*The Webs We Weave*

Alice Waters  
Editor  
cah2os2006@yahoo.com

I just returned from five days on the Varian (V6) Ranch, over 20,000 acres of absolutely breathtaking land, where I attended a bridle horse clinic with Bruce Sandifer and Jeff Mundell which included working with cattle. I was nervous going into the clinic, being relatively new to riding (about 4 years), and to the discipline of Bridle Horse. Also, I ride a tall off-the-track Thoroughbred, a breed not exactly known for moving cattle. The education far exceeded the expectation. I learned better riding techniques and mechanics and, more importantly, I learned that controlling emotion is the key. We will never be partners with our horse unless we control our emotions. We will just be sitting on a "tool", forcing it to do what we want it to do until it just won't do it anymore. Riding is all about a quiet conversation between the rider and horse by use of body and mind.

I had the opportunity to see many riders on their horses, some very accomplished and some not so much. What intrigued me the most is that the accomplished riders had one thing in common: they all rode effortlessly. Their thoughts were the horse's thoughts; they didn't pull on the horse's mouth; they didn't kick the horse to get it to behave; the horse seemingly responded to the rider's thoughts; they were partners even in the roughest terrain. I frequently heard the terms "be soft", "soften", "it's the feel", "feel the horse". Not so easy to do when you're trying to demand of the horse certain techniques. Well, there it is. I said "demand" and that's the problem: we "demand" instead of ask. We prod, insist, yank and pull instead of ask. And we wonder why we're getting nowhere or why the horse loses its mind. During this clinic I had the pleasure of watching Amy and Cora Mundell, Jeff's wife and daughter, ride. It was like watching a beautiful dance. They both were beautiful in the saddle, balanced and soft, enjoying the horse beneath them doing their jobs. It seems we all would crave that kind of connection regardless of what discipline we ride. The tack we use or the clothes we wear matters not. The techniques we use to speak softly to our equine partners is what matters. I am not one of the very accomplished riders I spoke of previously but I did gain a direction for my journey. I can stay on a horse, even during difficult times, but that doesn't make me a good rider. It actually shows the opposite. If we train our horse to listen to a whisper (in our hands and body) we won't need to yell and those crazy horse incidents would be few and far between. Let me leave you with this to ponder: Bruce Sandifer said, "if you're not training your horse when you ride, you're un-training your horse when you ride." Do you train or un-train?

A final note. We lost a very valuable asset a couple of weeks ago. One of our dedicated volunteers, who spent countless hours at our facility cleaning up, became disheartened and quit after picking up an increasing amount of manure every week. Please pick-up after your horse. If you don't have time to clean up after your own horse, please don't use our facility. More poop cans will be added to make it easier to pick-up. Also, we still need volunteers to help with clean up. Many hands make light work.

# VP's Message

## MEMBER KUDOS

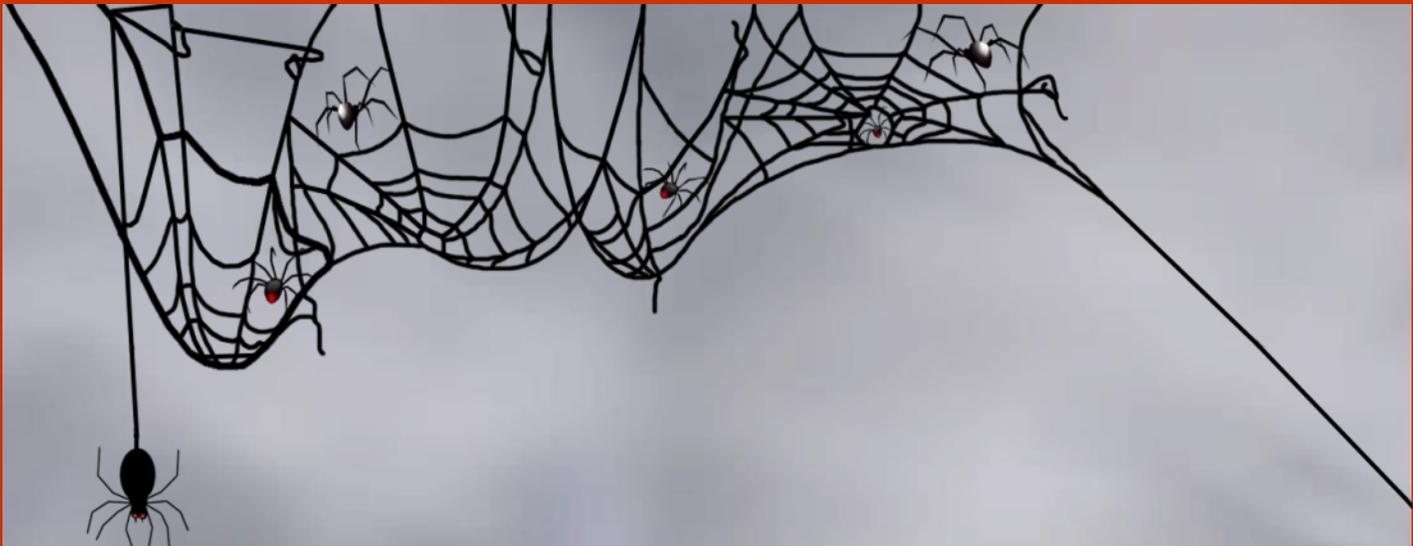

We have many wonderful members in our club who do many interesting things and have attained great accomplishments. We would like to acknowledge them whenever possible. If you know of anyone in the club who should be highlighted for their triumphs, please let us know at [altalomaridingclub@gmail.com](mailto:altalomaridingclub@gmail.com).

**CONGRATULATIONS** Ric and Pat Morris for producing and directing the 10<sup>th</sup> anniversary SILVER FOX FOLLIES at the Lewis Family Playhouse on September 9<sup>th</sup>.

**CONGRATULATIONS** Martha Cowan who, also on September 9<sup>th</sup>, won Best of Show in the Rancho Cucamonga Art Festival at the Lewis Center. She also won 1<sup>st</sup> place for one of her paintings.

**THANK YOU** Bret Dooley and his company, D.B. Building Fasteners, Inc., for donating \$413.00 to ALRC for the purchase of ALRC's new decal stickers, now available to all our members (see page 3 for details about the decals.)

Oct 14	General Membership Meeting. Come get your ALRC decals and share an evening with your fellow horsey friends! (see page 3 for details)
Oct 28	Halloween Trail Ride. Saddle-up in your Halloween costume for a local trail ride with Brent Dooley! (see page 4 for details)

# GENERAL Membership MEETING

FREE  
DECALS!

## OCTOBER 14

Heritage Park Equestrian Center

5:00 pm

- Delicious complimentary chicken dinner
- Roundtable discussion about activities and events members are interested in for the coming year
- Music and socializing with other horsey friends
- Raffle

Everybody Welcome  
Reservations Appreciated

FREE to all members to display on their trucks, trailers or wherever. Stop by October 14<sup>th</sup> and pick up your free decals. Let Rancho know how proud we are of our Alta Loma Riding Club!

# Halloween Trail Ride

## OCTOBER 28

**MEET AT**  
**Heritage Park**  
**Equestrian Center**  
**3:00 pm**

- Wonderful desserts and refreshing drinks after the ride
- Everybody welcome, (even if it's just for dessert.)
- Wear your Halloween costume and join in the fun!

**Brent Dooley**  
*Trail Boss*

# HOW HORSES SEE

*The equine eye is designed to help horses easily spot predators, footing, and food. Learning about the unique capabilities of your horse's eyes can help you better understand his behavior.*

*Article from [www.horseandrider.com](http://www.horseandrider.com)*

You've probably witnessed this scene during television coverage of equestrian events or at a horse show: Horse and rider gallop up to an imposing jump. Within a few strides of the obstacle, the rider tenses slightly; the horse rocks his weight back over his hindquarters in preparation for takeoff. All looks good...until the horse abruptly slams on the brakes at the jump's base, and the force hurtles his rider through the air and into the jump.

Is the horse being mean? Stubborn? Probably not. Odds are, if you saw what he saw on his approach to the fence (or what your own horse will see when he jumps a ditch or a fallen log, or crosses a trail obstacle), you'd stop, too. That's because just as a horse reaches his takeoff point, the obstacle in front of him disappears, entering a

cone-shaped blind spot that extends about 4 feet in front of his face. For your horse to go over any obstacle, it requires a leap of faith—faith in your ability to safely guide him over it, and faith in his ability to safely negotiate it. If you do anything to rattle that faith, as the rider in the above scenario did (by tensing up), chances are, your horse won't take the leap.

The disappearing obstacle is just one of the ways your horse's vision differs—radically—from yours. To help you gain a horse-eye view of the world, I'm going to take you on a short ride, comparing what you see, against what research tells us your horse sees. By the end of our ride, you'll find that viewing the world through your horse's eyes will open a window to equine behavior. You'll have a better understanding of why your horse spooks at "invisible" demons; why objects that look harmless to you send him flying sideways; and why he often reacts to things as though he's viewing them for the first time, even though you know he's seen them before. You'll also realize why it's truly amazing when your horse does do something you ask of him, such as walk calmly into your horse trailer, or trot past that big tree stump.

## THE INCREDIBLE JOURNEY

Journey with me as we ride down a long dirt driveway. Along the way, we'll pass sights common to every barnyard. With each, I'll describe what you'll see and then will explain your horse's view of the same sight.

### The Gate Has Arms

**What you see:** Just ahead, there's a 14-foot-wide gated opening through which we must pass to reach the end of the driveway. In preparation for our ride, I opened the aluminum gate earlier; you see it propped up on the grass beside my driveway, shimmering in the bright sun.

**Why you see it that way:** Your eyes are on the front of your face and, working together, they bring your brain a simultaneous 3-D image. This phenomenon, known as binocular vision, is indigenous to predators which, like cats, dogs, cougars, wolves, etc., we humans are. Nature designed binocular vision to enable predators to chase down, catch, and kill prey darting in front of them.

Your focusing apparatus works like that of an auto-focus camera. Your eyes automatically focus on the gate using flexible disc-like lenses that are attached to powerful ciliary muscles. These muscles instantly flex or relax as needed to adjust your lens shape so you can send a sharp image to your retina, the "switchboard" of nerve receptors on the back wall of your eyeballs. This switchboard then relays the picture to your brain.

**Your reaction:** You approach the open gate without giving it another thought.

**What your horse sees:** To him, the gate appears to be a hologram—a collage of silver arms shimmering into and out of focus, reaching forward and back as he approaches and passes it.

**Why he sees it that way:** As a prey animal, your horse has monocular vision, meaning he has one eye on each side of his head. A prey animal's eyes work independently of one another, sending separate images to separate sides of his brain as they constantly search for predators lying in wait. Only when your horse has directed both eyes on an object directly in front of him—beyond his front-end blind spot—do both eyes focus together in binocular vision.

Regardless of whether he's eyeing the gate or any other up-close object, using one eye or both, your horse's lenses are much less flexible than yours. His poorly developed ciliary muscles are ill-equipped to make more than small, slow adjustments—much too small and much too slow to allow him to make quick, informed decisions visually. (Which is why Mother Nature has programmed him to first flee to safety, then to check out the situation from a safe distance.) To help his eyes focus in spite of rigid lenses he must move his head, adjusting the distance, known as focal length, between his eye or eyes and the gate, and adjusting the angle of view until the image falls into focus on the appropriate portion of his retina.

As he moves through the opening, portions of the gate move into focus while other portions seem to be shimmering blurs that change as his every step and minor head movement alter the focal length and angle of view. To your horse, this appears as though portions of the gate are actually moving—an unsettling vision for a prey animal who believes that strange, moving objects are boogiemen until proven otherwise and are to be approached with the utmost caution, if at all.

**His reaction:** He raises his head for an up-close look through the lower half of his eyeballs (more about that later), then cautiously steps through the opening.

### Kitty Kong

**What you see:** My 10-pound yellow cat sitting on a stump to the right of my driveway.

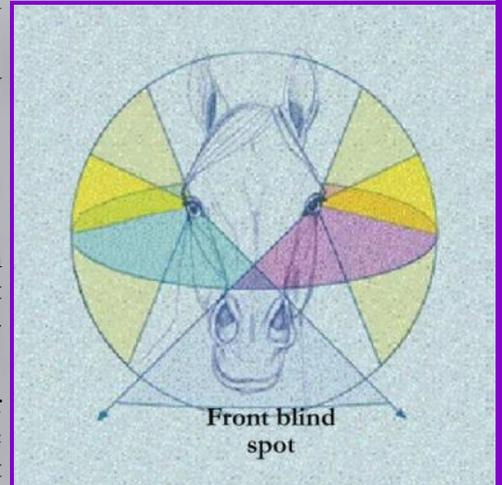

**Why you see it that way:** Your eyes' auto-focus mechanism instantly sends your retina a sharp image of the cat.

**Your reaction:** "What an adorable kitty!"

**What your horse sees:** A cat the size of a Cocker Spaniel.

**Why he sees it that way:** Your horse's eyeball is the largest orb found in any land mammal and has a correspondingly oversized retina. The effect of this large retina is that it magnifies everything he sees—to him, up-close objects look 50 percent larger than they appear to you.

**His reaction:** Yikes! Kitty's larger-than-life appearance ensures that your defenseless equine will be less apt to be surprised by a predator. While this feature keeps him on his toes toward danger (sometimes literally!), it also makes for a lot of false alarms.

### Oh, Deer

**What you see:** As we top a slight hill, you spot a couple of white-tail deer 50 yards below and to your left, grazing in front of a stand of trees.

**Why you see it that way:** As we top the hill, you turn your head slightly leftward so that the deer remain directly in your binocular line of vision. But, as you turn your attention back to the driveway to make your way down the backside of the hill, the deer fall into your peripheral vision, the area just outside the line of direct sight; they become a fuzzy clump of tan blobs off to your left.

**Your reaction:** Once the deer fall out of your front-line vision, you stop paying attention.

**What your horse sees:** This depends on his position on the hill. He may not even notice the deer as he crests it, since they're slightly ahead and to the left of him, at a level lower than his head. As he passes over the hilltop and begins to walk down the other side, the deer enter his peripheral vision—and become crisp, sharp images.

**Why he sees them that way:** He can't clearly see them from the hilltop, because his eyes operate in a manner similar to bifocal glasses. Looking through the lower half of his eyes—as he would be at the deer below—he can clearly see up-close objects, but not those in the distance. Looking through the upper half of his eye, he can clearly see distant objects, but not those up close. In your horse's peripheral vision, the deer come into sharp focus because images viewed in a 215-degree area spanning each side of him fall into a portion of his eye known as the "visual streak." This streak is a horizontal band just above and to the outside of his eyes' center. It's across this area that your horse's vision is sharpest, due to the density of nerve cells that receive visual information at the site. The result is superb peripheral vision, an imperative survival tool that helps him constantly monitor his

environment for predators lurking on either side of or behind him. Using this vision, he's genetically programmed to pick up slight, invisible-to-you movements. The fluttering of a wing, the flick of a branch, the blink of a predator's eye—these happenings, slight or invisible to the human eye, are big-screen occurrences to your horse. Even if he can't quickly focus on what moved, the abundance of specialized receptors within his retinas give him keen motion detection, putting him on instant alert. His survival instincts scream that a predatory attack could be imminent and he must be ready to flee at any moment. Subtle movement may elicit no more than a turn of his head or a slight spook; a larger commotion could trigger his flight instinct—run first, think about it later.

**His reaction:** As long as the deer are quietly grazing, your horse will likely take them in stride. But, if they were to suddenly bolt into the woods, which you can't see because they're out of range of your peripheral vision, your horse spooks. Silly horse, you think, as you quietly circle him to regain control, all the while looking around, trying to determine what on earth could have frightened him.

### Herd Work

**What you see:** The sight of my German Shepherd trotting in from the field to join our trail ride. You shift in your saddle so you can watch the dog make a beeline for your horse's heels. He zigzags from right to left, "herding" your horse.

**Why you see it that way:** Your "front-of-the-face" eye placement prompts you to turn around for a full view to better analyze the situation.

**Your reaction:** Convinced that the dog's herding is harmless, you turn around and face forward.

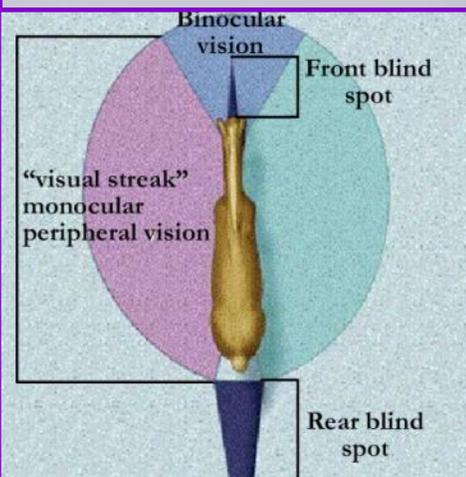

**What your horse sees:** His right eye sees a pony-sized dog. The dog then disappears, and another pony-sized dog appears in his left eye's field of vision.

**Why he sees it that way:** Your horse's bulging, side-of-the-head eye placement gives him a broad range of vision which includes the ability to see behind him (as he takes in some of your in-the-saddle movements), except for an 8-foot-long cone-shaped blind spot directly behind his hindquarters, into which my dog keeps disappearing only to have another pony-sized dog appear on the other side. However, with a slight tilt of his head to either side, your horse is able to eliminate this blind spot.

Because your horse has monocular vision, the area in his right eye's field of vision is perceived and processed by his brain separately from the area in his left eye's field of vision. The unfortunate side effect of this unique ability is that while the right side of his brain has already "seen" the dog, the left side of his brain has not and will perceive a new threat when it sees the dog.

**His reaction:** Because your horse must see an image with both sides of his brain before determining whether it's friend or foe, viewing objects with one eye doesn't adequately acclimate him to them. He's now familiar with the dog but when we head back up the driveway, your horse acts as though he's walking it for the first time. And, to each side of the brain, he is!

### Howdy, Neighbor

**What you see:** My neighbor, standing ahead of us at the end of the driveway, wearing a Panama hat with a hot-pink hatband, a brown-and-yellow striped pullover shirt, and a pair of unsightly, bilious-green stretch pants.

**Why you see it that way:** Because you see the world in a wide palette of colors, your neighbor's fashion faux-paus leaps out at you.

**Your reaction:** You secretly wish you were colorblind!

**What your horse sees:** A large human with green legs, a yellow and gray-toned body, and a brown/gray straw-looking thing on her head which may or may not be edible.

**Why he sees it that way:** Your horse can perceive some colors. The most vivid to his eyes are yellow, followed by green, then blue. Researchers believe that color perception in horses helps them find food: mix the

colors yellow and green, and you get the colors of spring grass; add a little blue and you get clover or alfalfa. Since brilliant colors aren't important for your horse's reproduction (as they are for other species like birds and monkeys) and his predators tend to be of the brown variety, the color red isn't imperative for his survival. He sees red as brown/gray or as a non-color.

**His reaction:** Your horse isn't frightened by bright colors—or bad taste. So long as my neighbor doesn't make any sudden, startling movements, he'll quietly accept her presence.

### Gazing Grazer

**What you see:** My fashion-impaired neighbor offering us a piece of pie while motioning to a small, grassy paddock where we can put our horses.

**Why you see it that way:** Your eyes work as one (though they often partner with your stomach).

**Your reaction:** You untack your horse, turn him loose in the paddock, and chow down on a helping of fresh peach pie.

**What your horse sees:** Grass. He immediately drops his head and digs in.

**Why he sees it that way:** Since he was designed to feed himself by grazing, he readily identifies food at ground level.

**His reaction:** Unless something catches his eye, he'll probably munch away. While grazing, your horse remains aware of his surroundings to detect potential threats by looking through the tops of his bifocal eyes. If he perceives anything warranting closer examination, he'll raise his head and arch his neck, so he can continue to use the top halves of his eyes. He'll then zoom in on the suspicious object with his binocular vision, phasing out any distracting peripheral scenes.

### After Dark

**What you see:** Dusk settling in, dimming your ability to discern shapes, or see long distances.

**Why you see it that way:** Your eyes are poorly designed for night vision, because they lack the light absorbing/reflecting mechanisms necessary to see clearly in dim light.

**Your reaction:** You hurry to finish your pie, re-tack your horse, and head back up the driveway, hoping to return to the barn before total darkness descends.

**What your horse sees:** Head-back-home images that look brand new to each side of his brain—images he can see clearly despite the lack of light.

**Why he sees them that way:** Due to the low-light perceiving receptors in his eyes, your horse's night vision is about 50 percent better than yours. He also benefits from reflective panels on his retinas that catch the small amount of light still available at night. These panels reflect light back through his retinas for processing. (The light that bounces back out of his eyes accounts for the ghostly glowing orbs you see when a light hits his eyes at night, or in photos taken with a flash.)

**His reaction:** He'll probably stroll homeward completely at ease. Because your horse can see well at night when there are usually fewer activities to clutter his constant search for danger, he'll likely be less spooky than at high noon—unless you're nervous which you can easily transmit to him.

# Board Actions

The following actions were taken by the Board.

FREE to all ALRC members, a newly designed club decal/sticker is now available. THANK YOU Martha Cowan for designing the sticker and THANK YOU Brent Dooley and his company, D.B. Building Fasteners, Inc., for donating \$413.00 for the production of the stickers.

If you have an item you would like to place on the agenda and bring before the Board, please contact Martha Cowan, Secretary, at: 909-912-2117 or marthacowanpaintings@gmail.com

Lovely Fall has arrived and riding couldn't be better. I love this time of year and even though we don't get the fall colors quite like some areas of the country, we do see some beautiful trees in our city turn lovely colors.

First of all, I want to thank Shelly Clark for her generous donation to the club. It will be very helpful in helping the club in several endeavors.

Congratulations to Jill Underwood on her new equine companion, Shots, but also condolences on the loss of her lovely pony Amber.

Riley and I are always interested in improving our partnership and towards that end we have been riding with Christina Willard as a trail instructor. She has given me so many constructive comments as well as expanding my understanding of how Riley views things on the trail. One of the most recent discussions was about how horses view things with their eyes: do they have a preference of left eye or right eye? Well, guess what? There are articles on the internet about that very subject. She clued me into one of the studies done regarding that very issue. You can view one of the articles at [www.horsehints.org](http://www.horsehints.org) and search for "Horse's Visual Preference/Left or Right Eye?" Here is a short excerpt:

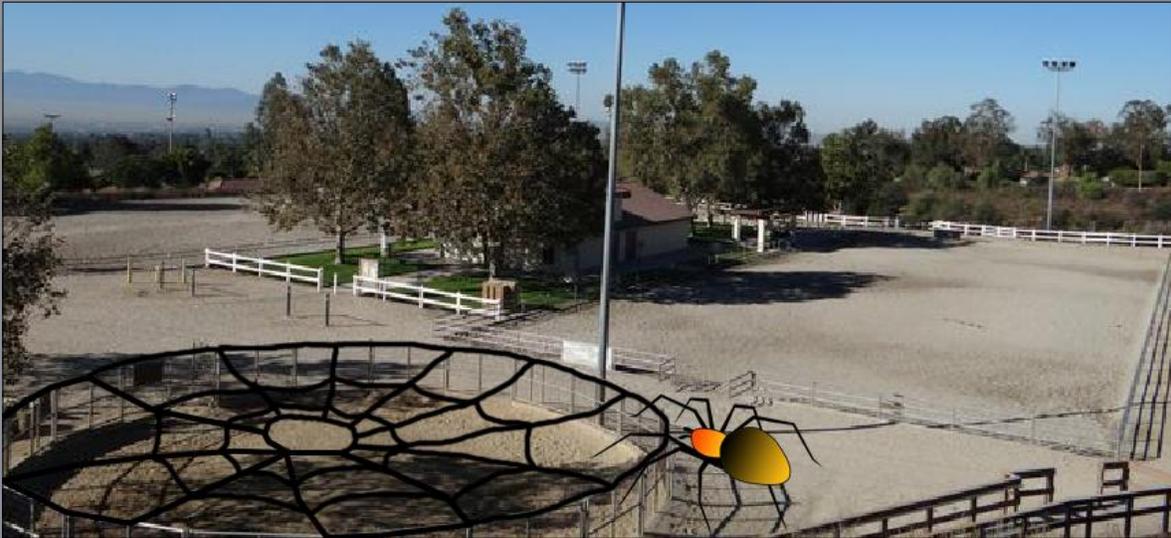

"It has been shown that the left eye is the 'rapid-reaction' eye, and has a stronger and faster flight reaction to a frightening stimulus presented on the left. The study indicated that this affects the horse's interaction with people. The horse that generally prefers you on the left, but is not bothered if you are on the right, is probably seeing you as a cooperative partner, whose lead it would like to follow."

I encourage all of you to look up the article and read it in its complete context. So besides other excellent comments she had noted in my reactions to Riley's actions, she has provided me with some excellent reading material.

Happy Trails and I hope to see many of you riding during the coming weeks.

Ali Smilgis – Membership Chairman

# HERITAGE PARK EQUESTRIAN CENTER A General Purpose Equestrian Facility

## BOOK YOUR 2017 EVENT!

If you have or know of an organization that would like to hold a horse show, clinic or other equestrian event, please share the information below about our wonderful facility

### Amenities

- Show Office & Clubhouse
- Concession Stand
- Restrooms
- Arena Lighting
- 2 Round Pens
- South Arena: 295' x 150'
- North Arena: 220' x 90' (Dressage)
- PA System
- Hitching Rails
- Water Trough
- Trailer Parking
- Trail Course
- Trail Access

### Low Rental Rates

- \$150/6 hrs: includes both arenas & grounds fee
- Kitchen: \$50/event
- Multipurpose Room: \$50/event
- Grounds Fee: \$5/horse
- Cleaning Deposit: \$150 (refundable)
