## Cell Cycle

1. The cell cycle is as follows:

Stages 1, 2 and 3 are called $\qquad$ . Stage 1 is the $\qquad$ phase, in which
$\qquad$ synthesis is occurring. Stage 2 is when $\qquad$
$\qquad$ occurs in preparation for
cell division. Stage 3, the $\qquad$ phase, is also a time of $\qquad$ synthesis and $\qquad$ of extra organelles.

Stages 4-6 are called $\qquad$ . This is the division of the $\qquad$ into two
$\qquad$ identical $\qquad$ -.

The cell cycle is regulated by proteins called $\qquad$ . They bind to $\qquad$ -dependent kinase enzymes, moving the cell into the next phase. These proteins were discovered by $\qquad$ ـ.

This graph shows the change in concentration in the different $\qquad$ . Complete it, and include a key.
$\qquad$

We will look at the steps in detail (you must make diagrams in the boxes):

Stage 1 of $\qquad$ is called $\qquad$ (4 on diagram).

In this stage, the sister $\qquad$ are $\qquad$ coiling. They are held together at the $\qquad$ . The $\qquad$ envelope is $\qquad$ down, and the $\qquad$ micro
$\qquad$ are spreading towards the poles.

Stage 2 is called $\qquad$ (5 on diagram). In this stage, the sister $\qquad$ are $\qquad$ up at the $\qquad$ .

The $\qquad$ micro $\qquad$ attach to $\qquad$ sides of the $\qquad$ .

Stage 3 is called $\qquad$ (6). In this stage, the sister
$\qquad$ separate because the $\qquad$ gets
broken. This creates two $\qquad$ that then migrate to
$\qquad$ poles.

Stage 4 is called $\qquad$ (7). In this stage, the
$\qquad$ envelope reforms around the $\qquad$ .

The $\qquad$ moves inwards and pinches off, forming two new cells. This is called $\qquad$ and is different in plant and animal cells, mostly because plant cells have a $\qquad$ .
2. The $\qquad$ of cell division can be used to detect $\qquad$ cells. These cells divide
$\qquad$ so a sample will show many cells in any of the above stages of $\qquad$ when comparing to the overall number of cells in a sample. This is called the $\qquad$ index and the formula is: $\qquad$ index $=$ $\qquad$ Remember, it is easy to see if a cell is in interphase or in $\qquad$ . In $\qquad$ the chromosomes are always visible because they have $\qquad$ .

Work out the mitotic index for these simulated tissue samples:

Which sample is more likely to be from a tumour?
3. $\qquad$ can be caused by $\qquad$ which alter the genetic code, or by
$\qquad$ which are genes that can, under certain circumstances, lead to the development of
$\qquad$ . These two factors can cause $\qquad$ tumours in one organ. If the
$\qquad$ spreads to other organs, this is called $\qquad$ . The new tumours
formed in other organs are called $\qquad$ tumours.
4. There is known to be a $\qquad$ correlation between $\qquad$ and getting
$\qquad$ cancer. It is important to understand that correlation does not mean $\qquad$ .
$\qquad$ it is not necessarily true that one causes the other.
