PLUTUS EXPLORATION INDEX

TRADING MANUAL AND USER GUIDE

Greetings Fellow Trader!

We have developed this simple and easy to use indicator so that all users can benefit from it by:

- 1 Time:** Reducing the amount of time spent trading.
- 2 Risk** Minimizing the risk of loss.
- 3 Accuracy:** Accurate timing on entries and exits means higher profits and better margins.
- 4 Conditions:** Signals are accurate regardless of the market conditions.

What is the PXI?

The Plutus eXploration Index falls under the centred momentum oscillator category which means that it fluctuates above and below a central point or line. Apex levels exist, where the indicator will reach a peak, and start moving in the opposite direction. Two lines move in unison and crossovers will signal a buy and a sell.

Setting up the indicator:

Once you have received your invite, the indicator will appear under your “my invite only” scripts in trading view detailed charts screen. Select HP_PXI and add it to your chart. For free accounts on TradingView, the indicator limit is set to x3, so please de-activate something if you hit this limit. You can access the PXI setting in the string of icons that follow after the indicators name. In order:

Name | Visibility | Settings | Show source code | Delete | More

Under the settings, there are two tabs. One for the style, which you may freely change to suit your preferences. And then the first tab, for Inputs. The default settings for Long Minima, Short Maxima and Integrated EMA should not be changed.

The critical change to make in the input settings is the time frame! The time frame on the price chart and the time frame on the indicator have to match! The range of allowable time frames is as follows:
15min | 30min | 1h | 4h | 12h | 1d | 2d | 1week

How to use the PXI:

The apex levels on the oscillator differ for each asset and vary depending on the selected time frame. The signals provided near apex points shall hold more weight. We recommend that traders assess these levels properly before considering a position.

Sell signal: Sell signals occur when the quick line (default blue) crosses over the slow line (default orange) from above.
A red arrow down will mark this point in time out on the chart.

Buy signal: Buy signals occur when the quick line (default blue) crosses the slow line (default orange) from bellow.
A green arrow down will mark this point in time out on the chart.

Additional points to consider:

Most profitable trading signals occur on the daily time frames while considering the duration of trades and timing of the signals. For the lowest risk levels, weekly time frames are most suitable. From the weekly timeframe down, the risk increases incrementally until you reach the 15min time frame. Signals at the lower levels occur more often and

Maximizing Profitability:

The indicator strives to keep positions open long enough to reap real rewards in the market. Maximum profit levels naturally occur around the apex points on the indicator chart, and the onus is on the trader to attempt an early exit once these levels are achieved.

they are effective but, they should, however, be monitored closely. Also, the lower the time frame, the higher the chances of false-positive signals.
