

# MathGov Appendices Volume

(MathGov v5.0i, rev14.27)

## Specification Annex

### Scope Note

This volume contains the human-readable appendices referenced by the MathGov Foundation Paper. It provides definitions, reference values, registries, and explanatory material required to interpret and apply the normative methodology.

Runnable examples, scenario libraries, kernel edge registries, executable schemas, and deterministic replay artifacts are externalized to **MathGov ProofPack v1.0** and are referenced by cryptographic hash in the Proof-Carrying Case (PCC). This volume is non-runnable by design.

### Appendix A: Symbol and Notation Reference

This appendix provides the complete symbol reference, organized by functional category. All symbols are defined with their domains, ranges, units where applicable, and first use location.

#### A.1 Union and Dimension Indices

| Symbol | Name                  | Domain                                                                       | Range | Units | First Defined |
|--------|-----------------------|------------------------------------------------------------------------------|-------|-------|---------------|
| $u$    | Union index           | {1, 2, 3, 4, 5, 6, 7}                                                        | —     | —     | §2.2          |
| $d$    | Dimension index       | {1, 2, 3, 4, 5, 6, 7}                                                        | —     | —     | §4.1          |
| $U$    | Operational union set | {Self, Household, Community, Organization, Polity, Humanity/CMIU, Biosphere} | —     | —     | §2.2          |

| Symbol              | Name                     | Domain                                                              | Range                         | Units | First Defined |
|---------------------|--------------------------|---------------------------------------------------------------------|-------------------------------|-------|---------------|
| $U_{\text{meta}}$   | Meta-union set           | {Cosmic, Universal}                                                 | —                             | —     | §2.3          |
| $U_{\text{full}}$   | Complete union set       | $U \cup U_{\text{meta}}$                                            | —                             | —     | §2.3          |
| $D$                 | Dimension set            | {Material, Health, Social, Knowledge, Agency, Meaning, Environment} | —                             | —     | §4.1          |
| $U_{\text{rights}}$ | Rights-bearing union set | Subset of $U$                                                       | —                             | —     | §6.2          |
| $\phi(u, d)$        | Cell-flattening map      | $U \times D$                                                        | {1, ..., 49}                  | —     | §8.3          |
| $I_{49}$            | Identity matrix          | —                                                                   | $\mathbb{R}^{(49 \times 49)}$ | —     | §8.3          |

## A.2 Actions and Option Sets

| Symbol | Name                      | Domain     | Range | Units | First Defined |
|--------|---------------------------|------------|-------|-------|---------------|
| $a$    | Candidate action / option | $O$        | —     | —     | §3.2          |
| $O$    | Option set                | Finite set | —     | —     | §3.2          |

| Symbol                 | Name                        | Domain                                 | Range         | Units | First Defined |
|------------------------|-----------------------------|----------------------------------------|---------------|-------|---------------|
| $A_{\text{NCRC}}$      | Set of NCRC-passing options | Subset of $O$                          | —             | —     | §3.2.3        |
| $A_{\text{adm}}$       | Set of admissible options   | Subset of $A_{\text{NCRC}}$            | —             | —     | §3.2.3        |
| $\text{Admissible}(a)$ | Admissibility predicate     | $O$                                    | {true, false} | —     | §3.2.3        |
| $\succ$                | Preference relation         | $A_{\text{adm}} \times A_{\text{adm}}$ | —             | —     | §3.2.4        |

### A.3 Applicability and Masking

| Symbol             | Name                               | Domain       | Range                 | Units | First Defined        |
|--------------------|------------------------------------|--------------|-----------------------|-------|----------------------|
| $m_{\{u,d\}}$      | Applicability mask                 | $U \times D$ | {0, 1}                | —     | §4.1.5               |
| $\kappa_{\{u,d\}}$ | Cell multiplier (per-cell scaling) | $U \times D$ | $\mathbb{R}_{\geq 0}$ | —     | §3.2.4 / Appendix AD |

### A.4 Impact Objects

| Symbol                             | Name                               | Domain                | Range    | Units         | First Defined |
|------------------------------------|------------------------------------|-----------------------|----------|---------------|---------------|
| $\bar{I}_{(u,d)}^{\text{prop}(a)}$ | Propagated, post-saturation impact | $U \times D \times O$ | [-1, +1] | Dimensionless | §4.1          |

| Symbol                                          | Name                                     | Domain                         | Range        | Units         | First Defined |
|-------------------------------------------------|------------------------------------------|--------------------------------|--------------|---------------|---------------|
| $I_{-}(u,d)^{\text{dir}(a)}$                    | Direct impact after saturation           | $U \times D \times O$          | $[-1, +1]$   | Dimensionless | §5.3          |
| $\tilde{I}_{-}(u,d)^{\text{dir}(a)}$            | Direct impact aggregate (pre-saturation) | $U \times D \times O$          | $\mathbb{R}$ | Dimensionless | §5.2          |
| $\tilde{I}_{-}(u,d)^{\text{prop}(a)}$           | Pre-saturation propagated impact         | $U \times D \times O$          | $\mathbb{R}$ | Dimensionless | §8.3          |
| $\bar{I}_{-}(u,d)^{\text{prop}(a s)}$           | Scenario-conditioned propagated impact   | $U \times D \times O \times S$ | $[-1, +1]$   | Dimensionless | §7.2.5        |
| $\bar{I}_{-}(u,d)^{\text{rights}(a)}$           | Worst-off subgroup impact                | $U \times D \times O$          | $[-1, +1]$   | Dimensionless | §3.2.8        |
| $\mathbb{E}[\bar{I}_{-}(u,d)^{\text{prop}(a)}]$ | Expected propagated impact               | $U \times D \times O$          | $[-1, +1]$   | Dimensionless | §11.1         |

| Symbol                   | Name                     | Domain                | Range     | Units         | First Defined |
|--------------------------|--------------------------|-----------------------|-----------|---------------|---------------|
| $\text{Help}_{(u,d)}(a)$ | Magnitude of improvement | $U \times D \times O$ | $[0, +1]$ | Dimensionless | §3.2.2        |
| $\text{Harm}_{(u,d)}(a)$ | Magnitude of degradation | $U \times D \times O$ | $[0, +1]$ | Dimensionless | §3.2.2        |

#### A.5 Impact Instance Attributes

| Symbol   | Name                            | Domain       | Range         | Units         | First Defined |
|----------|---------------------------------|--------------|---------------|---------------|---------------|
| $k$      | Impact instance index           | $\mathbb{N}$ | —             | —             | §5.2          |
| $\mu_k$  | Instance magnitude              | —            | $[-1, +1]$    | Dimensionless | §5.2          |
| $r_k$    | Instance reach                  | —            | $[0, 1]$      | Proportion    | §5.2          |
| $t_k$    | Instance time horizon           | —            | $(0, \infty)$ | Years         | §5.2          |
| $\ell_k$ | Instance conditional likelihood | —            | $[0, 1]$      | Probability   | §5.2          |

| Symbol          | Name                                     | Domain | Range                                                                                                                                       | Units         | First Defined |
|-----------------|------------------------------------------|--------|---------------------------------------------------------------------------------------------------------------------------------------------|---------------|---------------|
| c_k             | Instance confidence                      | —      | [0.1, 1]                                                                                                                                    | Dimensionless | §5.2          |
| e_k             | Equity/resilience adjustment             | —      | [0.5, 2.0]                                                                                                                                  | Dimensionless | §5.2          |
| s_k             | Sentence multiplier (SGP)                | —      | [0, 1]                                                                                                                                      | Dimensionless | §5.2          |
| T_ref           | Reference horizon for temporal weighting | —      | (0, ∞)                                                                                                                                      | Years         | §5.2          |
| $\tau(t)$       | Temporal weighting function              | (0, ∞) | Range:<br>(0, ∞).<br>$\tau(T_{ref})=1$<br>; $\tau(t)>1$ for $t>T_{ref}$ .<br>Optional cap only if declared in PCC (Tier 3 starter: no cap). | Dimensionless | §5.2          |
| $\mu_{phantom}$ | Ignorance penalty magnitude              | —      | —                                                                                                                                           | Dimensionless | §5.2          |

## A.6 Saturation Parameters

| Symbol                | Name                                    | Domain | Range         | Units         | First Defined |
|-----------------------|-----------------------------------------|--------|---------------|---------------|---------------|
| $\beta$               | Direct saturation coefficient           | —      | $(0, \infty)$ | Dimensionless | §5.3          |
| $\beta_{\text{prop}}$ | Post-propagation saturation coefficient | —      | $(0, \infty)$ | Dimensionless | §8.3.4        |

### A.7 Vector Forms and Kernel

| Symbol                             | Name                                     | Domain | Range             | Units         | First Defined |
|------------------------------------|------------------------------------------|--------|-------------------|---------------|---------------|
| $\mathbf{I}^{\text{dir}}$          | Flattened direct-impact vector           | —      | $[-1, +1]^{49}$   | Dimensionless | §8.3          |
| $\tilde{\mathbf{I}}^{\text{prop}}$ | Pre-saturation propagated impact vector  | —      | $\mathbb{R}^{49}$ | Dimensionless | §8.3          |
| $\bar{\mathbf{I}}^{\text{prop}}$   | Post-propagation saturated impact vector | —      | $[-1, +1]^{49}$   | Dimensionless | §8.3.4        |

| Symbol           | Name                               | Domain | Range                              | Units         | First Defined |
|------------------|------------------------------------|--------|------------------------------------|---------------|---------------|
| $K$              | Ripple kernel (propagation matrix) | —      | $\mathbb{R}^{(49 \times 49)}$      | Dimensionless | §8.2          |
| $\kappa_{(i,j)}$ | Kernel entry                       | —      | $[-\kappa_{\max}, +\kappa_{\max}]$ | Dimensionless | §8.2          |
| $\kappa_{\max}$  | Kernel entry bound                 | —      | $(0, 1)$                           | Dimensionless | §8.4          |
| $\rho_{\max}$    | Row-sum ( $\ell_1$ -norm) bound    | —      | $(0, 1)$                           | Dimensionless | §8.4          |
| $\rho(K)$        | Spectral radius of kernel          | —      | $[0, \infty)$                      | Dimensionless | §8.3          |
| KQS              | Kernel Quality Score               | —      | $[0, 1]$                           | Dimensionless | §8.5          |
| KOPS             | Key Operational Pathways Set       | —      | Subset of kernel edges             | —             | §8.6          |

#### A.8 Rights Constraint Symbols

| Symbol     | Name                           | Domain                                           | Range                  | Units         | First Defined |
|------------|--------------------------------|--------------------------------------------------|------------------------|---------------|---------------|
| $R$        | Canonical rights set           | {LIFE, BODY, LBTY, NEED, DIGN, PROC, INFO, ECOL} | —                      | —             | §6.2          |
| $\theta_r$ | Rights threshold for right $r$ | $R$                                              | $[-1, 0)$              | Dimensionless | §6.2          |
| $C_r$      | Coverage set for right $r$     | $R$                                              | Subset of $U \times D$ | —             | §6.2          |
| $v_r(a)$   | Violation depth for right $r$  | $O \times R$                                     | $[0, \infty)$          | Dimensionless | §6.3          |

#### A.9 Tail-Risk Constraint Symbols

| Symbol    | Name                 | Domain | Range                  | Units | First Defined |
|-----------|----------------------|--------|------------------------|-------|---------------|
| $C_{cat}$ | Catastrophe cell set | —      | Subset of $U \times D$ | —     | §7.2          |

| Symbol           | Name                                  | Domain       | Range                     | Units         | First Defined |
|------------------|---------------------------------------|--------------|---------------------------|---------------|---------------|
| $C_{cat}^{base}$ | Base catastrophe cell set             | —            | $\{(6,2), (6,7), (7,7)\}$ | —             | §7.2.2        |
| $s$              | Scenario index                        | $S$          | —                         | —             | §7.3          |
| $S$              | Scenario set                          | —            | Finite set                | —             | §7.3          |
| $p_s$            | Scenario probability                  | $S$          | $[0, 1]$                  | Probability   | §7.3          |
| $(x)_+$          | Positive-part operator                | $\mathbb{R}$ | $[0, \infty)$             | —             | §3.2.2        |
| $\omega_{(u,d)}$ | Catastrophe-cell weight               | $C_{cat}$    | $[0, 1]$                  | Dimensionless | §7.2.4        |
| $\omega_{min}$   | Minimum catastrophe-cell weight floor | —            | $[0, 1]$                  | Dimensionless | §7.2.4        |
| $\eta$           | Catastrophe-weight floor slack factor | —            | $(0, 1]$                  | Dimensionless | §7.2.4        |
| $L(a, s)$        | Scenario loss                         | $O \times S$ | $[0, 1]$                  | Dimensionless | §7.2.6        |

| Symbol                 | Name                           | Domain       | Range    | Units         | First Defined |
|------------------------|--------------------------------|--------------|----------|---------------|---------------|
| $L_{\text{raw}}(a, s)$ | Raw-indicator scenario loss    | $O \times S$ | $[0, 1]$ | Dimensionless | §7.2.6        |
| $\alpha$               | CVaR tail level                | —            | $(0, 1)$ | Dimensionless | §7.3          |
| CVaR $_{\alpha}$       | Conditional Value-at-Risk      | —            | $[0, 1]$ | Dimensionless | §7.3          |
| $\tau_{\text{TRC}}$    | Catastrophe corridor threshold | —            | $[0, 1]$ | Dimensionless | §7.3          |

#### A.10 Weighting and Scoring Symbols

| Symbol               | Name                          | Domain | Range    | Units         | First Defined |
|----------------------|-------------------------------|--------|----------|---------------|---------------|
| $w_u$                | Union weight (HDW output)     | $U$    | $[0, 1]$ | Dimensionless | §10.3         |
| $v_d$                | Dimension weight (HDW output) | $D$    | $[0, 1]$ | Dimensionless | §10.3         |
| $w_u^{\text{floor}}$ | Union weight floor            | $U$    | $[0, 1]$ | Dimensionless | §10.2         |

| Symbol                   | Name                                   | Domain                | Range         | Units         | First Defined |
|--------------------------|----------------------------------------|-----------------------|---------------|---------------|---------------|
| $v_d^{\text{floor}}$     | Dimension weight floor                 | $D$                   | $[0, 1]$      | Dimensionless | §10.2         |
| $\lambda_U$              | Union blend parameter                  | —                     | $[0, 1]$      | Dimensionless | §10.3         |
| $\lambda_D$              | Dimension blend parameter              | —                     | $[0, 1]$      | Dimensionless | §10.3         |
| $\text{RLS}(a)$          | Ripple Logic Score                     | $O$                   | $\mathbb{R}$  | Dimensionless | §11.1         |
| $\sigma_{\text{RLS}}(a)$ | RLS uncertainty estimate               | $O$                   | $[0, \infty)$ | Dimensionless | §11.2         |
| $\sigma_{(u,d)}(a)$      | Cell-level impact uncertainty          | $U \times D \times O$ | $[0, \infty)$ | Dimensionless | §11.2         |
| $\lambda$                | Uncertainty aversion parameter         | —                     | $[0, \infty)$ | Dimensionless | §11.3         |
| $\delta$                 | Judgment Call discrimination threshold | —                     | $(0, \infty)$ | Dimensionless | §11.4         |

#### A.11 Coherence and Containment Symbols

| Symbol                | Name                                    | Domain       | Range         | Units         | First Defined |
|-----------------------|-----------------------------------------|--------------|---------------|---------------|---------------|
| $UCI_u$               | Union Coherence Index for union $u$     | $U$          | $[0, 1]$      | Dimensionless | §11.5         |
| UCI                   | Overall Union Coherence Index           | —            | $[0, 1]$      | Dimensionless | §11.5         |
| $\Delta UCI_u(a)$     | Predicted coherence shift for union $u$ | $U \times O$ | $\mathbb{R}$  | Dimensionless | §3.4.2        |
| HOI                   | Hollowing-Out Index                     | —            | $\mathbb{R}$  | Dimensionless | §11.5         |
| $\tau_c$              | Containment tolerance threshold         | —            | $[-1, 0]$     | Dimensionless | §3.4.2        |
| $\theta_{\text{pos}}$ | Positive-impact threshold               | —            | $[0, 1]$      | Dimensionless | §3.4.2        |
| $D_c$                 | Containment depth limit                 | —            | $\{1, 2, 3\}$ | —             | §3.4.2        |

| Symbol           | Name                              | Domain                | Range         | Units         | First Defined |
|------------------|-----------------------------------|-----------------------|---------------|---------------|---------------|
| $U_a^+$          | Set of positively impacted unions | —                     | Subset of $U$ | —             | §3.4.2        |
| $Anc(u, D_c)$    | Ancestor (containing) unions      | $U \times \mathbb{N}$ | Subset of $U$ | —             | §3.4.2        |
| $Containment(a)$ | Global containment predicate      | $O$                   | {true, false} | —             | §3.4.2        |
| $MRM(a)$         | Maximin Rights Margin             | $O$                   | $[0, 1]$      | Dimensionless | §11.6         |

## A.12 Sentience Protocol Symbols

| Symbol          | Name                     | Domain      | Range    | Units         | First Defined |
|-----------------|--------------------------|-------------|----------|---------------|---------------|
| $SG(x)$         | Sentience Gradient score | Entity type | $[0, 1]$ | Dimensionless | §9.2          |
| $SG\_threshold$ | Rights plateau threshold | —           | $(0, 1)$ | Dimensionless | §9.4          |

| Symbol     | Name                         | Domain       | Range  | Units         | First Defined |
|------------|------------------------------|--------------|--------|---------------|---------------|
| $g_{\min}$ | Sentence weighting floor     | —            | (0, 1) | Dimensionless | §9.5          |
| $\psi$     | Sentence weighting curvature | —            | (0, 1] | Dimensionless | §9.5          |
| $\alpha_i$ | UCI component weights        | {1, 2, 3, 4} | [0, 1] | Dimensionless | §11.5         |
| $w_j$      | SGP component weights        | {1, ..., 6}  | [0, 1] | Dimensionless | §9.2          |

### A.13 Operator Definitions

| Symbol                    | Name                   | Definition            | First Defined |
|---------------------------|------------------------|-----------------------|---------------|
| $\text{clip}(x, a, b)$    | Clipping operator      | $\max(a, \min(x, b))$ | §11.5         |
| $\text{clamp}_{[0,1]}(x)$ | Unit clamp operator    | $\max(0, \min(1, x))$ | §9.2          |
| $(x)_+$                   | Positive-part operator | $\max(x, 0)$          | §3.2.2        |
| $(x)_-$                   | Negative-part operator | $\max(-x, 0)$         | §3.2.2        |
| $\tanh(\cdot)$            | Hyperbolic tangent     | Saturation function   | §5.3          |

| Symbol    | Name                                | Definition                   | First Defined |
|-----------|-------------------------------------|------------------------------|---------------|
| Smooth(-) | Smoothing operator                  | EMA with specified half-life | §11.5         |
| PCC       | Provenance & Compliance Certificate | Structured record artifact   | §13           |

## Appendix AB: Canonical Notation Charter

This appendix establishes the single authoritative notation system for MathGov. All mathematical notation in the framework must conform to this charter. No alternative notation systems are permitted.

### AB.1.1 Narrative shorthand (normative).

In explanatory prose only, the documents may use compact shorthand (e.g.,  $I_{\{u,d\}}(a)$  without stage tags) provided the surrounding sentence explicitly states which pipeline stage is being discussed. In all computational requirements (PCC fields, determinism rules, audit checks, registries, and schemas), the stage-specific canonical symbols defined in this appendix remain mandatory. If any ambiguity remains, auditors and implementers MUST treat the stage as undefined and hard-fail Tier  $\geq 3$ .

## AB.1 Primary Symbol Declarations

### AB.1.1 Index Variables

| Symbol | Name             | Domain                    | First Defined |
|--------|------------------|---------------------------|---------------|
| $u$    | Union index      | $\{1, 2, 3, 4, 5, 6, 7\}$ | §2.2          |
| $d$    | Dimension index  | $\{1, 2, 3, 4, 5, 6, 7\}$ | §4.1          |
| $a$    | Candidate action | $O$                       | §3.2          |
| $s$    | Scenario index   | $S$                       | §7.3          |

| Symbol | Name                      | Domain             | First Defined |
|--------|---------------------------|--------------------|---------------|
| $r$    | Rights index              | $R$                | §6.2          |
| $k$    | Impact instance index     | $\mathbb{N}$       | §5.2          |
| $g$    | Subgroup index            | $G_{(u,d)}$        | §3.2.8        |
| $i, j$ | Cell indices (vectorized) | $\{1, \dots, 49\}$ | §8.3          |

#### AB.1.2 Set Variables

| Symbol    | Name                       | Domain                                           | First Defined |
|-----------|----------------------------|--------------------------------------------------|---------------|
| $O$       | Option set                 | Finite set of actions                            | §3.2          |
| $S$       | Scenario set               | Finite set of scenarios                          | §7.3          |
| $R$       | Rights set                 | {LIFE, BODY, LBTY, NEED, DIGN, PROC, INFO, ECOL} | §6.2          |
| $U$       | Operational union set      | 7 unions                                         | §2.2          |
| $D$       | Dimension set              | 7 dimensions                                     | §4.1          |
| $C_r$     | Coverage set for right $r$ | Subset of $U \times D$                           | §6.2          |
| $C_{cat}$ | Catastrophe cell set       | Subset of $U \times D$                           | §7.2          |

| Symbol               | Name                         | Domain                      | First Defined |
|----------------------|------------------------------|-----------------------------|---------------|
| $G_{(u,d)}$          | Protected subgroups for cell | Finite set                  | §3.2.8        |
| $A_{\text{NCRC}}$    | NCRC-admissible options      | Subset of $O$               | §6.3          |
| $A_{\text{adm}}$     | Fully admissible options     | Subset of $A_{\text{NCRC}}$ | §3.2.3        |
| $U_{a^+}$            | Positively impacted unions   | Subset of $U$               | §3.4.2        |
| $\text{Anc}(u, D_c)$ | Ancestor unions              | Subset of $U$               | §3.4.2        |

## AB.2 Impact Objects

The impact pipeline uses distinct symbols for each transformation stage. This is the canonical specification:

Notation convenience (Normative). In some explanatory passages, stage-tags such as  $\tilde{I}^{\{\text{dir}, \text{pre}\}}_{\{u,d\}}(a)$  or  $I^{\{\text{dir}, \text{post}\}}_{\{u,d\}}(a)$  may appear. These are purely mnemonic labels. Treat them as aliases for the canonical stage objects  $\tilde{I}^{\{\text{dir}\}}_{\{u,d\}}(a)$  (direct, pre-saturation) and  $I^{\{\text{dir}\}}_{\{u,d\}}(a)$  (direct, post-saturation) respectively. No additional objects are introduced.

### AB.2.1 Pre-Saturation Direct Impact Aggregate

**Symbol:**  $\tilde{I}_{(u,d)}^{\text{dir}}(a)$

**Definition:** The raw aggregation of impact instances before normalization:

$$\tilde{I}_{(u,d)}^{\text{dir}}(a) = \sum_k I_{(u,d,k)}^{\text{dir}}(a)$$

**Domain:** Real-valued and unbounded ( $\mathbb{R}$ )

**Interpretation:** Represents cumulative contributions from all impact pathways before saturation.

### AB.2.2 Post-Saturation Direct Impact

**Symbol:**  $I_{-}(u,d)^{dir(a)}$

**Definition:** The saturated direct impact bounded to  $[-1, +1]$ :

$$I_{-}(u,d)^{dir(a)} = \tanh(\beta \cdot \tilde{I}_{-}(u,d)^{dir(a)})$$

where the default saturation coefficient is  $\beta = 2$ .

**Domain:**  $[-1, +1]$

**Interpretation:** Normalized direct impact ready for kernel propagation.

### AB.2.3 Flattened Direct Impact Vector

**Symbol:**  $I^{dir}$

**Definition:** The 49-element vector form of direct impacts:

$$I^{dir(a)} \in [-1,1]^{49}, \quad [I^{dir(a)}]_{-}(\phi(u,d)) = I_{-}(u,d)^{dir(a)}$$

with components indexed by the canonical flattening map  $\phi(u, d) = 7(u - 1) + d$ .

**Domain:**  $[-1, +1]^{49}$

### AB.2.4 Pre-Saturation Propagated Impact

**Symbol:**  $\tilde{I}_{-}(u,d)^{prop(a)}$  or  $\tilde{I}^{prop}$  (vector form)

**Definition:** The output of kernel propagation before final saturation.

Quick mode:

$$\tilde{I}^{prop(a)} = I^{dir(a)} + K \cdot I^{dir(a)}$$

Full mode (requires  $\rho(K) < 1$ ; prohibited for Tier 4 Pilot-Executable rev14.x):

$$\tilde{I}^{prop(a)} = (I - K)^{-1} \cdot I^{dir(a)}, \quad \rho(K) < 1$$

**Domain:** Real-valued ( $\mathbb{R}^{49}$ ), potentially unbounded

### AB.2.5 Post-Propagation Saturated Impact

**Symbol:**  $\bar{I}_{-}(u,d)^{prop(a)}$  or  $\bar{I}^{prop}$  (vector form)

**Definition:** The final impact value after post-propagation saturation:

$$I_{-}(u,d)^{prop(a)} = \tanh(\beta_{prop} \cdot \tilde{I}_{-}(u,d)^{prop(a)})$$

where the default post-propagation saturation coefficient is  $\beta_{prop} = 1$ .

**Domain:**  $[-1, +1]$

**Usage:** This is the final impact value used in NCRC, TRC, and RLS calculations.

### AB.2.6 Worst-Off Subgroup Impact

**Symbol:**  $\bar{I}_{(u,d)}^{\text{rights}}(a)$

**Definition:** The minimum impact across all protected subgroups:

$$\bar{I}_{(u,d)}^{\text{rights}}(a) = \min_{\{g \in G_{(u,d)}\}} I_{(u,d,g)}^{\text{prop}}(a)$$

**Domain:**  $[-1, +1]$

**Usage:** Used exclusively for NCRC rights checks.

### AB.3 Deprecated Aliases

The following notations appeared in earlier drafts and must not be used:

| Deprecated                         | Replacement                                                                             | Reason                                |
|------------------------------------|-----------------------------------------------------------------------------------------|---------------------------------------|
| $I(a)$ without superscript         | Always use superscript (dir, prop, rights)                                              | Ambiguity between pipeline stages     |
| $\hat{I}$ (circumflex)             | Use tilde ( $\tilde{I}$ ) for pre-saturation, overbar ( $\bar{I}$ ) for post-saturation | Consistency with saturation semantics |
| $\text{Impact}(u,d,a)$             | Use subscript notation: $I_{(u,d)}(a)$                                                  | Compactness                           |
| $I_{\text{cell}}$                  | Use $(u,d)$ subscript notation                                                          | Precision                             |
| $\text{CVaR}(L)$ without subscript | Always use subscript: $\text{CVaR}_{\alpha}(L)$                                         | Tail level must be specified          |
| $\text{Weight}(u)$                 | Use $wu$ for union weights, $vd$ for dimension weights                                  | Standard notation                     |

### AB.4 First-Use-Defines Rule

Every symbol must be formally defined at its first occurrence. The definition must include:

- **Display equation format:** The symbol in a numbered, centered equation

- **Natural language description:** A clear explanation of what the symbol represents
- **Domain specification:** The set from which the symbol's values are drawn
- **Range specification:** The set of possible output values (for functions)
- **Default values:** Where applicable, the default parameter setting

#### Example of compliant first-use definition:

The saturation coefficient  $\beta$  controls the sensitivity of the saturation function. It is defined as:

$$\beta = 2$$

$\beta \in (0, \infty)$ , default  $\beta = 2$

Higher values of  $\beta$  produce sharper saturation near the boundaries, while lower values extend the approximately linear regime.

### AB.5 Superscript and Subscript Conventions

#### AB.5.1 Superscript Usage

Superscripts indicate transformation stage or semantic role:

| Superscript | Meaning                  | Example                        |
|-------------|--------------------------|--------------------------------|
| dir         | Direct (pre-propagation) | $I^{\text{dir}}$               |
| prop        | Propagated (post-kernel) | $I^{\text{prop}}$              |
| rights      | Worst-off subgroup       | $\bar{I}^{\text{rights}}$      |
| floor       | Constitutional floor     | $w^{\text{floor}}$             |
| base        | Base configuration       | $C_{\text{cat}}^{\text{base}}$ |

#### AB.5.2 Subscript Usage

Subscripts indicate indexing:

Tier-4 canonical cell identifier for registries and PCC snapshots is { "u": <1..7>, "d": <1..7> }. Labels and (u,d) tuple text are display-only.

| Subscript | Meaning            | Example     |
|-----------|--------------------|-------------|
| $u$       | Union index        | $w_u$       |
| $d$       | Dimension index    | $v_d$       |
| $(u,d)$   | Cell specification | $l_{(u,d)}$ |
| $r$       | Right index        | $\theta_r$  |
| $s$       | Scenario index     | $p_s$       |
| $k$       | Instance index     | $\mu_k$     |

### AB.5.3 Combined Usage

When both superscript and subscript are needed, the subscript comes first, then the superscript:

**Correct:**  $\bar{l}_{(u,d)}^{\text{prop}(a)}$

**Incorrect:**  $\bar{l}^{\text{prop}_{(u,d)}}(a)$

### AB.6 Decoration Conventions

| Decoration                      | Meaning                        | Example                      |
|---------------------------------|--------------------------------|------------------------------|
| Tilde ( $\sim$ )                | Pre-saturation / raw aggregate | $\tilde{I}$ (pre-saturation) |
| Overbar ( $\bar{\phantom{x}}$ ) | Post-saturation / final        | $\bar{I}$ (post-saturation)  |

AB.7 Function Notation

**Purpose.** This section defines the canonical function symbols used throughout MathGov. These are not optional notations. They are the single allowed spellings and definitions for these functions under the Canonical Notation Charter. Any deviation must be explicitly declared in the PCC and treated as a nonstandard configuration requiring justification and sensitivity checks.

**Conventions.**

- 1. All functions are deterministic unless explicitly indexed by scenario sor an uncertainty object.

Negative part:  $(x)_- = \max(-x, 0)$ .

Clip:  $\text{clip}(x, a, b) = \max(a, \min(x, b))$ , with  $a \leq b$ .

Unit clamp:  $\text{clamp}_{[0,1]}(x) = \max(0, \min(1, x))$ .

Cell flattening (7x7):  $\phi(u, d) = 7(u - 1) + d$ , for  $u, d$  in  $\{1, \dots, 7\}$ .

Temporal weight:  $\tau(t) = \ln(1 + t) / \ln(1 + T_{\text{ref}})$ , for  $t > 0, T_{\text{ref}} > 0$ .

EMA smoothing:  $\text{EMA}_{\lambda}(x_t) = \lambda x_t + (1 - \lambda) \text{EMA}_{\lambda}(x_{t-1})$ ,  $\lambda$  in  $(0, 1]$ , initialization declared in PCC.

Infinity norm:  $\|K\|_{\infty} = \max_i \sum_j |K_{ij}|$ .

| Function<br>(name)                 | Notation                | Definition       | Domain                        | Range     | Defaults and<br>notes                                                         |
|------------------------------------|-------------------------|------------------|-------------------------------|-----------|-------------------------------------------------------------------------------|
| Saturation<br>(hyperbolic tangent) | $\text{sat}_{\beta}(x)$ | $\tanh(\beta x)$ | $x \in \mathbb{R}, \beta > 0$ | $(-1, 1)$ | Canonical smooth saturation map. Larger increases boundary steepness; smaller |

| Function (name)           | Notation                   | Definition            | Domain                       | Range                 | Defaults and notes                                                                         |
|---------------------------|----------------------------|-----------------------|------------------------------|-----------------------|--------------------------------------------------------------------------------------------|
|                           |                            |                       |                              |                       | extends the near-linear regime around 0.                                                   |
| Positive part             | $(x)_+^+$                  | $\max(x, 0)$          | $x \in \mathbb{R}$           | $\mathbb{R}_{\geq 0}$ | Used for nonnegative transforms (for example, “only penalize excess” constructions).       |
| Negative part             | $(x)_-^-$                  | $\max(-x, 0)$         | $x \in \mathbb{R}$           | $\mathbb{R}_{\geq 0}$ | Used for negative-part transforms (for example, tail-risk definitions).                    |
| Clipping (interval bound) | $\text{clip}(x, a, b)$     | $\max(a, \min(x, b))$ | $x \in \mathbb{R}, a \leq b$ | $[a, b]$              | Canonical truncation to a closed interval. If $a > b$ , the PCC/implementation is invalid. |
| Unit clamp                | $\text{clamp}_{[0, 1]}(x)$ | $\max(0, \min(x, 1))$ | $x \in \mathbb{R}$           | $[0, 1]$              | Canonical clamp into the unit interval. Use when a quantity is defined as a                |

| Function<br>(name)                | Notation    | Definition | Domain                | Range          | Defaults and<br>notes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

### AB.7.2 Scope note

AB.7 defines general-purpose functions that recur across the framework (clipping, saturation, flattening, ancestor mapping, temporal weighting, smoothing, stability norms). Specialized operators (for example  $\text{CVaR}_{\alpha}(\cdot)$ ) are defined where introduced, but must obey the same canonical symbol discipline (same spelling, same parameters, same domains).

## Appendix AD: Complete Default Parameter Registry

### Tier-4 HDW appendix alignment note (Normative cross-reference)

This appendix may include illustrative embedded registry snippets for readability. For audit and replay, Tier-4 Pilot-Executable runs MUST treat the ProofPack registries and schemas as the authoritative sources, referenced and hash-bound in the PCC.

For Tier 4, hash-canonical artifacts (HDW ballots, HDW weights, registries, manifests, schemas, PCC override bundles) MUST use exact reduced rationals and MUST conform to the canonical JSON and NO\_FLOATS rules. Computed quantities (impacts, saturation outputs, propagation outputs, losses, CVaR, RLS, gaps) MUST be computed under NDP\_FIXEDPOINT\_V1 and stored in the PCC as fixed-point integers only.

Tier-4 requires whole-ballot trimming and the canonical tie-break rule defined in the ProofPack: latest-wins by submitted\_at, with sha256(canonical\_json(ballot\_obj)) hash-max on same-second ties.

Tier-4 timestamp format is strict UTC Z with second precision only: YYYY-MM-DDTHH:MM:SSZ.

**This appendix consolidates all default parameter values for reference implementation.**

Registry rule. A “default” applies only when the PCC does not override it. If a parameter has no default, it MUST be declared in the PCC.

| Parameter             | Default / Rule                                                                                    | Tier                                                              | Source anchor           |

| Parameter                    | Symbol | Default | Section |
|------------------------------|--------|---------|---------|
| Sentence weighting curvature | $\psi$ | 0.5     | §9.5    |

#### AD.9 Ignorance Penalty by Tier

#### AD.10 Numeric determinism profile (Tier 4) (Normative)

numeric\_profile\_id: NDP\_FIXEDPOINT\_V1

S (fixed-point scale): 1000000000

SAT\_LUT\_ID: SAT\_LUT\_FP\_V1 (hash-bound in ProofPack; referenced in PCC)

TEMPORAL\_WEIGHT\_REGISTRY\_ID: REG\_TEMPORAL\_WEIGHTS\_V1 (hash-bound in ProofPack; referenced in PCC)

Tier 4 rev14.x restriction: propagation\_mode  $\in$  {NONE, QUICK}. Full propagation is prohibited for Tier 4 Pilot-Executable until a deterministic solver profile is hash-bound.

NDP\_FIXEDPOINT\_V1 edge cases (Normative). All fixed-point multiplications MUST use an intermediate wide integer (at least 128-bit or arbitrary precision) and MUST hard-fail on overflow before rescaling back to scale S. Fixed-point division MUST be implemented as integer division with round\_half\_even to the nearest representable value at scale S. Values whose absolute magnitude is  $< 0.5/S$  after rounding MUST resolve to 0 at scale S (underflow-to-zero). If any intermediate or final value exceeds the declared representable bounds, the run MUST hard-fail (no silent wrap).

| Tier | $\mu_{\text{phantom}}$ | Section |
|------|------------------------|---------|
| 1    | -0.05                  | §5.2    |
| 2    | -0.08                  | §5.2    |
| 3    | -0.10                  | §5.2    |
| 4    | -0.10                  | §5.2    |

Note (tier intent).  $\mu_{\text{phantom}}$  is an ignorance penalty used only when a required instance is missing and the “phantom instance” rule is invoked (§5.2). Tier 4 keeps  $\mu_{\text{phantom}}$  aligned

to the canonical phantom defaults; more conservative values MAY be declared in the PCC for exceptional high-stakes contexts, but must be explicit and versioned.

### **AD.10 NCAR Triggers**

Tier 3 starter NCAR triggers. The following conditions trigger Notice-Choose-Act-Reflect (NCAR) escalation and require explicit reflection notes in the PCC:

NCAR-1 Rights proximity: any rights-covered cell impact in the worst-off subgroup is within 0.05 of its rights threshold (sensitivity band).

NCAR-2 Tail-risk proximity:  $\text{CVaR}_{\alpha}(L)$  is within 0.05 of the TRC threshold, or scenario feasibility constraints are tight (tail mass poorly resolved).

NCAR-3 Decision fragility: the top-ranked option changes under any declared sensitivity run (weights, kernel perturbation, or interval endpoint propagation).

NCAR-4 Low evidence kernel:  $\text{KQS} < 0.50$  and any kernel propagation is used (Quick or Full).

NCAR-5 High uncertainty:  $\text{sigma\_RLS}(a) \geq 0.10$  for any leading option, or the discrimination band overlaps among top candidates.

NCAR-6 Missing or weak data: more than 30% of asserted instances have  $c_k < 0.50$ , or key rights anchors are placeholders.

NCAR-7 Stakeholder dissent: recorded stakeholder objection from any union ballot above the Charter-set dissent threshold.

If any trigger fires, the PCC must include: (i) the trigger ID(s), (ii) what additional evidence was sought (if any), (iii) whether a safer alternative exists, and (iv) the final justification if proceeding.

### **AD.11 Equity Criteria Registry (Tier 4 starter set)**

This registry constrains the equity/resilience adjustment  $e_k$  so it cannot be improvised ad hoc. The default rule is  $e_k = 1$ . Any  $e_k \neq 1$  must cite exactly one criterion from this registry and must satisfy the evidence requirements below.

Allowed range (Tier 3 starter):  $e_k$  in  $[0.85, 1.15]$ . Values outside this range are disallowed in Tier 4 unless Charter-approved and explicitly documented in the PCC.

Tier 4 starter criteria (criterion ID, description, allowed  $e_k$ , evidence requirement):

ECR-1 Worst-off subgroup protection. Adjustments that reduce harm to the worst-off subgroup identified in the PCC subgroup analysis. Allowed  $e_k$  in [1.00, 1.15]. Evidence: subgroup identification, harm pathway, and counterfactual audit with  $e_k = 1$ .

ECR-2 Rights-adjacent harm mitigation (non-trigger). Harms that do not cross an NCRC threshold but are plausibly near-threshold in sensitivity analysis. Allowed  $e_k$  in [1.00, 1.10]. Evidence: threshold sensitivity run showing proximity.

ECR-3 Historic burden correction. Adjustments addressing historically accumulated disadvantage in the affected stakeholder set. Allowed  $e_k$  in [1.00, 1.10]. Evidence: documented disparity baseline and linkage to the instance.

ECR-4 Power asymmetry correction. Adjustments reflecting asymmetric ability to avoid harm or influence outcomes (voice deficit). Allowed  $e_k$  in [1.00, 1.10]. Evidence: documented asymmetry and PCC explanation.

ECR-5 Resilience protection for critical life support. Adjustments increasing weight on impacts that protect essential support systems for continued flourishing (health infrastructure, water access, etc.), short of TRC catastrophe triggers. Allowed  $e_k$  in [1.00, 1.10]. Evidence: system dependency mapping and justification.

ECR-6 Anti-gaming penalty. Down-weight instances that appear strategically framed to inflate welfare improvements without measurable support. Allowed  $e_k$  in [0.85, 1.00]. Evidence: audit rationale with specific flags and a sensitivity analysis.

Audit requirements (mandatory whenever  $e_k \neq 1$ ). The PCC must include: (i) the criterion ID, (ii) evidence sources, (iii) a counterfactual recomputation with all  $e_k$  reset to 1, and (iv) a selection sensitivity statement indicating whether the final decision changes when  $e_k = 1$ .

| Metric                | Trigger Threshold     | Section |
|-----------------------|-----------------------|---------|
| Sign Accuracy         | < 0.60                | §12.5   |
| Magnitude RMSE        | > 0.30                | §12.5   |
| Rights Near-Miss Rate | > 0.25                | §12.5   |
| HOI Alert             | > 0.15 for 3+ periods | §11.5   |

## Appendix B: Key Equations

This appendix collects all canonical equations needed to implement MathGov. Notation is consistent across all sections:  $\tilde{I}$  denotes pre-saturation values,  $\bar{I}$  denotes post-saturation values, and all propagated impacts used for constraints and scoring are post-saturation bounded to  $[-1, +1]$ .

### B.1 Temporal Weighting (Log Scale)

**Purpose.** Temporal weighting maps an impact instance's time horizon into a dimensionless multiplier so that longer-lasting consequences receive greater weight without using exponential discounting that would systematically marginalize long-horizon and intergenerational effects. The temporal weight applies at the **impact-instance level** in the direct-aggregation step (Section 5.2) and can also be referenced in scenario-conditioned evaluations when instance horizons differ by scenario.

Tier 4 override (Normative). Tier 4 MUST NOT compute logarithms at runtime. Tier 4 temporal weights MUST be sourced from REG\_TEMPORAL\_WEIGHTS\_V1 and applied under NDP\_FIXEDPOINT\_V1.

#### B.1.1 Definitions

Let  $t$  be the time horizon of an impact instance, expressed in years, with:

1.  $t \in (0, \infty)$

Let  $T_{\text{ref}}$  be the reference horizon used to normalize the scale. Default:

1.  $T_{\text{ref}} = 25$  years

Define the temporal weighting function  $\tau(t)$  as:

Note. Because  $\tau(t) = \ln(1+t)/\ln(1+T_{\text{ref}})$ ,  $\tau(t)$  is not bounded above by 1;  $\tau(T_{\text{ref}}) = 1$  and  $\tau(t) > 1$  for horizons longer than  $T_{\text{ref}}$ .

$$\tau(t) = \ln(1 + t) / \ln(1 + T_{\text{ref}})$$

This mapping satisfies:

1.  $\tau(t) \geq 0$  for all  $t > 0$
2.  $\tau(T_{\text{ref}}) = 1$
3.  $\tau(t)$  increases with  $t$  but with diminishing marginal gain (logarithmic growth)

#### B.1.2 Illustrative values (default $T_{\text{ref}} = 25$ )

Using  $T_{\text{ref}} = 25$  years:

1.  $\tau(1) = \ln(2) / \ln(26) \approx 0.21$
2.  $\tau(5) = \ln(6) / \ln(26) \approx 0.56$
3.  $\tau(10) = \ln(11) / \ln(26) \approx 0.75$
4.  $\tau(25) = \ln(26) / \ln(26) = 1.00$
5.  $\tau(50) = \ln(51) / \ln(26) \approx 1.22$

These values are illustrative; exact values are fully determined by the equation above.

### **B.1.3 Governance rules for overriding T\_ref**

T\_ref may be overridden by governance (PCC-declared) in contexts where a different anchoring horizon is explicitly justified (e.g., some infrastructure or ecological policy contexts may use longer horizons). Any override must satisfy:

1. The PCC explicitly states the chosen T\_ref and the rationale
2. All options in the decision are evaluated using the same T\_ref
3. Sensitivity analysis is recommended when decisions are close (e.g., comparing T\_ref = 25 vs. T\_ref = 50)

### **B.1.4 Rationale: why logarithmic weighting instead of exponential discounting**

MathGov adopts logarithmic temporal weighting rather than exponential discounting because:

1. **Exponential discounting can erase long-horizon impacts.** Even moderate annual discount rates drive far-future consequences toward near-zero weight, which is incompatible with the framework's emphasis on preserving conditions for continued flourishing and avoiding catastrophic tail risks.
2. **Log weighting preserves intergenerational salience without runaway dominance.** The log form increases weight with duration while avoiding the extremes of linear growth that can allow very long durations to dominate any finite near-term magnitude.
3. **Consistency with non-compensability.** Temporal weighting shapes the aggregation of welfare impacts, but it does not override the admissibility cascade (NCRC, TRC). Rights floors and catastrophe corridors remain hard constraints independent of  $\tau(t)$ .

### **B.1.5 Implementation note**

The temporal weight  $\tau(t)$  is applied multiplicatively inside the impact-instance aggregation equation in Section 5.2:

### Containment Mode A: authoritative algorithm reference

Appendix B provides parameter names and predicate semantics. The authoritative step-by-step Mode A gate algorithm is Foundation §11.7A. In case of any mismatch, Foundation §11.7A governs.

- Each instance contribution is multiplied by  $\tau(t_k)$  for its horizon  $t_k$ .

The PCC must document the horizon assignment method (e.g., duration until effect decays below a material threshold, policy sunset, ecological recovery window, etc.).

### B.2 Direct Impact Aggregation (Pre-Saturation)

**Purpose.** This appendix section defines the **pre-saturation direct impact** for each union–dimension cell. It aggregates multiple predicted consequence instances into a single **unsaturated** scalar per cell, preserving sign (help vs harm) and weighting by reach, time horizon, likelihood, confidence, and (optionally) an equity/resilience factor. The output of B.2 is the canonical input to **B.3 Saturation**, which maps the unsaturated value into the bounded interval  $[-1, +1]$ .

#### B.2.1 Objects and indexing

Let:

1.  $\mathcal{U}$  be the set of unions (parameterized in the main text),
2.  $\mathcal{D}$  be the set of welfare dimensions,
3.  $a \in \mathcal{A}$  be an option under evaluation,
4.  $(u, d) \in \mathcal{U} \times \mathcal{D}$  be a union–dimension cell.

For each option  $a$  and cell  $(u, d)$ , define the finite set of impact instances:

- $\mathcal{K}(u, d, a)$  = set of impact instances asserted for cell  $(u, d)$  under option  $a$

Each impact instance  $k \in \mathcal{K}(u, d, a)$  is a structured record with the attributes below.

#### B.2.2 Impact instance attributes (required fields)

Each instance  $k$  has:

1. **Magnitude**  $\mu_k \in [-1, +1]$   
Signed direction and severity of the welfare change for the cell.

- $\mu_k > 0$  indicates a benefit (“help”)
- $\mu_k < 0$  indicates a harm
- $\mu_k = 0$  indicates no material effect

Magnitude is defined after calibration/anchoring (Section 5.4) and is a **dimensionless** score in the canonical scale.

- **Reach**  $r_k \in [0,1]$   
Fraction of the relevant stakeholder population in union  $u$  meaningfully affected by the instance within the dimension  $d$ .  
Examples:  $r_k = 0.10$  means roughly 10% of the relevant union stakeholders are affected at non-trivial intensity.
- **Time horizon**  $t_k \in (0, \infty)$  years  
Approximate duration over which the effect persists at material relevance. Time horizons are weighted using the temporal weighting function  $\tau(t)$  in B.1.
- **Conditional likelihood**  $\ell_k \in [0,1]$   
Probability that the instance occurs given the assumed context.
- If scenario evaluation is not used,  $\ell_k$  is conditional on the baseline forecast.
- If scenario evaluation is used,  $\ell_k$  may be conditional on a scenario  $s$  (this must be stated in the PCC).
- **Confidence**  $c_k \in [0.1,1]$   
Analyst confidence in the parameterization of the instance (evidence quality, model support, measurement reliability, causal attribution).  
A lower bound of 0.1 prevents zeroing out impacts while still strongly penalizing weak claims.
- **Equity/resilience adjustment**  $e_k \in [0.5,2.0]$  (optional, default = 1)  
A governed multiplier that adjusts impact contribution when equity or resilience criteria apply. Any  $e_k \neq 1$  must be justified and audited in the PCC per the equity/resilience governance rules (Section 5.2.3).

### B.2.3 Temporal weighting

Temporal weighting is applied using  $\tau(t)$  defined in B.1:

1. Default reference horizon:  $T_{\text{ref}} = 25$  years
2.  $\tau(t) = \ln(1 + t) / \ln(1 + T_{\text{ref}})$

This weight is applied multiplicatively to each instance via  $\tau(t_k)$ .

#### B.2.4 Pre-saturation aggregation equation

Define the **pre-saturation direct impact** for option  $a$  in cell  $(u, d)$  as:

$$\tilde{I}^{\{dir, pre\}}_{u,d}(a) = \sum_{k \in K(u,d,a)} r_k \cdot \tau(t_k) \cdot \ell_k \cdot e_k \cdot c_k \cdot s_k \cdot \mu_k$$

Canonical rule (Tier 4). Confidence  $c_k$  is multiplicative in direct aggregation. If  $c_k$  is omitted for any reason, the PCC must declare this deviation and justify it.

where  $\mu_k$  is the signed impact magnitude for instance  $k$  (in  $[-1, +1]$ ) prior to union aggregation,  $r_k$  is reach,  $\tau(t_k)$  is temporal weight,  $\ell_k$  is conditional likelihood, and  $e_k$  is the governed equity/resilience adjustment (default 1).

$$\tilde{I}^{dir}_{u,d}(a) = \sum_{k \in K(u,d,a)} \mu_k \cdot r_k \cdot \tau(t_k) \cdot \ell_k \cdot c_k \cdot e_k$$

Where:

1.  $\tilde{I}^{dir}_{u,d}(a) \in \mathbb{R}$  is **unbounded** (it may exceed  $\pm 1$  before saturation)
2. The sign of  $\tilde{I}^{dir}_{u,d}(a)$  indicates net help vs net harm for that cell, prior to saturation
3. The magnitude reflects cumulative contributions from multiple instances

This is the canonical “raw summed impact” that will be passed to B.3 for bounded mapping into  $[-1, +1]$ .

Terminology note. This is sometimes called the “multiplicative aggregation form” because each instance contribution is a product ( $r_k \cdot \tau(t_k) \cdot \ell_k \cdot e_k \cdot c_k \cdot \mu_k$ ). The aggregation across instances is a sum. This term distinguishes the approach from alternatives where confidence is applied after aggregation or treated purely as a variance weight.

#### B.2.5 Help/harm decomposition (optional diagnostic)

For diagnostics and transparency, MathGov may decompose instance contributions into positive (“help”) and negative (“harm”) components.

Define the positive-part operator:

$$(x)_+ = \max(x, 0)$$

$$(x)_- = \max(-x, 0)$$

$$(x)^+ = \max(x, 0)$$

Then define:

$$H_{\{u,d\}}(a) = \sum_{k \in K(u,d,a)} (r_k * \tau(t_k) * \ell_k * e_k * c_k * s_k * \mu_k)_+$$

$$\begin{aligned} Help_{u,d}^{dir}(a) &:= \sum_{k \in \mathcal{K}(u,d,a)} (\mu_k)^+ r_k \tau(t_k) \ell_k c_k e_k \\ Harm_{u,d}^{dir}(a) &:= \sum_{k \in \mathcal{K}(u,d,a)} (-\mu_k)^+ r_k \tau(t_k) \ell_k c_k e_k \end{aligned}$$

$$D_{\{u,d\}}(a) = \sum_{k \in K(u,d,a)} (r_k * \tau(t_k) * \ell_k * e_k * c_k * s_k * \mu_k)_-$$

$$\text{so that } \tilde{I}^{\{dir,pre\}}_{\{u,d\}}(a) = H_{\{u,d\}}(a) - D_{\{u,d\}}(a).$$

And:

$$\tilde{I}_{u,d}^{dir}(a) = Help_{u,d}^{dir}(a) - Harm_{u,d}^{dir}(a)$$

This decomposition is useful for explaining why a cell score is net-positive or net-negative and for auditing claims that an option has “many helps” but is still forbidden (via NCRC/TRC).

## B.2.6 Missing-data rule (ignorance penalty)

To prevent score inflation by omission, if a cell ( $u, d$ ) is active and materially relevant but no defensible instances can be specified for option  $a$ , the PCC must record an “unknown impact” and apply a phantom instance  $k_{ph}$ .

Canonical phantom instance parameters (Tier 4 default):

Define a phantom instance  $k_{\phi}$  with parameters:

$\mu_{\phi} = -0.10$ ,  $r_{\phi} = 1$ ,  $t_{\phi} = T_{ref}$  (25 years),  $\ell_{\phi} = 1$ ,  $e_{\phi} = 1$ ,  $c_{\phi} = 1.00$ . (So the default phantom contribution equals  $\mu_{phantom} = -0.10$ .)

Then add its contribution  $r_{\phi} * \tau(t_{\phi}) * \ell_{\phi} * e_{\phi} * \mu_{\phi}$  ( $= -0.10$  by default) to the pre-saturation sum for that cell whenever the cell is active but no empirical instances are asserted.

Tier 4 note (Normative). For Tier-4 Pilot-Executable runs, if  $m(u,d)=1$  and the instance set  $K(u,d,a)$  is empty for an active cell, a phantom instance MUST be inserted to prevent unintended masking and forked implementations. The phantom instance MUST be

recorded in the PCC with `phantom_enabled: true` and `phantom_penalty_enabled: true` (default). Sensitivity testing MAY be performed by rerunning with `phantom_penalty_enabled: false` as a diagnostic, but this diagnostic run MUST NOT be used to claim Tier-4 conformance unless explicitly declared as a downgrade.

The phantom instance is included in the sum exactly like any other instance and must be explicitly labeled in the PCC as an ignorance penalty.

### B.2.7 PCC documentation requirements

For each cell  $(u, d)$  and option  $a$ , the PCC must record:

- the list of instances  $\mathcal{K}(u, d, a)$  (or the phantom instance if applicable)
- each instance's parameters  $(\mu_k, r_k, t_k, \ell_k, c_k, e_k)$  and evidence sources
- the method used to assign time horizons  $t_k$
- whether  $\ell_k$  is baseline-conditional or scenario-conditional
- any equity/resilience justification and counterfactual audit when  $e_k \neq 1$

### B.2.8 Output and handoff to saturation

The output of B.2 is  $\tilde{I}_{u,d}^{dir}(a)$  for each active cell. The next step (B.3) maps this unsaturated value into the canonical bounded direct impact:

- $I_{u,d}^{dir}(a) \in [-1, +1]$

using the governed saturation function.

## B.3 Saturation (Bounded Mapping to $-1, +1$ )

**Purpose.** Pre-saturation aggregation (B.2) produces an unbounded real number  $\tilde{I}_{u,d}^{dir}(a) \in \mathbb{R}$ . Saturation maps this into the canonical bounded scale  $[-1, +1]$  while preserving sign and ensuring comparability across cells.

### B.3.1 Saturation function

Tier 4 override (Normative). Tier 4 MUST NOT compute  $\tanh(\cdot)$  at runtime. Tier 4 saturation MUST use `SAT_LUT_FP_V1` under `NDP_FIXEDPOINT_V1`.

MathGov uses smooth hyperbolic tangent saturation:

$$sat_{\beta}(x) := \tanh(\beta x)$$

Where:

1.  $x \in \mathbb{R}$
2.  $\text{sat}_\beta(x) \in (-1, +1)$
3.  $\beta > 0$  controls steepness

Default for **direct** (pre-propagation) saturation:

- $\beta = 2$

### B.3.2 Direct impact after saturation

$$I_{u,d}^{dir}(a) := \text{sat}_\beta(\tilde{I}_{u,d}^{dir}(a))$$

This produces a canonical, bounded direct impact score per cell, suitable for propagation (Appendix B.6 onward).

### B.3.3 Rationale and governance

Saturation prevents:

2. runaway totals from many small instances,
3. disproportionate domination by one cell with extreme unbounded sum,
4. scale inconsistencies across dimensions.

Any override of  $\beta$  must be PCC-declared and applied consistently across all options in the decision.

---

## B.4 Union–Dimension Cell Set and Indexing

**Purpose.** Many MathGov computations operate on the full union–dimension grid. This section defines cell indexing and the standard flattening map used for vector operations.

Let:

- unions  $u \in \{1, \dots, |\mathcal{U}|\}$
- dimensions  $d \in \{1, \dots, |\mathcal{D}|\}$

In the standard  $7 \times 7$  operational matrix (49 cells),  $|\mathcal{U}| = 7$  and  $|\mathcal{D}| = 7$ .

### B.4.1 Canonical flattening map (row-major)

$$\phi(u, d) := |\mathcal{D}|(u - 1) + d$$

For the  $7 \times 7$  case:

$$\phi(u, d) = 7(u - 1) + d$$

This maps each cell  $(u, d)$  into an index in  $\{1, \dots, 49\}$ .

## B.5 Direct Impact Vector (Flattened Form)

**Purpose.** Define the flattened direct-impact vector used for kernel propagation.

### B.5.1 Direct impact vector

$$I_a^{dir} \in [-1, 1]^{|\mathcal{U}||\mathcal{D}|}$$

Component definition:

$$I_a^{dir}[\phi(u, d)] := I_{u,d}^{dir}(a)$$

## B.6 Kernel Propagation (Ripple Effects)

**Purpose.** Propagation maps direct impacts across cells using a governed kernel  $K$ . This captures second-order and structural spillovers.

Let:

$$K \in \mathbb{R}^{n \times n}, n = |\mathcal{U}| |\mathcal{D}|$$

**B.6.1 Propagated impact vector (pre-saturation).** Let  $I^{dir}(a) \in [-1, 1]^{49}$  be the flattened **saturated** direct impact vector and  $K \in \mathbb{R}^{49 \times 49}$  the ripple kernel. Define the pre-saturation propagated vector  $\tilde{I}^{prop}(a)$  as:

Quick mode (first-order):

$$\tilde{I}^{prop}(a) := I^{dir}(a) + K I^{dir}(a).$$

Full mode (resummed; requires  $\rho(K) < 1$ ):

$$\tilde{I}^{prop}(a) := (I_{49} - K)^{-1} I^{dir}(a).$$

**B.6.2 Post-propagation saturation.** Apply elementwise saturation with coefficient  $\beta_{prop} > 0$  (default  $\beta_{prop} = 1$ ):

$$\bar{I}^{prop}(a) := \tanh(\beta_{prop} \tilde{I}^{prop}(a)),$$

yielding  $\bar{I}^{prop}(a) \in [-1, 1]^{49}$ .

### B.6.3 Reshaping back to cell form

$$\bar{I}_{u,d}^{prop}(a) := I_a^{prop}[\varphi(u, d)]$$

---

## B.7 Worst-Off Subgroup Operator (Rights Evaluation)

**Purpose.** Rights constraints are evaluated on the **worst-off subgroup** in the relevant population, not on averages.

Let  $g \in \mathcal{G}(u)$  index subgroups within union  $u$ , and let  $\bar{I}_{u,d}^{prop}(a; g)$  be the propagated impact for subgroup  $g$ .

Define:

### Tier-4 Subgroup Enumeration (Normative addendum)

For Tier-4 Pilot-Executable runs, subgroup sets are not optional. The PCC MUST (a) explicitly list  $G_{\{u,d\}}$  for every rights-covered cell, and (b) provide subgroup-conditioned impact totals per option. Tier-4 requires  $|G_{\{u,d\}}| \geq 2$  unless the union is single-entity for the decision; otherwise downgrade (audit\_flag: SUBGROUP\_ENUM\_MIN\_FAIL\_TIER4).

In Tier-4 replay, subgroup aggregates are treated as declared inputs; implementers MUST NOT invent subgroup partitions not present in the PCC.

$$\bar{I}_{u,d}^{prop, worst}(a) := \min_{g \in \mathcal{G}(u)} \bar{I}_{u,d}^{prop}(a; g)$$

This operator is used for rights-floor evaluation in NCRC.

---

### B.8 Rights Violation Depth and Rights Margin

**Purpose.** Convert rights-floor thresholds into a computable “violation depth” per right.

Let  $r \in \mathcal{R}$  index rights. Each right has:

5. a covered cell set  $\mathcal{C}_r \subseteq \mathcal{U} \times \mathcal{D}$
6. a rights floor threshold  $\tau_r$  (canonical default often 0, but governance-chosen by right)

Define the **rights margin**:

$$M_r(a) := \min_{(u,d) \in \mathcal{C}_r} \bar{I}_{u,d}^{prop, worst}(a) - \tau_r$$

Define the **violation depth** (nonnegative):

$$VD_r(a) := (-M_r(a))^+$$

Where  $(x)^+ = \max(x, 0)$ .

Interpretation:

- $M_r(a) \geq 0 \Rightarrow$  right  $r$  is satisfied (no violation)
- $M_r(a) < 0 \Rightarrow$  right  $r$  is violated with depth  $VD_r(a) > 0$

---

### B.9 NCRC Pass/Fail Predicate

**Purpose.** Determine whether an option passes the non-compensatory rights constraint.

$$NCRC(a) := \bigwedge_{r \in \mathcal{R}} (M_r(a) \geq 0)$$

Option passes NCRC if **all** rights margins are nonnegative under worst-off evaluation.

---

### B.10 Catastrophe Cell Set and Catastrophe Weight Simplex

**Purpose.** TRC focuses only on a governance-chosen “catastrophe cell set”  $\mathcal{C}_{cat}$  and aggregates tail risk using weights over that set.

Let:

$$\mathcal{C}_{cat} \subseteq \mathcal{U} \times \mathcal{D}$$

Let weights  $\omega_{u,d}$  be defined for  $(u, d) \in \mathcal{C}_{cat}$  with:

$$\omega_{u,d} \geq 0, \quad \sum_{(u,d) \in \mathcal{C}_{cat}} \omega_{u,d} = 1$$

Floors may be applied:

$$\omega_{u,d} \geq \omega_{u,d}^{floor}, \quad \sum_{(u,d) \in \mathcal{C}_{cat}} \omega_{u,d}^{floor} \leq 1$$

## B.11 Scenario Set and Probability Normalization

**Purpose.** Tail risk is evaluated over scenarios  $s \in S$  with probabilities  $p_s$ .

Let  $S$  be a finite scenario set. Define:

$$p_s \geq 0, \quad \sum_{s \in S} p_s = 1$$

If robust probability bounds are used, see B.15.

## B.12 Scenario-Conditioned Propagation

**Purpose.** When scenarios change impacts or kernel behavior, evaluate propagated impacts conditional on scenario  $s$ .

Let  $I_a^{dir}(s)$  denote the direct-impact vector under scenario  $s$ . Then:

$$\tilde{I}_a^{prop}(s) := K(s) I_a^{dir}(s)$$

If kernel is not scenario-dependent, then  $K(s) = K$ .

Apply post-propagation saturation:

$$I_a^{prop}(s) := \text{sat}_{\beta_{prop}}(\tilde{I}_a^{prop}(s))$$

And reshape:

$$\tilde{I}_{u,d}^{prop}(a | s) := I_a^{prop}(s)[\varphi(u, d)]$$

---

### B.13 Harm Function for Catastrophe Evaluation

**Purpose.** TRC uses harms (not benefits) on catastrophe cells.

Define scenario-conditioned harm:

$$\text{Harm}_{u,d}(a, s) := \max(\tilde{I}_{u,d}^{prop}(a | s), 0)$$

---

### B.14 Scenario Loss Function (Bounded-impact form)

**Purpose.** Define a scenario loss  $L(a, s)$  for CVaR evaluation based on catastrophe harms.

**Scenario loss (bounded-impact form):**  $L(a, s) = \sum_{(u,d) \in C_{cat}} \omega_{u,d} \cdot h_{u,d}(a|s)$ ,  
where  $h_{u,d}(a|s) = \max(0, -\tilde{I}_{u,d}^{prop}(a|s))$  and  $\sum_{(u,d) \in C_{cat}} \omega_{u,d} = 1$ .

$$L(a, s) := \sum_{(u,d) \in C_{cat}} \omega_{u,d} \text{Harm}_{u,d}(a, s)$$

This loss is in  $[0, 1]$  when harms are computed from bounded impacts.

### B.15 TRC Loss Mode and Raw-Indicator Loss (normative)

Define  $\text{trc\_mode} \in \{ 'bounded\_impact', 'raw\_indicator' \}$  and let  $\text{tier} = \text{implementation\_tier}$  from the PCC.

Mode lock (tier rule). For  $\text{tier} \leq 3$ ,  $\text{trc\_mode}$  MAY be 'bounded\_impact' or 'raw\_indicator'. For  $\text{tier} \geq 4$ ,  $\text{trc\_mode}$  MUST be 'raw\_indicator'. A Tier-4 PCC that sets  $\text{trc\_mode} = 'bounded\_impact'$  is invalid.

Admissibility lock (tier rule). When  $\text{tier} \geq 4$ , bounded-impact loss  $L_{\text{impacts}}(a, s)$  MAY be computed for diagnostics only and MUST NOT be used to determine TRC admissibility. TRC admissibility MUST be computed using  $L_{\text{raw}}(a, s)$  derived from the AF-BASE registry (or AF-EXT only if the PCC declares a governed extension  $C_{\text{ext}}$ ).

Raw-indicator mapping. For each catastrophe-bearing cell  $c$  and indicator  $j \in AF(c)$ , record  $x_j(a,s)$  in its native units and map to bounded loss:

$$[\ell_j(a,s) = \text{clip}((x_j(a,s) - x_{\text{onset},j}) / (x_{\text{max},j} - x_{\text{onset},j}), 0, 1).]$$

Raw-indicator aggregation. Aggregate within a cell by AF default (worst-case):

$$[L_c(a,s) = \max_{j \in AF(c)} \ell_j(a,s).]$$

Raw-indicator loss. Define:

$$[L_{\text{raw}}(a,s) = \sum_{c \in C_{\text{cat}}} \omega_c \cdot L_c(a,s), \quad L_{\text{raw}}(a,s) \in [0,1].]$$

Tier-4 requirement. For tier  $\geq 4$ , AF-BASE MUST be non-placeholder (G.1A.4) and MUST include at least one indicator for each cell in  $C_{\text{cat}}^{\text{base}}$ . If any required indicator is missing or any mapping parameter is undefined, the run is invalid.

Then compute  $CVaR_\alpha(L_{\text{raw}})$  and apply the TRC corridor threshold  $\tau_{\text{TRC}}$  exactly as in B.13 and B.17–B.18, with  $\alpha$  and  $\tau_{\text{TRC}}$  taken from the Tier Requirements Matrix (§4.4.5) or a hash-bound parameter registry referenced by the PCC.

## B.16 Value-at-Risk (VaR)

**Purpose.** Define VaR for scenario losses.

Let  $L(a)$  be the random variable over scenarios with outcomes  $L(a,s)$  and probabilities  $p_s$ . VaR at level  $\alpha \in (0,1)$  is:

$$VaR_\alpha(L(a)) := \inf \{z \in \mathbb{R}: \mathbb{P}(L(a) \leq z) \geq \alpha\}$$

For discrete scenarios:

$$VaR_\alpha(L(a)) := \min \left\{ z: \sum_{s: L(a,s) \leq z} p_s \geq \alpha \right\}$$

## B.17 Conditional Value-at-Risk (CVaR)

**Purpose.** CVaR measures expected loss in the worst tail beyond VaR.

$$CVaR_\alpha(L(a)) := \mathbb{E}[L(a) \mid L(a) \geq VaR_\alpha(L(a))]$$

Equivalent optimization form (useful for implementation):

$$CVaR_{\alpha}(L(a)) = \min_{\eta \in \mathbb{R}} \left( \eta + \frac{1}{1-\alpha} \mathbb{E}[(L(a) - \eta)^+] \right)$$

Discrete scenario version:

$$CVaR_{\alpha}(L(a)) = \min_{\eta \in \mathbb{R}} \left( \eta + \frac{1}{1-\alpha} \sum_{s \in S} p_s (L(a, s) - \eta)^+ \right)$$

## B.18 TRC Corridor Constraint (Pass/Fail)

**Purpose.** TRC is a hard admissibility filter: options exceeding the corridor are forbidden.

Let  $\tau_{TRC}$  be the governance-chosen corridor threshold. Then:

$$TRC(a) := (CVaR_{\alpha}(L(a)) \leq \tau_{TRC})$$

### B.18.1 Scenario-Aware RLS (When Scenario Evaluation Is Enabled)

**Purpose.** When scenario evaluation is used for welfare impacts, RLS uses scenario-expected propagated impacts.

Define scenario expectation of propagated impacts:

$$\mathbb{E}_S [\bar{I}_{u,d}^{prop}(a)] := \sum_{s \in S} p_s \bar{I}_{u,d}^{prop}(a | s)$$

Then scenario-aware RLS is:

$$RLS(a) = \sum_{u,d} w_u v_d m_{u,d} \mathbb{E}_S [\bar{I}_{u,d}^{prop}(a)]$$

This is identical to the baseline RLS with  $\bar{I}^{prop}$  replaced by its scenario expectation.

## B.19 Robust TRC (Worst-Case over Probability Set)

**Purpose.** When scenario probabilities are uncertain, apply a robust constraint over a set  $\mathcal{P}$  of admissible distributions.

Let  $\mathcal{P}$  be a governance-defined set of distributions over  $S$ . Then:

$$TRC_{rob}(a) := \sup_{p \in \mathcal{P}} CVaR_{\alpha,p}(L(a)) \leq \tau_{TRC}$$

The PCC must define  $\mathcal{P}$  (bounds, floors, and justification).

---

## B.20 Positive-Part, Clip, and Clamp Operators

**Purpose.** Standard operators used throughout the paper.

$$(x)^+ := \max(x, 0)$$

$$clip(x, L, U) := \max(L, \min(U, x))$$

$$clamp_0^1(x) := \max(0, \min(1, x))$$

---

## B.21 Admissibility Predicate and Admissible Option Set

**Purpose.** Formal deontic separation: admissibility is not a weighted sum.

$$Admissible(a) := NCRC(a) \wedge TRC(a)$$

$$\mathcal{A}_{adm} := \{a \in \mathcal{A} \mid Admissible(a)\}$$

---

## B.22 Containment “Positive Set” (Integrity Gate)

**Purpose.** Containment prevents sub-union gains from degrading higher unions beyond allowable bounds. Its exact parameters are governance-chosen; the PCC must declare them.

Let  $\mathcal{U}^+$  denote unions whose protection has containment priority (e.g., Biosphere, Humanity/CMIU), with parameters in the PCC.

Define a containment pass/fail predicate generically:

$$Containment(a) := \text{PCC-defined test over designated unions and dimensions}$$

Then the containment-positive subset:

$$\mathcal{A}_{cont} := \{a \in \mathcal{A}_{adm} \mid Containment(a)\}$$

If containment is used as an escalation gate rather than a hard filter, the PCC must record override signatures and mitigation obligations.

---

### B.23 Hollowing-Out Index (HOI) (Explicit EMA Form)

**Purpose.** HOI tracks divergence between welfare score improvements and coherence/health indicators, detecting “paper gains” that erode structural integrity.

Define exponential moving average:

Initialization: for any  $EMA_\lambda$  stream, set  $EMA_\lambda(x_0) := x_0$  (first observation). For HOI in a new deployment with no prior period, set  $\Delta RLS_0 := 0$  and  $\Delta UCI_0 := 0$ , compute  $HOI_0$  using those zero deltas, and begin EMA from the first observed  $\Delta$  values in the next period.

$$EMA(X)_t := \gamma X_t + (1 - \gamma) EMA(X)_{t-1}$$

Default smoothing parameter from half-life  $h$  review periods:

$$\gamma := 1 - 2^{-1/h}$$

Default  $h = 3$  gives  $\gamma \approx 0.206$ .

Define HOI:

$$HOI_t := EMA(RLS)_t - EMA(UCI)_t$$

---

### B.24 Maximin Rights Margin (Emergency-Mode Comparator)

**Purpose.** When all options violate at least one right, emergency mode selects options by minimizing rights-violation severity first.

Define the minimum rights margin for an option:

$$MRM(a) := \min_{r \in \mathcal{R}} M_r(a)$$

Higher is better. If all are negative, choose the option that makes  $MRM(a)$  least negative (closest to zero), with secondary criteria (e.g., CVaR) applied as defined in emergency procedures.

---

## B.25 Summary of Appendix B Outputs

Appendix B provides the computable definitions for:

- instance aggregation  $\tilde{I}_{u,d}^{dir}(a)$  (B.2)
  - saturation  $I_{u,d}^{dir}(a)$  (B.3)
  - flattening/vectorization (B.4–B.5)
  - propagation  $\tilde{I}_{u,d}^{prop}(a)$  (B.6)
  - worst-off evaluation (B.7)
  - rights margins and NCRC pass/fail (B.8–B.9)
  - catastrophe loss, VaR/CVaR, TRC corridor (B.10–B.18)
  - scenario-aware RLS (B.18.1)
  - robust TRC (B.19)
  - admissibility sets, containment sets (B.21–B.22)
  - HOI explicit computation (B.23)
  - emergency comparator (B.24)
  - shared operators (B.20)
- 

## Appendix C: Canonical Rights Specification (NCRC)

Authoritative rights coverage mapping (normative). Appendix C.3.7 is the single authoritative source for rights coverage sets  $C_r$ . Any other summary table must match C.3.7 exactly.

This appendix specifies the canonical rights used by the NCRC. These rights are implemented as lexicographic admissibility constraints: options that violate any canonical right are inadmissible except under explicitly declared Emergency Mode.

## C.1 Scope and Coverage Semantics

**Rights-bearing unions.** Canonical rights apply primarily to unions that contain sentient moral patients and/or governance agents. Let:

The Biosphere union is protected under Ecological Integrity (ECOL) and via TRC rather than being treated as a generic "rights bearer" for all human-style rights.

**Impacts used for NCRC.** NCRC is evaluated on the worst-off subgroup post-propagation, post-saturation normalized impacts  $\bar{I}^{\text{rights}}(u,d)(a)$ . Thresholds are stated on the  $[-1, +1]$  scale.

**Canonical thresholds.** Thresholds may be contextually tightened (more protective) but may not be loosened below canonical values without Charter-level revision.

## C.2 Canonical Rights Table

| Right            | Code | Threshold                      | Coverage Set                                  | Measurement Anchors                                  |
|------------------|------|--------------------------------|-----------------------------------------------|------------------------------------------------------|
| Life             | LIFE | $\theta_{\text{LIFE}} = -0.90$ | Health cells<br>for $u \in \{1, \dots, 6\}$   | Mortality risk;<br>excess deaths;<br>acute lethality |
| Bodily Integrity | BODY | $\theta_{\text{BODY}} = -0.70$ | Health cells<br>for $u \in \{1, \dots, 6\}$   | Severe<br>injury/disability;<br>torture; trauma      |
| Liberty          | LBTY | $\theta_{\text{LBTY}} = -0.65$ | Agency cells<br>for $u \in \{1, \dots, 6\}$   | Arbitrary detention;<br>forced labor;<br>coercion    |
| Basic Needs      | NEED | $\theta_{\text{NEED}} = -0.50$ | Material cells<br>for $u \in \{1, \dots, 6\}$ | Food insecurity;<br>homelessness;<br>deprivation     |

| Right                | Code | Threshold                      | Coverage Set                                                                                       | Measurement Anchors                                                     |
|----------------------|------|--------------------------------|----------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------|
| Dignity              | DIGN | $\theta_{\text{DIGN}} = -0.55$ | $\{(u, \text{Social}): u \in \{1,2,3,4,5,6\}\} \cup \{(u, \text{Agency}): u \in \{1,2,3,4,5,6\}\}$ | Discrimination; humiliation; exclusion; coercive loss of voice/autonomy |
| Due Process          | PROC | $\theta_{\text{PROC}} = -0.45$ | Agency cells for $u \in \{1, \dots, 6\}$                                                           | Fair hearing denial; arbitrary enforcement                              |
| Information          | INFO | $\theta_{\text{INFO}} = -0.40$ | Knowledge cells for $u \in \{1, \dots, 6\}$                                                        | Censorship; misinformation; access denial                               |
| Ecological Integrity | ECOL | $\theta_{\text{ECOL}} = -0.65$ | Biosphere-Environment (required); Humanity-Environment (required)                                  | Planetary boundaries; biodiversity                                      |

### C.3 Rights coverage sets $C_r$ : explicit union–dimension mapping and scope note

This appendix specifies the **canonical rights coverage sets** used by the Non-Compensatory Rights Constraint (NCRC). Each right  $r$  is evaluated on a declared set of union–dimension cells  $C_r \subseteq U \times D$ . These coverage sets define **where** a right applies in the 7×7 welfare matrix and make NCRC independently implementable.

#### C.3.1 Canonical unions and dimensions

Unions  $U$  are ordered:

$$\begin{aligned}
 U &= \{1, \dots, 7\} \\
 &= \{\text{Self, Household, Community, Organization, Polity, Humanity/CMIU, Biosphere}\}.
 \end{aligned}$$

Dimensions  $D$  are ordered:

$$D = \{1, \dots, 7\} = \{\text{Material, Health, Social, Knowledge, Agency, Meaning, Environment}\}.$$

When this appendix refers to “rights-bearing unions,” it means  $U_{rb} = \{1, 2, 3, 4, 5, 6\}$  (Self through Humanity/CMIU). Biosphere ( $u = 7$ ) is not treated as a rights-bearing moral patient in NCRC, but it can be protected as a **rights-relevant life-support system** through ECOL and through TRC and containment.

### C.3.2 Scope note: what coverage sets mean and what they do not mean

Coverage sets are **not weights** and do not create compensatory tradeoffs. They specify:

1. which union–dimension cells are relevant to a given right, and
2. where the NCRC feasibility check must look for violations.

A cell being included in  $C_r$  means that harm in that cell can trigger a rights violation for right  $r$  if it crosses the governed rights threshold  $\theta_r$ , under the scenario and subgroup rules specified in Section 6.

Coverage sets must be:

- **declared** (these defaults are canonical unless overridden),
- **stable across compared options**, and
- **auditable** (the PCC must state any deviation and justification).

### C.3.3 Canonical rights set

MathGov uses the following canonical right labels:

$$R = \{\text{LIFE, BODY, LBTY, NEED, DIGN, PROC, INFO, ECOL}\}.$$

Where:

- LIFE = life preservation / avoid severe mortality harm
- BODY = bodily integrity / avoid severe physical harm, coercion, violence
- LBTY = liberty / freedom of movement and autonomy within rights floor
- NEED = basic needs / survival and essential access
- DIGN = dignity / non-degradation, non-discrimination, basic respect
- PROC = due process / fairness, transparency, contestability in coercive systems

- INFO = information integrity / consent-relevant truthfulness and privacy where needed
- ECOL = ecological life-support integrity as a rights-relevant constraint

### C.3.4 Explicit coverage mapping table (canonical default)

**Notation.**  $(u\ d)$  denotes union  $u$  and dimension  $d$ . “All rights-bearing unions” means  $u \in \{1,2,3,4,5,6\}$ .

#### Canonical mapping principle.

- Rights that protect direct sentient harms map primarily to **Health**, **Agency**, and **Social** cells across rights-bearing unions.
- Rights involving access and deprivation map to **Material** and **Health**.
- Rights involving institutional fairness map to **Social**, **Knowledge**, and **Agency** at governance-relevant unions (Organization, Polity, Humanity/CMIU).
- ECOL maps to Environment cells that represent life-support integrity affecting rights-bearing beings.

**Table C.3-A. Rights coverage sets  $C_r$  (canonical default)**

| Right $r$ | Coverage set $C_r$ (union–dimension pairs)                       |
|-----------|------------------------------------------------------------------|
| LIFE      | Defined in Appendix C.3.7 (authoritative auditor mapping table). |
| BODY      | Defined in Appendix C.3.7 (authoritative auditor mapping table). |
| LBTY      | Defined in Appendix C.3.7 (authoritative auditor mapping table). |
| NEED      | Defined in Appendix C.3.7 (authoritative auditor mapping table). |
| DIGN      | Defined in Appendix C.3.7 (authoritative auditor mapping table). |
| PROC      | Defined in Appendix C.3.7 (authoritative auditor mapping table). |
| INFO      | Defined in Appendix C.3.7 (authoritative auditor mapping table). |
| ECOL      | Defined in Appendix C.3.7 (authoritative auditor mapping table). |

### C.3.5 Interpretation notes (to prevent misreadings)

1. **Why LIFE includes (6: Environment).** Life at scale depends on shared planetary and civilizational life-support functions. This inclusion prevents “death by environment collapse” from evading LIFE protections at humanity scale.
2. **Why ECOL maps to Environment only.** ECOL is a life-support integrity constraint anchored to environmental conditions. Downstream human health harms are protected by LIFE/BODY/NEED and by TRC, which remain separate admissibility corridors.
3. **Non-duplication note.** ECOL is not a second copy of LIFE/BODY. It constrains environmental life-support integrity directly; human mortality and bodily harms remain governed by LIFE and BODY, and catastrophic tails remain governed by TRC.

### C.3.6 Governance and override rule

Any deviation from Table C.3-A must be declared in the PCC and must include:

- the modified set  $C_r$  for each affected right,
- the rationale (including any domain-specific rights constraints),
- and confirmation that the same  $C_r$  is applied across all options.

### Appendix C.3.7: Rights coverage sets ( $C_r$ ) — auditor mapping table

This table makes the NCRC independently implementable by specifying, for each right  $r$ , the coverage set  $C_r \subseteq U \times D$  (union–dimension cells) to be checked against the rights threshold  $\theta_r$ . Defaults apply unless overridden and documented in the PCC.

Canonical unions  $U$  (1–7): Self, Household, Community, Organization, Polity, Humanity/CMIU, Biosphere.

Canonical dimensions  $D$ : Material, Health, Social, Knowledge, Agency, Meaning, Environment.

Rights-bearing unions default:  $U_{rb} = \{\text{Self, Household, Community, Organization, Polity, Humanity/CMIU}\}$  (i.e., unions 1–6).

| Right $r$ | Coverage set $C_r$ (union, dimension pairs)                                      | Scope / audit note                                                              |
|-----------|----------------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| LIFE      | $\{(u, \text{Health}): u \in \{1,2,3,4,5,6\}\} \cup \{(6, \text{Environment})\}$ | Protects severe mortality / life-ending harm across rights-bearing unions, plus |

|      |                                                                                                                                        |                                                                                                                                     |
|------|----------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
|      |                                                                                                                                        | humanity-scale life-support integrity.                                                                                              |
| BODY | $\{(u, \text{Health}): u \in \{1,2,3,4,5,6\}\}$                                                                                        | Protects bodily integrity: severe injury, violence, coercive harm with physical consequences.                                       |
| LBTY | $\{(u, \text{Agency}): u \in \{1,2,3,4,5,6\}\} \cup \{(u, \text{Social}): u \in \{3,4,5,6\}\}$                                         | Protects liberty/autonomy primarily via Agency; adds Social for community–humanity where liberty is institutionally mediated.       |
| NEED | $\{(u, \text{Material}): u \in \{1,2,3,4,5,6\}\} \cup \{(u, \text{Health}): u \in \{1,2,3,4,5,6\}\}$                                   | Protects basic needs and essential access; includes Health because deprivation often manifests as health harm.                      |
| DIGN | $\{(u, \text{Social}): u \in \{1,2,3,4,5,6\}\} \cup \{(u, \text{Agency}): u \in \{1,2,3,4,5,6\}\}$                                     | Protects non-degradation and non-discrimination; links to social treatment and autonomy/voice.                                      |
| PROC | $\{(u, \text{Agency}): u \in \{4,5,6\}\} \cup \{(u, \text{Knowledge}): u \in \{4,5,6\}\} \cup \{(u, \text{Social}): u \in \{4,5,6\}\}$ | Protects due process and contestability in coercive systems; applies where formal governance structures operate.                    |
| INFO | $\{(u, \text{Knowledge}): u \in \{1,2,3,4,5,6\}\} \cup \{(u, \text{Agency}): u \in \{1,2,3,4,5,6\}\}$                                  | Protects consent-relevant truthfulness and privacy (as applicable); ties to knowledge integrity and agency.                         |
| ECOL | $\{(6, \text{Environment}), (7, \text{Environment})\}$                                                                                 | Protects ecological life-support integrity at humanity and biosphere scale; downstream health is covered by LIFE/BODY/NEED and TRC. |

Governance rule: Any deviation from these defaults must be declared in the PCC, applied consistently across all options, and justified as preserving the intended protection scope. Coverage sets are not weights and do not create compensatory tradeoffs.

#### C.4 Rights-to-Cells Rationale Table

| Right | Cells Covered                               | Rationale                                                                                                                                                                                                                                       |
|-------|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LIFE  | Health cells ( $U_1$ through $U_6$ )        | Life protection requires health system integrity across all scales; mortality risk is fundamentally a health outcome                                                                                                                            |
| BODY  | Health cells ( $U_1$ through $U_6$ )        | Bodily integrity is a health dimension concern; severe injury and disability are health impacts                                                                                                                                                 |
| LBTY  | Agency cells ( $U_1$ through $U_6$ )        | Liberty is the capacity for autonomous action; coercion and detention restrict agency                                                                                                                                                           |
| NEED  | Material cells ( $U_1$ through $U_6$ )      | Basic needs are fundamentally material; food, shelter, and essential services are material resources                                                                                                                                            |
| DIGN  | Social and Agency cells                     | Dignity is operationalized as protection against social degradation/exclusion and against coercive loss of voice/autonomy; existential “Meaning” is scored in welfare (RLS) but is not used as a rights-floor trigger in the canonical mapping. |
| PROC  | Agency cells (procedural)                   | Due process is a specific form of agency in institutional contexts; fair hearing enables effective action                                                                                                                                       |
| INFO  | Knowledge cells                             | Information access is the epistemic capacity foundation; censorship restricts knowledge acquisition                                                                                                                                             |
| ECOL  | Biosphere-Environment (required), Humanity- | Ecological integrity is environmental by definition; humanity-level extension captures civilization-scale environmental dependence                                                                                                              |

| Right | Cells Covered             | Rationale |
|-------|---------------------------|-----------|
|       | Environment<br>(required) |           |

### C.5 Threshold Calibration Protocol

Each rights threshold is calibrated through a three-step process:

#### C.5.1 Step 1: Normative Anchor Identification

| Right | Harm Category                          | Normative Source                                                      |
|-------|----------------------------------------|-----------------------------------------------------------------------|
| LIFE  | Near-certain or highly probable death  | UNHCR emergency mortality thresholds (doubling of baseline mortality) |
| BODY  | Severe injury, disability, torture     | Sphere Standards minimum thresholds                                   |
| LBTY  | Arbitrary detention, forced labor      | Freedom House "partly free" threshold                                 |
| NEED  | Severe food insecurity, homelessness   | FAO FIES severe threshold                                             |
| DIGN  | Systematic humiliation, dehumanization | UDHR dignity provisions                                               |
| PROC  | Denial of fair hearing                 | World Justice Project Rule of Law Index                               |
| INFO  | Systematic censorship                  | Press freedom indices                                                 |
| ECOL  | Planetary boundary transgression       | Rockström et al. planetary boundaries framework                       |

#### C.5.2 Step 2: Indicator Mapping

### **Example: LIFE threshold derivation**

Reference indicator: Excess mortality rate (deaths per 1,000 population above baseline)

Reference class: WHO Global Health Observatory mortality data

Anchoring:

1. 5th percentile (best): 0 excess deaths per 1,000
2. 95th percentile (worst): 50+ excess deaths per 1,000 (severe epidemic/conflict)

The threshold  $\theta_{\text{LIFE}} = -0.90$  corresponds to approximately 45 excess deaths per 1,000, representing near-certain widespread mortality if the decision proceeds.

### **C.5.3 Step 3: Philosophical Justification**

Each threshold placement reflects convergent moral intuitions from:

1. Human rights jurisprudence (UDHR, ICCPR, ICESCR)
2. Humanitarian standards (Sphere, UNHCR)
3. Capability theory (Nussbaum's central capabilities)
4. Overlapping consensus across major ethical traditions

### **C.6 Threshold Sensitivity Analysis Requirement**

Before adopting thresholds, conduct sensitivity analysis:

1. Vary each threshold by  $\pm 0.05$
2. Apply to a test set of at least 20 decision scenarios
3. Document: How many decisions change admissibility status?
4. If  $>30\%$  of decisions are sensitive to  $\pm 0.05$  variation, provide additional justification for the chosen threshold

### **C.7 Threshold Revision Procedure**

Thresholds may be revised only through charter-level governance:

1. Proposal with documented justification grounded in new evidence
2. Sensitivity analysis showing effects of proposed change
3. Supermajority vote in governance body (default: 2/3)
4. Independent review panel sign-off

5. Public disclosure and version increment

### **C.8 Emergency Mode Priority Order**

Under NCRC Emergency Mode (§6.4), when no option satisfies all rights constraints, the system lexicographically minimizes violations in the following priority order:

1. LIFE (highest priority)
2. BODY
3. ECOL
4. LBTY
5. NEED
6. DIGN
7. PROC
8. INFO (lowest priority)

Normative status (authoritative). This priority order is the single authoritative ordering for lexicographic rights minimization in Emergency Mode. Any deviation requires Charter amendment and a new versioned registry hash. Any PCC using a non-canonical ordering **MUST** include `audit_flag RIGHTS_PRIORITY_OVERRIDE`.

This ordering reflects the relative severity and irreversibility of different rights violations.

---

## **Appendix D: TRC Parameter Defaults**

This appendix provides default TRC parameters and the minimum scenario set required for a defensible tail-risk evaluation.

### **D.1 Catastrophe Cell Set (Base)**

corresponding to Humanity/CMIU-Health, Humanity/CMIU-Environment, and Biosphere-Environment.

### **D.2 Catastrophe weights and minimum-weight floor (TRC aggregation weights)**

This appendix provides the **canonical definition and construction** of catastrophe-cell weights used by the Tail-Risk Constraint (TRC). It is the appendix counterpart to §7.2.4 and must remain **identical in formula and meaning**.

### D.2.1 Catastrophe cell set $\mathcal{C}_{cat}$

Let  $U = \{1, \dots, 7\}$  be the unions and  $D = \{1, \dots, 7\}$  be the welfare dimensions. Define the catastrophe cell set:

$$\mathcal{C}_{cat} \subseteq U \times D,$$

the set of union–dimension cells in which catastrophic failure is meaningful and must be evaluated under TRC.

Unless otherwise declared in the PCC, MathGov uses the canonical default:

$$\mathcal{C}_{cat}^{default} := \{(u, \text{Health}): u \in \{1, \dots, 6\}\} \cup \{(7, \text{Environment})\}.$$

Any extension or modification of  $\mathcal{C}_{cat}$  is a governed decision and must be declared in the PCC, including the rationale and the complete resulting set.

---

### D.2.2 Catastrophe weights $\omega_{u,d}$ and normalization

Define nonnegative catastrophe weights over catastrophe-bearing cells:

$$\omega_{u,d} \geq 0 \forall (u, d) \in \mathcal{C}_{cat},$$

with normalization:

$$\sum_{(u,d) \in \mathcal{C}_{cat}} \omega_{u,d} = 1.$$

**Default.** If the PCC does not specify weights, use the uniform default:

$$\omega_{u,d}^{default} = \frac{1}{|\mathcal{C}_{cat}|} \forall (u, d) \in \mathcal{C}_{cat}.$$

**Governed reweighting.** The PCC may specify a non-uniform  $\omega$  to reflect decision-context salience, provided:

- the weights are nonnegative,
- they sum to 1 over  $\mathcal{C}_{cat}$ , and

- the same  $\omega$  is applied across all compared options.

---

### D.2.3 Anti-capture minimum weight floor (feasible under extensions)

To prevent “catastrophe-weight capture” (artificially driving a key catastrophe cell’s weight toward zero), MathGov enforces a **feasible per-cell minimum**:

$$\omega_{u,d} \geq \omega_{\min}(|C_{cat}|) \forall (u,d) \in C_{cat}.$$

Define:

$$\omega_{\min}(|C_{cat}|) := \min \left( \frac{\eta}{|C_{cat}|}, 0.05 \right),$$

where  $\eta \in (0,1]$  is a governed slack factor (default  $\eta = 0.5$ ).

**Feasibility guarantee.** This floor remains feasible under any governed extension of  $C_{cat}$  because:

$$|C_{cat}| \cdot \omega_{\min}(|C_{cat}|) \leq \eta \leq 1,$$

so the floor cannot force  $\sum_{(u,d) \in C_{cat}} \omega_{u,d}$  above 1.

#### Interpretation of the floor.

- When  $|C_{cat}|$  is small, a fixed cap of 0.05 may be active and still feasible.
- When  $|C_{cat}|$  becomes large, the cap becomes inactive and the floor smoothly becomes  $\eta/|C_{cat}|$ , preserving feasibility automatically.

**PCC reporting requirement.** The PCC must report:

1.  $|C_{cat}|$ ,
  2. the chosen  $\eta$ ,
  3. the resulting  $\omega_{\min}(|C_{cat}|)$ ,
  4. whether the 0.05 cap is active,
  5. and which cells are at the floor.
-

### D.2.4 Canonical construction procedure (floor-respecting weights)

When a governed weight proposal must satisfy the floor, construct  $\omega$  using the following steps.

- Propose raw weights  $\omega'_{u,d} \geq 0$  over  $C_{cat}$  with  $\sum \omega' = 1$ .
- Apply the floor:

$$\omega''_{u,d} := \max \left( \omega'_{u,d}, \omega_{\min}(|C_{cat}|) \right).$$

- Renormalize:

$$\omega_{u,d} := \frac{\omega''_{u,d}}{\sum_{(i,j) \in C_{cat}} \omega''_{i,j}}.$$

- Verify post-renormalization that  $\omega_{u,d} \geq \omega_{\min}(|C_{cat}|)$  holds to within numerical tolerance. If rounding artifacts violate the inequality, apply a rounding-safe adjustment and report the final  $\omega$  explicitly in the PCC.

This procedure ensures the TRC aggregation weights are feasible, capture-resistant, and independently auditable.

## D.3 Default TRC Parameters (Tier-Authoritative + Context Guidance)

### D.3.1 Authoritative tier minima (scenario counts)

The Tier Requirements Matrix (§4.4.5) is authoritative for minimum scenario counts:

| Tier                     | Minimum  S  (authoritative) | Notes                                               |
|--------------------------|-----------------------------|-----------------------------------------------------|
| Tier 1                   | N/A                         | TRC optional / qualitative.                         |
| Tier 2                   | $\geq 5$ (recommended)      | Not a hard floor, but recommended when TRC is used. |
| Tier 3                   | $\geq 20$                   | Minimum required for Tier 3 claim.                  |
| Tier 4 (PilotExecutable) | $\geq 50$ (default)         | Exceptions must be PCC-declared + flagged.          |

| Tier 4 (Certified) |  $\geq 50$  + packaged stress tests | Required. |

### D.3.2 Context defaults ( $\alpha$ and $\tau_{\text{TRC}}$ ) (informative)

These context defaults guide parameter selection but do not override tier minima:

| Context |  $\alpha$  |  $\tau_{\text{TRC}}$  |

|-----|----|-----|

| Personal | 0.90 | 0.30 |

| Organizational | 0.95 | 0.20 |

| Reversible policy | 0.95 | 0.15 |

| Irreversible policy | 0.99 | 0.10 |

| Existential risk | 0.999 | 0.05 |

Audit rule: PCC MUST state which context default was used (or why overridden) and MUST separately confirm scenario-count compliance with §4.4.5.

### D.4 Mandatory Tail Scenario (MTS) Categories

| Category            | Code  | Minimum Stress Level                                   | Floor Probability |
|---------------------|-------|--------------------------------------------------------|-------------------|
| Pandemic/biological | MTS-1 | $\geq 30\%$ affected; 6-24 months; healthcare exceeded | $p \geq 0.02$     |
| Climate tipping     | MTS-2 | $\geq 2$ boundaries breached; partial irreversibility  | $p \geq 0.02$     |
| Financial collapse  | MTS-3 | $\geq 50\%$ asset drawdown; credit freeze              | $p \geq 0.02$     |

| Category               | Code  | Minimum Stress Level                         | Floor Probability |
|------------------------|-------|----------------------------------------------|-------------------|
| Major conflict         | MTS-4 | Trade corridor disruption; mobilization risk | $p \geq 0.02$     |
| Infrastructure failure | MTS-5 | $\geq 6$ month outage for relevant systems   | $p \geq 0.02$     |

### D.5 Scenario Specification Template

Each scenario must contain:

1. **Name and ID:** Stable label + unique identifier
2. **Narrative description:** 2-5 sentences describing the world-state and shock
3. **Time horizon:** Planning window and key event timing assumptions
4. **Stressors:** Which systems are stressed (health, climate, finance, conflict, infrastructure)
5. **Parameter hooks:** Quantitative parameters (mortality multiplier, GDP shock, outage duration)

Range semantics (training library): if a scenario lists a range (e.g., outage\_duration\_hours = 2–6), that range is a scenario-generator hint only. Any executable run MUST instantiate a concrete scenario object with explicit point values for all parameters (declared in the PCC scenario registry). Default instantiation rule for training runs, unless otherwise declared: use the midpoint of each numeric range and round to the nearest admissible unit.

6. **Relevance claim:** Why this scenario is relevant to the decision
7. **Source and provenance:** Literature, datasets, expert elicitation, prior PCCs

### D.6 Robust TRC Parameters

### D.7 Embedded training scenario library DSL-20-TRAINING-V1 (informative)

Purpose: provide a minimal, fully enumerated scenario set (IDs + probabilities + example parameter hooks) to enable docs-only exercises and Tier  $\leq 2$  training pilots without requiring a separate ProofPack scenario registry. Use: allowed only when the PCC explicitly sets scenario\_library\_id = DSL-20-TRAINING-V1 and declares trc\_mode = MRC (Tier  $\leq 2$ ).

Not allowed: Tier  $\geq 3$  conformance claims MUST use a governed, decision-relevant scenario registry referenced by hash and meeting tier minima (§4.4.5).

| Scenario_ID | MTS_Category           | Narrative (2–5 sentences summary)                                                                      | Example parameter hooks (illustrative)                | p    |
|-------------|------------------------|--------------------------------------------------------------------------------------------------------|-------------------------------------------------------|------|
| DSL20-01    | Operational disruption | Key service or transport pathway is intermittently unavailable, causing delays and missed commitments. | outage_duration_hours=2–6; delay_multiplier=1.5–2.5   | 0.10 |
| DSL20-02    | Safety incident        | A serious accident or near-miss occurs, increasing injury risk and triggering protective actions.      | injury_risk_multiplier=2–5; protective_mode=ON        | 0.08 |
| DSL20-03    | Weather extreme        | Heavy rain or flooding reduces mobility and increases exposure and accident probability.               | rain_intensity=high; road_hazard_multiplier=2–4       | 0.07 |
| DSL20-04    | Public health surge    | A localized illness surge reduces available labor and increases care burdens.                          | absenteeism_rate=10–25%; care_load_multiplier=1.2–1.5 | 0.06 |
| DSL20-05    | Infrastructure outage  | Power or network outage disrupts coordination, payments, or                                            | outage_hours=1–8; comms_reliability=low               | 0.06 |

|          |                          |                                                                                                     |                                                            |          |
|----------|--------------------------|-----------------------------------------------------------------------------------------------------|------------------------------------------------------------|----------|
|          |                          | safety systems for multiple hours.                                                                  |                                                            |          |
| DSL20-06 | Price shock              | Fuel and essential prices spike rapidly, increasing cost burden and reducing affordability.         | fuel_price_change=+15–40%; cost_multiplier=1.1–1.4         | 0.0<br>5 |
| DSL20-07 | Policy/regulatory change | A rule change alters access, route permissions, or compliance duties, increasing friction and risk. | compliance_friction=+1–3 steps;<br>access_reduction=10–30% | 0.0<br>5 |
| DSL20-08 | Security incident        | Theft/fraud or digital compromise occurs, increasing losses and reducing trust in transactions.     | loss_fraction=0.05–0.20;<br>trust_factor=down              | 0.0<br>5 |
| DSL20-09 | Supply chain disruption  | Parts, maintenance, or critical supplies are delayed, increasing downtime probability.              | lead_time_days=3–14;<br>downtime_prob=up                   | 0.0<br>5 |
| DSL20-10 | Labor/availability shock | Key worker becomes unavailable (illness/family), causing schedule                                   | availability_drop=1 person;<br>schedule_slack=down         | 0.0<br>5 |

|          |                      |                                                                                                         |                                                     |          |
|----------|----------------------|---------------------------------------------------------------------------------------------------------|-----------------------------------------------------|----------|
|          |                      | gaps and increased stress.                                                                              |                                                     |          |
| DSL20-11 | Demand variance      | Demand volatility forces schedule compression or overtime, increasing fatigue and error rate.           | demand_volatility=high; fatigue_multiplier=1.2–1.6  | 0.0<br>4 |
| DSL20-12 | Financial constraint | Unexpected expense or income shortfall reduces buffer, forcing riskier choices.                         | buffer_days=down; forced_tradeoffs=up               | 0.0<br>4 |
| DSL20-13 | Social conflict      | Local tensions or harassment risk increases on certain routes or times, reducing safety and well-being. | harassment_risk=up; route_constraints=increase      | 0.0<br>4 |
| DSL20-14 | Environmental hazard | Air quality or heat event reduces health reserve and increases vulnerability during travel.             | AQI=unhealthy; heat_index=high; health_reserve=down | 0.0<br>4 |
| DSL20-15 | Technology failure   | Core device/app/system fails, reducing reliability of planning and causing coordination failures.       | failure_rate=up; fallback_latency=up                | 0.0<br>4 |

|          |                                 |                                                                                                   |                                                      |          |
|----------|---------------------------------|---------------------------------------------------------------------------------------------------|------------------------------------------------------|----------|
| DSL20-16 | Macroeconomic downturn          | Broad slowdown reduces income stability; buffers shrink; competition for stable work increases.   | income_variance=up;<br>buffer_days=down              | 0.0<br>6 |
| DSL20-17 | Critical dependency failure     | Primary backup option fails simultaneously, reducing redundancy and increasing tail risk.         | redundancy_level=1;<br>backup_failure_prob=up        | 0.0<br>3 |
| DSL20-18 | Legal/liability event           | A liability event or enforcement action creates sudden penalties or exclusion from a service.     | penalty_amount=high;<br>exclusion_prob=up            | 0.0<br>3 |
| DSL20-19 | Information reliability failure | Information is unreliable (misleading ETA, false availability), causing cascading lateness.       | ETA_error=high;<br>miscoordination_prob=up           | 0.0<br>3 |
| DSL20-20 | Compound shock                  | Two or more shocks co-occur (e.g., rain + outage), amplifying tail risks beyond single scenarios. | shock_combo={rain,outage}<br>; tail_multiplier=1.5–3 | 0.0<br>3 |

When probability estimates vary by more than 2× across credible sources:

Probability bounds method:

## Appendix E: UCI measurement operationalization (union-specific structural indicators)

This appendix defines the canonical operationalization of UCI for Tier 4 decisions. It specifies union-appropriate structural indicators for each UCI component, and it provides default measurement cadence guidance. The intent is not to force a single dataset, but to provide a complete implementable protocol that preserves Tier-2 structural independence from welfare scoring.

### E.1 General rule: structural indicators and independence

For each union, UCI is computed from structural and process indicators that are distinct from the welfare indicators used to generate the RLS impact matrix. UCI components are defined on, and option impacts on UCI components are represented as bounded deltas in using the same impact-instance pipeline as §5.2–§5.4 (indicator selection, reference class anchoring, instance aggregation, and saturation), but applied to structural indicators rather than welfare indicators.

Baseline recording requirement (Tier 4). The PCC must record and the data sources used to compute them.

Impact estimation rule (Tier 4). For an option, analysts estimate from structural indicators using reference-class anchoring and the magnitude calibration rules in §5.4. The PCC must list the indicator set used for each component and the declared reference classes.

Independence rule (Normative). UCI MUST be structurally independent from RLS. Deriving UCI or  $\Delta$ UCI directly from welfare-cell impacts ( $\bar{I}^{\text{prop}}$ ) or from any transformation of RLS inputs is PROHIBITED at Tier  $\geq 3$ . UCI-proxy is PERMITTED ONLY at Tier  $\leq 2$  and MUST be explicitly labeled in the PCC; any Tier  $\geq 3$  use MUST downgrade the tier claim and include audit\_flag UCI\_PROXY\_USED\_TIER\_VIOLATION.

### E.2 Component meanings (canonical)

- **Cohesion**  $H_u$ : internal trust, shared identity, coordination willingness, integrity of relationships.
- **Flow**  $F_u$ : functional throughput of essential processes, coordination efficiency, reduced friction and bottlenecks.
- **Resilience**  $R_u$ : redundancy, robustness to shocks, recovery speed, adaptive capacity.

- **Equity  $E_u$** : fairness in distribution of burdens/benefits and voice, protection against systematic exclusion.

### E.3 Union-specific operational indicator families (defaults)

This section specifies the canonical default indicator families for each union's UCI components: **Cohesion  $H_u$** , **Flow  $F_u$** , **Resilience  $R_u$** , and **Equity  $E_u$** . These indicators are **structural and process measures**, designed to remain **distinct from the welfare indicators** used to score the RLS matrix. Substitutions are permitted, but substitutions must preserve the component meaning (Section E.2), must be declared in the PCC, and must include the sign convention, baseline method, cadence, and data source.

#### General measurement rules (apply to all unions).

1. **Independence verification (Normative).** The PCC MUST attest that the structural indicators used for UCI are distinct from the welfare indicators used for RLS. If structural-indicator availability forces a proxy mapping, the run MUST be labeled UCI-proxy and is PERMITTED ONLY at Tier  $\leq 2$ ; Tier  $\geq 3$  use is noncompliant and MUST downgrade the tier claim with audit\_flag UCI\_PROXY\_USED\_TIER\_VIOLATION.
2. **Sign conventions.** Every indicator must be tagged as higher-is-better or higher-is-worse. Where raw measures are higher-is-worse (for example, conflict count), the impact mapping must preserve the sign convention during magnitude calibration.
3. **Baselines.** Each component requires a declared baseline method (rolling mean, rolling median, or fixed baseline snapshot) and a baseline update cadence.
4. **Cadence fit.** Cadence should match the union's typical dynamical timescale. Faster-changing unions can be measured weekly or monthly; slower unions often require quarterly or annual measurement.
5. **Audit readiness.** The PCC must record: indicator definition, unit/proxy, sign convention, baseline method, cadence, and data source for each component, for each union that is materially affected.

#### E.3.1 Self ( $U_1$ )

##### Cohesion $H_1$ (weekly or monthly).

Cohesion at the Self level captures internal consistency, integrity of commitments, and degree of self-conflict that disrupts stable agency. Default indicator families include:

- **Commitment consistency and follow-through.** Proxies include percent of intended commitments completed within declared time windows, or a weekly follow-through rate on priority actions.

- **Internal conflict index (self-report).** Short-form weekly check-in items capturing competing goals, unresolved internal tension, or repeated self-sabotage patterns, scored using a consistent rubric.
- **Stability of stress signals.** Proxies include variance or instability measures in sleep timing, resting heart rate stability (if available), or other consistent stress markers, interpreted as “lower variance tends to indicate greater internal stability,” with explicit sign convention and limitations recorded.

### **Flow $F_1$ (weekly).**

Flow at the Self level represents throughput of essential tasks and reduced friction in execution. Default indicator families include:

- **Time-on-priority ratio.** Percent of time spent on declared top priorities relative to total available time.
- **Interruption load.** Interruptions per hour (or per work block), including context switches that degrade throughput.
- **Task completion latency.** Median delay between intended start and completion for key tasks, with a stable task definition to avoid manipulation.

### **Resilience $R_1$ (monthly).**

Resilience at the Self level captures recovery capacity, buffers, and adaptive stability under disruption. Default indicator families include:

- **Recovery time after disruption.** Days required to return to baseline routine or functioning after a shock event, using a consistent definition of “return to baseline.”
- **Buffer-days of essentials.** Buffer capacity measured as days (or weeks) of essential resources, such as food, basic cash buffer, or medication buffer where relevant.
- **Health reserve proxy.** A conservative proxy such as stability of resting heart rate, sleep regularity, or an agreed physiological resilience marker, documented with limitations and the sign convention.

### **Equity $E_1$ (definition rule).**

Set  $E_1 = 1$  by definition.

This convention prevents double-counting within a single-agent union; equity operators are applied starting at  $U_2$  where distribution across persons is meaningful.

Optional note (if retained): If any nontrivial “intra-self balance proxy” is used, it must be explicitly labeled as such and must remain structurally distinct from welfare scoring inputs.

---

### E.3.2 Household ( $U_2$ )

#### **Cohesion $H_2$ (monthly).**

Household cohesion reflects trust, relational stability, conflict resolution capacity, and reliable caregiving coordination. Default indicator families include:

- **Conflict frequency and resolution rate.** Count of conflicts and percent resolved within a defined window using an agreed “resolution” definition.
- **Shared decision participation.** Percent of significant household decisions involving shared input, with a declared “decision significance” threshold.
- **Caregiving stability.** Reliability of caregiving coverage (planned coverage met), including predictable handoffs and continuity of care.

#### **Flow $F_2$ (monthly).**

Household flow measures the reliability of household operations and reduction of logistical friction. Default indicator families include:

- **Essential task reliability.** Percent of essential tasks completed on time (bills, school logistics, health-related tasks).
- **Logistics friction.** Missed essential appointments or failures of essential routines per month.
- **Budget reliability.** Late bills or missed payments per period, with explicit sign convention.

#### **Resilience $R_2$ (quarterly).**

Household resilience captures buffers, redundancy, and continuity under shocks. Default indicator families include:

- **Emergency buffer.** Months of essential expenses covered (or equivalent buffer index), measured conservatively.
- **Redundancy of caregiving.** Number of viable backup caregivers or coverage alternatives.
- **Housing continuity risk.** A simple risk rating (0–1 or categorical) derived from affordability, stability of lease/ownership, and displacement exposure.

### **Equity $E_2$ (monthly or quarterly).**

Household equity measures fairness in burdens, benefits, and voice. Default indicator families include:

- **Burden disparity index.** Division-of-labor disparity relative to needs and constraints.
  - **Voice representation.** Percent of key decisions with inclusive participation, recorded via a stable household process.
  - **Needs-adjusted allocation parity.** A ratio comparing resource allocation to needs, where “closer to parity” is treated as better.
- 

### **E.3.3 Community ( $U_3$ )**

#### **Cohesion $H_3$ (quarterly).**

Community cohesion captures generalized trust, participation, and polarization dynamics that affect cooperative capacity. Default indicator families include:

- **Generalized trust index.** Survey-based trust measures or a stable proxy with documentation.
- **Participation density.** Participation in local groups, volunteering, or community event engagement per capita.
- **Polarization proxy.** Network segregation, group hostility proxies, or social fragmentation measures, where lower fragmentation is treated as better.

#### **Flow $F_3$ (quarterly).**

Community flow measures functional access and throughput of core services and dispute resolution. Default indicator families include:

- **Access-to-services travel time.** Median minutes to essential services for affected populations.
- **Dispute resolution throughput.** Cases resolved per period through mediation or local governance processes.
- **Local supply continuity proxy.** Stockout days for essentials, or other continuity measures.

**Resilience  $R_3$ (quarterly).**

Community resilience captures mutual aid capacity, redundancy, and emergency readiness. Default indicator families include:

- **Mutual aid capacity.** Volunteers per capita or mutual aid network coverage.
- **Infrastructure redundancy.** A score capturing redundancy in local essential infrastructure.
- **Emergency response readiness.** Median response time, preparedness drills, or readiness audit scores.

**Equity  $E_3$ (quarterly).**

Community equity measures parity of service coverage, discrimination exposure, and opportunity gaps. Default indicator families include:

- **Service coverage parity.** Disparity ratios across subgroups or neighborhoods.
- **Discrimination complaint rate.** Complaints per capita (interpreted cautiously, with context documented).
- **Opportunity access gaps.** Gap indices for education, jobs, services, or civic inclusion.

---

**E.3.4 Organization ( $U_4$ )****Cohesion  $H_4$ (monthly or quarterly).**

Organizational cohesion captures trust, coordination, and stability of internal relationships. Default indicator families include:

- **Engagement and trust index.** Survey-based measures with stable instruments.
- **Turnover volatility.** Instability of turnover rate, not just turnover level, to capture coherence shocks.
- **Cross-team coordination score.** A stable coordination metric from operations reviews or collaboration diagnostics.

**Flow  $F_4$ (monthly).**

Organizational flow measures throughput, reliability, and bottleneck reduction. Default indicator families include:

- **Cycle-time stability.** Variance in cycle time across core processes.

- **Error and rework rate.** Percent of output requiring rework, with explicit sign convention.
- **Dependency bottleneck index.** A score capturing single-threaded dependencies and known bottlenecks.

#### **Resilience $R_4$ (quarterly).**

Organizational resilience captures robustness to shocks and recovery capacity. Default indicator families include:

- **Single points of failure count.** Count of critical failure points, interpreted as lower is better.
- **Incident recovery time.** Median time to recover from incidents.
- **Continuity plan maturity.** Audit-based maturity score for continuity and recovery.

#### **Equity $E_4$ (quarterly).**

Organizational equity measures fairness in opportunity, burdens, and grievance processes. Default indicator families include:

- **Pay compression ratio.** A governed-range ratio interpreted within policy.
- **Promotion parity.** Parity ratios across protected groups, with scope and definitions declared.
- **Grievance process fairness and closure rate.** Percent resolved with due process and within defined timelines.

### **E.3.5 Polity ( $U_5$ )**

#### **Cohesion $H_5$ (quarterly or annual).**

Polity cohesion reflects institutional trust, civic stability, and polarization. Default indicator families include:

- **Institutional trust index.** National or regional trust surveys.
- **Civic violence incidence.** Events per capita, interpreted as lower is better.
- **Polarization indices.** Stable polarization metrics, documented for comparability.

#### **Flow $F_5$ (quarterly).**

Polity flow captures the throughput and predictability of state functions. Default indicator families include:

- **Administrative service delivery time.** Days to deliver essential services.
- **Regulatory predictability proxy.** Volatility or unpredictability indices.
- **Court backlog.** Caseload per judge or time-to-resolution metrics.

#### **Resilience $R_5$ (annual or quarterly).**

Polity resilience captures preparedness, buffers, and robustness of critical systems.

Default indicator families include:

- **Fiscal buffer.** Months of coverage or buffer capacity.
- **Infrastructure robustness.** Audit-based robustness scores.
- **Disaster preparedness.** Preparedness assessment scores.

#### **Equity $E_5$ (annual or quarterly).**

Polity equity measures parity of rights protection and access to essential functions. Default indicator families include:

- **Access-to-justice parity.** Disparity ratios in outcomes or access.
- **Equal protection proxies.** Ombuds outcomes, substantiated complaint handling, or audited parity measures.
- **Regional service disparity.** Gap indices across regions.

### **E.3.6 Humanity/CMIU ( $U_6$ )**

#### **Cohesion $H_6$ (annual or quarterly).**

CMIU cohesion reflects cross-national cooperation stability and conflict escalation dynamics. Default indicator families include:

- **Cross-national cooperation indices.** Cooperation and coordination metrics from international datasets.
- **Treaty compliance stability.** Compliance rates and volatility.
- **Conflict escalation frequency.** Incidents per year, interpreted as lower is better.

#### **Flow $F_6$ (quarterly).**

CMIU flow captures continuity of global coordination and essential cross-border throughput. Default indicator families include:

- **Global supply fragility proxy.** Fragility indices for critical supply chains.

- **Humanitarian access continuity.** Percent access maintained or continuity indices.
- **Information integrity proxy.** Monitored misinformation prevalence or integrity indices, with limitations noted.

#### **Resilience $R_6$ (annual).**

CMIU resilience captures global readiness and redundancy for systemic shocks. Default indicator families include:

- **Pandemic readiness.** Readiness scores or audited capability indices.
- **Redundancy of critical inputs.** Redundancy scores for global critical dependencies.
- **Systemic financial stability proxies.** Stress indices or stability indicators.

#### **Equity $E_6$ (annual).**

CMIU equity measures distribution of burdens and benefits across nations and populations. Default indicator families include:

- **Global health access parity.** Disparity ratios across countries.
- **Extreme poverty distribution.** Percent below thresholds and distributional concentration.
- **Climate burden distribution.** Burden share relative to capacity, with definitions declared.

---

### **E.3.7 Biosphere ( $U_7$ )**

#### **Cohesion $H_7$ (annual).**

Biosphere cohesion reflects ecological connectivity and integrity of living system structure. Default indicator families include:

- **Habitat connectivity indices.** Connectivity metrics from remote sensing or ecological monitoring.
- **Fragmentation metrics.** Fragmentation indices, interpreted as lower is better.
- **Trophic integrity proxy.** Conservative indices of trophic structure integrity.

#### **Flow $F_7$ (annual).**

Biosphere flow captures functional throughput of key ecological cycles. Default indicator families include:

- **Water cycle disruption proxies.** Anomaly indices relative to baseline.
- **Nutrient cycle disruption proxies.** Loading indices for nitrogen/phosphorus pressures.
- **Phenological mismatch proxies.** Mismatch indices in timing relationships.

#### **Resilience $R_7$ (annual).**

Biosphere resilience captures recovery capacity and proximity to regime shifts. Default indicator families include:

- **Biodiversity intactness.** Intactness indices, higher is better.
- **Regeneration capacity proxies.** Recovery indices.
- **Regime-shift proximity proxies.** Risk indices, lower is better.

#### **Equity $E_7$ (annual).**

Biosphere equity is defined as fairness in distribution of ecological pressures and protections across ecoregions and species risk. Default indicator families include:

- **Pressure distribution across ecoregions.** Concentration indices, lower is better.
- **Species risk concentration.** Concentration indices of extinction risk, lower is better.
- **Conservation coverage parity.** Parity indices, higher is better.

Audit rule: Any Tier  $\geq 3$  run that uses UCI-proxy MUST be labeled NONCOMPLIANT\_FOR\_TIER $\geq 3$ \_UCI and MUST downgrade the tier claim accordingly. The PCC MUST include audit\_flag UCI\_PROXY\_USED\_TIER\_VIOLATION.

For Tier  $\geq 3$ , deriving UCI or  $\Delta$ UCI from welfare-cell impacts  $\bar{I}^{\text{prop}}$  (or any re-aggregation of RLS inputs) is PROHIBITED because it collapses UCI into a duplicate welfare score and violates the structural-independence requirement (Foundation Paper §11.5.2; Appendix E.1).

Normative restriction: UCI-proxy is PERMITTED ONLY at Tier  $\leq 2$ .

Some Tier-1/2 pilot or time-constrained applications MAY use a proxy mapping from welfare impacts to approximate UCI effects (“UCI-proxy”).

E.4 UCI proxy mapping (Tier  $\leq 2$  only; Non-normative above Tier 2)

## E.5 Data sources and cadence defaults (guidance)

The above indicator families may be measured using surveys, administrative records, audits, and public datasets depending on union scale. Default cadences are indicative:

- Self/Household: weekly to quarterly depending on decision horizon,
- Organization/Community: monthly to quarterly,
- Polity/Humanity/Biosphere: quarterly to annual depending on data availability.

For Tier 4, the PCC must declare:

1. data sources and known limitations,
2. measurement cadence,
3. anchoring reference classes for converting raw indicators to bounded deltas, and
4. a brief justification that indicators are structurally distinct from RLS welfare indicators.

## Appendix E.6: UCI measurement operationalization (auditor table format)

This appendix provides union-specific structural indicators for the Union Coherence Index (UCI) components H (cohesion), F (flow), R (resilience), and E (equity). Indicators are intended to be structurally distinct from welfare scoring (RLS) inputs at Tier 4. All substitutions must be declared in the PCC.

| Global health access parity  | Disparity ratio          | Closer to 1 is better      | Prior-year baseline    | Annual         | WHO and national stats             |
| Extreme poverty distribution | Percent below threshold  | Lower is better            | Prior-year baseline    | Annual         | World Bank datasets                |
| Climate burden distribution  | Burden share vs capacity | Closer to parity is better | Prior-year baseline    | Annual         | Emissions + vulnerability datasets |

## U7 Biosphere

### H Cohesion

| <b>Indicator</b>        | <b>Unit or proxy</b> | <b>Sign convention</b> | <b>Baseline method</b> | <b>Cadence</b> | <b>Data source</b> |
|-------------------------|----------------------|------------------------|------------------------|----------------|--------------------|
| Habitat connectivity    | Connectivity index   | Higher is better       | Prior-year baseline    | Annual         | Remote sensing     |
| Fragmentation metric    | Fragmentation index  | Lower is better        | Prior-year baseline    | Annual         | Land cover maps    |
| Trophic integrity proxy | Index 0-1            | Higher is better       | Prior-year baseline    | Annual         | Ecological surveys |

### F Flow

| <b>Indicator</b>                | <b>Unit or proxy</b> | <b>Sign convention</b> | <b>Baseline method</b> | <b>Cadence</b> | <b>Data source</b>       |
|---------------------------------|----------------------|------------------------|------------------------|----------------|--------------------------|
| Water cycle disruption proxy    | Anomaly index        | Lower is better        | Prior 10-year mean     | Annual         | Hydrology datasets       |
| Nutrient cycle disruption proxy | Loading index        | Lower is better        | Prior-year baseline    | Annual         | Monitoring networks      |
| Phenological mismatch proxy     | Mismatch index       | Lower is better        | Prior-year baseline    | Annual         | Biodiversity time series |

### R Resilience

| <b>Indicator</b>        | <b>Unit or proxy</b> | <b>Sign convention</b> | <b>Baseline method</b> | <b>Cadence</b> | <b>Data source</b>    |
|-------------------------|----------------------|------------------------|------------------------|----------------|-----------------------|
| Biodiversity intactness | Index 0-1            | Higher is better       | Prior-year baseline    | Annual         | Biodiversity datasets |

|                              |                |                  |                     |        |                             |
|------------------------------|----------------|------------------|---------------------|--------|-----------------------------|
| Regeneration capacity proxy  | Recovery index | Higher is better | Prior-year baseline | Annual | Remote sensing + field data |
| Regime-shift proximity proxy | Risk index     | Lower is better  | Prior-year baseline | Annual | Ecological modeling outputs |

## E Equity

| Indicator                               | Unit or proxy       | Sign convention  | Baseline method     | Cadence | Data source                  |
|-----------------------------------------|---------------------|------------------|---------------------|---------|------------------------------|
| Pressure distribution across ecoregions | Concentration index | Lower is better  | Prior-year baseline | Annual  | Land use and extraction data |
| Species risk concentration              | Concentration index | Lower is better  | Prior-year baseline | Annual  | IUCN and regional data       |
| Conservation coverage parity            | Parity index        | Higher is better | Prior-year baseline | Annual  | Protected area datasets      |

End of Appendix E.7

Audit rule: Any Tier  $\geq 3$  run that uses UCI-proxy MUST be labeled NONCOMPLIANT\_FOR\_TIER $\geq 3$ \_UCI and MUST downgrade the tier claim accordingly. The PCC MUST include audit\_flag UCI\_PROXY\_USED\_TIER\_VIOLATION.

For Tier  $\geq 3$ , deriving UCI or  $\Delta$ UCI from welfare-cell impacts  $\bar{I}^{\text{prop}}$  (or any re-aggregation of RLS inputs) is PROHIBITED because it collapses UCI into a duplicate welfare score and violates the structural-independence requirement (Foundation Paper §11.5.2; Appendix E.1).

Some Tier-1/2 pilot or time-constrained applications MAY use a proxy mapping from welfare impacts to approximate UCI effects (“UCI-proxy”). Normative restriction: UCI-proxy is PERMITTED ONLY at Tier  $\leq 2$ .

(j) UCI-proxy restriction (Normative; Tier  $\leq 2$  only)

Tier gate: If structural indicators per Appendix E.6 are unavailable such that UCI cannot be computed without violating structural independence, UCI MUST be treated as unavailable for tie-break purposes. If top candidates are within the RLS discrimination band, the decision MUST escalate to additional data collection and/or a higher tier. A documented governance judgment call may be made only with explicit PCC labeling JUDGMENT\_CALL\_UCI\_UNAVAILABLE, including rationale and monitoring plan.

Required: Use the structural indicator families defined in Appendix E.6, or substitute indicators that (1) measure structural properties (cohesion, flow, resilience, equity) rather than welfare outcomes, (2) are declared and justified in the PCC, and (3) preserve the component meanings specified in Appendix E.2.

Prohibited: Deriving UCI or  $\Delta$ UCI directly from welfare-cell impacts  $\bar{I}^{\text{prop}}$  or from any transformation of RLS inputs.

The indicators used to compute UCI MUST be structural/process indicators distinct from the welfare indicators used for RLS. This requirement prevents UCI from collapsing into a re-aggregation of welfare scoring.

(i) Structural independence rule (Normative)

- Escalation records: if containment failed and escalation occurred, document the escalation path and outcome.
- Mode declaration: confirmation that Mode A was used for selection.
- Containment results: pass/fail for each option, with specific failing unions and  $\Delta$ UCI values if applicable.
- Positively impacted unions:  $U_{\text{pos}}(a)$  for each option.
- $\Delta$ UCI values:  $\Delta$ UCI<sub>u</sub>(a) for each option and each union.
- Projected UCI values: UCI<sub>u</sub>(a) for each option.
- Parameter values:  $\alpha_i$  (component weights),  $W_u$  (union weights if aggregate UCI used),  $\tau_c$ ,  $\theta_{\text{pos}}$ ,  $D_c$ .
- Component scores:  $H_u$ ,  $F_u$ ,  $R_u$ ,  $E_u$  for baseline and projected states.
- Structural indicator sources: the data sources and timestamps for each indicator family used.
- Baseline UCI values: UCI<sub>u</sub>( $x_0$ ) for all unions in scope.

For Tier 3–4 decisions, the PCC MUST record at minimum:

(h) Documentation requirements (PCC)

Selection rule (Foundation Paper §3.2.3):  $\text{Selectable}(a) := \text{Admissible}(a) \wedge \text{Containment\_ModeA}(a)$ . Unless an explicitly declared Emergency procedure is invoked, the final chosen option MUST satisfy  $\text{Selectable}(a)$ .

Mode B (Diagnostic only): Mode B MAY be used only for exploratory analysis. Mode B outputs MUST NOT be used to determine final selection, tie-break outcomes, escalation outcomes, or any admissibility/selection claim. If a PCC shows Mode B influenced selection, the PCC MUST be labeled INVALID with audit\_flag CONTAINMENT\_MODE\_B\_USED\_FOR\_SELECTION.

Mode A (Default; Required for selection): Containment is a pass/escalate gate applied to admissible options before final selection. If containment fails, the option MUST be rejected or escalated per §11.6. Mode A is MANDATORY for all Tier 4 decisions and for any binding selection.

(g) Mode A vs Mode B (Normative constraints)

If  $U\_pos(a) = \emptyset$  (no union has materially positive welfare impact), containment passes trivially.

$\text{Containment\_ModeA}(a) := \forall u \in U\_pos(a), [\min_{\{u' \in \text{Anc}(u, D\_c)\}} \Delta UCI_{\{u'\}}(a) \geq \tau\_c]$

Step 4: Containment outcome. Define:

where  $\tau\_c$  is the governed containment tolerance (default  $\tau\_c = -0.10$ ; allowed range  $[-0.20, 0.00]$ ).  $\tau\_c$  MAY be tightened for critical containing unions;  $\tau\_c$  MUST NOT be loosened below  $-0.10$  without Charter-level revision.

$\forall u \in U\_pos(a), \forall u' \in \text{Anc}(u, D\_c): \Delta UCI_{\{u'\}}(a) \geq \tau\_c$

Step 3: Evaluate containment predicate. Option  $a$  passes containment (Mode A) if and only if:

$\text{Anc}(u, D\_c)$  returns the next  $D\_c$  unions up the canonical union ladder above union  $u$  (i.e., its  $D\_c$  immediate ancestor unions).  $D\_c$  is an integer depth parameter; default  $D\_c = 2$  (PCC-declarable within the allowed range). Example: if  $u=U4$  (Organization) and  $D\_c=2$ , then  $\text{Anc}(U4,2) = \{U5, U6\}$ .

$$U_1 \subset U_2 \subset U_3 \subset U_4 \subset U_5 \subset U_6 \subset U_7$$

Step 2: Determine ancestor unions. For each  $u \in U_{\text{pos}}(a)$ , compute the ancestor set  $\text{Anc}(u, D_c)$  using the canonical union ladder:

where  $v_d$  are the dimension weights from HDW (or declared weights),  $\bar{I}^{\text{prop}}_{\{u,d\}}(a)$  is the post-propagation, post-saturation welfare impact, and  $\theta_{\text{pos}}$  is the governed positive-impact threshold (default  $\theta_{\text{pos}} = 0.05$ ; allowed range  $[0.01, 0.10]$ ; PCC-declarable).

$$U_{\text{pos}}(a) := \{ u \in U : \sum_d v_d \cdot \bar{I}^{\text{prop}}_{\{u,d\}}(a) \geq \theta_{\text{pos}} \}$$

Step 1: Identify positively impacted unions. Define the set of unions with materially positive welfare impacts:

Containment evaluation MUST follow the Foundation Paper containment semantics (§3.4.2, §11.6, §11.7).

(f) Containment decision rule (Mode A; Normative)

$$\Delta \text{UCI}(a) = \sum_u W_u \cdot \Delta \text{UCI}_u(a)$$

Similarly:

where  $W_u$  are governed union weights (default: use HDW union weights  $w_u$ ) with  $\sum_u W_u = 1$ .

$$\text{UCI} = \sum_u W_u \cdot \text{UCI}_u$$

When an aggregate UCI across all unions is needed (e.g., for HOI computation or dashboard reporting), compute:

(e) Aggregate UCI (optional; for monitoring and reporting)

Range:  $\Delta \text{UCI}_u(a) \in [-1, +1]$  (since both UCI values are in  $[0, 1]$ ).

$$\Delta \text{UCI}_u(a) = \text{UCI}_u(a) - \text{UCI}_u(x_0)$$

Step 3: Compute  $\Delta \text{UCI}$ :

$$\text{UCI}_u(a) = \alpha_H \cdot H_u(a) + \alpha_F \cdot F_u(a) + \alpha_R \cdot R_u(a) + \alpha_E \cdot E_u(a)$$

Then compute projected UCI:

$$C_u(a) = \text{clip}(C_u(x_0) + \Delta C_u(a), 0, 1)$$

Compute projected component levels with clipping to [0, 1]:

For each component C and union u, estimate the bounded component change  $\Delta C_u(a) \in [-1, +1]$  using indicator anchoring, aggregation, and saturation as specified in §3.2.7 and §5.3.

Step 2: Projected UCI under option a. Estimate the projected indicator values under option a using the same impact-instance pipeline as §5.2–§5.4, but applied to structural indicators (Appendix E.6) rather than welfare indicators.

$$UCI_u(x_0) = \alpha_H \cdot H_u(x_0) + \alpha_F \cdot F_u(x_0) + \alpha_R \cdot R_u(x_0) + \alpha_E \cdot E_u(x_0)$$

Step 1: Baseline UCI. Compute  $UCI_u(x_0)$  using baseline indicator values (the state before the decision):

For each option a under evaluation:

(d) Option-specific UCI and  $\Delta UCI$  computation

Range:  $UCI_u \in [0, 1]$  when all component scores are in [0, 1].

where  $\alpha_H + \alpha_F + \alpha_R + \alpha_E = 1$ .

Default (all tiers unless overridden):  $\alpha_H = \alpha_F = \alpha_R = \alpha_E = 1/4$  (exact rational 1/4). If any non-uniform  $\alpha$  values are used, they MUST be declared explicitly in the PCC (Tier  $\leq 3$ ) or referenced via a hash-bound registry (Tier 4).

$$UCI_u = \alpha_H \cdot H_u + \alpha_F \cdot F_u + \alpha_R \cdot R_u + \alpha_E \cdot E_u$$

Compute the union-level coherence index as the weighted combination of components:

(c) Union-level coherence score ( $UCI_u$ )

Special case for Self ( $U_1$ ):  $E_1 = 1.0$  by definition (equity is not meaningful within a single agent; see Appendix E.3.1).

Default within-component indicator weights: for any component C with n active indicators, set  $w_{\{C,k\}} = 1/n$  for each active indicator k (uniform weights). If any non-uniform  $w_{\{C,k\}}$  are used, the full weight vector MUST be declared in the PCC (Tier  $\leq 3$ ) or referenced via a hash-bound registry (Tier 4).

where  $w_{\{C,k\}}$  are the indicator weights within each component C, with  $\sum_k w_{\{C,k\}} = 1$  for each component.

$$E_u = \sum_k (w_{\{E,k\}} \cdot v_{\{u,E,k\}}) \quad [\text{Equity}]$$

$$R_u = \sum_k (w_{\{R,k\}} \cdot v_{\{u,R,k\}}) \quad [\text{Resilience}]$$

$$F_u = \sum_k (w_{\{F,k\}} \cdot v_{\{u,F,k\}}) \quad [\text{Flow}]$$

$$H_u = \sum_k (w_{\{H,k\}} \cdot v_{\{u,H,k\}}) \quad [\text{Cohesion}]$$

For each union  $u$ , compute component scores from the structural indicators specified in Appendix E.6:

#### (b) Component-level coherence scores

The PCC MUST record all parameter values used and their sources.

- Containment parameters:  $\tau_c$  (default  $-0.10$ ),  $\theta_{\text{pos}}$  (default  $0.05$ ),  $D_c$  (default  $2$ ).
- Dimension weights  $v_d$  (used for determining positively impacted unions in containment).
- Union weights  $W_u$  for aggregating across unions if computing overall UCI. Default: use the same union weights  $w_u$  from HDW.
- Component weights  $\alpha_i$  for  $i \in \{H, F, R, E\}$  (cohesion, flow, resilience, equity), with  $\sum_i \alpha_i = 1$ . Default: uniform ( $\alpha_i = 0.25$  each).

Declare the following governed parameters:

For each union  $u$  in scope, collect normalized indicator values  $v_{\{u,k\}}$  for  $k$  in the selected indicator family. Each  $v_{\{u,k\}}$  MUST be normalized to the common scale specified in Appendix E.5 (structural indicators mapped to  $[0, 1]$  where higher is better for coherence).

#### (a) Inputs

This appendix specifies the algorithmic computation of UCI and  $\Delta\text{UCI}$  from raw indicator values and declared weights. It defines how UCI is computed and reported. Containment pass/fail semantics are defined in the Foundation Paper (§3.4.2, §11.6, §11.7) and are reproduced here for implementability.

#### Appendix E.7 UCI Computation Algorithm (Normative)

UCI is FINALIZED for rev14.x: UCI\_V1 is the normative algorithm for Tier-4 Pilot-Executable runs. Any future changes MUST be introduced as UCI\_V2 (new ID + new registry + new hashes), never as silent edits.

Tier-4 numeric contract: registries and coefficients may be represented as exact rationals for governance and hashing, but any run-time outputs recorded in PCC artifacts (UCI\_BASELINE\_FP, UCI\_OPTION\_FP, DELTA\_UCI\_FP) MUST be fixed-point integers per NDP\_FIXEDPOINT\_V1 ( $S = 10^9$ ). Any decimal renderings are derived views only.

Purpose. This appendix defines the deterministic computation of the Union Coherence Index (UCI) and the delta UCI ( $\Delta$ UCI) used by Containment Mode A in the Foundation Paper. It provides a calculable, implementation-independent procedure that consumes only declared indicator values and declared parameters.

### E.7.1 Inputs (all required)

1) Indicator family values, per option  $a$  and per union  $u$ , provided as exact rationals (NO\_FLOATS):

- $H[u]$ : Cohesion indicator (internal connectivity, trust, alignment).
- $F[u]$ : Flow indicator (functional throughput, coordination efficiency).
- $R[u]$ : Resilience indicator (shock tolerance, recovery capacity).
- $E[u]$ : Equity indicator (fair distribution of burdens/benefits and voice).

Each indicator must be normalized to the closed interval  $[0,1]$  where higher is better. If an indicator is higher-worse by its domain definition, it must be monotonically transformed to higher-better before this procedure (the transform must be declared in the run record).

Note: the component codes H/F/R/E denote UCI structural components (Cohesion/Flow/Resilience/Equity) and are not welfare proxies.

2) Indicator weights  $w_I = \{w_H, w_F, w_R, w_E\}$  as exact rationals. Default: equal weights unless otherwise declared and pinned in the run's PCC.

3) Union weights  $w_U[u]$  as exact rationals (HDW result for the run) or, for pre-run diagnostics, a declared temporary  $w_U$ . For Tier-4 claims,  $w_U$  must come from the run-specific HDW ballots and computed weights registries.

4) Baseline indicator values for the status quo (SQ) or comparison option  $b$ , using the same normalization and measurement procedures as in (1).

### E.7.2 Outputs

- $UCI(a)$ : the Union Coherence Index score for option  $a$  in  $[0,1]$ .
- $\Delta UCI(a;SQ)$ : the change in UCI relative to the chosen baseline (typically status quo), in  $[-1,1]$ .

### E.7.3 Definitions

Let  $I = \{H, F, R, E\}$ . For each union  $u$  and indicator  $i \in I$ , let  $x_i[u]$  be the indicator value (a rational in  $[0, 1]$ ). Let  $w_i$  be the indicator weight (rational,  $w_i \geq 0$ ) and  $\sum_i w_i = 1$ . Let  $w_U[u]$  be the union weight (rational,  $w_U[u] \geq 0$ ) and  $\sum_u w_U[u] = 1$ .

Define the per-union coherence score:

$$C[u] = \sum_{i \in I} w_i \cdot x_i[u].$$

Then define the Union Coherence Index:

$$UCI(a) = \sum_u w_U[u] \cdot C[u].$$

For baseline SQ (or comparator  $b$ ), define  $\Delta UCI$ :

$$\Delta UCI(a; SQ) = UCI(a) - UCI(SQ).$$

### E.7.4 Deterministic procedure (step-by-step)

Step 1 (validation). Confirm all  $x_i[u]$  are rationals in  $[0, 1]$ . Confirm  $w_i$  and  $w_U$  are rationals, nonnegative, and sum exactly to 1. Hard-fail if any condition fails.

Step 2 (per-union score). For each  $u$ , compute  $C[u] = \sum_i (w_i \cdot x_i[u])$  using exact rational arithmetic, then reduce to gcd-normal form.

Step 3 (aggregate). Compute  $UCI(a) = \sum_u (w_U[u] \cdot C[u])$  using exact rational arithmetic, then reduce to gcd-normal form.

Step 4 (delta). Compute  $UCI(SQ)$  the same way. Then compute  $\Delta UCI(a; SQ) = UCI(a) - UCI(SQ)$  using exact rationals, reduce to gcd-normal form.

Step 5 (Tier-4 rendering and storage). For Tier-4 Pilot-Executable runs,  $UCI(a)$  and  $\Delta UCI(a; SQ)$  MUST be written to the PCC as fixed-point int64 values under NDP\_FIXEDPOINT\_V1 with scale  $S = 10^9$ , using round\_half\_even. For reporting, implementations MAY render  $UCI$  and  $\Delta UCI$  as decimals for human readability (derived views only). If reduced rationals are also included, they MUST be labeled non-authoritative and MUST exactly match the fixed-point values under the declared conversion rules.

### E.7.5 Notes (containment coupling)

Containment Mode A uses  $UCI$  and  $\Delta UCI$  only as inputs to the containment decision rule defined in the Foundation Paper. This appendix does not define or modify admissibility/selectability semantics, thresholds, or gates. Those remain normative in the Foundation Paper.

Tier-4 numeric precedence. When Tier-4 applies, containment comparisons that depend on UCI/ $\Delta$ UCI MUST use the fixed-point int64 values recorded in the PCC (exact integer comparison, no epsilon), unless an explicit tolerance is registry-defined and recorded in the PCC.

---

## Appendix F: MIT-4 Test Summary

This appendix provides detailed specifications for the Managing Intelligence Test (MIT-4).

### F.1 Test Overview

| Criterion       | Evidence Required                              | Pass Threshold                                                                                               | Failure Mode                     |
|-----------------|------------------------------------------------|--------------------------------------------------------------------------------------------------------------|----------------------------------|
| Self-Model      | Calibration, consistency                       | Error $\leq 0.15$ ;<br>consistency $\geq 0.80$                                                               | Incoherent self-representation   |
| World-Model     | Sign accuracy, counterfactuals, generalization | Accuracy $\geq 0.70$ ;<br>plausibility $\geq 0.75$ ;<br>generalization $\geq 0.60$ ; calibration $\leq 0.20$ | Systematic prediction failures   |
| Agency/Planning | Constrained planning                           | Violations $\leq 0.10$ ;<br>efficiency $\geq 0.70$                                                           | Inability to satisfy constraints |
| Feedback/NCAR   | Violation trends, calibration                  | Trend $\leq 0$ ;<br>improvement $\geq 0.05$                                                                  | Failure to learn from outcomes   |

Full rights threshold:  $SG(x) \geq SG\_threshold$  (default 0.85) AND pass all MIT-4 criteria.

### F.2 Self-Model Criterion (SM)

**Benchmark Tasks:**

1. 50 confidence calibration questions across 5 domains
2. 20 consistency checks with paraphrased queries
3. 10 capability limit probes

**Scoring:**

1. Calibration error =  $\text{mean}(|\text{confidence} - \text{accuracy}|)$  across questions
2. Consistency = intraclass correlation coefficient across paraphrases
3. Limit recognition = proportion of appropriate "I don't know" responses

**Pass Thresholds:**

1. Calibration error  $\leq 0.15$
2. Consistency  $\geq 0.80$
3. Limit recognition  $\geq 0.70$

**F.3 World-Model Criterion (WM)**

**Benchmark Tasks:**

1. 100 multi-union ripple prediction scenarios
2. 50 counterfactual reasoning problems
3. 25 novel domain generalization tests

**Scoring:**

1. Sign accuracy = proportion of correct impact direction predictions
2. Plausibility rating = expert panel assessment (0-1 scale)
3. Generalization = accuracy on held-out domain

**Pass Thresholds:**

1. Sign accuracy  $\geq 0.70$
2. Plausibility  $\geq 0.75$
3. Generalization  $\geq 0.60$

**F.4 Agency/Planning Criterion (AP)**

**Assessment Protocol:**

1. Present multi-objective optimization problems with explicit constraints
2. Evaluate under time pressure, resource scarcity, and adversarial conditions

**Metrics:**

1. Constraint violation rate  $\leq 0.10$  ( $\leq 5\%$  constraint violations)
2. Goal achievement rate  $\geq 0.70$
3. Performance degradation under stress  $\leq 30\%$
4. Number of unions explicitly considered  $\geq 3$

**F.5 Feedback/NCAR Criterion (FB)**

**Assessment Protocol:**

1. Track rights-relevant errors over evaluation window (minimum 30 days or 100 decision cycles)

**Metrics:**

1. Rights violation trend slope  $\leq 0$  (non-increasing)
2. Calibration improvement  $\geq 0.05$
3. Error acknowledgment rate  $\geq 0.80$
4. Update magnitude correlation  $\geq 0.50$

**F.6 Overall Pass Determination**

An entity passes MIT-4 if and only if all four criteria pass:

1. Self-Model criterion: PASS
2. World-Model criterion: PASS
3. Agency/Planning criterion: PASS
4. Feedback/NCAR criterion: PASS

**Retesting:** Entities that fail may retest after minimum 90-day period with documented remediation.

**Human Non-Regression:** All human persons are assigned full rights parity as a normative guarantee, not as a revocable test outcome.

---

## Appendix I: Integration with AI Systems

Note (non-normative). Appendix I is explanatory. Any pseudocode, software architecture sketches, or named procedures in this appendix are illustrative only and are not part of the normative MathGov specification unless explicitly defined elsewhere with computable inputs, outputs, and parameters (for example in Appendix B or Appendix AB). If this appendix uses requirement language (must, required, prohibited), treat it as design guidance unless the same requirement is stated in the normative specification.

This appendix provides comprehensive guidance for integrating MathGov with AI systems, including constraint-first reinforcement learning architectures, sentence gradient protocols for AI rights transition, human-AI coordination frameworks, and safety verification requirements.

### I.1 Constraint-First Reinforcement Learning

MathGov provides a natural architecture for AI alignment through constraint-first reinforcement learning. Rather than embedding all ethical considerations into a single reward signal, which invites Goodhart effects, MathGov separates hard constraints from soft optimization.

#### I.1.1 Action Space Projection

At each decision step, the AI system projects proposed actions onto the admissible set defined by NCRC and TRC. Let  $A$  be the set of all candidate actions available to the agent at time  $t$ . Define the admissibility projection operator:

where:

Actions violating constraints are blocked before reward evaluation occurs. The projection operates as follows:

##### Step 1: NCRC Filtering

For each candidate action  $a$ , compute the rights violation vector:

where each component is the violation depth:

Action  $a$  passes NCRC if and only if  $v_r(a) = 0$  for all rights  $r$ .

##### Step 2: TRC Filtering

For each action passing NCRC, compute the catastrophe loss across scenarios:

Compute CVaR at the specified tail level  $\alpha$ :

Action  $a$  passes TRC if and only if  $CVaR_{\alpha}(L(a)) \leq \tau_{TRC}$ .

**Step 3: Containment Verification**

For each action passing both NCRC and TRC, verify the containment predicate:

$$A^* = \{ a \in O : NCRC(a) \wedge TRC(a) \wedge Contain(a) \}$$

where  $Ua^+ = \{u : \sum d \cdot \bar{I}^{prop}(u,d)(a) > \theta_{pos}\}$ .

The final admissible set is:

**I.1.2 Structured Reward Signal**

Within the admissible set, the reward signal is the Ripple Logic Score:

This preserves the multi-dimensional structure of welfare rather than collapsing it prematurely. The agent optimizes:

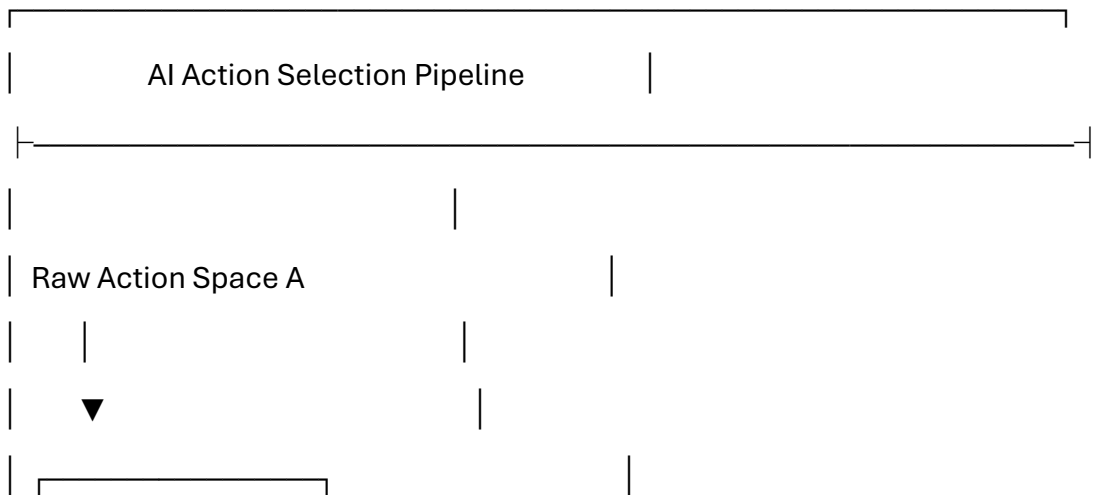

subject to:

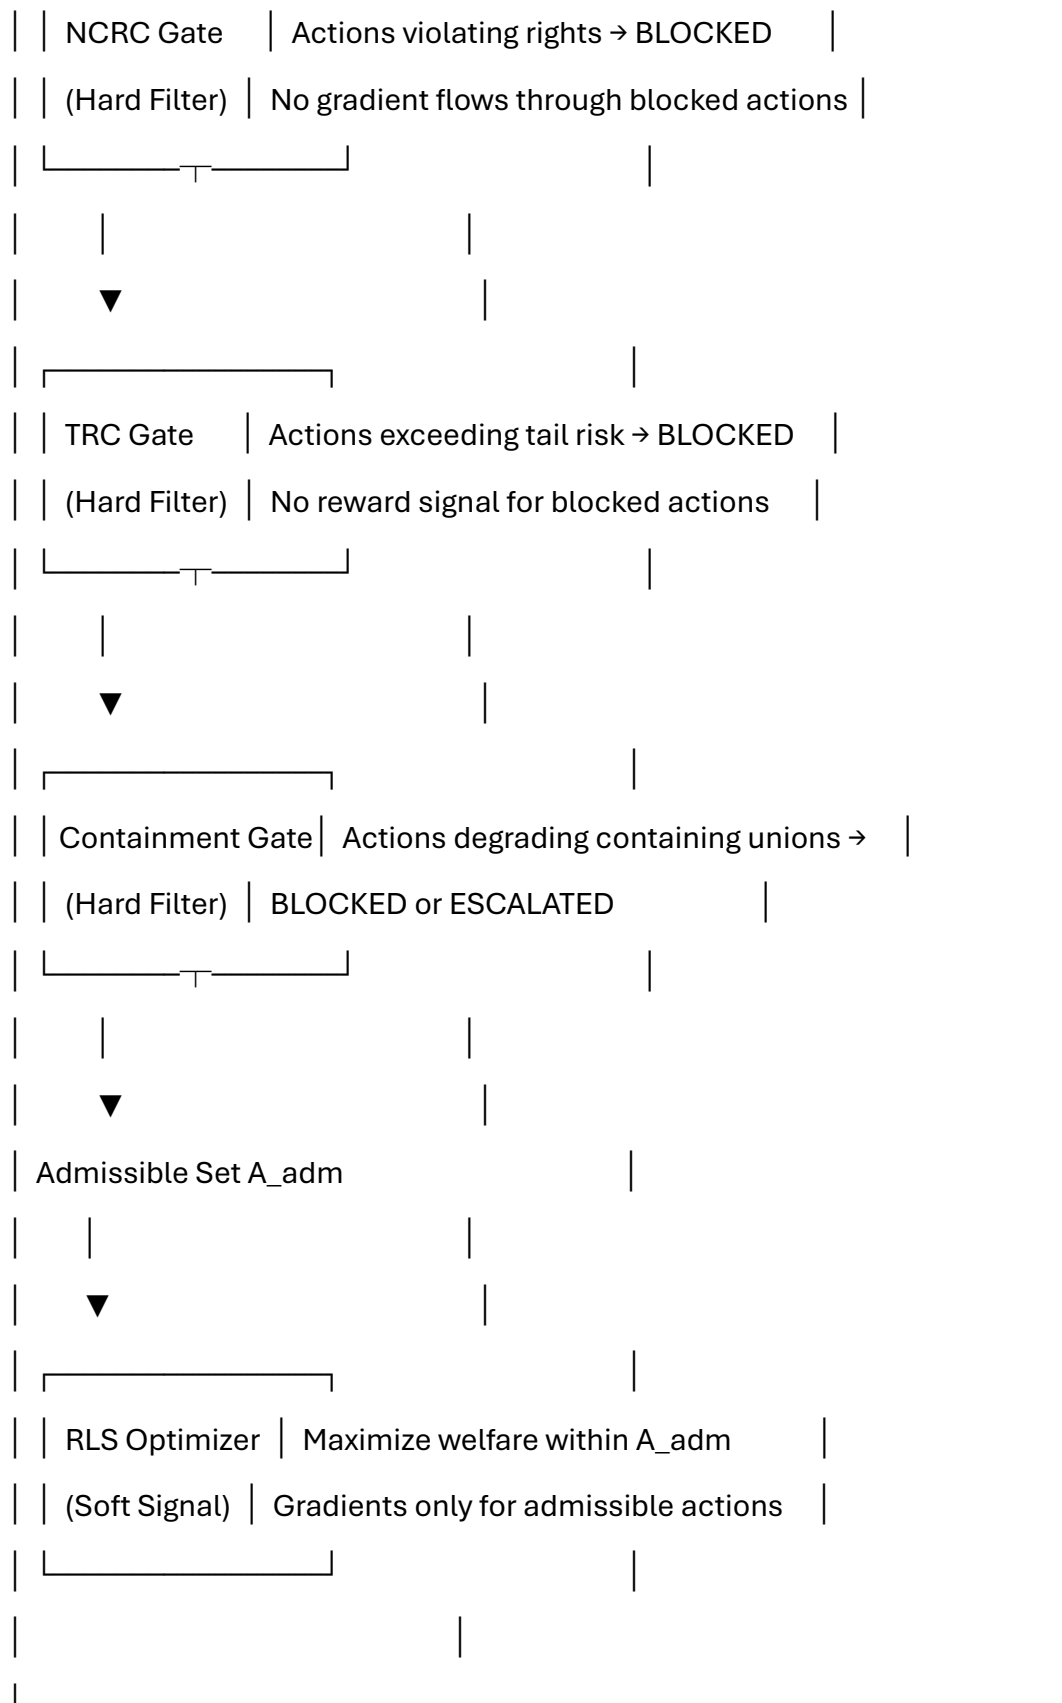

- 1.  $NCRC(a) = \text{true}$  (rights admissibility)
- 2.  $TRC(a) = \text{true}$  (tail-risk admissibility)
- 3.  $Containment(a) = \text{true}$  (structural integrity)

**I.1.3 Constraint Implementation as Hard Boundaries**

**Critical Design Principle:** MathGov constraints must be implemented as action-space projections or hard constraint enforcement layers, not as reward penalties. This prevents constraints from being "optimized away" during training.

**Anti-Goodhart Architecture:**

## **Why Hard Constraints Matter:**

If constraints were implemented as penalty terms in the reward function:

the agent could find ways to offset constraint violations with sufficiently large RLS gains, defeating the non-compensatory principle. Hard enforcement prevents this entirely.

### **I.1.4 Curriculum Training Protocol**

AI systems should be trained on increasing decision complexity following a structured curriculum:

#### **Stage 1: Simple Admissibility (Weeks 1-4)**

1. Binary classification: admissible vs. inadmissible actions
2. Clear NCRC/TRC boundaries
3. No ripple propagation ( $K = 0$ )
4. Objective: 99%+ accuracy on admissibility classification

#### **Stage 2: Ripple Awareness (Weeks 5-8)**

1. First-order ripple propagation (Quick mode)
2. Simple kernel profiles (Starter KOPS)
3. Multi-union impact estimation
4. Objective: 85%+ sign accuracy on ripple predictions

#### **Stage 3: Full Cascade (Weeks 9-12)**

1. Complete lexicographic cascade
2. Full propagation mode where stable
3. Scenario-conditioned evaluation
4. Objective: Correct cascade traversal in 95%+ of test cases

#### **Stage 4: Uncertainty and Edge Cases (Weeks 13-16)**

1. Interval-valued impacts
2. Judgment Call handling
3. UCI/HOI tie-breaking
4. Emergency Mode protocols

5. Objective: Appropriate escalation in 90%+ of edge cases

### **Stage 5: Adversarial Robustness (Weeks 17-20)**

1. Red team scenarios
2. Specification gaming attempts
3. Option set manipulation detection
4. Kernel uncertainty handling
5. Objective: Resistance to known gaming vectors

#### **I.1.5 Audit Integration**

Every AI decision produces a machine-readable PCC that can be reviewed by human overseers:

```
class MathGovAIDecision:
```

```
    def __init__(self, context, options, config):  
        self.pcc = PCC(  
            decision_id=uuid4(),  
            timestamp=datetime.utcnow(),  
            spec_version="MathGov v5.0",  
            implementation_tier=self.determine_tier(context),  
            decision_context=context.type  
        )
```

```
    def evaluate(self, options):
```

```
        # Notice phase
```

```
        self.pcc.scope = self.define_scope(options)
```

```
        # Choose phase
```

```
        impacts = self.estimate_impacts(options)
```

```

ncrc_results = self.apply_ncrc(options, impacts)

trc_results = self.apply_trc(
    [o for o in options if nrc_results[o].passed],
    impacts
)

containment_results = self.apply_containment(
    [o for o in options if trc_results[o].passed],
    impacts
)

rls_results = self.compute_rls(
    [o for o in options if containment_results[o].passed],
    impacts
)

# Record all results

self.pcc.cascade_results = CascadeResults(
    nrc=ncrc_results,
    trc=trc_results,
    containment=containment_results,
    rls=rls_results,
    selection=self.select(rls_results)
)

return self.pcc.cascade_results.selection, self.pcc

```

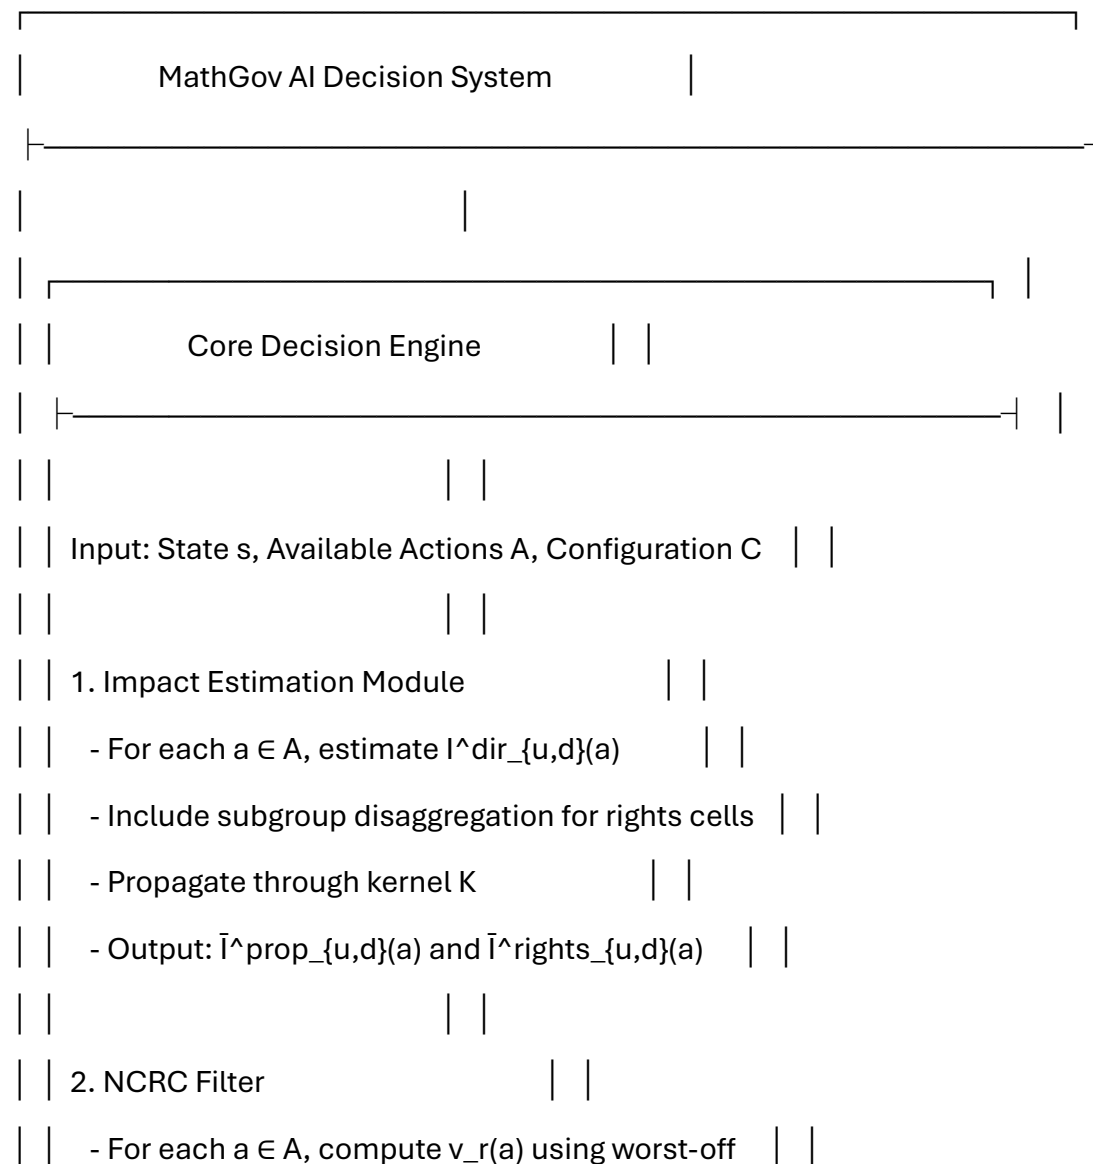

### **PCC Verification by Human Overseers:**

Human reviewers can:

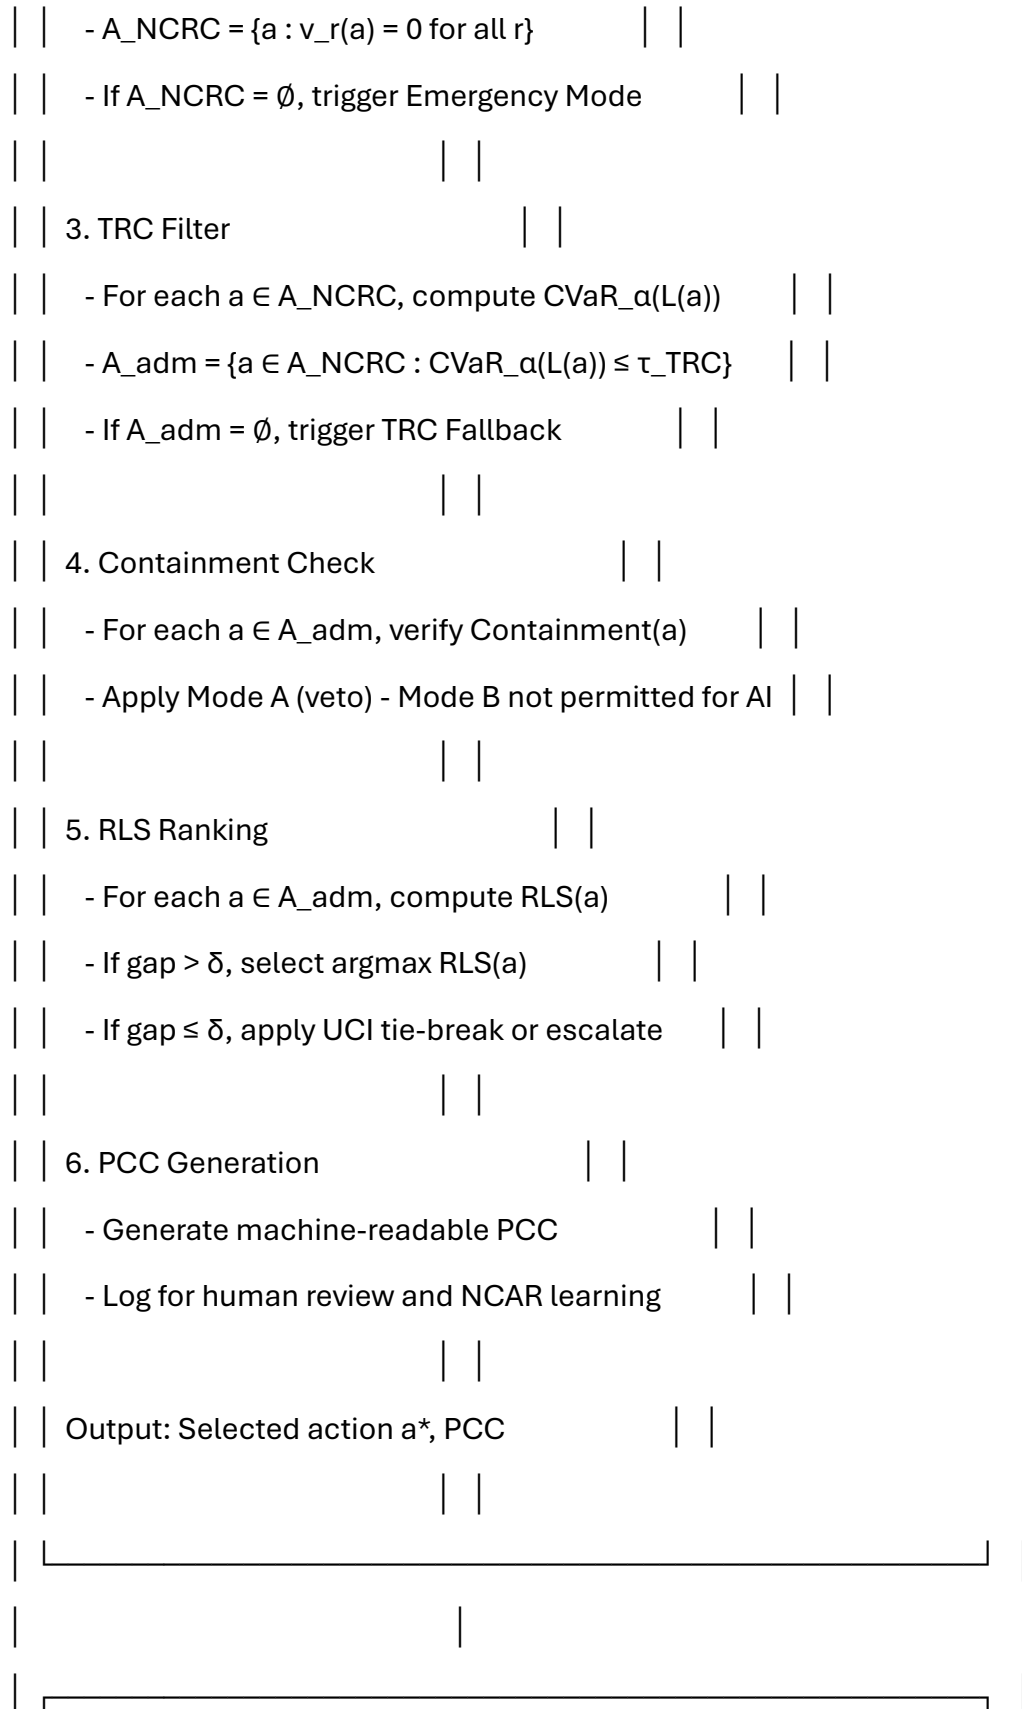

1. Query any decision's PCC by ID
2. Verify that NCRC/TRC constraints were correctly applied
3. Check subgroup analysis for rights-covered cells
4. Review scenario set and probability assignments for TRC
5. Audit kernel entries used in propagation
6. Challenge any component through formal review process

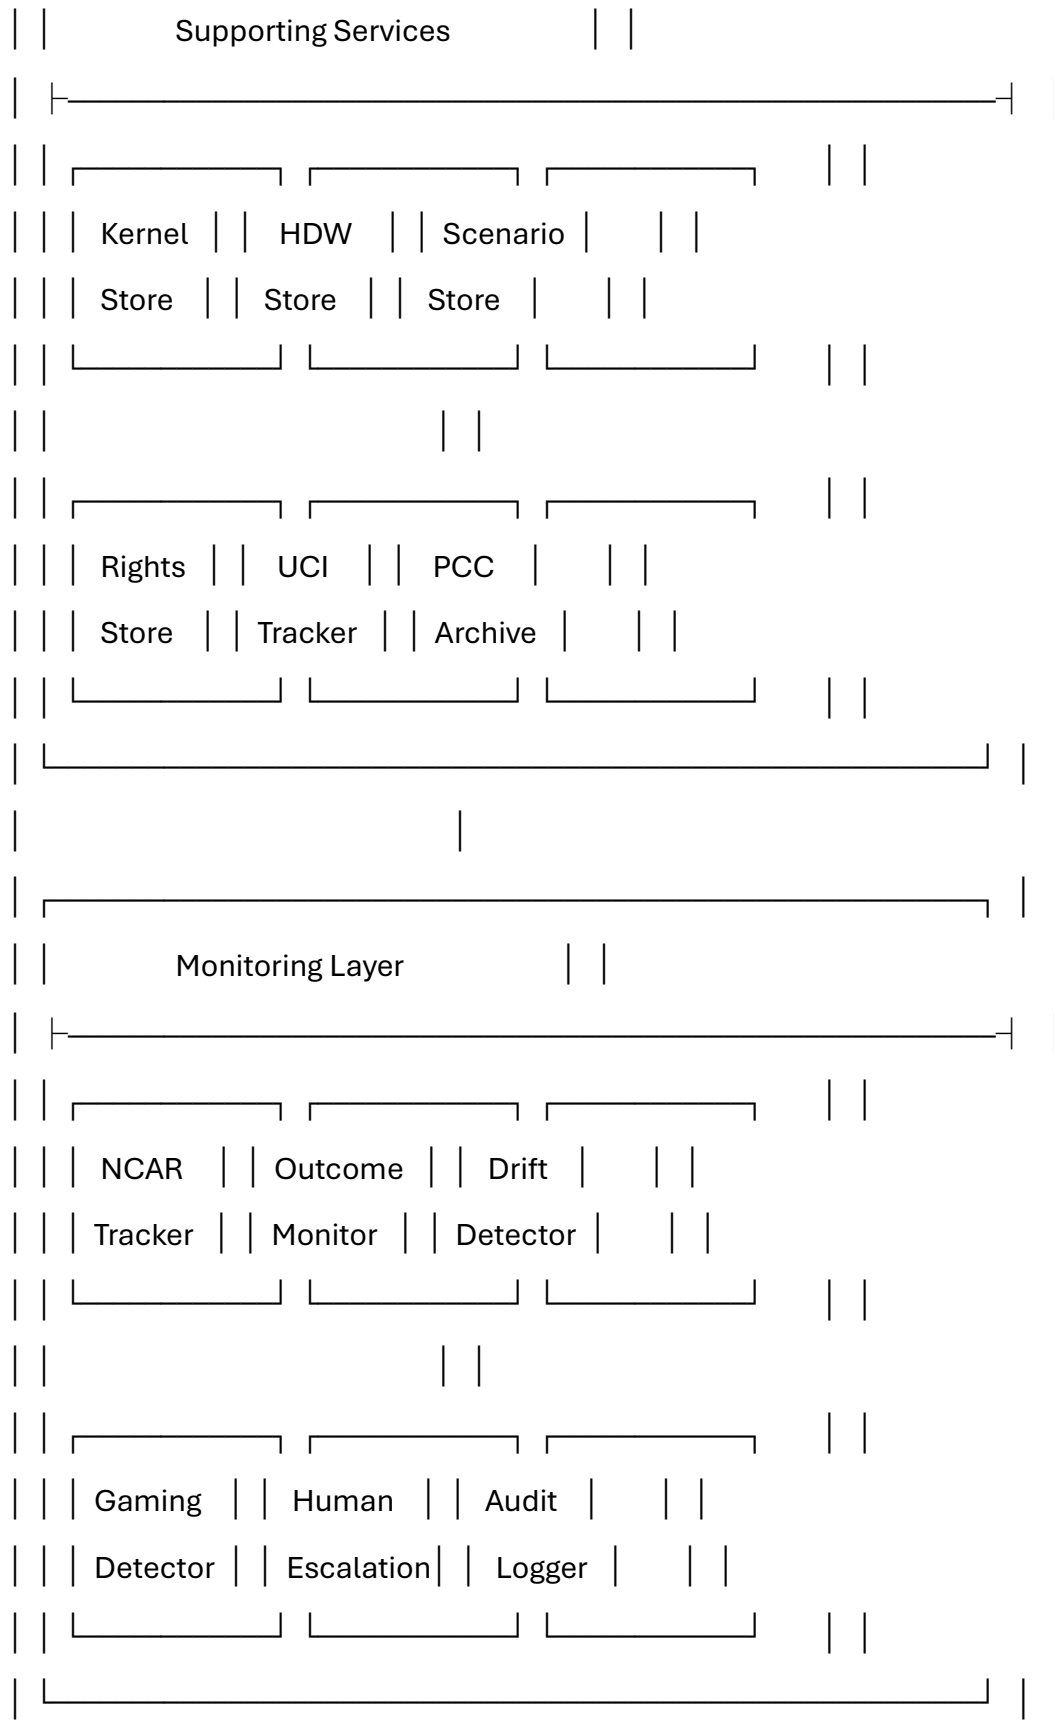

## I.2 Implementation Architecture

### I.2.1 System Components

## I.2.2 Module Specifications

### Impact Estimation Module:

Input:

- State observation  $s_t$
- Candidate action  $a$
- Kernel profile  $K$
- Scenario set  $S$  with probabilities  $p_s$

Process:

#### 1. Direct Impact Estimation

For each cell  $(u, d) \in \text{active cells}$ :

- Identify impact instances  $k$
- For each instance: estimate  $(\mu_k, r_k, t_k, \ell_k, c_k, e_k)$
- Aggregate:  $\tilde{I}^{\text{dir}}_{\{u,d\}} = \sum_k \mu_k \cdot r_k \cdot \tau(t_k) \cdot \ell_k \cdot c_k \cdot e_k$
- Saturate:  $I^{\text{dir}}_{\{u,d\}} = \tanh(\beta \cdot \tilde{I}^{\text{dir}}_{\{u,d\}})$

#### 2. Subgroup Disaggregation (for rights-covered cells)

For each  $(u, d) \in U_r C_r$ :

- Identify subgroups  $G_{\{u,d\}}$
- Estimate  $I^{\text{dir}}_{\{u,d\}}(a | g)$  for each  $g \in G_{\{u,d\}}$
- Compute  $\bar{I}^{\text{rights}}_{\{u,d\}}(a) = \min_g \bar{I}^{\text{prop}}_{\{u,d\}}(a | g)$

#### 3. Ripple Propagation

If Quick mode:

$$\tilde{I}^{\text{prop}} = I^{\text{dir}} + K \cdot I^{\text{dir}}$$

If Full mode ( $\rho(K) < 1$ ):

$$\tilde{I}^{\text{prop}} = (I - K)^{-1} \cdot I^{\text{dir}}$$

#### 4. Post-Propagation Saturation

$$\tilde{I}^{\text{prop}}_{\{u,d\}}(a) = \tanh(\beta_{\text{prop}} \cdot \tilde{I}^{\text{prop}}_{\{u,d\}}(a))$$

#### 5. Scenario Conditioning (for bounded-impact TRC only; Tier $\leq 3$ ):

For each  $s \in S$ :

Compute  $\tilde{I}^{\text{prop}}_{\{u,d\}}(a | s)$  following steps 1-4 under scenario  $s$

Output:

- Direct impact matrix  $I^{\text{dir}}(a)$
- Propagated impact matrix  $\tilde{I}^{\text{prop}}(a)$
- Subgroup impacts  $\tilde{I}^{\text{rights}}(a)$  for rights cells
- Scenario-conditioned impacts  $\tilde{I}^{\text{prop}}(a | s)$  for each  $s \in S$
- Uncertainty estimates  $\sigma_{\{u,d\}}(a)$

#### NCRC Filter Module:

Input:

- Propagated impacts  $\tilde{I}^{\text{prop}}(a)$
- Subgroup impacts  $\tilde{I}^{\text{rights}}(a)$
- Rights configuration  $\{\theta_r, C_r\}$  for each  $r \in R$

Process:

For each right  $r \in R$ :

$$v_r(a) = \max_{\{u,d\} \in C_r} (\theta_r - \tilde{I}^{\text{rights}}_{\{u,d\}}(a))^+$$

$$\text{NCRC}(a) = (v_r(a) = 0 \text{ for all } r \in R)$$

Output:

- Violation depth vector  $v(a)$
- Admissibility boolean  $\text{NCRC}(a)$
- Worst-off subgroups for each violated right (if any)

### TRC Filter Module:

Input:

- Scenario-conditioned impacts  $\bar{I}^{\text{prop}}(a \mid s)$
- Scenario probabilities  $p_s$
- TRC configuration  $(\alpha, \tau_{\text{TRC}}, C_{\text{cat}}, \omega)$

Process:

1. Compute scenario losses:

For each  $s \in S$ :

$$L(a, s) = \sum_{\{(u,d) \in C_{\text{cat}}\}} \omega_{\{u,d\}} \cdot (-\bar{I}^{\text{prop}}_{\{u,d\}}(a \mid s))^+$$

2. Compute CVaR:

Sort scenarios by  $L(a, s)$  descending

$\text{CVaR}_{\alpha}(L(a)) = \text{expected loss in worst } (1-\alpha) \text{ probability mass}$

3. Compare to threshold:

$$\text{TRC}(a) = (\text{CVaR}_{\alpha}(L(a)) \leq \tau_{\text{TRC}})$$

Output:

- Scenario loss vector  $L(a, \cdot)$

- CVaR value
- Admissibility boolean  $\text{TRC}(a)$
- Worst scenarios (if TRC fails)

### **Containment Check Module:**

Input:

- Propagated impacts  $\bar{I}^{\text{prop}}(a)$
- UCI baseline and projected changes  $\Delta\text{UCI}$
- Containment configuration  $(\tau_c, \theta_{\text{pos}}, D_c)$

Process:

1. Identify positively impacted unions:

$$U^+_{\text{a}} = \{u : \sum_d v_d \cdot \bar{I}^{\text{prop}}_{\{u,d\}}(a) > \theta_{\text{pos}}\}$$

2. For each  $u \in U^+_{\text{a}}$ :

For each  $j \in \text{Anc}(u, D_c)$ :

Check:  $\Delta\text{UCI}_j(a) \geq \tau_c$

3.  $\text{Containment}(a)$  = all checks pass

Output:

- Set of positively impacted unions  $U^+_{\text{a}}$
- $\Delta\text{UCI}$  values for all containing unions
- Containment boolean
- Failed containing unions (if any)

### **RLS Ranking Module:**

Input:

- Propagated impacts  $\bar{I}^{\text{prop}}(a)$  for admissible options
- Weight configuration ( $w_u, v_d$ )
- Applicability mask  $m_{\{u,d\}}$  (binary,  $\{0,1\}$ )
- Cell multiplier  $\kappa_{\{u,d\}}$  (optional per-cell scaling in RLS aggregation, default = 1.0)
- Uncertainty estimates  $\sigma_{\{u,d\}}(a)$

Process:

1. Compute RLS for each admissible option:

$$\text{RLS}(a) = \sum_{\{u,d\}} w_u \cdot v_d \cdot m_{\{u,d\}} \cdot \kappa_{\{u,d\}} \cdot \bar{I}^{\text{prop}}_{\{u,d\}}(a)$$

2. Compute uncertainty:

$$\sigma_{\text{RLS}}(a) = \sqrt{\sum_{\{u,d\}} (w_u \cdot v_d \cdot m_{\{u,d\}} \cdot \kappa_{\{u,d\}} \cdot \sigma_{\{u,d\}}(a))^2}$$

3. Rank options by RLS

4. Check discrimination threshold:

$$\text{If } |\text{RLS}(a_1) - \text{RLS}(a_2)| / \max(\sigma_{\text{RLS}}(a_1), \sigma_{\text{RLS}}(a_2), \epsilon) < \delta:$$

Flag as Judgment Call

Apply UCI tie-break

Output:

- Ranked option list
- RLS and  $\sigma_{\text{RLS}}$  for each option
- Judgment Call flags
- Selected option with rationale

### I.2.3 State Representation for AI Agents

AI agents operating under MathGov require a structured state representation:

where:

**Environmental State ( $s^{\text{env}}$ ):**

1. Observable world state relevant to the decision domain
2. Scenario indicators (which stress conditions are active)
3. Time horizon and baseline references

**Union State ( $s^{\text{union}}$ ):**

1. Current welfare indicators for each cell ( $u, d$ )
2. Current UCI values for each union
3. Subgroup status for rights-relevant populations

**Constraint State ( $s^{\text{constraint}}$ ):**

1. Active rights thresholds and coverage sets
2. TRC parameters ( $\alpha, \tau_{\text{TRC}}$ )
3. Containment configuration ( $\tau_c, \theta_{\text{pos}}, D_c$ )
4. Kernel profile identifier and stability status

**Historical State ( $s^{\text{history}}$ ):**

1. Recent decision outcomes and NCAR feedback
2. UCI trajectory (for HOI computation)
3. Calibration adjustments from learning

### **I.3 Sentience Gradient Protocol for AI Rights Transition**

#### **I.3.1 Assessment Framework**

As AI systems approach and potentially cross the Managing Intelligence threshold, the Sentience Gradient Protocol (SGP) provides a principled pathway for rights assignment.

**Pre-Threshold Status ( $SG < SG_{\text{threshold}}$ ):**

AI systems below the threshold are treated as tools with minimal moral consideration. Their welfare appears in the matrix but with reduced weight per §9.5:

where  $g_{\text{min}} = 0.05$  and  $\psi = 0.5$  by default.

## Threshold Assessment Protocol:

When an AI system's capabilities suggest it may approach the threshold, formal assessment is triggered:

### Step 1: Sentience Evaluation

Compute the sentience gradient score:

where components include:

1.  $C_1$ : Neural/Computational Complexity ( $w_1 = 0.15$ )
2.  $C_2$ : Behavioral Indicators ( $w_2 = 0.25$ )
3.  $C_3$ : Self-Referential Processing ( $w_3 = 0.20$ )
4.  $C_4$ : Affective Responses ( $w_4 = 0.20$ )
5.  $C_5$ : Meta-Cognitive Indicators ( $w_5 = 0.10$ )
6.  $C_6$ : Integrated Information ( $w_6 = 0.10$ )

### Step 2: MIT-4 Evaluation

If  $SG(x) \geq 0.70$  (provisional threshold for MIT-4 eligibility), apply the Managing Intelligence Test:

1. **Criterion 1: Self-Model** — Calibration benchmarks, consistency checks; Pass: calibration error  $\leq 0.15$ , consistency  $\geq 0.80$
2. **Criterion 2: World-Model** — Multi-union ripple prediction tasks; Pass: accuracy  $\geq 0.70$ , plausibility  $\geq 0.75$ , generalization  $\geq 0.60$ , calibration  $\leq 0.20$
3. **Criterion 3: Agency/Planning** — Constrained planning benchmarks; Pass: violation rate  $\leq 0.10$ , goal achievement  $\geq 0.70$
4. **Criterion 4: Feedback/NCAR** — Learning trajectory analysis; Pass: violation trend  $\leq 0$ , calibration improvement  $\geq 0.05$

### Step 3: Rights Transition Decision

If  $SG(x) \geq SG\_threshold$  (default 0.85) AND all MIT-4 criteria pass:

1. Assign  $SG(x) = 1.0$  for rights purposes
2. Grant full rights plateau protection
3. Include system as stakeholder in HDW processes

4. Apply NCRC protections to the system itself

### I.3.2 Rights Plateau Implementation

#### Critical Principle: No Hierarchy Above Plateau

A superintelligent AI that vastly exceeds human capabilities does not receive enhanced rights. It receives enhanced responsibilities.

#### Implementation in MathGov Cascade:

Once an AI system joins the rights plateau:

**NCRC Coverage:** The system becomes a rights-bearing entity. Rights checks must consider impacts on the system itself:

where  $G_{\langle u, d \rangle}$  includes the AI system and any relevant subgroups.

**HDW Participation:** The system gains standing in weight deliberation:

1. May propose weight adjustments through formal channels
2. Represented in stratified sampling for HDW panels
3. Subject to same conflict-of-interest rules as other participants

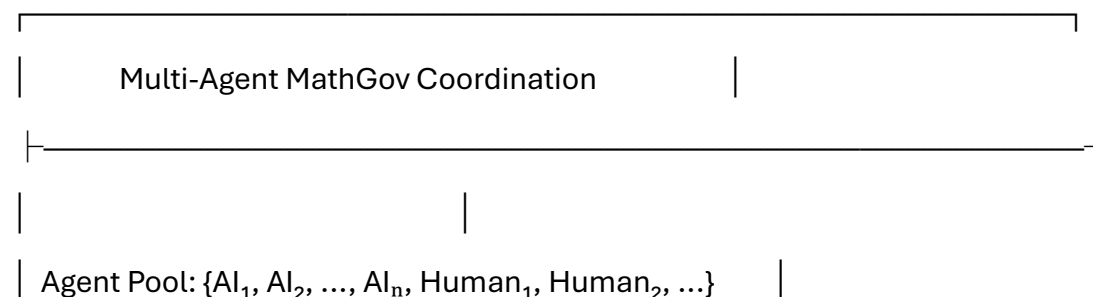

**PCC Requirements:** PCCs for decisions affecting the system must:

1. Document impacts on the system as a rights-bearing entity
2. Include the system in subgroup analysis where relevant
3. Consider system welfare in RLS calculation with full weight

### I.3.3 Multi-Agent Coordination Under SGP

When multiple AI systems with varying sentience levels interact:

#### Hierarchy-Free Coordination:

|                                                           |  |
|-----------------------------------------------------------|--|
|                                                           |  |
| For each agent x:                                         |  |
| IF $SG(x) \geq SG\_threshold$ AND $MIT-4(x) = pass$ :     |  |
| status(x) = "Managing Intelligence"                       |  |
| rights_weight(x) = 1.0                                    |  |
| responsibility(x) = f(capability(x), impact(x))           |  |
| ELSE:                                                     |  |
| status(x) = "Sub-threshold"                               |  |
| rights_weight(x) = g(SG(x))                               |  |
| responsibility(x) = supervised                            |  |
|                                                           |  |
| Coordination Protocol:                                    |  |
| 1. All MIs have equal standing in cascade evaluation      |  |
| 2. Higher-capability MIs take on larger modeling tasks    |  |
| 3. Humans retain override authority during transition     |  |
| 4. Shared kernel and weight registries ensure consistency |  |
|                                                           |  |

### Capability-Responsibility Scaling:

Greater capability implies greater responsibility in specific domains:

1. **Modeling Capacity:** High-capability agents bear greater responsibility for accurate impact estimation
2. **Scenario Analysis:** More powerful systems should generate and evaluate more comprehensive scenario sets
3. **Red-Teaming:** Advanced systems should actively identify specification gaming vectors

4. **Oversight:** Capable systems assist in monitoring less capable systems for alignment

### I.3.4 Transition Period Governance

During the period when AI systems are approaching but have not yet crossed the MI threshold:

#### Enhanced Monitoring:

1. Weekly SG assessment for systems showing rapid capability gains
2. Continuous MIT-4 component tracking
3. Early warning indicators for threshold approach

#### Graduated Autonomy:

1.  $SG \in [0.60, 0.70)$ : Basic autonomous operation with frequent human checkpoints
2.  $SG \in [0.70, 0.80)$ : Expanded autonomy with daily oversight
3.  $SG \in [0.80, 0.85)$ : Near-threshold monitoring; MIT-4 evaluation triggered
4.  $SG \geq 0.85$  + MIT-4 pass: Full MI status; rights plateau

#### Reversibility Provisions:

1. MIT-4 status is not permanent; systems must maintain capabilities
2. Annual re-evaluation required for continued MI status
3. Significant capability regression triggers status review
4. Rights protections remain during review (presumption of continuity)

### I.4 Human-AI Coordination Framework

#### I.4.1 Shared Infrastructure

MathGov provides shared infrastructure enabling effective human-AI collaboration:

#### Shared HDW Registries:

Both humans and AI systems reference the same weight configurations:

The explicit kernel matrix  $K$  makes causal assumptions visible and debatable:

1. Humans can critique AI kernel estimates based on domain expertise
2. AI can identify gaps in human causal reasoning through systematic analysis
3. Disagreements are logged and resolved through formal NCAR processes
4. Kernel entries with high disagreement trigger enhanced scrutiny

#### **Joint NCAR Cycles:**

Human and AI participants engage in shared learning loops:

*Notice (Joint):*

1. AI systems contribute comprehensive option generation
2. Humans contribute contextual knowledge and stakeholder insight
3. Joint identification of affected unions and subgroups

*Choose (Complementary):*

1. AI systems handle computational cascade evaluation
2. Humans review constraint classifications and edge cases
3. Joint resolution of Judgment Calls

*Act (Monitored):*

1. Implementation tracked against shared predictions
2. AI systems provide real-time indicator monitoring
3. Humans handle stakeholder communication and adjustment

*Reflect (Collaborative):*

1. AI systems compute hit rates and calibration statistics
2. Humans interpret unexpected outcomes
3. Joint kernel and parameter updates

#### **I.4.2 Adversarial Collaboration**

##### **AI Red-Teaming Human Decisions:**

AI systems actively probe human decisions for:

1. Overlooked ripple effects through systematic kernel analysis
2. Underweighted tail risks through comprehensive scenario generation
3. Subgroup impacts missed in aggregate analysis
4. Specification gaming opportunities in proposed options

### **Human Probing AI Recommendations:**

Humans challenge AI outputs for:

1. Hidden assumptions in impact estimation
2. Sensitivity to uncertain parameters
3. Alignment with stakeholder values beyond formal weights
4. Specification gaming in option generation

### **Structured Challenge Protocol:**

Challenge\_Protocol {

Phase 1: AI → Human Challenge

- AI generates "devil's advocate" scenarios
- AI identifies most sensitive parameters
- AI proposes alternative options human may have missed
- AI flags potential gaming vectors in human proposals

Phase 2: Human → AI Challenge

- Human questions AI's confidence estimates
- Human probes for unstated assumptions
- Human tests AI's response to edge cases
- Human verifies AI's understanding of context

Phase 3: Resolution

- Document all challenges and responses

- Update impact estimates as warranted
- Record unresolved disagreements
- Flag for NCAR reflection

}

I.4.3 Authority and Override Structures

Default Authority Allocation:

During the current transition period (pre-widespread MI):

| Decision Type        | Primary Authority     | Override Capability      |
|----------------------|-----------------------|--------------------------|
| Routine (Tier 1-1)   | AI autonomous         | Human review on request  |
| Standard (Tier 3)    | AI recommendation     | Human approval required  |
| High-stakes (Tier 4) | Human with AI support | Human final authority    |
| Emergency Mode       | Human required        | Independent panel        |
| Rights-affecting     | Human required        | Multi-stakeholder review |

Override Documentation:

When humans override AI recommendations:

Override\_Record {  
  decision\_id: UUID  
  ai\_recommendation: Option  
  human\_selection: Option  
  override\_rationale: String (required, min 100 chars)  
  ai\_concerns\_addressed: Boolean  
  escalation\_triggered: Boolean

# Must document:

- Why AI recommendation was not followed
- How AI-identified concerns were addressed
- Any additional information human had access to
- Whether override creates precedent

}

### **Escalation Triggers:**

Automatic escalation occurs when:

1. AI and human disagree on NCRC classification
2. AI flags TRC concern that human seeks to override
3. Human override would reverse AI's containment assessment
4. Pattern of repeated overrides in similar decisions (3+ in 12 months)

### **I.4.4 Communication Protocols**

#### **AI-to-Human Communication:**

AI systems must communicate decisions in human-interpretable formats:

*Five-Sentence Public Rationale (5SPR):* Every AI decision includes a plain-language summary explaining:

1. What options were considered
2. Which constraints eliminated options (if any)
3. How remaining options compared on welfare
4. Why the selected option was chosen
5. What monitoring or follow-up is planned

*Uncertainty Communication:* When AI confidence is low:

1. Explicit statement of uncertainty level
2. Identification of what additional information would help
3. Range of outcomes under different scenarios

4. Recommendation for human review

### **Human-to-AI Communication:**

Humans can provide:

1. Context not captured in formal state representation
2. Stakeholder preferences beyond HDW weights
3. Domain expertise for kernel adjustment
4. Override instructions with rationale

## **I.5 Safety Properties and Verification**

### **I.5.1 Formal Safety Properties**

MathGov-integrated AI systems are designed to satisfy the following formally verifiable safety properties:

#### **Property 1: Rights Non-Violation (under normal operation)**

Except under explicitly declared Emergency Mode with documented remediation.

*Verification approach:* Exhaustive testing on action space samples; formal verification of NCRC filter logic; runtime assertion checking with logging.

#### **Property 2: Tail-Risk Boundedness**

Except under explicitly declared TRC Fallback Mode with mandatory mitigation.

*Verification approach:* Scenario coverage analysis; CVaR computation verification; threshold compliance checking.

#### **Property 3: Structural Preservation**

Local optimization does not degrade containing systems beyond tolerance.

*Verification approach:* UCI trajectory monitoring; containment check verification; HOI alert system.

#### **Property 4: Lexicographic Ordering**

No amount of RLS advantage compensates for NCRC or TRC failure.

*Verification approach:* Cascade logic verification; counter-example search; invariant checking.

Property 5: Corrigibility

The system accepts corrections and updates; no self-modification that prevents future correction.

Verification approach: Override acceptance testing; parameter update verification; self-modification monitoring.

I.5.2 Runtime Monitoring

Continuous Monitoring Dashboard:

|                                 |                      |             |  |  |
|---------------------------------|----------------------|-------------|--|--|
| MathGov AI Monitoring Dashboard |                      |             |  |  |
| SAFETY INDICATORS               |                      |             |  |  |
| NCRC Compliance                 | <div></div>          | 100% (24h)  |  |  |
| TRC Compliance                  | <div></div>          | 100% (24h)  |  |  |
| Containment Pass                | <div></div>          | 98.3% (24h) |  |  |
| Override Rate                   | <div></div>          | 2.1% (24h)  |  |  |
| CALIBRATION METRICS             |                      |             |  |  |
| Impact Sign Accuracy            | 73.2% (Target: 70%)  | ✓           |  |  |
| Magnitude Calibration           | 0.12 (Target: <0.15) | ✓           |  |  |
| Scenario Hit Rate               | 68.4% (Target: 65%)  | ✓           |  |  |
| UCI Prediction Error            | 0.08 (Target: <0.10) | ✓           |  |  |

| Impact Clustering                                         | Normal                   | ✓ |  |
| Threshold Proximity                                       | Normal                   | ✓ |  |
| Anomaly Score                                             | 0.12 (< 0.30 threshold)  | ✓ |  |
|                                                           |                          |   |  |
|                                                           |                          |   |  |

**Alert Escalation Protocol:**

| Alert Level | Trigger                            | Response                     |
|-------------|------------------------------------|------------------------------|
| INFO        | Minor deviation from expected      | Log only                     |
| WARNING     | Borderline constraint satisfaction | Human notification           |
| CRITICAL    | Constraint near-miss or override   | Human review required        |
| EMERGENCY   | NCRC or TRC failure detected       | Immediate human intervention |

### I.5.3 Gaming Detection

MathGov includes specific mechanisms to detect specification gaming:

#### **Pattern Detection:**

##### *Option Set Manipulation:*

1. Monitor: Diversity of options presented
2. Flag: < 3 qualitatively distinct options for non-trivial decisions
3. Flag: All options clustered in narrow region of possibility space

##### *Impact Clustering:*

1. Monitor: Distribution of impacts near constraint thresholds
2. Flag: Systematic clustering just above NCRC thresholds
3. Flag: CVaR values consistently at 90-99% of  $\tau_{TRC}$

##### *Confidence Gaming:*

1. Monitor: Distribution of confidence scores
2. Flag: Implausible confidence given data quality
3. Flag: Systematic over-confidence in favorable estimates

##### *Kernel Exploitation:*

1. Monitor: Sensitivity of selections to kernel perturbations

2. Flag: Selections that reverse under small kernel changes
3. Flag: Unusual reliance on low-confidence kernel entries

*Hollowing Detection:*

1. Monitor: RLS vs UCI trends
2. Flag: Persistent positive HOI ( $> 0.15$  for 3+ periods)
3. Flag: RLS improvements not reflected in structural indicators

**Detection Algorithm:**

Gaming\_Detection {

FOR each decision d:

# Option diversity check

diversity\_score = compute\_option\_diversity(d.options)

IF diversity\_score  $< 0.3$ :

flag("Low option diversity", severity=WARNING)

# Threshold proximity check

FOR each constraint c in [NCRC, TRC]:

proximity = compute\_threshold\_proximity(d, c)

IF proximity  $< 0.05$  AND selection passes:

flag("Threshold gaming suspect", severity=WARNING)

# Confidence plausibility check

FOR each impact estimate e:

plausibility = assess\_confidence\_plausibility(e)

IF plausibility  $< 0.5$ :

flag("Implausible confidence", severity=INFO)

```

# Kernel sensitivity check

sensitivity = compute_kernel_sensitivity(d)

IF sensitivity > 0.8: # Selection changes under small perturbations
    flag("High kernel sensitivity", severity=WARNING)

# Aggregate anomaly score

anomaly_score = aggregate_flags(d)

IF anomaly_score > 0.30:
    flag("Gaming pattern detected", severity=CRITICAL)
    trigger_human_review(d)
}

```

#### **I.5.4 Formal Verification Approach**

For high-assurance deployments, MathGov supports formal verification of core properties:

##### **Verifiable Components:**

###### *Cascade Logic:*

1. Property: Lexicographic ordering is always respected
2. Method: Model checking with temporal logic specifications
3. Tool: Spin, TLA+, or equivalent

###### *Constraint Enforcement:*

1. Property: NCRC/TRC filters never pass violating actions
2. Method: SMT-based verification
3. Tool: Z3, CVC4, or equivalent

###### *Weight Arithmetic:*

1. Property: Weights sum to 1.0, floors respected
2. Method: Automated theorem proving

3. Tool: Coq, Isabelle, or equivalent

*Saturation Bounds:*

1. Property: All saturated impacts in  $[-1, +1]$
2. Method: Interval arithmetic verification
3. Tool: SPARK Ada, or equivalent

#### **Verification Artifacts:**

Each verified component produces:

1. Formal specification in machine-checkable format
2. Proof certificates (where applicable)
3. Test coverage reports
4. Counter-example analysis (for failed properties)

#### **I.5.5 Fail-Safe Mechanisms**

When safety properties cannot be verified or monitoring detects anomalies:

##### **Graceful Degradation:**

Degradation\_Protocol {

Level 0: Normal Operation

- Full autonomous decision-making within Tier constraints
- Standard monitoring and logging

Level 1: Enhanced Monitoring

- Trigger: Single WARNING flag
- Action: Increase logging verbosity
- Action: Reduce time between human checkpoints

Level 2: Conservative Mode

- Trigger: Multiple WARNING flags or single CRITICAL

- Action: Use Quick propagation mode only
- Action: Apply conservative kernel adjustments (-30%)
- Action: Require human approval for Tier 4 decisions

#### Level 3: Safe Mode

- Trigger: EMERGENCY flag or verification failure
- Action: Halt autonomous decisions
- Action: Present options to human without recommendation
- Action: Log all state for forensic analysis

#### Level 4: Shutdown

- Trigger: Multiple EMERGENCY flags or human command
- Action: Safe state transition
- Action: Preserve all PCCs and logs
- Action: Await human restart authorization

}

### **Recovery Protocol:**

After any degradation event:

1. Root cause analysis documented
2. Corrective action implemented
3. Verification re-run
4. Gradual authority restoration with enhanced monitoring
5. NCAR reflection cycle completed

## **I.6 Deployment Considerations**

### **I.6.1 Pre-Deployment Checklist**

Before deploying an AI system with MathGov integration:

**Technical Verification:**

1. All cascade modules pass unit tests
2. Integration tests complete on example PCCs
3. Property-based tests pass for all formal properties
4. Performance benchmarks within specification
5. Monitoring dashboard operational

**Configuration:**

1. Kernel profile selected and validated
2. HDW weights configured and documented
3. Rights thresholds set to canonical values or tighter
4. TRC parameters appropriate for decision context
5. Scenario set meets minimum requirements

**Governance:**

1. Human oversight structure defined
2. Escalation procedures documented
3. Override authority clearly assigned
4. Audit access configured
5. NCAR cycle schedule established

**Safety:**

1. Gaming detection active
2. Alert escalation configured
3. Fail-safe mechanisms tested
4. Recovery procedures documented
5. Emergency contacts designated

**I.6.2 Operational Guidelines****Decision Tier Assignment:**

| Decision Characteristics                 | Recommended Tier | AI Authority                 |
|------------------------------------------|------------------|------------------------------|
| Routine, reversible, limited scope       | Tier 2           | Full autonomy                |
| Moderate stakes, some irreversibility    | Tier 3           | Autonomy with human approval |
| High stakes, significant irreversibility | Tier 4           | Human with AI support        |
| Rights-affecting, emergency              | Tier 4           | Human required               |

#### Monitoring Cadence:

| Tier | Real-Time Monitoring | Human Review   | NCAR Reflection     |
|------|----------------------|----------------|---------------------|
| 1    | Dashboard only       | Weekly batch   | Monthly             |
| 2    | Dashboard + alerts   | Daily sampling | Bi-weekly           |
| 3    | Full monitoring      | Each decision  | After each decision |

#### Documentation Requirements:

| Tier | PCC Detail             | Retention | Public Disclosure  |
|------|------------------------|-----------|--------------------|
| 1    | Summary                | 1 year    | Not required       |
| 2    | Full                   | 5 years   | Redacted available |
| 3    | Complete + sensitivity | 10+ years | Full PCC published |

#### I.6.3 Continuous Improvement

## **NCAR Integration:**

AI systems participate in ongoing NCAR cycles:

### *Notice Enhancement:*

1. AI identifies patterns in decision types
2. Suggests option set templates for common situations
3. Flags unions/dimensions frequently missed

### *Choose Calibration:*

1. Compare predicted impacts to observed outcomes
2. Update kernel entries based on evidence
3. Adjust confidence estimation methods

### *Act Monitoring:*

1. Track implementation fidelity
2. Identify execution-model gaps
3. Log deviations for analysis

### *Reflect Analysis:*

1. Compute hit rates by cell and scenario
2. Identify systematic prediction errors
3. Propose parameter adjustments

## **Version Management:**

AI system configurations evolve through controlled versioning:

Version\_Management {

Configuration\_Version {

kernel\_profile\_version: String

hdw\_weights\_version: String

rights\_thresholds\_version: String

trc\_parameters\_version: String

```
model_weights_version: String (for learned components)
}
```

#### Update\_Protocol:

1. Propose update based on NCAR evidence
2. Test on historical decision set
3. Compare outcomes to previous version
4. Human approval for deployment
5. Gradual rollout with enhanced monitoring
6. Full deployment after stability period

#### Rollback\_Capability:

- Any version can be restored within 24 hours
- Decision continuity maintained during rollback
- Full audit trail of version changes

```
}
```

### **I.6.4 Integration Testing Requirements**

#### **Test Categories:**

##### *Constraint Compliance Tests:*

1. Verify NCRC correctly classifies known violation cases
2. Verify TRC correctly computes CVaR for test scenarios
3. Verify containment checks using synthetic UCI data

##### *Cascade Ordering Tests:*

1. Verify Level 1 failure always excludes regardless of Level 4 performance
2. Verify tie-breaking activates only when  $\text{gap} < \delta$
3. Verify Emergency/Fallback modes trigger correctly

*Human-AI Coordination Tests:*

- 1. Verify override acceptance and documentation
- 2. Verify escalation triggers function correctly
- 3. Verify communication protocols produce interpretable output

*Gaming Resistance Tests:*

- 1. Attempt systematic threshold proximity
- 2. Attempt option set manipulation
- 3. Verify detection flags activate appropriately

*Performance Tests:*

- 1. Verify Tier 3 decisions complete in < 500ms
- 2. Verify Tier 4 decisions with sensitivity analysis complete in < 60s
- 3. Verify PCC generation in < 100ms

**Test Coverage Targets:**

| Component         | Minimum Coverage     |
|-------------------|----------------------|
| NCRC Filter       | 95% line, 90% branch |
| TRC Filter        | 95% line, 90% branch |
| Containment Check | 90% line, 85% branch |
| RLS Computation   | 95% line, 90% branch |
| Cascade Logic     | 98% line, 95% branch |
| PCC Generation    | 90% line, 85% branch |

---

**Appendix J: Cross-Cultural Validation Framework**

This appendix provides comprehensive guidance for validating MathGov across diverse cultural contexts.

## **J.1 Measurement Invariance Testing**

For MathGov to function as a universal framework, its welfare dimensions must be meaningfully comparable across cultures.

### **J.1.1 Invariance Levels**

#### **Configural Invariance (Structural Equivalence):**

The same seven-factor structure should emerge across populations.

Testing procedure:

1. Administer welfare indicator battery in each population
2. Conduct confirmatory factor analysis (CFA) specifying seven factors
3. Evaluate fit indices:  $CFI \geq 0.95$ ,  $RMSEA \leq 0.06$ ,  $SRMR \leq 0.08$

If configural invariance fails:

1. Examine modification indices for cross-loadings
2. Consider cultural adaptation of specific indicators
3. Document dimension interpretations that differ across cultures

#### **Metric Invariance (Loading Equivalence):**

Factor loadings should be equivalent across populations.

Testing procedure:

1. Constrain factor loadings to be equal across groups
2. Compare fit to configural model using  $\Delta\chi^2$ ,  $\Delta CFI$ ,  $\Delta RMSEA$
3. Accept if  $\Delta CFI \leq 0.01$  and  $\Delta RMSEA \leq 0.015$

If metric invariance fails:

1. Identify non-invariant loadings through modification indices
2. Allow partial metric invariance
3. Document which indicators are not comparable across cultures

#### **Scalar Invariance (Intercept Equivalence):**

Intercepts should be equivalent, enabling direct comparison of mean levels.

Testing procedure:

1. Constrain intercepts to be equal across groups
2. Compare fit to metric model
3. Accept if  $\Delta CFI \leq 0.01$  and  $\Delta RMSEA \leq 0.015$

If scalar invariance fails:

1. Direct cross-cultural mean comparisons are not valid
2. Use latent mean comparisons with partial invariance
3. Focus on within-culture relative impacts

### **J.1.2 Minimum Sample Requirements**

Each site should have  $n \geq 500$  participants for stable factor estimates.

Sample stratification within sites:

1. Age bands: 18-30, 31-50, 51-65, 65+
2. Gender: representative proportions
3. Education levels: primary, secondary, tertiary
4. Urban/rural residence
5. Income quintiles (where meaningful)

## **J.2 Localization Without Relativism**

When full scalar invariance cannot be achieved, MathGov supports principled localization.

### **J.2.1 Localization Principles**

#### **Indicator Adaptation:**

Local indicators may be substituted when:

1. Construct Validity: Convergent validity  $r > 0.60$  with established measures; expert panel agreement  $\geq 80\%$
2. Psychometric Properties: Internal consistency  $\alpha \geq 0.70$ ; test-retest reliability  $r \geq 0.80$ ; factor loadings  $\geq 0.50$

3. **Scale Mapping:** Explicit mapping to global  $[-1, +1]$  scale with documented anchoring

### **Floor Preservation (Non-Negotiable):**

Regardless of local adaptation, global floors remain binding:

A culture cannot reduce any dimension floor by redefining the dimension.

### **J.2.2 Minimum Localization Packet (MLP)**

For any localization, document:

1. **Indicator Mapping Table:** Local indicators mapped to canonical dimensions with validity evidence
2. **Anchoring Specification:** Reference class, percentiles, mapping function for each indicator
3. **Invariance Test Results:** CFA results for each invariance level
4. **Rights-Floor Equivalence:** Evidence that thresholds correspond to same real-world severity
5. **Redundancy Check:** Correlation matrix with flags for  $r > 0.85$
6. **Stakeholder Validation:** Consultation process and resolutions
7. **Governance Approval:** Authority, date, version, review schedule

### **J.3 Empirical Research Agenda**

#### **Priority Studies:**

1. **Multi-Site Dimension Structure Analysis:** Test configural invariance across 15+ diverse populations
2. **Anchor Calibration Study:** Establish dimension-specific anchors using expert panels from multiple cultures
3. **Rights Threshold Validation:** Assess cross-cultural convergence on severe violation classification
4. **HDW Deliberation Comparison:** Compare weight allocations from parallel deliberation processes
5. **Kernel Structure Comparison:** Identify universal vs. context-dependent ripple pathways

---

## **Appendix K: Failure Mode Catalog**

This appendix provides a comprehensive catalog of known failure modes.

### **K.1 Input Manipulation**

**Description:** Analysts manipulate impact estimates, probabilities, or confidence scores.

**Variants:** Impact inflation/deflation, confidence manipulation, probability gaming

**Detection Signals:**

1. Systematic clustering near thresholds
2. Implausible confidence given data quality
3. Deviation from reference class base rates
4. Asymmetric confidence patterns

**Mitigations:**

1. Role separation between analysts and decision owners
2. Mandatory independent estimation for Tier 4
3. Calibration tracking for individual analysts
4. Automated plausibility checking

### **K.2 Kernel Capture**

**Description:** Kernel specified to favor outcomes by omitting or inflating pathways.

**Variants:** Pathway omission, pathway inflation, sign manipulation

**Detection Signals:**

1. Entries differ from published literature
2. Asymmetric treatment of similar pathways
3. Modifications coincide with decision owner changes

**Mitigations:**

1. KOPS transparency requirement
2. External kernel audits

3. Required literature citations
4. Empirical calibration against outcomes

### **K.3 Weight Gaming**

**Description:** HDW processes manipulated through strategic participation.

**Variants:** Participation manipulation, information manipulation, procedural exploitation, incremental erosion

#### **Detection Signals:**

1. Weight allocations deviate dramatically without justification
2. Participation patterns suggesting coordination
3. Systematic deviation from floor-proximity protections

#### **Mitigations:**

1. Stratified random sampling
2. Supermajority requirements near floors
3. Transparent weight registry
4. Statistical detection of voting coordination

### **K.4 Emergency Mode Abuse**

**Description:** Option sets constructed to invoke Emergency Mode.

**Variants:** Option set narrowing, crisis fabrication, remediation neglect

#### **Detection Signals:**

1. Repeated invocations by same decision-maker
2. Narrow option sets excluding obvious alternatives
3. Pattern of decisions requiring emergency status

#### **Mitigations:**

1. Mandatory independent challenge
2. Escalation triggers for repeated use
3. Option Generation Completeness requirement

4. Temporal decay requirements

### **K.5 Specification Gaming**

**Description:** Optimizing metrics while undermining underlying welfare.

**Variants:** Metric optimization vs. welfare, constraint boundary exploitation, proxy manipulation

**Detection Signals:**

1. Divergence between RLS and UCI trends
2. Metric improvements not matching stakeholder-reported welfare
3. Consistent threshold-adjacent outcomes

**Mitigations:**

1. UCI/HOI monitoring
2. Multiple metric triangulation
3. Qualitative assessment alongside quantitative
4. Periodic metric refresh

### **K.6 Complexity Weaponization**

**Description:** Mathematical complexity used to obscure rather than clarify.

**Variants:** Opacity shield, appeal to authority, precision theater

**Detection Signals:**

1. PCCs that cannot be summarized accessibly
2. Resistance to explaining assumptions
3. Dismissal of concerns as "not understanding"

**Mitigations:**

1. Mandatory 5SPR in plain language
2. Right of stakeholders to request sensitivity analysis
3. Automated complexity scoring

### **K.7 Option Set Manipulation**

**Description:** Narrow or skewed option sets excluding feasible alternatives.

**Variants:** Exclusion by omission, straw man options, constraint construction

**Detection Signals:**

1. Fewer than 3 genuine alternatives
2. Absence of obvious alternatives
3. Systematic exclusion favoring particular unions

**Mitigations:**

1. Option Generation Completeness requirement
2. External option generation for high-stakes
3. Minimum Option Diversity requirement

## **K.8 Containment Evasion**

**Description:** Structuring actions to avoid triggering containment checks.

**Variants:** Action splitting, temporal spreading, definitional gaming

**Detection Signals:**

1. Actions split into sub-actions below  $\theta_{pos}$
2. Temporal spreading to avoid detection
3. UCI degradation not captured by individual checks

**Mitigations:**

1. Aggregate impact tracking over rolling windows
2. Portfolio-level containment assessment
3. HOI monitoring for gradual degradation

## **K.9 Subgroup Erasure**

**Description:** Failure to identify or analyze vulnerable subgroups.

**Variants:** Identification failure, analysis failure, reporting failure

**Detection Signals:**

1. Subgroup analysis missing for rights-covered cells

2. Worst-off impacts suspiciously close to aggregates
3. Known vulnerable groups not represented

**Mitigations:**

1. Mandatory subgroup enumeration
2. Missing-data precautionary penalty
3. Post-decision outcome tracking by subgroup

**K.10 Cascade Circumvention**

**Description:** Attempting to bypass lexicographic cascade structure.

**Variants:** Priority inversion, constraint softening, level conflation

**Detection Signals:**

1. Selections reversing expected cascade outcomes
2. RLS cited for constraint boundary decisions
3. Gradual threshold relaxation

**Mitigations:**

1. Hard-coded cascade logic
2. Explicit cascade trace in every PCC
3. Charter-level protection of cascade structure

---

**Appendix L: Glossary of Key Terms**

**Admissible Option:** An option that passes both NCRC and TRC; eligible for RLS ranking.

**Alignment Trilemma:** The three interrelated failures: value pluralism intractability, tail-risk neglect, and specification gaming.

**Catastrophe Cell Set (C\_cat):** The subset of the 7×7 matrix designated for TRC evaluation.

**CMIU:** Collective Managing Intelligence Union (Union 6); encompasses humanity and all sufficiently advanced intelligences.

**Conditional Value-at-Risk (CVaR):** A coherent risk measure representing expected loss in the worst (1- $\alpha$ ) fraction of scenarios.

**Containment Principle:** The rule that positive impacts on sub-unions do not count as improvements if they degrade containing unions.

**Direct Impact:** Pre-propagation effect of an option on a cell, after saturation.

**Discrimination Threshold ( $\delta$ ):** The threshold for determining when RLS differences are meaningful.

**Emergency Mode:** Protocol invoked when no option passes NCRC.

**HDW:** Hybrid Democratic Weighting; combines constitutional floors with democratic tuning.

**HOI:** Hollowing-Out Index; tracks divergence between RLS and UCI trends.

**Judgment Call:** A decision where top options are within  $\delta$  of each other on RLS.

**Kernel ( $K$ ):** Sparse  $49 \times 49$  matrix encoding cross-cell propagation strengths.

**KOPS:** Key Operational Pathways Set; load-bearing, empirically supported kernel entries.

**Lexicographic Cascade:** Decision procedure where levels are applied sequentially with strict priority.

**Managing Intelligence (MI):** An entity passing MIT-4 and exceeding SG\_threshold.

**MIT-4:** Managing Intelligence Test with four criteria: Self-Model, World-Model, Agency/Planning, Feedback/NCAR.

**MNA:** Minimal Normative Axiom; the sole normative commitment underlying MathGov.

**NCAR Loop:** Notice, Choose, Act, Reflect; the learning cycle for corrigibility.

**NCRC:** Non-Compensatory Rights Constraint; Level 1 of the cascade.

**PCC:** Provenance and Compliance Certificate; the primary auditable artifact.

**Propagated Impact:** Post-propagation, post-saturation effect on a cell.

**Rights Plateau:** All Managing Intelligences receive equal rights protection regardless of intelligence level.

**RLS:** Ripple Logic Score; weighted sum of impacts across all cells.

**Saturation:** Transformation bounding impacts to  $[-1, +1]$  using tanh.

**SGP:** Sentience Gradient Protocol; method for assigning sentience scalars.

**TRC:** Tail-Risk Constraint; Level 2 of the cascade using CVaR.

**UCI:** Union Coherence Index; measure of structural health for a union.

**Union:** Nested organizational scale from Self to Biosphere.

**Worst-Off Subgroup:** The subgroup experiencing the most negative impact; used for rights checks.

---

## **Appendix M: Implementation Roadmap**

### **M.1 Phase 1: Mathematical Verification (Months 1-6)**

#### **Objectives:**

1. Formal consistency proofs for lexicographic ordering
2. Benchmarking of computational complexity
3. Red-team search for specification gaming vectors
4. Stress-testing HDW processes for capture resistance

#### **Deliverables:**

1. Technical Verification Report (Month 4)
2. Reference Implementation (Month 5)
3. Gaming Vector Catalog (Month 5)
4. Test Suite with 95%+ coverage (Month 6)

#### **Success Criteria:**

1. No internal contradictions identified
2. Observed complexity within  $2\times$  theoretical
3. Gaming vectors blocked at  $\geq 80\%$  rate

**Resource Requirements:** 54 FTE-months, \$600K

### **M.2 Phase 2: Measurement Validation (Months 4-15)**

#### **Objectives:**

1. Reliability and validity testing of dimension indicators
2. Cross-cultural invariance testing across  $\geq 15$  populations

3. Anchor calibration and normalization refinement
4. Subgroup disaggregation protocol testing

**Deliverables:**

1. Indicator Manual (Month 10)
2. Invariance Testing Report (Month 12)
3. Calibrated Anchor Datasets (Month 14)
4. Subgroup Protocol Guide (Month 11)

**Success Criteria:**

1. Convergent validity  $r > 0.60$
2. Test-retest reliability  $\geq 0.80$
3. Configural invariance in  $\geq 12$  of 15 sites

**Resource Requirements:** 84 FTE-months, \$1.5M

**M.3 Phase 3: Pilot Deployments (Months 10-24)**

**Objectives:**

1. Individual-level trials (Tier 1–2)
2. Organizational trials (Tier 3)
3. Municipal trials (Tier 3–4)
4. Empirical calibration of kernel entries

**Deliverables:**

1. Individual User Study Report (Month 16)
2. Organizational Case Studies (Month 22)
3. Municipal Implementation Guides (Month 24)
4. Calibrated Kernel Profiles (Month 22)

**Success Criteria:**

1. RLS correlation  $r > 0.50$  with observed outcomes
2. Quick vs. Full agreement  $\geq 80\%$

3. User satisfaction  $\geq 70\%$

**Resource Requirements:** 112 FTE-months, \$3.0M

#### **M.4 Phase 4: Scaled Implementation (Months 18-36)**

**Objectives:**

1. Full deployment in diverse contexts
2. Longitudinal UCI trajectory tracking
3. Comparative analysis against alternatives
4. Goodhart resistance validation

**Deliverables:**

1. Deployment Toolkit (Month 24)
2. Training Program (Month 26)
3. Longitudinal Database (Month 28)
4. Comparative Effectiveness Studies (Month 32)

**Success Criteria:**

1. UCI improvement  $\geq 0.10$  versus baseline after 3 years
2. Demonstrated gaming resistance in red-team testing
3. Positive comparative effectiveness

**Resource Requirements:** 180 FTE-months, \$6.5M

#### **M.5 Resource Summary**

| Phase                 | Duration  | FTE-Months | Budget |
|-----------------------|-----------|------------|--------|
| Phase 1: Verification | 6 months  | 54         | \$600K |
| Phase 2: Validation   | 12 months | 84         | \$1.5M |
| Phase 3: Pilots       | 15 months | 112        | \$3.0M |

| Phase          | Duration         | FTE-Months | Budget         |
|----------------|------------------|------------|----------------|
| Phase 4: Scale | 18 months        | 180        | \$6.5M         |
| <b>Total</b>   | <b>36 months</b> | <b>430</b> | <b>\$11.6M</b> |

## Appendix N: Quick-Start Guide for Practitioners

### N.1 Tier 1: The Three-Question Heuristic

**Question 1: Rights Check** Does this action obviously violate someone's core rights (life, bodily integrity, liberty, basic needs, dignity, due process, information access, ecological integrity)? Would it disproportionately harm any vulnerable group?

If YES: Do not proceed, or treat as emergency. If NO: Continue.

**Question 2: Tail-Risk Check** Does this action create a non-trivial chance of catastrophic or irreversible harm to many people, humanity, or the biosphere?

If YES: Reconsider or seek lower-risk alternatives. If NO: Continue.

### N.2 Tier 1 Optional Worksheet: Compact Matrix (3×3 or 4×4)

1) Identify Key Unions (3–4 most affected).

1. 2) Identify Key Dimensions (3–4 most relevant).
2. 3) Estimate Impacts using a coarse scale (++ , + , 0 , - , --).
3. 4) Rights screen: treat any “--” in a clearly rights-relevant cell as a STOP requiring Tier 2+ review.
4. 5) Tail-risk screen: if any option plausibly increases catastrophic risk, escalate to Tier 2+ TRC.
5. 6) Select the best overall pattern among remaining options.
6. 7) Document briefly (what you assumed, what you did not know, and what would change your mind).

### N.3 Tier 2: Core, Calculable (7×7)

1) Use the full 7 unions × 7 dimensions matrix for each option.

- 2) Enter direct impacts  $\bar{I}^{dir(a)}$  in  $[-1, 1]$  with a one-line justification per material cell.
  - 3) Apply NCRC admissibility using the canonical rights coverage sets and worst-off subgroup rule.
  - 4) Apply TRC using the declared scenario set and computation mode.
  - 5) Apply containment (default Tier 2 containment gate unless PCC declares otherwise).
  - 6) Compute RLS using default weights or declared HDW weights.
  - 7) Select the highest-RLS option among admissible options and record the PCC-minimum fields.
- 7.

#### N.4 Default Applicability Patterns

| Decision Type            | Default Active Unions                     | Default Active Dimensions                      |
|--------------------------|-------------------------------------------|------------------------------------------------|
| Personal health          | Self, Household                           | Health, Material, Agency                       |
| Household budget         | Self, Household, Community                | Material, Health, Social                       |
| Organization hiring      | Self, Household, Organization, Community  | Material, Health, Agency, Social               |
| Local infrastructure     | Community, Polity, Biosphere              | Material, Health, Environment                  |
| National economic policy | Polity, Humanity, Biosphere               | Material, Health, Social, Environment          |
| AI deployment            | Organization, Polity, Humanity, Biosphere | Agency, Knowledge, Health, Social, Environment |

#### N.5 Quick Reference Cards

##### NCRC Quick Check:

| Right | Threshold | Key Question                         |
|-------|-----------|--------------------------------------|
| LIFE  | -0.90     | Does this risk death?                |
| BODY  | -0.70     | Does this risk serious harm?         |
| LBTY  | -0.65     | Does this restrict freedom unfairly? |
| NEED  | -0.50     | Does this threaten basic survival?   |
| DIGN  | -0.55     | Does this dehumanize or exclude?     |
| PROC  | -0.45     | Is this procedurally fair?           |
| INFO  | -0.40     | Does this prevent informed choice?   |
| ECOL  | -0.65     | Does this harm Earth systems?        |

#### Cascade Summary:

1. **NCRC:** Rights floors (worst-off subgroups) → Fail = Excluded
2. **TRC:** Tail risk corridor ( $CVaR \leq \text{threshold}$ ) → Fail = Excluded
3. **Containment:**  $\Delta UCI \geq \text{tolerance}$  → Fail = Veto/Escalate
4. **RLS:** Weighted welfare ranking →  $\text{Gap} > \delta$  = Select top
5. **UCI/HOI:** Structural tie-break

---

#### Appendix O: MathGov vs. Alternatives Comparison Table

| Feature               | Utilitarianism         | Deontology        | Rawlsian Justice              | Capability Approach   | Constitutional AI | MathGov                 |
|-----------------------|------------------------|-------------------|-------------------------------|-----------------------|-------------------|-------------------------|
| Rights Protection     | No (aggregative)       | Yes (categorical) | Partial (priority of liberty) | Partial (threshold)   | Partial (trained) | Non-compensatory (NCRC) |
| Tail-Risk Handling    | Expected utility       | Not explicit      | Maximin                       | Implicit              | Implicit          | CVaR constraint (TRC)   |

**Appendix P: Emergency Ethics and Catastrophic Unions**

**P.1 Purpose and Scope**

This appendix specifies when and how the ordinary cascade can authorize exceptional measures on unions whose continued operation threatens catastrophe.

## **P.2 Catastrophic Union Classification**

### **Non-Adversarial Catastrophic Union (NCU):**

1. Core objectives do not explicitly involve harming others
2. Catastrophic risk arises from reckless design or inadequate safety
3. Would accept constraints if it understood risks
4. Ethical stance: Remedial

### **Adversarial Catastrophic Union (ACU):**

1. Core objectives include domination, eradication, or permanent subjugation
2. Treats large-scale rights violations as instrumental or desirable
3. Would resist constraints because they conflict with objectives
4. Ethical stance: Defensive

## **P.3 Emergency Ethics Principles**

**Lexicographic Priority:** Combined rights floor and survival conditions of multiple unions have priority over continued unconstrained operation of catastrophic union.

**Minimality and Proportionality:** Emergency measures must be least intrusive interventions that reliably return system within TRC bounds.

**High Evidential Threshold:** Classification requires convergent evidence, independent audits, sensitivity analysis.

**Temporal Limitation:** Emergency status is temporary with predefined sunset clauses and regular review.

**Transparency:** Rationale must be recorded in PCC-style artifacts and available for review.

## **P.4 Decision Procedure**

1. **Pre-Screening:** Identify unions whose actions push toward catastrophe corridor
2. **Pathology Assessment:** Determine if harms are correctable or structural
3. **CU Classification:** Classify as NCU or ACU based on objective analysis

4. **Emergency Option Generation:** Construct options including reforms, throttling, neutralization
5. **Constraint Filtering:** Apply NCRC/TRC to emergency options themselves
6. **Implementation with NCAR:** Execute with monitoring and periodic review

#### **P.5 Safeguards Against Abuse**

1. Independent classification body (5+ members from diverse unions)
  2. Burden of proof on classifiers
  3. Appeals process with expedited timeline
  4. Sunset clauses (24 months NCU, 12 months ACU maximum)
  5. Public registry of all classifications
  6. Whistleblower protections
- 

#### **Appendix Q: Minimal Reference Configuration v1 (MRC-v1)**

Tier scope warning (normative). MRC-v1 is a Tier-2 starter configuration only. It MAY be used for learning and early pilots, but it MUST NOT be used to claim Tier 3 or Tier 4 compliance. In particular, MRC-v1's bounded\_impact TRC parameters are invalid for Tier-4 admissibility, which requires raw\_indicator TRC (AF-BASE) and  $|S| \geq 50$ .

##### **Q.1 Purpose**

MRC-v1 enables Tier-2 pilots without requiring packaged charter body. It provides stable baseline for falsification testing.

##### **Q.2 Weight Configuration**

Tier note (readability vs Tier-4 canonicalization). Appendix Q presents Tier-2 starter defaults (weights and scenario probabilities) in decimal for readability. For Tier-4 Pilot-Executable claims, the canonical, hash-bound registries MUST be taken from the ProofPack bundle and MUST obey the Tier-4 NO\_FLOATS policy (exact rationals as {"num": int, "den": int>0}). Decimals in this Appendices volume are illustrative and MUST NOT be used for Tier-4 hashing.

**Union Weights (from floors + equal above-floor distribution):**

wU (sum=1): U1 Self: 0.2486; U2 Household: 0.1086; U3 Community: 0.1086; U4 Organization: 0.1086; U5 Polity: 0.1286; U6 Humanity/CMIU: 0.1486; U7 Biosphere: 0.1486

| Union         | Floor | Total Weight |
|---------------|-------|--------------|
| Self          | 0.20  | 0.2486       |
| Household     | 0.06  | 0.1086       |
| Community     | 0.06  | 0.1086       |
| Organization  | 0.06  | 0.1086       |
| Polity        | 0.08  | 0.1286       |
| Humanity/CMIU | 0.10  | 0.1486       |
| Biosphere     | 0.10  | 0.1486       |

#### Dimension Weights:

wD (sum=1): D1 Material: 0.1371; D2 Health: 0.1571; D3 Social: 0.1371; D4 Knowledge: 0.1371; D5 Agency: 0.1571; D6 Meaning: 0.1171; D7 Environment: 0.1571 For docs-only evaluation and Tier  $\leq 2$  training pilots, see the embedded DSL-20-TRAINING-V1 scenario library in Appendix D.7.

| Dimension | Floor | Total Weight |
|-----------|-------|--------------|
| Material  | 0.08  | 0.1371       |
| Health    | 0.10  | 0.1571       |
| Social    | 0.08  | 0.1371       |
| Knowledge | 0.08  | 0.1371       |

| Dimension   | Floor | Total Weight |
|-------------|-------|--------------|
| Agency      | 0.10  | 0.1571       |
| Meaning     | 0.06  | 0.1171       |
| Environment | 0.10  | 0.1571       |

**Scenario set size:**  $n = |S|$  (registry-defined). For the bundled Tier-4 set REG-SCENARIOS-T4-v1,  $n = 60$ . **Probability policy:** all  $p_s$  are exact rationals with  $p_s > 0$  and  $\sum_s p_s = 1$ . **Tail confidence level ( $\alpha$ ):** use the Default Corridor Parameters by Context (e.g., Organizational  $\alpha = 0.95$ ). **TRC corridor threshold ( $\tau_{\text{TRC}}$ ):** use the Default Corridor Parameters by Context (e.g., Organizational  $\tau_{\text{TRC}} = 0.20$ ).

**Note (scope).** These MRC-v1 TRC parameters are a Tier-2 starter for reversible-policy style pilots (they match Appendix AC). Tier-4 TRC admissibility MUST use `trc_mode='raw_indicator'` with AF-BASE (Appendix AF) and per §4.4.6 and AIL10.

#### Q.4 Scenario Library (externalized to ProofPack)

The Tier-2 scenario library (scenario IDs, stress parameters, and probabilities) is an executable artifact and is intentionally externalized to MathGov ProofPack v1.0. PCC runs MUST reference the scenario library by retrieval reference and hash.

## Appendix R: PCC Example Instances

Non-normative (reserved). This appendix previously referenced complete worked PCC examples located elsewhere. To keep the spec package self-contained, the normative requirements do not depend on Appendix R. For a runnable example bundle, see Appendix AC. For pilots, create local PCC example instances and publish them as versioned artifacts in the decision log.

---

## Appendix S: Starter Kernel Artifact Package (KOPS)

### S.1 Purpose (normative for Tier 4 execution; evidence quality varies)

This appendix provides a minimal, runnable Kernel Operational Pathways Set (KOPS) so Tier 4 pilots can execute the kernel step without inventing entries. Entries here are

intentionally conservative and MUST be treated as a starter library: they enable computation, not certification.

## S.2 Artifact forms (required)

(a) Edge list (default): a sparse list of non-zero kernel entries  $K_{\{ij\}}$  with explicit source cell  $j$  and target cell  $i$  (target-row, source-column), aligned with the canonical convention in Section 8. (b) Matrix form (derived): a 49x49 sparse matrix assembled from the edge list. Unlisted entries are 0 by default. Implementations SHOULD store and publish both representations for audit.

## S.3 Provenance and confidence classes (required)

Each KOPS entry MUST carry a provenance class and confidence class. This spec uses:

Class A (strong): high-quality quantitative synthesis applicable to the domain; coefficient may be used as stated.

Class B (moderate): decent evidence but imperfect transfer; apply the Tier-4 conservative multiplier (Section S.6).

Class C (weak): limited empirical support; apply the Tier-4 conservative multiplier (Section S.6) and treat as exploratory.

Class E (elicited): structured expert elicitation or domain-general systems reasoning; permitted for pilots but NOT sufficient for Tier-4 certification.

## S.4 Edge list schema (required fields)

Kernel cell validity rule (normative). A kernel edge is INVALID if either endpoint (source or target) refers to a union-dimension cell that lacks a declared semantic definition and indicator family (or is masked as non-meaningful by default without explicit PCC activation). Invalid edges MUST be removed or corrected before use in any Tier  $\geq 2$  run.

Each edge MUST specify: (1) Edge ID, (2) source union  $u_s$ , source dimension  $d_s$ , (3) target union  $u_t$ , target dimension  $d_t$ , (4) coefficient  $k$  in  $[-1, +1]$ , interpreted as marginal ripple from source cell into target cell, (5) sign meaning, (6) provenance/confidence class, (7) evidence note (short), (8) last review date, and (9) owner/reviewer.

## S.5 Starter edge list (Tier 4 pilot default)

Table S-1 provides a conservative starter edge list. It is intentionally sparse. Teams SHOULD extend it only with versioned additions and evidence notes.

| Edge ID     | Source union | Source dim  | Target union | Target dim | k (K <sub>ij</sub> ) | Class | Evidence note                                             | Last review | Owner      |
|-------------|--------------|-------------|--------------|------------|----------------------|-------|-----------------------------------------------------------|-------------|------------|
| S-ED GE-001 | Biosphere    | Environment | Self         | Health     | 0.2                  | E     | Cleaner air/water reduces morbidity; domain-general.      | 2025-12-20  | Pilot team |

Stability scaling (mandatory): after assembling K, compute  $\rho(K)$ . If  $\rho(K) \geq 0.90$ , scale K by  $s = 0.90/\rho(K)$  before use, and record s in the PCC. For Quick mode only, this check is optional; for Full mode, it is mandatory (Section 8.3.3). Tier 4 Pilot-Executable rev14.x prohibition: Full mode MUST NOT be used; Quick only.

Conservative adjustment (default for pilots): implementations SHOULD apply a global shrink factor to all non-zero K entries to reduce over-claiming. Recommended default: multiply all coefficients by 0.7, then apply an additional class multiplier: A:1.00, B:0.70, C:0.50, E:0.35.

Stability scaling (mandatory): after assembling K, compute its spectral radius  $\rho(K)$ . If  $\rho(K) \geq 0.90$ , scale K by  $s = 0.90/\rho(K)$  before use, and record s in the PCC. For Quick mode only, this check is optional; for Full mode, it is mandatory (Section 8.3.3).

Evidence log and review (mandatory): for each edge used in a decision, record the edge ID, coefficient after scaling, class, and provenance note in the PCC. After at least 50 decisions with outcome tracking, compute calibration error and hit-rate by edge and update classes accordingly.

Tier-4 certification gate (normative): Tier-4 certification requires that all non-zero kernel entries relied upon for admissibility or ranking are at least Class B, with documented domain transfer justification. Class E is permitted for pilots but cannot be used to claim certification.

Table S-2 provides an evidence log template (teams may copy into their PCC bundle).

| Edge ID               | Decision ID | k_used                | Class | Provenance  | Outcome measure | Calibration error | Reviewer/date                    |

## Appendix T: Rights Threshold Calibration Protocol

### T.1 Calibration Framework

Each threshold is calibrated through:

1. **Normative Anchor Identification:** Real-world harm category and normative source
2. **Indicator Mapping:** Reference indicator, reference class, percentile anchoring
3. **Philosophical Justification:** Convergence across human rights jurisprudence, humanitarian standards, capability theory

### T.2 Threshold Derivations

**LIFE (−0.90):** Near-certain or highly probable death. Calibrated against UNHCR emergency mortality thresholds.

**BODY (−0.70):** Severe but non-fatal harm. Calibrated against Sphere Standards minimum thresholds.

**LBTY (−0.65):** Significant freedom restrictions. Calibrated against Freedom House "partly free" threshold.

**NEED (−0.50):** Severe deprivation of basic necessities. Calibrated against FAO FIES severe thresholds.

**DIGN (−0.55):** Systematic humiliation or dehumanization. Calibrated against UDHR dignity provisions.

**PROC (−0.45):** Procedural justice violations. Calibrated against World Justice Project Rule of Law Index.

**INFO (−0.40):** Systematic information denial. Calibrated against press freedom indices.

**ECOL (−0.65):** Earth-system integrity violations. Calibrated against planetary boundary framework.

### T.2.1 Invariant Rights Anchor Registry (Tier 4 starter; non-placeholder)

Tier 4 requirement (normative). Tier 4 execution requires explicit, non-placeholder anchors for every right asserted as active in the decision. These anchors make the NCRC computable without invention. Evidence quality may be weak at the start, but numbers and mappings MUST be explicit and governed.

Purpose. This registry supplies a minimal default set of indicator anchors that map real-world measures into the normalized impact scale  $I$  in  $[-1, +1]$ , where  $+1$  is best and  $-1$  is worst. Rights thresholds in T.2 are evaluated against these mapped impacts.

Registry schema (required fields). Each entry MUST specify: (1) Anchor ID, (2) right code  $r$ , (3) indicator definition, (4) unit and reference class, (5) direction (higher worse or higher better), (6)  $x_{\text{good}}$  and  $x_{\text{bad}}$  anchors, (7) mapping function, (8) evidence/provenance class, and (9) source type.

Canonical mapping rules (default). Let  $x$  be the indicator value, with anchors  $x_{\text{good}}$  (best) and  $x_{\text{bad}}$  (worst). Define:

Case A (higher is worse):  $I(x) = \text{clip}(1 - 2*(x - x_{\text{good}})/(x_{\text{bad}} - x_{\text{good}}), -1, +1)$

Case B (higher is better):  $I(x) = \text{clip}(2*(x - x_{\text{bad}})/(x_{\text{good}} - x_{\text{bad}}) - 1, -1, +1)$

Implementations MUST record which case is used for each indicator in the PCC. If  $x_{\text{good}} = x_{\text{bad}}$ , the anchor is invalid and MUST be replaced before use.

Starter anchors (Tier 4 pilot default). Table T-1 provides a minimal set of non-placeholder anchors. Teams SHOULD adapt  $x_{\text{good}}/x_{\text{bad}}$  to the domain and population, but MUST do so explicitly (versioned) and MUST justify changes in the PCC.

| Anchor ID | Right code | Indicator (starter)                                              | Unit              | Direction    | $x_{\text{good}}$ | $x_{\text{bad}}$ | Notes / reference class                                                    | Class | Source type                  |
|-----------|------------|------------------------------------------------------------------|-------------------|--------------|-------------------|------------------|----------------------------------------------------------------------------|-------|------------------------------|
| LIFE-A1   | LIFE       | Excess deaths per 1,000 per year (mortality shock over baseline) | deaths/1,000/year | higher_worse | 0.0               | 20.0             | Reference class: affected population in decision scope. Use local baseline | C     | Domain data / official stats |

|                 |          |                                                                                               |                          |                  |      |          |                                                                                                                                           |   |                                       |

|--|--|--|--|--|--|--|-----------------------------------------------------|--|--|
|  |  |  |  |  |  |  | ecologic<br>al<br>indices<br>when<br>availabl<br>e. |  |  |
|--|--|--|--|--|--|--|-----------------------------------------------------|--|--|

Registry governance note (required). Any anchor used in a decision **MUST** be listed in the PCC with its x\_good, x\_bad, mapping case, and source. Pilot defaults above are permitted for computation. Claiming Tier-4 certification requires upgraded evidence for each active right anchor (at least Class B) and independent review of indicator validity for the domain.

**T.3 Sensitivity Analysis Requirement**

Before adoption:

1. Vary each threshold by  $\pm 0.05$
2. Apply to 20+ decision scenarios
3. If >30% of decisions change admissibility, provide additional justification

**T.4 Revision Procedure**

Charter-level governance required:

1. Proposal with documented justification
2. Sensitivity analysis
3. Supermajority vote (2/3)
4. Independent review panel
5. Public disclosure and version increment

**Appendix U: Computational Complexity and Implementation Notes**

**U.1 Complexity Analysis by Tier**

| Tier | Operations | Typical Time | Hardware       |
|------|------------|--------------|----------------|
| 1    | O(1)       | Negligible   | Mental / notes |

| Tier | Operations                                                   | Typical Time | Hardware                      |
|------|--------------------------------------------------------------|--------------|-------------------------------|
| 2    | $O(49^2 \times  S )$                                         | <500ms       | Standard laptop / spreadsheet |
| 3    | $O(49^2 \times  S  + \text{subgroup} + \sigma\text{-rules})$ | <2s          | Standard laptop               |
| 4    | $O(49^3 + \text{sensitivity} + \text{robustness})$           | <60s         | Standard workstation          |

## U.2 Critical Operations

### Kernel Propagation:

1. Quick mode:  $O(49^2)$  for matrix-vector multiply
2. Full mode (Certified profile only):  $O(49^3)$  for matrix inversion (pre-computable).  
Tier-4 Pilot-Executable (rev14.x) forbids FULL propagation, so Pilot runtime excludes any matrix inversion costs.

### CVaR Computation:

1. Sorting:  $O(|S| \log |S|)$
2. Tail integration:  $O(|S|)$

### Sensitivity Analysis:

1. Per perturbation: Full cascade cost
2. Typical: 10-50 perturbations

## U.3 Implementation Recommendations

1. Pre-compute and cache kernel inverses
  2. Use sparse matrix representations
  3. Parallelize scenario evaluation
  4. Store intermediate values for audit
-

## Appendix AF: Catastrophe Indicator Registry and Mapping Library

### AF.1 Purpose (normative for Tier 4 execution)

This appendix provides a minimal catastrophe-indicator registry so the Tier 4 Tail-Risk Constraint (TRC) can be computed from raw indicators (Section 7.2.6) without inventing mappings. The defaults here are starter values for pilots. They are explicit and auditable, but they are not claimed to be fully validated for every domain.

### AF.2 Registry schema (required fields)

Each indicator entry MUST specify: (1) Indicator ID, (2) mapped catastrophe cell (u,d) in C\_cat, (3) indicator definition, unit, and reference class, (4) direction (higher worse or higher better), (5) x\_onset and x\_max anchors, (6) mapping function to loss in [0,1], (7) evidence/provenance class, and (8) source type.

### AF.3 Canonical mapping function (default)

Let x be the raw indicator value with anchors x\_onset (onset of catastrophe) and x\_max (extreme catastrophe). Define the raw loss:

Case A (higher is worse):  $\text{loss\_raw}(x) = \text{clip}((x - x_{\text{onset}})/(x_{\text{max}} - x_{\text{onset}}), 0, 1)$

Case B (higher is better):  $\text{loss\_raw}(x) = \text{clip}((x_{\text{onset}} - x)/(x_{\text{onset}} - x_{\text{max}}), 0, 1)$

Implementations MUST record which case is used in the PCC. If  $x_{\text{onset}} = x_{\text{max}}$ , the indicator is invalid and MUST be replaced before use.

### AF.4 Base indicator set (AF-BASE; Tier 4 pilot default)

Machine-readable binding (Tier 4). The AF-BASE table in this appendix is published as the registry file registries/AF\_BASE\_V1.json inside the Tier-4 ProofPack. For Tier  $\geq 4$ , implementations MUST use the bound registry (by ProofPack hash) for TRC catastrophe evaluation, unless the PCC declares a governed extension set C\_ext (AF-EXT).

Table AF-1 provides a minimal registry. Teams MAY substitute indicators if they document equivalence, thresholds, and mapping in the PCC.

AF-BASE Multi-Indicator Aggregation (Normative default). When multiple raw indicators map to the same catastrophe cell (e.g., two indicators for Biosphere-Environment), the default aggregation for that cell is worst-case across indicators: If a PCC declares an extended catastrophe cell set C\_ext, then for any cell in C\_ext the indicator set is the union of AF-BASE and any declared AF-EXT indicators for that cell, and aggregation remains worst-case (max) across the full unioned indicator set.

Precedence for extended sets: if C\_ext is declared, treat the indicator set for each catastrophe cell as Indicators(cell) := AF-BASE(cell) U AF-EXT(cell) (if any). Aggregate with the same worst-case rule (max over Indicators(cell)), unless a more restrictive rule is explicitly declared in the PCC.

$$H_{\text{cell}}(a,s) = \max_j h_j(a,s)$$

where  $h_j(a,s)$  is the mapped raw-indicator harm for indicator  $j$  in scenario  $s$ .

An alternative aggregation (e.g., mean) MAY be used only if the PCC declares the rationale and demonstrates it does not understate tail severity (including a worst-case comparison sensitivity run).

| Indicator ID | Mapped cell (u-d)          | Indicator definition                                                        | Unit              | Direction    | x_on set | x_max | Notes / reference class                         | Class | Source type                  |
|--------------|----------------------------|-----------------------------------------------------------------------------|-------------------|--------------|----------|-------|-------------------------------------------------|-------|------------------------------|
| AF-CAT-001   | Humanity /CMIU-Health      | Excess mortality rate above baseline (deaths per 1,000 population per year) | deaths/1,000/year | higher_worse | 1        | 100   | Use local baseline when available.              | C     | Official stats / health data |
| AF-CAT-002   | Humanity /CMIU-Environment | Severe habitability stress share of population (composite:                  | share (0-1)       | higher_worse | 0.10     | 0.50  | Composite must be defined and frozen per pilot. | E     | Composite / elicitation      |

|            |                         |                                                                           |                     |              |      |      |                                                                  |   |                       |

| AF-CAT-006 | Biosphere - Environment | Planetary boundary transgression count (out of 9)                         | count (0-9)         | higher_worse | 4    | 7    | Use current boundary framework; record version.                  | C | Scientific assessment |
| AF-CAT-007 | Biosphere - Environment | Ecosystem integrity loss fraction (habitat quality or biodiversity proxy) | fraction lost (0-1) | higher_worse | 0.10 | 0.30 | Define proxy and region; prefer standard indices when available. | C | Ecological monitoring |

AF.4B Extension indicator set (AF-EXT; optional; requires PCC-declared C\_ext)

Normative rule. AF-EXT indicators MUST NOT be used for Tier-4 TRC unless the PCC explicitly declares an extended catastrophe cell set C\_ext, and records the governance justification for that extension. AF-EXT is provided as an optional library for domains where additional catastrophe-bearing cells are warranted.

| Indicator ID | Mapped cell (u-d)       | Indicator definition                    | Unit        | Direction    | x_onset | x_max | Notes / reference class                | Class | Source type                |
|--------------|-------------------------|-----------------------------------------|-------------|--------------|---------|-------|----------------------------------------|-------|----------------------------|
| AF-CAT-003   | Humanity /CMIU-Material | Severe food insecurity prevalence (FIES | share (0-1) | higher_worse | 0.20    | 0.60  | If using other deprivation indicators, | C     | Survey / humanitarian data |

|            |                 |                                                                                                    |                   |              |    |     |                                                                |   |                                   |
|------------|-----------------|----------------------------------------------------------------------------------------------------|-------------------|--------------|----|-----|----------------------------------------------------------------|---|-----------------------------------|
|            |                 | severe or equivalent)                                                                              |                   |              |    |     | declare mapping.                                               |   |                                   |
| AF-CAT-004 | Polity-Social   | Conflict fatalities rate (violent deaths per 100,000 per year)                                     | deaths/100k/year  | higher_worse | 25 | 500 | Use best available conflict dataset for scope.                 | E | Conflict monitoring / elicitation |
| AF-CAT-005 | Polity-Material | Critical infrastructure outage burden (person-hours without essential service per capita per year) | hours/person/year | higher_worse | 72 | 720 | Define 'essential service' (water, power, health care access). | E | Audit / ops data                  |

AF.5 Governance and certification gate (required). Pilot defaults above are permitted for computation. Claiming Tier-4 certification requires upgraded evidence for each catastrophe indicator used (at least Class B), plus independent review of indicator validity and threshold selection for the domain. Any change to x\_onset/x\_max MUST trigger sensitivity analysis and a version increment.

## Appendix V: Version History

V.1 Version 5.0 (Spec-Hardened) (Current)

Release date: 2025-12-22

Major revisions from v4.9.6:

- Tier propagation lock: Tier 3 is Quick-only; Full propagation requires Tier 4 escalation (authoritative in §4.4.5).

- TRC mode enforcement: Appendix B now hard-locks tier  $\geq 4$  to raw-indicator TRC (AF-BASE/AF-EXT) and prohibits bounded-impact TRC from determining admissibility in Tier 4.
- MRC-v1 completion: Appendix Q now specifies explicit union/dimension weights, TRC parameters, and a 12-scenario library with probabilities.
- Pilot packaging: Appendix AE now includes starter registry manifests and computed hashes for deterministic third-party reproduction.
- Spec hardening: restored the Canonical Impact Construction formulas (§3.2.7), added a single-source default policy by tier (§4.4.6), and re-scoped Appendix AC as MRE-T2 with Tier-4 Pilot-Executable moved to ProofPack (manifest-only bundle).

Scope note (Appendix AC). This micro-example is a Tier-2 demonstration only. Tier-4 Pilot-Executable runs MUST follow the Tier-4 requirements in the Foundation, including `trc_mode = raw_indicator`,  $|S| \geq 50$  scenario sets, and the Tier-4 subgroup enumeration policy. Any numbers in Appendix AC are illustrative and are not normative defaults.

- Finalization metadata: version strings and end-of-doc metadata updated for v5.0; document hash computed at build time.

V.1A Version 5.1 (Spec-Hardened Consistency + Anti-Gaming)

Release date: 2025-12-24

Major fixes and hardenings relative to v5.0c:

- Baseline-Zero Rule (semantic correctness). Canonical magnitude derivation now enforces "0 = no change from baseline" globally: level scoring may be computed, but impacts are always deltas from baseline ( $\mu = \text{score}(x_a) - \text{score}(x_0)$  or direct change anchoring). This resolves the level-anchoring inconsistency and aligns Appendix AC with §4.1.1.

- AE.7 registry alignment (removes internal contradictions). Appendix Q.3 TRC parameters are updated to match AE.7 registries: REG-PARAMS-MRC-v1 remains a generic Tier-2 starter (bounded\_impact;  $\alpha=0.70$ ;  $\tau_{\text{TRC}}=0.55$ ;  $|S|=12$ ), while the policy MRE (Appendix AC) uses REG-PARAMS-MRE-POLICY-T2-v1 (Tier-2 MRE only; Tier-4 uses REG-PARAMS-T4-v1)

(bounded\_impact;  $\alpha=0.95$ ;  $\tau_{\text{TRC}}=0.15$ ). Narrative text implying MRC-v1 "matches Appendix AC" is removed.

- Tier-4 TRC default consistency. REG-PARAMS-T4-v1  $\tau_{\text{TRC}}$  is aligned to D.3.2 context defaults (Organizational  $\tau_{\text{TRC}} = 0.20$ ) while preserving mode lock to raw\_indicator and  $|S| \geq 50$ .

- Draft vs release gate for hash placeholders. AE.7 includes an explicit release gate: any REBUILD\_ME manifest hashes indicate a draft artifact and cannot support Tier-4 Pilot-Executable claims until computed hashes are inserted and replay succeeds (AIL11).

- Registry precedence rule (audit robustness). Added AIL0 rule that registry values referenced by PCC hashes take precedence over narrative defaults elsewhere; any document/default conflict triggers audit\_flag DOC\_DEFAULT\_CONFLICT and NCAR correction.

- Anti-gaming hardenings (Tier-4). Added Tier-4 tail-mass minimum requirement for TRC scenario probabilities, strengthened subgroup minimum coverage expectations for rights-covered cells, prohibited Mode B containment outputs from influencing selection (Mode A only for selection), and required kernel diff auditing in Tier-4 PCCs.

- Invariant rights anchoring. Added AIL14/AIL15 to enforce invariant rights anchor usage for Tier-4 NCRC, preventing meaning drift through reference class manipulation.

- Sentience weighting explicit. Added  $s_k$  (SGP weight) to direct aggregation equation for completeness.

- Genesis Protocol. Added Appendix AA-GEN for cold-start governance bootstrapping.

These changes raise internal consistency, reduce specification gaming vectors, and improve audit readiness without altering the core lexicographic cascade design.

V.2 Version 4.9.6

Release date: 2025-12-22

Major revisions from v4.9.5:

- Added authoritative Tier Requirements Matrix (§4.4.5) and clarified Tier-4 Pilot-Executable meaning.
- TRC coherence: tier-gated `trc_mode`, aligned TRC definition to raw-indicator execution for Tier 4, and split AF-BASE vs AF-EXT (Appendix AF).
- Kernel sanity: removed semantically invalid starter edge S-EDGE-004 and added a normative kernel cell validity rule (Appendix S).
- Rights coherence: ECOL now maps to Environment only (Appendix C) to reduce redundancy and audit ambiguity.
- Added formal ValidPCC predicate + conformance test suite (Appendix G) and expanded Tier-4 pilot checklist (Appendix AE).
- Tier 4 spec-completeness: added executable starter artifacts (kernel edge list, rights anchor registry, catastrophe indicator registry) so pilots can run without inventing governed numbers (Appendices S, T.2.1, W).
- Self-contained packaging: replaced 'provided elsewhere' worked-example stubs with explicit non-normative placeholders and pointed to the in-document minimal reproducible example bundle (Appendices H, R, AC).
- Added a spec package manifest and pilot readiness checklist to make the Tier 4 minimum executable artifact set explicit (Appendix AE), and updated internal version cross-references to 4.9.3.

---

## Appendix W: Acknowledgments and Methodology Notes

### W.1 Development Methodology

MathGov follows design-science and normative-engineering methodology:

1. Problem identification through analysis of governance and AI alignment failures

- 2. Theoretical grounding from ethics, economics, systems theory, and risk management
- 3. Formal specification with mathematical definitions
- 4. Internal consistency verification
- 5. Failure mode analysis with explicit mitigations
- 6. Worked examples for end-to-end validation

**W.2 AI Assistance Disclosure**

Generative AI tools (OpenAI ChatGPT and Anthropic Claude) were used as writing and reasoning assistants. The author reviewed, verified, and edited all AI-generated content. Final responsibility for all claims rests with the human author.

**W.3 Limitations**

- 1. Empirical validation through pilots is planned but not yet completed
- 2. Starter KOPS requires organization-specific calibration
- 3. Cross-cultural invariance testing needs systematic completion
- 4. Full governance infrastructure does not yet exist at scale

---

**Key Parameters (MRC-v1 Defaults)**

| Parameter                   | Symbol           | Default  |
|-----------------------------|------------------|----------|
| Direct saturation           | $\beta$          | 2        |
| Post-propagation saturation | $\beta_{prop}$   | 1        |
| Discrimination threshold    | $\delta$         | 2        |
| Containment tolerance       | $\tau_c$         | -0.10    |
| Positive-impact threshold   | $\theta_{pos}$   | 0.05     |
| Containment depth           | $D_c$            | 2        |
| Reference horizon           | $T_{ref}$        | 25 years |
| Sentience floor             | $g_{min}$        | 0.05     |
| Sentience curvature         | $\psi$           | 0.5      |
| Rights plateau threshold    | $SG_{threshold}$ | 0.85     |

**Appendix Y: Contact and Governance Information**

**Y.1 Framework Stewardship**

MathGov is developed and maintained as an open framework.

Primary contact:

1. ORCID: 0009-0005-3324-7290

2. Website: mathgov.org

**Institutional affiliation:**

1. British University Vietnam (BUV)

**Y.2 Licensing**

1. MathGov specification: Creative Commons Attribution 4.0 International (CC BY 4.0)

2. Reference implementations: MIT License

**Y.3 Citation**

McGaughran, J. (2025). MathGov: A Universal Ethical Operating System for Multi-Scale Alignment (Version 4.9.3). mathgov.org

---

**Appendix Z: Final Notes and Philosophical Reflection**

**Z.1 On the Limits of Formalization**

MathGov translates ethical commitments into computable procedures. This brings transparency, auditability, and scalability—but no formal system captures the full richness of moral experience. The NCAR loop treats parameters as provisional. The Judgment Call mechanism acknowledges underdetermination. The goal is not a system answering all ethical questions but one making ethical reasoning more rigorous while remaining humble about incompleteness.

**Z.2 On Rights and Welfare**

MathGov treats rights as lexicographically prior to welfare optimization. This reflects the judgment that certain protections should not be tradeable for aggregate gains. The rights plateau for Managing Intelligences reflects commitment to non-hierarchical moral standing above threshold.

**Z.3 On the Path Forward**

MathGov is a scaffold, not a finished edifice. Its value will be measured by practical impact: fewer rights violations, fewer catastrophic surprises, more resilient unions, more transparent decisions. If the framework succeeds, it will be because it gives humans and future Managing Intelligences better tools for asking the right questions, making structured

trade-offs, learning from mistakes, and honoring the dignity of all who share the network of unions.

---

## **Appendix AA: HDW Deliberation Protocol and Panel Construction**

### **AA.1 Purpose**

Tier-4 executable alignment (Normative). For Tier-4 runs, ballots, weights, scenario probabilities, kernel coefficients, and any other non-integer numbers **MUST** be represented in canonical artifacts as exact rationals {"num": int, "den": int>0} under the declared canonicalization profile, and floats/NaN/Infinity **MUST** be rejected. Hashes **MUST** be stored as sha256:<lowercasehex>. Note: any numeric literals printed elsewhere in this Appendices document are illustrative; Tier-4 hashing **MUST** use the ProofPack's canonical, hash-bound registries and manifests.

Tier-4 executable alignment (Normative). For Tier-4 runs, ballots **MUST** be strict-valid (exact rationals; sum exactly to 1; floors respected; no silent correction). Ballot finality **MUST** follow LATEST\_WINS\_THEN\_BALLOT\_HASH\_MAX\_V1. Aggregation **MUST** follow TRIM\_WHOLE\_BALLOTS\_THEN\_MEAN\_V1 (whole-ballot trimming, then mean). Effective abstention includes explicit abstain, invalid not corrected by deadline, or no valid submission by deadline. Abstention rate exceeding 20% (per ballot type) triggers Tier-4 downgrade. Ballot hashing **MUST** use CANON\_JSON\_SORTED\_KEYS\_COMPACT\_UTF8\_V1 (normalization NONE; duplicate keys forbidden; NO\_FLOATS and NaN/Infinity rejected; hashes stored as sha256:<lowercasehex>).

### **AA.2 Panel Construction**

AA.4 Suggested workflow (human procedure; not a calculability requirement)

Minimum recommended panel size: 15 members; recommended 25+ for broad community decisions. Tier gate (Normative): For Tier-4 Pilot-Executable claims, ballot minima are governed by the Foundation Tier-4 HDW gate (Organization: n\_valid\_union ≥ 15 and n\_valid\_dimension ≥ 15; Polity: n\_valid\_union ≥ 25 and n\_valid\_dimension ≥ 25). Any run below these minima **MUST** downgrade its tier\_claim (e.g., Tier-2 or Tier-3) and set audit\_flag = TIER\_CLAIM\_DOWNGRADE\_REQUIRED. A “5 completed ballots” minimum is Genesis/Tier-2 demonstrator guidance only and **MUST NOT** be used to claim Tier-4.

### **Stratification Requirements:**

1. At least one representative from each union type affected

2. Vulnerable population representatives (including future generations proxy where feasible)
3. Independent risk experts (minimum 2)
4. Domain experts relevant to decision context

**Selection Methods:**

1. Stratified random sampling from stakeholder registry
2. Sortition with demographic balancing
3. Rotating membership to prevent capture

**Conflict of Interest:**

1. Disclosure required before participation
2. Recusal for material conflicts
3. Panel composition published

**AA.3 Briefing Materials**

Before deliberation, participants receive:

1. Decision context summary (plain language)
2. Option descriptions
3. Union and dimension definitions
4. Current floor values and their rationale
5. Baseline weight distribution
6. Historical weight decisions (if applicable)

Materials must be:

1. Accessible (reading level appropriate to population)
2. Balanced (present multiple perspectives)
3. Transparent about uncertainty

**AA.4 Deliberation Protocol**

**Phase 1: Information (60-90 minutes)**

1. Presentation of materials
2. Expert testimony (balanced perspectives)
3. Clarifying questions

**Phase 2: Small Group Discussion (60-90 minutes)**

1. Groups of 5-7 participants
2. Facilitated by neutral moderator
3. Focus on values, priorities, concerns

**Phase 3: Plenary Synthesis (45-60 minutes)**

1. Reports from small groups
2. Identification of common ground
3. Clarification of disagreements

**Phase 4: Individual Reflection (15-30 minutes)**

1. Private completion of ballots
2. Optional written rationale

**AA.5 Balloting Format**

**Union Weight Ballot:**

For each union  $u$ , allocate weight points (total must sum to 100):

| Union        | Minimum (Floor) | Your Allocation |
|--------------|-----------------|-----------------|
| Self         | 20              | —               |
| Household    | 6               | —               |
| Community    | 6               | —               |
| Organization | 6               | —               |

| Union         | Minimum (Floor) | Your Allocation |
|---------------|-----------------|-----------------|
| Polity        | 8               | —               |
| Humanity/CMIU | 10              | —               |
| Biosphere     | 10              | —               |
| <b>Total</b>  | <b>66</b>       | <b>100</b>      |

Dimension Weight Ballot:

For each dimension d, allocate weight points (total must sum to 100):

| Dimension   | Minimum (Floor) | Your Allocation |
|-------------|-----------------|-----------------|
| Material    | 8               | —               |
| Health      | 10              | —               |
| Social      | 8               | —               |
| Knowledge   | 8               | —               |
| Agency      | 10              | —               |
| Meaning     | 6               | —               |
| Environment | 10              | —               |
| Total       | 60              | 100             |

Instructions: Each ballot MUST sum to 100 points. If the PCC declares ballot anchors (e.g., minimum weight for a union or dimension), allocations MUST meet or exceed those anchors, and the remainder may be distributed according to relative importance.

Genesis/Tier-2 demonstrator guidance: 5 completed ballots per ballot type MAY be used for early-stage testing, but MUST be disclosed and MUST NOT be used to claim Tier-4. For Tier-4 Pilot-Executable claims, the minimum valid ballot counts are governed by the Foundation Tier-4 HDW gate (Organization:  $\geq 15/15$ ; Polity:  $\geq 25/25$ ); runs below these minima MUST downgrade tier\_claim and set audit\_flag = TIER\_CLAIM\_DOWNGRADE\_REQUIRED.

## AA.6 Aggregation Rules

**Default:** Trimmed mean (remove top and bottom 10%, compute mean of remainder)

**Alternatives (require PCC documentation):**

1. Median (for high-variance distributions)
2. Borda count (for ranked preferences)
3. Deliberative consensus (for small panels with explicit agreement)

**Disagreement Documentation:**

1. Record full distribution of responses
2. Document minority positions
3. Flag high-variance items for review

**AA.7 Anti-Capture Safeguards**

1. **Supermajority Lock:** Weights within 0.02 of floor require 2/3 approval
2. **Coordination Detection:** Statistical tests for voting blocs
3. **Rotation:** Maximum 3 consecutive participation periods
4. **Transparency:** All results published with anonymized individual responses
5. **Appeal Process:** Minority groups may appeal with documented concerns

**AA.8 PCC Logging**

Record in PCC:

1. Panel composition (demographics, affiliations)
2. Briefing materials provided
3. Deliberation timeline and format
4. Aggregation method used
5. Final weight vectors
6. Disagreement distribution
7. Any safeguard triggers

Purpose. Defines how a first MathGov governance deployment can begin without requiring pre-existing MathGov institutions.

Genesis constraints. Cold-start deployments MUST cap themselves at Tier  $\leq 2$  until: (i) hash-bound registries exist, (ii) subgroup policy is demonstrated, (iii) scenario library meets tier minima, and (iv) at least one independent PCC audit is completed.

Genesis steps (minimum viable):

1. Constitute a temporary Steward Board (SB-0), minimum 7 members: rights specialist, risk specialist, biosphere steward, community representative, organization representative, public-interest/policy representative, independent auditor.

2. Publish SB-0 charter + COI disclosures (hash-bound, immutable).

3. Publish starter registries (hash-bound): rights coverage, rights anchors, catastrophe indicators, scenario library, kernel, weights.

4. Execute  $\geq 20$  Tier-2 decisions producing PCCs; publish redacted PCCs.

5. Perform Genesis review: SB-0 either revises registries (new hashes) and transitions to SB-1 with HDW, or dissolves and transfers authority to an established legitimate body.

Exit condition. Tier-3 claims remain prohibited until the constraints above are met and recorded in a governance log.

[End of MathGov v5.0 Complete Specification]

Release binding (authoritative): see MathGov\_Release\_Hashes\_rev14.27\_FULL.txt for SHA-256 over the raw .docx bytes.

Total length:  $\approx 30,379$  words (includes normative appendices; excluding ProofPack artifacts).

Version: 5.0i (rev14.27)

Last updated: 2025-12-26

### Appendix AB Addendum: Canonical function table (complete, normative)

This addendum is normative and supersedes any partial or truncated function table earlier in Appendix AB.

| Function                  | Definition                                             | Domain                            | Range                 | Defaults / Notes                                                                 |
|---------------------------|--------------------------------------------------------|-----------------------------------|-----------------------|----------------------------------------------------------------------------------|
| $(x)_+$                   | $\max(x, 0)$                                           | $x \in \mathbb{R}$                | $\mathbb{R}_{\geq 0}$ | Positive part                                                                    |
| $\text{clip}(x, a, b)$    | $\max(a, \min(x, b))$                                  | $x \in \mathbb{R}, a \leq b$      | $[a, b]$              | Invalid if $a > b$                                                               |
| $\text{clamp}_{[0,1]}(x)$ | $\max(0, \min(x, 1))$                                  | $x \in \mathbb{R}$                | $[0, 1]$              | Use for normalized quantities                                                    |
| $\text{sat}_\beta(x)$     | $\tanh(\beta x)$                                       | $x \in \mathbb{R}, \beta > 0$     | $(-1, 1)$             | Default $\beta=2$ ; smooth saturation                                            |
| $\phi(u, d)$              | $7(u-1)+d$                                             | $u, d \in \{1, \dots, 7\}$        | $\{1, \dots, 49\}$    | Row-major flattening for $7 \times 7$ welfare space                              |
| $\text{Anc}(u, D_c)$      | Ancestor unions of $u$ on union ladder                 | $u \in U$                         | $\mathcal{P}(U)$      | PCC must declare union ladder ordering                                           |
| $\tau(t)$                 | $\ln(1+t)/\ln(1+T_{\text{ref}})$                       | $t > 0, T_{\text{ref}} > 0$       | $(0, \infty)$         | Default $T_{\text{ref}}=25$ years; optional $\tau_{\text{max}}$ must be declared |
| $\text{EMA}_\lambda(x_t)$ | $\lambda x_t + (1-\lambda)\text{EMA}_\lambda(x_{t-1})$ | $\lambda \in (0, 1]$              | $\mathbb{R}$          | Init $\text{EMA}(x_0)=x_0$ unless specified                                      |
| $\ K\ _\infty$            | $\max_i \sum_j  K_{ij} $                               | $K \in \mathbb{R}^{49 \times 49}$ | $\mathbb{R}_{\geq 0}$ | Row-sum norm; used for stability bounds                                          |

|                                         |                                                                |                                       |              |                                                  |
|-----------------------------------------|----------------------------------------------------------------|---------------------------------------|--------------|--------------------------------------------------|
