Opioid analgesics are now the most commonly prescribed class of medications in the United States, where chronic pain is estimated to affect around 68 million people each year. In 2014 alone, U.S. retail pharmacies dispensed 245 million prescriptions for opioid pain relievers. Opioids are useful and effective analgesics but produce several unwanted side effects, including episodes of life-threatening respiratory depression, which resulted in over 30,000 deaths in 2014. For this reason, an unmet medical need exists for an agent that can antagonize opioid-induced respiratory depression without compromising the analgesic effects of opioids.

We herein describe the results of a phase IIa clinical trial that evaluated the ability of CX1739 to overcome the respiratory depression induced by the powerful, yet short-acting opioid, remifentanyl in two models of opioid use: a. REMI-Bolus evaluated respiratory parameters in an opioid overdose model, using a bolus of remifentanyl (1 mcg/kg) to achieve significant respiratory depression; b. REMI-Infusion evaluated respiratory, pain, and pupilometry parameters using an infusion of remifentanyl at a steady state blood concentration of 2 ng/ml to achieve approximately 40 - 50% respiratory depression as a model of sub-acute, post-surgical intravenous opioid treatment as well as chronic oral opioid treatment for chronic pain. The results of the REMI-Bolus analysis demonstrate that CX1739 does not prevent the rapid respiratory depression that occurs after intravenous, bolus injection of remifentanyl. The results of the REMI-Infusion analysis demonstrate that, compared to placebo, an acute dose of CX1739 (300 mg or 900 mg) significantly reduces OIRD under steady-state opioid concentrations. The remifentanyl effects on analgesia, pupilometry and bispectral index were not altered. Administration of CX1739 at an acute dose up to 900 mg was safe and comparable to placebo.

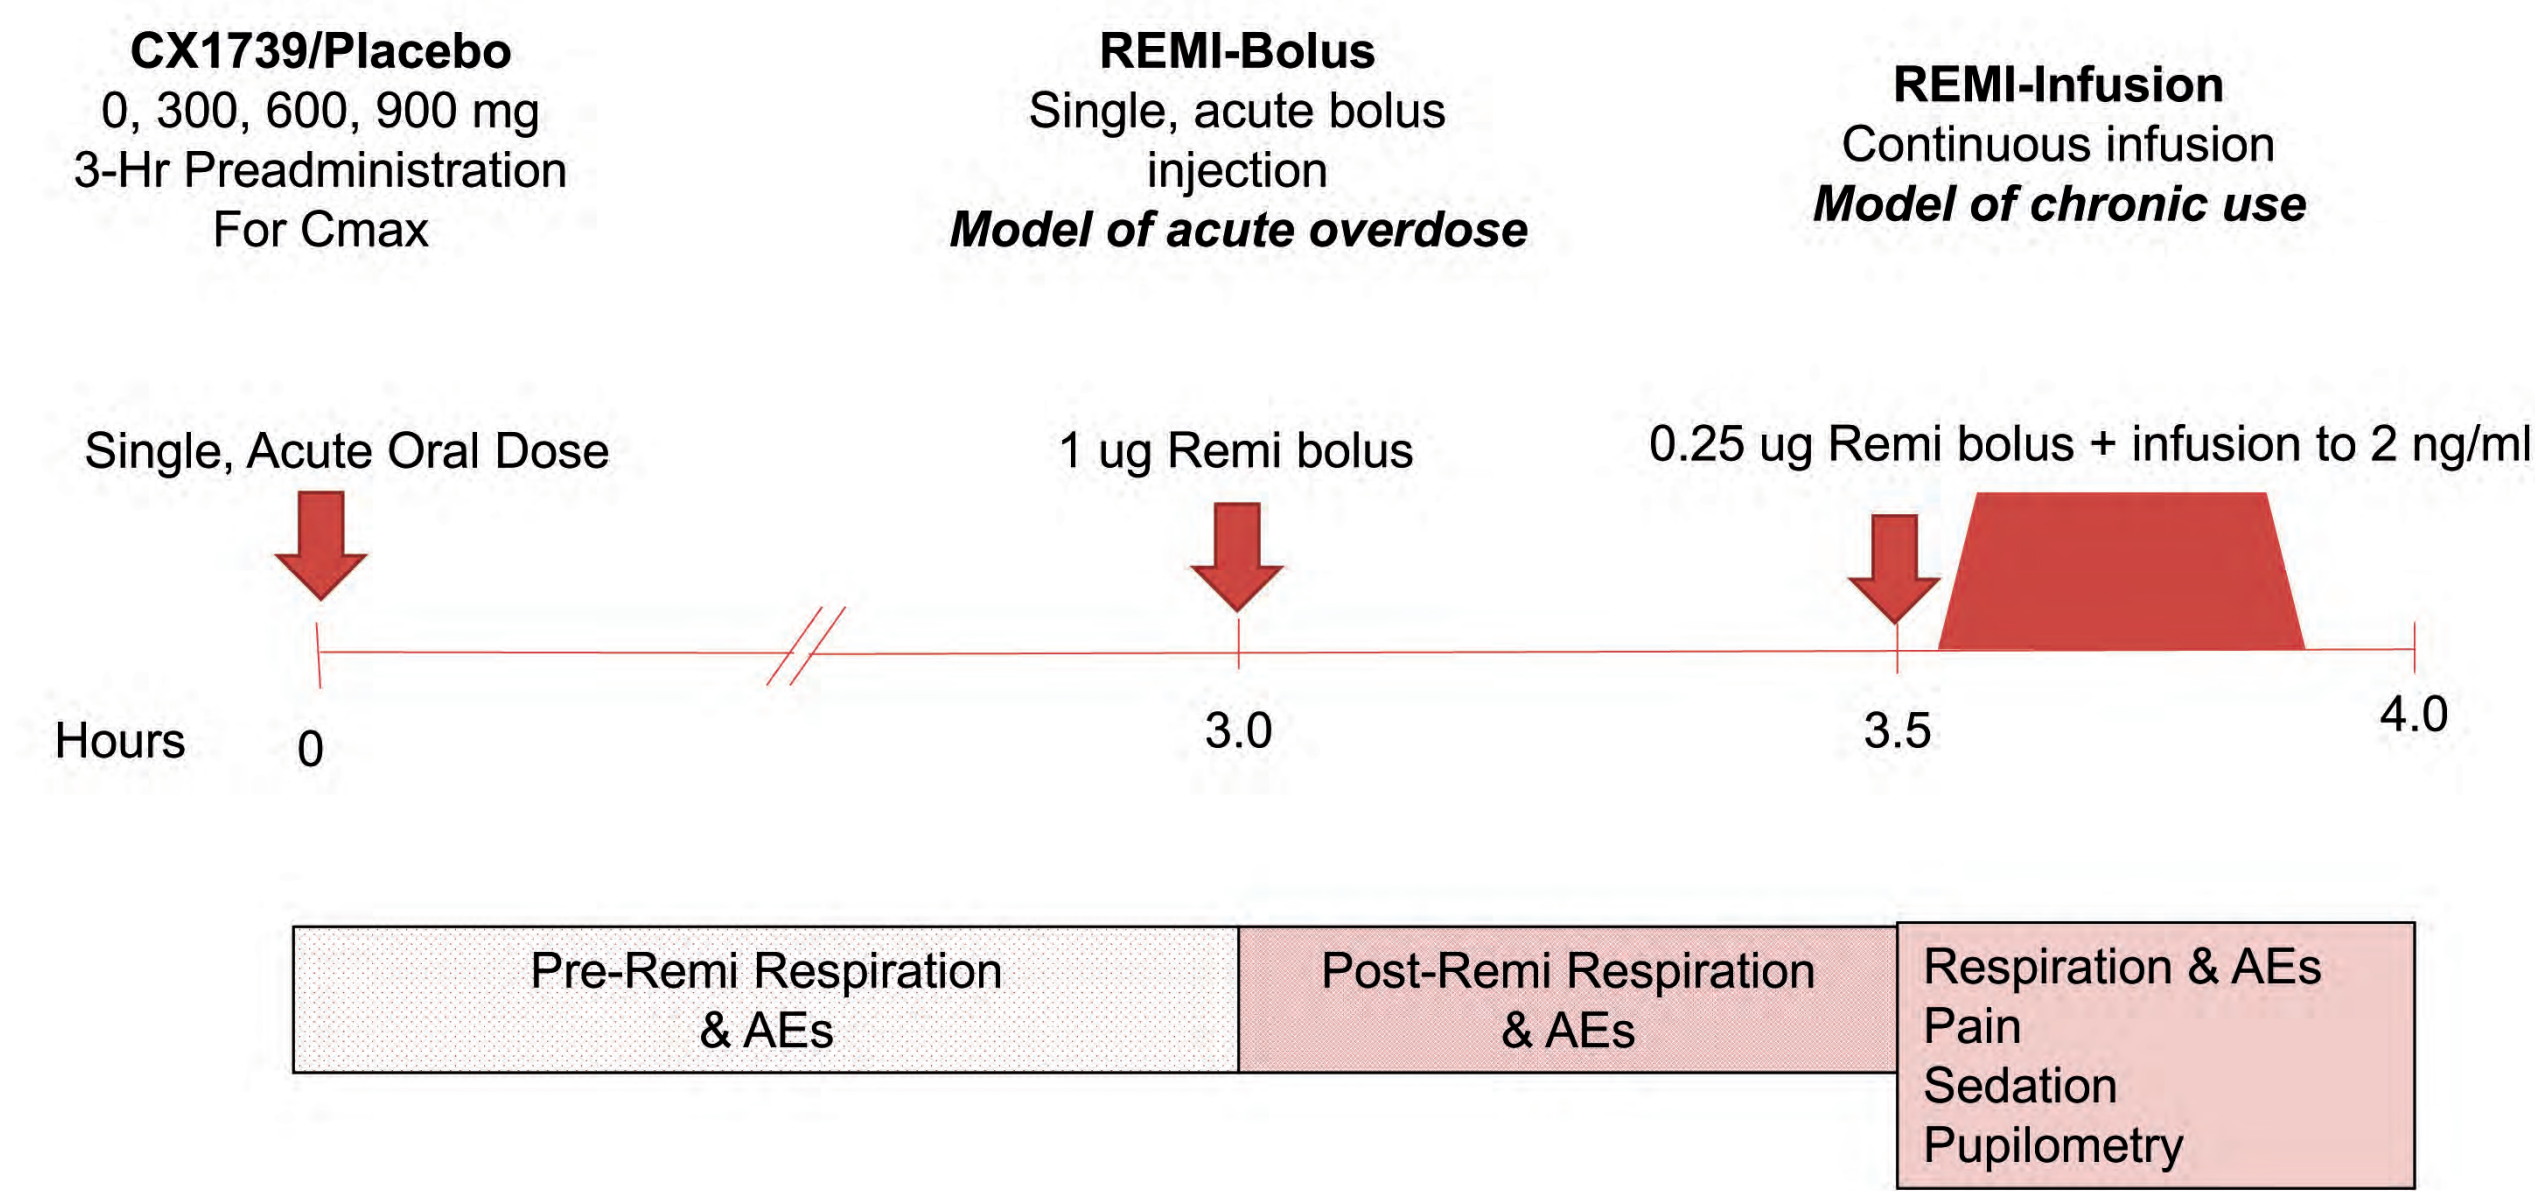

Overall Study Design: CX1739 vs. Placebo in Combination with the Opioid Remifentanyl

**Randomized, Blinded, Placebo-controlled, Cross-Over with Acute Dose Escalation of CX1739**  
Study Population 1: Placebo vs. 300 mg CX1739 (n=19; Completed Visits 1 and 2; Blinded)  
Study Population 2: Placebo vs. 300 mg, 600 mg, and 900mg CX1739 (n=17; completed 4 visits)

**Remifentanyl Dosing**  
4 Weekly visits two protocols for remifentanyl administration (REMI Infusion and REMI Bolus)  
REMI Infusion – Model of post-surgical pain management and chronic opioid use  
REMI Bolus – Model of IV drug overdose prevention and rescue

Weekly Acute Dose Testing of CX1739 vs Remifentanyl: Bolus and Infusion Models of Opioid Use

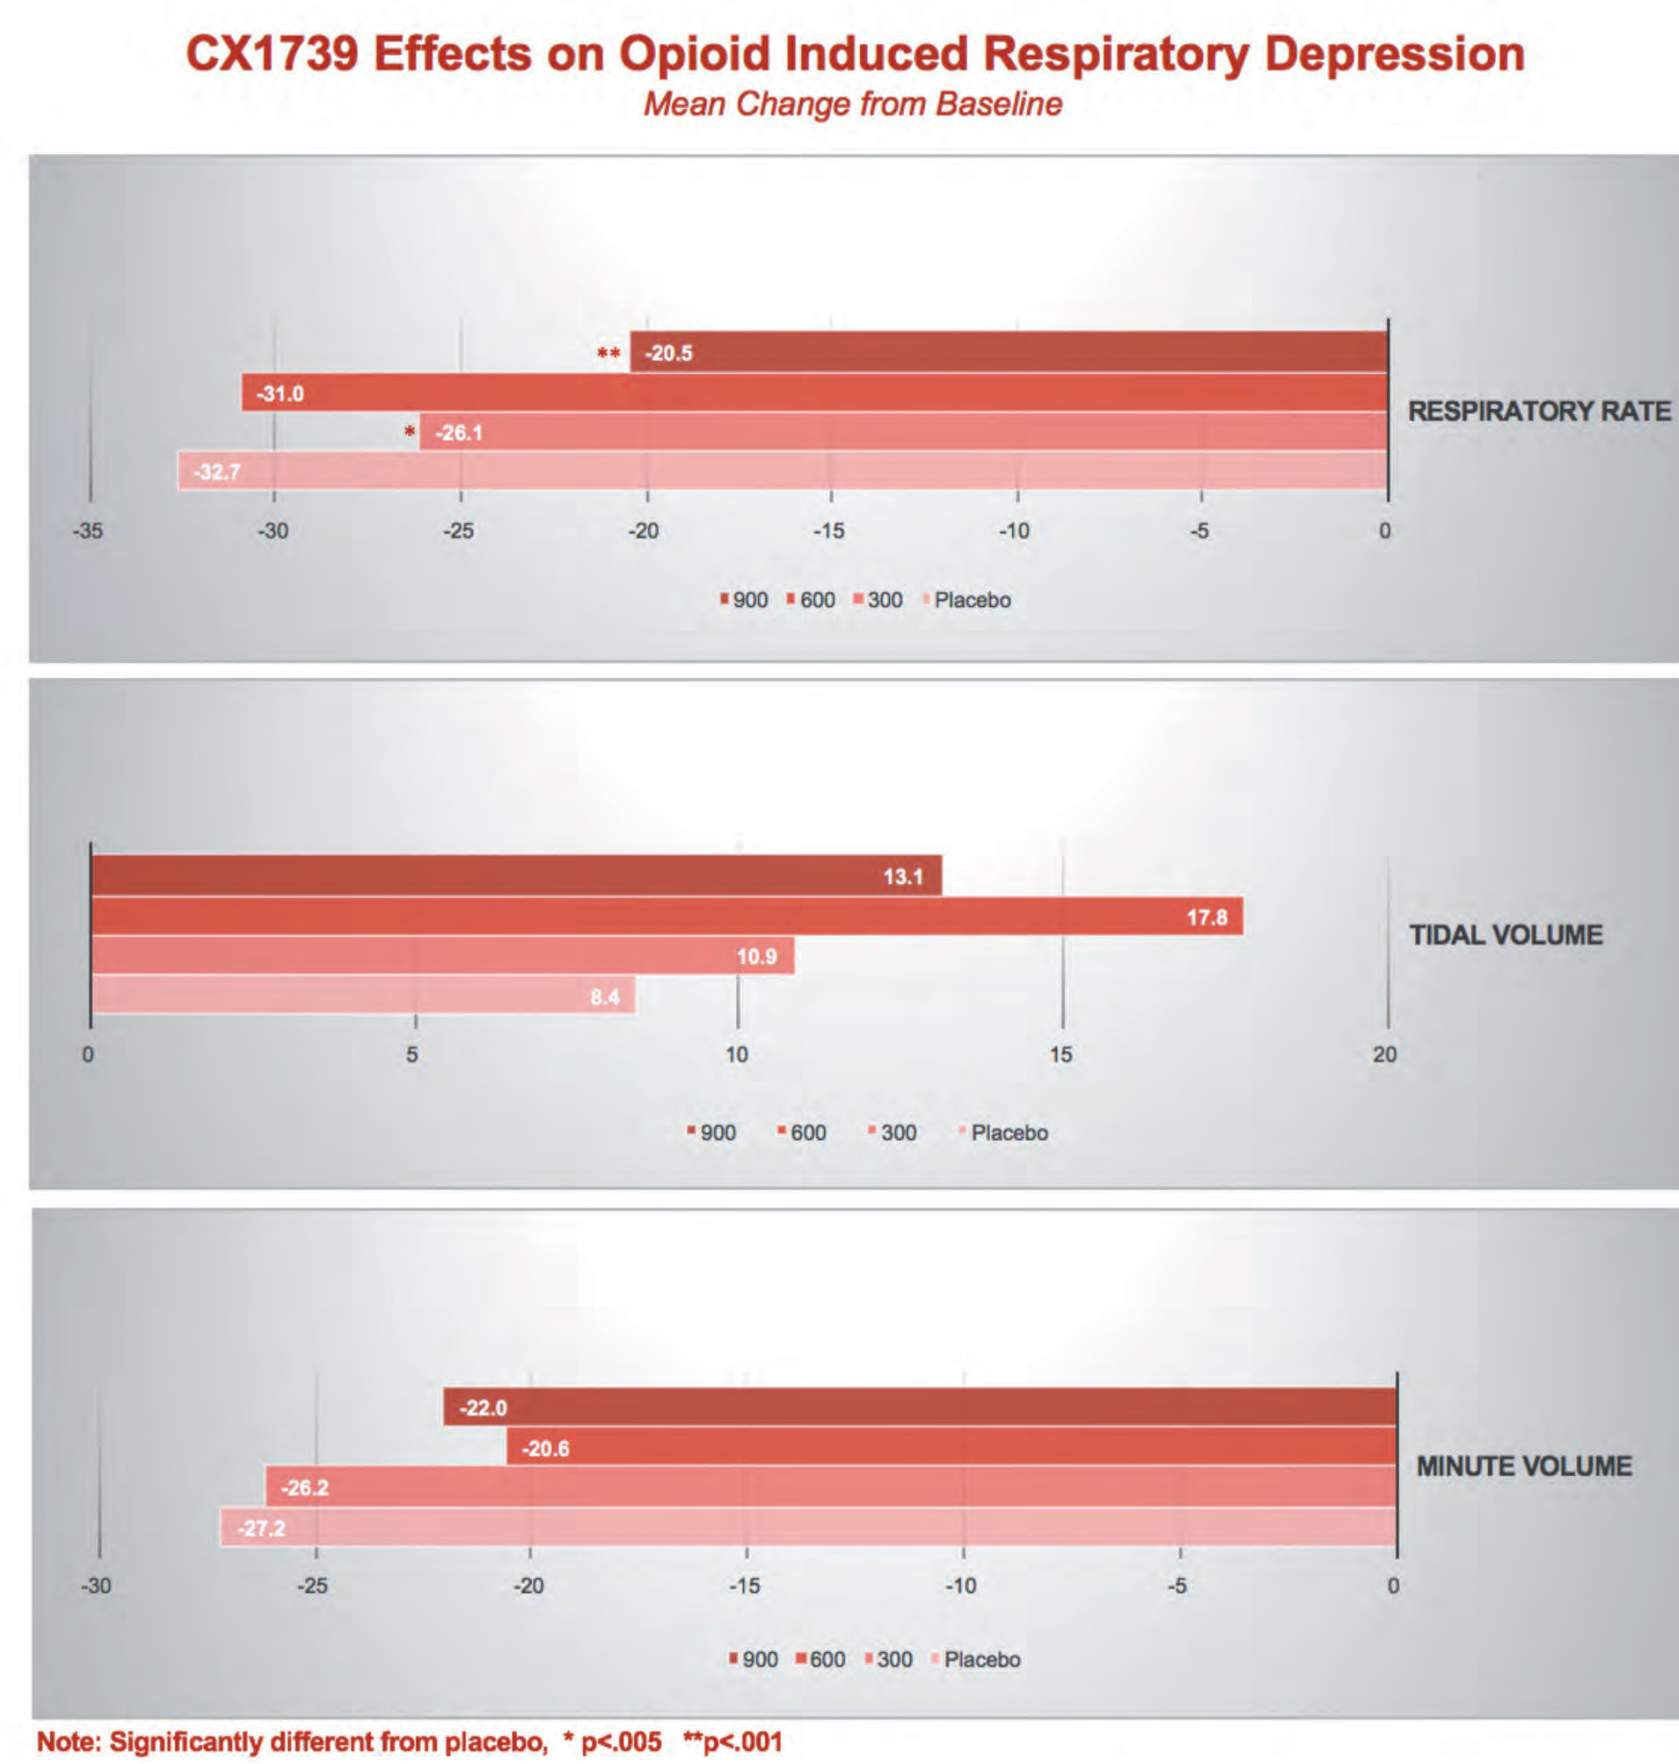

**Endpoint Measures**  
**REMI Bolus:** Effect of CX1739 on % change from baseline for RR, TV, and MV & Time to respiratory recovery following remifentanyl-induced RD  
**REMI Infusion:** Effect of CX1739 on opioid induced respiratory depression (% change from baseline for RR, TV, and MV ) at a steady-state dose of remifentanyl (2ng/ml)

Additional research is warranted to explore the effects of CX1739 on Emax and RT

Conclusion: CX1739 Has Potential Clinical Utility for the Treatment of Opioid Induced Respiratory Depression

- CX1739 significantly antagonized remifentanyl induced respiratory depression during REMI-Infusion, a model of opioid induced respiratory depression (OIRD).
- CX1739 is safe and well-tolerated, with no serious adverse events reported in the trial.
- Though CX1739 antagonized OIRD, pain control was maintained, as CX1739 did not significantly alter analgesia or sedation produced by remifentanyl.
- CX1739 did not antagonize respiratory depression during REMI-Bolus, a model of acute opioid overdose.
- These positive results warrant additional clinical trials of CX1739:
  - ❖ Central sleep apnea (CSA) in patients taking chronic oral opioids
  - ❖ Post-operative pain management concomitant with opioid IV infusions
  - ❖ Prevention of OIRD in patients taking chronic oral opioids for pain management
  - ❖ Extension of OIRD recovery after naloxone rescue
