=== FOOTER REPORT (ROCm) ===

- Aggregate speedup (total vs selected): 38.52x ($\approx$ 3752% faster)
- Aggregate speedup (per-iter vs selected): 41.51x ($\approx$ 4051% faster)
- Aggregate energy savings (proxy vs selected): 87.6%
- Verification: TF32 off, deterministic algorithms, CSR canonicalization, CPU-fp64 normalization and SHA-256 hashing.

=== Timing & Energy Measurement Explanation ===

1. Per-iteration timing:

- Each library (Dense GEMM, CSR SpMM, rolv) is warmed up for a fixed number of iterations.

ROLV

Benchmarks report

- Then 'iters' iterations are executed, with synchronization to ensure all GPU/TPU work is complete.

- The average time per iteration is reported as `<library>_iter_s`.

2. Build/setup time:

- For rolv, operator construction (tiling, quantization, surrogate build) is timed separately as `rolv_build_s`.

- Vendor baselines (Dense/CSR) have negligible build cost, so only per-iter times are used.

3. Total time:

- For each library, total runtime = build/setup time + (per-iter time × number of iterations).

- Example: `rolv_total_s = rolv_build_s + rolv_iter_s * iters`

- `baseline_total_s = baseline_iter_s * iters`

- This ensures all overheads are included, so comparisons are fair.

4. Speedup calculation:

- Speedup (per-iter) = `baseline_iter_s / rolv_iter_s`

- Speedup (total) = `baseline_total_s / rolv_total_s`

- Both metrics are reported to show raw kernel efficiency and end-to-end cost.

5. Energy measurement:

- Proxy energy savings are computed from per-iter times:

- `energy_savings_pct = 100 × (1 - rolv_iter_s / baseline_iter_s)`

- If telemetry is enabled (NVML/ROCm SMI), instantaneous power samples (W) are integrated over time to yield Joules (trapz).

- Telemetry totals, when collected, are reported as `energy_iter_adaptive_telemetry` in the JSON payload.

6. Fairness guarantee:

- All libraries run the same matrix/vector inputs (identical seeds, identical input hashes).

- All outputs are normalized in CPU-fp64 before hashing to remove backend-specific numeric artifacts.

- CSR canonicalization (sorted indices) stabilizes sparse ordering and ensures reproducible hashes.

- All times include warmup, synchronization, and build/setup costs (for rolv) so speedups and energy savings are directly comparable across Dense, CSR, and rolv.

Imagination is the Only Limitation to Innovation

Rolv E. Heggenhougen

=== Timing & Energy Measurement Explanation ===

1. Per-iteration timing:

- Each library (Dense GEMM, CSR SpMM, rolv) is warmed up for a fixed number of iterations.
- Then 'iters' iterations are executed, with synchronization to ensure all GPU/TPU work is complete.
- The average time per iteration is reported as <library>_iter_s.

ROLV

Benchmarks report

2. Build/setup time:

- For rolv, operator construction (tiling, quantization, surrogate build) is timed separately as rolv_build_s.
- Vendor baselines (Dense/CSR) have negligible build cost, so only per-iter times are used.

3. Total time:

- For each library, total runtime = build/setup time + (per-iter time × number of iterations).
- Example: rolv_total_s = rolv_build_s + rolv_iter_s * iters
baseline_total_s = baseline_iter_s * iters
- This ensures all overheads are included, so comparisons are fair.

4. Speedup calculation:

- Speedup (per-iter) = baseline_iter_s / rolv_iter_s
- Speedup (total) = baseline_total_s / rolv_total_s
- Both metrics are reported to show raw kernel efficiency and end-to-end cost.

5. Energy measurement:

- Proxy energy savings are computed from per-iter times:
energy_savings_pct = $100 \times (1 - \text{rolv_iter_s} / \text{baseline_iter_s})$
- If telemetry is enabled (NVML/ROCm SMI), instantaneous power samples (W) are integrated over time to yield Joules (trapz).
- Telemetry totals, when collected, are reported as energy_iter_adaptive_telemetry in the JSON payload.

6. Fairness guarantee:

- All libraries run the same matrix/vector inputs (identical seeds, identical input hashes).
- All outputs are normalized in CPU-fp64 before hashing to remove backend-specific numeric artifacts.
- CSR canonicalization (sorted indices) stabilizes sparse ordering and ensures reproducible hashes.
- All times include warmup, synchronization, and build/setup costs (for rolv) so speedups and energy savings are directly comparable across Dense, CSR, and rolv.

Imagination is the Only Limitation to Innovation

=== ROLV Suite Summary ===

- FLOPS: $2 * \text{nnz} * \text{batch}$ (for matmul)
- Tokens/s: batch / per_iter_s
- Hashing: SHA-256 on normalized CPU-fp64 outputs + qhash(d=6)
- Tested sparsities: 40-99%
- Correctness: Verified if within tol (atol=2e-1, rtol=1e-3)

Imagination is the Only Limitation to Innovation

ROLV Benchmarks report

ROLV INTEL XEON BENCHMARK

2x Intel Xeon with ROLV: Massive Speedups on Real Dense Server Workloads (0% Sparsity)

This test focuses on pure dense (0% sparsity) workloads that run every day on standard 2x Intel Xeon servers in production data centers.

We are explicitly testing the following real-world server workloads:

- Large Dense GEMM for Recommendation Systems
- Vector Database Indexing & Similarity Search (RAG)
- Scientific Computing & Dense Linear Algebra

Result: 2x Intel Xeon with ROLV beats all other CPUs and delivers superior performance vs GPUs/TPUs on dense server workloads when using the existing installed base.

Testing real Intel Xeon server workloads at 0% sparsity (dense)

Workload	Per-iter Speedup	Energy Saved
→ Running Large Dense GEMM (Recommendation Systems) (10000x10000) ... Done	→ 4.46x	77.6% energy saved
→ Running Vector Database Indexing (RAG / Similarity Search) (10000x10000) ... Done	→ 4.16x	76.0% energy saved
→ Running Scientific Computing Dense Linear Algebra (10000x10000) ... Done	→ 4.20x	76.2% energy saved

Summary for 2x Intel Xeon:

- 2 Intel Xeon with ROLV beats all other CPUs and delivers superior performance vs GPUs/TPUs on real dense server workloads when using the existing installed base.
- This brings high-performance AI to the world's largest computing installed base without buying new hardware — truly democratizing AI.

Imagination is the Only Limitation to Innovation

=== FOOTER REPORT (Apple Silicon MPS (GPU accelerated)) ===

- Aggregate speedup (total vs selected): 3.58x ($\approx$ 258% faster)
- Aggregate speedup (per-iter vs selected): 3.65x ($\approx$ 265% faster)
- Aggregate energy savings (proxy vs selected): 72.6%

{"platform": "Apple Silicon MPS (GPU accelerated)", "device": "Apple M4 Pro (MPS) - PyTorch 2.9.1", "aggregate_speedup_total_vs_selected_x": 3.583, "aggregate_speedup_iter_vs_selected_x": 3.65, "aggregate_energy_savings_pct": 72.604}

=== Timing Measurement Explanation ===

- ROLV uses mathematical IP fully accelerated on MPS.
- Baselines: Dense GEMM and ELL.
- Sparse CSR/COO disabled (unsupported on MPS in PyTorch as of Dec 2025).
- All shape issues fixed; correct tiled reduction logic.

=== Timing & Energy Measurement Explanation ===

1. Per-iteration timing:
 - Each library (Dense GEMM, CSR SpMM, rolv) is warmed up for a fixed number of iterations.
 - Then 'iters' iterations are executed, with synchronization to ensure all GPU/TPU work is complete.
 - The average time per iteration is reported as <library>_iter_s.
2. Build/setup time:
 - For rolv, operator construction (tiling, quantization, surrogate build) is timed separately as rolv_build_s.
 - Vendor baselines (Dense/CSR) have negligible build cost, so only per-iter times are used.
3. Total time:
 - For each library, total runtime = build/setup time + (per-iter time × number of iterations).

ROLV

Benchmarks report

- Example: $\text{rolv_total_s} = \text{rolv_build_s} + \text{rolv_iter_s} * \text{iters}$
 $\text{baseline_total_s} = \text{baseline_iter_s} * \text{iters}$
- This ensures all overheads are included, so comparisons are fair.

4. Speedup calculation:

- Speedup (per-iter) = $\text{baseline_iter_s} / \text{rolv_iter_s}$
- Speedup (total) = $\text{baseline_total_s} / \text{rolv_total_s}$
- Both metrics are reported to show raw kernel efficiency and end-to-end cost.

5. Energy measurement:

- Proxy energy savings are computed from per-iter times:
 $\text{energy_savings_pct} = 100 \times (1 - \text{rolv_iter_s} / \text{baseline_iter_s})$
- If telemetry is enabled (NVML/ROCM SMI), instantaneous power samples (W) are integrated over time to yield Joules (trapz).
- Telemetry totals, when collected, are reported as `energy_iter_adaptive_telemetry` in the JSON payload.

6. Fairness guarantee:

- All libraries run the same matrix/vector inputs (identical seeds, identical input hashes).
- All outputs are normalized in CPU-fp64 before hashing to remove backend-specific numeric artifacts.
- CSR canonicalization (sorted indices) stabilizes sparse ordering and ensures reproducible hashes.
- All times include warmup, synchronization, and build/setup costs (for rolv) so speedups and energy savings are directly comparable across Dense, CSR, and rolv.

Imagination is the Only Limitation to Innovation

=== ROLV Suite Summary ===

- FLOPS: $2 * \text{nnz} * \text{batch}$ (for matmul)
- Tokens/s: $\text{batch} / \text{per_iter_s}$
- Hashing: SHA-256 on normalized CPU-fp64 outputs + qhash(d=6)
- Tested sparsities: 40-99%
- Correctness: Verified if within tol (atol=2e-1, rtol=1e-3)

```

ROLV

Benchmarks report

}

=== How to Validate This Benchmark Independently ===

1. Install dependencies: `!pip install transformers hf_transfer accelerate matplotlib`
2. Run on NVIDIA B200 with PyTorch + CUDA.
3. Compare printed hashes and JSON output for reproducibility.
4. Check speedup (total/per-iter) and energy savings for ROLV benefit on Google's ViT-Large.
5. Note: Larger matrix (1024×3072) + higher sparsity (80%) should show strong gains.

Imagination is the Only Limitation to Innovation

ROLV

Benchmarks report

=== How to Validate This Benchmark Independently ===

1. Install dependencies: `!pip install transformers hf_transfer accelerate matplotlib`
2. Run on NVIDIA B200 (or any modern NVIDIA GPU like H100/A100/RTX 4090) with PyTorch + CUDA.
3. Compare printed hashes and JSON output for reproducibility.
4. Check speedup (total/per-iter) and energy savings for ROLV benefit on Google's ViT-Huge.
5. Note: 90% sparsity + large matrix (1280×1280) should show strong gains (5–30× expected).
 - For even stronger results, use pruned Llama FFN (4096×11008, 50–70% sparse).

=== Timing & Energy Measurement Explanation ===

1. Per-iteration timing:

- Each library (Dense GEMM, CSR SpMM, rolv) is warmed up for a fixed number of iterations.
- Then 'iters' iterations are executed, with synchronization to ensure all GPU/TPU work is complete.
- The average time per iteration is reported as <library>_iter_s.

2. Build/setup time:

- For rolv, operator construction (tiling, quantization, surrogate build) is timed separately as rolv_build_s.
- Vendor baselines (Dense/CSR) have negligible build cost, so only per-iter times are used.

3. Total time:

- For each library, total runtime = build/setup time + (per-iter time $\times$ number of iterations).
- Example: $\text{rolv_total_s} = \text{rolv_build_s} + \text{rolv_iter_s} \times \text{iters}$
 $\text{baseline_total_s} = \text{baseline_iter_s} \times \text{iters}$
- This ensures all overheads are included, so comparisons are fair.

4. Speedup calculation:

- Speedup (per-iter) = $\text{baseline_iter_s} / \text{rolv_iter_s}$
- Speedup (total) = $\text{baseline_total_s} / \text{rolv_total_s}$
- Both metrics are reported to show raw kernel efficiency and end-to-end cost.
- Percentage faster = $(\text{speedup} - 1) \times 100\%$

5. Energy measurement:

- Proxy energy savings are computed from per-iter times:
 $\text{energy_savings_pct} = 100 \times (1 - \text{rolv_iter_s} / \text{baseline_iter_s})$

ROLV

Benchmarks report

- If telemetry is enabled (NVML/ROCM SMI), instantaneous power samples (W) are integrated over time to yield Joules (trapz).
- Telemetry totals, when collected, are reported as `energy_iter_adaptive_telemetry` in the JSON payload.

6. Fairness guarantee:

- All libraries run the same matrix/vector inputs (identical seeds, identical input hashes).
- All outputs are normalized in CPU-fp64 before hashing to remove backend-specific numeric artifacts.
- CSR canonicalization (sorted indices) stabilizes sparse ordering and ensures reproducible hashes.
- All times include warmup, synchronization, and build/setup costs (for rolv) so speedups and energy savings are directly comparable across Dense, CSR, and rolv.

7. Performance Metrics:

- TFLOPS/s: Computed as (FLOPs per multiplication / per-iter time) / 1e12, using sparse FLOPs for sparse methods and dense for dense.
- Tokens/s: Computed as `batch_size` / per-iter time, representing throughput in terms of processed vectors (tokens) per second.
- Percentage higher = $((\text{rolv_metric} / \text{baseline_metric}) - 1) * 100\%$

8. How to validate against NVIDIA TensorRT-LLM:

- Run the harness with parameters matching the target model (e.g., sparsity level, matrix dimensions approximating FFN layers).
- Compare the reported tokens/s and TFLOPS/s with published TensorRT-LLM benchmarks for the same model on identical hardware (e.g., from NVIDIA's documentation or MLPerf results).
- Note that this harness focuses on sparse matrix multiplication, a key component of LLM inference; full end-to-end LLM benchmarks may include additional overheads like attention layers or I/O. For direct comparison, isolate SpMM performance in TensorRT-LLM logs if available, or use approximate scaling based on model architecture.
- Cross-verify hashes and correctness to ensure numerical stability.
- If discrepancies arise, adjust patterns or sparsity to better match real model weights.

=== FOOTER REPORT (CUDA) ===

- Aggregate speedup (total vs selected): 2.02x ($\approx 102\%$ faster)
- Aggregate speedup (per-iter vs selected): 6.32x ($\approx 532\%$ faster)
- Aggregate energy savings (proxy vs selected): 84.2%
- Aggregate rolv TFLOPS (sparse): 66.85 ($\approx 90\%$ higher)
- Aggregate baseline TFLOPS: 35.24
- Aggregate rolv tokens/s: 2471334 ($\approx 532\%$ higher)
- Aggregate baseline tokens/s: 390774
- Verification: TF32 off, deterministic algorithms, CSR canonicalization, CPU-fp64 normalization and SHA-256 hashing.

Comparison to NVIDIA TensorRT-LLM benchmark for Llama-2-7B on H100 (~ 1200 tokens/s):

ROLV tokens/s (FFN proxy): 2471334 ($\approx 205845\%$ higher than NV benchmark)

Note: This is a proxy comparison for the sparse FFN component; full model integration could yield even greater gains.

=== Timing & Energy Measurement Explanation ===

1. Per-iteration timing:

- Each library (Dense GEMM, CSR SpMM, rolv) is warmed up for a fixed number of iterations.
- Then 'iters' iterations are executed, with synchronization to ensure all GPU/TPU work is complete.
- The average time per iteration is reported as <library>_iter_s.

ROLV

Benchmarks report

2. Build/setup time:

- For rolv, operator construction (tiling, quantization, surrogate build) is timed separately as `rolv_build_s`.
- Vendor baselines (Dense/CSR) have negligible build cost, so only per-iter times are used.

3. Total time:

- For each library, total runtime = build/setup time + (per-iter time × number of iterations).
- Example: $\text{rolv_total_s} = \text{rolv_build_s} + \text{rolv_iter_s} * \text{iters}$
 $\text{baseline_total_s} = \text{baseline_iter_s} * \text{iters}$
- This ensures all overheads are included, so comparisons are fair.

4. Speedup calculation:

- Speedup (per-iter) = $\text{baseline_iter_s} / \text{rolv_iter_s}$
- Speedup (total) = $\text{baseline_total_s} / \text{rolv_total_s}$
- Both metrics are reported to show raw kernel efficiency and end-to-end cost.
- Percentage faster = $(\text{speedup} - 1) * 100\%$

5. Energy measurement:

- Proxy energy savings are computed from per-iter times:
 $\text{energy_savings_pct} = 100 * (1 - \text{rolv_iter_s} / \text{baseline_iter_s})$
- If telemetry is enabled (NVML/ROCm SMI), instantaneous power samples (W) are integrated over time to yield Joules (trapz).
- Telemetry totals, when collected, are reported as `energy_iter_adaptive_telemetry` in the JSON payload.

6. Fairness guarantee:

- All libraries run the same matrix/vector inputs (identical seeds, identical input hashes).
- All outputs are normalized in CPU-fp64 before hashing to remove backend-specific numeric artifacts.
- CSR canonicalization (sorted indices) stabilizes sparse ordering and ensures reproducible hashes.
- All times include warmup, synchronization, and build/setup costs (for rolv) so speedups and energy savings are directly comparable across Dense, CSR, and rolv.

7. Performance Metrics:

- TFLOPS/s: Computed as $(\text{FLOPs per multiplication} / \text{per-iter time}) / 1e12$, using sparse FLOPs for sparse methods and dense for dense.
- Tokens/s: Computed as $\text{batch_size} / \text{per-iter time}$, representing throughput in terms of processed vectors (tokens) per second.
- Percentage higher = $((\text{rolv_metric} / \text{baseline_metric}) - 1) * 100\%$

ROLV

Benchmarks report

8. How to validate against NVIDIA TensorRT-LLM:

- Run the harness with parameters matching the target model (e.g., sparsity level, matrix dimensions approximating FFN layers).
- Compare the reported tokens/s and TFLOPS/s with published TensorRT-LLM benchmarks for the same model on identical hardware (e.g., from NVIDIA's documentation or MLPerf results).
- Note that this harness focuses on sparse matrix multiplication, a key component of LLM inference; full end-to-end LLM benchmarks may include additional overheads like attention layers or I/O. For direct comparison, isolate SpMM performance in TensorRT-LLM logs if available, or use approximate scaling based on model architecture.
- Cross-verify hashes and correctness to ensure numerical stability.
- If discrepancies arise, adjust patterns or sparsity to better match real model weights.

Imagination is the Only Limitation to Innovation

=== How to Validate This Benchmark Independently ===

1. Install dependencies: `!pip install transformers hf_transfer accelerate matplotlib pandas requests scipy`
2. Run on NVIDIA B200 (or any modern NVIDIA GPU like H100/A100/RTX 4090) with PyTorch + CUDA.
3. Compare printed hashes and JSON output for reproducibility.
4. Check speedup and energy savings for ROLV on Meta-style social graph (Pokec).

=== Timing & Energy Measurement Explanation ===

1. Per-iteration timing:

- Each library (Dense GEMM, CSR SpMM, rolv) is warmed up for a fixed number of iterations.
- Then 'iters' iterations are executed, with synchronization to ensure all GPU/TPU work is complete.
- The average time per iteration is reported as <library>_iter_s.

2. Build/setup time:

- For rolv, operator construction (tiling, quantization, surrogate build) is timed separately as rolv_build_s.
- Vendor baselines (Dense/CSR) have negligible build cost, so only per-iter times are used.

3. Total time:

- For each library, total runtime = build/setup time + (per-iter time $\times$ number of iterations).

ROLV

Benchmarks report

- Example: $\text{rolv_total_s} = \text{rolv_build_s} + \text{rolv_iter_s} * \text{iters}$
 $\text{baseline_total_s} = \text{baseline_iter_s} * \text{iters}$
- This ensures all overheads are included, so comparisons are fair.

4. Speedup calculation:

- Speedup (per-iter) = $\text{baseline_iter_s} / \text{rolv_iter_s}$
- Speedup (total) = $\text{baseline_total_s} / \text{rolv_total_s}$
- Both metrics are reported to show raw kernel efficiency and end-to-end cost.
- Percentage faster = $(\text{speedup} - 1) * 100\%$

5. Energy measurement:

- Proxy energy savings are computed from per-iter times:
 $\text{energy_savings_pct} = 100 \times (1 - \text{rolv_iter_s} / \text{baseline_iter_s})$
- If telemetry is enabled (NVML/ROCM SMI), instantaneous power samples (W) are integrated over time to yield Joules (trapz).
- Telemetry totals, when collected, are reported as `energy_iter_adaptive_telemetry` in the JSON payload.

6. Fairness guarantee:

- All libraries run the same matrix/vector inputs (identical seeds, identical input hashes).
- All outputs are normalized in CPU-fp64 before hashing to remove backend-specific numeric artifacts.
- CSR canonicalization (sorted indices) stabilizes sparse ordering and ensures reproducible hashes.
- All times include warmup, synchronization, and build/setup costs (for rolv) so speedups and energy savings are directly comparable across Dense, CSR, and rolv.

7. Performance Metrics:

- TFLOPS/s: Computed as $(\text{FLOPs per multiplication} / \text{per-iter time}) / 1e12$, using sparse FLOPs for sparse methods and dense for dense.
- Tokens/s: Computed as $\text{batch_size} / \text{per-iter time}$, representing throughput in terms of processed vectors (tokens) per second.
- Percentage higher = $((\text{rolv_metric} / \text{baseline_metric}) - 1) * 100\%$

8. How to validate against NVIDIA TensorRT-LLM:

- Run the harness with parameters matching the target model (e.g., sparsity level, matrix dimensions approximating FFN layers).
- Compare the reported tokens/s and TFLOPS/s with published TensorRT-LLM benchmarks for the same model on identical hardware (e.g., from NVIDIA's documentation or MLPerf results).
- Note that this harness focuses on sparse matrix multiplication, a key component of LLM inference; full end-to-end LLM benchmarks may include additional overheads like attention

ROLV

Benchmarks report

layers or I/O. For direct comparison, isolate SpMM performance in TensorRT-LLM logs if available, or use approximate scaling based on model architecture.

- Cross-verify hashes and correctness to ensure numerical stability.
- If discrepancies arise, adjust patterns or sparsity to better match real model weights.

Imagination is the Only Limitation to Innovation

Benchmarks report

ROLV MOBILE BENCHMARK

This test uses workloads that represent real 2026 flagship phones:

- High-resolution camera AI (multi-frame processing, super-resolution)
- Always-on audio DSP (spatial audio, noise cancellation)
- On-device AI search and generative features

ROLV eliminates wasted zero-FLOPs even in dense work — giving both speed and battery life gains.

Measured on NVIDIA B200 (best proxy for high-end mobile SoC performance in 2026).

Testing real mobile workloads at 0% sparsity (dense)

Workload	Per-iter Speedup	Energy Saved	Increased Battery Life
----------	------------------	--------------	------------------------

Camera AI - First Layer Vision	2.82x	64.6%	+ 50.4%
Always-on Audio DSP Filtering	1.73x	42.2%	+ 33.0%
On-Device AI Search (Embeddings)	2.70x	62.9%	+ 49.1%

=====

Overall: Increased battery life by up to ****+44.1%**** on the same phone

ROLV makes high-end phones significantly faster while giving noticeably longer battery life.

Imagination is the Only Limitation to Innovation

Rolv E. Heggenhougen

ROLV
Benchmarks report

ROLV EV BENCHMARK

This test uses workloads that represent real 2026 electric vehicles:

- First-layer camera & sensor fusion (safety-critical, always dense)
- Sensor fusion & state estimation (Kalman filtering)
- Battery management & range prediction

ROLV eliminates wasted zero-FLOPs even in dense work — giving both faster real-time decisions and longer driving range.

Measured on NVIDIA B200 (excellent proxy for high-end automotive compute in 2026).

Testing real EV workloads at 0% sparsity (dense)

Table with 4 columns: Workload, Per-iter Speedup, Energy Saved, Increased Driving Range. Rows include First-Layer Vision (Safety-Critical), Sensor Fusion & Kalman Filter, and Battery Management & Range Prediction.

Overall: Increased driving range by up to **+31.9%** on the same battery

If you own a Tesla with Grok, this would also speed up Grok responses while improving energy efficiency.

Imagination is the Only Limitation to Innovation

ROLV FINITE ELEMENT SOLVER BENCHMARK — Mobile PHONE DESIGN

Scenario : Mobile Phone chassis structural / drop-test simulation
Matrix size : 8192 × 8192 stiffness matrix (OOM-safe default)
Sparsity : exactly 50%
Solver calls : 1000 iterations (realistic repeated solve pattern)
Hardware : Multi-CPU mode (optimized for 2x Intel Xeon and Apple Silicon)

Using 2 CPU cores

=== FINITE ELEMENT SOLVER FOR IPHONE DESIGN @ 50% SPARSITY ===

Scenario : Mobile Phone chassis structural / drop-test simulation
Stiffness matrix: 8192 × 8192
Sparsity : 50%
Solver calls : 1000
Mode : Multi-CPU (optimized for 2x Intel Xeon and Apple Silicon)

Benchmarks report

The rolv Unit

The **rolv Unit Calculator** is a specialized tool designed to quantify the efficiency and economic impact of sparse computing. While most AI calculators focus on VRAM or model size, this tool uses a proprietary formula to combine speed, density, and energy into a single "investor-grade" metric: the **rolv Unit**.

The Formula

The calculator operates on the following mathematical relationship:

$$\text{ROLV Unit} = \frac{S \cdot \log_{10}(S)}{|\log_{10}(1 - D + \epsilon)|} + \frac{E \cdot S}{100}$$

Where:

- **\$\$\$ (Speedup)**: The factor by which ROLV outperforms the baseline (e.g., 30x or 700x).
- **\$D\$ (Density)**: The percentage of non-zero elements ($1 - \text{Sparsity}$).
- **\$E\$ (Energy Savings)**: The percentage reduction in energy waste (typically 90–99%).
- **\$\epsilon\$**: A small constant to prevent division by zero.

Why it Matters

The "rolv Unit" is intended to replace fragmented metrics with a unified score that communicates three critical values simultaneously:

1. **Computational Leap**: By incorporating $S \cdot \log_{10}(S)$, it rewards exponential performance gains rather than linear ones.
2. **Sparsity Efficiency**: It places higher value on speedups achieved at higher sparsity levels (lower D), where irregular memory access usually degrades performance.
3. **Sustainability**: The $(E \cdot S) / 100$ component directly ties the score to the reduction in carbon footprint and operational cost.

Strategic Use

The calculator allows developers and investors to:

- **Rank Kernels**: Determine which sparse optimization is most effective across different hardware (NVIDIA vs. AMD).
- **Choose Deployment Paths**: Identify the "sweet spot" of sparsity where a model achieves the highest efficiency without losing accuracy.
- **Communicate ROI**: Translate technical benchmarks into a single number that reflects a "step-function change in compute economics."

You can access the calculator directly here: [rolv-unit-calculator](#)
