PHIL 313Q: Inductive Logic

ch. 5 of "Probability and Inductive Logic" by Ian Hacking

Alex Rausch

PhD Candidate, The University of Texas at Austin

Conditional Probability

- We've been dealing mostly with “categorical” probability: probability with no assumptions
 - e.g. the probability of drawing an ace on the 1st card
 - $\Pr(A_1)$
- Now we'll focus on “conditional” probability: probability on one event *on the condition of another*
 - e.g. the probability of drawing an ace on the 2nd card *on the condition that we drew an ace on the 1st card*
 - $\Pr(A_2 \mid A_1)$
- We already saw that $\Pr(A \& B) = \Pr(A) \times \Pr(B \mid A)$.
- So, $\Pr(B \mid A) = \Pr(A \& B) / \Pr(A)$, if $\Pr(A) > 0$
- Note that, also, $\Pr(A \& B) = \Pr(B \& A) = \Pr(B) \times \Pr(A \mid B)$
- So, $\Pr(A \mid B) = \Pr(B \& A) / \Pr(B)$

Conditional Probability

You basically have 4 equations at your disposal:

$$(1) \quad \Pr(A \ \& \ B) = \Pr(A) \times \Pr(B \mid A)$$

$$(2) \quad \Pr(A \ \& \ B) = \Pr(B) \times \Pr(A \mid B)$$

$$(3) \quad \Pr(A \mid B) = \Pr(A \ \& \ B) / \Pr(B) \quad \textit{from (2)}$$

$$(4) \quad \Pr(B \mid A) = \Pr(A \ \& \ B) / \Pr(A) \quad \textit{from (1)}$$

In conditional probability problems, you'll be able to infer from the setup, or calculate, some of these terms in order to solve for the others.

Conditional Probability (Examples)

Take a fair die. What's the probability of rolling a 6 assuming you roll an even?

Let R_n = roll n , E = roll even

What's $\Pr(R_6 \mid E)$?

Intuitively, half (3) of the faces are even, and 6 is one of them. So, $\frac{1}{3}$.

$$\begin{aligned}\Pr(R_6 \mid E) &= \Pr(R_6 \& E) / \Pr(E) \\ &= \Pr(R_6) / \Pr(E) \\ &= \frac{1}{6} / \frac{1}{2} \\ &= \frac{1}{3}\end{aligned}$$

<- this requires insight. R_6 and E are NOT mutually exclusive, so I can't multiply their probabilities to get $\Pr(R_6 \& E)$

Checks out!

Conditional Probability (Examples)

Let **M** = roll a 1 or a prime number

Let **E** = roll an even number

Let **R_n** = roll an n

What's $\Pr(E \mid M)$?

Intuitively, there are 4 ways to get **M** (1, 2, 3, 5), one of which (2) is even. So, $\frac{1}{4}$.

$$\Pr(E \mid M) = \Pr(E \& M) / \Pr(M)$$

$$= \Pr(R_2) / (4/6)$$

$$= \frac{1}{6} / (4/6) = \frac{1}{4}$$

<- this requires insight. R_6 and E are NOT mutually exclusive

Checks out!

Conditional Probability (Examples)

Take a standard 52-card, shuffled deck. You're dealt a card at random.

Let **R** = dealt red, **C** = dealt clubs, **A** = dealt ace

Suppose you're told you've been dealt either red or clubs, i.e. **R v C**

What's $\Pr(\mathbf{A} \mid \mathbf{R} \vee \mathbf{C})$?

Intuitively: 26 red + 13 clubs = 39 red-or-club cards. 3 are aces. So, $3/39 = 1/13$.

$$\Pr(\mathbf{A} \mid \mathbf{R} \vee \mathbf{C}) = \Pr(\mathbf{A} \& (\mathbf{R} \vee \mathbf{C})) / \Pr(\mathbf{R} \vee \mathbf{C})$$

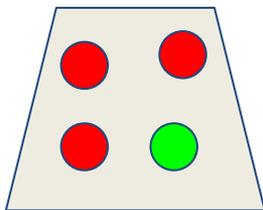

$$= (3/52) / (39/52) \quad \leftarrow \text{this requires insight, but I could have added } \Pr(\mathbf{R}) \text{ and } \Pr(\mathbf{C})$$

$$= 3/39 = 1/13 \quad \text{to get } \Pr(\mathbf{R} \vee \mathbf{C}), \text{ since those are mutually exclusive}$$

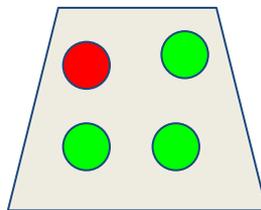

Checks out!

Compounding Events (Again)

Urn 1

Urn 2

Setup: flip a fair coin. If Heads, pull from Urn 1. If Tails, pull from Urn 2.

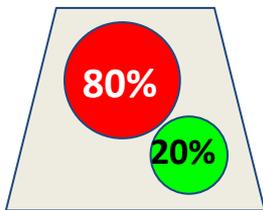

R = Pull a red ball, **H** = Flip heads, **T** = Flip tails

What is $\Pr(\mathbf{R})$?

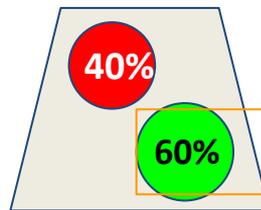

$$\begin{aligned}
 \Pr(\mathbf{R}) &= \Pr(\mathbf{H\&R}) \vee (\mathbf{T\&R}) \\
 &= \Pr(\mathbf{H\&R}) + \Pr(\mathbf{T\&R}) \\
 &= [\Pr(\mathbf{H}) \times \Pr(\mathbf{R} \mid \mathbf{H})] + [\Pr(\mathbf{T}) \times \Pr(\mathbf{R} \mid \mathbf{T})] \\
 &= [\frac{1}{2} \times \frac{3}{4}] + [\frac{1}{2} \times \frac{1}{4}] = \frac{1}{8} + \frac{3}{8} = \frac{4}{8} = \frac{1}{2}
 \end{aligned}$$

Conditional Probability (Examples)

Urn A

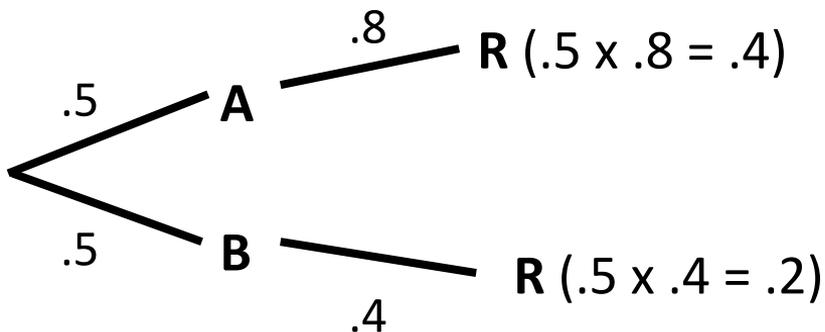

Urn B

Setup: Pick a ball at random. Then replace.

R = Pull a red ball, **A** = Pull from A, **B** = Pull from B

What is $\Pr(A \mid R)$?

Intuitively: these are mutually exclusive paths, so $\Pr(R) = .4 + .2 = .6$

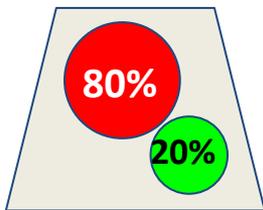

60% chance of pulling red.

60% = 40% from A + 20% from B
 So, 40/60 Rs are from A.

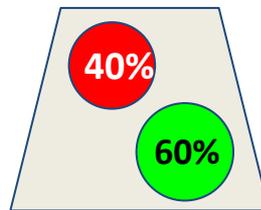

So, $\Pr(A \mid R) = 40/60 = \frac{2}{3}$

Conditional Probability (Examples)

Urn A

Urn B

Setup: Pick a ball at random. Then replace.

R = Pull a red ball, **A** = Pull from A, **B** = Pull from B

Notice $\Pr(R \mid A) = .8$, $\Pr(R \mid B) = .4$, and $\Pr(A) = \Pr(B) = .5$

Suppose you pull a red ball. What's the probability it came from A?

$$\Pr(A \mid R) = \Pr(A \& R) / \Pr(R)$$

$$= [\Pr(R \mid A) \times \Pr(A)] / \Pr((A \& R) \vee (B \& R))$$

$$= [\Pr(R \mid A) \times \Pr(A)] / [\Pr(A \& R) + \Pr(B \& R)]$$

$$= [.8 \times .5] / [\Pr(R \mid A) \times \Pr(A) + \Pr(R \mid B) \times \Pr(B)]$$

$$= .4 / [.4 + .2] = .4 / .6 = \frac{2}{3}$$

Conditional Probability (Examples)

Acme (supplies 60%)

Bolt (supplies 40%)

| | |
|-----------------|-----------------|
| 96% reliable | 72% reliable |
|-----------------|-----------------|

What's the probability that a random shock absorber is reliable?

A = Shock absorber chosen randomly is from Acme

B = Shock absorber chosen randomly is from Bolt

R = Shock absorber chosen randomly is reliable

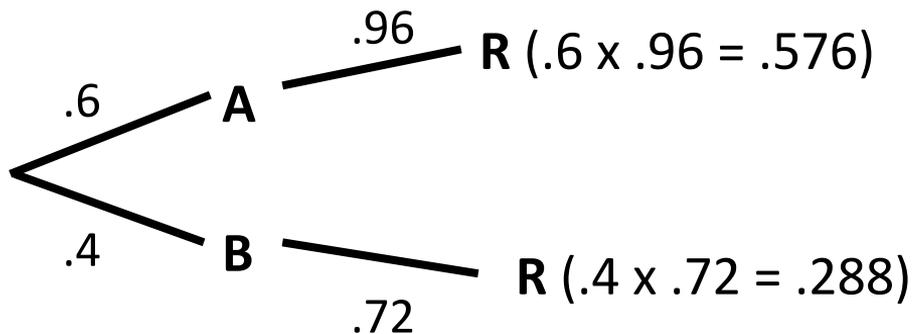

$$\begin{aligned}
 \Pr(R) &= \Pr((A \& R) \vee (B \& R)) = \Pr(A \& R) + \Pr(B \& R) \\
 &= \Pr(A)\Pr(R \mid A) + \Pr(B)\Pr(R \mid B) \\
 &= [.6 \times .96] + [.4 \times .72] = .864
 \end{aligned}$$

Conditional Probability (Examples)

Acme (supplies 60%)

Bolt (supplies 40%)

| | |
|-----------------|-----------------|
| 96% reliable | 72% reliable |
|-----------------|-----------------|

Mutually exclusive paths,
 so chance of R is
 $.576 + .288 = .864$

Conditional Probability (Examples)

Steroid Team (80% juice)

Clean Team (20% juice)

Setup: Coach sends a team randomly. Then the team that goes gets a member tested. Suppose the team-member tests positive for steroids.

What's the chance the coach sent the Steroid Team?

S = coach sent Steroid Team, **C** = coach sent Clean Team, **U** = tested positive

$$\Pr(\mathbf{S} \mid \mathbf{U}) = \Pr(\mathbf{S} \& \mathbf{U}) / \Pr(\mathbf{U}) =$$

$$= \Pr(\mathbf{S})\Pr(\mathbf{U} \mid \mathbf{S}) / \Pr(\mathbf{S} \& \mathbf{U}) \vee (\mathbf{C} \& \mathbf{U}))$$

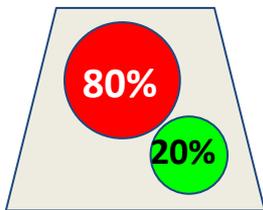

$$= (.5 \times .8) / (\Pr(\mathbf{S})\Pr(\mathbf{U} \mid \mathbf{S}) + \Pr(\mathbf{C})\Pr(\mathbf{U} \mid \mathbf{C}))$$

$$= .4 / [(.5 \times .8) + (.5 \times .2)]$$

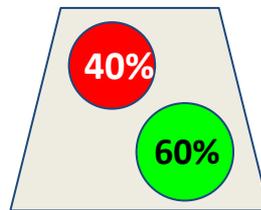

$$= .4 / (.4+.1) = .4/.5 = 80\%$$

Conditional Probability (Examples)

Urn A

Urn B

Setup: Flip a coin. If heads, draw from Urn A twice with replacement. If tails, draw from Urn B twice with replacement.

R_n = Pull a red ball on n^{th} draw, **A** = Pulled from Urn A (heads), **B** = Pulled from Urn B (tails)

What is $\Pr(\mathbf{A} \mid R_1 \& R_2)$?

$$= \Pr(\mathbf{A} \& R_1 \& R_2) / \Pr(R_1 \& R_2)$$

$$= \Pr(\mathbf{A} \& R_1) * \Pr(R_2 \mid \mathbf{A} \& R_1) / (\Pr(\mathbf{A} \& R_1 \& R_2) + \Pr(\mathbf{B} \& R_1 \& R_2))$$

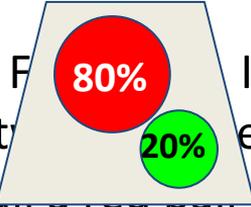

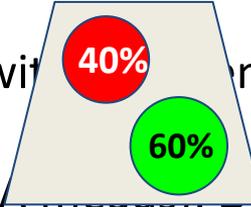

$$= \Pr(\mathbf{A})\Pr(R_1 \mid \mathbf{A}) * .8 / (\Pr(\mathbf{A} \& R_1 \& R_2) + \Pr(\mathbf{B} \& R_1 \& R_2))$$

$$= (\frac{1}{2})(.8) * .8 / (\Pr(\mathbf{A} \& R_1 \& R_2) + \Pr(\mathbf{B} \& R_1 \& R_2))$$

$$= .32 / (.4 + \Pr(\mathbf{B} \& R_1)\Pr(R_2 \mid \mathbf{B} \& R_1))$$

Conditional Probability (Examples)

Setup: Flip a coin. If heads, draw from Urn A twice with replacement. If tails, draw from Urn B twice with replacement.

R_n = Pull from Urn on n^{th} draw, A = Pulled from Urn A (heads), B = Pulled from Urn B (tails)

What is $\Pr(A \mid R_1 \& R_2)$?

$$\begin{aligned}
 &= \Pr(A \& R_1 \& R_2) / \Pr(R_1 \& R_2) \\
 &= \Pr(A \& R_1) * \Pr(R_2 \mid A \& R_1) / (\Pr(A \& R_1 \& R_2) + \Pr(B \& R_1 \& R_2)) \\
 &= \Pr(A) \Pr(R_1 \mid A) * .8 / (\Pr(A \& R_1 \& R_2) + \Pr(B \& R_1 \& R_2)) \\
 &= (1/2)(.8) * .8 / (\Pr(A \& R_1 \& R_2) + \Pr(B \& R_1 \& R_2)) \\
 &= .32 / (.32 + \Pr(B \& R_1) \Pr(R_2 \mid B \& R_1)) \\
 &= .32 / (.32 + \Pr(B) \Pr(R_1 \mid B) .4) \\
 &= .32 / (.32 + (1/2)(.4)(.4)) \\
 &= .32 / .32 + .08 = .32 / .4 = .8
 \end{aligned}$$

Group Practice

- see slide #7, and imagine running two consecutive trials. How would you think about the probability of the following event: *pulling a red ball on the first trial and a green ball on the second trial?* (cf. #3 on Pset 5)
 - Since there is replacement between trials, the probability of these (independent) compound event is the probability of the first multiplied by the probability of the second.
- *p56. #3*
 - **T** = Randomly selected child lives in Triangle
 - **P** = Randomly selected child tests positive
 - **Pr(T) = .02, Pr(P | T) = .14, Pr(P | ~T) = .01**
 - (a) **Pr(T & P) = Pr(T)Pr(P | T) = .02 x .14 = .0028**
 - (b) **Pr(P) = Pr((P&T) v (P&~T)) = Pr(P&T) + Pr(P&~T) = .0028 + Pr(~T)Pr(P | ~T)**

$$= .0028 + (.98 \times .01) = .0028 + .0098 = .0126$$
 - (c) **Pr(T | P) = Pr(T & P)/Pr(P) = .0028 / .0126 = 2/9** (or about .22...)
