Syllabus Content:

2.2.1 Algorithms
- show understanding that an algorithm is a solution to a problem expressed as a sequence of defined steps
- use suitable identifier names for the representation of data used by a problem
  - summarise identifier names using an identifier table
- show understanding that many algorithms are expressed using the four basic constructs of assignment, sequence, selection and repetition
- show understanding that simple algorithms consist of input, process, output at various stages
- document a simple algorithm using:
  - **Structured English**
  - **pseudocode** (on the examination paper, any given pseudocode will be presented using the Courier New font)
  - **program flowchart**
- derive pseudocode or a program flowchart from a structured English description of a problem
- derive pseudocode from a given program flowchart or vice versa
- use the process of stepwise refinement to express an algorithm to a level of detail from which the task may be programmed
- decompose a problem into sub-tasks leading to the concept of a program module (procedure/function)
- show an appreciation of why logic statements are used to define parts of an algorithm solution
- use logic statements to define parts of an algorithm solution

2.2.1 Data types
- select appropriate data types for a problem solution
- use in practical programming the data types that are common to procedural high-level languages: integer, real, char, string, Boolean, date (pseudocode will use the following data types: `INTEGER, REAL, CHAR, STRING, BOOLEAN, DATE, ARRAY, FILE`)
- show understanding of how character and string data are represented by software including the ASCII and Unicode character sets

2.2.2 Arrays
- use the technical terms associated with arrays including upper and lower bound
- select a suitable data structure (1D or 2D array) to use for a given task
- use pseudocode for 1D and 2D arrays (pseudocode will use square brackets to contain the array subscript, for example a 1D array as A[1:n] and a 2D array as C[1:m, 1:n])
- write program code using 1D and 2D arrays
- write algorithms/program code to process array data including:
Syllabus Content:

2.3.1 Programming basics
- write a program in a high-level language (The nature of the language should be procedural and will be chosen by the Centre from the following: Python, Visual Basic (console mode), Pascal/Delphi (console mode))
- implement and write a program from a given design presented as either a program flowchart or pseudocode
- write program statements for:
  - the declaration of variables and constants
  - the assignment of values to variables and constants
  - expressions involving any of the arithmetic or logical operators
  - input from the keyboard and output to the console given pseudocode will use the following structures:
    - DECLARE <identifier> : <data type> // declaration
    - CONSTANT <identifier> = <value>
    - <identifier> ← <value> or <expression> // assignment
    - INPUT <identifier>
    - OUTPUT <string> , OUTPUT <identifier(s)>

2.3.2 Transferable skills
- recognise the basic control structures in a high-level language other than the one chosen to be studied in depth
- appreciate that program coding is a transferable skill

2.3.3 Selection
- use an ‘IF’ structure including the ‘ELSE’ clause and nested IF statements
- use a ‘CASE’ structure

2.3.4 Iteration
- use a ‘count-controlled’ loop:
  - FOR <identifier> ← <value1> TO <value2> <statement(s)> ENDFOR
  - alternatively: FOR <identifier> ← <value1> TO <value2> STEP <value3> <statement(s)> ENDFOR
- use a ‘post-condition’ loop:
  - REPEAT <statement(s)> UNTIL <condition>
- use a ‘pre-condition’ loop
  - WHILE <condition> <statement(s)> ENDFOR • justify why one loop structure may be better suited to a problem than the others
Algorithms:
An algorithm is a sequence of steps done to perform some task.
- The essential aim of an algorithm is to get a specific output,
- An algorithm involves with several continuous steps,
- The output comes after the algorithm finished the whole process.

So basically, all algorithms perform logically while following the steps to get an output for a given input.

Types of Algorithms:
- Structured English
- Flowcharts
- Pseudo codes
- Program Code

STRUCTURED ENGLISH:
Structured English provides a more formal way of documenting the stages of the algorithm. Structured English is a subset of English language that consists of command statements used to describe an algorithm.

FLOWCHARTS:
Flow chart is a graphical representation of a program. Flowcharts use different symbols containing information about steps or a sequence of events.

Flowchart Symbols:

PSEUDOCODE:
Pseudo code is an outline of a program, written as a series of instruction using simple English sentences. Pseudo code uses keywords commonly found in high-level languages and mathematical notation. It
describes an algorithm’s steps like program statements, without being bound by the strict rules of vocabulary and syntax of any particular language, together with ordinary English.

**Variable:**
Variable is memory location where a value can be stored.

**Constants:**
Just like variables, constants are "dataholders". They can be used to store data that is needed at runtime. In contrast to variable, the content of a constant can't change at runtime, it has a constant value. Before the program can be executed (or compiled) the value for a constant must be known.

**Arithmetic**
Use the arithmetic operators.

**Assignment**
Assignment is the process of writing a value into a variable (a named memory location). For example, Count ← 1 can be read as ‘Count is assigned the value 1’, ‘Count is made equal to 1’ or ‘Count becomes 1’.

**Initialization:**
If an algorithm needs to read the value of a variable before it assigns input data or a calculated value to the variable, the algorithm should assign an appropriate initial value to the variable, known as Initialization.

**Input**
We indicate input by words such as INPUT, READ or ENTER, followed by the name of a variable to which we wish to assign the input value.

**Output:**
We indicate output by words such as OUTPUT, WRITE or PRINT, followed by a comma-separated list of expressions.

**Totaling**
To keep a running total, we can use a variable such as Total or Sum to hold the running total and assignment statements such as:
Total ← Total + Number
ADD Number to Total

**Counting**
It is sometimes necessary to count how many times something happens.
To count up or increment by 1, we can use statements such as:
Count ← Count + 1
INCREMENT Count by 1
Structured statements

In the sequence structure the processing steps are carried out one after the other. The instructions are carried out in sequence, unless a selection or loop is encountered.

<table>

</tbody>
</table>

Data types

The following table shows the Visual Basic data types, their supporting common language runtime types, their nominal storage allocation, and their value ranges.

**Basic Data Types**

A variable can store one type of data. The most used data types are:

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer</td>
<td>Stores a whole number, e.g. 78</td>
</tr>
<tr>
<td>double</td>
<td>Stores a decimal number, e.g. 74.23754</td>
</tr>
<tr>
<td>Char</td>
<td>Stores one character, e.g. A</td>
</tr>
<tr>
<td>string</td>
<td>Stores text, e.g. Hello</td>
</tr>
<tr>
<td>Boolean</td>
<td>Stores True or False</td>
</tr>
</tbody>
</table>
Declaration of Variables and Constant:

The process of creating a variable is called declaring a variable. Variables must be created or declared where users enter their data.

**Pseudo code**

BEGIN

DECLARE variable As Datatype

Variable ← 0 //initialization

OUTPUT ("What is your Email address")

INPUT variable value

IF valid email address?

Then ...

END

Each declaration needs 4 things:

**Pseudo code**
- DECLARE keyword
- Variable name
- AS keyword
- Variable data type

DECLARE variable As Datatype

**VB code example:**

- DIM keyword
- Variable name
- AS keyword
- Variable data type

Dim mark As Integer

Declaring Multiple Variables:

**Pseudocodes**

- DECLARE index As Integer
- DECLARE grade As Integer
- DECLARE counter As Integer

**VB Code Console Mode**

- Dim index As Integer
- Dim grade As Integer
- Dim counter As Integer

The three declarations above can be rewritten as one declaration if same data type is used:

DECLARE index, grade, counter As Integer

Dim index, grade, counter As Integer
Constants

Creating Constants in Pseudocode is just writing constant name and value with it. In contrast to variable, the content of a constant can't change at runtime, it has a constant value.

CONSTANT  <identifier>  =  <Value>
CONSTANT  Pi  ←  3.1415  or  CONSTANT  Pi  =  3.14

Const pi As Double = 3.1415
'create a constant called pi with a value 3.1415
Dim radius As Double = 10
'creates a constant called radius with a value 10
Dim circumference As Double = radius * 2 * pi
'creates a constant with a calculation
Dim area As Double = radius ^ 2 * pi
'creating a constant with a calculation
Console.WriteLine("Circle Circumference : " & circumference)
Console.WriteLine("Circle Area : " & area)

Type of Programs:
- Sequence
- Selection
- Repetitions/Loops

Sequence

Statements are followed in sequence so the order of the statements in a program is important.

Assignment statements rely on the variables used in the expression on the right-hand side of the statement all having been given values. Input statements often provide values for assignment statements. Output statements often use the results from assignment statements.
PSEUDOCODE

BEGIN

DECLARE number1 As Integer
DECLARE number2 As Integer
DECLARE sum As Integer
DECLARE product As Integer

PRINT (”Enter number 1”)
INPUT number1

PRINT (”Enter number 2”)
INPUT number2

Sum ← number1 + number2
product ← number1 * number2

PRINT (”the sum is”)
PRINT (sum)
PRINT (”the product is”)
PRINT (product)

END

VB code example

Sub Main()
    Dim number1 As Integer
    Dim number2 As Integer
    Dim sum As Integer
    Dim product As Integer

    Console.WriteLine(”Enter number 1”)
    number1 = Console.ReadLine()

    Console.WriteLine(”Enter number 2”)
    number2 = Console.ReadLine()

    sum = number1 + number2
    product = number1 * number2

    Console.Write(”the sum is ”)
    Console.WriteLine(sum)

    Console.Write(”the product is ”)
    Console.WriteLine(product)
End Sub

STRUCTURED ENGLISH

WORKED EXAMPLE 11.01

Using input, output, assignment and sequence constructs
The problem to be solved: Convert a distance in miles and output the equivalent distance in km.

Step 1: Write the problem as a series of structured English statements:
INPUT number of miles
Calculate number of km
OUTPUT calculated result as km

Step 2: Analyse the data values that are needed.
We need a variable to store the original distance in miles and a variable to store the result of multiplying the number of miles by 1.61. It is helpful to construct an identifier table to list the variables.

<table>
<thead>
<tr>
<th>Identifier</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>miles</td>
<td>Distance as a whole number of miles</td>
</tr>
<tr>
<td>Km</td>
<td>The result from using the given formula: Km = Miles * 1.61</td>
</tr>
</tbody>
</table>

Table 11.02 Identifier table for miles to km conversion

FLOWCHART

Start

INPUT "Enter miles:"
Miles

Km ← Miles * 1.61

OUTPUT "Km:"
Km

End
2.1.1, 2.2.2 - 2.3.4 Algorithm, Flowcharts & Programming

Pseudocode

BEGIN
DECLARE miles, km As REAL
OUTPUT ("Enter miles:")
INPUT miles
km ← miles * 1.61
OUTPUT ("Km are: " & km)
END

Structured statements for selection (conditional statements)
These statements are used to select alternative routes through an algorithm; selection's logical expressions often involve comparisons, which can operate on text strings as well as numbers.

- IF...THEN...ELSE...ENDIF
- CASE...OF...OTHERWISE...ENDCASE

IF...THEN...ELSE...ENDIF
For an IF condition the THEN path is followed if the condition is true and the ELSE path is followed if the condition is false.
There may or may not be an ELSE path. The end of the statement is shown by ENDIF.
A condition can be set up in different ways:

IF ((Height > 1) OR (Weight > 20) OR (Age > 5)) AND (Age < 70)
THEN PRINT "You can ride"
ELSE PRINT "Too small, too young or too old"
ENDIF

CASE ... OF ... OTHERWISE ... ENDCASE
For a CASE condition the value of the variable decides the path to be taken. Several values are usually specified. OTHERWISE is the path taken for all other values. The end of the statement is shown by ENDCASE.
The algorithm below specifies what happens if the value of Choice is 1, 2, 3 or 4.
CASE Choice OF
1: Answer ← Num1 + Num2
2: Answer ← Num1 - Num2
3: Answer ← Num1 * Num2
4: Answer ← Num1 / Num2
OTHERWISE PRINT "Please enter a valid choice"
ENDCASE

The IF THEN statement

IF Condition THEN Statements ENDIF

PSEUDOCODE
BEGIN
DECLARE grade As Integer
PRINT ("Enter your grade")
INPUT grade
IF grade > 50 THEN PRINT ("You have passed") ELSE PRINT ("You have failed") END IF
END

VB Code
Sub Main()
Dim grade As Integer
Console.WriteLine("Enter your grade")
grade = Console.ReadLine()
If grade > 50 Then
    Console.WriteLine("You have passed")
Else
    Console.WriteLine("You have failed")
End If
Console.ReadLine()
End Sub

FLOWCHART:

START
INPUT marks
IF marks>50
    OUTPUT ("Pass")
ELSE
    OUTPUT ("Fail")
END IF
STOP
IF THEN, ELSE-IF statements

BEGIN
DECLARE grade As Integer
PRINT ("Enter a grade")
INPUT grade
IF grade > 80
    THEN PRINT ("Grade A")
ELSE IF grade > 60
    THEN PRINT ("Grade B")
ELSE IF grade > 50
    THEN PRINT ("Grade C")
ELSE PRINT ("Grade U")
END IF
END IF
END IF
END

The IF statement is useful, but can get clumsy if you want to consider "multi-way selections

CASE OF OTHERWISE...

Pseudo code

BEGIN
DECLARE grade As Integer
PRINT ("Enter your grade")
INPUT grade
CASE grade OF
    grade >= 80
        PRINT ("Grade A")
    grade >= 70
        PRINT ("Grade B")
    grade >= 60
        PRINT ("Grade C")
    grade >= 50
        PRINT ("Grade D")
    grade >= 40
        PRINT ("Grade E")
OTHERWISE
    PRINT("Grade U, Repeat Exam")
END CASE
END
Program Code in Visual Basic Console Mode:

```vbnet
Sub Main()
    Dim marks As Integer
    Console.WriteLine("Please Input your marks")
    marks = Console.ReadLine()
    While marks > 100 Or marks < 0
        Console.WriteLine("Wrong Entry, Please Enter Between 0 and 100")
        Console.WriteLine("Please Input your marks")
        marks = Console.ReadLine()
    End While
    Select Case marks 'NOTES by Sir Majid Tahir
        Case Is >= 90 'Download notes at www.majidtahir.com
            Console.WriteLine("Your Grade is A")
        Case Is >= 88
            Console.WriteLine("Your Grade is A")
        Case Is >= 70
            Console.WriteLine("Your Grade is B")
        Case Is >= 60
            Console.WriteLine("Your Grade is C")
        Case Is >= 50
            Console.WriteLine("Your Grade is D")
        Case Else
            Console.WriteLine("Your Grade is U, Please Repeat the Exam")
    End Select
    Console.ReadLine()
End Sub
End Module
```

LOOPS (Structured statements for iteration (repetition))

Many problems involve repeating one or more statements, so it is useful to have structured statements for controlling these iterations or repetitions. Exit conditions consist of logical expressions whose truth can be tested, such as Count = 10 or Score < 0. At a particular time, a logical expression is either True or False.

- FOR...TO...NEXT
- WHILE...DO...ENDWHILE
- REPEAT...UNTIL

FOR ... NEXT LOOP

This is to be used when loop is to be repeated a known fixed number of times. The counter is automatically increased each time the loop is performed.

```
FOR count = 1 to 10
    INPUT number
    total = total + number
NEXT count
```
WHILE ... Do LOOP

This loop is used when we don’t know how many times the loop is to be performed. The Loop is ended when a certain condition is true. This condition is checked before starting the loop.

```
While COUNT < 10 Do
  Input NUMBER
  TOTAL = TOTAL + NUMBER
  COUNT = COUNT + 1
Endwhile
Output TOTAL
```

REPEAT ... UNTIL LOOP

REPEAT UNTIL Loop is used when we do not know how many times loop will be performed. The Loop is ended when a certain condition is true. The Condition is checked at the end of the Loop and so a REPEAT Loop always has to be performed at least once.

```
REPEAT
  Input NUMBER
  TOTAL = TOTAL + NUMBER
  COUNT = COUNT + 1
Until COUNT = 10
Output Total
```

FOR loop

The fore loop repeats statements a set number of time. It uses a variable to count how many time it goes round the loop and stops when it reaches its limit.

```
BEGIN
DECLARE index As Integer
FOR index = 1 To 20
  PRINT (index & “times 5 is” & index * 5”)
NEXT
```

VB code example:

```vbnet
Sub Main()
  Dim index As Integer
  For index = 1 To 20
    Console.WriteLine(index & " times 5 is " & index * 5)
  Next
End Sub
End Module
```
Other examples of FOR loop

BEGIN
DECLARE BiggestSoFar, NextNumber, Counter As Integer

INPUT BiggestSoFar

FOR Counter ← 1 TO 5

INPUT NextNumber

IF NextNumber > BiggestSoFar
    THEN
        BiggestSoFar ← NextNumber
    ENDIF

END FOR

OUTPUT ("The biggest number so far is" & BiggestSoFar)
END

Sample VB Code of above Pseudocode:

```vbnet
Module Module1
    Sub Main()
        Dim biggestSoFar, NextNum, counter As Integer

        Console.WriteLine("Enter Bigest number")
        biggestSoFar = Console.ReadLine()

        For counter = 1 To 5
            NextNum = Console.ReadLine()
            If NextNum > biggestSoFar Then
                biggestSoFar = NextNum
            End If
        Next

        Console.WriteLine("The biggest number entered is" & biggestSoFar)
        Console.ReadLine()
    End Sub
End Module
```
FLOWCHART FOR LOOP

for( init; condition; increment )
{
    loop body;
}

Initialize Variable

Condition
If condition is false
If condition is true
Loop Body
Increment or Decrement

Contact: 03004003666   www.majidtahir.com   Email: majidtahir61@gmail.com
WHILE DO ENDWHILE loop

The while loop is known as a test before loop. The condition is tested before entering the loop, but tested each time it goes round the loop. The number of times the statements within the loop are executed varies. The test before loop goes round 0 or more times. This method is useful when processing files and using “read ahead” data.

BEGIN
DECLARE name As String

INPUT name
WHILE name <> "x"
PRINT ("Your name is: " name)
INPUT name
END WHILE

END

REPEAT UNTIL loop

The repeat loop is similar to the while loop, but it tests the condition after the statements have been executed once. This means that this test after loop goes round 1 or more times.

BEGIN
DECLARE name As String

REPEAT
INPUT name
PRINT ("Your name is: " name)
UNTIL name = "x"

END

VB Code example

```vbnet
Sub Main()
    Dim name As String
    name = Console.ReadLine()
    'Test before loop - 'only enter the loop is name not equal "x"
    While name <> "x"
        Console.WriteLine(name)
        name = Console.ReadLine()
    End While
End Sub
```

Keep in putting name and keeps printing name until user enters “X”

VB Code example

```vbnet
Sub Main()
    Dim name As String
    Do
        name = Console.ReadLine()
        Console.WriteLine(name)
    Loop Until name = "X"
    'Test after loop
End Sub
```
FLOWCHART...WHILE-ENDWHILE

START

INPUT name

WHILE name <> "x"

OUTPUT ("Your name is")

OUTPUT (name)

No

STOP

FLOWCHART...REPEAT-UNTIL

START

INPUT name

OUTPUT ("Your name is")

OUTPUT (name)

UNTIL name= "x"

Yes

STOP

while (condition)
{
    loop body;
    increment or decrement;
}

If condition is false

Loop Update

If condition is true

Loop Body

Process Results

Array Data Type

An array is a special variable that has one name, but can store multiple values. Each value is stored in an element pointed to by an index. The first element in the array has index value 0, the second has index 1, etc.

One Dimensional Arrays

A one dimensional array can be thought as a list. An array with 10 elements, called names, can store 10 names and could be visualized as this:

<table>
<thead>
<tr>
<th>Index</th>
<th>Element</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Fred</td>
</tr>
<tr>
<td>1</td>
<td>James</td>
</tr>
<tr>
<td>2</td>
<td>Tom</td>
</tr>
<tr>
<td>3</td>
<td>Robert</td>
</tr>
<tr>
<td>4</td>
<td>Jonah</td>
</tr>
<tr>
<td>5</td>
<td>Chris</td>
</tr>
<tr>
<td>6</td>
<td>Jon</td>
</tr>
<tr>
<td>7</td>
<td>Matthew</td>
</tr>
<tr>
<td>8</td>
<td>Mikey</td>
</tr>
<tr>
<td>9</td>
<td>Jack</td>
</tr>
</tbody>
</table>

Arrays (One-dimensional arrays)

In order to use a one-dimensional array in a computer program, you need to consider:

- What the array is going to be used for, so it can be given a meaningful name
- How many items are going to be stored, so the size of the array can be determined.
- What sort of data is to be stored, so that the array can be the appropriate data type.

This array would be created by:

```
DECLARE names (9) As String
PRINT (names (1))
will display James
PRINT (names (7))
Will display Mathew
```

VB code example:

```
Dim names(9) As String
Elements indexed from 0 to 9
The statement:
Console.WriteLine(names(1))
Will display James
Console.WriteLine(names(7))
Will display Matthew
```
Entering Values in One-Dimension Array

BEGIN

DECLARE count As Integer
DECLARE name (5) As String  // for declaring 5 elements in ARRAY
DECLARE marks (5) As Integer

FOR count = 1 to 5  // for inputting 5 names and grades
PRINT ("Enter Name " & count)
INPUT name (count)
PRINT ("Enter grade for " & name (count))
INPUT grades (count)
NEXT count  // for displaying 5 names and grades

FOR count 1 to 5
PRINT (name (count) & " has grade " & grades (count))
NEXT count

END

VB Code in Console Mode

```vbnet
Sub Main()
    Dim name(5) As String 'Declaration of Array (Notes by Sir Majid Tahir)
    Dim marks(5) As Double 'Declaration of Array (www.majidtahir.com)

    For count = 1 To 5 'Loop used to enter values in an array
        Console.WriteLine("Please enter your name " & count)
        name(count) = Console.ReadLine()
        Console.WriteLine("Please enter your marks " & count)
        marks(count) = Console.ReadLine()
    Next

    For count = 1 To 5 'Loop used to display values of Arrays
        Console.WriteLine("Our student " & name(count) & " has scored " & marks(count))
    Next

    Console.ReadKey()
End Sub
End Module
```
Another example of One-Dimensional Array

```vbnet
Module Module1
    Sub Main()
        Dim count As Integer
        Dim name(4) As String
        Dim marks(4) As Integer
        Dim gender(4) As String
        For count = 0 To 4
            Console.WriteLine("please enter your name" & count) name(count) = Console.ReadLine()
            Console.WriteLine("please enter your gender" & count) gender(count) = Console.ReadLine()
            Console.WriteLine("please enter your marks" & count) marks(count) = Console.ReadLine()
        Next count
        For count = 0 To 4
            Console.WriteLine("your name is : " & name(count))
            Console.WriteLine("your gender is : " & gender(count))
            Console.WriteLine("your marks are : " & marks(count))
        Next count
        Console.ReadKey()
    End Sub
End Module
```

Output of VB code displayed above
Two Dimensional Arrays (2-D Arrays)

Using pseudocode, the algorithm to set each element of array ThisTable to zero is:

```
FOR Row ← 1 TO MaxRows
    FOR Column ← 1 TO MaxColumns
        ThisTable[Row, Column] ← 0
    ENDFOR
ENDFOR
```

When we want to output the contents of a 2D array, we again need nested loops. We want to output all the values in one row of the array on the same line. At the end of the row, we want to output a new line.

```
FOR Row ← 1 TO MaxRows
    FOR Column ← 1 TO MaxColumns
        OUTPUT ThisTable[Row, Column] // stay on same line
    ENDFOR
    OUTPUT Newline // move to next line for next row
ENDFOR
```

VB Code Example of Two-Dimension Array

```vbnet
Sub Main()
    Dim matrix(2, 3) As Integer
    For row = 0 To 2
        For column = 0 To 3
            Console.WriteLine("Please Input Value in Row: " & row & " column: " & column)
            matrix(row, column) = Console.ReadLine()
        Next
    Next
    Console.Clear()

    For row = 0 To 2
        For column = 0 To 3
            Console.WriteLine("Row = " & row & " column = " & column & " has Value")
            Console.WriteLine(matrix(row, column))
        Next
    Next
    Console.ReadKey()
End Sub
```
Multi-Dimensional Arrays:

A multi-dimensional array can be thought of as a table, each element has a row and column index. Following example declares a two-dimensional array called `matrix` and would be declared by

```vbnet
Dim matrix(2, 3) As Integer
```

Usually we refer to the first dimension as being the rows, and the second dimension as being the columns.

<table>
<thead>
<tr>
<th>index</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>A</td>
<td>B</td>
<td>C</td>
<td>D</td>
</tr>
<tr>
<td>1</td>
<td>E</td>
<td>F</td>
<td>G</td>
<td>H</td>
</tr>
<tr>
<td>2</td>
<td>I</td>
<td>J</td>
<td>K</td>
<td>L</td>
</tr>
</tbody>
</table>

The following statements would generate the following:

```vbnet
Console.WriteLine(matrix(0, 0))
Would display A
```

```vbnet
Console.WriteLine(matrix(2, 1))
Would display J
```

```vbnet
Console.WriteLine("first row, first column : " & matrix(2, 3))
Would display first row, first column : L
```

VB Code for 2-D Array is:

```vbnet
Sub Main()

    Dim matrix(2, 3) As Integer
    matrix(0, 0) = 10
    matrix(1, 0) = 20
    matrix(1, 2) = 30
    Console.WriteLine("first row, first column : " & matrix(0, 0))
    Console.WriteLine("second row, first column : " & matrix(1, 0))
    Console.WriteLine("second row, second column : " & matrix(1, 1))
    Console.WriteLine("third row, third column : " & matrix(1, 2))
    Console.ReadLine()
End Sub
```
