This table shows the relative performance information on each bull. They are in order by age, with the oldest bull first and the youngest last. A 3-month spread.

All the weights are actual weights on the dates shown above the columns. The performance measures in red highlight the best performers in the respective category.

These bulls were fed a corn ration limited to 2% of their body weight for just 79 days (from February 5 to April 25) prior to ultrasounding. They were never fat, but the ultrasound scan should indicate relative carcass merit between the bulls.

Weaning WDA (Weight per Day of Age) is the animal's weight on October 26 divided by how many days old he was on that day.

Feed ADG (Average Daily Gain) is the number of pounds gained while on the limited corn ration divided by 79 days. Our steers on full feed averaged 4.7. These bulls would gain at a much higher rate if given all they wanted to eat.

The grass gain column shows how many pounds they gained last summer on grass AFTER having been pushed with corn. Our commercial steers averaged 350 pounds of gain over the summer.

Scrotal circumference is shown (in centimeters) because university studies have shown a correlation between scrotal circumference and his offspring's fertility rates.
