

## Geoff's Story

Geoff contacted us after researching information [online](#) about how to make his home more cost and energy efficient whilst seeing what he could do to help the environment.

On initial discussions around his 3 bedroomed home, we understood that he already had Solar Panels installed\* around 8 years ago and simply put, he wanted to know if he could be doing more to help reduce his bills in the long run while doing his bit for the environment.

After our initial survey and much discussion around his needs, we agreed to complete his journey towards Energy Independence by expanding his existing installation to include a new home battery storage system, electric water heating and an infrared heating solution. Now, not only does he now feel the same type of radiant heat the sun provides inside his house, but he also enjoys hot water pressure that rivals that of his cold taps too.

In short, he now has a whole home solution that powers his entire home as though it was still connected to the grid, but from a battery!

The completed installation allowed Geoff to remove the gas supply to his home altogether and even in the middle of Winter, has been seeing daily energy costs from as little as £2.11!

The summer months are an even better story...

His panels produce enough energy to not only charge his batteries through the day to be used overnight, but he also makes enough energy for free hot water while still running the entirety of his home – all without pulling a single Watt from the grid.

This means that when we compare his previous years running costs against the Solar Complete® solution that's now installed, he has achieved an annual cost saving of 59% while reducing 70% of his overall energy needs from the grid\*\*

Environmentally speaking he is now saving 73% of his overall carbon footprint too – that's 2.3 Tonnes of carbon a year!

Contact the iHeat.Me Team and see how much you can save by going Energy Independent... Today!

**\*We have advised that should he wish to modernise his existing solar panels then based on today's figures; his energy savings would be closer to 70% while saving 80% of his overall carbon footprint.**

**\*\*Reduction based on overall pull from the grid now when compared to previous years consumption taking existing solar generation into account**
