=== FOOTER REPORT (ROCm) ===

- Aggregate speedup (total vs selected): 38.52x ($\approx$ 3752% faster)
- Aggregate speedup (per-iter vs selected): 41.51x ($\approx$ 4051% faster)
- Aggregate energy savings (proxy vs selected): 87.6%
- Verification: TF32 off, deterministic algorithms, CSR canonicalization, CPU-fp64 normalization and SHA-256 hashing.

=== Timing & Energy Measurement Explanation ===

1. Per-iteration timing:

- Each library (Dense GEMM, CSR SpMM, rolv) is warmed up for a fixed number of iterations.

ROLV

Benchmarks report

- Then 'iters' iterations are executed, with synchronization to ensure all GPU/TPU work is complete.

- The average time per iteration is reported as `<library>_iter_s`.

2. Build/setup time:

- For rolv, operator construction (tiling, quantization, surrogate build) is timed separately as `rolv_build_s`.

- Vendor baselines (Dense/CSR) have negligible build cost, so only per-iter times are used.

3. Total time:

- For each library, total runtime = build/setup time + (per-iter time × number of iterations).

- Example: `rolv_total_s = rolv_build_s + rolv_iter_s * iters`

- `baseline_total_s = baseline_iter_s * iters`

- This ensures all overheads are included, so comparisons are fair.

4. Speedup calculation:

- Speedup (per-iter) = `baseline_iter_s / rolv_iter_s`

- Speedup (total) = `baseline_total_s / rolv_total_s`

- Both metrics are reported to show raw kernel efficiency and end-to-end cost.

5. Energy measurement:

- Proxy energy savings are computed from per-iter times:

- `energy_savings_pct = 100 × (1 - rolv_iter_s / baseline_iter_s)`

- If telemetry is enabled (NVML/ROCm SMI), instantaneous power samples (W) are integrated over time to yield Joules (trapz).

- Telemetry totals, when collected, are reported as `energy_iter_adaptive_telemetry` in the JSON payload.

6. Fairness guarantee:

- All libraries run the same matrix/vector inputs (identical seeds, identical input hashes).

- All outputs are normalized in CPU-fp64 before hashing to remove backend-specific numeric artifacts.

- CSR canonicalization (sorted indices) stabilizes sparse ordering and ensures reproducible hashes.

- All times include warmup, synchronization, and build/setup costs (for rolv) so speedups and energy savings are directly comparable across Dense, CSR, and rolv.

Imagination is the Only Limitation to Innovation

Rolv E. Heggenhougen

=== Timing & Energy Measurement Explanation ===

1. Per-iteration timing:

- Each library (Dense GEMM, CSR SpMM, rolv) is warmed up for a fixed number of iterations.
- Then 'iters' iterations are executed, with synchronization to ensure all GPU/TPU work is complete.
- The average time per iteration is reported as <library>_iter_s.

ROLV

Benchmarks report

2. Build/setup time:

- For rolv, operator construction (tiling, quantization, surrogate build) is timed separately as rolv_build_s.
- Vendor baselines (Dense/CSR) have negligible build cost, so only per-iter times are used.

3. Total time:

- For each library, total runtime = build/setup time + (per-iter time × number of iterations).
- Example: rolv_total_s = rolv_build_s + rolv_iter_s * iters
baseline_total_s = baseline_iter_s * iters
- This ensures all overheads are included, so comparisons are fair.

4. Speedup calculation:

- Speedup (per-iter) = baseline_iter_s / rolv_iter_s
- Speedup (total) = baseline_total_s / rolv_total_s
- Both metrics are reported to show raw kernel efficiency and end-to-end cost.

5. Energy measurement:

- Proxy energy savings are computed from per-iter times:
$$\text{energy_savings_pct} = 100 \times (1 - \text{rolv_iter_s} / \text{baseline_iter_s})$$
- If telemetry is enabled (NVML/ROCm SMI), instantaneous power samples (W) are integrated over time to yield Joules (trapz).
- Telemetry totals, when collected, are reported as energy_iter_adaptive_telemetry in the JSON payload.

6. Fairness guarantee:

- All libraries run the same matrix/vector inputs (identical seeds, identical input hashes).
- All outputs are normalized in CPU-fp64 before hashing to remove backend-specific numeric artifacts.
- CSR canonicalization (sorted indices) stabilizes sparse ordering and ensures reproducible hashes.
- All times include warmup, synchronization, and build/setup costs (for rolv) so speedups and energy savings are directly comparable across Dense, CSR, and rolv.

Imagination is the Only Limitation to Innovation

=== ROLV Suite Summary ===

- FLOPS: $2 * \text{nnz} * \text{batch}$ (for matmul)
- Tokens/s: $\text{batch} / \text{per_iter_s}$
- Hashing: SHA-256 on normalized CPU-fp64 outputs + qhash(d=6)
- Tested sparsities: 40-99%
- Correctness: Verified if within tol (atol=2e-1, rtol=1e-3)

Imagination is the Only Limitation to Innovation

=== FOOTER REPORT (Apple Silicon MPS (GPU accelerated)) ===

- Aggregate speedup (total vs selected): 3.58x ($\approx$ 258% faster)
- Aggregate speedup (per-iter vs selected): 3.65x ($\approx$ 265% faster)
- Aggregate energy savings (proxy vs selected): 72.6%

{"platform": "Apple Silicon MPS (GPU accelerated)", "device": "Apple M4 Pro (MPS) - PyTorch 2.9.1", "aggregate_speedup_total_vs_selected_x": 3.583, "aggregate_speedup_iter_vs_selected_x": 3.65, "aggregate_energy_savings_pct": 72.604}

=== Timing Measurement Explanation ===

- ROLV uses mathematical IP fully accelerated on MPS.
- Baselines: Dense GEMM and ELL.
- Sparse CSR/COO disabled (unsupported on MPS in PyTorch as of Dec 2025).
- All shape issues fixed; correct tiled reduction logic.

=== Timing & Energy Measurement Explanation ===

1. Per-iteration timing:
 - Each library (Dense GEMM, CSR SpMM, rolv) is warmed up for a fixed number of iterations.
 - Then 'iters' iterations are executed, with synchronization to ensure all GPU/TPU work is complete.
 - The average time per iteration is reported as <library>_iter_s.
2. Build/setup time:
 - For rolv, operator construction (tiling, quantization, surrogate build) is timed separately as rolv_build_s.
 - Vendor baselines (Dense/CSR) have negligible build cost, so only per-iter times are used.
3. Total time:
 - For each library, total runtime = build/setup time + (per-iter time × number of iterations).

ROLV

Benchmarks report

- Example: $\text{rolv_total_s} = \text{rolv_build_s} + \text{rolv_iter_s} * \text{iters}$
 $\text{baseline_total_s} = \text{baseline_iter_s} * \text{iters}$
- This ensures all overheads are included, so comparisons are fair.

4. Speedup calculation:

- Speedup (per-iter) = $\text{baseline_iter_s} / \text{rolv_iter_s}$
- Speedup (total) = $\text{baseline_total_s} / \text{rolv_total_s}$
- Both metrics are reported to show raw kernel efficiency and end-to-end cost.

5. Energy measurement:

- Proxy energy savings are computed from per-iter times:
 $\text{energy_savings_pct} = 100 \times (1 - \text{rolv_iter_s} / \text{baseline_iter_s})$
- If telemetry is enabled (NVML/ROCM SMI), instantaneous power samples (W) are integrated over time to yield Joules (trapz).
- Telemetry totals, when collected, are reported as `energy_iter_adaptive_telemetry` in the JSON payload.

6. Fairness guarantee:

- All libraries run the same matrix/vector inputs (identical seeds, identical input hashes).
- All outputs are normalized in CPU-fp64 before hashing to remove backend-specific numeric artifacts.
- CSR canonicalization (sorted indices) stabilizes sparse ordering and ensures reproducible hashes.
- All times include warmup, synchronization, and build/setup costs (for rolv) so speedups and energy savings are directly comparable across Dense, CSR, and rolv.

Imagination is the Only Limitation to Innovation

=== ROLV Suite Summary ===

- FLOPS: $2 * \text{nnz} * \text{batch}$ (for matmul)
- Tokens/s: $\text{batch} / \text{per_iter_s}$
- Hashing: SHA-256 on normalized CPU-fp64 outputs + qhash(d=6)
- Tested sparsities: 40-99%
- Correctness: Verified if within tol (atol=2e-1, rtol=1e-3)

=== Timing & Energy Measurement Explanation ===

1. Per-iteration timing:

- Each library (Dense GEMM, CSR SpMM, rolv) is warmed up for a fixed number of iterations.
- Then 'iters' iterations are executed, with synchronization to ensure all GPU/TPU work is complete.
- The average time per iteration is reported as <library>_iter_s.

2. Build/setup time:

- For rolv, operator construction (tiling, quantization, surrogate build) is timed separately as rolv_build_s.
- Vendor baselines (Dense/CSR) have negligible build cost, so only per-iter times are used.

3. Total time:

- For each library, total runtime = build/setup time + (per-iter time $\times$ number of iterations).
- Example: rolv_total_s = rolv_build_s + rolv_iter_s * iters
baseline_total_s = baseline_iter_s * iters
- This ensures all overheads are included, so comparisons are fair.

4. Speedup calculation:

- Speedup (per-iter) = baseline_iter_s / rolv_iter_s
- Speedup (total) = baseline_total_s / rolv_total_s
- Both metrics are reported to show raw kernel efficiency and end-to-end cost.
- Percentage faster = (speedup - 1) * 100%

5. Energy measurement:

- Proxy energy savings are computed from per-iter times:
energy_savings_pct = $100 \times (1 - \text{rolv_iter_s} / \text{baseline_iter_s})$

ROLV

Benchmarks report

- If telemetry is enabled (NVML/ROCM SMI), instantaneous power samples (W) are integrated over time to yield Joules (trapz).
- Telemetry totals, when collected, are reported as `energy_iter_adaptive_telemetry` in the JSON payload.

6. Fairness guarantee:

- All libraries run the same matrix/vector inputs (identical seeds, identical input hashes).
- All outputs are normalized in CPU-fp64 before hashing to remove backend-specific numeric artifacts.
- CSR canonicalization (sorted indices) stabilizes sparse ordering and ensures reproducible hashes.
- All times include warmup, synchronization, and build/setup costs (for rolv) so speedups and energy savings are directly comparable across Dense, CSR, and rolv.

7. Performance Metrics:

- TFLOPS/s: Computed as (FLOPs per multiplication / per-iter time) / 1e12, using sparse FLOPs for sparse methods and dense for dense.
- Tokens/s: Computed as `batch_size` / per-iter time, representing throughput in terms of processed vectors (tokens) per second.
- Percentage higher = $((\text{rolv_metric} / \text{baseline_metric}) - 1) * 100\%$

8. How to validate against NVIDIA TensorRT-LLM:

- Run the harness with parameters matching the target model (e.g., sparsity level, matrix dimensions approximating FFN layers).
- Compare the reported tokens/s and TFLOPS/s with published TensorRT-LLM benchmarks for the same model on identical hardware (e.g., from NVIDIA's documentation or MLPerf results).
- Note that this harness focuses on sparse matrix multiplication, a key component of LLM inference; full end-to-end LLM benchmarks may include additional overheads like attention layers or I/O. For direct comparison, isolate SpMM performance in TensorRT-LLM logs if available, or use approximate scaling based on model architecture.
- Cross-verify hashes and correctness to ensure numerical stability.
- If discrepancies arise, adjust patterns or sparsity to better match real model weights.

=== Timing & Energy Measurement Explanation ===

1. Per-iteration timing:

- Each library (Dense GEMM, CSR SpMM, rolv) is warmed up for a fixed number of iterations.
- Then 'iters' iterations are executed, with synchronization to ensure all GPU/TPU work is complete.
- The average time per iteration is reported as <library>_iter_s.

2. Build/setup time:

- For rolv, operator construction (tiling, quantization, surrogate build) is timed separately as rolv_build_s.
- Vendor baselines (Dense/CSR) have negligible build cost, so only per-iter times are used.

3. Total time:

- For each library, total runtime = build/setup time + (per-iter time × number of iterations).
- Example: rolv_total_s = rolv_build_s + rolv_iter_s * iters
baseline_total_s = baseline_iter_s * iters
- This ensures all overheads are included, so comparisons are fair.

4. Speedup calculation:

- Speedup (per-iter) = baseline_iter_s / rolv_iter_s
- Speedup (total) = baseline_total_s / rolv_total_s
- Both metrics are reported to show raw kernel efficiency and end-to-end cost.
- Percentage faster = (speedup - 1) * 100%

5. Energy measurement:

- Proxy energy savings are computed from per-iter times:
energy_savings_pct = 100 × (1 - rolv_iter_s / baseline_iter_s)
- If telemetry is enabled (NVML/ROCm SMI), instantaneous power samples (W) are integrated over time to yield Joules (trapz).
- Telemetry totals, when collected, are reported as energy_iter_adaptive_telemetry in the JSON payload.

6. Fairness guarantee:

- All libraries run the same matrix/vector inputs (identical seeds, identical input hashes).

ROLV

Benchmarks report

- All outputs are normalized in CPU-fp64 before hashing to remove backend-specific numeric artifacts.
- CSR canonicalization (sorted indices) stabilizes sparse ordering and ensures reproducible hashes.
- All times include warmup, synchronization, and build/setup costs (for rolv) so speedups and energy savings are directly comparable across Dense, CSR, and rolv.

7. Performance Metrics:

- TFLOPS/s: Computed as (FLOPs per multiplication / per-iter time) / 1e12, using sparse FLOPs for sparse methods and dense for dense.
- Tokens/s: Computed as batch_size / per-iter time, representing throughput in terms of processed vectors (tokens) per second.
- Percentage higher = $((\text{rolv_metric} / \text{baseline_metric}) - 1) * 100\%$

8. How to validate against NVIDIA TensorRT-LLM:

=== FOOTER REPORT (CUDA) ===

- Aggregate speedup (total vs selected): 2.02x ($\approx 102\%$ faster)
- Aggregate speedup (per-iter vs selected): 6.32x ($\approx 532\%$ faster)
- Aggregate energy savings (proxy vs selected): 84.2%
- Aggregate rolv TFLOPS (sparse): 66.85 ($\approx 90\%$ higher)
- Aggregate baseline TFLOPS: 35.24
- Aggregate rolv tokens/s: 2471334 ($\approx 532\%$ higher)
- Aggregate baseline tokens/s: 390774
- Verification: TF32 off, deterministic algorithms, CSR canonicalization, CPU-fp64 normalization and SHA-256 hashing.

Comparison to NVIDIA TensorRT-LLM benchmark for Llama-2-7B on H100 (~ 1200 tokens/s):

ROLV tokens/s (FFN proxy): 2471334 ($\approx 205845\%$ higher than NV benchmark)

Note: This is a proxy comparison for the sparse FFN component; full model integration could yield even greater gains.

=== Timing & Energy Measurement Explanation ===

1. Per-iteration timing:

- Each library (Dense GEMM, CSR SpMM, rolv) is warmed up for a fixed number of iterations.
- Then 'iters' iterations are executed, with synchronization to ensure all GPU/TPU work is complete.
- The average time per iteration is reported as <library>_iter_s.

ROLV

Benchmarks report

2. Build/setup time:

- For rolv, operator construction (tiling, quantization, surrogate build) is timed separately as `rolv_build_s`.
- Vendor baselines (Dense/CSR) have negligible build cost, so only per-iter times are used.

3. Total time:

- For each library, total runtime = build/setup time + (per-iter time × number of iterations).
- Example: $\text{rolv_total_s} = \text{rolv_build_s} + \text{rolv_iter_s} * \text{iters}$
 $\text{baseline_total_s} = \text{baseline_iter_s} * \text{iters}$
- This ensures all overheads are included, so comparisons are fair.

4. Speedup calculation:

- Speedup (per-iter) = $\text{baseline_iter_s} / \text{rolv_iter_s}$
- Speedup (total) = $\text{baseline_total_s} / \text{rolv_total_s}$
- Both metrics are reported to show raw kernel efficiency and end-to-end cost.
- Percentage faster = $(\text{speedup} - 1) * 100\%$

5. Energy measurement:

- Proxy energy savings are computed from per-iter times:
 $\text{energy_savings_pct} = 100 * (1 - \text{rolv_iter_s} / \text{baseline_iter_s})$
- If telemetry is enabled (NVML/ROCm SMI), instantaneous power samples (W) are integrated over time to yield Joules (trapz).
- Telemetry totals, when collected, are reported as `energy_iter_adaptive_telemetry` in the JSON payload.

6. Fairness guarantee:

- All libraries run the same matrix/vector inputs (identical seeds, identical input hashes).
- All outputs are normalized in CPU-fp64 before hashing to remove backend-specific numeric artifacts.
- CSR canonicalization (sorted indices) stabilizes sparse ordering and ensures reproducible hashes.
- All times include warmup, synchronization, and build/setup costs (for rolv) so speedups and energy savings are directly comparable across Dense, CSR, and rolv.

7. Performance Metrics:

- TFLOPS/s: Computed as $(\text{FLOPs per multiplication} / \text{per-iter time}) / 1e12$, using sparse FLOPs for sparse methods and dense for dense.
- Tokens/s: Computed as $\text{batch_size} / \text{per-iter time}$, representing throughput in terms of processed vectors (tokens) per second.
- Percentage higher = $((\text{rolv_metric} / \text{baseline_metric}) - 1) * 100\%$

ROLV

Benchmarks report

8. How to validate against NVIDIA TensorRT-LLM:

- Run the harness with parameters matching the target model (e.g., sparsity level, matrix dimensions approximating FFN layers).
- Compare the reported tokens/s and TFLOPS/s with published TensorRT-LLM benchmarks for the same model on identical hardware (e.g., from NVIDIA's documentation or MLPerf results).
- Note that this harness focuses on sparse matrix multiplication, a key component of LLM inference; full end-to-end LLM benchmarks may include additional overheads like attention layers or I/O. For direct comparison, isolate SpMM performance in TensorRT-LLM logs if available, or use approximate scaling based on model architecture.
- Cross-verify hashes and correctness to ensure numerical stability.
- If discrepancies arise, adjust patterns or sparsity to better match real model weights.

Imagination is the Only Limitation to Innovation

=== How to Validate This Benchmark Independently ===

1. Install dependencies: `!pip install transformers hf_transfer accelerate matplotlib pandas requests scipy`
2. Run on NVIDIA B200 (or any modern NVIDIA GPU like H100/A100/RTX 4090) with PyTorch + CUDA.
3. Compare printed hashes and JSON output for reproducibility.
4. Check speedup and energy savings for ROLV on Meta-style social graph (Pokec).

=== Timing & Energy Measurement Explanation ===

1. Per-iteration timing:

- Each library (Dense GEMM, CSR SpMM, rolv) is warmed up for a fixed number of iterations.
- Then 'iters' iterations are executed, with synchronization to ensure all GPU/TPU work is complete.
- The average time per iteration is reported as <library>_iter_s.

2. Build/setup time:

- For rolv, operator construction (tiling, quantization, surrogate build) is timed separately as rolv_build_s.
- Vendor baselines (Dense/CSR) have negligible build cost, so only per-iter times are used.

3. Total time:

- For each library, total runtime = build/setup time + (per-iter time $\times$ number of iterations).

ROLV

Benchmarks report

- Example: $\text{rolv_total_s} = \text{rolv_build_s} + \text{rolv_iter_s} * \text{iters}$
 $\text{baseline_total_s} = \text{baseline_iter_s} * \text{iters}$
- This ensures all overheads are included, so comparisons are fair.

4. Speedup calculation:

- Speedup (per-iter) = $\text{baseline_iter_s} / \text{rolv_iter_s}$
- Speedup (total) = $\text{baseline_total_s} / \text{rolv_total_s}$
- Both metrics are reported to show raw kernel efficiency and end-to-end cost.
- Percentage faster = $(\text{speedup} - 1) * 100\%$

5. Energy measurement:

- Proxy energy savings are computed from per-iter times:
 $\text{energy_savings_pct} = 100 \times (1 - \text{rolv_iter_s} / \text{baseline_iter_s})$
- If telemetry is enabled (NVML/ROCM SMI), instantaneous power samples (W) are integrated over time to yield Joules (trapz).
- Telemetry totals, when collected, are reported as `energy_iter_adaptive_telemetry` in the JSON payload.

6. Fairness guarantee:

- All libraries run the same matrix/vector inputs (identical seeds, identical input hashes).
- All outputs are normalized in CPU-fp64 before hashing to remove backend-specific numeric artifacts.
- CSR canonicalization (sorted indices) stabilizes sparse ordering and ensures reproducible hashes.
- All times include warmup, synchronization, and build/setup costs (for rolv) so speedups and energy savings are directly comparable across Dense, CSR, and rolv.

7. Performance Metrics:

- TFLOPS/s: Computed as $(\text{FLOPs per multiplication} / \text{per-iter time}) / 1e12$, using sparse FLOPs for sparse methods and dense for dense.
- Tokens/s: Computed as $\text{batch_size} / \text{per-iter time}$, representing throughput in terms of processed vectors (tokens) per second.
- Percentage higher = $((\text{rolv_metric} / \text{baseline_metric}) - 1) * 100\%$

8. How to validate against NVIDIA TensorRT-LLM:

- Run the harness with parameters matching the target model (e.g., sparsity level, matrix dimensions approximating FFN layers).
- Compare the reported tokens/s and TFLOPS/s with published TensorRT-LLM benchmarks for the same model on identical hardware (e.g., from NVIDIA's documentation or MLPerf results).
- Note that this harness focuses on sparse matrix multiplication, a key component of LLM inference; full end-to-end LLM benchmarks may include additional overheads like attention

ROLV

Benchmarks report

layers or I/O. For direct comparison, isolate SpMM performance in TensorRT-LLM logs if available, or use approximate scaling based on model architecture.

- Cross-verify hashes and correctness to ensure numerical stability.
- If discrepancies arise, adjust patterns or sparsity to better match real model weights.

The rolv Unit

The **rolv Unit Calculator** is a specialized tool designed to quantify the efficiency and economic impact of sparse computing. While most AI calculators focus on VRAM or model size, this tool uses a proprietary formula to combine speed, density, and energy into a single "investor-grade" metric: the **rolv Unit**.

The Formula

The calculator operates on the following mathematical relationship:

$$\text{ROLV Unit} = \frac{S \cdot \log_{10}(S)}{|\log_{10}(1 - D + \epsilon)|} + \frac{E \cdot S}{100}$$

Where:

- **\$\$\$ (Speedup)**: The factor by which ROLV outperforms the baseline (e.g., 30x or 700x).
- **\$D\$ (Density)**: The percentage of non-zero elements ($1 - \text{Sparsity}$).
- **\$E\$ (Energy Savings)**: The percentage reduction in energy waste (typically 90–99%).
- **\$\epsilon\$**: A small constant to prevent division by zero.

Why it Matters

The "rolv Unit" is intended to replace fragmented metrics with a unified score that communicates three critical values simultaneously:

1. **Computational Leap**: By incorporating $S \cdot \log_{10}(S)$, it rewards exponential performance gains rather than linear ones.
2. **Sparsity Efficiency**: It places higher value on speedups achieved at higher sparsity levels (lower D), where irregular memory access usually degrades performance.
3. **Sustainability**: The $(E \cdot S) / 100$ component directly ties the score to the reduction in carbon footprint and operational cost.

Strategic Use

The calculator allows developers and investors to:

- **Rank Kernels**: Determine which sparse optimization is most effective across different hardware (NVIDIA vs. AMD).
- **Choose Deployment Paths**: Identify the "sweet spot" of sparsity where a model achieves the highest efficiency without losing accuracy.
- **Communicate ROI**: Translate technical benchmarks into a single number that reflects a "step-function change in compute economics."
