

## Carbohydrates

1. The carbohydrate monomers you have to learn, called \_\_\_\_\_ saccharides, are \_\_\_\_\_ (a pentose sugar, important for RNA structure), \_\_\_\_\_ (from fruit), \_\_\_\_\_ (a sugar in milk) and \_\_\_\_\_ for which there are two varieties, \_\_\_\_ - D and \_\_\_\_ - D, both of which you can draw here:
2. These \_\_\_\_\_ saccharides can join through \_\_\_\_\_ reactions, which is a type of metabolism. These reactions \_\_\_\_\_ water, so are called \_\_\_\_\_ reactions. Write the three reactions you must know that form disaccharides:
3. When many monomers join, they form polymers. For carbohydrates, the polymers are called \_\_\_\_\_ saccharides. There are several important ones to learn:
  - a) Plants form \_\_\_\_\_, which is a polymer of \_\_\_\_ - D - glucose found in plant \_\_\_\_\_ walls. The molecules \_\_\_\_\_ their orientation, forming long \_\_\_\_\_ molecules that can link together by \_\_\_\_ - bonds. Thus, this polymer has a lot of \_\_\_\_\_ strength.
  - b) Plants also form \_\_\_\_\_ which is a polymer of \_\_\_\_ - D - glucose and is a component of what is commonly called starch. The glucose molecules form only \_\_\_\_\_ linkages, which then curl into a \_\_\_\_\_. This is also a result of \_\_\_\_ - bonds between \_\_\_\_\_ molecules..

- c) Lastly, plants also form \_\_\_\_\_ which is also a polymer of \_\_\_\_ – D – glucose and a component of starch. The glucose molecules form \_\_\_\_\_ and \_\_\_\_\_ linkages, which means this polymer has \_\_\_\_\_. It is much larger than \_\_\_\_\_.
- d) Animals form \_\_\_\_\_ which is also a polymer of \_\_\_\_ – D – glucose and also forms \_\_\_\_\_ and \_\_\_\_\_ linkages, which means this polymer has \_\_\_\_\_ as well. However, it has more \_\_\_\_\_ than \_\_\_\_\_ which is one way to distinguish these two similar \_\_\_\_\_ saccharides.

Need a little help? Here are the words to fill in. Some appear more than once.
