{q5}$$
$$m\,b(\ddot{y}\cos\phi - \ddot{x}\sin\phi) + I_C\,\ddot{\phi} = M\,, \tag{q6}$$

and coincide, respectively, with the earlier-found equations (o8), (o7), and (o3); that is, the Maggi approach constitutes a systematization of the earlier uncoupling of the Routh–Voss equations into kinetic and kinetostatic.

- Clearly, equations (q1, 2 / 4, 5) express, respectively, the principle of *linear* momentum *normally* and *along* the sled; while (q3/6) expresses that of *angular* momentum about C.
- If we express (any) one of the holonomic velocities, say $\dot{x}$, in terms of the other two via the constraint (a) [i.e., $\dot{x} = \dot{x}(\dot{y}, \dot{\phi}; \phi)$], and use this to eliminate $\dot{x}$ and $\ddot{x}$ from the kinetic Maggi equations (q2, 3), these two *new* (kinetic) equations in $\dot{y}, \ddot{y}, \dot{\phi}, \ddot{\phi}, \phi$ would be the *Chaplygin–Voronets* equations of our problem; equivalently, these would be our Lagrangean equations of motion based on the kinetic energy expressed in terms of the two *independent* velocities $\dot{y}$ and $\dot{\phi}$: $T \to T[\dot{x}(\dot{y}, \dot{\phi}), \dot{y}, \dot{\phi}; \phi] = T_o(\dot{y}, \dot{\phi}) \equiv T_o =$ *completely constrained kinetic energy* [recall (3.8.13a ff.)]. The details, for any of the three possible choices of dependent velocity, are left to the reader. See also Dobronravov (1970, pp. 92–104).

The Appell Equations

(i) *Holonomic variables:* Due to the kinematico-inertial identities $\partial S/\partial \ddot{q}_k = (\partial T/\partial \dot{q}_k)^{\cdot} - \partial T/\partial q_k$, the holonomic variable Appellian equations are

$$\partial S/\partial \ddot{q}_k = Q_k + \sum \lambda_D \, a_{Dk} \qquad (k = 1, 2, 3 = x, y, \phi;\ D = 1), \tag{r}$$

and, of course, they coincide completely with the earlier Routh–Voss equations (o3).

(ii) *Nonholonomic variables*: With the help of the earlier results [(n1) ff.], we readily find

$$\begin{aligned}
\partial S^*/\partial \dot{\omega}_k &= (m\ddot{q}_1)(\partial \dot{q}_1/\partial \omega_k) + (m\ddot{q}_2)(\partial \dot{q}_2/\partial \omega_k) + (mb^2\ddot{q}_3)(\partial \dot{q}_3/\partial \omega_k) \\
&\quad + mb(\partial \dot{q}_3/\partial \omega_k)(\ddot{q}_2 \cos\phi - \ddot{q}_1 \sin\phi) \\
&\quad + mb\ddot{q}_3[(\partial \dot{q}_2/\partial \omega_k) \cos\phi - (\partial \dot{q}_1/\partial \omega_k) \sin\phi] \\
&\quad - mb(\dot{q}_3)^2[(\partial \dot{q}_1/\partial \omega_k) \cos\phi + (\partial \dot{q}_2/\partial \omega_k) \sin\phi] + I_G\ddot{q}_3(\partial \dot{q}_3/\partial \omega_k) \\
&= (m\ddot{q}_1)\, A_{1k} + (m\ddot{q}_2)\, A_{2k} + \cdots,
\end{aligned}$$

or, explicitly (recalling that $I_C = I_G + mb^2$),

$$\begin{aligned}
&\partial S^*/\partial \dot{\omega}_1 = m\,\dot{\omega}_1 + m\,b\,\dot{\omega}_3 + m\,\omega_2\,\omega_3 \Rightarrow (\partial S^*/\partial \dot{\omega}_1)_o = m(b\,\dot{\omega}_3 + \omega_2\,\omega_3), \\
&\partial S^*/\partial \dot{\omega}_2 = m\,\dot{\omega}_2 - m\,\omega_1\,\omega_3 - m\,b\,{\omega_3}^2 \Rightarrow (\partial S^*/\partial \dot{\omega}_2)_o = m(\dot{\omega}_2 - b\,{\omega_3}^2), \\
&\partial S^*/\partial \dot{\omega}_3 = I_C\,\dot{\omega}_3 + m\,b\,\dot{\omega}_1 + m\,b\,\omega_2\,\omega_3 \Rightarrow (\partial S^*/\partial \dot{\omega}_3)_o = I_C\,\dot{\omega}_3 + m\,b\,\omega_2\,\omega_3. \quad \text{(s1, 2, 3)}
\end{aligned}$$

From the above and (n12–15), we see that the nonholonomic Appellian equations of our problem are

$$(\partial S^*/\partial \dot{\omega}_1)_o = \Theta_1 + \lambda_1: \qquad m\,(b\,\dot{\omega}_3 + \omega_2\,\omega_3) = N + \lambda, \tag{s4}$$

$$(\partial S^*/\partial \dot{\omega}_2)_o = \Theta_2: \qquad m\,(\dot{\omega}_2 - b\,{\omega_3}^2) = K, \tag{s5}$$

$$(\partial S^*/\partial \dot{\omega}_3)_o = \Theta_3: \qquad I_C\,\dot{\omega}_3 + m\,b\,\omega_2\,\omega_3 = M. \tag{s6}$$

Upon recalling the definitions of $\omega_{1,2,3}$, we immediately see that the above are nothing but (p3, 1, 2) in that order. Clearly, the above constitute a (determinate) system of three equations in $\omega_2(t), \omega_3(t), \lambda(t)$: first, we solve (s5, 6) for ω_2, ω_3, and, substituting the results into (s4) (which then becomes algebraic), we obtain λ.

If we were not interested in finding the reaction $\Lambda_1 = \lambda_1 = \lambda$ (perpendicular to the sled at C, and due to the constraint $\omega_1/d\theta_1/\delta\theta_1 = 0$), we would only need to evaluate all relevant quantities for $\omega_1 = 0$, $\dot{\omega}_1 = 0$, and denote them by $(\ldots)_o$; that is, instead of the relaxed holonomic accelerations (n1–3), we would only need their constrained values (n4–6) and corresponding constrained Appellian (m1, 2). Then, the two kinetic Appellian equations would read

$$\partial S^*{}_o/\partial\dot{\omega}_2 = (\partial S^*/\partial\dot{\omega}_2)_o = m(\dot{\omega}_2 - b\,\omega_3{}^2) = \Theta_2, \tag{s7}$$

$$\partial S^*{}_o/\partial\dot{\omega}_3 = (\partial S^*/\partial\dot{\omega}_3)_o = I_C\,\dot{\omega}_3 + m\,b\,\omega_2\,\omega_3 = \Theta_3, \tag{s8}$$

as before.

It is such "constrained" Appellian derivations, based on $\partial S^*{}_o/\partial\dot{\omega}_I = (\partial S^*/\partial\dot{\omega}_I)_o$ $(I = 2, 3)$, that one usually finds in the literature.

The Hamel Equations

Invoking the earlier equations (e, g), we easily find

$$P_1 = (\partial T^*/\partial\omega_1)_o = m\,b\,\omega_3, \tag{t1}$$

$$P_2 = (\partial T^*/\partial\omega_2)_o = m\,\omega_2, \tag{t2}$$

$$P_3 = (\partial T^*/\partial\omega_3)_o = (m\,b\,\omega_1 + I_C\,\omega_3)_o = I_C\,\omega_3, \tag{t3}$$

and therefore the master variational equation (3.6.12)
