Multicenter Trial of Cryotherapy for Retinopathy of Prematurity (CRYO-ROP)

Objective	or a non-t	To determine changes in clinical outcomes following cryotherapy treatment control in the management of retinopathy of prematurity (ROP).
Methods		Results
 Design: Randomized Controlled Trial Sample Size: 291 infants with ROP Treatment Groups: Bilateral ROP patients received cryotherapy in one eye only Unilateral ROP patients either received cryotherapy in that eye or received no treatment Outcome Measures: Anatomic outcomes based on fundus photography grading Functional outcomes based on visual acuity testing (different based on age) 		 Point 1: There were improvements in structural outcomes with treatment There was a 49.3% reduction in the unfavorable outcome rate at 3 months in the treated eyes vs the untreated eye (21.8% compared with 43.0%) There was a 45.8% reduction in the unfavorable outcome rate at 12 months in the treated vs untreated eye (25.7% compared to 47.4%) Point 2: There were similar improvements in functional outcomes with treatment, though not a significant improvement in highly functional vision (20/40 or better) There was a reduction in the unfavorable outcome rate at 10 years (44.4% in treated vs 62.1% in controls, P < 0.001) At 10 years, the percentage of eyes with VA better than 20/40 vision was similar in control and treated eyes (23.7% to 25.2%, P = 0.63) It was felt that anatomic success may have overestimated the efficacy of treatment compared to long-term functional success Point 3: Treated eyes had lower rates of retinal detachment At 5.5 years, 22.1% of treated eyes had total retinal detachments compared to 38.6% of control eyes At 10 years, treated eyes were stable at 22%, whereas untreated eyes were up to 41.4%

TLDR: Cryotherapy ablative treatment led to significantly improved anatomic outcomes and mostly improved functional outcomes for patients with threshold ROP
