

Valkyrie Carbs and Custom Fuel Solenoid Assembly Description

A positive fuel shutoff is a vital component of preventing hydrolock on a Valkyrie. We custom build an electric solenoid fuel shutoff harness with a relay.

We are using the “safety circuit” 12V connection to trigger the relay. When the key is turned on, if the safety circuit is satisfied, 12V energizes the relay. The relay then routes power from the battery and energizes the fuel solenoid. The fuel solenoid will remain energized until any shutoff signal is received. The safety shutoff signals such as the ignition key, kill switch, bank angle sensor, kickstand sensor, deenergize the fuel solenoid and stop fuel flow.

Construction notes:

Loctite 580 thread sealant is applied to the brass fuel fitting threads before assembly. The fuel lines and stainless-steel hose clamps are installed. Heat shrink is placed on the solenoid wires for abrasion protection. Wire labels are placed on the wires, and a 2 pin Molex connector is installed on the solenoid wires.

A flyback diode is soldered in parallel with the coil of the automotive relay. There are 2 power sources for the relay circuit. One to trigger the relay, and one to supply power to the fuel solenoid through the relay. Each is fitted with an inline fuse. The bike “safety circuit” is fused at 10 Amps. We fused the connection to it at 3 Amps to trigger the relay. The circuit connected to

Valkyrie Carbs and Custom Fuel Solenoid Assembly Description

We are using the “safety circuit” 12 V Coil Black/White wire connection to trigger the relay. When the key is turned on, if the safety circuit is satisfied, 12 V is supplied to 85 of the relay, which energizes the relay. The relay then routes power from the battery through 30, to 87 of the relay, and energizes the fuel solenoid. The fuel solenoid will remain energized until any shutoff signal is received. The safety shutoff signals such as the ignition key, kill switch, bank angle sensor, and kickstand sensor, deenergize the fuel solenoid and stop fuel flow.

D1 across the coil of the relay is a flyback diode. When the relay coil is deenergized, the magnetic field on the relay windings collapses and generates a high voltage kick. The diode protects the connected circuitry from the voltage spike.

Components:

- AFC-121 Solenoid Fuel Shutoff valve.
- Fuel Fitting Brass TEE 3/8" ID X 1/4" Male NPT to Hose Barb
- Loctite 580 Thread Sealant
- Hose clamps
- Fuel line tubing
- Heat shrink tubing
- Automotive 12VDC relay
- 3M Dual Lock mounting for relay
- Diode
- Solder
- Wire
- Wire terminals
- Wire marks
- Fuses
- Alcohol swab
- Ty Wraps
- Stabilant 22A Contact Enhancer
- Molex 2 pin connectors
- In-line fuses
- Tesa Wire Loom Harness Wrap Tape

Operational Notes:

To use the fuel shutoff, simply start the bike as you usually do. The solenoid will energize when you turn on the key. It will turn off with any signal that shuts down the bike.
