## **A Now Major To Extreme Heatwave In The Making + A Thundery Breakdown Later Or More Major Heat...**

The expected intense high pressure will begin to really make its presence felt across our shores from Sunday and deep into next week and up until around the middle to the end of the working week in terms of peaking and maximum temperatures in at least the high 30s in parts of the south and possibly not too far from or quite close to that fabled 40°C marker or higher by around midweek and the end of the working week.

Additionally, and to explain this a little better and as an example of what is coming in reality, my own location in Lancashire for tomorrow alone has now suddenly jumped from 19C to a much warmer 23/24C for tomorrow (Sunday) and within the space of just 24 hours and from the so-called main and public weather apps from elsewhere.

This is also just as we said they would and expected for this now imminent and developing period, with parts of the south also now suddenly in the mid 30s and also likely to be a good degree or two higher in the currently projected hot days for next week at least, and with this type of high pressure build and with parts much further north also being able to expect a good staggering UP of temperatures on their apps over the coming

days to something more akin to our now repeatedly repeated forecasts for these exact dates over recent weeks, and those of the GFS and ECM (not just me, these continuous and repeated charts from them alternatively strengthened my thinking on something hotter than my original idea).

Additionally, and as usual with such an intense heat rise, we could see some bubbling-up but quite detached thunderstorms pushing in across some parts of the south-west from around Tuesday and Wednesday, but again quite detached from many areas as they track quickly eastwards and dissipate but with offerings of some quick and heavy downpours in places as it does.

However, towards next weekend and around Friday or Saturday is when we could see some changes or thundery rumbles ushering in from the north and west, and this is also a repeated and similar feature from both the GFS and ECM computer models.

Additionally, and importantly, this is some high pressure area we will be facing through much of this next week, and although we could see some thundery rumbles or downpours being induced from these changes, it is still likely to remain warm to hot for many as this high pressure area becomes more stubborn to shift that the models realise at present and therefore bringing some 'less hot' and possibly unsettled and cloudy conditions at worst for a day or two and prior to more intense high pressure rises on current projections also away from our own forecasts beyond this brief and 'if at all' weather for later next week.

Have a great Saturday all,

James Madden, Exacta Weather
