# Database Dependencies with Examples

# 1. Functional Dependencies (FD)

# **Basic Example - Employee Table**

EmployeeID   Name   Email   DepartmentID	
101   John Doe   john@company.com  5	
102   Jane Smith  jane@company.com  3	
103   Bob Wilson  bob@company.com   5	

## **Functional Dependencies:**

- EmployeeID  $\rightarrow$  Name (Employee ID determines Name)
- EmployeeID  $\rightarrow$  Email (Employee ID determines Email)
- Email  $\rightarrow$  EmployeeID (Email determines Employee ID assuming unique emails)

# **Types of Functional Dependencies**

# **Trivial FD Example:**

- EmployeeID, Name  $\rightarrow$  EmployeeID (trivial because EmployeeID is part of both sides)
- Name, Email  $\rightarrow$  Name (trivial because Name appears on both sides)

# Non-trivial FD Example:

• EmployeeID  $\rightarrow$  Name (non-trivial because Name is not part of EmployeeID)

# **Completely Non-trivial FD Example:**

• EmployeeID → Email (completely non-trivial because EmployeeID and Email share no common attributes)

## 2. Partial Dependencies

## **Problem Example - Course Enrollment Table**

```
StudentID | CourseID | StudentName | CourseName | Grade | Instructor |
            -----|-----|-----|
                                                              ----|
S001
         | C101
                    | Alice Brown | Math 101
                                             I A
                                                     | Dr. Smith
S001
           C102
                    | Alice Brown | Physics
                                              I B+
                                                     | Dr. Jones
         L
S002
         | C101
                                 | Math 101
                                             I B
                                                     | Dr. Smith
                    | Bob Green
```

Primary Key: (StudentID, CourseID)

## Partial Dependencies (violations of 2NF):

- StudentID  $\rightarrow$  StudentName (StudentName depends only on part of the key)
- CourseID  $\rightarrow$  CourseName (CourseName depends only on part of the key)
- CourseID  $\rightarrow$  Instructor (Instructor depends only on part of the key)

#### **Full Dependencies:**

• (StudentID, CourseID)  $\rightarrow$  Grade (Grade depends on the complete key)

## 3. Full Functional Dependencies

**Corrected Example - After 2NF Normalization** 

```
Students Table:
 | StudentID | StudentName |
 |-----|
 | S001 | Alice Brown |
 | S002 | Bob Green |
Courses Table:
 | CourseID | CourseName | Instructor |
 |-----|-----|------|------|
 | C101 | Math 101 | Dr. Smith |
 | C102 | Physics | Dr. Jones |
Enrollments Table:
 | StudentID | CourseID | Grade |
 |-----|-----|-----|
          | C101
                   I A
 | S001
                          - 1
 | S001 | C102
                   | B+
                          - 1
 | S002 | C101
                 | B |
Now (StudentID, CourseID) \rightarrow Grade is a full functional dependency.
```

#### 4. Transitive Dependencies

## **Problem Example - Employee Department Table**

```
| EmployeeID | Name| DepartmentID | DepartmentName | ManagerName| ------| ------| 101| John Doe | D001| Engineering| 102| Jane Smith | D002| Marketing| Mike Johnson || 103| Bob Wilson | D001| Engineering| Sarah Wilson |
```

**Transitive Dependencies (violations of 3NF):** 

- EmployeeID  $\rightarrow$  DepartmentID  $\rightarrow$  DepartmentName
- EmployeeID  $\rightarrow$  DepartmentID  $\rightarrow$  ManagerName

Here, DepartmentName and ManagerName depend on DepartmentID, which depends on EmployeeID, creating transitive dependencies.

## **Solution - 3NF Normalization**

```
Employees Table:
 | EmployeeID | Name | DepartmentID |
 | John Doe | D001
 | 101
         | Jane Smith| D002
 | 102
                             I
     | Bob Wilson| D001
                             L
 | 103
Departments Table:
 | DepartmentID | DepartmentName | ManagerName |
 | Engineering | Sarah Wilson |
 | D001
          | Marketing | Mike Johnson |
 | D002
```

5. Multivalued Dependencies (MVD)

# **Example - Employee Skills and Projects**

EmployeeID	Skill	Project
101	Java	ProjectA
101	Java	ProjectB
101	Python	ProjectA
101	Python	ProjectB
102	JavaScript	ProjectC
102	React	ProjectC

# **Multivalued Dependencies:**

- EmployeeID →→ Skill (Employee 101 has skills Java and Python, independent of projects)
- EmployeeID →→ Project (Employee 101 works on ProjectA and ProjectB, independent of skills)

This creates redundancy because every combination of skills and projects must be stored.

# Solution - 4NF Normalization

Employee_Skills Table:							
EmployeeID	Skill						
101	Java						
101	Python						
102	JavaScript						
102	React						
Employee_Projects Table:							
EmployeeID	Project						
101	ProjectA						
101	ProjectB						
102	ProjectC						

#### 6. Join Dependencies

#### **Example - Supplier-Part-Project Relationship**

Supplier	I	Part	I	Project
	-   -		·	
S1	I	P1	I	J1
S1	I	P2	I	J1
S2	I	P1	I	J2
S2	I	P2	I	J2

If this table can be decomposed into three binary relations without loss:

- Supplier-Part: {(S1,P1), (S1,P2), (S2,P1), (S2,P2)}
- Part-Project: {(P1,J1), (P2,J1), (P1,J2), (P2,J2)}
- Supplier-Project: {(S1,J1), (S2,J2)}

And these can be joined back to recreate the original table, then there's a join dependency.

## 7. Inclusion Dependencies

**Example - Foreign Key Relationships** 

```
Orders Table:
 OrderID | CustomerID | OrderDate |
  -----|-----|------|
 1001
        | C001
                 | 2024-01-15 |
 1002
        C002
                 2024-01-16
| 1003
        | C001
                 2024-01-17
Customers Table:
| CustomerID | CustomerName | Email
| Alice Johnson| alice@email.com
| C001
 C002
          | Bob Smith
                      | bob@email.com
```

**Inclusion Dependency:** Orders[CustomerID] ⊆ Customers[CustomerID]

This means every CustomerID in the Orders table must exist in the Customers table.

#### 8. Key Dependencies

**Example - Student Course System** 

#### **Students Table:**

**Key Dependencies:** 

- Candidate Keys:
  - StudentID (minimal set that uniquely identifies each row)
  - Email (assuming emails are unique)
- **Primary Key:** StudentID (chosen candidate key)
- Alternate Key: Email (candidate key not chosen as primary)

**Course\_Enrollment Table:** 

```
| StudentID | CourseID | Grade |
|------|-----|
| S001 | C101 | A |
| S002 | C101 | B |
```

Foreign Key: StudentID references Students(StudentID)

## **Composite Key Example**

I	OrderID	I	ProductID	I	Quantity	I	UnitPrice	I
1.		· [·		·		·		·
Ι	1001	I	P001	I	2	I	25.00	1
Ι	1001	I	P002	I	1	I	50.00	1
Ι	1002	I	P001	I	3	I	25.00	1

Composite Primary Key: (OrderID, ProductID) Foreign Keys:

- OrderID references Orders(OrderID)
- ProductID references Products(ProductID)
