

Reddam

# Project introduction

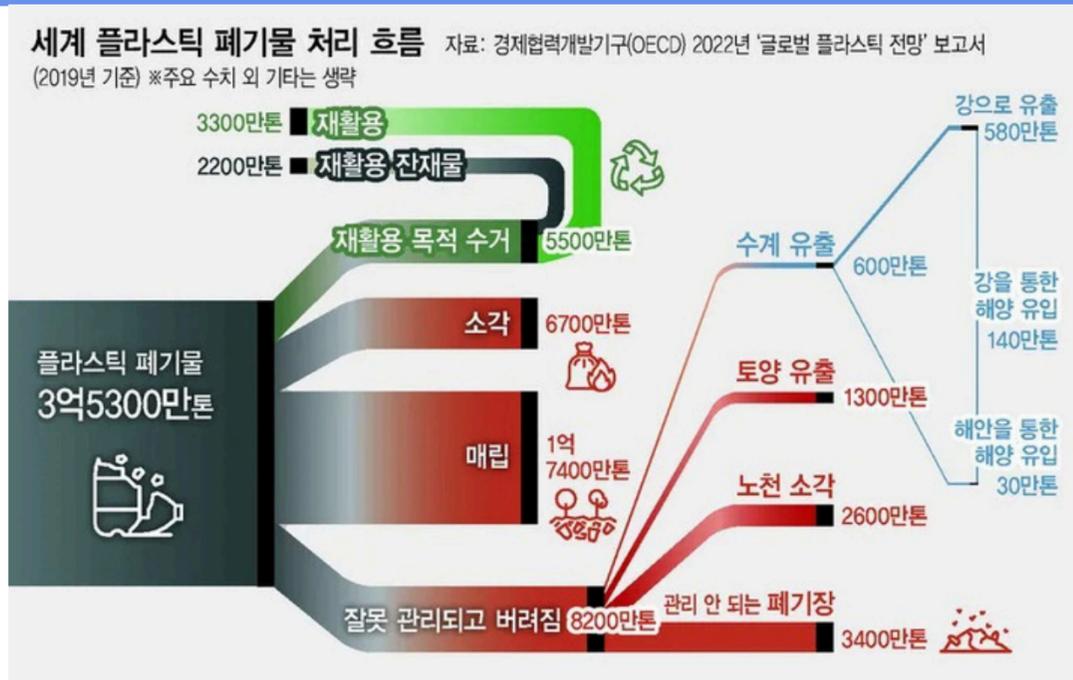

Redam is a platform that helps to classify recyclable waste for contamination and recycling by using an AI robot arm that has learned an object recognition model based on machine learning.

# problem

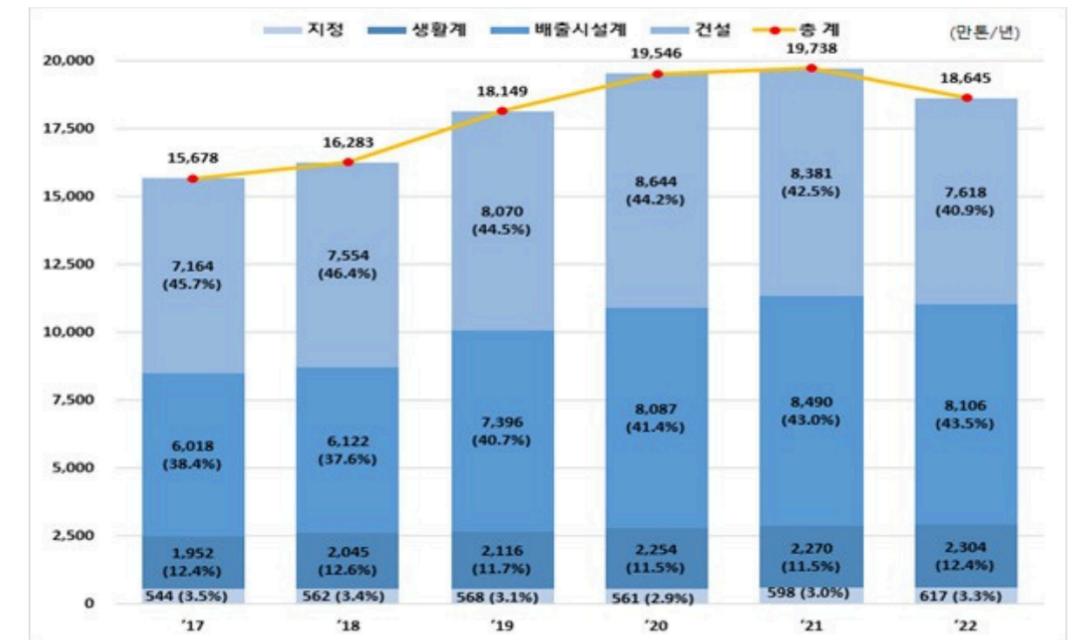

## plastic processing flow

Most plastics cannot be recycled because they are difficult to sort and clean accurately.

## waste generation

The amount of waste generated continues to increase

01

# Main features

# Redam

Automatic classification through object recognition

\*accuracy 97 % higher

In the midst of climate and environmental disasters, the technology to recycle waste is an AI convergence product that helps with AI recycling separation and collection through AI convergence technology.

accuracy 97 % higher

## Fire and Explosion Detection

Fire accidents that may occur due to not separating waste such as butane gas and used batteries that have a risk of explosion are protected through the explosive detection function.

# Automatic classification and handling of hazardous waste

Plastic  
classification

Detailed  
classification  
by material

glass classification

Separated by color

Dangerous goods  
handling

Safe protocol operation

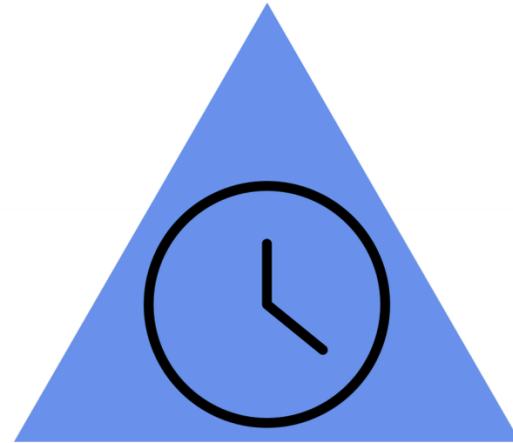

Can/Metal  
classification

Magnetic identification  
and classification

The ReDAM system uses an AI robotic arm trained on tens of thousands of recycled images. Real-time image recognition and classification of hazardous materials.

02

Expected effects

**Improved recycling separation speed**

More than 3 times faster than conventional manual work

**Increased accuracy**

Classified as performance with accuracy of 97% or higher  
**cost reduction**

Reduce labor costs by more than 30%

PLASTIC

Thank you
