Between 1930 (2330 GMT) and 1945 (2345 GMT), all the Burns security personnel at the X-ray machine were assigned to other duties and the three suspect suitcases remained in the baggage area without supervision. At about 2140 (0140 GMT), the Air India security officer went to the baggage room and inspected the three suitcases with the X-ray machine and a sniffer that was in the possession of the security officer. The Air India security officer decided to keep the three suitcases and, if further examination proved negative, send them on a later flight. At approximately 2155 (0155 GMT), the Air Canada Operations Centre supervisor contacted the airport RCMP detachment regarding the suspect suitcases. At about 2205 (0205 GMT), an RCMP member located the suitcases in the baggage room and requested that an Air India representative be sent to the baggage room. About five minutes later, the Air India security officer contacted the baggage room by telephone and advised that he could not come to the room immediately. The Air India security officer arrived in the baggage room at about 2235 (0235 GMT) and, when asked to determine the owners of the suitcases, informed the RCMP member that the flight had already departed [2218 (0218 GMT)]. The three suspect suitcases were later examined with negative results. The remainder of the checked baggage which cleared the security check was identified by a green sticker. The baggage was then forwarded to Air Canada personnel who loaded the baggage in containers to be placed on board the aircraft. A later check with Canada Customs and Air Canada at Mirabel revealed no unclaimed baggage associated with AI 181/182. A similar check at Dorval Airport was conducted with negative results.

No record was kept as to the location and number of individual pieces of checked-in luggage. Records were kept as to the location of the containers according to destination, where loaded and the number of pieces of luggage in each container (see Appendix B).

The Mirabel Detachment of the RCMP provided the following security at the airport on 22 June 1985:

- one member in a police vehicle for airside security;
- one member on patrol in the arrival and departure areas;
- one member on general foot patrol throughout the terminal; and
- one member as a telecommunications operator in the detachment office.

In addition, due to the increased threat to Air India flights, the RCMP provided the following supplementary coverage to Air India Flight 181/182 on 22 June 1985:

- one member in a police vehicle escorted the aircraft to and from the runway and the terminal building and remained with the aircraft while it was stationary;

- one member in a police vehicle remained at the entrance to the ramp;
- two members patrolled the area of the ticket counter and access corridors, and one of these members also served in a liaison capacity with the airline representatives.

2.4 International Standards and Recommended Practices

International security standards and recommendations to safeguard international civil aviation against acts of unlawful interference are listed in ICAO Annex 17 to the Convention on International Civil Aviation. Suggested security measures and procedures are amplified in the ICAO Security Manual for Safeguarding Civil Aviation Against Acts of Unlawful Interference.

Annex 17 requires contracting States of which Canada is one to "take the necessary measures to prevent weapons or any other dangerous devices, the carriage or bearing of which is not authorized, from being introduced by any means whatsoever, on board an aircraft engaged in the carriage of passengers."

In addition to other recommendations, Annex 17 recommends that contracting States should establish the necessary procedures to prevent the unauthorized introduction of explosives or incendiary devices in baggage, cargo, mail and stores to be carried on board aircraft.

The Security Manual specifies that,

EMBED MSWordArt.2 \s

EMBED MSWordArt.2 \s

Recently, ICAO has proposed amendments to Annex 17. These proposals arise from a decision taken by the Council in its 115th Session on 10 July 1985. The Council instructed its Committee on Unlawful Interference, as a matter of urgency, to review the entirety of Annex 17 and to report on those provisions which might be immediately introduced, upgraded to Standards, strengthened or improved. Among the proposed amendments is the following upgrading in the Standards:

- Each contracting State ensure the implementation of measures at airports to protect cargo, baggage, mail stores and operator's supplies being moved within an airport to safeguard such aircraft against an act of unlawful interference.

2.5 Canadian Law

In terms of Canadian statutory requirements, the Civil Aviation Security Measures Regulations and the Foreign Aircraft Security Measures Regulations made pursuant to the Aeronautics Act require specified owners or operators of aircraft registered in Canada or specified owners or operators who land foreign aircraft in Canada to establish, maintain, and carry out security measures at airports consisting of:

- systems of surveillance of persons, personal belongings, baggage, goods and cargo by persons or by mechanical or electronic devices;
- systems of searching persons, personal belongings, baggage, goods and cargo by persons or by mechanical or electronic devices;
- a system that provides, at airports where facilities are available, for locked, closed or restricted areas that are inaccessible to any person other than a person who has been searched and the personnel of the owner or operator;
- a system that provides, at airports where facilities are available, for check-points at which persons intending to board the aircraft of an owner or operator can be searched;
- a system that provides, at airports where facilities are available, for locked, closed or restricted areas in which cargo, goods and baggage that have been checked for loading on aircraft are inaccessible to persons other than those persons authorized by the owner or operator to have access to those areas;
- a system of identification that prevents baggage, goods and cargo from being placed on board the aircraft if it is not authorized to be placed on board by the owner or operator; and
- a system of identification of surveillance and search personnel and the personnel of the owner or operator.

Specified carriers including Air Canada, CP Air, and Air India were required to provide a description of their security measures to the Canadian Minister of Transport.

An Order-in-Council on 29 September 1960 established that the RCMP was responsible for the direction and administration of police functions at major airports operated by Transport Canada. The duties of the Police and Security Detail at these designated airports include the following:

- carry out policing and security duties to guard against unauthorized entry, sabotage, theft, fire or damage;
- enforce federal legislation;
- respond to violations of the Criminal Code of Canada, Federal, Provincial, and Territorial statutes, and perform a holding action pending arrival of the police department having primary criminal jurisdiction;
- man guard posts; and
- provide a police response in those areas of airports where pre-board screening takes place.

Section 5.1(9) of the Aeronautics Act states that "The Minister may designate as security officers for the purposes of this section any persons or classes of persons who, in his opinion, are qualified to be so designated." Pursuant to this section Transport Canada has established criteria for persons or classes of persons that are designated as security officers in a Schedule registered on 11 April 1984. The criteria also specify that a security guard company and its employees will meet Transport Canada requirements provided that the company:

- is under contract with a carrier to conduct passenger screening under the Aeronautics Act and Regulations;
- is licensed in the province or territory;
- complies with the security guard criteria as follows in that the guard must:
  - be 18 years or older,
  - be in good general health without physical defects or abnormalities which would interfere with the performance of duties,
  - be licensed as a security guard and in possession of the licence while on duty, and
  - meet the training standards of Transport Canada consisting of successfully completing the Transport Canada passenger inspection training program, attaining an average mark of 70 per cent, and undergoing refresher training within 12 months from previous training;

- uses a comprehensive training program which has been approved by Transport Canada and is capable of being monitored and evaluated;
- keeps records showing the date each employee received initial training and/or refresher training and the mark attained; and
- provides supervision to ensure that their employees maintain competency and act responsibly in the conduct of searching passengers and carry-on baggage being carried aboard aircraft.

2.6 Canadian Security Procedures

In accordance with the Canadian Aeronautics Act and pursuant regulations, air carriers are assigned the responsibility for security. Transport Canada provides the following security services for the air carriers using major Canadian airports, including the international airports in Vancouver, Toronto and Montreal:

- security and policing staff including RCMP airport detachments;
- specific airport security plans and procedures;
- secure facilities (e.g., secure areas, pass identification systems, etc.); and
- security equipment and facilities (e.g., X-ray detection units, walk-through metal detectors, hand-held metal detectors, explosive detection dogs).

As of 22 June 1985, the following general security measures were in place at Canadian airports:

- metal detection screening of passengers; and
- X-raying of carry-on baggage.

Checked baggage was not normally subject to any security screening. A few air carriers such as Air India had extra security measures in place because of an assessed higher threat level (see section 2.7 below).

On 23 June 1985, Transport Canada required additional security measures to be implemented by all Canadian and foreign air carriers for all international flights from Canada except those to the continental United States. These measures required:

- the physical inspection or X-ray inspection of all checked baggage;
- the full screening of all passengers and carry-on baggage; and
- a 24-hour hold on cargo except perishables received from a known

shipper unless a physical search or X-ray inspection is completed. Further, on 29 June 1985, Transport Canada directed that all baggage or cargo being interlined within Canada to an Air India flight was to be physically inspected or X-rayed at the point of first departure and that matching of passengers to tickets was to be verified prior to departure.

2.7 Air India Security Program in Canada

In accordance with the Foreign Aircraft Security Measures Regulations, Air India had provided the Minister of Transport with a copy of its security program. It included measures to:

- establish sterile areas;
- physically inspect all carry-on baggage by means of hand-held devices or X-ray equipment;
- control boarding passes;
- maintain aircraft security;
- ensure baggage and cargo security; and
- off-load baggage of passengers who fail to board flights.

Under these procedures established by Air India, passengers, carry-on baggage, and checked baggage destined for AI 181/182 on 22 June 1985 were subjected to extra security checks. A security officer from the Air India New York office arrived in Toronto on 22 June 1985 to oversee the security operation at Toronto and Montreal.

On 17 May 1985, the High Commission of India presented a diplomatic note to the Department of External Affairs regarding the threat to Indian diplomatic missions or Air India aircraft by extremist elements. Subsequently, in early June, Air India forwarded a request for "full and strict security coverage and any other appropriate security measures" to Transport Canada offices in Ottawa, Montreal and Toronto, and RCMP offices in Montreal and Toronto.

2.8 PD-4 Sniffer

On 18 January 1985, prior to the inaugural Air India flight out of Toronto on 19 January, a meeting on security for Air India flights (Toronto) was held with representatives from Transport Canada, RCMP and Air India. At this meeting, a PD-4 sniffer belonging to Air India was produced. It was explained that it would be used to screen checked baggage as the X-ray machine had not yet arrived. At that time, an RCMP member tested its effectiveness. The test revealed that it could not detect a small container of gunpowder until the head of the sniffer was moved to less than an inch from the gunpowder. Also, the next day the sniffer was tried on a piece of C4 plastic explosives and it did not function even when it came directly in contact with the explosive substance. It is not known if this was the same sniffer used on 22 June 1985.

2.9 Medical Evidence

Medical examination was conducted on the 131 bodies recovered after the accident. This comprises about 40 per cent of the 329 persons on board. It should be noted that assigned seating is based on preliminary information. Also, the exact position of passengers is not certain because it is not known if passengers changed their seats after lift-off. On the information available, the passengers were seated as follows:

Passengers:*

	Seats Available	Occupied	Bodies Identified
Zone A	16	1	0
Zone B	22	0	0
Upper Deck	18	7	0
Zone C	112	104 + 2	29
Zone D	86	84 + 1	38
Zone E	123	105 + 3	50
SUB-TOTAL	377	301 (+6 infants)	117
Crew:			
Flight Deck	3	3	0
Cabin	19	19	5
TOTAL	399	329	122

There were 30 children recovered and they showed less overall injury. The average severity of injury increases from Zone C to E and is significantly less in C than in Zones D and E.

Flail pattern injuries were exhibited by eight bodies. Five of these were in Zone E, one in Zone D, two in Zone C and one crew member. The

significance of flail injuries is that it indicates that the victims came out of the aircraft at altitude before it hit the water.
There were 26 bodies that showed signs of hypoxia (lack of oxygen), including 12 children, 9 in Zones C, 6 in Zone D and 11 in Zone E. There were 25 bodies showing signs of decompression, including 7 children. They were evenly
*See Appendix C for interior seating arrangement.
distributed throughout the zones, but with a tendency to be seated at the sides, particularly the right side (12 bodies).
Twenty-three bodies showed evidence of receiving injuries from a vertical force. They tended to be older, seated to the rear of the aircraft (4 in Zone C, 5 in Zone D, 11 in Zone E, 2 crew and 1 unknown), and 16 had little or no clothing.
Twenty-one bodies were found with no clothing, including three children. They tended to be seated to the rear and to the right (3 in Zone C, 5 in Zone D, 11 in Zone E and 2 unknown).
There were 49 cases showing signs of impact-type injuries, including 19 children (15 in Zone C, 15 in Zone D, 15 in Zone E, 1 crew member and 3 unknown).
There is a general absence of signs indicating the wearing of lap belts. Pathological examination failed to reveal any injuries indicative of a fire or explosion.
2.10 Flight Recorders and Shannon Air Traffic Control (ATC) Tape Analyses
VT-EFO was equipped with a Fairchild A100 Cockpit Voice Recorder (CVR) and a Lockheed 209E Digital Flight Data Recorder (DFDR). These were each equipped with Dukane Underwater Acoustic Beacons and were installed adjacent to each other in the cabin on the left side near the aft pressure bulkhead. The serial digital signal recorded by the DFDR was generated by a Teledyne Flight Data Acquisition Unit installed in the forward electronics bay below the cabin floor.
The Shannon Air Traffic Control Centre was in contact with VT-EFO and recorded radio communications with the aircraft. At the time of the accident, 5.4 seconds of noise was recorded, and the transponder signal

seen on the radar scope was lost from the aircraft. This signal which displays aircraft altitude showed no deviation before disappearing from the radar scope.

2.10.1 Analysis by National Research Council, Canada

From the CVR and DFDR, AI 182 was proceeding normally en route from Montreal to London at an altitude of 31,000 feet and an indicated airspeed of 296 knots when the cockpit area microphone detected a sudden loud sound. The sound continued for about 0.6 seconds, and then almost immediately, the line from the cockpit area microphone to the cockpit voice recorder at the rear of the pressure cabin was most probably broken. This was followed by a loss of electrical power to the recorder. The initial waveform of the cockpit area microphone signal is not consistent with the sharp pressure rise expected with detonation of an explosive device close to the flight deck, but, with the multiplicity of paths by which sound may be conducted from other regions of the aircraft, the possibility that it originated from such a device elsewhere in the aircraft cannot be excluded.

By correlating the oscillograph records of the CVR and the Shannon ATC VHF recording, it was estimated that the unusual sounds recorded on the ATC tape started 1.4 ± 0.5 seconds after the start of the sudden sound detected by the cockpit area microphone and lasted intermittently for 5.4 seconds. It was felt the closeness in time of the two noises indicated the 5.4 seconds recorded on the ATC tapes originated from AI 182. The ATC recording that followed the cockpit area microphone sounds appeared at first to contain a series of short intermittent sounds. Listening to the sounds, it also appeared that a human cry occurred near the end of the recording. Spectral analysis of these sounds and comparison with voice imitations revealed that the recorded sounds do not contain all the pitch harmonic frequencies normally associated with voice sounds. The origin of these sounds has not been determined.

An examination of the DFDR showed no abnormal variations before the accident. With the spare engine, this aircraft was restricted to altitudes below 35,200 feet and indicated airspeeds less than 290 knots. During the last 27 minutes of the flight, the computed airspeed did gradually increase to nine knots above this limit in the first part of this period and the power was readjusted several times. The speed fell below the 290 knot limit at about 07h:09m GMT as recorded by the DFDR; power was increased again at about 07h:10m causing the aircraft to accelerate to six knots above the limit by the time the accident occurred at 07h:13m:59s. The observed excursions outside the specified limits are not considered significant.

The aircraft was flown with 1.5-degree left-wing-down with 4.2 degrees clockwise control wheel as compared to the aircraft without the 5th engine installation. Also, 9.4 per cent of right rudder pedal was applied giving a 1.1-degree right deflection of the upper and lower rudders. Considering the carriage of the 5th engine on the left side, these figures are not considered abnormal.

When synchronized with the other recordings, it was determined, within the accuracy that the procedure permitted, that the DFDR stopped recording simultaneously with the CVR.

Irregular signals were observed over the last 0.27 inches of the DFDR tape. Laboratory tests indicated that the irregular signals most likely occurred as a result of the recorder being subjected to sharp angular accelerations about the lateral axis of the recorder, causing rapid changes in tape speed over the record head. This equates to an angular acceleration on the recorder about the aircraft's longitudinal axis in a left-wing-down sense. Therefore, these tests indicate that the digital recorder was subjected to a sharp jolt separate from any violent motion of the aircraft.

The other possibility for the irregular signals is that the Flight Data Acquisition Unit which generated the serial digital data signal and which is located in the electronics bay under the cabin floor forward of the cargo compartment could have suffered some damage or had an intermittent power supply that caused it to generate the irregular signals.

2.10.2 Analysis by Accidents Investigation Branch (AIB), United Kingdom

The AIB analysis was restricted to the CVR and the Shannon ATC tape. The correlation of the CVR and ATC tapes showed that the ATC recording started after the CVR had stopped recording and 1.1 ± 0.4 seconds from the start of the sudden sound. The total duration of the signal on the ATC tape was 5.4 seconds.

An analysis of the CVR audio found no significant very low frequency content which would be expected from the sound created by the detonation of a high explosive device. Evidence of the presence of audio warning signals buried amongst the noise was investigated with negative results. A comparison with CVRs recording an explosive decompression* on a DC-10, a bomb in the cargo hold of a B737, and a gun shot on the flight deck of a B737 was made. Considering the different acoustic characteristics between a DC-10 and a B747, the AIB analysis indicates that there were distinct similarities between the sound of the explosive decompression on the DC-10 and the sound recorded on the AI 182 CVR.

The analysis of the ATC tape audio determined three or four words could be heard at the beginning of the transmission, but extensive filtering did not allow the sounds to be transcribed. Two bursts of tone occurred during the first second. The spectrum of the tone does not coincide with any B747 audio warning. The transmission is chopped until at about 2.7 seconds into the transmission a loud noise lasting about 200 milliseconds is heard. This is followed about 0.5 seconds later by a sound which increases in volume. This sound is similar to that heard in other accidents where there has been a rapid increase in airspeed. Toward the end of the transmission a crying sound was heard; however, a study of the noise indicates a human cry would contain more harmonics. The origin of this sound was not determined. Knocking sounds were also heard during the transmission. These were initially thought to be due to hand-held microphone vibration, but this was discounted because of the frequency of the sounds. Almost identical sounds were heard on the DC-10 CVR after the explosive decompression had occurred. Their source was not identified. On the DC-10, the pressurization audio warning sounded 2.2 seconds after the decompression. No such warning was identified on the ATC tape.

*Explosive decompression is an aviation term used to mean a sudden and rapid loss of cabin pressurization. A loud noise is associated with this event but not necessarily an explosion.

Every aircraft provides a different signature when the press-to-transmit button is released. These signatures were compared with transients which occurred during the open microphone transmission. There is a close match with the previous AI 182 signatures. Therefore, it is almost certain that the ATC tape recording originated from AI 182.

The AIB report concluded that the analysis of the CVR and ATC recordings showed no evidence of a high-explosive device having been detonated on AI 182. It further states there is strong evidence to suggest a sudden explosive decompression of undetermined origin occurred. Although there is no evidence of a high-explosive device, the possibility cannot be ruled out that a detonation occurred in a location remote from the flight deck and was not detected on the microphone. However, the AIB report is of the opinion that the device would have to be small not to be detected as it is considered that a large high-explosive device could not fail to be detected on the CVR.

2.10.3 Analysis by Bhabha Atomic Research Centre (BARC), India

The BARC analysis was restricted to the CVR and the Shannon ATC tape.

Channel 3 of the recording which corresponded to the cockpit area microphone showed the first indication of a rising audio signal. The signal level rises from the ambient level in the cockpit by about 18.5 decibels in approximately 45 milliseconds. The signal starts falling and stabilizes at a level about 10 decibels higher than ambient for about 375 milliseconds. The total duration of the signal is about 460 milliseconds.

The timings of the CVR and the Shannon ATC tape were correlated, and it was determined that the explosive sound on the CVR coincided with the beginning of the series of audio bursts on the ATC tape. The report concluded that the sounds recorded on the ATC tape emanated from AI 182 at the time of the occurrence.

The noise on the CVR was compared with an explosion which caused the crash of an Indian Airlines B737. In this occurrence, the explosive sound recorded on the cockpit area microphone showed a rise time of about 8 milliseconds. It was also determined that the explosion occurred 8 feet from the microphone. The report concluded that the rise time is a measure of the distance from the cockpit area microphone to the source of an explosion. Hence, the exact location in the aircraft at which the explosion occurred is likely to be about 40 to 50 feet from the cockpit judging from the rise time of 45 milliseconds.

The report concluded that the series of audio bursts on the ATC tape were most probably generated by the break-up of AI 182 in mid-air.

2.11 Aircraft Structures Examination

The examination of aircraft structures consisted of the following areas: floating wreckage, wreckage mapping and surveying, wreckage distribution, photographic and video interpretation of wreckage, wreckage recovery and initial examination, and examination of recovered wreckage.

2.11.1 Floating Wreckage

During the search, aircraft wreckage was sited and recovered by several search vessels. The wreckage was transported to Cork, Ireland, where preliminary examination was conducted. This examination took place in June and July, 1985.

The wreckage consisted mainly of various leading edge skin panels of the left and right wings, left wing tip, spoilers, leading edge and trailing edge flaps, engine cowlings, flap track canoe fairing pieces, landing gear wheel well doors, pieces of elevator and aileron, cabin floor panels, cabin overhead and upper deck bins, passenger seats, life vests, slide rafts, hand baggage, suitcases, personal effects and a number of internal fittings. The floating wreckage constitutes about three to five percent of the aircraft structure.

The wreckage was then transported from Ireland to Bombay, India where it underwent further examination by the Floating Wreckage Structures Group which then produced a report which was submitted to the Indian Inquiry. The report concluded:

- There was no evidence of fire damage.
- There was no evidence of lightning strike damage.
- The cabin floor panels from the forward and rear sections of the

aircraft separated from the support structure in an upward direction (floor to ceiling) pulling free from the attaching screws and, in some cases, breaking the vertical web of the seat track/floor beams.

- The position of the leading edge flap rotary actuator and the damage to the flap structure indicated that the leading edge flaps were in the retracted position.
- The six spoiler actuators found were in the retracted position. The lower surface of all the spoiler panels showed signs of spanwise skin splits with the edges curled into the core of the honeycomb. The report concluded that this was possibly due to the loading of the spoilers by being deployed in flight at high speed, resulting in compression on the lower surfaces. This, in turn, caused splitting of the lower skin into the honeycomb.
- The right wing root leading edge, number 3 engine inboard fan cowling, the right inboard midflap inboard leading edge, and the right stabilizer root leading edge all exhibited damage possibly due to objects striking the right wing and stabilizer before water impact.

In addition to the above conclusions, the following significant information regarding the floating wreckage is noted in the report:

- The aircraft was carrying a -7Q engine at the 5th pod and a -7J 5th pod kit in the aft cargo compartment. In all there were 14 engine fan cowls (four in the aft cargo compartment). Out of these 14 fan cowls, nine, including six from the working engines and three from the aft cargo compartment, and two additional pieces of fan cowls were found. Five of the fan cowls from the working engines showed folding damage lines at about the three and nine o'clock positions. The number 3 engine inboard fan cowl had severe impact damage on its leading edge and had small outward puncture holes but no penetration through the outer skin in the lower centre region. The two fan cowls of the -7J 5th pod kit stowed in the aft cargo compartment showed severe damage. One piece was cut at one corner in an arc of about 20 inches diameter and its external skin was peeled back.
- The cockpit entry door and the side bulkhead panel were found relatively intact but had come out of their attachments.

- Twelve toilet doors out of 16 were found and were relatively intact but had come out of their attachments.
- Cabin interior panels and overhead bins of the main and upper decks which were recovered exhibited only minor damage.
- The wooden boxes which contained the fan blades of the 5th pod engine were loaded in container 24L in the forward cargo compartment and were found broken apart exhibiting no burn marks.
- One passenger oxygen bottle and one portable oxygen bottle were recovered and showed no sign of damage.

Mr. V.J. Clancy, an aviation explosives expert representing Boeing Aircraft Corporation, prepared a preliminary report based on his examinations of certain items of recovered and floating wreckage. Mr. Clancy's report notes the following with respect to floating wreckage:

- A foam-backed floor panel which showed a small number of perforations was recovered. Mr. Clancy recommended that it should be X-rayed and a detailed examination completed.
- One of the lavatory doors had, into its inner surface, a number of fragments of glass mirror - presumably from breakage of a mirror normally fitted into the lavatory. Most of the fragments, buried edgeways, were oriented parallel to each other. The remainder were approximately at right angles to the others. Mr. Clancy concluded that it would be improbable that any reliance could be placed on the penetration by mirror fragments as being indicative of an explosion.
- Three steel oxygen cylinders which were stowed in the forward cargo compartment were recovered. One had been dented apparently by the impact of an object measuring about one to two centimetres. The depression had a maximum depth of about four millimetres.
- A few suitcases recovered among the floating wreckage were examined. Mr. Clancy felt that one might provide useful information. It was of red plastic material with a blue lining. Mr. Clancy reported that plastic material has been found to retain identifiable traces of explosive after long immersion in the sea. Also, the lining which was severely tattered resembled that of one found after an explosion in an aircraft in Angola.

- A wooden spares box was found on the foreshore of Wales. It was of the kind used on the aircraft. It was charred on one side and partially on the bottom. The depth of charring suggested that the burn time was three to four minutes. This box was normally stowed in the aft cargo compartment; however, on this flight it may have been stowed in the forward compartment.
- Two pieces of the cover of an overhead locker originating above either door 2R or 4R were also found on the foreshore. They were partially damaged and blackened by fire. Mr. Clancy concluded that this indicated the presence of fire.
- Two pieces of U-section alloy channel partially filled with plastic foam were found on the foreshore. The alloy was of a kind not used in aircraft structure; however, it could have been from some fitting supplied by a sub-contractor. Also, since the pieces were found near an area where practice firings at targets are carried out off the west coast of the United Kingdom, it could have come from some other source. One piece of the alloy bore marks ("mooncraters") typical of an attack by very high velocity fragments such as produced by an explosion. X-rays showed the presence of a few small particles buried in the foam which Mr. Clancy recommended should be extracted and examined. He also felt that this provided the strongest single indication of an explosion and that it was essential to determine if these pieces came from the aircraft or any of the equipment or cargo aboard the aircraft.

The CASB in its examination of the floating wreckage noted the following:

- The fan cowls of the number 4 engine had a series of five marks in a vertical line across the centre of the Air India logo on the inboard facing side of the fan cowl. These marks had the characteristic airfoil shape of a turbine blade tip. It is possible that a portion of the turbine parted from the number 3 engine and struck the cowl of the number 4 engine.
- The upper deck storage cabinet which was located on the left side had unusual damage to its bottom. A large rounded dent in the bottom inboard edge of this stiff cabinet structure revealed smooth stretching without breakthrough. The damage did not seem to be achievable by

inertia or impact forces as the cabinet except for the bottom was undamaged. The damage was considered by a CASB investigator to be compatible with the spherical front of an explosive shock wave generated below the cabin floor and inboard from the cabinet; however, it is not known if this damage could be caused by some other means.

- The right wing root fillet which faired the leading edge of the wing to the fuselage ahead of the front spar had a vertical dent similar to that which would have resulted had the fillet run into a soft cylindrical object with significant relative velocity. The paint on the inboard chord appeared to be scorched brown in the centre areas of three honeycomb panels. It has been determined that sudden heat can turn these panels brown, but it is not known if other reasons for the discolouration exist. The fillet abutted the fuselage side at the aft end of the forward cargo compartment.
- There was blackened erosion damage to the bottoms of some seat cushions. The damage had an appearance similar to that which would have been caused by an explosive device. It is not known if marine life feeding on the cushions or some other cause could have produced the same effect.
- The charred wooden spares box contained some sand and small shellfish. The flesh from the shellfish appeared to be charred, indicating that the box was subjected to fire after the occurrence.

An electronic device was found among some floating wreckage and was forwarded to the Bhabha Atomic Research Centre for analysis. There was some concern that it could have been used to detonate an explosive device. The device was forwarded to the RCMP who in conjunction with the CASB determined it to be an item manufactured for use in radiosondes (weather balloons) and was not modified as a detonating device.

2.11.2 Wreckage Mapping and Surveying

The Canadian Coast Guard Ship (CCGS) John Cabot was given the task of mapping the wreckage on the ocean floor. On 19 July 1985, the Cabot with a SCARAB deep submersible on board departed Cork. On arrival at the site, and based on surface wreckage distribution and bottom side scan sonar plots, four transmitters were placed on the sea bed. These transmitters provided signals for the ALLNAV navigation system used to accurately plot the sea bed wreckage.

Based on all the data available, the SCARAB was launched on 24 July 1985 to begin the bottom search in position 51°01.9'N 12°41.0'W.

During the mapping, stage areas were designated for search and each progressive area was determined based on the information gained during the search. The search was conducted using sonar and video. Wreckage found was recorded on video tape and on 35mm positive film.

The first object plotted on the sea bed was a torn suitcase located at lat 51°02.63'N, long 12°53.15'W and was the most westerly object located. This suitcase has not been recovered, nor has it been positively identified as having come from the accident aircraft.

As the search progressed eastward, the first positive identification of aircraft wreckage was made at lat 51°02.9'N, long 12°49.93'W. Slowly, over a period of about 90 days, a detailed bottom wreckage plot was developed.

While mapping was in progress, some of the wreckage was revisited to obtain additional data. During the transit through areas already searched, wreckage not previously plotted was found, and, in some areas, the density of wreckage physically precluded 100 per cent coverage.

Components and major structural items were identified from all sections of the aircraft and when the mapping of the sea bed ended, most of the aircraft had been found and photographed. Although positive identification of each piece of wreckage could not be made, it was decided in late October 1985 that the search phase was essentially completed and wreckage recovery could begin. A bottom wreckage distribution plot is contained separately in an envelope as Appendix F.

2.11.3 Wreckage Distribution

The wreckage distribution as determined by the mapping of the sea bed provided some distinct distribution patterns. The depth of the wreckage varies between about 6000 and 7000 feet, and the effect of the ocean current, tides and the way objects may have descended to the sea bed was not determined, thus some distortion of an object's relationship from time of water entry to its location on the bottom cannot be discounted. In general, the items found east of long 12°43.00'W are small, lightweight and often made of a structure which traps air. These items may have taken considerable time to sink and may have moved horizontally in sea currents before settling on the bottom. Marks left on the sea bed beside some wreckage does indicate horizontal movement of the wreckage as it settled.

Although badly damaged, sections 41, 42 and 44*, and the wing structure were located in a relatively localized area centred about lat 51°03.30'N and long 12°47.80'W, and the wreckage scatter was oriented north/south. The wreckage scatter in this area was so dense that it is probable that some of the wreckage may not have been plotted or photographed.

Sections 46 and 48, including the vertical fin and horizontal stabilizer, extended in a west to east pattern with the westernmost identified aircraft component located at lat 51°02.90'N and long 12°50.1'W. The wreckage extended in a line about 110 degrees True to an eastern position of lat 51°02.04'N and long 12°41.26'W, a distance of approximately 6.5 nautical miles. The aircraft structure had a random scatter pattern. That is, items such as the aft pressure bulkhead were broken into several pieces, and these pieces were located throughout the pattern.

A?? third area which had some distinctive pattern was that of the engines, engine struts and components and was localized about lat 51°03.25'N and long 12°47.4'W in a northwest/southeast orientation. One of the operating engines was displaced 0.5 nautical miles to the north of this area, and it was also geographically separated from the wing structure. The number 3 engine nacelle strut was also separated from the rest of the engine components and was located about one nautical mile to the west-southwest at lat 51°02.87'N, long 12°48.05'W. The reasons for the displacement of the number 3 engine nacelle strut and one of the operating engines from the other engines are not known.

*See Appendix D for location of aircraft sections and aircraft body stations (BS).

2.11.4 Photographic and Video Interpretation of Wreckage

2.11.4.1 Photographic Interpretation

All wreckage sighted was recorded on video tape and all major items were recorded on 35mm positive film. During the course of the investigation, several members of the investigation team had the opportunity to view the tapes and photographs. Subsequently, when some items were recovered, it became apparent that the optical image presented on video and still film had some limitation with respect to identification of damage or damage patterns. For example, the sine wave bending of target 7* appeared in the video and photographs as a sine wave fracture, and some of the buckling on target 35 was not evident in either the video or photographs. The interpretation of damage through photographic/video evidence without the physical evidence might be misleading, and any interpretation should take this into account.

2.11.4.2 Engines

The four operating engines were all extensively damaged. A view of the fan blades did not show signs of any rotational damage, and it could not be determined whether any pre-impact failures had occurred. The external damage to the engines varied, and at least one engine appeared to be attached to part of the nacelle strut. Except for the non-operational fifth engine, the engines could not be matched with their original positions on the aircraft.

2.11.4.3 Landing Gear

The nose, wing, and body landing gear were all located. Photographic examination indicated that all the gear were in the 'up' position at the time of impact.

2.11.4.4 Flaps and Spoilers

Positive identification of all the flap and spoiler surfaces was not made. All the flap jackscrews indicated that the flaps were retracted at impact. Of the spoilers identified, six had actuators attached. The actuators were in the fully retracted position.

*See Appendix E for location of targets on aircraft.

2.11.4.5 Section 41

Section 41, consisting of the cockpit, first-class section, and electronics bay and identified as target 192, was found in a near-inverted attitude. This section was severely damaged. The electronics bay and cockpit areas could not be located within the wreckage. The first officer's seat was found on the sea bed near section 41 wreckage.

2.11.4.6 Section 42

Portions of section 42, consisting of the forward cargo hold, main deck passenger area, and the upper deck passenger area, were located near section 41. This area was severely damaged and some of section 42 was attached to section 44. Some of the structure identified from section 42 was the crown skin, the upper passenger compartment deck, the belly skin, and some of the cargo floor including roller tracks. The right-hand, number two passenger door including some of the upper and aft frame and outer skin was located beside section 44. Scattered on the sea bed near this area were a large number of suitcases and baggage as well as several badly damaged containers.

All cargo doors were found intact and attached to the fuselage structure except for the forward cargo door which had some fuselage and cargo floor attached. This door, located on the forward right side of the aircraft, was broken horizontally about one-quarter of the distance above the lower frame. The damage to the door and the fuselage skin near the door appeared to have been caused by an outward force. The fractured surface of the cargo door appeared to have been badly frayed. Because the damage appeared to be different than that seen on other wreckage pieces, an attempt to recover the door was made by CCGS John Cabot. Shortly after the wreckage broke clear of the water, the area of the door to which the lift cable was attached broke free from the cargo door, and the wreckage settled back onto the sea bed. An attempt to relocate the door was unsuccessful.

2.11.4.7 Section 44

Section 44, containing the aircraft structure between body station (BS) 1000 and BS 1480 including that area where the fuselage and wings were mated was located in the same general area as the forward sections of the aircraft. This section was severely damaged but maintained its overall shape and was lying on its right side. Part of the left wing upper skin was attached to the fuselage and a large portion, about one-third of the upper wing skin, separated and was lying against the fuselage crown skin. Some of the body and wing landing gear were found beside this section of the aircraft. The gear was detached from the main structure. The interior of the fuselage was extensively damaged.

2.11.4.8 Wing Structure

The wing structure was located near the forward area of the aircraft structure and towards the northernmost area of the wreckage pattern. The wings showed extreme damage patterns with the top and bottom surfaces separated and the wing surfaces broken into segments.

2.11.4.9 Sections 46 and 48

Sections 46 and 48 contain that part of the aircraft structure aft of BS 1480 and, for purposes of this Submission, will include the horizontal stabilizer and vertical fin. This section of the aircraft was scattered in a west to east pattern about 6.5 nautical miles in length and exhibited severe break-up characteristics.

The aft cargo and bulk cargo doors were found in place and intact, and 5L, 5R and 4R entry doors were identified. Four segments of the aft pressure bulkhead were identified (targets 35, 37, 73 and 296), and one portion of the bulkhead was never located. Much of the fuselage which was forward of the number five door and above the passenger floor area was not located, or if located was not recognizable as having come from a specific area of the aircraft.

Sections of the outer skin below the cargo area were located as was some of the cargo floor structure. Generally, the stringers and stiffeners are attached to the skin; however, the lower frames, which provided the cargo floor support, were detached from the skin. The rear cargo floor from BS 1600 to BS 1760 was located and was found to have little or no distortion; however, the lower skin and stringers were missing. A second portion of the aft cargo compartment floor containing cargo drive wheels and cargo roller trays was located. This structure was severely damaged and mangled.

The tail cone and the auxiliary power unit (APU) housing were located and had received relatively minor damage; however, the APU had broken free and was never located.

A large portion of the outer skin panels showed signs of a force being applied from the inside out. On several pieces of wreckage, the skin was curled outwards away from the stringers and formers. This could have been the result of an overpressure of air or water.

The vertical tail was found in good condition, in a single piece with both rudders attached. The top cap was partially separated and a small dent was noticed in the middle of the leading edge at the bottom. A curved broken portion of fuselage was observed with a portion of the "Y" ring and pressure bulkhead attached. Another small segment of the pressure bulkhead was leaning on the lower section of the tail.

The horizontal stabilizer tail section was located and was one unit with the elevators attached. The actuator jackscrew was attached to the assembly. The stabilizer jackscrew ballnut was observed to be located at the upper jackscrew stop. This equates to a full deflection of elevator trim. Since there is nothing on the DFDR or CVR to indicate a malfunction of the trim, it is deduced that this was not the lead event. It is not known if the position of the ballnut resulted from a pilot trim selection, a result of the initial event or if it rotated to the observed position under the influence of gravity. Two-thirds of the leading edge of the right horizontal stabilizer was missing and the auxiliary spar was exposed. There was localized damage to the right-hand root of the leading edge through about a span of five ribs. The leading edge skin and part of the leading edge ribs were torn downwards. Some localized damage to the root of the left leading edge was visible with the remainder of the leading edge undamaged. There was minor damage to the trailing edge of the outboard left elevator, and a major portion of the inboard left elevator was missing.

2.11.4.10 Passenger Seats

Many of the passenger seats located among the wreckage pattern and identified as having come from sections 46 and 48 appeared to have the aft support legs buckled with little or no damage to the forward support legs. Seats located in the wreckage containing sections 41, 42, and 44 appeared to have varying types of damage, that is, aft support legs only buckled, and all legs buckled. One consistent feature noted was that in the majority of seats located it was possible to ascertain that the seat-belts were not fastened.

2.11.5 Wreckage Recovery and Initial Examination

During the wreckage mapping, some small items were recovered, and an unsuccessful attempt was made to recover a portion of the forward cargo door. On completion of the sea bed survey, an offshore supply ship, Kreuztrum, chartered by the National Transportation Safety Board (NTSB), joined John Cabot for a wreckage recovery operation. Prior to the commencement of the wreckage recovery, the structures group met at the Boeing facility in Seattle, USA and reviewed the video tapes and photographs of the wreckage. Based on their findings, a list of items was identified as being most desirable for recovery. The priority list was prepared by a group in Cork, Ireland, headed by Dr. V. Ramachandran. On 8 October 1985, the John Cabot sailed, and on 9 October 1985, the Kreuztrum sailed for the accident site. The following target numbers and items were recovered during the mapping and wreckage recovery stages of the investigation: 7, 8, 35, 47, 117, 193, 223, 245, 287, 296, 299, 362/396, and 399 (as the location on the aircraft of some of the targets was not known when Appendix E was created, some are not shown in the appendix). The first officer's seat, some suitcases and small debris were also recovered using a metal frame basket. Initial examination of the wreckage was carried out in Cork and then it was transported to Bombay for detailed examination.

2.11.6 Examination of Recovered Wreckage

Although all the recovered wreckage was examined, only those items exhibiting characteristics which provided some evidence as to what may have happened to the aircraft during its final moments of flight are discussed. CASB engineering personnel and other participants examined the recovered wreckage at Cork and Bombay. The observations made during their examinations are discussed below.

2.11.6.1 Target 7 - Lower Fuselage Skin Panel

This skin panel was located below the aft cargo area and contained the keel beam. Target 7 extended from BS 1480 to 1860 and was about eight feet in width and 32 feet in length. The left edge had a full length rivet line tear, and the torn edge was buckled in waves, like the trace of a sine wave. On the right side, between the one-quarter and midway segment, a large flap of skin was attached. The skin was folded aft, diagonally underneath, from right to left and the paint was scoured off the leading edge. The forward break was at the joint at BS 1480. The skin tear located at about BS 1860 was irregular in nature. The forward keel joint splice plate was bent, and the keel joint bolt holes were distorted and elongated.

The left and right trunnion vertical support fittings located at BS 1480 were examined optically using the stereomicroscope. Both trunnions were fractured through the three bolt holes. The right fracture characteristics were consistent with an overload mode of failure. Although most of the left fracture surface was also characterized by overload features, there were heavily corroded areas where the fracture mode could not be confirmed through optical examination. One lug fracture was sectioned from the left trunnion and prepared for scanning electron microscope (SEM) examination. After the corroded area was cleaned, the examination revealed some ductile characteristics on the fracture surface. There was no evidence of intergranular fracture observed to suggest a stress corrosion cracking mode of failure, nor was there any evidence of progressive failure observed. The corrosion appeared to have developed after the accident.

2.11.6.2 Target 8 - Lower Fuselage Skin Panel

This skin panel was located below the aft cargo area and extended from BS 1860 to 1960 and from stringer 46L to 46R. A small section from the aft end along the belly skin splice at stringer 46L was removed for examination. SEM examination revealed that the fracture was characterized by slightly elongated ductile dimples along its length, including areas adjacent to the edges of the rivet holes. On the aft edge of each rivet hole examined, a distinctive shear lip was observed. These features are consistent with an overload mode of failure along the skin splice with an apparent direction of failure from aft to forward.

2.11.6.3 Target 35 - Portion of Rear Pressure Bulkhead

Looking forward from behind the aircraft, this segment of pressure bulkhead occupied the 9 to 1 o'clock position. The piece from 12 to 1 o'clock had the flange from the outer ring attached. The web below the outer ring flange had areas of buckling. From the 11 to 12 o'clock position, the outer edge showed sinusoidal buckling, and the edge sector at 9 o'clock was partially collapsed and its edge was turned under. Samples taken for optical stereomicroscope and SEM examination revealed that the fracture characteristics were consistent with an overload mode of failure. The examination suggested a general direction of failure from the aft to the forward edge of the rear pressure bulkhead panel.

2.11.6.4 Target 296 - Portion of Rear Pressure Bulkhead

Looking forward from the rear of the aircraft, this segment of the bulkhead occupied the 7 to 9 o'clock position. Optical and SEM examination were undertaken on this item.

The fracture along the left-hand edge of target 296 (viewed from the rear) was examined optically prior to removing any representative samples. The fracture was at the rivet line at a skin splice, except for a length of fracture about 15 inches long near the forward end, which was through the skin away from the rivet line. Most of the rivet holes along the fracture path showed some slight elongation and skin deformation. Representative fracture samples were cut from the left-hand and right-hand edges of the fracture surfaces. Optical and SEM examination revealed that the fracture characteristics are consistent with an overload mode of failure.

2.11.6.5 Target 47 - Aft Cargo Compartment

This portion of the aft cargo compartment roller floor was located between BS 1600 and BS 1760. Based on the direction of cleat rotation on the skin panel (target 7) and the crossbeam displacement on this structure, target 47 moved aft in relation to the lower skin panel when it was detached from the lower skin. No other significant observation was noted. There was no evidence to indicate characteristics of an explosion emanating from the aft cargo compartment.

2.11.6.6 Target 117 - Floor with Seats Attached

These seats were right-section doubles, located between BS 1880 and 1980 and were from rows 46, 47 and 48, F and G (Zone E). The seats were displaced to the left with the rear legs buckled to the left. The front leg supports exhibited only minor damage. The middle and rear doubles had aisle-side seat arms bent to the right. There was no impact damage to the seat backs or seat pans, and all life vests except one were gone from the underseat container bags.

2.11.6.7 Target 399 - Left-Hand Side Triple Seat with Tray Arms

It would appear that this section was from row 18, seats A, B and C, the first set of triple seats aft of door 2L. The notable damage to this unit was as follows: front leg aisle side buckled and crushed in place; front leg window side buckled and crushed in place; forward edge tube to seat broken and bent downwards at joint with fore and aft tube between window and centre seats; and fore and aft tube between centre and aisle seat broken at start of T-connection to rear edge of seat tube. The damage suggests that the failures resulted from vertical loading. All the life-jackets were in place.

2.11.6.8 Target 399 - Fuselage Side and 2R Entry Door

The fuselage segment was located between BS 780 and 940. This piece was badly damaged and buckled inwards along a line through the lower door hinge. There were 12 holes or damaged areas on the skin generally with petals bending outwards. The curl on a flap around a hole had one full turn. This curl was in the outward direction. Cracks were also noticed around some of the holes. Part of the metal was missing in some of the holes. The edges of some of the petals showed reverse slant fracture. In one of the holes, spikes were noticed at the edge of a petal. When this target was recovered from the sea, along with it came a few hundred tiny fragments and medium-sized pieces. One of the medium-sized pieces recovered with this target was a floor stantion about 35 inches long. It was confirmed that this stantion belonged to the right side of the forward cargo hold. The inner face of the stantion had a fracture with a curl at the lower end, the curl being in the outboard direction and up into the centre of the stantion.

Scientists from the Bhabha Atomic Research Centre, the National

Aeronautical Laboratory and the Explosives Research and Development Laboratory in India conducted a metallurgical examination of certain items of wreckage. Their report on target 399 concluded that:

- the curling of the metal on the floor channel was indicative of a shock wave effect;
- the large number of tiny fragments from the disintegration of nonbrittle aluminum was a characteristic indication of explosive forces; and
- the indications of punctures, outward petalling around holes, curling of metal lips, reverse slant fracture, formation of spikes at fracture edges and certain microstructural changes all were indicative of an explosion.

2.11.6.9 Target 193 - Fuselage Side and 2L Entry Door

The fuselage segment was located between BS 720 and 840. The door and fuselage skin were buckled outwards, approximately in line with the buckling on the fuselage and 2R entry door directly opposite.

2.11.6.10 Target 362/396 - Lower Skin Panel - Forward Cargo Area

This section of skin panel was located between BS 720 and 860 and is just below target 399. The skin was badly crumpled and torn and had several punctures. It was pulled free from a large mass of debris which included some mangled cargo floor beams and roller trays. Some of the punctures had a feathered or spiked profile, with spikes angled at approximately 45 degrees to the edge. Other puncture holes gave clear indication of being formed by underlying stiffeners at impact. Two of these holes contained pieces of web stiffener. Most of the punctures were the result of penetrations from inside.

In the preliminary report of Mr. V.J. Clancy, representing Boeing, the following observations regarding target 362/396 were made:

- There were about 20 holes in the lower skin panel clearly resulting from penetration from inside.
- In addition to the fact that perforation was from inside, there were certain features which suggested that they were made by high velocity fragments such as those produced by an explosion. Mr. Clancy's report describes these features as follows:
- the presence of toothed or spiked edges at some parts of the metal

which has petalled out from the perforations;
(Tardif and Sterling, Canadian Aeronautics and Space Journal, 1969, 15, 1, 19-27, obtained spiked fractures in fragments from sheet alloy subjected closely to an explosion. They stated that they had not obtained this effect in fractures otherwise produced.)

- the presence of marked curling (in some cases of more than 360 degrees) of some of the petals;

(Tardif and Sterling stated that such curling was a feature of explosively produced fragments.)

- the virtual absence of scratches or score marks on the petals such as might be expected if something were slowly forced through the metal;
- the virtual absence of other impact marks on the inside surface such as might have been produced by a massive impact with a substantial object, thereby suggesting that the production of at least many of the perforations were separate independent events; and
- the presence of one perforation (identified as number 14) resembling a "bullet hole" that was clearly punched out - a type of hole usually associated with a high velocity missile.
- There was evidence that the forward part of the skin panel had been folded back inward along the line of station 760 and then bent back again along a line slightly forward of this station.
- Such folding, perhaps violently produced on impact with the water, could have brought broken metal of stringers or stiffeners into forceful contact with the internal surfaces, thus producing perforations outwards. The overlap of such folding would conceivably have covered the area up to station 800 and thus included most of the perforations.
- One hole (identified as number 13) was almost certainly caused by a slipping wire rope used as a sling.
- Part of the inner surface, aft of station 780 was superficially blackened as if by soot from a fire. Swabs were taken of this area for further examination for evidence of fire or explosives.
- A large number (several hundred) of small fragments were recovered. These varied in size from an inch or less to a few inches. They included fragments broken out of sheet metal, and these were reported to be from

the same area as T362.

- The production of a large number of small fragments is generally regarded as an indication of an explosion.
- One piece, which was isolated, was about an inch square of sheet alloy with characteristic spikes on one edge similar to those described by Tardif and Sterling.

The following is an excerpt from the report by Mr. V.J. Clancy wherein he gives his opinion and conclusions regarding target 362.

"Opinion

The features discernible to a careful close visual examination point towards the possibility of an explosion but taken alone do not justify a firm conclusion.

Curling of petals and spiked or toothed fractures may be observed in other events than explosions despite the failure by Tardif and Sterling to obtain them in their limited number of attempts. It is probable that these features indicate a rapid rate of failure but not necessarily of a rapidity which could only be produced by an explosion.

A more detailed study, metallurgical and fractographic, is required.

The studies by Tardif and Sterling were done on fragments produced from aluminium alloy in contact with the explosive. Very little information is available on the behaviour of aluminium alloy some distance from the explosive and subjected to attack by secondary fragments. To determine this some trials will be necessary, to obtain reference samples for comparison.

The single "bullet hole," No. 14, strongly supports an explosion hypothesis but, being the sole example of its kind, is not, by itself determinative.

If the forward part of this item was forcefully and rapidly folded back to impact on the other part, it might explain the other features apparent to visual examination. It would require detailed laboratory examination and tests to eliminate this possibility.

The production of a large number of small fragments is generally regarded as a pointer towards an explosive cause but cannot be relied upon unless it is clear that they could not have been produced by some

other means. It is known that the break-up of an aircraft at high speed may produce great fragmentation.
The single spiked fragment must be regarded as important but a single specimen is not, by itself, determinative."
Mr. Clancy concluded that:
"there is strong circumstantial evidence that an explosion occurred but neither individually nor collectively do the several pointers give the degree of confidence necessary for a firm and final conclusion, at this time."
With respect to target 362/396, in his report Mr. Clancy recommended:
"that firing trials be carried out projecting various size missiles at targets similar to the material of T362 to obtain reference samples for laboratory comparison with the perforations in T362."
The Indian report, in addition to the observations made by Mr. Clancy, noted the following with respect to the metallurgical examination:
- The microstructure in the various areas examined on target 362/396 confirmed explosive loading in this part of the aircraft.
- The holes and other features observed in targets 362/396 and 399 must have been due to shock waves and penetration by fragments resulting from an explosion inside the forward cargo hold.
- The chemical nature of the explosive material was not identified. No part of an explosive device, its detonator or timing mechanism was recovered.

2.11.6.11 Examination of Wreckage in India with CASB Participation

The examination of the targets recovered did not reveal any pre-existing defect, premature cracking or pre-impact corrosion damage associated with any of the failures.

3.0 DISCUSSION

3.1 Initial Event

From the correlation of the recordings of the DFDR, CVR and Shannon ATC tape, the unusual sounds heard on the ATC tape started shortly after the flight recorders stopped recording. The conversations in the cockpit were normal, and there was no indication of an emergency situation prior to the loud noise heard on the CVR a fraction of a second before it stopped recording. The DFDR showed no abnormal variations in parameters recorded before it stopped functioning. The only unusual observation was the irregular signals recorded over the last 0.27 inches of the DFDR tape. Laboratory tests indicated the possibility that these signals resulted from the recorder being subjected to a sharp disturbance at the time it stopped recording. The other possibility for the irregular signals on the DFDR is that they were caused by a disturbance to the Flight Data Acquisition Unit in the main electronics bay. Since there was an almost simultaneous loss of the transponder signal, this indicates the possibility of an abrupt aircraft electrical failure. The medical evidence showed a general absence of signs indicating that seat-belts were fastened. From the video and photographic examination of the wreckage on the bottom, it was ascertained that the majority of seats located did not have the seat-belts fastened. The above evidence indicates that the initial occurrence was sudden and without warning. The abrupt cessation of the data recorder could be caused by airframe structural failure or the detonation of an explosive device as the initial event. The millisecond noise on a CVR as observed in this case is usually, as described in the available literature, the result of the shock wave from detonation of an explosive device. However, in this case, certain characteristics of the noise indicate the possibility that the noise was the result of an explosive decompression. There is some disagreement regarding the cause and location of the source of the noise heard on the CVR, that is, whether the noise resulted from an explosive device or an explosive decompression and whether the noise originated from the rear or closer to the front of the aircraft.

3.2 Passenger/Flight Deck Area

From the examination of the wreckage recovered and wreckage on the bottom, there is no indication that a fire or explosion emanated from the cabin or flight deck areas. The medical examination of the bodies also showed no fire or explosion type injuries. However, pieces of an overhead locker coming from above door 2R or 4R had been blackened by fire. There was blackened erosion damage to the bottoms of some seat cushions, showing damage possibly from an explosive device, and the upper deck storage cabinet had a large rounded dent in the bottom inboard edge which might have been caused by an explosive shock wave generated below the cabin floor and inboard from the cabinet. It should be noted that the pieces of the overhead locker were found on the Welsh shore some time after the accident, and it is not known if the pieces were subjected to a fire after the accident. Also, it is not known if the damage to the seat cushions and the upper deck storage cabinet could have been caused by other means. Nevertheless, the above evidence suggests that some areas of the passenger cabin may have been subjected to minor fire and explosive damage possibly emanating from below the cabin floor.

3.3 Aircraft Break-up Sequence

The medical evidence showed a proportion of the passengers with indications of hypoxia, decompression, flail injuries and loss of clothing. The incidence of hypoxia and decompression indicates that the aircraft experienced a decompression at a high altitude. The flail injuries and loss of clothing indicate a proportion of the passengers were ejected from the aircraft before water impact. The severity of injuries increased from Zones C to E and was significantly less in Zone C than in Zones D and E.

The wreckage of the forward portion of the aircraft up to and including the aircraft body wheel well area and the wings was lying about 0.8 miles north of the vertical and horizontal stabilizers. Hence, it is likely that the aft portion of the aircraft separated from the forward portion before striking the water. In addition, the wreckage found west of longitude 12°48' consisted of suitcases and aft cargo compartment lower skin panels. There was also a wide scatter of sections 46 and 48 in an east-west direction, whereas the wreckage of the forward portion was mainly localized within a relatively small area.

The higher severity of injuries in the aft end of the passenger cabin appears to coincide with the break-up of the aft end, sections 46 and 48 of the aircraft. The fact that items from the aft cargo compartment were found further west than the tail section indicates that the aft cargo compartment ruptured first during the break-up sequence of the aft end.

The forward portion of the aircraft was highly localized, which indicates that it struck the water in one large mass.

3.4 Aircraft Structural Integrity

As described earlier, the sudden nature of the occurrence indicates the possibility of a massive airframe structural failure or the detonation of an explosive device.

3.4.1 Aircraft Break-up

The examination of the floating wreckage indicates that the right wing root leading edge, the number 3 engine inboard fan cowling, the right inboard midflap leading edge, and the right horizontal stabilizer root leading edge all exhibit damage consistent with objects striking the right wing and stabilizer before water impact. In addition, the right wing root interior area appears to have been scorched briefly by a heat source. The fan cowls of the number 4 engine show evidence of being struck by a portion of the turbine from number 3 engine.

The number 3 engine nacelle strut was separated from the rest of the engine components and was located about one nautical mile to the west indicating that there was some break-up of the number 3 engine before water impact.

The forward cargo door which had some fuselage and cargo floor attached was located on the sea bed. The door was broken horizontally about one-quarter of the distance above the lower frame. The damage to the door and the fuselage skin near the door appeared to have been caused by an outward force and the fracture surfaces of the door appeared to be badly frayed. This damage was different from that seen on other wreckage pieces. A failure of this door in flight would explain the impact damage to the right wing areas. The door failing as an initial event would cause an explosive decompression leading to a downward force on the cabin floor as a result of the difference in pressure between the upper and lower portions of the aircraft. However, examination showed that the cabin floor panels separated from the support structure in an upward direction. Also, passenger seats viewed and recovered exhibited that they had been subjected to an upward force from below. They showed that the seats to the rear in sections 46 and 48 had their back legs buckled, and the seats toward the front had both front and back legs buckled. This indicates the vertical force was greater at the front than the rear of the aircraft. It is possible that this vertical force on the floor was caused by the force of the water during impact, but the rear of the aircraft broke up before impact and therefore any vertical loading on the floor in this area is unlikely to have occurred at impact. Twenty-three passengers also showed evidence of vertical impact injuries. These could have been caused from a force from below during flight or at water impact. Sixteen of these passengers had little or no clothing indicating that some may have been ejected before water impact. Therefore, there is some indication that the upward force on the floor may have occurred in flight and was more severe toward the front.

3.4.2 Aft Pressure Bulkhead

The localized impact mark found on the leading edge of the right horizontal root leading edge is indicative of an object striking the stabilizer in flight before water impact. This suggests that the loss of the tail plane was not the first event. The horizontal and vertical stabilizers were found separated and each was intact and in good condition. Items from the aft cargo compartment were found further to the west of the tail plane. The absence of the type of damage to the tail plane as was found in the Japan Airlines (JAL) Boeing 747 accident where the aft pressure bulkhead failed and which took place shortly after this occurrence, and the rupture of the aft cargo compartment before the loss of the tail indicate that there was not an in-flight failure of the aft pressure bulkhead. In addition, examination of the recovered portions of the bulkhead shows evidence of overload failures from the rear to front only and no evidence of any pre-existing defect, premature cracking or pre-impact corrosion damage.

3.4.3 Target 7 - Lower Fuselage Skin Panel

Target 7 which extends from BS 1480 to 1860 shows a break at the joint at BS 1480. The forward keel joint splice plate is bent and the keel joint holes are distorted and elongated. Some of the fracture surface was heavily corroded. An in-flight failure in this area would cause a massive failure of the aircraft's structural integrity. Further examination showed the fractures to be overload, and there was no evidence of an intergranular type fracture to suggest a stress corrosion cracking mode of failure. The corrosion was concluded to be post-impact and, therefore, there is no evidence to suggest an in-flight failure in this area as the initial event.

3.4.4 Structural Failure

The examination of the floating and recovered wreckage and the analysis of the photos and videos of the wreckage on the bottom failed to indicate any evidence of a failure of the primary or secondary structure as a result of a pre-existing defect. The initial event has been established as sudden and without warning. The abrupt cessation of the flight recorders indicates the possibility of a massive and sudden failure of primary structure; however, there is evidence to suggest that there were ruptures in the forward and aft cargo compartments prior to any failure of the primary structure in flight. Therefore, available evidence tends to rule out a massive structural failure as the initial event.

3.4.5 Explosive Device

A violent explosion occurring within an aircraft in flight usually leads to a complicated break-up mode and sequence of failure. Fractures of metal caused by an explosion are normally different in character to those caused by overstressing or crash impact forces. Shattering of metal into very small and numerous fragments and minute deep penetration of a metal surface are not usually found in aircraft accident wreckage. The size and characteristics of these particles often accompanied by rolled edges, surface spalling, pitting or evidence of heat are indicative of an explosion.

Of the floating wreckage, there is little to indicate the possibility of an explosion:

- the lining in one suitcase was severely tattered;
- although the wooden spares box was burned, this could have happened after the occurrence;
- although pieces of an overhead locker were damaged by fire, it is not known if the burning happened at the time of the occurrence;
- although the pieces of U-section alloy clearly indicated evidence of

an explosion, it is quite possible that these pieces were not associated with the aircraft;

- the bottoms of some seat cushions show indications of a possible explosion;
- the inside of the right wing root fillet appears to have been scorched; and
- the deformation of the floor of the upper deck storage cabinet might have been caused by an explosive shock wave generated below the cabin floor and inboard from the cabinet.

It is not known if the suitcase came from the aft or forward cargo compartment, and the location of the seats from which the cushions came is also unknown.

The scorching of the right wing root fillet and the damage to the upper deck cabinet suggest, if there was an explosion, it emanated from the forward cargo compartment.

From the examination of the recovered wreckage, the following deductions can be made:

- Target 47, which is a portion of the aft cargo compartment roller floor, shows no indications characteristic of an explosion emanating from the aft cargo compartment.
- Target 362/396, which is a lower skin panel from the forward cargo compartment is badly crumpled and torn and has about 20 punctures resulting from penetration from inside. It appears that some folding occurred on water impact which brought stringers or stiffeners from the aircraft structure into forceful contact with the internal surface of the panel producing most of the penetrations. However, there are certain punctures which indicate no evidence of impact marks on the inside surface and show evidence of being produced by high velocity fragments. Part of the inner surface of the skin panel appeared to have been blackened by soot from a fire.
- Target 399, consisting of a piece of the skin and stringers on the right side in the area of the forward cargo compartment contained holes and several hundred metal fragments. The damage to the floor stantion and the presence of the fragments are consistent with an explosion.

The examination of the recovered wreckage contains no evidence of an explosion except for targets 362/396 and 399 which contain some evidence that an explosion emanated from the forward cargo compartment.

An explosion in the forward cargo compartment would explain the loss of the DFDR, CVR and transponder signal as the electronics bay is immediately ahead of the cargo compartment.

3.5 Security Aspects

There is a considerable amount of circumstantial and other evidence that an explosive device caused the occurrence. Therefore, it is reasonable to examine the security measures in place on 22 June 1985. The evidence indicates that if there was an explosion, it most likely occurred in the forward cargo hold, not the passenger and flight deck areas or exterior to the fuselage. Although an explosive device could have been placed in a cargo hold in a number of ways, the available evidence points to the events involving the checked baggage of M. and L. Singh in Vancouver. The investigation determined that a suitcase was interlined unaccompanied from Vancouver via CP Air Flight 060 to Toronto. In Toronto, there is nothing to suggest that the suitcase was not transferred to Terminal 2 and placed on board Air India Flight 181/182 in accordance with normal practice. The aircraft departed Toronto for Mirabel and London with the suitcase unaccompanied. Similarly, a suitcase was interlined unaccompanied on CP Air Flight 003 from Vancouver to Tokyo to be placed on Air India Flight 301 to Bangkok. The explosion of a bag from CP 003 at Narita Airport, Tokyo, took place 55 minutes before the AI 182 accident. Therefore, the nature of the link between the two occurrences raises the possibility that the suitcase which was unaccompanied on AI 182 contained an explosive device.

3.5.1 Canadian Security Situation

Canadian security arrangements in place prior to 23 June 1985 met or exceeded the international requirements for civil air transportation. However, before this date, the emphasis was on preventing the boarding of weapons including explosive devices in hand luggage. Hence, the screening of checked baggage was only undertaken in conditions of a heightened threat as was the case with respect to Air India flights.

In Canada, the Department of Transport (Transport Canada) is responsible for establishing overall security standards for airports and airlines, and for the provision of certain security equipment and facilities at airports. By regulation, air carriers are responsible for applying security standards for passengers, for baggage and cargo and for ensuring security within individual aircraft. The RCMP provides airport physical security and responds to criminal incidents.

Air carriers contract for or otherwise provide the personnel who operate the security check-points through which passengers and their carry-on baggage enter the secure area of the airport terminal. These personnel also operate security equipment for the screening of cargo, passengers and checked baggage. Usually, air carriers use the service of private security firms. Transport Canada has established certain standards required for licensed security guards, such as the successful completion of the Transport Canada passenger inspection training program and annual refresher training. As stated earlier, a significant number of the security guards did not meet the criteria with respect to the completion of the training program and refresher training. In addition, the criteria do not require training for the screening of cargo and checked baggage.

ICAO Annex 17 recommends that contracting States establish the necessary procedures to prevent the unauthorized introduction of explosives or incendiary devices in baggage or cargo intended to be carried on board aircraft. For all Canadian airlines, Canadian regulations before 23 June 1985 required a system of identification that prevented baggage, goods and cargo from being placed on board an aircraft if it was not authorized to be placed on board by the airline operator. However, if someone were to purchase a ticket, check in baggage and not board the aircraft, the baggage would in all likelihood have been authorized by the airline to be placed on board the aircraft. Therefore, it was possible to interline baggage unaccompanied and this explains how a suitcase was interlined to AI 181/182 from CP 060. It is not the normal practice of airlines to interline baggage if there is not a confirmed reservation to the destination. In this case, the ticket agent allowed the suitcase to proceed; however, if there had been a confirmed reservation, the suitcase would have been interlined unaccompanied without question.

3.5.2 Air India Security

Air India, as required by Canadian regulation, had a security program. Because of the threat level assessed against the airline, Air India had more extensive security measures than almost any other Canadian or international airline. These measures were generally in accordance with the recommended procedures of the ICAO Security Manual for special risk flights. Air India had also requested and received extra security from Transport Canada and the RCMP for the month of June 1985. For Air India Flight 181/182, Air India provided a security officer from its New York office to oversee the security arrangements at Toronto and Mirabel. The security program at each airport was under the overall supervision of the respective Air India station managers. In Toronto, it was not clear who, if anyone, was undertaking this function.

It is not known if the suitcase interlined from CP 060 was screened before or after the X-ray machine broke down in Toronto. Although baggage not examined by X-ray was screened by a PD-4 sniffer, there are indications that the sniffer could have been ineffective in detecting explosives, especially plastics. Rather than using the sniffer, it would have been more effective to open all bags and physically inspect them. Even though a number of security personnel were not adequately trained in the screening of passengers and baggage, it is not known whether more training would have prevented an explosive device from being placed on board.

Although airline procedures required baggage to be accompanied, the agents checking in passengers in Toronto used a passenger security numbering system but did not number checked-in baggage, and baggage was not correlated with passengers. Therefore, the interlined unaccompanied suitcase from CP 060 was not detected. At Mirabel, checked-in passengers and baggage were numbered so that the number of passengers checking in baggage could be correlated with the number of passengers boarding the aircraft. Had a passenger-baggage correlation been carried out in Toronto, the suitcase from CP 060 would have been detected. The airline procedures would have prevented the placement of the suitcase on the aircraft.

Once loaded on the aircraft, the suitcase would have been placed in container 11L and 12L (see Appendix B) if in the forward cargo compartment, in container 44L or 44R if in the aft cargo compartment, or in position 52 if in the bulk cargo compartment. It could not be determined in which cargo compartment the suitcase was loaded.

Therefore, although the procedures were in place to prevent an explosive device from being placed on board the aircraft in checked-in baggage, there was a breakdown in the X-ray machine used to screen baggage, and there are indications that the PD-4 sniffer was inadequate. Also, the security numbering system used in Toronto was ineffective in preventing unaccompanied interlined baggage from being placed on board the aircraft.

4.0 CONCLUSIONS

The Canadian Aviation Safety Board respectfully submits as follows:

4.1 Cause-Related Findings

1. At 0714 GMT, 23 June 1985, and without warning, Air India Flight 182 was subjected to a sudden event at an altitude of 31,000 feet resulting in its crash into the sea and the death of all on board.
2. The forward and aft cargo compartments ruptured before water impact.
3. The section aft of the wings of the aircraft separated from the forward portion before water impact.
4. There is no evidence to indicate that structural failure of the aircraft was the lead event in this occurrence.
5. There is considerable circumstantial and other evidence to indicate that the initial event was an explosion occurring in the forward cargo compartment. This evidence is not conclusive. However, the evidence does not support any other conclusion.

4.2 Other Findings

Even though they may not be causal or related to the accident, the following additional conclusions can be drawn from the investigation with respect to certain security arrangements and their application pertaining to this flight:

1. In compliance with the International Civil Aviation Organization Annex 17 to the Convention on International Civil Aviation, the Department of Transport of Canada has made regulations requiring foreign aircraft operators who land in Canada to establish, maintain, and carry out certain security measures at airports.

2. In accordance with these regulations, Air India submitted a security program to the Minister of Transport which included security measures with respect to aircraft, cargo, baggage, and passengers.

3. On 22 June 1985, an unaccompanied suitcase was interlined from Vancouver to Toronto on CAP Flight 060 for transfer in Toronto to Air India Flight 181/182.

4. The baggage loaded in Toronto was screened through an X-ray machine process but, during the course of this procedure, the X-ray machine broke down.

5. After the X-ray machine breakdown, an explosives detector was used to screen the baggage; the baggage was not opened and physically examined.

6. The effectiveness of the explosives detector is in doubt.

7. It is not known whether the unaccompanied suitcase interlined from Vancouver was screened before or after the X-ray machine broke down.

8. The security numbering system used in Toronto did not prevent unaccompanied interlined baggage from being placed on board the aircraft.

9. The normal procedures for interlining baggage in Toronto indicate that the unaccompanied suitcase was loaded on Air India Flight 181/182.

REPORT OF THE COURT INVESTIGATING
ACCIDENT TO AIR INDIA BOEING 747 AIRCRAFT VT-EFO,
"KANISHKA" ON 23RD JUNE 1985

HON'BLE MR. JUSTICE B. N. KIRPAL JUDGE, HIGH COURT OF DELHI
ASSESSORS
DR. V. RAMACHANDRAN MR. J. S. GHARIA
CAPT. J. S. DHILLON MR. J. K. MEHRA
CAPT. B. K. BHASIN
SECRETARY
MR. S. N. SHARMA

FEBRUARY 26, 1986

CONTENTS

INTRODUCTION

1.1.1 On the morning of 23rd June, 1985 Air India's Boeing 747 aircraft VT-EFO (Kanishka) was on a scheduled passager flight (AI-182) from Montreal and was proceeding to London enroute to Delhi and Bombay. It was being monitored at Shannon on the Radar Scope. At about 0714 GMT it suddenly disappeared from the Radar Scope and the aircraft, which has been flying at an altitude of approximately 31,000 feet, plunged into the Atlantic Ocean off the south-west coast of Ireland at position latitude 51° 3.6'N and Longitude 12° 49'W. This was one of the worst air disasters wherein all the 307 passengers plus 22 crew members perished.

1.1.2 The fact that emergency had arisen was first noticed by Shannon Upper Area Control (UAC) after the aircraft had disappeared from the Radar Scope. The control gave a number of calls to the aircraft but there was obviously no response. Thereafter various messages were transmitted and that is how the rest of the world came to know of the

accident.
1.1.3 Shannon Control at 0730 hours advised the Marine Rescue Coordination Centre (MRCC) about the situation which appeared to have arisen. MRCC, in turn, explained the situation to Valencia Coast Station and requested for a Pan Broadcast. Thereafter ships started converging on the scene of the accident and they commenced search and rescue operations.
1.1.4 The aircraft in question - Kanishka, was named after the most powerful and famous king of the Kushanas who perhaps ruled in India from AD 78 to AD 103. Besides being a great conqueror, he was an ardent supporter and follower of Budhism - a religion which preaches non-violence. Emperor Kanishka, however, met a violent end. After 25 years of reign he was killed by some of his own subjects. His life was thus brought to an abrupt end.
1.1.5 It is indeed ironical that the Jumbo Jet which bore the name 'Kanishka' also met with a violent and a sudden end on that fateful morning of 23rd June, 1985.

INITIAL ACTION TAKEN BY THE GOVERNMENT OF INDIA

1.2.1 Initial intimation of the accident was received by Air India who, in turn, communicated the same to Mr. H.S. Khola, Director of Air Safety, Civil Aviation Department, New Delhi. The Accident Investigation Branch of United Kingdom also sent information to the Director General of Civil Aviation, New Delhi to the effect that the accident had taken place on international waters and as such it was India which was the authority to investigate the accident in accordance with the provisions of ICAO Annex 13.
1.2.2 Thereupon Order No. AV.15013/8/85-AS dated 23rd June, 1985 was issued by the Director General of Civil Aviation whereby Mr. H.S.Khola was appointed Inspector of Accidents for the purpose of carrying out the investigation into the aforesaid air accident. This appointment was made under Rule 71 of the Aircraft Rules, 1937.
1.2.3 While search and rescue operations were underway at the site of the accident, a team of officials headed by Dr.S.S. Sidhu, Secretary, Ministry of Tourism & Civil Aviation rushed from India to Cork. The

said team was joined by Mr. Kiran Doshi, the Indian Ambassador to Ireland, and also by two officers of the Indian Navy who were attached to the Indian High Commission at London. Subsequently two Medical Experts from India also joined the said Team.

1.2.4 The Indian Team arrived at Cork, Ireland on 24th June, 1985. Representatives of the Governments of United States of America, Canada and United Kingdom also reached there that day. They were met by the representatives of the Government of Ireland.

1.2.5 The members of the Team saw the rescue and salvage operations being conducted. They also visited the Cork Regional Hospital and had discussions with Irish and other Authorities with a view to release the bodies of the victims which were being brought to Cork.

1.2.6 For facilitating the process of investigation the Inspector of Accidents after consulting the representatives of the aforesaid Governments formed the following groups:

a. Structures, Power Plant and Systems Group.

b. Operations Weather & ATS Group.

c. Medical and Human Factor Group.

d. Search & Rescue Group.

The aforesaid groups were required to collect evidence and to submit their respective reports to the Inspector of Accidents.

1.2.7 The bodies which were being recovered were brought to the Cork Regional Hospital for identification and post-mortem. At that time it was considered proper that apart from the two medical experts from India, Wing Commandor Dr.I.R. Hill, who is an expert in aviation pathology should also be called from United Kingdom.

1.2.8 It was also being speculated that the accident may have occurred due to an explosion on board the aircraft. In order to see whether there was any evidence of an explosion which could be gathered from the floating wreckage which was being salvaged, the Government of India requisitioned the services of Mr. Eric Newton, a Specialist in the detection of explosives sabotage in aircraft wreckage.

1.2.9 In order to coordinate and guide the operations of the various ships working at the crash site, a control centre was set up at Cork

Airport on 30th June, 1985.
1.2.10 The control centre was manned by representatives of the Governments of Ireland, Canada and United States. The Indian Naval Officers from the High Commission at London were overall in-charge of this centre. After the flight recorders had been recovered the centre continued to function, but the representatives of the United States departed.

1.2.11 For retrieving the Cockpit Voice Recorder (CVR) and Digital Flight Data Recorder (DFDR), a cable ship named Leon Thevenin was engaged which had on board Submersible Robot (Scarab) which was fitted with a Sonar receiver and TV Cameras. The aforesaid ship was engaged and after an intensive search CVR and the DFDR (more popularly known as 'the black boxes') were located and retrieved on 10th July and 11th July, 1985 respectively.

1.2.12 The Government of India, in exercise of the powers conferred by Rule 75 of the Aircraft Rules, 1937 vide Notification No. AV. 15013/10/85-A, dated 13th July, 1985, directed that a formal investigation of the accident be carried out. Mr Justice B.N. Kirpal, Judge of the Delhi High Court, was appointed as the Court to hold the said investiation. The Central Government also appointed Dr. V. Ramachandran of National Aeronautical Laboratory, Bangalore; Mr. J.S. Gharia of Explosive Research and Development Laboratory, Pune; Captian J.S. Dhillon, retired Director of Operations, Air India, Bombay; Mr. J.K. Mehra, retired Manager (Technical Training), Indian Airlines, Hyderabad and Captain B.K. Bhasin, Deputy Managing Director of Indian Airlines, New Delhi to act as Assessors of the said Investigation. The Court was required to make its report to the Central Government by 31st December, 1985, which date was later extended to 28th February, 1986.

1.2.13 Mr. S.N. Sharma, Director of Airworthiness, Civil Aviation Department, was appointed as Secretary to the Court vide Ministry of Tourism & Civil Aviation letter No. AV/15013/10/85-A, dated 22nd August, 1985. The appointment was to take effect from 13th July, 1985.

ACTION TAKEN BY IRELAND, INCLUDING THE CORK

REGIONAL HOSPITAL

1.3.1 The accident had occurred on the Atlantic Ocean approximately 100 miles south-west of the coast of Ireland. It is the Air Traffic Control at Shannon, Ireland who first became aware of the tragic event.

1.3.2 On coming to know of the accident, various authorities in Ireland took immediate action. The Shannon ATC asked the Marine and Rescue Coordinating Centre there to take emergency action. Thereupon MRCC, Shannon asked Valantia Coast Radio Station (CRS) for a PAN broadcast requiring all the vessels in areas 51N/1250W to keep a look out for the wreckage of an aircraft. The PAN broadcast was repeated and all ships were directed to proceed to the site of accident which was determined as 5101.9N/1242.5 W.

1.3.3 Irish authorities also took great pains in rendering every possible assistance to the Indian and other authorities. Some of the wreckage which had floated in to the west coast of ireland was transported to Cork where a boat house had been hired by the Government of India. The wreckage which was placed in the said boat house was protected from any outside interference by the local Gardai (police).

1.3.4 Irish ships proceeded to the scene of accident and helped in search and rescue operations. The ATC at Shannon gave details about the accident, in so far as they were aware of it, and copies of the ATC tapes were supplied. Aer Lingus, national airline of Ireland, provided assistance by making available its local engineering facilities to the coordinating centre at Cork and also to the other authorities.

1.3.5 Cork is a city having a population of approximately 1,34,000. One of the hospitals which was opened in 1978 is the Cork Regional Hospital which had been set up to meet the needs of the people. This 600-bed hospital was designated for the purposes of the Major Accident Plan of the Southern Health Board and thus became the appropriate centre for the reception of the casualities of the Air India disaster. Since the hospital first opened, it had dealt with a number of major accidents involving road, rail and marine incidents. The Major Accident Plan of the Southern Health Board sets out formally, the strategy and procedure which the hopital is required to follow while deailing with major accidents.

1.3.6 On the morning of 23rd June, 1985 at approximately 11.20 A.M. the hospital was put on alert following the disappearance of the Air India Flight 182 off the south-west coast of Ireland. The first message which was communicated to the hospital indicated that it was unlikely that there would be any survivors. The key hospital personnel were alerted and a meeting was arranged in the hospital for the purposes of discussing and making arrangements for the receipt of the bodies on the basis of the information which was available at that time.

1.3.7 On being informed that there were no survivors in the accident and that the hospital should be prepared to receive a large number of bodies, then, in accordance with the Major Accident Plan, mortuary facilities were improvised by appropriating the gymnasium attached to the Deparatment of Rheumatology. Subsequently it became evident that additional mortuary and postmortem facilities would be needed. In order to decide where the second mortuary was to be located, the hospital had to take into cosideration the following factors:-

(a) The number and the condition of the bodies;

(b) The period during which the bodies would be retained;

(c) The hospital would be required to provide an on-going service for in-patients, out-patients and serious accident and emergency cases;

(d) To avoid unnecessary internal transport problems, the bodies should be near the Post-Mortem and Pathology Departments; and

(e) To facilitate traffic flow in the hospital curtilage and to to aviod unduc public access.

The hospital authorities accordingly located the second mortuary in a recreational room adjoining the gymnasium.

1.3.8 Two rooms were put at the disposal of the Garda (Police) authorities for use as Garda Control Rooms in the hospital. Telecommunications lines were set up immediately for their assistance as the Gardai was responsible for the forensic and identification procedures in regard to the bodies brought to the hospital.

1.3.9 A small Co-ordinating Group was set up consisting of the Chief Executive Officer of the Southern Health Board, Medical Co-ordinating

Officer, Press Liaison Officer, a Senior Registrar who knew about Indian customs and traditions and a Hospital Administrator. This small Co-ordinating Group, whose membership never changed, worked together and were capable of assessing situations, making decisions, liaising with other agencies and services and undertaking with other agencies and services and undertaking responsibility for hospital press releases. Apart from individual contact between members, the Group had a standing arrangement to meet every morning and afternoon. In the late evening, the Group, met the Garda, Hospital Pathologists and key staff members for a general review of progress and to decide the tasks and objectives for the following day.

1.3.10 Within a few hours, the Co-ordinating Group realised that the hospital was a world focal point of the international media, and was required to:

a. Accommodate 131 bodies;

b. Provide pathological and Radiological services for each body;

c. Co-operate with the Garda in their forensic work;

d. Cater for relatives of the victims;

e. eet representatives of foreign Governments; and

f. Keep press agencies informed.

Thus began an operation which demanded a quick and dedicated response from all staff working in close cooperation with the Gardai. At the same time, the hospital was required to continue functioning in the delivery of normal in-patient and out-patient services. The Major Accident Plan, apart from alerting staff, provided the framework and basis for many decisions taken as events evolved. An additional advantage in the practical implementation of the Plan was the fact that the hospital had staff experienced in dealing with previous emergency situations and could marshal the extensive manpower resources available.

1.3.11 The hospital authorities also made the following arrangements:-

a. They briefed Government Ministers and Officials and other dignitaries who visited the hospital. They were taken round the hospital and were explained the arrangements which had been made.

b. Some of the services which were being provided at the hospital were either discontinued or postponed.

c. Bodies were received at the hospital and arrangements were made on their arrival to numerically label and certify as dead all the 131 bodies which were initially received. All the bodies, at that stage, had been individually placed in special purpose body bags. Initially, bodies were placed on tables, but, it was subsequently decided that it would be much easier for all concerned to place the wrapped bodies on polythene covered floors.

d. Arrangements were made for carrying out of the post-mortem examinations. Three Pathologists from other city Hospitals were recruited to augment the existing staff. Dr. Harbison, State Pathologist, was in charge of this aspect of the operation. All the post mortem were completed by 27th June, 1985.

e. For the preservation of the bodies five refrigerated containers with a capacity to hold 140 bodies were hired. These containers were fitted with timber shelving.

f. Government Information Service was located in the Matron's Office.

g. The Army provided troops for the unloading of the bodies from the helicoplers at Cork Airport. They also supplied and erected two large tents for storing bodies after post mortem and embalming. Under Garda escort transport of all the bodies which were recovered was undertaken by the

Army and these arrangements were co-ordinated by Chief Ambulance Officer.

h. Embalming was carried out in the hospital and bodies were then coffined and the coffins with appropriate number plaques were subsequently laid out in the numerical order on the floor when all the post mortems had been completed.

I. All the embalmed bodies were x-rayed (whole body). The examination was completed on 28th June, 1985.

j. A provision was made for a 24 hour extended catering service to meet the needs of staff, Gardai, Army and other personnel involved including visiting relatives.

k. A simple plan was devised for dealing with the relatives. This was a sensitive task bearing in mind the varying religious beliefs, customs and cultures generally of the visiting relatives. Their main function was to provide moral and emotional support to the relatives.

l. As identification progressed, special arrangements were made to assist the relatives. They were met by teams of councellors from the Hospital as soon as they disembarked at Cork Airport and subsequently at the Hospital. The relatives had the same Counsellor and Garda Officer throughout the identification procedure. An interesting development noted was that each family group of relatives, their Counsellor and Garda officers formed a single family unit transcending cultural barriers. On subsequent visits, families appeared lost if their own Counsellor was not immediately available to them. Usually, the Counsellor and the Garda officers accompanied the relatives, at their own request, for visual identification.

m. When plans were being formulated to receive the relatives, it had been hoped to discourage them from coming to the Hospital until such time as progress had been reported on the identification process. Practical experience subsequently proved this strategy to be inappropriate for a number of reasons. Apart from facilitating the collection from relatives of salient information on the victims, the most fundamental reason was the underestimation of the abiding wish of the relatives to be physically and psychologically as close as possible to their deceased dear ones. Moreover, it was the express wish of almost all relatives on arriving at Cork Airport to proceed directly to Cork Regional Hospital; there, they were given an informal talk by Air India and Garda representatives on the progress of the investigation and the methods of identification. Many of the relatives visited the hospital daily and remained there throughout each day.

n. Coach trips were arranged to Bantry Bay for the relatives; Bantry Bay is the nearest landmark from the site of the crash. Relatives visited the seaside to pay their last respects to the departed souls. These were solemn occasions when each relative prayed in his/her own way. Rose petals and wreaths were immersed in the sea in keeping with Indian traditions. The visit gave them mental satisfaction and in the early days following the crash, helped in diverting their attention while the investigative procedures were being completed.

o. A small number of visiting relatives had personal medical problems and they were treated at out-patient and in-patient levels at the Hospital.

p. Cork/Kerry Tourism Organisation helped to co-ordinate the accommodation of relatives between a number of hotels. Approximately seven hotels were used within a radius of twenty miles of the city for this purpose.

g. A number of press conferences were held. The Chief Executive Officer, directed that press photography and television filming be not allowed within the hospital in deference to the privacy of patients and in respect for the relatives wishes.

r. Responsibility for the identification of bodies rested with the Garda Authorities and the conditions under which bodies were released are summarised as follows :-

(I) Satisfactory identification

(ii) Consent of the Coroner

(iii) Proper authentification of the person claiming each body

All bodies arriving at Cork Regional Hospital had already been numerically labelled by the Garda Authorities. To prevent confusion, the bodies were then given identical numbers under the hospital major accident labelling system and this proved to be very helpful later during identification, investigations and recordings. A routine was established for examining and recording information about each body. Teams consisting of a doctor, nurse, clerical officer and Garda made the necessary examination, labelling and recording each body and such details as :-

a. Sex

b. Adult or child

c. Clothing

d. Jewellery and personal effects
e. Injuries
f. Obvious scars

Death was confimed in all cases. Each body was fingerprinted and photographed by Garda Technical Bureau Staff. Each body was subjected to autopsy, forensic and dental examination. All bodies were embalmed and following embalming, were photographed and x-rayed. This procedure was completed in respect of all the bodies by the evening of the fifth day of the crash. The data from these investigations was collated on an Interpol form (pink) for each body. Similar ante-mortem information was obtained from the relatives about each victim on a separate Interpol form (yellow). When the information on the pink and yellow forms matched beyond doubt, a positive identification was made. It might be noted that the photographs originally taken by the Garda Technical Bureau Officers of each body were matched with photographs of the 131 embalmed bodies. When a positive identification was made, the relatives were shown photographs of the deceased. These photographs were available for inspection by Saturday, 29th June. As positive identification progressed,

personal effects were added to the identification process and finally, visual identification took place. For obvious forensic reasons, positive identification was necessarily slow and meticulous and, in fact, was made more difficult by reason of the fact that only 131 bodies out of the 329 passengers and crew were recovered. All 131 bodies were identified, the first positive identification was made on 27th June and the last on the 6th August. Each coffin had affixed to it a metal plaque clearly indicating the number assigned in the first instance to the body it contained. The bodies when identified were released by the Garda Authorities through the undertaker. The Coroner directed that a reasonable time would have to elapse before unidentified bodies could be disposed off an this was to be by way of burial. The final date for this purpose was fixed for 3rd August, 1985, but, this date was subsequently extended to 6th August, 1985, to coincide with the date of the Civic Commemoration Ceremony.

(s) Bodies of victims for identification were brought individually to separate viewing rooms, suitably decordated with flowers and with incense burning. Visual identification was performed in private by the relatives and moreover, it allowed them to pay their last respects in their own religious beliefs. An adjoining room was also made available where they could grieve in private. Subsequently, it was learnt that these arrangements were much appreciated by the relatives who articulated this appreciation by commenting that the arrangements provided were as near as possible to the funeral rites observed in their domestic communities. The relatives were of the opinion that the special arrangements made conveyed a deep personal and individual response to the dignity of each victim which might otherwise be lost with such a large number of bodies.

(t) Procedures were laid down which were required to be followed and observed for the purposes of preventing infection.

(u) On 6th August, 1985 an interdenominational service was held in the morning. In the evening on that day a Civic Commemoration Ceremony was held which was attended by a large number of persons.

(v) A formal inquest was held by the Coroner in the Courthouse, Cork, which commenced on 17th September, 1985 and ended on 23rd September, 1985. The Coroner's Jury returned a verdict in accordance withmedical and pathological evidence.

ACTION TAKEN BY THE COURT

1.4.1 Despite the fact that Mr. H.S. Khola had been appointed as the Inspector of Accidents under Rule 71 of the Aircraft Rules, the Government thought it proper to appoint Mr.Justice B.N. Kirpal as the Court to investigate into the circumstances of the accident.

1.4.2 The appointment of the Court was made under Rule 75 of the Aircraft Rules, which is as follows :-

"75. Formal Investigation - Where it appears to the Central Government that it is expedient to hold a formal investigation of an accident it may, whether or not an investigation or an inquiry has been made under rule 71 or 74, by order direct a formal investigation to be held and with respect to any such formal investigation the following provisions shall apply namely

(1) The Central Government shall appoint a competent person (hereinafter referred to as "the Court"), to hold the investigation, and may appoint one or more persons possessing legel, aeronautical, engineering, or other special knowledge to act as assessors, it may also direct that the Court and the assessors shall receive such remuneration as it may determine.

(2) The Court shall hold the investigation in open court in such manner and under such conditions as the Court may think fit most effectual for ascertining the causes and circumstances of the accident and for enabling the Court to make the report hereinafter mentioned.

(3) (i) The Court shall have, for the purpose of the investigation, all the powers of a Civil Court under the Code of Civil Procedure, 1908 and without prejudice to those powers the Court may :-

(a) enter and inspect, or authorise any person to enter and inspect, any place or building, the entry or inspection whereof appears to the court reguisite for the purpose of the investigation; and

(b) enforce the attendance of witness and compel the production of documents and material objects; and every person required by the Court to furnish any information shall be deemed to be legally bound to do so within the meaning of section 176 of the Indian Penal Code.

(ii) The assessors shall have the same powers of entry and inspection as the Court.

(4) The investigation shall be conducted in such manner that, if a charge is made or likely to be made against any person, that person shall have an opportunity of being present and of making any statement or giving any evidence and producing witness on his behalf.

(5)Every person attending as a witness before the Court shall be allowed such expenses as the Court may consider reasonable: Provided that, in the case of the owner or hirer of any aircraft concerned in the accident and of any person in his employment or of any other person concerned in the accident, any such expenses may be disallowed if the Court, in its discretion, so directs.

(6)The court shall make a report to the Central Government stating its findings as to the causes of the accident and the circumstances thereof and adding any observations and recommendations which the Court thinks fit to make with a view to the preservation of life and avoidance of similar accidents in future, including, a recommendation for the cancellation, suspension or endorsement of any licence or certificate issued under the rules.

(7)The assessors (if any) shall either sign the report, with or without reservations, or state in writing their dissent therefrom and their reasons for such dissent, and such reservations or dissent and reasons (if any) shall be forwarded to the Central Government with the report. The Central Government may cause any such report and reservation or dissent and reason (if any) to be made public, wholly or in part, in such manner as it thinks fit."

1.4.3 The Court, which is appointed under Rule 75, does not act as a 'Commission of Inquiry' which is usually appointed under the Commissions of Inquiry Act to inquire into any definite matters of public importance. The role of the Court, on its appointment under Rule 75 of the Aircraft Rules, is essentially that of an Investigator. It is for this reason that no procedure has been prescribed in the Rules which the Court is required to follow. While carrying out its functions, the Court is not only required to comply with the provisions of the Aircraft Act, and the Rules framed thereunder, but it must necessarily also keep in view the provisions of ICAO Annex. 13.

1.4.4. As an Investigator, investigating into an accident, the Court had to perform multi-farious duties and functions. Before referring to them, it would be pertinent to point out that whereas an Inspector of Accidents, who is appointed under Rule 71, would normally be belonging to the Civil Aviation Department and would have all the machinery available to him for conducting the investigation, the Court, when it is appointed to hold an investigation under Rule 75, lacks the basic infrastructure to conduct the investigation of such a magnitude. Assessors are appointed to assist the Court but the actual investigation work cannot be carried out by them. Despite these handicaps, the investigation continued smoothly primarily due to the fact that whenever directions were issued by the Court to any of the participants before it or to the Civil Aviation Department or any other Organisations, the directions of the Court were readily complied with. On a few occasions it also became necessary to require the Assessors to conduct the investigation, which they did with the help of other organisations.

1.4.5 As an Investigator, the first task which was undertaken was to see that the tapes from the Cockpit Voice Recorder, which had been salvaged, were recoverd from the recorders and subsequently analysed. Requisite directions were issued and the tapes were removed from their respective recorders on 16th July, 1985. This operation was carried out at the Air India workshop at Santacruz in the presence of the accredited representatives of Lockheed (manufactures of DFDR), Fairchild (manufacturers of CVR), Boeing Airplane Co., Canadian Air Safety Board (CASB), National Transportation Safety Board, USA (N.T.S.B), Air India and Government of India. The tapes so recovered were subsequently played and analysed.

1.4.6 On an appointment being made under Rule 75 the Court would become incharge of overall investigation of the accident. In that capacity, and in order to effectively discharge its functions, it became necessary for the Court to undertake the following tasks :-

(a) For getting first hand information, the Court had to personally inspect the wreckage which had been recovered and was housed in a boat yard in Cork. While in Cork opportunity was also taken to go to the Cork Regional Hospital and to have discussions with and be briefed by the hospital staff. A trip was also made to Shannon with a view to see and understand the working of the Secondary Radar System which was in use there. On this visit the original ATC tape, which contained communication betwen Kanishka and the ATC, was also heard.

As it was suspected that there may be a link between the blast which had taken place at Narita Airport on 23rd June, 1985 and the accident to Air India's flight 182, it was felt necessary to inspect the site of the bomb blast at Narita Airport.

On the aforesaid visit to Tokyo, the site where the blast had taken place was inspected which gave some, though very vague, idea of the detonating power of the blast. While in Tokyo meetings and discussions were also held with the police and Aviation Authorities. The Court also had the advantage of being able to meet members of the team investigating into the Japan Airlines Flight JL 123 accident which had occurred near Tokyo on 12th August, 1985. Similarities and dissimilarities between the two accidents were, to some extent, noticed and some information was exchanged.

Information was received, that some floating wreckage had been picked on the coast of England and it was possible that some of the places, which were so received, should be subjected to further detailed chemical and metallurgical examination. In order to decide this, it became necessary to visit RADRE, Kent, U.K. As a result of the inspection and the discussions there, it was decided by the Court that the pieces so recovered should be sent to BARC at Bombay for further analysis.

(b) Directions had to be given, from time to time, with regard to the mapping and salvaging of the wreckage which was being effected. It had to be decided as to how, and in what areas, the Scarab should continue to map the wreckage and take video films and still photographs. Based on the information received therefrom and after discussions with the experts, both Indian and foreign, a list was drawn up indicating the items which had to be salvaged. As the weather was likely to be unpredictable, with a possibility of its deteriorating rapidly, a priority list of items to be salvaged had also to be prepared, and this was done. In view of the fact that the Canadian ship John Cabot and the Scarab had a limited capacity, with regard to the size and weight of pieces which could be lifted from the bottom of the ocean, decision had also to be taken with regard to the deployment of another ship. As a consequence thereof a ship 'Kreuzturm' was also engaged in salvage operations.

(c) Directions had also to be given assigning work and duties to different teams of persons. As an Investigator, the Court was incharge of the entire work of investigation which was being carried out in different parts of the world. It not being possible for the Court itself to undertake all the tasks, decisions had to be taken as to how the investigating work was to progress and who would carry out the directions issued from time to time. For example, immediately after reaching Cork on 25th July, 1985 it was felt necessary that a team should be immediately sent to Canada in an effort to get relevant information from there in connection with the flight AI 182. Accordingly, a team of 3 persons headed by Mr. H.S. Khola was directed to proceed to Canada immediately. As a result of the efforts put in by this team, and with the considerable amount of cooperation, help and assistance rendered by the Canadian Authorities valuable information was received by the Court having direct bearing on the investigation. Yet another example in this regard was of requiring Dr. V. Ramachandran, one of the Assessors and an expert in Metallurgy, to be stationed on board the salvage ships during the recovery operations. The procedure which had to be followed by him was also determined. Information about the progress of the salvage operations was communicated on telephone to the Court at all times of day and night. On receipt of such information further instructions, when ever necessary, used to be issued.

(d) Discussions were held with the Indian experts in order to understand some of the complicated questions which had arisen during the investigation.

In an effort to be able to fully appreciate the effect of decompression, the Court visited the Institute of Aviation Medicine at Bangalore where explsoive decompression was simulated for the Court's benefit. Discussions were also held with other experts of aviation medicine who were also given copies of the post-mortem reports for their opinion. National Aeronautics Laboratory was also visited in Bangalore where meeting was held with experts in aerodynamics, structure and metallurgy. Visits to Bombay where more frequent and necessary so that the Court could get first hand information with regard to the work which was being done at BARC.

The investigation involved looking into matters concerning aviation, electronics, medicine etc. Not being familiar with these branches, the discussions which were held, were of immense help and assistance to the Court who had to understand all the evidence and information which it was gathering.

(e) The accident had attracted world wide attention. Right from the start of the investigation by the Court when the recorders were first opened in Bombay on 16th July, 1985 till the conclusion of the hearing, the Press and the TV were eager for information. It was felt that rather than the media resorting to speculation of getting wrong information, the Court itself or its representative should, as and when necessary, brief the media. In this connection interviews were given, both in India and abroad, which were broadcast over the television and printed in the Press. As a result of this, correct information was disseminated with regard to the progress of the investigation without disclosing the Court's opinion on the evidence which had been received.

(f) Finally, the Court had to conduct the formal investigation in Court. For this purpose it laid down the procedure which would be followed. Rule 75 of the Aircraft Rules required that the investigation would be in open court. It was, however, felt that in this particular case it would be advisable that some evidence should be obtained in Camera. The Court, accordingly, recommended that necessary amendment should be made in Rule 75 so that the Court was given the power to hold certain proceedings in camera when the circumstances so warranted. The suggestion of the Court was accepted and that resulted in Rule 75(2) being amended and, as a result thereof, the Court was given the power to hold proceedings in camera if the stipulated conditions existed.

COMMENCEMENT OF FORMAL INVESTIGATION

1.5.1 The object of setting up a court to investigate into an accident is primarily to find out the causes and circumstances of the accident and thereafter to make recommendations. Such an investigation is not in the nature of an adversary litigation between the participants before the Court. As such it should be the endeavour of all the participants to assist the Court in arriving at a correct conclusion.

1.5.2 Under Rule 75 of the Aircraft Rules, the procedure which has to be followed in the investigation of an accident is to be determined by the Court itself. While laying down the procedure which is required to be followed, the endeavour of the Court has necessarily to be to adopt such procedure which would help the court in being able to complete its task satisfactorily, and in the shortest possible time. Whenever an accident takes place, it is of utmost importance that the cause of the accident must be ascertained at the earliest so that if any remedial measures are to be taken then those steps should be taken without any undue delay.

1.5.3 In the present case, there were a number of factors which had to be kept in view while determining the procedure whichshould be followed. The accident had occurred over international waters and approximately at a distance of about 5000 miles from the place where the investigation was to be conducted, namely, New Delhi. The ill fated flight itself had commenced from Canada, and this meant that most of the evidence would only be available there. Matters were not simplified by the fact that the debris itself was lying at the bottom of the ocean, 2 miles under water. It became apparent, at the very beginning, that to recover the entire debris would be a superhuman task and it will not be possible to do so within the limited time span which was available.

1.5.4 It was thought that it would be of assistance if all the participants got together so as to determine what procedure should be followed. The procedure had to be such which would give an effective opportunity of hearing to all the participants, without in any way unduly prolonging the investigation.

1.5.5 The Court decided that, in order to obtain the views, it would be necessary and advisable to have a Pre-hearing Conference.

1.5.6 The first decision which had to be taken was as to who were to be given a participants status. Keeping inview the provisions of Annex 13, participants status was given to Governments of Ireland, Canada, USA and India. Similar status was also given to Boeing Airplane Co. and Air India. As there might have been some similarities or dissimilarities between the present accident and the accident of the Japan Airlines Boeing 747-SR and also because there may have been a possibility of the present accident being linked with the explosion which had taken, place at Narita Airport, Tokyo on 23rd June, 1985, an Observer's status was given to the Government of Japan.

1.5.7 Notices for holding of the Pre-hearing Conference on 16th September, 1985 were accordingly issued on 29th August, 1985. The agenda for the Conference was to be as follows :-

a. To make suggestions to the Court for its consideration, regarding the procedure to be followed in the conduct of the formal proceedings in the Court.

b. To draw up a tentative list of witness.

c. To draw up a tentative list of exhibits.

d. To determine the areas to be inquired into

e. To fix a date for the commencement of the public hearing.

f. Any other matter with the permission of the Court.

1.5.8 Except for the Government of Japan, all the other participants were represented at the said Pre-hearing Conference. After discussions had been held between the Court and the Participants, some decisions were arrived at regarding different items of the agenda.

1.5.9 Firstly the following points were framed, indicating the areas to be inquired into by the Court:

a. Whether the accident was caused by a structural failure?

b. Whether the accident was caused by some human effort?

c. Whether the accident was caused by some criminal act?

d. Whether the accident was caused by an external non-criminal act?

e. Based on the evidence on record, what steps should or can be taken so as to ensure greater air safety.

1.5.10 It was further decided that, as suggested by all the participants, at least critical portions of the wreckage should be recovered.

1.5.11 With regard to the recording of the evidence it was decided that evidence will, in the first instance, be taken by filling affidavits or by filling statements alongwith affidavits. Copies of the same were to be supplied to the other participants for their consideration. These affidavits were to be filed on or before 18th October, 1985 and a second Pre-hearing Conference was to take place on 30th October, 1985 at New Delhi when it was to be decided as to which of the persons should be called for cross-examination. It was determined that it is only thereafter that hearing would commence in open court.

1.5.12 A tentative list of witnesses was also drawn up and it was decided that on the next date names of more witnesses may be added and, furthermore, the participants would be free to file any affidavits which they deem fit including affidavits in rebuttal.

1.5.13 Another important decision which was taken at the Pre-hearing Confence was that a Structural Group was formed consisting of (1) Mr. H.S. Khola or his nominee (2) Representative of the Canadian Government (3) Representative of NTSB, USA (4) Representative of Boeing Airplane Co., USA (5) Representative of Air India. This group was entrusted with the task of examining and analysing, initially in Seattle, USA, the video films and the still photographs of the wreckage. This group was also to indicate and decide the items of priorities of wreckage which had to be recovered. The report of this group was required to be submitted by 18th October, 1985. The report of the work done at Seattle was in fact submitted only on 25th October, 1985. This group was also given the liberty to associate any other experts or persons from Boeing or any other Authority. The group was also to inspect the floating wreckage which had already been salvaged and any further wreckage which would be salvaged.

1.5.14 Although the affidavits by way of evidence had to be filed by 18th October, 1985, it was only the Government of Ireland who filed an affidavit by at date. On behalf of the Government of India, an application was filed asking for more time. The reason stated was that the affidavit which had to be filed was to be of Mr. H.S. Khola but he was out of India as he was heading the structures group which was evaluating the video films and photographs at Seattle. The Court had no option but to grant further time to the Union of India to file its affidavits and this necessarily resulted in the adjournment of the Pre-hearing Conference which had been fixed for 30th October 1985.

1.5.15 As the salvage operations were reaching a critical point it became necessary for the Court to go to Cork on 27th October, 1985. Taking advantage of the presence of the Court in Cork, other participants also came there. Besides them, representatives of CP Air and Air Canada also arrived. At one of the informal meetings between the Court and the representatives of the participants, applications were filed by CP Air and the Air Canada, inter alia, praying that they should be permitted to participate in the investigation. It might be mentioned here that CP Air had interlined one of the passangers from Vancouver to AI-182, while Air Canada was the handling agents in Canada of Air India. After hearing the participants it was decided that participant status should also be given to these two viz., CP Air and Air Canada.

1.5.16 The participant had all filed their affidavits by way of submissions. The Court indicated that formal hearings would be held for the purpose of cross-examining some of the witnesses about three weeks after the receipt of all the reports of the various groups. While in Cork, in the first week of November, 1985 some of the salvaged pieces of the wreckage were brought there. After they were inspected by all the participants and their advisers, who were present in Cork, it was decided by the Court that further detailed metallurgical and other examination of those pieces would be done at BARC, Bombay. In order that there should be no undue delay the Court decided that a Group be constituted consisting of expert representatives of all the participants and also the nominees of the Court. This group was asked to carry out metallurgical and other examination of some of the critical pieces salvaged and give its report to the Court. The group consituted as a 'Committee of Experts' was as under :-

a. Mr. A.J.W. Melson, Canadian Aviation Safety Board, Canada.
b. Mr. R.K. Phillips, Canadian Pacific Air, Canada.
c. Mr. T. Swift, Federal Aviation, Administration, USA.
d. Mr. R.Q. Taylor, Boeing Commercial Airplane Co., USA.
e. Mr. J.P. Tryzl, Boeing Commercial Airplane Co., USA.
f. Mr. J.F. Wildey II, National Transportation Safety Board USA.
g. Mr. S.N. Seshadri, Bhabha Atomic Research Centre, India (Coordinator).

1.5.17 The parties were informed in Cork that the report of Mr. H.S. Khola, Inspector of Accidents, would be available by about 8th November, 1985. It was then decided that the statements of the first batch of witnesses should be recorded from 20th November, 1985. It was also agreed that if some of the reports of the experts were not received, further examination of the witness may have to postponed.

1.5.18 After receipt of the report from Mr. Khola. on the 8th November, 1985, a notice of the holding of the Public Hearing was issued to all the participants. This notice indicated that the hearing would commence on 20th November, 1985. In the meantime, a Public Notice was also published in the daily "Times of India" in Delhi and Bombay editions on 21st October, 1985 in which it was stated as follows :-

NOTICE AIR INDIA KANISHKA ACCIDFNT INVESTIGATION

The Government of India, vide Notification dated 13th July, 1985, appointed Hon'ble Mr. Justice B.N. Kirpal as a Court to investigate into the accident to Air India's Boeing 747 aircraft VT-EFO (KANISHKA) near the Irish Coast on 23rd June, 1985, when the aircraft was engaged on a scheduled passenger flight from Montreal to Bombay via London and New Delhi.

Any person having direct knowledge, who may desire to make representation concerning the circumstances or causes of the accident, may do so in writing in the form of an affidavit duly attested by an Oath Commissioner or a Notary Public and address the same to the undersigned so as to reach him within 15 days of the publication of this Notice.

S.N. SHARMA SECRETARY COURT OF INVESTIGATION COURT NO.10,DELHI HIGH COURT SHERSHAH ROAD NEW DELHI - 110 003

Pursuant to the aforesaid public notice no affidavit was received from any one.

1.5.19 The public hearing commenced on 20th November, 1985 and the first session concluded on 28th November, 1985. During this period statements of Mr. H.S. Khola, Wing Commander Dr. I.R. Hill and Sgt. Atkinson of R.C.M.P., Canada were recorded.

1.5.20 Till that date, report on the examination of the salvaged pieces had not been received. It was anticipated that the report would be available by mid December, 1985. In order to give the parties sufficient time to study the reports of all the experts it was decided that further evidence would be recorded from 22nd January, 1986.

1.5.21 After the reports were received from BARC; AIB; Farnborrough; NTSB; USA; and Mr. Bernard Caiger of CASB, Canada and the copies of the same had also been received by all the participants, recording of evidence commenced from 22nd January, 1986 and concluded on 30th January, 1986. In all statements of 13 witnesses were recorded.

1.5.22 At this stage it will be pertinent to make a few observations with regard to the procedure which was laid down for recording of evidence etc. As already indicated, most of the evidence was such which was not available in India. As a Court investigating the accident under the provisions of Aircraft Rules, it had no jurisdication to compel attendance of any witness from abroad. The Court also had no jurisdication, either under the Rules or under the provisions of Annex 13, to require any witness to be examined in a country other than the one in which the Court is holding the investigation. The Court was informed that, if called upon, some of the persons who were outside India may not be inclined to testify before the Court.

1.5.23 Faced with the aforesaid difficulty it became necessary, therefore, to evolve a procedure which would enable the Court to get the requisite information. As long as the Court was satisfied that the information which was being received was one which had been truthfully given by a person, it was immaterial as to the manner in which the information was received. It is for this reason that it was decided that evidence will, in the first instance, be given by way of affidavits. It was also provided that the statements could also be filed along with affidavits. This latter course was permitted so as to enable some of the statements, which had been recorded by members of the Royal Canadian Mounted Police, to be placed before the Court. These statements, of course, had to be accompanied, as they were, with the affidavits of the persons who had recorded the statements.

1.5.24 At one stage, by a formal application in writing, Air India had protested against this procedure being followed. By order dated 22nd

November, 1985, an objection by Air India to the filing of the statements accompanied by affidavits, was dealt with by the Court in the following words :-

"With regard to the affidavits which have been filed by the Government of Canada, I would only like to observe in the Pre-hearing Conference on 16th September, 1985, it was decided that "Evidence will, in the first instance, 1985 be taken by filing affidavits or by filling of Statements along with affidavits." It was understood that if it is not possible to file affidavits of the persons who are in a position to give information then affidavits may be filed of other persons who may have recorded the statements of the persons who are in a position to give information. This is not an adversary litigation where one of the parties may lose because of lack of proof. One of the objects of setting up a Court to investigate into an accident is to find out the causes of the accident and to make recommendations. It is necessary for this purpose to get information which may be relevant. It is true that strictly speaking the statements which are annexed to the affidavits may not be admissible as evidence in a Court of Law when there is a litigation between the parties but considering limitations which we have, namely, where a Court like the present has no jurisdication to enforce the attendance of any witness who is outside this country and furthermore, the Court has no jurisdication to compel any one to give information, the procedure which was adopted was thought to be the most practical one for obtaining information in connection with the accident. Under the circumstances, the affidavits which have been filed along with the statements which have been annexed thereto which give information with regard to the accident, have to be taken on record."

1.5.25 Another advantage of following the aforesaid procedure was that the time which would have been taken in Court in examining of the witnesses was considerably reduced. After the participants had filed affidavits, the same were to be secrutinised and it was then to be decided as to which of the deponents or persons should be called for examination in Court. Effectiveness of this procedure which was adopted is apparent from the fact that though affidavits by way of evidence were filed in

Court, ultimately only 13 witnesses had to be examined in Court and sitings were held in Court only on 14 days.

1.5.26 Written arguments were filed on the forenoon of the 4th February, 1986 and oral arguments were heard in the afternoon of that day. No written arguments or oral submissions were made by the Government of Ireland, CP Air or Boeing Company.

1.5.27 Mr. I.G. Whitehall, councel for the Government of Canada took exception to some of the submissions which were contained in the written submissions filed by Air India. Mr. Whitehall contended that the Court had opined that it will not go into the question of responsibility of the unfortunate accident and therefore, there was no; justification for Air India to include in its written submissions numberous passages which tended to fix responsibilities.

1.5.28 By the order dated 4th February, 1986, it was made clear that it was not the intention of the investigation to apportion blame if any lapse had been committed and, therefore, the Court would ignore any written submissions which tended to apportion blame or responsibility for any lapse of any participants. It might here be mentioned that such a question had earlier arisen while the statement of Sgt. Atkinson was being recorded. The Court had then held that it will not go into the question as to who was responsible for the accident. It was in view of this order that no evidence was led by any of the parties on the question as to who may have been responsible for any possible lapse which could have led to this accident.

2.1 Flight Preparation

2.1.1. Air India Boeing 747 aircraft VT-EFO 'Kanishka' was operating flight AI-181 (Bombay-Delhi-Frankfurt-Toronto-Montreal) on 22nd June, 1985. From Montreal it becomes AI-182 from Mirabel to Heathrow Airport, London enroute to Delhi and Bombay. The aircraft arrived at Toronto from Frankfurt at 1830 Z and was parked at gate No. 107 Terminal 2 at L.N. Pearson International Airport. In accordance with the Canadian regulations, all the passengers and their baggage were off loaded to complete the customs and immigration checks. Transit cards were handed out to 68 transit passengers destined to Montreal who disembarked at Toronto for customs and immigration checks.

2.1.2. The flight from Toronto to Montreal was made up of the following:-

(I) Passengers originating at Toronto and their baggage.

(ii) Transit passengers, and their baggage, continuing their flight to Montreal.

(iii) Two diplomatic bags from Indian Consulate General, Vancouver via Air Canada Cargo Flight, and some Air India Mail.

(iv) Fifth Pod engine and its associated parts.

(v) Interline passengers and their baggage from connecting flights as detailed below:-

a) Air Canada flight AC-102
from Sasktoon - 2 Passengers

b) Air Canada flight AC-106
from Edmonton - 4 Passengers

c) Air Canada flight AC-170
from Winnipeg - 1 Passenger

d) Air Canada flight AC-170
from Winnipeg - 4 Passengers

e) Air Canada flight AC-136
from Vancouver - 10 Passengers

2.1.3. One passenger by name 'M. Singh', checked in at Vancouver on Canadian Pacific flight CP-060 (Vancouver-Toronto) of 22nd June 1985, and got his one piece of baggage interlined to Air India flight AI-181
even though he had no confirmed reservation on AI-181. This passenger, however, did not board the flight CP-060 at Vancouver and also did not check-in for Air India flight AI-181/182 at Toronto.

2.1.4 The checking-in of passengers for Air India flight AI-181/182 at Toronto began at 1830 Z. The checking-in of the passengers was carried out by Air Canada personnel who are the handling agents for Air India, and was supervised by Air India personnel. The Air Canada personnel indicated the computer sequeritial numbers (security numbers) on the passenger boarding card stubs. At about 1930 Z announcement was made for the primary security check of passengers and their hand baggage. The passengers passed through the Door Frame Metal Detector and their hand baggage was checked through X-Ray machine. The passengers were also subjected to physical security check with the help of Hand Held Metal Detectors. The transit passengers to Montreal and their hand baggage were also subjected to these security checks, while their checked in baggage, after clearance by the Canadian Customers authorities was placed by the passengers themselves on the conveyor belt while they were still in sterile area. In this way there was personal identification by the passengers of all checked in baggage, except the baggage which had been interlined to this flight.

2.1.5 The flight was closed for check-in at about 2150 Z. There were 10 'NO SHOWS' and 4 'GO SHOWS'. The security checked passengers remained in the holding area gate No. 107 till boarding was announced at about 2210 Z. At the boarding gate secondary security check of the passengers and their hand baggages was carried out. The passengers were frisked with the help of Hand Held Metal Detectors and their hand baggages were opened and physically checked.

2.1.6 The security numbers on the stubs were circled on the pre-numbered Security Control Sheet to ensure that all the checked-in passengers have boarded the aircraft. Passenger boarding was completed by 2300 Z. Traffic/Sales representative of Air India verified the Security Control Sheet with the number of stubs collected and the number of passengers checked-in.

He found that all the 202 passengers, who had checked-in, had boarded the aircraft.

2.1.7 As stated earlier, 68 transit passengers had disembarked at Toronto for completing the customs and immigration checks. However, only 65 of these passengers re-boarded the aircraft as per transit cards collected at the boarding gate. It is in evidence that almost every flight of Air India to Canada, two or three transit passengers do not re-board the flight at Toronto. Some Toronto passengers travelling to India buy their tickets "Montreal-India-Montreal" instead of "Toronto-India-Toronto", for which the fare is higher, and they travel by bus to Montreal to catch the Air India flight to India. On their return journey, when they get down at Toronto for customs and immigration checks, they simply do not re-board the flight even though their reservations are upto Montrteal. These passengers sometimes inform Air India personnel at Toronto about their not re-boarding the aircraft. On 22nd June, 1985, however, no such passenger informed Air India personnel.

2.1.8 There was a crew change at Toronto. The flight and cabin crew members who took over the flight AI-181/182 had been laid over in Toronto for the week prior to the accident flight and were scheduled to take the flight upto London where they were to be relieved by another set of crew. Capt H.S.Narendra was the Commander of the flight, with Capt S.S.Bhinder as co-pilot and Mr.D.D.Dumasia as the Flight Engineer. In addition there were 19 cabin crew members. All the crew members reported together at the airport at 2130 Z. As per the practice existing at that time, the flight crew and cabin crew members were not subjected to frisking checks and their hand baggage were also not security checked. Their checked-in baggage was, howevewr, security checked along with the other checked-in baggage of passengers.

2.1.9 The interline baggage was brought to the international baggage make-up area by the Air Canada staff but, as mentioned earlier, it was not personally identified and matched with the passengers.

2.1.10 The checked-in baggage of the originating passengetrs and crew members of AI-181/182 was sent on a conveyer belt to the baggage make-up area. All the checked-in baggage along with the interline baggage was required to be security checked on the X-ray machine which was located in the baggage make-up area at the end of international belt No.4.

2.1.11 It has been reported that the X-ray machine worked intermittently for some period and at about 2045Z it broke down and there was no picture on the screen. The Machine could not be repaired on that day as it was a week-end and no technician could be contacted. Air India's Security Officer then advised that the rest of the baggage be checked with a PD-4 explosive detector provided by him. He also demonstrated the use of the PD-4 detec- tor to the concerned personnel.

It has been reported that about 60 to 70 baggages were checked and cleared by the PD-4 detector.

2.1.12 The security checked baggage was loaded in the containers by the Air Canada personnel. The loading of the baggage in containers was over by about 2230 Z. The ramp personnel of Air Canada carried the container and loaded them in the aircraft.

2.1.13 From March, 1985, after the introduction of Air India flight AI-181 through Toronto, diplomatic bags from Indian Consulate General at Vancouver were being sent to India by Air India flight from Toronto. Accordingly, two diplomatic bags, duly sealed and escorted, were delivered to Air Canada office at Vancouver on 21st June and they arrived at Toronto by Air Canada flight AC-580. One of the bags Sl.No. 49 contained 13 empty large diplomatic bags while the other bag Sl.No. 50 contained diplomatic mail. The total weight of the bags was 13.8 Kgs.

2.1.14 In addition to the above, a few envelopes containing some flight documents addressed to Accounts Office, Air India, Bombay, and one envelope addressed to Commercial Headquarters, Air India, Bombay from Air India Town Office in Toronto, were collected by Messrs Mega International.

2.1.15 The aircraft was refueled by CAFAS with 14,602 litres of fuel.

2.1.16 On 8th June No. 1 engine of Air India Boeing 747 aircraft VT-EGC had failed during take off. The failed engine was to be ferried to Bombay on flight AI-181/182 of 22nd June.

2.1.17 The failed engine and the associated parts were placed in Air Canada Engineering Hangar at Toronto airport since June 8,when the aircraft was brought to the engineering hangar for engine replacement. Air India had requested Air Canada on 15th June for preparing the failed engine for installation as fifth pod mounting of the aircraft on 22nd June.

2.1.18 On 15th June Air India deputed one of their foremen to Toronto to bring back the failed engine. From 17th to 21st June, Air Canada technicians prepared the failed engine for installation as fifth pod. This preparation involved removal of cowlings, fan blades, locking of compressor rotors etc. Air Canada Engineering/Maintence personnel loaded the aircraft/engine parts on 4 pallets and one container. These pallets and container were then delivered at 0100 Z on 22nd June by Air Canada personnel to Messrs Mega International cargo warehouse at Toronto Airport within restricted airport area. (Messrs Mega International Cargo Warehouse at Toronto Airport within restricted airport area. (Messrs Mega International is the cargo handling agent of Air India at Toronto). The fifth pod engine was transported by Air Canada directly from their premises to the 'Kanishka' aircraft for mounting it on the fifth pod.

2.1.19 Installation of the engine on the fifth pod began immediately on arrival of flight AI-181 at Toronto on 22nd June and the work was completed by 1930 Z. One of the mechanics of Air Canada installed the Mach Air Speed Warning Switch in the Main Equipment Centre as part of the fifth pod engine installation.

2.1.20 The pre-loaded four pallets and one container were brought to the aircraft by M/s Mega International personnel from their warehouse in the afternoon of 22nd June for loading them into the aircraft cargo compartment at positions assigned by the Air Canada load agent. Difficulty was experienced while loading one of the pallets having inlet cowl of the pod engine. To enable loading of the cowl, Air Canada engineering/maintenance personnel removed door stop fitting from the aft cargo compartment door cut-out. After removal of the fittings, the cowl could be loaded. All the removed fittings were then reinstalled.

2.1.21. On account of the delay in loading the cowls, departure of the flight was delayed by one hour and twentyfive minutes.

2.1.22 Maintenance Manager of Air India, Montreal carried out the Terminal Transit Check 'E' of the aircraft and no snag was observed by him. The commander duly accepted the aircraft.

2.1.23 Senior Flight Despatcher, Air India, Toronto did the flight despatch of AI-181/182 for sectors Toronto-Montreal-London. He briefed the flight crew members about flight plan, weather, Air Traffic Control and fuel requirements. The flight plans for the sectors Toronto-Montreal-London were duly accepted and signed by the Commander.

2.2 Progress of the Flight

2.2.1. The Aircraft took off from Toronto Runway 24L at 0016 Z on 23rd June, 1985. The Maintenance Manager, Security Officer and Passenger Service Supervisor of Air India travelled on board the aircraft for their duties at Montreal. In all there were 270 passengers on board in addition to 22 crew members.

2.2.2. The route from Toironto to Montreal was V-98/JHL-594/MSS/ V 203/FRANX at flight level 290. The flight was uneventful and the aircraft landed at Montreal at 0110 Z. No snag was reported by the flight crew. The aircraft was parked at Cluster 1 Bay No.114.

2.2.3 Sixtyfive passengers destined to Montreal along with the three Air India personnel mentioned above deplaned at Montreal. The remaining 202 passengers, who had joined the flight at Toronto, remained on board the aircraft as transit passengers were not allowed to disembark at Montreal.

2.2.4 Baggage handlers off loaded three containers of baggage, one valuable container and four cargo containers from the aircraft.

2.2.5 Transit Check 'C' of the aircraft was carried out at Montreal. The Flight Engineer also carried out his pre-flight inspection and found that rear latch handle of the fifth pod engine fan cowl was loose. He informed the same to an Air Canada Technician who flaired the handle and applied the high speed tape. There was no other snag observed during the inspection. The personnel of CAFAS refueled the aircraft with 96,000 litres of fuel. Total fuel on board at the time of take off from Montreal was 104,000 Kgs. which was adequate for 8 hours 40 minutes of flying. The commander accepted the aircraft and signed the 'Certificate of Acceptance' of the aircraft.

2.2.6 At approximately 2130 Z Air Canada personnel opened the passenger check-in counter for flight AI-182 (The flight AI-181 terminates at Montreal and the flight from Montreal to London-Delhi-Bombay is designated as AI-182). The checked-in baggage was sent to the baggage make-up area. Between 2300-2350 Z, a suspect suitcase was identified as the X-Ray showed what appeared to be some wires next to the suitcase opening. The suitcase was placed on the floor next to the X-Ray machine. Subsequently two more suspect suitcases were located. These suitcases were also placed next to the X-Ray machine to await the arrival of the Air India Security Officer who was to arrive on Air India flight AI-181 from Toronto. The remainder of the checked-in baggage, which cleared the security check, was loaded in containers by Air Canada personnel for loading on board the aircraft.

2.2.7 Two diplomatic pouches from the Indian High Commission, Ottawa were brought to Mirabel. After the flight arrived, one of the pouches of Category 'A' weighing 1 Kg. was given to the Flight Purser. The other Category 'B' pouch weighing 9 Kgs. was placed in an valuable container 14R.

2.2.8 No other cargo was accepted for this flight except a small package (weighing less than 1 Kg) containing medicines for cancer treatment of a patient in New Delhi. This parcel was received at 1530 Z on 21st June and was loaded in container 14R by Messrs Mega International on 22nd June, more than 24 hours after its receipt.

2.2.9 Five baggage containers, one valuables container and two empty containers were loaded in the aircraft.

2.2.10 The checked-in passengers with their hand baggage went to the departure sterile area. At the entrance to the departure sterile area security staff used X-Ray units and metal detectors to check passengers and their hand baggages.

2.2.11. At approximately 0100 Z, 23rd June, after the primary security check was completed, the passengers proceeded to boarding gate No.80. At this lcoation the secondary security check was done on passengers using hand held metal detectors. Hand baggages were also subjected to further physical and visual check by them.

2.2.12. A total of 105 passengers boarded the flight AI-182 at Mirabel Airport. It was determined that all the passengers who had checked-in, boarded the aircraft. There was no interline passenger. At Montreal there were five 'NO SHOWS' and two 'GO SHOWS'. In all 307 passengers were on board the aircraft. The flight plan and the load and trim sheet, however, indicated 303 passengers as four of the 6 infants were not included in the passenger list.

2.2.13. The seating distribution of the passengers was as given below:-

Zone/Class Total number of Seats Occupied seats Zone 'A' - First Class 16 1 Zone 'B'- Club Class 22 - Upper deck - Club class 18 7 Zone 'C' - Economy Class 112 104+ 2 Zone 'D' - Economy Class 86 84+ 1 Zone 'E' - Economy Class 123 105+ 3 377 301+ 6 (Infants)

2.2.14 The seating distribution of the 19 cabin crew members was as follows:-

Two at door L1 and two at door R1
Two at door L2 and two at door R2
Two at door L3 and one at door R3
Two at door L4 and one at door R4
One at door L5 and one at door R5
One in crew rest area, Zone 'A'
One in jump seat upper deck
One crew rest area upper deck.

2.2.15 The three suspected suit cases were not loaded on the aircraft and were detained in the baggage make-up room. After the names of the passengers to whom the suit cases had belonged had been identified the same were transferred to the decompression chamber of E1 A1 Airline where they were examined, with the aid of a Police Explosive Dog, with negative results. The suit cases were kept overnight in the said chamber and when they were opened it was found that they contained no explosive items.

2.2.16. No unclaimed baggage pertaining to the Air India flight was recovered either at Toronto or at Mirabel or Dorval Airport in Montreal.

2.2.17. The flight plan for the sector Montreal to London was filed on telephone by the Air India Flight despatch from Toronto to Dorval ATC Centre. He requested for route SHERBROOKE-COLOR-NAT XRAYBUNTY-MERLY-EXMOR-IBLEY-SAMTN-HAZEL-OCKHAM-LONDON at flight level 290 upto COLOR and flight level

330 thereafter. The reporting points on Track XRAY on that day were COLOR, 47N/50W, 49N/40W, 50N/30W, 51N/20W, 51N/15W, 51N/08W and BUNTY.

2.2.18 The aircraft took off from Montreal at 0218 Z. Its estimated time of arrival at London was 0833 Z. The CVR and the ATC tapes show that the flight was normal and quite uneventful. Suddenly at about 0714 Z, when the flight was being monitored by the Air Traffic Controller at Shannon, with the help of secondary surveillance radar, the aircraft disappeared from the radar scope. Subsequently, the ATC at Shannon got the know that the aircraft had met with an accident and its wreckage was sighted about 110 miles west south-west of Cork, Ireland.

PERSONNEL INFORMATION

2.3.1 Pilot-in-Command (Capt. H.S. Narendra)

2.3.1.1 Cap.t H.S. Narendra (age 561/2 years, date of birth 25th November, 1928) joined Air India on 1st October, 1956. He held ALTP Licence No. 247 valid upto 29th October, 1985 and FRTO No. 478 valid upto 23rd October, 1985. He was released as a Co-pilot on Boeing 707 aircraft on 21st July, 1960 and as a Commander on Boeing 707 aircraft on 17th September, 1964.

2.3.1.2 For conversion as Pilot-in-Command on Boeing 747 aircraft, Capt. Narendra had undergone ground training at Boeing Airplane Company, USA and simulator and aircraft flying training at Bombay in 1972. He completed his route checks for Pilot-in-Command endorsement between December, 72 and January, 73. He became a Commander on Boeing 747 aircraft on 14th February, 1973.

2.3.1.3 Details of Capt. Narendra's flying experience and licence renewal checks are as given below:

a. Total flying experience : 20, 379:15 hours

b. Flying experience on B-747 as

(i) Pilot-in-Command : 6,364.50 hours

(ii) Co-pilot : 123:45 hours

c. Day flying experience
on B-747 aircraft : 3,980:00 hours

d. Night flying experience

on B-747 aircraft : 2,508:35 hours

e. Flying experience during

(i) last 6 months : 301:45 hours

(ii) last 3 months : 159:40 hours

(iii) last 30 days : 68:45 hours

(iv) last 7 days : 9:00 hours

He had last flown as Pilot-in-Command on flight AI 181 (Frank- furt to Toronto) on 15th June, 1985.

f. Date of last licence renewal and IR check : 8 May, 1985

g. Date of last route check : 24 March, 1985

h. Date of last medical examination at CME, Delhi : 29 April, 1985

i. Date of last simulator refresher course : 19 December, 1984

j. Date of ground technical refresher course : 6/7 May, 1985

k. Date of last flight safety refresher course : 25 July, 1984

l. Rest period before operating the accident flight : 1 week

2.3.1.4 Records indicate that on 29th June, 1966, Captain Narendra was declared medically unfit for 2 months to reduce his weight by 10 Lbs. In February, 1973 he was advised to wear corrective by-focal glasses while flying. In May, 1975 he was again declared medically unfit for 3 months.

2.3.1.5 Capt. Narendra was earlier involved in the following two incidents:

(a) On 25th August, 1984, while operating flight AI-1100 from London to Delhi, there was a deviation of the aircraft by about 170 nautical miles from the track over Rahimyar Khan in Pakistan. He was given necessary INS refresher and Route checks with particular emphasis on cross checking procedure.

(b) On 6th December, 1984, while operating flight AI-124 Delhi-Bombay, the aircraft was observed approaching runway 32 at Bombay Airport when runway in use was 27. Captain Narendra was given simulator training for a series of approaches and landings and visual circuits from right hand and left hands seats for approaches and landings on runway 27 at Bombay Airport.

2.3.1.6 Captain Narendra was not involved in any accident previously.

2.3.2 Co-pilot (Capt. S.S. Bhinder)

2.3.2.1 Capt. S.S. Bhinder (age 411/2 years, date of birth 30th November, 1943) joined Air India on 12th October, 1977. He held ALTP Licence

No. 940 valid upto 25th July, 1985 and FRTO Licence No. 2290 valid upto 2nd February, 1986.

2.3.2.2 Capt. Bhinder was released as a Co-pilot on Boeing 707 aircraft on 18th November, 1978 and as a Co-pilot on Boeing 747 aircraft on 17th May, 1980.

2.3.2.3 Details of his flying experience and licence renewal checks are as given below:

a. Total flying experience : 7,489:00 hours

b. Experience on B-747
aircraft as Co-pilot : 2,469:30 hours

c. Day flying experience
on B-747 aircraft : 1,426:15 hours

d. Night flying experience
on B-747 aircraft : 1,043:15 hours

e. Flying experience during

(i) last 6 months : 157:45 hours

(ii) last 3 months : 65:00 hours

(iii) last 30 days : 20:15 hours

(iv) last 7 days : 9:00 hours

He had last flown as Co-pilot on flight AI-181 (Frankfurt to Toronto) on 15th June, 1985).

f. Date of last licence
renewal check : 25th March, 1985

g. Date of last IR check : 23rd November, 1984

h. Date of last route check : 9 April, 1985

i. Date of last medical
examination at CME
Delhi : 14 January, 1985

j. Date of last simulator
refresher course : 16 July, 1984

k. Date of last ground technical
refresher course : 8/9 October, 1984

l. Date of last flight
safety refresher course : 3 December, 1984

m. Rest period before operating
the accident flight : 1 week.

2.3.2.4 Records indicate that Capt. Bhinder was not involved in any accident earlier.

2.3.3 Flight Engineer (Mr. D.D. Dumasia)

2.3.3.1 Flight Engineer Mr. D.D. Dumasia (age 57 1/2 years, date of birth 10th October, 1927) joined Air India on 27th December 1954. He held flight Engineer's Licence No. 37 valid upto 6th December, 1985. Mr. Dumasia was released as a Flight Engineer on Boeing 707 airecaft on 16th December, 1963 and on Boeing 747 aircraft on 6th February, 1974. He had a total flying experience of 14,885 hours out of which 5,512:35 hours were on Boeing 747 aircraft.

2.3.3.2 Last medical examination of Mr. Dumasia was completed on 1st October, 1984 at CME Delhi. He had completed simulator refresher course on 14th February, 1985, ground technical refresher course on 14/15th January, 1985 and flight safety refresher course on 13th August, 1984.

2.3.4 Cabin Crew

2.3.4.1 A total of 19 cabin crew members were on duty on Flight AI-181/182 on 23rd June, 1985. Their brief details are as given below:

Sl.No. Names Designation Flight Safety course completed on 1. Mr. S.L. Lazar Inflight Supervisor 1/2 April, 1985 2. Mr. K.M. Thakur Flight Purser 18 February, 1985 3. Mr. Inder Thakur Flight Purser 9/10 May, 1984 4. Mr. Shukla Flight Purser 23 January, 1985 5. Mr. S.P. Singh Flight Purser 15 January, 1985 6. Mr. N. Vaid Asst. Flight Purser 2/3 May, 1985 7. Mr. B.K. Sena Asst. Flight Purser 3 December, 1984 8. Mr. N. Kashipri Asst. Flight Purser 12/13 Sept., 1984 9. Mr. J.S. Dinshaw Asst. Flight Purser 17/18 Dec., 1984 10. Mr. K.K. Seth Asst. Flight Purser 11/12 February, 1985

11. Miss Raghavan Airhostess 13 July, 1984 12. Miss S. Ghatge Airhostess 10/11 April, 1985 13. Miss R. Bhasin Airhostess 11/12 February, 1985 14. Miss L. Kaj Airhostess 17/18 April, 1985 15. Miss P. Dinshaw Airhostess 17/18 Dec., 1984 16. Miss S. Lasarado Airhostess 15/16 April, 1985 17. Miss E.S. Rodricks Airhostess 10/11 June, 1985 18. Miss S. Gaonkar Airhostess 3/4 April, 1985 19. Miss R.R. Phansekar Airhostess 29/30 April, 1985 AIRCRAFT INFORMATION

2.4.1 General

2.4.1.1. Boeing 747-237B 'Kanishka' aircraft VT-EFO was manufactured by Messrs Boeing Company under Sl.No. 21473. The aircraft was acquired by Air India on 19th June, 1978. Initially, it came with the expert Certificate of Airworthiness No. E-161805. Subsequently, the Certificate of Airworthiness No. 1708 was issued by the Director General of Civil Aviation, India on 5th July, 1978. The C of A was renewed periodically and was valid upto 29th June, 1985. From the beginning of June, 1985, C of A renewal work of the aircraft was in progress. The aircraft had the Certificate of Registration No. 2179 issued by the DGCA on 5th May, 1978. The commercial flight of 'Kanishka' aircraft started on 7th July, 1978.

2.4.1.2 The aircraft was maintained by Air India following the approved maintenance schedules. It had logged 23634:49 hours and had completed 7525 cycles till the time of accident.

2.4.1.3 The aircraft was fitted with four P & W JT9D-7J engines having thrust rating of 48650 pounds. The hours and cycles logged by

the engines since new till the time of accident are as given below:
Engine No.1 : P662927-7J - 29,663:26 Hrs (9422 cycles)
Engine No.2 : P695610-7J - 20,810:28 Hrs (6031 cycles)
Engine No.3 : P695602-7J - 21,992:31 Hrs (6564 cycles)
Engine No.4 : P662926-7J - 32,332:15 Hrs (11295 cycles)

2.4.1.4 All the DGCA mandatory modifications and inspections applicable to the subject aircraft had been compiled with. No major component installed on this aircraft and its engines had exceeded the stipulated life period.

2.4.1.5 The last quarter Periodic Check of the aircraft was carried out on 24th May, 1985, at 23274:53 hours and 7439 cycles. Subsequent to this check, two Check 'B' schedules were carried out. The last Check 'B' was carried out on 17th June, 1985, at 23564:14 hours and 7510 cycles and was valid for 200 flying hours.

2.4.1.6 The aircraft had flown 359:56 hours and 86 cycles since last quarter Periodic Check and 70:35 hours and 15 cycles since last Check 'B' till the time of accident.

2.4.1.7 The last Flight Release Certificate was issued on 24th May, 1985 on completion of quarter Periodic Check and was valid for 1100 hours or 150 days elapsed time whichever occurred first. After the last departure from Bombay on 21st June, 1985, the aircraft had flown for 22:34 hours till the time of crash.

2.4.1.8 Mr. Rajendra, Maintenanace Manager, Air India, Montreal carried out the Terminal Transit Check 'E' of the aircraft at Toronto on 22nd June, 1985 and no snag was observed by him. No snag was reported by the flight crew during the flight from Toronto to Montreal. Transit Check 'C' of the aircraft for the flight AI-182 was carried out at Montreal by Mr. Rajendra and three Air Canada technicians. The flight engineer also carried out his pre-flight inspection and found that the rear latch handle of the fifth pod engine fan cowl was loose. He informed the same to Mr. P. Bayle, Air Canada technician who faired the handle and applied high speed tape. No other snag was observed during the inspection.

2.4.2 Previous Incidents and Snags

2.4.2.1 A maintenance Group was formed with representatives from Air India and Airworthiness Directorate with Mr. R.K. Paul, Senior Air Safety Officer as the Group Leader to scrutinise the maintenance documents and various defects experienced on this aircraft. The report submitted by the Group (Attachment 'B') indicates that the aircraft was involved in six incidents since the last C of A renewal, details of which are given below

(I) On 13th July, 1984 at Dubai -- flight AI-868 The aircraft returned after aborting take off due to no rise in the EPR and N1 on No.1 engine (Sl.No. 695612). The engine front and rear were checked and found OK. Slight wetness was noticed in the bleed outlets. No external oil leak was noticed. Oil quantity was topped up. The chip detectors and oil filter were found OK. EVC Ph filter was found OK. EVC linkage wes exercised. The engine was run up and its operation was found satisfactory. The snag was suspected to be due to lack of pressurising air at low N1.

(ii) On 18th July, 1984 at Delhi -- flight AI-105 The right hand side fuselage skin between stations 480 and 500 in line with lower portion of forward cargo door cut-out was damaged by high lift. The same was repaired at Delhi. Permanent repair was carried out at Bombay. The repairs were accomplished using guidelines given in the Boeing Structural Repair Manual.

(iii) On 12th August, 1984, at Rome -- flight AI-135 The aircraft landed with No. 2 engine (Sl.No. 662826) shut down in flight due to oil pressure and oil quantity droping. On motoring the engine, oil leak was observed from metal line between F C O C and L O P switch at the switch end. The line was found cracked which was welded and refitted. The line was subsequently replaced at Bombay.

(iv) On 24th October, 1984, at London -- flight AI-104 There was total loss of No.1 hydraulic system fluid. The fluid leak was traced to inlet pressure adapter of flap control module in the left hand body gear wheel well. Two of the four bolts holding the adaptor on the flap control module had sheared. The hydraulic pump, seal, back-up ring and case drain filter were replaced. The flap control module was replaced when

the aircraft arrived at Bombay.
(v) On 14th February, 1985, at Delhi -- flight AI-164 On arrival the leading edge honey comb of the left hand aft trailing edge flap was found damaged about 18 inches in length due foreign object damage. Necessary repair was carried out at Delhi. The aft flap was replaced at Bombay.
(vi) On 28th May, 1985, at Dubai -- flight AI-103 On arrival, the left hand wing to fuselage botton fairing forward rubber seal with strip was found turn off. Temporary repair was carried out at Dubai. Permanent repair was carried out subsequently at Bombay.
2.4.2.2 The flight snags recorded in the flight report books of the aircraft during the 4 1/2 month period prior to the accident were scrutinised by the Maintenance Group and the only significant repetitive defect observed was "R2 door not going to manual". On ground checks by the aircraft maintenance engineers, the operation of the selector was, however, found normal.
2.4.2.3 Prior to operating the accident flight, the aircraft arrived at Toronto from Frankfurt. Capt. R.K. Spencer was the commander of the flight. The flight crew had reported the following three snags:
(I) HF system No. 2 had a lot of distortion
(ii) E P R L indicator unserviceable in 'Go around' mode
(iii) Hydraulic system No.1 pressure indication unserviceable (This snag was carried forward from Delhi).
2.4.2.4 The Auxiliary Power Unit (APU) was unserviceable ex-Bombay and had been released under M E L.
2.4.2.5 For rectification of the above stated snag No.1, Shri Rajendra, Air India's Maintenance Engineer at Totonto checked the connections of the transreceiver and reracked the unit. No snag was reported on this system on Toronto-Montreal sector.
2.4.2.6 Snag No. 2 was carried forward.
2.4.2.7 Regarding the third snag, Mr. Rajendra has stated that the indicator showed 4000 P S I pressure even with no pump running. He therefore, interchanged No.1 and No.3 indicators. The snag, however, persisted. He then replaced transmitter No.1 with a spare transmitter

from the aircraft SE box and the snag was rectified. No rectification work was however, recorded by the AME in the Flight Report Book. No snag was reported on this system on Toronto-Montreal sector.

2.4.3 Installation of 5th Pod Engine

2.4.3.1 On 8th June, 1985, No.1 engine of Air India Boeing 747 aircraft VT-EGC operating flight AI-181 failed during take off at Toronto. The aircraft returned and the engine was replaced by a loaned engine from Air Canada. The removed engine was a P & W JT9D-7Q type (Sl. No. P702353-7Q).

2.4.3.2 Air India had planned to bring back the failed engine of VT-EGC aircraft to Bombay, as fifth pod on their flight AI-181/182 of 22/23 June, 1985 and had sent an Engineer along with the necessary kit to Toronto on 15th June, 1985. The engine borrowed from Air Canada on 8th June, 1985, was flown back to Toronto as a fifth pod engine on flight AI-181 of 22nd June, to return it to Air Canada.

2.4.3.3 Shri C.D. Kolhe, Controller of Airworthiness, Bombay examined the aspects relating to installation of the 5th Pod engine, loading of its components and certification of the related work. Shri Kolhe's report indicates that the failed engine and the associated parts were kept in the Air Canada engineering hanger at Toronto airport since June 8 when the aircraft was brought to the hanger for engine replacement. Air India requested Air Canada on 15th June, 1985, for prepairing the failed engine for installation as fifth pod engine on 22nd June. Accordingly, Air Canada's technicians undertook the preparatory work of removing the cowlings, fan blades, panels, locking of compressor, turbine rotors etc. on 17th June, 1985, and completed the work on 21st June, 1985. The fan blades (46 in number) from the failed engine were placed in 12 wooden shipping boxes provided by Air India. These boxes were then loaded in a container. The other components of the failed engine were loaded on 4 pallets.

2.4.3.4 Installation of the fith pod engine was carried out by Air Canada technicians and the individual items on the task card were certified by the individuals who had carried out the work.

2.4.3.5 Some difficulty was experienced while loading one of the pallets having inlet cowl of the pod engine. To enable loading of the cowl, Air Canada engineering/maintenance personnel removed door stop fittings from the aft cargo compartment door cut-out. After removal of the fittings, the pallet could be loaded. All the removed fittings were then re-installed. Removal and installation of the fittings was certified by Mr. Rajendra.

2.4.3.6 A question arose whether removal of the door stop fittings could have caused some difficulty in flight. From the video films of the werckage it was found that the complete aft cargo door was intact and in its position except that it had come adrift slightly. The door was found latched at the bottom. The door was found lying along with the wreckage of the aft portion of the aircraft. This indicates that the door remained in position and did not cause any problem in flight. In the front cargo compartment, there were 16 containers out of which four were empty. Five containers had baggage of Delhi bound passengers. Container at Position 13L had baggage of the first class and London passengers and container at position 13R had crew baggage. The entire baggage of passengers ex-Montreal was loaded in containers at positions 12R, 21R, 22R, 23R and 24R in the front cargo compartment. Container at position 24L contained fan blades in wooden boxes and the other components of the pod engine. Valuable container was at position 14R.

2.4.3.7 In the aft cargo compartment, there were four pallets containing parts of the fifth pod engine and two containers at positions 44L and 44R containing baggage of Delhi bound passengers. The bulk cargo compartment contained passenger baggage bound for Delhi and Bombay. All the baggage and engine parts in the aft and bulk cargo compartments were loaded at Toronto.

2.4.3.8 The total weight of the fifth pod engine and its items was about 9000 kgs. As a result of carriage of the fifth pod engine, the payload of the flight was considerably reduced on London-Delhi sector.

2.4.3.9 At the time of take off from Montreal the aircraft had 104,000 kgs of fuel on board which was adequate for 08:40 hours of flying as against sector flying time of 06:15 hours. The flight plan fuel was calculated taking Paris as the alternate airport for London.

2.4.3.10 The load and trim sheet from the sector Montreal London was prepared and was duly counter-signed by the commander. The take off weight of the aircraft was 317,877 kgs which was within the maximum take off weight limit of 334,500 kgs. The estimated landing weight of the aircraft was 237,177 kgs which was also within the maximum landing weight limit of 256,279 kgs. The centre of gravity of the aircraft was at 21.3 percent
of MAC at take off and the estimated C G position at the time of landing at London was 25.8 percent of MAC which was within the limits.

2.4.3.11 The load and trim sheet and the flight plan of the aircraft indicated that there was 301+2 passengers on board the aircraft whereas there were actually 301+6 passengers on board. The error occured because four of the six infants were not taken into account.

2.4.4 Corrosion Control Measures

2.4.4.1 Boeing Company have recommended various measure to control corrosion on Boeing 747 aircraft through different documents such as Maintenance Planning Data Document, Corrosion Prevention Manual and Service Bulletins. Compliance of these measures on Air India fleet is accomplished as follows:

(I) Support structure under galleys and lavatories

Boeing Company have recommended repeat inspections of under galley/toilet structure at intervals of 12000 hours. However, in order to detect corrosion at an early stage, these inspections are carried out by Air India at intervals not exceeding 9000 hours.

(ii) Fuselage Lower Bilge Area:

Boeing Company have recommended modifications to provide improved drainage systems by incorporation of various Service Bulletins. All the relevant modification have been completed by Air India on the affected aircraft. In addition to completion of these modifications, repeat inspection of lower bilge area is being carried out to meet the requirements of Boeing Service Bulletins.

(iii) Canted Pressure Deck:

In order to prevent water accomulation and consequent corrosion in the area, Boeing Company have issued SBs 51-2015, 51-2026 and 51-2032. Air India have incorporated Service Bulletins 51-2015, and 51-2032 on all their affected airplanes SB 51-2026 is being complied progressively.

(iv) Cargo Compartments:

Inspection of all the cargo compartment interior structures for corrosion and cracks is being accomplished periodically by Air India after removal of linings and insulation blankets.

(v) Aft Pressure Bulkhead:

During every equalised Periodic Check routine, the aft surface of aft pressure bulkhead is being visually inspected for corrosion condition and security of attachements. The forward surface of the pressure bulkhead, which is covered by aft toilets, is inspected after removal of toilets at intervals not exceeding 9000 hours although the recommended interval by Boeing Company is 12000 hours.

2.4.4.2 Air India has stated that in addition to the above specific measures, aircraft structure particularly the areas below toilets, galleys, cargo compartments, outflow valve area etc. which are prone to corrosion, are inspected for corrosion, cleaned and protected during every equalised Periodic Check. Air India have further stated that no serious corrosion problem has been experienced by them so far on their fleet.

2.4.5 Supplemental Structural Inspection Programme

2.4.5.1 In the case of airplanes which have completed 10,000 flight cycles as on June 30, 1983, Federal Aviation Administration (FAA) U S A and Boeing Company had recommended additional structural inspections known as Supplemental Structural Inspection Programme. In the Air India fleet, the first three 747 aircraft, namely, VT-EBE, VT-EBN and VT-EBO fell in this category and are known as 'Candidate Airplanes'. The subject aircraft (VT-EFO) had completed only 7525 flight cycles at the time of the accident on 23rd June, 1985, and therefore, the Supplemental Structural Inspection Programme was not applicable to this aircraft.

2.4.6 Special Corrosion Inspection of B-747 Aircraft Fleet of Air India

2.4.6.1 In order to examine whether corrosion to the aircraft structure of Kanishka aircraft could have contributed to the accident, a group was constituted by Mr. H.S. Khola, Inspector of Accidents to carry out special corrosion Inspection of all the Boeing 747 aircraft of Air India.

The group consisted of the following members:

(a) Senior Air Safety Officer of the D.G.C.A.

(b) Senior Airworthiness Officer of the D.G.C.A.

(c) Air India's Representative.

2.4.6.2 The inspection was carried out in the following areas:

(a) Below toilets and galleys

(b) Forward and aft cargo compartments belly areas - internally and externally

(c) The forward and aft pressure bulkheads

(d) Canted pressure web area from inside the passenger cabin.

(e) Area around outflow valves

(f) MEC area inside and outside.

2.4.6.3 The inspection reports submitted by the Group show that no corrosion was noticed on the significant primary structural members of the aircraft. Surface corrosion was, however, noticed on some of the members below the toilets and galleys. The corrosion observed during the inspection was of minor nature which is normally expected on such inspection schedule. The Kanishka aircraft was subjected to Periodic Check on 24th May, 1985 at 23,274.53 hours/7,439 cycles and no significant corrosion was observed. Among the Nine 747 aircraft inspected for corrosion, 5 aircraft had logged hours more than the Kanishka aircraft. Three of the aircraft had actually logged nearly double the flying hours. Taking into consideration that the corrosion prevention measures recommended by the Boeing Company were followed by Air India and that even the high life aircraft (45,000 hours approximately) subjected to corrosion inspection at the time when Periodic Check was due i.e. 1100 hours since previous check, had no significant corrosion, it is considered unlikely that Kanishka aircraft, which had logged only 23,275 hours since new and 360 hours since last

Periodic Check, had corrosion which could have contributed to the accident.

METEOROLOGICAL INFORMATION

2.5.1 A report on the Meteorological conditions prevailing en-route near the location where the aircraft crashed was provided by the Meteorological Service, Department of Communications, Dublin, Ireland. This report covers a period of one to two hours before and after the time of accident (0714 Z).

2.5.2 From the report it is seen that the surface Synoptic Situation in the vicinity of 51°N, 12.50°W at 0715 Z on 23rd June was as given below:

Surface wind : 250/15 knots

Surface visibility : 10 Kms (occasionally 4 kms in drizzle)

Surface temperature : 13°C

Cloud conditions : Cloud cover in the area was estimated to have been layered upto about FL 100 with a base of 600 feet. There is no evidence of cumulonimbus or thunderstorm activity.

Freezing Level : 700 feet.

2.5.3 With regard to Upper Air situation the report indicates that a mainly West or West North West airflow covered the area of FL 310 The Jet stream was centred at about 48°N. The estimated wind and temperature at FL 310 were 270/65 knots and -47°C. As per the report, at FL 310, 51°N 12.50°W and at 0715 Z any significant clear air turbulence was not expected.

2.5.4 Sunlight condition was prevailing at the time of accident. There were no sigmets valid for the area at that time.

AIDS TO NAVIGATION

2.6.1 The aircraft was equipped with Inertial Navigation System (INS) and was cruising normally at its assigned flight level 310 on track X-ray over Atlantic. It was under the control of Shannon Upper Area Control and was being monitored on the Secondary Surveillance Radar (SSR) located at Mount Gabreal. Till the time of accident, the aircraft was beyond the range of Shannon primary radar.

2.6.2 The aircraft entered Shannon airspace at the correct position and level and remained on the assigned track and flight level till it disappeared from the radar screen.

2.6.3. There is no evidence to indicate that AI-182 experienced any navigational problem during the flight.

COMMUNICATIONS

2.7.1 Two-way communication between the ill-fated aircraft and the ATS units of Canada and Ireland was maintained during the flight from Montreal till the time of crash. The communications were recorded on the ATC tapes. Transcripts of the relevant tapes were provided by the Canadian Aviation Safety Board and the Director of Air Traffic Services, Ireland.

2.7.2 From the Transcript of the conversations, it is observed that two-way communication between AI-182 and the various ATS units was normal. The last R/T contact with the aircraft was at 0709:58 Z when AI-182 informed Shannon UAC that it was squawking 2005. The tape transcript also shows that the aircraft did not transmit any information regarding the emergency on frequency 131.15 MHz on which it was last working with Shannon UAC or on distress frequency 121.5 MHz. Indecipheiable noise was, however, found recorded on the Shannon ATC tape just at the time of crash i.e. 0714:01 Z. Thereafter, repeated calls were made by Shannon UAC to AI-182, but there was no response.

SEARCH AND RESCUE

2.8.1 The report of the Search and Rescue Group gives the details of the Search and Rescue operations. From the report it is seen that at 0730 Z, Shannon UAC informed Marine Rescue Co-ordination centre (MRCC) shannon that AI-182, a Boeing 747 aircraft enroute Montreal-London had disappeared from the Secondary Surveillance Radar (SSR) at 0713 Z in position 51N/120W. Shannon UAC requested MRCC Shannon to take emergency section. At 0740 Z MRCC Shannon telephonically explained the situation to Valantia Coast Radio Station (CRS) and requested a PAN Broadcast urgently and to ask any vessels in area to keep sharp lookout and report to Valantia Radio. At 0746 Z Valantia Radio transmitted to all stations PAN message and above advice to ships. The transmission was repeated.

2.8.2 At 0750 Z, an Irish Naval Vessel AISLING reported on R/T to Valantia Radio that it was 54 miles from site of accident and was proceeding to the site. Valantia Radio passed on this information by Telex to MRCC Shannon. Between 0740/ 0750 Z MRCC briefed the Irish Naval Service (INS) Haulbowline, MRCC Swansea, RCC Plymouth and Irish Army Air Corps (IAAC) on the situation. At 0754 Z MRCC relayed a distress message to Shannon Aeradio via the Aeronautical Fixed Telecommunication Network (AFTN)

2.8.3 At 0803 Z Valantia Radio again transmitted the PAN message and the advice to ships. At 0840 Z Cargo vessel M W Laurentian Forest/ HBWP (Registered in PANAMA and owned by Federal Commerce of Montreal, Canada) at position 51.09N/12.18W reported that it was 22 miles away from distress area and was proceeding there. Laurantian enquired if there were other ships in the area and was informed about position of Aisling. At 0813 Z Valantia Radio informed MRCC Shannon by telex about Laurentain Forest.

2.8.4 Between 0815/0820 Z, MRCC Shannon updated RCC plymouth and they advised that a Nimrod Rescue Aircraft would depart shortly for the area and that SEA KING helicopters were already enroute the Cork Airport initially. Edinburgh RCC advised MRCC Shannon that a Nimrod Rescue Aircraft was also being prepared at Kinloss. At 0820 Shannon Aeradio informed Valantia Radio that there was message from Shanwick Oceanic Control that aircraft were picking up ELT signal in position 51N/15W and 51N/08W and the actual position was beleived to be 51W/1250W. At 0833 Z, Valentia Radio sent message giving the above information and requesting ships in the area to report to Valentia Radio.

2.8.5 At 0842 Z, Ali Baba informed Valentia Radio that it was at position 5125.5N/0825.4W and was listening on 121.5 MHz. At 0850 Z Western Arctic informed Valentia Radio its position 5207N/1151W and that it would proceed in about 20 minutes after bringing in cable. At 0857 Z, High Seas Driller informed Valentia Radio that Vessel Kongstain could be released, ETA 51/2 to 6 hours and they would standby. At 0858 Z, Valentia Radio informed MRCC Shannon about reports from Ali Baba Western Arctic and High Seas Driller.

2.8.6 At 0905 Z, Laurentian forest reported to Valdentia Radio that it was 5 miles from SOS position 51N/12.5 W and it had not sighted anything. Between 0905/0908 Z, three more vessels viz. Atlantic Concern, MV Norman Amstel and MV Tasman reported their positions to Valentia Radio. At 0908 Z, Swansea advised MRCC Shannon that four Seaking helicopters and two Nimrod Aircraft were enroute.

2.8.7 At 0913 Z, Laurentin Forest reported to Valentia Radio that they had sighted what looked like 2 rafts about 2 miles away. At 0914 Valentia Radio informed MRCC Shannon about the report from Laurentian Forest.

2.8.8 At 0918 Z, Laurentian Forest reported to Valentia Radio that it had sighted wreckage in water at position 5101.9N/1242.5W and the liferafts were not inflated. Valentia Radio passed the message to MRCC Shannon at 0920 and also sent transmission about wreckage sighting. Lifeboats Valentia and Baltimore reported to Valentia Radio that they were proceeding to the position of wreckage.

2.8.9 At 0937 Z, Laurentian Forest reported that it had sighted 3 bodies in water. Valentia Radio informed the same to MRCC Shannon at 0940 Z. At 0945 Z, MRCC Shannon and MRCC Swansea decided that for security and operational reasons Cork Airport would be the primary operational base and ATC Cork were informed of this decision.

2.8.10 At 0953 Z, S MYROLI informed Valentia Radio that it was 80 miles north of position and had a group of 10 to 20 French vessesls and desired to know if they should proceed to site. After consulting Laurentian Forest, S MYROLI was advised that it was not necessary. Valentia Radio kept on giving Mayday relay frequently.

2.8.11 At 1045 Z, a prohibited flying area was established with a radius of 40 N Miles from the datum point from sea level to 5000 feet. Falmouth Coast Guard reqested Valentia Radio the position of all ships in the distress area and those proceeding so that each vessel could be designated to search a particular area.

2.8.12 At 1126 Z, Laurentian Forest reported Valentia Radio that it had located numerous bodies in water and Seaking helicopter was hovering there. Valantia Radio Transmitted this information to all stations.

2.8.13 At 1133 Z, Valentia Radio informed Coast Guard Falmouth the position and ETA of various ships and also of the Lifeabouts Valentia and Beltimore. At 1150 Z, RRC Plymouth requested MRCC Shannon that "Le Aisling" assume duty as "On Scene Commander Surface Unit". At 1204 Z, information was received by Valentia Radio that 8 Spannish Trawlers were proceeding to distress position of AI-182 and their ETAs were between 1630/2000 Z. At 1246 Z, Star Orion informed Valentia Radio that it would be able to refuel any vessel in medium or small quantities at the accident site. Valentia Radio informed MRCC Shannon and Falmouth about the Spanish Vessels and Star Orion.

2.8.14 Falmouth requested Valentia Radio at 1303 to advise Laurentian Forest to inform Aisling that 8 Spanish trawlers would arrive in search area between 1600 Z and 2000 Z and Aisling should deploy trawlers in conjunction with lifeboats to recover bodies as it would be easier to recover than from large vessels. Valentia Radio sent the above message.

2.8.15 Laurentian Forest informed Valentia Radio at 1307 Z that 10 bodies were on Aisling, 4 on Helo, and they had some alongside and had launched lifeboats to pick them up. Valentia Radio informed the same to MRCC Shannon and Falmouth. At 1338Z, MRCC Shannon requested Valentia Radio to include the following in their broadcast:

"Vessels within 100 N Miles of datum 5101.9N/1242.5W are requested to proceed to search area and contact Aisling/EIYP. Any vessels recovering bodies or wreckage are requested to retain them on board and inform MRCC Falmouth of total number of bodies recovered."

2.8.16 Valentia Radio transmitted the above message at 1340 Z to all stations and also informed MRCC Shannon. At 1503 Z Aisling informed Valentia Radio that they had recovered 56 bodies. MRCC Shannon requested Valentia Radio to advise Aisling that if they could locate "Black Box", they should drop buoy. Valentia Radio advised Aisling accordingly. At 1530 Z, on advice from MRCC Shannon, Valentia Radio asked Baltimore, Courtmaesherry and Ballycotton lifeboats to return to base. At 1633 Aisling requested Valentia Radio to inform Falmouth that they were unable to transfer bodies to Valentia Lifeboat as latter was returning to base owing to fuel shortage. At 1659, Laurentia Forest informed Valentia Radio that 66 bodies had been picked up by then. Aisling advised Valentia Radio that Valentia lifeboat was returning with four bodies.

2.8.17 At 1721 Z Falmouth requested Valentia Radio to relay following to all surface units at scene:

1. One mimrod remaining on scene overnight.
2. All other air units will be recalled at 2200 Z. One Helo remains at 15 minutes notice at Cork
3. Air Search recommences at 240400 Z.
4. All Civil surface units will be released by 2200 and may proceed on passage. Bodies should be landed at Irish Post for transfer to receiving station at Cork Airport.
5. Warship Challenger, Emer and Aisling acknowledge".

2.8.18 At 1723 Z Aisling informed Valentia Radio that they saw 3 Spanish vessels approaching and they were using Ch.16 which Aisling was using for co-ordination with RESCUE 52 and requested that Spanish Vessels be asked to stay outside 5 miles radius. Spanish Agent was told about Aisling request.

2.8.19. Valentia lifeboat informed Valentia Radio that they were heading for home (Valientia) at reduced spead of 11 knots and they had five bodies on board. At 1822 Z, Aisling requested Valentia Radio information on 'Black Box' that might help its location. Aisling was advised of ELT signal on 121.5 MHz. At 1840 Z Cork ATC Advised MRCC Shannon that a total of 64 bodies were in Cork.

2.8.20 At 1920 Z, MRCC Shannon downgraded the 'MAYDAY' Broadcast to 'PAN' (Urgency) Broadcast, Aisling informed Valentia Radio that 79 bodies had been recovered. At 1958 Z Laurentian Forest informed Valentia Radio that they were proceeding to Dublin. Valentia Radio thanked them for assistance.

2.8.21 At 2000 Z, MRCC Swansea advised MRCC Shannon that main air search would cease at 2200 Z and would recommence at 240400 Z. The overnight search would continue with one Nimrod providing air cover for the surface search by three warships. Vessels transiting the area were requested to keep a sharp look out and to report to HMS Challenger.

2.8.22 By 0300 Z on 24th June, four Seaking helicopters had deported from Cork to resume the airborne search. At that time the search area covered a six nautical mile radius of position 5059.2 N/1225.3W and the vessels Le Emer and HMS Challenger were requested to search this area. HMS Challenger was the coordinator of the surface search and Nimrod Rescue 02 was on-Scene-Commander.

2.8.23 At 0450 Z Rescue 02 reported sighting of wreckage in position 5101 M/1245 W. Between 0505 and 0543, three USAF Chinook helicopters departed from Cork Airport to join the search. At 0556, MRCC

Swansea confirmed that there were 329 people on board the aircraft (Earlier reportes had idicated 325 people on board).

2.8.24 A continuous search was maintained throughtout the day (24th June) but only one further body and numerous pieces of wreckage were recovered. An extensive surface search was also maintained throughout the day and instructions were passed by MRCC Shannon to Valentia Radio requestiong all shipping to recover any wreckage or bodies sighted.

2.8.25 At 0900 Z, Capt. G Mc. Stay of Department of Communications advised MRCC Shannon that Aisling was bound for Cork, ETA 1300 Z and he (Capt. Mc Stay) was assuming responsibility for collection of wreckage. MRCC were also advised by Mr. Gregory of Britoil that their two vessels 'Constine' and 'Star Orion' were enroute to Foynes having picked up quantities of wreckage.

2.8.26 At 1740 Z, SRCC Plymouth advised Shannon that the Search will terminate at 242200 Z, at 1800 Z Falmouth MRCC advised MRCC Shannon to direct the Portisheal and Valentia Radios to concel Urgency Broadcast from 242000 and to release HMS Challenger and Le Aisling from the search at 242000 hours. All the aircraft were released at 24000. It was also decided that Le Emer would remain at the area. At 242003 Z, a message was transmitted to all stations on R/T and W/T that air and sea search was being terminated at 242000 Z and all the participant were thanked for their assistance.

INJURIES TO PERSONS

3.1.1 Post mortem examination was carried out by Irish Authorities at Cork. At that time Wing Commandor Dr. LR. Hill was also present. Subsequently Air Vice Marshall Kunzru also reached Cork. Both of them were members of the Medical Group which had been constituted by Mr. H.S. Khola.

3.1.2 By then 131 bodies had been recovered. None of the bodies of the flying crew were revocered. The bodies which were recovered represented 39.8 per cent of the victims. The exact seating position of passengers is not certain, because it is known if the passengers had changed their seats after the take off of the aircraft from Montreal. On the information which is available, the passengers were supposed to have been as follows:-

Passengers: Seats Occupied Bodies Available identified Zone A 16 1 0 Zone B 22 0 0 Upper Deck 18 7 0 Zone D 112 104 + 2 29 Zone D 86 84 + 1 38 Zone E 123 105 + 3 50 Sub-Total 377 301 +(6 infants) 117 Crew: Flight Deck 3 3 0 Cabin 19 19 5 Total 399 329 122

3.1.3 The Post-mortem reports were examined by Wing Commander Dr. Hill. He submitted two reports being Exhibits H-1 and H-2. He was also examined in Court as Witness No. 2. Dr. Hill who had developed a system which would indicate the severity of the accident and the injuries suffered. He used a scale from 0 to 4, with naught being no injury and 4 being a fatal lesion. Though there is some amount of subjectivity involved in the system, nevertheless categorising the injuries according to the sacle does give an overall picture of what had happened to the victims. After adding up all the injury scale for a particular body, Dr. Hill in his Report Exhibit H-1 divided the injuries as under:-

No. of victims Mild injury (0-49) total 34.4% 45% Moderate injury (50-99) 38.9% 51% Severe Injury (100-149) 25.2% 33% Catestrophic Injury (150 +) 1.5% 2 Total 100.1% 131 3.1.4 A further break up showing the overall injury score of the recovered victims is as follows:

	Minor			Moderate			Severe			
Zone	No.	%	%	No.	%	%	No.	%	%	Total
C	8	6.1	17.8	9	6.9	17.7	4	3.1	11.4	21
D	9	6.9	20	15	11.5	29.4	9	6.9	25.7	33
E	15	11.5	33.3	15	11.5	29.4	14	10.7	40	44
Unknown	13	9.9	28.9	12	9.2	23.5	8	6.1	22.9	33
Total	145	34.4	100	51	39.1	100%	35	26.8	100%	131

3.1.5 The reports submitted by Dr.Hill further indicted as follows

(a) There were 30 children recovered and they showed less overall injury. The average severity of injury increases from zone C to E and is significantly less in C than in Zones D and E.

(b) Flail pattern injuries were exhibited by eight bodies, five of these were in Zones E, one in Zone D, two in Zone C and one crew member. The significance of flail injuries is that it indicates that the victims came out of the aircraft at altitude before it hit the water.

(c) There were 26 bodies that showed signs of hypoxia (lack of oxygen), including 12 children, 9 in Zones C, 6 in Zone D and 11 in Zone E. There were 25 bodies showing signs of decompression, including 7 children. They were evently distributed throughout the zones, but with a tendency to be seated at the sides, particularly the right side (12 bodies).

(d) Twenty-three bodies showed evidence of receiving injuries from a vertical force. They tended to be older, seated to the rear of the aircraft (4 in Zone C, 5 Zone D, 11 inZone E, 2 crew and 1 unknown), and 16 had little or no clothing.

(e) Twenty-one bodies were found with no clothing, including three children. They tended to be seated to the rear and to the right (3 in Zone C, 5 in Zone D, 11 in Zone E and 2 unknown).

(f) There were 49 cases showing signs of impact-type injuries, including 19 children (15 in Zone C, 15 in Zone D, 15 in Zone E, 1 crew member and 3 unknown).

(g) There is a general absence of signs indicating the wearing of lap belts.

(h) Pathological examination failed to reveal any injuries indicative of

a fire or explosion.
3.1.6 In his testimony in Court, Wing Commander Dr. I.R. Hill further stated that the significance of flail injuries being suffered by some of the passengers was that it indicated that the aircraft had broken in mid-air at an altitude and that the victims had come out of the aeroplane at an altitude. He further explained that if an explosion had occurred in the cargo hold, it was possible that the bodies may not show any sign of explosion. It may here be mentioned that the forensic examination of the bodies do not disclose any evidence of an explosion. Furthermore, the seating pattern also shows that none of the bodies from Zone A or B was recovered, in fact as per the seating plan Zone B was supposed to have been unoccupied. This Zone is directly above the forward cargo compartment.
3.1.7 Dr. Hill further stated that the pattern of the accident as suggested by the injuries indicated that it was a complex affair and there were at least two phases of injuries, one in the air and the other at water impact. In answer to a specific question that if there was an explosive device in the cargo hold then could the passengers who were seated have suffered such injuries, the answer of Dr. Hill was that "it is possible". According to him, the pattern of injuries indicated that if there was an explosion in the aircraft it was more likely that the explosion had occurred in the rear cargo compartment than in the front cargo compartment. This conclusion was apparently based on the fact that, according to him, in zone E of the aircraft there were larger vertical load type injuries. Dr. Hill was also asked if he had to make any suggestions which would minimise injuries to passangers in the event of an accident. In answer, the witness made his suggestion in the following words "There are very complicated things one would have to do such as rearward facing seats; having safety belts which incorporated restraint for the upper part of the body; increasing the space between aircraft seats; incorporating shocks absorbing system within the seat and using materials which do not break easily like plastic. We would also need fuel systems which would not immediately set on fire and furnishing which would be resistant to burining, and also passengers should not carry into

the aeroplanes large amount of hand bags which only get in way in the event of evacuation, and I personally feel that the carriage of large amount of alchohol both in the passengers and in the aeroplane is a hazard to flight and safety. Finally the passengers should take heed of the flight safety instructions given to them by the crew of the aeroplane".

3.1.8 Air Vice Marshal Kunzru, witness No. 10 in his report dated 14th November, 1985, Ex.A-48, gave his comments not only on the post-mortem reports but also on the statement of Wing Commander Dr. I.R. Hill. With regard to the post-mortem examination, the comment of AVM Kunzru was as follows:

"All victims have been stated in the PM reports to have died of Multiple injuries. However two of the dead, one infant and one child, are reported to have dies of Asphyxia. There is no doubt about the asphyxial death of the infant. In the case of the other child (Body No. 93) there could be doubt because the findings could also be caused due to the child undergoing tumbling or spinning with the anchor point at the ankles. Three other victims undoubtedly died of drowning. There was no evidence of significant Lap-belt injuries.

Considering rupture of the ear-drum, without injury to skull, as a criterion to indicate rapid decompression, two cases may be considered to fall in this category.

Histological examination has been carried out only in 57 bodies out of 131. Lung examination on almost all of them showed decelerative changes. Six bodies (Nos. 6,22,70,103,121 and 131) showed presence of Bone Marrow Embolism in Lung Sections. Though not of much significance in this accident, this finding does indicate survicval after a bony injury for an undefined period of time No evidence of fire burns or explosive material, other than Kerosene burns on some bodies, which I had myself seen at Cork, could be found. Kerosene burns in such acidents is a fairly common findings and is of no significance".

AVM Kunzru generally agreed with the crash injury analysis on the victims which had been furnished by Wing Commander Dr. Hill. He, however, gave the following comments with regard to hypoxia,

decompression and decelerative changes:
"Hypoxia : The main Post Mortem findings in hypoxia is generalised congestion if the hypoxia is of the type described as "hypoxic hypoxia". In other causes of hypoxia of more severe degree such as "histotoxic hypoxia", "asphyxia" or "drowning" additional histological findings such as petechial haemorrhages and generalised congestion, and lung findings such as haemorrhage and extrusion of alvoolar phagocytos are seen.
Decompression : The term used by Dr. Hill is "Decompression". It is presumed that he means "Rapid/Explosive Decompression" which occurs within one Sec. and not "decompression sickness" which takes a minimum of 5 to 7 mnts to occur even at 31,000 ft. altitude and which in this case can positively be ruled out.
The Post-Mortem and histological signs of rapid Decompressions are :-
(a) Possibility of rupture of Ear drums without any injury to the skull.
*(b) Patchy Lung Haemorrhages
*(c) Emphysomatus changes
*(These occur more commonly in those cases where the individual was in the phase of breathing-in at the time of decompression.
3.1.9 If it is assumed that the aircraft suddenly broke up in Mid-Air at an altitude of 31,000 ft. the bodies will be at once exposed to hypoxia and rapid decompression and as a consequence will suffer body changes as mentioned above. As the aircraft/occupants start descending, they will be exposed to increasing amounts of Oxygen and as soon as ;they come down below 15,000 ft. and then below 10,000 ft. the effect of hypoxia rapidly diminishes. Finally, the aircraft/individuals come down and hit the ground/water with a very heavy impact, thus submitting the individuals to extremely severe G-loads of decelarative type.
Decelerative Changes : Decelerative impact brings about well established changes in the lungs besides many other associated injuries. It is relevant to note the decelerative lung changes which are :-
(a) Patchy haemorrhages in Lung.
(b) Marked Emphysomatus Changes.
(c) Extrusion of alvoolar Phagocytes

(d) Desqummation of bronchcolar epitherium.

"Comparative study of the PM/histological findings of hypoxia, Decompression and Decelerative Lung injuries reveal that they are more or less similar. Decelerative injury being the most severe of the three and last to occur tends to so modify the Post-Mortem and Histological findings that it becomes extremely difficult and some times impossible to isolate one from the other."

3.1.10 AVM Kunzru was, therefore, of the opinion that in this accident evidence of hypoxia/decompression (except in 2 cases) had not been confirmed or established.

3.1.11 The difference of opinion between Wing Commander Dr. hill and AVM Kunzru, with regard to evidence of hypoxia and decompression, is of no significance in the present case. What is important to note, however, is that they have agreed that the injury pattern does indicate break up of the aircraft in mid-air and that the occupants of Zone E had suffered the greatest amount of injuries as compared to the occupants of the other zones.

MAPPING, WRECKAGE DISTRIBUTION AND SALVAGE

3.2.1 Introduction

3.2.1.1 Oceanographic charts indicated that the depth of sea in the crash area was about 6700 feet and the site appeared to be a flat sea bed, without any valleys or hills. The immediate necessity after rescuing/searching crash victims, was to locate and recover the digital flight data recorder (DFDR) and the cockpit voice recorder (CVR). The operation was unique of its kind and had never been undertaken earlier in the world at this depth of the sea. It required an equipment which could home on the transmitted signals from the underwater locater acoustic beacons fitted on DFDR/ CVR, identify the units, clear them from attachments/wreckages, grab them and bring them to the surface.

3.2.1.2 The pressure exerted by the water at 6700 feet below mean sea level is extremely high and the temperature is very low. No light penetrates to that depth and it is pitch dark. Scarab I fitted on French Ship "Leon Thevenin" which had undertaken the challenging job of locating DFDR and CVR, and recovering the same, was not designed to operate at 6700 feet depth. Its maximum design operating depth was only 6000 feet. However, it was decided to exceed the design operating depth for this emergency operation.

3.2.1.3 By using the preliminary information of probable area of location OF CVR and DFDR as indicated by ship 'Gardline Locator', the Scarab I was Lowered in the sea to locate and recover these units which it accomplished on 10.7.85 and 11.7.85 respectively.

3.2.1.4 Prior to recovery of DFDR/CVR by the ship 'Leon Thevenin', sufficient spade work was done by the ship 'Gardline Locator' (A ship provided by Accident Investigation Branch, U.K.) and 'Le Aoife' (an Irish Naval Ship). The survey of the crash area, carried out with the help of side-scan sonars fitted on these ships, had indicated a general distribution of the wreckage and a rough idea about the sizes of the parts. Each part of the wreckage was called a target. The method used for survey was triangulation with multiple passes through the crash site.

3.2.1.5 Next phase was the task of :

(a) Locating hundreds of pieces of wreckage by the combined use of sonar and video monitors.

(b) Video and still photography of the pieces of wreckage.

(c) Plotting the distribution of the wreckage.

All this was to be carried out under the directions of the Court.

3.2.2 Scarab

3.2.2.1 The means (vehicles/equipment) proposed to be used in the locating, mapping and video photography of the wreckage were the CCGS John Cabot and SCARAB II.

3.2.2.2 The John Cabot is an ice breaker of the Canadian Coast Guard. Since utilisation as an ice breaker is seasonal, the John Cabot is also equipped for submarine cable laying. In order to enlarge its capabilities in this regard, the John Cabot is equipped to have on its deck the Scarab and to operate it. Thus the John Cabot can be used for repair of submarine cables. The John Cabot has complete facilities for operation, maintenance and repair of the Scarab. This includes a Control Hut, a Test Room, Workshop, Stores etc. The John Cabot has considerable experience in work on deep sea bed.

3.2.2.3 The SCARAB II is a submersible craft assisting repair and burial of cables. As will be clear from the following details, the Scarab is not ipso facto a submarine. It is a total system for carrying out its complex functions.

3.2.2.4 The SCARAB II is a state-of-the-art system designed and built for tethered unmanned work at ocean depths of upto 6000 feet. Scarab's standard equipment are :

Two rugged manipulators.

A complete optical suite.

Six thrusters of 5 hp each.

CTFM Sonar.

Navigation System.

3.2.2.5 The manipulators have a choice of grippers/claws/cutters etc. of any required description and size. The Scarab has three TV cameras mounted on separate pan/tilt mechanism to allow real time observation and video tape documentation. A 35 mm still camera was also installed and used in the present work. There was a choice of quartz-iodide flood lights to provide illumination.

3.2.2.6 The location and control of the Scarab is accomplished through a phased array navigation system.

3.2.2.7 The Scarab was equipped with a 360° high resolution Sonar with a range of 1000 meters. The Sonar was also capable of interrogating and detecting 37 KHz and 27 KHz pingers. It can function independently of the ship's facilities and is equipped with power generators and semiautomatic handling equipment.

3.2.2.8 The John Cabot can salvage items, but it is not a salvage ship as it does not have the specialised high capacity cranes, derricks etc. required for salvage of large objects. Further, it does not have deck space for keeping large salvaged items like the wings, fuselage or tail surfaces of an aircraft as large as a 747. The John Cabot was, therefore, adequate and fully satisfactory for the work envisaged in this phase of the programme, as salvage of large items was not planned in this phase. The task was, as mentioned earlier, locating, mapping and photography of the hundreds of pieces of wreckage. (The salvage work was part of the next phase of the programme).

3.2.3 Control and Monitoring of Operations

3.2.3.1 It was realised that the operation proposed would pose problems of control, monitoring and logistics.

3.2.3.2 Consider : A ship operating on the high seas in international waters on the task of locating, mapping and video photographing the hundreds of pieces of wreckage. The state of art system for Sonar location and photography (Scarab) used by the ship for handling this task. The group located on shore in charge of the operations. Finally, the Court in Delhi was in overall charge of the operatins.

3.2.3.3 It was realised that a proper line of control and communication was essential if the operations were to be smooth and successful.

3.2.3.4 Therefore it was decided that the following would be the chain of command :

Court Investigating the Accident
(Mr. Justice B.N. Kripal)
Control Centre at Cork
(Court's representative)
CCGS John Cabot
(Commanding Officer)
Scarab
(Project Manager)

3.2.3.5 Because of the multiplicity of agencies involved in the operations, the need was felt for a proper delineation of power at all levels. It was, therefore, decided that :

a. Overall responsibility for the operations would rest with the Indian authority viz. the Court. This would cover the identification and definition of assignment of the overall tasks, laying down of the priorities, overall control of the coverage of the operation and, finally, the time schedule for the operation.

b. Decisions taken at the Control Centre, flowing from the above, were to be taken solely by the Court's representative. The experts from CASB, NTSB and Boeing were free to give their views and recommendations, but the final decisions were to be left to the Court's representative. Examples of such matters are : Track of the survey, areas to be covered by John Cabot, assignment of priorities for specific tasks, amount of time to be devoted to any piece of wreckage, whether any item of wreckage is to be picked up, etc.

c. Operation Control of John Cabot would be in the hands of the Canadian Coast Guard Officer in the Control Centre,

who would co-ordinate with the Commanding Officer of John Cabot. This would cover decision on feasibility or otherwise of operations under adverse weather conditions, manner of covering the area, method of retrieving any wreckage, etc.

d. Decisions relating to the Scarab (i.e. whether the weather was suitable for Scarab operations, whether the size, weight etc. of an item would permit its being picked up by Scarab, etc.) would be left to the Scarab Project Manager on Board John Cabot.

3.2.3.6 It might appear at first sight that in the above system excessive power was delegated at certain levels to the detriment of overall control. Any such impression would not be correct. In actual fact, because of proper delegation of responsibility and power at different levels, the operations were carried out with extraordinary efficiency, smoothness and coordination, In this connection, it is relevant to point out that the operations were not a uni-disciplinary one. The operation (aircraft accident investigation) was totally dependent on experts from other disciplines, like naval (coast guard) operations, deep sea photograph, salvage from sea bed etc. It was therefore, decided that for smooth and efficient operations, adequate power and responsibility should be delegated at all levels, particularly to specialists engaged in the different areas of work as above.

3.2.3.7 It was also considered that adequate communication was a sine qua non for smooth operation. Therefore, the following communication facilities were established :

Control Centre at Cork Airport

Telex

Telephones (2)

3.2.3.8 The ship John Cabot had both telex and telephone facility. These links were through satellite (IN MARSAT). The Control Centre was in continuous communication contact with John Cabot through telex and telephones. In order to establish a reliable and satisfactory line of communication it was decided that instructions or communication from Control Centre to the Indian experts on John Cabot would follow the path as under :

Control Centre

Court's representative --- Canadian Coast Guard Officer

John Cabot

Indian experts --- Commanding Officer

3.2.3.9 It was felt that this would eliminate any possibility of inconsistent or contradictory orders/messages going to John Cabot.

3.2.3.10 With a view to have an ordered system of communications between the control centre and John Cabot (which is essential for proper control and monitoring of the operations), it was decided that John Cabot would sent to the Control Centre daily Situation Reports (SITREPS) at specified times viz. 0800 hrs, 1200 hrs, 1600 hrs and 2000 hrs. This however did not preclude the despatch of telexes by both Control Centre and John Cabot at any other time.

3.2.3.11 In order to inform all agencies of the above system of Control and Communication a number of meetings were held. These were on 12.8.85 and 3.9.85 on board John Cabot and on a number of occasions at the Control Centre. The purpose of these meetings was not only to inform all concerned about the specific task, the programme and the line of control and communication but also to sort out differences and to understand the technical and operational difficulties faced by the personnel on the spot and to find a way out.

3.2.4 Daily Monitoring of Progress

3.2.4.1 It may be relevant to point out here that search, location and video photography work was to be carried out round the clock. Thus a considerable volume of data would be coming into Control Centre. This required regular, almost hourly, monitoring, study and analysis for

(a) proper understanding of the data collected and (b) advising John Cabot of any changes in its programme, such as additional photography on an item etc. For this purpose (i) SITREPS were filed in the Control Centre (ii) all data (description, latitude and longitude) obtained on every target was tabulated and the cumulative list updated daily.

3.2.4.2 The location of the targets was plotted on charts every 4 hours. This was in addition to the plotting of targets carried out on John Cabot.

3.2.4.3 Every day (including holidays and week ends) all the officers posted at Control Centre assembled at about 0900 hrs. They studied the SITREPS received at 0800 hrs and any other telexes received from John Cabot in the night. The lists of targets were updated and the new targets plotted on the charts. John Cabot generally also sent brief remarks such as description, nature of failure/damage, dimensions etc. Discussions were held on the significance of the targets and their implications. Instructions if any to be telexed to John Cabot were also discussed. Similarly SITREPS received at 1200 hrs and 1600 hrs were studied.

3.2.5 Monitoring at Cork

3.2.5.1 The Scarab provided video tapes and still photographs. In the initial stages (upto 9.8.1985) the John Cabot was operating in peripheral areas and therefore few targets were found. Hence the output of videotapes was small. In fact upto 9.8.85, only about 10 targets were found and only 3 video tapes were used up. But later, when John Cabot came close to and into the crucial areas, video tapes were recorded at a fast rate. Further, still photography facility on the Scrab was activated at about this time. Therefore, arrangements were made periodically to obtain the video tapes and films from John Cabot. Video tapes and still photographs (these required to be processed) were transported from John Cabot to Cork Control Centre.

3.2.5.2 About 50 video tapes and nearly 3000 still photographs (positives and transparencies) provided the visual information on the targets.

Arrangements had to be made at Cork for such viewing and study of the video tapes and still photographs. Video equipment (TV monitor plus

VCR) suitable for viewing the video tapes had to be arranged.

3.2.5.3 The still photography used special professional quality colour film (35 mm), each roll having 800 frames. The film was diapositive. These had to be developed and transparencies obtained from them. Thereafter negatives and prints had to be made. Special equipment for viewing the transparencies had to be provided for continuous work. The video tapes, transparencies and prints provided the principal means of monitoring of the results of the operation.

3.2.6 Operations

3.2.6.1 The Charts prepared by 'Gardline Locator' were on a different type of grid system, and had to be translated into LAT-LONG system, for use by John Cabot. For the convenience of search/mapping operation the search area was divided into 4 blocks viz. Block 1, Block 2, Block 3 and Block 4.

3.2.6.2 The navigation system used by John Cabot is PULSE-8 system. This system needs the transponders to be placed on the sea bed. These transponders help in getting the correct fix of a target and in obtaining relative positions of the targets on the sea bed which is highly useful for revisit for the purpose of rephotography or recovery. Initially 4 transponders were placed, and subsequently the number was increased as the search operation was continued. The strategic locations for placing the transponders was decided by considering :

(a) frequencies of relative transponders,

(b) distances required between relative transponders,

(c) wreckage distribution suggested by side scan sonar plots of Eithena and Garline Locator, and

(d) size of search area.

These transponders were calibrated to match the navigation system of the ship.

3.2.6.3 In order to obtain the maximum information from search, it was decided that the Scarab search paths should be as follows :

(a) Normally the search paths should be east to west, or west to east within the individual blocks.

(b) The pattern of search should be a parallel search method.

(c) Distances between the parallel paths to be 1,200 feet (i.e. 2 cable widths), for effective use of sonar fitted on the Scarab.
(d) If Scarab deviates from its planned path for photography or recovery, it should return to its planned path for further search.
(e) In each block, the search was to be made, at least 1/2 mile (North or South) beyond the last target sighted, so as to ensure no target is missed out from the given block.
3.2.6.4 However, when there was a need to modify the search pattern, due to wreckage distribution in particular areas, the following changes were made:
(a) Expanding box type search pattern was used in Block 1.
(b) Some North to South and South to North passes were made in Block 3.
(c) In Block 3 northern end, the distances between the search passes was reduced to 600 feet i.e. 1 cable width.
However, these deviations were made basically to improve the reliability of search in specific areas, as demanded by peculiar distribution of aircraft wreckage.
3.2.6.5 To facilitate identification of the wreckage located by Scarab it was necessary to position aircraft maintenance personnel on board the ship. As the aircraft structure was badly torn, mutilated and distorted, serious difficulty was anticipated in identification of small pieces of structure. It was therefore essential that these maintenance personnel were provided with aircraft photographs, manufacturing drawings, parts catalogue, wiring diagram manuals and maintenance manuals. Since carriage of such voluminous literature was not praticable, 3M micro film reader printer
machines with micro film cassettes of the above literature were produced and installed on the ship. In case of difficulty of locating any particular information, the engineers were advised to contact Cork Search Centre by telex or telephone who, in turn, could seek the desired information from the manufacturers.
3.2.7 Wreckage Distribution
3.2.7.1 The wreckage distribution as determined by the mapping of the

sea bed provided some distinct distribution patterns. The depth of the wreckage varies between about 6000 and 7000 feet, and the effect of the ocean current, tides and the way objects may have descended to the sea bed was not determined, thus some distortion of an object's relationship from time of water entry to its location on the bottom cannot be discounted. In general, the items found east of long 12°43.00'W are small, lightweight and often made of a structure which traps air. These items may have taken considerable time to sink and may have moved horizontally in sea currents before settling at the bottom. Marks left on the sea bed beside some wreckage does indicate horizontal movement of the wreckage as it settled. Although badly damaged, sections 41, 42 and 44, and the wing structure were located in a relatively localized area centred about lat 51°03.30'N and long 12°47.80'W, and the wreckage scatter was oriented north/south. The wreckage scatter in this area was so dense that it is probable that some of the wreckage may not have been mapped or photographed. Section 46 and 48, including the vertical fin and horizontal stabilizer, extended in a west to east pattern with the western most identified aircraft component located at lat 51°02.90'N and long 12°50.1'N. The wreckage extended in a line about 110 degrees to an eastern position of lat 51°02.04'N and long 12°41.26'W, a distance of approximately 6.5 nautical miles. The aircraft structure had a random scatter pattern. That is, items such as the aft pressure bulkhead were broken into several pieces, and these pieces were located throughout the pattern. A third area which had some distinctive pattern was that of the engines, engine struts and components and was localized about lat 51°03.25'N and long 12°47.4'W in a northwest/southwest orientation. One of the operating engines was displaced 0.5 nautical mile to the north of this area, and it was also geographically separated from the wing structure. The number 3 engine nacelle strut was also separated from the rest of the engine components

and was located about one nautical mile to the west-southwest at lat 51°02.87'N, long 12°48.05'W. The reasons for the displacement of the number 3 engine nacelle strut and one of the operating engines from the other engines are not known.

3.2.7.2 Details of the various targets which were identified by the Structures Group is contained in Appendix 1 of this Report.

3.2.8 The Break up Pattern

3.2.8.1 The forward fuselage section of the aircraft was found inverted and badly broken into many pieces, the major pieces being :

(I) Section of fuselage right side below cockpit windows containing part of the name 'Kanishka' (in Hindi) and 3 passenger windows (Target No. 192)

(ii) Portion of upper skin between B S 360 and B S 520 below window belt right side, up and over crown. This portion includes the crew door and last letter of the "Air India" (in Hindi) logo (Target No. 192).

(iii) Section of fuselage between B S 510 to B S 700, including the passenger window belt right side, up and over crown to include upper deck windows left side (Target No. 218).

(iv) Section of fuselage between B S 720 to B S 840 including left side passenger window belt, up and over crown to right side passenger window belt. Forward and upper edges of L H No.2 door cutout can be seen (Target No. 193).

(v) Large section of fuselage between B S 1000 to B S 1460 including left side passenger window belt, up and over crown to right side passenger window belt. This section was found lying on its right side (Target No. 137).

(vi) The lower portion of the fuselage skin/frame between the nose and B S 1000 was damaged past recognition except for a small portion with the forwarded cargo door (Target No.204) and another portion containing the aft access door cutout at B S 810 (Target No. 362).

3.2.8.2 The aft fuselage was found in the following major pieces :

(I) Section of RH fuselage skin between B S 1640 and B S 1940 below the window belt up to the crown (Target No. 321).

(ii) The RH fuselage bottom skin between B S 1820 (forward edge of C2 door) and B S 2060 and between two stringers above the door cutout to just below stringer 46 lap joint (Target No. 40).

(iii) The lower fuselage skin with stringers between B S 1480 and B S

1846 about 100 inches wide approximately (Target No. 7).
(iv) The LH fuselage skin panel between B S 1740 and B S 1880 about 110 inches wide (Target No. 11).
(v) The LH fuselage skin between B S 1460 and B S 1800 width 80 inches including No. 4L door and passenger windows (Target No. 28).
(vi) The RH fuselage skin between B S 1660 and B S 1920, from below window belt up to the crown including the 4R door cutout (Target No. 321).
(vii) A fuselage lower skin panel (containing out flow valve) between B S 2120 and B S 2240 and 120 inches wide (Target No. 320).
(viii) A fuselage LH skin panel (containing 5 windows with "T -" part of registration) between B S 1980and B S 2080 between stringers 19L and 24L (Target No. 369 and 26).
(ix) A fuselage LH skin panel between B S 1460 and B S 1800 with 8 stringers below the bottom of the door and 3 stringers above the top of the door (Target No. 28).
3.2.8.3 The tail portion of the fuselage was found in the following pieces:
(I) The lower fuselage skin between B S 2412 and B S 2598 about 20 stringers wide (Target No. 371).
(ii) The vertical fin with rudders attached was lying on the ground by itself with a portion of B S 2517 frame. This includes a small portion of the aft pressure bulkhead (Target No.37).
(iii) The horizontal tail with elevators attached was lying on ocean floor with the jack screw and drive motor attached (Target No. 31).
(iv) The fuselage tail cone aft of B S 2669 was found basically intact and lying separately (Target No. 27).
3.2.9 Extent of Damage
Photographic and Video Interpretation of Wreckage
Photographic Interpretation
3.2.9.1 All wreckage sighted was recorded on video tapes and all major items were recorded on 35 mm positive film. During the course of the investigation, several members of the investigation team had the opportunity to view the tapes and photographs. Subsequently, when

some items were recovered, it became apparent that the optical image presented on video and still film had some limitation with respect to identification of damage or damage pattern. For example, the sine wave bending of target 7 appeared in the video and photographs as a sine wave fracture, and some of the buckling on target 35 was not evident in either the video or photographs. The interpretation of damage through photographic/video evidence without the physical evidence might be misleading, and any interpretation should take this into acount.

3.2.9.2 Engines

The four operating engines were all extensively damaged. A view of the fan blades did not show signs of any rotational damage, and it could not be determined whether any pre-impact failures had occurred. The external damage to the engines varied, and at least one engine appeared to be attached to part of the nacelle strut. Except for the non-operational fifth engine, the engines could not be matched with their original positions on the aircraft.

3.2.9.3 Landing Gear

The nose, wing, and body landing gear were all located. Photographic examination indicated that all the gears were in the 'up' position at the time of impact.

3.2.9.4 Flaps and Spoilers

Positive identification of all the flap and spoiler surfaces was not made. All the flap jackscrews indicated that the flaps were retracted at impact. Of the spoilers identified, six had actuators attached. The actuators were in the fully retracted position.

3.2.9.5 Section 41

Section 41, consisting of the cockpit, first-class section, and electronics bay and identified as target 192, was found in a near-inverted attitude. This section was severely damaged. The electronics bay and cockpit areas could not be located within the wreckage. The first officer's seat was found on the sea bed near section 41 wreckage.

3.2.9.6 Section 42

Portions of Section 42, consisting of the forward cargo hold, main deck passenger area, and the upper deck passenger area, were located near section 41. This area was severely damaged and some of section 42 was attached to section 44. Some of the structure identified from section 42 was the crown skin, the upper passenger compartment deck, the belly skin, and some of the cargo floor including roller tracks. The right-hand, number two passenger door including some of the upper and aft frame and outer skin was located beside section 44. Scattered on the sea bed near this area were a large number of suitcases and baggage as well as several badly damaged containers. All cargo doors were found intact and attached to the fuselage structure, except for the forward cargo door which had some fuselage and cargo floor attached. This door, located on the forward right side of the aircraft, was broken horizontally about one-quarter of the distance above the lower frame. The damage to the door and the fuselage skin near the door appeared to have been caused by an outward force. The fractured surface of the cargo door appeared to have been badly frayed. Because the damage appeared to be different from that seen on other wreckage pieces, an attempt to recover the door was made by CCGS John Cabot. Shortly after the wreckage broke clear of the water, the area of the door to which the lift cable was attached broke free from the cargo door, and the wreckage settled back on to the sea bed. An attempt to relocate the door was unsuccessful.

3.2.9.7 Section 44

Section 44 containing the aircraft structure between B S 1000 and B S 1480 including that area where the fuselage and wings were mated was located and identified. This section was severely damaged but maintained its overall shape and was lying on its right side. Part of the left wing upper skin was attached to the fuselage and a large portion, about one third of the upper wing skin, separated and was lying against the fuselage crown skin. Some of the body and wing landing gears were found beside this section of the aircraft. The gear was detached from the main structure. The interior of the fuselage was extensively damaged.

3.2.9.8 Wing Structure

The wing structure was located near the forward area of the aircraft structure and towards the northern most area of the wreckage pattern. The wings showed extreme damage patterns with the top and bottom surfaces separated and the wing surfaces broken into segments.

3.2.9.9 Sections 46 and 48

Sections 46 and 48 contain that part of the aircraft structure aft of B S 1480 and, for purposes of this report, will include the horizontal stabilizer and vertical fin. This section of the aircraft was scattered in a west to east pattern about 6.5 nautical miles in length and exhibited severe break-up characteristics.

3.2.9.10 The aft cargo and bulk cargo doors were found in place and intact, and 5L, 5R and 4R entry doors were identified. Four segments of the aft pressure bulkhead were positively identified (targets 35, 37, 73 and 296). Much of the fuselage which was forward of the number five door and above the passenger floor area was not located, or if located was not recognisable as having come from a specific area of the aircraft.

3.2.9.11 Sections of the outer skin below the cargo area were located as was some of the cargo floor structure. Generally, the stringers and stiffeners are attached to the skin; however, the lower frames, which provided the cargo floor support, were detached from the skin. The rear cargo floor from B S 1600 to B S 1760 was located and was found to have little or no distortion; however, the lower skin and stringers were missing. A second portion of the aft cargo compartment floor containing cargo drive
wheels and cargo roller trays was located. This structure was severely damaged and mangled.

3.2.9.12 The tail cone and the auxillary power unit (APU) housing were located and had received relatively minor damage; however, the APU had broken free and was never located.

3.2.9.13 A large portion of the outer skin panels showed signs of a force being applied from the inside out. On several pieces of wreckage, the skin was curled outwards away from the stringers and formers. This could have been the result of an overpressure.

3.2.9.14 The vertical tail was found in good condition, in a single piece with both rudders attached. The top cap was partially separated and a small dent was noticed in the middle of the leading edge at the bottom. A curved broken portion of fuselage was observed with a portion of the "Y" ring and pressure bulkhead attached. Another small segment of the pressure bulkhead was leaning on the lower section of the tail.

3.2.9.15 The horizontal stabilizer tail section was located and was one unit with the elevators attached. The actuator jackscrew was attached to the assembly. The stabilizer jackscrew ballnut was observed to be located at the upper jackscrew stop. This equates° to a full deflection of elevator trim. Since there is nothing on the DFDR or CVR to indicate a malfunction of the trim, it is deduced that this was not the lead event. It is not known if the position of the ballnut resulted from a pilot trim selection, a result of the initial event or if it rotated to the observed position under the influence of gravity. Two-thirds of the leading edge of the right horizontal stabiliser was missing and the auxilliary spar was exposed. There was localized damage to the right-hand root of the loading edge through about a span of five ribs. The leading edge skin and part of the leading edge ribs were torn downwards. Some localized damage to the root of the left leading edge was visible with the remainder of the leading edge undamaged. There was minor damage to the trailing edge of the outboard left elevator, and a major portion of the inboard left elevator was missing.

3.2.9.16 Passenger Seats

Many of the passenger seats located among the wreckage pattern and identified as having come from section 46 and 48 appeared to have the aft support legs buckled with little or no damage to the forward support legs. Seats located in the wreckage containing sections 41, 42 and 44 appeared to have varying types of damage, that is, aft support legs only buckled, and all legs buckled. One consistent feature noted was that in the majority of seats located it was possible to ascertain that the seat belts were not fastened.

3.2.10 Salvage Operations

3.2.10.1 During recovery operation the video tapes as well as photographs of the wreckage to be recovered, were supplied to the personnel on board the ship for facilitating identification and recovery of correct targets.

3.2.10.2 Whenever any component/part of the aircraft wreckage was salvaged it was essential to immediately subject the same to inspection and to identify the damage sustained during recovery operation. In order to oversee this critical operation, the Court deputed one of its Assessors, Dr. V. Ramachandran, to be on board the ships. Under his supervision, the components/parts were thoroughly washed with fresh water, dried and treated with corrosion inhibiting compounds. A detailed inspection was thereafter carried out, observations recorded and the targets were appropriately labelled and their numbers were painted thereon. A laboratory microscope was taken on board by Dr Ramachandran. With that, fragments of significance were segregated for further investigation. Indeed some of these fragments did give important clues.

3.2.10.3 All the investigating personnel on board the ship were provided with leather gloves, fisherman's shoes, raincoat, life floating suits, writing and labelling material, camera with coloured films, etc. Sufficient number of "body bags" were positioned on each ship to cater for the eventuality of recovery of bodies with the wreckage. This precaution helped when a body did come along with wreckage on 25.10.1985.

3.2.10.4 The ship John Cabot completed the operation of locating, mapping and photography of the wreckage and returned to Cork on 1.10.85 at 2020 hours. The next phase of operation was to recover the significant wreckage parts which would be useful for deciding the cause of the crash.

3.2.10.5 Subsequent to the accident to Japan Airlines Boeing 747 aircraft, suspected to have been caused by failure of the repair to the rear pressure bulkhead, NTSB and FAA decided to fund the U.S. Navy for a two week operation over the seas for recovery of significant pieces of wreckage. For this purpose, U.S. Navy appointed Commander J.R. Buckingham, a deep sea salvage expert, to head the recovery operation. An offshore supply vessel M.V. Kreuzturm, of Canada was hired by U.S. Navy to recover the wreckage with the help of Scarab on John Cabot. One nylon lift line together with winch and ram were installed on the ship prior to its sailing to Cork where it arrived on 4th October,

1985. One crane was installed on the ship Kreuzturm in Cork.

3.2.10.6 One inch dia Kevlar lines coated with black plastic for abrasion resistance and braided with Dacron lining were used by John Cabot as primary lift lines.

3.2.10.7 The structure group after studying the photographic data, had formulated a list of 32 targets for recovery on 3.10.85. A systemwise priority list proposed by the Court of Inquiry was received through Dr V. Ramachandran on 4.10.85. Using these two lists, and taking into account the operating restrictions imposed by two ship operation, a final list of targets was prepared for recovery by the ships, assigning a priority number to each target. However, as the recovery operation progressed, changes in priority list were made to achieve optimum utilisation of the ships.

3.2.10.8 A meeting was held at 1400 hrs. on 4.10.85 on board CCGS John Cabot to establish/clarify the priorities for the wreckage recovery operation and coordination between John Cabot, Kreuzturm and Cork Search Centre. All the personnel involved in the recovery operation were shown the slides and photographs of the targets which were chosen for recovery on priority basis. The method and procedure of the recovery operation was discussed in detail and finalised. Another meeting was convened on 6.10.85

to clarify the doubts and to present the picture albums containing various photographs of targets to be recovered. The mode of attaching grippers/grabbers to the targets at strong points was clarified. A serialised list of priorities was prepared based on the mode of operation indicated by the the crew of John Cabot and Kreuzturm. Dr Ramachandran was given the authority to make on-the-spot decisions during the salvage operations.

3.2.10.9 A detail log of the activities of the ships John Cabot and Kreuzturm which started the recovery operation of 10.10.85, reveals the following :

(a) The Scarab working independently recovered the following

(1) Basket at target 192 containing copilot's chair, 2 suitcases and radar antenna (12.10.85)

(2) Target 8 - Lower fuselage skin of aft cargo compartment. (11.10.85).
(3) Target 245 - Forward belly skin just aft of radome (16.10.85).
(4) Target 350 - Economy class seats and carpet (23.10.85).
(5) Target 296 - Piece of aft pressure bulkhead.

(b) The Scarab after attaching the grippers, bridal cable and lift line to the targets buoyed off the same to Kreuzturm which recovered the following targets :

(1) Target 362/396 - Forward cargo fuselage skin from station 700 to 840 and STR 41L to 43R. (16.10.85).
(2) Target 193 - Fueselage skin from station 720 to 860 and passenger door 2L (17.10.85)
(3) Target 223 - Nose landing gear pressure deck web and stiffeners, container pieces (staion 260-340)(19.10.85).
(4) Target 181 - Wing skin with forward cargo compartment SLIPPED OFF WITH GRIPPERS (21.10.85) AND WAS LOST.
(5) Target 399/358 - Fuselage skin from station 780 to 940 and STR 7R to 35R with 2R door (25.10.85). A body entrapped in target 399/358 was recovered. Another body which came upto surface with the wreckage fell off into sea and was lost while hauling the wreckage on board. The recovered body was identified as of Dr. Mathew Alexander, a Canadian passenger and was brought to Cork by Fisherman's vessel "Orion" at 0130 hrs. on 28.10.85 and was sent for Post Mortem etc.
(6) Target 7 - Aft cargo compartment fuselage skin from station 1480 to 1860 (26.10.85).
(7) Target 47/50 - Aft cargo floor structure with roller tracks, frames, latch etc. from station 1600 to 1760 (27.10.85).
(8) Target 117 - Three rows of coach class seats with passenger cabin floor boards, broken floor beam (28.10.85).
(9) Target 35 - Aft Pressure Bulkhead piece (30.10.85).

3.2.10.10 The Scarab experienced malfunctions with its arms, Sonar equipment, multiplex system, junction box, microprocessor unit, etc. off and on during the above period of operation. Fouling of lift line with umbilical cord was also experienced in the early stages of operation. Since the assigned recovery by Kreuzturm was over by 30.10.85, and as the Scarab became unserviceable due to breakdown of its power suppluy, the OSV MV Kreuzturm was directed to return to Cork to off-load the recovered wreckage and its operation was terminated, (Indian Government had funded the cost of operation of M.V. Kreuzturm from 21.10.85 onwards).

3.2.10.11 Since the Scrab continued to remain unserviceable, the ship John Cabot was called back to Cork. It anchored in Cork at 1100 hrs. on 5.11.85. All the wreckage on board the ship was transported to the boat yard, in the afternoon.

3.2.10.12 After detailed macro photography of the recovered wreckage, the experts group mentioned in section 1.5.16 prepared a detailed factual report after carefully inspecting each of the targets recovered. It was decided to send the wreckage to Bombay for which necessary crates were then prepared and the large pieces of wreckage were cut along the lines indicated by the experts group to facilitate their packing.

3.2.10.13 RCMP investigators carried out a close visual and microscopic examination of the fragments recovered with the wreckage, suitcases, seats and cushions, etc. For further laboratory analysis. Dr A.D. Beveridge collected a few samples.

3.2.10.14 The Scarab appeared to be serviceable on 19.11.85 and the ship John Cabot sailed for completion of recovery of left over targets, on 20.11.85. However, the serviceability of Scarab proved elusive, it became inoperable on 21.11.85 and the ship returned to Cork at 1700 hrs on 25.11.85.

3.2.10.15 Efforts were made to repair Scarab so that the ship John Cabot could sail again in order to salvage as many pieces as possible. It was fortunate that the weather had not deteriorated. Some of the important but small pieces which had to be recovered had been placed in a basket at the bottom of the ocean. The ship sailed out again after Scarab had been repared. The basket was sought to be lifted, but, unfortunately, when it reached near the surface of the sea it overturned and the contents of the basket spilled and were never traced again.

3.2.10.16 At this juncture it was decided that the salvage operations should be terminated. The ship returned and sailed for home in the first week of December 1985.

3.2.11 Examination of Wreckage

3.2.11.1 Floating Wreckage

Soon after the accident, a number of light weight parts of the aircraft were found floating over a wide area at the crash site. These were picked up by the ships engaged in rescue operations and were brought to Cork where they were kept in the boat yard. The floating wreckage recovery continued for four days i.e. upto 26th June.

3.2.11.2 Some of the wreckage items were subsequently washed to the west coast of Ireland. These were picked up by the Irish Police and were brought to Cork. Some wreckage items were taken by a ship to Halifax, Canada. These were flown to Cork by the Canadian Aviation Safety Board. With the assitance of Air India engineers, the wreckage items were identified, labelled, photographed and laid out in the boat yard hangar for examination.

3.2.11.3 The wreckage was initially examined at Cork by the Structures, Power Plant and Systems Group. It was subsequently transported to Bombay for further examination. A few wreckage items which were taken by the Spanish trawlers to Madrid were also transported to Bombay. Some wreckage items had washed to the west coast of England. These were collected by the Accident Investigation Branch of UK and were transported to Cork and then to Bombay.

3.2.11.4 The floating wreckage recovered constituted approximately 3 to 5 per cent of the aircraft structure. The major items of the wreckage recovered were :

Various leading edge skin panels of LH nd RH wing, LH wing tip, spoilers, leading edge and trailing edge flaps, engine cowlings, flap track canon fairings aft end pieces, landing gear wheel wall doors, pieces of elevator and aileron, toilet doors, cabin floor panels, cabin overhead and upper deck bins, passenger seats, life vests, slide rafts, hand baggages, suitcases etc. and three empty oxygen bottles.

3.2.11.5 The Structures Group which had been constituted by the Court examined the floating wreckage and submitted its report. From the report the following significant information about the damage to major items of the floating wreckage is noted :

(I) VT-EFO aircraft was carrying a -7Q engine on 5th pod and a -7Q 5th pod kit in the aft cargo compartment. It had therefore, in all 14 engine fan cowls (eight working engine fan cowls plus two 5th pod engine fan cowls plus two -7T engine kit fan cowls in the aft cargo compartment plus two -7Q engine fan cowls in the aft cargo compartment). Out of these 14 fan cowls, 9 cowls (6 of working engines plus 2 of -7J kit plus one of 7Q kit) and two additional pieces of fan cowls were found. Five of the fan cowls of working engines show folding damage lines at approximately 3 O'Clock and 9 O'Clock positions. The number 3 engine inboard fan cowl has severe impact damage on its leading edge and has small inward to outward puncture holes (not penetrating through outer skin) in the lower centre region. The two fan cowls of -7J 5th pod kit stowed in the aft cargo compartment exhibit severe damage. One of these cowls is broken in two pieces. One of the pieces is cut at one corner in an arc of about 20 inches diameter and its external skin is pealed back. The external surfaces of all the three pieces have considereable scratches, tears and holes from outside to inside. None of the punctures penetrates the inner skin. Some punctures are also present from inside to outside but none of these penetrates the outer skin.

(ii) Out of the 12 spoilers, seven (number 2, 3, 5, 7, 8, 9 and 12) have been retrieved. Of these, six have their actuators attached to them in fully retracted position. Six spoilers have splits in their lower skin with split edges curled into the cores of honeycomb. Number 8 spoiler (located just inboard of number 3 engine) has a concentrated local impact damage on front spar and trailing edge beam from forward to aft and up direction over a span of 2 feet starting from outboard of spoiler actuator.

(iii) The left hand wing tip assembly with a part of H F Antenna was retrieved. No burning/discolouration marks around lightning arrester of H F system were noticed. The rib inboard of the lightning arrester was found intact. There were no burn marks anywhere on the panel.

(iv) The right hand wing leading edge top panel inboard of number 3 engine with a position of kruger flap frame along with bull nose attached was recovered. The bull nose was found crushed from top in the area just below the stay rod and the lower surface of stay rod has scratch marks from front to rear.

(v) The right hand wing root leading edge (inboard of W S 268.81) shows an impact damage at the leading edge. Bottom skin and internal structure are torn away. The leading edge skin is caved in over a span of about 3 feet and shows signs of heavy body impact in air. The impact damage shows signs of downward and backward movement of the impacting body.

(vi) A 3' x 2' piece of right hand inboard trailing edge fore flap with accordian seal was recovered. The inboard 8" portion of leading edge was found damaged by impact of an object going from lower forward to upper aft.

(vii) All the floor panels recovered from upper deck and main cabin indicate that these were detached from their attachments in an upward direction from all sides.

(viii) One main deck blow out door located between B S 2040 and 2140 left hand side was available. Out of its four metal clips, one clip was broken off with 2 nylon rivet heads sheared.

(ix) The cockpit entry door and the side bulkhead panel were found fairly intact but had come out of their attachment.

(x) Twelve toilet doors, out of a total of 16, were available and were found fairly intact, but had come out of their attachments.

(xi) The available cabin interior panels and overhead bins of the main deck and upper deck have only minor damage.

(xii) The woodent boxes which contained the fan blades of 5th pod engine and were loaded in container at position 24L in the forward cargo compartment were found broken apart with no burn marks.

3.2.11.6 Wreckage Salvaged from Sea

The wreckage salvaged from the sea was visually examined at Cork by the Committee of Experts as mentioned in section 1.5.16 and the observations thereon recorded. Subsequently detailed metallurgical examination was carried out at the Bhabha Atomic Research Centre, Bombay by
Dr. M.K. Asundi and Dr. G.E. Prasad of B.A.R.C., Mr. S. Radhakrishnan and Dr. R.V. Krishnan of National Aeronautical Laboratory and Mr. B.K. Athawale of the Explosives Research and Development Laboratory, under the guidance of Dr. V. Ramachandran. During this examination, representatives of CASB, CP Air and Boeing were present in the first week. These represntatives left Bombay while the metallurgical examination was being carried out. The metallurgical examination was continued and the aforesaid group submitted the metallurgical report to the Court in December, 1985.

3.2.11.7 Although all the recovered wreckage was examined, only those items exhibiting characteristics which provide some evidence as to what may have happened to the aircraft during its final moments of flight are discussed herein below :

3.2.11.8 Target 7 - Lower Fuselage Skin Panel

This skin panel was located below the aft cargo area and contained the keel beam. Target 7 extended from B S 1480 to 1850 and was about eight feet in width and 32 feet in length. The left edge had a full length rivet line tear and the torn edge was buckled in waves, like the trace of a sine wave. One the right side, between the one quarter and midway segment, a large flap of skin was attached. The skin was folded aft, diagonally underneath, from right to left and the paint was scoured off the leading edge. The forward break was at the joint at B S 1480. The skin tear located at about B S 1860 was irregular in nature. The forward keel joint splice plate was bent, and the keel joint bolt holes were distored and elongated.

3.2.11.9 This panel was examined by the committee of experts at BARC and according to their report the keel beam trunnion fitting beneath the outer chord of the station 1480 bulkhead had fractured at the aft set of bolt holes. The fracture surface of the right side of the trunnion fitting was clean. As per the report, it was typical of overload failure in tension. The fracture surface of the left side of the trunnion fitting was covered with corrosion products, especially, at one corner, due to sea water. After cleaning this area by the recommended techniques, scanning electron microscopy revealed morphology of overload fracture consisting of dimples. Away from this corner also the fracture was similar as being due to overload. There was no evidence of there having been any fatigue failure.

3.2.11.10 At B.A.R.C., a sample was cut from the corroded corner of the failed left side trunnion fitting and metallographic examination was carried out on the same. The said examination showed on a face perpendicular to the corroded fracture surface, pits due to corrosion by sea water. The basic microstructure was however free from intergranular cracking. It was thus concluded by the experts that the material in the region corroded by sea water had not suffered stress corrosion cracking which generally manifests as intergranular cracking.

3.2.11.11 A piece of the trunnion fitting was cut and the hardness and electrical conductivity values were measured by the said experts. As per their report, the electrical conductivity values were within the specified limits.

3.2.11.12 Target 8 - Lower Fuselage Skin Panel

This skin panel was located below the aft cargo area and extended from B S 1860 to 1960 and from stringer 46L to 46R. The forward end of target 8 matched with the aft end of Target 7. A region of fracture along the rivet holes near stringer 46L was marked for SEM examination. SEM examination after cleaning revealed that the fracture was characterised by dimples along its length, including areas adjacent to the edges of the rivet holes. These features are consistent with an overload mode of failure.

3.2.11.13 According to the metallurgical report, there was no evidence of fatigue failure on this target.

3.2.11.14 Target 35 - Portion of Rear Pressure Bulkhead

Looking forward from behind the aircraft, this segment of pressure bulkhead occupied the 9 to 1 O'Clock position, the piece from 12 to 1

O'Clock position had the flange from the outer ring attached. The web below the outer ring flange had areas of buckling. From the 11 to 12 O'Clock position the outer edge showed sinusoidal buckling, and the edge sector at 9 O'Clock position was partially collapsed and its edge was turned under. Samples taken for optical stereo microscope and SEM examination revealed that the fracture characteristics were consistent with an ovrload mode of failure.

3.2.11.15 According to the metallurgical report, there was no evidence of fatigue or any other mode of failure.

3.2.11.16 Target 296 - Portion of Rear Pressure Bulkhead

Looking forward from the rear of the aircraft, this segment of the bulkhead occuped the 7 to 9 O'Clock position. Optical and SEM examination were undertaken on this item.

3.2.11.17 The fracture alont the left-hand edge of target 296 (viewed from the rear) was examined optically prior to removing any representative samples. The fracture was at the rivet line at a skin splice, except for a length of fracture about 15 inches long near the forward end, which was through the skin away from the rivet line. Most of the rivet holes along the fracture path showed some slight elongation and skin deformation.

3.2.11.18 Representative fracture samples were cut from the left-hand side and circumferential fracture edges of the fracture surfaces. Optial and SEM examination revealed that the fracture characteristics are consistent with an overload mode of failure.

3.2.11.19 Target 47 - Aft Cargo Floor Structure

This portion of the aft cargo compartment was located between B S 1600 and B S 1760. No significant observation was noted. There was no evidence to indicate characteristics of an explosion emanating from the aft cargo compartment.

3.2.11.20 Target 117 - Floor with Seats Attached

These seats were right-section doubles, located between B S 1880 and 1980 and were from rows 46, 47 and 48, F and G (Zone E). The seats were displaced to the left with the rear legs buckled to the left. The front leg supports exhibited only minor damage. The middle and rear doubles had aisle-side seat arms bent to the right. There was no impact damage to the seat backs or seat pans, and all life vests except one were gone from the underseat container bags.

3.2.11.21 In the metallurgical report it is stated that on an examination of this target it was also found that on the underside of this floor near the forward end, a number of dents and impact marks were observed. This region appeared to have suffered shrapnel penetration. This area was radiographed but no metallic fragment was detected.

3.2.11.22 Target 193 - Fuselage Side and 2L Entry Door

The fuselage segement was located between B S 720 and 840. The door and fuselage skin were buckled outwards, approximately in line with the buckling on the fuselage and 2R entry door directly opposite.

3.2.11.23 Target 399 - Fuselage around 2R Door

This target is shown in Fig. 399-1. A detailed description is given below :

TARGET 399 Fuselage Station 780 to 940 in the longitudinal direction and stringer 7R down to stringer 35R circumferentially.

This piece contained five window frames, one in the 2R passenger entry door. Three of the window frames, including the door window frame, still contained window panes. Little overall deformation was found in the stringers and skin above the door. The structure did contain a significant amount of damage and fractures in the skin and stringers beneath the window level. In the area beneath the level of the windows, the original convex outward shape of the surface had been deformed into an inward concave shape. Further inward concavity was found in the skin between many of the stringers below stringer 28R. The skin at the forward edge of the piece was folded outward and back between stringers 25R and 30R. Over most of the remaining edges of the piece a relatively small amount of overall deformation was noted in the skin adjacent to the edge separations. Twelve holes or damage areas were numbered and are further described.

No.1 : Hole, 5 inches by 9 inches with two large flaps and one smaller curl, all folded outward. Reversing slant fractures, small area missing.

No.2 : Hole, 2 inches by 3/4 inch, one flap folded outward, reversing slant fractures, one curled sliver, no missing metal.

No.3 : Triangular shaped hole about 2 inches on each side. One flap, folding inward, with one area with a serrated edge. No missing metal, extensive cracking away from corners of the hole, reversing slant fracture.

No.4 : Tear area, 8 inches overall, with deformation inward in the centre of the area. Reversing slant fracture.

No.5 : Fracture area with two legs measuring 14 inches and about 24 inches. Small triangular shaped piece missing from a position slightly above stringer 27R. Inward fold noted near the joint of the legs. An area of 45° scuff marks extend onto this fold.

No.6 : Hole about 2.5 inches by 3 inches with a flap folded outward, reversing slant fracture. Approximately half the metal from the hole is missing.

No.7 : Hole about 3 inches by 1 inch, all metal from the hole is missing. Fracture edges are deformed outward.

No.8 : Forward edge of the skin is deformed into an "S" shaped flap. Three inward curls noted on an edge.

No.9 : Inwardly deformed flap of metal between stringers 11R and 12R at a frame splice separation. No evidence of an impact on the outside surface.

No.10 : Door lower sill fractured and deformed downward at the aft edge of the door.

No.11 : Frame 860 missing above stringer 14R. Upper auxilliary frame of the door has its inner chord and web missing at station 860. A 10 inch piece of stringer 12R is missing aft of station 860.

No.12 : Attached piece of floor panel (beneath door) has one half of a seat track attached. The floor panel is perforated and the lower surface skin is torn.

3.2.11.24 Much of the damage on this target was on the skin and stringers beneath the window level, i.e., on the starboard side of the front cargo hold. The inside and outside surface of the skin in this region are shown in Fig. 399-2 and 399-3 respectively. There were 12 holes or damaged areas on the skin as described above, generally with petals bending outwards. The curl on a flap around hole no.1 shown in Figh 399-4 has one full turn.

This curl is in the outward direction. Cracks were also noticed around some of the holes. Part of the metal was missing in some of the holes. The edges of some of the petals showed reverse slant fracture. In one of the holes, spikes were noticed at the edge of a petal.

3.2.11.25 When this target was recovered from the sea, along with it came a large number, a few hundreds, of tiny fragments and medium size pieces, All of the fragmets were recovered from the area below the passenger entry door 2R. One of the medium size pieces recovered with this target was a floor stantion, about 35 inches long, shown in Fig. 399-5. It is a square tube. It had the mark station 880 painted on its inner face, i.e. facing the centre line of the cargo hold. The part number printed on this station is 69B06115 12 and the assembly number is ASSY 65B06115-942 E3664 1/31/78*. It was confirmed that this stantion belongs to the starboard side of the forward cargo hold. The inner face of the stantion had a fracture with a curl at the lower end, the curl being in the outboard direction and up into the centre of the station. Fig. 399-6 is a print from the radiograph of this station. The inward curling can be seen clearly in this figure. Curling of the metal in this manner is a shock wave effect.

3.2.11.26 A piece near the fracture edge of this stantion was cut, and examined metallographically. Fig. 399-7 and 399-8 show the micro-structure of this piece. Twins are seen in the grains close to the fracture edge. The normal microstructure of the stantion material is free from twins as shown in Fig. 399-9.

3.2.11.27 Fig. 399-10 shows a collection of small fragments recovered along with target 399. There were some curved fragments with small radius of curvature (A). Reverse slant fracture (B) was noticed in some of the skin pieces. A piece 3/4" x 1/2" and 3/16" thick was found to have three blunt spikes at the edge (C). This piece was metallographicaly polished on the longitudinal edge. The microstructre of the piece is shown in Fig. 399-11. It may be seen that the grains in this fragment also contain a large number of twins.

3.2.11.28 Target 362/396 Forward Cargo Skin

This piece indluded the station 815 electronic access door, portions of seven longitudinal stringers to the left of bottom centre and five longitudinal stringers to the right of bottom centre. The original shape of the piece (convex in the circumferential direction) had been deformed to a concave inward overall shape. Multiple separations were found in the skin as well as in the underlying stringers. Further inward concavity was found in the skin between most of the stringers.

3.2.11.29 The two sides of this piece are shown in Fig. 362-1 and 362-2. This piece has 25 holes or damaged areas in most of which there are multiple petals curling outwards. These holes are numbered 1 to 3, 4a, 4b, 4c and 5 to 23. These are described below. Unless otherwise noted, holes did not have any material missing :

No.1 : Hole with a large flap of skin, reversing slant fracture.

No.2 : Hole with multiple curls, reverse slant fracture.

No.3 : Hole with multiple flaps and curls, reversing slant fracture, one area of spikes (ragged sawtooth)

No.4A : One large flap, reverse slant fracture, one area of spikes.

No.4B : Hole with two flaps.

No.4C : Hole with two flaps, one area of spikes

No.5 : HOle with two flaps.

No.6 : Braching tear from the left side of the piece, reversing slant fracture.

No.7 : Hole, with one flap, one curl and one area of spikes.

No.8 : Very large tear from the left side of the piece with multiple flaps and curls, reversing slant fracture and at least two areas of spikes.

No.9 : Hole with multiple flaps, one curl.

No. 10 : 2.5 inch tear

No.11 : One flap

No. 12 : Grip hole, plus a curl with spikes on both sides of the curl.

No.13 : "U" shaped notch with gouge marks in the inboard/outboard direction. Three curls are nearby with one are of spikes. Gouges found on a nearby stringer and on a nearby flap.

No. 14 : Nearly circular hole, 0.3 inch to 0.4 inch in diameter. Small metal lipping on outside surface of the skin. Most of the metal from the hole is missing.

No. 15 : Hole in the skin beneath the first stringer to the left of centre bottom. Small piece missing.

No. 16 : Hole in the stringer above hole No. 15. Most of the metal from this hole is missing.

No. 17 : Hole through the second stringer to the left of centre bottom, 0.4 inch in diameter. The hole encompassed a rivet which attached the stringer to the outer skin. Small pieces of metal missing.

No. 18 : Hole at the aft end of the piece between the third and fourth stringers to the left of centre bottom. The hole consisted of a circular portion (0.4 inch diameter), plus a folded lip extending away from the hole. The metal from the circular area was missing.

No. 19 : Hole with metal folded from the outside to the inside, about 0.6 inch by 1.5 inch. Flap adjacent to the hole contained a heavy gouge mark on the outside surface of the skin.

No. 20 : Hole containing a piece of extruded angle.

No. 21 : Hole containing a piece of extruded angle.

No. 22 : Hole with one flap.

No. 23 : Hole about 0.3 inch in diameter, with tears away from the hole. Small piece missing.

3.2.11.30 Fig. 362-3 to 362-7 show a few of these holes. There were also cracks or tears around some of the holes. The curls around some of the holes had nearly one full turn. In the large tear between body stations 700 and 740 and stringers between 41L and 45L, there were many pronounced curls as shown in Fig. 362-8. On the edges of the petals around several holes, reverse slant fracture was seen at a number of places. This slant fracture is at an angle of about 45° to the skin surface, the fracture continuing in the same general direction but with the slope of the slant fracture reversing frequently.

3.2.11.31 Sharp spikes were observed at the edges of the holes or at the edges of the petals around the holes No. 3, 4A, 4C, 7, 8 (at two locations), 12, 13 and 16. Some of the spikes are shown in Fig. 362-9 to 362-12. One of the holes, No. 14, on the skin was nearly elliptical with metal completely missing, as shown in Fig. 362-13. On the inside surface of the skin, paint surrounding this hole was missing. Hole No. 16 was through the hat section stringer, as shown in Fig. 362-14. In this, most of the metal was missing. On the inside of the hat section, the fracture edge of this hole had spikes, as shown in Fig. 362-15. Hole No. 17 was through the stringer and the skin, as shown in 362-16.

3.2.11.32 Through holes No. 20 and 21, extruded angles were found stuck inside, as shown in Fig. 362-17 and 362-18 respectively. In the petal around hole No. 20, there was an impact mark by hit from the angle as seen in Fig. 362-19 photographed after removing the angle. Such a mark was not present in the petals around other holes.

3.2.11.33 On the skin adjacent to hole No. 13 gouge marks were noticed, Fig. 362-20. These marks were on the inside surface of the skin. To check whether these could be due to rubbing by the bridal cable of Scarab during the recovery operations, a sample of bridal cable was obtained from "John Cabot" and gouge marks were produced by pressing this cable against an aluminium sheet. The gouge marks thus produced, as shown in Fig. 362-21, appear to be different from those observed near hole No. 13.

3.2.11.34 A piece surrounding hole No. 14 was cut out and examined in a Jeol 840 scanning electron microscope at the Naval Chemical and Metallurgical Laboratory, Bombay. Fig. 362-22 and 362-23 are the scanning electron micrographs showing the inside surface and outside surface of the skin around this hole. Flow of metal from inside to outside can be seen from these figures. Energy dispersive x-ray analysis was carried out on the edges of this hole. Only the elements present in this alloy and sea water residue were detected.

3.2.11.35 A portion of the skin containing part of hole No. 14 was cut, polished on the thickness side of the skin and examined in a metallurgical microscope. Fig. 362-24 shows the microstructure of this region. The flow of metal along the edge of the hole can be seen from the shape of the deformed grains near the hole. This can be compared with the bulk of the grains shown in Fig. 362-25, away from the hole. In addition, in Fig. 362-24, a series of twin bands can be seen in some of the grains near the hole. Fig. 362-26 shows these bands at a higher magnification. Normal deformation rates at various temperatures do not produce such twinning in aluminium or its alloys. It may be noted that this microstructural feature is absent in the microstructure of the skin, away from hole No. 14, Fig. 362-25.

3.2.11.36 Metallography was also carried out on a petal around hole No.7 and on a curl with spikes around hole No. 12. The microstructures indicate twins, however they could not be recorded due to their poor contrast.

3.2.11.37 Small pieces containing the spikes around holes No. 12 and 16 were cut and energy dispersive x-ray chemical analysis on the region of spikes in both was carried out in the Jeol 840 SEM. Only elements present in the alloys and sea water residue were detected.

3.2.11.38 A number of small fragments were found along with the forward cargo skin in target 362. Amongst them was a piece from the web of a roller tray. This has pronounced curling of the edges towards the drive wheel, Fig. 362-27.

3.2.11.39 Another small fragment was found from the above target. This piece, identified as specimen No. 12 in box No. 1, target 362, has a number of spikes along the edge. A scanning electron micrograph of the spikes is shown in Fig. 362-28. The sides of the spikes on SEM examination revealed elongated dimples as shown in Fig. 362-29, characteristic of shear mode of fracture. Metallography was carried out on the thickness side of this specimen. Fig. 362-30 and 362-31 show the microstructure near the apex of the spike and at the root of the spike respectively. Extensive twinning can be seen in these regions of the spikes.

3.2.11.40 Another fragment recovered with target 362 and identified as specimen No. 8 in box No. 1, also showed extensive twinning. The microstructure is recorded in Fig. 362-32.

3.2.11.41 Reference has also to be made to two other reports concerning wreckage.

3.2.11.42 The floating wreckage recovered was initially examined at Cork. On 25th June, Mr. Eric Newton a retired investigator of AIB, UK, was requested to examine the floating wreckage recovered and other materials with specific reference to the possibility of explosive sabotage having taken place. Mr. Newton examined the floating wreckage, passenger clothings and the other materials recovered from the crash victims The findings of Mr. Newton on the material available at that time are summarised below:

a. Taking the scatter of the wreckage and bodies into consideration and the condition of the limited wreckage recovered indicates that the aircraft had broken up in flight before impact with the sea.

b. Detailed examination of the structural wreckage recovered did not reveal any evidence of collision with another aircraft. Nothing was found suggestive of an external missile attack.

c. There was no evidence of fire internal or external.

d. There was no evidence of lightning strike.

e. Examination of all available structural parts recovered, did not reveal any evidence of significant corrosion, metal fatigue or other material defects. All fractures and failures were consistent with overstressing material and crash impact forces

f. Examination of clothing from the bodies did not show any explosive fractures or any signs of burning. The seat cushions and head cushions also did not show any explosive characteristics.

g. The damage to the suitcases (14 large and 29 small) which were examined was due to impact crash forces. The presence of 14 large suitcases could, however, indicate that one of the baggage containers had been broken to permit these suitcases to escape.

h. A number of lavatory doors and structure also did not show any damage consistent with explosion. The flight deck door showed no explosion damage inside or outside.

i The circumstatnial evidence strongly suggests a sudden and unexpected disaster occurred in flight.

j. There was no significant fire or explosion in the flight deck, first and tourist passenger cabin including several lavatories and the rear bulk

cargo hold.
3.2.11.43 The other report dated 30th November, 1985 is of Mr. V.J. Clancy. Mr. Clancey had examined the wreckage and had also taken part, though only for a few days, in the metallurgical examination which was being conducted at BARC, Bombay.
3.2.11.44 Mr. Clancey examined practically all the items of wreckage which had been brought to BARC and in his report he has dealt with all of them. His report contained a description of the recovered items and also his comments thereon.
3.2.11.45 With regard to the aforesaid target 362, he observed that there were about 20 holes in it clearly resulting from penetrations from inside.
3.2.11.46 He further stated that:
"In addition to the fact that perforation was from inside there are certain features which suggest that they were made by high velocity fragments such as are produced by an explosion. These features are:
(a) Presence of toothed or spiked edges at some parts of the metal which had petalled out from the perforations.
"Tardif and Sterling (Canadian Aeronautics and Space Journal, 1969, 16, 1, 19-27) obtained spiked fractures in fragments from sheet alloy subjected closely to an explosion. They stated that they had not obtained this effect in fractures otherwise produced.
(b) Presence of marked curling, in some cases of more than 360°, of some of the petals.
Tradif and Sterling stated that such curling was a feature of explosively produced fragments.
(c) The virtual absence of scratches or score marks on the petals such as might be expected if something were slowly forced through the metal.
(d) The virtual absence of other impact marks on the inside surface such as might have been produced by a massive impact with a substantial object. This suggested that the production of at least many of the perforations were separate independent events.
(e) One perforation (identified as No. 14) resembles a "bullet hole", that is cleanly punched out - a type of hole usually associated with a

high velocity missile.
"There is evidence that the forward part of this item had been folded back inwards along the line of station 760 and then bent back again along a line slightly forward of this station.
"Such folding, may be violently produced on impact with the water, could have brought broken metal of stringers or stiffeners into forceful contact with the internal surfaces producing perforations outwards. The overlap of such folding would conceivably have covered the area up to station 800 and thus included most of the perforations.
"One hole identified as No. 13, was almost certainly caused by a slipping wire rope used as a sling.
"Part of the inner surface, aft of station 780 was superficially blackened as if by soot from a fire. Swabs were taken by me of this area and are being examined by R.A.R.D.E. for evidence of fire or explosives".
3.2.11.47 There were several hundred small fragments which were recovered from the same general area as Target 362. While dealing with these Mr. Clancey observed that the production of a large number of small fragments is generally regarded as indicative of an explosion. One piece out of this was isolated, which was about one inch square of sheet alloy, and it was noted by Mr. Clancey that this piece had characteristic spikes on one edge similar to those described by Tardif and Sterling. (This piece is the same as shown in Fig. 362-28).
3.2.11.48 Mr. Clancey also examined a few suit cases which had been recovered. One particular suit case to which reference was made by him was of red plastic material with blue lining. With regard to this he stated that the damaged lining, severely tattered, resembles that of one found after an explosion in an aircraft in Angola. In that case microscopic examination showed definite evidence of damage by an explosion.
3.2.11.49 The later part of the report of Mr. Clancey contained his opinion. With regard to Target 362 his opinion was as follows:
"The features discernible to a careful close visual examination point towards the possibility of an explosion but taken alone do not justify a firm conclusion.

"Curling of petals and spiked or toothed fractures may be observed in other events than explosions despite the failure by Tardif and Sterling to obtain them in their limited number of attempts. It is probable that these features indicate a rapid rate of failure but not necessarily of a rapidity which could only be produced by an explosion.

"A more detailed study, metallurgical and fractographic, is required.

"The studies by Tardif and Sterling were done on fragments produced from aluminium alloy in contact with the explosive. Very little information is available on the behaviour of aluminium alloy some distance

from the explosive and subjected to attack by secondary fragments. To determine this some trials will be necessary, to obtain reference samples for comparison.

"The single "bullet hole", No. 14, strongly supports an explosion hypothesis but, being the sole example of its kind, is not, by itself determinative.

"If the forward part of this item was forcefully and rapidly folded back to impact on the other part it might explain the other features apparent to visual examination. It would require detailed laboratory examination and tests to eliminate this possibility".

3.2.11.50 The opinion of Mr. Clancey about the small fragments was as follows:

"The production of a large number of small fragments is generally regarded as a pointer towards an explosive cause but cannot be relied upon unless it is clear that they could not have been produced by some other means. It is known that the break-up of an aircraft at high speed may produce great fragmentation.

"The single spiked fragment must be regarded as important but a single specimen is not, by itself, determinative."

3.2.11.51 It appeared to the Court that the report of Mr. Clancey required certain clarifications. It was suggested to Boeing Commercial Airplane Company by the Court that Mr. Clancey should appear as a witness. The Court received a message to the effect that Mr. Clancey felt that he could not add anything useful to his report.

3.2.11.52 A close examination of the report of Mr. Clancey shows that the opinion expressed by him in the later part of the report is at considerable variance with the observations contained in the earlier part of the report. Particularly with regard to Target 362 and the small fragments, Mr. Clancey has stated in his observations that there was strong evidence of explosion. In his opinion, however, he has stated that more detailed study is required. It is interesting to note that though Mr. Clancey has referred to the opinion of Tardif and Sterling, he has not chosen to contradict the conclusions arrived by them. Mr. Clancey has also not stated as to what could possibly have caused the special features which were noted on Target 362.

3.2.11.53 We find the metallurgical report inspires more confidence. Not only is reference and reliance made in the report to other expert opinions contained in various articles written by experts all over the world, certain explosion experiments were also carried out by the experts which led them to the same conclusion.

3.2.11.54 The particulars of the experiments so carried out and the results obtained therefrom have been stated in their report as follows:

EXPLOSION EXPERIMENTS

"To determine the damage by high velocity fragments or shock waves on a structure similar to the one in aircraft cargo hold, the following experiments were conducted on November 30 and December 1, 1985 at the Explosives Research and Development Laboratory, Pune, using plastic explosive (PEKI) and different mixtures of plastic explosive and TNT. The explosive was kept in a box made of sheet metal of 6" x 6" x 6" of 1/16" thickness. This box was kept inside another box made of sheet metal 2' x 2' x 2' of .04 or .06" thickness. The boxes were made of 2024 aluminium alloy sheets used for aircraft skin. To the inner surface of the outer box, hat section stringers similar to those used in the aircraft were riveted. The quantity of explosive used in the inner box was varied from 60 g to 100 g. The explosive was detonated with an electrical detonator. After the explosions the fragments and the panels were collected and examined.

"Experiments were also conducted to produce explosive damage on skin panels, individual hat section stringers and individual stantion tubes. In the case of stantion tubes experiments were carried out placing the explosive charge both inside and outside. The quantity of explosive used was varied from 5 g to 50 g.

"Various types of damages were recorded on all the targets. These include punched holes, petaling and curling around holes, spikes at fracture edges, curved fragments with small radius of curvature and reverse slant fracture. Fig. EXP-1 shows a collection of fragments. The features mentioned above are shown in Fig. EXP-2 to EXP-7. It may be noticed that the features produced by experimental explosion were similar to the features observed largely in target 362 of the wreckage. The small fragments had features similar to those in the fragments from targets 362 and 399.

"Metallography was carried out in (a) a specimen surrounding a punched hole in the skin (b) a specimen surrounding a hole in the stringer, (c) a curl in the stantion and (d) spikes in a fragment. In all these cases, the grains adjacent to the area of explosive damage are having twins. Two typical microstructures are shown in Fig. EXP-8 and EXP-9. Away from these areas the microstructure is normal. Thus it is confirmed that twinning in the microstructure of these structural members is a unique feature of explosive fracture, not produced by any other measns known so far."

3.2.11.55 The findings in the said metallurgical report are also strengthened by the observations of Eric Newton in the article "Investigating Explosive Sabotage in Aircraft" published in the International Journal of Aviation Safety, March 1985, p. 43. Mr. Newton is an acknowledged authority in the detection of explosive sabotage in aircraft. The conclusions contained in the article are based on his review of incidents of explosion between 1946 and 1984 which were known to him. Some of the conclusions arrived at by him which were relevant in the present case are when he states "Generally speaking, the smaller the fragment, higher the velocity of the detonation. Minute fragmentation is indicative of high explosive having been used, and provides clues to the focal point or region of the explosion. The mode of break up of the aircraft itself and its sequence of failure is usually very complicated and quite without the logic dictated by normal aerodynamic overstressing".

3.2.11.56 Mr. Newton has also observed that curling, cork-screwing, and saw tooth edges may also be indicative of an explosion though such fractures by themselves may not be conclusive evidence that an explosion was involved. Firmer evidence, according to him, was of fusing of metal, scorching, pitting and blast effect. He further states that "Perhaps the most conclusive material evidence to be found on metal specimens is cratering, very often in groups, often minute and numerous".

3.2.11.57 Mr. Newton also refers to the positive explosive signatures which remain on a detonation in an aircraft. These positive singatures, according to him, are as follows:

"(a) The formation of distinctive surface effects such as pitting or very small craters formed in metal surfaces, caused by extremely high velocity impacts from small particles of explosive material. Such craters, when viewed under the microscope, have raised and rolled over edges and often have explosive residue in the bottom of the crater.

"(b) Small fragments of metal, some less than 1 mm in diameter, which, under the scanning electron microscope, reveal features such as rolled edges, hot gas washing (orange peel effect, surface melting and pitting and general evidence of heat; such features have been proved and observed following explosive experiments with known explosives). Supporting strong evidence would be if such fragments (normally found embedded in structures, furnishing or suitcases) were found embedded in a body where evidence of burning of tissue is present at the puncture entry and where the fragment came to rest.

"(c) As well as surface effects on metal fragments produced by explosives there are deformation mechanisms which are peculiar to high rates of strain at normal temperature. At normal rates of strain metals deform by usual mechanism associated with dislocation movement. However, because this process in an explosion is thermally activated at

very high rates of strain, there is insufficient time for the normal process to occur. In some metals such as copper, iron and steel, deformation in the crystals of the metal takes place by 'twinning', that is to say by parallel lines or cracks cutting across the crystal. Such a phenomenon can occur only if the specimen has been subjected to extreme shock wave loading at velocities in the order of 8000 m/sec. Such specimens, usually distorted must be selected with care, prepared in a metallurgical laboratory, polished, mounted
and microscopically examined. Where such twinning of the crystals is found it establishes (a) that the specimen was close to the seat of the explosion and (b) that a military type explosive had been used with a detonating velocity of 8000 m/sec or more. Twinning is rarely produced when shock impact loadings are below 8000 m/sec.

"The above features, singly or combined, are considered to be proof positive evidence of a detonation of a high explosive; they could not be produced in any other way."

3.2.11.58 The metallurgical report indicates that the microscopic examination (conducted by them) discloses such features being present which had been described as positive signatures of the detonation of an explosive device in an aircraft by Mr. Newton. Furthermore, twinning effect has also been noticed at a number of places - around holes and in fragments. These have been categorised by Mr. Newton as positive signature of an explosion.

3.2.11.59 In the primary zone of explosion, metallic structures disintegrate into numerous tiny fragments and usually these fragments contain the above mentioned distinct signatures of explosion. In the present case the explosive damage had occurred at an altitude of 31000 feet when the aircraft was flying over the ocean. The fragments that formed due to explosion must have been scattered over a wide area and it is impossible to locate and recover all of them from the ocean bed. Nevertheless, some of the fragments which were recovered along with the targets 362 and 399 do contain signatures of explosive fracture.

3.2.11.60 From the aforesaid discussion it would, therefore, be safe to conclude that the examination of targets 362 and 399 clearly reveals that there had been a detonation of an explosive device on the Kanishka aircraft and that detonation has taken place not too far away from where these targets had been located.

FIRE

3.3.1 There is no evidence that there was any fire on board the aircraft before it met with the accident.

3.3.2 Amongst the floating wreckage, however, was found, what was later on identified as, a spares equipment box belonging to this aircraft. This box was charred on one side and partially on the bottom. The depth of charring suggested that the burning time was three to four minutes. This box contained some sand and small shellfish. The flesh from the shelfish appeared to be charred, indicating that the box was subjected to fire after the occurrence.

FLIGHT RECORDERS

3.4.1 Recovery of Flight Recorders

3.4.1.1 Recovery of the flight recorders was a very difficult and challenging job. At the site of accident, depth of water is about 6700 feet. The job involved fixing the location of recorders and then retrieving them. For this purpose three ships viz. Guardline Locator (a ship provided by Accident Investigation Branch of U.K.), Le Aoife (an Irish Naval Ship) and Leon Thevenin (a French Cable laying ship, charterd by the Government of India) were utilised. Guardline Locator and Le Aoife were solely for fixing the positions of recorders and also had the capability to lift the recorders with the help of its scarab.

3.4.1.2 Both the Cockpit Voice Recorder and the Digital Flight Data Recorder were fitted with Dukane Underwater Acoustic Beacons (Pingers) which enabled establishing the location of flight recorders under water. The Beacons are designed to provide a signal at 37.5 ñ 1 Khz frequency that can be heard for approximately 2 miles in any direction for 30 days after water entry. Its high strength case permits operation in water depth to 20,000 feet. Its pulse repetition rate is not less than 0.9 pulse per second.

3.4.1.3 On 4th July, 1985, Guardline Locator reported strong possibility of two separate sound sources of frequencies between 39 KHz and 42

KHz. On 5th July, Guardline Locator gave coordinates of an area, which it believed contained the pinger. Guardline Locator later reported that using a Dukane Hand Locator, it had located pinger (2) at 5102.6N, 1248.6W. Leon Thevenin then concentrated its search in this area for retrieving the recorders.

3.4.1.4 In response to a query, Messrs Dukane Corporation advised that Pinger transducer is made of ceramic and if cracked during impact, its frequency could be elevated. The pulse rate should, however, be uneffected. Keeping this in mind, the Leon Thevenin increased its Sonar Band one upper frequency limit from 40 KHz to 45 KHz.

3.4.1.5 On 9th July at about 2300 hours the Scarab of Leon Thevenin located the Cockpit Voice Recorder at 5102.67N, 1248.93W and the recorder was brought on the deck at 0747 hrs on 10th July. The CVR was kept in a drum filled with water. The scarab was again lowered on 10th July in the same area and at about 2130 hours faint signals were picked up on Sonar. By about 2200 hours the signals became louder and the pulse rate frequency was calculated to be 72 transmissions per minute. At about 2230 hours the DFDR was also located at 5103.10N, 1249.59W and it was brought on deck at 0245 Z on 11th July.

3.4.1.6 The DFDR was also placed alongside the CVR in the drum filled with water. Leon Thevenin was then advised to return to Cork with the Flight Recorders. Leon Thevenin reached Cork on the morning of 12th July and the flight recorders were placed in two specially fabricated water tight steel containers filled with water. The recorders were then carried to Bombay on the same day by Mr. Satendra Singh, Reginal Controller of Air Safety, Bombay, accompanied by Mr. Vishwanath of Air India for preparing read-outs and transcript of the recorders. Necessary precautions were taken to ensure that the data recorded was not affected during transportation to Bombay.

3.4.1.7 Both the recorders reached Bombay on the morning of 13th July and were kept in the office of the Regional Controller of Air Safety under Armed Police Guard.

3.4.2 Description of Flight Recorders

3.4.2.1 Kanishka was equipped with a Fairchild A-100 Cockpit Voice

Recorder Serial No. 5809 and a Lockheed 209E Digital Flight Data Recorder Serial No. 1282. These were each equipped with Dukane Underwater Acoustic Beacons and were installed adjacent to each other in the cabin on the left side near the rear pressure bulkhead.

3.4.2.2 The CVR records all crew communications and sounds in the cockpit on a continuous tape loop which has a tape speed of 1-7/8 inches per second. The Recorder has two heads, one head which erases the previous recording and the second which records the current information and thus the last 30 minutes of recorded signals are retained, the previous being automatically erased. It continuously records convervations/sounds from 4 different sources on the following four separate channels:

Channel 1 : Radio channel of pilot

Channel 2 : Radio channel of flight engineer

Channel 3 : Cockpit Area Mike

Channel 4: Radio channel of co-pilot.

3.4.2.3 The serial digital signal recorded by the DFDR was generated by a Teledyne Flight Data Acquisition Unit installed in the forward electronics bay below the cabin floor. Adjacent to this unit was a Lockheed Model 280 Quick Access Recorder that recorded the same serial digital signals on to a 50 hour cassette.

3.4.2.4 The DFDR records 52 basic parameters on a magnetic tape. The tape preserves records of the last 25 hours. The serial digital signal has a bit rate of 768 bits per second and is recorded at a tape speed of 0.37 inches per second.

3.4.3 Examination of Flight Recorders and Tapes

3.4.3.1 General

The recorders brought to Bombay from Cork were opened on 16th July, 1985 at the Air India's Facilities in Bombay in the presence of the Court and Assessors. A team of foreign experts including one each representatives from both the Recorder Manufacturers, three from National Transportation Safety Board, one from Canadian Aviation Safety Board and one from NRC Flight Recorder Playback Centre, Canada were present when the tapes were taken out of the recorders.

Apart from them, representatives of the Government of India and Air India were also present.

3.4.3.2 Cockpit Voice Recorder

When the unit was removed from its shipping and storage container, some mechanical damage was immediately evident. The top of the cover had been deformed inwards, probably due to initial external strong attachments for the horizontally mounted Underwater Acoustic Beacon. The plate had torn away from the light structure behind it. The cause of the damage was not obvious. The light outer cover was removed by cutting it open with hand shears and pliers.

3.4.3.3 When the armoured and insulated containment was opened, the tape transport was found to be in relatively good condition and the tape physically undamaged. Eighteen inches of the tape was pulled from the centre of the tape stack and the tape cut near the stack well clear of the end of recording. The tape was then removed from the recorder, transferred to standard tape reels, laboriously cleaned several times with distilled water and dried with lint free absorbent material.

3.4.3.4 Digital Flight Data Recorder

When the recorder was removed from its shipping and storage container, it was noted that there was very little external damage. A cover on the rear section was removed and it was observed that, when viewed from the front of the recorder, the right hand edges of the four rearmost printed circuit cards were displaced towards the front of the recorder. The left hand edges were restrained by plug-in connectors to the boards. The rearmost card, that controls track selection on the tape, and the one in front of it, had bowed along the right-hand edges and popped out of their plastic guides in the top and bottom of the recorder. Deflection of the other two cards had occurred following failure of the attachments of the right hand ends of the plastic guides to the chassis. The damage could have been caused by a high lontitudinal decelaration, as would occur if the front face of the recorder impacted the water.

3.4.3.5 When the tape deck was opened, it was found that the tape was intact but had become dislodged from the last tape guide when the tape was moving in the direction of the odd-numbered tracks and had also jumped out of the adjacent end-of-tape sensor. One edge of the tape had been streteched in this area. The drive belt to the tape transport was still in its correct position. The tape was stuck to the third tape guide in the odd-numbered track direction and suffered some damage when it was finally detached from it. This was repeaired with a splicing tape.

3.4.3.6 The location of the record heads was marked on the back of the tape with a waterproof felt pen. It was noted that there was slightly more tape on the supply reel for the odd tracks than on the other reel. The tape reels and tape were removed from the recorder, keeping the tape wet with distilled water, and the tape transferred to the standard reels for meticulous cleaning. During the cleaning process, it was found that the edge of the tape had also been stretched locally 336 inches down- stream from the splice repair in the odd track direction. The tape was dried by patting it with absorbent lint-free material before loading it into a serviceable recorder as this was the only means by which it could be replayed at the Air India base.

3.4.3.7 The circuit card controlling track selection was removed from the accident recorder and the status of the latching relays checked to determine the last track on which recording was being made. It was found that the relay states indicated Track 1, but since this requires all relays to be set in the same condition, it was considered possible that they had been mechanically set on water impact. The card was subsequently inserted to another recorder and the Track 1 setting confirmed on a test bench.

3.4.3.8 When a change in track selection was attempted, it was found that the relays would not switch, probably due to the effects of salt water corrosion or high water pressure. It was decided that Track 1 would be considered as the most likely one to contain the accident data with the possibility that it could have occurred on any of the other tracks. When the data was recored, the accident information was found some distance past the mid-point of Track 1.

3.4.4. Recovery of Information

3.4.4.1 Cockpit Voice Recorder Tape

The spool was removed from the CVR and was washed with distilled water, dried and loaded on to another spool. The cleaned and dried tape was taken to the Bhabha Atomic Research Centre (BARC), and a copy of the tape was prepared which was used for preparing transcript and carrying out further analysis. The transcript of the CVR conversation is given in Appendix 2.

3.4.4.2 Shannon Air Traffic Control Tape

A copy of this tape that contains all radio communications between the aircraft and Shannon was provided to the Indian Authorities by the Air Traffic Control Authorities, Shannon. The recording also included the short series of unusual sounds that occurred about the time of the accident.

3.4.4.3 When the CVR and the ATC tapes were played it was found that some adjustment in speed was necessary so as to synchronize the two. This adjustment was independently carried out by different experts who analysed the CVR tapes.

3.4.4.4 Digitial Flight Data Recorder Tape

The Lockheed representative had brought a Lockheed Model 235 Copy Recorder from his plant. This unit copies all the 25 hours of data from the recorder by running it at high speed for only two passes of the tape, an operation lasting only 16 minutes. A copy tape was made by this procedure before embarking on the standard Air India recovery procedure to serve as a back-up tape in the event of physical damage to the original tape in subsequent playback.

3.4.4.5 Air India playback equipment for the DFDR required that the tape be re-installed in another DFDR in which it was driven at high speed. In the standard playback procedure, the tape was first run to the beginning of Track 1 through 6 sequentially on to a computer tape followed by a repeat of Track 1. The computer tape was then taken to Air India's main computing facility where selected information was printed out in engineering units.

3.4.4.6 The first printouts showed that the accident was recorded on Track 1, as indicated by the latching relays, and suggested a rather abrupt end to the recording. There was a loss in bit synchronization in word 26 of the last Subframe 3 of data that was followed by a normal Subframe 4. Prior to the loss in bit synchronization, all measurements appeared normal. Plans were made to borrow the high speed oscillograph recorder previously used to studythe final CVR signals from BARC to examine the end of the recorded serial digital signal in detail.

3.4.4.7 Meanwhile, the critical section of the tape and the heads of the playback recorder were re-cleaned and a second transfer of data on to the computer tape was made. Printouts from this computer tape showed no significant difference from the first one.

3.4.4.8 The recorder was then opened and the tape positioned about 1.5 inches before the final resting place of the tape that was clearly indicated by head imprints on the magnetic oxide coating side. A high speed oscillograph record of a few seconds of data was made and visually decoded. It was found that the recorded GMT was 21 hr 16 min. This time corresponded to 15 min or about 333 inches of the tape after start of the oldest recording downstream of the accident.

3.4.4.9 The tape was then re-positioned using a Lockheed analogue playback unit, that had a display of the recorded time and a stopwatch was used to locate the accident timing. Two oscillograph copies of the end of the serial digital data were made, the second one having more data preceding the end. Visual reading of the traces confirmed that recording became erratic and irrecoverable at the end of Word 26 in Subframe 3 at the recorded time of 07 h : 14m : 35s. The erratic signal continued for about 0.27 inches of the tape before switching back to the data recorded 25 hours earlier.

3.4.4.10 Examination of the printouts confirmed a suspicion that the complete Subframe 4 of data following the partial Subframe 3, was data from 32 seconds earlier that had not been cleared from the data buffer in the computer and that Word 26 of the Subframe 3 was the last normal measurement provided by the recorder.

3.4.4.11 The end of recording occurred at the point on the tape at which some damage had been observed during the cleaning process. It was apparent that, after the end of the recording, the tape had run on for 336 inches before finally coming to rest.

3.4.4.12 A copy tape of the DFDR tape was made at Bombay and taken to Ottawa. Data from the accident flight, the preceeding Toronto-to-Montreal flight and part of the cruise conditions of the earlier flight to Toronto were transcribed on to the computer tape. The tape was edited to minimize errors and converted to engineering units using standards calibration. Time histories of all parameters for periods of interest were plotted. In addition, chart records were made of all parameters in raw data form for the total duration of the last lap of the flight.

3.4.4.13 The DFDR read out shows that the aircraft was cruising at an altitude of 31,000 ft. and a computed air speed of 296 knots till it suddently stopped recording at 07:14:35 GMT recorded time.

3.4.5 Reports received by the Court

3.4.5.1 The CVR was taken to B.A.R.C. This tape was played by the CVR group a number of times and hard copies of the time information were also prepared using an ultra violet (UV) Recorder. The group consisted of Mr. Satendra Singh, Regional Controller of Air Safety of D.G.C.A., Mr. S.N. Seshadri of BARC, Mr. Paul C. Turner of NTSB, USA, Mr. John G. Young of NTSB, USA and Mr. P. dE Niverville of CASB, Canada. On 18th July, 1985 this group made the following observations after playing the aforesaid tape (UV recording of CVR is at Fig. 1) :-

"The first visible rising signal volume was observed on channel number three the CAM channel It reaches a maximum in about 50 milliseconds. At this time noticeable disturbances are observable on the other three channels. A smaller disturbance is observable on channels 2 and 4 earlier than observable on channel 1. A major disturbance is observed to begin approx. ninety milliseconds following the initial observation on channel number 3 (CAM), on channels 1,2 and 4. Following this point

at 75 milliseconds the CAM signal subsides to a lower level but much higher than observed ambient (prior to disturbance) where it remains for approximately 375 milliseconds from initiation when it ceases. Channel four goes off at the same time. Channel 1 goes off twenty five milliseconds earlier. Channel two is inconclusive and had a different pattern. All four channels exhibit a disturbance at approx. 450 milliseconds. The cockpit voice recorder power then shuts off at 650 milliseconds.

The Shannon area control centre tape made the night of the accident was examined and printed. It shows a signal was received at approximately the time the aircraft disappeared from radar. It isn't conclusive at this time that the signal originated from the accident aircraft. The signal was received in pulses for approximately five seconds."

3.4.5.2 The tape was again played on 19th July, 1985 and a further report was prepared which was signed by the aforesaid persons and Mr. B. Caiger of NRC, Canada. In this report it was stated as follows:-

"The Shannon area control centre tape was again printed at .05"/second per inch speed from approximately 22 sec. before the first broadcast from the accident aircraft at 0709.58 until Radio carrier with indecipherable modulation can be heard at 0714:01. The print contains a time encoded signal.

A similar print was made from the CVR channel 4 (Co-Pilot's) of the same audio as received on the ATC tape. Although the tape speed is different, the events when corrected for tape speed errors occur at the same time. It appears that the ATC recording contains the beginning of the aircraft breaking until power is lost to the transmitter since channel one and channel four (Capt + Co-pilot's radio) appear to contain a transmitted signal on the CVR. It is probable that the ATC signal at 0714:01 coincides with the final quarter second of CVR radio channels".

3.4.5.3 On the date i.e. 19th July, 1985, Mr. Paul Turner of NTSB also gave an additional report which is to the following effect :-

"During my observations of numerous cockpit voice recorders I have heard and observed a number of aircraft breakages due to various causes. In this case the explosive sound on the CAM channels occurs prior to any electrical disturbance observable on the selector panel signals. Electrical disturbances can generally be seen prior to audio signal when explosive sounds originate at any significant measureable distance from the microphone (15 feet) and in the area where there is significant electrical systems. It is my opinion that an explosive event

occurred close to the cockpit. The CAM signal which follows the explosive event shows a very much higher noice level than cockpit ambient 85 db, indicating to me the cockpit area was penetrated and opened to the atmosphere. The selector panel signals show signatures similar to those of an aircraft breaking up and are apparantly caused by electrical systems disturbance (circuit breaker blowing, fuse switching etc.). The lack of Mayday call and apparent inadvertant signal from the cockpit crew incapacitation. The transmitter coming on due to breakup is phenomena observed previously.
This contains only my personal opinion and in no way should be considered a final determination of cause without corroborating evidence".

3.4.5.4 Copies of the tapes were also sent to some of the participants who wanted to carry out independent analysis.

3.4.5.5 With regard to DFDR the Court received reports from Dr. Caroll Roberts of NTSB and report dated 11th November of Mr. B. Caiger.

3.4.5.6 With regard to CVR the Court received reports from Mr. B. Caiger dated 11th November, 1985, report dated November, 1985 of Mr. R.A. Davis, Head, Flight Recorder Section, Accidents Investigation Branch, Farnborough, U.K., report dated 31st August, 1985 of Mr. S.N. Seshadri of BARC, Bombay.

3.4.6 Court Observations

3.4.6.1 Digital Flight Data Recorder

The reports of Dr. Caroll Roberts and Mr. Caiger which also coincide with the report submitted by Mr. Satendra Singh disclose that the DFDR showed no evidence of abnormal values of any of the many parameters being monitored upto a point at which the recorded data signal became irregular for a fraction of a second and recording ceased. Both the DFDR and the CVR stopped at the same time.

3.4.6.2 The short period of irregular digital data that occupied only 0.27 inches of tape, most probably indicates that the recorder was subjected to a sharp angular acceleration in the left wing down sense about the aircraft longitudinal axis.

3.4.6.3 According to Mr. Caiger's report the possibility that the digital recorder was subjected to a sharp disturbance more rapid than violent motion of the aircraft lends some credence to the possibility of a detonatiaon of an explosive device in the aircraft. The other alternative, according to Mr. Caiger, which could have led to this was that the Flight Data Acquisition Unit in the main electronics bay .or its power supply were suddenly disturbed. As the Lockheed Quick Access Recorder was not recovered from the wreckage, this possibility could not be investigated further. A perusal of the DFDR print out, however, shows that whereas there was a speed limit of 290 knots (.81 Mach) of the aircraft due to carriage of the 5th pod engine, in actual fact the aircraft's speed during cruise varied from 287 to 296 knots. Mr. H.S. Khola asked the Boeing Airplane Company to examine the effect of aircraft cruising at a speed of 296 knots with a 5th pod engine installed on it. The Boeing company sent a reply, inter alia, stating as follows:

"The operating speed limit of Air India 747-237B, JT9D-7J with fifth engine pod was 290 knots indicated airspeed, with an altitude limit of 35,200 feet. Flight testing of this model airplane configuration was successfully accomplished to a dive speed of 386 knots calibrated airspeed and 0.92 Mach number, with no adverse effects.

In the event that the operating speed placard was exceeded an increase in perceptible vibration levels would be felt. As the dive Mach number (0.92) is approached the buffet vibration would increase to level that could become objectional to the flight crew, but would not he bazardous".

3.4.6.4 It would thus be clear that if no adverse effects could have been noticed with a dive speed of 386 knots calibrated airspeed and 0.92 Mach number, there was little likelihbood of the aircraft having been subjected to any adverse effect by reason of the speed varying from 287 to 296 knots while it was cruising at a height of about 31,000 feet.

3.4.6.5 Cockpit Voice Recorder

The Court received four reports of the CVR tape analysis. These reports were of Mr. B. Caiger, Mr. R.A. Davis, Mr. S.N. Seshadri and Mr. Paul C. Turner. Whereas the first three experts appeared and deposed in

Court, Mr. Paul Turner did not come.

3.4.6.6. There were certain aspects of the report of Mr. Turner which required clarification. After the Court had failed to secure his presence, it sent a questionnaire to Mr. Turner for his answers thereto. It is indeed unfortunate that till now no reply has been received. It is in this background that the report dated 13th November, 1985 of Mr. Turner and the reports of other experts have to be judged and analysed.

3.4.6.7 Mr. B. Caiger's Report and Deposition

Mr. Caiger has said in his report that the Cockpit Area Microphone signal was studied in detail. According to him, in an aircraft, sound can be transmitted by multiplicity of paths. If an explosive device was located close to the microphone then the short wave from the disturbance would cause a sharp rise in pressure which was not noticed. From more remote location, however, structurally transmitted sounds could reach the microphone first and induce more complex signals. According to Mr. Caiger, at this time he did not have any evidence from occurrences of this nature that would permit any meaningful comparisons or conclusions.

3.4.6.8 Mr. Caiger obtained from the manufacturers details of Automatic Gain Control (AGC) on the cockpit area microphone. According to the information so provided it was indicated that the decrease in amplitude of the recorded noise over about 33 msec after the peak level was reached 40 msec from the start of the disturbance is most probably due to the AGC and that the actual envelope of the pressure levels at the microphone continued to increase until 90 msec from the start before establishing at about four times the recorded level until the 160 msec point when the recorded amplitude started to decrease rapidly. Mr. Caiger could not find any explanation for this marked reduction. Mr. Caiger further recorded that the large amplitude lower frequency signature, that immdediately followed this reduction, is similar to signatures observed by the manufacturer when there was an abrupt break in the line from the cockpit area microphone pre-amplifier output to the voice recorder. No similar signature was observed in tests on the crew audio channels when the appropriate lines to the recorder were similarly

interrupted.
3.4.6.9 The observation of Mr. Caiger with regard to ATC tape was as follows :-
"The ATC recording that followed the cockpit area microphone sounds appears at first to contain a series of short intermittant sounds. Closer study reveals that the background noise only returns to its steady level for about 160 msec immediately after the first low level noise and again for about 85 msec just over halfway through the 5.4 sec duration of the recordings. At the end of all routine radio transmissions, a damped sine wave transmitter keying signature is observed with a frequency in the region of 450 Hz. In the accident recordings, only two of these are observed".
"Listening to the sounds, it also appears that a human cry occurs near the end of the recordings. Spectral analysis of these sounds and comparison with voice limitations reveals that the accident sounds do not contain all the pitch harmonic frequencies normally associated with such voice sounds. The origin of all the sounds has not been identified."
3.4.6.10 From the aforesaid investigation Mr. Caiger concluded that :-
"From the voice and data recorders, Air India Flight 182 was proceeding normally enroute from Montreal to London, England at an altitude of 31,000 feet and a computed airspeed of 296 knots when the cockpit area microphone detected a sudden loud sound the cause of which has not yet been identified. The sound continued for about 0.35 seconds, and then almost immediately, the line from the cockpit area microphone to the cockpit voice recorder at the rear of the pressure cabin was most probably broken. This was followed by a loss of electrical power to the recorder".
"The initial waveform of the cockpit area microphone signal is not consistant with the sharp pressure rise expected with detonation of an explosive device close to the flight deck but, with the multiplicity of paths by which sound may be conducted from other regions of the aircraft, we cannot at this time exclude the possibility that it originated from such a device elsewhere in the aircraft".
"Within 1 to 2 seconds of the first detection of the loud sound on the

cockpit area microphone, a series of unidentified noises were recorded on the Shannon ATC tape. These extended over a period of 5.4 seconds and are assumed to have origniated from VT-EFO. They gave the impression of abnormal conditions on the flight deck".

3.4.6.11 In his evidence in court, Mr. Caiger explained about Automatic Gain Control. He stated that the CAM channel of the CVR had an Automatic Gain Gontrol in a pre-amplifier that is installed close to the microphone. This AGC is designed to prevent excessively loud signals from saturating the microphone and the associated electronics. He further stated that from the tests conducted by the manufacturers it could be concluded that most likely at 45 msec. point the AGC came into effect which gradually reduced the signal over the next 33 msec. before letting it stabilise at a roughly constant value. This figure of 33 msec. was taken by Mr. Caiger not by carrying out any experiment himself but it was provided to him by the manufacturers. He also stated that there was no positive indication of structural failure being evident from the flight recorders. Mr. Caiger was asked to explain as to what was the reason for loud sound to which reference had been made in his report. In answer to the said question from the Court he said that there could be a number of reasons. The detonation of an explosive device not close to the microphone was one possibility, the occurrence of some type of structural failure was another possibility. He was further of the opinion that at the present stage of development in structural acoustics, he did not think it was possible to come up with any reasonable estimate of the location of either explosive device or some type of possible structural failure. When asked for his opinion about the sequence of events which he could determine by looking at the sound spectrum, he said as follows:

"From the study that we have made which have of course been augmented by studies done by several other groups it would appear that there was a very sharp bang that was detected by the CAM. Approximately one-third of a second after this happened the line from the CAM to the CVR was disconnected but intermitant power supply was still being sent to the voice recorder for approximately one and a half seconds. During this 1-1/2 seconds period sounds were being transmitted from the 'Kanishka' aircraft that tend to suggest that the aircraft was in some distress. Though it is difficult to be specific about the basis on which we assesss the state of the aircraft, this signal ceased after a period of 5.4 seconds and we have no more audio information concerning the aircraft from that point onwards."

3.4.6.12 Mr. R.A. Davis's Report and Deposition

Mr. R.A. Davis in his report on the analysis of CVR has stated that he did not have with him a faithful copy of the original CVR tape. The tape supplied to his contained signals which warranted investigation but any measurement could be hampered by a decreased signal to noise ratio due to the copying process. Mr. Davis however analysed the tape which admittedly according to him was not of good quality. Mr. Davis in his report states that he carried out a spectrum analysis of the different channels of the CVR. The spectra did contain the sound of a bang. He however, could not find any significant low frequency content in the spectrum which according to him, would have been expected if the sound was of a high explosive detonation.

3.4.6.13 While carrying out detailed study of the tape he also looked out for any evidence of various audio warning signals which may have been buried in the noise. One such audio warning which could have been detected was that of pressurisation warning. Mr. Davis stated that this warning possessed a very defined frequency spectrum which was not present in the signal of the CVR of Kanishka. With regard to this he, however, stated that absence of this signal was not surprising as any decompression would take a finite time before reaching the warning level. Mr. Davis further observed that the presence of warnings due to attititude display disagreement, excessive speed and fire were investigated but with negative results.

3.4.6.14 During the course of investigations, Mr. Davis had compared Kanishka CVR recording with the recordings of an explosive decompression on a DC-10, a bomb in the freight hold of a B-737 and a gun shot on the flight deck of a B-737. According to Mr. Davis the spectrum of VCR tape of B-737 showed a much low frequency content with very little content at upper frequencies. This bomb, in the forward baggage hold of B-737, had exploded while the aircraft was at a low level and therefore the CVR did not have the sound accompanied with that of depressurization. That aircraft had landed safely. Mr. Davis, however, observed that if Kanishka's accident was caused by detonation of a high explosive device, then the spectra should have shown large low frequency content, but this was absent. He further opined that, even if there was a possibility of a bomb remote from the flight deck and of a low power, even then the characteristics of a bomb would still be apparent in the time record. He also analysed the spectrum of the sound of the hand gun shot on a B-737 flight deck and according to him the said signal was sharp edged and did not compare with that of Kanishka's signal.

3.4.6.15 Mr. Davis also analysed the sounds recorded on the ATC tape. He concluded that the sounds emanated from Air India's Kanishka aircraft. According to him the transmission from the ATC is "chopped" until at approximately 2.7 seconds into the transmission a loud noise lasting about 200 milliseconds is heard. This is followed about 0.5 seconds later by a sound which increases in volume. This sound was similar to that heard in other accidents where there had been a rapid increase in airspeed.

In the noise which continues until the end of the transmission is heard a crying sound. This was originally thought to be a human cry. He, however, noted that a human cry would contain more harmonics than was noticed in this case. It was also reported by Mr. Davis that knocking sounds which were heard during the transmission were initially thought to be due to hand-held microphone vibration. This was discounted because of the frequency of the sounds. He noticed that almost identical sounds were heard on the DC-10 CVR after the decompression had occured and the source of that sound had not been identified. On the DC-10 the pressurization audio warning commenced 2.2 seconds after the decompression. Analysing the ATC tape Mr. Davis observed that no such warning was identified during the open microphone transmission.

3.4.6.16 In conclusion, Mr. Davis reported as follows :-

"It is considered that from the CVR and ATC recordings supplied for analysis, there is no evidence of a high explosive device having detonated on AI 182.

"There is strong evidence to suggest that a sudden explosive decompression occurred but the cause has not been identified.

"Although there is no evidence of a high-explosive device, the possibility cannot be ruled out that a detonation occurred in a location remote from the flight deck and was not detected on the microphone. Such a situation would be most unusual, if not unique, in that we have never failed to detect sounds of structural failure, decompression, explosives etc., on any accident CVR, even though the event occurred at the rear of the aircraft. If such a device was used on AI 182 it is considered that it would have to be a very small device in order not to be detected (unlikely in itself). Such a device would be unlikely to cause the sudden total destruction which occurred in this instance. It is considered that a device of sufficient power to produce this effect could not fail to be detected on the CVR. The B-747 explosions referred to earlier, blew holes several feet wide in the structure but the crew were still able to control and operate the aircraft.

"It must be concluded that without positive evidence of an explosive device from either the wreckage or pathological examinations, some other cause has to be established for the accident".

3.4.6.17 In reply to a question it was stated by Mr. Davis, when he was examined in Court, that it was true that there was no evidence that rapid decompression was caused by any structural failure. In an answer to another question, as to whether in his opinion there is a low frequency content present in every situation whereever there has been a high explosive device detonated, Mr. Davis answered in the affirmative, he however added that "But we do not have sufficient numbers to indicate that that would always be the case". Mr. Davis, however, agreed that DC-10 aircraft was quite dissimilar to Boeing 747, and the sound of an explosive decompression in the aft cargo hold of a DC-10 would not be identical to an explosive decompression in the aft cargo hold of a Boeing 747.

3.4.6.18 Mr. Davis further agreed that he was looking for low frequencies in Kanishka tape, but he did not know what type of low frequencies should be looked out for because there was no available data anywhere in the world for the sound of a bomb explosion in a Boeing 747. Mr. Davis was however emphatic in saying that he could not measure the distance of the origin of the sound from the cockpit area mike. In his report, and also in the earlier part of the examination, Mr. Davis had referred to the absence of low frequency component in the spectrum and had sought to conclude that such absence showed that there was no detonation of a high explosive device. In an answer to the question put by the Court however, Mr. Davis appeared to have altered his stand. This is evident from the following deposition of Mr. Davis :-

"Court Ques Am I to understand that there must necessarily be a low frequency whenever an explosion occurs?

Ans. No. What we thought was there would be. There was only one sample of explosion in B-737. But we would need more accidents of that nature to able to say that yes we must have a low frequency component.

Court Ques: Am I to understand that the absence of a low frequency component would not therefore necessarily mean that the sound was not that of an explosion?

Ans. Because of the absence of a low frequency component we would not be able to say positively that there was an explosion or it was not explosion."

Court Ques : Would the frequency of a particular type of sound change depending upon the environment in which that sound occurs?

Ans Yes.

Court Ques If an event results in low frequency sounds in one type of environment, can it mean that the same event can result in a high frequency sound in a different environment?

Ans. That must be possible".

3.4.6.19 Mr. S.N. Seshadri's Report and Deposition

A detailed analysis of the CVR and the ATC tapes was also carried out by Mr. S.N. Seshadri at BARC. For the purposes of comparison, CVR tapes of Iranian Air Force Boeing 747 accident as well as that of Indian Airlines Boeing 737 accident were also analysed at BARC.

3.4.6.20 The original CVR tape of Kanishka was played on a 4 channel tape recorder modified to run at 1-7/8" per second. The output of this tape recorder was copied faithfully on an eight channel HP 3968A instrumentation tape recorder. Channels 1 to 4 were used for recording the CVR data and channels 5 for recording a time marker. For further processing and signal analysis this copy of the original tape was used.

3.4.6.21 The observations of the data so recorded, as contained in the said report inter-alia are as follows :

"Repeated and careful listening to all the four channels revealed the presence of explosive sounds on all these channels occuring nearly at the end at the same time. Speech information is present on channels 3 and 4 during the last few minutes. Channel 1 does not contain any speech data during this period. Channel 2 contains indecipherable speech data about 20 to 25 seconds before the explosive sound".

"It was decided to analyse in detail the tape data during the final few seconds within which significant audio and electrical changes were observed to be present. Data from all the four channels were displayed on a Tektronix 2-channel storage oscilloscope Model 466 for initial observations. Based on this study the relevant portion of the tape was selected for more intensive snalysis. Simultanious ultraviolet recording of all the four channels on this portion of the tape was next carried out".

The following observations are relevant.

1. Channel 3, which corresponds to the area mike shows the first indication of a rising audio signal. This instant is termed, for conveniece, as zero time reference. The signal level rises from the ambient level in the cockpit by about 18.5 db in approximately 45 milliseconds. The signal then starts falling and stablises at a level about 10 db higher than the ambient level before zero time. The signal continues to remain at this level for about 275 milliseconds. The total duration of the signal from zero reference is thus about 360 milliseconds.

2. Channels 1 and 2, which are the radio channels of the pilot and the flight engineer respectively, show start of electrical disturbance signals 45 milliseconds from zero time at which the audio signal on channel 3 is at its maximum. These signals, which have do minant frequencies in the range of 70 to 210 Hz, persist for about 100 milliseconds on both channels. Subsequent to this, channel 1, shows an audio burst lasting about 200 milliseconds. Channel 2 shows a delayed audio burst lasting 25 milliseconds, 220 milliseconds from zero time, or in other words, 175 milliseconds after the peak signal from channel 3. A low amplitude tail appears after this burst and lasts around 40 milliseconds. Channel 4 which is the co-pilot's radio channel shows an electrical disturbance commencing at 85 milliseconds from zero time and lasting around 60 milliseconds. The frequency distribution during this period is similar to those on channels 1 and 2. This is followed
by an audio burst of 230 milliseconds duration. The frequency spectra of the audio portions of channels 1,2 and 4 are reasonably similar."

3.4.6.22 "Correlation of Events of ATC Shannon Tape and Channel 4 of CVR tape :

"It was observed that during the last few minutes before the stoppage of the CVR, information recorded on the ATC tape and channel 4 of the CVR tape are identical. However, the ATC tape contains a series of audio bursts approximately corresponding to the instant at which a single explosive sound is recorded on channel 4. Thus a doubt arose whether the series of audio bursts recorded on the ATC tape had originated from channel 4 of Kanishka CVR since these are not recorded on the CVR tape. In order to obtain an answer to this it was necessary to check with very good accuracy the simultaneity of the explosive sound on channel 4 and the series of audio bursts on the ATC. The procedure followed for the same is given below.

"The ATC Shannon tape and the CVR tape were run on two independent tape recorders. It was found that the speeds of the two tapes were mismatched. In order to match speeds the earliest speech signal on both the tapes.

"Seven seventy that checks maintain three five zero" was used as the

reference point. The speech signals which mostly contain the conversation between the co-pilot and ATC Shannon lasts for about 146 seconds. Channel four was kept ready for starting exactly at the reference point. The ATC was next played starting well before the reference point. The tape recorder playing channel 4 was started manually exactly at the time when the reference point on the ATC was audible. By noting the time of ending of the conversation on both the tapes which corresponds to
"Right Sir squaking two zero zero five one eight two" the speed of the recorder playing the ATC tape was corrected by pitch control to approach the speed of CVR tape. The process was repeated a number of times till audibly the speeds were matched. The two tapes were next synchronously played and both the channels were simultaneously recorded on a third recorder to a point well after the explosive sound on channel 4. This tape was used for all further analysis.

"The first significant observation was that the explosive sound on channel 4 coincided with the beginning of the series of audio bursts on the ATC tape as heard by the ear. It was thus clear that both the recordings correspond to those generated by Kanishka during its last moments.

"To confirm this preliminary conclusion which was judged solely by the ear, accurate instrumented tests were carried out. The two channels were simultaneously recorded on an ultraviolet recorder at the four speeds, 0.1"/sec, 1"/sec, 10"/sec and 160"/sec for study of synchronism as well as frequency details. It was noticed that the two waveforms were not exactly suynchronised though by the ear they appeared to be so. In order to find out exactly the difference in synchronisation the following tests were done:

UV recordings at 16" per second were taken at three representative points relating to the communication of ATC with Kanishka. These points correspond to speech portions at 070838 "Five eh Squawking and eh Air India", at 070958 "Right Sir Squawking" and near the blast on channel 4. It was found that the ATC was running slightly faster. At the first point the ATC was leading by 90 milliseconds, and at the second point by 130 milliseconds. The time interval between these points is about 80 sec. By extrapolating this lead to the time of the blast which occurs about 243 sec. from the second point, it is clear that the lead of the ATC with respect to channel 4 at this point will be given by 130 + (130-90) (243/80) which is approximately 250 milliseconds. This error is very small."

"Thus one can conclude that the sounds recorded on the ATC Shannon tape are those which emanated from Kanishka during its last seconds."

3.4.6.23 "Frequency Analysis:

Mr. Seshadri also carried out frequency analysis of the CVR and the ATC tapes. His opinion with regard to the same was the follows:

"Significant audio and electrical disturbances were observed in the final few seconds of the CVR tape. It was therefore decided to analyse all the four channels for their frequency contents at the various places in this pertinent region. For Fourier analysis of each signal, digitized time data of 200 milliseconds duration was processed. The frequency analysis was carried out using Bruel & Kjaer model 2033, high resolution signal analyser. Frequency spectrum was computed over a base band of 2 KHz with a resolution of 5 Hz.

3.4.6.24 "The frequency analysis of electrical disturbances in channels 1,2 and 4 indicate presence of low frequencies in the region of 20 Hz to 600 Hz. The dominant frequencies are in the range of 70 Hz to 210 Hz.

3.4.6.25 "The frequency spectrum of the background noise in channel 3 just before the explosive sound has a broad band spectrum with some dominant frequencies in the region of 650 Hz to 1550 Hz. At the bang, many additional frequencies appear. The frequency spectrum of bang on channel 3 indicates an increase in the bandwidth.

3.4.6.26 "The frequency spectrum of channel 1 at the bang position indicates a fairly broad spectrum with dominant frequencies in the range of 150 Hz to 1 KHz. Channel 2 displays a frequency spectrum at the bang position in which low frequencies are dominant. It has a significant frequency range between 20 Hz to about 1 KHz. The frequency spectrum of channel 4 at the bang is wide-band with a broad peak in the range of 150 Hz to 800 Hz.

3.4.6.27 "At the beginning of the crackling sound, the frequency spectrum shows narrow band peaks around 1.6 KHz. About 90 and 300 milliseconds later, the spectrum changes with additional peaks appearing around 400 Hz, 600 Hz and 1150 Hz. Frequency analysis was also carried out at 600, 800 and 1000 milliseconds before the start of the crackling sound."

3.4.6.28 The conclusions which were arrived at by Mr. Seshadri on the basis of what he had heard and after studying the various spectra were as follows:

"The signal in channel 3 of the CVR which corresponds to the cockpit Area Mike shows the first signs of an audio disturbance. The signal time data of 200 milliseconds duration was processed. The frequency analysis was carried out using Bruel & Kjaer model 2033, high resolution signal analyser. Frequency spectrum was computed over a base band of 2 KHz with a resolution of 5 Hz.

3.4.6.24 "The frequency analysis of electrical disturbances in channels 1,2 and 4 indicate presence of low frequencies in the region of 20 Hz to 600 Hz. The dominant frequencies are in the range of 70 Hz to 210 Hz.

3.4.6.25 "The frequency spectrum of the background noise in channel 3 just before the explosive sound has a broad band spectrum with some dominant frequencies in the region of 650 Hz to 1550 Hz. At the bang, many additional frequencies appear. The frequency spectrum of bang on channel 3 indicates on increase in the bandwidth.

3.4.6.26 "The frequency spectrum of channel 1 at the bang position indicates a fairly broad spectrum with dominant frequencies in the range of 150 Hz to 1 KHz. Channel 2 displays a frequency spectrum at the bang position in which low frequencies are dominant. It has a significant frequency range between 20 Hz to about 1 KHz. The frequency spectrum of channel 4 at the bang is wide-band with a broad peak in the range of 150 Hz to 800 Hz.

3.4.6.27 "At the beginning of the crackling sound, the frequency spectrum shows narrow band peaks around 1.6 KHz. About 90 and 300 milliseconds later, the spectrum changes with additional peaks appearing

around 400 Hz, 600 Hz and 1150 Hz. Frequency analysis was also carried out at 600, 800 and 1000 milliseconds before the start of the crackling sound."

3.4.6.28 The conclusions which were arrived at by Mr. Seshadri on the basis of what he had heard and after studying the various spectra were as follows:

"The signal in channel 3 of the CVR which corresponds to the cockpit Area Mike shows the first signs of an audio disturbance. The signal peaks to its maximum of 18.5 db above ambient level in about 45 milliseconds. A loud audible blast is heard when this channel is played at this point. An analysis of the frequency spectra before this loud blast and during the blast shows a definite change in the frequency composition. From all the above results it can be concluded that an explosion occurred in the aircraft. The exact position in the aircraft at which the explosion occurred is likely to be about 40 to 50 feet from the Cockpit judging from the rise time of 45 milliseconds.

3.4.6.29 "Explosive sounds on all the four radio channels preceded by electrical disturbance reinforce the evidence provided by channel 3.

3.4.6.30 The synchronised recording and detailed analysis of the ATC and channel 4 confirm that the sounds recorded in the ATC Shannon tape are undoubtedly attributable to the transmissions from AI 182 Kanishka during its last moments. The sounds indicate possible breaking up of the aircraft in mid air and the air blast which follows a decompression. A very detailed UV recording does not indicate the presence of a second explosion."

3.4.6.31 "Copies of CVR tapes of well understood air crashes pertaining to an Indian Airlines Boeing 737 in 1979 and Iranian Air Force Boeing 747 in 1976 were analysed for possible reference in connection with the analysis of the CVR tape of Kanishka.

3.4.6.32 "A definite explosion near the Cockpit was the cause of the crash of the Indian Airlines Boeing 737. An explosive sound recorded on the Cockpit Area Mike shows a rise time of about 8 milliseconds which corresponds to a distance of about 8 feet. This indicates that the rise time is a measure of the distance from the Cockpit Area Mike at which an explosion has occurred.

3.4.6.33 "The Iranian Air Force Boeing 747 broke up in mid air. Analysis of the CVR tape clearly indicates that the frequency spectra of the electrical disturbances are similar to those obtained for Kanishka. Thus the series of audio bursts recorded on the ATC Shannon tape have been most probably generated by the break-up of kanishka in midair.

3.4.6.34 Mr. Seshadri was also examined in Court on 27th January, 1986. In his deposition he very succintly explained some aspects of the work which was done by him. He also dealt with the aspect of AGC to which reference has been made by Mr. R.A. Davis and Mr. Paul Turner in their reports. The relevant part of the testimony in this connection is as follows :-

"We wanted to make sure that the CVR recording and the ATC corresponded to the same aircraft Kanishka. When we played the tapes for the first time we found that there was a difference of about 1 second. Though this figure may be tolerable because of the accuracy of the tape speeds, we wanted to investigate further to make really sure that the ATC corresponded to Kanishka. For this purpose we had simultaneously "recorded channel 4 of the CVR and the ATC on a single tape on 2 channels after synchronising the common speech signals to the best of our ability by the ear. We started with the first speech which was available on both the tapes, namely, "770 that checks maintain 350". This was a conversation with the TWA aircraft which is available on both channel 4 and the ATC. The last sound which is recorded common to CVR and ATC is the speech of the co-pilot who says "right Sir, squaking 2005 182". After this recording though by the ear the explosive sounds on the ATC. as well as the CVR seemed to match, we wanted to check it in more detail. For this purpose we had detailed UV recordings of different portions of the synchronised tapes pertaining to the conversation between ATC and Kanishka. This was done and we noticed that the ATC was running slightly fast. We had about 80 seconds reference time of conservation from Air India Boeing Kanishka and the ATC for reference and we had to extrapolate the information in this section for another 243 seconds at which time the explosive sound occurs. During the beginning of this 80 seconds reference period, we find that the ATC was leading by 90 milli-seconds and at the end of 80 seconds the lead of ATC was 130 milli-seconds. Thus, in 80 seconds, the ATC had gained 40 milliseconds.

"This extrapolated to 243 seconds and gives a figure of 250milliseconds. This is how we arrived at the conclusion that both are synchronised within 250 milliseconds. I would like to bring to the notice of the Court that we have taken great pains to confirm this information by reapeating the tests a number of times. We did not take the 400 cycle signal available on the tape as the time reference. We took for reference the bunching of signals produced by the conversation and the gaps in between the convervation which are very clear on both tapes. Hence we are sure that our results are right. The UV recording which was made has been filed along with my report.

"The main channel which was examined was the CAM channel. This was agreed to by all the experts who were present during the first analysis of the tape at the BARC between 16th and 20th July, 1985. One of the most noticeable things is that channel 3 which corresponds to cockpit area shows the first sign of disturbance. Let us say for reference that the disturbance starts at 0 time. In about 45 milliseconds the signal rises to a peak value which is approximately 18.5 db above the ambient level before the commencement of the signal. After this point the signal decays roughly exponentially in about 40 milliseconds to be almost a steady level which is 10 db above the ambient level before the explosive sound. From this we could draw conclusions. Assuming that an explosion occurred on the aircraft. The explosion produces a shock wave with a steep wave front which travels in air as well as through the aluminium body and the speed of travel will depend upon the distance of the explosive from the point of observation. It will depend on the cube root of the explosive and it will also depend on the ratio of the distance to the cube root of the weight of the explosive. The shock wave is very fast. It can travel at about 10 times the speed of sound. Also when the shock wave hits the aluminium body of the aircraft the vibrating panels which are defined by the stringers and longerons transmit the sound to the CAM location. Because the speed of sound in aluminium is about 19,200 feet per second which is 16 to 18 times that of the speed of sound in air and the shock velocity is also about 10 to 12 times. This signal will be received

"first by the CAM. Nevertheless the shock wave gets attenuated diffracted and refracted during its travels to the cockpit. Hence the signal received at the cockpit will be an attenuated signal and this small signal we have taken as instantaneous with the time of explosion. As the time passes the sound waves travel from the explosion site reinforcing the sound in the cockpit area thereby there is a rise time. Then when all the complete sound information is transmitted we get the peak of the signal and thus the rise time corresponds to the delay between the first rise in signal to the peak as compared to the speed of sound. One may ask the question what is the speed of sound because the aircraft has an explosion and is exposed to the outside environment but since the de-pressurization of the aircraft through the explosive fracture will take a minimum of a few seconds, we can reasonably assume that the pressure of the air in the aircraft corresponds to about 5000 to 6000 feet of altitude. At this presure and temperature, the sound velocity is roughly 1000 feet per second and from the 45 milliseconds delay we concluded that the explosion should have occurred about 40 to 50 feet from the cockpit. A question may be asked that the decay of the signal might be due to the AGC of the CVR coming into action. Mr. Turner, who is an acknowledged expert in the field of CVR has reported that Messrs Fairchild tested the cockpit voice recorders with a 10 db rise and fall of signals at the threshold of AGC and they got a result indicating a decay time of 33 milliseconds. The fall in the waveform of Channel 3 is about 40 milliseconds and is well near 33 milliseconds, so an argument may be advanced that the sound continued to remain steady and the fall in the signal level was effected by the AGC. In order to confirm this we tested the Cockpit Voice Recorder which was identical to the one which was on Kanishka by applying 1 KHz waveform of rectuangular modulation. To our surprise, we found that the decay time roughly was 130 milliseconds as compared to 33 milliseconds given by Mr. Turner. We repeated the tests with an initial background and without any background at all. We further tested with ramp waveforms, in other words, "slowly rising and falling waveforms of triangular shape with modulations of 1000 cycle carrier. This also confirms our finding. In order to clarify how the tests were performed so that others can judge whether it was a realistic test, I will explain the procedure. The modulated waveform was produced by a signal generator. This was fed to an amplifier. The amplifier output was fed to a loudspeaker. The output of the amplifier was checked to ensure that there was no distortion. Thus the signal going into the loudspeaker is the same modulated signal which has been applied at the input of the amplifier. This sound coming from the loudspeaker was recorded on the CVR through the CAM in the laboratory. This is how the test was performed. We were given a CVR tape by the Department of Civil Aviation purported to be that of an explosion which occurred on a Boeing 737 aircraft which crash- landed at Madras. We did the CVR analysis of this aircraft. We first recorded the output of the CVR of Indian Airlines CAM channel on a UV recorder. We found the rise time to be very small. This was of the order of a few milliseconds, about 8 milliseconds or so. We have been told that the explosion occurred just by the side of the front toilet i.e. just behind the cockpit. This to some extent confirms that the rise time is related to the distance of the explosion from the detecting CAM. The next thing that we did was the frequency analysis of this waveform. Mr. Davis has indicated in his report that if an explosion occurs on board the aircraft there should be low frequencies present. When we analysed the frequencies of the Kaniskha aircraft Channel 3, we did not find very low frequencies in case of an explosion abroad the aircraft. When we analysed the Boeing 737 tape we did not find any low frequencies in the signals. The report of Mr. Davis also provides the frequency analysis of a pistol shot which has been fired in the cockpit of the aeroplane. This also shows no low frequency components. So our conclusion, that it is not essential for low frequencies to be present in case of an explosion abroad an aircraft, was confirmed. I will go a step further to say that the frequency received by an area mike which responds to an explosive action abroad the aircraft will contain frequencies of the structure of the defracted " and dragging shock wave, the resonant frequencies of the aluminium panels defined by the longerons and the stiffening channel members and also some frequencies which may be of objects that the shock wave encounters in its path. It is, therefore, impossible to calculate the frequency spectrum that one would expect in the cockpit due to an explosion taking place in the aircraft".

3.4.6.35 In answer to a question Mr. Seshadri categorically stated that the word "explosion" in his report meant "a bomb, a very fast device".

3.4.6.36 Mr. Paul C. Turner's Report

Lastly, a reference may be made to the report dated 13th November, 1985 of Mr. Paul C. Turner. The evaluation of Mr. Turner of the analysis done by him of the CVR and the ATC tapes, as contained in the said report, was as follows:-

"With the foregoing as background, we can make several observations. The CVR record on the CAM channel, captain's channel and flight engineer's channel show that they were all affected at about the same time; the copilot's perhaps 20 milliseconds later. Major disturbances which are recognized as electrical system disturbances can be seen to begin about 60 milliseconds after the initial disturbance. This approximates the time it would take for the electrical system protective circuitry to become active.

3.4.6.37 "A steep wave front which would be indicative of a shock wave cannot be seen on the CAM channel sound spectrum; however, the spectrum analaysis shows that impulse type sounds occurred at the beginning of the event recorded on the CAM channel of the CVR. Since audio signals propagate through aluminium approximately 16 times the speed of sound in air, the CAM channel would probably have been affected by structurally transmitted noise before being affected by airborne noise. The geometry of the aircraft was such that structure borne disturbances could be recorded before the airborne transmitted information appeared at the cockpit microphone and an air transmitted shock wave or steep wave front may not be evident on the CVR.

3.4.6.38 The captain's and copilot's selector box channels recorded signals which appeared to be electrically inducted and similar to those seen on the Huete Boeing 747 breakups. These are then followed by a signal resembling audio frequency noises similar to an open microphone in a noisy environment or the opening of a receiver squelch. Both effects have been seen during aircraft breakups. The audio noise on the captain's and copilot's channels appears to have come from a different source. The flight engineer's channel does not contain audio noise. A spectral diagram of the copilot's and captain's channel noises just show broad band noise across the spectrum. The signal frequncies extend beyond the frequency range of a microphone both on the high and the low end. It does not fit the normal microphone envelope. Spectral diagrams of the event on the CAM channel show the normal microphone preamplifier envelope summed with wide band signal of unspecified origin. Since the signal quits abruptly with a doublet, it indicates that the interference was added upstream of the CVR and was not just reflected in the CVR power supply.

3.4.6.39 "The CVR record shows a signal stayed on for about 200 milliseconds when it appears that the power may have been interrupted to both the radio channel and the CAM channel of the CVR at the same time. It further appears that the signals to the CVR were probably interrupted at 360 milliseconds from the initial disturbance possibly by severance of the signal wires. It further appears from the action of the erase head and record that the main electrical system began to fail at this point and the CVR bus voltage value dropped to a value below 70 volts but not below 20 volts. This fluctuating voltage continued intermittently for a minimum of 1-1/4 seconds at which time the voltage evidently dropped to some value below 20 volts and the recorder ceased to operate. The power for operation of the No. 1 VHF transmitter can be explained by the operation of the standby bus and battery and connection of the No. 1 VHF radio to this standby bus.

3.4.6.40 "The necking down of the signal to a low value shows that no signal was coming to the CVR from the CAM preamplifier. The lack of a signal on the radio channels, which do not need to be erased before being recorded, further suggest that the wires were severed or "that the transmission to Cork began after what appeared to be the loss of the primary electrical system approximately 1-1/2 seconds following the event. Standby power would have become available upon loss of the primary power, the number one VHF would have become available, and CVR would have ceased to operate.

3.4.6.41 "The action of the erase circuitry in the CVR suggests that the fluctuating voltage seen was coming from the main electrical system bus. Anything else causing this fluctuating voltage down stream of the CVR circuit breaker would probably blow it.

3.4.6.42 "The signal received in Ireland indicated that a radio, most probably this aircraft's No. 1 VHF transmitter, stayed operational for about 5.4 seconds following the event at which time the entire aircraft electrical system ceased to function. This assumes that the No. 1 transmitter ceased to operate due to standby bus failure.

3.4.6.43 "In the conclusion, it appears that a catastrophic event occurred on Kanishka. It was reflected in all channels of the CVR and the CVR power supply at the same time. The main electrical bus began to fail within 0.35 second and the standby bus survived for only 6 seconds more at which time the aircraft's electrical system ceased to function. It appears that the event occurred in a manner to affect the cockpit area microphone operation severely and to force operation of the automatic gain control on the CVR. This loud noise continued for the life of the aircraft's main electrical system as reflected in the CVR.

3.4.6.44 "The mechanism of how the ATC transmission was made from Kanishka to Cork is unclear. The sound was not recorded on the CVR, indepentent studies by Canadian and British investigators have the Cork ATC call originating approximately 1-1/2 seconds following the event on the CVR. This is about the time that standby power would have become available to the No. 1 VHF.

3.4.6.45 "This report should be viewed as an accident investigation tool only and used in conjunction with other evidence gathered during the investigation.

3.4.6.46 "The United States Noard/Space Command has confirmed that there was no incoming space debris in the vicinity of Ireland on June 23, 1985."

3.4.6.47 It is pertinent to note that according to Mr. Turner there was "catastrophic event" which had occurrred on Kanishka. He has, however, not elucidated as to what this event was.

3.4.6.48 After the receipt of the report, the Court requested the NTSB that Mr. Turner should come and depose. It is unfortunate that permission was not granted to him. Faced with this situation and as it was thought necessary that some clarification was called for, the Court sent a telex to Mr. Turner whereby he was asked to give replies to the queries contained therein. He was requested that the reply be sent by 27th January 1986. A copy of the telex was also forwarded to the American Embassy at New Delhi for sending the same to NTSB by way of confirmation. Previously all communications addressed to NTSB were being routed through American Embassy. No reply has been received by the Court till this day either from NTSB or from Mr. Paul Turner. According to paragraph 5.14 of Annex 13 the State is required, on request from the State conducting the investigation of an accident, to provide to that State with all the relevant information available to it. It was, therefore, obligatory on the NTSB to have seen that the information sought for by the Court by way of answers to the queries was supplied.

3.4.6.49 Court Evaluation

From the reports of all the experts and the testimonies of M/s Caiger, Davis and Seshadri it is clear, and it is agreed to by all of them, that there was a breakup of the aircraft in mid-air. The experts also agreed that the sounds recorded on the ATC Shannon tape at 0714:01 Z emanated from the Kanishka aircraft.

3.4.6.50 Mr. Caiger has not said either in the report or in his statement as to what was the cause of the bang. Mr. Davis, on the other hand, is categorical in stating in his report that there was explosive decompression (meaning rapid decompression) on the aircraft. He has, however,
stated in the report that there is no evidence of an explosive device. The

main reason for his coming to this conclusion is that he had not been able to find low frequencies in the spectra of the CVR of Kanishka. Mr. Seshadri, on the other hand is equally vehement in concluding that an explosive device had detonated in the front cargo hold of Kanishka.

3.4.6.51 It may be that the frequency spectrum of Kanishka CVR did not contain low frequencies but, as has been admitted by Mr. Davis himself in answer to a Court question, it is not necessary that in the case of every detonation there must necessarily be low frequencies in the spectrum. Frequency spectra of 'Kanishka CVR before 'bang' and at the 'bang' position are shown in Figs. 2 & 3, indicating presence of additional high frequncies at the bang. Indeed in the case of Indian Airlines Boeing 737, which admittedly was a case where there was an explosion of a device within about 8 feet of the CAM, the frequency analysis showed absence of low frequencies. Frequency spectrum of Indian Airlines Boeing 737 CVR is shown at Fig. 4. Merely, because therefore, there were no low frequencies present would not mean that there was no detonating device on board the Kanishka. The CVR of Indian Airlines Boeing 737 has not been analysed either by Mr. Caiger or Mr. Davis. The analysis was, however, conducted by Mr. Seshadri and as is evident from his report, there were marked similarities between the spectra of Indian Airlines 737 and Air India's Kanishka CVR. One of the important reasons for coming to this conclusion, which has been indicated by Mr. Seshadri, is the rise time of the bang signal. From the analysis of the Indian Airlines Boeing 737 tape it was observed that it had taken 8 milliseconds for the peak to be reached. It was also seen that the explosive device was approximately 8 feet away from the cockpit area mike. Keeping this in view Mr. Seshadri observed that in the case of Kanishka the peak of the bang signal was reached in about 40 milliseconds. He, therefore, concluded that the origin of the bang sound was about 40 feet away from the cockpit area mike.

3.4.6.52 It would be pertinent to note that even according to the report of Mr. Davis the rise time in the case of Kanishka, which has been given for the peak is about 40 milliseconds. He, however, does not attach much importance to this because according to him after about 40 ms automatic gain control would become effective.

3.4.6.53 Mr. Davis has no personal experience of the time which it would take for the Automatic Gain Control to take effect. He has got the figures from the manufacturer. Mr. Davis admitted that the time which it will take for the AGC to be effective is not indicated in any published document of the manufacturer.

3.4.6.54 Mr. Seshadri, however, personally carried out the experiments on a Boeing 747 by using an instrument similar to what was on board Kanishka. From the testimony of Mr. Seshadri it is apparent that the results which he got were different. As per his testimony, for the AGC to be effective it will take 130 ms. If this be so then it may be possible to conclude that in the case of Kanishka the peak was reached in 40 ms. and thereafter the signal decayed and the signal was in no way effected by the AGC.

3.4.6.55 A reference may also be made, at this stage, the frequency spectrum of the sound of the hand gun which was fired on a boeing 737 flight deck. Frequency spectrum prepared by Mr. R.A. Davis is shown at Fig. 5. He has stated that the rise time for reaching the peak is almost instantaneous. Same is the case with regard to the frequency spectrum prepared by him of a bomb in a B-737 aircraft where the bomb had been placed in the freight hold which is shown in Fig. 6. A perusal of that spectrum also shows that the peak was reached in approximately 5 ms. The forward freight hold compartment of Boeing 737 is much more than five feet away from the cockpit area mike. If the theory of Mr. Seshadri was to be applied then as per the frequency analysis of this Boeing 737 bomb, the distance from the area mike could not have been more than 5 ft. It is, however, known, as per the report of Davis, that the bomb was actually in the freight hold which would mean not nearer than about 25 feet.

3.4.6.56 From what has been stated in the various reports, as well as in the testimony of the 3 experts who apperared in the Court, the only safe conclusion which can be drawn is that possibly enough study has not been done, due to lack of adequate data, which can lead one to the conclusion as to the exact nature of the sound and the distance from which it originated.

3.4.6.57 The fact that a bang was heard is evident to the ear when the CVR as well as the ATC tapes are played. The bang could have been caused by a rapid decompression but it could also have been caused by an explsoive device. One fact which has, however, to be noticed is that the sound from the explosion must necessarily emanate a few milliseconds or seconds earlier than the sound of rapid decompression because the explosion must necessarily occur before a hole is made, which results in decompression. In the event of there being an explosive detonation then the sound from there must reach the area mike first before the sound of decompression is received by it. The sound may travel either through the air or through the structure of the aircraft, but if there is no explosion of a device, but there is nevertheless an explosive decompression for some other reason, then it is that sound which will reach the area mike. To my mind it will be difficult to say, merely by looking at the spectra of the sound, that the bang recorded on the CVR tape was from an explosive device.

3.4.6.58 There are various hypothesis and theories which the experts have to investigate before any acceptable conclusions are arrived at. It so happens that in the present case we have the opinions of four experts, but they do not agree with one another on some material aspects. Two of the experts, namely, Mr. Caiger and Mr. Davis are categorical in saying that it is not possible to measure the distance of the origin of the sound on the cockpit area mike, whereas Mr. Seshadri has come to a different conclusion. Mr. Paul Turner in his report dated 13th November, 1985 in silent on this aspect, though in his earlier report dated 19th July, 1985 he had categorically said that there was an explosive device close to the cockpit.

3.4.6.59 With regard to the nature of the sound also we have 3 different opinions. Mr. Caiger is unable to give the nature of the sound, Mr. Davis says it is rapid decompression while Mr. Seshadri says it is a sound of an explosive device followed by decompression.

3.4.6.60 In the absence of any other technical literature on the subject, it is not possible for this Court to come to the conclusion as to which of the Experts is right. The only conclusion which can, however, be arrived at is that the aircraft had broken in midair and that there has been a rapid decompression in the aircraft. Just as it is not possible to say that the spectrum discloses that the bang is due to an explosive device similarly, and as has also been admitted by Mr. Caiger and Mr. Davis, it is not possible to say that the bang is due to break up of a structure.

3.4.6.61 The bang could have been due to either of the aforesaid two causes i.e. a bomb explosion or the sound emanating due to rapid decompression. The advantage of carrying out the said analysis is that a number of possible causes of the accident are eliminated. On the other hand, if the analysis is viewed in conjunction with other evidence on the record it is further possible to determine the exact nature or cause of the bang. In the present case the bang, as already noticed, could have been due to the sound originating from the detonation of a device or by reason of rapid decompression. Other evidence on the record, however, clearly indicates that the accident occurred due to a bomb having exploded in the forward cargo hold of Kanishka. The spectra analysis and the conclusions of Mr. S.N. Seshadri are corroborated by other evidence.

TESTS AND RESEARCH

3.5.1 During the course of investigation a number of groups were formed to study and analyse evidence and data which was available. Materials like CVR, ATC and DFDR tapes were also given to the various participants.

3.5.2 The groups as well as other experts studied and analysed the material with them and submitted their reports which have been referred to earlier.

3.5.3 The experts examining the CVR tapes did carry out a number of tests. Different graphs and traces were prepared and the sound was analysed by them. The result of their analysis has been referred to in Chapter 3.4 on Flight Recorders.

3.5.4. The metallurgical examination of some of the recovered pieces was carried out at BARC. The examination of some of the pieces showed different types of damages having been recorded on the targets such as petalling and curling round the holes, spikes etc. The said team carried out certain explosion experiments. Their report on the experiments so carried out has already been set-out in paragraph 3.2 above.

3.5.5 The Indian Air Force has set up an Institute of Aviation Medicine at Bangalore. The Court visited the said Institute on 9th December 1985. During that visit an experiment was conducted in the explosive decompression and high altitude chamber to demonstrate what actually happens during explosive decompression and subsequently on exposure to hypoxia.

3.5.6 Subjects were taken to 8,000 feet in the explosive decompression chamber with oxygen. They were exposed to an altitude of 25,000 feet within one second. During the course of this explosion a loud bang was heard and inside the chamber there was misting and drop in temperature. After this the chamber was allowed to run at 22,000 feet for roughly two minutes and an experiment to show the adverse affects of hypoxia on the subjects was done. In this experiment, subjects were asked to write a given sentence while their oxygen supply was cut off. It was observed that initially the subjects kept on writing the sentence correctly and then

after about 120 seconds they started making errors while writing the sentence and finally they stopped writing. At this stage oxygen was re-started and within a few seconds, the subjects started writing their sentence once again. The experiment was completed at this stage and the altitude chamber was brought down to ground level.

3.5.7 The subjects were taken out and were asked questions as to what did they feel. They explained that at the time of explosive decompression, they heard a loud bang, felt cold and saw misting inside the chamber. They also found air escaping from their lungs. On further enquiry about the experiment pertaining to hypoxia, they said that they felt light headed and after that they did not know what happened till they once again noticed that they were writing on a piece of paper.

SECURITY

3.6.1 The evidence and the statements filed on record show that Canadian Security arrangements in place prior to 23rd June, 1985 met the international requirements for civil air transportation. However, before this date, the emphasis was on preventing the boarding of weapons including explosive devices in hand baggage. Hence, the screening of checked baggage was only undertaken in conditions of a heightened threat as was the case with respect to Air India flights.

3.6.2 Air India, as required by Canadian regulation, had a security programme. Because of the threat level assessed against the Airline, Air India had more extensive security measures than almost any other Canadian or international airline. These measures were generally in accordance with the recommended procedures of the ICAO Security Manual for special risk flights. Air India had also requested and had received and arranged for extra security for the month of June, 1985. For Air India flight 181/182, Air India provided a security officer from its New York Office to oversee the security at Toronto and Montreal.

3.6.3 As it became apparent during the course of investigation that security would be an important aspect whilch would require the attention of the Court, Mr. Rodney Wallis, Director, Facilitation and Security, International Air Transport Association was good enough to appear in Court on 24th January, 1986. His testimony on certain aspects of security was recorded in camera by the Court on that date. The expert evidence has been taken into consideration while formulating some of the recommendations.

INTERNATIONAL COOPERATION

3.7.1 The manner in which persons and organisations from five different countries combined their resources and efforts in connection with this accident is an object lesson in international cooperation.

3.7.2 From the time the accident occurred, till the conclusion of the investigation proceedings by the Court in Delhi, there has been a consistent interplay amongst different persons and organisations. When all the persons got together, for the first time, at Cork the group was very heterogeneous. Each one had his own point of view, which did not necessarily coincide with that of another. At times, the atmosphere was

charged with a bit of tension which continued even when the Court was constituted to investigate into the accident.
3.7.3 It was noticed that not only were the participants a bit apprehensive and suspicious but, during the course of investigation, there were also occasions when there appeared some acrimony between a few of them.
3.7.4 In such a sensitive situation, careful handling was called for. The participants' honesty of purpose could not be doubted. All that was wanted was that there should be an effort to try and understand the point of view of all the persons. This is precisely what the Court tried to do.
3.7.5 It is indeed fortunate that the efforts of the Court, in this regard, succeeded. After the Court had decided that it was not the purpose or the function of the investigation to affix responsibility for any lapse which may have been committed, one could see the general relieving of tension. With the passage of time there was a gradual building up of the confidence of the participants in the conduct of the investigation. The participants' interest for air safety transcended all barriers and any apprehension or suspicion, which was present in the minds of some, was soon dispelled. In its place there grew a deep sense of urgency, anxiety and cooperation in an effort to see that all the participants rendered utmost assistance for the satisfactory completion of the task in hand.
3.7.6 The main beneficiary of this international cooperation was not only the Court investigating the accident but it was the cause of air safety which benefited the most. Countries and Organisations went out of the way to help each other, financially and otherwise, even when they were not obliged to do so. Money and services were readily and voluntarily offered and usually the requirements of the Court were always fulfilled.
3.7.7 As the accident had occurred only about 100 miles off the coast of Ireland, the centre of activity, initially, was centred at Cork. The Government of Ireland, and the Irish people in particular, acted as though they regarded this as a national disaster. Not only did they render every assistance with regard to the search and rescue operation, hospital

facilities, police etc. but the people acted as if one of their own kith and kin had died. In the situation which existed they were pillars of strength to the relatives of the deceased. Not only did complete strangers comfort such relatives but, more often than not, they even joined in their grief. The residents of Cork did everything possible to try and mitigate the sorrow of the victims' relatives. Everyone did their small bit, even the children of Cork queued up to place flowers at the coffins of the victims.

3.7.8 The Representatives of the Government of Canada also came to the scene, at the initial stages itself, and rendered full help and cooperation till the last. The major brunt of the mapping and the salvage operations was borne by Canada. Willingly and without any demur it incurred huge expenses, which must have been to the tune of a few million dollars, in carrying out these operations. It rendered full help and assitance to the Court whenever called upon to do so. For example, it offorded full facilities and help to the team which had been sent to Canada by the Court in August, 1985. It was only with the help of the Canadian Government, and the CASB and RCMP in particular, that the Court was able to obtain evidence and information relating to the accident. Without Canadian help the conduct of the investigation would have only been speculative in nature.

3.7.9 On their own, and without any request from the Court or from the Government of India, the Government of United States decided to lend a helping hand in the salvage operations. This was done at a very critical juncture when financial help and expertise were required so as to salvage the important critical pieces of the wreckage. It arranged for the services of a salvage expert and it also made necessary arrangements for the deployment of a second ship, duly fitted with necessary equipment to enable it to salvage some of the heavier pieces of the wreckage. The Court understands that the amount which was contributed in meeting the expenses by the United States was to the tune of U.S. $ 700,000.

3.7.10 The Government of United Kingdom also provided ship and helicopters in connection with the search and rescue operations. Even during the time when salvage operations were being carried out it was the British Helicopters which assisted in transporting personnel to and from the ship which were engaged in the salvage operations. The A.I.B. at Farnborough, on being asked by the Court to do so, carried out a very detailed analysis of the CVR and the ATC tapes.

3.7.11 Being the state of Registry of the aircraft and also the state holding the investigation, the major brunt of the work fell on the shoulders of officers of the Government of India and BARC. They acted as coordinators who had to oversee the work being carried out by persons belonging to diverse organisations and coming from different countries. Young engineers of Air India took turns in going aboard the ships and manning the Control Centre at Cork. They worked in conjunction with the engineers of Boeing and CASB and the crew members of the ships during the salvage operations. Without their enthusiastic participation the progress of the salvage operations would have been severely hampered.

3.7.12 The Scientists from BARC and National Aeronautical Laboratory, Bangalore were ever ready and willing to work together with the experts from abroad. Whenever called upon to do so, they rendered whatever assistance which was desired by the Court and the other participants.

3.7.13 It was seen that when the persons, coming from different countries and backgrounds, worked together with sincerety and honesty of purpose then they functioned smoothly and harmoniously, and usually arrived at an agreed solution or finding. These days it is indeed rare to see such a degree of international cooperation between different persons, organisations and countries.

ANALYSIS AND CONCLUSIONS

4.1 From the evidence which is available what has now to be determined is as to what caused the accident.

4.2 Finding the cause of the accident is usually a deduction from known set of facts. In the present case known facts are not very many, but there are a number of possible events which might have happened which could have led to the crash.

4.3 The first task is to try and marshal the facts which may have a bearing as to the cause of the accident.

4.4 It is undisputed, and there is ample evidence on the record to prove it, that Air India's Kanishka had a normal and uneventful flight out of Montreal. The aircraft had been in air for about five hours and was cruising smoothly at an altitude of 31,000 feet. The readout from the CVR shows that there was no emergency on board till the catastrophic event had occurred. This is corroborated by the printout available from the DFDR. The event occurred at approximately 0714 Z and that brought the aircraft down, and it probably hit the surface of the sea within a distance of 5 miles. The time within which the plane came down at such a steep angle could not have been more than very few minutes. There was a sudden snapping of the communication between the aircraft and the ground. The aircraft had also suddenly disappeared from the radar.

4.5 It is evident that an event had occurred at 31,000 feet which had brought down 'Kanishka'. What could have possibly happened to it? The aircraft was apparently incapacitated and this was due either to it having been hit from outside; or due to some structural failure; or due to the detonation of an explosive device within the aircraft.

4.6 Evidence indicates that after the event had occurred, though the pilots did not or were not in a position to communicate with the ground, they nevertheless appeared to have taken some action. According to Mr. Laflamme, witness No. 12, the examination of the wreckage showed that spoilers had been deployed and this must have been done with a view to enter into emergency descent. He has further speculated that such an emergency descent would support or perhaps cause a rupture in the forward area or a partial damage to the hydraulic system or damage to the control system which created such a condition that the pilots were not able to control the flight. The wreckage fruther showed that the jack screw for the stabilizer trim was found in the nose-up position and it was hard to explain how this got there merely as a result of impact with the water. The trim being in that position could only have been due to the pilot selecting it or as a result of a situation created by an explosion. In that position, and at a high aircraft speed, there would have been an extremely high g-loading on the aircraft.

4.7 It can further be speculated that if an explosion takes place in the forward cargo compartment, the oxygen stream might have been damaged so that when the pilots donned their masks as part of the emergency drill for explosive decompression, they were not breathing enriched oxygen and the time of useful consciousness at about 31,000 feet would be significantly less than 30 seconds under high stress and if the pilots became unconscious as a result of this, then the aircraft would have got out of control which would explain the subsequent events.

4.8 None of the participants have produced any evidence which could lead one to the conclusion, that there was any external hit to the aircraft. In fact in the report dated 13th November, 1985, Mr. Paul Turner has stated as follows:

"The United States Norad/Space Command has confirmed that there was no incoming space debris in the vicinity of Ireland on June 23, 1985."

4.9 Thus we are left with only two of the possibilities viz., structural failure or accident having been caused due to a bomb having been placed inside the aircraft.

4.10 After going through the entire record we find that there is circumstantial as well as direct evidence which directly points to the cause of the accident as being that of an explosion of a bomb in the forward cargo hold of the aircraft. At the same time there is complete lack of evidence to indicate that there was any structural failure.

4.11 The circumstantial and direct evidence which leads to the aforesaid conclusion is as follows :

A. Connection with an explosion at Narita Airport :

On 23rd June, 1985 there was an explosion at the Narita Airport. The explosion occurred when a bomb exploded in a suit case which was to be interlined to Air India's Flight No. 301 from Tokyo to Bangkok. The following events, which had occurred prior to this explosion, clearly establish the connection between the two incidents :

(i) On 19 June 1985, at approximately 1800 PDT (0100 GMT, 20 June), a CP Air reservations agent in Vancouver received a telephone call from a male with a slight Indian accent. He identified himself as Mr.

Singh and informed the agent that he was making bookings for two different males also with the surname of Singh. One booking was made in the name of Jaswand Singh with CP 086 from Vacouver to Dorval on 22 June 1985 to link with AI 182 departing from Mirabel. The other booking was to Bangkok using CP 003 from Vancouver to Tokyo and AI 301 from Tokyo to Bangkok. This booking was made in the name of Mohinderbel Singh. A local telephone contact number was given and the call lasted about one-half hour.

(ii) On the same date at approxmimately 1920 PDT (0220 GMT), another reservations agent for CP Air was contacted and requested to change the booking for Jaswand Singh. The confirmed flight on CP 086 was cancelled and a reservation was made on CP 060 from Vancouver to Toronto, and a request to be wait-listed on AI 181/182 from Toronto to Delhi was made.

(iii) On 20 June, 1985 at about 1210 PDT (1910 GMT), a male appearing to be of Indian origin purchased the tickets with cash from a CP Air Ticket office in Vancouver. The booking in the name of Mohinderbel Singh was changed to L. Singh and the booking using the name of Jaswand Singh changed to 'M. Singh'. The telephone contact number was also changed. The final itinerary was as follows :

(a) M. Singh - CP 060 Vancouver - Toronto Confirmed Scheduled to depart Vancouver at 0900 PDT, 22 June 1985

- AI 181 Toronto - Montreal Wait-listed Scheduled to depart Toronto at 1835 EDT, 22nd June, 1985
- AI 182 Montreal - Delhi Wait-listed Scheduled to depart Montreal at 2020 EDT, 22nd June, 1985

(b) L. Singh - CP 003 Vacouver - Tokyo Confirmed Scheduled to depart Vancouver at 1315 PDT, 22 June, 1985

- Air India 301 Tokyo - Bangkok Confirmed Scheduled to depart Tokyo at 1705 time in Tokyo, local 23 June, 1985

(iv) On 22 June, 1985 at about 0630 PDT (1330 GMT), a caller identifying himself as Mr. Manjit Singh called the CP Air reservations office. The caller spoke with a heavy Indian accent and wanted to know if his booking on AI 181/182 was confirmed. The caller was informed by the agent that the was still wait-listed out of Toronto and offered to make alternate arrangements to Delhi. The caller stated that he would rather go to the airport and take his chances. The caller also asked if he could send his luggage from Vancouver to Delhi and was told he could not check his baggage past Toronto unless his flight was confirmed.

(v) On Saturday morning, 22 June, 1985, a CP Air passenger agent worked check-in position number 26 at the CP AIR ticket counter, Vancouver International Airport, and recalls dealing with a passenger of Indian origin booked on CP 060 and then on to Delhi. The passenger stated that he wanted his bag tagged right to Delhi from Vancouver. After checking the computer, the agent explained that since he was not confirmed past Toronto his baggage could not be interlined. The passenger insisted and, as the line-up were long, the agent relented and interlined his suitcase. The flight manifest for CP 060 shows that 'M. Singh' checked in through this passenger agent, was assigned seat 10B, and checked one piece of baggage.

(vi) The flight manifest for CP 003 shows that on the same day the person using the name of 'L. Singh' with an interline ticket to Bangkok also checked through the same counter, was assigned seat 38H, and checked one piece of baggage.

(vii) A check of CP Air's records and interviews with passengers on flights CP 003 and CP 060 indicates that the persons identifying themselves as 'M. Singh' and 'L. Singh' did not board these respective flights.

(viii) In a statement of William Long, annexed to the affidavit of I.G. Pole, Police Officer, City of Toronto, he has stated that on 22nd June, 1985 he was employed as a driver whose responsibility was to deliver interlined baggage between terminal 2 to Terminal 1 and vice versa at Toronto. He has further stated that he had picked up 4 bags from Terminal 1 which were destined for terminal 2 Air India. Three of these bags were from U.S. Air originating from New York city. Regarding the last bag he stated as follows :

"The fourth bag destined for Air India was, I distinctly remember looking at the baggage tag and it was pink with the CP logo in blue and letters saying CP on it there were also numbers but I can't remember the number, from CP Air and I remember it was from Vancouver. On the bottom of the tag it said vancouver using the initials YVR and the flight number which I can't remember. The bag was destined for India. When I arrived at the CP Air belt there were a number of bags from other airlines on the belt included in these were the three U.S. Air bags destined for Air India. As I was finishing loading the carts, a CP Air station attendant who had been unloading bags from containers, I noticed as I checked once more for anymore bags, drop another bag on the conveyer belt. This was the bag destined for Air India. It was dark brown Samsonite Hard sided Type 01A on the Baggage Identification Chart. After they were loaded onto the cart I took them over to Air Canada domestic belt at Gate 89-91".

To further questions posed to him, Long stated that this bag from CP Air weighed approximately 70 lbs and there was something which rattled inside the bag. He could not say what it was but he said that "it sounded small". When specifically asked whether he thought there was something big inside the bag, he answered in the affirmative, and added that he did not know what was in it but it was heavy. There was discrepancy in the time when he is alleged to have picked up the bags which he had indicated in his schedule when compared with CP Air Vancouver flight which had arrived at 1622 hours. When this was pointed out to Long, he answered "I could have may be got the time wrong, it was during the busy period. It could have been an estimate time. But I do remember the bag came off CP air. It could have been 16:34 Hrs. I don't know."

(ix) The aircraft departed from Toronto for Mirable and London with the suitcase unaccompained by the passenger who had checked it in at Vancouver. Similarly, CP Air 003 departed Toronto for Tokyo with the baggage of one passenger 'L. Singh' to be interlined to Air India flight AI 301 to Bangkok even though 'L Singh' had not boarded that flight.

(x) The linking of the two occurrences namely the blast at Narita Airport and the Air India accident becomes startingly evident if we look at the following chronology of events:

CPA 003 (VANCOUVER-TOKYO) CPA 060 (VANCOUVER-TORONTO) Connection to Connecting to Air India 301 Air India 182 WESTBOUND EASTBOUND All Times GMT Thurs 20 June, 1985 0057 A male called C.P. Air Reservations in Vancouver and after discussing a number of routings, booked a one-way ticket and CPA 060 to Toronto with connections to Air India 182 under the name of Jaswand SINGH. A return ticket was also booked on CPA 003 to Tokyo connecting with Air India 301 to Bangkok in the name of Mohinderbel SINGH.

1912 A male attended the CP Air Ticket Office in Vancouver. He paid $ 3005.00 in cash for the above tickets after changing the ticket of Mohinderbel SINGH to L. SINGH and changing
from a return to a one-way ticket. He changed the Jaswand SINGH ticket to M. SINGH.

Saturday 22 June A Mr. SINGH called Reservations and got 1330 confirmation on his one-way ticket to Toronto with luggage to be sent through to India. M. SINGH checked in with seat 10B confirmed to 1550 Toronto. Wanted suitcase interlined to AI 182. Agent relents. 1618 CPA 060 departed Vancouver 18 minutes late. M. SINGH not in assigned seat. L. SINGH checked in for CPA 003 and one suitcase interlined to Air India 301. Assigned seat 38H. CPA 060 arrived Toronto 2022 12 minutes late. Some passengers and baggage interlined to AI 181.
CPA 003 departed 17 min. late for Tokyo. L. SINGH not in 2037 assigned seat. Sunday 23 June Air India 181 departed 0015 Toronto for Mirabel 1 hour 40 minutes late. 0100 Air India arrived Mirabel. 0218 Air India 182 departed Mirabel 1 hour 38 minutes late. CPA 003 arrived Narita Airport, Tokyo. Arrived 14 minutes early 0541 Baggage cart explodes in transit area. 2 killed, 4 injured, 0619 0714 Air India 182 disappeared from

Radar

Air India 301 departed Narita. 0805 0815 Air India 182 Scheduled arrival Heathrow (fuel stop).

(xi) It would indeed to too much of a coincidence that two persons, whose tickets were bought at the same time and who had checked in under the names of 'L. Singh' and 'M. Singh' missed their respective flights, more so when 'M. Singh' had insisted at the check in counter at Vancouver that he should be interlined, even though his seat from Toronto on AI 181/182 was not confirmed, and his baggage (one suitcase) accepted and be routed through to Delhi. If there had been some reason for 'gate no-show' by both of them, one would ordinarily have expected both, or at least one of them, to have made efforts, at that time or thereafter, either to ask for refund of money or they should have contacted the airline staff at the Airport and asked that they should be put on another flight.

(xii) A large amount of money had been spent on the purchase of the two tickets and a question which comes to mind is as to why was this money spent if both the tickets were to be wasted and no one was to travel on them, after having checked in and obtained boarding cards. Furthermore, no effort has been made by any of these two persons to try and lodge a claim for the baggage which they had checked in.

(xiii) The aforesaid facts clearly indicate the connection between the travel plans of so called 'L. Singh' and 'M. Singh'. In fact the manner in which the reservations were changed to the names of 'M. Singh' and 'L. Singh' shows the anxiety of some one to hide behind the identity of persons who bore notorious names.

(xiv) The interlined baggage exploded at Narita Airport and there is strong probability that the suticase from Vancouver, which was interlined to AI 182, contained a device similar to the one which had exploded at Narita Airport on 23 June, 1985.

B. CVR and DFDR both stopped simultaneously:

There was simultaneous interruption of electrical power to the flight recorders. The electrical supply could have been interrupted either because of the cables being cut or because of total electric failure. Power supply wires to the CVR and the DFDR run under the passenger cabin ceiling on the left and the right hand side. The supply of electricity through these cables originates from the MEC compartment, which is in front of the forward cargo hold. If the CVR and the DFDR had stopped due to the breakage of electrical supply wires as a result of possible explosion in the aft cargo hold there would have had to be an instantaneous break of almost the entire section of fuselage, because both these recorders had stoped simultaneously. In such a catastrophic event it is not possible that the bottom skin panels of the aft cargo compartment would remain undistorted, or would have no rupture or holes in them. Furthermore, in such an event the tail portion of the aircraft would have been found in the beginning of the wreckage trail, but this was not so. On the other hand, and explosion in the forward cargo compartment would have resulted in damage to the electrical buses located in the MEC and that would, in turn, result in cutting off the electrical power supply causing simultaneous stoppage of the recorders.

C. The ATC Transponder Stopped Transmitting :

The transponder is located at the bottom of the one of the forward rakes immediately forward of the front cargo compartment. Signals from this also stopped being received by the secondary radar at Shannon. Keeping in view that the CVR and the DFDR had stopped simultaneously at about the same time, when the signals from ATC transponder had also ceased, it is reasonable to presume that there must have been a complete breackdown of electrical supply which had affected all the three units. The only event which could have caused such a damage to paralyse the entire MEC compartment could only have been an explosion in the forward cargo hold. It was not possible that any rapid decompression caused by a structural failure could have disrupted the entire electricl power supply from the MEC compartment. In known cases of aircraft being subjected to rapid decompression there has never been such an instantaneous and total stoppage of electrical power and in fact aircrafts have been known to have continued to fly and communicate with the ground even after decompression.

D. Non-supply of Oxygen :

Oxygen supply cylinders are located in the ceiling of the forward cargo compartment. Any rupture of the only pipeline which supplies oxygen to the passengers would result in there being no surge of oxygen flow, which alone drops the oxygen masks. The inspection of the wreckage shows that there is no indication of the oxygen masks ever having dropped. A rupture of this pipeline, simultaneously with power rupture, could only have been caused if there had been a detonation of the explosive device in the front cargo hold.

E. Damage in air :

The examination of the floating and the other wreckage shows that the right hand wing leading edge, the No. 3 engine fan cowl, right hand inboard mid flap leading edge and the leading edge of the right hand stabilizer were damaged in flight. This damage could have occurred only if objects had been ejected from the front portion of the aircraft when it was still in the air. The cargo door of the front cargo compartment was also found ruptured from above. This also indicates that the explosion perhaps occurred in the forward cargo compartment causing the objects to come out and thereby damaging the components on the right hand side.

F. Evidence of Overpressurization :

The examination of the structural panels and the other parts of the forward cargo compartment and the aft cargo compartment, recovered from the sea bed, indicates that overpressure condition had occurred in both the cargo compartments. The failure of the passenger cabin floor panels in upward direction also indicates that overpressure was created in both the compartments. It cannot be disputed that whenever an explosive detonates very high pressure shockwaves are formed which travel in all directions and high speed fragments of the container, or the loose material, also move away from the source of explosion. It is, therefore, clear that there was overpressurization in the cargo compartments which resulted in such rupture of the cabin floor panels.

G. Holes in the front cargo hold panels

While the skin panels of the aft cargo compartment are fairly straight and undamaged, the panels of the front cargo compartment are ruptured and have a large number of holes. This shows that there was occurrence of an event in the front cargo compartment and not in the aft cargo compartment.

H. Buckling of Seats :

The seats towards the rear of the aircraft had only the aft legs buckled, whereas the seats towards the front had both the front and the aft legs buckled. This indicated that the whole floor was subjected to a vertical force and was more severe towards the front. Moreover, the upper deck storage cabin was found among floating wreckage. The bottom of this cabin was pushed up in the shape of a dome with no evidence of impact damage. This deformation was indicative of having been caused, possibly, as a result of a shockwave.

I. Metallurgical Examination Results :

A metallurgical examination, especially of Targets 362 and 399, clearly confirms that there was an explosion in the forward cargo compartment. Microscopy around some of the holes discloses that they have such characteristics like twinning which can be present only if the holes had been puntured due to the detonation of an explosive device.

J. CVR Tape Analysis :

The report of CVR tape analysis by Mr. S.N. Seshadri also corroborates the aforesaid evidence i.e. that there was a bomb in the forward cargo hold of the aircraft.

RECOMMENDATIONS

5.1 ICAO, IATA and the States should :-

(a) undertake an ongoing review of established aviation security standards to prevent the placement of explosive substances on board commercial aircraft;

(b) establish a programme of monitoring the implimentation of security measures in airports around the world, in cooperation with the Governments concerned. For each airport studied, it should report its findings and recomend any improvements that may be required;

(c) consider establishing a group of civil aviation experts to investigate serious breaches of security. The purpose of these investigations would be to determine the facts of an incident so that necessary measures could be developed and implemented world wide to prevent similar breaches in the future.

Note : As it may take some time for ICAO and IATA to implement these recommendations, at least those countries which have international air traffic should take up effective measures without delay.

5.2 ICAO should :-

(a) develop a model clause on security that could be used in the bilateral air agreements that govern the exchange of air traffic rights between countries;

(b) consider establishing standards for the training of security personnel.

5.3 IATA should develop practical procedures for reconciliation of interlined passengers and their baggage at intermediate airports.

5.4 Interlining of checked-in baggage should not be done if a passenger does not have a confirmed reservation on the onward carrier flight.

5.5 The baggage of interlined passengers should be matched with passengers by the onward carriers before loading the baggage on the aircraft.

5.6 Whenever a Government becomes aware of particular high risk security threat it should notify not only the airline at risk, but also all connecting airlines in order that extra precaution can be taken at potential points of introduction of interline baggage into the system.

5.7 When an Airline is aware of a high security threat it should communicate the same to the host state as well as, if possible and prudent, to the other airlines operating there.

5.8 Passenger count should be done at boarding gate and in case of 'no gate show' of a passenger, his baggage must be off-loaded.

5.9 All checked-in baggage, whether it has been screened by X-ray machine or not, should be personally matched and identified with the passengers boarding an aircraft. Any baggage which is not so identified should be off-loaded. This is advisable as examination of the baggage with the help of an X-ray machine has its own limitations and is not fool proof. Some explosives hidden in Radios, Cameras etc. may not be readily detected by such a machine. In fact an explosive not placed in a metallic container will not be detectable by an X-ray machine. Similarly, a plastic explosive can be given an innocuous shape or form so as to avoid detection by an X-Ray. Reliance on an X-Ray machine alone may in fact provide a false sense of security.

5.10 Effectiveness of the instrument known as PD-4 is highly questionable. It is not advisable to rely on it.

5.11 All unaccompanied baggage should be placed on the aircraft after their contents have been physically checked. In the alternative, it should be loaded only after it has been placed in a decompression chamber and the host state is satisfied that the baggage is clean and the shipper has been identified.

5.12 Airlines should have effective backup security equipment or procedures available in case of machanical break down of security equipment.

5.13 All hand baggage, including that of the crew, should be opened and the contents physically checked even if the said baggage has been x-rayed. This will no doubt be a bit time consuming and laborius but if security is to be meaningful, then slight inconvenience has to be endured in order to ensure a safer flight.

5.14 The manufacturers of aircraft should take effective steps for protecting sensitive parts of the aircraft from explosive damage.

5.15 Studies should be undertaken to determine the feasibility of physically separating the avionics bay and emergency oxygen systems from the cargo area in aircraft so that these sensitive and essential areas of the aircraft cannot be damaged or destroyed by a relatively small explosive deivce concealed in luggage.

5.16 The seats should have safety belts which can act as restraint for the upper part of the body e.g. like a shoulder harness with inertial restraint.

5.17 The seats in the aircraft should be so designed so as to incorporate shock absorbing systems within the seat and they should be manufactured by using material which does not break easily.

5.18 In addition to the cockpit voice recorder, there should be in the cockpit a video/scanning camera which would record the movements and the audio sounds in the cockpit. This will not only assist in ascertaining as to how the pilots act during as emergency but, in the case of hijacking, would also assist in the identification of the hijackers.

5.19 The CVR should record all the conservation and sounds in the cockpit for the entire duration of the flight, and not merely for the last 30 minutes.

5.20 The CVR and the DFDR should be powered from two alternative sources of energy.

5.21 The oxygen for the flight crew should be supplied from two different sources i.e. in the event of an emergency the pilot and the co-pilot must don the oxygen mask and the oxygen must be supplied from different source.

5.22 Suitable provisions should be incorporated in Annex 13 which would give power to an Investigator to record evidence outside the country of investigation and also to summon witness from abroad. It should also be mandatory on the contracting States to give information sought for by an Investigator.

(B. N. KIRPAL)

February 26, 1986 COURT

We agree with the conclusions and recommendations stated above.

ASSESSORS

(V. Ramachandran) (J.S. Gharia)

(J.S. Dhillon) (J.K. Mehra)

(B.K. Bhasin)

ACKNOWLEDGEMENTS

When I was appointed as the Court to investigate into the accident, the magnitude of the task involved was known. With the help, assistance and cooperation of a team of dedicated workers, the work was, however, completed in not too long time. The assistance received from those who helped me cannot be too highly praised.

From amongst my Assessors, Captian B.K. Bhasin was the only one who was permanently stationed in Delhi. We met for the first time on

15th July, 1985 and little did I realise then that, by the time our work would be over, how much I would be depending upon him. Not only was his advice on the technical aspects of flying and air safety invaluable but, whenever any difficulty or a problem arose, I invariably turned to him for assistance and advice which I readily got. I found him having a very practical and positive approach to all the problems but, at the same time, he very rightly was not prepared to compromise on any principal issues.

The only interest Dr. V. Ramachandran appeared to have was to do his work to perfection. No praise can be too high for the manner in which this Metallurgist from landlocked Bangalore volunteered and boarded the salvage ships which were carrying out operations in the cold and choppy waters of Atlantic Ocean. He sarificed all comforts and went to sea with a view to be present on board the ships at the time when salvaged pieces of wreckage were brought on board. His deep knowledge of metallurgy greatly assisted the examination of the salvaged pieces of wreckage. In this connection the entire metallurgical examination was planned and organised by him.

Whenever any information was required concerning explosives, Mr. J.S. Gharia was ever eager and in a position to provide the information.

Mr. J.K. Mehra looked into the engineering aspect of the accident and he spent a lot of time in going through various Air-India Maintenance Manuals. He always made discussions very lively and interesting.

Captain J.S. Dhillon came out of his retirement and provided useful information to the Court on some aspects of flying.

This work would never have been satisfactorily completed without the help and assistance received by the Court from late Mr. S.N. Seshadri of Bhabha Atomic Research Centre. From the time when the CVR was first played by him at BARC on 16 July, 1985 till the very end, he most willingly and pleasantly undertook any assignment which was given to him by the Court. It was a great national loss when he suddenly passed away on 2nd February, 1986, only a few days after he had deomonstrated his brilliance when his testimony, regarding the analysis of the CVR tape, was recorded by me in the Court.

I am also grateful to the other Scientists and staff of B.A.R.C. who rendered considerable assistance to the Court. The facilities made available by Dr. P.K. Iyengar, Director, B.A.R.C. with regard to the finalisation and completion of the report cannot be easily forgotten. In the absence of late Mr. S.N. Seshadri, with whom I had developled a personal rapport, Dr. Ashok Mohan and Mr. V.K. Chadda met with all our requirements in the finalisation and preparation of the Report. Dr. Asundi of BARC and the other Metallurgists of that Organisation and of the National Aeronautical Laboratory also spent a considerable amount of their time and energy in successfully carrying out metallurgical tests and examination of the salvaged pieces.

During the investigation I had to visit Ireland on two occasions. I immediately realised the extent of help, assistance and guidance which was being rendered to all of us by Mr. Kiran Doshi, the Indian Ambassador to Ireland. There was no problem to which he did not have a solution. On my visit to Dublin not only did I enjoy the hospitality of Kiran and his wife Razia but it also gave an opportunity to personally meet Mr. Mitchel, the Minister of Communications, and senior officials of his Ministry, and to express my gratitude to them for all the help and assistance which the Government and people of Ireland had, most willingly, rendered.

At Tokyo the Indian Ambassador and members of his staff looked after all our needs and arranged meetings with the Japanese officials whom we wanted to meet.

As representatives of the Court in Cork, Mr. P.R. Chandrasekhar and Mr. C.D. Kolhe did a commendable job. They kept me informed of the progress which was taking place at Cork and, whenever required to do so, they took vital decisions while coordinating the mapping and salvage operations.

Mr. H.S. Khola, Director of Air Safety, New Delhi willingly carried out all the directions of the Court. Special mention must also be made of Mr. Satendra Singh, Regional Controller of Air Safety, Bombay, who worked day and night when the flight recorders were first opened and the copies of the tapes made and the data analysed.

I have also to express my gratitude to the Counsel who assisted the Court in the Investigation. Without their help and cooperation, it would not have been possible to complete the work in 7-1/2 months.

On my trip to Bombay, the Staff and Management of Centaur Hotel made my stay very comfortable. It was like a home away from home.

The work done during the salvage operarations by four young engineers of Air-India was highly commendable and valuable. All of them namely, Mr. Balasubramanium, Mr. L.S. Carvalho, Mr. G.D. Nayar and Mr. A.K. Sheode, worked round the clock even during adverse climatic conditions.

The Registrar of the Delhi High Court, Ms. Usha Mehra spared no efforts in rendering every assistance whenever the same was required. She ably marshalled all the resources available in the High Court in order to ensure the smooth and efficient functioning of my office. My own personal staff in particular, headed by Mr. V.P. Ahuja, Court Master and Mr. Balram Chopra, Private Secretary, as usual, rose to the occasion. While Mr. Ahuja kept complete control of hundreds of documents and affidavits which had been filed, Mr. Chopra besides bearing the brunt of the typing work, very ably supervised the work of other Stenographers.

It was most fortunate that I was able to persuade Mr. S.N. Sharma to accept the trying job of being the Secretary to the Court. His vast experience in such Investigations, he had been a Secretary in three such Investigations earlier, made my task much lighter. Moreover, as an Aircraft Engineer, he was always ready to explain technical intricacies involved in the case. Without his help I could not have completed my work within the stipulated time.

(B. N. KIRPAL)

Air Accidents Investigation Branch
Aircraft Accident Report No 2/90 (EW/C1094)

Report on the accident to
Boeing 747-121, N739PA
at Lockerbie, Dumfriesshire, Scotland
on 21December 1988

Contents

Operator: Pan American World Airways
Aircraft Type: Boeing 747-121
Nationality: United States of America
Registration: N 739 PA
Place of Accident Lockerbie, Dumfries, Scotland
Latitude 55¡ 07' N
Longitude 003¡ 21' W
Date and Time (UTC): 21 December 1988 at 19.02:50 hrs
All times in this report are UTC

SYNOPSIS

The accident was notified to the Air Accidents Investigation Branch at 19.40 hrs on the 21 December 1988 and the investigation commenced that day. The members of the AAIB team are listed at Appendix A.

The aircraft, Flight PA103 from London Heathrow to New York, had been in level cruising flight at flight level 310 (31,000 feet) for approximately seven minutes when the last secondary radar return was received just before 19.03 hrs. The radar then showed multiple primary returns fanning out downwind. Major portions of the wreckage of the aircraft fell on the town of Lockerbie with other large parts landing in the countryside to the east of the town. Lighter debris from the aircraft was strewn along two trails, the longest of which extended some 130 kilometres to the east coast of England. Within a few days items of wreckage were retrieved upon which forensic scientists found conclusive evidence of a detonating high explosive. The airport security and criminal aspects of the accident are the subject of a separate investigation and are not covered in this report which concentrates on the technical aspects of the disintegration of the aircraft.

The report concludes that the detonation of an improvised explosive device led directly to the destruction of the aircraft with the loss of all 259 persons on board and 11 of the residents of the town of Lockerbie. Five recommendations are made of which four concern flight recorders, including the funding of a

study to devise methods of recording violent positive and negative pressure pulses associated with explosions. The final recommendation is that Airworthiness Authorities and aircraft manufacturers undertake a systematic study with a view to identifying measures that might mitigate the effects of explosive devices and improve the tolerance of the aircraft's structure and systems to explosive damage.

1. FACTUAL INFORMATION

1.1 History of the Flight

Boeing 747, N739PA, arrived at London Heathrow Airport from San Francisco and parked on stand Kilo 14, to the south-east of Terminal 3. Many of the passengers for this aircraft had arrived at Heathrow from Frankfurt, West Germany on a Boeing 727, which was positioned on stand Kilo 16, next to N739PA. These passengers were transferred with their baggage to N739PA which was to operate the scheduled Flight PA103 to New York Kennedy. Passengers from other flights also joined Flight PA103 at Heathrow. After a 6 hour turnround, Flight PA103 was pushed back from the stand at 18.04 hrs and was cleared to taxy on the inner taxiway to runway 27R. The only relevant Notam warned of work in progress on the outer taxiway. The departure was unremarkable.

Flight PA103 took-off at 18.25 hrs. As it was approaching the Burnham VOR it took up a radar heading of 350¡ and flew below the Bovingdon holding point at 6000 feet. It was then cleared to climb initially to flight level (FL) 120 and subsequently to FL 310. The aircraft levelled off at FL 310 north west of Pole Hill VOR at 18.56 hrs. Approximately 7 minutes later, Shanwick Oceanic Control transmitted the aircraft's oceanic clearance but this transmission was not acknowledged. The secondary radar return from Flight PA103 disappeared from the radar screen during this transmission. Multiple primary radar returns were then seen fanning out downwind for a considerable distance. Debris from the aircraft was strewn along two trails, one of which extended some 130 km to the east coast of England. The upper winds were between 250¡ and 260¡ and decreased in strength from 115 kt at FL 320 to 60 kt at FL 100 and 15 to 20 kt at the surface.

Two major portions of the wreckage of the aircraft fell on the town of Lockerbie; other large parts, including the flight deck and forward fuselage section, landed in the countryside to the east of the town. Residents of Lockerbie reported that, shortly after 19.00 hrs, there was a rumbling noise like thunder which rapidly increased to deafening proportions like the roar of a jet engine under power. The noise appeared to come from a meteor-like object which was trailing flame and came down in the north-eastern part of the town. A larger, dark, delta shaped object, resembling an aircraft wing, landed at about the same time in the Sherwood area of the town. The delta shaped object was not on fire while in the air, however, a very large fireball ensued which was of short duration and carried large amounts of debris into the air, the lighter particles being deposited several miles downwind. Other less well defined objects were seen to land in the area.

1.2 Injuries to persons

Injuries	Crew	Passengers	Others
Fatal	16	243	11
Serious	-	-	2
Minor/None	-	-	3

1.3 Damage to aircraft

The aircraft was destroyed

1.4 Other damage

The wings impacted at the southern edge of Lockerbie, producing a crater whose volume, calculated from a photogrammetric survey, was approximately 560 cubic metres. The weight of material displaced by the wing impact was estimated to be well in excess of 1500 tonnes. The wing impact created a fireball, setting fire to neighbouring houses and carrying aloft debris which was then blown downwind for several miles. It was subsequently established that domestic properties had been so seriously damaged as a result of fire and/or impact that 21 had to be demolished and an even greater number of homes required substantial repairs. Major portions of the aircraft, including the engines, also landed on the town of Lockerbie and other large parts, including the flight deck and forward fuselage section, landed in the countryside to the east of the town. Lighter debris from the aircraft was strewn as far as the east coast of England over a distance of 130 kilometres.

1.5 Personnel information

1.5.1 Commander: Male, aged 55 years
Licence: USA Airline Transport Pilot's Licence
Aircraft ratings: Boeing 747, Boeing 707, Boeing 720, Lockheed L1011 and

Douglas DC3
Medical Certificate: Class 1,valid to April 1989, with the limitation that the holder shall wear lenses that correct for distant vision and possess glasses that correct for near vision

Flying experience:
Total all types: 10,910 hours
Total on type: 4,107 hours
Total last 28 days 82 hours
Duty time: Commensurate with company requirements
Last base check: 11 November 1988
Last route check: 30 June 1988
Last emergencies check: 8 November 1988

1.5.2 Co-pilot: Male, aged 52 years
Licence: USA Airline Transport Pilot's Licence
Aircraft ratings: Boeing 747, Boeing 707, Boeing 727
Medical Certificate: Class 1, valid to April 1989, with the limitation that the holder shall possess correcting glasses for near vision
Flying experience:
Total all types: 11,855 hours
Total on type: 5,517 hours
Total last 28 days: 51 hours
Duty time: Commensurate with company requirements
Last base check: 30 November 1988
Last route check: Not required
Last emergencies check: 27 November 1988

1.5.3 Flight Engineer: Male, aged 46 years
Licence: USA Flight Engineer's Licence
Aircraft ratings: Turbojet
Medical certificate: Class 2, valid to June 1989, with the limitation that the holder shall wear correcting glasses for near vision
Flying experience:
Total all types: 8,068 hours
Total on type: 487 hours

Total last 28 days: 53 hours
Duty time: Commensurate with company requirements
Last base check: 30 October 1988
Last route check: Not required
Last emergencies check: 27 October 1988

1.5.4 Flight Attendants: There were 13 Flight Attendants on the aircraft, all of whom met company proficiency and medical requirements

1.6 Aircraft information

1.6.1 Leading particulars

Aircraft type: Boeing 747-121
Constructor's serial number: 19646
Engines: 4 Pratt and Whitney JT9D-7A turbofan

1.6.2 General description

The Boeing 747 aircraft, registration N739PA, was a conventionally designed long range transport aeroplane. A diagram showing the general arrangement is shown at Appendix B, Figure B-1 together with the principal dimensions of the aircraft.

The fuselage of the aircraft type was of approximately circular section over most of its length, with the forward fuselage having a diameter of 21† feet where the cross-section was constant. The pressurised section of the fuselage (which included the forward and aft cargo holds) had an overall length of 190 feet, extending from the nose to a point just forward of the tailplane. In normal cruising flight the service pressure differential was at the maximum value of 8.9 pounds per square inch. The fuselage was of conventional skin, stringer and frame construction, riveted throughout, generally using countersunk flush riveting for the skin panels. The fuselage frames were spaced at 20 inch intervals and given the same numbers as their stations, defined in terms of the distance in inches from the datum point close to the nose of the aircraft [Appendix B, Figure B-2]. The skin panels were joined using vertical butt joints and horizontal lap joints. The horizontal lap joints used three rows of rivets together with a cold bonded adhesive.

Accommodation within the aircraft was predominately on the main deck, which extended throughout the whole length of the pressurised compartment. A separate upper deck was incorporated in the forward part of the aircraft. This upper deck was reached by means of a spiral staircase from the main deck and incorporated the flight crew compartment together with additional passenger accommodation. The cross-section of the forward fuselage differed considerably from the near circular section of the remainder of the aircraft, incorporating an additional smaller radius arc above the upper deck section joined to the main circular arc of the lower cabin portion by elements of straight fuselage frames and flat skin.

In order to preserve the correct shape of the aircraft under pressurisation loading, the straight portions of the fuselage frames in the region of the upper deck floor and above it were required to be much stiffer than the frame portions lower down in the aircraft. These straight sections were therefore of very much more substantial construction than most of the curved sections of frames lower down and further back in the fuselage. There was considerable variation in the gauge of the fuselage skin at various locations in the forward fuselage of the aircraft.

The fuselage structure of N739PA differed from that of the majority of Boeing 747 aircraft in that it had been modified to carry special purpose freight containers on the main deck, in place of seats. This was known as the Civil Reserve Air Fleet (CRAF) modification and enabled the aircraft to be quickly converted for carriage of military freight containers on the main deck during times of national emergency. The effect of this modification on the structure of the fuselage was mainly to replace the existing main deck floor beams with beams of more substantial cross-section than those generally found in passenger carrying Boeing 747 aircraft. A large side loading door, generally known as the CRAF door, was also incorporated on the left side of the main deck aft of the wing.

Below the main deck, in common with other Boeing 747 aircraft, were a number of additional compartments, the largest of which were the forward and aft freight holds used for the storage of cargo and baggage in standard air-transportable containers. These containers were placed within the aircraft hold by means of a freight handling system and were carried on a system of rails approximately 2 feet above the outer skin at the bottom of the aircraft, there being no continuous floor, as such, below these baggage containers. The forward freight compartment had a length of approximately 40 feet and a depth of approximately 6 feet. The containers were loaded into the forward hold through a large cargo door on the right side of the aircraft.

1.6.3 Internal fuselage cavities

Because of the conventional skin, frame and stringer type of construction, common to all large public transport aircraft, the fuselage was effectively divided into a series of 'bays'. Each bay, comprising two adjacent fuselage frames and the structure between them, provided, in effect, a series of interlinking cavities bounded by the frames, floor beams, fuselage skins and cabin floor panels etc. The principal cavities thus formed were:

(i) A semi-circular cavity formed in between the fuselage frames in the lower lobe of the hull, i.e. from the crease beam (at cabin floor level) on one side down to the belly beneath the containers and up to the opposite crease beam, bounded by the fuselage skin on the outside and the containers/cargo liner on the inside [Appendix B, Figure B-3, detail A].
(ii) A horizontal cavity between the main cabin floor beams, the cabin floor panels and the cargo bay liner. This extended the full width of the fuselage and linked the upper ends of the lower lobe cavity [Appendix B, Figure B-3, detail B].
(iii) A narrow vertical cavity between the two containers [Appendix B, Figure B-3, detail C].
(iv) A further narrow cavity around the outside of the two containers, between the container skins and the cargo bay liner, communicating with the lower lobe cavity [Appendix B, Figure B-3, detail D].
(v) A continuation of the semi-circular cavity into the space behind the cabin wall liner [Appendix B, Figure B-3, detail E]. This space was restricted somewhat by the presence of the window assembly, but nevertheless provided a continuous cavity extending upwards to the level of the upper deck floor. Forward of station 740, this cavity was effectively terminated at its upper end by the presence of diaphragms which formed extensions of the upper deck floor panels; aft of station 740, the cavity communicated with the ceiling space and the cavity in the fuselage crown aft of the upper deck.

All of these cavities were repeated at each fuselage bay (formed between pairs of fuselage frames), and all of the cavities in a given bay were linked together, principally at the crease beam area [Appendix B, Figure B-3, region F]. Furthermore, each of the set of bay cavities was linked with the next by the longitudinal cavities formed between the cargo hold liner and the outer hull, just below the crease beam [Appendix B, Figure B-3, detail F]; i.e. this cavity formed a manifold linking together each of the bays within the cargo hold.

The main passenger cabin formed a large chamber which communicated directly with each of the sub floor bays, and also with the longitudinal manifold cavity, via the air conditioning and cabin/cargo bay de-pressurisation vent passages in the crease beam area. (It should be noted that a similar communication did not exist between the upper and lower cabins because there were no air conditioning/depressurisation passages to bypass the upper deck floor.)

1.6.4 Aircraft weight and centre of gravity

The aircraft was loaded within its permitted centre of gravity limits as follows:

Loading:	lb	kg
Operating empty weight	366,228	166,120
Additional crew	130	59
243 passengers (1)	40,324	18,291
Load in compartments:		
1	11,616	5,269
2	20,039	9,090
3	15,057	6,830
4	17,196	7,800
5	2,544	1,154
Total in compartments (2)	66,452	30,143
Total traffic load	106,776	48,434
Zero fuel weight	472,156	214,554
Fuel (Take-off)	239,997	108,862
Actual take-off weight(4)	713,002	323,416
Maximum take-off weight	733,992	332,937

Note 1:
Calculated at standard weights and including cabin baggage.

Note 2:
Despatch information stated that the cargo did not include dangerous goods, perishable cargo, live animals or known security exceptions.

1.6.5 Maintenance details

N739PA first flew in 1970 and spent its whole service life in the hands of Pan American World Airways Incorporated. Its Certificate of Airworthiness was issued on 12 February 1970 and remained in force until the time of the accident, at which time the aircraft had completed a total of 72,464 hours flying and 16,497 flight cycles. Details of the last 4 maintenance checks carried out during the aircraft's life are shown below:

DATE	SERVICE	HOURS	CYCLES
27 Sept 88	C Check (Interior upgrade)	71,502	16,347
2 Nov 88	B Service Check	71,919	16,406
27 Nov 88	Base 1	72,210	16,454
13 Dec 88	Base 2	72,374	16,481

The CRAF modification programme was undertaken in September 1987. At the same time a series of modifications to the forward fuselage from the nose back to station 520 (Section 41) were carried out to enable the aircraft to continue in service without a continuing requirement for structural inspections in certain areas.

All Airworthiness Directives relating to the Boeing 747 fuselage structure between stations 500 and 1000 have been reviewed and their applicability to this aircraft checked. In addition, Service Bulletins relating to the structure in this area were also reviewed. The applicable Service Bulletins, some of which implement the Airworthiness Directives are listed below together with their subjects. The dates, total aircraft times and total aircraft cycles at which each relevant inspection was last carried out have been reviewed and their status on aircraft N739PA at the time of the accident has been established.

N739PA Service Bulletin compliance:

SB 53-2064 Front Spar Pressure Bulkhead Chord Reinforcement and Drag Splice Fitting Rework.
Modification accomplished on 6 July 1974.
Post-modification repetitive inspection IAW (in accordance with) AD 84-18-06 last accomplished on 19 November 1985 at 62,030 TAT hours (Total Aircraft Time) and 14,768 TAC (Total Aircraft Cycles).
SB 53-2088 Frame to Tension Tie Joint Modification - BS760 to 780.
Repetitive inspection IAW AD 84-19-01 last accomplished on 19 June 1985 at 60,153 hours TAT and 14,436 TAC.
SB 53-2200 Lower Cargo Doorway Lower Sill Truss and Latch Support Fitting Inspection Repair and Replacement.
Repetitive inspection IAW AD 79-17-02 R2 last accomplished 2 November

1988 at 71,919 hours TAT and 16,406 TAC.
SB 53-2234 Fuselage - Auxiliary Structure - Main Deck Floor - BS 480 Floor Beam Upper Chord Modification.
Repetitive inspection per SB 53A2263 IAW AD 86-23-06 last accomplished on 26 September 1987 at 67,376 hours TAT and 15,680 TAC.
SB 53-2237 Fuselage - Main Frame - BS 540 thru 760 and 1820 thru 1900 Frame Inspection and Reinforcement.
Repetitive inspection IAW AD 86-18-01 last accomplished on 27 February 1987 at 67,088 hours TAT and 15,627 TAC.
SB 53-2267 Fuselage - Skin - Lower Body Longitudinal Skin Lap Joint and Adjacent Body Frame Inspection and Repair.
Terminating modification accomplished 100% under wing-to-body fairings and approximately 80% in forward and aft fuselage sections on 26 September 1987 at 67,376 hours TAT and 15,680 TAC.
Repetitive inspection of unmodified lap joints IAW AD 86-09-07 R1 last accomplished on 18 August 1988 at 71,043 hours TAT and 16,273 TAC.
SB 53A2303 Fuselage - Nose Section - station 400 to 520 Stringer 6 Skin Lap Splice Inspection, Repair and Modification.
Repetitive inspection IAW AD 89-05-03 last accomplished on 26 September 1987 at 67,376 hours TAT and 15,680 TAC.

This documentation, when viewed together with the detailed content of the above service bulletins, shows the aircraft to have been in compliance with the requirements laid down in each of those bulletins. Some maintenance items were outstanding at the time the aircraft was despatched on the last flight, however, none of these items relate to the structure of the aircraft and none had any relevance to the accident.

1.7 Meteorological Information

1.7.1 General weather conditions

An aftercast of the general weather conditions in the area of Lockerbie at about 19.00 hrs was obtained from the Meteorological Office, Bracknell. The synoptic situation included a warm sector covering northern England and most of Scotland with a cold front some 200 nautical miles to the west of the area moving eastwards at about 35 knots. The weather consisted of intermittent rain or showers. The cloud consisted of 4 to 6 oktas of stratocumulus based at 2,200 feet with 2 oktas of altocumulus between 15,000 and 18,000 feet. Visibility was over 15 kilometers and the freezing level was at

8,500 feet with a sub-zero layer between 4,000 and 5,200 feet.

1.7.2 Winds

There was a weakening jet stream of around 115 knots above Flight Level 310. From examination of the wind profile (see below), there appeared to be insufficient shear both vertically and horizontally to produce any clear air turbulence but there may have been some light turbulence.

Flight Level	Wind
320	260¡/115 knots
300	260¡/ 90 knots
240	250¡/ 80 knots
180	260¡/ 60 knots
100	250¡/ 60 knots
050	260¡/ 40 knots
Surface	240¡/ 15 to 20 gusting 25 to 30 knots

1.8 Aids to navigation

Not relevant.

1.9 Communications

The aircraft communicated normally on London Heathrow aerodrome, London control and Scottish control frequencies. Tape recordings and transcripts of all radio telephone (RTF) communications on these frequencies were available.

At 18.58 hrs the aircraft established two-way radio contact with Shanwick Oceanic Area Control on frequency 123.95 MHz. At 19.02:44 hrs the clearance delivery officer at Shanwick transmitted to the aircraft its oceanic route clearance. The aircraft did not acknowledge this message and made no subsequent transmission.

1.9.1 ATC recording replay

Scottish Air Traffic Control provided copy tapes with time injection for both Shanwick and Scottish ATC frequencies. The source of the time injection on the tapes was derived from the British Telecom "TIM" signal.

The tapes were replayed and the time signals corrected for errors at the time of the tape mounting.

1.9.2 Analysis of ATC tape recordings

From the cockpit voice recorder (CVR) tape it was known that Shanwick was transmitting Flight PA103's transatlantic clearance when the CVR stopped. By synchronising the Shanwick tape and the CVR it was possible to establish that a loud sound was heard on the CVR cockpit area microphone (CAM) channel at 19.02:50 hrs ±1 second.

As the Shanwick controller continued to transmit Flight PA103's clearance instructions through the initial destruction of the aircraft it would not have been possible for a distress call to be received from N739PA on the Shanwick frequency. The Scottish frequency tape recording was listened to from 19.02 hrs until 19.05 hrs for any unexplained sounds indicating an attempt at a distress call but none was heard.

A detailed examination and analysis of the ATC recording together with the flight recorder, radar, and seismic recordings is contained in Appendix C.

1.10 Aerodrome information

Not relevant

1.11 Flight recorders

The Digital Flight Data Recorder (DFDR) and the Cockpit Voice Recorder (CVR) were found close together at UK Ordnance Survey (OS) Grid Reference 146819, just to the east of Lockerbie, and recovered approximately 15 hours after the accident. Both recorders were taken directly to AAIB Farnborough for replay. Details of the examination and analysis of the flight recorders together with the radar, ATC and seismic recordings are contained in Appendix C.

1.11.1 Digital flight data recorder

The flight data recorder installation conformed to ARINC 573B standard with a Lockheed Model 209 DFDR receiving data from a Teledyne Controls Flight Data Acquisition Unit (FDAU). The system recorded 22 parameters and 27 discrete (event) parameters. The flight recorder control panel was located in the flight deck overhead panel. The FDAU was in the main equipment centre at the front end of the forward hold and the flight recorder was mounted in the aft equipment centre.

Decoding and reduction of the data from the accident flight showed that no abnormal behaviour of the data sensors had been recorded and that the recorder had simply stopped at 19.02:50 hrs ±1 second.

1.11.2 Cockpit voice recorder

The aircraft was equipped with a 30 minute duration 4 track Fairchild Model A100 CVR, and a Fairchild model A152 cockpit area microphone (CAM). The CVR control panel containing the CAM was located in the overhead panel on the flight deck and the recorder itself was mounted in the aft equipment centre.

The channel allocation was as follows:-

Channel 1 Flight Engineer's RTF.
Channel 2 Co-Pilot's RTF.
Channel 3 Pilot's RTF.
Channel 4 Cockpit Area Microphone.

The erase facility within the CVR was not functioning satisfactorily and low level communications from earlier recordings were audible on the RTF channels. The CAM channel was particularly noisy, probably due to the combination of the inherently noisy flight deck of the B747-100 in the climb and distortion from the incomplete erasure of the previous recordings. On two occasions the crew had difficulty understanding ATC, possibly indicating high flight deck noise levels. There was a low frequency sound present at irregular intervals on the CAM track but the source of this sound could not be identified and could have been of either acoustic or electrical origin.

The CVR tape was listened to for its full duration and there was no indication of anything abnormal with the aircraft, or unusual crew behaviour. The tape record ended, at 19.02:50 hrs ±1 second, with a sudden loud sound on the CAM channel followed almost immediately by the cessation of recording whilst the crew were copying their transatlantic clearance from Shanwick ATC.

1.12 Wreckage and impact information

1.12.1 General distribution of wreckage in the field

The complete wing primary structure, incorporating the centre section, impacted at the southern edge of Lockerbie. Major portions of the aircraft, including the engines, also landed in the town. Large portions of the aircraft fell in the countryside to the east of the town and lighter debris was strewn to the east as far as the North Sea. The wreckage was distributed in two trails which became known as the northern and southern trails respectively and these are shown in Appendix B, Figure B-4. A computer database of approximately 1200 significant items of wreckage was compiled and included a brief description of each item and the location where it was found

Appendix B, Figures B-5 to B-8 shows photographs of a model of the aircraft on which the fracture lines forming the boundaries of the separate items of structure have been marked. The model is colour coded to illustrate the way in which the wreckage was distributed between the town of Lockerbie and the northern and southern trails.

1.12.1.1 The crater

The aircraft wing impacted in the Sherwood Crescent area of the town leaving a crater approximately 47 metres (155 feet) long with a volume calculated to be 560 cubic metres.

The projected distance, measured parallel from one leading edge to the other wing tip, of the Boeing 747-100 was approximately 143 feet, whereas the span is known to be 196 feet. This suggests that impact took place with the wing structure yawed. Although the depth of the crater varied from one end to the other, its widest part was clearly towards the western end suggesting that the wing structure impacted whilst orientated with its root and centre section to the west.

The work carried out at the main crater was limited to assessing the general nature of its contents. The total absence of debris from the wing primary structure found remote from the crater confirmed the initial impression that the complete wing box structure had been present at the main impact.

The items of wreckage recovered from or near the crater are coloured grey on the model at Appendix B, Figures B-5 to B-8.

1.12.1.2 The Rosebank Crescent site

A 60 feet long section of fuselage between frame 1241 (the rear spar attachment) and frame 1960 (level with the rear edge of the CRAF cargo door) fell into a housing estate at Rosebank Crescent, just over 600 metres from the crater. This section of the fuselage was that situated immediately aft of the wing, and adjoined the wing and fuselage remains which produced the crater. It is colour coded yellow on the model at Appendix B, Figures B-5 to B-8. All fuselage skin structure above floor level was missing except for the following items:

Section containing 3 windows between door 4L and CRAF door;
The CRAF door itself (latched) apart from the top area containing the hinge;
Window belt containing 8 windows aft of 4R door aperture
Window belt containing 3 windows forward of 4R door aperture;
Door 4R.

Other items found in the wreckage included both body landing gears, the right wing landing gear, the left and right landing gear support beams and the cargo door (frames 1800-1920) which was latched. A number of pallets, luggage containers and their contents were also recovered from this site.

1.12.1.3 Forward fuselage and flight deck section.

The complete fuselage forward of approximately station 480 (left side) to station 380 (right side) and incorporating the flight deck and nose landing gear was found as a single piece [Appendix B, Figure B-9] in a field approximately 4 km miles east of Lockerbie at OS Grid Reference 174808. It was evident from the nature of the impact damage and the ground marks that it had fallen almost flat on its left side but with a slight nose-down attitude and with no discernible horizontal velocity. The impact had caused almost complete crushing of the structure on the left side. The radome and right nose landing gear door had detached in the air and were recovered in the southern trail.

Examination of the torn edges of the fuselage skin did not indicate the presence of any pre-existing structural or material defects which could have accounted for the separation of this section of the fuselage. Equally so, there were no signs of explosive blast damage or sooting evident on any part of the structure or the interior fittings. It was noted however that a heavy, semi-eliptical scuff mark was present on the lower right side of the fuselage at approximately station 360. This was later matched to the intake profile of the No 3 engine.

The status of the controls and switches on the flight deck was consistent with normal operation in cruising flight. There were no indications that the crew had attempted to react to rapid decompression or loss of control or that any emergency preparations had been actioned prior to the catastrophic disintegration.

1.12.1.4 Northern trail

The northern trail was seen to be narrow and clearly defined, to emanate from a point very close to the main impact crater and to be orientated in a direction which agreed closely with the mean wind aftercast for the height band from sea level to 20,000 ft. Also at the western end of the northern trail were the lower rear fuselage at Rosebank Crescent, and the group of Nos. 1, 2 and 4 engines which fell in Lockerbie.

The trail contained items of structure distributed throughout its length, from the area slightly east of the crater, to a point approximately 16 km east, beyond which only items of low weight / high drag such as insulation, interior trim, paper etc, were found. For all practical purposes this trail ended at a range of 25 km.

The northern trail contained mainly wreckage from the rear fuselage, fin and the inner regions of both tailplanes together with structure and skin from the upper half of the fuselage forward to approximately the wing mid-chord position. A number of items from the wing were also found in the northern trail, including all 3 starboard Kreuger flaps, most of the remains of the port Kreuger flaps together with sections of their leading edge attachment structures, one portion of outboard aileron approximately 10 feet long, the aft ends of the flap-track fairings (one with a slide raft wrapped around it), and fragments of glass reinforced plastic honeycombe structure believed to be from the flap system, i.e. fore-flaps, aft-flaps, mid-flaps or adjacent fairings. In addition, a number of pieces of the engine cowlings and both HF antennae (situated projecting aft from the wing-tips) were found in this trail.

All items recovered from the northern trail, with the exception of the wing, engines, and lower rear fuselage in Rosebank Crescent, are coloured red on the model of the aircraft in Appendix B, Figures B-5 to B-8.

1.12.1.5 Southern trail

The southern trail was easily defined, except within 12 km of Lockerbie where it tended to merge with the northern trail. Further east, it extended across southern Scotland and northern England, essentially in a straight band as far as the North Sea. Most of the significant items of wreckage were found in this trail within a range of 30 km from the main impact crater. Items recovered from the southern trail are coloured green on the model of the aircraft at Appendix B, Figures B-5 to B-8.

The trail contained numerous large items from the forward fuselage. The flight deck and nose of the aircraft fell in the curved part of this trail close to Lockerbie. Fragments of the whole of the left tailplane and the outboard portion of the right tailplane were distributed almost entirely throughout the southern trail. Between 21 and 27 km east of the main impact point (either side of Langholm) substantial sections of tailplane skin were found, some bearing distinctive signs of contact with debris moving outwards and backwards relative to the fuselage. Also found in this area were numerous isolated sections of fuselage frame, clearly originating from the crown region above the forward upper deck.

1.12.1.6 Datum line

All grid references relating to items bearing actual explosive evidence, together with those attached to heavily distorted items found to originate immediately adjacent to them on the structure, were plotted on an Ordnance Survey (OS) chart. These references, 11 in total, were all found to be distributed evenly about a mean line orientated 079¡(Grid) within the southern trail and were spread over a distance of 12 km. The distance of each reference from the line was measured in a direction parallel to the aircraft's track and all were found to be within 500 metres of the line, with 50% of them being within 250 metres of the line. This line is referred to as the datum line and is shown in Appendix B, Figure B-4.

1.12.1.7 Distribution of wreckage within the southern trail

North of the datum line and parallel to it were drawn a series of lines at distances of 250, 300, 600 and 900 metres respectively from the line, again measured in a direction parallel to the aircraft's track. The positions on the aircraft structure of specific items of wreckage, for which grid references were known with a high degree of confidence, within the bands formed between these lines, are shown in Appendix B, Figures B-10 to 13. In addition, a separate assessment of the grid references of tailplane and elevator wreckage established that these items were distributed evenly about the 600 metre line.

1.12.1.8 Area between trails

Immediately east of the crater, the southern trail converged with the northern trail such that, to an easterly distance of approximately 5 km, considerable wreckage existed which could have formed part of either trail. Further east, between 6 and 11 km from the crater, a small number of sections and fragments of the fin had fallen outside the southern boundary of the northern trail. Beyond this a large area existed between the trails in which there was no wreckage.

1.12.2 Examination of wreckage at CAD Longtown

The debris from all areas was recovered by the Royal Air Force to the Army Central Ammunition Depot Longtown, about 20 miles from Lockerbie. Approximately 90% of the hull wreckage was successfully recovered, identified, and laid out on the floor in a two-dimensional reconstruction [Appendix B, Figure B-14]. Baggage container material was incorporated into a full three-dimensional reconstruction. Items of wreckage added to the reconstructions was given a reference number and recorded on a computer database together with a brief description of the item and the location where it was found.

1.12.2.1 Fuselage

The reconstruction revealed the presence of damage consistent with an explosion on the lower fuselage left side in the forward cargo bay area. A small region of structure bounded approximately by frames 700 & 720 and stringers 38L & 40L, had clearly been shattered and blasted through by material exhausting directly from an explosion centred immediately inboard of this location. The material from this area, hereafter referred to as the 'shatter zone', was mostly reduced to very small fragments, only a few of which were recovered, including a strip of two skins [Appendix B, Figure B-15] forming part of the lap joint at the stringer 39L position.

Surrounding the shatter zone were a series of much larger panels of torn fuselage skin which formed a 'star-burst' fracture pattern around the shatter zone. Where these panels formed the boundary of the shatter zone, the metal in the immediate locality was ragged, heavily distorted, and the inner surfaces were pitted and sooted - rather as if a very large shotgun had been fired at the inner surface of the fuselage at close range. In contrast, the star-burst fractures, outside the boundary of the shatter zone, displayed evidence of more typical overload tearing, though some tears appeared to be rapid and, in the area below the missing panels, were multi-branched. These surrounding skin panels were moderately sooted in the regions adjacent to the shatter zone, but otherwise were lightly sooted or free of soot altogether. (Forensic analysis of the soot deposits on frame and skin material from this area confirmed the presence of explosive residues.) All of these skin panels had pulled away from the supporting structure and had been bent and torn in a manner which indicated that, as well as fracturing in the star burst pattern, they had also petalled outwards producing characteristic, tight curling of the sheet material.

Sections of frames 700 and 720 from the area of the explosion were also recovered and identified. Attached to frame 720 were the remnants of a section of the aluminium baggage container (side) guide rail, which was heavily distorted and displayed deep pitting together with very heavy sooting, indicating that it had been very close to the explosive charge. The pattern of distortion and damage on the frames and guide rail segment matched the overall pattern of damage observed on the skins.

The remainder of the structure forming the cargo deck and lower hull was, generally, more randomly distorted and did not display the clear indications of explosive processes which were evident on the skin panels and frames nearer the focus of the explosion. Nevertheless, the overall pattern of damage was consistent with the propagation of explosive pressure fronts away from the focal area inboard of the shatter zone. This was particularly evident in the fracture and bending characteristics of several of the fuselage frames ahead of, and behind station 700.

The whole of the two-dimensional fuselage reconstruction was examined for general evidence of the mode of disintegration and for signs of localised damage, including overpressure damage and pre-existing damage such as corrosion or fatigue. There was some evidence of corrosion and dis-bonding at the cold-bond lap joints in the fuselage. However, the corrosion was relatively light and would not have compromised significantly the static strength of the airframe. Certainly, there was no evidence to suggest that corrosion had affected the mode of disintegration, either in the area of the explosion or at areas more remote. Similarly, there were no indications of fatigue damage except for one very small region of fatigue, involving a single crack less than 3 inches long, which was remote from the bomb location. This crack was not in a critical area and had not coincided with a fracture path.

No evidence of overpressure fracture or distortion was found at the rear pressure bulkhead. Some suggestion of 'quilting' or 'pillowing' of skin panels between stringers and frames, indicative of localised overpressure, was evident on the skin panels attached to the larger segments of lower fuselage wreckage aft of the blast area. In addition, the mode of failure of the butt joint at station

520 suggested that there had been a rapid overpressure load in this area, causing the fastener heads to 'pop' in the region of stringers 13L to 16L, rather than producing shear in the fasteners. Further evidence of localised overpressure damage remote from the source of the explosion was found during the full three-dimensional reconstruction, detailed later in paragraph 1.12.3.2.

An attempt was made to analyse the fractures, to determine the direction and sequence of failure as the fractures propagated away from the region of the explosion. It was found that the directions of most of the fractures close to the explosion could be determined from an analysis of the fracture surfaces and other features, such as rivet and rivet hole distortions. However, it was apparent that beyond the boundary of the petalled region, the disintegration process had involved multiple fractures taking place simultaneously - extremely complex parallel processes which made the sequencing of events not amenable to conventional analysis.

1.12.2.2 Wing structure and adjacent fuselage area

On completion of the initial layout at Longtown it became evident that, in the area from station 1000 to approximately station 1240 the only identifiable fuselage structure consisted of elements of fuselage skin, stringers and frames from above the cabin window belts. The wreckage from in and around the crater was therefore sifted to establish more accurately what sections of the aircraft had produced the crater. All of the material was highly fragmented, but it was confirmed that the material comprised mostly wing structure, with a few fragments of fuselage sidewall and passenger seats. The badly burnt state of these fragments made it clear that they were recovered from the area of the main impact crater, the only scene of significant ground fire. Amongst these items a number of cabin window forgings were recovered with sections of thick horizontal panelling attached having a length equivalent to the normal window spacing/frame pitch. This arrangement, with skins of this thickness, is unique to the area from station 1100 to 1260. It is therefore reasonable to assume that these fragments formed parts of the missing cabin sides from station 1000 to station 1260, which must have remained attached to the wing centre section at the time of its impact. Because of the high degree of fragmentation and the relative insignificance of the wing in terms of the overall explosive damage pattern, a reconstruction of the wing material was not undertaken. The sections of the aircraft which went into the crater are colour coded grey in Appendix B, Figures B-5 to B-8.

1.12.2.3 Fin and aft section of fuselage

Examination of the structure of the fin revealed evidence of in-flight damage to the leading edge caused by the impact of structure or cabin contents. This damage was not severe or extensive and the general break-up of the fin did not suggest either a single readily defined loading direction, or break-up due to the effects of leading edge impact. A few items of fin debris were found between the northern and southern trails.

A number of sections of fuselage frame found in the northern trail exhibited evidence of plastic deformation of skin attachment cleats and tensile overload failure of the attachment rivets. This damage was consistent with that which would occur if the skin had been locally subjected to a high loading in a direction normal to its plane. Although this was suggestive of an internal overpressure condition, the rear fuselage revealed no other evidence to support this possibility. Examination of areas of the forward fuselage known to have been subjected to high blast overpressures revealed no comparable evidence of plastic deformation in the skin attachment cleats or rivets, most skin attachment failures appearing to have been rapid.

Calculations made on the effects of internal pressure generated by an open ended fuselage descending at the highest speed likely to have been experienced revealed that this could not generate an internal pressure approaching that necessary to cause failure in an intact cabin structure.

1.12.2.4 Baggage containers

During the wreckage recovery operation it became apparent that some items, identified as parts of baggage containers, exhibited damage consistent with being close to a detonating high explosive. It was therefore decided to segregate identifiable container parts and reconstruct any that showed evidence of explosive damage. It was evident, from the main wreckage layout, that the explosion had occurred in the forward cargo hold and, although all baggage container wreckage was examined, only items from this area which showed the relevant characteristics were considered for the reconstruction. Discrimination between forward and rear cargo hold containers was relatively straightforward as the rear cargo hold wreckage was almost entirely confined to Lockerbie, whilst that from the forward hold was scattered along the southern wreckage trail.

All immediately identifiable parts of the forward cargo containers were segregated into areas designated by their serial numbers and items not identified at that stage were collected into piles of similar parts for later assessment. As a result of this, two adjacent containers, one of metal construction the other fibreglass, were identified as exhibiting damage likely to have been caused by the explosion. Those parts which could be positively identified as being from these two containers were assembled onto one of three simple wooden frameworks, one each for the floor and superstructure of the metal container and one for the superstructure of the fibreglass container. From this it was positively determined that the explosion had occurred within the metal container (serial number AVE 4041 PA), the direct effects of this being evident also on the forward face of the adjacent fibreglass container (serial number AVN 7511 PA) and on the local airframe on the left side of the aircraft in the region of station 700. It was therefore confirmed that this metal container had been loaded in position 14L in agreement with the aircraft loading records. While this work was in progress a buckled section of the metal container skin was found by an AAIB Inspector to contain, trapped within its folds, an item which was subsequently identified by forensic scientists at the Royal Armaments Research and Development Establishment (RARDE) as belonging to a specific type of radio-cassette player and that this had been fitted with an improvised explosive device (IED).

The reconstruction of these containers and their relationship to the aircraft structure is described in detail in Appendix F. Examination of all other components of the remaining containers revealed only damage consistent with ejection into the high speed slipstream and/or ground impact, and that only one device had detonated within the containers on board the aircraft.

1.12.3 Fuselage three-dimensional reconstruction

1.12.3.1 The reconstruction

The two-dimensional reconstruction successfully established that there had been an explosion in the forward hold; its location was established and the general damage characteristics in the vicinity of the explosion were determined. However, the mechanisms by which the failure process developed from local damage in the immediate vicinity of the explosion to the complete structural break-up and separation of the whole forward section of the fuselage, could not be adequately investigated without recourse to a more elaborate reconstruction.

To facilitate this additional work, wreckage forming a 65 foot section of the fuselage (approximately 30 feet each side of the explosion) was transported to

AAIB Farnborough, where it was attached to a specially designed framework to form a fully three-dimensional reconstruction [Appendix B, Figures B-16 and B-17] of the complete fuselage between stations 360 & 1000 (from the separated nose section back to the wing cut out). The support framework was designed to provide full and free access to all parts of the structure, both internally and externally. Because of height constraints, the reconstruction was carried out in two parts, with the structure divided along a horizontal line at approximately the upper cabin floor level. The previously reconstructed containers were also transported to AAIB Farnborough to allow correlation of evidence with, and partial incorporation into, the fuselage reconstruction.

Structure and skin panels were attached to the supporting framework by their last point of attachment, to provide a better appreciation of the modes and direction of curling, distortion, and ultimate separation. Thus, the panels of skin which had petalled back from the shatter zone were attached at their outer edges, so as to identify the bending modes of the panels, the extent of the petalled region, and also the size of the resulting aperture in the hull. In areas more remote from the explosion, the fracture and tear directions were used together with distortion and curling directions to determine the mode of separation, and thus the most appropriate point of attachment to the reconstruction. Cabin floor beam segments were supported on a steel mesh grid and a plot of the beam fractures is shown at Appendix B, Figure B-18.

The cargo container base elements were separated from the rest of the container reconstruction and transferred to the main wreckage reconstruction, where the re-assembled container base was positioned precisely onto the cargo deck. To assist in the correlation of the initial shatter zone and petalled-out regions with the position of the explosive device, the boundaries of the skin panel fractures were marked on a transparent plastic panel which was then attached to the reconstruction to provide a transparent pseudo-skin showing the positions of the skin tear lines. This provided a clear visual indication of the relationship between the skin panel fractures and the explosive damage to the container base, thus providing a more accurate indication of the location of the explosive device.

1.12.3.2 Summary of explosive features evident

The three-dimensional reconstruction provided additional information about the region of tearing and petalling around the shatter zone. It also identified a number of other regions of structural damage, remote from the explosion, which were clearly associated with severe and rapidly applied pressure loads acting normal to the skin's internal surface. These were sufficiently sharp-edged to pre-empt the resolution of pressure induced loads into membrane tension stresses in the skin: instead, the effect was as though these areas of skin had been struck a severe 'pressure blow' from within the hull.

The two types of damage, i.e. the direct blast/tearing/petalling damage and the quite separate areas of 'pressure blow' damage at remote sites were evidently caused by separate mechanisms, though it was equally clear that each was caused by explosive processes, rather than more general disintegration.

The region of petalling was bounded (approximately) by frames 680 and 740, and extended from just below the window belt down nearly to the keel of the aircraft [Appendix B, Figure B-19, region A]. The resulting aperture measured approximately 17 feet by 5 feet. Three major fractures had propagated beyond the boundary of the petalled zone, clearly driven by a combination of hull pressurisation loading and the relatively long term (secondary) pressure pulse from the explosion. These fractures ran as follows:

(i) rearwards and downward in a stepped fashion, joining the stringer 38L lap joint at around station 840, running aft along stringer 38L to around station 920, then stepping down to stringer 39L and running aft to terminate at the wing box cut-out [Appendix B, Figure B-19, fracture 1].
(ii) downwards and forward to join the stringer 44L lap joint, then running forward along stringer 44L as far as station 480 [Appendix B, Figure B-19, fracture 2].
(iii) downwards and rearward, joining the butt line at station 740 to run under the fuselage and up the right side to a position approximately 18 inches above the cabin floor level [Appendix B, Figures B-19 and B-20, fracture 3].

The propagation of tears upwards from the shatter zone appeared to have taken the form of a series of parallel fractures running upwards together before turning towards each other and closing, forming large flaps of skin which appear to have separated relatively cleanly.

Regions of skin separation remote from the site of the explosion were evident in a number of areas. These principally were:

(i) A large section of upper fuselage skin extending from station 500 back to station 760, and from around stringers 15/19L up as far as stringer 5L [Appendix B, Figures B-19 and B-20, region B], and probably extending further

up over the crown. This panel had separated initially at its lower forward edge as a result of a pressure blow type of impulse loading, which had popped the heads from the rivets at the butt joint on frame 500 and lifted the skin flap out into the airflow. The remainder of the panel had then torn away rearwards in the airflow.
A region of 'quilting' or 'pillowing', i.e. spherical bulging of skin panels between frames and stringers, was evident on these panels in the region between station 560 and 680, just below the level of the upper deck floor, indicative of high internal pressurisation loading [Appendix B, Figure B-19, region C].
(ii) A smaller section of skin between stations 500 and 580, bounded by stringers 27L and 34L [Appendix B, Figure B-19, region D], had also been 'blown' outwards at its forward edge and torn off the structure rearwards. A characteristic curling of the panel was evident, consistent with rapid, energetic separation from the structure.
(iii) A section of thick belly skin extending from station 560, stringers 40R to 44R, and tapering back to a point at stringer 45R/station720 [Appendix B, Figure B-19 and B-20, region E], had separated from the structure as a result of a very heavy 'pressure blow' load at its forward end which had popped the heads off a large number of substantial skin fasteners. The panel had then torn away rearwards from the structure, curling up tightly onto itself as it did so - indicating that considerable excess energy was involved in the separation process (over and above that needed simply to separate the skin material from its supporting structure).
(iv) A panel of skin on the right side of the aircraft, roughly opposite the explosion, had been torn off the frames, beginning at the top edge of the panel situated just below the window belt and tearing downwards towards the belly [Appendix B, Figure B-20, region F]. This panel was curled downwards in a manner which suggested significant excess energy.

Appendix B, Figure B-21 shows a plot of the fractures noted in the fuselage skins between stations 360 and 1000.

The cabin floor structure was badly disrupted, particularly in the general area above the explosion, where the floor beams had suffered localised upward loading sufficient to fracture them, and the floor panels were missing. Elsewhere, floor beam damage was mainly limited to fractures at the outer ends of the beams and at the centreline, leaving sections of separated floor structure comprising a number of half beams joined together by the Nomex honeycomb floor panels.

1.12.3.3 General damage features not directly associated with explosive forces.

A number of features appeared to be a part of the general structural break-up which followed on from the explosive damage, rather than being a part of the explosive damage process itself. This general break-up was complex and, to a certain extent, random. However, analysis of the fractures, surface scores, paint smears and other features enabled a number of discreet elements of the break-up process to be identified. These elements are summarised below.

(i) Buckling of the window belts on both sides of the aircraft was evident between stations 660 and 800. That on the left side appeared to be the result of in-plane bending in a nose up sense, followed by fracture. The belt on the right side had a large radius curve suggesting lateral deflection of the fuselage possibly accompanied by some longitudinal compression. This terminated in a peeling failure of the riveted joint at station 800.
(ii) On the left side three fractures, apparently resulting from in-plane bending/buckling distortion, had traversed the window belt [Appendix B, Figure B-21, detail G]. Of these, the forward two had broken through the window apertures and the aft fracture had exploited a rivet line at the region of reinforcement just forward of the L2 door aperture. On the right side, the window belt had peeled rearwards, after buckling had occurred, separating from the rest of the fuselage, following rivet failure, at the forward edge of the R2 door aperture.
(iii) All crown skins forward of frame 840 were badly distorted and a number of pieces were missing. It was clearly evident that the skin sections from this region had struck the empennage and/or other structure following separation.
(iv) The fuselage left side lower lobe from station 740 back to the wing box cut-out, and from the window level down to the cargo deck floor (the fracture line along stringer 38L), had peeled outwards, upwards and rearwards - separating from the rest of the fuselage at the window belt. The whole of this separated section had then continued to slide upwards and rearwards, over the fuselage, before being carried back in the slipstream and colliding with the outer leading edge of the right horizontal stabiliser, completely disrupting the outer half. A fragment of horizontal stabiliser spar cap was found embedded in the fuselage structure adjacent to the two vent valves, just below, and forward of, the L2 door [Appendix B, Figure B-22].
(v) A large, clear, imprint of semi-eliptical form was apparent on the lower right side at station 360 which had evidently been caused by the separating forward fuselage section striking the No 3 engine as it swung rearwards and to the right (confirmed by No 3 engine fan cowl damage).

1.12.3.4 Tailplane three-dimensional reconstruction

The tailplane structural design took the form of a forward and an aft torque box. The forward box was constructed from light gauge aluminium alloy sheet skins, supported by closely pitched, light gauge nose ribs but without lateral stringers. The aft torque box incorporated heavy gauge skin/stringer panels with more widely spaced ribs. The front spar web was of light gauge material. Leading edge impacts inflicted by debris would therefore have had the capacity to reduce the tailplane's structural integrity by passing through the light gauge skins and spar web into the interior of the aft torque box, damaging the shear connection between top and bottom skins in the process and thereby both removing the bending strength of the box and opening up the weakened structure to the direct effects of the airflow.

Examination of the rebuilt tailplane structure at AAIB Farnborough left little doubt that it had been destroyed by debris striking its leading edges. In addition, the presence on the skins of smear marks indicated that some unidentified soft debris had contacted those surfaces whilst moving with both longitudinal and lateral velocity components relative to the aircraft.

The reconstructed left tailplane [Appendix B, Figure B-23] showed evidence that disruption of the inboard leading edge, followed respectively by the forward torque box, front spar web and main torque box, occurred as a result of frontal impact by the base of a baggage container. Further outboard, a compact object appeared to have struck the underside of the leading edge and penetrated to the aft torque box. In both cases, the loss of the shear web of the front spar appeared to have permitted local bending failure of the remaining main torque box structure in a tip downwards sense, consistent with the normal load direction. For both events to have occurred it would be reasonable to assume that the outboard damage preceded that occurring inboard.

The right tailplane exhibited massive leading edge impact damage on the outboard portion which also appeared to have progressed to disruption of the aft torsion box. A fragment of right tailplane spar cap was found embedded in the fuselage structure adjacent to the two vent valves, just below, and forward of, the L2 door and it is clear that this area of forward left fuselage had travelled over the top of the aircraft and contributed to the destruction of the outboard right tailplane.

CLICK HERE TO RETURN TO INDEX

1.12.4 Examination of engines

All four engines had struck the ground in Lockerbie with considerable velocity and therefore sustained major damage, in particular to most of the fan blades. The No 3 engine had fallen 1,100 metres north of the other three engines, striking the ground on its rear face, penetrating a road surface and coming to rest without any further change of orientation i.e. with the front face remaining uppermost. The intake area contained a number of loose items originating from within the cabin or baggage hold. It was not possible initially to determine whether any of the general damage to any of the engine fans or the ingestion noted in No 3 engine intake occurred whilst the relevant engines were delivering power or at a later stage.

Numbers 1, 2 and 3 engines were taken to British Airways Engine Overhaul Limited for detailed examination under AAIB supervision in conjunction with a specialist from the Pratt and Whitney Engine Company. During this examination the following points were noted:

(i) No 2 engine (situated closest to the site of the explosion) had evidence of blade "shingling" in the area of the shrouds consistent with the results of major airflow disturbance whilst delivering power. (This effect is produced when random bending and torsional deflection occurs, permitting the mid-span shrouds to disengage and repeatedly strike the adjacent aerofoil surfaces of the blades). The interior of the air intake contained paint smears and other evidence suggesting the passage of items of debris. One such item of significance was a clear indentation produced by a length of cable of diameter and strand size similar to that typically attached to the closure curtains on the baggage containers.

(ii) No 3 engine, identified on site as containing ingested debris from within the aircraft, nonetheless had no evidence of the type of shingling seen on the blades of No 2 engine. Such evidence is usually unmistakable and its absence is a clear indication that No 3 engine did not suffer a major intake airflow disturbance whilst delivering significant power. The intake structure was found to have been crushed longitudinally by an impact on the front face although, as stated earlier, it had struck the ground on its rear face whilst falling vertically.

(iii) All 3 engines had evidence of blade tip rubs on the fan cases having a combination of circumference and depth greater than hitherto seen on any investigation witnessed on Boeing 747 aircraft by the Pratt and Whitney specialists. Subsequent examination of No 4 engine confirmed that it had a similar deep, large circumference tip rub. These tip-rubs on the four engines were centred at slightly different clock positions around their respective fan cases.

The Pratt and Whitney specialists supplied information which was used to interpret the evidence found on the blades and fan cases including details of engine dynamic behaviour necessary to produce the tip rub evidence. This indicated that the depth and circumference of tip rubs noted would have required a marked nose down change of aircraft pitch attitude combined with a roll rate to the left.

Pratt and Whitney also advised that:

(i) Airflow disruption such as that presumed to have caused the shingling observed on No 2 engine fan blades was almost invariably the result of damage to the fan blade aerofoils, resulting from ingestion or blade failure.
(ii) Tip rubs of a depth and circumference noted on all four engines could be expected to reduce the fan rotational energy on each to a negligible value within approximately 5 seconds.
(iii) Airflow disruption sufficient to cause the extent of shingling noted on the fan blades of No 2 engine would also reduce the rotational fan energy to a negligible value within approximately 5 seconds.

1.13 Medical and pathological information

The results of the post mortem examination of the victims indicated that the majority had experienced severe multiple injuries at different stages, consistent with the in-flight disintegration of the aircraft and ground impact. There was no pathological indication of an in-flight fire and no evidence that any of the victims had been injured by shrapnel from the explosion. There was also no evidence which unequivocally indicated that passengers or cabin crew had been killed or injured by the effects of a blast. Although it is probable that those passengers seated in the immediate vicinity of the explosion would have suffered some injury as a result of blast, this would have been of a secondary or tertiary nature.

Of the casualties from the aircraft, the majority were found in areas which indicated that they had been thrown from the fuselage during the disintegration. Although the pattern of distribution of bodies on the ground was not clear cut there was some correlation with seat allocation which suggested that the forward part of the aircraft had broken away from the rear early in the disintegration process. The bodies of 10 passengers were not recovered and of these, 8 had been allocated seats in rows 23 to 28 positioned over the wing at the front of the economy section. The fragmented remains of

13 passengers who had been allocated seats around the eight missing persons were found in or near the crater formed by the wing. Whilst there is no unequivocal proof that the missing people suffered the same fate, it would seem from the pattern that the missing passengers remained attached to the wing structure until impact.

1.14 Fire

Of the several large pieces of aircraft wreckage which fell in the town of Lockerbie, one was seen to have the appearance of a ball of fire with a trail of flame. Its final path indicated that this was the No 3 engine, which embedded itself in a road in the north-east part of the town. A small post impact fire posed no hazard to adjacent property and was later extinguished with water from a hosereel. The three remaining engines landed in the Netherplace area of the town. One severed a water main and the other two, although initially on fire, were no risk to persons or property and the fires were soon extinguished.

A large, dark, delta shaped object was seen to fall at about the same time in the Sherwood area of the town. It was not on fire while in the air, however, a fireball several hundred feet across followed the impact. It was of relatively short duration and large amounts of debris were thrown into the air, the lighter particles being carried several miles downwind, while larger pieces of burning debris caused further fires, including a major one at the Townfoot Garage, up to 350 metres from the source. It was determined that the major part of both wings, which included the aircraft fuel tanks, had formed the crater. A gas main had also been ruptured during the impact.

At 19.04 hrs the Dumfries Fire Brigade Control received a call from a member of the public which indicated that there had been a "huge boiler explosion" at Westacres, Lockerbie, however, subsequent calls soon made it clear that it was an aircraft which had crashed. At 19.07 hrs the first appliances were mobile and at 1910 hrs one was in attendance in the Rosebank area. Multiple fires were identified and it soon became apparent that a major disaster had occurred in the town and the Fire Brigade Major Incident Plan was implemented. During the initial phase 15 pumping appliances from various brigades were deployed but this number was ultimately increased to 20.

At 22.09 hrs the Firemaster made an assessment of the situation. He reported that there was a series of fires over an area of the town centre extending 1† by € mile. The main concentration of the fire was in the southwest of the town around Sherwood Park and Sherwood Crescent. Appliances were in attendance at other fires in the town, particularly in Park Place and Rosebank Crescent. Water and electricity supplies were interrupted and water had to be brought into the town.

By 02.22 hrs on 22 December, all main seats of fire had been extinguished and the firemen were involved in turning over and damping down. At 04.42 hrs small fires were still occurring but had been confined to the Sherwood Crescent area.

1.15 Survival aspects

1.15.1 Survivability

The accident was not survivable.

1.15.2 Emergency services

A chronology of initial responses by the emergency services is listed below:-

Time	Event
19.03 hrs	Radio message from Police patrol in Lockerbie to Dumfries and Galloway Constabulary reporting an aircraft crash at Lockerbie.
19.04 hrs	Emergency call to Dumfries and Galloway Fire Brigade.
19.37 hrs	First ambulances leave for Dumfries and Galloway Royal Infirmary with injured town residents. (2- serious; 3- minor)
19.40 hrs	Sherwood Park and Sherwood Crescent residents evacuated to Lockerbie Town Hall.
20.25 hrs	Nose section of N739PA discovered at Tundergarth (approximately 4 km east of Lockerbie).

During the next few days a major emergency operation was mounted using the guidelines of the Dumfries and Galloway Regional Peacetime Emergency Plan. The Dumfries and Galloway Constabulary was reinforced by contingents from Strathclyde and Lothian & Borders Constabularies. Resources from HM Forces were made available and this support was subsequently authorised by the Ministry of Defence as Military Aid to the Civil Power. It included the provision of military personnel and a number of helicopters used mainly in the search for and recovery of aircraft wreckage. It was apparent at an early stage that there were no survivors from the aircraft and the search and recovery of bodies was mainly a Police task with military assistance.

Many other agencies were involved in the provision of welfare and support services for the residents of Lockerbie, relatives of the aircraft's occupants and personnel involved in the emergency operation.

1.16 Tests and research

An explosive detonation within a fuselage, in reasonably close proximity to the skin, will produce a high intensity spherically propagating shock wave which will expand outwards from the centre of detonation. On reaching the inner surface of the fuselage skin, energy will partially be absorbed in shattering, deforming and accelerating the skin and stringer material in its path. Much of the remaining energy will be transmitted, as a shock wave, through the skin and into the atmosphere but a significant amount of energy will be returned as a reflected shock wave, which will travel back into the fuselage interior where it will interact with the incident shock to produce Mach stem shocks - re-combination shock waves which can have pressures and velocities of propagation greater than the incident shock.

The Mach stem phenomenon is significant because it gives rise (for relatively small charge sizes) to a geometric limitation on the area of skin material which the incident shock wave can shatter, irrespective of charge size, thus providing a means of calculating the standoff distance of the explosive charge from the fuselage skin. Calculations suggest that a charge standoff distance of aproximately 25 inches would result in a shattered region approximately 18 to 20 inches in diameter, comparable to the size of the shattered region evident in the wreckage. This aspect is covered in greater detail in [Appendix G].

1.17 Additional information

1.17.1 Recorded radar information

Recorded radar information on the aircraft was available from 4 radar sites. Initial analysis consisted of viewing the recorded information as it was shown to the controller on the radar screen from which it was clear that the flight had progressed in a normal manner until secondary surveillance radar (SSR) was lost.

The detailed analysis of the radar information concentrated on the break-up of the aircraft. The Royal Signals and Radar Establishment (RSRE) corrected the radar returns for fixed errors and converted the SSR returns to latitude and longitude so that an accurate time and position for the aircraft could be determined. The last secondary return from the aircraft was recorded at 19.02:46.9 hrs, identifying N739PA at Flight Level 310, and at the next radar return there is no SSR data, only 4 primary returns. It was concluded that the aircraft was, by this time, no longer a single return and, considering the approximately 1 nautical mile spread of returns across track, that items had been ejected at high speed probably to both right and left of the aircraft.

Each rotation of the radar head thereafter showed the number of returns increasing, with those first identified across track having slowed down very quickly and followed a track along the prevailing wind line. The radar evidence then indicated that a further break-up of the aircraft had occurred and formed a parallel wreckage trail to the north of the first. From the absence of any returns travelling along track it was concluded that the main wreckage was travelling almost vertically downwards for much of the time.

A detailed analysis of the recorded radar information, together with the radar, ATC and seismic recordings is contained in Appendix C.

1.17.2 Seismic data

The British Geological Survey has a number of seismic monitoring stations in Southern Scotland. Stations close to Lockerbie recorded a seismic event measuring 1.6 on the Richter scale and, with appropriate corrections for the times of the waves to reach the sensors, it was established that this occurred at 19.03:36.5 hrs ±1 second. A further check was made by triangulation techniques from the information recorded by the various sensors.

An analysis of the seismic recording, together with the radar, ATC and radar information is contained in Appendix C.

1.17.3 Trajectory analysis

A detailed trajectory analysis was carried out by Cranfield Institute of Technology in an effort to provide a sequence for the aircraft disintegration. This analysis comprised several separate processes, including individual trajectory calculations for a limited number of key items of wreckage and mathematical modelling of trajectory paths adopted by a series of hypothetical items of wreckage encompassing the drag/weight spectrum of the actual wreckage.

The work carried out at Cranfield enabled the reasons for the two separate trails to be established. The narrow northern trail was shown to be created by debris released from the aircraft in a vertical dive between 19,000 and 9,000 feet overhead Lockerbie. The southern trail, longer and straight for most of its length, appeared to have been created by wreckage released during the initial disintegration at altitude whilst the aircraft was in level flight. Those items falling closest to Lockerbie would have been those with higher density which would travel a significant distance along track before losing all along-track velocity, whilst only drifting a small distance downwind, owing to the high speed of their descent. The most westerly items thus showed the greatest such effect. The southern trail therefore had curved boundaries at its western end with the curvature becoming progressively less to the east until the wreckage essentially fell in a straight band. Thus wreckage in the southern trail positioned well to the east could be assumed to have retained negligible velocity along aircraft track after separation and the along-track distribution could be used to establish an approximate sequence of initial disintegration.

The analysis calculated impact speeds of 120 kts for the nose section weighing approximately 17,500 lb and 260 kts for the engines and pylons which each weighed about 13,500 lb. Based on the best available data at the time, the analysis showed that the wing (approximately 100,000 lb of structure containing an estimated 200,000 lb of fuel) could have impacted at a speed, in theory, as high as 650 kts if it had 'flown' in a streamlined attitude such that the drag coefficient was minimal. However, because small variations of wing incidence (and various amounts of attached fuselage) could have resulted in significant increases in drag coefficient, the analysis also recognized that the final impact speed of the wing could have been lower.

1.17.4 Space debris re-entry

Four items of space debris were known to have re-entered the Earth's atmosphere on 21 December 1988. Three of these items were fragments of debris which would not have survived re-entry, although their burn up in the upper atmosphere might have been visible from the Earth's surface. The fourth item landed in the USSR at 09.50 hrs UTC.

2 ANALYSIS

2.1 Introduction

The airport security and criminal aspects of the destruction of Boeing 747 registration N739PA near Lockerbie on 21 December 1988 are the subjects of a separate investigation and are not covered in this report. This analysis discusses the technical aspects of the disintegration of the aircraft and considers possible ways of mitigating the effects of an explosion in the future.

2.2 Explosive destruction of the aircraft

The geographical position of the final secondary return at 19.02:46.9 hrs was calculated by RSRE to be OS Grid Reference 15257772, annotated Point A in Appendix B, Figure B-4, with an accuracy considered to be better than ±300 metres This return was received 3.1±1 seconds before the loud sound was recorded on the CVR at 19.02:50 hrs. By projecting from this position along the track of 321¡(Grid) for 3.1±1 seconds at the groundspeed of 434 kts, the position of the aircraft was calculated to be OS Grid Reference 14827826, annotated Point B in Appendix B, Figure B-4, within an accuracy of ±525 metres. Based on the evidence of recorded data only, Point B therefore represents the geographical position of the aircraft at the moment the loud sound was recorded on the CVR.

The datum line, discussed at paragraph 1.12.1.6, was derived from a detailed analysis of the distribution of specific items of wreckage, including those exhibiting positive evidence of a detonating high performance plastic explosive. The scatter of these items about the datum line may have been due partly to velocities imparted by the force of the detonating explosive and partly by the difficulty experienced in pinpointing the location of the wreckage accurately in relatively featureless terrain and poor visibility. However, the random nature of the scatter created by these two effects would have tended to counteract one another, and a major error in any one of the eleven grid references would have had little overall effect on the whole line. There is, therefore, good reason to have confidence in the validity of the datum line.

The items used to define the datum line, included those exhibiting positive evidence of a detonating high performance plastic explosive, would have been the first pieces to have been released from the aircraft. The datum line was projected westwards until it intersected the known radar track of the aircraft in order to derive the position of the aircraft along track at which the explosive items were released and therefore the position at which the IED had detonated. This position was OS grid reference 146786 and is annotated Point C in Appendix B, Figure B-4. Point C was well within the circle of accuracy

(±525 metres) of the position at which the loud noise was heard on the CVR (Point B). There can, therefore, be no doubt that the loud noise on the CVR was directly associated with the detonation of the IED and that this explosion initiated the disintegration process and directly caused the loss of the aircraft.

2.3 Flight recorders

2.3.1 Digital flight data recordings

A working group of the European Organisation for Civil Aviation Electronics (EUROCAE) was, during the period of the investigation, formulating new standards (Minimum Operational Performance Requirement for Flight Data Recorder Systems, Ref:- ED55) for future generation flight recorders which would have permitted delays between parameter input and recording (buffering) of up to € second. These standards are intended to form the basis of new CAA specifications for flight recorders and may be adopted worldwide.

The analysis of the recording from the DFDR fitted to N739PA, which is detailed in Appendix C, showed that the recorded data simply stopped. Following careful examination and correlation of the various sources of recorded information, it was concluded that this occurred because the electrical power supply to the recorder had been interrupted at 19.02:50 hrs ±1 second. Only 17 bits of data were not recoverable (less that 23 milliseconds) and it was not possible to establish with any certainty if this data was from the accident flight or was old data from a previous recording.

The analysis of the final data recorded on the DFDR was possible because the system did not buffer the incoming data. Some existing recorders use a process whereby data is stored temporarily in a memory device (buffer) before recording. The data within this buffer is lost when power is removed from the recorder and in currently designed recorders this may mean that up to 1.2 seconds of final data contained within the buffer is lost. Due to the necessary processing of the signals prior to input to the recorder, additional delays of up to 300 milliseconds may be introduced. If the accident had occurred when the aircraft was over the sea, it is very probable that the relatively few small items of structure, luggage and clothing showing positive evidence of the detonation of an explosive device would not have been recovered. However, as flight recorders are fitted with underwater location beacons, there is a high probability that they would have been located and recovered. In such an event the final milliseconds of data contained on the DFDR could be vital to the successful determination of the cause of an accident whether due to an explosive device or other catastrophic failure. Whilst it may not be possible to reduce some of the delays external to the recorder, it is possible to reduce any data loss due to buffering of data within the data acquisition unit.

It is, therefore, recommended that manufacturers of existing recorders which use buffering techniques give consideration to making the buffers non-volatile, and hence recoverable after power loss. Although the recommendation on this aspect, made to the EUROCAE working group during the investigation, was incorporated into ED55, it is also recommended that Airworthiness Authorities re-consider the concept of allowing buffered data to be stored in a volatile memory.

2.3.2 Cockpit voice recorders

The analysis of the cockpit voice recording, which is detailed in Appendix C, concluded that there were valid signals available to the CVR when it stopped at 19.02:50 hrs ±1 second because the power supply to the recorder was interrupted. It is not clear if the sound at the end of the recording is the result of the explosion or is from the break-up of the aircraft structure. The short period between the beginning of the event and the loss of electrical power suggests that the latter is more likely to be the case. In order to respond to events that result in the almost immediate loss of the aircraft's electrical power supply it was therefore recommended during the investigation that the regulatory authorities consider requiring CVR systems to contain a short duration (i.e. no greater than 1 minute) back-up power supply.

2.3.3 Detection of explosive occurrences

In the aftermath of the Air India Boeing 747 accident (AI 182) in the North Atlantic on 23 June 1985, RARDE were asked informally by AAIB to examine means of differentiating, by recording violent cabin pressure pulses, between the detonation of an explosive device within the cabin (positive pulse) and a catastrophic structural failure (negative pulse). Following the Lockerbie disaster it was considered that this work should be raised to a formal research project. Therefore, in February 1989, it was recommended that the Department of Transport fund a study to devise methods of recording violent positive and negative pressure pulses, preferably utilising the aircraft's flight recorder systems. This recommendation was accepted.

Preliminary results from the trials indicate that, if a suitable sensor can be developed, its output will need to be recorded in real time and therefore it may require wiring to the CVR installation. This will further strengthen the requirement for battery back up of the CVR electrical power supply.

2.4 IED position within the aircraft

From the detailed examination of the reconstructed luggage containers, discussed at paragraph 1.12.2.4 and in Appendix F, it was evident that the IED had been located within a metal container (serial number AVE 4041 PA), near its aft outboard quarter as shown in Appendix F, Figure F-13. It was also clear that the container was loaded in position 14L of the forward hold which placed the explosive charge approximately 25 inches inboard from the fuselage skin at frame 700. There was no evidence to indicate that there was more than one explosive charge.

2.5 Engine evidence

To produce the fan blade tip rub damage noted on all engines by means of airflow inclined to the axes of the nacelles would have required a marked nose down change of aircraft pitch attitude combined with a roll rate to the left while all of the engines were attached to the wing.

The shingling damage noted on the fan blades of No 2 engine can only be attributed to airflow disturbance caused by ingestion related fan blade damage occurring when substantial power was being delivered. This is readily explained by the fact that No 2 engine intake is positioned some 27 feet aft and 30 feet outboard of the site of the explosion and that the interior of the intake exhibited a number of prominent paint smears and general foreign object damage. This damage included evidence of a strike by a cable similar to that forming part of the closure curtain of a typical baggage container. It is inconceivable that an independent blade failure could have occurred in the short time frame of this event. By similar reasoning, the absence of such shingling damage on blades of No 3 engine was a reliable indication that it suffered no ingestion until well into the accident sequence.

The combination of the position of the explosive device and the forward speed of the aircraft was such that significant sized debris resulting from the explosion would have been available to be ingested by No 2 engine within milliseconds of the explosion. In view of the fact that the tip rub damage observed on the fan case of No 2 engine is of similar magnitude to that observed on the other three engines it is reasonable to deduce that a manoeuvre of the aircraft occurred before most of the energy of the No 2 engine fan was lost due to the effect of ingestion (seen only in this engine). Since this shingling effect could only readily be produced as a by-product of ingestion whilst delivering considerable power, it is reasonable to assume that this was also occurring before loss of major fan energy due to tip rubbing took place. Hence both phenomena must have been occurring simultaneously, or nearly so, to produce the effects observed and must have occupied a time frame of substantially less than 5 seconds. The onset of this time period would have been the time at which debris from the explosion first inflicted damage to fan blades in No 3 engine and, since the fan is only approximately 40 feet from the location of the explosive device, this would have been an insignificant time interval after the explosion.

It was therefore concluded from this evidence that the wing with all of the engines attached had achieved a marked nose down and left roll attitude change well within 5 seconds of the explosion.

2.6 Detachment of forward fuselage

Examination of the three major structural elements either side of the region of station 800 on the right side of the fuselage makes it clear that to produce the curvature of the window belt and peeling of the riveted joint at the R2 door aperture requires the door pillar to be securely in position and able to react longitudinal and lateral loads. This in turn requires the large section of fuselage on the right side between stations 760 and 1000 (incorporating the right half of the floor) to be in position in order to locate the lower end of the door pillar. Thus both these sections must have been in position until the section from station 560 to 800 (right side) had completed its deflection to the right and peeled from the door pillar. Separation of the forward fuselage must thus have been complete by the time all three items mentioned above had fallen free.

CLICK HERE TO RETURN TO INDEX
2.7 Speed of initial disintegration

The distribution of wreckage in the bands between the datum line and the 250, 300, 600 and 900 metre lines was examined in detail. The positions of these items of structure on the aircraft are shown in Appendix B, Figures B-10 to B-13. It should be noted that the position on the ground of these items, although separated by small distances when measured in a direction along aircraft track, were distributed over large distances when measured along the wreckage trail. All were recovered from positions far enough to the east to be in that part of the southern trail which was sufficiently close, theoretically, to a straight line for any curvature effect to be neglected.

The wreckage found in each of the bands enabled an approximate sequence of break-up to be established. It was clear that as the distance travelled from the datum line increased, items of wreckage further from the station of the IED were encountered. The items shown on the diagram as falling on the 250 metre band also include those fragments of lower forward fuselage skin having evidence of explosive damage and presumed to have separated as a direct result of the blast. However, a few portions of the upper forward fuselage were also found within the 250 metre band, suggesting that these items had also separated as a result of the blast.

By the time the 300 metre line was reached much of the structure from the right side in the region of the explosive device had been shed. This included the area of window belt, referred to in paragraph 2.6 above, which gave clear indications that the forward structure had detached to the right and finally peeled away at station 800. It also included the areas of adjacent structure immediately to the rear of station 800 about which the forward structure would have had to pivot. By the time the 600 metre line was reached, there was clearly insufficient structure left to connect the forward fuselage with the remainder of the aircraft. Wreckage between the 600 and 900 metre lines consisted of structure still further from the site of the IED.

There is evidence that a manoeuvre occurred at the time of the explosion which would have produced a significant change of the aircraft's flight path, however, it is considered that the change in the horizontal velocity component in the first few seconds would not have been great. The original groundspeed of the aircraft was therefore used in conjunction with the distribution of wreckage in the successive bands to establish an approximate time sequence of break-up of the forward fuselage. Assuming the original ground speed of 434 Kts, the elapsed flight times from the datum to each of the parellel lines were calculated to be:

Distance (metres)	250	300	600	900
Time (seconds)	1.1	1.3	2.7	4.0

Thus, there is little doubt that separation of the forward fuselage was complete within 2 to 3 seconds of the explosion.

The separate assessment of the known grid references of tailplane and elevator wreckage in the southern trail revealed that those items were evenly distributed about the 600 metre line and therefore that most of the tailplane damage occurred after separation of the forward fuselage was complete.

2.8 The manoeuvre following the explosion

The engine evidence, timing and mode of disintegration of the fuselage and tailplane suggests that the latter did not sustain significant damage until the forward fuselage disintegration was well advanced and the pitch/roll manoeuvre was also well under way.

Examination of the three dimensional reconstruction makes it clear that both main and upper deck floors were disrupted by the explosion. Since pitch control cables are routed through the upper deck floor beams and the roll control cables through the main deck beams, there is a strong possibility that movement of the beams under explosive forces would have applied inputs to the control cables, thus operating control surfaces in both axes.

2.9 Secondary disintegration

The distribution of fin debris between the trails suggests that disintegration of the fin began shortly before the vertical descent was established. No single mode of failure was identified and the debris which had struck the leading edge had not caused major disruption. The considerable fragmentation of the thick panels of the aft torque box was also very different from that noted on the corresponding structure of the tailplanes. It was therefore concluded that the mode of failure was probably flutter.

The finding, in the northern trail, of a slide raft wrapped around a flap track fairing suggests that at a later stage of the disintegration the rear of the aircraft must have experienced a large angle of sideslip. The loss of the fin would have made this possible and also subjected the structure to large side loads. It is possible that such side loading would have assisted the disintegration of the rear fuselage and also have caused bending failure of the pylon attachments of the remaining three engines.

2.10 Impact speed of components

The trajectory analysis carried out by Cranfield Institute of Technology calculated impact speeds of 120 kts for the nose section, and 260 kts for the engines and pylons. These values were considered to be reliable because the drag coefficients could be estimated with a reasonable degree of confidence. Based on the best available data at the time, the analysis also showed that the wing could have impacted at a speed, in theory, as high as 650 kts if it had flown in a streamlined attitude such that the drag coefficient was minimal. However, it was also recognized that relatively small changes in the angle of incidence of the wing would have produced a significant increase in drag with a consequent reduction in impact speed. Refinement of timing information and radar data subsequent to the Cranfield analysis has enabled a revised estimate to be made of the mean speed of the wing during the descent.

The engine evidence indicated that there had been a large nose down attitude change of the aircraft early in the event. The Cranfield analysis also showed that the rear fuselage had disintegrated while essentially in a vertical descent between 19,000 and 9,000 feet over Lockerbie. Assuming that, following the explosion, the wing followed a straight line descending flight profile from 31,000 feet to 19,000 feet directly overhead Lockerbie and then descended vertically until impact, the wing would have travelled the minimum distance practicable. The ground distance between the geographical position at which the disintegration started (Figure B-4, Point B) and the crater made by the wing impact was 2997 ±525 metres (9833 ±1722 feet). The time interval between the explosion and the wing impact was established in Appendix C as 46.5 ±2 seconds. Based on the above times and distances the mean linear speed achieved by the wing would have been about 440 kts.

The impact location of Nos 1, 2, and 4 engines closely grouped in Lockerbie was consistent with their nearly vertical fall from a point above the town. If they had separated at about 19,000 feet and the wing had then flown as much as one mile away from the overhead position before tracking back to impact, the total flight path length of the wing would not have required it to have achieved a mean linear speed in excess of 500 kts.

Any speculation that the flight path of the wing could have been longer would have required it to have undergone manoeuvres at high speed in order to arrive at the 19,000 feet point. The manoeuvres involved would almost certainly have resulted in failure of the primary wing structure which, from distribution of wing debris, clearly did not occur. Alternatively the wing could have travelled more than one mile from Lockerbie after reaching the 19,000 feet point, but this was considered unlikely. It is therefore concluded that the mean speed of the wing during the descent was in the region of 440 to 500 kts.

2.11 Sequence of disintegration

Analysis of wreckage in each of the bands, taken in conjunction with the engine evidence and the three-dimensional reconstruction, suggests the following sequence of disintegration:

(i) The initial explosion triggered a sequence of events which effectively destroyed the structural integrity of the forward fuselage. Little more then remained between stations 560 and 760 (approximately) than the window belts and the cabin sidewall structure immediately above and below the windows, although much of the cargo-hold floor structure appears to have remained briefly attached to the aircraft. [Appendix B, Figure B-24]
(ii) The main portion of the aircraft simultaneously entered a manoeuvre involving a marked nose down and left roll attitude change, probably as a result of inputs applied to the flying control cables by movement of structure.
(iii) Failure of the left window belt then occurred, probably in the region of station 710, as a result of torsional and bending loads on the fuselage imparted by the manoeuvre (i.e. the movement of the forward fuselage relative to the remainder of the aircraft was an initial twisting motion to the right, accompanied by a nose up pitching deflection).
(iv) The forward fuselage deflected to the right, pivoting about the starboard window belt, and then peeled away from the structure at station 800. During this process the lower nose section struck the No 3 engine intake causing the engine to detach from its pylon. This fuselage separation was apparently complete within 3 seconds of the explosion.
(v) Structure and contents of the forward fuselage struck the tail surfaces contributing to the destruction of the outboard starboard tailplane and causing substantial damage to the port unit. This damage occurred approximately 600 metres track distance after the explosion and therefore appears to have happened after the fuselage separation was complete.
(vi) Fuselage structure continued to break away from the aircraft and the separated forward fuselage section as they descended.
(vii) The aircraft maintained a steepening descent path until it reached the vertical in the region of 19,000 feet approximately over the final impact point. Shortly before it did so the tail fin began to disintegrate.
(viii) The mode of failure of the fin is not clear, however, flutter of its structure is suspected.
(ix) Once established in the vertical dive, the fin torque box continued to disintegrate, possibly permitting the remainder of the aircraft to yaw sufficiently to cause side load separation of Nos 1, 2 and 4 engines, complete with their pylons.
(x) Break-up of the rear fuselage occurred during the vertical descent, possibly as a result of loads induced by the yaw, leaving a section of cabin floor and baggage hold from approximately stations 1241 to 1920, together with 3 landing gear units, to fall into housing at Rosebank Terrace.

(xi) The main wing structure struck the ground with a high yaw angle at Sherwood Crescent.

2.12 Explosive mechanisms and the structural disintegration

The fracture and damage pattern analysis was mainly of an interpretive nature involving interlocking pieces of subtle evidence such as paint smears, fracture and rivet failure characteristics, and other complex features. In the interests of brevity, this analysis will not discuss the detailed interpretation of individual fractures or damage features. Instead, the broader 'damage picture' which emerged from the detailed work will be discussed in the context of the explosive mechanisms which might have produced the damage, with a view to identifying those features of greatest significance.

It is important to keep in mind that whilst the processes involved are considered and discussed separately, the timescales associated with shock wave propagation and the high velocity gas flows are very short compared with the structural response timescales. Consequently, material which was shattered or broken by the explosive forces would have remained in place for a sufficiently long time that the structure can be considered to have been intact throughout much of the period that these explosive propagation phenomena were taking place.

2.12.1 Direct blast effect

2.12.1.1 Shock wave propagation

The direct effect of the explosive detonation within the container was to produce a high intensity spherically propagating shock wave which expanded from the centre of detonation close to the side of the container, shattering part of the side and base of the container as it passed through into the gap between the container and the fuselage skin. In breaking out of the container, some internal reflection and Mach stem interaction would have occurred, but this would have been limited by the absorptive effect of the baggage inboard, above, and forward of the charge. The force of the explosion breaking out of the container would therefore have been directed downwards and rearwards.

The heavy container base was distorted and torn downwards, causing buckling of the adjoining section of frame 700, and the container sides were blasted through and torn, particularly in the aft lower corner. Some of the material in the direct path of the explosive pressure front was reduced to shrapnel sized pieces which were rapidly accelerated outwards behind the primary shock front. Because of the overhang of the container's sloping side, fragments from both the device itself and the container wall impacted the projecting external flange of the container base edge member, producing micro cratering and sooting. Metallurgical examination of the internal surfaces of these craters identified areas of melting and other features which were consistent only with the impact of very high energy particles produced by an explosion at close quarters. Analysis of material on the crater surfaces confirmed the presence of several elements and compounds foreign to the composition of the edge member, including material consistent with the composition of the sheet aluminium forming the sloping face of the container.

On reaching the inner surface of the fuselage skin, the incident shock wave energy would partially have been absorbed in shattering, deforming and accelerating the skin and stringer material in its path. Much of its energy would have been transmitted, as a shock wave, through the skin and into the atmosphere [Appendix B, Figure B-25], but a significant amount of energy would have been returned as a reflected shock wave, back into the cavity between the container and the fuselage skin where Mach stem shock waves would have been formed. Evidence of rapid shattering was found in a region approximately bounded by frames 700 & 720 and stringers 38L & 40L, together with the lap joint at 39L.

The shattered fuselage skin would have taken a significant time to move, relative to the timescales associated with the primary shock wave propagation. Clear evidence of soot and small impact craters were apparent on the internal surfaces of all fragments of container and structure from the shatter zone, confirming that the this material had not had time to move before it was hit by the cloud of shrapnel, unburnt explosive residues and sooty combustion products generated at the seat of the explosion.

Following immediately behind the primary shock wave, a secondary high pressure wave - partly caused by reflections off the baggage behind the explosive material but mainly by the general pressure rise caused by the chemical conversion of solid explosive material to high temperature gas - emerged from the container. The effect of this second pressure front, which would have been more sustained and spread over a much larger area, was to cause the fuselage skin to stretch and blister outwards before bursting and petalling back in a star-burst pattern, with rapidly running tear fractures propagating away from a focus at the shatter zone. The release of stored energy as the skin ruptured, combined with the outflow of high pressure gas through the aperture, produced a characteristic curling of the skin 'petals' - even against the slipstream. For the most part, the skins which petalled back in this manner were torn from the frames and stringers, but the frames and stringers themselves were also fractured and became separated from the rest of the structure, producing a very large jagged hole some 5 feet longitudinally by 17 feet circumferentially (upwards to a region just below the window belt and downwards virtually to the centre line).

From this large jagged hole, three of the fractures continued to propagate away from the hole instead of terminating at the boundary. One fracture propagated longitudinally rearwards as far as the wing cut-out and another forwards to station 480, creating a continuous longitudinal fracture some 43 feet in length. A third fracture propagated circumferentially downwards along frame 740, under the belly, and up the right side of the fuselage almost as far as the window belt - a distance of approximately 23 feet.

These extended fractures all involved tearing or related failure modes, sometimes exploiting rivet lines and tearing from rivet hole to rivet hole, in other areas tearing along the full skin section adjacent to rivet lines, but separate from them. Although the fractures had, in part, followed lap joints, the actual failure modes indicated that the joints themselves were not inherently weak, either as design features or in respect of corrosion or the conditions of the joints on this particular aircraft.

Note: The cold bond process carried out at manufacture on the lap joints had areas of disbonding prior to the accident. This disbonding is a known feature of early Boeing 747 aircraft which, by itself, does not detract from the structural integrity of the hull. The cold bond adhesive was used to improve the distribution of shear load across the joint, thus reducing shear transfer via the fasteners and improving the resistance of the joint to fatigue damage; the fasteners were designed to carry the full static loading requirements of the joint without any contribution from the adhesive. Thus, the loss of the cold bond integrity would only have been significant if it had resulted in the growth of fatigue cracks, or corrosion induced weaknesses, which had then been exploited by the explosive forces. No evidence of fatigue cracking was found in the bonded joints. Inter-surface corrosion was present on most lap joints but only one very small region of corrosion had resulted in significant material thinning; this was remote from the critical region and had not played any part in the break-up.

The cracks propagating upwards as part of the petalling process did not extend beyond the window line. The wreckage evidence suggests that the vertical fractures merged, effectively closing off the fracture path to produce a relatively clean bounding edge to the upper section of the otherwise jagged hole produced by the petalling process. There are at least two probable reasons for this. Firstly the petalling fractures above the shattered zone did not diverge, as they had tended to do elsewhere. Instead, it appears that a large skin panel separated and peeled upwards very rapidly producing tears at each side which ran upwards following almost parallel paths. However, there are indications that by the time the fractures had run several feet, the velocity of fracture had slowed sufficiently to allow the free (forward) edge of the skin panel to overtake the fracture fronts, as it flexed upwards, and forcibly strike the fuselage skin above, producing clear witness marks on both items. Such a tearing process, in which an approximately rectangular flap of skin is pulled upwards away from the main skin panel, is likely to result in the fractures merging. Secondly, this merging tendency would have been reinforced in this particular instance by the stiff window belt ahead of the fractures, which would have tended to turn the fractures towards the horizontal.

It appears that the presence of this initial ('clean') hole, together with the stiff window belt above, encouraged other more slowly running tears to break into it, rather than propagating outwards away from the main hole.

2.12.1.2 Critical crack considerations

The three very large tears extending beyond the boundary of the petalled region resulted in a critical reduction of fuselage structural integrity.

Calculations were carried out at the Royal Aerospace Establishment to determine whether these fractures, growing outwards from the boundary of the petalled hole, could have occurred purely as a result of normal differential pressure loading of the fuselage, or whether explosive forces were required in addition to the pressurisation loads.

Preliminary calculations of critical crack dimensions for a fuselage skin punctured by a 20 by 20 inches jagged hole indicated that unstable crack growth would not have occurred unless the skin stress had been substantially greater than the stress level due to normal pressurisation loads alone. It was therefore clear that explosive overpressure must have produced the gross enlargement of the initially small shattered hole in the hull. Furthermore, it was apparent from the degree of curling and petalling of the skin panels within the star-burst region that this overpressure had been relatively long term, compared with the shock wave overpressure which had produced the shatter zone. A more refined analysis of critical crack growth parameters was therefore carried out in which it was assumed that the long term explosive overpressure was produced by the chemical conversion of solid explosive material into high temperature gas.

An outline of the fracture propagation analysis is given at Appendix D. This analysis, using theoretical fracture mechanics, showed that, after the incident shock wave had produced the shatter zone, significant explosive overpressure loads were needed to drive the star-burst fractures out to the boundary of the petalled skin zone. Thereafter, residual gas overpressure combined with fuselage pressurisation loads were sufficient to produce the two major longitudinal cracks and a single major circumferential crack, extending from the window belt down to beyond the keel centreline.

2.12.1.3 Damage to the cabin floor structure

The floor beams in the region immediately above the baggage container in which the explosive had detonated were extensively broken, displaying clear indications of overload failure due to buckling caused by localised upward loading of the floor structure.

No direct evidence of bruising was found on the top panel of the container. It therefore appears that the container did not itself impact the floor beams, but instead the floor immediately above the container was broken through as a result of explosive overpressure as gases emerged from the ruptured container and loaded the floor panels. Data on floor strengths, provided by Boeing, indicated that the cabin floor (with the CRAF modification) would fail at a uniform static differential pressure of between 3.5 and 3.9 psi (high pressure below the cabin floor), and that the floor panel to floor beam attachments would not fail before the floor beams. Whilst there is no direct evidence of the pressure loading on the floor structure immediately following detonation, there can be no doubt that in the region of station 700 it would have exceeded the ultimate failure load by a large margin.

2.12.2 Indirect explosive damage (damage at remote sites)

All of the damage considered in the foregoing analysis, and the mechanisms giving rise to that damage, resulted from the direct impact of explosive shock waves and/or the short-term explosive overpressure on structure close to the source of the explosion. However, there were several regions of skin separation at sites remote from the explosion (see para 1.12.3.2) which were much more difficult to understand. These remote sites formed islands of indirect explosive damage separated from the direct damage by a sea of more generalised structural failure characterised by the progressive aerodynamic break-up of the weakened forward fuselage. All of these remote damage sites were consistent with the impact of very localised pressure impulses on the internal surfaces of the hull -effectively high energy 'pressure blows' against the inner surfaces produced by explosive shock waves and/or high pressure gas flows travelling through the interior spaces of the hull.

The propagation of explosive shock waves and supersonic gas flows within multiple, interlinking, cavities having indeterminate energy absorption and reflection properties, and ill-defined structural response, is extremely complex. Work has been initiated in an attempt to produce a three-dimensional computer analysis of the shock wave and supersonic flow propagation inside the fuselage, but full theoretical analysis is beyond present resources.

Because of the complexity of the problem, the following analysis will be restricted to a qualitative consideration of the processes which were likely to have taken place. Whilst such an approach is necessarily limited, it has identified a number of propagation mechanisms which appear to have been of fundamental importance to the break-up of Flight PA103, and which are likely to be critical in any future incident involving the detonation of high explosive inside an aircraft hull.

2.12.2.1 Shock wave propagation through internal cavities

When Mach stem shocks are produced not only are the shock pressures very high but they propagate at very high velocity parallel to the reflecting surface. In the context of the lower fuselage structure in the region of Mach stem formation, it can readily be seen that the Mach stem will be perfectly orientated to enter the narrow cavity formed between the outer skin and the cargo liner/containers, bounded by the fuselage frames [Appendix B, Figure B-25]. This cavity enables the Mach stem shock wave to propagate, without causing damage to the walls (due to the relatively low pressure where the Mach stem sweeps their surface), and reach regions of the fuselage remote from the source of the explosion. Furthermore, energy losses in the cavity are likely to be less than would occur in the 'free' propagation case, resulting in the efficient transmission of explosive energy. The cavity would tend to act like a 'shock tube', used for high speed aerodynamic research, confining the shock wave and keeping it running along the cavity axis, with losses being limited to kinetic heating due to friction at the walls.

Paragraph 1.6.3 contains a general description of the structural arrangements in the area of the cargo hold. Before proceeding further and considering how the shock waves might have propagated through this network of cavities, it should be pointed out that the timescale associated with the propagation of the shock waves is very short compared with the timescale associated with physical movement and separation of skin and structure fractured or damaged by the shock. Therefore, for the purpose of assessing the shock propagation through the cavities, the explosive damage to the hull can be ignored and the structure regarded as being intact. A further simplification can usefully be made by considering the structure to be rigid. This assumption would, if the analysis were quantitative, result in over-estimations of the shock strengths. However, for the purposes of a purely qualitative assessment, the assumption should be valid, in that the general trends of behaviour should not be materially altered.

It has already been argued that the shock wave emerging from the container was, in part, reflected back off the inner surface of the fuselage skin, forming a Mach stem shock wave which would then have tended to travel into the semi-circular lower lobe cavity. The Mach stem waves would have propagated away through this cavity in two directions:

(i) under the belly, between the frames [Appendix B, Figure B-3, detail A], and
(ii) up the left side, expanding into the cavity formed by the longitudinal manifold chamber where it joins the lower lobe cavity.

As the shock waves travelled along the cavity, little attenuation or other change of characteristic was likely to have occurred until the shocks passed the entrances to other cavities, or impinged upon projections and other local changes in the cavity. A review of the literature dealing with propagation of blast waves within such cavities provides useful insights into some of the physical mechanisms involved.

As part of a research program carried out into the design of ventilation systems for blast hardened installations intended to survive the long duration blast waves following the detonation of nuclear weapons, the propagation of blast waves along the primary passages and into the side branches of ventilation ducts was studied. The research showed that 90¡ bends in the ducts produced very little attenuation of shock wave pressure; a series of six right angle bends produced only a 30% pressure attenuation, together with an extension of the shock duration. It is therefore evident that the attenuation of shock waves propagating through the fuselage cavities, all of which were short with hardly any right angle turns, would have been minimal.

It was also demonstrated that secondary shock waves develop within the entrance to any side branch from the main duct, produced by the interaction of the primary shock wave with the geometric changes in the duct walls at the side-branch location. These secondary shock waves interact as they propagate into the side branch, combining together within a relatively short distance (typically 7 diameters) to produce a single, plane shock wave travelling along the duct axis. In a rigid, smooth walled structure, this mechanism produces secondary shock overpressures in the side branch of between 30% and 50% of the value of the primary shock, together with a corresponding attenuation of the primary shock wave pressure by approximately 20% to 25%.

This potential for the splitting up and re-transmission of shock wave energy within the lower hull cavities is of extreme importance in the context of this accident. Though the precise form of the interactions is too complex to predict quantitatively, it is evident that the lower hull cavities will serve to convey the overpressure efficiently to other parts of the aircraft. Furthermore, the cavities are not of serial form, i.e. they do not simply branch (and branch again) in a divergent manner, but instead form a parallel network of short cavities which reconnect with each other at many different points, principally along the crease beams. Thus, considerable scope exists for: the additive recombination of blast waves at cavity junctions; for the sustaining of the shock overpressure over a greater time period; and, for the generation of multiple shocks produced by the delay in shock propagation inherent in the different shock path (i.e. cavity) lengths.

Whilst it has not been possible to find a specific mechanism to explain the regions of localised skin separation and peel-back (i.e. the 'pressure blow' regions referred to in para 2.12.2), they were almost certainly the result of high intensity shock overpressures produced locally in those regions as a result of the additive recombination of shock waves transmitted through the lower hull cavities. It is considered that the relatively close proximity of the left side region of damage just below floor level at station 500, [Appendix B, Figure B-19, region D] to the forward end of the cargo hold may be significant insofar as the reflections back from the forward end of the hold would have produced a local enhancement of the shock overpressure. Similarly, 'end blockage effects' produced by the cargo door frame might have been responsible for local enhancements in the area of the belly skin separation and curl-back at station 560 [Appendix B, Figure B-19 and B-20, region E].

The separation of the large section of upper fuselage skin [Appendix B, Figure B-19 and B-20, detail B] was almost certainly associated with a local overpressure in the side cavities between the main deck window line and the upper deck floor, where the cavity is effectively closed off. It is considered that the most probable mechanism producing this region of impulse overpressure was a reflection from the closed end of the cavity, possibly combined with further secondary reflections from the window assembly, the whole being driven by reflective overpressures at the forward end of the longitudinal manifold cavity caused by the forward end of the cargo hold. The local overpressure inside the sidewall cavity would have been backed up by a general cabin overpressure resulting from the floor breakthrough, giving rise to an increased pressure acting on the inner face of the cabin side liner panels. This would have provided pseudo mass to the panels, effectively preventing them from moving inwards and allowing them to react the impulse pressure within the cavity, producing the region of local high pressure evidenced by the region of quilting on the skin panels [Appendix B, Figure B-19, region C].

2.12.2.2 Propagation of shock waves into the cabin

The design of the air-conditioning/depressurisation-venting systems on the Boeing 747 (and on most other commercial aircraft) is seen as a significant factor in the transmission of explosive energy, as it provides a direct connection between the main passenger cabin and the lower hull at the confluence of the lower hull cavities below the crease beam. The floor level air conditioning vents along the length of the cabin provided a series of apertures through which explosive shock waves, propagating through the sub floor cavities, would have radiated into the main cabin.

Once the shock waves entered the cabin space, the form of propagation would have been significantly different from that which occurred in the cavities in the lower hull. Again, the precise form of such radiation cannot be predicted, but it is clear that the energy would potentially have been high and there would also (potentially) have been a large number of shock waves radiating into the cabin, both from individual vents and in total, with further potential to recombine additively or to 'follow one another up' producing, in effect, sustained shock overpressures.

Within the cabin, the presence of hard, reflective, surfaces are likely to have been significant. Again, the precise way in which the shock waves interacted is vastly beyond the scope of current analytical methods and computing power, but there clearly was considerable potential for additive recombination of the many different shock waves entering at different points along the cabin and the reflected shock waves off hard surfaces in the cabin space, such as the toilet and galley compartments and overhead lockers. These recombination effects, though not understood, are known phenomena. Appendix B, Figure

B-26 shows how shock waves radiating from floor level might have been reflected in such a way as produce shock loading on a localised area of the pressure hull.

2.12.2.3 Supersonic gas flows

The gas produced by the explosive would have resulted in a supersonic flow of very high pressure gas through the structural cavities, which would have followed up closely behind the shock waves. Whilst the physical mechanisms of propagation would have been different from those of the shock wave, the end result would have been similar, i.e. there would have been propagation via multiple, linked paths, with potential for additive recombination and successive pressure pulses resulting from differing path lengths. Essentially, the shock waves are likely to have delivered initial 'pressure blows' which would then have been followed up immediately by more sustained pressures resulting from the high pressure supersonic gas flows.

2.13 Potential limitation of explosive damage

Quite clearly the detonation of high explosive material anywhere on board an aircraft is potentially catastrophic and the most effective means of protecting lives is to stop such material entering the aircraft in the first place. However, it is recognised that such risks cannot be eliminated entirely and it is therefore essential that means are sought to reduce the vulnerability of commercial aircraft structures to explosive damage.

The processes which take place when an explosive detonates inside an aircraft fuselage are complex and, to a large extent, fickle in terms of the precise manner in which the processes occur. Furthermore, the potential variation in charge size, position within the hull, and the nature of the materials in the immediate vicinity of the charge (baggage etc) are such that it would be unrealistic to expect to neutralise successfully the effect of every potential explosive device likely to be placed on board an aircraft. However, whilst the problem is intractable so far as a total solution is concerned, it should be possible to limit the damage caused by an explosive device inside a baggage container on a Boeing 747 or similar aircraft to a degree which would allow the aircraft to land successfully, albeit with severe local damage and perhaps resulting in some loss of life or injuries.

In Appendix E the problem of reducing the vulnerability of commercial aircraft to explosive damage is discussed, both in general terms and in the context of aircraft of similar size and form to the Boeing 747. In that discussion, those damage mechanisms which appear to have contributed to the catastrophic structural failure of Flight PA103 are identified and possible ways of reducing their damaging effects are suggested. These suggestions are intended to stimulate thought and discussion by manufacturers, airworthiness authorities, and others having an interest in finding solutions to the problem; they are intended to serve as a catalyst rather than to lay claim to a definitive solution.

2.14 Summary

It was established that the detonation of an IED, loaded in a luggage container positioned on the left side of the forward cargo hold, directly caused the loss of the aircraft. The direct explosive forces produced a large hole in the fuselage structure and disrupted the main cabin floor. Major cracks continued to propagate from the large hole under the influence of the service pressure differential. The indirect explosive effects produced significant structural damage in areas remote from the site of the explosion. The combined effect of the direct and indirect explosive forces was to destroy the structural integrity of the forward fuselage, allow the nose and flight deck area to detach within a period of 2 to 3 seconds, and subsequently allow most of the remaining aircraft to disintegrate while it was descending nearly vertically from 19,000 to 9,000 feet.

The investigation has enabled a better understanding to be gained of the explosive processes involved in such an event and to suggest ways in which the effects of such an explosion might be mitigated, both by changes to future design and also by retrospective modification of aircraft. It is therefore recommended that Regulatory Authorities and aircraft manufacturers undertake a systematic study with a view to identifying measures that might mitigate the effects of explosive devices and improve the tolerance of the aircraft structure and systems to explosive damage.

3. CONCLUSIONS

(a) Findings

(i) The crew were properly licenced and medically fit to conduct the flight.

(ii) The aircraft had a valid Certificate of Airworthiness and had been

maintained in compliance with the regulations.
(iii) There was no evidence of any defect or malfunction in the aircraft that could have caused or contributed to the accident.
(iv) The structure was in good condition and the minimal areas of corrosion did not contribute to the in-flight disintegration.
(v) One minor fatigue crack approximately 3 inches long was found in the fuselage skin but this had not been exploited during the disintegration.
(vi) An improvised explosive device detonated in luggage container serial number AVE 4041 PA which had been loaded at position 14L in the forward hold. This placed the device approximately 25 inches inboard from the skin on the lower left side of the fuselage at station 700.
(vii) The analysis of the flight recorders, using currently accepted techniques, did not reveal positive evidence of an explosive event.
(viii) The direct explosive forces produced a large hole in the fuselage structure and disrupted the main cabin floor. Major cracks continued to propagate from the large hole under the influence of the service pressure differential.
(ix) The indirect explosive effects produced significant structural damage in areas remote from the site of the explosion.
(x) The combined effect of the direct and indirect explosive forces was to destroy the structural integrity of the forward fuselage.
(xi) Containers and items of cargo ejected from the fuselage aperture in the forward hold, together with pieces of detached structure, collided with the empennage severing most of the left tailplane, disrupting the outer half of the right tailplane, and damaging the fin leading edge structure.
(xii) The forward fuselage and flight deck area separated from the remaining structure within a period of 2 to 3 seconds.
(xiii) The No 3 engine detached when it was hit by the separating forward fuselage.
(xiv) Most of the remaining aircraft disintegrated while it was descending nearly vertically from 19,000 to 9,000 feet.
(xv) The wing impacted in the town of Lockerbie producing a large crater and creating a fireball.

(b) Cause

The in-flight disintegration of the aircraft was caused by the detonation of an improvised explosive device located in a baggage container positioned on the left side of the forward cargo hold at aircraft station 700.

4. SAFETY RECOMMENDATIONS

The following Safety Recommendations were made during the course of the investigation :

4.1 That manufacturers of existing recorders which use buffering techniques give consideration to making the buffers non-volatile, and the data recoverable after power loss.

4.2 That Airworthiness Authorities re-consider the concept of allowing buffered data to be stored in a volatile memory.

4.3 That Airworthiness Authorities consider requiring the CVR system to contain a short duration, i.e. no greater than 1 minute, back-up power supply to enable the CVR to respond to events that result in the almost immediate loss of the aircraft's electrical power supply.

4.4 That the Department of Transport fund a study to devise methods of recording violent positive and negative pressure pulses, preferably utilising the aircraft's flight recorder systems.

4.5 That Airworthiness Authorities and aircraft manufacturers undertake a systematic study with a view to identifying measures that might mitigate the effects of explosive devices and improve the tolerance of aircraft structure and systems to explosive damage.

APPENDIX A

PERSONNEL CONDUCTING THE INVESTIGATION

The following Inspectors of the Air Accidents Investigation Branch conducted the investigation:

Mr M M Charles — Investigator-in-Charge

Mr D F King — Principal Inspector (Engineering)

Mr P F Sheppard

Assistant Principal Inspector (Engineering)

Mr A N Cable

Senior Inspector (Engineering)

Mr R G Carter

Senior Inspector (Engineering)

Mr P T Claiden

Senior Inspector (Engineering)

Mr P R Coombs

Senior Inspector (Engineering)

Mr S R Culling

Senior Inspector (Engineering)

Miss A Evans

Senior Inspector (Engineering)

Mr B M E Forward

Senior Inspector (Operations)

Mr P N Giles

Senior Inspector (Operations)

Mr S W Moss

Senior Inspector (Engineering)

Mr R Parkinson

Senior Inspector (Engineering)

Mr J D Payling

Senior Inspector (Operations)

Mr C G Pollard

Senior Inspector (Engineering)

Mr C A Protheroe

Senior Inspector (Engineering)

Mr A H Robinson

Senior Inspector (Engineering)

Mr A P Simmons

Senior Inspector (Engineering)

Mr R G Vance

Senior Inspector (Engineering)

Mr R StJ Whidborne

Senior Inspector (Operations)

The Air Accidents Investigation Branch would like to thank the following organisations from the United Kingdom, United States of America, France, and Canada who participated in the investigation:

Air Line Pilot's Association International

Boeing Commercial Airplane Company

British Airways

British Army

British Geological Survey

Bureau Enquete Accidents

Canadian Aviation Safety Bureau

Civil Aviation Authority

Cranfield Institute of Technology

Federal Aviation Administration

Federal Bureau of Investigation

Independent Union of Flight Attendants

National Transportation Safety Board

Pan American World Airways

Police Service

Royal Aerospace Establishment

Royal Air Force

Royal Armaments Research and Development Establishment

Royal Navy

Royal Ordnance

Royal Signals and Radar Establishment

United Technologies International Operations (Pratt and Whitney)

The Air Accidents Investigation Branch would also like to acknowledge the excellent work of the Dumfries & Galloway Regional Council and to thank all the many voluntary organisations who gave such unstinting support to the investigation.

APPENDIX C

ANALYSIS OF RECORDED DATA

1. Introduction

This appendix describes and analyses the different types of recorded data which were examined during the investigation of the accident to Boeing 747 registration N739PA at Lockerbie on 21 December 1988.
The recorded data consists of that from the Cockpit Voice Recorder (CVR), the Digital Flight Data Recorder (DFDR), Air Traffic Control (ATC) radio telephony (RTF), ATC radar, and British Geological Survey seismic records. The time correlation of the records is also discussed.

2. Digital flight data recorder

The flight data recorder installation conformed to ARINC 573B standard with a Lockheed Model 209 DFDR receiving data from a Teledyne Controls Flight Data Acquisition Unit (FDAU). The system recorded 22 analogue parameters and 27 discrete (event) parameters. The flight recorder control panel was located in the flight deck overhead panel. The FDAU was in the main equipment centre at the front end of the forward hold and the flight recorder was mounted in the aft equipment centre.

2.1 DFDR strip and examination

Internal inspection of the DFDR showed that there was considerable disruption to the control electronics circuits. The crash protection was removed and the plastic recording tape was found detached from its various guide rollers and tangled in the tape spools. There was no tension in the negator springs. This indicated that the tape had probably moved since electrical power was removed from the recorder. The position of the tape in relation to the record/replay heads was marked with a piece of splicing tape in order to quantify the movement. To ensure that no additional damage was caused to the tape it was necessary to cut the negator springs to separate the upper and lower tape reels.

The crinkling and stretching of the tape and the damage to the control electronics meant that the tape had to be replayed outside the recorder. AAIB experience has shown that the most efficient method of replaying stretched Lockheed recorder tapes is to re-spool the tape into a known serviceable recorder, in this case a Plessey 1584G.

2.2 DFDR replay

The 25 hour duration of the DFDR was satisfactorily replayed. Data relating to the accident flight was recorded on track 2. The only significant defect in the recording system was that normal acceleration was inoperative. There was one area on the tape, 2 minutes from the end, where data synchronisation was lost for 1 second.

Decoding and reduction of the data from the accident flight showed that no abnormal behaviour of the data sensors had been recorded. The recorded data simply stopped. Figure C-1 is a graphical representation of the main flight parameters.

2.3 DFDR analysis

In order to ensure that all recorded data from the accident flight had been decoded and to examine the quality of the data at the end of the recording, a section of tape, including both the most recently recorded data and the oldest data (data from 25 hours past), was replayed through an ultra-violet (UV) strip recorder. The data was also digitised and the resulting samples used to reconstruct the tape signal on a VDU.

Both methods of signal representation were used to determine the manner by which the recorder stopped. There was no gap between the most recently recorded data and the 25 hour old data. This showed that the recorder stopped while there was an incoming data stream from the FDAU. The recorder, therefore, stopped because its electrical supply was disconnected. The tape signal was examined for any transients or noise signals that would have indicated the presence of electrical disturbances prior to the recorder stopping. None was found and this indicated that there had been a quick clean break of the electrical supply.

The last seconds of data were decoded independently using both the UV record and the digitised signal. Only 17 bits of data were not recoverable (less that 23 milliseconds) and it was not possible to establish with any certainty if this data was from the accident flight or if it was old data from a previous recording.

A working group of the European Organisation for Civil Aviation Electronics (EUROCAE) was, during the period of the investigation, formulating new standards (Minimum Operational Performance Requirement for Flight Data Recorder Systems, Ref:- ED55) for future generation flight recorders which would have permitted delays between parameter input and recording (buffering) of up to ? second. These standards are intended to form the basis of new CAA specifications for flight recorders and may be adopted worldwide.

The analysis of the final data recorded on the DFDR was possible because the system did not buffer the incoming data. Some existing recorders use a process whereby data is stored temporarily in a memory device (buffer) before recording. The data within this buffer is lost when power is removed from the recorder and in currently designed recorders this may mean that up to 1.2 seconds of final data contained within the buffer is lost. Due to the necessary processing of the signals prior to input to the recorder, additional delays of up to 300 milliseconds may be introduced. If the accident had occurred when tha aircraft was over the sea, it is very probable that the relatively few small items of structure, luggage and clothing showing positive evidence of the detonation of an explosive device would not have been recovered. However, as flight recorders are fitted with underwater location beacons, there is a high probability that they would have been located and recovered. In such an event the final milliseconds of data contained on the DFDR could be vital to the successful determination of the cause of an accident whether due to an explosive device or other catastrophic failure. Whilst it may not be possible to reduce some of the delays external to the recorder, it is possible to reduce any data loss due to buffering of data within the data acquisition unit.

It is, therefore, recommended that manufacturers of existing recorders which use buffering techniques give consideration to making the buffers non-volatile, and hence recoverable after power loss. Although the recommendation on this aspect, made to the EUROCAE working group during the investigation, was incorporated into ED55, it is also recommended that Airworthiness Authorities re-consider the concept of allowing buffered data to be stored in a volatile memory.

3. Cockpit voice recorder (CVR)

The aircraft was equipped with a 30 minute duration 4 track Fairchild Model A100 CVR, and a Fairchild model A152 cockpit area microphone (CAM). The CVR control panel containing the CAM was located in the overhead panel on the flight deck and the recorder itself was mounted in the aft equipment centre.

The channel allocation was as follows:-

Channel 1	Flight Engineer's RTF.
Channel 2	Co-Pilot's RTF.
Channel 3	Pilot's RTF.
Channel 4	Cockpit Area Microphone.

3.1 CVR strip and examination

To gain access to the recording tape it was necessary to cut away the the outer case and saw through part of the crash protected enclosure. No damage to the tape transport or the recording tape was found. The endless loop of tape was cut and the tape transferred to the replay equipment. The electronic modules in the CVR were crushed and there was evidence of long term overheating of the dropper resistors on the power supply module. The CAM had been crushed breaking internal wiring and damaging components on the printed circuit board.

3.2 CVR replay

The erase facility within the CVR was not functioning satisfactorily and low level communications from earlier recordings was audible on the RTF channels. The CAM channel was particularly noisy, this was probably due to the combination of the inherently noisy cockpit of the B747-100 in the climb and distortion from the incomplete erasure of the previous recordings. On two occasions the crew had difficulty understanding ATC, possibly indicating high cockpit noise levels. There was a low frequency sound present at irregular intervals on the CAM track but the source of this sound could not be identified as of either acoustic or electrical in origin.

The CVR tape was listened to for its full duration and there was no indication of anything abnormal with the aircraft, or unusual in crew behaviour. The tape record ended with a sudden loud sound on the CAM channel followed almost immediately by the cessation of recording. The sound occurred whilst the crew were copying their transatlantic clearance from Shanwick ATC.

3.3 Analysis of the CVR record

3.3.1 The stopping of the recorder

To determine the mechanism that stopped the recorder a bench test rig was constructed utilizing an A100 CVR and an A152 CAM. Figures C-2 to C-5 show the effect of shorting, earthing or disconnecting the CAM signal wires. Figure C-8 shows the CAM channel signal response to the event which occurred on Flight PA103. From this it can be seen that there are no characteristic transients similar to those caused by shorting or earthing the CAM signal wires. Neither does the signal stop cleanly and quickly as shown in Figure C-5, indicating that the CAM signal wires were not interrupted. The UV trace shows the recorded signal decaying in a manner similar to that shown in Figure C-6, which demonstrates the effect of disconnecting electrical power from the recorder. The tests were repeated on other CVRs with similar results and it is therefore concluded that Flight PA103's CVR stopped because its electrical power was removed.

Figures C-9A to C-9D show the recorded signals for the Air India B747 (AI 182) accident in the North Atlantic on 23 June 1985. These show that there is a large transient on the CAM track indicating earthing or shorting of the CAM signal wires and that recorder power-down is more prolonged, indicating attempts to restore the electrical power supply either by bus switching or healing of the fault. The Flight PA103 CVR shows no attempts at power restoration with the break being clean and final.

In order to respond to events that result in the almost immediate loss of the aircraft's electrical power supply it was therefore recommended during the investigation that the regulatory authorities consider requiring CVR systems to contain a short duration (i.e. no greater than 1 minute) back-up power supply.

3.3.2 Information concerning the event

Figure C-8 is an expanded UV trace of the final milliseconds of the CVR record. Three tracks have been used, the flight engineer's RTF channel which contained similar information to the P2's channel has been replaced with a timing signal. Individual sections of interest are identified by number. On the bottom trace, the P1 RTF track, section 1 is part of the Shanwick transatlantic clearance. During this section the loud sound on the CAM channel is evident.

Examination of the DFDR event recordings shows that the Shanwick oceanic clearance was being received on VHF2, the aerial for which is on the underside of the fuselage close to the seat of the explosion.
Section 2 identifies a transient, on the P1 channel, typical of an end of ATC transmission transient for this CVR. The start and finish of most of the recorded ATC transmissions were analysed and they produce a similar signature to the three shown in Figure C-10. The signature on the P1 channel more closely resembles the end of transmission signature and it is open to conjecture that this transient was caused by the explosion damaging the aerial feeder and/or its supporting structure.

Section 3 shows what is considered to be a high speed power supply transient which is evident on all the RTF channels and is probably on the CAM channel, but cannot be identified because of the automatic gain control (AGC), limiting the audio event. This transient is considered to coincide with the loss of electrical power to the CVR. Section 5 identifies the period to the end of recording and this agrees well with tests carried out by AAIB and independently by Fairchild as part of the AI 182 investigation. The typical time from removal of the electrical supply until end of recording is 110 milliseconds.

During the period identified as section 4 it is considered that the disturbances on the RTF channels are electrical transients probably channelled through the communications equipment. Section 6 identifies the 170 millisecond period from the point when the sound was first heard on the CAM until the recording stopped.

The CAM unit is of the old type which has a frequency response of 350 to 3500 Hz. The useable duration of the signal is probably confined to the first 60 milliseconds of the final 170 milliseconds and even during this period the AGC is limiting the signal. In the remaining time the sound is being distorted because power to the recorder has been disconnected. The ambient cockpit noise may have been high enough to have caused the AGC to have been active prior to the event and in this event the full volume of the sound would not be audible. Distortion from the incomplete erasure of the last recording may form part of the recorded signal.

It is not clear if the recorded sound is the result of the explosion or is from the break-up of the aircraft structure. The short period between the beginning of the event and the loss of electrical power suggests that the latter is more likely to be the case.

Additionally some of the frequencies present on the recording were not present in the original sound, but are the result of the rise in total harmonic distortion caused by the increased amplitude of the incoming signal. Outputs from a frequency analysis of the recorded signal for the same frequency of input to the CVR, but at two input amplitudes, are shown in Figures C-11 and C-12. These illustrate the effects on harmonic distortion as the signal level is increased. Finally the recorded signal does not lend itself to analysis by a digital spectrum analyser as it is, in a large measure, aperiodic and most digital signal analysis algorithms are unable to deal with a short duration signal of this type, however, it is hoped that techniques being developed in Canada will enable more information to be deduced from the end of the recording.

In the aftermath of the Air India Boeing 747 accident (AI 182) in the North Atlantic on 23 June 1985 the Royal Armaments Research and Development Establishment (RARDE) were asked informally by AAIB to examine means of differentiating, by recording violent cabin pressure pulses, between the detonation of an explosive device within the cabin (positive pulse) and a catastrophic structural failure (negative pulse). Following the Lockerbie disaster it was considered that this work should be raised to a formal research project. Therefore, in February 1989, it was recommended that the Department of Transport fund a study to devise methods of recording violent positive and negative pressure pulses, preferably utilising the aircraft's flight recorder systems.

Preliminary results from these trials indicates that if a suitable sensor can be developed its output will need to be recorded in real time and therefore it may require wiring into the CVR installation. This will further strengthen the requirement for battery back up of the CVR electrical power supply.

4. Flight recorder electrical system

4.1 CVR/DFDR electrical wiring.

The flight recorders were located in the left rear fuselage just forward of the rear pressure bulkhead. Audio information to the CVR ran along the left hand side of the aircraft, at stringer 11. Electrical power to the CVR followed a similar route on the right hand side of the aircraft crossing to the left side above the rear passenger toilets. DFDR electrical power and signal information followed the same route as the CVR audio information.

4.2 Flight recorder power supply

The DFDR, CVR and the transponders were all powered from the essential alternating current (AC) bus. This bus was capable of being powered by any generator, however, in normal operation the selector switch on the flight engineers panel is selected to "normal" connecting the essential bus to number 4 generator. When the cockpit of Flight PA103 was examined the selector switch was found in the normal position.

4.3 Aircraft alternating current power supplies

AC electrical power to the aircraft was provided by 4 engine driven generators, see Figure C-13. Each generator was driven at constant speed through a constant speed drive (CSD) and connected to a separate bus-bar through a generator control breaker (GCB). The 4 generators were connected to a parallel bus-bar (sync bus) by individual bus tie breakers (BTBs). Control and monitoring of the AC electrical system was achieved through the flight engineer's instrument panel. In normal operation the generators operated in parallel, i.e with the BTBs closed.

4.4 Fault conditions

Analysis of the CVR CAM channel signal indicated that approximately 60 milliseconds after the sound on the CAM channel an electrical transient was recorded on all 4 channels and that approximately 110 milliseconds later the CVR had ceased recording. Within the accuracy of the available timing information it is believed that the incoming VHF was lost at the same time, indicating an AC power supply fault.

The AC electrical system was protected from faults in individual systems or equipment by fuses or circuit breakers. Faults in the generators or in the distribution bus-bars and feeders were dealt with automatically by opening of the GCBs and opening or closing of the BTBs. In the event of fault conditions causing the disconnection of all 4 generators electrical power for essential services, including VHF radio, was provided by a battery located in the cockpit.

The short time interval of 55 milliseconds after which the AC supply to the flight recorders was lost limits the basis on which a fault path analysis of the AC electrical system can be undertaken. On the available information only a differential (feeder) fault could have isolated the bus-bar this quickly, with the generator field control relay taking 20 milliseconds to trip. However, in normal operation, the generators would have been operating in parallel and the essential AC bus-bar would have been supplied via the number 4 BTB from the sync bus. If the fault conditions had continued, a further 40 to 100 milliseconds would have elapsed before the BTB opened. If the BTB was open prior to the fault it would have attempted to close and restore the supply to the essential bus. Any automatic switching causes electrical transients to appear on the CVR and data losses on the FDR. Both the CVR and the FDR indicate that a clean break of the AC supply occurred with no electrical transients associated with BTBs open or closing in an attempt to restore power. In the absence of any additional information only two possibilities are apparent:

i) That all 4 generators were simultaneously affected causing a total loss of AC electrical power. The feeders for the left and right side generators run on opposite sides of the aircraft under the passenger cabin floor. The only situation envisaged that could cause simultaneous loss of all 4 generators is the disruption of the passenger cabin floor across its entire width.

ii) That disruption of the main equipment centre, housing the control units for the AC electrical system, caused the loss of all AC power. However, again it would have to affect both the left and right sides of the aircraft as the control equipment is located at left and right extremes of the main equipment centre.

The nature of the event may also produce effects that are not understood. It is also to be noted that a sudden loss of electrical power to the flight recorders has been reported in other B747 accidents, e.g. Air India, AI 182.

5. Seismic data

The British Geological Survey has a number of seismic monitoring stations in Southern Scotland. Stations close to Lockerbie recorded a seismic event caused by the wing section crashing on Lockerbie. The seismic monitors are time correlated with the British Telecom Rugby standard. Using this and calculating the time for the various waves to reach the recording stations it was possible for the British Geological Survey to conclude that the event occurred at 19.03:36.5 hrs ± 1 second.

Attempts were made to correlate various smaller seismic events with other wreckage impacts. However, this was not conclusive because the nearest recording station was above ground and due to the high winds at the time of the accident had considerable noise on the trace. In addition, little of the other wreckage had the mass or impact velocity to stimulate the sensors.

6. Time correlation

6.1 Introduction

The sources of each time encoded recording were asked to provide details of their time standard and any known errors in the timings on their recordings. Although the resolution of the recorded time sources is high it was not possible to attach an accuracy of better than ±1 second due to possible errors in synchronising the recorded time with the associated standard. The following time sources were available and used in determining the significant events in the investigation:-

i) ATC

ATC communications were recorded along with a time signal. The time source for the ATC tape was the British Telecom "Tim" signal. Any error in setting the time when individual tapes are mounted was logged.

ii) Recorded rada data

A time signal derived from the British Telecom "Rugby" standard was included on radar recordings. The Rugby and Tim times were assumed to be of equal accuracy for timing purposes.

iii) The DFDR had UTC recorded.

The source of this time was the flight engineer's clock. This clock was set manually and therefore this time was subject to a significant fixed error as well any inaccuracy in the clock.

iv) The CVR had no time signal.

However, the CVR was correlated with the ATC time through the RTF and with the DFDR, by correlating the press to talk events on the FDR with the press to talk signature on the CVR.

v) Seismic recordings

Seismic recordings included a timing signal derived from the British Telecom Rugby standard.

6.2 Analysis and correlation of times

The Scottish and Shanwick ATC tapes were matched with each other and with the CVR tape. The CVR recording speed was adjusted by peaking its recorded 400 Hz AC power source frequency. This correlation served as a double check on any fixed errors on the ATC recordings and to fix events on the CVR to UTC. The timing of the sound on the CAM channel of the CVR was made simpler because Shanwick was transmitting when it occurred. From this it was possible to determine that the sound on the CVR occurred at 19.02:50 hrs ±1 second.

With the CVR now tied to the Tim standard it was possible to match the RTF keying on the CVR with the RTF keying events on the FDR. These events on the FDR were sampled and recorded once per second, it was therefore possible for a 1 second delay to be present on the FDR. This potential error was reduced by obtaining the best fit between a number of RTF keyings and a time correlation between the

FDR and CVR of ±? second was achieved. From this it was determined, within this accuracy, that electrical power was removed from the CVR and FDR at the same time.

From the recorded radar data it was possible to determine that the last recorded SSR return was at 19.02:46.9 hrs and that by the next rotation of the radar head a number of primary returns, some left and right of track, were evident. Time intervals between successive rotations of the radar head became more difficult to use as the head painted more primary returns.

The point at which aircraft wreckage impacted Lockerbie was determined using the time recorded by seismic activity detectors. A seismic event measuring 1.6 on the Richter scale was detected and, with appropriate time corrections for times of the waves to reach the sensors, it was established that this occurred at 19.03:36.5 hrs ±1 second. A further check was made by triangulation techniques from the information recorded by the various sensors.

7. Recorded radar information

7.1 Introduction

Recorded radar information on the aircraft was available from from 4 radar sites. Initial analysis consisted of viewing the recorded information as it was shown to the controller on the radar screen, from this it was clear that the flight had progressed in a normal manner until Secondary Surveillance Radar (SSR) was lost. There was a single primary return received by both Great Dun Fell and Claxby radars approximately 16 seconds before SSR returns were lost. The Lowther Hill and St. Annes radars did not see this return. The Great Dun Fell radar recording was watched for 1 hour both before and after this single return for any signs of other spurious returns, but none was seen. The return was only present for one paint and no explanation can be offered for its presence.

7.2 Limitations of recorded radar data

Before evaluating the recorded radar data it is important to highlight limitations in radar performance that must be taken into account when interpreting primary radar data. The radar system used for both primary and secondary radar utilised a rotating radar transmitter/receiver (Head). This means that a return was only visible whilst the radar head was

pointing at the target, commonly called painting or
illuminating the target. In the case of this accident the rotational speeds of the radar heads varied from approximately 10 seconds for the Lowther Hill Radar to 8 Seconds for the Great Dun Fell Radar.

Whilst it was possible to obtain accurate positional information within a resolution of 0.09¡ of bearing and ± 1/16 nautical mile range for an aircraft from SSR, incorporating mode C height encoding, primary
radar provided only slant range and bearing and therefore positional information with respect to the ground was not accurate.

The structural break-up of an aircraft releases many items which were excellent radar reflectors eg. aluminium cladding, luggage containers, sections of skin and aircraft structure. These and other debris with
reflective properties produce "clutter" on the radar by confusing the radar electronics in a manner similar to chaff ejected by military aircraft to avoid radar detection.

Even when the target is not masked by clutter repetitive detection of individual targets may not be possible because detection is a function of the target effective area which, for wreckage with its irregular
shape, is not constant but fluctuates wildly. These factors make it impossible to follow individual returns through successive sweeps of the radar head.

7.3 Analysis of the radar data

The detailed analysis of the radar information concentrated on the break-up of the aircraft. The Royal Signals and Radar Establishment (RSRE) corrected the radar returns for fixed errors and converted the
SSR returns to latitude and longitude so that an accurate time and position for the aircraft could be determined. This information was correlated with the CVR and ATC times to establish a time and position
for the aircraft at the initial disintegration.

For the purposes of this analysis the data from Great Dun Fell Radar has been presented. Figures C-14 to C-23 show a mosaic picture of the radar data i.e. each figure contains the information on the preceding
figure together with more recently recorded information. Figure C-14 shows the radar returns from an aircraft tracking 321¡(Grid) with a calculated ground speed of 434 kts. Reading along track (towards the
top left of Figure C-14) there are 6 SSR returns with the sixth and final SSR return shown decoded: squawk code 0357 (identifying the aircraft as

N739PA); mode C indicating FL310; and the time in seconds (68566.9 seconds from 00:00, i.e. 19.02:46.9 hrs).

At the next radar return there is no SSR data, only 4 primary returns. One return is along track close to the expected position of the aircraft if it had continued at its previous speed and heading. There are 2 returns to the left of track and 1 to the right of track. Remembering the point made earlier about clutter, it is unlikely that each of these returns are real targets. It can, however, be concluded that the aircraft is no longer a single return and, considering the approximately 1 nautical mile spread of returns across track, that items have been ejected at high speed probably to both right and left of the aircraft. Figure C-15 shows the situation after the next head rotation. There is still a return along track but it has either slowed down or the slant range has decreased due to a loss of altitude.

Each rotation of the radar head thereafter shows the number of returns increasing with those first identified across track in Figure C-14 having slowed down very quickly and followed a track along the prevailing wind line. Figure C-20 shows clearly that there has been a further break-up of the aircraft and subsequent plots show a rapidly increasing number of returns, some following the wind direction and forming a wreckage trail parallel to and north of the original break-up debris. Additionally it is possible that there was some break-up between these points with a short trail being formed between the north and south trails. From the absence of any returns travelling along track it can be concluded that the main wreckage was travelling almost vertically downwards for much of the time.

The geographical position of the final secondary return at 19.02:46.9 hrs was calculated by RSRE to be OS Grid Reference 15257772, annotated Point A in Appendix B, Figure B-4, with an accuracy considered to be better than ±300 metres This return was received 3.1±1 seconds before the loud sound was recorded on the CVR at 19.02:50 hrs. By projecting from this position along the track of 321¡(Grid) for 3.1±1 seconds at the groundspeed of 434 kts, the position of the aircraft was calculated to be OS Grid Reference 14827826, annotated Point B in Appendix B, Figure B-4, within an accuracy of ±525 metres. Based on the evidence of recorded data only, Point B therefore represents the geographical position of the aircraft at the moment the loud sound was recorded on the CVR.

8. Conclusions

The almost instant destruction of Flight PA103 resulted in no direct evidence on the cause of the accident being preserved on the DFDR. The CVR CAM track contained a loud sound 170 milliseconds before recording ceased. Sixty milliseconds of this sound were while power was applied to the recorder; after this period the amplitude decreased. It cannot be determine whether the decrease was because of reducing recorder drive or if the sound itself decreased in amplitude. Analysis of both flight recorders shows that they stopped because the electrical supply was removed and that there were valid signals available to both recorders at that time.

The most important contribution to the investigation that the flight recorders could make was to pinpoint the time and position of the event. As the timescale involved was so small in relation to the resolution and accuracy of many of the recorded time sources it was necessary to analyse collectively all the available recordings. From the analysis of the CVR, DFDR, ATC tapes, radar data and the seismic records it was concluded that the loud sound on the CVR occurred at 19.02:50 hrs ±1 second and wreckage from the aircraft crashed on Lockerbie at 19.03:36.5 hrs ±1 second, giving a time interval of 46.5 ±2 seconds between these two events. When the loud sound was recorded on the CVR, the geographical position of the aircraft, based on the evidence of recorded data, was calculated to be within 525 metres of OS Grid Reference 14827826.

Eight seconds after the sound on the CVR the Great Dun Fell radar showed 4 primary radar returns. The returns indicated a spread of wreckage in the order of 1 nautical mile across track. On successive returns of the radar, two parallel wreckage trails are seen to develop with the second trail, to the north, becoming evident 30 to 40 seconds after the first.

APPENDIX D

CRITICAL CRACK CALCULATIONS

It was assumed that the fuselage rupture and associated star-burst petalling process was driven by an expanding 'bubble' of high pressure gas, produced by the conversion of solid explosive material into gas products. As the explosive gas pressures reduced due to dissipation through the structure and external venting, the service differential pressure loading would have taken over from the explosive pressures as the principal force driving the skin fractures.

The high temperature gas would initially have been confined within the container where, because of the low volume, the pressure would have been extremely high (too high for containment) and the gas bubble would have expanded violently into the cavities of the fuselage between the outer skin and the container. This gas bubble would have continued to expand, with an accompanying fall in pressure due to the increasing volume combined with a corresponding drop in temperature.

The precise nature of the gas expansion process could not be determined directly from the evidence and it was therefore necessary to make a number of assumptions about its behaviour, based on the geometry of the hull and the area of fuselage skin which the high pressure bubble would have ruptured. Essentially, it was assumed that the gas bubble would expand freely in the circumferential direction, into the cavity between the fuselage skin and the container. In contrast, the freedom for the bubble to expand longitudinally would have been restricted by the presence of the fuselage frames, which would have partially blocked the passage of gas in the fore and aft directions. However, the pressures acting on the frames would have been such that they would have buckled and failed, allowing the gas to vent into the next 'bay', producing failure of the next frame. This sequential frame-failure process would have continued until the pressure had fallen to a level which the frames could withstand. During the period of frame failure and the associated longitudinal expansion of the gas bubble, this expansion rate was assumed to be half that of the circumferential rate.

It was assumed that venting would have taken place through the ruptured skin and that the boundary of the petalled hole followed behind the expanding gas bubble, just inside its outer boundary, i.e. the expanding gas bubble would have stretched and 'unzipped' the skins as it expanded. This process would have continued until the gas bubble had expanded/vented to a level where the pressure was no longer able to drive the petalling mechanism because the skin stresses had reduced to below the natural strength of the material.

The following structural model was assumed:

(i)

The pressurised hull was considered to be a cylinder of radius 128 inches, divided into regular lengths by stiff frames.

(ii)

The contributions of the stringers and frames beyond the petalled region were considered to be the equivalent of a reduction of stress in the skins by 20%, corresponding to an increase in skin thickness from 0.064 inches to 0.080 inches.

(iii)

Standing skin loads were assumed to be present due to the service differential pressure, i.e.. it was assumed that no significant venting of internal cabin pressure occurred within the relevant timescale.

(iv)

The mechanism of bubble pressure load transfer into the skins was:

a)

Hoop direction -conventional membrance reaction into hoop stresses

b)

Longitudinal direction - reaction of pressures locally by the frames, restrained by the skins.

The critical crack calculations were based upon the generalised model of a plate under biaxial loading in which there was an elliptical hole with sharp cracks emanating from it. This is a good approximation of the initial condition, i.e.. the shattered hole, and an adequate representation of the subsequent phase, when the hole was enlarging in its star-burst, petalling, mode.

The analyses of critical crack dimensions in the circumferential and longitudinal directions were based on established Fracture Resistance techniques. The method utilises fracture resistance data for the material in question to establish the critical condition at which the rate of energy released by the crack just balances the rate of energy absorbed by the material in the cracking process, i.e. the instantaneous value of the parameter Kr, commonly referred to as the fracture toughness Kc. From this, the relationship between critical stress and crack length can be determined.

Using conventional Linear Elastic Fracture Mechanics (LEFM) with fracture toughness data from RAE experimental work and published geometric factors relating to cracks emanating from elliptical holes,
the stress levels required to drive cracks of increasing lengths in both circumferential and longitudinal directions were calculated. The skin stresses at sequential stages of the expanding gas bubble/skin
petalling process were then calculated and compared with these data.

The results of the analysis indicated that, once the large petalled hole had been produced by explosive gas overpressure, the hoop stresses generated by fuselage pressurisation loads acting alone would have
been sufficient to drive cracks longitudinally for large distances beyond the boundaries of the petalled hole. Thus, with residual gas overpressure acting as well, the 43 feet (total length) longitudinal fractures
observed in the wreckage are entirely understandable. The calculations also suggested that the hoop fractures, due to longitudinal stresses in the skins, would have extended beyond the boundary of the petalled
hole, though the excess stress driving the fractures in this direction would have been much smaller than for the longitudinal fractures, and the level of uncertainty was greater due to the difficulty of producing
an accurate model reflecting the diffusion of longitudinal loads into the skins. Nevertheless, the results suggested that the circumferential cracks would extend downwards just beyond the keel, and upwards as
far as the window belt - conclusions which accord reasonably well with the wreckage evidence.

APPENDIX E

POTENTIAL REMEDIAL MEASURES

1. Introduction

In the following discussion, those damage mechanisms which appear to have contributed to the catastrophic structural failure of Flight PA103 are identified and possible ways of reducing their damaging
effects are suggested. These suggestions are intended to stimulate thought and discussion by manufacturers, airworthiness authorities, and others having an interest in finding solutions to the problem; they are
intended to serve as a catalyst rather than to lay claim to a definitive solution. On the basis of the Flight PA103 investigation, damage is likely to fall into two categories: direct explosive damage, and indirect

explosive damage.

2. Direct explosive damage

The most serious aspect of the direct explosive damage on the structure is the large, jagged aperture in the pressure hull, combined with frame and stringer break-up, which results from the star-burst rupture of the fuselage skin. Because of its uncontrolled size and position, and the naturally radiating cracks which form as part of the petalling process, the skin's critical crack length (under pressurisation loading) is likely to be exceeded, resulting in unstable crack propagation away from the boundary of the aperture. Such cracks can lead to a critical loss of structural integrity at a time when additional loads are likely to be imposed on the structure due to reflected blast pressure and/or aircraft aerodynamic and inertial loading.

A further complicating factor is that the size of this aperture is likely to be sufficiently large to allow complete cargo containers and other debris to be ejected into the airstream, with a high probability of causing catastrophic structural damage to the empennage.

3. Indirect explosive damage

Indirect explosive damage (channelling or ducting of explosive energy in the form of both shock waves and supersonic gas flows) is likely to occur because of the network of interlinked cavities which exist, in various forms, in all large commercial aircraft, particularly below cabin floor level. This channeling mechanism can produce critical damage at significant distances from the source of the explosion.

In addition to the structural damage, aircraft flight control and other critical systems will potentially be disrupted, both by the explosive forces and as a result of structural break-up and distortions. The discussion which follows focuses on possible means of limiting structural damage of the kind which occurred on Flight PA103. Undoubtedly, such measures will also have beneficial effects in limiting systems damage. However, system vulnerability can further be reduced by applying, wherever possible, those techniques used on military aircraft to reduce vulnerability to battle damage; multiplexed, multiply redundant systems using distributed hardware to minimise risk of a single area of damage producing major system disruption. Fly by wire flight control systems potentially offer considerable scope to achieve these goals, but the same distributed approach would also be required for the electronic and other equipment which, in current aircraft, tends to be concentrated into a small number of 'equipment centres'.

4. Remedial measures to reduce structural damage

Whilst pure containment of the explosive energy is theoretically possible, in an aviation context such a scheme would not be viable. Any unsuccessful attempt to contain the explosive will probably produce greater devastation than the original (uncontained) explosion since all the explosive energy would merely be stored until the containment finally ruptured, when the stored energy would be released together with massive fragmentation of the containment.

However, a mixed approach involving a combination of containment, venting, and energy absorption should provide useful gains provided that a systematic rather than piecemeal approach is adopted, and that the scheme also addresses blast channelling. The following scheme is put forward for discussion, primarily as means of identifying, by example, how the various elements of the problem might be approached at a conceptual level and to provide a stimulus for debate. No detailed engineering solutions are offered, but it is firmly believed that the requirements of such a scheme could be met from a technical standpoint. The proposed scheme is based on the need to counter a threat similar to that involving Flight PA103, i.e. a high explosive device placed within a baggage container, however, the principles should be applicable to other aircraft types.

Such a scheme might comprise several 'layers' of defence. The first two layers, one within the other, are essentially identical and provide partial containment of the explosive energy and the redirection of blast out from the compartment via pre-determined vent paths. Although the containment is temporary, it must provide an effective barrier to uncontrolled venting, preventing the escape of blast except via the pre-designated paths.

The third layer comprises a pre-determined area of fuselage skin, adjoining the outer end of the vent path, designed to rupture or burst in a controlled manner, providing a large vent aperture which will not tend to crack or rupture beyond the designated boundaries.

A fourth layer of protection has two elements, both intended to limit the propagation of shock waves through the internal cavities in the hull. The first element comprises the closure of any gaps between the vent apertures in the two innermost containment layers and the vent aperture in the outer skin. This effectively provides an exhaust duct connecting the inner and outer vent apertures to minimise leakage into the intervening structure and cavities around the cargo hold. The second element comprises the incorporation of an energy absorbing lining material within all the cavities in the lower hull, to absorb shock energy, limit shock reflection and limit the propagation of pressure waves which might enter the cavities, for example because of containment layer breakthrough.

5 Possible application to Boeing 747 type aircraft

5.1 Container Modification

The obvious candidates for the inner containment layer are the baggage containers themselves. Existing containers are of crude construction, typically comprising aluminium sheet sides and top attached to an aluminium frame with a fabric reinforced access curtain, or have sides and top of fibreglass laminate attached to a robust aluminium base section.

These containers are stacked in the aircraft in such a manner that on three sides (except for the endmost containers) the baggage within the adjoining containers provides an already highly effective energy absorbing barrier. If the container is modified so that loading access is via the outboard side of the container rather than at the end, i.e. the curtain is put on the faces shown in Figure E-1, then only the top and base are 'unbacked' by other containers, leaving the outboard face as a vent region.

The proposal is therefore that a modified container is developed in which the access is changed from the end to the outside face only, and which is modified to improve the resistance to internal pressures and thus encourage venting via the new access curtain only. How the container is actually modified to achieve the containment requirement is a matter of detail design, but two approaches suggest themselves, both involving the use of composite type materials. The first approach is to adopt a scheme for a rigid container which relies on a combination of energy absorption and burst strength to prevent uncontrolled breakout of explosive energy. The second approach is to use a 'flexible' container, i.e. rigid enough for normal use, but sufficiently flexible to allow gross deformation of shape without rupture. This, particularly if used with a backing blanket made from high performance material to resist fragmentation, could deform sufficiently to allow the container to bear against, and partially crush, adjoining containers. In this way, the shock energy transmission should be significantly reduced and the inherent energy absorption capability and mass of the baggage in adjoining containers could be utilised, whilst still retaining the high pressure gas for long enough to allow venting via the side face. Clearly, care would need to be taken to ensure that the container vent aperture remained as undistorted as possible, to ensure minimal leakage at the interface.

5.2 Cargo bay liner

The existing cargo bay liner is a thin fibreglass laminate which lines the roof and sidewalls of the cargo hold. There is no floor as such; instead, the containers are supported on rails running fore and aft on the tops of the fuselage frame lower segments. In a number of areas, there are zipped fabric panels let into the liner to provide access to equipment located behind. The liner 'ceiling' is suspended on plastic pillars approximately 2 centimeters below the bottom of the main cabin floor beams. The purpose of the liner is solely to act as a general barrier to protect wiring looms and systems components.

The proposal is to produce a new liner designed to provide the second level of containment, essentially at 'floor' and 'roof' level only [Figure E-1]. The dimensional constraints are such that potentially quite thick material could be incorporated (leaving aside the weight problem), permitting not only a rigid liner design, but semi-rigid or flexible linings backed by energy absorbing blanket materials.

The liner would be designed to provide an additional barrier at the base and roof of the containers, which unlike the sides, are not protected by adjoining containers. The outside ends of these barrier elements must effectively seal against the vent apertures in the containers, to minimise leakage into the fuselage cavities.

5.3 Structural blow-out regions.

The final element in the containment/venting part of the scheme is a line of blow-out regions in the fuselage skins, coinciding exactly with the positions of the vent apertures in the cargo containers and cargo bay liner. These should extend along the length of the cargo hold, zoned in such a way that rupture due to rapid overpressure will occur in a controlled manner. The primary function of the blow-out regions would be to provide immediate pressure relief by allowing the inevitable skin rupture to take place only within pre-determined zones, limiting the extent of the skin tearing by means of careful stiffness control at the boundary of the blow-out regions.

The structural requirements of such panels are perhaps the most difficult challenge to meet, particularly for existing designs. However, it is believed that by giving appropriate consideration to the directionality of fastening strengths, and the use of external tear straps, it should be possible to design the structure to carry the normal service loads whilst creating a pre-disposition to rupturing in a controlled manner in response to gross pressure impulse loading.

The implementation of such features will need carefully balanced design in order to provide local stiffening, sufficient to control and direct the tear processes, without creating stiffness discontinuities which could lead to fatigue problems during extended service. However, the degree of reinforcement needed at the blow-out aperture need only be sufficient to limit tearing and to sustain the aircraft long enough to complete the flight unpressurised.

All aircraft have pre-existing strength discontinuities, despite the efforts of the designers to eliminate them. By choosing the positions of butt joints, lap joints, anti-tear straps and similar structural features in future designs, so as to incorporate them into the boundary of the blow-out panel region, the natural "tear here" tendencies of such features could possibly be turned to advantage. In the case of current generation aircraft, the positions of existing lines of weakness at such features will determine the optimum position for structural blow-out areas, and hence the positions of the container and cargo bay liner blow-out panels. A limited amount of local structural reinforcement (e.g. in the form of external anti-tear straps), carried out as part of a modification program, could perhaps fine tune the tearing properties of existing lines of weakness, potentially producing significant improvements.

5.4 Closure of cavities

There are four main classes of cavity which will need to be addressed on the Boeing 747, and most other modern aircraft. These are:

(i) The channels formed between fuselage frames

(ii) The cross-ship cavities between cabin floor beams

(iii) Longitudinal 'manifold' cavities on each side of the cargo deck, running fore and aft in the space behind the upper sidewall areas of the cargo bay liner.

(iv) Air conditioning vents along the bottom of the cabin side-liner panels, which connect the side cavities below cabin floor level with the main passenger cabin.

If the containment barriers (i.e. modified cargo containers and cargo hold liner) can be made to prevent blast breakthrough into these cavities directly, then the only area where transfer can occur is at the interface between the container/cargo hold liner vent apertures and the fuselage skins at the blow-out region. This short distance will need to be sealed in order to form a short 'exhaust duct' between the container vent aperture and the fuselage skin. Since the shock and general explosive pressure will act mainly along the vent-duct axis, the pressure loading on the vent duct walls should not be excessive.

5.5 Attenuation of shock waves in structural cavities

To prevent the 'ducting' of any blast which does enter the fuselage cavities, either because of partial penetration of the containment barriers or leakage at the vent duct interfaces, the scheme requires the provision of lightweight energy absorbing material within the cavities to limit reflection and propagation of pressure waves within the cavities, and radiation of shock waves into the cabin from the conditioning air vents. Materials such as vermiculite, which are of low density yet have excellent explosive energy absorption properties, may have application in this area, perhaps in lieu of the existing insulation material.

Since the existing cavities often serve as part of the air conditioning outflow circuit, some consideration will need to be given to finding an alternative route. However, the flow rates are small compared with the total cross-sectional flow potential of the cavities and this function could be served by separate air conditioning ducts, or perhaps by restricting access to

one or two cavities only (thus limiting the risk), or
by using some form of blast valve to close off the air conditioning vents. Similarly, the requirement to vent pressure from the cabin in the event of a cargo bay decompression would also need to be addressed.

APPENDIX F

BAGGAGE CONTAINER EXAMINATION, RECONSTRUCTION AND RELATIONSHIP TO THE AIRCRAFT STRUCTURE

1. Introduction

During the wreckage recovery operation it became apparent that some items, identified as parts of baggage containers, exhibited blast damage. It was confirmed by forensic scientists at the Royal Armaments Research and Development Establishment (RARDE), after detailed physical and chemical examination, that these items showed conclusive evidence of a detonating high performance plastic explosive. It was therefore decided to segregate identifiable container parts and reconstruct any that showed evidence from the effect of Improvised Explosive Device (IED). It was evident, from the main wreckage layout that the IED had been located in the forward cargo hold and, although all baggage container wreckage was examined, only items from the forward hold showing the relevant characteristics were considered for the reconstruction. This Appendix documents the reconstruction of two particular containers and, from their position within the forward fuselage, defines the location of the IED.

2 Container Arrangement

Information supplied by Pan Am showed that this aircraft had been loaded with 12 baggage containers and two cargo pallets in the forward hold located as shown in Figure F-1. Three containers were recorded as being of the glass fibre reinforced plastic type (those at positions 11L, 13L and 21L) with the remaining 9 being of metal construction.

3. Container Description

All the baggage containers installed in the forward cargo hold were of the LD3 type (lower deck container, half width - cargo) and designated with the codes AVE, for those constructed from aluminum alloy, and AVA or AVN for those constructed from fibreglass. Each container was specifically identified with a four digit serial number followed by the letters PA and this nine digit identifier was present at the top of three sides of each container in black letters/numbers approximately 5 inches tall. Detail drawings and photographs of a typical metal container are shown in Figure F-2. Each container was essentially a 5 feet cube with a 17 inch extension over its full length to the left of the access aperture. In order to fit within the section of the lower fuselage this extension had a sloping face at its base joining the edge of the container floor to the left vertical sidewall at a position some 20 inches above the floor. The access aperture on the AVE type container was covered by a blue reinforced plastic curtain, fixed to the container at its top edge, braced by two wires and central and lower edge cross bars which engaged with the aperture structure. The strength of this type of container superstructure was provided by the various extruded section edge members, attached to a robust floor panel, with a thin aluminum skin providing baggage containment and weatherproofing.

4. Container Identification

Discrimination between forward and rear cargo hold containers was relatively straightforward as the rear cargo hold wreckage was almost entirely confined to the town of Lockerbie and was characteristically different from that from the forward hold, in that it was generally severely crushed and covered in mud. The forward hold debris, by comparison, was mostly recovered from the southern wreckage trail some distance from Lockerbie and had mainly been torn into relatively large sections.

All immediately identifiable parts of the forward cargo containers were segregated into areas designated by their serial numbers and items not identified at that stage were collected into piles of similar parts for later assessment. As a result of this two containers, one metal and one fibreglass, were identified as exhibiting damage likely to have been caused by the IED. From the Pan Am records the metal container of these two had been positioned at position 14L, and the fibreglass at position 21L (adjacent positions, 4th and 5th from the front of the forward cargo hold on the left side). The serial numbers of these containers were respectively AVE 4041 PA and AVN 7511 PA.

5. Container Reconstruction

Those parts which could be positively identified as being from containers AVE

4041 PA and AVN 7511 PA were assembled onto one of three wooden frameworks; one each for the floor and superstructure of container 4041, and one for the superstructure of container 7511. Figures F-3 to F-9 show the reconstruction of container 4041 and Figure F-10 shows the reconstructed forward face of container 7511.
Approximately 85% of container 4041 was identified, the main missing sections being the aft half of the sloping face skin and all of the curtain. Two items were included which could not be fracture or tear matched to container 4041, however, they showed the particular type of blast damage exhibited only by items from this container.

While this work was in progress a buckled section of skin from container 4041 was found by an AAIB Inspector to contain, trapped within its folds, an item which was subsequently identified by forensic scientists at the Royal Armaments Research and Development Establishment (RARDE) as belonging to a specific type of radio-cassette player and that this had been fitted with an improvised explosive device.

Examination of all other component parts of the remaining containers from the front and rear cargo holds did not reveal any evidence of blast damage similar to that found on containers 4041 and 7511.

6. Wreckage Distribution

Those items which were positively identified as parts of container 4041 or 7511, and for which a grid reference was available, were found to have fallen close to the southern edge of the southern wreckage trail. This indicated that one of the very early events in the aircraft break-up sequence was the blast damage to, and ejection of, parts of these two containers.

7. Fuselage Reconstruction

In order to gain a better understanding of the failure sequence, that part of the aircraft's fuselage encompassing the forward cargo hold was reconstructed at AAIB Farnborough. After all available blast damaged pieces of structure had been added, the floor of container 4041 was installed as near to its original position as the deformation of the wreckage would allow and this is shown in Figure F-11. The presence of this floor panel in the fuselage greatly assisted the three-dimensional assessment of the IED location. Witness marks between this floor and the aircraft structure, tie down rail, roller rail and relative areas of blast damage left no doubt that container 4041 had been located at position 14L at the time of detonation.

8. Analysis

The general character of damage that could be seen on the reconstructions of containers 4041 and 7511 was not of a type seen on the wreckage of any of the other containers examined. In particular, the reconstruction of the floor of container 4041 revealed an area of severe distortion, tearing and blackening localised in its aft outboard quarter which, together with the results of the forensic examination of items from this part of the container, left no doubt that the IED had detonated within this container.

Within container 4041 the lack of direct blast damage (of the type seen on the outboard floor edge member and lower portions of the aft face structural members) on most of the floor panel in the heavily distorted area suggested that this had been protected by, presumably, a piece of luggage. The downward heaving of the floor in this area was sufficient to stretch the floor material, far enough to be cut by cargo bay sub structure, and distort the adjacent fuselage frames. This supported the view that the item of baggage containing the IED had been positioned fairly close to the floor but not actually placed upon it. The installation of the floor of container 4041 into the fuselage reconstruction (Figure F-11) showed the blast to have been centered almost directly above frame 700 and that its main effects had not only been directed mostly downwards and outboard but also rearwards. The blast effects on the aircraft skin were onto stringer 39L but centered at station 710 (Figure F-12). Downwards crushing at the top, and rearwards distortion of frame 700 was apparent as well as rearwards distortion of frame 720.

With the two container reconstructions placed together it became apparent that a relatively mild blast had exited container 4041 through the rear lower face to the left of the curtain and impinged at an angle on the forward face of container 7511. This had punched a hole, Figure F-10, approximately 8 inches square some 10 inches up from its base and removed the surface of this face inboard from the hole for some 50 inches. Radiating out from the hole were areas of sooting, and other black deposits, extending to the top of the container. No signs were present of any similar damage on other external or internal faces of container 7511 or the immediately adjacent containers 14R and 21R.

The above assessment of the directions of distortion, comparison of damage to both containers, and the related airframe damage adjacent to the container position, enabled the most probable lateral and vertical location of the IED to be established as shown in Figure F-13, centered longitudinally on station 700.

9. Conclusions

Throughout the general examination of the aircraft wreckage, direct evidence of blast damage was exhibited on the airframe only in the area bounded, approximately, by stations 700 and 720 and stringers 38L and 40L. Blast damage was found only on pieces of containers 4042 and 7511, the relative location and character of which left no doubt that it was directly associated with airframe damage. Thus, these two containers had been loaded in positions 14L and 21L as recorded on the Pan Am cargo loading documents. There was also no doubt that the IED had been located within container 14L, specifically in its aft outboard quarter as indicated in Figure F-13, centered on station 700.

Blast damage to the forward face of container 7511 was as a direct result of hot gases/fragments escaping from the aft face of container 4041. No evidence was seen to suggest that more than one IED had detonated on Flight PA103.

APPENDIX G

MACH STEM SHOCK WAVE EFFECTS

1. Introduction

An explosive detonation within a fuselage, in reasonably close proximity to the skin, will produce a high intensity shock wave which will propagate outwards from the centre of detonation. On reaching the inner surface of the fuselage skin, energy will partially be absorbed in shattering, deforming and accelerating the skin and stringer material in its path. Much of the remaining energy will be transmitted, as a shock wave, through the skin and into the atmosphere but a significant amount of energy will be returned as a reflected shock wave, which will travel back into the fuselage interior where it will interact with the incident shock to produce Mach stem shocks - re-combination shock waves which can have pressures and velocities of propagation greater than the incident shock.

The Mach stem phenomenon is significant for two reasons. Firstly, it gives rise (for relatively small charge sizes) to a geometric limitation on the area of skin material which the incident shock wave can shatter. This geometric limitation occurs irrespective of charge size (within the range of charge sizes considered realistic for the Flight PA103 scenario), and thus provides a means of calculating the standoff distance of the explosive charge from the fuselage skin. Secondly, the Mach stem may have been a significant factor in transmitting explosive energy through the fuselage cavities, producing damage at a number of separate sites remote from the source of the explosion.

2. Mach stem shock wave formation

A Mach stem shock is formed by the interaction between the incident and reflected shock waves, resulting in a coalescing of the two waves to produce a new, single, shock wave. If an explosive charge is detonated in a free field at some standoff distance from a reflective surface, then the incident shock wave expands spherically until the wave front contacts the reflective surface, when that element of the wave surface will be reflected back (Figure G-1). The local angle between the spherical wave front and the reflecting surface is zero at the point where the reflecting surface intersects the normal axis, resulting in wave reflection directly back towards the source and maximum reflected overpressure at the reflective surface. The angle between the wave front and the reflecting surface at other locations increases with distance from the normal axis, producing a corresponding increase in the oblique angle of reflection of the wave element, with a corresponding reduction in the reflected overpressure. (To a first order of approximation, explosive shock waves can be considered to follow similar reflection and refraction paths to light waves, ref: "Geometric Shock Initiation of Pyrotechnics and Explosives", R Weinheimer, McDonnel Douglas Aerospace Co.) Beyond some critical (conical) angle about the normal axis, typically around 40 degrees, the reflected and incident waves coalesce to form Mach stem shock waves which, effectively, bisect the angle between the incident and reflected waves, and thus travel approximately at right angles to the normal axis, i.e.parallel with the reflective surface (detail "A", figure G-1).

3. Estimation of charge standoff distance from the fuselage skin

Within the constraint of the likely charge size used on Flight PA103, calculations suggested that the initial Mach stem shock wave pressure close to the region of Mach stem formation (i.e. the shock wave face-on pressure, acting at right angles to the skin), was likely to be more than twice that of the incident shock wave, with a velocity of propagation perhaps 25% greater. However, the Mach stem out-of-plane pressure, i.e.the pressure felt by the reflecting surface where the Mach stem touches it, would have been relatively low and insufficient to shatter the skin material. Therefore, provided that the charge had sufficient energy to produce skin shatter within the conical central region where no Mach stems form, the size of the shattered region would be a function mainly of charge standoff distance, and charge weight would have had little influence. Consequently, it was possible to calculate the charge standoff distance required to produce a given size of shattered skin from geometric considerations alone. On this basis, a charge standoff distance of approximately 25 to 27 inches would have resulted in a shattered region of some 18 to 20 inches in diameter, broadly comparable to the size of the shattered region evident on the three-dimensional wreckage reconstruction.

Whilst the analytical method makes no allowance for the effect of the IED casing, or any other baggage or container structure interposed between the charge and the fuselage skin, the presence of such a barrier would have tended to absorb energy rather than re-direct the transmitted shock wave; therefore its presence would have been more critical in terms of charge size than of position. Certainly, the standoff distance predicted by this method was strikingly similar to the figure of 25 inches derived independently from the container and fuselage reconstructions.

Subject: **meritorious case involving aviation matters**

Dear Jerry,

Here is your personal connection to AI 182: from Canadian and Indian AAR: (Sent in next email)

"Considering the different acoustic characteristics between a DC-10 and a B747, the AIB analysis indicates that there were distinct similarities between the sound of the explosive decompression on the DC-10 and the sound recorded on the AI 182 CVR."

So, important match between the DC 10 explosive decompression sudden loud sound and the AI 182 sudden loud sound. I contend they are both explosive decompression sounds and not bomb sounds. I believe you know all about DC 10 and explosive decompression sound from a ruptured/opened cargo door.

As you read the AI 182 report or portions thereof, interpret from the point of view of wiring/cargo door/explosive decompression explanation such as UAL 811, (AAR sent in next after next email.) It will all make sense and match up until the nose stays on UAL 811 and comes off for AI 182. Thereafter the evidence matches PA 103 (AAR sent by separate email) and TWA 800. AAR at **http://www.ntsb.gov/Publictn/2000/aar0003.htm**

Electronic versions are good for the 'search' feature. 'cargo door' will lead right to relevant sections.

Cheers,
Barry

The answers to AI 182 are below:

3.4.1 Aircraft Break-up

The examination of the floating wreckage indicates that the right wing root leading edge, the number 3 engine inboard fan cowling, the right inboard midflap leading edge, and the right horizontal stabilizer root leading edge all exhibit damage consistent with objects striking the right wing and stabilizer before water impact. In addition, the right wing root interior area appears to have been scorched briefly by a heat source. The fan cowls of the number 4 engine show evidence of being struck by a portion of the turbine from number 3 engine.

The number 3 engine nacelle strut was separated from the rest of the engine components and was located about one nautical mile to the west indicating that there was some break-up of the number 3 engine before water impact.

The forward cargo door which had some fuselage and cargo floor attached was located on the sea bed. The door was broken horizontally about one-quarter of the distance above the lower frame. The damage to the door and the fuselage skin near the door appeared to have been caused by an outward force and the fracture surfaces of the door appeared to be badly frayed. This damage was different from that seen on other wreckage pieces. A failure of this door in flight would explain the impact damage to the right wing areas. The door failing as an initial event would cause an explosive decompression leading to a downward force on the cabin floor as a result of the difference in pressure between the upper and lower portions of the aircraft.

The abrupt cessation of the flight recorders indicates the possibility of a massive and sudden failure of primary structure; however, there is evidence to suggest that there were ruptures in the forward and aft cargo compartments prior to any failure of the primary structure in flight.

3.4.6.50 Mr. Caiger has not said either in the report or in his statement as to what was the cause of the bang. Mr. Davis, on the other hand, is categorical in stating in his report that there was explosive decompression (meaning rapid decompression) on the aircraft. He has, however, stated in the report that there is no evidence of an explosive device. The main reason for his coming to this conclusion is that he had not been able to find low frequencies in the spectra of the CVR of Kanishka. Mr. Seshadri, on the other hand is equally vehement in concluding that an explosive device had detonated in the front cargo hold of Kanishka.

3.4.6.57 The fact that a bang was heard is evident to the ear when the CVR as well as the ATC tapes are played. The bang could have been caused by a rapid decompression but it could also have been caused by an explosive device. One fact which has, however, to be noticed is that the sound from the explosion must necessarily emanate a few milliseconds or seconds earlier than the sound of rapid decompression because the explosion must necessarily occur before a hole is made, which results in decompression. In the event of there being an explosive detonation then the sound from there must reach the area mike first before the sound of decompression is received by it. The sound may travel either through the air or through the structure of the aircraft, but if there is no explosion of a device, but there is nevertheless an explosive decompression for some other reason, then it is that sound which will reach the area mike. To my mind it will be difficult to say, merely by looking at the spectra of the sound, that the bang recorded on the CVR tape was from an explosive device.

3.4.6.59 With regard to the nature of the sound also we have 3 different opinions. Mr. Caiger is unable to give the nature of the sound, Mr. Davis says it is rapid decompression while Mr. Seshadri says it is a sound of an explosive device followed by decompression.

3.4.6.60 In the absence of any other technical literature on the subject, it is not possible for this Court to come to the conclusion as to which of the Experts is right. The only conclusion which can, however, be arrived at is that the aircraft had broken in midair and that there has been a rapid decompression in the aircraft. Just as it is not possible to say that the spectrum discloses that the bang is due to an explosive device similarly, and as has also been admitted by Mr. Caiger and Mr. Davis, it is not possible to say that the bang is due to break up of a structure.

3.4.6.61 The bang could have been due to either of the aforesaid two causes i.e. a bomb explosion or the sound emanating due to rapid decompression. The advantage of carrying out the said analysis is that a number of possible causes of the accident are eliminated. On the other hand, if the analysis is viewed in conjunction with other evidence on the record it is further possible to determine the exact nature or cause of the bang. In the present case the bang, as already noticed, could have been due to the sound originating from the detonation of a device or by reason of rapid decompression.

2.10.2 Analysis by Accidents Investigation Branch (AIB), United Kingdom

The AIB analysis was restricted to the CVR and the Shannon ATC tape. The correlation of the CVR and ATC tapes showed that the ATC recording started after the CVR had stopped recording and 1.1 ± 0.4 seconds from the start of the sudden sound. The total duration of the signal on the ATC tape was 5.4 seconds.

An analysis of the CVR audio found no significant very low frequency content which would be expected from the sound created by the detonation of a high explosive device. Evidence of the presence of audio warning signals buried amongst the noise was investigated with negative results. A comparison with CVRs recording an explosive decompression* on a DC-10, a bomb in the cargo hold of a B737, and a gun shot on the flight deck of a B737 was made. Considering the different acoustic characteristics between a DC-10 and a B747, the AIB analysis indicates that there were distinct similarities between the sound of the explosive decompression on the DC-10 and the sound recorded on the AI 182 CVR.

' In his report, and also in the earlier part of the examination, Mr. Davis had referred to the absence of low frequency component in the spectrum and had sought to conclude that such absence showed that there was no detonation of a high explosive device. In an answer to the question put by the Court however, Mr. Davis appeared to have altered his stand. This is evident from the following deposition of Mr. Davis :-

"Court Ques Am I to understand that there must necessarily be a low frequency whenever an explosion occurs?

Ans. No. What we thought was there would be. There was only one sample of explosion in B-737. But we would need more accidents of that nature to able to say that yes we must have a low frequency component.

Court Ques: Am I to understand that the absence of a low frequency component would not therefore necessarily mean that the sound was not that of an explosion?

Ans. Because of the absence of a low frequency component we would not be able to say positively that there was an explosion or it was not explosion."

Court Ques : Would the frequency of a particular type of sound change depending upon the environment in which that sound occurs?

Ans Yes.

Court Ques If an event results in low frequency sounds in one type of environment, can it mean that the same event can result in a high frequency sound in a different environment?

Ans. That must be possible".

Subject: **Introduction**

At 8:28 PM -0800 3/11/01, Aniljit Singh wrote:

please add jaswinder singh parmar to the general list. his address is
jaswinderp@hotmail.com
he is the son in law of Ajaib Singh and is heading his defense team.

Hello, Mr. Jaswinder Singh Parmar,

My name is John Barry Smith, proponent of the 'no bomb' on AI 182 but there was a wiring/cargo door/explosive decompression.

Aniljit has informed me you are to lead the defence team for Mr. Ajaib Singh Bagri. Very good. I am at your service to answer any questions regarding the decompression explanation. I have sent many emails to Mr. Campbell and can resend them to you if you wish. There has been much discussion among the defence team for Mr. Malik about the decompression explanation and I can tell by the quality of questions from Aniljit and others that the explanation closely examined and has been taken seriously. I invite further analysis by you regarding the validity of the theory.

My latest thoughts are a three pronged defence consisting of: 1. Mr. Malik and Mr. Bagri had nothing to do with AI 182, whether it was bomb, center tank explosion, door design, or installation of wiring. 2. Most unlikely bomb. 3. Most probably wiring/cargo door/explosive decompression.

I can lead in number 3 and assist in number 2 but can't help in number 1 in establishing alibis, etc.

I've included below some thoughts on how to present the wiring/ cargo door/explosive decompression explanation to the Court and the public and the sequence to best serve Mr. Malik. I value your opinion on what sequence to follow to best present this most interesting defence. I can prepare a statement for the press regarding the wiring/cargo door/explosive decompression explanation in layman's language.

I can come up to Vancouver and testify in front of the judge on April 4th, if you think it would do any good. I think the sooner the Court and the public is exposed to the idea that there was no bomb on AI 182 and a reasonable alternative exists that's mechanical, the better they can absorb the shock of being wrong for 15 years.

Feel free to call me at home at any time for information or questions. Email is always good.

Excerpts below from previous email but relevant now:

The Crown is flying people all over the world, from Scotland to Vancouver, they have experts of their own from all over the world, they will call in people from India, they have multi million dollar agencies saying bomb and the defence can not possibly fairly and adequately provide the required standard of fairness without financial assistance as well as expert advice. I would ask for cash and a Boeing structural expert and a TSB accident investigator assigned to the case on our side. It's something to ask the judge April 4.

If the wiring/cargo door/explosive decompression explanation is brought up at 4 April hearing, then the heat will be transferred to me to justify it. I can do that. All our ducks are not in a row but the media attention on the mechanical explanation will help persuade the Crown to give us all our discovery requests. It gives legitimate hope to the accused and his supporters. It gives time for the prosecutors to prepare against the mechanical explanation but if you have faith, as I do, in the evidence, then the explanation can not be refuted no matter how much time they have. In addition, the revelation of the mechanical explanation for AI 182 on 4 April will justify to the Court to grant our request for technical assistance in the form of an assigned Canadian government official from the Transportation Safety Board. I will persuade the TSB the wiring/cargo door/explosive decompression is worthy of further investigation for AI 182, all I need is a face to face with them and my documents.

In addition, if the idea is confirmed that AI 182 may not have been a bomb, then bail proceedings may be fruitful.

Do you have the necessary four Aircraft Accident Reports? AAR for AI 182, PA 103, TWA 800, and UAL 811. I can send three and direct you the web address for the other. To understand AI 182 is to understand UAL 811.

Many Sikhs may believe your father in law did the heinous crimes he is accused of because they feel he was justified in revenge. Many Sikhs may believe he did not do the crimes because they know the man and feel he is not capable of doing the crimes but can't prove it. I know he did not do it because I know nobody did it and I can prove it. I can provide reasonable doubt a bomb exploded on AI 182, I can prove the forward cargo door ruptured/opened in flight for AI 182, and I can provide the probable cause of that door rupture as faulty wiring turning on the door unlatch motor.

Discovery evidence needed:

Aircraft:
AI 182:
1. Copies of all videotapes, photographs, interview notes, and sketches now held by the RCMP and TSB.
2. Access to all hard evidence of the wreckage which was retrieved from ocean.
3. Interviews with TSB, AAIB, and NTSB investigators who contributed to the AI 182 report through deposition or voluntary meeting.
4. Autopsy reports.
5. Wreckage database and plots.
6. Passenger and cargo manifests.
7. CVR and FDR printouts.

PA 103: The same officials who worked on the AI 182 report also worked on the PA 103 AAIB report.
1. Interviews with NTSB metallurgists and Boeing explosive expert and British law enforcement involved with the investigation.
2. Copies of all videotapes, photographs, interview notes, and sketches now held by the AAIB and Scotland Yard.
3. Access inside the hangar at Farnborough of the Pan Am 103 wreckage for at least 40 hours (five days at 8 hours a day) by at least five of your team.
4. Autopsy reports.
5. Wreckage database and plots.
6. Passenger and cargo manifests.
7. CVR and FDR printouts.

TWA 800: The same officials who worked on AI 182 and PA 103 worked on TWA 800.
1. Access to the hangar where the wreckage of TWA 800 is stored for at least 40 hours (five days at 8 hours a day) by at least

five of your team.
2. Copies of all photographs, videotapes, interviews about TWA 800 now held by FBI and NTSB.
3. Interviews with NTSB metallurgists, explosive expert and American law enforcement involved with the investigation.
4. Autopsy reports.
5. Wreckage database and plots.
6. Passenger and cargo manifests.
7. CVR and FDR printouts.

UAL 811:
1. Copies of all videotapes, photographs, interview notes, and sketches now held by the NTSB.
2. Access to any existing wreckage.
3. Interviews with NTSB metallurgists, explosive expert and American law enforcement involved with the investigation.
4. Autopsy reports.
5. Wreckage database and plots.
6. Passenger and cargo manifests.
7. CVR and FDR printouts.

Airport:
Narita:
1. Copies of all videotapes, photographs, interview notes, and sketches now held by the RCMP and TSB and Japanese airport and police authorities
2. Transcripts of the trial

Manufacturer:
Boeing:
1. Copies of all memos, data, and information about cargo doors and cargo holds on Boeing 747s.
2. Copies of all memos, data, and information about cargo doors

and cargo holds on DC-10, MD-11, and MD-12.

Airlines:
Pan Am, TWA, Air India, United Airlines:
1. Copies of all videotapes, photographs, interview notes, and sketches regarding PA 103, AI 182, TWA 800, and UAL 811
2. Access to any existing wreckage held by them.
3. Interviews with airline staff involved with the accidents.
4. Maintenance logs for the accident aircraft long before and just before the fatal flights.

Miscellaneous:
1. Copies of all data about Canadian Pacific Air Flight 003, another Boeing 747 supposed to have a bomb on board and by inference, abetted by you, sir, or your fellow Sikh, Mr. Reyat.
2. Copies of all Data about Airworthiness Directives about cargo door on commercial airliners held by FAA and NTSB databanks.
3. Bruntingthorpe 747 evidence.
4. DC 10 CVR data, explosive decompression accidents, Windsor and Paris.

Sincerely,
Barry

I am sorry for the confusion but last night I re-read the crown's theory and
they have stated that the "bomb would have been located near Target 7 and 8
(rear cargo hold"

How does this affect us???

as

'There is considerable circumstantial and other evidence to indicate that the initial event was an explosion occurring in the forward cargo compartment.'

'...cause of the accident as being that of an explosion of a bomb in the forward cargo hold of the aircraft.'

'There was no evidence to indicate characteristics of an explosion emanating from the aft cargo compartment.'

4.0 CONCLUSIONS

The Canadian Aviation Safety Board respectfully submits as follows:

4.1 Cause-Related Findings

1. At 0714 GMT, 23 June 1985, and without warning, Air India Flight 182 was subjected to a sudden event at an altitude of 31,000 feet resulting in its crash into the sea and the death of all on board.
2. The forward and aft cargo compartments ruptured before water impact.
3. The section aft of the wings of the aircraft separated from the forward portion before water impact.
4. There is no evidence to indicate that structural failure of the aircraft was the lead event in this occurrence.
5. There is considerable circumstantial and other evidence to indicate that the initial event was an explosion occurring in the forward cargo compartment. This evidence is not conclusive. However, the evidence does not support any other conclusion

4.9 Thus we are left with only two of the possibilities viz., structural failure or accident having been caused due to a bomb having been placed inside the aircraft.

4.10 After going through the entire record we find that there is circumstantial as well as direct evidence which directly points to the cause of the accident as being that of an explosion of a bomb in the forward cargo hold of the aircraft. At the same time there is complete lack of evidence to indicate that there was any structural failure.

2.11.6.5 Target 47 - Aft Cargo Compartment

This portion of the aft cargo compartment roller floor was located between BS 1600 and BS 1760. Based on the direction of cleat rotation on the skin panel (target 7) and the crossbeam displacement on this structure, target 47 moved aft in relation to the lower skin panel when it was detached from the lower skin. No other significant observation was noted. There was no evidence to indicate characteristics of an explosion emanating from the aft cargo compartment.

Dear Aniljit, the excerpts are from the AI 182 report.

It appears to me that the Kirpal commission said probable cause was "explosion occurring in the forward cargo compartment," which I agree with and is consistent with wiring/cargo door/ explosive decompression explanation. It also said no explosion in the aft compartment, which I agree with.

The report is very favorable to us because it keeps on repeating 'At this time' which we now can say, yes, in 1985 that was correct, no evidence of structural failure, but now in 2001, at our time, there is, specifically, the 1989 accident of UAL 811 which showed that in fact, a cargo door opening in flight would and did cut of electrical power to the FDR, and would make a sudden loud sound on the CVR, and would do many other strange things that match AI 182 such as frayed door from outward force.

In essence we agree with the raw findings of the AI 182 Kirpal report of an outward force in the forward cargo compartment causing the accident but disagree on the cause of the force. Not a bomb but we do understand in 1985 that conclusion may have been reached. Only now, in hindsight, with more evidence of a similar nature, is the true probable cause revealed and it is not a bomb, but wiring/cargo door/explosive decompression. Matching

UAL 811 to AI 182 is the magic mystery solver. We do have the evidence that indicates that structural failure of the aircraft was the lead event in this occurrence.

I appreciate you going over and over the reports, that is so important. We will have to almost memorize them. There is much in there to support our explanation which coupled with the new evidence of UAL 811 confirm the guesses of Mr. Davis in 1985. When the raw data is read in all the AAR, it is apparent the accurate evaluations are made, it is only when it gets 'interpreted' that it swings toward the political 'bomb'. We must concentrate on the facts and the data that really match UAL 811 to AI 182 and is incontrovertible.

I may have unintentionally offended Parmajit and I wish to apologize. If you see him, tell him I fully understand and respect any decision he makes regarding his contribution to our purpose and wish him good luck in his endeavors.

Regarding all the forensic and chemical evidence you sent:

The medical information is based on recovery of 131 bodies of 329. Regardless of what anyone says, others could say, well the evidence of bomb damage in on the bodies not recovered. The only thing we can say for sure is that usually when real bombs go off on airplanes there is conclusive proof of the bomb damage on the victims; and explosive decompression gives damage to humans such as baro trauma. It also causes damage to metal similar to a bomb force. The evidence of AI 182 is lacking in the conclusive proof of bomb damage to the recovered victims which may mean there was no bomb. There is human damage on AI 182 victims such as baro trauma which is consistent with explosive decompression which may mean there was explosive decompression. There is damage on the airframe of AI 182 consistent of explosive decompression such as outward force on the metal which may mean there was explosive decompression. There is no chemical conclusive proof of a bomb explosion on AI 182 which may mean there was no bomb.

A bomb would cause explosive decompression but would appear on the CVR before the sound of the explosive decompression. In 1985 they did not have the CVR of UAL 811 to match with AI 182 and did not know the sudden loud sound and the abrupt power cut of AI 182 was possible by ruptured cargo door in flight.

In summary, the conclusive evidence of bomb explosion on humans and machine is absent and or real bomb explosion, the proof is clearly there. That is reasonable doubt as to ba bomb right there and good enough to win acquittal for Mr. Malik if the jury were fair. Next, the evidence which supports explosive decompression is present on the humans and machine which demonstrates that explosive decompression of a non-chemical nature occurred. Again the raw data of chemical analysis and forensic autopsy supports the wiring/cargo door/explosive decompression and mitigates against a bomb...when viewed objectively.

It is interesting to conjecture if UAL 811 had happened just before or just after AI 182 and the matching similarities would have quickly become apparent, how the probable cause would have been. I say it would have been wiring/cargo door/explosive decompression explanation. But in the absence of the matching mechanical cause of UAl 811, they went with the political decision, against the Sikhs. A wrong choice with tragic consequences years later for UAL 811, PA 103, and TWA 800.

Please keep up these interesting questions, it is better that we get our explanations clear and supported with proof now among ourselves than later in front of the TV or the attorney on the witness stand.

What do you think of the three pronged approach for defence? 1. Mr. Malik had nothing to do with AI 182, whether it was bomb, center tank explosion, door design, or installation of wiring. 2. Most unlikely bomb. 3. Most probably wiring/cargo door/ explosive decompression.

When are you going to announce to the Court the mechanical alternative decompression explanation as a defence?

When do you think it is advisable to make a press statement? I can start work on that now, if you wish.

Sincerely,
Barry

Subject: **AAR 92/02**

hey Barry!

My last e-mail was not meant to convey a sense of mistrust. I just don't want to send a resume. I'm 25 years old and other than graduating from law school have no experience of any relevance to this case.

I also prefer contact via e-mail but you can see that you can occasionally find miscommunication there as well.

Jaspreet

Dear Jaspreet, fine. Oh, to be 25 again....

Yes, email is good, I worry about the quick emotions that result in flames. Many times I have fired off a email and regretted it later. Oh, well.

The UAL 811 report is essential to understand AI 182. I'll add it to the end of this. I assume you already have the electronic version of AI 182. My website at www.corazon.com has details of all.

Narinder is coming down again tomorrow and we work up a plan on this explosive decompression explanation.

Sincerely,
Barry

Abstract: This report explains the explosive decompression resulting from the loss of a cargo door in flight on United Airlines flight 811, a Boeing 747-122, near Honolulu, Hawaii, on February 24, 1989. The safety issues discussed in the report are the design and certification of the B-747 cargo doors, the operation and maintenance to assure the continuing airworthiness of the doors, and emergency response. Recommendations concerning these issues were made to the Federal Aviation Administration, the State of Hawaii, and the U.S. Department of Defense.
CONTENTS

EXECUTIVE SUMMARY

On February 24, 1989, United Airlines flight 811, a Boeing 747-122, experienced an explosive decompression as it was climbing between 22,000 and 23,000 feet after taking off from Honolulu, Hawaii, en route to Sydney, Australia with 3 flightcrew, 15 flight attendants, and 337 passengers aboard.

The airplane made a successful emergency landing at Honolulu and the occupants evacuated the airplane. Examination of the airplane revealed that the forward lower lobe cargo door had separated in flight and had caused extensive damage to the fuselage and cabin structure adjacent to the door. Nine of the passengers had been ejected from the airplane and lost at sea.

A year after the accident, the Safety Board was uncertain that the cargo door would be located and recovered from the Pacific Ocean. The Safety Board decided to proceed with a final report based on the available evidence without the benefit of an actual examination of the door mechanism. The original report was adopted by the Safety Board on April 16, 1990, as NTSB/AAR-90/01.

Subsequently, on July 22, 1990, a search and recovery operation was begun by the U.S. Navy with the cost shared by the Safety Board, the Federal Aviation Administration, Boeing Aircraft Company, and United Airlines. The search and recovery effort was supported by Navy radar data on the separated cargo door, underwater sonar equipment, and a manned submersible vehicle. The effort was successful, and the cargo door was recovered in two pieces from the ocean floor at a depth of 14,200 feet on September 26 and October 1, 1990.

Before the recovery of the cargo door, the Safety Board believed that the door locking mechanisms had sustained damage in service prior to the accident flight to the extent that the door could have been closed and appeared to have been locked, when in fact the door was not fully latched. This belief was expressed in the report and was supported by the evidence available at the time. However, upon examination of the door, the damage to the locking mechanism did not support this hypothesis. Rather, the evidence indicated that the latch cams had been backdriven from the closed position into a nearly open position after the door had been closed and locked. The latch cams had been driven into the lock sectors that deformed so that they failed to prevent the back-driving.

Thus, as a result of the recovery and examination of the cargo door, the Safety Board's original analysis and probable cause have been modified. This report incorporates these changes and supersedes NTSB/AAR-90/01.

The issues in this investigation centered around the design and certification of the B-747 cargo doors, the operation and maintenance to assure the continuing airworthiness of the doors, cabin safety, and emergency response.

The National Transportation Safety Board determines that the probable cause of this accident was the sudden opening of the forward lower lobe cargo door in flight and the subsequent explosive decompression. The door opening was attributed to a faulty switch or wiring in the door control system which permitted electrical actuation of the door latches toward the unlatched position after initial door closure and before takeoff. Contributing to the cause of the accident was a deficiency in the design of the cargo door locking mechanisms, which made them susceptible to deformation, allowing the door to become unlatched after being properly latched and locked. Also contributing to the accident was a lack of timely corrective actions by Boeing and the FAA following a 1987 cargo door opening incident on a Pan Am B-747.

As a result of this investigation, the Safety Board issued safety recommendations concerning cargo doors and other nonplug doors on pressurized transport category airplanes, cabin safety, and emergency response.

AIRCRAFT ACCIDENT REPORT

EXPLOSIVE DECOMPRESSION-- LOSS OF CARGO DOOR IN FLIGHT UNITED AIRLINES FLIGHT 811 BOEING 747-122, N4713U HONOLULU, HAWAII FEBRUARY 24, 1989

1. FACTUAL INFORMATION

1.1 History of the Flight

On February 24, 1989, United Airlines (UAL) flight 811, a Boeing 747-122 (B-747), N4713U, was being operated as a regularly scheduled flight from Los Angeles, California (LAX) to Sydney, Australia (SYD), with intermediate stops in Honolulu, Hawaii (HNL) and Auckland, New Zealand (AKL).

The flightcrew assigned to the LAX/HNL route segment reported no difficulty during their flight.

A flightcrew change occurred when flight 811 arrived at HNL. The oncoming captain stated that he and his crew reported to UAL operations 1 hour and 15 minutes prior to the flight's scheduled departure time from HNL. The crew had completed a 34-hour layover (rest period) in HNL.

The captain reviewed the flight plan, the weather, pertinent NOTAMs, and maintenance records, and signed the Instrument Flight Rules (IFR) clearance before boarding the airplane.

Flight 811 departed HNL gate 10 at 0133 Honolulu Standard Time (HST), 3 minutes after the scheduled departure time, with 3 flight crewmembers, 15 cabin crewmembers, and 337 passengers. The flightcrew attributed the short delay to cabin crew problems with arming the 5L cabin door emergency exit slide and the normal securing of the 2L door after a somewhat extended passenger boarding process. The second officer stated that all cabin and cargo door warning lights were out prior to the airplane's departure from the gate. He said that he dimmed the annunciator panel lights at his station while the airplane was departing the gate area.

The captain was at the controls when the flight was cleared for takeoff on HNL runway 8R at 0152:49 HST. The auxiliary power unit (APU), which was used during the takeoff, was shutdown shortly after making the initial power reduction to climb thrust. The flightcrew reported the airplane's operation to be normal during the takeoff and during the initial and intermediate segments of the climb. The flightcrew observed en route thunderstorms both visually and on the airplane's weather radar, so they requested and received clearance for a deviation to the left of course from the HNL Combined Center Radar Approach Control (CERAP). The captain elected to leave the passenger seat belt sign "on."

The flightcrew stated that the first indication of a problem occurred while the airplane was climbing between 22,000 and 23,000 feet at an indicated airspeed (IAS) of 300 knots. They heard a sound, described as a "thump," which shook the airplane. They said that this sound was followed immediately by a "tremendous explosion." The airplane had experienced an explosive decompression. They said that they donned their respective oxygen masks but found no oxygen available. The airplane cabin altitude horn sounded and the flightcrew believed the passenger oxygen masks had deployed automatically.

The captain immediately initiated an emergency descent, turned 180(to the left to avoid a thunderstorm, and proceeded toward HNL. The first officer informed CERAP that the airplane was in an emergency descent and appeared to have lost power in the No. 3 engine. The appropriate 7700 emergency code was placed in the airplane's radar beacon transponder and an emergency was declared with CERAP at approximately 0220 HST. The No. 3 engine was shut down shortly after commencing the descent because of heavy vibration, no N1 compressor indication, low exhaust gas temperature (EGT), and low engine pressure ratio (EPR).

The second officer then left the cockpit to inspect the cabin area and returned to inform the captain that a large portion of the forward right side of the cabin fuselage was missing. The captain subsequently shut down the No. 4 engine because of high EGT and no N1 compressor indication, accompanied by visible flashes of fire. The flightcrew initiated fuel dumping during the descent to reduce the airplane landing weight.

The airplane was cleared for an approach to HNL runway 8L. The final approach was flown at 190 to 200 knots with the No. 1 and No. 2 engines only. During flap extension, the flightcrew observed an indication of asymmetrical flaps as the flap position approached 5(. The flightcrew decided to extend inboard trailing edge flaps to 10(for the landing. The right outboard leading edge flaps did not extend during the flap lowering sequence. The airplane touched down on the runway, approximately 1,000 feet from the approach end, and came to a stop about 7,000 feet later. The captain applied idle reverse on the Nos. 1 and No. 2 engines and employed moderate to heavy braking to stop the airplane. At 0234 (HST), HNL tower was notified by the flightcrew that the airplane was stopped and an emergency evacuation had commenced on the runway.

After the accident, UAL ramp service personnel, who had been involved with the cargo loading and unloading of flight 811 before takeoff from HNL, stated that they had opened and closed the forward cargo door electrically. They said that they had observed no damage to the cargo door. The ramp service personnel said that they had verified that the forward cargo door was flush with the fuselage of the airplane, that the master door latch handle was stowed, and that the pressure relief doors were flush with the exterior skin of the cargo door.

The dispatch mechanic stated that, in accordance with UAL procedures, he had performed a "circle check" prior to the airplane's departure from the HNL gate. This check included verification that the cargo doors were flush with the fuselage of the airplane, that the master latch lock handles were stowed, and that the pressure relief doors were flush or within 1/2 inch of the cargo door's exterior skin. He said a flashlight was used during this inspection.

The second officer stated that, in accordance with UAL Standard Operating Procedures (SOP) he had performed an operational check of the door warning annunciator lights as part of his portion of the cockpit preparation. The second officer also stated that he used a flashlight while performing an exterior inspection, again in accordance with UAL procedures. The exterior inspection was conducted while ramp service personnel were performing cargo loading operations and the cargo doors were open. He stated that he had observed no abnormalities or damage.

1.2 Injuries to Persons

Injuries Flightcrew Cabincrew Passengers Others Serious *Lost in flight. An extensive air and sea search for the passengers was unsuccessful.

1.3 Damage to the Airplane

The primary damage to the airplane consisted of a hole on the right side in the area of the forward lower lobe cargo door, approximately 10 by 15 feet large. The cargo door fuselage cutout lower sill and side frames were intact but the door was missing (see figures 1 and 2). An area of fuselage skin measuring about 13 feet lengthwise by 15 feet vertically, and extending from the upper sill of the forward cargo door to the upper deck window belt, had separated from the airplane at a location above the cargo door extending to the upper deck windows. The floor beams adjacent to and inboard of the cargo door area had been fractured and buckled downward.

Examination of all structure around the area of primary damage disclosed no evidence of preexisting cracks or corrosion. All

fractures were typical of fresh overstress breaks.
Debris had damaged portions of the right wing, the right horizontal stabilizer, the vertical stabilizer and engines Nos. 3 and 4. No damage was noted on the left side of the airplane, including engines Nos. 1 and 2.
The right wing had sustained impact damage along the leading edge between the No. 3 engine pylon and the No. 17 variable camber leading edge flap. Slight impact damage to the No. 18 leading edge flap was noted.
There was a break and scuff in the wing leading edge aft of engine No. 4 and a scuff in the wing leading edge outboard of engine No. 4. There was a large indentation (to a depth of nearly 8 inches) in the area just above the outboard landing light, and the landing light covers were broken. There was a small puncture in the upper surface of the No. 14 krueger flap and impact damage to the wing leading edge just aft of the No. 14 krueger flap. There was a gash on the upper wing surface aft of the No. 14 krueger flap and leading edge, as well as punctures to the wing leading edge aft of the number 16 krueger flap. The under wing surface aft of the krueger flaps also sustained impact damage.
The right wing also had sustained damage at the wing-to-body fairing and two flap track canoe fairings.1 Wing-to-body fairing damage was limited to surface scraping forward of and below the wing. The outboard surface of the No. 6 flap track canoe fairing revealed a slightly more significant gouge mark. The most severe damage was evident on the inboard surface of the No. 8 flap track canoe fairing, where three separate punctured areas were observed. The trailing edge flaps were not damaged.
The leading edge of the right horizontal stabilizer had several dents. The most severe dents, located 8 to 10 feet from the stabilizer root, were approximately 3 inches wide and 1 inch deep. No punctures were found. The vertical stabilizer had multiple small and elongated indentations with a maximum

depth of 1/2 inch near the right base of the leading edge. A small gouge and two small scrapes were noted at midspan of the upper rudder.

A piece of cargo container was found lodged between the No. 3 engine pylon (inboard) and the wing underside. The piece of metal had severed the pneumatic duct for the leading edge flaps. Various nicks and punctures were evident on the inboard side of the No. 3 engine pylon. The No. 4 engine pylon had a small puncture near the leading edge of the wing.

The external surfaces of the No. 3 engine inlet cowl assembly exhibited foreign object damage including small tears, scuffs and a large outwardly directed hole. The entire circumference of all the acoustic (sound attenuator) panels installed on the inlet section of the cowl had been punctured, torn, or dented. None of the No. 3 engine cases were penetrated by objects, nor was there evidence of fire damage to any visible engine components and accessories. The

leading edges of all fan blade airfoils on the No. 3 engine exhibited extensive foreign object damage.

External damage to the No. 4 engine inlet and core cowls was confined to the inboard side of the inlet cowl assembly. The damage consisted of one major scuff mark, four lesser scuff marks and one crescent- shaped cut. The sound attenuator panels that were installed in the inlet area of the inlet cowl assembly had not been penetrated. The No. 4 engine fan blade airfoils had sustained both soft and hard object damage from foreign objects.

The cargo door separation resulted in the loss of fuselage shell structure above the cargo door, along with main cabin floor structure below seats 8GH through 12GH (see figure 3). The missing floor area extended inboard from the interior of the right side fuselage wall to the inboard seat track of seats 8GH through 12GH.

The supply and fill lines from the flightcrew oxygen bottle, and the supply line for the passenger oxygen system had been broken below the cabin floor inboard of the missing cargo door.

The two cabin pressurization out-flow valves, located on the underside of the fuselage, aft of the rear cargo compartment, were found fully open. The two over-pressure relief valves located on the forward left side of the airplane were found in the normal closed position. These valves were removed and bench tested. (See section 1.16.3, Pressurization System.) The majority of the cabin floor-to-cargo compartment blowout panels were found activated. The blowout panels are designed to relieve excess pressure differential following an explosive decompression to prevent catastrophic damage to the cabin floor structures.

The estimated damage to the airplane was $14,000,000, based on UAL's costs to repair it.

1.4 Other Damage

No other property damage resulted from this accident.

1.5 Personnel Information

The crew consisted of 3 flight crewmembers (the captain, the first officer, and the second officer) and 15 cabin crewmembers. (See appendix B.)

1.6 Aircraft Information

1.6.1 General

On February 24, 1989, the United Airlines B-747 fleet consisted of 31 airplanes, including: 2 B-747-222B, 11 B-747-SP, 5 B-747-123, and 13 B-747-122 series airplanes. N4713U was equipped with four Pratt & Whitney model JT9D engines.

The accident airplane, serial No. 19875, registered in the United States as N4713U, was manufactured as a Boeing 747-122 transport category airplane by the Boeing Commercial Airplane Company (Boeing), Seattle, Washington, a Division of the Boeing Company. N4713U, the 89th B-747 built by Boeing, was manufactured in accordance with Federal Aviation Administration (FAA) type certificate No. A20WE, as approved on December 30, 1969. The airplane was certificated in accordance with the provisions of 14 CFR Part 25, effective February 1, 1965. The maximum calculated takeoff weight for flight 811 was 706,000 pounds. The flight plan data showed an actual takeoff weight of 697,900 pounds. The center of gravity (CG) for takeoff was computed at 20.4 percent mean aerodynamic chord (MAC). The forward and aft CG limits were 12 and 29.7 percent MAC, respectively.

At the time of the accident, N4713U had accumulated 58,815 total flight hours and 15,028 flight cycles. N4713U had not been involved in any previous accident. Records indicated that the airplane had been inspected and maintained in accordance with the General Maintenance Program as defined in UAL Operations Specifications and in accordance with the FAA approved Aircraft and Powerplants Reliability Program. The records indicated that all required inspection and maintenance actions had been completed within specified time limits and all applicable airworthiness directives (AD) had been accomplished or were in the process of being accomplished, with the exception of AD 88-12-04, which was applicable to the B-747 lower lobe cargo door, and which had only been complied with partially. (See section 1.6.8 for explanation).

1.6.2 Cargo Door Description and Operation

Both the forward and aft lower cargo doors are similar in appearance and operation. They are located on the lower right side of the fuselage and are outward-opening. The door opening is approximately 110 inches wide by 99 inches high, as measured along the fuselage.

Electrical power for operation of the cargo door switches and actuators is supplied from the ground handling bus, which is powered by either external power or the APU. See figure 17 for a diagram of the cargo door electrical circuitry. The engine generators cannot provide power to the ground handling bus.

APU generator electrical power to the ground handling bus is interrupted when an engine generator is brought on line after engine start. The APU generator "field" switch can be reengaged by the flightcrew, if necessary on the ground, to power the ground handling bus. The air/ground safety relay automatically disconnects the APU generator from the ground handling bus, if it is energized, when the airplane becomes airborne and the air/ground relay senses that the airplane is off the ground.

The cargo door and its associated hardware are designed to carry circumferential (hoop) loads arising from pressurization of the airplane. These loads are transmitted from the piano hinge at the top of the door, through the door itself, and into the eight latches located along the bottom of the door. The eight latches consist of eight latch pins attached to the lower door sill and eight latch cams attached to the bottom of the door. The cargo door also has two midspan latches located along the fore and aft sides of the door. These midspan latches primarily serve to keep the sides of the door aligned with the fuselage. There are also four door stops which limit inward movement of the door. There are two pull-in hooks located on the fore and aft lower portion of the door, with pull-in hook pins on the sides of the door frame. (See figure 4 for cargo door components).

The cargo doors on the B-747 have a master latch lock handle installed on the exterior of the door. The handle is opened and closed manually. The master latch lock handle simultaneously controls the operation of the latch lock sectors, which act as locks for the latch cams, and the two pressure relief doors located on the door. Figure 5 depicts a lock sector and latch cam in an unlocked and locked condition.

Figure 4.--Boeing 747 lower lobe forward cargo door.

Figure 5.--Cargo door latch cam and lock sector in unlocked and locked ositions.

The door has three electrical actuators for opening/closing and latching of the door. One actuator (main actuator) moves the door from the fully open position to the near closed position, and vice versa. A second actuator (pull-in hook actuator) moves the pull-in hooks closed or open, and the third actuator (latch actuator) rotates the latch cams from the unlatched position to the latched position, and vice versa. The latch actuator has an internal clutch, which slips to limit the torque output of the actuator.

Normally, the cargo doors are operated electrically by means of a switch located on the exterior of the fuselage, just forward of the door opening. The switch controls the opening and closing and the latching of the door. If at any time the switch is released, the switch will return to a neutral position, power is removed from all actuators, and movement of the actuators ceases.

In order to close the cargo door, the door switch is held to the "closed" position, energizing the closing actuator, and the door moves toward the closed position. After the door has reached the near closed position, the hook position switch transfers the electrical control power to the pull- in hook actuator, and the cargo door is brought to the closed position by the pull-in hooks. When the pull-in hooks reach their fully closed position, the hook-closed switch transfers electrical power to the latch actuator. The latch actuator rotates the eight latch cams, mounted on the lower portion of the door, around the eight latch pins, attached to the lower door sill. At the same time, the two midspan latch cams, located on the sides of the door rotate around the two midspan latch pins located on the sides of the door frame. When the eight latch cams and the two mid-span cams reach their fully closed position, electrical power is removed from the latch actuator by the latch-closed switch. This completes the electrically powered portion of the door closing operation. The door can also be operated in the same manner electrically by a switch located inside the cargo compartment adjacent to the door.

The final securing operation is the movement of lock sectors across the latch cams. These are manually moved in place across the open mouth of each of the eight lower cams through mechanical linkages to the master latch lock handle. The position of the lock sectors is indicated indirectly by noting visually the closed position of the two pressure relief doors located on the upper section of each cargo door. The pressure relief doors are designed to relieve any residual pressure differential before the cargo doors are opened after landing, and to prevent pressurization of the airplane should the airplane depart with the cargo doors not properly secured. The pressure relief doors are mechanically linked to the movement of the lock sectors. This final procedure also actuates the master latch lock switch, removing electrical control power from the opening and closing control circuits, and also extinguishes the cockpit cargo door warning light through a switch located on one of the pressure relief doors. Opening the cargo door is accomplished by reversing the above procedure.

The B-747 cargo door has eight (8) view ports located beneath the latch cams for direct viewing of the position of the cams by means of alignment stripes. Procedures for using these view ports for verifying the position of the cams were not in place or required by Boeing, the FAA, or UAL (see 1.17.5 for additional information).

Closing the door manually is accomplished through the same sequence of actions without electrical power. The door actuator mechanisms are manually driven to a closed and latched position by the use of a one-half inch socket driver. The door can also be opened manually with the use of the socket driver. There are separate socket drives for the door raising/lowering mechanism, the pull-in hooks, and the latches.

Operating procedures for the normal electrical operation of the forward and aft cargo doors are outlined in the UAL Maintenance Manual (MM). Authorization for deferral of maintenance on the door power system is contained in the UAL B-747 Minimum Equipment List (MEL). In addition, operating procedures for dispatching aircraft with an inoperative door electrical power system (manual operation) are specified in the operator's MEL. The UAL MM differs from Boeing's recommended MM. UAL had modified Boeing printed material or replaced pages with their own methods and procedures for conducting maintenance functions. The modifications to the manufacturer's MM were accepted by the FAA through "approval" by the FAA Principal Maintenance Inspector (PMI). Electrical cargo door open/close operations in the UAL and Boeing MM's are approximately the same, except the final "Caution" statement differs in methods to ensure that the latch cams are closed:

United Airlines Maintenance Manual

CAUTION DO NOT FORCE HANDLE. LATCH CAMS NOT FULLY CLOSED COULD CAUSE HANDLE MECHANISM SHEAR RIVET TO SHEAR.

Boeing Airplane Company Maintenance Manual

CAUTION DO NOT FORCE HANDLE. IF RESISTANCE IS FELT, CHECK LATCH ALIGNMENT STRIPES THROUGH VIEWING PORTS IN DOOR. LATCH CAMS NOT FULLY CLOSED COULD CAUSE HANDLE MECHANISM SHEAR RIVET TO SHEAR.

The following step in Boeing's MM does not appear in the UAL MM: "Check that the Cargo Door Warning Light on flight engineer panel goes out." The UAL flightcrew checklist includes a check of the warning light as part of the cockpit procedures for dispatch.

Prior to the issuance of AD-88-12-04 (see 1.6.8), UAL ramp service personnel only operated the cargo doors electrically. Manual operation was accomplished only by maintenance personnel. AD-88-12-04 required the additional procedure of recycling the master latch lock handle following manual operation of the latch actuator.

1.6.3 UAL Boeing 747 Special Procedures--Doors

The Safety Board's investigation revealed that UAL had published a "special maintenance procedure" in the UAL MEL for manual operation of the cargo door. The Maintenance Manual Special Procedures, 5-8-2-52, dated January 1988, were incorporated into UAL's MEL for use by maintenance controllers and work foremen in issuing instructions or procedures to mechanics. The procedure allowed the use of a special 1/2-inch socket drive wrench as the primary tool for use in manually opening or closing the cargo door. The document further authorized, as an alternate tool, an air-driven torque-limiting screwdriver. UAL procedures required approval by San Francisco Line Maintenance and the station maintenance coordinator before an air-driven screwdriver could be used to operate the doors of a B-747 airplane with an inoperative cargo door power system.

At the Safety Board's public hearing, the FAA PMI and the FAA B-747 maintenance inspector for UAL testified that prior to the accident they were unaware of an FAA authorization for UAL's use of an air-driven torque-limiting screwdriver on B-747 cargo doors. However, the FAA's approval for the use of the tool was noted in the MEL section of the airline's maintenance manual. The original approval had occurred before the current inspectors assumed their respective positions. Both testified that they had not reviewed UAL's B-747 MEL because they assumed that the previous inspectors had reviewed it.

According to UAL, the calibration/adjustment for the torque-limited air-driven screwdrivers was tested every six months. Safety Board investigators found no records for the calibration/adjustment of the power tools used to manually open and close UAL B-747 cargo doors.

The Safety Board received statements from UAL supervisory maintenance personnel at all UAL stations and contract facilities for B-747 operations indicating that air-driven screwdrivers had not been used by maintenance personnel to open or close the forward cargo door on N4713U in the months prior to the accident.

1.6.4 UAL Maintenance Program

Airplanes operated by UAL are maintained under an FAA-approved continuous airworthiness maintenance program, as required by 14 CFR Part 121, Subpart L. The requirements of the UAL maintenance program are detailed in their Operations Specifications, dated November 21, 1988. Generally, UAL has an overall in-house capability to perform virtually all of the maintenance required on its own airframes and powerplants. All of the required major airframe and powerplant maintenance for N4713U had been performed at the UAL maintenance facility in San Francisco, California.

UAL's maintenance and inspection program is scheduled either at specific flight hour or calendar intervals. These maintenance and inspection programs are designated as: Service No. 1, Service No. 2, or A, B, C, MPV, and D Checks.

The work scope of Service Checks consists of a general inspection of the airplane and engines, including servicing of consumable fluids, oxygen, and tire pressures. The Service No. 1 check involves an inspection at each maintenance facility where the airplane lands. The Service No. 2 check is performed at a maintenance facility where the airplane is scheduled for at least 12 hours of ground time. The maximum time interval between Service No. 2 Checks is not to exceed 65 flight hours.

The "A" Check is performed at intervals not to exceed 350 flight hours. This check includes an extended inspection of the cockpit, cabin, cargo compartments, landing gear, tires, and brakes. It does not include a detailed inspection of the cargo doors.

The Phase Check ("B" Check) is scheduled on a calendar basis, not to exceed 131 days. The scope of the "B" Check contains items of inspection such as interior safety equipment and functional verification of various aircraft systems and components. It does not include a detailed inspection of the cargo doors.

The "C" Check is heavy maintenance oriented and is scheduled on a calendar basis, every 13 months. The "C" Check work scope is substantial and includes:

structural inspection items;

corrosion repair;

prevention and inspection of critical flight control systems; and,

a detailed inspection of the cargo doors.

The Mid-Period Visit (MPV) Check is a heavy maintenance inspection that is scheduled at intervals not to exceed 5 years. Items requiring scheduled overhaul are contained in the check as well as inspections of the airplane structure and interior.

The D Check, completes the routine scheduled B-747 maintenance plan and is scheduled at intervals not to exceed 9 years. The work scope is very similar to the MPV Check and consists of heavy maintenance to the airplane structure, landing gear, interior, and airplane systems, including the cargo doors.

1.6.5 Maintenance Records Review

A review of the airplane's history indicated that the forward and aft cargo doors were the original doors and neither had been removed for repair or replaced for cause. There was no record of major repair to either door or adjacent airplane structure.

The forward cargo door's forward mid-span latch pin had been removed because of gouging of the pin surface, during the last "C" check on

November 28, 1988. According to the available maintenance documents, including the most recent "D" check, a full cargo door rigging check had not been accomplished. UAL maintenance personnel indicated that no rigging of the forward or aft cargo doors was required during the following checks:

1. "D" check accomplished April 1984;
2. "C" checks accomplished November 11, 1987, and November 28, 1988; and,
3. "B" checks accomplished March 21, 1988 and July 27, 1988;

The records prior to the "D" check in 1984 and the "C" check accomplished in November 1987 were not required to be retained. This procedure complies with FAR 121.380.

The logbook of N4713U was reviewed and all numbered pages were in sequential order with none missing. The airplane had been released for flight by UAL, HNL Maintenance, in accordance with UAL procedures. The Los Angeles to HNL segment of flight 811, on February 23, 1989, generated four logbook discrepancy entries. All items were cleared by HNL maintenance and none were related to the cargo door. No new deferred items were generated and no current deferred items were corrected. The Maintenance Release document for flight 811 indicated that all deferred items were in accordance with the UAL Minimum Equipment List (MEL) and none referenced the forward cargo door.

UAL stores its maintenance information in an "electronic logbook," entitled Aircraft Maintenance Information System (AMIS). This system tracks on a daily and worldwide basis the flightcrew defect reports, all nonroutine maintenance defects, and maintenance corrective actions for the UAL airplane fleet. The system follows an Airline Transport Association (ATA) chapter format. According to UAL, the AMIS information is used as part of UAL's FAA approved maintenance reliability program affording the capability to assess trends at any given time.

A complete history of N4713U was reviewed for the following ATA Chapters:

Chapter-00-Miscellaneous

No significant items associated with the cargo door systems.

Chapter-21-Air Conditioning and Pressurization

An entry, dated August 19, 1988, indicated "Auto and Standby pressure controllers were erratic." UAL maintenance cleared this item as "Checked per Maintenance Manual Chapter (MM) 21-31-00.

Chapter-31-Instruments (Not related to any specific system)

No significant items associated with the cargo door systems.

Chapter-52-Doors (Cargo door section only)

During the period September 7, 1988, through November 1, 1988, a series of five discrepancies on the forward cargo door's electrical opening and closing system were noted. Ground handling personnel were required to operate the door by the manual system. On November 1, 1988, UAL maintenance corrective action for this discrepancy was signed off as, "replaced power unit [lift mechanism] per Maintenance Manual Chapter 52-34-02.

An expanded AMIS history of the N4713U forward cargo door system was prepared beginning December 1, 1988, and continuing until the date of the accident. The history tracked the airplane by each flight and station transited.

During the period December 5, 1988, through December 23, 1988, eight defect reports regarding the opening and closing of the forward cargo door were entered into the system. The reported defects involved problems with the cargo door not always operating with the normal electrical system. Appendix E contains the details of the writeups and corrective actions.

During the period December 23, 1988, through February 23, 1989, two forward cargo door discrepancies were noted on N4713U. On January 3, 1989, the discrepancy was, "Manual lock seals broken." The corrective action was signed off as, "recycled [door] per placard on door and documented. No door problems." On January 15, 1989, the discrepancy was, "cargo door seal, lower aft corner is torn and loose from retainer." The corrective action was "repaired seal." There were no further

recorded discrepancies.
On February 23, 1989, a written discrepancy noted "Aft cargo door damaged aft lower corner." The corrective action listed, "Interim repair per (EVA) LM-8-433. Accomplish permanent repair within 60 flight hours."

Chapter-53-Structures (Fuselage)

During the period March 1988, through February 24, 1989, one defect was noted for each of the forward and aft cargo doors on N4713U.

Forward Cargo Door.--On September 6, 1988, the discrepancy was, "Approximately six inches of forward cargo door jamb damaged center of lower side sealing surface." The corrective action was, "Installed doubler and sealed area."

Aft Cargo Door.--On April 22, 1988, the discrepancy was, "Aft cargo door rear sill latch does not spring up to lock." The corrective action was, "Replaced latch."

1.6.6 Service Difficulty Report Information

A review was made of the Service Difficulty Reports (SDRs) for ATA Chapter 52 for all UAL Boeing 747 airplanes. Thirty-nine SDRs were recorded over the period January 31, 1983, through March 21, 1989. The following summarizes data concerning the forward and aft cargo doors:

cases of corrosion;
cases of cracking;
cases of door open (false) indications;
cases where cabin did not pressurize;
cases of cabin pressure loss; and
case of dent caused by ground equipment.

None of the noted SDR cases were recorded for N4713U.

1.6.7 Service Letters and Service Bulletins

Boeing issues information to its customers via Service Letters (SL's) and Service Bulletins (SB's) to inform operators of reported and anticipated difficulties with various airplane models. Twelve

SL's provided guidance for maintenance or information applicable to the B-747 cargo doors. Twenty-nine SB's provided guidance for maintenance or information applicable to the B-747 cargo door.

SB-747-52-2097, "Pressure Relief Door Shroud Installation--Lower Lobe and Side Cargo Doors," was issued on June 27, 1975. Revision 1 to SB-747-52-2097 was issued November 14, 1975. In general, the SB recommended the installation of shrouds on the inboard sides of the cargo door pressure relief door openings. The purpose of the shrouds was to prevent the possibility of the pressure relief doors being rotated (blown) to the closed position during the pressurization cycle. This condition could only occur if the master latch lock handle had been left open and the flightcrew failed to note the cargo door open warning before takeoff.

UAL records for N4713U indicated that SB-747-52-2097 had been complied with and the shrouds had been installed on the forward and aft cargo doors. However, examination of the aft cargo door on N4713U revealed that the shrouds were not in place. UAL could not find records to verify if the shrouds had been installed or if they had been removed from either door.

1.6.8 Airworthiness Directives

There had been 141 Airworthiness Directives (ADs) issued that were applicable to the accident airplane. Two ADs were pertinent to the cargo door. AD 79-17-02-R2 ("Inspection of Fore and Aft Lower Cargo Door Sill Latch Support Fittings,") required an inspection every 1,700 flight hours. The second, AD 88-12-04 ("To Insure That Inadvertent Opening Of The Lower Cargo Door Will Not Occur In Flight,") issued on May 13, 1988, required an initial one time inspection of the cargo door latch locking mechanisms within 30 days of issuance of the AD, and certain repetitive inspections until terminating action for the AD was taken.

The circumstances of a Pan American World Airways (Pan Am), Boeing 747-122 cargo door opening in flight (see 1.17.1 for details) led to the issuance of Boeing Alert Service Bulletins (ASB) 52A2206 on April 8, 1987, and 52A2209 on August 27, 1987, entitled, "Doors - Cargo Doors Lower Lobe Forward and Aft Cargo Doors, Latch Locking System Tests, Operation and Modification." Tests and investigation revealed that latch lock sectors would, in some instances, not restrain the latch cams from being driven open manually or electrically. Movement of the latch cams without first moving the lock sectors to the stowed [unlocked] position would cause bending, gouging, and breaking of the sectors. The FAA issued AD-88-12-04 to make the provisions of SB's 52A2206 and 52A2209 mandatory.

The terminating action for AD 88-12-04 called for installing steel doublers to add strength to the lock sectors to prevent the latch cams from being able to be driven to the open position manually or electrically with the sectors in the locked position. AD 88-12-04 also required that, if the door could not be operated normally (electrically), a trained and qualified mechanic was to open and close the door manually, rather than ramp service personnel. Further, the AD required an inspection of the lock sectors for damage once a cargo door was restored to electrical operation after any malfunction had required manual operation of the door. The amount of time allowed for completing the terminating action portion of AD 88-12-04 was either 18 months or 24 months, from the issue date of the AD, depending on the Boeing 747 model series. Terminating action for the AD had not been accomplished on N4713U prior to the accident, nor was it required since, for this airplane, the deadline for compliance with the terminating action was January 1990. According to UAL, N4713U was scheduled for completion of the terminating action in April 1989, when the airplane was scheduled for other heavy maintenance.

During the Safety Board's investigation it was determined that a clerical error was made by UAL personnel, while attempting to expedite the processing of an advanced copy of a Notice of Proposed Rulemaking (NPRM 87-NM-148-AD), preceding AD 88-12-04. The error involved the omission of one line of text during the typing of the document. Because of that error, the portion of the text of the NPRM (and the final text of the AD) was left out of UAL's maintenance procedures. The omitted text required an inspection of the B-747 cargo door lock sectors every time a cargo door was restored to normal (electrical) operation after manual operation was required.

The UAL maintenance internal auditing system, including quality assurance personnel, did not detect the omission until after the accident. UAL personnel stated that, for unknown reasons, no one within the maintenance or quality assurance programs had reviewed the final AD language for comparison with the UAL maintenance procedure.

A review by Safety Board investigators of forms used by UAL to verify compliance with applicable FAA AD's issued indicated that all of the applicable mandatory ADs were satisfied within their specified time limits. The list provided by UAL to the FAA as part of the FAA's oversight responsibilities showed compliance with AD-88-12-04, with the exception of the terminating action.

Section 1.17.3 contains information relevant to the B-747 cargo door corrective actions taken since the accident.

1.7 Meteorological Information

The accident occurred in night visual meteorological conditions. No adverse weather was experienced, although the flight did have to deviate around thunderstorms during the descent.

1.8 Aids to Navigation

There were no navigational problems.

1.9 Communications

There were no radio communication difficulties between flight 811 and air traffic control (ATC). Members of the flightcrew did not have any difficulty in verbally communicating with each other; however, attempts to communicate with the cabin crewmembers by interphone were unsuccessful following the explosive decompression.

1.10 Aerodrome Information

After the explosive decompression, the airplane returned to HNL, a 14 CFR Part 139 certificated airport on the island of Oahu, Hawaii. The airport is located about 4 miles west of Honolulu, Hawaii.

HNL is a "joint use" airport that is used by the State of Hawaii, the U.S. Air Force, general aviation, commercial, air carrier, air taxi, and military aircraft. Aircraft Rescue and Fire Fighting (ARFF) services are provided by State and Hickam Air Force Base ARFF units. Prior to the emergency landing at Honolulu, flight 811 requested that all available rescue and medical equipment to be on hand when they landed. When the crash alarm was broadcast, all civilian and military fire units responded and were in position in 1-minute at pre-designated stations at runway 8 left.

The Safety Board's investigation revealed that there was no direct radio communications between the State Airport vehicles and Hickam ARFF vehicles. Because there were no direct radio communications, the Chief of the airport's units had to drive his vehicle to the vehicle of the Chief of the Hickam units to coordinate the positioning of ARFF units prior to the landing of United 811.

The Hickam vehicles are painted olive drab camouflage. During the response, the Chief of the State ARFF vehicles observed a near collision between a State and a Hickam vehicle. He attributed this to the camouflaged Hickam vehicle not being visually conspicuous in spite of the fact that each of the vehicles had a red rotating beacon operating. The response took place on a moonless night and in light rain.

1.11 Flight Recorders

The airplane was equipped with a Sundstrand model 573 digital type Flight Data Recorder (DFDR) and a Sundstrand model AV557-B Cockpit Voice Recorder (CVR).

Examination of the data plotted from the DFDR indicated that the flight was normal from liftoff to the accident. The recorder operated normally during the period. However, the decompression event caused a data loss of approximately 2 1/2 seconds. When the data resumed being recorded, all values appeared valid with the exception of the pitch and roll parameters. Lateral acceleration showed a sharp increase immediately following the decompression. Vertical acceleration showed a sharp, rapid change just after the decompression and a slight increase as the airplane began its descent.

The CVR revealed normal communication before the decompression. At 0209:09:2 HST, a loud bang could be heard on the CVR. The loud bang was about 1.5 seconds after a "thump" was heard on the CVR for which one of the flightcrew made a comment. The electrical power to the CVR was lost for approximately 21.4 seconds following the loud bang. The CVR returned to normal operation at 0209:29 HST, and cockpit conversation continued to be recorded in a normal manner.

1.12 Wreckage and Impact Information

An extensive air and surface search of the ocean conducted immediately following the accident failed to locate the portions of the airplane lost during the explosive decompression. However, the Safety Board, as well as other parties to the investigation, pursued several avenues to search for and recover the cargo door. Navy radar near Honolulu tracked debris that fell from the airplane when the cargo door was lost. Refinement of the radar data led to a probable "splashdown" point in the ocean. Further assistance from the Navy regarding the ocean currents and drift information led to a probable location of the cargo door and

associated debris on the ocean floor.
The undersea search operation was begun on July 22, 1990, using the Orion, a state-of-the-art Navy side-scanning sonar "fish." Searching in the area selected by analysis of radar data and undersea currents, the Orion located a debris field on its first pass over the 14,200-foot-deep ocean floor. The second pass located a significant sonar target, which later analysis indicated was probably the cargo door. Since the Orion is only capable of searching, the debris field was marked with transponders for use during the subsequent recovery phase.
On September 14, 1990, the recovery ship Laney Chouest sailed from Pearl Harbor with the manned, deep-sea submersible Sea Cliff. Safety Board, FAA, Boeing, and UAL engineering staff assisted the recovery team aboard the Laney Chouest. After four dives in the area previously identified as the debris field, only pieces of cargo container and other small debris from the airplane had been recovered. (It appears that the significant target identified by the Orion was a piece of cargo container rather than the cargo door.) On the following dive, however, the lower portion of the cargo door was located and recovered. The fuselage structure above the cargo door was located and raised to the surface on the sixth dive, but heavy seas prevented its recovery. The upper portion of the door was recovered during the Sea Cliff's seventh dive on October 1, 1990. Afterward, it was decided that no further effort could be justified to recover the fuselage structure above the cargo door, and the recovery mission was terminated.
Following recovery of the cargo door, each piece was sprayed with a corrosion inhibitor. The ship promptly returned to Pearl Harbor, and the retrieved door portions were removed and examined before being shipped to Seattle, Washington, for detailed examinations under the supervision of Safety Board staff.
Visual examinations on the recovery ship and in Pearl Harbor

confirmed that the cargo door lock sectors were in the locked position and that the latch cams were in the nearly open position. Figure 6 depicts the position of the lock sectors and cams as recovered from the ocean. There was no evidence of progressive fractures in the door structure.

The cost for the search mission was $193,000, and the cost for the recovery mission was $250,000. These costs were shared by the Safety Board, the FAA, UAL, and Boeing. Section 1.16 contains information on the examination of the recovered wreckage.

1.13 Medical and Pathological Information

Appendix D contains a list of injuries.

1.14 Fire

There was no fire in the cabin or fuselage. The fires in engines No. 3 and 4 were extinguished after the engines were shut down.

1.15 Survival Aspects

The fatal injuries were the result of the explosive nature of the decompression, which swept nine of the passengers from the airplane.

At 0210, the FAA notified the U.S. Coast Guard that a United Airlines, Inc., B-747, with a possible bomb on board, had experienced an explosion and was returning to HNL. The Coast Guard Cutter, Cape Corwin, departed Maui at 0248 to search the area for debris and the missing passengers. Ultimately, 4 shore commands, 13 surface/air units, and approximately 1,000 persons took part in the combined search and rescue (SAR) operation. The search was t™ erminated at 1200 on February 26, 1989, without recovery of any passenger bodies.

The flight attendants had approximately 20 minutes to prepare the cabin and the passengers for an imminent ocean ditching, and subsequently, for an emergency evacuation. During the 20 minutes they attended to injured flight attendants and passengers, attached the face masks to their emergency oxygen bottles, helped each other don life preservers, helped numerous passengers don life preservers, held up safety cards and life vests to call attention to these items for passengers to use, briefed "helper" passengers to assist in the evacuation, cleared debris away from the exit doors and aisles, closed the doors of the storage compartment above doors 2 left and 2 right, prepared the cabin for an emergency evacuation, and told the passengers to brace for impact.

Several problems were experienced by the flight attendants and the passengers following the decompression, while preparing for a possible ditching, and preparing for the emergency evacuation. These problems included difficulties encountered by flight attendants in connecting face masks to their portable oxygen bottles, the lack of a sufficient number of megaphones, limited visibility from a flight attendant seat, overhead storage compartment doors opening, and donning and fastening life preservers.

Federal Aviation Regulation 14 CFR 25.1447 (c)(4) requires that "portable oxygen equipment must be immediately available for each cabin attendant." Those portable oxygen bottles on N4713U, which were readily available, were not immediately usable because the masks were not attached to the regulators. The flight attendants reported difficulties in attaching the masks to the regulators.

The aft purser ran back to the flight attendant jumpseat at door 5-left for a portable oxygen bottle. However, she found no bottle at this location (none was installed). She then ran back to the 4-left jumpseat, by which time she was "light headed." After the aft purser reached jumpseat 4-left, flight attendant No. 14, who was already sitting there, placed an oxygen mask on her face. The aft purser further stated, "considering the fact that in this case there was no other available source of oxygen, you can't imagine how horrible I felt going back there needing oxygen but finding no oxygen bottle at 5-left. It was terrifying."

A portable emergency oxygen bottle was not required to be stowed at the flight attendant seat at exit 5-right; however, one was stowed in the right coat closet behind the flight attendant seat. In addition, the left side closet and rest rooms were physically separated from the right side closet and rest rooms. This arrangement requires a flight attendant, who was seated at exit 5-left to walk around to the right side of the cabin to obtain the oxygen bottle.

Communication between the flight attendants and passengers was very difficult because of the high ambient noise level in the cabin after the decompression, even though the public address (PA) system was operational. Flight attendants were located at each of the 10 exit doors, yet there were only two megaphones required to be on the airplane; one located at door 1-left and another located a 4-left.

The flight attendants, who were responsible for each of these two doors, used the megaphones to broadcast commands to passengers in their immediate areas and to other flight attendants in preparation for the landing and subsequent evacuation. The other 13 flight attendants (including the one deadheading flight attendant) had to shout, use hand signals, and show passengers how to prepare for the evacuation by holding up passenger safety cards, so passengers could review the information and also know how to put on their life preservers.

As soon as the decompression occurred, the flight attendant in the upper deck business class section went to her jumpseat and donned her oxygen mask, life preserver, and restraint system. While she waited for instructions, and because of intense cabin noise she had to communicate with passengers by holding up a safety card and a life preserver. Passengers sitting in the front rows, in turn, showed safety cards and life preservers to other passengers seated behind them. Eventually everyone understood that they were to read the safety card and put on their preservers.

However, the 5 foot 3 1/2 inch flight attendant stated that her jumpseat was so low that she could not directly observe the passengers in the 4th row (last).

A two door overhead stowage compartment that had formerly stored a life raft was located above each exit door. These compartments contained blankets and passenger carry-on luggage. At doors 2-left and 2-right the doors of each compartment had opened downward and blocked each exit. Also the contents of the compartments fell to the floor at the exits. The doors had to be closed before the evacuation because they partially blocked the exit.

The chief purser was not able to tighten the life preserver's two straps around her waist and needed the deadheading flight attendant to tighten them for her. Several flight attendants and passengers had difficulties connecting the two straps around their waists. One flight attendant helped about 36 passengers don their preservers.

Safety Board investigators and United Airlines personnel examined several life preservers from each of the types of preservers produced by five manufacturers. The strap of one manufacturer's preserver was very difficult to tighten around the waist while another from the same manufacturer was easy to tighten. The two vests had different strap material and strap adjustment fittings. Also, the straps are very difficult, if not impossible, to tighten when they are pulled at an acute angle from the wearer's body, i.e. from about 45 to 70 degrees. Holding the hands and straps closer to the waist facilitates easier adjustment of the straps.

1.16 Tests and Research

1.16.1 Cargo Door Hardware Examinations

1.16.1.1 Before Recovery of the Door

The following forward cargo door closing and latching components were returned to the Safety Board's Materials

Laboratory for analysis after they were documented in place on the airplane:

Two pull-in hook pins, one from the lower end of the forward side of the door body cutout forward frame, and one from the lower end of the aft side of the body cutout aft frame, with housings;

Two mid-span pins, one from the forward side of the door body cutout forward frame, and one from the aft side of the door body cutout aft frame.

All components were initially examined while installed on the airplane. All eight forward cargo door latch pins, with housings, were removed for further laboratory examination. Also, for comparison, one of the latch pins, with housing, from the aft cargo door was also removed. For orientation purposes, the eight lower latch pin assemblies are referred to by number, with the No. 1 latch pin being the most forward on the lower door sill, and the No. 8 pin being the most aft. When referencing a circumferential location on the latch pins or mid-span pins, a clock position was used. The clock code was oriented looking forward with 12 o'clock being straight up and 9 o'clock being directly inboard.

Based on the orientation of the latching mechanisms, the fully unlatched latching cams would first contact the latch pins from about the 1:15 o'clock position to the 7:15 position as the door was closed. As the cams are being latched around the pins, they would rotate approximately 80(, making contact with the pins from about the 4:15 position to the 10:15 position (See figure 7).

Detailed examination of the exposed surface of the pins (the portion of the pins extending from the housings) revealed various types of wear and damage. In general, all of the forward door cargo latch pins had smooth wear over the entire portion of the pin area contacted by the cams during normal closing and opening of the door. The pins also had distinct roughened (smeared) areas between the 6:15 and the 7:30 positions (See figure 8). The roughened areas had evidence of "heat tinting" and transfer of cam material to the surface of the pins. On pins 1 and 8 the roughened areas extended past the pin bottom to the 5:00 position. The 7:30 position approximately corresponds to the area on the pin where the lower surface of the cam would be relative to the pin when the latch cams are in the unlatched or nearly unlatched position.

The forward pull-in hook pin was not significantly bent, but the structure to which it was attached was deformed outward, so the hook pin was deflected significantly outward. Three of the four bolts holding the aft pull-in hook pin had sheared, so the hook pin was also deflected outward. Both hook pin ends were damaged, but neither pin was significantly deformed along its length. There was significant heat tinting on the damaged area of the forward hook pin. Boeing engineering calculations determined that the pull-in hook pins would fail at a 3.5 psi differential cabin pressure with the latch cams unlatched.

The forward mid-span latch pin was relatively undamaged. The aft mid-span latch pin had definite areas of damage. Both pins had wear areas where the cams would contact the pins during latching.

1.16.1.2 After Recovery of the Door

The documentation of the recovered cargo door was divided into four areas: 1) door structure, 2) master latch lock system, 3) latch system, and 4) hook system. A description of the recovered door follows.

1. Door Structure:

The cargo door had fractured longitudinally near the mid-span lap joint near stringer 34R, just beneath the mid-span torque tubes. Except for an area of missing skin between frames 2 and 3 and a portion of frame webs where the upper latch lock torque tube had torn out, the frames and skin of the upper door

piece mated to the lower door piece.2 Several areas of the upper door skin along the longitudinal fracture were bent back. In addition, a large area of lower door skin between frame 6 and the aft door edge had peeled downward from the fracture line. The two door pieces are shown together in Figures 9 and 10.
Examinations of the fracture surfaces of the skin and frames revealed no evidence of pre-existing cracks. All fractures were typical of overstress separation.
Seven of the eight lock sector slots in the lower beam showed evidence of contact and scraping by the lock sectors. Only the No. 1 lock sector slot was undamaged, although the bracket forward and above the No. 1 slot did appear to have been damaged by contact from the lock sector (slots numbered 1-8, forward-aft).
The direction of the scraping on the slots could not be determined conclusively.
The decal covering the latch actuator manual drive port was found broken circumferentially around the edge of the port cover, which was loose and rotated from its normal position (See figure 11). There was an impression in the decal similar to a Phillips-head screw slot in line with the center of the retainer screw securing the cover. There was also a 0.06-inch-long linear slit from 10 to 4 o'clock approximately centered over the retainer screw head (See figures 12 and 13). There was no rotational tearing and no loss of decal material in the area covering the screw head location. During examinations of the door at Boeing, it was noted that the retainer bracket on the inside of the latch actuator manual drive port cover was bowed outward; the port cover was not deformed. The retainer bracket on the inside of the hook actuator manual drive port cover was similarly bowed outward, and the port cover was bowed outward.
The hinge that attaches the cargo door to the fuselage is comprised of several hinge sections--those attached along the upper edge of the cargo door and those along the fuselage just

above the cargo door cutout--interconnected with hinge pins. The hinge pins and all hinge sections from N4713U's forward cargo door were intact; all hinge sections rotated relatively easily. All attach bolts from the hinge sections on the door remained attached; conversely, no bolts remained attached to the hinge sections on the fuselage. Several areas on the hinge sections, such as the fuselage hinge sections, showed evidence of contact from the door during overtravel (See figure 14). In addition, the fuselage forward hinge sections

were slightly bent. The upper flange of the door, to which the door hinges are attached, was not deformed. The forward cargo door can rotate open 143 degrees before the hinge would deform, permitting the door to contact the fuselage above.

Examination of the outer skin contour of the upper door piece revealed that it had been crushed inward. There were also many areas on the outer skin where blue and red paint transfer marks could be seen. These marks were generally forward of the aft pressure-relief door, and the blue marks were located above the red marks. The UAL paint pattern incorporates red and blue stripes along the fuselage above the cargo door. Figure 15 is a plot of the documented paint marks on the upper door piece.

There was no evidence of the pressure relief door shrouds found on the forward door; however, most of the inner door lining to which the shrouds attach was missing.

2. Master Latch Lock System:

All eight lock sectors were found in the locked position--actually past the fully locked position. They had been pulled through the lock sector slots in the lower beam of the cargo door. (When they are fully locked, the lock sectors should be recessed in the lower beam approximately 3/8 inch). All lock sectors had deflected off the high shoulder of the latch cams due to interference with the partially unlatched cams. Prior to disassembly of the components, the interference between the cams and the lock sectors was

removed by rotating the cams to the latched position.
Examination of the lock sectors disclosed that the bottom of the lower arm of each lock sector was gouged. For seven of the eight lock sectors, the distance from the main gouge area to the location of the interference between the latch cam and the lock sector was approximately 0.75 inch. (The No. 2 lock sector was corroded and had fractured at the location of the large gouge common to the other seven lock sectors. Consequently, it was not in contact with the No. 2 latch cam when the door was retrieved).
The master latch lock handle housing and trigger were found relatively flush with the door outer skin. The top of the handle was recessed approximately 0.50 inch inward from flush, and the bottom of the handle was protruding approximately 0.40 inch outward from flush (See figure 16). This
Figure 15.--Documented paint marks on outer skin of upper door piece. Dashed line is approximately 8 degrees from horizontal.
position of the handle indicates that the lock sectors were in a position past fully locked. The fuse pin was found in three pieces but was heavily corroded. The handle housing was undamaged.
Two of the three connecting rods between the master latch lock handle and the lock sector torque tube were bowed slightly, but they were otherwise intact. No deformation was observed on any section of the lock sector torque tube, although one of the six bearings assembled on the torque tube had been damaged. The No. 3 bearing inner race and its torque tube locator sleeve were displaced forward approximately 0.20 inch from the bearing housing centerline. The outer race was broken and pushed forward out of the housing.
The lower two connecting rods between the lock sector torque tube and the torque tube below the pressure-relief doors were undamaged; however, the upper connecting rod had separated at the upper, tapered end. The torque tube below the pressure-relief doors were missing, and the pressure-relief door connecting rods

had separated at the lower, tapered end. The remaining portion of each rod was undamaged, but the forward pressure-relief door was jammed open into the cutout.

3. Latch System:

All eight lower latch cams were found in a nearly unlatched position, and all of them were binding against the lock sectors except the No. 2 cam (lock sector No. 2 had broken). Latch cams 1-6 were approximately 62 degrees from the fully latched position, and cams 7 and 8 were approximately 70 degrees from fully latched. Full rotation of the latch cams is 80 degrees.

Several of the lower latch cams contained compression and smearing damage on the lower lip of the latch cam cavity ("lower" relative to an open cam). This damage is consistent with the forceful movement of the cams across the latch pins.

The four rods between the latch actuator torque tube and the four bellcranks containing the latch cams were attached and undamaged. No section of the latch actuator torque tube was damaged, and the bearings/supports along the tube were intact.

The latch actuator was removed and later disassembled. No anomalies were found.

4. Pull-in Hook System:

The forward and aft pull-in hooks were found near the closed position. Both of them exhibited wear patterns consistent with contact with the pull-in hook pins during door operation. For both the forward and aft hooks, the inboard edge of the pull-in hook channel contained compression and smearing damage consistent with a forceful movement of the hooks over the pins while the hooks were in the closed or nearly closed position.

1.16.2 Forward Cargo Door Electrical Component Examinations

1.16.2.1 Before Recovery of the Door

Several electrical components associated with the operation of the forward cargo door were examined on the airplane and were then removed for further testing. These components included the No. 2 ground handling power bus relay, the air/ground safety relay, the No. 1 auxiliary power circuit breaker, and the outside and inside door control switches. All of these components were tested for both single faults and intermittent failures. The test results showed that all of the switches/relays were functional, although a loose wire connection was found on the outside door control switch. This loose wire connection showed evidence of overheated insulation on the two terminal lugs that attach to terminal No. 5, and there was evidence of a burn (arc point) on the top of the screw head for terminal No. 5. Terminal No. 5 is associated with power for the door "close" cycle, and not the door "open" cycle.

An electrical continuity check was performed on the cockpit cargo door warning light system components that remained with the airplane. This check confirmed the integrity of the circuit from the door area to the cockpit. The examination of the two bulbs that comprise the forward cargo door warning light revealed that one bulb was inoperative. The other bulb, which is in parallel with the inoperative bulb, was found operative. The illumination of the display legend, which reads "FWD CARGO DR" on the flight engineer's panel, was discernible with one bulb inoperative. A functional check of the circuit, which allows the cockpit warning lights to be dimmed during night operations, was also performed. The check consisted of removing the card containing this circuit and installing it in another B-747. The test was satisfactory in that the dim/bright circuit functioned properly.

1.16.2.2 After Recovery of the Door Switches--General

The cargo door was recovered with all of its position sensing switches installed in their proper locations. The electrical junction box was found attached to the door but damaged. The switches recovered and examined were: S2 Master Latch Lock; S3 Door

Warning; S4 Latch Close; S5 Hook Position; S6 Fwd Mid-Span Latch Open; S7 Door Close; S8 Hook Close; and S9 Aft Mid-Span Latch Open. Figure 17 provides a diagram of the cargo door's electrical circuitry.

Five of the eight position-sensing switches installed on the door had evidence of external damage to the switch housing. The damage on four switches (S2,S3,S4,S8) consisted of primarily compression dimpling on the housing. The S5 switch exhibited mechanical impact damage on the switch housing and mounting bracket. The striker assembly for switch S8 was loose (2 of 3 rivet fasteners sheared). The electrical wiring recovered with the door exhibited signs of tensile separation from overload at all failure points examined.

Each switch was photographed and its installed position was documented. Electrical continuity readings were taken with an ohmmeter across the poles of each switch at the first point of wire separation as found on the door. After the readings were recorded, all switches were removed from the door so that photographs and x-rays of each switch could be taken. Electrical continuity readings were retaken.

Disassembly of each switch consisted of: (1) drilling two holes in the switch housing to release trapped water from the switch (2) cutting a small window in the switch housing to examine the internal basic switches (3) removing the housing, (4) removing the internal bracket, and (5) removing basic switch covers.

During the drilling step, water was released from every switch when the holes were drilled in the switch housing. The water was filtered into a glass container. The quantity was not measured but appeared to be less than 5 mL. The residue from the filtered water trapped on the filter media had a blue-green color.

After the switch housing was removed, an ohmmeter was connected across the 1-2 poles of the switches that would not transfer electrical continuity (S2,S3,S4,S6,S7) when actuated. The rivets were then drilled out of the internal bracket. After the last of the two rivets were drilled out, the switch contacts

Figure 17b.--Diagram of cargo door electrical circuitry.

transferred to the other pole on S2, S3, and S4. On S6, the used3 basic switch was held closed by its plunger. S7 transferred after the switch housing and water inside were removed.

During removal of the basic switch covers, a trend was noted in the discoloration of some of the basic switches. The used switch had a reddish-brown coloration. The unused switch was not discolored.

Each switch was found to be wired correctly to its poles and through its contacts within the basic switches. All contacts operated with light finger pressure after removal of the basic switch covers. There was no evidence of pitting, excessive corrosion, or heat distress in the contacts of any of the switches.

The following sections detail pertinent observations concerning each switch.

The S2 master latch lock is given particular significance because of its function to protect against inadvertent door operation and is thus described in more detail. It is a single-pole double-throw (SPDT) switch used to sense the unlocked position of the door lock sectors. The switch is mounted in the aft lower corner of the door. A bracket attached to the No. 7 lock sector depresses the switch when the door lock sectors are rotated to their unlocked position. When the bracket attached to the lock sector contacts the switch plunger and depresses it, the circuit path through the switch is closed and 28VDC electrical control power to the door is established. When the force on the plunger is relaxed, the circuit is opened and 28VDC electrical control circuit is removed.

The wires leading to the S2 switch had been cut by the team after the recovery in an attempt to test continuity through the switch. The door recovery team reported that it found continuity through the 1-3 contacts but not through the 1-2 contacts. The switch plunger was actuated by the recovery team. The recovery team noted that the switch did not transfer continuity during these tests. The operation of the switch plunger would normally transfer continuity. Subsequent detailed examination of the S2 switch confirmed the findings of the recovery team.

The area around the upper face of the internal bracket was bent toward the basic switches and had evidence of corrosion residue. The bracket was found broken. The switch contacts transferred from the 1-3 actuated position to the 1-2 nonactuated position when the bracket was removed. Scanning electron microscope examination of the fracture surfaces revealed evidence of overload and corrosion.

The external switch housing was dented. The final examination performed on the switch consisted of removing the plastic covers on the basic switches. Prior to removal of the basic switch covers, it was noted that the cover to the used basic switch was cracked. The contacts functioned normally when exercised by light finger pressure.

Microscopic examination revealed a black discoloration near one of the lower contact posts of the used basic switch. Energy dispersive spectrometric examination of the residue disclosed the presence of gold, iron, magnesium, sodium, and chlorine. No mechanical or electrical anomalies were detected with the basic switch contacts.

Additional testing was performed by Boeing on switches of a similar design to those used on the accident airplane's cargo door. The testing was conducted to identify conditions that would result from salt water immersion at a pressure depth of 14,200 feet for 18 months. The testing verified that external damage to the switch housing occurred at pressure depths of 7,000 feet and greater. Switch seal leakage and subsequent internal corrosion was also noted. None of the testing performed by Boeing duplicated internal switch damage that caused basic switch

contact closure or internal damage to the switch support bracket.
Wiring:
The electrical wiring recovered with the cargo door was documented in place before being removed for further tests. About 40 percent or 112 feet of wire from the original length of approximately 274 feet was recovered and examined. Of this amount, about 46 feet of wire installed in the aircraft forward of the cargo door was not examined. Most of the wires leading from the door to the fuselage were not recovered. There was no visible external evidence of burning, arcing, or heat distress in any of the wires removed. Several areas of wire insulation damage were found.
Thirty five wires were identified that could provide a possible short circuit path that could drive the latch actuator open with or without failures of other door electrical components if the ground handling bus was energized. The wires were schematically coded by function. Wires coded (-..-..-) were denoted for wiring that provides open command logic to the latch actuator. Wires coded (--.--.--.) were denoted for additional wiring enabled by an activated (failed) S2 switch. Wires coded (-o-o-o-o) were denoted for wiring providing 28VDC power from the C285 circuit.
Potential short circuit paths were identified for the cargo door that could provide 28VDC to the latch actuator control circuit relay. These potential short circuit paths can cause the latch actuator to drive the latches toward their open position if 115VAC power is available to the latch actuator motor. The potential short circuit paths include two bare wires shorting against each other, bare wire-to-metal structure-to-bare wire contact, wire to conductive fluid (such as water) to wire, or a combination of the aforementioned.
Conductive contact of (-o-o-o-o) or (--.--.--) coded wire with (-..-..-) coded wire could potentially result in providing a 28VDC circuit path to the latch actuator open circuit. Direct wire-to-wire paths

are coded in Figure 17 as defined above. The two-wire short circuit paths are identified as wire pairs consisting of wire 101-20 shorting with any of the following wires; 108-20, 121-20, 122-20, 124-20, 135-20, or 136-20.

If the S2 master latch lock switch fails in the "Not Locked" position, there are additional wire pairs that provide short circuit paths. These are coded in Figure 17 as (--.--.--) to (-..-..-..) wire pairs.

Short Circuit Wire Damage Simulation Tests:

Tests were conducted by Boeing and United to simulate typical examples of bare wire short circuiting to determine the extent of visible wire damage that would be expected in the 28VDC cargo door control circuit.

United performed tests on BMS 13-42 wire, the wire type used in the B-747 cargo door control circuit. Visible electrical short circuit damage on bare BMS 13-42 wire surfaces was difficult to create at 28VDC. Surface damage was considered visible when detected by microscopic examination at 15X magnification. United testing simulated the relay coil resistance variations that would be found during typical in-service conditions. A current of 1.0 A at 28VDC created visible surface damage on momentary bare wire-to-bare wire contact. Multiple contacts at 1.0 A provided a more positive indication. A single momentary contact between two bare BMS 13-42 wires with 0.160 A at 28VDC did not create visible surface damage. Contact between a BMS 13-42 bare wire and Alclad 2024-T3 metal (airplane and cargo door structure) with 0.160A at 28VDC did not create visible surface damage.

Boeing performed wire tests on BMS 13-48 20 gauge wire. The test setup used the MS27418-2B door latch actuator control relay in parallel with the 60B00311-2 door restraint solenoid, the actual electrical loads used in the B-747 cargo door latch actuator control circuit. A single momentary contact of a bare 28VDC power wire, with a bare wire connecting to the relay of the solenoid, showed small pithead area developed at the point of wire contact that was visible without magnification.

Wire Examination Procedure:

All of the recovered wires were examined in the Safety Board's Materials Laboratory on a mylar sheet to simulate their installed positions. Labels were used to identify the coded wires using the manufacturer's original wire identification numbers imprinted on each wire's insulation. Wire pairs for direct electrical short circuiting were located in two common wire bundles installed on the cargo door. One common wire bundle was associated with the P3 plug connector, the other with the P4 plug junction box. The wire bundles were examined visually for areas of obvious insulation damage. Each individual wire was also examined with a stereo-microscope. Representative wire damage features were photographed.

Wire Damage Found:

Seven wires numbered 101-20, 102-20, 105-20, 107-20, 108-20, 122-20, and 135-20 had visible damage located near a 3.8 inch position as measured from the P3 plug pin tips. This common position on the wire corresponds to a 360-degree loop in the wire bundle, which is located immediately below the junction box. Figures 18 and 19 show typical wire damage. Wire 122-20 had an open insulation area approximately 0.25 inch long. The other four wires had flattened insulation damage areas.

In the P4 plug connector wire bundle, three wires displayed insulation damage. Wires 113-20, 121-20, and 124-20 had transverse insulation nicks, which exposed bare conductors. All three had insulation nicks 3 inches from the P4 plug pin tips; wires 121-20 and 124-20 had additional insulation nicks 34 inches from the plug pin tips. The two P4 insulation damage locations corresponded to wire bundle clamp positions.

1.16.3 Pressurization System

The pressure relief valves located on the left side of the fuselage in the forward cargo compartment were removed from the airplane and subjected to bench tests at the UAL maintenance facility in San Francisco, California. No significant anomalies were discovered and both valves performed within specified tolerances.

1.16.4 General Inspection of Other UAL Airplanes

During the on-scene phase of the investigation, the Safety Board investigators examined six other B-747 airplanes while they were on the ground at HNL (four UAL airplanes and two operated by other carriers) to observe routine cargo door operations and to assess the condition of latching components. Generally, the door operations were normal. During the examination of latch pins on these airplanes, it was noted that most had a smooth wear ridge at the 9:00 position (looking forward) or were undamaged. All wear areas on the pins were smooth.

During electrical operation of the aft cargo door on one of the other UAL B-747 airplanes (N4718U), the pull-in hooks did not pull the door fully closed and the latch cams completed the closure. During operation of the latch cams, the bottom of the door moved, first circumferentially downward and then inboard. This additional movement was approximately 1/4 inch. A definite "thunking" noise was discernible as the door moved to its closed position at the end of cam rotation. On one occasion, the door would not open under electrical power. The door was "kicked" by a UAL mechanic, power was reapplied, and the door opened properly. Examination of the door by UAL mechanics, disclosed that the riveted plate holding the aft pull-in hook switch striker was loose.

All eight lower latch pins for the forward cargo door on N4718U exhibited a smooth ridge near the 9:00 position. Pins No. 1 and 2 also showed a smooth ridge at the 6:30 position with a smooth wear area between the 6:30 and 9:00 position. The forward and aft midspan cams of both forward and aft cargo doors had a heavy gouge mark corresponding to the end of the midspan latch pin. N4718U was subsequently removed from service for repair of the aft cargo door latching mechanisms.

1.17 Additional Information

1.17.1 Previous Cargo Door Incident

On March 10, 1987, a Pan American Airways B-747-122, N740PA, operating as flight 125 from London to New York, experienced an incident involving the forward cargo door. According to Pan Am and Boeing officials who investigated this incident, the flightcrew experienced pressurization problems as the airplane was climbing through about 20,000 feet. The crew began a descent and the pressurization problem ceased about 15,000 feet. The crew began to climb again, but about 20,000 feet, the cabin altitude began to rise rapidly again. The flight returned to London.

When the airplane was examined on the ground, the forward cargo door was found open about 1 1/2 inches along the bottom with the latch cams unlatched and the master latch lock handle closed. The cockpit cargo door warning light was off.

According to the persons who examined the airplane, the cargo door had been closed manually and the manual master latch lock handle was stowed, in turn closing the pressure relief doors and extinguishing the cockpit cargo door warning light. Subsequent investigation on N740PA revealed that the latch lock sectors had been damaged and would not restrain the latch cams from being driven open electrically or manually. It was concluded by Boeing and Pan Am that the ground service person who closed the cargo door apparently had back-driven (opened) the latches manually after the door had been closed and locked. The damage to the sectors, and the absence of other mechanical or electrical failures supported this conclusion.

Further testing of the door components from N740PA and attempts to recreate the events that led to the door opening in flight revealed that the lock sectors, even in their damaged condition, prevented the master latch lock handle from being stowed, until the latch cams had been rotated to within 20 turns (using the manual 1/2 inch socket drive) of being fully closed. A full cycle, from closed to open, is about 95 turns with the manual drive system.

1.17.2 FAA Surveillance of UAL Maintenance

The Denver, Colorado, FAA Flight Standards District Office (FSDO) holds the operating certificate for United Airlines, Inc. The FAA FSDO in San Francisco, California, has the primary surveillance and oversight responsibility for UAL maintenance.

The FAA's PMI has the responsibility to oversee an airline's compliance with Federal Regulations with respect to maintenance, preventive maintenance, and alteration programs. The PMI determines the need for, and then establishes work programs for, surveillance and inspection of the airline to assure adherence to the applicable regulations. A portion of the PMIs position description reads as follows:

Provides guidance to the assigned air carrier in the development of required maintenance manuals and recordkeeping systems. Reviews and determines adequacy of manuals associated with the air carrier's maintenance programs and revisions thereto. Assures that manuals and revisions comply with regulatory requirements, prescribe safe practices, and furnish clear and specific instructions governing maintenance programs. Approves operations specifications and amendments thereto.

Determines if overhaul and inspection time limitations warrant revision.

Determines if the air carrier's training program meets the requirements of the FARs, is compatible with the maintenance program, is properly organized and effectively conducted, and results in trained and competent personnel.

Directs the inspection and surveillance of the air carrier's continuous airworthiness maintenance program. Monitors all phases of the air carrier's maintenance operation, including the following: maintenance, engineering, quality control, production control, training, and reliability programs.

At the Safety Board's public hearing on this accident, the PMI for United Airlines at the time of the flight 811 accident stated that he was trained as an FAA air carrier inspector and had been assigned to United Airlines since November 25, 1985. In addition to attending the normal FAA indoctrination course, he had received training in accident investigation, compliance enforcement, nondestructive testing, enforcement, and composite materials. To qualify for the position of PMI, he had completed a 3-week management training course at Lawton, Oklahoma. This was supplemented by a 2-week course on management training systems.

According to the PMI, FAA surveillance of UAL B-747 maintenance activities was organized around the daily work schedule of the FAA air safety inspector, specifically assigned to the UAL B-747 fleet by the PMI. The schedule for surveillance is normally prepared a year in advance by the FAA computerized Work Planning Management System (WPMS). Each FAA inspector is assigned specific responsibilities in the surveillance and monitoring of the airplane fleet to which he is assigned.

The PMI stated that assigned inspectors conducted surveillance of the UAL airplanes while they were in light or heavy maintenance and when they were released to service or in the process of preparing for a flight. Postflight surveillance was also performed. He said, as a routine, the inspectors visually inspected the airplanes and reviewed the airplane log records either during en route checks, while in flight, or upon termination of various flights. He said that inspectors conduct spot ramp inspections; however, they do not routinely observe ramp service operations as part of the surveillance program.

He said that FAA inspectors are not required to inspect the airplanes, but merely are to observe ramp service activities. Deficiencies or malfunctions were to be noted. The assigned inspector or the PMI would then report these observations to the UAL quality assurance liaison person or directly to UAL management.

The PMI stated that the FAA had conducted five special surveillance inspections of UAL in the previous 3 years and 5 months. The last special inspection, an MEL Survey Inspection, was completed in 1988. That inspection primarily addressed how many deferred maintenance items were being carried or deferred on each aircraft during a specified time period.

The PMI stated that his office does not approve the method by which the carrier complies with an AD, unless specified in the AD. However, a scheduled surveillance method was in place to review the carrier's AD compliance process and the ADs applicable to certain fleets. Each assigned inspector had a schedule for performing this oversight in his work program. The PMI or his staff review a monthly report from the carrier listing ADs applicable to a particular fleet and their compliance. The FAA's surveillance of the carrier's AD compliance process involved a review of this list, not actual shop visits to verify compliance.

The inspector assigned to the UAL B-747 fleet stated that approximately 30 percent of his time was spent on actual ramp maintenance surveillance. Other activities included: en route inspections, station inspections, meetings, classes and administrative paper work. Spot ramp inspections were scheduled as a normal routine, as well as by mandate in a particular AD.

The PMI stated that foreign contract maintenance bases were inspected once a year at a minimum. The PMI had the prerogative to use geographical surveillance inspectors

(inspectors from other FAA offices), or inspectors from his office more familiar with UAL maintenance procedures to conduct inspections or investigations.

The PMI and the B-747 maintenance inspector assigned to UAL testified that, prior to this accident, they were not aware of any problems involving the operation of B-747 cargo doors, including the problems reported with N4713U during December 1988. The PMI testified that he could always use more inspectors to "conduct more in-depth surveillance and monitor UAL's fleet more adequately."

The extensive documentation of maintenance performed on UAL B-747 airplanes was forwarded to the PMI's official library by US mail. The data were ultimately channeled to the B-747 maintenance inspector. The PMI and maintenance inspector testified that the voluminous paperwork and work schedules precluded their monitoring the information to determine trends on problem areas.

1.17.3 Corrective Actions

On March 31, 1989, the FAA issued telegraphic (AD) ADT 89-05-54. This AD superseded AD 88-12-04 and required certain procedures to be accomplished when operating the cargo doors. These included: confidence checks of the door mechanical and electrical systems, inspections of the door locking mechanisms, and repairs if necessary. The AD also accelerated the schedule for terminating action to place steel doublers on the latch lock sectors, and it reinstituted the procedures for using the eight view ports to verify the position of the latch cams, after the door is latched and locked.

The FAA, in conjunction with the Air Transport Association, the manufacturers, and other interested parties, are collectively working to address the human factor issues in the readability and understandability of ADs and SBs by line maintenance personnel. They are also reviewing the entire range of design, maintenance, and operation of outward opening doors to develop advisory information for pertinent parties.

FAA representatives stated at the Safety Board's public hearing that the FAA is increasing their operations and airworthiness inspector staffing by approximately 1,000 new hires in the next 3 fiscal years.

The PMI for UAL at the time of the accident stated at the Safety Board's public hearing that, as a result of the accident, "we have intensified our surveillance on the cargo door activities to the point where the assigned inspectors and inspectors who are not assigned to that particular fleet, 747s, are doing night surveillance, early morning surveillance, and we have intensified our surveillance on the cargo door in watching the operation of the cargo door to comply with the Airworthiness Directive."

On August 23, 1989, the Safety Board issued three safety recommendations (A-89-92 through -94) to the FAA. The recommendations urged the FAA to:

Issue an Airworthiness Directive (AD) to require that the manual drive units and electrical actuators for Boeing 747 cargo doors have torque limiting devices to ensure that the lock sectors, modified per AD-88-12-04, cannot be overridden during mechanical or electrical operation of the latch cams.

Issue an Airworthiness Directive (AD) for non-plug cargo doors on all transport category airplanes requiring the installation of positive indicators to ground personnel and flightcrews confirming the actual position of both the latch cams and locks, independently.

Require that fail-safe design considerations for non-plug cargo doors on present and future transport category airplanes account for conceivable human errors in addition to electrical and mechanical malfunctions.

Section 4.0 contains the FAA's response to the recommendations and the status of the followup actions.

On October 12, 1989, the FAA issued NPRM 89-NM-148-AD, which proposed the amendment of ADT-89-05-54. The proposed revisions would require modification of the warning systems for the forward and aft cargo door, and the main deck cargo door, if installed. The modifications would provide visual warnings to flightcrew and ground crew when the doors are not fully closed, the latch cams are not rotated to the closed position, or the lock sectors are not in the locked position. Further, the source for the warning signal would monitor the position of the latch cams. Public comments for the NPRM were due by December 27, 1989.

Boeing has completed tests that have verified the integrity of the upgraded latch lock sectors to prove that the latch cams cannot be back-driven through the lock sectors mechanically or electrically. Boeing also has been conducting tests on the B-747 cargo door to evaluate the effects of unrepaired damage and abuse on the latch/lock system. The tests, which determined the allowable damage limits on the latch lock system and mechanism support structures, were completed in March 1990. Additionally, Boeing conducted tests to evaluate any unlatching tendencies under cabin pressure loads. These tests were completed in November 1990 and included the measurement of loads in the latch system as the latch cams are rotated incrementally from the fully latched position to the unlatched position under pressurization loads.

The first series of tests included electrical backdriving of the latch cams into the lock sectors (both steel and steel reinforced were tested) with a modified latch actuator (the maximum output torque of the modified latch actuator was roughly twice that of a normal, torque-limiting latch actuator.) During these tests, the maximum cam rotation was 22.2 degrees against steel reinforced lock sectors and 18.8 degrees against the all-steel lock sectors.

During the second set of tests, which measured the effects of internal pressure loads on partially unlatched cams, it was discovered that pressurization did not create any significant loads in the latch mechanism with the door fully closed and the latch cams positioned up to 45 degrees from the fully latched position. Both series of tests show that if the latch cams were somehow electrically backdriven by a latch actuator that had no torque-limiting ability, the steel or steel-reinforced lock sectors would limit the amount of cam rotation such that the partially unlatched cams would still prevent pressure loads from forcing the door open.

1.17.4 Boeing 747 Cargo Door Certification

Title 14 CFR 25.783, Amendment 25-15, effective October 24, 1967, was the original certification basis for Boeing 747 cargo doors. Specifically, Part 25.783(e) and (f) applied to doors for which the initial opening movement is outward (non-plug type doors). Those rules specified that:

(e) There must be a provision for direct visual inspection of the locking mechanism by crewmembers to determine whether external doors, for which the initial opening movement is outward (including passenger, crew, service, and cargo doors), are fully locked. In addition, there must be a visual means to signal to appropriate crewmembers when normally used external doors are closed and fully locked.

(f) Cargo and service doors not suitable for use as an exit in an emergency need only meet paragraph (e) of this section and be safeguarded against opening in flight as a result of mechanical failure.

Amendment 25-23, effective May 8, 1970, added the following text to paragraph (f): "...or failure of a single structural element." Amendment 25-23 did not apply to the initial certification basis for the B-747.

Amendment 25-54, effective October 14, 1980, expanded Part 25.783 (e), (f), and (g) to read:

(e) There must be a provision for direct visual inspection of the locking mechanism to determine if external doors, for which the initial opening movement is not inward (including passenger, crew, service and cargo doors), are fully closed and locked. The provision must be discernible under operational lighting conditions by appropriate crewmembers using a flashlight or equivalent lighting source. In addition, there must be a visual warning means to signal the appropriate flight crewmembers if any external door is not fully closed and locked. The means must be designed such that any failure or combination of failures that would result in an erroneous closed and locked indication is improbable for doors for which the initial opening movement is not inward.

(f) External doors must have provisions to prevent the initiation of pressurization of the airplane to an unsafe level if the door is not fully closed and locked. In addition, it must be shown by safety analysis that inadvertent opening is extremely improbable.

(g) Cargo and service doors not suitable for use as an exit in an emergency need only meet paragraph (e) of this section and be safeguarded against opening in flight as a result of mechanical failure or failure of a single structural element.

At the Safety Board's public hearing, the FAA and the Boeing representatives acknowledged that during certification of the Boeing 747 the loss of a lower lobe cargo door was not considered to be an "acceptable event." Therefore, redundant mechanical devices and operational procedures were incorporated to protect against loss of the door in flight. Initial FAA certification approval of the Boeing cargo door design and operation included the installation and use of eight view ports on the door for ground personnel to observe the alignment of paint stripes on the latch cams with arrows on the latch pin support fitting, thereby complying with the requirements of 14 CFR 25.783(e), which require a ". . . provision for direct visual inspection of the door locking mechanism ...," to determine if the door is closed and

locked.
In correspondence dated November 24, 1969, and May 15, 1970, Boeing requested that the FAA approve the use of a visual inspection of the pressure relief doors of the cargo doors as an alternate method for determining the locked condition of the door. This design also provided a visual indication to the flightcrew via the cargo door warning light on the flight engineer's warning light annunciator panel. Boeing's request stated that this means of compliance "... provides a simpler check whereby only the pressure relief doors need to be checked ...," by the ground crew, in lieu of actually observing the latch cams and alignment stripes through the eight view ports. Boeing also provided a Failure Analysis to support its request. The conclusion of the Failure Analysis reads: "Any failure, mechanical or electrical, within the latching system which results in open latches will always be indicated by open pressure relief doors." The FAA approved their alternate method on June 8, 1970. Subsequently, the procedures for maintaining the view ports and the alignment stripes in a serviceable condition,
which had been included in the UAL MM were removed. Also, the provision for observing the alignment stripes as part of the door closing procedure were not required for B-747 airline operators.
At the Safety Board's public hearing, a Boeing witness, in answer to a question relative to Boeing's possible consideration of modifications or design changes to the B-747 cargo door indication system to install a position switch directly on the latch cams, stated, "We are looking into the best possible designs that would provide indication on the cams and door closed, both exterior to the aircraft and in the flight deck. We are going to look into that.... However, we want to achieve the required indication in the most reliable method and we have not yet determined what that will be, or any changes (that) are necessary, or would

make it more reliable than the way the system operates currently."

1.17.5 Advisory Circular AC 25.783-1

Advisory Circular (AC) 25.783-1 was issued December 10, 1986, on the subject, "Fuselage Doors, Hatches, and Exits." AC 25.783-1 set forth the acceptable means of compliance with the provisions of Part 25 of the FAR's dealing with the certification of fuselage doors. Specifically, it provides for an acceptable method for showing compliance with the provisions of Part 25.783, Amendment 25-54.

Neither the provisions of Part 25.783, Amendment 25-54, nor the guidelines of AC 25.783-1 were part of the certification basis of the Boeing 747.

1.17.6 Uncommanded Cargo Door Opening--UAL B-747, JFK Airport

On June 13, 1991, UAL maintenance personnel were unable to electrically open the aft cargo door on a Boeing 747-222B, N152UA, at JFK Airport, Jamaica, New York. The airplane was one of two used exclusively on nonstop flights between Narita, Japan, and JFK. This particular airplane had accumulated 19,053 hours and 1,547 cycles at the time of the occurrence.

The airplane was being prepared for flight at the UAL maintenance hangar when an inspection of the circuit breaker panel revealed that the C-288 (aft cargo door) circuit breaker had popped. The circuit breaker, located in the electrical equipment bay just forward of the forward cargo compartment, was reset, and it popped again a few seconds later. A decision was made to defer further work until the airplane was repositioned at the gate for the flight. The airplane was then taxied to the gate, and work on the door resumed.

The aft cargo door was cranked open manually, the C-288 circuit breaker was reset, and it stayed in place. The door was then closed electrically and cycled a couple of times without incident.

With the door closed, one of the two "cannon plug" (multiple pin) connectors was removed from the J-4 junction box located on the upper portion of the interior of the door. The wiring bundle from the junction box to the fuselage was then manipulated while readings were taken on the cannon plug pins using a volt/ ohmmeter. Fluctuations in electrical resistance were noted. When the plug was reattached to the J-4 junction box, the door began to open with no activation of the electrical door open switches. The C-288 circuit breaker was pulled, and the door operation ceased. When the circuit breaker was reset, the door continued to the full open position, and the lift actuator motor continued to run for several seconds until the circuit breaker was again pulled. At this time, a flexible conduit, which covered a portion of the wiring bundle, was slid along the bundle toward the J-4 junction box, revealing several wires with insulation breaches and damage.
UAL personnel notified the Safety Board of the occurrence, and the airplane was examined at JFK by representatives of the Safety Board, United Airlines, and Boeing. After the wires in the damaged area were electrically isolated, electrical operation of the door was normal when the door was unlocked. When the door was locked (master latch lock handle closed), activation of the door control switches had no effect on the door. This indicated that the S2 master latch lock switch was operating as expected (removing power from the door when it was locked). After the on-site examinations, the wiring bundle was cut from the airplane and taken to the Safety Board's materials laboratory for further examination.
The wiring bundle with the damaged wires contained all electric control wires (28 volt DC) and power wires (115 volt AC) that pass between the fuselage and the aft cargo door. From the forward side of the J-4 junction box, the bundle progresses in the forward direction, just above the forward pressure relief door, then upward, following the forward lift actuator arms. The

bundle then enters an empty space between two floor beams, where the bundle has an approximate 180-degree bend when the door is closed. From this location, the wiring bundle progresses inboard, through a fore-to-aft intercostal between two floor beams. The wiring bundle then splits, with wires going in several directions.

The bundle is covered by the flexible conduit approximately from the lower end of the lift actuator arms to the fore-to-aft intercostal between the floor beams.

The conduit covering the wiring bundle is intended to prevent the wire bundle from being damaged during opening and closing of the door and during cargo handling operations. The conduit is a sealed flexible interconnector consisting of a convoluted helical brass innercore covered by a bronze braid. The innercore is soldered at every other convolute, and should be capable of withstanding pressures exceeding 1,000 pounds per square inch (psi). Boeing has indicated that the conduit is an evolutionary improvement and that it has been installed on all B-747 airplanes produced since 1981 (from line number 489 on). Airplane N152UA was delivered in April 1987.

Airplanes produced prior to 1981, including N4713U, used a bungee retraction system, to retract the cargo door wire bundle. Guidelines for the replacement of the bungee sys tem with the flexible conduit were covered in Boeing Service Bulletin 747-752-2170, dated August 1981. The service bulletin was prompted by reports that the wire bundle bungee retraction system had not retracted the wire bundle sufficiently to prevent trapping the bundle between the cargo door and the door frame. UAL did not perform the retrofit on N4713U, which was line number 89, nor was the company required to do so.

Examination of the wires in the damaged area on the wiring bundle revealed that four of the wires were similar in appearance, with insulation breaches that progressed through to the underlying conductor. Adjacent to the breach on these four wires, the insulation was blackened, as if it had been burned. Another wire contained an extensive breach but no evidence of burned insulation. The damaged area was located on the bundle at a position approximately corresponding to a conduit support bracket and attached standoff pin on the upper arm of the forward lift actuator mechanism. This support bracket was found bent in the forward direction. In addition, mechanical damage was noted on adjacent components in this area.

A second damaged area was noted on the wiring bundle at a position approximately corresponding to the conduit swivel clamp at the elbow between the two arms of the forward lift actuator mechanism. Wires in this area were missing portions of their exterior coating, but no breaches to the underlying conductors were noted.

The exterior braid on the conduit contained minor rub marks and was slightly kinked at a position corresponding to the area on the wires with breached insulation. Additional examinations revealed that the innercore of the conduit contained multiple circumferential cracks in the areas corresponding to the damage areas on the wires. The cracks were in the convoluted innercore directly adjacent to the inside diameter of the conduit.

The lock sectors, latch cams, and latch pins from the aft cargo door were examined on the incident airplane and were generally in excellent condition. There was no evidence to suggest that the cams had ever been electrically (or manually) driven into or through the lock sectors.

Boeing also informed the Safety Board that, in May of 1991, a B-747 operated by Quantas was found to have chafing of the wires in the wire bundle to the aft cargo door. This airplane also had a flexible conduit protecting the wires, and the chafing was located approximately at the standoff pin on the bracket at the upper arm of the forward lift actuator.

The Safety Board determined that the chafing of the wires on the airplane involved in the JFK occurrence was caused by, or was greatly accelerated by, the circumferential cracks in the conduit and that the cracks in the conduit were caused either by repeated flexing of the conduit as the cargo door opens and shuts or by unusual stresses on the conduit generated concurrently with damage to the conduit guide bracket and attached standoff pin on the upper end of the forward lift actuator upper arm.

A portion of the wire bundle for the forward cargo door on many B-747 airplanes is also covered by a flexible conduit that is very similar to the conduit for the aft cargo door. However, there are substantial differences between the orientation of the flexible conduits for the two doors, and the Safety Board has not become aware of problems associated with the flexible conduit for the forward door.

Nevertheless, because of the concerns about the chafed wires and possible electrical short circuits, on August 28, 1991, the Safety Board recommended that the FAA:

Issue an Airworthiness Directive applicable to all Boeing 747 airplanes with a flexible conduit protecting the wiring bundle between the fuselage and aft cargo door to require an expedited inspection of:

(1) the wiring bundle in the area normally covered by the conduit for the presence of damaged insulation (using either an electrical test method or visual examination);

(2) the conduit support bracket and attached standoff pin on the upper arm of the forward lift actuator mechanism;

(3) the flexible conduit for the presence of cracking in the convoluted innercore.

Wires with damaged insulation should be repaired before further service. Damage to the flexible conduit, conduit support bracket and standoff pin should result in an immediate replacement of the conduit as well as the damaged parts. The inspection should be repeated at an appropriate cyclic interval. (Class II, Priority Action) (A-91-83)

Evaluate the design, installation, and operation of the forward cargo door flexible conduits on Boeing 747 airplanes so equipped and issue, if warranted, an Airworthiness Directive for inspection and repair of the flexible conduit and underlying wiring bundle, similar to the provisions recommended in A-91-83. (Class II, Priority Action) (A-91-84)

The FAA responded to these safety recommendations on November 1, 1991, stating that it agreed with the intent of the recommendations and that the issuance of an NPRM was being considered to address the issues in the safety recommendations. The Safety Board replied on November 27, 1991, classifying each of the recommendations as "Open--Acceptable Response," pending the completion of the rulemaking process. Since that exchange of correspondence, the FAA has published an NPRM which is now being reviewed by the Safety Board. Safety Recommendations A-91-83 and -84 will continue to be classified as "Open--Acceptable Response" until an acceptable final rule is published.

2. ANALYSIS

2.1 General

This analysis is based on the facts gathered during the initial investigation phase, without the benefit of the evidence from the cargo door, updated to include the findings from the subsequent examinations of the door after it was recovered.

The flightcrew and flight attendants were trained and qualified in accordance with the applicable Federal regulations and UAL standards and requirements. There were no air traffic control or weather factors related to the cause of this accident.

The airplane had been properly maintained, with the exception of certain requirements pertaining to the cargo doors. Those discrepancies will be discussed in detail in this analysis.

The evidence examined by the Safety Board during its investigation revealed conclusively that this accident was precipitated by the sudden loss of the forward lower lobe cargo door, which led to an explosive decompression. There was no evidence of preexisting metal fatigue or corrosion in the structure surrounding the cargo door. All breaks were the result of overload at the time of the loss of the door. There was no evidence of a bomb or similar device that caused an explosion on the airplane.

The explosive decompression of the cabin when the cargo door separated caused the nine fatalities. The floor structure and seats where the nine fatally injured passengers had been seated were subjected to the destructive forces of the decompression and the passengers were lost through the hole in the fuselage. Their remains were not recovered. Most of the injuries sustained by the survivors were caused by the events associated with the decompression, such as baro-trauma to ears, and cuts and abrasions from the flying debris in the cabin. Other injuries were incurred during the emergency evacuation.

The loss of power to the Nos. 3 and 4 engines was caused by foreign object damage when debris were ejected from the cargo compartment and cabin during the explosive decompression. The debris also caused damage to the right wing leading edge flap pneumatic ducting, and other areas along the right side and empennage of the airplane.

During the approach to HNL, all of the leading edge flaps had extended, except the outboard sections 22 through 26 on the right wing. The reason that they failed to extend probably was the damage to the pneumatic duct caused by the ejected debris. The pneumatic pressure probably was too low to actuate the most outboard flaps to the extended position.

The failure of the flightcrew and passenger oxygen systems was caused by structural deformation and damage to the supply lines in the area adjacent to the cargo door and failed fuselage structure.

The Safety Board's analysis of this accident concentrated on the reasons for the loss of the cargo door and the events that led to its loss in flight. The analysis included an evaluation of the design, certification, and approval processes for the B-747 cargo doors, and the operational, maintenance, and inspection processes for the doors. Also, the analysis included an evaluation of the historical events that had occurred over the past months and years that eventually led to this accident.

2.2 Loss of the Cargo Door

The calculated pressure differential at the time of the loss was about 6.5 psi, which would have exerted a load on a properly closed and locked door that was substantial, but well within design limits.

There was no evidence of a structural problem with the cargo door that could have caused it to fail from metal fatigue or corrosion. Although the cargo door was recovered in two pieces on the floor of the ocean, there was no evidence of a preseparation structural failure of the door. All fractures and damage found on the door were determined to be the result of the sudden opening of the door rather than the cause. The evidence showed that the door was intact when it flew open violently and that its integrity was compromised when it struck the upper fuselage structure and most likely when it struck the water. The fracture in the cargo door occurred just below the midspan latch cams. Paint marks on the outer surface of the door that matched upper fuselage structure paint pattern, damage to the latch pins, pull-in hooks and hook pins, as well as damage to the floor structure near the upper door hinge area were consistent evidence that the door was intact when it flew open.

The evidence was also conclusive that the failure of the door did not result from the failure of the structure surrounding the door.

The damage to the cabin floor beam structure, adjacent to the cargo door hinge area, showed that decompression loads in the cabin broke the beams downward when pressure was released from the cargo compartment. The fuselage skin above the door was torn away during the decompression as the door separated violently from the airplane. Unfortunately, the upper skin structure was not recovered from the sea.

There are no reasonable means by which the door could open in flight with the cams properly closed and locked. If the lock sectors were in proper condition, and were properly situated over the closed latch cams, the lock sectors had sufficient strength to prevent the cams from vibrating to the open position during ground operation and flight. Thus, the only ways in which the cargo door could open while in flight involve the placement of the cams in a partially latched or unlatched position. Either the latching mechanisms were forced open electrically through the lock sectors after the door was secured, or the door was not properly latched and locked before departure. Then the door opened when the pressurization loads reached a point at which the latches could not hold.

2.3 Partially Closed Door

Examination of the eight latch pins that had been removed from the lower sill of the forward cargo door revealed smooth wear patterns where the latch cams had normally rotated around the pins. These wear patterns indicate that interference had existed during normal operation between the cams and the pins over an extended period of time. All eight pins also had roughened areas from approximately the 6:15 position to the 7:30 position (clock references are as looking forward, 9:00 being directly inboard). The 7:30 position corresponds closely to the area where the lower surface of the cam first contacts the pin as the door reaches the nearly closed position, before the cams are rotated to the latched position.

The hoop stresses generated by pressurization of the airplane create a bearing load against the cam/pin contacting points. Even if the cams are in the unlatched position, and the airplane is pressurized, this bearing load could act as a frictional latch between the cams and the pins and would tend to keep the door in the closed position.

Transferred cam material and heat tinting of the pin surface was found to extend from the point where the cam-to-pin interface at the near fully open position of the latch cams (7:30 position) to a position corresponding to the bottom of the pin (6:15 position). This evidence was found on the roughened areas on all of the pins. The heat tinting and metal transfer are indicative of the high stress and rapid movement of the cam across the pin when the door separation occurred. Therefore, the location of this evidence indicates the probable location of the cams just before, and at the time of, separation of the door. The Safety Board concludes that these markings and their location on the pins resulted from a very fast, high bearing stress, separation of the cams across the pins, when the cams were in or very close to the unlatched position. Further, examination of the recovered cargo door confirmed that the latch cams were in a nearly unlatched position at the time the separation occurred. The lock sectors were found in the locked position jammed against the cams. Therefore, the cargo door latch cams had been closed, the master latch lock handle had been closed, and the lock sectors had moved to the locked position. Subsequently, the cams had been back-driven to the near-open position, deforming the lock sectors.

The pull-in hooks and pull-in hook pins would also counteract the pressurization loads in the outward direction, providing that the latch cams were not engaged on the latch pins and carrying the pressurization loads. However, Boeing studies showed that the pull-in hooks would fail at a pressure differential of about 3.5 psi, assuming that the cams are in the unlatched position and that there is no bearing load on the pins. Therefore, based on the probable pressure differential of about 6.5 psi just before the door separated, it is concluded that forces other than the pull-in hooks/pins were holding the door closed. Since the flightcrew and passengers reported no pressurization difficulties until the explosive decompression, it is reasonable to conclude that the door was being held closed by the bearing stresses of the cam-to-pin interfaces as well as by the pull-in hooks.

The Safety Board believes that the approximate 1.5 to 2.0 seconds between the first sound (a thump) and the second very loud noise recorded on the CVR at the time of the door separation was probably the time difference between the initial failure of the latches at the bottom of the door, and the subsequent separation of the door, explosive decompression, and destruction of the cabin floor and fuselage structure. The door did not fail and separate instantaneously; rather, it first opened at the bottom and then flew open violently. As the door separated, it tore away the hinge and surrounding structure as the pressure in the cabin forced the floor beams downward in the area of the door to equalize with the loss of pressure in the cargo compartment.

Three possible theories to explain why the latch cams could have been in a partially latched condition during flight are examined: (1) they were never closed fully before the door was "locked" before takeoff. (2) they were backdriven manually after the door had been fully latched and locked or (3) they were back-driven electrically after the door had been fully latched and locked.

2.4 Incomplete Latching of the Door During Closure

The Safety Board considered the possibility that the master latch lock handle had not been closed before the airplane departed the gate, and the possibility that the shrouds recommended by SB-747-52-2097 for the cargo door pressure relief doors were not installed on the forward door. If this were the case, it is possible that this condition allowed the pressure relief doors to be rotated

closed when the airplane pressurized.
The Safety Board believes that these events were very unlikely based on the statements of the ramp personnel, line maintenance personnel, and the flightcrew. The ramp and maintenance personnel would have to have missed seeing the master latch lock handle in the unstowed position and the pressure relief doors open before departure. Also, the flightcrew would have to have missed seeing the cockpit cargo door warning light indication.
The examination of the recovered forward cargo door did not provide confirmation that the pressure relief door shrouds were actually installed on the forward door, although UAL records showed that they had been installed on both cargo doors of N4713U, in accordance with SB-747-52-2097. However, the shrouds were found not to be installed on the aft door, contrary to UAL records, and therefore may not have been installed on the forward door. Without the shrouds, the pressure relief doors could have rotated shut during the pressurization cycle. Because the closure of the pressure relief doors would back-drive the lock sectors, this scenario would presume previous damage to the sectors, which would permit the sectors to move over the unlatched cams.
Before recovery of the cargo door, the Safety Board believed that the lock sectors might have been damaged some time prior to the accident flight to the extent that they could have been moved to the locked position even though the latching cams were not fully closed.
During closure of the door, the latch actuator may not be able to rotate the cams to the fully closed position because of excessive binding forces between the latch cams and pins. This could occur if the cargo door is misaligned (out of rig) or if the pull-in hooks do not pull the door in far enough to properly engage the cams around the pins. There is sufficient evidence of wear on the pins

and from the previous discrepancies with the door to indicate that the door was misaligned and not properly rigged.

The smooth wear areas found on the pins from N4713U are signs of heavy contact (interference) between the cams and pins during numerous past closings and openings of the door. This wear, other evidence from the door, and the maintenance history of the door, suggest strongly that the door was out of rig during the weeks and months before the accident.

The wear pattern damage to the pull-in hook pins also showed interference during the normal ground operations prior to the accident. This is further evidence of an out-of-rig door. It is also possible that the excessive binding force acting over a period of time precipitated a failure of the latch actuator. Regardless of the reason(s), the conditions of the latch pins and pull-in hook pins showed prolonged out-of-rig operation.

Most of the previous discrepancies with the forward cargo door on N4713U during December 1988 involved problems with closing the door electrically. These problems always occurred when the airplane was fully or nearly fully loaded, just before departure. The trouble-shooting and corrective actions by UAL maintenance, which on some occasions only involved cycling the door and finding it functional, were performed when the airplane was not fully loaded, during overnight maintenance inspections. The flexing of the fuselage with a full load of fuel, cargo, and passengers could have caused distortion of the door frame and resulted in misalignment between the cams and pins. In this case, the pull-in hooks may not have pulled the door fully in before the cam actuator attempted to latch the door. The wear evidence on the latch pins from N4713U suggests that this event had been occurring before the accident.

Safety Board investigators also witnessed this event during inspection and operation of the aft door on another UAL B-747, N4718U, in HNL. It was noted that the door on N4718U was not being pulled in fully by the pull-in hooks, so the latch cams completed the closing cycle with significant interference and "thunking" sounds. In fact, the out-of-rig door on N4718U failed to operate electrically at one point during its examination.

By design, any attempt to close the master latch lock handle and move undamaged lock sectors into place would not be successful unless the cams were rotated to near the fully latched position. This condition was substantiated by Boeing tests. Even with severely damaged lock sectors, as found on the Pan Am B-747, if the cams were more than 20 turns from the fully closed position on the Pan Am airplane, the master latch lock handle could not be stowed. Examination of the recovered N4713U door indicated that the door lock sectors were generally intact and jammed against the cams that had been back-driven into the lock sectors. Consequently, if the latch cams had been in the nearly unlatched position as found on the recovered door at the time the cargo handler attempted to move the master latch lock handle, the interference between the cams and the lock sectors would have prevented the master latch lock handle from moving to the closed position. Furthermore, this interference would have prevented the closure of the pressure relief doors as the airplane pressurized, irrespective of the possible absence of the pressure relief door shrouds. This conclusion is supported by extensive testing of the latch/lock mechanisms following the recovery of the door.

Therefore, based upon the examination of the lock sectors and the tests that were conducted, the Safety Board concludes that the latches were fully closed and that the locking handle was placed in the stowed position after the cargo was loaded.

2.5 Manual Unlatching of the Door Following Closure

It is possible that the cams could have been manually back-driven (about 95 turns) after the door had been secured; however, the UAL ramp personnel involved with dispatching the flight stated that the door was operated electrically. Furthermore, it seems unlikely that the ramp personnel would have driven the manual latch actuator 95 turns toward the open position after the door was fully latched.

The placard/seal located over the latch actuator manual drive on the recovered door was found with damage that initially suggested it had been previously compromised. If this were the case, it would indicate that someone may have used the manual drive to operate the door latches on an earlier flight or possibly immediately before the accident flight. However, the Safety Board believes that an insertion of a screw driver and rotation of the plate retaining screw would have caused rotational tearing around the circumference of the screw head. There was no such tear. Rather, the damage to the placard/seal was more consistent with that which would occur from impact and underwater pressure forces. Therefore, the evidence strongly suggests that manual operation of the latch actuator by ground service personnel after the door was properly closed is unlikely.

2.6 Electrical Unlatching of the Door Following Closure

2.6.1 Conditions or Malfunctions Required to Support Hypothesis

It was determined in 1987, after the Pan Am incident, that the locking sectors for B-747's, including those installed on N4713U, could be overcome by the force of the latch cam actuator, electrically or mechanically. If the latch cam actuator had been energized for some reason with the originally designed unstrengthened lock sectors installed, the latch actuator motor was capable of driving the latch cams open through properly positioned lock sectors, whether they were damaged or undamaged. Therefore, the locking sectors installed as original equipment for B-747's, and those installed on N4713U, would not perform the locking function as intended by the design. They would not "lock" the latches in place as implied by the name "lock sectors."

The investigation has shown that there are several conditions that must be met before the latch actuator will electrically drive the latch cams to the unlatched position on the B-747 after the door has been properly closed and locked. First, the ground handling power bus must be energized by having external power connected, or the APU must be operating and the APU generator field switch in the cockpit must be set to power the bus via the No. 2 ground handling power relay. Second, the air/ground relay must be in the "airplane on the ground" position. These two conditions are normally present when the airplane is on the ground before engine startup. Third, there must be a signal to the door open position in one of the two door open/close switches. Fourth, the S2 master latch lock switch, which cuts off power to the door actuators when the handle is stowed, must sense "not locked."

Therefore, it would take several independent conditions and some failures to provide for electrical power to be available to drive the door open electrically once it is closed and locked. The number of conditions and combinations depend upon the phase of operation of the airplane.

While the airplane was on the ground, before engine startup, with the master latch lock handle stowed, the external power connected (or with the APU running), and the ground handling bus powered, an "open" signal to the cargo door latch actuator would have occurred if any of the following combinations of conditions had been met: (1) a malfunction of the S2 master latch lock switch and the placement by someone of one of the door control switches to the "open" position; (2) a malfunction of the S2 master latch lock switch and certain short circuits; or (3) a two-wire short circuit path consisting of wire 101-20 shorting with any of the following wires: 108-20, 121-20, 122-20, 124-20, 135-20, or 136-20.

While the airplane was on the ground, after engine startup, and with the cargo door master latch lock handle stowed and the APU running, an "open" signal to the door latch actuator would have occurred if the following conditions had been met: (1) an energized ground handling bus resulting from the flightcrew reenergizing the APU generator field or failure of the No. 2 ground handling power relay; (2) a malfunction of the S2 master latch lock switch; (3) a malfunction of either of the door open/close switches or the placement of the switch in the "open" position by someone. An "open" signal would have also occurred had certain wire short circuits been present with condition (1) alone, or with conditions (1) and (2).

Regardless of the cause, electrical power to the latch actuator would have had to persist for the time necessary to rotate the cams to the nearly open position. If the electrical power had been applied for a longer time, the latch cams could have opened fully and caused the pull-in hooks to rotate open, a situation that would have prevented the airplane from pressurizing after takeoff. However, it is also possible that the latch actuator stalled before they opened fully because of the forces of the interference between the lock sectors and the cams as they were back-driven.

After takeoff, electrical operation of the door latch actuator would have required: (1) the APU to be running; (2) malfunction of the air/ground relay, (3) malfunction of the No. 2 ground handling power relay; and (4) malfunction of the S2 master latch lock switch and one of the cargo door open/close switches or a short circuit of the aforementioned wire pairs. Although the flightcrew could conceivably energize the ground handling bus from the APU by actuating the APU generator "field" switch, there was no evidence that they did so.

Thus, regardless of the phase of operation, either a wiring short circuit or a failure of the S2 master latch lock switch combined

with some other anomaly or action would be required to cause the latches to move toward the open position. Before the recovery of the door, the Safety Board was able to examine two of the electrical relays and the door open/close switches from N4713U that would have to have failed to allow electrical operation of the cargo door in flight, with the APU
running. These were the No. 2 ground handling power relay, the air/ground relay, and the internal and external door open/close switches. The examination of the relays and switches revealed no evidence of a single fault or conditions that might have caused an intermittent failure mode. The arcing noted on the No. 5 terminal of the outside door control switch was on the door "close" circuit and could not have been related to a short to the open mode. Further, because the flightcrew did not note a cargo door warning light, and the fact that the airplane was able to be pressurized, confirms that the master latch lock handle was in the closed position before takeoff. This position would actuate the master latch lock switch to disconnect power to the door opening actuators.

According to the flightcrew testimony and the pilots' comments recorded on the CVR during the flight, the APU was shut down shortly after takeoff and remained in that condition. Engine generators cannot power the ground handling bus from which the cargo door actuating mechanisms are powered. Once the APU was shut down, there was no power available to any of the cargo door electrical components. Therefore, an electrical actuation of the latch cam actuator at the time of the door loss was not possible.

The Safety Board believes that there is another reason why the opening of the door could not have been caused by electrical actuation shortly before the explosive decompression. Because the door carries the structural loads (hoop stresses) through its hinge and latches, the latch cams would be heavily loaded against the latch pins when the airplane was pressurized to the 6.5 psi differential pressure that was calculated to have been present at the time of the decompression. In that case, the torque limiter within the actuator would probably slip well before the actuator could achieve the torque necessary to drive the cams open against the frictional lock produced by the high bearing stresses resulting from pressurization.

2.6.2 Electrical Switches and Wiring Examinations--Recovered Door

All cargo door position sensing switches (S2 through S9) were found installed in their proper position. The cargo door recovery team found the S2 master latch lock switch in the "not-locked" position immediately after the door was aboard the recovery ship. This position would be consistent with the master latch lock handle being open. Further tests of the S2 switch revealed damage that probably resulted from the pressures under the sea. The only notable exception was a broken internal bracket that may have affected the operation of the switch prior to the accident. Other similar switches did not exhibit this failure. It is therefore possible that the S2 master latch lock switch failed prior to the accident, allowing more possibilities for electrical short circuits to power the latch actuator. Nevertheless, despite extensive testing, it could not be determined whether the S2 switch was functional before the accident.

The examination of 35 wires that remained with the recovered cargo door revealed several areas of damaged insulation that could have permitted an electrical short circuit to power the latch actuator. However, no evidence was noted of arcing that was indicative of short circuits. Furthermore, a significant number of the wires that had the potential for allowing for short circuits to power the latch actuator were not recovered. Testing conducted by Boeing and by UAL was inconclusive regarding whether a short circuit would have left detectable evidence of arcing.

Therefore, the Safety Board was unable to determine whether the latch actuator was inadvertently powered by a short circuit in the cargo door wires.

The incident involving a UAL Boeing 747 at JFK Airport on June 13, 1991, confirmed that electrical short circuits in the cargo door wiring could cause the door to open. In this case, the short circuits were in the fuselage-to-cargo door wiring bundle where the bundle was covered by a flexible conduit. Although N4713U did not have a flexible conduit installed at the forward door position, its wiring was routed over the top of the door hinge where exposure to damage could occur. That portion of the wiring from N4713U was not recovered from the sea. The wires located at the door hinge area are more susceptible to in-service damage from movement during the open/close cycle, as compared with the wires mounted on the door that are normally static.

Following the incident at JFK, UAL directed that the circuit breaker that terminates power to the cargo doors be pulled after the door is closed and before departure of every B-747 flight. UAL obtained approval for this practice from the FAA and requested Boeing and the FAA to make such a practice part of the approved manual for the airplane. Neither Boeing nor the FAA acted on UAL's request.

Nevertheless, the Safety Board believes that the FAA should initiate rulemaking to include design considerations for nonplug transport category aircraft cargo doors that would deactivate the electrical circuitry to the door actuators after the doors are closed and locked. The catastrophic nature of the loss of a cargo door dictates the need to provide additional redundancies and fail-safe features in the door mechanisms to supplement the hardware safety features.

2.6.3 Possibility of Electrical Malfunction

Due to the lack of physical evidence, the Safety Board was unable to conclude that an electrical short caused the cargo door actuator to move the latch cams to the nearly open position, allowing the door to separate when the cabin pressure exceeded the load-carrying capability of the door latches. Neither could this possibility be eliminated. A momentary actuation of the door open switch by someone on the ground in the presence of a faulty S2 switch could also have caused the latches to open through the closed lock sectors. However, no evidence has been found that someone actuated the switch after the door was initially closed and locked.

The Safety Board concludes that it was not possible for the cargo door to have opened electrically at the time of the loss of the door. There was no power to the ground handling bus to power the actuator, even if there had been an electrical short. Further, the Safety Board concludes that it is highly improbable that an electrical short could have caused the latches to open after the airplane was airborne. Although the ground handling bus could conceivably have been powered, failures of other components that were tested as functional would also have been necessary.

The Safety Board believes that the electrical operation of the latch actuators from the fully closed and locked position most likely occurred before the engines were started when the ground handling bus was powered. The precise source of the electrical actuation could not be determined. Once the engines were started, the possibility of an electrical short decreases significantly because the ground handling bus is disengaged from the APU when the engines start. There was no evidence that the flightcrew reengaged the ground handling bus.

Because the preaccident condition of the S2 master latch lock switch could not be determined, it could also not be determined whether its proper functioning would have prevented the accident. The Safety Board did not determine whether damaged cargo door wires or a malfunctioning S2 switch could have been found by UAL maintenance had they been more aggressive in troubleshooting the cargo door problem in the weeks prior to the accident.

2.7 Design, Certification, and Continuing Airworthiness Issues

The Safety Board's analysis of this accident went beyond the conclusions about how the door failed. The Safety Board also examined the initial design and certification of the B-747 cargo door, and the continuing airworthiness system that should have prevented this accident, to identify the breakdowns in this system that led to the accident. As is the case with most aviation accidents, there are many factors that led up to the actual failure of the door on flight 811.

The Safety Board found that there were multiple opportunities during the design, certification, operation, and maintenance of the forward cargo door for N4713U for persons to have taken actions that could have precluded the accident involving flight 811. The circumstances that led to this accident exemplify the need for human factors considerations in the promulgation of regulations, the application of regulatory policies, the design of airplane systems, and the quality of airline operational and maintenance practices.

The first opportunity to prevent this accident occurred during the design and certification of the B-747 cargo door mechanical systems, when the design was chosen and approved, which allowed for the overriding of the lock sectors by either mechanical or electrical actuation. It is apparent that the original design was not tested sufficiently to verify that the locking sectors in fact "locked" the latch cams in the closed position. This shortcoming should have become apparent during the initial certification testing and approval process. Later, it should have become apparent when Boeing applied for, and the FAA granted, an alternative method of compliance with the certification regulations (25.783 [e]) that permitted the elimination of operational practices that included a visual verification of the cargo door latch positions via view ports in the doors.

The failure mode analysis performed by Boeing, and the FAA's acceptance of its content in granting the exemption, probably were based on the assumption that the lock sectors would always prevent the master latch lock handle from being in a stowed position when the latch cams were not fully closed. This assumption was not valid, as evidenced by the findings in 1987 following the Pan Am incident that the lock sectors could not prevent the latch cams from being driven from the fully latched position with the master latch lock handle stowed, while a false indication was provided to the flightcrew that the cargo door was properly latched and locked. At the time that Boeing sought approval of the alternative compliance, Boeing and the FAA should have reviewed the design and required testing of the door latch/lock mechanisms to verify their integrity. Thus, the procedure for direct viewing of the latches via the view ports before the airplane could be dispatched should not have been eliminated without adequate verification that the lock sectors were totally effective.

The next opportunity for the FAA and Boeing to have reexamined the original assumptions and conclusions about the B-747 cargo door design and certification was after the findings of the Turkish Airline DC-10 accident in 1974 near Paris, France. The concerns for the DC-10 cargo door latch/lock mechanisms and the human and mechanical failures, singularly and in combination, that led to that accident, should have prompted a review of the B-747 cargo door's continuing airworthiness. In the Turkish Airlines case, a single failure by a ramp service agent, who closed the door, in combination with a poorly designed latch/lock system, led to a catastrophic accident. The revisions to the DC-10 cargo door mechanisms mandated after that accident

apparently were not examined and carried over to the design of the B-747 cargo doors.
Specifically, the mechanical retrofit of more positive locking mechanisms on the DC-10 cargo door to preclude an erroneous locked indication to the flightcrew, and the incorporation of redundant sensors to show the position of the latches/locks, were not required to be retrofitted at that time for the B-747. Of similar concern is the fact that the cargo doors for the L-1011 required redundant latch/lock indication sensors at initial certification, during the approximate same time frame the DC-10 and B-747 were certificated.
More recently, when Boeing and the FAA learned about the circumstances of the Pan Am cargo door opening incident in March 1987, more timely and positive corrective actions should have been taken. The Safety Board believes that the findings of that incident investigation should have called into question the assumptions and conclusions about the original design and certification of the B-747 cargo door, especially the alternative method for verifying that the door was latched and locked that was sought by Boeing and was granted by the FAA. Since a B-747 cargo door opening in flight was considered to be an "unacceptable event", once a door did come open in flight, the FAA and Boeing should have acted much quicker to prevent another failure.
It took nearly 16 months from the date of the Pan Am Incident (March 10, 1987) until the FAA issued AD-88-12-04 (July 1, 1988). And then, the AD allowed 18 or 24 months, depending on the model B-747, from the date of its issuance for compliance with the terminating actions of the AD. The fact that Boeing had issued an Alert SB as a result of the Pan Am incident is an indication of the apparent urgency with which Boeing treated this issue. Alert SB's are issued for "safety of flight" reasons, while regular SB's deal with "reliability" and not necessarily safety of flight items.

Despite this, the terminating action, issued as
revision 3 to the Alert SB, on August 27, 1987, was not mandated by the FAA for 11 months.

The Safety Board found no evidence that the FAA or Boeing reassessed the original design and certification conclusions regarding the safety of the B-747 cargo door during this period.

Several opportunities for preventive action were also missed by UAL during this period. First, UAL delayed the completion of the terminating actions of Alert SB 52A2206 (Rev 3 and AD-88-12-04. In fact, there was no evidence that UAL had intended to comply with the terminating action of the Alert SB, until it was mandated by the FAA.

It is understandable that an airline would not take its aircraft out of service to incorporate revisions that do not appear to be safety critical. Although by definition an Alert SB is safety related, there was no implication from Boeing's and FAA's actions regarding this matter that urgency was required. The airlines rely on the airframe manufacturers and the FAA to evaluate the need for urgent airworthiness actions that might take airplanes out of revenue service. In this case, UAL had scheduled completion of its B-747 fleet modifications in accordance with the terminating actions for AD-88-12-04 before the final allowable date; however, the schedule was based on other heavy maintenance schedules to prevent unnecessary down-time of its airplanes.

UAL personnel stated after the UAL 811 accident that its personnel did not fully appreciate the importance, or safety implications, of the terminating actions, or they would have incorporated the improvements much earlier. The usual difficulties in setting short suspense dates for performing terminating actions in AD's, such as parts availability, did not seem to exist in this case, because the parts were not complex components and probably could have been fabricated fairly quickly in-house by most airlines.

Human performance certainly contributed to UAL's failure to incorporate an important inspection step into its maintenance program as mandated by AD-88-12-04. When UAL obtained an advance draft copy of the forthcoming NPRM that eventually led to the AD, the airline began preparing its work orders to implement the forthcoming the AD requirements into its B-747 fleet (30 airplanes at the time). UAL developed its maintenance work sheets from the text of the draft NPRM, which was virtually identical to the text of the final rule. As a result of a clerical error, one of the important inspection steps required by the AD was omitted.

Apparently, UAL maintenance personnel never compared the work sheets they received with the actual requirements of the AD, or if they did, the omission was not detected. FAA inspectors responsible for oversight of UAL's maintenance program also did not detect this error because normal surveillance of AD compliance merely involved verifying the correctness of UAL's paperwork that listed the applicable AD's and compliance dates. The inspectors did not actually verify UAL's compliance action by shop visits, or by comparison of work sheets with AD provisions. These omissions by the UAL maintenance and quality assurance personnel, and the limitations of the FAA surveillance procedures were probably significant in setting the stage for the events that led to the actual cause of the door separation from N4713U.

Another matter of concern is the quality of UAL's trend analysis program. There was no indication that the repeated discrepancies with the forward cargo door on N4713U "raised a flag" within the UAL maintenance department. A quality assurance or trend analysis program should have detected an adverse trend and should have prompted efforts to resolve the repeated problems. If it had, any faults in the door electrical system or damage to mechanical components might have been detected.

In summary, the Safety Board concludes that there were several opportunities wherein Boeing, the FAA, and UAL could have taken action during the initial design and certification of the B-747 cargo door, as well as during the operation and maintenance of the cargo door installed on N4713U, to ensure the continuing airworthiness of the cargo door. The Safety Board further concludes that these deficiencies and oversights contributed to the cause of this accident.

2.8 Survival Aspects

The Hickam ARFF units and the airport's ARFF units operated on separate radio networks and thus they could not communicate directly on-scene by radio. This situation required them to communicate by voice. Although the two ARFF services had a common radio frequency (as per the Airport Emergency Plan), procedures for its use had not yet been developed. The Safety Board believes that such communication procedures should be expeditiously developed.

The use of camouflage paint schemes on military ARFF vehicles may be appropriate for military purposes; however, the Safety Board believes that camouflage is not appropriate for ARFF vehicles that are operated at a joint- use airport. It is obvious that these vehicles must be conspicuous to be seen by other responding vehicles and by persons who are involved in the accident, such as airport and airline personnel, crew and passengers, and off-airport firefighting and rescue vehicles.

The National Fire Protection Association Standards recommend for primary firefighting, rapid intervention and combined agent vehicles, that, "Paint finish shall be selected for maximum visibility and shall be resistant to damage from firefighting agents."4 Furthermore, Federal Aviation Regulation 14 CFR 139.319 (f) (2) requires emergency vehicles, "Be painted or marked in colors to enhance contrast with the background environment and optimize daytime and nighttime visibility and identification."

Further guidance for the high visibility color of ARFF vehicles is provided in a Federal Aviation Administration Advisory Circular where the vehicle paint color is specified as, "lime yellow" Dupont No. 7744 UH or its equivalent.5

Because flight attendants are vital to the safety and survival of the passengers following a decompression, measures should be taken to prevent flight attendants from being incapacitated by hypoxia. The Safety Board believes that oxygen masks should be attached to the emergency oxygen bottles to avoid any delay in their use in order to be in compliance with the intent of 14 CFR 25.1447 (c)(4). Therefore, the FAA should direct its inspector staff to survey B-747 airplanes for compliance with 14 CFR 25.1447(c)(4), and correct deficiencies found.

In this accident, the use of megaphones was vital because of the inability to be heard over the public address (PA) system. Title 14CFR 121.309 (f)(1) requires one megaphone on each airplane with a seating capacity of more that 60 and less that 100 passengers; 14 CFR 121.309 (f)(2) requires two megaphones in the cabins on each airplane with a seating capacity of more than 99 passengers. As this decompression demonstrated, additional megaphones are necessary on wide-body and large narrow-body airplanes to ensure communication in the cabin during emergencies when the PA system is inoperative.

Had there been a need for an immediate evacuation, or a water ditching, rapid egress would not have been possible at doors 2-left and 2-right because they were blocked by open storage compartments and spilled contents. The possibility also exists that a compartment door could release during a hard landing or turbulence and swing down and injure a flight attendant. Thus, the Safety Board believes that improved latches should be installed and the downward movement of stowage compartments doors should be restricted to prevent the doors from striking a seated flight attendant or block the exit door.

The Safety Board believes that the problems with life preserver donning and adjustment demonstrated in this accident should be addressed by the FAA. The straps and fittings on life preservers need to be evaluated to determine where improvements can be made, and clearer donning instructions should be developed. TSO-C13d, Life Preservers 1/3/83 prescribes the minimum performance standards for life preservers. With regard to donning, the TSO requires:

Donning. It must be demonstrated that an adult, after receiving only the customary preflight briefing on the use of life preservers, can don the life preserver within 15 seconds unassisted while seated. It must be demonstrated that an adult can install the life preserver on another adult, a child, or an infant within 30 seconds unassisted. The donning demonstration is begun with the unpackaged life preserver in hand.

Based on flight attendant interviews and information obtained from passengers these donning times were exceeded in many instances.

The Safety Board has made numerous recommendations to the FAA in the past regarding needed improvements in life preserver donning instructions, donning procedures, and timing of donning.6 The FAA has adopted most of the Safety Board's recommendations in its April 23, 1986, revision to TSO-C13e, Life Preservers, which now requires the wearer to be able to secure the preserver with no more than one attachment and make no more than one adjustment for fit. Also, donning tests are required for age groups of users starting with 20-29 years and ending with 60-69 years. At least 60% of the test subjects in each age group must be able to don then life preserver within 25 seconds unassisted with their seatbelts fastened starting with the life preserver in its storage package. TSO-C13e contains requirements that would have eliminated some of the problems that passengers had in this accident in correctly donning and

adjusting their life preservers.
The Safety Board has recommended (A-85-35 through-37) to the FAA to amend 14 CFR 121, 125, and 135 to require air carriers to install life preservers that meet TSO-C13e within a reasonable time. The FAA adopted TSO-C13e on April 23, 1986, and originally had specified an effective date of April 23, 1988, after which all newly manufactured life preservers approved under the TSO system would have to meet the requirements of TSO-C13e. The objective of the cut off date was to introduce life preservers into the fleets with the higher performance level as specified in TSO-C13e by assuring that replacement articles met the higher standards. On March 3, 1988, the FAA rescinded the cut off date to seek further public comments of fleet retrofit in accord with the proposed rulemaking. See Section 4.0 for FAA action and status of the recommendations.

3. CONCLUSIONS

3.1 Findings

1. There were no flightcrew or cabincrew factors in the cause of the accident or injuries.
2. There were no air traffic control or weather factors in the cause of the accident.
3. The airplane had not been maintained in accordance with the provisions of AD-88-12-04 that required an inspection of the cargo door locking mechanisms after each time the door was operated manually and restored to electrical operation. However, this circumstance was determined not to be a factor in the accident.
4. All but one of the electrical components remaining with the airplane or found with the cargo door that were necessary to have malfunctioned in order to cause an inadvertent electrical opening of the cargo door after dispatch were found to function properly.
5. The forward cargo door lock sectors were found in the locked position (actually in an "over-locked" position) and jammed against the latch cams. The latch cams were found in the

nearly open position.

6. The latch actuator manual drive port seal was found damaged from the forces involved in the separation of the door and did not indicate that the drive port had been used to open the door latches manually before the accident.

7. Electrical continuity tests indicated that the S2 master latch lock switch was in the "not locked" position when it was recovered with the cargo door. Because it had sustained damage from being submerged in the sea, its preaccident condition could not be determined.

8. An S2 switch functioning as found after recovery would permit electrical power to the door during ground operation so that additional failure modes or activation of the door control switch could result in movement of the latching cams.

9. All other switches associated with operation of the cargo door were found damaged from being submerged in the sea; however, they were determined to be properly installed and probably functional.

10. Short circuit paths in the cargo door circuit were identified that could have led to an uncommanded electrical actuation of the latch actuator; this situation occurred most likely before engine start, although limited possibilities for an uncommanded electrical actuation exist after engine start while an airplane is on the ground with the APU running.

11. It was not possible for electrical short circuits to command the cargo door to open at the time of the loss of the door, and it is highly improbable that such an event occurred when the airplane was airborne during the short period while the APU was running.

12. Insulation breaches were found on recovered portions of the cargo door wires that could have allowed short circuiting and power to the latch actuator, although no evidence of arcing was noted. All of the wires were not recovered, and tests showed that

arcing evidence may not be detectable.
13. An uncommanded movement of cargo door latches that occurred on another UAL B-747 on June 13, 1991, was attributed to insulation damage and a consequent short between wires in the wiring bundle between the fuselage and the moveable door. Because the S2 switch functioned properly on that airplane, movement of the latches would not have occurred after the door was locked.
14. UAL's maintenance trend analysis program was inadequate to detect an adverse trend involving the cargo door on N4713U. This circumstance was determined not to be a factor in the accident.
15. FAA oversight of the UAL maintenance and inspection program did not ensure adequate trend analysis and adherence to the provisions of airworthiness directives. This circumstance was determined not to be a factor in the accident.
16. The smooth wear patterns on the latch pins of the forward cargo door installed on N4713U were signs that the door was not properly aligned (out of rig) for an extended period of time, causing significant interference during the normal open/close cycle.
17. The rough heat-tinted wear areas on the latch pins of the forward cargo door installed on N4713U marked the positions of the cams at the time the door opened in flight.
18. The design of the B-747 cargo door locking mechanisms did not provide for the intended "fail-safe" provisions of the locking and indicating systems for the door.
19. Boeing's Failure Analysis, which was the basis upon which the FAA granted an alternative method of compliance with the provisions of 14 CFR 25.783(e), was not valid as evidenced by the findings of the Pan Am incident in 1987, and the accident involving flight 811.
20. Boeing and the FAA did not take immediate action to

require the use of the cam position view ports following the Pan Am incident, and did not include this requirement in the provisions of the Alert Service Bulletins or AD-88-12-04.

21. There were several opportunities for the manufacturer and the FAA to have taken action during the service life of the Boeing 747 that might have prevented this accident.

22. The fact that the crash fire rescue vehicles responding to this accident did not use a common radio frequency led to problems in communication among the responding vehicles.

23. The camouflage paint scheme of the military fire rescue units led to reduced visibility of these units and resulted in at least one near-collision.

24. Megaphones were used in flight to communicate with passengers because of the high ambient noise level. However, more megaphones would have afforded better communication in all parts of the cabin.

25. Some flight attendants and passengers had difficulties tightening straps of their life preservers around their waists because of the fabric used, the design of the adjustment fittings, and the angle the straps were pulled.

26. Articles that fell to the floor from stowage bins above the L-2 and R-2 exits and galley service items had to be cleared away from the exits before the emergency evacuation could be initiated.

3.2 Probable Cause

The National Transportation Safety Board determines that the probable cause of this accident was the sudden opening of the forward lower lobe cargo door in flight and the subsequent explosive decompression. The door opening was attributed to a faulty switch or wiring in the door control system which permitted electrical actuation of the door latches toward the unlatched position after initial door closure and before takeoff. Contributing to the cause of the accident was a deficiency in the design of the cargo door locking mechanisms, which made them susceptible to deformation, allowing the door to become unlatched after being properly latched and locked. Also contributing to the accident was a lack of timely corrective actions by Boeing and the FAA following a 1987 cargo door opening incident on a Pan Am B-747.

4. RECOMMENDATIONS

As a result of the investigation, including evidence from the recovered cargo door and a June 13, 1991, incident involving the uncommanded electrical operation of a cargo door on a UAL Boeing 747 at JFK Airport, the National Transportation Safety Board recommends that the FAA:

Require that the electrical actuating systems for nonplug cargo doors on transport-category aircraft provide for the removal of all electrical power from circuits on the door after closure (except for any indicating circuit power necessary to provide positive indication that the door is properly latched and locked) to eliminate the possibility of uncommanded actuator movements caused by wiring short circuits. (Class II, Priority Action) (A-92-21)

As a result of this investigation, on August 23, 1989, the Safety Board issued the following safety recommendations to the FAA:

Issue an Airworthiness Directive (AD) to require that the manual drive units and electrical actuators for Boeing 747 cargo doors have torque limiting devices to ensure that the lock sectors, modified per AD-88-12-04, cannot be overridden during mechanical or electrical operation of the latch cams. (Class II, Priority Action)(A-89-92)

Issue an Airworthiness Directive (AD) for non-plug cargo doors on all transport category airplanes requiring the installation of positive indicators to ground personnel and flightcrews confirming the actual position of both the latch cams and locks, independently. (Class II, Priority Action)(A-89-93)

Require that fail-safe design considerations for non-plug cargo doors on present and future transport category airplanes account for conceivable human errors in addition to electrical and mechanical malfunctions. (Class II, Priority Action)(A-89-94)

The FAA responded to Safety Recommendations A-89-92 through -94 on November 3, 1989. During its evaluation of Safety Recommendation A-89-92, the FAA determined that Boeing 747 cargo doors with lock sectors, modified in compliance with AD 88-12-04, cannot be overridden during mechanical or

least one torque-limiting device. The Safety Board has reviewed AD 88-12-04 and has confirmed the FAA's findings. Based on this, Safety Recommendation A-89-92 has been classified as "Closed--Reconsidered."

The FAA responded to Safety Recommendations A-89-93 and -94 describing action to review all outward opening (nonplug) doors and all jetpowered transport-category airplanes to determine what, if any, modifications are needed to ensure that these doors will not open in flight. The FAA pointed out that the door latch indicating system is to be only part of the review and that door designs will be evaluated against criteria specified in 14 CFR 25.783 as amended by Amendment 25-54, and the policy material published in Advisory Circular 25.783.1, adopted in 1980 and will take into account human factors involved in the routine operation of closing and locking doors to ensure that the latch and lock systems are fail-safe. Further, to emphasize the importance of human factors, the FAA has developed a training program for FAA certification personnel to enhance their knowledge of human factors in aircraft design. This training program will be offered to approximately 100 certification personnel during the next year. Based on this response, Safety Recommendations A-89-93 and -94 have been classified as "Open--Acceptable Action." The Safety Board believes it necessary to point out that this hazard exists for any pressurized aircraft using nonplug doors and that the FAA should not be limiting this review to only those transports which

are jetpowered.
On November 29, 1990, Boeing issued service bulletin number 747-52-2224 applicable to all 747-100, 747-200, and 747-300 airplanes to add a new "door latch" switch to all 747 cargo doors. In addition to the door warning switch that monitors the position of the pressure relief doors, the new door latch switch is activated by the latch cam bellcrank to separately sense the position of the latch cams. The existing "door closed" switch is also replaced with a double pole switch. The additional pole is used to separately sense the position of the door. Another single pole switch is also added to redundantly sense the position of the door. If any of these switches are not actuated, the warning light on the flight engineer's panel and a new light added to pilot's glareshield panel will be illuminated. The modification also requires installation of new cargo door control panels on the forward and aft lower cargo doors. The new panel incorporates an additional light to indicate proper door locking.
The FAA mandated the incorporation of this service bulletin within 18 months by AD 90-09-06, Amendment 39-6581, effective May 29, 1990.
Also, as a result of this accident, on May 4, 1990, the National Transportation Safety Board issued the following safety recommendations to the FAA:
Amend 14 CFR 25.1447(c)(4) to require that face masks be attached to the regulators of portable emergency oxygen bottles. (Class II, Priority Action) (A-90-54)
Require, in accordance with the requirements of 14 CFR 25.1447 (c)(4), that a portable oxygen bottle be located at the flight attendant stations at exit door 5 right and at exit door 5 left in B-747 airplanes. (Class II, Priority Action) (A-90-55)
Require that no articles be placed in storage compartments that are located over emergency exit doors. (Class II, Priority Action) (A-90-56)

Amend 14 CFR 121.309(f) to require a readily accessible megaphone at each seat row at which a flight attendant is stationed. (Class II, Priority Action) (A-90-57)
Take corrective action to improve direct visibility to passengers from the upper level flight attendant jumpseat in the B-747 airplanes using eye reference data contained in Federal Aviation Administration report FAA-AM-75-2 "Anthropometry of Airline Stewardesses." (Class II, Priority Action) (A-90-58)
Issue an Airworthiness Directive to require that stronger latches be installed in oversized storage compartments that formerly held liferafts on all B-747 airplanes and also limit the distance that these compartments can be opened. (Class II, Priority Action) (A-90-59)
Demonstrate for each make and model of life preserver that it can be donned, adjusted, and tightened within the elapsed time required by TSO-C13d. Direct particular attention to the ease with which straps pass through adjustment fittings when the straps are pulled at all possible angles. (Class II, Priority Action) (A-90-60)
Establish a cutoff date of [within 1 year of this recommendation letter] after which all life preservers manufactured for passengercarrying aircraft would be required to meet the specifications of TSO-C13e. (Class II, Priority Action) (A-90-61)
The FAA first responded to these safety recommendations in a July 26, 1990, letter. Further responses to various safety recommendations in the group came in letters dated October 26, 1990 (A-90-59); May 13, 1991 (A-90-58); September 23, 1991 (A-90-55, -56, and -59); and March 9, 1992 (A-90-59). The current status of each safety recommendation is:
A-90-54: "Open--Acceptable Response," pending outcome of potential rulemaking initiative by the FAA.
A-90-55: "Open--Unacceptable Response," pending a review by the FAA of B-747 airplanes for compliance with portable oxygen bottle placement and securement requirements and for

modifications that do not meet the intent of the type certification.
A-90-56: "Open--Unacceptable Response," pending a reexamination by the FAA of the potential for contents of compartments spilling out during an emergency and obstructing passengers.
A-90-57: "Open--Unacceptable Response," pending the FAA's review of its position regarding a requirement for multiple megaphones on passenger airplanes.
A-90-58: "Closed--Reconsidered" as a result of the Safety Board's acceptance of the FAA position that the cabin jumpseat design on B-747's does not constitute an unsafe condition.
A-90-59: "Open--Acceptable Response," pending the issuance of an Airworthiness Directive to require stronger latches on oversized storage compartments on B-747 airplanes.
A-90-60: "Open--Acceptable Response," pending the implementation of the latest iteration of TSO-C13.
A-90-61: "Open--Unacceptable Response," pending inclusion in TSO-C13 (latest iteration) of a cutoff date after which all life preservers manufactured for passenger-carrying aircraft would be required to meet the specifications of the TSO.
The FAA's March 9, 1992, response to Safety Recommendation A-90-59 included the final AD addressing this issue. The AD does meet the intent of the recommendation, which is now classified as "Closed--Acceptable Action."
Also as a result of this accident, on May 4, 1990, the Safety Board reiterated the following recommendations to the FAA:
A-85-35
Amend 14 CFR 121 to require that all passenger-carrying air carrier aircraft operating under this Part be equipped with approved life preservers meeting the requirements of the most current revision of TSO-C13 within a reasonable time after the adoption of the current revision of the TSO; ensure that 14 CFR 25 is consistent with the amendments to Part 121.

A-85-36
Amend 14 CFR 125 to require that all passenger-carrying air carrier aircraft operating under this Part be equipped with approved life preservers meeting the requirements of the most current revision of TSO-C13 within a reasonable time after the adoption of the current revision of the TSO; amend Part 125 to require approved flotation-type seat cushions (TSO-C72) on all such aircraft; ensure that 14 CFR 25 is consistent with the amendments of Part 125.
A-85-37
Amend 14 CFR 135 to require that all passenger-carrying air carrier aircraft operating under this Part be equipped with approved life preservers meeting the requirements of the most current revision of TSO-C13 within a reasonable time after the adoption of the current revision of the TSO; Amend Part 135 to require approved floatation-type seat cushions (TSO-C72) on all such aircraft; ensure that 14 CFR SFAR No. 23 is consistent with the amendments to Part 135.

In a November 28, 1988, letter to the FAA, the Safety Board recommended that a cutoff date January 1, 1989, be reestablished. Based on this accident, the Safety Board's again urges the FAA to establish a cutoff date by which life preservers meeting TSO-C13e would be introduced into the fleets within a reasonable time (A-85-36). The Safety Board recognizes that the FAA has complied with the part of this recommendation pertaining to the flotation-type seat cushions.

Safety Recommendations A-85-35 and -37 are being held in an "Open--Acceptable Action" status pending the publication of the final rule. Safety Recommendation A-85-36 is being held in an "Open--Unacceptable Action" status because Part 125 operations were not included in the FAA rulemaking action.

As a result of its investigation, on May 4, 1990, the Safety Board also recommended that the State of Hawaii, Department of

Transportation, Airports Division:
Develop, in cooperation with the Department of Defense, procedures for direct radio communication between aircraft rescue and fire fighting vehicles operated by the State of Hawaii and Hickam Air Force Base that would be used when responding to airport emergencies at Honolulu International Airport. (Class II, Priority Action) (A-90-62)
Additionally, as a result of its investigation, on May 4, 1990, the Safety Board recommended that the Department of Defense:
Develop, in cooperation with the State of Hawaii Department of Transportation, procedures for direct radio communication between aircraft rescue and firefighting vehicles operated by Hickam Air Force Base and the State of Hawaii that would be used when responding to airport emergencies at Honolulu International Airport. (Class II, Priority Action) (A-90-63)
Comply with Federal Regulation 14 CFR 139.319(f)(2) and the guidance contained in Federal Aviation Administration Advisory Circular 150/5220-14 by using high visibility color for aircraft rescue and firefighting vehicles that operate at Honolulu International Airport. (Class II, Priority Action) (A-90-64)
The Department of Defense responded to Safety Recommendations A-90-63 and -64 on August 17, 1990, citing the establishment of emergency radio communication ability between ARFF vehicles operated by Hickam Air Force Base and the State of Hawaii at Honolulu International Airport. Based on this action, Safety Recommendation A-90-63 was classified as "Closed--Acceptable Action" on December 12, 1990. With the establishment of the communications system as recommended, the Safety Board now classifies Safety Recommendation A-90-62 as "Closed--Acceptable Action."
Also, with regard to Safety Recommendation A-90-64, the Department of Defense pointed out that the Air Force has initiated a program to rep™ aint the vehicles over a 3-year period

to spread out funding concerns. This safety recommendation is being held as "Open--Acceptable Response," pending the completion of the repainting program in 1993.

APPENDIX A

INVESTIGATION AND HEARING

1. Investigation

The Washington Headquarters of the National Transportation Safety Board was notified of the United Airlines accident within a short time after the occurrence. A full investigation team departed Washington, D.C. at 1400 eastern daylight time on the same day and arrived in Honolulu at 0030 Hawaiian standard time the next day.

The team was composed of the following investigation groups: Operations, Structures/Systems, Maintenance Records, Metallurgy, and Survival Factors. In addition, specialist reports were prepared relevant to the CVR, FDR and radar plots.

Parties to the field investigation were United Airlines, the FAA, the Boeing Commercial Airplane Company, the Air Line Pilots Association, the International Association of Machinists, and the Association of Flight Attendants.

2. Public Hearing

A 3-day public hearing was held in Seattle, Washington, beginning on April 25, 1989. Parties represented at the hearing were the FAA, United Airlines, the Boeing Commercial Airplanes Company, the Air Line Pilots Association, and the International Association of Machinists.

APPENDIX B

PERSONNEL INFORMATION

Captain David Cronin

Captain David Cronin, 59, was hired by UAL on December 10, 1954. The captain holds Airline Transport Pilot (ATP) Certificate No. 1268493 with airplane multiengine land ratings and commercial privileges in airplane single-engine land, sea and gliders. The captain is type rated in the B747, DC10, DC8, B727, Convair (CV) 440, CV340, CV240 and the learjet. The captain was issued a first class medical certificate on November 1, 1988, with no limitations.

The captain's initial operating experience (IOE) check out in the B747 occurred in December, 1985. The captain's latest line and proficiency checks in the B747 were completed in August and December, 1988, respectively. Training in ditching and evacuation was included with the proficiency check. The captain had flown a total of about 28,000 hours, 1,600 to 1,700 hours of which were in the B747. During the 24-hour, 72-hour and 30-day periods, prior to the accident, the captain had flown: 1 hour, 5 minutes; 13 hours, 35 minutes; and 76 hours, 18 minutes, respectively.

First Officer Gregory Slader

First Officer Gregory Slader, 48, was hired by UAL on June 15, 1964. The first officer holds ATP Certificate No. 1528630 with airplane multiengine land ratings and commercial privileges in airplane single-engine land. The first officer is type rated in B747, DC10, B727, and B737. The first officer was issued a first class medical certificate on February 14, 1989, with no limitations.

The first officer's initial operating experience (IOE) check out in the B747 occurred in August, 1987. The first officer's latest proficiency check in the B747 was completed in October, 1988. Training on ditching and evacuation was included with the proficiency check. The first officer had flown a total of about 14,500 hours, 300 hours of which were in the B747. During the 24-hours, 72-hour and 30-day periods prior to the accident, the first officer had flown: 1 hour, 5 minutes; 13 hours, 35 minutes; and 46 hours, 25 minutes, respectively.

Second Officer Randal Thomas

Second Officer Randal Thomas, 46, was hired by UAL on May 22, 1969. The second officer holds Flight Engineer Certificate No. 1947041 for turbo jet powered airplanes, issued July 18, 1969. The second officer holds commercial pilot certificate No. 1585899 with ratings and limitations of airplane single and multiengine land with instrument privileges. The second officer was issued a first class medical certificate on December 6, 1988, with no limitations. The second officer's IOE check out in the B747 occurred in March, 1987. The second officer's latest proficiency check in the B747 was completed in October, 1988. Training in ditching and evacuation was included with the proficiency check. He had flown a total of about 20,000 hours, about 1,200 hours of which were as second officer on the B747. During his 24-hour, 72-hour and 30 day-periods, prior to the accident, the second officer had flown: 1 hour, 5 minutes; 13 hours, 35 minutes; and 46 hours, 25 minutes, respectively.

Flight Attendant and Chief Purser Laura Brentlinger

Flight attendant Laura Brentlinger, 38, was employed by UAL in May 1982; and had completed B747 recurrent training on September 19, 1988.

Flight Attendant and AFT Purser Sarah Shanahan

Flight attendant Sarah Shanahan, 42, was employed by UAL in August 1967; and had completed B747 recurrent training on

October 10, 1988.

Flight Attendant Richard Lam

Flight attendant Richard Lam, 41, was employed by UAL on April 1970; and had completed B747 recurrent training on September 16, 1988.

Flight Attendant John Horita

Flight attendant John Horita, 44, was employed by UAL in June 1970; and had completed B747 recurrent training on November 1, 1988.

Flight Attendant Curtis Christensen

Flight attendant Curtis Christensen, 34, was initially employed by PAA in May 1978. He was subsequently employed by UAL in February 1986 when UAL purchased PAA Pacific Division. Flight attendant Chrisensen had completed B747 recurrent training on December 12, 1988.

Flight Attendant Tina Blundy

Flight attendant Tina Blundy, 36, was employed by UAL in May 1973; and had completed B747 recurrent training on October 28, 1988.

Flight Attendant Jean Nakayama

Flight attendant Jane Nakayama, 37, was employed by UAL in August 1973; and had completed B747 recurrent training on December 6, 1988.

Flight Attendant Mae Sapolu

Flight attendant Mae Sapolu, 38, was initially employed by Pan American Airlines (PAA) in March 1973. She was subsequently employed by UAL in February 1986; when UAL purchased PAA Pacific Division. Flight attendant Sapolu completed B747 recurrent training on October 13, 1988.

Flight Attendant Robyn Nakamoto

Flight attendant Robyn Nakamoto, 26, was employed by UAL in April, 1986, and transferred to the Inflight Service Division in May, 1988. She was initially trained on the B747 in May 1988; and had not attended recurrent training.

Flight Attendant Edward Lythgoe

Flight attendant Edward Lythgoe, 37, was employed by UAL in December 1978; and had completed B747 recurrent training on October 21, 1988.

Flight Attendant Sharol Preston

Flight attendant Sharol Preston, 39, was employed by UAL in July 1970; and had completed B747 recurrent training on July 29, 1988.

Flight Attendant Ricky Umehira

Flight attendant Ricky Umehira, 35, was employed by UAL in November 1983; and had completed B747 recurrent training on November 15, 1988.

Flight Attendant Darrell Blankenship

Flight attendant Darrell Blankenship, 28, was employed by UAL in February 1984; and had completed B747 recurrent training on February 10, 1988.

Flight Attendant Linda Shirley

Flight attendant Linda Shirley, 30, was employed by UAL in March 1979; and had completed B747 recurrent training on November 3, 1989.

Flight Attendant Ilona Benoit

Flight attendant Ilona Benoit, 48, was initially employed by PAA in November 1969. She was subsequently employed by UAL in February 1986; and had completed B747 recurrent training on November 17, 1988.

Lead Ramp Serviceman Paul Engalla

Lead ramp serviceman Paul Engalla was employed by UAL in 1959. Because of his extensive ramp service experience, Mr. Engalla was selected as a ramp service trainer in 1986.

Ramp Serviceman Daniel Sato

Ramp serviceman Daniel Sato was employed by UAL in May 1987. Company records indicate that his proficiency in the opening and closing of B747 cargo doors and the operation of

container loads was attained in September 1988.
Ramp Serviceman Brian Kitaoka
Ramp serviceman Brian Kitaoka was employed by UAL in November 1986. Company records indicate that his proficiency in the operation of container loaders was attained in November 1987. His proficiency in the opening and closing of B747 cargo doors was attained in October 1988.
Dispatch Mechanic Steve Hajanos
Dispatch mechanic Steve Hajanos was employed as an airplane mechanic by UAL on October 30, 1986. He holds FAA Airplane and Powerplants Certificate No. 362583850, issued November 14, 1981. He was formerly employed by Aloha Airlines as a maintenance supervisor and by World Airways as a mechanic and maintenance supervisor. He began his aviation career as an airplane mechanic in the United States Air Force.

Note 2: Aircraft with layover of 12 hours or more will receive a

Service No. 2 not to exceed 65 flight hours between checks.

APPENDIX D

INJURY INFORMATION

Flight Crewmember.--The second officer sustained minor superficial brush burns to both elbows and forearms, during the evacuation.

Cabin Crewmembers.--The cabin crewmembers sustained the following injuries during the evacuation:

Flight attendant No. 1 sustained a strained left shoulder;

Flight attendant No. 2 sustained acute thoracic and lumbosacral strain;

Flight attendant No. 3 sustained a mild right bicep strain;

Flight attendant No. 4 sustained a left elbow contusion, left shoulder dislocation, and mild lumbosacral strain;

Flight attendant No. 5 sustained a left calf contusion;

Flight attendant No. 6 sustained a mild left elbow bruise;

Flight attendant No. 7 sustained mild left arm and lower back strain;

Flight attendant No. 8 sustained a soft tissue injury to the back;

Flight attendant No. 9 sustained abrasions to both palms and the left knee;

Flight attendant No. 10 sustained a fracture of the left tenth rib;

Flight attendant No. 11 sustained a minimal injury to the right middle finger PIP joint and left first MP joint;

Flight attendant No. 12 sustained a pulled muscle on the left side of the neck;

Flight attendant No. 13 sustained a comminuted fracture of the right ulna and radius;

Flight attendant No. 14 sustained a mild thoracic back strain;

Flight attendant No. 15 sustained a non-displaced fracture of C-6, a cerebral concussion, a fracture of the proximal right humerus, and multiple lacerations;

A flight attendant, flying as a passenger, sustained mild lumbosacral strain, a laceration of the right little finger, and a left elbow abrasion.

Passengers.--Nine Passengers who were seated in seats 8H, 9FGH, 10GH, 11GH, and 12H, were ejected from the fuselage and were not found; and thus, are assumed to have been fatally injured in the accident.

Passengers seated in the indicated seats sustained the following injuries:

Seat

7C - Barotrauma to both ears

9C - Half-inch laceration to the upper left arm, superficial abrasions to left arm and hand, barotrauma to both ears

9E - Superficial abrasions and contusions to the left hand, mild barotrauma to both ears

10B - Superficial abrasions to the left elbow and left middle finger

10E - Superficial abrasions to the torso and left forearm, bruising of the left hand and fingers

11E - Laceration on the right ankle tendon, multiple bruises

11F - Slight contusion of the right shoulder

13D - Barotrauma to both ears

13E - Bleeding in both ears

13H - Contusion to the left periorbital area

14A - Laceration in the parietal occipital area, barotrauma to both ears

15J - Comminuted fracture of the lateral epicondyle of the left distal humerus (about 5mm separation)

16B - Superficial abrasions to the right arm

16J - Barotrauma to both ears

16K - Right temporal abrasions

26A - Barotrauma to both ears

26B - barotrauma to both ears

26H - Barotitis to both ears, low back pain, irritation to the

right eye due to foreign bodies
27A - Barotrauma to the right ear
28J - Superficial abrasions and a contusion to the left hand, mild barotrauma to both ears

1The flap track canoe fairings are numbered 1 through 8, from left outboard to right outboard.

2For ease in reference, the following numbering was used to relate forward cargo door frames to fuselage body stations (BS): frame 1--BS 567.10, frame 2--BS 580.95, frame 3--BS 596.75, frame 4--BS 608.15, frame 5--BS 623.96, frame 6--BS 636.02, frame 7--BS 651.50, frame 8--BS 662.90.

3 The "used" switch is the switch through which electricity passes; the "unused" switch does not have electricity pass through it.

4NFPA 414 - Aircraft Rescue and Fire Fighting Vehicles, National Fire Protection Association, 1984, Batterymarch Park, Quincy, MA 02269.

Subject: **AI 182 AAR and URL for TWA 800**

http://www.ntsb.gov/Publictn/2000/aar0003.htm

Abstract: On July 17, 1996, about 2031 eastern daylight time, Trans World Airlines, Inc. (TWA) flight 800, a Boeing 747-131, N93119, crashed in the Atlantic Ocean near East Moriches, New York. TWA flight 800 was operating under the provisions of 14 Code of Federal Regulations Part 121 as a scheduled international passenger flight from John F. Kennedy International Airport (JFK), New York, New York, to Charles DeGaulle International Airport, Paris, France. The flight departed JFK about 2019, with 2 pilots, 2 flight engineers, 14 flight attendants, and 212 passengers on board. All 230 people on board were killed, and the airplane was destroyed. Visual meteorological conditions prevailed for the flight, which operated on an instrument flight rules flight plan.

The National Transportation Safety Board determines that the probable cause of the TWA flight 800 accident was an explosion of the center wing fuel tank (CWT), resulting from ignition of the flammable fuel/air mixture in the tank. The source of ignition energy for the explosion could not be determined with certainty, but, of the sources evaluated by the investigation, the most likely was a short circuit outside of the CWT that allowed excessive voltage to enter it through electrical wiring associated with the fuel quantity indication system.

Contributing factors to the accident were the design and certification concept that fuel tank explosions could be prevented solely by precluding all ignition sources and the design and certification of the Boeing 747 with heat sources located beneath the CWT with no means to reduce the heat transferred into the CWT or to render the fuel vapor in the tank nonflammable.

The safety issues in this report focus on fuel tank flammability, fuel tank ignition sources, design and certification standards, and the maintenance and aging of aircraft systems. Safety recommendations concerning these issues are addressed to the Federal Aviation Administration.

Canadian Aviation Bureau canadien Safety Board de la sécurité aérienne AVIATION OCCURRENCE AIR INDIA BOEING 747-237B VT-EFO CORK, IRELAND 110 MILES WEST 23 JUNE 1985 1.0 INTRODUCTION

Air India Flight 182, a Boeing 747-237B, registration VT-EFO, was on a flight from Mirabel to London when it disappeared from the radar scope at a position of latitude 51°O'N and longitude 12°50'W at 0714 Greenwich Mean Time (GMT), 23 June 1985, and crashed into the ocean about 110 miles west of Cork, Ireland. There were no survivors among the 329 passengers and crew members. The depth of the water at the crash site is about 6,700 feet.

At 0541 GMT, 23 June 1985, CP Air Flight 003 arrived at Narita Airport, Tokyo, Japan, from Vancouver. At 0619 GMT a bag from this flight exploded on a baggage cart in the transit area of the airport within an hour of the Air India occurence. Two persons were killed and four were injured. From the day of the occurrences, there have been questions about a possible linkage between the events.

This Submission examines the information available to the Canadian Aviation Safety Board (CASB) with respect to the circumstances surrounding the AI 182 accident. The sources of information include: information made public to the Indian Inquiry as a result of the RCMP investigation; the flight data recorder (FDR), cockpit voice recorder (CVR) and Shannon ATC tape recording analyses by Canadian, United Kingdom, and Indian authorities; the medical evidence obtained from Dr. Hill of the Accident Investigations Branch of the United Kingdom; and the evidence obtained by examination of the wreckage recovered, the wreckage distribution pattern, photographs, and videotapes of the wreckage on the ocean bottom.

2.0 EXAMINATION

2.1 Vancouver

On 19 June 1985, at approximately 1800 PDT (0100 GMT, 20 June), a CP Air reservations agent in Vancouver received a telephone call from a male with a slight East Indian accent.* He identified himself as Mr. Singh and informed the agent that he was making bookings for two different males also with the surname of Singh. One booking was made in the name of Jaswand Singh with CP 086 from Vancouver to Dorval on 22 June 1985 to link with AI 182 departing from Mirabel. The other booking was to Bangkok using CP 003 from Vancouver to Tokyo and AI 301 from Tokyo to Bangkok. This booking was made in the name of Mohinderbel Singh. A local telephone contact number was given and the call lasted about one-half hour.

On the same date at approximately 1920 PDT (0220 GMT), another reservations agent for CP Air was contacted and requested to change the booking for Jaswand Singh. The confirmed flight on CP 086 was cancelled and a reservation was made on CP 060 from Vancouver to

Toronto, and a request to be wait-listed on AI 181/182 from Toronto to Delhi was made.

On 20 June 1985 at about 1210 PDT (1910 GMT), a male appearing to be of East Indian origin purchased the tickets with cash from a CP Air ticket office in Vancouver. The booking in the name of Mohinderbel Singh was changed to L. Singh and the booking using the name of Jaswand Singh changed to M. Singh. The telephone contact number was also changed. The final itinerary was as follows:

a) M. Singh - CP 060 Vancouver - Toronto Confirmed Scheduled to depart Vancouver at 0900 PDT, 22 June 1985

- AI 181 Toronto - Montreal Wait-listed Scheduled to depart Toronto at 1835 EDT, 22 June 1985

*See Appendix A for chronology of events.

- AI 182 Montreal - Delhi Wait-listed Scheduled to depart Montreal at 2020 EDT, 22 June 1985

b) L. Singh - CP 003 Vancouver - Tokyo Confirmed Scheduled to depart Vancouver at 1315 PDT, 22 June 1985

- Air India 301 Tokyo - Bangkok Confirmed Scheduled to depart Tokyo at 1705 (local time in Tokyo), 23 June 1985

On 22 June 1985 at about 0630 PDT (1330 GMT), a caller identifying himself as Mr. Manjit Singh called the CP Air reservations office. The caller spoke with a heavy East Indian accent and wanted to know if his booking on AI 181/182 was confirmed. The caller was informed by the agent that he was still wait-listed out of Toronto and offered to make alternate arrangements to Delhi. The caller stated that he would rather go to the airport and take his chances. The caller also asked if he could send his luggage from Vancouver to Delhi and was told he could not check his baggage past Toronto unless his flight was confirmed.

On Saturday morning, 22 June 1985, a CP Air passenger agent worked check-in position number 26 at the CP Air ticket counter, Vancouver International Airport, and recalls dealing with a passenger booked on CP 060 and then on to Delhi. The passenger stated that he wanted his bag tagged right to Delhi from Vancouver. After checking the computer, the agent explained that since he was not confirmed past Toronto he could not interline his baggage. The passenger insisted and, as the line-ups were long, the agent relented and interlined his suitcase. The flight manifest for CP 060 shows that M. Singh checked in through this passenger agent, was assigned seat 10B, and checked one piece of baggage. The flight manifest for CP 003 shows that on the same day the person using the name of L. Singh with a ticket to Bangkok also checked in through the same counter, was assigned seat 38H, and checked one piece of baggage.

A check of CP Air's records and interviews with passengers on flights CP 003 and CP 060 indicates that the persons identifying themselves as M. and L. Singh did not board these respective flights.

2.2 Toronto

Air India Flight 181 from Frankfurt arrived at Toronto on 22 June 1985 at 1430 EDT (1830 GMT) and was parked at gate 107 of Terminal 2. All passengers and baggage were removed from the aircraft and processed through Canada Customs. Passengers continuing on the flight to Montreal were given transit cards, and on this flight 68 cards were handed out. These transit passengers are required to claim their luggage and proceed through Canada Customs. Prior to entering the public area, there is a belt which is designated for interline or transit baggage. Transit passengers deposit their luggage on this belt which carries it to be reloaded on the aircraft. This baggage was not subjected to X-ray inspection as it was presumed to have been screened at the passengers' overseas departure point. When the transit passengers checked in to proceed to Montreal, their carry-on baggage was subjected to the normal security checks in place on this date. Passenger and baggage security checks were conducted by Burns International Security Services Ltd. and all passenger and baggage processing for both off-loading and on-loading was handled by Air Canada staff.

Air India Flight 181 was composed of the following:

- passengers continuing to Montreal (68)
- passengers from connecting flights

AC 102 (Saskatoon) 2

AC 106 (Edmonton) 4

AC 192 (Winnipeg) 1
AC 170 (Winnipeg) 4
AC 136 (Vancouver) 10
CP 060 (Vancouver) 1 Standby (M. Singh)

- passengers originating at Toronto
- diplomatic bags from the Vancouver India Consul General via AC 508
- produce cargo from India
- cargo in the form of 5th pod engine components loaded in the aft cargo compartment.

It should be noted that some passengers from India book flights to Montreal with their intended destination being Toronto. The reason is that the fare to Montreal is cheaper and therefore some passengers get off the flight in Toronto, claim their luggage and leave without reporting a cancellation of the trip to Montreal. It has been established that 65 of the 68 transit passengers reboarded the flight to Montreal.

Air India personnel were in charge for the overall operation at Toronto regarding the unloading and loading of both passengers and cargo. Although the actual work was performed by various companies under contract, Air India personnel oversaw the operation. The Air India station manager was away on vacation on 22 June 1985. The evidence does not clearly establish who had been assigned to replace the station manager and assume his duties.

Air Canada had stored in a hangar an engine that had failed on a previous Air India flight from Toronto on 8 June 1985. Air Canada received a message from Air India stating that the failed engine was to be mounted as a 5th pod on Flight 181/182 on 22 June 1985. The engine was prepared for loading and component parts were crated for loading into the aft cargo compartment. On 22 June, the component parts were taken from the hangar and placed outside to be delivered to the aircraft by MEGA International Air Cargo. The component parts were placed just inside the airport fence separating the restricted and unrestricted areas. The installation began immediately upon the arrival of Flight 181 and was completed at 1530 EDT (1930 GMT). The front engine cowling was crated but would not fit through the aft cargo door. The crating was rearranged, and the door stops on the cargo door were removed to permit the loading of the crate and the remaining engine parts were loaded on pallets. Due to problems with loading the 5th pod and component parts, the departure was delayed from 1835 EDT (2235 GMT) to 2015 EDT (0015 GMT, 23 June).

CP Air Flight 060 arrived in Toronto at 1610 EDT (2010 GMT) and docked at gate 44, Terminal 1. A number of passengers on this flight were interlined to other flights including passenger M. Singh wait-listed on Air India Flight 181/182. It has been established that this passenger did not board Flight CP 060 but did check baggage onto the flight. This baggage was to be interlined to the Air India flight departing from Terminal 2. In this case, CP Air employees would have off-loaded all baggage from CP 060 and deposited the baggage at Racetrack 6 on the ring road of Terminal 1 to be transported to the Air Canada sorting room at Terminal 2.

Consolidated Aviation Fuelling and Services (CAFAS) is a company which is contracted to pick up and deliver baggage from one terminal to the other. The CAFAS driver on duty at the time recalls picking up a bag from a CP Air flight originating in Vancouver and destined for Air India at Terminal 2. As this piece of luggage did not turn up as found luggage, it is deduced that normal practice was followed, and the luggage was interlined and loaded on AI 181/182.

MEGA International Air Cargo is a firm that handled air cargo and containers for Air India. Since the flight was carrying a 5th engine and component parts, no commercial cargo could be loaded at Toronto. MEGA delivered the engine component parts to be loaded in the cargo compartment by Air Canada employees. Later, MEGA received two diplomatic bags and delivered these to the aircraft. The bags were loaded into the valuable goods container (see Appendix B). These bags were not subjected to X-ray or any other security checks.

All checked-in baggage for AI 181/182 was to be screened by an X-ray machine which was located in Terminal 2 at the end of international belt number 4. This location would permit all baggage from the check-in counters and interline carts to be fed through the X-ray machine before being loaded. It has been established that this machine worked intermittently for a period of time and stopped working during the loading process at about 1700 EDT (2100 GMT). Rather than opening the bags and physically inspecting them, the Burns security personnel performing the X-ray screening were told by the Air India security officer to start using the hand-held PD-4 sniffer.

One Burns security officer checked the bags with the sniffer while another put stickers on the bags and forwarded them. The security officer forwarding the baggage recalls the sniffer making short beeping noises not long whistling ones. The security officer who used the sniffer claims it never went off, and the only time any sound was made was when it was turned on and off. At those times, it would emanate a short beep (refer to section 2.8 for further information regarding the PD-4 sniffer).

Burns International Security had a contract with Air India for the security of the aircraft while it was docked. The security arrangements contracted from Burns were as follows:

- security at the bridge door leading to the aircraft;
- security inside the aircraft from the time the passengers disembarked upon flight arrival until flight departure;
- security guards assigned the physical inspection of all carry-on baggage in the departure room; and
- security guards in the international baggage make-up room conducting screening of baggage using an X-ray machine and a hand-held PD-4 sniffer.

The statements taken from Burns security personnel in Toronto indicated that a significant number of personnel, including those handling passenger screening, had never had the Transport Canada passenger inspection training program or, if they had, had not undergone refresher training within 12 months of the previous training.

As a result of official requests made by Air India in early June 1985 for increased security for Air India flights, the RCMP provided additional security as follows:

- one member in a marked police motor vehicle patrolling the apron area;
- one member in a marked police motor vehicle parked under the right wing from time of arrival until push-back;
- one member on foot patrol at Air India check-in counter; and
- one member at the loading bridge during boarding.

In addition, all RCMP members working in that particular area of Terminal 2 were aware of the Air India flight and would check in with the assigned personnel during their patrols in the area of the aircraft and check-in/boarding lounges. Uniformed members are to patrol and monitor security within the airport premises as detailed in section 2.5 below.

Passenger check-in was handled for Air India by Air Canada under contract with Air India. The check-in included passengers originating in Toronto and interline passengers but did not include the transit passengers to Montreal. The check-in passengers were numbered using a security control sheet in accordance with instructions from Air India; however, the check-in and interline baggage was not numbered, and no attempt was made to correlate baggage with passengers. Hence, any unaccompanied interline baggage would not have been detected.

The flight and cabin crew had been in Toronto for the week prior to this flight and were to take the aircraft to London where they would be replaced by another crew. The crew members themselves and their carry-on baggage were not subjected to any security checks; however, their checked-in baggage was screened in the same manner as other baggage.

2.3 Montreal

Air India Flight 181 from Toronto arrived at Mirabel International Airport at about 2100 EDT (0100 GMT, 23 June) and parked in supply area number 14 at 2106 EDT (0106 GMT). The 65 passengers destined for Montreal along with three Air India personnel deplaned and were transported by bus to the terminal building. The remaining passengers remained on board as transit passengers and were not permitted to disembark at Montreal. Air Canada baggage handlers off-loaded four containers of cargo, three containers of baggage and a valuables container. Two diplomatic pouches from the Indian High Commission in Ottawa were delivered to the aircraft by MEGA International Cargo. One pouch weighing one kilogram was hand-delivered to the flight purser for storage in a valuables locker within the cabin and the other pouch was loaded into the valuables container.

During the check of the aircraft at Montreal, the second officer pointed out to an Air Canada mechanic that a rear latch on the fan cowl for the 5th engine did not appear to be properly secured. The mechanic examined the latch and found it well secured, but the handle was not flush and was hanging about five degrees. The mechanic applied high-speed tape to the latch handle for aerodynamic smoothness. This repair was examined by the second officer who was satisfied with the work. No records were completed by Air Canada in connection with this temporary repair.

At about 1730 EDT (2130 GMT), Air Canada, which is Air India's contracted agent, opened its check-in counter to passengers who would be flying on Air India Flight 182. Burns security personnel were also assigned at this time to screen the checked baggage. Passenger tickets were checked, issued a number, and copies of the tickets were removed and retained by Air Canada. Boarding passes were then issued and affixed to the numbered tickets. Also attached to the ticket booklets were numbered tickets which corresponded to each piece of checked baggage. The numbered checked baggage was sent to the baggage area by Air Canada personnel to be security-checked by Burns security personnel. The passengers for AI 182 after checking in were free to enter the departure area. At the entrance to the departure area, Burns security staff used X-ray units and metal detectors to screen passengers and carry-on baggage. At about 2100 EDT (0100 GMT), the passengers proceeded to gate 80 where they gave their boarding passes and numbered tickets to an Air Canada agent. The agent kept the numbered flight tickets and checked the numbers against the passenger list. Also, at gate 80, a secondary security check was done on passengers by a Burns security officer using a metal detector. Hand-carried baggage was subjected to

further physical and visual checks. A total of 105 passengers boarded the flight at Mirabel Airport; there were no interline passengers.
Between 1900 (2300 GMT) and 1930 EDT (2330 GMT), Burns security personnel identified a suspect suitcase using the X-ray machine. The suitcase was placed on the floor next to the machine. The Burns security supervisor told Air India personnel that a suspect suitcase had been located and was advised within 15 to 20 minutes to wait for the Air India security officer who would be arriving on the flight from Toronto. Subsequently, a second suspect suitcase was identified and a little later a third. The three suitcases were placed next to the X-ray machine.
Between 1930 (2330 GMT) and 1945 (2345 GMT), all the Burns security personnel at the X-ray machine were assigned to other duties and the three suspect suitcases remained in the baggage area without supervision. At about 2140 (0140 GMT), the Air India security officer went to the baggage room and inspected the three suitcases with the X-ray machine and a sniffer that was in the possession of the security officer. The Air India security officer decided to keep the three suitcases and, if further examination proved negative, send them on a later flight.
At approximately 2155 (0155 GMT), the Air Canada Operations Centre supervisor contacted the airport RCMP detachment regarding the suspect suitcases. At about 2205 (0205 GMT), an RCMP member located the suitcases in the baggage room and requested that an Air India representative be sent to the baggage room. About five minutes later, the Air India security officer contacted the baggage room by telephone and advised that he could not come to the room immediately. The Air India security officer arrived in the baggage room at about 2235 (0235 GMT) and, when asked to determine the owners of the suitcases, informed the RCMP member that the flight had already departed [2218 (0218 GMT)]. The three suspect suitcases were later examined with negative results.
The remainder of the checked baggage which cleared the security check was identified by a green sticker. The baggage was then forwarded to Air Canada personnel who loaded the baggage in containers to be placed on board the aircraft. A later check with Canada Customs and Air Canada at Mirabel revealed no unclaimed baggage associated with AI

181/182. A similar check at Dorval Airport was conducted with negative results.

No record was kept as to the location and number of individual pieces of checked-in luggage. Records were kept as to the location of the containers according to destination, where loaded and the number of pieces of luggage in each container (see Appendix B).

The Mirabel Detachment of the RCMP provided the following security at the airport on 22 June 1985:

- one member in a police vehicle for airside security;
- one member on patrol in the arrival and departure areas;
- one member on general foot patrol throughout the terminal; and
- one member as a telecommunications operator in the detachment office.

In addition, due to the increased threat to Air India flights, the RCMP provided the following supplementary coverage to Air India Flight 181/182 on 22 June 1985:

- one member in a police vehicle escorted the aircraft to and from the runway and the terminal building and remained with the aircraft while it was stationary;
- one member in a police vehicle remained at the entrance to the ramp;
- two members patrolled the area of the ticket counter and access corridors, and one of these members also served in a liaison capacity with the airline representatives.

2.4 International Standards and Recommended Practices

International security standards and recommendations to safeguard international civil aviation against acts of unlawful interference are listed in ICAO Annex 17 to the Convention on International Civil Aviation. Suggested security measures and procedures are amplified in the ICAO Security Manual for Safeguarding Civil Aviation Against Acts of Unlawful Interference.

Annex 17 requires contracting States of which Canada is one to "take the necessary measures to prevent weapons or any other dangerous devices, the carriage or bearing of which is not authorized, from being introduced by any means whatsoever, on board an aircraft engaged in the carriage of passengers."

In addition to other recommendations, Annex 17 recommends that contracting States should establish the necessary procedures to prevent the unauthorized introduction of explosives or incendiary devices in baggage, cargo, mail and stores to be carried on board aircraft.

The Security Manual specifies that,

EMBED MSWordArt.2 \s

EMBED MSWordArt.2 \s

Recently, ICAO has proposed amendments to Annex 17. These proposals arise from a decision taken by the Council in its 115th Session on 10 July 1985. The Council instructed its Committee on Unlawful Interference, as a matter of urgency, to review the entirety of Annex 17 and to report on those provisions which might be immediately introduced, upgraded to Standards, strengthened or improved. Among the proposed amendments is the following upgrading in the Standards:

- Each contracting State ensure the implementation of measures at airports to protect cargo, baggage, mail stores and operator's supplies being moved within an airport to safeguard such aircraft against an act of unlawful interference.

2.5 Canadian Law

In terms of Canadian statutory requirements, the Civil Aviation Security Measures Regulations and the Foreign Aircraft Security Measures Regulations made pursuant to the Aeronautics Act require specified owners or operators of aircraft registered in Canada or specified owners or operators who land foreign aircraft in Canada to establish, maintain, and carry out security measures at airports consisting of:

- systems of surveillance of persons, personal belongings, baggage, goods and cargo by persons or by mechanical or electronic devices;
- systems of searching persons, personal belongings, baggage, goods and cargo by persons or by mechanical or electronic devices;
- a system that provides, at airports where facilities are available, for locked, closed or restricted areas that are inaccessible to any person other than a person who has been searched and the personnel of the owner or operator;

- a system that provides, at airports where facilities are available, for check-points at which persons intending to board the aircraft of an owner or operator can be searched;
- a system that provides, at airports where facilities are available, for locked, closed or restricted areas in which cargo, goods and baggage that have been checked for loading on aircraft are inaccessible to persons other than those persons authorized by the owner or operator to have access to those areas;
- a system of identification that prevents baggage, goods and cargo from being placed on board the aircraft if it is not authorized to be placed on board by the owner or operator; and
- a system of identification of surveillance and search personnel and the personnel of the owner or operator.

Specified carriers including Air Canada, CP Air, and Air India were required to provide a description of their security measures to the Canadian Minister of Transport.

An Order-in-Council on 29 September 1960 established that the RCMP was responsible for the direction and administration of police functions at major airports operated by Transport Canada. The duties of the Police and Security Detail at these designated airports include the following:

- carry out policing and security duties to guard against unauthorized entry, sabotage, theft, fire or damage;
- enforce federal legislation;
- respond to violations of the Criminal Code of Canada, Federal, Provincial, and Territorial statutes, and perform a holding action pending arrival of the police department having primary criminal jurisdiction;
- man guard posts; and
- provide a police response in those areas of airports where pre-board screening takes place.

Section 5.1(9) of the Aeronautics Act states that "The Minister may designate as security officers for the purposes of this section any persons or classes of persons who, in his opinion, are qualified to be so designated." Pursuant to this section Transport Canada has established criteria for persons or classes of persons that are designated as security officers in a Schedule registered on 11 April 1984. The criteria also specify that a security guard company and its employees will meet Transport Canada requirements provided that the company:

- is under contract with a carrier to conduct passenger screening under the Aeronautics Act and Regulations;
- is licensed in the province or territory;
- complies with the security guard criteria as follows in that the guard must:
  - be 18 years or older,
  - be in good general health without physical defects or abnormalities which would interfere with the performance of duties,
  - be licensed as a security guard and in possession of the licence while on duty, and
  - meet the training standards of Transport Canada consisting of successfully completing the Transport Canada passenger inspection training program, attaining an average mark of 70 per cent, and undergoing refresher training within 12 months from previous training;
- uses a comprehensive training program which has been approved by Transport Canada and is capable of being monitored and evaluated;
- keeps records showing the date each employee received initial training and/or refresher training and the mark attained; and
- provides supervision to ensure that their employees maintain competency and act responsibly in the conduct of searching passengers and carry-on baggage being carried aboard aircraft.

2.6 Canadian Security Procedures

In accordance with the Canadian Aeronautics Act and pursuant regulations, air carriers are assigned the responsibility for security. Transport Canada provides the following security services for the air carriers using major Canadian airports, including the international airports in Vancouver, Toronto and Montreal:

- security and policing staff including RCMP airport detachments;
- specific airport security plans and procedures;
- secure facilities (e.g., secure areas, pass identification systems, etc.); and

- security equipment and facilities (e.g., X-ray detection units, walk-through metal detectors, hand-held metal detectors, explosive detection dogs).

As of 22 June 1985, the following general security measures were in place at Canadian airports:

- metal detection screening of passengers; and
- X-raying of carry-on baggage.

Checked baggage was not normally subject to any security screening. A few air carriers such as Air India had extra security measures in place because of an assessed higher threat level (see section 2.7 below).

On 23 June 1985, Transport Canada required additional security measures to be implemented by all Canadian and foreign air carriers for all international flights from Canada except those to the continental United States. These measures required:

- the physical inspection or X-ray inspection of all checked baggage;
- the full screening of all passengers and carry-on baggage; and
- a 24-hour hold on cargo except perishables received from a known shipper unless a physical search or X-ray inspection is completed.

Further, on 29 June 1985, Transport Canada directed that all baggage or cargo being interlined within Canada to an Air India flight was to be physically inspected or X-rayed at the point of first departure and that matching of passengers to tickets was to be verified prior to departure.

2.7 Air India Security Program in Canada

In accordance with the Foreign Aircraft Security Measures Regulations, Air India had provided the Minister of Transport with a copy of its security program. It included measures to:

- establish sterile areas;
- physically inspect all carry-on baggage by means of hand-held devices or X-ray equipment;
- control boarding passes;
- maintain aircraft security;
- ensure baggage and cargo security; and
- off-load baggage of passengers who fail to board flights.

Under these procedures established by Air India, passengers, carry-on baggage, and checked baggage destined for AI 181/182 on 22 June 1985 were subjected to extra security checks. A security officer from the Air India New York office arrived in Toronto on 22 June 1985 to oversee the security operation at Toronto and Montreal.

On 17 May 1985, the High Commission of India presented a diplomatic note to the Department of External Affairs regarding the threat to Indian diplomatic missions or Air India aircraft by extremist elements. Subsequently, in early June, Air India forwarded a request for "full and strict security coverage and any other appropriate security measures" to Transport Canada offices in Ottawa, Montreal and Toronto, and RCMP offices in Montreal and Toronto.

2.8 PD-4 Sniffer

On 18 January 1985, prior to the inaugural Air India flight out of Toronto on 19 January, a meeting on security for Air India flights (Toronto) was held with representatives from Transport Canada, RCMP and Air India. At this meeting, a PD-4 sniffer belonging to Air India was produced. It was explained that it would be used to screen checked baggage as the X-ray machine had not yet arrived. At that time, an RCMP member tested its effectiveness. The test revealed that it could not detect a small container of gunpowder until the head of the sniffer was moved to less than an inch from the gunpowder. Also, the next day the sniffer was tried on a piece of C4 plastic explosives and it did not function even when it came directly in contact with the explosive substance. It is not known if this was the same sniffer used on 22 June 1985.

2.9 Medical Evidence

Medical examination was conducted on the 131 bodies recovered after the accident. This comprises about 40 per cent of the 329 persons on board. It should be noted that assigned seating is based on preliminary information. Also, the exact position of passengers is not certain because it is not known if passengers changed their seats after lift-off. On the information available, the passengers were seated as follows:

Passengers:*

Seats Bodies

	Available	Occupied	Identified
Zone A	16	1	0
Zone B	22	0	0
Upper Deck	18	7	0
Zone C	112	104 + 2	29
Zone D	86	84 + 1	38
Zone E	123	105 + 3	50
SUB-TOTAL	377	301 (+6 infants)	117
Crew:			
Flight Deck	3	3	0
Cabin	19	19	5
TOTAL	399	329	122

There were 30 children recovered and they showed less overall injury. The average severity of injury increases from Zone C to E and is significantly less in C than in Zones D and E.

Flail pattern injuries were exhibited by eight bodies. Five of these were in Zone E, one in Zone D, two in Zone C and one crew member. The significance of flail injuries is that it indicates that the victims came out of the aircraft at altitude before it hit the water.

There were 26 bodies that showed signs of hypoxia (lack of oxygen), including 12 children, 9 in Zones C, 6 in Zone D and 11 in Zone E.

There were 25 bodies showing signs of decompression, including 7 children. They were evenly

*See Appendix C for interior seating arrangement.

distributed throughout the zones, but with a tendency to be seated at the sides, particularly the right side (12 bodies).

Twenty-three bodies showed evidence of receiving injuries from a vertical force. They tended to be older, seated to the rear of the aircraft (4 in Zone C, 5 in Zone D, 11 in Zone E, 2 crew and 1 unknown), and 16 had little or no clothing.

Twenty-one bodies were found with no clothing, including three children. They tended to be seated to the rear and to the right (3 in Zone C, 5 in Zone D, 11 in Zone E and 2 unknown).

There were 49 cases showing signs of impact-type injuries, including 19 children (15 in Zone C, 15 in Zone D, 15 in Zone E, 1 crew member and 3 unknown).

There is a general absence of signs indicating the wearing of lap belts. Pathological examination failed to reveal any injuries indicative of a fire or explosion.

2.10 Flight Recorders and Shannon Air Traffic Control (ATC) Tape Analyses

VT-EFO was equipped with a Fairchild A100 Cockpit Voice Recorder (CVR) and a Lockheed 209E Digital Flight Data Recorder (DFDR). These were each equipped with Dukane Underwater Acoustic Beacons and were installed adjacent to each other in the cabin on the left side near the aft pressure bulkhead. The serial digital signal recorded by the DFDR was generated by a Teledyne Flight Data Acquisition Unit installed in the forward electronics bay below the cabin floor.

The Shannon Air Traffic Control Centre was in contact with VT-EFO and recorded radio communications with the aircraft. At the time of the accident, 5.4 seconds of noise was recorded, and the transponder signal seen on the radar scope was lost from the aircraft. This signal which displays aircraft altitude showed no deviation before disappearing from the radar scope.

2.10.1 Analysis by National Research Council, Canada

From the CVR and DFDR, AI 182 was proceeding normally en route from Montreal to London at an altitude of 31,000 feet and an indicated airspeed of 296 knots when the cockpit area microphone detected a sudden loud sound. The sound continued for about 0.6 seconds, and then almost immediately, the line from the cockpit area microphone to the cockpit voice recorder at the rear of the pressure cabin was most probably broken. This was followed by a loss of electrical power to the recorder. The initial waveform of the cockpit area microphone signal is not consistent with the sharp pressure rise expected with detonation of an explosive device close to the flight deck, but, with the multiplicity of paths by which sound may be conducted from other regions of the aircraft, the possibility that it originated from such a device elsewhere in the aircraft cannot be excluded.

By correlating the oscillograph records of the CVR and the Shannon ATC VHF recording, it was estimated that the unusual sounds recorded on the ATC tape started 1.4 ± 0.5 seconds after the start of the sudden sound detected by the cockpit area microphone and lasted intermittently for 5.4 seconds. It was felt the closeness in time of the two noises indicated the 5.4 seconds recorded on the ATC tapes originated from AI 182. The ATC recording that followed the cockpit area microphone sounds appeared at first to contain a series of short intermittent sounds. Listening to the sounds, it also appeared that a human cry occurred near the end of the recording. Spectral analysis of these sounds and comparison with voice imitations revealed that the recorded sounds do not contain all the pitch harmonic frequencies normally associated with voice sounds. The origin of these sounds has not been determined.

An examination of the DFDR showed no abnormal variations before the accident. With the spare engine, this aircraft was restricted to altitudes below 35,200 feet and indicated airspeeds less than 290 knots. During the last 27 minutes of the flight, the computed airspeed did gradually increase to nine knots above this limit in the first part of this period and the power was readjusted several times. The speed fell below the 290 knot limit at about 07h:09m GMT as recorded by the DFDR; power was increased again at about 07h:10m causing the aircraft to accelerate to six knots above the limit by the time the accident occurred at 07h:13m:59s. The observed excursions outside the specified limits are not considered significant.

The aircraft was flown with 1.5-degree left-wing-down with 4.2 degrees clockwise control wheel as compared to the aircraft without the 5th engine installation. Also, 9.4 per cent of right rudder pedal was applied giving a 1.1-degree right deflection of the upper and lower rudders. Considering the carriage of the 5th engine on the left side, these figures are not considered abnormal.

When synchronized with the other recordings, it was determined, within the accuracy that the procedure permitted, that the DFDR stopped recording simultaneously with the CVR.

Irregular signals were observed over the last 0.27 inches of the DFDR tape. Laboratory tests indicated that the irregular signals most likely occurred as a result of the recorder being subjected to sharp angular accelerations about the lateral axis of the recorder, causing rapid changes in tape speed over the record head. This equates to an angular acceleration on the recorder about the aircraft's longitudinal axis in a left-wing-down sense. Therefore, these tests indicate that the digital recorder was subjected to a sharp jolt separate from any violent motion of the aircraft.

The other possibility for the irregular signals is that the Flight Data Acquisition Unit which generated the serial digital data signal and which is located in the electronics bay under the cabin floor forward of the cargo compartment could have suffered some damage or had an intermittent power supply that caused it to generate the irregular signals.

2.10.2 Analysis by Accidents Investigation Branch (AIB), United Kingdom

The AIB analysis was restricted to the CVR and the Shannon ATC tape. The correlation of the CVR and ATC tapes showed that the ATC recording started after the CVR had stopped recording and 1.1 ± 0.4 seconds from the start of the sudden sound. The total duration of the signal on the ATC tape was 5.4 seconds.

An analysis of the CVR audio found no significant very low frequency content which would be expected from the sound created by the detonation of a high explosive device. Evidence of the presence of audio warning signals buried amongst the noise was investigated with negative results. A comparison with CVRs recording an explosive decompression* on a DC-10, a bomb in the cargo hold of a B737, and a gun shot on the flight deck of a B737 was made. Considering the different acoustic characteristics between a DC-10 and a B747, the AIB analysis indicates that there were distinct similarities between the sound of the explosive decompression on the DC-10 and the sound recorded on the AI 182 CVR.

The analysis of the ATC tape audio determined three or four words could be heard at the beginning of the transmission, but extensive filtering did not allow the sounds to be transcribed. Two bursts of tone occurred during the first second. The spectrum of the tone does not coincide with any B747 audio warning. The transmission is chopped until at about 2.7 seconds into the transmission a loud noise lasting about 200 milliseconds is heard. This is followed about 0.5 seconds later by a sound which increases in volume. This sound is similar to that heard in other accidents where there has been a rapid increase in airspeed. Toward the end of the transmission a crying sound was heard; however, a study of the noise indicates a human cry would contain more harmonics. The origin of this sound was not determined. Knocking sounds were also heard during the transmission. These were initially thought to be due to hand-held microphone vibration, but this was discounted because of the frequency of the sounds. Almost identical sounds were heard on the DC-10 CVR after the explosive decompression had occurred. Their source was not identified. On the DC-10, the pressurization audio warning sounded 2.2 seconds after the decompression. No such warning was identified on the ATC tape.

*Explosive decompression is an aviation term used to mean a sudden and rapid loss of cabin pressurization. A loud noise is associated with this event but not necessarily an explosion.

Every aircraft provides a different signature when the press-to-transmit button is released. These signatures were compared with transients which occurred during the open microphone transmission. There is a close match with the previous AI 182 signatures. Therefore, it is almost certain that the ATC tape recording originated from AI 182.

The AIB report concluded that the analysis of the CVR and ATC recordings showed no evidence of a high-explosive device having been detonated on AI 182. It further states there is strong evidence to suggest a sudden explosive decompression of undetermined origin occurred. Although there is no evidence of a high-explosive device, the possibility cannot be ruled out that a detonation occurred in a location remote from the flight deck and was not detected on the microphone. However, the AIB report is of the opinion that the device would have to be small not to be detected as it is considered that a large high-explosive device could not fail to be detected on the CVR.

2.10.3 Analysis by Bhabha Atomic Research Centre (BARC), India

The BARC analysis was restricted to the CVR and the Shannon ATC tape.

Channel 3 of the recording which corresponded to the cockpit area microphone showed the first indication of a rising audio signal. The signal level rises from the ambient level in the cockpit by about 18.5 decibels in approximately 45 milliseconds. The signal starts falling and stabilizes at a level about 10 decibels higher than ambient for about 375 milliseconds. The total duration of the signal is about 460 milliseconds. The timings of the CVR and the Shannon ATC tape were correlated, and it was determined that the explosive sound on the CVR coincided with the beginning of the series of audio bursts on the ATC tape. The report concluded that the sounds recorded on the ATC tape emanated from AI 182 at the time of the occurrence.

The noise on the CVR was compared with an explosion which caused the crash of an Indian Airlines B737. In this occurrence, the explosive sound recorded on the cockpit area microphone showed a rise time of about 8 milliseconds. It was also determined that the explosion occurred 8 feet from the microphone. The report concluded that the rise time is a measure of the distance from the cockpit area microphone to the source of an explosion. Hence, the exact location in the aircraft at which the explosion occurred is likely to be about 40 to 50 feet from the cockpit judging from the rise time of 45 milliseconds.

The report concluded that the series of audio bursts on the ATC tape were most probably generated by the break-up of AI 182 in mid-air.

2.11 Aircraft Structures Examination

The examination of aircraft structures consisted of the following areas: floating wreckage, wreckage mapping and surveying, wreckage distribution, photographic and video interpretation of wreckage, wreckage recovery and initial examination, and examination of recovered wreckage.

2.11.1 Floating Wreckage

During the search, aircraft wreckage was sited and recovered by several search vessels. The wreckage was transported to Cork, Ireland, where preliminary examination was conducted. This examination took place in June and July, 1985.

The wreckage consisted mainly of various leading edge skin panels of the left and right wings, left wing tip, spoilers, leading edge and trailing edge flaps, engine cowlings, flap track canoe fairing pieces, landing gear wheel well doors, pieces of elevator and aileron, cabin floor panels, cabin overhead and upper deck bins, passenger seats, life vests, slide rafts, hand baggage, suitcases, personal effects and a number of internal fittings. The floating wreckage constitutes about three to five percent of the aircraft structure.

The wreckage was then transported from Ireland to Bombay, India where it underwent further examination by the Floating Wreckage Structures Group which then produced a report which was submitted to the Indian Inquiry. The report concluded:

- There was no evidence of fire damage.
- There was no evidence of lightning strike damage.
- The cabin floor panels from the forward and rear sections of the aircraft separated from the support structure in an upward direction (floor to ceiling) pulling free from the attaching screws and, in some cases, breaking the vertical web of the seat track/floor beams.
- The position of the leading edge flap rotary actuator and the damage to the flap structure indicated that the leading edge flaps were in the retracted position.
- The six spoiler actuators found were in the retracted position. The lower surface of all the spoiler panels showed signs of spanwise skin splits with the edges curled into the core of the honeycomb. The report concluded that this was possibly due to the loading of the spoilers by being deployed in flight at high speed, resulting in compression on the lower surfaces. This, in turn, caused splitting of the lower skin into the honeycomb.
- The right wing root leading edge, number 3 engine inboard fan cowling, the right inboard midflap inboard leading edge, and the right stabilizer root leading edge all exhibited damage possibly due to objects striking the right wing and stabilizer before water impact.

In addition to the above conclusions, the following significant information regarding the floating wreckage is noted in the report:

- The aircraft was carrying a -7Q engine at the 5th pod and a -7J 5th pod kit in the aft cargo compartment. In all there were 14 engine fan cowls (four in the aft cargo compartment). Out of these 14 fan cowls, nine, including six from the working engines and three from the aft cargo compartment, and two additional pieces of fan cowls were found. Five of the fan cowls from the working engines showed folding damage lines at about the three and nine o'clock positions. The number 3 engine inboard fan cowl had severe impact damage on its leading edge and had small outward puncture holes but no penetration through the outer skin in the lower centre region. The two fan cowls of the -7J 5th pod kit stowed in the aft cargo compartment showed severe damage. One piece was cut at one corner in an arc of about 20 inches diameter and its external skin was peeled back.
- The cockpit entry door and the side bulkhead panel were found relatively intact but had come out of their attachments.
- Twelve toilet doors out of 16 were found and were relatively intact but had come out of their attachments.
- Cabin interior panels and overhead bins of the main and upper decks which were recovered exhibited only minor damage.
- The wooden boxes which contained the fan blades of the 5th pod engine were loaded in container 24L in the forward cargo compartment and were found broken apart exhibiting no burn marks.
- One passenger oxygen bottle and one portable oxygen bottle were recovered and showed no sign of damage.

Mr. V.J. Clancy, an aviation explosives expert representing Boeing Aircraft Corporation, prepared a preliminary report based on his examinations of certain items of recovered and floating wreckage. Mr. Clancy's report notes the following with respect to floating wreckage:

- A foam-backed floor panel which showed a small number of perforations was recovered. Mr. Clancy recommended that it should be X-rayed and a detailed examination completed.
- One of the lavatory doors had, into its inner surface, a number of

fragments of glass mirror - presumably from breakage of a mirror normally fitted into the lavatory. Most of the fragments, buried edgeways, were oriented parallel to each other. The remainder were approximately at right angles to the others. Mr. Clancy concluded that it would be improbable that any reliance could be placed on the penetration by mirror fragments as being indicative of an explosion.

- Three steel oxygen cylinders which were stowed in the forward cargo compartment were recovered. One had been dented apparently by the impact of an object measuring about one to two centimetres. The depression had a maximum depth of about four millimetres.
- A few suitcases recovered among the floating wreckage were examined. Mr. Clancy felt that one might provide useful information. It was of red plastic material with a blue lining. Mr. Clancy reported that plastic material has been found to retain identifiable traces of explosive after long immersion in the sea. Also, the lining which was severely tattered resembled that of one found after an explosion in an aircraft in Angola.
- A wooden spares box was found on the foreshore of Wales. It was of the kind used on the aircraft. It was charred on one side and partially on the bottom. The depth of charring suggested that the burn time was three to four minutes. This box was normally stowed in the aft cargo compartment; however, on this flight it may have been stowed in the forward compartment.
- Two pieces of the cover of an overhead locker originating above either door 2R or 4R were also found on the foreshore. They were partially damaged and blackened by fire. Mr. Clancy concluded that this indicated the presence of fire.
- Two pieces of U-section alloy channel partially filled with plastic foam were found on the foreshore. The alloy was of a kind not used in aircraft structure; however, it could have been from some fitting supplied by a sub-contractor. Also, since the pieces were found near an area where practice firings at targets are carried out off the west coast of the United Kingdom, it could have come from some other source. One piece of the alloy bore marks ("mooncraters") typical of an attack by

very high velocity fragments such as produced by an explosion. X-rays showed the presence of a few small particles buried in the foam which Mr. Clancy recommended should be extracted and examined. He also felt that this provided the strongest single indication of an explosion and that it was essential to determine if these pieces came from the aircraft or any of the equipment or cargo aboard the aircraft.

The CASB in its examination of the floating wreckage noted the following:

- The fan cowls of the number 4 engine had a series of five marks in a vertical line across the centre of the Air India logo on the inboard facing side of the fan cowl. These marks had the characteristic airfoil shape of a turbine blade tip. It is possible that a portion of the turbine parted from the number 3 engine and struck the cowl of the number 4 engine.
- The upper deck storage cabinet which was located on the left side had unusual damage to its bottom. A large rounded dent in the bottom inboard edge of this stiff cabinet structure revealed smooth stretching without breakthrough. The damage did not seem to be achievable by inertia or impact forces as the cabinet except for the bottom was undamaged. The damage was considered by a CASB investigator to be compatible with the spherical front of an explosive shock wave generated below the cabin floor and inboard from the cabinet; however, it is not known if this damage could be caused by some other means.
- The right wing root fillet which faired the leading edge of the wing to the fuselage ahead of the front spar had a vertical dent similar to that which would have resulted had the fillet run into a soft cylindrical object with significant relative velocity. The paint on the inboard chord appeared to be scorched brown in the centre areas of three honeycomb panels. It has been determined that sudden heat can turn these panels brown, but it is not known if other reasons for the discolouration exist. The fillet abutted the fuselage side at the aft end of the forward cargo compartment.
- There was blackened erosion damage to the bottoms of some seat cushions. The damage had an appearance similar to that which would have been caused by an explosive device. It is not known if marine life

feeding on the cushions or some other cause could have produced the same effect.

- The charred wooden spares box contained some sand and small shellfish. The flesh from the shellfish appeared to be charred, indicating that the box was subjected to fire after the occurrence.

An electronic device was found among some floating wreckage and was forwarded to the Bhabha Atomic Research Centre for analysis. There was some concern that it could have been used to detonate an explosive device. The device was forwarded to the RCMP who in conjunction with the CASB determined it to be an item manufactured for use in radiosondes (weather balloons) and was not modified as a detonating device.

2.11.2 Wreckage Mapping and Surveying

The Canadian Coast Guard Ship (CCGS) John Cabot was given the task of mapping the wreckage on the ocean floor. On 19 July 1985, the Cabot with a SCARAB deep submersible on board departed Cork. On arrival at the site, and based on surface wreckage distribution and bottom side scan sonar plots, four transmitters were placed on the sea bed. These transmitters provided signals for the ALLNAV navigation system used to accurately plot the sea bed wreckage.

Based on all the data available, the SCARAB was launched on 24 July 1985 to begin the bottom search in position 51°01.9'N 12°41.0'W. During the mapping, stage areas were designated for search and each progressive area was determined based on the information gained during the search. The search was conducted using sonar and video. Wreckage found was recorded on video tape and on 35mm positive film.

The first object plotted on the sea bed was a torn suitcase located at lat 51°02.63'N, long 12°53.15'W and was the most westerly object located. This suitcase has not been recovered, nor has it been positively identified as having come from the accident aircraft.

As the search progressed eastward, the first positive identification of aircraft wreckage was made at lat 51°02.9'N, long 12°49.93'W. Slowly, over a period of about 90 days, a detailed bottom wreckage plot was developed.

While mapping was in progress, some of the wreckage was revisited to obtain additional data. During the transit through areas already searched, wreckage not previously plotted was found, and, in some areas, the density of wreckage physically precluded 100 per cent coverage. Components and major structural items were identified from all sections of the aircraft and when the mapping of the sea bed ended, most of the aircraft had been found and photographed. Although positive identification of each piece of wreckage could not be made, it was decided in late October 1985 that the search phase was essentially completed and wreckage recovery could begin. A bottom wreckage distribution plot is contained separately in an envelope as Appendix F.

2.11.3 Wreckage Distribution

The wreckage distribution as determined by the mapping of the sea bed provided some distinct distribution patterns. The depth of the wreckage varies between about 6000 and 7000 feet, and the effect of the ocean current, tides and the way objects may have descended to the sea bed was not determined, thus some distortion of an object's relationship from time of water entry to its location on the bottom cannot be discounted. In general, the items found east of long 12°43.00'W are small, lightweight and often made of a structure which traps air. These items may have taken considerable time to sink and may have moved horizontally in sea currents before settling on the bottom. Marks left on the sea bed beside some wreckage does indicate horizontal movement of the wreckage as it settled.

Although badly damaged, sections 41, 42 and 44*, and the wing structure were located in a relatively localized area centred about lat 51°03.30'N and long 12°47.80'W, and the wreckage scatter was oriented north/south. The wreckage scatter in this area was so dense that it is probable that some of the wreckage may not have been plotted or photographed.

Sections 46 and 48, including the vertical fin and horizontal stabilizer, extended in a west to east pattern with the westernmost identified aircraft component located at lat 51°02.90'N and long 12°50.1'W. The wreckage extended in a line about 110 degrees True to an eastern position of lat 51°02.04'N and long 12°41.26'W, a distance of approximately 6.5 nautical miles. The aircraft structure had a random scatter pattern. That is, items such as the aft pressure bulkhead were broken into several pieces, and these pieces were located throughout the pattern.

A?? third area which had some distinctive pattern was that of the engines, engine struts and components and was localized about lat 51°03.25'N and long 12°47.4'W in a northwest/southeast orientation. One of the operating engines was displaced 0.5 nautical miles to the north of this area, and it was also geographically separated from the wing structure. The number 3 engine nacelle strut was also separated from the rest of the engine components and was located about one nautical mile to the west-southwest at lat 51°02.87'N, long 12°48.05'W. The reasons for the displacement of the number 3 engine nacelle strut and one of the operating engines from the other engines are not known.

*See Appendix D for location of aircraft sections and aircraft body stations (BS).

2.11.4 Photographic and Video Interpretation of Wreckage

2.11.4.1 Photographic Interpretation

All wreckage sighted was recorded on video tape and all major items were recorded on 35mm positive film. During the course of the investigation, several members of the investigation team had the opportunity to view the tapes and photographs. Subsequently, when some items were recovered, it became apparent that the optical image presented on video and still film had some limitation with respect to identification of damage or damage patterns. For example, the sine wave bending of target 7* appeared in the video and photographs as a sine wave fracture, and some of the buckling on target 35 was not evident in either the video or photographs. The interpretation of damage through photographic/video evidence without the physical evidence might be misleading, and any interpretation should take this into account.

2.11.4.2 Engines

The four operating engines were all extensively damaged. A view of the fan blades did not show signs of any rotational damage, and it could not be determined whether any pre-impact failures had occurred. The external damage to the engines varied, and at least one engine appeared to be attached to part of the nacelle strut. Except for the non-operational fifth engine, the engines could not be matched with their original positions on the aircraft.

2.11.4.3 Landing Gear

The nose, wing, and body landing gear were all located. Photographic examination indicated that all the gear were in the 'up' position at the time of impact.

2.11.4.4 Flaps and Spoilers

Positive identification of all the flap and spoiler surfaces was not made. All the flap jackscrews indicated that the flaps were retracted at impact. Of the spoilers identified, six had actuators attached. The actuators were in the fully retracted position.

*See Appendix E for location of targets on aircraft.

2.11.4.5 Section 41

Section 41, consisting of the cockpit, first-class section, and electronics bay and identified as target 192, was found in a near-inverted attitude. This section was severely damaged. The electronics bay and cockpit areas could not be located within the wreckage. The first officer's seat was found on the sea bed near section 41 wreckage.

2.11.4.6 Section 42

Portions of section 42, consisting of the forward cargo hold, main deck passenger area, and the upper deck passenger area, were located near section 41. This area was severely damaged and some of section 42 was attached to section 44. Some of the structure identified from section 42 was the crown skin, the upper passenger compartment deck, the belly skin, and some of the cargo floor including roller tracks. The right-hand, number two passenger door including some of the upper and aft frame and outer skin was located beside section 44. Scattered on the sea bed near this area were a large number of suitcases and baggage as well as several badly damaged containers.

All cargo doors were found intact and attached to the fuselage structure except for the forward cargo door which had some fuselage and cargo floor attached. This door, located on the forward right side of the aircraft, was broken horizontally about one-quarter of the distance above the lower frame. The damage to the door and the fuselage skin near the door appeared to have been caused by an outward force. The fractured surface of the cargo door appeared to have been badly frayed. Because the damage appeared to be different than that seen on other wreckage pieces, an attempt to recover the door was made by CCGS John Cabot. Shortly after the wreckage broke clear of the water, the area of the door to which the lift cable was attached broke free from the cargo door, and the wreckage settled back onto the sea bed. An attempt to relocate the door was unsuccessful.

2.11.4.7 Section 44

Section 44, containing the aircraft structure between body station (BS) 1000 and BS 1480 including that area where the fuselage and wings were mated was located in the same general area as the forward sections of the aircraft. This section was severely damaged but maintained its overall shape and was lying on its right side. Part of the left wing upper skin was attached to the fuselage and a large portion, about one-third of the upper wing skin, separated and was lying against the fuselage crown skin. Some of the body and wing landing gear were found beside this section of the aircraft. The gear was detached from the main structure. The interior of the fuselage was extensively damaged.

2.11.4.8 Wing Structure

The wing structure was located near the forward area of the aircraft structure and towards the northernmost area of the wreckage pattern. The wings showed extreme damage patterns with the top and bottom surfaces separated and the wing surfaces broken into segments.

2.11.4.9 Sections 46 and 48

Sections 46 and 48 contain that part of the aircraft structure aft of BS 1480 and, for purposes of this Submission, will include the horizontal stabilizer and vertical fin. This section of the aircraft was scattered in a west to east pattern about 6.5 nautical miles in length and exhibited severe break-up characteristics.

The aft cargo and bulk cargo doors were found in place and intact, and

5L, 5R and 4R entry doors were identified. Four segments of the aft pressure bulkhead were identified (targets 35, 37, 73 and 296), and one portion of the bulkhead was never located. Much of the fuselage which was forward of the number five door and above the passenger floor area was not located, or if located was not recognizable as having come from a specific area of the aircraft.

Sections of the outer skin below the cargo area were located as was some of the cargo floor structure. Generally, the stringers and stiffeners are attached to the skin; however, the lower frames, which provided the cargo floor support, were detached from the skin. The rear cargo floor from BS 1600 to BS 1760 was located and was found to have little or no distortion; however, the lower skin and stringers were missing. A second portion of the aft cargo compartment floor containing cargo drive wheels and cargo roller trays was located. This structure was severely damaged and mangled.

The tail cone and the auxiliary power unit (APU) housing were located and had received relatively minor damage; however, the APU had broken free and was never located.

A large portion of the outer skin panels showed signs of a force being applied from the inside out. On several pieces of wreckage, the skin was curled outwards away from the stringers and formers. This could have been the result of an overpressure of air or water.

The vertical tail was found in good condition, in a single piece with both rudders attached. The top cap was partially separated and a small dent was noticed in the middle of the leading edge at the bottom. A curved broken portion of fuselage was observed with a portion of the "Y" ring and pressure bulkhead attached. Another small segment of the pressure bulkhead was leaning on the lower section of the tail.

The horizontal stabilizer tail section was located and was one unit with the elevators attached. The actuator jackscrew was attached to the assembly. The stabilizer jackscrew ballnut was observed to be located at the upper jackscrew stop. This equates to a full deflection of elevator trim. Since there is nothing on the DFDR or CVR to indicate a malfunction of the trim, it is deduced that this was not the lead event. It is not known if the position of the ballnut resulted from a pilot trim selection, a result of the initial event or if it rotated to the observed position under the influence of gravity. Two-thirds of the leading edge of the right horizontal stabilizer was missing and the auxiliary spar was exposed. There was localized damage to the right-hand root of the leading edge through about a span of five ribs. The leading edge skin and part of the leading edge ribs were torn downwards. Some localized damage to the root of the left leading edge was visible with the remainder of the leading edge undamaged. There was minor damage to the trailing edge of the outboard left elevator, and a major portion of the inboard left elevator was missing.

2.11.4.10 Passenger Seats

Many of the passenger seats located among the wreckage pattern and identified as having come from sections 46 and 48 appeared to have the aft support legs buckled with little or no damage to the forward support legs. Seats located in the wreckage containing sections 41, 42, and 44 appeared to have varying types of damage, that is, aft support legs only buckled, and all legs buckled. One consistent feature noted was that in the majority of seats located it was possible to ascertain that the seat-belts were not fastened.

2.11.5 Wreckage Recovery and Initial Examination

During the wreckage mapping, some small items were recovered, and an unsuccessful attempt was made to recover a portion of the forward cargo door. On completion of the sea bed survey, an offshore supply ship, Kreuztrum, chartered by the National Transportation Safety Board (NTSB), joined John Cabot for a wreckage recovery operation. Prior to the commencement of the wreckage recovery, the structures group met at the Boeing facility in Seattle, USA and reviewed the video tapes and photographs of the wreckage. Based on their findings, a list of items was identified as being most desirable for recovery. The priority list was prepared by a group in Cork, Ireland, headed by Dr. V. Ramachandran. On 8 October 1985, the John Cabot sailed, and on 9 October 1985, the Kreuztrum sailed for the accident site. The following target numbers and items were recovered during the mapping and wreckage recovery stages of the investigation: 7, 8, 35, 47, 117, 193, 223, 245, 287, 296, 299, 362/396, and 399 (as the location on the aircraft of some of the targets was not known when Appendix E was created, some are not shown in the appendix). The first officer's seat, some suitcases and small debris were also recovered using a metal frame basket. Initial examination of the wreckage was carried out in Cork and then it was transported to Bombay for detailed examination.

2.11.6 Examination of Recovered Wreckage

Although all the recovered wreckage was examined, only those items exhibiting characteristics which provided some evidence as to what may have happened to the aircraft during its final moments of flight are discussed. CASB engineering personnel and other participants examined the recovered wreckage at Cork and Bombay. The observations made during their examinations are discussed below.

2.11.6.1 Target 7 - Lower Fuselage Skin Panel

This skin panel was located below the aft cargo area and contained the keel beam. Target 7 extended from BS 1480 to 1860 and was about eight feet in width and 32 feet in length. The left edge had a full length rivet line tear, and the torn edge was buckled in waves, like the trace of a sine wave. On the right side, between the one-quarter and midway segment, a large flap of skin was attached. The skin was folded aft, diagonally underneath, from right to left and the paint was scoured off the leading edge. The forward break was at the joint at BS 1480. The skin tear located at about BS 1860 was irregular in nature. The forward keel joint splice plate was bent, and the keel joint bolt holes were distorted and elongated.

The left and right trunnion vertical support fittings located at BS 1480 were examined optically using the stereomicroscope. Both trunnions were fractured through the three bolt holes. The right fracture characteristics were consistent with an overload mode of failure. Although most of the left fracture surface was also characterized by overload features, there were heavily corroded areas where the fracture mode could not be confirmed through optical examination. One lug fracture was sectioned from the left trunnion and prepared for scanning electron microscope (SEM) examination. After the corroded area was cleaned, the examination revealed some ductile characteristics on the fracture surface. There was no evidence of intergranular fracture observed to suggest a stress corrosion cracking mode of failure, nor was there any evidence of progressive failure observed. The corrosion appeared to have developed after the accident.

2.11.6.2 Target 8 - Lower Fuselage Skin Panel

This skin panel was located below the aft cargo area and extended from BS 1860 to 1960 and from stringer 46L to 46R. A small section from the aft end along the belly skin splice at stringer 46L was removed for examination. SEM examination revealed that the fracture was characterized by slightly elongated ductile dimples along its length, including areas adjacent to the edges of the rivet holes. On the aft edge of each rivet hole examined, a distinctive shear lip was observed. These features are consistent with an overload mode of failure along the skin splice with an apparent direction of failure from aft to forward.

2.11.6.3 Target 35 - Portion of Rear Pressure Bulkhead

Looking forward from behind the aircraft, this segment of pressure bulkhead occupied the 9 to 1 o'clock position. The piece from 12 to 1 o'clock had the flange from the outer ring attached. The web below the outer ring flange had areas of buckling. From the 11 to 12 o'clock position, the outer edge showed sinusoidal buckling, and the edge sector at 9 o'clock was partially collapsed and its edge was turned under. Samples taken for optical stereomicroscope and SEM examination revealed that the fracture characteristics were consistent with an overload mode of failure. The examination suggested a general direction of failure from the aft to the forward edge of the rear pressure bulkhead panel.

2.11.6.4 Target 296 - Portion of Rear Pressure Bulkhead

Looking forward from the rear of the aircraft, this segment of the bulkhead occupied the 7 to 9 o'clock position. Optical and SEM examination were undertaken on this item.

The fracture along the left-hand edge of target 296 (viewed from the rear) was examined optically prior to removing any representative samples. The fracture was at the rivet line at a skin splice, except for a length of fracture about 15 inches long near the forward end, which was through the skin away from the rivet line. Most of the rivet holes along the fracture path showed some slight elongation and skin deformation. Representative fracture samples were cut from the left-hand and right-hand edges of the fracture surfaces. Optical and SEM examination revealed that the fracture characteristics are consistent with an overload mode of failure.

2.11.6.5 Target 47 - Aft Cargo Compartment

This portion of the aft cargo compartment roller floor was located between BS 1600 and BS 1760. Based on the direction of cleat rotation on the skin panel (target 7) and the crossbeam displacement on this structure, target 47 moved aft in relation to the lower skin panel when it was detached from the lower skin. No other significant observation was noted. There was no evidence to indicate characteristics of an explosion emanating from the aft cargo compartment.

2.11.6.6 Target 117 - Floor with Seats Attached

These seats were right-section doubles, located between BS 1880 and 1980 and were from rows 46, 47 and 48, F and G (Zone E). The seats were displaced to the left with the rear legs buckled to the left. The front leg supports exhibited only minor damage. The middle and rear doubles had aisle-side seat arms bent to the right. There was no impact damage to the seat backs or seat pans, and all life vests except one were gone from the underseat container bags.

2.11.6.7 Target 399 - Left-Hand Side Triple Seat with Tray Arms

It would appear that this section was from row 18, seats A, B and C, the first set of triple seats aft of door 2L. The notable damage to this unit was as follows: front leg aisle side buckled and crushed in place; front leg window side buckled and crushed in place; forward edge tube to seat broken and bent downwards at joint with fore and aft tube between window and centre seats; and fore and aft tube between centre and aisle seat broken at start of T-connection to rear edge of seat tube. The damage suggests that the failures resulted from vertical loading. All the life-jackets were in place.

2.11.6.8 Target 399 - Fuselage Side and 2R Entry Door

The fuselage segment was located between BS 780 and 940. This piece was badly damaged and buckled inwards along a line through the lower door hinge. There were 12 holes or damaged areas on the skin generally with petals bending outwards. The curl on a flap around a hole had one full turn. This curl was in the outward direction. Cracks were also noticed around some of the holes. Part of the metal was missing in some of the holes. The edges of some of the petals showed reverse slant fracture. In one of the holes, spikes were noticed at the edge of a petal. When this target was recovered from the sea, along with it came a few hundred tiny fragments and medium-sized pieces. One of the medium-sized pieces recovered with this target was a floor stantion about 35 inches long. It was confirmed that this stantion belonged to the right side of the forward cargo hold. The inner face of the stantion had a fracture with a curl at the lower end, the curl being in the outboard direction and up into the centre of the stantion.

Scientists from the Bhabha Atomic Research Centre, the National Aeronautical Laboratory and the Explosives Research and Development Laboratory in India conducted a metallurgical examination of certain items of wreckage. Their report on target 399 concluded that:

- the curling of the metal on the floor channel was indicative of a shock wave effect;
- the large number of tiny fragments from the disintegration of nonbrittle aluminum was a characteristic indication of explosive forces; and
- the indications of punctures, outward petalling around holes, curling of metal lips, reverse slant fracture, formation of spikes at fracture edges and certain microstructural changes all were indicative of an explosion.

2.11.6.9 Target 193 - Fuselage Side and 2L Entry Door

The fuselage segment was located between BS 720 and 840. The door and fuselage skin were buckled outwards, approximately in line with the buckling on the fuselage and 2R entry door directly opposite.

2.11.6.10 Target 362/396 - Lower Skin Panel - Forward Cargo Area

This section of skin panel was located between BS 720 and 860 and is just below target 399. The skin was badly crumpled and torn and had several punctures. It was pulled free from a large mass of debris which included some mangled cargo floor beams and roller trays. Some of the punctures had a feathered or spiked profile, with spikes angled at approximately 45 degrees to the edge. Other puncture holes gave clear indication of being formed by underlying stiffeners at impact. Two of these holes contained pieces of web stiffener. Most of the punctures were the result of penetrations from inside.

In the preliminary report of Mr. V.J. Clancy, representing Boeing, the following observations regarding target 362/396 were made:

- There were about 20 holes in the lower skin panel clearly resulting from penetration from inside.
- In addition to the fact that perforation was from inside, there were certain features which suggested that they were made by high velocity fragments such as those produced by an explosion. Mr. Clancy's report describes these features as follows:

- the presence of toothed or spiked edges at some parts of the metal which has petalled out from the perforations;

(Tardif and Sterling, Canadian Aeronautics and Space Journal, 1969, 15, 1, 19-27, obtained spiked fractures in fragments from sheet alloy subjected closely to an explosion. They stated that they had not obtained this effect in fractures otherwise produced.)

- the presence of marked curling (in some cases of more than 360 degrees) of some of the petals;

(Tardif and Sterling stated that such curling was a feature of explosively produced fragments.)

- the virtual absence of scratches or score marks on the petals such as might be expected if something were slowly forced through the metal;
- the virtual absence of other impact marks on the inside surface such as might have been produced by a massive impact with a substantial object, thereby suggesting that the production of at least many of the perforations were separate independent events; and
- the presence of one perforation (identified as number 14) resembling a "bullet hole" that was clearly punched out - a type of hole

usually associated with a high velocity missile.
- There was evidence that the forward part of the skin panel had been folded back inward along the line of station 760 and then bent back again along a line slightly forward of this station.
- Such folding, perhaps violently produced on impact with the water, could have brought broken metal of stringers or stiffeners into forceful contact with the internal surfaces, thus producing perforations outwards. The overlap of such folding would conceivably have covered the area up to station 800 and thus included most of the perforations.
- One hole (identified as number 13) was almost certainly caused by a slipping wire rope used as a sling.
- Part of the inner surface, aft of station 780 was superficially blackened as if by soot from a fire. Swabs were taken of this area for further examination for evidence of fire or explosives.
- A large number (several hundred) of small fragments were recovered. These varied in size from an inch or less to a few inches. They included fragments broken out of sheet metal, and these were reported to be from the same area as T362.
- The production of a large number of small fragments is generally regarded as an indication of an explosion.
- One piece, which was isolated, was about an inch square of sheet alloy with characteristic spikes on one edge similar to those described by Tardif and Sterling.

The following is an excerpt from the report by Mr. V.J. Clancy wherein he gives his opinion and conclusions regarding target 362.

"Opinion

The features discernible to a careful close visual examination point towards the possibility of an explosion but taken alone do not justify a firm conclusion.

Curling of petals and spiked or toothed fractures may be observed in other events than explosions despite the failure by Tardif and Sterling to obtain them in their limited number of attempts. It is probable that these features indicate a rapid rate of failure but not necessarily of a rapidity which could only be produced by an explosion.

A more detailed study, metallurgical and fractographic, is required.
The studies by Tardif and Sterling were done on fragments produced from aluminium alloy in contact with the explosive. Very little information is available on the behaviour of aluminium alloy some distance from the explosive and subjected to attack by secondary fragments. To determine this some trials will be necessary, to obtain reference samples for comparison.
The single "bullet hole," No. 14, strongly supports an explosion hypothesis but, being the sole example of its kind, is not, by itself determinative.
If the forward part of this item was forcefully and rapidly folded back to impact on the other part, it might explain the other features apparent to visual examination. It would require detailed laboratory examination and tests to eliminate this possibility.
The production of a large number of small fragments is generally regarded as a pointer towards an explosive cause but cannot be relied upon unless it is clear that they could not have been produced by some other means. It is known that the break-up of an aircraft at high speed may produce great fragmentation.
The single spiked fragment must be regarded as important but a single specimen is not, by itself, determinative."
Mr. Clancy concluded that:
"there is strong circumstantial evidence that an explosion occurred but neither individually nor collectively do the several pointers give the degree of confidence necessary for a firm and final conclusion, at this time."
With respect to target 362/396, in his report Mr. Clancy recommended:
"that firing trials be carried out projecting various size missiles at targets similar to the material of T362 to obtain reference samples for laboratory comparison with the perforations in T362."
The Indian report, in addition to the observations made by Mr. Clancy, noted the following with respect to the metallurgical examination:
- The microstructure in the various areas examined on target 362/396 confirmed explosive loading in this part of the aircraft.

- The holes and other features observed in targets 362/396 and 399 must have been due to shock waves and penetration by fragments resulting from an explosion inside the forward cargo hold.
- The chemical nature of the explosive material was not identified. No part of an explosive device, its detonator or timing mechanism was recovered.

2.11.6.11 Examination of Wreckage in India with CASB Participation

The examination of the targets recovered did not reveal any pre-existing defect, premature cracking or pre-impact corrosion damage associated with any of the failures.

3.0 DISCUSSION

3.1 Initial Event

From the correlation of the recordings of the DFDR, CVR and Shannon ATC tape, the unusual sounds heard on the ATC tape started shortly after the flight recorders stopped recording. The conversations in the cockpit were normal, and there was no indication of an emergency situation prior to the loud noise heard on the CVR a fraction of a second before it stopped recording. The DFDR showed no abnormal variations in parameters recorded before it stopped functioning. The only unusual observation was the irregular signals recorded over the last 0.27 inches of the DFDR tape. Laboratory tests indicated the possibility that these signals resulted from the recorder being subjected to a sharp disturbance at the time it stopped recording. The other possibility for the irregular signals on the DFDR is that they were caused by a disturbance to the Flight Data Acquisition Unit in the main electronics bay. Since there was an almost simultaneous loss of the transponder signal, this indicates the possibility of an abrupt aircraft electrical failure. The medical evidence showed a general absence of signs indicating that seat-belts were fastened. From the video and photographic examination of the wreckage on the bottom, it was ascertained that the majority of seats located did not have the seat-belts fastened. The above evidence indicates that the initial occurrence was sudden and without warning. The abrupt cessation of the data recorder could be caused by airframe structural failure or the detonation of an explosive device as the initial event. The millisecond noise on a CVR as observed in this case is usually, as described in the available literature, the result of the shock wave from detonation of an explosive device. However, in this case, certain characteristics of the noise indicate the possibility that the noise was the result of an explosive decompression. There is some disagreement regarding the cause and location of the source of the noise heard on the CVR, that is, whether the noise resulted from an explosive device or an explosive decompression and whether the noise originated from the rear or closer to the front of the aircraft.

3.2 Passenger/Flight Deck Area

From the examination of the wreckage recovered and wreckage on the bottom, there is no indication that a fire or explosion emanated from the cabin or flight deck areas. The medical examination of the bodies also showed no fire or explosion type injuries. However, pieces of an overhead locker coming from above door 2R or 4R had been blackened by fire. There was blackened erosion damage to the bottoms of some seat cushions, showing damage possibly from an explosive device, and the upper deck storage cabinet had a large rounded dent in the bottom inboard edge which might have been caused by an explosive shock wave generated below the cabin floor and inboard from the cabinet. It should be noted that the pieces of the overhead locker were found on the Welsh shore some time after the accident, and it is not known if the pieces were subjected to a fire after the accident. Also, it is not known if the damage to the seat cushions and the upper deck storage cabinet could have been caused by other means. Nevertheless, the above evidence suggests that some areas of the passenger cabin may have been subjected to minor fire and explosive damage possibly emanating from below the cabin floor.

3.3 Aircraft Break-up Sequence

The medical evidence showed a proportion of the passengers with indications of hypoxia, decompression, flail injuries and loss of clothing. The incidence of hypoxia and decompression indicates that the aircraft experienced a decompression at a high altitude. The flail injuries and loss of clothing indicate a proportion of the passengers were ejected from the aircraft before water impact. The severity of injuries increased from Zones C to E and was significantly less in Zone C than in Zones D and E.

The wreckage of the forward portion of the aircraft up to and including the aircraft body wheel well area and the wings was lying about 0.8 miles north of the vertical and horizontal stabilizers. Hence, it is likely that the aft portion of the aircraft separated from the forward portion before striking the water. In addition, the wreckage found west of longitude 12°48' consisted of suitcases and aft cargo compartment lower skin panels. There was also a wide scatter of sections 46 and 48 in an east-west direction, whereas the wreckage of the forward portion was mainly localized within a relatively small area.

The higher severity of injuries in the aft end of the passenger cabin appears to coincide with the break-up of the aft end, sections 46 and 48 of the aircraft. The fact that items from the aft cargo compartment were found further west than the tail section indicates that the aft cargo compartment ruptured first during the break-up sequence of the aft end. The forward portion of the aircraft was highly localized, which indicates that it struck the water in one large mass.

3.4 Aircraft Structural Integrity

As described earlier, the sudden nature of the occurrence indicates the possibility of a massive airframe structural failure or the detonation of an explosive device.

3.4.1 Aircraft Break-up

The examination of the floating wreckage indicates that the right wing root leading edge, the number 3 engine inboard fan cowling, the right inboard midflap leading edge, and the right horizontal stabilizer root leading edge all exhibit damage consistent with objects striking the right wing and stabilizer before water impact. In addition, the right wing root interior area appears to have been scorched briefly by a heat source. The fan cowls of the number 4 engine show evidence of being struck by a portion of the turbine from number 3 engine.

The number 3 engine nacelle strut was separated from the rest of the engine components and was located about one nautical mile to the west indicating that there was some break-up of the number 3 engine before water impact.

The forward cargo door which had some fuselage and cargo floor attached was located on the sea bed. The door was broken horizontally about one-quarter of the distance above the lower frame. The damage to the door and the fuselage skin near the door appeared to have been caused by an outward force and the fracture surfaces of the door appeared to be badly frayed. This damage was different from that seen on other wreckage pieces. A failure of this door in flight would explain the impact damage to the right wing areas. The door failing as an initial event would cause an explosive decompression leading to a downward force on the cabin floor as a result of the difference in pressure between the upper and lower portions of the aircraft. However, examination showed that the cabin floor panels separated from the support structure in an upward direction. Also, passenger seats viewed and recovered exhibited that they had been subjected to an upward force from below. They showed that the seats to the rear in sections 46 and 48 had their back legs buckled, and the seats toward the front had both front and back legs buckled. This indicates the vertical force was greater at the front than the rear of the aircraft. It is possible that this vertical force on the floor was caused by the force of the water during impact, but the rear of the aircraft broke up before impact and therefore any vertical loading on the floor in this area is unlikely to have occurred at impact. Twenty-three passengers also showed evidence of vertical impact injuries. These could have been caused from a force from below during flight or at water impact. Sixteen of these passengers had little or no clothing indicating that some may have been ejected before water impact. Therefore, there is some indication that the upward force on the floor may have occurred in flight and was more severe toward the front.

3.4.2 Aft Pressure Bulkhead

The localized impact mark found on the leading edge of the right horizontal root leading edge is indicative of an object striking the stabilizer in flight before water impact. This suggests that the loss of the tail plane was not the first event. The horizontal and vertical stabilizers were found separated and each was intact and in good condition. Items from the aft cargo compartment were found further to the west of the tail plane. The absence of the type of damage to the tail plane as was found in the Japan Airlines (JAL) Boeing 747 accident where the aft pressure bulkhead failed and which took place shortly after this occurrence, and the rupture of the aft cargo compartment before the loss of the tail indicate that there was not an in-flight failure of the aft pressure bulkhead. In addition, examination of the recovered portions of the bulkhead shows evidence of overload failures from the rear to front only and no evidence of any pre-existing defect, premature cracking or pre-impact corrosion damage.

3.4.3 Target 7 - Lower Fuselage Skin Panel

Target 7 which extends from BS 1480 to 1860 shows a break at the joint at BS 1480. The forward keel joint splice plate is bent and the keel joint holes are distorted and elongated. Some of the fracture surface was heavily corroded. An in-flight failure in this area would cause a massive failure of the aircraft's structural integrity. Further examination showed the fractures to be overload, and there was no evidence of an intergranular type fracture to suggest a stress corrosion cracking mode of failure. The corrosion was concluded to be post-impact and, therefore, there is no evidence to suggest an in-flight failure in this area as the initial event.

3.4.4 Structural Failure

The examination of the floating and recovered wreckage and the analysis of the photos and videos of the wreckage on the bottom failed to indicate any evidence of a failure of the primary or secondary structure as a result of a pre-existing defect. The initial event has been established as sudden and without warning. The abrupt cessation of the flight recorders indicates the possibility of a massive and sudden failure of primary structure; however, there is evidence to suggest that there were ruptures in the forward and aft cargo compartments prior to any failure of the primary structure in flight. Therefore, available evidence tends to rule out a massive structural failure as the initial event.

3.4.5 Explosive Device

A violent explosion occurring within an aircraft in flight usually leads to a complicated break-up mode and sequence of failure. Fractures of metal caused by an explosion are normally different in character to those caused by overstressing or crash impact forces. Shattering of metal into very small and numerous fragments and minute deep penetration of a metal surface are not usually found in aircraft accident wreckage. The size and characteristics of these particles often accompanied by rolled edges, surface spalling, pitting or evidence of heat are indicative of an explosion.

Of the floating wreckage, there is little to indicate the possibility of an explosion:

- the lining in one suitcase was severely tattered;
- although the wooden spares box was burned, this could have happened after the occurrence;
- although pieces of an overhead locker were damaged by fire, it is not known if the burning happened at the time of the occurrence;
- although the pieces of U-section alloy clearly indicated evidence of an explosion, it is quite possible that these pieces were not associated with the aircraft;
- the bottoms of some seat cushions show indications of a possible explosion;
- the inside of the right wing root fillet appears to have been scorched; and
- the deformation of the floor of the upper deck storage cabinet might have been caused by an explosive shock wave generated below the cabin floor and inboard from the cabinet.

It is not known if the suitcase came from the aft or forward cargo compartment, and the location of the seats from which the cushions came is also unknown.

The scorching of the right wing root fillet and the damage to the upper deck cabinet suggest, if there was an explosion, it emanated from the forward cargo compartment.

From the examination of the recovered wreckage, the following deductions can be made:

- Target 47, which is a portion of the aft cargo compartment roller floor, shows no indications characteristic of an explosion emanating from the aft cargo compartment.
- Target 362/396, which is a lower skin panel from the forward cargo compartment is badly crumpled and torn and has about 20 punctures resulting from penetration from inside. It appears that some folding occurred on water impact which brought stringers or stiffeners from the aircraft structure into forceful contact with the internal surface of the panel producing most of the penetrations. However, there are certain punctures which indicate no evidence of impact marks on the inside surface and show evidence of being produced by high velocity fragments. Part of the inner surface of the skin panel appeared to have been blackened by soot from a fire.
- Target 399, consisting of a piece of the skin and stringers on the right side in the area of the forward cargo compartment contained holes and several hundred metal fragments. The damage to the floor stantion and the presence of the fragments are consistent with an explosion.

The examination of the recovered wreckage contains no evidence of an explosion except for targets 362/396 and 399 which contain some evidence that an explosion emanated from the forward cargo compartment.

An explosion in the forward cargo compartment would explain the loss of the DFDR, CVR and transponder signal as the electronics bay is immediately ahead of the cargo compartment.

3.5 Security Aspects

There is a considerable amount of circumstantial and other evidence that an explosive device caused the occurrence. Therefore, it is reasonable to examine the security measures in place on 22 June 1985. The evidence indicates that if there was an explosion, it most likely occurred in the forward cargo hold, not the passenger and flight deck areas or exterior to the fuselage. Although an explosive device could have been placed in a cargo hold in a number of ways, the available evidence points to the events involving the checked baggage of M. and L. Singh in Vancouver. The investigation determined that a suitcase was interlined unaccompanied from Vancouver via CP Air Flight 060 to Toronto. In Toronto, there is nothing to suggest that the suitcase was not transferred to Terminal 2 and placed on board Air India Flight 181/182 in accordance with normal practice. The aircraft departed Toronto for Mirabel and London with the suitcase unaccompanied. Similarly, a suitcase was interlined unaccompanied on CP Air Flight 003 from Vancouver to Tokyo to be placed on Air India Flight 301 to Bangkok. The explosion of a bag from CP 003 at Narita Airport, Tokyo, took place 55 minutes before the AI 182 accident. Therefore, the nature of the link between the two occurrences raises the possibility that the suitcase which was unaccompanied on AI 182 contained an explosive device.

3.5.1 Canadian Security Situation

Canadian security arrangements in place prior to 23 June 1985 met or exceeded the international requirements for civil air transportation. However, before this date, the emphasis was on preventing the boarding of weapons including explosive devices in hand luggage. Hence, the screening of checked baggage was only undertaken in conditions of a heightened threat as was the case with respect to Air India flights.

In Canada, the Department of Transport (Transport Canada) is responsible for establishing overall security standards for airports and airlines, and for the provision of certain security equipment and facilities at airports. By regulation, air carriers are responsible for applying security standards for passengers, for baggage and cargo and for ensuring security within individual aircraft. The RCMP provides airport physical security and responds to criminal incidents.

Air carriers contract for or otherwise provide the personnel who operate the security check-points through which passengers and their carry-on baggage enter the secure area of the airport terminal. These personnel also operate security equipment for the screening of cargo, passengers and checked baggage. Usually, air carriers use the service of private security firms. Transport Canada has established certain standards required for licensed security guards, such as the successful completion of the Transport Canada passenger inspection training program and annual refresher training. As stated earlier, a significant number of the security guards did not meet the criteria with respect to the completion of the training program and refresher training. In addition, the criteria do not require training for the screening of cargo and checked baggage.

ICAO Annex 17 recommends that contracting States establish the necessary procedures to prevent the unauthorized introduction of explosives or incendiary devices in baggage or cargo intended to be carried on board aircraft. For all Canadian airlines, Canadian regulations before 23 June 1985 required a system of identification that prevented baggage, goods and cargo from being placed on board an aircraft if it was not authorized to be placed on board by the airline operator. However, if someone were to purchase a ticket, check in baggage and not board the aircraft, the baggage would in all likelihood have been authorized by the airline to be placed on board the aircraft. Therefore, it was possible to interline baggage unaccompanied and this explains how a suitcase was interlined to AI 181/182 from CP 060. It is not the normal practice of airlines to interline baggage if there is not a confirmed reservation to the destination. In this case, the ticket agent allowed the suitcase to proceed; however, if there had been a confirmed reservation, the suitcase would have been interlined unaccompanied without question.

3.5.2 Air India Security

Air India, as required by Canadian regulation, had a security program. Because of the threat level assessed against the airline, Air India had more extensive security measures than almost any other Canadian or international airline. These measures were generally in accordance with the recommended procedures of the ICAO Security Manual for special risk flights. Air India had also requested and received extra security from Transport Canada and the RCMP for the month of June 1985. For Air India Flight 181/182, Air India provided a security officer from its New York office to oversee the security arrangements at Toronto and Mirabel. The security program at each airport was under the overall supervision of the respective Air India station managers. In Toronto, it was not clear who, if anyone, was undertaking this function.

It is not known if the suitcase interlined from CP 060 was screened before or after the X-ray machine broke down in Toronto. Although baggage not examined by X-ray was screened by a PD-4 sniffer, there are indications that the sniffer could have been ineffective in detecting explosives, especially plastics. Rather than using the sniffer, it would have been more effective to open all bags and physically inspect them. Even though a number of security personnel were not adequately trained in the screening of passengers and baggage, it is not known whether more training would have prevented an explosive device from being placed on board.

Although airline procedures required baggage to be accompanied, the agents checking in passengers in Toronto used a passenger security numbering system but did not number checked-in baggage, and baggage was not correlated with passengers. Therefore, the interlined unaccompanied suitcase from CP 060 was not detected. At Mirabel, checked-in passengers and baggage were numbered so that the number of passengers checking in baggage could be correlated with the number of passengers boarding the aircraft. Had a passenger-baggage correlation been carried out in Toronto, the suitcase from CP 060 would have been detected. The airline procedures would have prevented the placement of the suitcase on the aircraft.

Once loaded on the aircraft, the suitcase would have been placed in container 11L and 12L (see Appendix B) if in the forward cargo compartment, in container 44L or 44R if in the aft cargo compartment, or in position 52 if in the bulk cargo compartment. It could not be determined in which cargo compartment the suitcase was loaded. Therefore, although the procedures were in place to prevent an explosive device from being placed on board the aircraft in checked-in baggage, there was a breakdown in the X-ray machine used to screen baggage, and there are indications that the PD-4 sniffer was inadequate. Also, the security numbering system used in Toronto was ineffective in preventing unaccompanied interlined baggage from being placed on board the aircraft.

4.0 CONCLUSIONS

The Canadian Aviation Safety Board respectfully submits as follows:

4.1 Cause-Related Findings

1. At 0714 GMT, 23 June 1985, and without warning, Air India Flight 182 was subjected to a sudden event at an altitude of 31,000 feet resulting in its crash into the sea and the death of all on board.

2. The forward and aft cargo compartments ruptured before water impact.

3. The section aft of the wings of the aircraft separated from the forward portion before water impact.

4. There is no evidence to indicate that structural failure of the aircraft was the lead event in this occurrence.

5. There is considerable circumstantial and other evidence to indicate that the initial event was an explosion occurring in the forward cargo compartment. This evidence is not conclusive. However, the evidence does not support any other conclusion.

4.2 Other Findings

Even though they may not be causal or related to the accident, the following additional conclusions can be drawn from the investigation with respect to certain security arrangements and their application pertaining to this flight:

1. In compliance with the International Civil Aviation Organization Annex 17 to the Convention on International Civil Aviation, the Department of Transport of Canada has made regulations requiring foreign aircraft operators who land in Canada to establish, maintain, and carry out certain security measures at airports.

2. In accordance with these regulations, Air India submitted a security program to the Minister of Transport which included security measures with respect to aircraft, cargo, baggage, and passengers.

3. On 22 June 1985, an unaccompanied suitcase was interlined from Vancouver to Toronto on CAP Flight 060 for transfer in Toronto to Air India Flight 181/182.

4. The baggage loaded in Toronto was screened through an X-ray machine process but, during the course of this procedure, the X-ray machine broke down.

5. After the X-ray machine breakdown, an explosives detector was

used to screen the baggage; the baggage was not opened and physically examined.

6. The effectiveness of the explosives detector is in doubt.

7. It is not known whether the unaccompanied suitcase interlined from Vancouver was screened before or after the X-ray machine broke down.

8. The security numbering system used in Toronto did not prevent unaccompanied interlined baggage from being placed on board the aircraft.

9. The normal procedures for interlining baggage in Toronto indicate that the unaccompanied suitcase was loaded on Air India Flight 181/182.

Cockpit Voice Recorder Tape Transcript

INTRODUCTION

1.1.1 On the morning of 23rd June, 1985 Air India's Boeing 747 aircraft VT-EFO (Kanishka) was on a scheduled passager flight (AI-182) from Montreal and was proceeding to London enroute to Delhi and Bombay. It was being monitored at Shannon on the Radar Scope. At about 0714 GMT it suddenly disappeared from the Radar Scope and the aircraft, which has been flying at an altitude of approximately 31,000 feet, plunged into the Atlantic Ocean off the south-west coast of Ireland at position latitude 51° 3.6'N and Longitude 12° 49'W. This was one of the worst air disasters wherein all the 307 passengers plus 22 crew members perished.

1.1.2 The fact that emergency had arisen was first noticed by Shannon Upper Area Control (UAC) after the aircraft had disappeared from the Radar Scope. The control gave a number of calls to the aircraft but there was obviously no response. Thereafter various messages were transmitted and that is how the rest of the world came to know of the accident.

1.1.3 Shannon Control at 0730 hours advised the Marine Rescue Coordination Centre (MRCC) about the situation which appeared to have arisen. MRCC, in turn, explained the situation to Valencia Coast Station and requested for a Pan Broadcast. Thereafter ships started converging on the scene of the accident and they commenced search and rescue operations.

1.1.4 The aircraft in question - Kanishka, was named after the most powerful and famous king of the Kushanas who perhaps ruled in India from AD 78 to AD 103. Besides being a great conqueror, he was an ardent supporter and follower of Budhism - a religion which preaches non-violence. Emperor Kanishka, however, met a violent end. After 25 years of reign he was killed by some of his own subjects. His life was thus brought to an abrupt end.

1.1.5 It is indeed ironical that the Jumbo Jet which bore the name 'Kanishka' also met with a violent and a sudden end on that fateful morning of 23rd June, 1985.

INITIAL ACTION TAKEN BY THE GOVERNMENT OF INDIA

1.2.1 Initial intimation of the accident was received by Air India who, in turn, communicated the same to Mr. H.S. Khola, Director of Air Safety, Civil Aviation Department, New Delhi. The Accident Investigation Branch of United Kingdom also sent information to the Director General of Civil Aviation, New Delhi to the effect that the accident had taken place on international waters and as such it was India which was the authority to investigate the accident in accordance with the provisions of ICAO Annex 13.

1.2.2 Thereupon Order No. AV.15013/8/85-AS dated 23rd June, 1985 was issued by the Director General of Civil Aviation whereby Mr. H.S.Khola was appointed Inspector of Accidents for the purpose of carrying out the investigation into the aforesaid air accident. This appointment was made under Rule 71 of the Aircraft Rules, 1937.

1.2.3 While search and rescue operations were underway at the site of the accident, a team of officials headed by Dr.S.S. Sidhu, Secretary, Ministry of Tourism & Civil Aviation rushed from India to Cork. The said team was joined by Mr. Kiran Doshi, the Indian Ambassador to Ireland, and also by two officers of the Indian Navy who were attached to the Indian High Commission at London. Subsequently two Medical Experts from India also joined the said Team.

1.2.4 The Indian Team arrived at Cork, Ireland on 24th June, 1985. Representatives of the Governments of United States of America, Canada and United Kingdom also reached there that day. They were met by the representatives of the Government of Ireland.

1.2.5 The members of the Team saw the rescue and salvage operations being conducted. They also visited the Cork Regional Hospital and had discussions with Irish and other Authorities with a view to release the bodies of the victims which were being brought to Cork.

1.2.6 For facilitating the process of investigation the Inspector of Accidents after consulting the representatives of the aforesaid Governments formed the following groups:

a. Structures, Power Plant and Systems Group.

b. Operations Weather & ATS Group.

c. Medical and Human Factor Group.
d. Search & Rescue Group.

The aforesaid groups were required to collect evidence and to submit their respective reports to the Inspector of Accidents.

1.2.7 The bodies which were being recovered were brought to the Cork Regional Hospital for identification and post-mortem. At that time it was considered proper that apart from the two medical experts from India, Wing Commandor Dr.I.R. Hill, who is an expert in aviation pathology should also be called from United Kingdom.

1.2.8 It was also being speculated that the accident may have occurred due to an explosion on board the aircraft. In order to see whether there was any evidence of an explosion which could be gathered from the floating wreckage which was being salvaged, the Government of India requisitioned the services of Mr. Eric Newton, a Specialist in the detection of explosives sabotage in aircraft wreckage.

1.2.9 In order to coordinate and guide the operations of the various ships working at the crash site, a control centre was set up at Cork Airport on 30th June, 1985.

1.2.10 The control centre was manned by representatives of the Governments of Ireland, Canada and United States. The Indian Naval Officers from the High Commission at London were overall in-charge of this centre. After the flight recorders had been recovered the centre continued to function, but the representatives of the United States departed.

1.2.11 For retrieving the Cockpit Voice Recorder (CVR) and Digital Flight Data Recorder (DFDR), a cable ship named Leon Thevenin was engaged which had on board Submersible Robot (Scarab) which was fitted with a Sonar receiver and TV Cameras. The aforesaid ship was engaged and after an intensive search CVR and the DFDR (more popularly known as 'the black boxes') were located and retrieved on 10th July and 11th July, 1985 respectively.

1.2.12 The Government of India, in exercise of the powers conferred by Rule 75 of the Aircraft Rules, 1937 vide Notification No. AV. 15013/10/85-A, dated 13th July, 1985, directed that a formal investigation of the accident be carried out. Mr Justice B.N. Kirpal, Judge of the Delhi High Court, was appointed as the Court to hold the said investiation. The Central Government also appointed Dr. V. Ramachandran of National Aeronautical Laboratory, Bangalore; Mr. J.S. Gharia of Explosive Research and Development Laboratory, Pune; Captian J.S. Dhillon, retired Director of Operations, Air India, Bombay; Mr. J.K. Mehra, retired Manager (Technical Training), Indian Airlines, Hyderabad and Captain B.K. Bhasin, Deputy Managing Director of Indian Airlines, New Delhi to act as Assessors of the said Investigation. The Court was required to make its report to the Central Government by 31st December, 1985, which date was later extended to 28th February, 1986.

1.2.13 Mr. S.N. Sharma, Director of Airworthiness, Civil Aviation Department, was appointed as Secretary to the Court vide Ministry of Tourism & Civil Aviation letter No. AV/15013/10/85-A, dated 22nd August, 1985. The appointment was to take effect from 13th July, 1985.

ACTION TAKEN BY IRELAND, INCLUDING THE CORK REGIONAL HOSPITAL

1.3.1 The accident had occurred on the Atlantic Ocean approximately 100 miles south-west of the coast of Ireland. It is the Air Traffic Control at Shannon, Ireland who first became aware of the tragic event.

1.3.2 On coming to know of the accident, various authorities in Ireland took immediate action. The Shannon ATC asked the Marine and Rescue Coordinating Centre there to take emergency action. Thereupon MRCC, Shannon asked Valantia Coast Radio Station (CRS) for a PAN broadcast requiring all the vessels in areas 51N/1250W to keep a look out for the wreckage of an aircraft. The PAN broadcast was repeated and all ships were directed to proceed to the site of accident which was determined as 5101.9N/1242.5 W.

1.3.3 Irish authorities also took great pains in rendering every possible assistance to the Indian and other authorities. Some of the wreckage which had floated in to the west coast of ireland was transported to Cork where a boat house had been hired by the Government of India. The wreckage which was placed in the said boat house was protected from any outside interference by the local Gardai (police).

1.3.4 Irish ships proceeded to the scene of accident and helped in search and rescue operations. The ATC at Shannon gave details about the accident, in so far as they were aware of it, and copies of the ATC tapes were supplied. Aer Lingus, national airline of Ireland, provided assistance by making available its local engineering facilities to the coordinating centre at Cork and also to the other authorities.

1.3.5 Cork is a city having a population of approximately 1,34,000. One of the hospitals which was opened in 1978 is the Cork Regional Hospital which had been set up to meet the needs of the people. This 600-bed hospital was designated for the purposes of the Major Accident Plan of the Southern Health Board and thus became the appropriate centre for the reception of the casualities of the Air India disaster. Since the hospital first opened, it had dealt with a number of major accidents involving road, rail and marine incidents. The Major Accident Plan of the Southern Health Board sets out formally, the strategy and procedure which the hopital is required to follow while deailing with major accidents.

1.3.6 On the morning of 23rd June, 1985 at approximately 11.20 A.M. the hospital was put on alert following the disappearance of the Air India Flight 182 off the south-west coast of Ireland. The first message which was communicated to the hospital indicated that it was unlikely that there would be any survivors. The key hospital personnel were alerted and a meeting was arranged in the hospital for the purposes of discussing and making arrangements for the receipt of the bodies on the basis of the information which was available at that time.

1.3.7 On being informed that there were no survivors in the accident and that the hospital should be prepared to receive a large number of bodies, then, in accordance with the Major Accident Plan, mortuary facilities were improvised by appropriating the gymnasium attached to the Deparatment of Rheumatology. Subsequently it became evident that additional mortuary and postmortem facilities would be needed. In order to decide where the second mortuary was to be located, the hospital had to take into cosideration the following factors:-

(a) The number and the condition of the bodies;
(b) The period during which the bodies would be retained;
(c) The hospital would be required to provide an on-going service for in-patients, out-patients and serious accident and emergency cases;
(d) To avoid unnecessary internal transport problems, the bodies should be near the Post-Mortem and Pathology Departments; and
(e) To facilitate traffic flow in the hospital curtilage and to to aviod unduc public access.

The hospital authorities accordingly located the second mortuary in a recreational room adjoining the gymnasium.

1.3.8 Two rooms were put at the disposal of the Garda (Police) authorities for use as Garda Control Rooms in the hospital. Telecommunications lines were set up immediately for their assistance as the Gardai was responsible for the forensic and identification procedures in regard to the bodies brought to the hospital.

1.3.9 A small Co-ordinating Group was set up consisting of the Chief Executive Officer of the Southern Health Board, Medical Co-ordinating Officer, Press Liaison Officer, a Senior Registrar who knew about Indian customs and traditions and a Hospital Administrator. This small Co-ordinating Group, whose membership never changed, worked together and were capable of assessing situations, making decisions, liaising with other agencies and services and undertaking with other agencies and services and undertaking responsibility for hospital press releases. Apart from individual contact between members, the Group had a standing arrangement to meet every morning and afternoon. In the late evening, the Group, met the Garda, Hospital Pathologists and key staff members for a general review of progress and to decide the tasks and objectives for the following day.

1.3.10 Within a few hours, the Co-ordinating Group realised that the hospital was a world focal point of the international media, and was required to:

a. Accommodate 131 bodies;
b. Provide pathological and Radiological services for each body;
c. Co-operate with the Garda in their forensic work;

d. Cater for relatives of the victims;
e. eet representatives of foreign Governments; and
f. Keep press agencies informed.

Thus began an operation which demanded a quick and dedicated response from all staff working in close cooperation with the Gardai. At the same time, the hospital was required to continue functioning in the delivery of normal in-patient and out-patient services. The Major Accident Plan, apart from alerting staff, provided the framework and basis for many
decisions taken as events evolved. An additional advantage in the practical implementation of the Plan was the fact that the hospital had staff experienced in dealing with previous emergency situations and could marshal the extensive manpower resources available.

1.3.11 The hospital authorities also made the following arrangements:-

a. They briefed Government Ministers and Officials and other dignitaries who visited the hospital. They were taken round the hospital and were explained the arrangements which had been made.

b. Some of the services which were being provided at the hospital were either discontinued or postponed.

c. Bodies were received at the hospital and arrangements were made on their arrival to numerically label and certify as dead all the 131 bodies which were initially received. All the bodies, at that stage, had been individually placed in special purpose body bags. Initially, bodies were placed on tables, but, it was subsequently decided that it would be much easier for all concerned to place the wrapped bodies on polythene covered floors.

d. Arrangements were made for carrying out of the post-mortem examinations. Three Pathologists from other city Hospitals were recruited to augment the existing staff. Dr. Harbison, State Pathologist, was in charge of this aspect of the operation. All the post mortem were completed by 27th June, 1985.

e. For the preservation of the bodies five refrigerated containers with a capacity to hold 140 bodies were hired. These containers were fitted with timber shelving.

f. Government Information Service was located in the Matron's Office.

g. The Army provided troops for the unloading of the bodies from the helicoplers at Cork Airport. They also supplied and erected two large tents for storing bodies after post mortem and embalming. Under Garda escort transport of all the bodies which were recovered was undertaken by the

Army and these arrangements were co-ordinated by Chief Ambulance Officer.

h. Embalming was carried out in the hospital and bodies were then coffined and the coffins with appropriate number plaques were subsequently laid out in the numerical order on the floor when all the post mortems had been completed.

I. All the embalmed bodies were x-rayed (whole body). The examination was completed on 28th June, 1985.

j. A provision was made for a 24 hour extended catering service to meet the needs of staff, Gardai, Army and other personnel involved including visiting relatives.

k. A simple plan was devised for dealing with the relatives. This was a sensitive task bearing in mind the varying religious beliefs, customs and cultures generally of the visiting relatives. Their main function was to provide moral and emotional support to the relatives.

l. As identification progressed, special arrangements were made to assist the relatives. They were met by teams of councellors from the Hospital as soon as they disembarked at Cork Airport and subsequently at the Hospital. The relatives had the same Counsellor and Garda Officer throughout the identification procedure. An interesting development noted was that each family group of relatives, their Counsellor and Garda officers formed a single family unit transcending cultural barriers. On subsequent visits, families appeared lost if their own Counsellor was not immediately available to them. Usually, the Counsellor and the Garda officers accompanied the relatives, at their own request, for visual identification.

m. When plans were being formulated to receive the relatives, it had been hoped to discourage them from coming to the Hospital until such time as progress had been reported on the identification process. Practical experience subsequently proved this strategy to be inappropriate for a number of reasons. Apart from facilitating the collection from relatives

of salient information on the victims, the most fundamental reason was the underestimation of the abiding wish of the relatives to be physically and psychologically as close as possible to their deceased dear ones. Moreover, it was the express wish of almost all relatives on arriving at Cork Airport to proceed directly to Cork Regional Hospital; there, they were given an informal talk by Air India and Garda representatives on the progress of the investigation and the methods of identification. Many of the relatives visited the hospital daily and remained there throughout each day.

n. Coach trips were arranged to Bantry Bay for the relatives; Bantry Bay is the nearest landmark from the site of the crash. Relatives visited the seaside to pay their last respects to the departed souls. These were solemn occasions when each relative prayed in his/her own way. Rose petals and wreaths were immersed in the sea in keeping with Indian traditions. The visit gave them mental satisfaction and in the early days following the crash, helped in diverting their attention while the investigative procedures were being completed.

o. A small number of visiting relatives had personal medical problems and they were treated at out-patient and in-patient levels at the Hospital.

p. Cork/Kerry Tourism Organisation helped to co-ordinate the accommodation of relatives between a number of hotels. Approximately seven hotels were used within a radius of twenty miles of the city for this purpose.

g. A number of press conferences were held. The Chief Executive Officer, directed that press photography and television filming be not allowed within the hospital in deference to the privacy of patients and in respect for the relatives wishes.

r. Responsibility for the identification of bodies rested with the Garda

Authorities and the conditions under which bodies were released are summarised as follows :-

(I) Satisfactory identification

(ii) Consent of the Coroner

(iii) Proper authentification of the person claiming each body

All bodies arriving at Cork Regional Hospital had already been numerically labelled by the Garda Authorities. To prevent confusion, the bodies were then given identical numbers under the hospital major accident labelling system and this proved to be very helpful later during identification, investigations and recordings. A routine was established for examining and recording information about each body. Teams consisting of a doctor, nurse, clerical officer and Garda made the necessary examination, labelling and recording each body and such details as :-

a. Sex

b. Adult or child

c. Clothing

d. Jewellery and personal effects

e. Injuries

f. Obvious scars

Death was confimed in all cases. Each body was fingerprinted and photographed by Garda Technical Bureau Staff. Each body was subjected to autopsy, forensic and dental examination. All bodies were embalmed and following embalming, were photographed and x-rayed. This procedure was completed in respect of all the bodies by the evening of the fifth day of the crash. The data from these investigations was collated on an Interpol form (pink) for each body. Similar ante-mortem information was obtained from the relatives about each victim on a separate Interpol form (yellow). When the information on the pink and yellow forms matched beyond doubt, a positive identification was made. It might be noted that the photographs originally taken by the Garda Technical Bureau Officers of each body were matched with photographs of the 131 embalmed bodies. When a positive identification was made, the relatives were shown photographs of the deceased. These photographs were available for inspection by Saturday, 29th June. As positive identification progressed, personal effects were added to the identification process and finally, visual identification took place. For obvious forensic reasons, positive identification was necessarily slow and meticulous and, in fact, was made more difficult by reason of the fact that only 131 bodies out of the 329 passengers and crew were recovered. All 131 bodies were identified, the first positive identification was made on 27th June and the last on the 6th August. Each coffin had affixed to it a metal plaque clearly indicating the number assigned in the first instance to the body it contained. The bodies when identified were released by the Garda Authorities through the undertaker. The Coroner directed that a reasonable time would have to elapse before unidentified bodies could be disposed off an this was to be by way of burial. The final date for this purpose was fixed for 3rd August, 1985, but, this date was subsequently extended to 6th August, 1985, to coincide with the date of the Civic Commemoration Ceremony.

(s) Bodies of victims for identification were brought individually to separate viewing rooms, suitably decordated with flowers and with incense burning. Visual identification was performed in private by the relatives and moreover, it allowed them to pay their last respects in their own religious beliefs. An adjoining room was also made available where they could grieve in private. Subsequently, it was learnt that these arrangements were much appreciated by the relatives who articulated this appreciation by commenting that the arrangements provided were as near as possible to the funeral rites observed in their domestic communities. The relatives were of the opinion that the special arrangements made conveyed a deep personal and individual response to the dignity of each victim which might otherwise be lost with such a large number of bodies.

(t) Procedures were laid down which were required to be followed and observed for the purposes of preventing infection.

(u) On 6th August, 1985 an interdenominational service was held in the morning. In the evening on that day a Civic Commemoration Ceremony was held which was attended by a large number of persons.

(v) A formal inquest was held by the Coroner in the Courthouse, Cork, which commenced on 17th September, 1985 and ended on 23rd September, 1985. The Coroner's Jury returned a verdict in accordance withmedical and pathological evidence.

ACTION TAKEN BY THE COURT

1.4.1 Despite the fact that Mr. H.S. Khola had been appointed as the Inspector of Accidents under Rule 71 of the Aircraft Rules, the Government thought it proper to appoint Mr.Justice B.N. Kirpal as the Court to investigate into the circumstances of the accident.

1.4.2 The appointment of the Court was made under Rule 75 of the Aircraft Rules, which is as follows :-

"75. Formal Investigation - Where it appears to the Central Government that it is expedient to hold a formal investigation of an accident it may, whether or not an investigation or an inquiry has been made under rule 71 or 74, by order direct a formal investigation to be held and with respect to any such formal investigation the following provisions shall apply namely

(1) The Central Government shall appoint a competent person (hereinafter referred to as "the Court"), to hold the investigation, and may appoint one or more persons possessing legel, aeronautical, engineering, or other special knowledge to act as assessors, it may also direct that the Court and the assessors shall receive such remuneration as it may determine.

(2) The Court shall hold the investigation in open court in such manner and under such conditions as the Court may think fit most effectual for ascertining the causes and circumstances of the accident and for enabling the Court to make the report hereinafter mentioned.

(3) (i) The Court shall have, for the purpose of the investigation, all the powers of a Civil Court under the Code of Civil Procedure, 1908 and without prejudice to those powers the Court may :-

(a) enter and inspect, or authorise any person to enter and inspect, any place or building, the entry or inspection whereof appears to the court reguisite for the purpose of the investigation; and

(b) enforce the attendance of witness and compel the production of documents and material objects; and every person required by the Court to furnish any information shall be deemed to be legally bound to do so within the meaning of section 176 of the Indian Penal Code.

(ii) The assessors shall have the same powers of entry and inspection as the Court.

(4) The investigation shall be conducted in such manner that, if a charge is made or likely to be made against any person, that person shall have an opportunity of being present and of making any statement or giving any evidence and producing witness on his behalf.

(5)Every person attending as a witness before the Court shall be allowed such expenses as the Court may consider reasonable: Provided that, in the case of the owner or hirer of any aircraft concerned in the accident and of any person in his employment or of any other person concerned in the accident, any such expenses may be disallowed if the Court, in its discretion, so directs.

(6)The court shall make a report to the Central Government stating its findings as to the causes of the accident and the circumstances thereof and adding any observations and recommendations which the Court thinks fit to make with a view to the preservation of life and avoidance of similar accidents in future, including, a recommendation for the cancellation, suspension or endorsement of any licence or certificate issued under the rules.

(7)The assessors (if any) shall either sign the report, with or without reservations, or state in writing their dissent therefrom and their reasons for such dissent, and such reservations or dissent and reasons (if any) shall be forwarded to the Central Government with the report. The Central Government may cause any such report and reservation or dissent and reason (if any) to be made public, wholly or in part, in such manner as it thinks fit."

1.4.3 The Court, which is appointed under Rule 75, does not act as a 'Commission of Inquiry' which is usually appointed under the Commissions of Inquiry Act to inquire into any definite matters of public importance. The role of the Court, on its appointment under Rule

75 of the Aircraft Rules, is essentially that of an Investigator. It is for this reason that no procedure has been prescribed in the Rules which the Court is required to follow. While carrying out its functions, the Court is not only required to comply with the provisions of the Aircraft Act, and the Rules framed thereunder, but it must necessarily also keep in view the provisions of ICAO Annex. 13.

1.4.4. As an Investigator, investigating into an accident, the Court had to perform multi-farious duties and functions. Before referring to them, it would be pertinent to point out that whereas an Inspector of Accidents, who is appointed under Rule 71, would normally be belonging to the Civil Aviation Department and would have all the machinery available to him for conducting the investigation, the Court, when it is appointed to hold an investigation under Rule 75, lacks the basic infrastructure to conduct the investigation of such a magnitude. Assessors are appointed to assist the Court but the actual investigation work cannot be carried out by them. Despite these handicaps, the investigation continued smoothly primarily due to the fact that whenever directions were issued by the Court to any of the participants before it or to the Civil Aviation Department or any other Organisations, the directions of the Court were readily complied with. On a few occasions it also became necessary to require the Assessors to conduct the investigation, which they did with the help of other organisations.

1.4.5 As an Investigator, the first task which was undertaken was to see that the tapes from the Cockpit Voice Recorder, which had been salvaged, were recoverd from the recorders and subsequently analysed. Requisite directions were issued and the tapes were removed from their respective recorders on 16th July, 1985. This operation was carried out at the Air India workshop at Santacruz in the presence of the accredited representatives of Lockheed (manufactures of DFDR), Fairchild (manufacturers of CVR), Boeing Airplane Co., Canadian Air Safety Board (CASB), National Transportation Safety Board, USA (N.T.S.B), Air India and Government of India. The tapes so recovered were subsequently played and analysed.

1.4.6 On an appointment being made under Rule 75 the Court would become incharge of overall investigation of the accident. In that capacity, and in order to effectively discharge its functions, it became necessary for the Court to undertake the following tasks :-

(a) For getting first hand information, the Court had to personally inspect the wreckage which had been recovered and was housed in a boat yard in Cork. While in Cork opportunity was also taken to go to the Cork Regional Hospital and to have discussions with and be briefed by the hospital staff. A trip was also made to Shannon with a view to see and understand the working of the Secondary Radar System which was in use there. On this visit the original ATC tape, which contained communication betwen Kanishka and the ATC, was also heard.

As it was suspected that there may be a link between the blast which had taken place at Narita Airport on 23rd June, 1985 and the accident to Air India's flight 182, it was felt necessary to inspect the site of the bomb blast at Narita Airport.

On the aforesaid visit to Tokyo, the site where the blast had taken place was inspected which gave some, though very vague, idea of the detonating power of the blast. While in Tokyo meetings and discussions were also held with the police and Aviation Authorities. The Court also had the advantage of being able to meet members of the team investigating into the Japan Airlines Flight JL 123 accident which had occurred near Tokyo on 12th August, 1985. Similarities and dissimilarities between the two accidents were, to some extent, noticed and some information was exchanged.

Information was received, that some floating wreckage had been picked on the coast of England and it was possible that some of the places, which were so received, should be subjected to further detailed chemical and metallurgical examination. In order to decide this, it became necessary to visit RADRE, Kent, U.K. As a result of the inspection and the discussions there, it was decided by the Court that the pieces so recovered should be sent to BARC at Bombay for further analysis.

(b) Directions had to be given, from time to time, with regard to the mapping and salvaging of the wreckage which was being effected. It had to be decided as to how, and in what areas, the Scarab should continue to map the wreckage and take video films and still photographs. Based on the information received therefrom and after discussions with the experts, both Indian and foreign, a list was drawn up indicating the items which had to be salvaged. As the weather was likely to be unpredictable, with a possibility of its deteriorating rapidly, a priority list of items to be salvaged had also to be prepared, and this was done. In view of the fact that the Canadian ship John Cabot and the Scarab had a limited capacity, with regard to the size and weight of pieces which could be lifted from the bottom of the ocean, decision had also to be taken with regard to the deployment of another ship. As a consequence thereof a ship 'Kreuzturm' was also engaged in salvage operations.

(c) Directions had also to be given assigning work and duties to different teams of persons. As an Investigator, the Court was incharge of the entire work of investigation which was being carried out in different parts of the world. It not being possible for the Court itself to undertake all the tasks, decisions had to be taken as to how the investigating work was to progress and who would carry out the directions issued from time to time. For example, immediately after reaching Cork on 25th July, 1985 it was felt necessary that a team should be immediately sent to Canada in an effort to get relevant information from there in connection with the flight AI 182. Accordingly, a team of 3 persons headed by Mr. H.S. Khola was directed to proceed to Canada immediately. As a result of the efforts put in by this team, and with the considerable amount of cooperation, help and assistance rendered by the Canadian Authorities valuable information was received by the Court having direct bearing on the investigation. Yet another example in this regard was of requiring Dr. V. Ramachandran, one of the Assessors and an expert in Metallurgy, to be stationed on board the salvage ships during the recovery operations. The procedure which had to be followed by him was also determined. Information about the progress of the salvage operations was communicated on telephone to the Court at all times of day and night. On receipt of such information further instructions, when ever necessary, used to be issued.

(d) Discussions were held with the Indian experts in order to understand some of the complicated questions which had arisen during the investigation.

In an effort to be able to fully appreciate the effect of decompression, the Court visited the Institute of Aviation Medicine at Bangalore where explsoive decompression was simulated for the Court's benefit. Discussions were also held with other experts of aviation medicine who were also given copies of the post-mortem reports for their opinion. National Aeronautics Laboratory was also visited in Bangalore where meeting was held with experts in aerodynamics, structure and metallurgy. Visits to Bombay where more frequent and necessary so that the Court could get first hand information with regard to the work which was being done at BARC.

The investigation involved looking into matters concerning aviation, electronics, medicine etc. Not being familiar with these branches, the discussions which were held, were of immense help and assistance to the Court who had to understand all the evidence and information which it was gathering.

(e) The accident had attracted world wide attention. Right from the start of the investigation by the Court when the recorders were first opened in Bombay on 16th July, 1985 till the conclusion of the hearing, the Press and the TV were eager for information. It was felt that rather than the media resorting to speculation of getting wrong information, the Court itself or its representative should, as and when necessary, brief the media. In this connection interviews were given, both in India and abroad, which were broadcast over the television and printed in the Press. As a result of this, correct information was disseminated with regard to the progress of the investigation without disclosing the Court's opinion on the evidence which had been received.

(f) Finally, the Court had to conduct the formal investigation in Court. For this purpose it laid down the procedure which would be followed. Rule 75 of the Aircraft Rules required that the investigation would be in open court. It was, however, felt that in this particular case it would be advisable that some evidence should be obtained in Camera.

The Court, accordingly, recommended that necessary amendment should be made in Rule 75 so that the Court was given the power to hold certain proceedings in camera when the circumstances so warranted. The suggestion of the Court was accepted and that resulted in Rule 75(2) being amended and, as a result thereof, the Court was given the power to hold proceedings in camera if the stipulated conditions existed.

COMMENCEMENT OF FORMAL INVESTIGATION

1.5.1 The object of setting up a court to investigate into an accident is primarily to find out the causes and circumstances of the accident and thereafter to make recommendations. Such an investigation is not in the nature of an adversary litigation between the participants before the Court. As such it should be the endeavour of all the participants to assist the Court in arriving at a correct conclusion.

1.5.2 Under Rule 75 of the Aircraft Rules, the procedure which has to be followed in the investigation of an accident is to be determined by the Court itself. While laying down the procedure which is required to be followed, the endeavour of the Court has necessarily to be to adopt such procedure which would help the court in being able to complete its task satisfactorily, and in the shortest possible time. Whenever an accident takes place, it is of utmost importance that the cause of the accident must be ascertained at the earliest so that if any remedial measures are to be taken then those steps should be taken without any undue delay.

1.5.3 In the present case, there were a number of factors which had to be kept in view while determining the procedure whichshould be followed. The accident had occurred over international waters and approximately at a distance of about 5000 miles from the place where the investigation was to be conducted, namely, New Delhi. The ill fated flight itself had commenced from Canada, and this meant that most of the evidence would only be available there. Matters were not simplified by the fact that the debris itself was lying at the bottom of the ocean, 2 miles under water. It became apparent, at the very beginning, that to recover the entire debris would be a superhuman task and it will not be possible to do so within the limited time span which was available.

1.5.4 It was thought that it would be of assistance if all the participants got together so as to determine what procedure should be followed. The procedure had to be such which would give an effective opportunity of hearing to all the participants, without in any way unduly prolonging the investigation.

1.5.5 The Court decided that, in order to obtain the views, it would be necessary and advisable to have a Pre-hearing Conference.

1.5.6 The first decision which had to be taken was as to who were to be given a participants status. Keeping inview the provisions of Annex 13, participants status was given to Governments of Ireland, Canada, USA and India. Similar status was also given to Boeing Airplane Co. and Air India. As there might have been some similarities or dissimilarities between the present accident and the accident of the Japan Airlines Boeing 747-SR and also because there may have been a possibility of the present accident being linked with the explosion which had taken, place at Narita Airport, Tokyo on 23rd June, 1985, an Observer's status was given to the Government of Japan.

1.5.7 Notices for holding of the Pre-hearing Conference on 16th September, 1985 were accordingly issued on 29th August, 1985. The agenda for the Conference was to be as follows :-

a. To make suggestions to the Court for its consideration, regarding the procedure to be followed in the conduct of the formal proceedings in the Court.

b. To draw up a tentative list of witness.

c. To draw up a tentative list of exhibits.

d. To determine the areas to be inquired into

e. To fix a date for the commencement of the public hearing.

f. Any other matter with the permission of the Court.

1.5.8 Except for the Government of Japan, all the other participants were represented at the said Pre-hearing Conference. After discussions had been held between the Court and the Participants, some decisions were arrived at regarding different items of the agenda.

1.5.9 Firstly the following points were framed, indicating the areas to be inquired into by the Court:

a. Whether the accident was caused by a structural failure?
b. Whether the accident was caused by some human effort?
c. Whether the accident was caused by some criminal act?
d. Whether the accident was caused by an external non-criminal act?
e. Based on the evidence on record, what steps should or can be taken so as to ensure greater air safety.

1.5.10 It was further decided that, as suggested by all the participants, at least critical portions of the wreckage should be recovered.

1.5.11 With regard to the recording of the evidence it was decided that evidence will, in the first instance, be taken by filling affidavits or by filling statements alongwith affidavits. Copies of the same were to be supplied to the other participants for their consideration. These affidavits were to be filed on or before 18th October, 1985 and a second Pre-hearing Conference was to take place on 30th October, 1985 at New Delhi when it was to be decided as to which of the persons should be called for cross-examination. It was determined that it is only thereafter that hearing would commence in open court.

1.5.12 A tentative list of witnesses was also drawn up and it was decided that on the next date names of more witnesses may be added and, furthermore, the participants would be free to file any affidavits which they deem fit including affidavits in rebuttal.

1.5.13 Another important decision which was taken at the Pre-hearing Confence was that a Structural Group was formed consisting of (1) Mr. H.S. Khola or his nominee (2) Representative of the Canadian Government (3) Representative of NTSB, USA (4) Representative of Boeing Airplane Co., USA (5) Representative of Air India. This group was entrusted with the task of examining and analysing, initially in Seattle, USA, the video films and the still photographs of the wreckage. This group was also to indicate and decide the items of priorities of wreckage which had to be recovered. The report of this group was required to be submitted by 18th October, 1985. The report of the work done at Seattle was in fact submitted only on 25th October, 1985. This group was also given the liberty to associate any other experts or persons from Boeing or any other Authority. The group was also to inspect the floating wreckage which had already been salvaged and any further wreckage which would be salvaged.

1.5.14 Although the affidavits by way of evidence had to be filed by 18th October, 1985, it was only the Government of Ireland who filed an affidavit by at date. On behalf of the Government of India, an application was filed asking for more time. The reason stated was that the affidavit which had to be filed was to be of Mr. H.S. Khola but he was out of India as he was heading the structures group which was evaluating the video films and photographs at Seattle. The Court had no option but to grant further time to the Union of India to file its affidavits and this necessarily resulted in the adjournment of the Pre-hearing Conference which had been fixed for 30th October 1985.

1.5.15 As the salvage operations were reaching a critical point it became necessary for the Court to go to Cork on 27th October, 1985. Taking advantage of the presence of the Court in Cork, other participants also came there. Besides them, representatives of CP Air and Air Canada also arrived. At one of the informal meetings between the Court and the representatives of the participants, applications were filed by CP Air and the Air Canada, inter alia, praying that they should be permitted to participate in the investigation. It might be mentioned here that CP Air had interlined one of the passangers from Vancouver to AI-182, while Air Canada was the handling agents in Canada of Air India. After hearing the participants it was decided that participant status should also be given to these two viz., CP Air and Air Canada.

1.5.16 The participant had all filed their affidavits by way of submissions. The Court indicated that formal hearings would be held for the purpose of cross-examining some of the witnesses about three weeks after the receipt of all the reports of the various groups. While in Cork, in the first week of November, 1985 some of the salvaged pieces of the wreckage were brought there. After they were inspected by all the participants and their advisers, who were present in Cork, it was decided by the Court that further detailed metallurgical and other examination of those pieces would be done at BARC, Bombay. In order that there should be no undue delay the Court decided that a Group be constituted

consisting of expert representatives of all the participants and also the nominees
of the Court. This group was asked to carry out metallurgical and other examination of some of the critical pieces salvaged and give its report to the Court. The group consituted as a 'Committee of Experts' was as under :-

a. Mr. A.J.W. Melson, Canadian Aviation Safety Board, Canada.
b. Mr. R.K. Phillips, Canadian Pacific Air, Canada.
c. Mr. T. Swift, Federal Aviation, Administration, USA.
d. Mr. R.Q. Taylor, Boeing Commercial Airplane Co., USA.
e. Mr. J.P. Tryzl, Boeing Commercial Airplane Co., USA.
f. Mr. J.F. Wildey II, National Transportation Safety Board USA.
g. Mr. S.N. Seshadri, Bhabha Atomic Research Centre, India (Coordinator).

1.5.17 The parties were informed in Cork that the report of Mr. H.S. Khola, Inspector of Accidents, would be available by about 8th November, 1985. It was then decided that the statements of the first batch of witnesses should be recorded from 20th November, 1985. It was also agreed that if some of the reports of the experts were not received, further examination of the witness may have to postponed.

1.5.18 After receipt of the report from Mr. Khola. on the 8th November, 1985, a notice of the holding of the Public Hearing was issued to all the participants. This notice indicated that the hearing would commence on 20th November, 1985. In the meantime, a Public Notice was also published in the daily "Times of India" in Delhi and Bombay editions on 21st October, 1985 in which it was stated as follows :-

NOTICE AIR INDIA KANISHKA ACCIDFNT INVESTIGATION

The Government of India, vide Notification dated 13th July, 1985, appointed Hon'ble Mr. Justice B.N. Kirpal as a Court to investigate into the accident to Air India's Boeing 747 aircraft VT-EFO (KANISHKA) near the Irish Coast on 23rd June, 1985, when the aircraft was engaged on a scheduled passenger flight from Montreal to Bombay via London and New Delhi.

Any person having direct knowledge, who may desire to make representation concerning the circumstances or causes of the accident, may do so in writing in the form of an affidavit duly attested by an Oath Commissioner or a Notary Public and address the same to the undersigned so as to reach him within 15 days of the publication of this Notice.

S.N. SHARMA SECRETARY COURT OF INVESTIGATION COURT NO.10,DELHI HIGH COURT SHERSHAH ROAD NEW DELHI - 110 003

Pursuant to the aforesaid public notice no affidavit was received from any one.

1.5.19 The public hearing commenced on 20th November, 1985 and the first session concluded on 28th November, 1985. During this period statements of Mr. H.S. Khola, Wing Commander Dr. I.R. Hill and Sgt. Atkinson of R.C.M.P., Canada were recorded.

1.5.20 Till that date, report on the examination of the salvaged pieces had not been received. It was anticipated that the report would be available by mid December, 1985. In order to give the parties sufficient time to study the reports of all the experts it was decided that further evidence would be recorded from 22nd January, 1986.

1.5.21 After the reports were received from BARC; AIB; Farnborrough; NTSB; USA; and Mr. Bernard Caiger of CASB, Canada and the copies of the same had also been received by all the participants, recording of evidence commenced from 22nd January, 1986 and concluded on 30th January, 1986. In all statements of 13 witnesses were recorded.

1.5.22 At this stage it will be pertinent to make a few observations with regard to the procedure which was laid down for recording of evidence etc. As already indicated, most of the evidence was such which was not available in India. As a Court investigating the accident under the provisions of Aircraft Rules, it had no jurisdication to compel attendance of any witness from abroad. The Court also had no jurisdication, either under the Rules or under the provisions of Annex 13, to require any witness to be examined in a country other than the one in which the Court is holding the investigation. The Court was informed that, if called upon, some of the persons who were outside India may not be inclined to testify before the Court.

1.5.23 Faced with the aforesaid difficulty it became necessary, therefore, to evolve a procedure which would enable the Court to get the requisite information. As long as the Court was satisfied that the information which was being received was one which had been truthfully given by a person, it was immaterial as to the manner in which the information was received. It is for this reason that it was decided that evidence will, in the first instance, be given by way of affidavits. It was also provided that the statements could also be filed along with affidavits. This latter course was permitted so as to enable some of the statements, which had been recorded by members of the Royal Canadian Mounted Police, to be placed before the Court. These statements, of course, had to be accompanied, as they were, with the affidavits of the persons who had recorded the statements.

1.5.24 At one stage, by a formal application in writing, Air India had protested against this procedure being followed. By order dated 22nd November, 1985, an objection by Air India to the filing of the statements accompanied by affidavits, was dealt with by the Court in the following words :-

"With regard to the affidavits which have been filed by the Government of Canada, I would only like to observe in the Pre-hearing Conference on 16th September, 1985, it was decided that "Evidence will, in the first instance, 1985 be taken by filing affidavits or by filling of Statements along with affidavits." It was understood that if it is not possible to file affidavits of the persons who are in a position to give information then affidavits may be filed of other persons who may have recorded the statements of the persons who are in a position to give information. This is not an adversary litigation where one of the parties may lose because of lack of proof. One of the objects of setting up a Court to investigate into an accident is to find out the causes of the accident and to make recommendations. It is necessary for this purpose to get information which may be relevant. It is true that strictly speaking the statements which are annexed to the affidavits may not be admissible as evidence in a Court of Law when there is a litigation between the parties but considering limitations which we have, namely, where a Court like the present has no jurisdication to enforce the attendance of any witness who is outside this country and furthermore, the Court has no jurisdication to compel any one to give information, the procedure which was adopted was thought to be the most practical one for obtaining information in connection with the accident. Under the circumstances, the affidavits which have been filed along with the statements which have been annexed thereto which give information with regard to the accident, have to be taken on record."

1.5.25 Another advantage of following the aforesaid procedure was that the time which would have been taken in Court in examining of the witnesses was considerably reduced. After the participants had filed affidavits, the same were to be secrutinised and it was then to be decided as to which of the deponents or persons should be called for examination in Court. Effectiveness of this procedure which was adopted is apparent from the fact that though affidavits by way of evidence were filed in Court, ultimately only 13 witnesses had to be examined in Court and sitings were held in Court only on 14 days.

1.5.26 Written arguments were filed on the forenoon of the 4th February, 1986 and oral arguments were heard in the afternoon of that day. No written arguments or oral submissions were made by the Government of Ireland, CP Air or Boeing Company.

1.5.27 Mr. I.G. Whitehall, councel for the Government of Canada took exception to some of the submissions which were contained in the written submissions filed by Air India. Mr. Whitehall contended that the Court had opined that it will not go into the question of responsibility of the unfortunate accident and therefore, there was no; justification for Air India to include in its written submissions numberous passages which tended to fix responsibilities.

1.5.28 By the order dated 4th February, 1986, it was made clear that it was not the intention of the investigation to apportion blame if any lapse had been committed and, therefore, the Court would ignore any written submissions which tended to apportion blame or responsibility for any lapse of any participants. It might here be mentioned that such a question had earlier arisen while the statement of Sgt. Atkinson was being recorded. The Court had then held that it will not go into the question as to who was responsible for the accident. It was in view of this order that no evidence was led by any of the parties on the question as to who may have been responsible for any possible lapse which could have led to this accident.

2.1 Flight Preparation

2.1.1. Air India Boeing 747 aircraft VT-EFO 'Kanishka' was operating flight AI-181 (Bombay-Delhi-Frankfurt-Toronto-Montreal) on 22nd June, 1985. From Montreal it becomes AI-182 from Mirabel to Heathrow Airport, London enroute to Delhi and Bombay. The aircraft arrived at Toronto from Frankfurt at 1830 Z and was parked at gate No. 107 Terminal 2 at L.N. Pearson International Airport. In accordance with the Canadian regulations, all the passengers and their baggage were off loaded to complete the customs and immigration checks. Transit cards were handed out to 68 transit passengers destined to Montreal who disembarked at Toronto for customs and immigration checks.

2.1.2. The flight from Toronto to Montreal was made up of the following:-

(I) Passengers originating at Toronto and their baggage.

(ii) Transit passengers, and their baggage, continuing their flight to Montreal.

(iii) Two diplomatic bags from Indian Consulate General, Vancouver via Air Canada Cargo Flight, and some Air India Mail.

(iv) Fifth Pod engine and its associated parts.

(v) Interline passengers and their baggage from connecting flights as detailed below:-

a) Air Canada flight AC-102
from Sasktoon - 2 Passengers

b) Air Canada flight AC-106
from Edmonton - 4 Passengers

c) Air Canada flight AC-170
from Winnipeg - 1 Passenger

d) Air Canada flight AC-170
from Winnipeg - 4 Passengers

e) Air Canada flight AC-136
from Vancouver - 10 Passengers

2.1.3. One passenger by name 'M. Singh', checked in at Vancouver on Canadian Pacific flight CP-060 (Vancouver-Toronto) of 22nd June 1985, and got his one piece of baggage interlined to Air India flight AI-181 even though he had no confirmed reservation on AI-181. This passenger, however, did not board the flight CP-060 at Vancouver and also did not check-in for Air India flight AI-181/182 at Toronto.

2.1.4 The checking-in of passengers for Air India flight AI-181/182 at Toronto began at 1830 Z. The checking-in of the passengers was carried out by Air Canada personnel who are the handling agents for Air India, and was supervised by Air India personnel. The Air Canada personnel indicated the computer sequeritial numbers (security numbers) on the passenger boarding card stubs. At about 1930 Z announcement was made for the primary security check of passengers and their hand baggage. The passengers passed through the Door Frame Metal Detector and their hand baggage was checked through X-Ray machine. The passengers were also subjected to physical security check with the help of Hand Held Metal Detectors. The transit passengers to Montreal and their hand baggage were also subjected to these security checks, while their checked in baggage, after clearance by the Canadian Customers authorities was placed by the passengers themselves on the conveyor belt while they were still in sterile area. In this way there was personal identification by the passengers of all checked in baggage, except the baggage which had been interlined to this flight.

2.1.5 The flight was closed for check-in at about 2150 Z. There were 10 'NO SHOWS' and 4 'GO SHOWS'. The security checked passengers remained in the holding area gate No. 107 till boarding was announced at about 2210 Z. At the boarding gate secondary security check of the passengers and their hand baggages was carried out. The passengers were frisked with the help of Hand Held Metal Detectors and their hand baggages were opened and physically checked.

2.1.6 The security numbers on the stubs were circled on the pre-numbered Security Control Sheet to ensure that all the checked-in passengers have boarded the aircraft. Passenger boarding was completed by 2300 Z. Traffic/Sales representative of Air India verified the Security Control Sheet with the number of stubs collected and the number of passengers checked-in.

He found that all the 202 passengers, who had checked-in, had boarded the aircraft.

2.1.7 As stated earlier, 68 transit passengers had disembarked at Toronto for completing the customs and immigration checks. However, only 65 of these passengers re-boarded the aircraft as per transit cards collected at the boarding gate. It is in evidence that almost every flight of Air India to Canada, two or three transit passengers do not re-board the flight at Toronto. Some Toronto passengers travelling to India buy their tickets "Montreal-India-Montreal" instead of "Toronto-India-Toronto", for which the fare is higher, and they travel by bus to Montreal to catch the Air India flight to India. On their return journey, when they get down at Toronto for customs and immigration checks, they simply do not re-board the flight even though their reservations are upto Montrteal. These passengers sometimes inform Air India personnel at Toronto about their not re-boarding the aircraft. On 22nd June, 1985, however, no such passenger informed Air India personnel.

2.1.8 There was a crew change at Toronto. The flight and cabin crew members who took over the flight AI-181/182 had been laid over in Toronto for the week prior to the accident flight and were scheduled to take the flight upto London where they were to be relieved by another set of crew. Capt H.S.Narendra was the Commander of the flight, with Capt S.S.Bhinder as co-pilot and Mr.D.D.Dumasia as the Flight Engineer. In addition there were 19 cabin crew members. All the crew members reported together at the airport at 2130 Z. As per the practice existing at that time, the flight crew and cabin crew members were not subjected to frisking checks and their hand baggage were also not security checked. Their checked-in baggage was, howevewr, security

checked along with the other checked-in baggage of passengers.
2.1.9 The interline baggage was brought to the international baggage make-up area by the Air Canada staff but, as mentioned earlier, it was not personally identified and matched with the passengers.
2.1.10 The checked-in baggage of the originating passengetrs and crew members of AI-181/182 was sent on a conveyer belt to the baggage make-up area. All the checked-in baggage along with the interline baggage was required to be security checked on the X-ray machine which was located in the baggage make-up area at the end of international belt No.4.
2.1.11 It has been reported that the X-ray machine worked intermittently for some period and at about 2045Z it broke down and there was no picture on the screen. The Machine could not be repaired on that day as it was a week-end and no technician could be contacted. Air India's Security Officer then advised that the rest of the baggage be checked with a PD-4 explosive detector provided by him. He also demonstrated the use of the PD-4 detec- tor to the concerned personnel. It has been reported that about 60 to 70 baggages were checked and cleared by the PD-4 detector.
2.1.12 The security checked baggage was loaded in the containers by the Air Canada personnel. The loading of the baggage in containers was over by about 2230 Z. The ramp personnel of Air Canada carried the container and loaded them in the aircraft.
2.1.13 From March, 1985, after the introduction of Air India flight AI-181 through Toronto, diplomatic bags from Indian Consulate General at Vancouver were being sent to India by Air India flight from Toronto. Accordingly, two diplomatic bags, duly sealed and escorted, were delivered to Air Canada office at Vancouver on 21st June and they arrived at Toronto by Air Canada flight AC-580. One of the bags Sl.No. 49 contained 13 empty large diplomatic bags while the other bag Sl.No. 50 contained diplomatic mail. The total weight of the bags was 13.8 Kgs.
2.1.14 In addition to the above, a few envelopes containing some flight documents addressed to Accounts Office, Air India, Bombay, and

one envelope addressed to Commercial Headquarters, Air India, Bombay from Air India Town Office in Toronto, were collected by Messrs Mega International.

2.1.15 The aircraft was refueled by CAFAS with 14,602 litres of fuel.

2.1.16 On 8th June No. 1 engine of Air India Boeing 747 aircraft VT-EGC had failed during take off. The failed engine was to be ferried to Bombay on flight AI-181/182 of 22nd June.

2.1.17 The failed engine and the associated parts were placed in Air Canada Engineering Hangar at Toronto airport since June 8,when the aircraft was brought to the engineering hangar for engine replacement. Air India had requested Air Canada on 15th June for preparing the failed engine for installation as fifth pod mounting of the aircraft on 22nd June.

2.1.18 On 15th June Air India deputed one of their foremen to Toronto to bring back the failed engine. From 17th to 21st June, Air Canada technicians prepared the failed engine for installation as fifth pod. This preparation involved removal of cowlings, fan blades, locking of compressor rotors etc. Air Canada Engineering/Maintence personnel loaded the aircraft/engine parts on 4 pallets and one container. These pallets and container were then delivered at 0100 Z on 22nd June by Air Canada personnel to Messrs Mega International cargo warehouse at Toronto Airport within restricted airport area. (Messrs Mega International Cargo Warehouse at Toronto Airport within restricted airport area. (Messrs Mega International is the cargo handling agent of Air India at Toronto). The fifth pod engine was transported by Air Canada directly from their premises to the 'Kanishka' aircraft for mounting it on the fifth pod.

2.1.19 Installation of the engine on the fifth pod began immediately on arrival of flight AI-181 at Toronto on 22nd June and the work was completed by 1930 Z. One of the mechanics of Air Canada installed the Mach Air Speed Warning Switch in the Main Equipment Centre as part of the fifth pod engine installation.

2.1.20 The pre-loaded four pallets and one container were brought to the aircraft by M/s Mega International personnel from their warehouse in the afternoon of 22nd June for loading them into the aircraft cargo compartment at positions assigned by the Air Canada load agent. Difficulty was experienced while loading one of the pallets having inlet cowl of the pod engine. To enable loading of the cowl, Air Canada engineering/maintenance personnel removed door stop fitting from the aft cargo compartment door cut-out. After removal of the fittings, the cowl could be loaded. All the removed fittings were then reinstalled.

2.1.21. On account of the delay in loading the cowls, departure of the flight was delayed by one hour and twentyfive minutes.

2.1.22 Maintenance Manager of Air India, Montreal carried out the Terminal Transit Check 'E' of the aircraft and no snag was observed by him. The commander duly accepted the aircraft.

2.1.23 Senior Flight Despatcher, Air India, Toronto did the flight despatch of AI-181/182 for sectors Toronto-Montreal-London. He briefed the flight crew members about flight plan, weather, Air Traffic Control and fuel requirements. The flight plans for the sectors Toronto-Montreal-London were duly accepted and signed by the Commander.

2.2 Progress of the Flight

2.2.1. The Aircraft took off from Toronto Runway 24L at 0016 Z on 23rd June, 1985. The Maintenance Manager, Security Officer and Passenger Service Supervisor of Air India travelled on board the aircraft for their duties at Montreal. In all there were 270 passengers on board in addition to 22 crew members.

2.2.2. The route from Toironto to Montreal was V-98/JHL-594/MSS/ V 203/FRANX at flight level 290. The flight was uneventful and the aircraft landed at Montreal at 0110 Z. No snag was reported by the flight crew. The aircraft was parked at Cluster 1 Bay No.114.

2.2.3 Sixtyfive passengers destined to Montreal along with the three Air India personnel mentioned above deplaned at Montreal. The remaining 202 passengers, who had joined the flight at Toronto, remained on board the aircraft as transit passengers were not allowed to disembark at Montreal.

2.2.4 Baggage handlers off loaded three containers of baggage, one valuable container and four cargo containers from the aircraft.

2.2.5 Transit Check 'C' of the aircraft was carried out at Montreal. The Flight Engineer also carried out his pre-flight inspection and found that rear latch handle of the fifth pod engine fan cowl was loose. He informed the same to an Air Canada Technician who flaired the handle and applied the high speed tape. There was no other snag observed during the inspection. The personnel of CAFAS refueled the aircraft with 96,000 litres of fuel. Total fuel on board at the time of take off from Montreal was 104,000 Kgs. which was adequate for 8 hours 40 minutes of flying. The commander accepted the aircraft and signed the 'Certificate of Acceptance' of the aircraft.

2.2.6 At approximately 2130 Z Air Canada personnel opened the passenger check-in counter for flight AI-182 (The flight AI-181 terminates at Montreal and the flight from Montreal to London-Delhi-Bombay is designated as AI-182). The checked-in baggage was sent to the baggage make-up area. Between 2300-2350 Z, a suspect suitcase was identified as the X-Ray showed what appeared to be some wires next to the suitcase opening. The suitcase was placed on the floor next to the X-Ray machine. Subsequently two more suspect suitcases were located. These suitcases were also placed next to the X-Ray machine to await the arrival of the Air India Security Officer who was to arrive on Air India flight AI-181 from Toronto. The remainder of the checked-in baggage, which cleared the security check, was loaded in containers by Air Canada personnel for loading on board the aircraft.

2.2.7 Two diplomatic pouches from the Indian High Commission, Ottawa were brought to Mirabel. After the flight arrived, one of the pouches of Category 'A' weighing 1 Kg. was given to the Flight Purser. The other Category 'B' pouch weighing 9 Kgs. was placed in an valuable container 14R.

2.2.8 No other cargo was accepted for this flight except a small package (weighing less than 1 Kg) containing medicines for cancer treatment of a patient in New Delhi. This parcel was received at 1530 Z on 21st June and was loaded in container 14R by Messrs Mega International on 22nd June, more than 24 hours after its receipt.

2.2.9 Five baggage containers, one valuables container and two empty containers were loaded in the aircraft.

2.2.10 The checked-in passengers with their hand baggage went to the departure sterile area. At the entrance to the departure sterile area security staff used X-Ray units and metal detectors to check passengers and their hand baggages.

2.2.11. At approximately 0100 Z, 23rd June, after the primary security check was completed, the passengers proceeded to boarding gate No.80. At this lcoation the secondary security check was done on passengers using hand held metal detectors. Hand baggages were also subjected to further physical and visual check by them.

2.2.12. A total of 105 passengers boarded the flight AI-182 at Mirabel Airport. It was determined that all the passengers who had checked-in, boarded the aircraft. There was no interline passenger. At Montreal there were five 'NO SHOWS' and two 'GO SHOWS'. In all 307 passengers were on board the aircraft. The flight plan and the load and trim sheet, however, indicated 303 passengers as four of the 6 infants were not included in the passenger list.

2.2.13. The seating distribution of the passengers was as given below:-

Zone/Class	Total number of Seats	Occupied seats
Zone 'A' - First Class	16	1
Zone 'B'- Club Class	22	-
Upper deck - Club class	18	7
Zone 'C' - Economy Class	112	104+ 2
Zone 'D' - Economy Class	86	84+ 1
Zone 'E' - Economy Class	123	105+ 3
	377	301+ 6 (Infants)

2.2.14 The seating distribution of the 19 cabin crew members was as follows:-

Two at door L1 and two at door R1
Two at door L2 and two at door R2
Two at door L3 and one at door R3
Two at door L4 and one at door R4
One at door L5 and one at door R5
One in crew rest area, Zone 'A'

One in jump seat upper deck
One crew rest area upper deck.

2.2.15 The three suspected suit cases were not loaded on the aircraft and were detained in the baggage make-up room. After the names of the passengers to whom the suit cases had belonged had been identified the same were transferred to the decompression chamber of E1 A1 Airline where they were examined, with the aid of a Police Explosive Dog, with negative results. The suit cases were kept overnight in the said chamber and when they were opened it was found that they contained no explosive items.

2.2.16. No unclaimed baggage pertaining to the Air India flight was recovered either at Toronto or at Mirabel or Dorval Airport in Montreal.

2.2.17. The flight plan for the sector Montreal to London was filed on telephone by the Air India Flight despatch from Toronto to Dorval ATC Centre. He requested for route SHERBROOKE-COLOR-NAT XRAYBUNTY-MERLY-EXMOR-IBLEY-SAMTN-HAZEL-OCKHAM-LONDON at flight level 290 upto COLOR and flight level 330 thereafter. The reporting points on Track XRAY on that day were COLOR, 47N/50W, 49N/40W, 50N/30W, 51N/20W, 51N/15W, 51N/08W and BUNTY.

2.2.18 The aircraft took off from Montreal at 0218 Z. Its estimated time of arrival at London was 0833 Z. The CVR and the ATC tapes show that the flight was normal and quite uneventful. Suddenly at about 0714 Z, when the flight was being monitored by the Air Traffic Controller at Shannon, with the help of secondary surveillance radar, the aircraft disappeared from the radar scope. Subsequently, the ATC at Shannon got the know that the aircraft had met with an accident and its wreckage was sighted about 110 miles west south-west of Cork, Ireland.

PERSONNEL INFORMATION

2.3.1 Pilot-in-Command (Capt. H.S. Narendra)

2.3.1.1 Cap.t H.S. Narendra (age 561/2 years, date of birth 25th November, 1928) joined Air India on 1st October, 1956. He held ALTP Licence No. 247 valid upto 29th October, 1985 and FRTO No. 478 valid upto 23rd October, 1985. He was released as a Co-pilot on Boeing 707 aircraft on 21st July, 1960 and as a Commander on Boeing 707 aircraft on 17th September, 1964.

2.3.1.2 For conversion as Pilot-in-Command on Boeing 747 aircraft, Capt. Narendra had undergone ground training at Boeing Airplane Company, USA and simulator and aircraft flying training at Bombay in 1972. He completed his route checks for Pilot-in-Command endorsement between December, 72 and January, 73. He became a Commander on Boeing 747 aircraft on 14th February, 1973.

2.3.1.3 Details of Capt. Narendra's flying experience and licence renewal checks are as given below:

a. Total flying experience : 20, 379:15 hours

b. Flying experience on B-747 as

(i) Pilot-in-Command : 6,364.50 hours

(ii) Co-pilot : 123:45 hours

c. Day flying experience
on B-747 aircraft : 3,980:00 hours

d. Night flying experience
on B-747 aircraft : 2,508:35 hours

e. Flying experience during

(i) last 6 months : 301:45 hours

(ii) last 3 months : 159:40 hours

(iii) last 30 days : 68:45 hours

(iv) last 7 days : 9:00 hours

He had last flown as Pilot-in-Command on flight AI 181 (Frank- furt to Toronto) on 15th June, 1985.

f. Date of last licence
renewal and IR check : 8 May, 1985

g. Date of last route check : 24 March, 1985

h. Date of last medical
examination at CME,
Delhi : 29 April, 1985

i. Date of last simulator
refresher course : 19 December, 1984

j. Date of ground technical

refresher course : 6/7 May, 1985
k. Date of last flight
safety refresher course : 25 July, 1984
l. Rest period before
operating the accident
flight : 1 week

2.3.1.4 Records indicate that on 29th June, 1966, Captain Narendra was declared medically unfit for 2 months to reduce his weight by 10 Lbs. In February, 1973 he was advised to wear corrective by-focal glasses while flying. In May, 1975 he was again declared medically unfit for 3 months.

2.3.1.5 Capt. Narendra was earlier involved in the following two incidents:

(a) On 25th August, 1984, while operating flight AI-1100 from London to Delhi, there was a deviation of the aircraft by about 170 nautical miles from the track over Rahimyar Khan in Pakistan. He was given necessary INS refresher and Route checks with particular emphasis on cross checking procedure.

(b) On 6th December, 1984, while operating flight AI-124 Delhi-Bombay, the aircraft was observed approaching runway 32 at Bombay Airport when runway in use was 27. Captain Narendra was given simulator training for a series of approaches and landings and visual circuits from right hand and left hands seats for approaches and landings on runway 27 at Bombay Airport.

2.3.1.6 Captain Narendra was not involved in any accident previously.

2.3.2 Co-pilot (Capt. S.S. Bhinder)

2.3.2.1 Capt. S.S. Bhinder (age 411/2 years, date of birth 30th November, 1943) joined Air India on 12th October, 1977. He held ALTP Licence
No. 940 valid upto 25th July, 1985 and FRTO Licence No. 2290 valid upto 2nd February, 1986.

2.3.2.2 Capt. Bhinder was released as a Co-pilot on Boeing 707 aircraft on 18th November, 1978 and as a Co-pilot on Boeing 747 aircraft on

17th May, 1980.

2.3.2.3 Details of his flying experience and licence renewal checks are as given below:

a. Total flying experience : 7,489:00 hours

b. Experience on B-747 aircraft as Co-pilot : 2,469:30 hours

c. Day flying experience on B-747 aircraft : 1,426:15 hours

d. Night flying experience on B-747 aircraft : 1,043:15 hours

e. Flying experience during

(i) last 6 months : 157:45 hours

(ii) last 3 months : 65:00 hours

(iii) last 30 days : 20:15 hours

(iv) last 7 days : 9:00 hours

He had last flown as Co-pilot on flight AI-181 (Frankfurt to Toronto) on 15th June, 1985).

f. Date of last licence renewal check : 25th March, 1985

g. Date of last IR check : 23rd November, 1984

h. Date of last route check : 9 April, 1985

i. Date of last medical examination at CME Delhi : 14 January, 1985

j. Date of last simulator refresher course : 16 July, 1984

k. Date of last ground technical refresher course : 8/9 October, 1984

l. Date of last flight safety refresher course : 3 December, 1984

m. Rest period before operating the accident flight : 1 week.

2.3.2.4 Records indicate that Capt. Bhinder was not involved in any accident earlier.

2.3.3 Flight Engineer (Mr. D.D. Dumasia)

2.3.3.1 Flight Engineer Mr. D.D. Dumasia (age 57 1/2 years, date of birth 10th October, 1927) joined Air India on 27th December 1954. He held flight Engineer's Licence No. 37 valid upto 6th December, 1985. Mr. Dumasia was released as a Flight Engineer on Boeing 707 airecaft on 16th December, 1963 and on Boeing 747 aircraft on 6th February, 1974. He had a total flying experience of 14,885 hours out of which 5,512:35 hours were on Boeing 747 aircraft.

2.3.3.2 Last medical examination of Mr. Dumasia was completed on 1st October, 1984 at CME Delhi. He had completed simulator refresher course on 14th February, 1985, ground technical refresher course on 14/15th January, 1985 and flight safety refresher course on 13th August, 1984.

2.3.4 Cabin Crew

2.3.4.1 A total of 19 cabin crew members were on duty on Flight AI-181/182 on 23rd June, 1985. Their brief details are as given below:

Sl.No. Names Designation Flight Safety course completed on 1. Mr. S.L. Lazar Inflight Supervisor 1/2 April, 1985 2. Mr. K.M. Thakur Flight Purser 18 February, 1985 3. Mr. Inder Thakur Flight Purser 9/10 May, 1984 4. Mr. Shukla Flight Purser 23 January, 1985 5. Mr. S.P. Singh Flight Purser 15 January, 1985 6. Mr. N. Vaid Asst. Flight Purser 2/3 May, 1985 7. Mr. B.K. Sena Asst. Flight Purser 3 December, 1984 8. Mr. N. Kashipri Asst. Flight Purser 12/13 Sept., 1984 9. Mr. J.S. Dinshaw Asst. Flight Purser 17/18 Dec., 1984 10. Mr. K.K. Seth Asst. Flight Purser 11/12 February, 1985

11. Miss Raghavan Airhostess 13 July, 1984 12. Miss S. Ghatge Airhostess 10/11 April, 1985 13. Miss R. Bhasin Airhostess 11/12 February, 1985 14. Miss L. Kaj Airhostess 17/18 April, 1985 15. Miss P. Dinshaw Airhostess 17/18 Dec., 1984 16. Miss S. Lasarado Airhostess 15/16 April, 1985 17. Miss E.S. Rodricks Airhostess 10/11 June, 1985 18. Miss S. Gaonkar Airhostess 3/4 April, 1985 19. Miss R.R. Phansekar Airhostess 29/30 April, 1985 AIRCRAFT INFORMATION

2.4.1 General

2.4.1.1. Boeing 747-237B 'Kanishka' aircraft VT-EFO was manufactured by Messrs Boeing Company under Sl.No. 21473. The aircraft was acquired by Air India on 19th June, 1978. Initially, it came with the expert Certificate of Airworthiness No. E-161805. Subsequently, the Certificate of Airworthiness No. 1708 was issued by the Director General of Civil Aviation, India on 5th July, 1978. The C of A was renewed periodically and was valid upto 29th June, 1985. From the beginning of June, 1985, C of A renewal work of the aircraft was in progress. The aircraft had the Certificate of Registration No. 2179 issued by the DGCA on 5th May, 1978. The commercial flight of 'Kanishka' aircraft started on 7th July, 1978.

2.4.1.2 The aircraft was maintained by Air India following the approved maintenance schedules. It had logged 23634:49 hours and had completed 7525 cycles till the time of accident.

2.4.1.3 The aircraft was fitted with four P & W JT9D-7J engines having thrust rating of 48650 pounds. The hours and cycles logged by the engines since new till the time of accident are as given below:

Engine No.1 : P662927-7J - 29,663:26 Hrs (9422 cycles)
Engine No.2 : P695610-7J - 20,810:28 Hrs (6031 cycles)
Engine No.3 : P695602-7J - 21,992:31 Hrs (6564 cycles)
Engine No.4 : P662926-7J - 32,332:15 Hrs (11295 cycles)

2.4.1.4 All the DGCA mandatory modifications and inspections applicable to the subject aircraft had been compiled with. No major component installed on this aircraft and its engines had exceeded the stipulated life period.

2.4.1.5 The last quarter Periodic Check of the aircraft was carried out on 24th May, 1985, at 23274:53 hours and 7439 cycles. Subsequent to this check, two Check 'B' schedules were carried out. The last Check 'B' was carried out on 17th June, 1985, at 23564:14 hours and 7510 cycles and was valid for 200 flying hours.

2.4.1.6 The aircraft had flown 359:56 hours and 86 cycles since last quarter Periodic Check and 70:35 hours and 15 cycles since last Check 'B' till the time of accident.

2.4.1.7 The last Flight Release Certificate was issued on 24th May, 1985 on completion of quarter Periodic Check and was valid for 1100 hours or 150 days elapsed time whichever occurred first. After the last departure from Bombay on 21st June, 1985, the aircraft had flown for 22:34 hours till the time of crash.

2.4.1.8 Mr. Rajendra, Maintenanace Manager, Air India, Montreal carried out the Terminal Transit Check 'E' of the aircraft at Toronto on 22nd June, 1985 and no snag was observed by him. No snag was reported by the flight crew during the flight from Toronto to Montreal. Transit Check 'C' of the aircraft for the flight AI-182 was carried out at Montreal by Mr. Rajendra and three Air Canada technicians. The flight engineer also carried out his pre-flight inspection and found that the rear latch handle of the fifth pod engine fan cowl was loose. He informed the same to Mr. P. Bayle, Air Canada technician who faired the handle and applied high speed tape. No other snag was observed during the inspection.

2.4.2 Previous Incidents and Snags

2.4.2.1 A maintenance Group was formed with representatives from Air India and Airworthiness Directorate with Mr. R.K. Paul, Senior Air Safety Officer as the Group Leader to scrutinise the maintenance documents and various defects experienced on this aircraft. The report submitted by the Group (Attachment 'B') indicates that the aircraft was involved in six incidents since the last C of A renewal, details of which are given below

(I) On 13th July, 1984 at Dubai -- flight AI-868 The aircraft returned after aborting take off due to no rise in the EPR and N1 on No.1 engine (Sl.No. 695612). The engine front and rear were checked and found OK. Slight wetness was noticed in the bleed outlets. No external oil leak was noticed. Oil quantity was topped up. The chip detectors and oil filter were found OK. EVC Ph filter was found

OK. EVC linkage wes exercised. The engine was run up and its operation was found satisfactory. The snag was suspected to be due to lack of pressurising air at low N1.

(ii) On 18th July, 1984 at Delhi -- flight AI-105 The right hand side fuselage skin between stations 480 and 500 in line with lower portion of forward cargo door cut-out was damaged by high lift. The same was repaired at Delhi. Permanent repair was carried out at Bombay. The repairs were accomplished using guidelines given in the Boeing Structural Repair Manual.

(iii) On 12th August, 1984, at Rome -- flight AI-135 The aircraft landed with No. 2 engine (Sl.No. 662826) shut down in flight due to oil pressure and oil quantity droping. On motoring the engine, oil leak was observed from metal line between F C O C and L O P switch at the switch end. The line was found cracked which was welded and refitted. The line was subsequently replaced at Bombay.

(iv) On 24th October, 1984, at London -- flight AI-104 There was total loss of No.1 hydraulic system fluid. The fluid leak was traced to inlet pressure adapter of flap control module in the left hand body gear wheel well. Two of the four bolts holding the adaptor on the flap control module had sheared. The hydraulic pump, seal, back-up ring and case drain filter were replaced. The flap control module was replaced when the aircraft arrived at Bombay.

(v) On 14th February, 1985, at Delhi -- flight AI-164 On arrival the leading edge honey comb of the left hand aft trailing edge flap was found damaged about 18 inches in length due foreign object damage. Necessary repair was carried out at Delhi. The aft flap was replaced at Bombay.

(vi) On 28th May, 1985, at Dubai -- flight AI-103 On arrival, the left hand wing to fuselage botton fairing forward rubber seal with strip was found turn off. Temporary repair was carried out at Dubai. Permanent repair was carried out subsequently at Bombay.

2.4.2.2 The flight snags recorded in the flight report books of the aircraft during the 4 1/2 month period prior to the accident were scrutinised by the Maintenance Group and the only significant repetitive defect observed was "R2 door not going to manual". On ground checks by the aircraft maintenance engineers, the operation of the selector was, however, found normal.

2.4.2.3 Prior to operating the accident flight, the aircraft arrived at

Toronto from Frankfurt. Capt. R.K. Spencer was the commander of the flight. The flight crew had reported the following three snags:

(I) HF system No. 2 had a lot of distortion

(ii) E P R L indicator unserviceable in 'Go around' mode

(iii) Hydraulic system No.1 pressure indication unserviceable (This snag was carried forward from Delhi).

2.4.2.4 The Auxiliary Power Unit (APU) was unserviceable ex-Bombay and had been released under M E L.

2.4.2.5 For rectification of the above stated snag No.1, Shri Rajendra, Air India's Maintenance Engineer at Totonto checked the connections of the transreceiver and reracked the unit. No snag was reported on this system on Toronto-Montreal sector.

2.4.2.6 Snag No. 2 was carried forward.

2.4.2.7 Regarding the third snag, Mr. Rajendra has stated that the indicator showed 4000 P S I pressure even with no pump running. He therefore, interchanged No.1 and No.3 indicators. The snag, however, persisted. He then replaced transmitter No.1 with a spare transmitter from the aircraft SE box and the snag was rectified. No rectification work was however, recorded by the AME in the Flight Report Book. No snag was reported on this system on Toronto-Montreal sector.

2.4.3 Installation of 5th Pod Engine

2.4.3.1 On 8th June, 1985, No.1 engine of Air India Boeing 747 aircraft VT-EGC operating flight AI-181 failed during take off at Toronto. The aircraft returned and the engine was replaced by a loaned engine from Air Canada. The removed engine was a P & W JT9D-7Q type (Sl. No. P702353-7Q).

2.4.3.2 Air India had planned to bring back the failed engine of VT-EGC aircraft to Bombay, as fifth pod on their flight AI-181/182 of 22/23 June, 1985 and had sent an Engineer along with the necessary kit to Toronto on 15th June, 1985. The engine borrowed from Air Canada on 8th June, 1985, was flown back to Toronto as a fifth pod engine on flight AI-181 of 22nd June, to return it to Air Canada.

2.4.3.3 Shri C.D. Kolhe, Controller of Airworthiness, Bombay examined the aspects relating to installation of the 5th Pod engine, loading of its components and certification of the related work. Shri Kolhe's report indicates that the failed engine and the associated parts were kept in the Air Canada engineering hanger at Toronto airport since June 8 when the aircraft was brought to the hanger for engine replacement. Air India requested Air Canada on 15th June, 1985, for prepairing the failed engine for installation as fifth pod engine on 22nd June. Accordingly, Air Canada's technicians undertook the preparatory work of removing the cowlings, fan blades, panels, locking of compressor, turbine rotors etc. on 17th June, 1985, and completed the work on 21st June, 1985. The fan blades (46 in number) from the failed engine were placed in 12 wooden shipping boxes provided by Air India. These boxes were then loaded in a container. The other components of the failed engine were loaded on 4 pallets.

2.4.3.4 Installation of the fith pod engine was carried out by Air Canada technicians and the individual items on the task card were certified by the individuals who had carried out the work.

2.4.3.5 Some difficulty was experienced while loading one of the pallets having inlet cowl of the pod engine. To enable loading of the cowl, Air Canada engineering/maintenance personnel removed door stop fittings from the aft cargo compartment door cut-out. After removal of the fittings, the pallet could be loaded. All the removed fittings were then re-installed. Removal and installation of the fittings was certified by Mr. Rajendra.

2.4.3.6 A question arose whether removal of the door stop fittings could have caused some difficulty in flight. From the video films of the werckage it was found that the complete aft cargo door was intact and in its position except that it had come adrift slightly. The door was found latched at the bottom. The door was found lying along with the wreckage of the aft portion of the aircraft. This indicates that the door remained in position and did not cause any problem in flight. In the front cargo compartment, there were 16 containers out of which four were empty. Five containers had baggage of Delhi bound passengers. Container at Position 13L had baggage of the first class and London passengers and container at position 13R had crew baggage. The entire baggage of passengers ex-Montreal was loaded in containers at positions 12R, 21R, 22R, 23R and 24R in the front cargo compartment. Container at position 24L contained fan blades in wooden boxes and the other components of the pod engine. Valuable container was at position 14R.

2.4.3.7 In the aft cargo compartment, there were four pallets containing parts of the fifth pod engine and two containers at positions 44L and 44R containing baggage of Delhi bound passengers. The bulk cargo compartment contained passenger baggage bound for Delhi and Bombay. All the baggage and engine parts in the aft and bulk cargo compartments were loaded at Toronto.

2.4.3.8 The total weight of the fifth pod engine and its items was about 9000 kgs. As a result of carriage of the fifth pod engine, the payload of the flight was considerably reduced on London-Delhi sector.

2.4.3.9 At the time of take off from Montreal the aircraft had 104,000 kgs of fuel on board which was adequate for 08:40 hours of flying as against sector flying time of 06:15 hours. The flight plan fuel was calculated taking Paris as the alternate airport for London.

2.4.3.10 The load and trim sheet from the sector Montreal London was prepared and was duly counter-signed by the commander. The take off weight of the aircraft was 317,877 kgs which was within the maximum take off weight limit of 334,500 kgs. The estimated landing weight of the aircraft was 237,177 kgs which was also within the maximum landing weight limit of 256,279 kgs. The centre of gravity of the aircraft was at 21.3 percent

of MAC at take off and the estimated C G position at the time of landing at London was 25.8 percent of MAC which was within the limits.

2.4.3.11 The load and trim sheet and the flight plan of the aircraft indicated that there was 301+2 passengers on board the aircraft whereas there were actually 301+6 passengers on board. The error occured because four of the six infants were not taken into account.

2.4.4 Corrosion Control Measures

2.4.4.1 Boeing Company have recommended various measure to control corrosion on Boeing 747 aircraft through different documents such as Maintenance Planning Data Document, Corrosion Prevention Manual and Service Bulletins. Compliance of these measures on Air India fleet is accomplished as follows:

(I) Support structure under galleys and lavatories

Boeing Company have recommended repeat inspections of under galley/ toilet structure at intervals of 12000 hours. However, in order to detect corrosion at an early stage, these inspections are carried out by Air India at intervals not exceeding 9000 hours.

(ii) Fuselage Lower Bilge Area:

Boeing Company have recommended modifications to provide improved drainage systems by incorporation of various Service Bulletins. All the relevant modification have been completed by Air India on the affected aircraft. In addition to completion of these modifications, repeat inspection of lower bilge area is being carried out to meet the requirements of Boeing Service Bulletins.

(iii) Canted Pressure Deck:

In order to prevent water accomulation and consequent corrosion in the area, Boeing Company have issued SBs 51-2015, 51-2026 and 51-2032. Air India have incorporated Service Bulletins 51-2015, and 51-2032 on all their affected airplanes SB 51-2026 is being complied progressively.

(iv) Cargo Compartments:

Inspection of all the cargo compartment interior structures for corrosion and cracks is being accomplished periodically by Air India after removal of linings and insulation blankets.

(v) Aft Pressure Bulkhead:

During every equalised Periodic Check routine, the aft surface of aft pressure bulkhead is being visually inspected for corrosion condition and security of attachements. The forward surface of the pressure bulkhead, which is covered by aft toilets, is inspected after removal of toilets at intervals not exceeding 9000 hours although the recommended interval by Boeing Company is 12000 hours.

2.4.4.2 Air India has stated that in addition to the above specific measures, aircraft structure particularly the areas below toilets, galleys, cargo compartments, outflow valve area etc. which are prone to corrosion, are inspected for corrosion, cleaned and protected during every equalised Periodic Check. Air India have further stated that no serious corrosion problem has been experienced by them so far on their fleet.

2.4.5 Supplemental Structural Inspection Programme

2.4.5.1 In the case of airplanes which have completed 10,000 flight cycles as on June 30, 1983, Federal Aviation Administration (FAA) U S A and Boeing Company had recommended additional structural inspections known as Supplemental Structural Inspection Programme. In the Air India fleet, the first three 747 aircraft, namely, VT-EBE, VT-EBN and VT-EBO fell in this category and are known as 'Candidate Airplanes'. The subject aircraft (VT-EFO) had completed only 7525 flight cycles at the time of the accident on 23rd June, 1985, and therefore, the Supplemental Structural Inspection Programme was not applicable to this aircraft.

2.4.6 Special Corrosion Inspection of B-747 Aircraft Fleet of Air India

2.4.6.1 In order to examine whether corrosion to the aircraft structure of Kanishka aircraft could have contributed to the accident, a group was constituted by Mr. H.S. Khola, Inspector of Accidents to carry out special corrosion Inspection of all the Boeing 747 aircraft of Air India.

The group consisted of the following members:

(a) Senior Air Safety Officer of the D.G.C.A.

(b) Senior Airworthiness Officer of the D.G.C.A.

(c) Air India's Representative.

2.4.6.2 The inspection was carried out in the following areas:

(a) Below toilets and galleys

(b) Forward and aft cargo compartments belly areas - internally and externally

(c) The forward and aft pressure bulkheads

(d) Canted pressure web area from inside the passenger cabin.

(e) Area around outflow valves

(f) MEC area inside and outside.

2.4.6.3 The inspection reports submitted by the Group show that no corrosion was noticed on the significant primary structural members of the aircraft. Surface corrosion was, however, noticed on some of the members below the toilets and galleys. The corrosion observed during the inspection was of minor nature which is normally expected on such inspection schedule. The Kanishka aircraft was subjected to Periodic Check on 24th May, 1985 at 23,274.53 hours/7,439 cycles and no significant corrosion was observed. Among the Nine 747 aircraft inspected for corrosion, 5 aircraft had logged hours more than the Kanishka aircraft. Three of the aircraft had actually logged nearly double the flying hours. Taking into consideration that the corrosion prevention measures recommended by the Boeing Company were followed by Air India and that even the high life aircraft (45,000 hours approximately) subjected to corrosion inspection at the time when Periodic Check was due i.e. 1100 hours since previous check, had no significant corrosion, it is considered unlikely that Kanishka aircraft, which had logged only 23,275 hours since new and 360 hours since last Periodic Check, had corrosion which could have contributed to the accident.

METEOROLOGICAL INFORMATION

2.5.1 A report on the Meteorological conditions prevailing en-route near the location where the aircraft crashed was provided by the Meteorological Service, Department of Communications, Dublin, Ireland. This report covers a period of one to two hours before and after the time of accident (0714 Z).

2.5.2 From the report it is seen that the surface Synoptic Situation in the vicinity of 51°N, 12.50°W at 0715 Z on 23rd June was as given below:

Surface wind : 250/15 knots

Surface visibility : 10 Kms (occasionally 4 kms in drizzle)

Surface temperature : 13°C

Cloud conditions : Cloud cover in the area was estimated to have been layered upto about FL 100 with a base of 600 feet. There is no evidence of cumulonimbus or thunderstorm activity.

Freezing Level : 700 feet.

2.5.3 With regard to Upper Air situation the report indicates that a mainly West or West North West airflow covered the area of FL 310 The Jet stream was centred at about 48°N. The estimated wind and temperature at FL 310 were 270/65 knots and -47°C. As per the report, at FL 310, 51°N 12.50°W and at 0715 Z any significant clear air turbulence was not expected.

2.5.4 Sunlight condition was prevailing at the time of accident. There were no sigmets valid for the area at that time.

AIDS TO NAVIGATION

2.6.1 The aircraft was equipped with Inertial Navigation System (INS) and was cruising normally at its assigned flight level 310 on track X-ray over Atlantic. It was under the control of Shannon Upper Area Control and was being monitored on the Secondary Surveillance Radar (SSR) located at Mount Gabreal. Till the time of accident, the aircraft was beyond the range of Shannon primary radar.

2.6.2 The aircraft entered Shannon airspace at the correct position and level and remained on the assigned track and flight level till it disappeared from the radar screen.

2.6.3. There is no evidence to indicate that AI-182 experienced any navigational problem during the flight.

COMMUNICATIONS

2.7.1 Two-way communication between the ill-fated aircraft and the ATS units of Canada and Ireland was maintained during the flight from Montreal till the time of crash. The communications were recorded on the ATC tapes. Transcripts of the relevant tapes were provided by the Canadian Aviation Safety Board and the Director of Air Traffic Services, Ireland.

2.7.2 From the Transcript of the conversations, it is observed that two-way communication between AI-182 and the various ATS units was normal. The last R/T contact with the aircraft was at 0709:58 Z when AI-182 informed Shannon UAC that it was squawking 2005. The tape transcript also shows that the aircraft did not transmit any information regarding the emergency on frequency 131.15 MHz on which it was last working with Shannon UAC or on distress frequency 121.5 MHz. Indecipheiable noise was, however, found recorded on the Shannon ATC tape just at the time of crash i.e. 0714:01 Z. Thereafter, repeated calls were made by Shannon UAC to AI-182, but there was no response.

SEARCH AND RESCUE

2.8.1 The report of the Search and Rescue Group gives the details of the Search and Rescue operations. From the report it is seen that at 0730 Z, Shannon UAC informed Marine Rescue Co-ordination centre (MRCC) shannon that AI-182, a Boeing 747 aircraft enroute Montreal-London had disappeared from the Secondary Surveillance Radar (SSR) at 0713 Z in position 51N/120W. Shannon UAC requested MRCC Shannon to take emergency section. At 0740 Z MRCC Shannon telephonically explained the situation to Valantia Coast Radio Station (CRS) and requested a PAN Broadcast urgently and to ask any vessels in area to keep sharp lookout and report to Valantia Radio. At 0746 Z Valantia Radio transmitted to all stations PAN message and above advice to ships. The transmission was repeated.

2.8.2 At 0750 Z, an Irish Naval Vessel AISLING reported on R/T to Valantia Radio that it was 54 miles from site of accident and was proceeding to the site. Valantia Radio passed on this information by Telex to MRCC Shannon. Between 0740/ 0750 Z MRCC briefed the Irish Naval Service (INS) Haulbowline, MRCC Swansea, RCC Plymouth and Irish Army Air Corps (IAAC) on the situation. At 0754 Z MRCC relayed a distress message to Shannon Aeradio via the Aeronautical Fixed Telecommunication Network (AFTN)

2.8.3 At 0803 Z Valantia Radio again transmitted the PAN message and the advice to ships. At 0840 Z Cargo vessel M W Laurentian Forest/ HBWP (Registered in PANAMA and owned by Federal Commerce of Montreal, Canada) at position 51.09N/12.18W reported that it was 22 miles away from distress area and was proceeding there. Laurantian enquired if there were other ships in the area and was informed about position of Aisling. At 0813 Z Valantia Radio informed MRCC Shannon by telex about Laurentain Forest.

2.8.4 Between 0815/0820 Z, MRCC Shannon updated RCC plymouth and they advised that a Nimrod Rescue Aircraft would depart shortly for the area and that SEA KING helicopters were already enroute the Cork Airport initially. Edinburgh RCC advised MRCC Shannon that a Nimrod Rescue Aircraft was also being prepared at Kinloss. At 0820 Shannon Aeradio informed Valantia Radio that there was message from Shanwick Oceanic Control that aircraft were picking up ELT signal in position 51N/15W and 51N/08W and the actual position was beleived to be 51W/1250W. At 0833 Z, Valentia Radio sent message giving the above information and requesting ships in the area to report to Valentia Radio.

2.8.5 At 0842 Z, Ali Baba informed Valentia Radio that it was at position 5125.5N/0825.4W and was listening on 121.5 MHz. At 0850 Z Western Arctic informed Valentia Radio its position 5207N/1151W and that it would proceed in about 20 minutes after bringing in cable. At 0857 Z, High Seas Driller informed Valentia Radio that Vessel Kongstain could be released, ETA 51/2 to 6 hours and they would standby. At 0858 Z, Valentia Radio informed MRCC Shannon about reports from Ali Baba Western Arctic and High Seas Driller.

2.8.6 At 0905 Z, Laurentian forest reported to Valdentia Radio that it was 5 miles from SOS position 51N/12.5 W and it had not sighted anything. Between 0905/0908 Z, three more vessels viz. Atlantic Concern, MV Norman Amstel and MV Tasman reported their positions to Valentia Radio. At 0908 Z, Swansea advised MRCC Shannon that four Seaking helicopters and two Nimrod Aircraft were enroute.

2.8.7 At 0913 Z, Laurentin Forest reported to Valentia Radio that they had sighted what looked like 2 rafts about 2 miles away. At 0914 Valentia Radio informed MRCC Shannon about the report from Laurentian Forest.

2.8.8 At 0918 Z, Laurentian Forest reported to Valentia Radio that it had sighted wreckage in water at position 5101.9N/1242.5W and the liferafts were not inflated. Valentia Radio passed the message to MRCC Shannon at 0920 and also sent transmission about wreckage sighting. Lifeboats Valentia and Baltimore reported to Valentia Radio that they were proceeding to the position of wreckage.

2.8.9 At 0937 Z, Laurentian Forest reported that it had sighted 3 bodies in water. Valentia Radio informed the same to MRCC Shannon at 0940 Z. At 0945 Z, MRCC Shannon and MRCC Swansea decided that for security and operational reasons Cork Airport would be the primary operational base and ATC Cork were informed of this decision.

2.8.10 At 0953 Z, S MYROLI informed Valentia Radio that it was 80 miles north of position and had a group of 10 to 20 French vessesls and desired to know if they should proceed to site. After consulting Laurentian Forest, S MYROLI was advised that it was not necessary. Valentia Radio kept on giving Mayday relay frequently.

2.8.11 At 1045 Z, a prohibited flying area was established with a radius of 40 N Miles from the datum point from sea level to 5000 feet. Falmouth Coast Guard reqested Valentia Radio the position of all ships in the distress area and those proceeding so that each vessel could be designated to search a particular area.

2.8.12 At 1126 Z, Laurentian Forest reported Valentia Radio that it had located numerous bodies in water and Seaking helicopter was hovering there. Valantia Radio Transmitted this information to all stations.

2.8.13 At 1133 Z, Valentia Radio informed Coast Guard Falmouth the position and ETA of various ships and also of the Lifeabouts Valentia and Beltimore. At 1150 Z, RRC Plymouth requested MRCC Shannon that "Le Aisling" assume duty as "On Scene Commander Surface Unit". At 1204 Z, information was received by Valentia Radio that 8 Spannish Trawlers were proceeding to distress position of AI-182 and their ETAs were between 1630/2000 Z. At 1246 Z, Star Orion informed Valentia Radio that it would be able to refuel any vessel in medium or small quantities at the accident site. Valentia Radio informed MRCC Shannon and Falmouth about the Spanish Vessels and Star Orion.

2.8.14 Falmouth requested Valentia Radio at 1303 to advise Laurentian Forest to inform Aisling that 8 Spanish trawlers would arrive in search area between 1600 Z and 2000 Z and Aisling should deploy trawlers in conjunction with lifeboats to recover bodies as it would be easier to recover than from large vessels. Valentia Radio sent the above message.

2.8.15 Laurentian Forest informed Valentia Radio at 1307 Z that 10 bodies were on Aisling, 4 on Helo, and they had some alongside and had launched lifeboats to pick them up. Valentia Radio informed the same to MRCC Shannon and Falmouth. At 1338Z, MRCC Shannon requested Valentia Radio to include the following in their broadcast:
"Vessels within 100 N Miles of datum 5101.9N/1242.5W are requested to proceed to search area and contact Aisling/EIYP. Any vessels recovering bodies or wreckage are requested to retain them on board and inform MRCC Falmouth of total number of bodies recovered."
2.8.16 Valentia Radio transmitted the above message at 1340 Z to all stations and also informed MRCC Shannon. At 1503 Z Aisling informed Valentia Radio that they had recovered 56 bodies. MRCC Shannon requested Valentia Radio to advise Aisling that if they could locate "Black Box", they should drop buoy. Valentia Radio advised Aisling accordingly. At 1530 Z, on advice from MRCC Shannon, Valentia Radio asked Baltimore, Courtmaesherry and Ballycotton lifeboats to return to base. At 1633 Aisling requested Valentia Radio to inform Falmouth that they were unable to transfer bodies to Valentia Lifeboat as latter was returning to base owing to fuel shortage. At 1659, Laurentia Forest informed Valentia Radio that 66 bodies had been picked up by then. Aisling advised Valentia Radio that Valentia lifeboat was returning with four bodies.
2.8.17 At 1721 Z Falmouth requested Valentia Radio to relay following to all surface units at scene:
1. One mimrod remaining on scene overnight.
2. All other air units will be recalled at 2200 Z. One Helo remains at 15 minutes notice at Cork
3. Air Search recommences at 240400 Z.
4. All Civil surface units will be released by 2200 and may proceed on passage. Bodies should be landed at Irish Post for transfer to receiving station at Cork Airport.
5. Warship Challenger, Emer and Aisling acknowledge".
2.8.18 At 1723 Z Aisling informed Valentia Radio that they saw 3 Spanish vessels approaching and they were using Ch.16 which Aisling

was using for co-ordination with RESCUE 52 and requested that Spanish Vessels be asked to stay outside 5 miles radius. Spanish Agent was told about Aisling request.

2.8.19. Valentia lifeboat informed Valentia Radio that they were heading for home (Valientia) at reduced spead of 11 knots and they had five bodies on board. At 1822 Z, Aisling requested Valentia Radio information on 'Black Box' that might help its location. Aisling was advised of ELT signal on 121.5 MHz. At 1840 Z Cork ATC Advised MRCC Shannon that a total of 64 bodies were in Cork.

2.8.20 At 1920 Z, MRCC Shannon downgraded the 'MAYDAY' Broadcast to 'PAN' (Urgency) Broadcast, Aisling informed Valentia Radio that 79 bodies had been recovered. At 1958 Z Laurentian Forest informed Valentia Radio that they were proceeding to Dublin. Valentia Radio thanked them for assistance.

2.8.21 At 2000 Z, MRCC Swansea advised MRCC Shannon that main air search would cease at 2200 Z and would recommence at 240400 Z. The overnight search would continue with one Nimrod providing air cover for the surface search by three warships. Vessels transiting the area were requested to keep a sharp look out and to report to HMS Challenger.

2.8.22 By 0300 Z on 24th June, four Seaking helicopters had deported from Cork to resume the airborne search. At that time the search area covered a six nautical mile radius of position 5059.2 N/1225.3W and the vessels Le Emer and HMS Challenger were requested to search this area. HMS Challenger was the coordinator of the surface search and Nimrod Rescue 02 was on-Scene-Commander.

2.8.23 At 0450 Z Rescue 02 reported sighting of wreckage in position 5101 M/1245 W. Between 0505 and 0543, three USAF Chinook helicopters departed from Cork Airport to join the search. At 0556, MRCC

Swansea confirmed that there were 329 people on board the aircraft (Earlier reportes had idicated 325 people on board).

2.8.24 A continuous search was maintained throughtout the day (24th June) but only one further body and numerous pieces of wreckage were recovered. An extensive surface search was also maintained throughout the day and instructions were passed by MRCC Shannon to Valentia Radio requestiong all shipping to recover any wreckage or bodies sighted.

2.8.25 At 0900 Z, Capt. G Mc. Stay of Department of Communications advised MRCC Shannon that Aisling was bound for Cork, ETA 1300 Z and he (Capt. Mc Stay) was assuming responsibility for collection of wreckage. MRCC were also advised by Mr. Gregory of Britoil that their two vessels 'Constine' and 'Star Orion' were enroute to Foynes having picked up quantities of wreckage.

2.8.26 At 1740 Z, SRCC Plymouth advised Shannon that the Search will terminate at 242200 Z, at 1800 Z Falmouth MRCC advised MRCC Shannon to direct the Portisheal and Valentia Radios to concel Urgency Broadcast from 242000 and to release HMS Challenger and Le Aisling from the search at 242000 hours. All the aircraft were released at 24000. It was also decided that Le Emer would remain at the area. At 242003 Z, a message was transmitted to all stations on R/T and W/T that air and sea search was being terminated at 242000 Z and all the participant were thanked for their assistance.

INJURIES TO PERSONS

3.1.1 Post mortem examination was carried out by Irish Authorities at Cork. At that time Wing Commandor Dr. LR. Hill was also present. Subsequently Air Vice Marshall Kunzru also reached Cork. Both of them were members of the Medical Group which had been constituted by Mr. H.S. Khola.

3.1.2 By then 131 bodies had been recovered. None of the bodies of the flying crew were revocered. The bodies which were recovered represented 39.8 per cent of the victims. The exact seating position of passengers is not certain, because it is known if the passengers had changed their seats after the take off of the aircraft from Montreal. On the information which is available, the passengers were supposed to have been as follows:-

Passengers: Seats Occupied Bodies Available identified Zone A 16 1 0 Zone B 22 0 0 Upper Deck 18 7 0 Zone D 112 104 + 2 29

Zone D 86 84 + 1 38 Zone E 123 105 + 3 50 Sub-Total 377 301 +(6 infants) 117 Crew: Flight Deck 3 3 0 Cabin 19 19 5 Total 399 329 122

3.1.3 The Post-mortem reports were examined by Wing Commander Dr. Hill. He submitted two reports being Exhibits H-1 and H-2. He was also examined in Court as Witness No. 2. Dr. Hill who had developed a system which would indicate the severity of the accident and the injuries suffered. He used a scale from 0 to 4, with naught being no injury and 4 being a fatal lesion. Though there is some amount of subjectivity involved in the system, nevertheless categorising the injuries according to the sacle does give an overall picture of what had happened to the victims. After adding up all the injury scale for a particular body, Dr. Hill in his Report Exhibit H-1 divided the injuries as under:-

No. of victims Mild injury (0-49) total 34.4% 45% Moderate injury (50-99) 38.9% 51% Severe Injury (100-149) 25.2% 33% Catestrophic Injury (150 +) 1.5% 2 Total 100.1% 131 3.1.4 A further break up showing the overall injury score of the recovered victims is as follows:

Minor Moderate Severe Zone No. % % No. % % No. % % Total C 8 6.1 17.8 9 6.9 17.7 4 3.1 11.4 21 D 9 6.9 20 15 11.5 29.4 9 6.9 25.7 33 E 15 11.5 33.3 15 11.5 29.4 14 10.7 40 44 Unknown 13 9.9 28.9 12 9.2 23.5 8 6.1 22.9 33 Total 145 34.4 100 51 39.1 100% 35 26.8 100% 131 3.1.5 The reports submitted by Dr.Hill further indicted as follows

(a) There were 30 children recovered and they showed less overall injury. The average severity of injury increases from zone C to E and is significantly less in C than in Zones D and E.

(b) Flail pattern injuries were exhibited by eight bodies, five of these were in Zones E, one in Zone D, two in Zone C and one crew member. The significance of flail injuries is that it indicates that the victims came out of the aircraft at altitude before it hit the water.

(c) There were 26 bodies that showed signs of hypoxia (lack of oxygen), including 12 children, 9 in Zones C, 6 in Zone D and 11 in

Zone E. There were 25 bodies showing signs of decompression, including 7 children. They were evently distributed throughout the zones, but with a tendency to be seated at the sides, particularly the right side (12 bodies).

(d) Twenty-three bodies showed evidence of receiving injuries from a vertical force. They tended to be older, seated to the rear of the aircraft (4 in Zone C, 5 Zone D, 11 inZone E, 2 crew and 1 unknown), and 16 had little or no clothing.

(e) Twenty-one bodies were found with no clothing, including three children. They tended to be seated to the rear and to the right (3 in Zone C, 5 in Zone D, 11 in Zone E and 2 unknown).

(f) There were 49 cases showing signs of impact-type injuries, including 19 children (15 in Zone C, 15 in Zone D, 15 in Zone E, 1 crew member and 3 unknown).

(g) There is a general absence of signs indicating the wearing of lap belts.

(h) Pathological examination failed to reveal any injuries indicative of a fire or explosion.

3.1.6 In his testimony in Court, Wing Commander Dr. I.R. Hill further stated that the significance of flail injuries being suffered by some of the passengers was that it indicated that the aircraft had broken in mid-air at an altitude and that the victims had come out of the aeroplane at an altitude. He further explained that if an explosion had occurred in the cargo hold, it was possible that the bodies may not show any sign of explosion. It may here be mentioned that the forensic examination of the bodies do not disclose any evidence of an explosion. Furthermore, the seating pattern also shows that none of the bodies from Zone A or B was recovered, in fact as per the seating plan Zone B was supposed to have been unoccupied. This Zone is directly above the forward cargo compartment.

3.1.7 Dr. Hill further stated that the pattern of the accident as suggested by the injuries indicated that it was a complex affair and there were at least two phases of injuries, one in the air and the other at water impact. In answer to a specific question that if there was an explosive device in the cargo hold then could the passengers who were seated have suffered such injuries, the answer of Dr. Hill was that "it is possible". According to him, the pattern of injuries indicated that if there was an explosion in the aircraft it was more likely that the explosion had occurred in the rear cargo compartment than in the front cargo compartment. This conclusion was apparently based on the fact that, according to him, in zone E of the aircraft there were larger vertical load type injuries. Dr. Hill was also asked if he had to make any suggestions which would minimise injuries to passangers in the event of an accident. In answer, the witness made his suggestion in the following words

"There are very complicated things one would have to do such as rearward facing seats; having safety belts which incorporated restraint for the upper part of the body; increasing the space between aircraft seats; incorporating shocks absorbing system within the seat and using materials which do not break easily like plastic. We would also need fuel systems which would not immediately set on fire and furnishing which would be resistant to burining, and also passengers should not carry into the aeroplanes large amount of hand bags which only get in way in the event of evacuation, and I personally feel that the carriage of large amount of alchohol both in the passengers and in the aeroplane is a hazard to flight and safety. Finally the passengers should take heed of the flight safety instructions given to them by the crew of the aeroplane".

3.1.8 Air Vice Marshal Kunzru, witness No. 10 in his report dated 14th November, 1985, Ex.A-48, gave his comments not only on the post-mortem reports but also on the statement of Wing Commander Dr. I.R. Hill. With regard to the post-mortem examination, the comment of AVM Kunzru was as follows:

"All victims have been stated in the PM reports to have died of Multiple injuries. However two of the dead, one infant and one child, are reported to have dies of Asphyxia. There is no doubt about the asphyxial death of the infant. In the case of the other child (Body No. 93) there could be doubt because the findings could also be caused due to the child undergoing tumbling or spinning with the anchor point at the ankles.

Three other victims undoubtedly died of drowning. There was no evidence of significant Lap-belt injuries.
Considering rupture of the ear-drum, without injury to skull, as a criterion to indicate rapid decompression, two cases may be considered to fall in this category.
Histological examination has been carried out only in 57 bodies out of 131. Lung examination on almost all of them showed decelerative changes. Six bodies (Nos. 6,22,70,103,121 and 131) showed presence of Bone Marrow Embolism in Lung Sections. Though not of much significance in this accident, this finding does indicate survicval after a bony injury for an undefined period of time No evidence of fire burns or explosive material, other than Kerosene burns on some bodies, which I had myself seen at Cork, could be found. Kerosene burns in such acidents is a fairly common findings and is of no significance".
AVM Kunzru generally agreed with the crash injury analysis on the victims which had been furnished by Wing Commander Dr. Hill. He, however, gave the following comments with regard to hypoxia, decompression and decelerative changes:
"Hypoxia : The main Post Mortem findings in hypoxia is generalised congestion if the hypoxia is of the type described as "hypoxic hypoxia". In other causes of hypoxia of more severe degree such as "histotoxic hypoxia", "asphyxia" or "drowning" additional histological findings such as petechial haemorrhages and generalised congestion, and lung findings such as haemorrhage and extrusion of alvoolar phagocytos are seen.
Decompression : The term used by Dr. Hill is "Decompression". It is presumed that he means "Rapid/Explosive Decompression" which occurs within one Sec. and not "decompression sickness" which takes a minimum of 5 to 7 mnts to occur even at 31,000 ft. altitude and which in this case can positively be ruled out.
The Post-Mortem and histological signs of rapid Decompressions are :-
(a) Possibility of rupture of Ear drums without any injury to the skull.
*(b) Patchy Lung Haemorrhages
*(c) Emphysomatus changes

*(These occur more commonly in those cases where the individual was in the phase of breathing-in at the time of decompression.

3.1.9 If it is assumed that the aircraft suddenly broke up in Mid-Air at an altitude of 31,000 ft. the bodies will be at once exposed to hypoxia and rapid decompression and as a consequence will suffer body changes as mentioned above. As the aircraft/occupants start descending, they will be exposed to increasing amounts of Oxygen and as soon as ;they come down below 15,000 ft. and then below 10,000 ft. the effect of hypoxia rapidly diminishes. Finally, the aircraft/individuals come down and hit the ground/water with a very heavy impact, thus submitting the individuals to extremely severe G-loads of decelarative type.

Decelerative Changes : Decelerative impact brings about well established changes in the lungs besides many other associated injuries. It is relevant to note the decelerative lung changes which are :-

(a) Patchy haemorrhages in Lung.
(b) Marked Emphysomatus Changes.
(c) Extrusion of alvoolar Phagocytes
(d) Desqummation of bronchcolar epitherium.

"Comparative study of the PM/histological findings of hypoxia, Decompression and Decelerative Lung injuries reveal that they are more or less similar. Decelerative injury being the most severe of the three and last to occur tends to so modify the Post-Mortem and Histological findings that it becomes extremely difficult and some times impossible to isolate one from the other."

3.1.10 AVM Kunzru was, therefore, of the opinion that in this accident evidence of hypoxia/decompression (except in 2 cases) had not been confirmed or established.

3.1.11 The difference of opinion between Wing Commander Dr. hill and AVM Kunzru, with regard to evidence of hypoxia and decompression, is of no significance in the present case. What is important to note, however, is that they have agreed that the injury pattern does indicate break up of the aircraft in mid-air and that the occupants of Zone E had suffered the greatest amount of injuries as compared to the occupants of the other zones.

MAPPING, WRECKAGE DISTRIBUTION AND SALVAGE

3.2.1 Introduction

3.2.1.1 Oceanographic charts indicated that the depth of sea in the crash area was about 6700 feet and the site appeared to be a flat sea bed, without any valleys or hills. The immediate necessity after rescuing/ searching crash victims, was to locate and recover the digital flight data recorder (DFDR) and the cockpit voice recorder (CVR). The operation was unique of its kind and had never been undertaken earlier in the world at this depth of the sea. It required an equipment which could home on the transmitted signals from the underwater locater acoustic beacons fitted on DFDR/ CVR, identify the units, clear them from attachments/wreckages, grab them and bring them to the surface.

3.2.1.2 The pressure exerted by the water at 6700 feet below mean sea level is extremely high and the temperature is very low. No light penetrates to that depth and it is pitch dark. Scarab I fitted on French Ship "Leon Thevenin" which had undertaken the challenging job of locating DFDR and CVR, and recovering the same, was not designed to operate at 6700 feet depth. Its maximum design operating depth was only 6000 feet. However, it was decided to exceed the design operating depth for this emergency operation.

3.2.1.3 By using the preliminary information of probable area of location OF CVR and DFDR as indicated by ship 'Gardline Locator', the Scarab I was Lowered in the sea to locate and recover these units which it accomplished on 10.7.85 and 11.7.85 respectively.

3.2.1.4 Prior to recovery of DFDR/CVR by the ship 'Leon Thevenin', sufficient spade work was done by the ship 'Gardline Locator' (A ship provided by Accident Investigation Branch, U.K.) and 'Le Aoife' (an Irish Naval Ship). The survey of the crash area, carried out with the help of side-scan sonars fitted on these ships, had indicated a general distribution of the wreckage and a rough idea about the sizes of the parts. Each part of the wreckage was called a target. The method used for survey was triangulation with multiple passes through the crash site.

3.2.1.5 Next phase was the task of :

(a) Locating hundreds of pieces of wreckage by the combined use of sonar and video monitors.

(b) Video and still photography of the pieces of wreckage.

(c) Plotting the distribution of the wreckage.

All this was to be carried out under the directions of the Court.

3.2.2 Scarab

3.2.2.1 The means (vehicles/equipment) proposed to be used in the locating, mapping and video photography of the wreckage were the CCGS John Cabot and SCARAB II.

3.2.2.2 The John Cabot is an ice breaker of the Canadian Coast Guard. Since utilisation as an ice breaker is seasonal, the John Cabot is also equipped for submarine cable laying. In order to enlarge its capabilities in this regard, the John Cabot is equipped to have on its deck the Scarab and to operate it. Thus the John Cabot can be used for repair of submarine cables. The John Cabot has complete facilities for operation, maintenance and repair of the Scarab. This includes a Control Hut, a Test Room, Workshop, Stores etc. The John Cabot has considerable experience in work on deep sea bed.

3.2.2.3 The SCARAB II is a submersible craft assisting repair and burial of cables. As will be clear from the following details, the Scarab is not ipso facto a submarine. It is a total system for carrying out its complex functions.

3.2.2.4 The SCARAB II is a state-of-the-art system designed and built for tethered unmanned work at ocean depths of upto 6000 feet. Scarab's standard equipment are :

Two rugged manipulators.

A complete optical suite.

Six thrusters of 5 hp each.

CTFM Sonar.

Navigation System.

3.2.2.5 The manipulators have a choice of grippers/claws/cutters etc. of any required description and size. The Scarab has three TV cameras mounted on separate pan/tilt mechanism to allow real time observation and video tape documentation. A 35 mm still camera was also installed and used in the present work. There was a choice of quartz-iodide flood

lights to provide illumination.
3.2.2.6 The location and control of the Scarab is accomplished through a phased array navigation system.
3.2.2.7 The Scarab was equipped with a 360° high resolution Sonar with a range of 1000 meters. The Sonar was also capable of interrogating and detecting 37 KHz and 27 KHz pingers. It can function independently of the ship's facilities and is equipped with power generators and semiautomatic handling equipment.
3.2.2.8 The John Cabot can salvage items, but it is not a salvage ship as it does not have the specialised high capacity cranes, derricks etc. required for salvage of large objects. Further, it does not have deck space for keeping large salvaged items like the wings, fuselage or tail surfaces of an aircraft as large as a 747. The John Cabot was, therefore, adequate and fully satisfactory for the work envisaged in this phase of the programme, as salvage of large items was not planned in this phase. The task was, as mentioned earlier, locating, mapping and photography of the hundreds of pieces of wreckage. (The salvage work was part of the next phase of the programme).
3.2.3 Control and Monitoring of Operations
3.2.3.1 It was realised that the operation proposed would pose problems of control, monitoring and logistics.
3.2.3.2 Consider : A ship operating on the high seas in international waters on the task of locating, mapping and video photographing the hundreds of pieces of wreckage. The state of art system for Sonar location and photography (Scarab) used by the ship for handling this task. The group located on shore in charge of the operations. Finally, the Court in Delhi was in overall charge of the operatins.
3.2.3.3 It was realised that a proper line of control and communication was essential if the operations were to be smooth and successful.
3.2.3.4 Therefore it was decided that the following would be the chain of command :
Court Investigating the Accident
(Mr. Justice B.N. Kripal)

Control Centre at Cork
(Court's representative)
CCGS John Cabot
(Commanding Officer)
Scarab
(Project Manager)

3.2.3.5 Because of the multiplicity of agencies involved in the operations, the need was felt for a proper delineation of power at all levels. It was, therefore, decided that :

a. Overall responsibility for the operations would rest with the Indian authority viz. the Court. This would cover the identification and definition of assignment of the overall tasks, laying down of the priorities, overall control of the coverage of the operation and, finally, the time schedule for the operation.

b. Decisions taken at the Control Centre, flowing from the above, were to be taken solely by the Court's representative. The experts from CASB, NTSB and Boeing were free to give their views and recommendations, but the final decisions were to be left to the Court's representative. Examples of such matters are : Track of the survey, areas to be covered by John Cabot, assignment of priorities for specific tasks, amount of time to be devoted to any piece of wreckage, whether any item of wreckage is to be picked up, etc.

c. Operation Control of John Cabot would be in the hands of the Canadian Coast Guard Officer in the Control Centre, who would co-ordinate with the Commanding Officer of John Cabot. This would cover decision on feasibility or otherwise of operations under adverse weather conditions, manner of covering the area, method of retrieving any wreckage, etc.

d. Decisions relating to the Scarab (i.e. whether the weather was suitable for Scarab operations, whether the size, weight etc. of an item would permit its being picked up by Scarab, etc.) would be left to the Scarab Project Manager on Board John Cabot.

3.2.3.6 It might appear at first sight that in the above system excessive power was delegated at certain levels to the detriment of overall control. Any such impression would not be correct. In actual fact, because of proper delegation of responsibility and power at different levels, the operations were carried out with extraordinary efficiency, smoothness and coordination, In this connection, it is relevant to point out that the operations were not a uni-disciplinary one. The operation (aircraft accident investigation) was totally dependent on experts from other disciplines, like naval (coast guard) operations, deep sea photograph, salvage from sea bed etc. It was therefore, decided that for smooth and efficient operations, adequate power and responsibility should be delegated at all levels, particularly to specialists engaged in the different areas of work as above.

3.2.3.7 It was also considered that adequate communication was a sine qua non for smooth operation. Therefore, the following communication facilities were established :

Control Centre at Cork Airport

Telex

Telephones (2)

3.2.3.8 The ship John Cabot had both telex and telephone facility. These links were through satellite (IN MARSAT). The Control Centre was in continuous communication contact with John Cabot through telex and telephones. In order to establish a reliable and satisfactory line of communication it was decided that instructions or communication from Control Centre to the Indian experts on John Cabot would follow the path as under :

Control Centre

Court's representative --- Canadian Coast
Guard Officer

John Cabot

Indian experts --- Commanding Officer

3.2.3.9 It was felt that this would eliminate any possibility of inconsistent or contradictory orders/messages going to John Cabot.

3.2.3.10 With a view to have an ordered system of communications between the control centre and John Cabot (which is essential for proper control and monitoring of the operations), it was decided that John

Cabot would sent to the Control Centre daily Situation Reports (SITREPS) at specified times viz. 0800 hrs, 1200 hrs, 1600 hrs and 2000 hrs. This however did not preclude the despatch of telexes by both Control Centre and John Cabot at any other time.

3.2.3.11 In order to inform all agencies of the above system of Control and Communication a number of meetings were held. These were on 12.8.85 and 3.9.85 on board John Cabot and on a number of occasions at the Control Centre. The purpose of these meetings was not only to inform all concerned about the specific task, the programme and the line of control and communication but also to sort out differences and to understand the technical and operational difficulties faced by the personnel on the spot and to find a way out.

3.2.4 Daily Monitoring of Progress

3.2.4.1 It may be relevant to point out here that search, location and video photography work was to be carried out round the clock. Thus a considerable volume of data would be coming into Control Centre. This required regular, almost hourly, monitoring, study and analysis for (a) proper understanding of the data collected and (b) advising John Cabot of any changes in its programme, such as additional photography on an item etc. For this purpose (i) SITREPS were filed in the Control Centre (ii) all data (description, latitude and longitude) obtained on every target was tabulated and the cumulative list updated daily.

3.2.4.2 The location of the targets was plotted on charts every 4 hours. This was in addition to the plotting of targets carried out on John Cabot.

3.2.4.3 Every day (including holidays and week ends) all the officers posted at Control Centre assembled at about 0900 hrs. They studied the SITREPS received at 0800 hrs and any other telexes received from John Cabot in the night. The lists of targets were updated and the new targets plotted on the charts. John Cabot generally also sent brief remarks such as description, nature of failure/damage, dimensions etc. Discussions were held on the significance of the targets and their implications. Instructions if any to be telexed to John Cabot were also discussed. Similarly SITREPS received at 1200 hrs and 1600 hrs were studied.

3.2.5 Monitoring at Cork

3.2.5.1 The Scarab provided video tapes and still photographs. In the initial stages (upto 9.8.1985) the John Cabot was operating in peripheral areas and therefore few targets were found. Hence the output of videotapes was small. In fact upto 9.8.85, only about 10 targets were found and only 3 video tapes were used up. But later, when John Cabot came close to and into the crucial areas, video tapes were recorded at a fast rate. Further, still photography facility on the Scrab was activated at about this time. Therefore, arrangements were made periodically to obtain the video tapes and films from John Cabot. Video tapes and still photographs (these required to be processed) were transported from John Cabot to Cork Control Centre.

3.2.5.2 About 50 video tapes and nearly 3000 still photographs (positives and transparencies) provided the visual information on the targets.

Arrangements had to be made at Cork for such viewing and study of the video tapes and still photographs. Video equipment (TV monitor plus VCR) suitable for viewing the video tapes had to be arranged.

3.2.5.3 The still photography used special professional quality colour film (35 mm), each roll having 800 frames. The film was diapositive. These had to be developed and transparencies obtained from them. Thereafter negatives and prints had to be made. Special equipment for viewing the transparencies had to be provided for continuous work. The video tapes, transparencies and prints provided the principal means of monitoring of the results of the operation.

3.2.6 Operations

3.2.6.1 The Charts prepared by 'Gardline Locator' were on a different type of grid system, and had to be translated into LAT-LONG system, for use by John Cabot. For the convenience of search/mapping operation the search area was divided into 4 blocks viz. Block 1, Block 2, Block 3 and Block 4.

3.2.6.2 The navigation system used by John Cabot is PULSE-8 system. This system needs the transponders to be placed on the sea bed. These transponders help in getting the correct fix of a target and in obtaining relative positions of the targets on the sea bed which is highly useful for revisit for the purpose of rephotography or recovery. Initially 4 transponders were placed, and subsequently the number was increased as the search operation was continued. The strategic locations for placing the transponders was decided by considering :

(a) frequencies of relative transponders,

(b) distances required between relative transponders,

(c) wreckage distribution suggested by side scan sonar plots of Eithena and Garline Locator, and

(d) size of search area.

These transponders were calibrated to match the navigation system of the ship.

3.2.6.3 In order to obtain the maximum information from search, it was decided that the Scarab search paths should be as follows :

(a) Normally the search paths should be east to west, or west to east within the individual blocks.

(b) The pattern of search should be a parallel search method.

(c) Distances between the parallel paths to be 1,200 feet (i.e. 2 cable widths), for effective use of sonar fitted on the Scarab.

(d) If Scarab deviates from its planned path for photography or recovery, it should return to its planned path for further search.

(e) In each block, the search was to be made, at least 1/2 mile (North or South) beyond the last target sighted, so as to ensure no target is missed out from the given block.

3.2.6.4 However, when there was a need to modify the search pattern, due to wreckage distribution in particular areas, the following changes were made:

(a) Expanding box type search pattern was used in Block 1.

(b) Some North to South and South to North passes were made in Block 3.

(c) In Block 3 northern end, the distances between the search passes was reduced to 600 feet i.e. 1 cable width.

However, these deviations were made basically to improve the reliability of search in specific areas, as demanded by peculiar distribution of aircraft wreckage.

3.2.6.5 To facilitate identification of the wreckage located by Scarab it was necessary to position aircraft maintenance personnel on board the ship. As the aircraft structure was badly torn, mutilated and distorted, serious difficulty was anticipated in identification of small pieces of structure. It was therefore essential that these maintenance personnel were provided with aircraft photographs, manufacturing drawings, parts catalogue, wiring diagram manuals and maintenance manuals. Since carriage of such voluminous literature was not praticable, 3M micro film reader printer
machines with micro film cassettes of the above literature were produced and installed on the ship. In case of difficulty of locating any particular information, the engineers were advised to contact Cork Search Centre by telex or telephone who, in turn, could seek the desired information from the manufacturers.

3.2.7 Wreckage Distribution

3.2.7.1 The wreckage distribution as determined by the mapping of the sea bed provided some distinct distribution patterns. The depth of the wreckage varies between about 6000 and 7000 feet, and the effect of the ocean current, tides and the way objects may have descended to the sea bed was not determined, thus some distortion of an object's relationship from time of water entry to its location on the bottom cannot be discounted. In general, the items found east of long 12°43.00'W are small, lightweight and often made of a structure which traps air. These items may have taken considerable time to sink and may have moved horizontally in sea currents before settling at the bottom. Marks left on the sea bed beside some wreckage does indicate horizontal movement of the wreckage as it settled. Although badly damaged, sections 41, 42 and 44, and the wing structure were located in a relatively localized area centred about lat 51°03.30'N and long 12°47.80'W, and the wreckage scatter was oriented north/south. The wreckage scatter in this area was so dense that it is probable that some of the wreckage may not have been mapped or photographed. Section 46 and 48, including the vertical fin and horizontal stabilizer, extended in a west to east pattern with the western most identified aircraft component located at lat 51°02.90'N and long 12°50.1'N. The wreckage extended in a line about 110 degrees to an eastern position of lat 51°02.04'N and long 12°41.26'W, a distance of approximately 6.5 nautical miles. The aircraft structure had a random scatter pattern. That is, items such as the aft pressure bulkhead were broken into several pieces, and these pieces were located throughout the pattern. A third area which had some distinctive pattern was that of the engines, engine struts and components and was localized about lat 51°03.25'N and long 12°47.4'W in a northwest/southwest orientation. One of the operating engines was displaced 0.5 nautical mile to the north of this area, and it was also geographically separated from the wing structure. The number 3 engine nacelle strut was also separated from the rest of the engine components

and was located about one nautical mile to the west-southwest at lat 51°02.87'N, long 12°48.05'W. The reasons for the displacement of the number 3 engine nacelle strut and one of the operating engines from the other engines are not known.

3.2.7.2 Details of the various targets which were identified by the Structures Group is contained in Appendix 1 of this Report.

3.2.8 The Break up Pattern

3.2.8.1 The forward fuselage section of the aircraft was found inverted and badly broken into many pieces, the major pieces being :

(I) Section of fuselage right side below cockpit windows containing part of the name 'Kanishka' (in Hindi) and 3 passenger windows (Target No. 192)

(ii) Portion of upper skin between B S 360 and B S 520 below window belt right side, up and over crown. This portion includes the crew door and last letter of the "Air India" (in Hindi) logo (Target No. 192).

(iii) Section of fuselage between B S 510 to B S 700, including the passenger window belt right side, up and over crown to include upper deck windows left side (Target No. 218).

(iv) Section of fuselage between B S 720 to B S 840 including left side passenger window belt, up and over crown to right side passenger window belt. Forward and upper edges of L H No.2 door cutout can be seen (Target No. 193).

(v) Large section of fuselage between B S 1000 to B S 1460 including left side passenger window belt, up and over crown to right side passenger window belt. This section was found lying on its right side (Target No. 137).

(vi) The lower portion of the fuselage skin/frame between the nose and B S 1000 was damaged past recognition except for a small portion with the forwarded cargo door (Target No.204) and another portion containing the aft access door cutout at B S 810 (Target No. 362).

3.2.8.2 The aft fuselage was found in the following major pieces :

(I) Section of RH fuselage skin between B S 1640 and B S 1940 below the window belt up to the crown (Target No. 321).

(ii) The RH fuselage bottom skin between B S 1820 (forward edge of C2 door) and B S 2060 and between two stringers above the door cutout to just below stringer 46 lap joint (Target No. 40).

(iii) The lower fuselage skin with stringers between B S 1480 and B S 1846 about 100 inches wide approximately (Target No. 7).

(iv) The LH fuselage skin panel between B S 1740 and B S 1880 about 110 inches wide (Target No. 11).

(v) The LH fuselage skin between B S 1460 and B S 1800 width 80 inches including No. 4L door and passenger windows (Target No. 28).

(vi) The RH fuselage skin between B S 1660 and B S 1920, from below window belt up to the crown including the 4R door cutout (Target No. 321).

(vii) A fuselage lower skin panel (containing out flow valve) between B S 2120 and B S 2240 and 120 inches wide (Target No. 320).

(viii) A fuselage LH skin panel (containing 5 windows with "T -" part of registration) between B S 1980and B S 2080 between stringers 19L and 24L (Target No. 369 and 26).

(ix) A fuselage LH skin panel between B S 1460 and B S 1800 with 8 stringers below the bottom of the door and 3 stringers above the top of the door (Target No. 28).

3.2.8.3 The tail portion of the fuselage was found in the following pieces:

(I) The lower fuselage skin between B S 2412 and B S 2598 about 20 stringers wide (Target No. 371).

(ii) The vertical fin with rudders attached was lying on the ground by itself with a portion of B S 2517 frame. This includes a small portion of the aft pressure bulkhead (Target No.37).

(iii) The horizontal tail with elevators attached was lying on ocean floor with the jack screw and drive motor attached (Target No. 31).

(iv) The fuselage tail cone aft of B S 2669 was found basically intact and lying separately (Target No. 27).

3.2.9 Extent of Damage

Photographic and Video Interpretation of Wreckage

Photographic Interpretation

3.2.9.1 All wreckage sighted was recorded on video tapes and all major items were recorded on 35 mm positive film. During the course of the investigation, several members of the investigation team had the opportunity to view the tapes and photographs. Subsequently, when some items were recovered, it became apparent that the optical image presented on video and still film had some limitation with respect to identification of damage or damage pattern. For example, the sine wave bending of target 7 appeared in the video and photographs as a sine wave fracture, and some of the buckling on target 35 was not evident in either the video or photographs. The interpretation of damage through photographic/video evidence without the physical evidence might be misleading, and any interpretation should take this into acount.

3.2.9.2 Engines

The four operating engines were all extensively damaged. A view of the fan blades did not show signs of any rotational damage, and it could not be determined whether any pre-impact failures had occurred. The external damage to the engines varied, and at least one engine appeared to be attached to part of the nacelle strut. Except for the non-operational fifth engine, the engines could not be matched with their original positions on the aircraft.

3.2.9.3 Landing Gear

The nose, wing, and body landing gear were all located. Photographic examination indicated that all the gears were in the 'up' position at the time of impact.

3.2.9.4 Flaps and Spoilers

Positive identification of all the flap and spoiler surfaces was not made. All the flap jackscrews indicated that the flaps were retracted at impact. Of the spoilers identified, six had actuators attached. The actuators were in the fully retracted position.

3.2.9.5 Section 41

Section 41, consisting of the cockpit, first-class section, and electronics bay and identified as target 192, was found in a near-inverted attitude. This section was severely damaged. The electronics bay and cockpit areas could not be located within the wreckage. The first officer's seat was found on the sea bed near section 41 wreckage.

3.2.9.6 Section 42

Portions of Section 42, consisting of the forward cargo hold, main deck passenger area, and the upper deck passenger area, were located near section 41. This area was severely damaged and some of section 42 was attached to section 44. Some of the structure identified from section 42 was the crown skin, the upper passenger compartment deck, the belly skin, and some of the cargo floor including roller tracks. The right-hand, number two passenger door including some of the upper and aft frame and outer skin was located beside section 44. Scattered on the sea bed near this area were a large number of suitcases and baggage as well as several badly damaged containers. All cargo doors were found intact and attached to the fuselage structure, except for the forward cargo door which had some fuselage and cargo floor attached. This door, located on the forward right side of the aircraft, was broken horizontally about one-quarter of the distance above the lower frame. The damage to the door and the fuselage skin near the door appeared to have been caused by an outward force. The fractured surface of the cargo door appeared to have been badly frayed. Because the damage appeared to be different from that seen on other wreckage pieces, an attempt to recover the door was made by CCGS John Cabot. Shortly after the wreckage broke clear of the water, the area of the door to which the lift cable was attached broke free from the cargo door, and the wreckage settled back on to the sea bed. An attempt to relocate the door was unsuccessful.

3.2.9.7 Section 44

Section 44 containing the aircraft structure between B S 1000 and B S 1480 including that area where the fuselage and wings were mated was located and identified. This section was severely damaged but maintained its overall shape and was lying on its right side. Part of the left wing upper skin was attached to the fuselage and a large portion, about one third of the upper wing skin, separated and was lying against the fuselage crown skin. Some of the body and wing landing gears were found beside this section of the aircraft. The gear was detached from the main structure. The interior of the fuselage was extensively damaged.

3.2.9.8 Wing Structure

The wing structure was located near the forward area of the aircraft structure and towards the northern most area of the wreckage pattern. The wings showed extreme damage patterns with the top and bottom surfaces separated and the wing surfaces broken into segments.

3.2.9.9 Sections 46 and 48

Sections 46 and 48 contain that part of the aircraft structure aft of B S 1480 and, for purposes of this report, will include the horizontal stabilizer and vertical fin. This section of the aircraft was scattered in a west to east pattern about 6.5 nautical miles in length and exhibited severe break-up characteristics.

3.2.9.10 The aft cargo and bulk cargo doors were found in place and intact, and 5L, 5R and 4R entry doors were identified. Four segments of the aft pressure bulkhead were positively identified (targets 35, 37, 73 and 296). Much of the fuselage which was forward of the number five door and above the passenger floor area was not located, or if located was not recognisable as having come from a specific area of the aircraft.

3.2.9.11 Sections of the outer skin below the cargo area were located as was some of the cargo floor structure. Generally, the stringers and stiffeners are attached to the skin; however, the lower frames, which provided the cargo floor support, were detached from the skin. The rear cargo floor from B S 1600 to B S 1760 was located and was found to have little or no distortion; however, the lower skin and stringers were missing. A second portion of the aft cargo compartment floor containing cargo drive wheels and cargo roller trays was located. This structure was severely damaged and mangled.

3.2.9.12 The tail cone and the auxillary power unit (APU) housing were located and had received relatively minor damage; however, the APU had broken free and was never located.

3.2.9.13 A large portion of the outer skin panels showed signs of a force being applied from the inside out. On several pieces of wreckage, the skin was curled outwards away from the stringers and formers. This could have been the result of an overpressure.

3.2.9.14 The vertical tail was found in good condition, in a single piece with both rudders attached. The top cap was partially separated and a small dent was noticed in the middle of the leading edge at the bottom. A curved broken portion of fuselage was observed with a portion of the "Y" ring and pressure bulkhead attached. Another small segment of the pressure bulkhead was leaning on the lower section of the tail.

3.2.9.15 The horizontal stabilizer tail section was located and was one unit with the elevators attached. The actuator jackscrew was attached to the assembly. The stabilizer jackscrew ballnut was observed to be located at the upper jackscrew stop. This equates° to a full deflection of elevator trim. Since there is nothing on the DFDR or CVR to indicate a malfunction of the trim, it is deduced that this was not the lead event. It is not known if the position of the ballnut resulted from a pilot trim selection, a result of the initial event or if it rotated to the observed position under the influence of gravity. Two-thirds of the leading edge of the right horizontal stabiliser was missing and the auxilliary spar was exposed. There was localized damage to the right-hand root of the loading edge through about a span of five ribs. The leading edge skin and part of the leading edge ribs were torn downwards. Some localized damage to the root of the left leading edge was visible with the remainder of the leading edge undamaged. There was minor damage to the trailing edge of the outboard left elevator, and a major portion of the inboard left elevator was missing.

3.2.9.16 Passenger Seats

Many of the passenger seats located among the wreckage pattern and identified as having come from section 46 and 48 appeared to have the aft support legs buckled with little or no damage to the forward support legs. Seats located in the wreckage containing sections 41, 42 and 44 appeared to have varying types of damage, that is, aft support legs only buckled, and all legs buckled. One consistent feature noted was that in the majority of seats located it was possible to ascertain that the seat belts were not fastened.

3.2.10 Salvage Operations

3.2.10.1 During recovery operation the video tapes as well as photographs of the wreckage to be recovered, were supplied to the personnel on board the ship for facilitating identification and recovery of correct targets.

3.2.10.2 Whenever any component/part of the aircraft wreckage was salvaged it was essential to immediately subject the same to inspection and to identify the damage sustained during recovery operation. In order to oversee this critical operation, the Court deputed one of its Assessors, Dr. V. Ramachandran, to be on board the ships. Under his supervision, the components/parts were thoroughly washed with fresh water, dried and treated with corrosion inhibiting compounds. A detailed inspection was thereafter carried out, observations recorded and the targets were appropriately labelled and their numbers were painted thereon. A laboratory microscope was taken on board by Dr Ramachandran. With that, fragments of significance were segregated for further investigation. Indeed some of these fragments did give important clues.

3.2.10.3 All the investigating personnel on board the ship were provided with leather gloves, fisherman's shoes, raincoat, life floating suits, writing and labelling material, camera with coloured films, etc. Sufficient number of "body bags" were positioned on each ship to cater for the eventuality of recovery of bodies with the wreckage. This precaution helped when a body did come along with wreckage on

25.10.1985.

3.2.10.4 The ship John Cabot completed the operation of locating, mapping and photography of the wreckage and returned to Cork on 1.10.85 at 2020 hours. The next phase of operation was to recover the significant wreckage parts which would be useful for deciding the cause of the crash.

3.2.10.5 Subsequent to the accident to Japan Airlines Boeing 747 aircraft, suspected to have been caused by failure of the repair to the rear pressure bulkhead, NTSB and FAA decided to fund the U.S. Navy for a two week operation over the seas for recovery of significant pieces of wreckage. For this purpose, U.S. Navy appointed Commander J.R. Buckingham, a deep sea salvage expert, to head the recovery operation. An offshore supply vessel M.V. Kreuzturm, of Canada was hired by U.S. Navy to recover the wreckage with the help of Scarab on John Cabot. One nylon lift line together with winch and ram were installed on the ship prior to its sailing to Cork where it arrived on 4th October, 1985. One crane was installed on the ship Kreuzturm in Cork.

3.2.10.6 One inch dia Kevlar lines coated with black plastic for abrasion resistance and braided with Dacron lining were used by John Cabot as primary lift lines.

3.2.10.7 The structure group after studying the photographic data, had formulated a list of 32 targets for recovery on 3.10.85. A systemwise priority list proposed by the Court of Inquiry was received through Dr V. Ramachandran on 4.10.85. Using these two lists, and taking into account the operating restrictions imposed by two ship operation, a final list of targets was prepared for recovery by the ships, assigning a priority number to each target. However, as the recovery operation progressed, changes in priority list were made to achieve optimum utilisation of the ships.

3.2.10.8 A meeting was held at 1400 hrs. on 4.10.85 on board CCGS John Cabot to establish/clarify the priorities for the wreckage recovery operation and coordination between John Cabot, Kreuzturm and Cork Search Centre. All the personnel involved in the recovery operation were shown the slides and photographs of the targets which were chosen

for recovery on priority basis. The method and procedure of the recovery operation was discussed in detail and finalised. Another meeting was convened on 6.10.85
to clarify the doubts and to present the picture albums containing various photographs of targets to be recovered. The mode of attaching grippers/grabbers to the targets at strong points was clarified. A serialised list of priorities was prepared based on the mode of operation indicated by the the crew of John Cabot and Kreuzturm. Dr Ramachandran was given the authority to make on-the-spot decisions during the salvage operations.

3.2.10.9 A detail log of the activities of the ships John Cabot and Kreuzturm which started the recovery operation of 10.10.85, reveals the following :

(a) The Scarab working independently recovered the following

(1) Basket at target 192 containing copilot's chair, 2 suitcases and radar antenna (12.10.85)

(2) Target 8 - Lower fuselage skin of aft cargo compartment. (11.10.85).

(3) Target 245 - Forward belly skin just aft of radome (16.10.85).

(4) Target 350 - Economy class seats and carpet (23.10.85).

(5) Target 296 - Piece of aft pressure bulkhead.

(b) The Scarab after attaching the grippers, bridal cable and lift line to the targets buoyed off the same to Kreuzturm which recovered the following targets :

(1) Target 362/396 - Forward cargo fuselage skin from station 700 to 840 and STR 41L to 43R. (16.10.85).

(2) Target 193 - Fueselage skin from station 720 to 860 and passenger door 2L (17.10.85)

(3) Target 223 - Nose landing gear pressure deck web and stiffeners, container pieces (staion 260-340)(19.10.85).

(4) Target 181 - Wing skin with forward cargo compartment SLIPPED OFF WITH GRIPPERS (21.10.85) AND WAS LOST.

(5) Target 399/358 - Fuselage skin from station 780 to 940 and STR 7R to 35R with 2R door (25.10.85). A body entrapped in target 399/358

was recovered. Another body which came upto surface with the wreckage fell
off into sea and was lost while hauling the wreckage on board. The recovered body was identified as of Dr. Mathew Alexander, a Canadian passenger and was brought to Cork by Fisherman's vessel "Orion" at 0130 hrs. on 28.10.85 and was sent for Post Mortem etc.

(6) Target 7 - Aft cargo compartment fuselage skin from station 1480 to 1860 (26.10.85).

(7) Target 47/50 - Aft cargo floor structure with roller tracks, frames, latch etc. from station 1600 to 1760 (27.10.85).

(8) Target 117 - Three rows of coach class seats with passenger cabin floor boards, broken floor beam (28.10.85).

(9) Target 35 - Aft Pressure Bulkhead piece (30.10.85).

3.2.10.10 The Scarab experienced malfunctions with its arms, Sonar equipment, multiplex system, junction box, microprocessor unit, etc. off and on during the above period of operation. Fouling of lift line with umbilical cord was also experienced in the early stages of operation. Since the assigned recovery by Kreuzturm was over by 30.10.85, and as the Scarab became unserviceable due to breakdown of its power suppluy, the OSV MV Kreuzturm was directed to return to Cork to off-load the recovered wreckage and its operation was terminated, (Indian Government had funded the cost of operation of M.V. Kreuzturm from 21.10.85 onwards).

3.2.10.11 Since the Scrab continued to remain unserviceable, the ship John Cabot was called back to Cork. It anchored in Cork at 1100 hrs. on 5.11.85. All the wreckage on board the ship was transported to the boat yard, in the afternoon.

3.2.10.12 After detailed macro photography of the recovered wreckage, the experts group mentioned in section 1.5.16 prepared a detailed factual report after carefully inspecting each of the targets recovered. It was decided to send the wreckage to Bombay for which necessary crates were then prepared and the large pieces of wreckage were cut along the lines indicated by the experts group to facilitate their packing.

3.2.10.13 RCMP investigators carried out a close visual and microscopic examination of the fragments recovered with the wreckage, suitcases, seats and cushions, etc. For further laboratory analysis. Dr A.D. Beveridge collected a few samples.

3.2.10.14 The Scarab appeared to be serviceable on 19.11.85 and the ship John Cabot sailed for completion of recovery of left over targets, on 20.11.85. However, the serviceability of Scarab proved elusive, it became inoperable on 21.11.85 and the ship returned to Cork at 1700 hrs on 25.11.85.

3.2.10.15 Efforts were made to repair Scarab so that the ship John Cabot could sail again in order to salvage as many pieces as possible. It was fortunate that the weather had not deteriorated. Some of the important but small pieces which had to be recovered had been placed in a basket at the bottom of the ocean. The ship sailed out again after Scarab had been repared. The basket was sought to be lifted, but, unfortunately, when it reached near the surface of the sea it overturned and the contents of the basket spilled and were never traced again.

3.2.10.16 At this juncture it was decided that the salvage operations should be terminated. The ship returned and sailed for home in the first week of December 1985.

3.2.11 Examination of Wreckage

3.2.11.1 Floating Wreckage

Soon after the accident, a number of light weight parts of the aircraft were found floating over a wide area at the crash site. These were picked up by the ships engaged in rescue operations and were brought to Cork where they were kept in the boat yard. The floating wreckage recovery continued for four days i.e. upto 26th June.

3.2.11.2 Some of the wreckage items were subsequently washed to the west coast of Ireland. These were picked up by the Irish Police and were brought to Cork. Some wreckage items were taken by a ship to Halifax, Canada. These were flown to Cork by the Canadian Aviation Safety Board. With the assitance of Air India engineers, the wreckage items were

identified, labelled, photographed and laid out in the boat yard hangar for examination.

3.2.11.3 The wreckage was initially examined at Cork by the Structures, Power Plant and Systems Group. It was subsequently transported to Bombay for further examination. A few wreckage items which were taken by the Spanish trawlers to Madrid were also transported to Bombay. Some wreckage items had washed to the west coast of England. These were collected by the Accident Investigation Branch of UK and were transported to Cork and then to Bombay.

3.2.11.4 The floating wreckage recovered constituted approximately 3 to 5 per cent of the aircraft structure. The major items of the wreckage recovered were :

Various leading edge skin panels of LH nd RH wing, LH wing tip, spoilers, leading edge and trailing edge flaps, engine cowlings, flap track canon fairings aft end pieces, landing gear wheel wall doors, pieces of elevator and aileron, toilet doors, cabin floor panels, cabin overhead and upper deck bins, passenger seats, life vests, slide rafts, hand baggages, suitcases etc. and three empty oxygen bottles.

3.2.11.5 The Structures Group which had been constituted by the Court examined the floating wreckage and submitted its report. From the report the following significant information about the damage to major items of the floating wreckage is noted :

(I) VT-EFO aircraft was carrying a -7Q engine on 5th pod and a -7Q 5th pod kit in the aft cargo compartment. It had therefore, in all 14 engine fan cowls (eight working engine fan cowls plus two 5th pod engine fan cowls plus two -7T engine kit fan cowls in the aft cargo compartment plus two -7Q engine fan cowls in the aft cargo compartment). Out of these 14 fan cowls, 9 cowls (6 of working engines plus 2 of -7J kit plus one of 7Q kit) and two additional pieces of fan cowls were found. Five of the fan cowls of working engines show folding damage lines at approximately 3 O'Clock and 9 O'Clock positions. The number 3 engine inboard fan cowl has severe impact damage on its leading edge and has small inward to outward puncture holes (not penetrating through outer skin) in the lower centre region. The two fan cowls of -7J 5th pod kit stowed in the aft cargo compartment exhibit severe damage. One of these cowls is broken in two pieces. One of the pieces is cut at one corner in an arc of about 20 inches diameter and its external skin is pealed back. The external surfaces of all the three pieces have consideable scratches, tears and holes from outside to inside. None of the punctures penetrates the inner skin. Some punctures are also present from inside to outside but none of these penetrates the outer skin.

(ii) Out of the 12 spoilers, seven (number 2, 3, 5, 7, 8, 9 and 12) have been retrieved. Of these, six have their actuators attached to them in fully retracted position. Six spoilers have splits in their lower skin with split edges curled into the cores of honeycomb. Number 8 spoiler (located just inboard of number 3 engine) has a concentrated local impact damage on front spar and trailing edge beam from forward to aft and up direction over a span of 2 feet starting from outboard of spoiler actuator.

(iii) The left hand wing tip assembly with a part of H F Antenna was retrieved. No burning/discolouration marks around lightning arrester of H F system were noticed. The rib inboard of the lightning arrester was found intact. There were no burn marks anywhere on the panel.

(iv) The right hand wing leading edge top panel inboard of number 3 engine with a position of kruger flap frame along with bull nose attached was recovered. The bull nose was found crushed from top in the area just below the stay rod and the lower surface of stay rod has scratch marks from front to rear.

(v) The right hand wing root leading edge (inboard of W S 268.81) shows an impact damage at the leading edge. Bottom skin and internal structure are torn away. The leading edge skin is caved in over a span of about 3 feet and shows signs of heavy body impact in air. The impact damage shows signs of downward and backward movement of the impacting body.

(vi) A 3' x 2' piece of right hand inboard trailing edge fore flap with accordian seal was recovered. The inboard 8" portion of leading edge was found damaged by impact of an object going from lower forward to upper aft.

(vii) All the floor panels recovered from upper deck and main cabin indicate that these were detached from their attachments in an upward direction from all sides.

(viii) One main deck blow out door located between B S 2040 and 2140 left hand side was available. Out of its four metal clips, one clip was broken off with 2 nylon rivet heads sheared.

(ix) The cockpit entry door and the side bulkhead panel were found fairly intact but had come out of their attachment.

(x) Twelve toilet doors, out of a total of 16, were available and were found fairly intact, but had come out of their attachments.

(xi) The available cabin interior panels and overhead bins of the main deck and upper deck have only minor damage.

(xii) The woodent boxes which contained the fan blades of 5th pod engine and were loaded in container at position 24L in the forward cargo compartment were found broken apart with no burn marks.

3.2.11.6 Wreckage Salvaged from Sea

The wreckage salvaged from the sea was visually examined at Cork by the Committee of Experts as mentioned in section 1.5.16 and the observations thereon recorded. Subsequently detailed metallurgical examination was carried out at the Bhabha Atomic Research Centre, Bombay by
Dr. M.K. Asundi and Dr. G.E. Prasad of B.A.R.C., Mr. S. Radhakrishnan and Dr. R.V. Krishnan of National Aeronautical Laboratory and Mr. B.K. Athawale of the Explosives Research and Development Laboratory, under the guidance of Dr. V. Ramachandran. During this examination, representatives of CASB, CP Air and Boeing were present in the first week. These represntatives left Bombay while the metallurgical examination was being carried out. The metallurgical examination was continued and the aforesaid group submitted the metallurgical report to the Court in December, 1985.

3.2.11.7 Although all the recovered wreckage was examined, only those items exhibiting characteristics which provide some evidence as to what may have happened to the aircraft during its final moments of flight are discussed herein below :

3.2.11.8 Target 7 - Lower Fuselage Skin Panel
This skin panel was located below the aft cargo area and contained the keel beam. Target 7 extended from B S 1480 to 1850 and was about eight feet in width and 32 feet in length. The left edge had a full length rivet line tear and the torn edge was buckled in waves, like the trace of a sine wave. One the right side, between the one quarter and midway segment, a large flap of skin was attached. The skin was folded aft, diagonally underneath, from right to left and the paint was scoured off the leading edge. The forward break was at the joint at B S 1480. The skin tear located at about B S 1860 was irregular in nature. The forward keel joint splice plate was bent, and the keel joint bolt holes were distored and elongated.

3.2.11.9 This panel was examined by the committee of experts at BARC and according to their report the keel beam trunnion fitting beneath the outer chord of the station 1480 bulkhead had fractured at the aft set of bolt holes. The fracture surface of the right side of the trunnion fitting was clean. As per the report, it was typical of overload failure in tension. The fracture surface of the left side of the trunnion fitting was covered with corrosion products, especially, at one corner, due to sea water. After cleaning this area by the recommended techniques, scanning electron microscopy revealed morphology of overload fracture consisting of dimples. Away from this corner also the fracture was similar as being due to overload. There was no evidence of there having been any fatigue failure.

3.2.11.10 At B.A.R.C., a sample was cut from the corroded corner of the failed left side trunnion fitting and metallographic examination was carried out on the same. The said examination showed on a face perpendicular to the corroded fracture surface, pits due to corrosion by sea water. The basic microstructure was however free from intergranular cracking. It was thus concluded by the experts that the material in the region corroded by sea water had not suffered stress corrosion cracking which generally manifests as intergranular cracking.

3.2.11.11 A piece of the trunnion fitting was cut and the hardness and electrical conductivity values were measured by the said experts. As per their report, the electrical conductivity values were within the specified limits.

3.2.11.12 Target 8 - Lower Fuselage Skin Panel

This skin panel was located below the aft cargo area and extended from B S 1860 to 1960 and from stringer 46L to 46R. The forward end of target 8 matched with the aft end of Target 7. A region of fracture along the rivet holes near stringer 46L was marked for SEM examination. SEM examination after cleaning revealed that the fracture was characterised by dimples along its length, including areas adjacent to the edges of the rivet holes. These features are consistent with an overload mode of failure.

3.2.11.13 According to the metallurgical report, there was no evidence of fatigue failure on this target.

3.2.11.14 Target 35 - Portion of Rear Pressure Bulkhead

Looking forward from behind the aircraft, this segment of pressure bulkhead occupied the 9 to 1 O'Clock position, the piece from 12 to 1 O'Clock position had the flange from the outer ring attached. The web below the outer ring flange had areas of buckling. From the 11 to 12 O'Clock position the outer edge showed sinusoidal buckling, and the edge sector at 9 O'Clock position was partially collapsed and its edge was turned under. Samples taken for optical stereo microscope and SEM examination revealed that the fracture characteristics were consistent with an ovrload mode of failure.

3.2.11.15 According to the metallurgical report, there was no evidence of fatigue or any other mode of failure.

3.2.11.16 Target 296 - Portion of Rear Pressure Bulkhead

Looking forward from the rear of the aircraft, this segment of the bulkhead occuped the 7 to 9 O'Clock position. Optical and SEM examination were undertaken on this item.

3.2.11.17 The fracture alont the left-hand edge of target 296 (viewed from the rear) was examined optically prior to removing any representative samples. The fracture was at the rivet line at a skin splice, except for a length of fracture about 15 inches long near the forward end, which was through the skin away from the rivet line. Most of the rivet holes along the fracture path showed some slight elongation and skin deformation.

3.2.11.18 Representative fracture samples were cut from the left-hand side and circumferential fracture edges of the fracture surfaces. Optial and SEM examination revealed that the fracture characteristics are consistent with an overload mode of failure.

3.2.11.19 Target 47 - Aft Cargo Floor Structure

This portion of the aft cargo compartment was located between B S 1600 and B S 1760. No significant observation was noted. There was no evidence to indicate characteristics of an explosion emanating from the aft cargo compartment.

3.2.11.20 Target 117 - Floor with Seats Attached

These seats were right-section doubles, located between B S 1880 and 1980 and were from rows 46, 47 and 48, F and G (Zone E). The seats were displaced to the left with the rear legs buckled to the left. The front leg supports exhibited only minor damage. The middle and rear doubles had aisle-side seat arms bent to the right. There was no impact damage to the seat backs or seat pans, and all life vests except one were gone from the underseat container bags.

3.2.11.21 In the metallurgical report it is stated that on an examination of this target it was also found that on the underside of this floor near the forward end, a number of dents and impact marks were observed. This region appeared to have suffered shrapnel penetration. This area was radiographed but no metallic fragment was detected.

3.2.11.22 Target 193 - Fuselage Side and 2L Entry Door

The fuselage segement was located between B S 720 and 840. The door and fuselage skin were buckled outwards, approximately in line with the buckling on the fuselage and 2R entry door directly opposite.

3.2.11.23 Target 399 - Fuselage around 2R Door

This target is shown in Fig. 399-1. A detailed description is given below :

TARGET 399 Fuselage Station 780 to 940 in the longitudinal direction and stringer 7R down to stringer 35R circumferentially.

This piece contained five window frames, one in the 2R passenger entry door. Three of the window frames, including the door window frame, still contained window panes. Little overall deformation was found in the stringers and skin above the door. The structure did contain a significant amount of damage and fractures in the skin and stringers beneath the window level. In the area beneath the level of the windows, the original convex outward shape of the surface had been deformed into an inward concave shape. Further inward concavity was found in the skin between many of the stringers below stringer 28R. The skin at the forward edge of the piece was folded outward and back between stringers 25R and 30R. Over most of the remaining edges of the piece a relatively small amount of overall deformation was noted in the skin adjacent to the edge separations. Twelve holes or damage areas were numbered and are further described.

No.1 : Hole, 5 inches by 9 inches with two large flaps and one smaller curl, all folded outward. Reversing slant fractures, small area missing.

No.2 : Hole, 2 inches by 3/4 inch, one flap folded outward, reversing slant fractures, one curled sliver, no missing metal.

No.3 : Triangular shaped hole about 2 inches on each side. One flap, folding inward, with one area with a serrated edge. No missing metal, extensive cracking away from corners of the hole, reversing slant fracture.

No.4 : Tear area, 8 inches overall, with deformation inward in the centre of the area. Reversing slant fracture.

No.5 : Fracture area with two legs measuring 14 inches and about 24 inches. Small triangular shaped piece missing from a position slightly above stringer 27R. Inward fold noted near the joint of the legs. An area of 45° scuff marks extend onto this fold.

No.6 : Hole about 2.5 inches by 3 inches with a flap folded outward, reversing slant fracture. Approximately half the metal from the hole is missing.

No.7 : Hole about 3 inches by 1 inch, all metal from the hole is missing. Fracture edges are deformed outward.

No.8 : Forward edge of the skin is deformed into an "S" shaped flap.

Three inward curls noted on an edge.
No.9 : Inwardly deformed flap of metal between stringers 11R and 12R at a frame splice separation. No evidence of an impact on the outside surface.
No.10 : Door lower sill fractured and deformed downward at the aft edge of the door.
No.11 : Frame 860 missing above stringer 14R. Upper auxilliary frame of the door has its inner chord and web missing at station 860. A 10 inch piece of stringer 12R is missing aft of station 860.
No.12 : Attached piece of floor panel (beneath door) has one half of a seat track attached. The floor panel is perforated and the lower surface skin is torn.
3.2.11.24 Much of the damage on this target was on the skin and stringers beneath the window level, i.e., on the starboard side of the front cargo hold. The inside and outside surface of the skin in this region are shown in Fig. 399-2 and 399-3 respectively. There were 12 holes or damaged areas on the skin as described above, generally with petals bending outwards. The curl on a flap around hole no.1 shown in Figh 399-4 has one full turn.
This curl is in the outward direction. Cracks were also noticed around some of the holes. Part of the metal was missing in some of the holes. The edges of some of the petals showed reverse slant fracture. In one of the holes, spikes were noticed at the edge of a petal.
3.2.11.25 When this target was recovered from the sea, along with it came a large number, a few hundreds, of tiny fragments and medium size pieces, All of the fragmets were recovered from the area below the passenger entry door 2R. One of the medium size pieces recovered with this target was a floor stantion, about 35 inches long, shown in Fig. 399-5. It is a square tube. It had the mark station 880 painted on its inner face, i.e. facing the centre line of the cargo hold. The part number printed on this station is 69B06115 12 and the assembly number is ASSY 65B06115-942 E3664 1/31/78*. It was confirmed that this stantion belongs to the starboard side of the forward cargo hold. The inner face of the stantion had a fracture with a curl at the lower end, the

curl being in the outboard direction and up into the centre of the station. Fig. 399-6 is a print from the radiograph of this station. The inward curling can be seen clearly in this figure. Curling of the metal in this manner is a shock wave effect.

3.2.11.26 A piece near the fracture edge of this stantion was cut, and examined metallographically. Fig. 399-7 and 399-8 show the microstructure of this piece. Twins are seen in the grains close to the fracture edge. The normal microstructure of the stantion material is free from twins as shown in Fig. 399-9.

3.2.11.27 Fig. 399-10 shows a collection of small fragments recovered along with target 399. There were some curved fragments with small radius of curvature (A). Reverse slant fracture (B) was noticed in some of the skin pieces. A piece 3/4" x 1/2" and 3/16" thick was found to have three blunt spikes at the edge (C). This piece was metallographicaly polished on the longitudinal edge. The microstructre of the piece is shown in Fig. 399-11. It may be seen that the grains in this fragment also contain a large number of twins.

3.2.11.28 Target 362/396 Forward Cargo Skin

This piece indluded the station 815 electronic access door, portions of seven longitudinal stringers to the left of bottom centre and five longitudinal stringers to the right of bottom centre. The original shape of the piece (convex in the circumferential direction) had been deformed to a concave inward overall shape. Multiple separations were found in the skin as well as in the underlying stringers. Further inward concavity was found in the skin between most of the stringers.

3.2.11.29 The two sides of this piece are shown in Fig. 362-1 and 362-2. This piece has 25 holes or damaged areas in most of which there are multiple petals curling outwards. These holes are numbered 1 to 3, 4a, 4b, 4c and 5 to 23. These are described below. Unless otherwise noted, holes did not have any material missing :

No.1 : Hole with a large flap of skin, reversing slant fracture.

No.2 : Hole with multiple curls, reverse slant fracture.

No.3 : Hole with multiple flaps and curls, reversing slant fracture, one area of spikes (ragged sawtooth)

No.4A : One large flap, reverse slant fracture, one area of spikes.
No.4B : Hole with two flaps.
No.4C : Hole with two flaps, one area of spikes
No.5 : HOle with two flaps.
No.6 : Braching tear from the left side of the piece, reversing slant fracture.
No.7 : Hole, with one flap, one curl and one area of spikes.
No.8 : Very large tear from the left side of the piece with multiple flaps and curls, reversing slant fracture and at least two areas of spikes.
No.9 : Hole with multiple flaps, one curl.
No. 10 : 2.5 inch tear
No.11 : One flap
No. 12 : Grip hole, plus a curl with spikes on both sides of the curl.
No.13 : "U" shaped notch with gouge marks in the inboard/outboard direction. Three curls are nearby with one are of spikes. Gouges found on a nearby stringer and on a nearby flap.
No. 14 : Nearly circular hole, 0.3 inch to 0.4 inch in diameter. Small metal lipping on outside surface of the skin. Most of the metal from the hole is missing.
No. 15 : Hole in the skin beneath the first stringer to the left of centre bottom. Small piece missing.
No. 16 : Hole in the stringer above hole No. 15. Most of the metal from this hole is missing.
No. 17 : Hole through the second stringer to the left of centre bottom, 0.4 inch in diameter. The hole encompassed a rivet which attached the stringer to the outer skin. Small pieces of metal missing.
No. 18 : Hole at the aft end of the piece between the third and fourth stringers to the left of centre bottom. The hole consisted of a circular portion (0.4 inch diameter), plus a folded lip extending away from the hole. The metal from the circular area was missing.
No. 19 : Hole with metal folded from the outside to the inside, about 0.6 inch by 1.5 inch. Flap adjacent to the hole contained a heavy gouge mark on the outside surface of the skin.
No. 20 : Hole containing a piece of extruded angle.

No. 21 : Hole containing a piece of extruded angle.

No. 22 : Hole with one flap.

No. 23 : Hole about 0.3 inch in diameter, with tears away from the hole. Small piece missing.

3.2.11.30 Fig. 362-3 to 362-7 show a few of these holes. There were also cracks or tears around some of the holes. The curls around some of the holes had nearly one full turn. In the large tear between body stations 700 and 740 and stringers between 41L and 45L, there were many pronounced curls as shown in Fig. 362-8. On the edges of the petals around

several holes, reverse slant fracture was seen at a number of places. This slant fracture is at an angle of about 45° to the skin surface, the fracture continuing in the same general direction but with the slope of the slant fracture reversing frequently.

3.2.11.31 Sharp spikes were observed at the edges of the holes or at the edges of the petals around the holes No. 3, 4A, 4C, 7, 8 (at two locations), 12, 13 and 16. Some of the spikes are shown in Fig. 362-9 to 362-12. One of the holes, No. 14, on the skin was nearly elliptical with metal completely missing, as shown in Fig. 362-13. On the inside surface of the skin, paint surrounding this hole was missing. Hole No. 16 was through the hat section stringer, as shown in Fig. 362-14. In this, most of the metal was missing. On the inside of the hat section, the fracture edge of this hole had spikes, as shown in Fig. 362-15. Hole No. 17 was through the stringer and the skin, as shown in 362-16.

3.2.11.32 Through holes No. 20 and 21, extruded angles were found stuck inside, as shown in Fig. 362-17 and 362-18 respectively. In the petal around hole No. 20, there was an impact mark by hit from the angle as seen in Fig. 362-19 photographed after removing the angle. Such a mark was not present in the petals around other holes.

3.2.11.33 On the skin adjacent to hole No. 13 gouge marks were noticed, Fig. 362-20. These marks were on the inside surface of the skin. To check whether these could be due to rubbing by the bridal cable of Scarab during the recovery operations, a sample of bridal cable was obtained from "John Cabot" and gouge marks were produced by pressing this cable against an aluminium sheet. The gouge marks thus produced, as shown in Fig. 362-21, appear to be different from those observed near hole No. 13.

3.2.11.34 A piece surrounding hole No. 14 was cut out and examined in a Jeol 840 scanning electron microscope at the Naval Chemical and Metallurgical Laboratory, Bombay. Fig. 362-22 and 362-23 are the scanning electron micrographs showing the inside surface and outside surface of the skin around this hole. Flow of metal from inside to outside can be seen from these figures. Energy dispersive x-ray analysis was carried out on the edges of this hole. Only the elements present in this alloy and sea water residue were detected.

3.2.11.35 A portion of the skin containing part of hole No. 14 was cut, polished on the thickness side of the skin and examined in a metallurgical microscope. Fig. 362-24 shows the microstructure of this region. The flow of metal along the edge of the hole can be seen from the shape of the deformed grains near the hole. This can be compared with the bulk of the grains shown in Fig. 362-25, away from the hole. In addition, in Fig. 362-24, a series of twin bands can be seen in some of the grains near the hole. Fig. 362-26 shows these bands at a higher magnification. Normal deformation rates at various temperatures do not produce such twinning in aluminium or its alloys. It may be noted that this microstructural feature is absent in the microstructure of the skin, away from hole No. 14, Fig. 362-25.

3.2.11.36 Metallography was also carried out on a petal around hole No.7 and on a curl with spikes around hole No. 12. The microstructures indicate twins, however they could not be recorded due to their poor contrast.

3.2.11.37 Small pieces containing the spikes around holes No. 12 and 16 were cut and energy dispersive x-ray chemical analysis on the region of spikes in both was carried out in the Jeol 840 SEM. Only elements present in the alloys and sea water residue were detected.

3.2.11.38 A number of small fragments were found along with the forward cargo skin in target 362. Amongst them was a piece from the web of a roller tray. This has pronounced curling of the edges towards the drive wheel, Fig. 362-27.

3.2.11.39 Another small fragment was found from the above target. This piece, identified as specimen No. 12 in box No. 1, target 362, has a number of spikes along the edge. A scanning electron micrograph of the spikes is shown in Fig. 362-28. The sides of the spikes on SEM examination revealed elongated dimples as shown in Fig. 362-29, characteristic of shear mode of fracture. Metallography was carried out on the thickness side of this specimen. Fig. 362-30 and 362-31 show the microstructure near the apex of the spike and at the root of the spike respectively. Extensive twinning can be seen in these regions of the spikes.

3.2.11.40 Another fragment recovered with target 362 and identified as specimen No. 8 in box No. 1, also showed extensive twinning. The microstructure is recorded in Fig. 362-32.

3.2.11.41 Reference has also to be made to two other reports concerning wreckage.

3.2.11.42 The floating wreckage recovered was initially examined at Cork. On 25th June, Mr. Eric Newton a retired investigator of AIB, UK, was requested to examine the floating wreckage recovered and other materials with specific reference to the possibility of explosive sabotage having taken place. Mr. Newton examined the floating wreckage, passenger clothings and the other materials recovered from the crash victims The findings of Mr. Newton on the material available at that time are summarised below:

a. Taking the scatter of the wreckage and bodies into consideration and the condition of the limited wreckage recovered indicates that the aircraft had broken up in flight before impact with the sea.

b. Detailed examination of the structural wreckage recovered did not reveal any evidence of collision with another aircraft. Nothing was found suggestive of an external missile attack.

c. There was no evidence of fire internal or external.

d. There was no evidence of lightning strike.

e. Examination of all available structural parts recovered, did not reveal any evidence of significant corrosion, metal fatigue or other material defects. All fractures and failures were consistent with overstressing material and crash impact forces

f. Examination of clothing from the bodies did not show any explosive fractures or any signs of burning. The seat cushions and head cushions also did not show any explosive characteristics.

g. The damage to the suitcases (14 large and 29 small) which were examined was due to impact crash forces. The presence of 14 large suitcases could, however, indicate that one of the baggage containers had been broken to permit these suitcases to escape.

h. A number of lavatory doors and structure also did not show any damage consistent with explosion. The flight deck door showed no explosion damage inside or outside.

i The circumstatnial evidence strongly suggests a sudden and unexpected disaster occurred in flight.

j. There was no significant fire or explosion in the flight deck, first and tourist passenger cabin including several lavatories and the rear bulk cargo hold.

3.2.11.43 The other report dated 30th November, 1985 is of Mr. V.J. Clancy. Mr. Clancey had examined the wreckage and had also taken part, though only for a few days, in the metallurgical examination which was being conducted at BARC, Bombay.

3.2.11.44 Mr. Clancey examined practically all the items of wreckage which had been brought to BARC and in his report he has dealt with all of them. His report contained a description of the recovered items and also his comments thereon.

3.2.11.45 With regard to the aforesaid target 362, he observed that there were about 20 holes in it clearly resulting from penetrations from inside.

3.2.11.46 He further stated that:

"In addition to the fact that perforation was from inside there are certain features which suggest that they were made by high velocity fragments such as are produced by an explosion. These features are:

(a) Presence of toothed or spiked edges at some parts of the metal which had petalled out from the perforations.

"Tardif and Sterling (Canadian Aeronautics and Space Journal, 1969, 16, 1, 19-27) obtained spiked fractures in fragments from sheet alloy subjected closely to an explosion. They stated that they had not obtained this effect in fractures otherwise produced.

(b) Presence of marked curling, in some cases of more than 360°, of some of the petals.

Tradif and Sterling stated that such curling was a feature of explosively produced fragments.

(c) The virtual absence of scratches or score marks on the petals such as might be expected if something were slowly forced through the metal.

(d) The virtual absence of other impact marks on the inside surface such as might have been produced by a massive impact with a substantial object. This suggested that the production of at least many of the perforations were separate independent events.

(e) One perforation (identified as No. 14) resembles a "bullet hole", that is cleanly punched out - a type of hole usually associated with a high velocity missile.

"There is evidence that the forward part of this item had been folded back inwards along the line of station 760 and then bent back again along a line slightly forward of this station.

"Such folding, may be violently produced on impact with the water, could have brought broken metal of stringers or stiffeners into forceful contact with the internal surfaces producing perforations outwards. The overlap of such folding would conceivably have covered the area up to station 800 and thus included most of the perforations.

"One hole identified as No. 13, was almost certainly caused by a slipping wire rope used as a sling.

"Part of the inner surface, aft of station 780 was superficially blackened as if by soot from a fire. Swabs were taken by me of this area and are being examined by R.A.R.D.E. for evidence of fire or explosives".

3.2.11.47 There were several hundred small fragments which were recovered from the same general area as Target 362. While dealing with these Mr. Clancey observed that the production of a large number of small fragments is generally regarded as indicative of an explosion. One piece out of this was isolated, which was about one inch square of sheet alloy, and it was noted by Mr. Clancey that this piece had characteristic spikes on one edge similar to those described by Tardif and Sterling. (This piece is the same as shown in Fig. 362-28).

3.2.11.48 Mr. Clancey also examined a few suit cases which had been recovered. One particular suit case to which reference was made by him was of red plastic material with blue lining. With regard to this he stated that the damaged lining, severely tattered, resembles that of one found after an explosion in an aircraft in Angola. In that case microscopic examination showed definite evidence of damage by an explosion.

3.2.11.49 The later part of the report of Mr. Clancey contained his opinion. With regard to Target 362 his opinion was as follows:

"The features discernible to a careful close visual examination point towards the possibility of an explosion but taken alone do not justify a firm conclusion.

"Curling of petals and spiked or toothed fractures may be observed in other events than explosions despite the failure by Tardif and Sterling to obtain them in their limited number of attempts. It is probable that these features indicate a rapid rate of failure but not necessarily of a rapidity which could only be produced by an explosion.

"A more detailed study, metallurgical and fractographic, is required.

"The studies by Tardif and Sterling were done on fragments produced from aluminium alloy in contact with the explosive. Very little information is available on the behaviour of aluminium alloy some distance from the explosive and subjected to attack by secondary fragments. To determine this some trials will be necessary, to obtain reference samples for comparison.

"The single "bullet hole", No. 14, strongly supports an explosion hypothesis but, being the sole example of its kind, is not, by itself determinative.

"If the forward part of this item was forcefully and rapidly folded back to impact on the other part it might explain the other features apparent to visual examination. It would require detailed laboratory examination and tests to eliminate this possibility".

3.2.11.50 The opinion of Mr. Clancey about the small fragments was as follows:

"The production of a large number of small fragments is generally regarded as a pointer towards an explosive cause but cannot be relied upon unless it is clear that they could not have been produced by some other means. It is known that the break-up of an aircraft at high speed may produce great fragmentation.

"The single spiked fragment must be regarded as important but a single specimen is not, by itself, determinative."

3.2.11.51 It appeared to the Court that the report of Mr. Clancey required certain clarifications. It was suggested to Boeing Commercial Airplane Company by the Court that Mr. Clancey should appear as a witness. The Court received a message to the effect that Mr. Clancey felt that he could not add anything useful to his report.

3.2.11.52 A close examination of the report of Mr. Clancey shows that the opinion expressed by him in the later part of the report is at considerable variance with the observations contained in the earlier part of the report. Particularly with regard to Target 362 and the small fragments, Mr. Clancey has stated in his observations that there was strong evidence of explosion. In his opinion, however, he has stated that more detailed study is required. It is interesting to note that though Mr. Clancey has referred to the opinion of Tardif and Sterling, he has not chosen to contradict the conclusions arrived by them. Mr. Clancey has also not stated as to what could possibly have caused the special features which were noted on Target 362.

3.2.11.53 We find the metallurgical report inspires more confidence. Not only is reference and reliance made in the report to other expert opinions contained in various articles written by experts all over the world, certain explosion experiments were also carried out by the experts which led them to the same conclusion.

3.2.11.54 The particulars of the experiments so carried out and the results obtained therefrom have been stated in their report as follows:

EXPLOSION EXPERIMENTS

"To determine the damage by high velocity fragments or shock waves on a structure similar to the one in aircraft cargo hold, the following experiments were conducted on November 30 and December 1, 1985 at the Explosives Research and Development Laboratory, Pune, using plastic explosive (PEKI) and different mixtures of plastic explosive and TNT. The explosive was kept in a box made of sheet metal of 6" x 6" x 6" of 1/16" thickness. This box was kept inside another box made of sheet metal 2' x 2' x 2' of .04 or .06" thickness. The boxes were made of 2024 aluminium alloy sheets used for aircraft skin. To the inner surface of the outer box, hat section stringers similar to those used in the aircraft were riveted. The quantity of explosive used in the inner box was varied from 60 g to 100 g. The explosive was detonated with an electrical detonator. After the explosions the fragments and the panels were collected and examined.

"Experiments were also conducted to produce explosive damage on skin panels, individual hat section stringers and individual stantion tubes. In the case of stantion tubes experiments were carried out placing the explosive charge both inside and outside. The quantity of explosive used was varied from 5 g to 50 g.

"Various types of damages were recorded on all the targets. These include punched holes, petaling and curling around holes, spikes at fracture edges, curved fragments with small radius of curvature and reverse slant fracture. Fig. EXP-1 shows a collection of fragments. The features mentioned above are shown in Fig. EXP-2 to EXP-7. It may be noticed that the features produced by experimental explosion were similar to the features observed largely in target 362 of the wreckage. The small fragments had features similar to those in the fragments from targets 362 and 399.

"Metallography was carried out in (a) a specimen surrounding a punched hole in the skin (b) a specimen surrounding a hole in the stringer, (c) a curl in the stantion and (d) spikes in a fragment. In all these cases, the grains adjacent to the area of explosive damage are having twins. Two typical microstructures are shown in Fig. EXP-8 and EXP-9. Away from these areas the microstructure is normal. Thus it is confirmed that twinning in the microstructure of these structural members is a unique feature of explosive fracture, not produced by any other measns known so far."

3.2.11.55 The findings in the said metallurgical report are also strengthened by the observations of Eric Newton in the article "Investigating Explosive Sabotage in Aircraft" published in the International Journal of Aviation Safety, March 1985, p. 43. Mr. Newton is an acknowledged authority in the detection of explosive sabotage in aircraft. The conclusions contained in the article are based on his review of incidents of explosion between 1946 and 1984 which were known to him. Some of the conclusions arrived at by him which were relevant in the present case are when he states "Generally speaking, the smaller the fragment, higher the velocity of the detonation. Minute fragmentation is indicative of high explosive having been used, and provides clues to the focal point or region of the explosion. The mode of break up of the aircraft itself and its sequence of failure is usually very complicated and quite without the logic dictated by normal aerodynamic overstressing".

3.2.11.56 Mr. Newton has also observed that curling, cork-screwing, and saw tooth edges may also be indicative of an explosion though such fractures by themselves may not be conclusive evidence that an explosion was involved. Firmer evidence, according to him, was of fusing of metal, scorching, pitting and blast effect. He further states that "Perhaps the most conclusive material evidence to be found on metal specimens is cratering, very often in groups, often minute and numerous".

3.2.11.57 Mr. Newton also refers to the positive explosive signatures which remain on a detonation in an aircraft. These positive singatures, according to him, are as follows:

"(a) The formation of distinctive surface effects such as pitting or very small craters formed in metal surfaces, caused by extremely high velocity impacts from small particles of explosive material. Such craters, when viewed under the microscope, have raised and rolled over edges and often have explosive residue in the bottom of the crater.

"(b) Small fragments of metal, some less than 1 mm in diameter, which, under the scanning electron microscope, reveal features such as rolled edges, hot gas washing (orange peel effect, surface melting and pitting and general evidence of heat; such features have been proved and observed following explosive experiments with known explosives). Supporting strong evidence would be if such fragments (normally found embedded in structures, furnishing or suitcases) were found embedded in a body where evidence of burning of tissue is present at the puncture entry and where the fragment came to rest.

"(c) As well as surface effects on metal fragments produced by explosives there are deformation mechanisms which are peculiar to high rates of strain at normal temperature. At normal rates of strain metals deform by usual mechanism associated with dislocation movement. However, because this process in an explosion is thermally activated at very high rates of strain, there is insufficient time for the normal process to occur. In some metals such as copper, iron and steel, deformation in the crystals of the metal takes place by 'twinning', that is to say by parallel lines or cracks cutting across the crystal. Such a phenomenon can occur only if the specimen has been subjected to extreme shock wave loading at velocities in the order of 8000 m/sec. Such specimens, usually distorted must be selected with care, prepared in a metallurgical laboratory, polished, mounted and microscopically examined. Where such twinning of the crystals is found it establishes (a) that the specimen was close to the seat of the explosion and (b) that a military type explosive had been used with a detonating velocity of 8000 m/sec or more. Twinning is rarely produced when shock impact loadings are below 8000 m/sec.

"The above features, singly or combined, are considered to be proof positive evidence of a detonation of a high explosive; they could not be produced in any other way."

3.2.11.58 The metallurgical report indicates that the microscopic examination (conducted by them) discloses such features being present which had been described as positive signatures of the detonation of an explosive device in an aircraft by Mr. Newton. Furthermore, twinning effect has also been noticed at a number of places - around holes and in fragments. These have been categorised by Mr. Newton as positive signature of an explosion.

3.2.11.59 In the primary zone of explosion, metallic structures disintegrate into numerous tiny fragments and usually these fragments contain the above mentioned distinct signatures of explosion. In the present case the explosive damage had occurred at an altitude of 31000 feet when the aircraft was flying over the ocean. The fragments that formed due to explosion must have been scattered over a wide area and it is impossible to locate and recover all of them from the ocean bed. Nevertheless, some of the fragments which were recovered along with the targets 362 and 399 do contain signatures of explosive fracture.

3.2.11.60 From the aforesaid discussion it would, therefore, be safe to conclude that the examination of targets 362 and 399 clearly reveals that there had been a detonation of an explosive device on the Kanishka aircraft and that detonation has taken place not too far away from where these targets had been located.

FIRE

3.3.1 There is no evidence that there was any fire on board the aircraft before it met with the accident.

3.3.2 Amongst the floating wreckage, however, was found, what was later on identified as, a spares equipment box belonging to this aircraft. This box was charred on one side and partially on the bottom. The depth of charring suggested that the burning time was three to four minutes. This box contained some sand and small shellfish. The flesh from the shelfish appeared to be charred, indicating that the box was subjected to fire after the occurrence.

FLIGHT RECORDERS

3.4.1 Recovery of Flight Recorders

3.4.1.1 Recovery of the flight recorders was a very difficult and challenging job. At the site of accident, depth of water is about 6700 feet. The job involved fixing the location of recorders and then retrieving them. For this purpose three ships viz. Guardline Locator (a ship provided by Accident Investigation Branch of U.K.), Le Aoife (an Irish Naval Ship) and Leon Thevenin (a French Cable laying ship, charterd by the Government of India) were utilised. Guardline Locator and Le Aoife were solely for fixing the positions of recorders and also had the capability to lift the recorders with the help of its scarab.

3.4.1.2 Both the Cockpit Voice Recorder and the Digital Flight Data Recorder were fitted with Dukane Underwater Acoustic Beacons (Pingers) which enabled establishing the location of flight recorders under water. The Beacons are designed to provide a signal at 37.5 ñ 1 Khz frequency that can be heard for approximately 2 miles in any direction for 30 days after water entry. Its high strength case permits operation in water depth to 20,000 feet. Its pulse repetition rate is not less than 0.9 pulse per second.

3.4.1.3 On 4th July, 1985, Guardline Locator reported strong possibility of two separate sound sources of frequencies between 39 KHz and 42 KHz. On 5th July, Guardline Locator gave coordinates of an area, which it believed contained the pinger. Guardline Locator later reported that using a Dukane Hand Locator, it had located pinger (2) at 5102.6N, 1248.6W. Leon Thevenin then concentrated its search in this area for retrieving the recorders.

3.4.1.4 In response to a query, Messrs Dukane Corporation advised that Pinger transducer is made of ceramic and if cracked during impact, its frequency could be elevated. The pulse rate should, however, be uneffected. Keeping this in mind, the Leon Thevenin increased its Sonar Band one upper frequency limit from 40 KHz to 45 KHz.

3.4.1.5 On 9th July at about 2300 hours the Scarab of Leon Thevenin located the Cockpit Voice Recorder at 5102.67N, 1248.93W and the recorder was brought on the deck at 0747 hrs on 10th July. The CVR was kept in a drum filled with water. The scarab was again lowered on 10th July in the same area and at about 2130 hours faint signals were picked up on Sonar. By about 2200 hours the signals became louder and the pulse rate frequency was calculated to be 72 transmissions per minute. At about 2230 hours the DFDR was also located at 5103.10N, 1249.59W and it was brought on deck at 0245 Z on 11th July.

3.4.1.6 The DFDR was also placed alongside the CVR in the drum filled with water. Leon Thevenin was then advised to return to Cork with the Flight Recorders. Leon Thevenin reached Cork on the morning of 12th July and the flight recorders were placed in two specially fabricated water tight steel containers filled with water. The recorders were then carried to Bombay on the same day by Mr. Satendra Singh, Reginal Controller of Air Safety, Bombay, accompanied by Mr. Vishwanath of Air India for preparing read-outs and transcript of the recorders. Necessary precautions were taken to ensure that the data recorded was not affected during transportation to Bombay.

3.4.1.7 Both the recorders reached Bombay on the morning of 13th July and were kept in the office of the Regional Controller of Air Safety under Armed Police Guard.

3.4.2 Description of Flight Recorders

3.4.2.1 Kanishka was equipped with a Fairchild A-100 Cockpit Voice Recorder Serial No. 5809 and a Lockheed 209E Digital Flight Data Recorder Serial No. 1282. These were each equipped with Dukane Underwater Acoustic Beacons and were installed adjacent to each other in the cabin on the left side near the rear pressure bulkhead.

3.4.2.2 The CVR records all crew communications and sounds in the cockpit on a continuous tape loop which has a tape speed of 1-7/8 inches per second. The Recorder has two heads, one head which erases the previous recording and the second which records the current information and thus the last 30 minutes of recorded signals are retained, the previous being automatically erased. It continuously records convervations/sounds from 4 different sources on the following four separate channels:

Channel 1 : Radio channel of pilot

Channel 2 : Radio channel of flight engineer

Channel 3 : Cockpit Area Mike

Channel 4: Radio channel of co-pilot.

3.4.2.3 The serial digital signal recorded by the DFDR was generated by a Teledyne Flight Data Acquisition Unit installed in the forward electronics bay below the cabin floor. Adjacent to this unit was a Lockheed Model 280 Quick Access Recorder that recorded the same serial digital signals on to a 50 hour cassette.

3.4.2.4 The DFDR records 52 basic parameters on a magnetic tape. The tape preserves records of the last 25 hours. The serial digital signal has a bit rate of 768 bits per second and is recorded at a tape speed of 0.37 inches per second.

3.4.3 Examination of Flight Recorders and Tapes

3.4.3.1 General

The recorders brought to Bombay from Cork were opened on 16th July, 1985 at the Air India's Facilities in Bombay in the presence of the Court and Assessors. A team of foreign experts including one each representatives from both the Recorder Manufacturers, three from National Transportation Safety Board, one from Canadian Aviation Safety Board and one from NRC Flight Recorder Playback Centre, Canada were present when the tapes were taken out of the recorders. Apart from them, representatives of the Government of India and Air India were also present.

3.4.3.2 Cockpit Voice Recorder

When the unit was removed from its shipping and storage container, some mechanical damage was immediately evident. The top of the cover had been deformed inwards, probably due to initial external

strong attachments for the horizontally mounted Underwater Acoustic Beacon. The plate had torn away from the light structure behind it. The cause of the damage was not obvious. The light outer cover was removed by cutting it open with hand shears and pliers.

3.4.3.3 When the armoured and insulated containment was opened, the tape transport was found to be in relatively good condition and the tape physically undamaged. Eighteen inches of the tape was pulled from the centre of the tape stack and the tape cut near the stack well clear of the end of recording. The tape was then removed from the recorder, transferred to standard tape reels, laboriously cleaned several times with distilled water and dried with lint free absorbent material.

3.4.3.4 Digital Flight Data Recorder

When the recorder was removed from its shipping and storage container, it was noted that there was very little external damage. A cover on the rear section was removed and it was observed that, when viewed from the front of the recorder, the right hand edges of the four rearmost printed circuit cards were displaced towards the front of the recorder. The left hand edges were restrained by plug-in connectors to the boards. The rearmost card, that controls track selection on the tape, and the one in front of it, had bowed along the right-hand edges and popped out of their plastic guides in the top and bottom of the recorder. Deflection of the other two cards had occurred following failure of the attachments of the right hand ends of the plastic guides to the chassis. The damage could have been caused by a high lontitudinal decelaration, as would occur if the front face of the recorder impacted the water.

3.4.3.5 When the tape deck was opened, it was found that the tape was intact but had become dislodged from the last tape guide when the tape was moving in the direction of the odd-numbered tracks and had also jumped out of the adjacent end-of-tape sensor. One edge of the tape had been streteched in this area. The drive belt to the tape transport was still in its correct position. The tape was stuck to the third tape guide in the odd-numbered track direction and suffered some damage when it was finally detached from it. This was repeaired with a splicing tape.

3.4.3.6 The location of the record heads was marked on the back of the tape with a waterproof felt pen. It was noted that there was slightly more tape on the supply reel for the odd tracks than on the other reel. The tape reels and tape were removed from the recorder, keeping the tape wet with distilled water, and the tape transferred to the standard reels for meticulous cleaning. During the cleaning process, it was found that the edge of the tape had also been stretched locally 336 inches down- stream from the splice repair in the odd track direction. The tape was dried by patting it with absorbent lint-free material before loading it into a serviceable recorder as this was the only means by which it could be replayed at the Air India base.

3.4.3.7 The circuit card controlling track selection was removed from the accident recorder and the status of the latching relays checked to determine the last track on which recording was being made. It was found that the relay states indicated Track 1, but since this requires all relays to be set in the same condition, it was considered possible that they had been mechanically set on water impact. The card was subsequently inserted to another recorder and the Track 1 setting confirmed on a test bench.

3.4.3.8 When a change in track selection was attempted, it was found that the relays would not switch, probably due to the effects of salt water corrosion or high water pressure. It was decided that Track 1 would be considered as the most likely one to contain the accident data with the possibility that it could have occurred on any of the other tracks. When the data was recored, the accident information was found some distance past the mid-point of Track 1.

3.4.4. Recovery of Information

3.4.4.1 Cockpit Voice Recorder Tape

The spool was removed from the CVR and was washed with distilled water, dried and loaded on to another spool. The cleaned and dried tape was taken to the Bhabha Atomic Research Centre (BARC), and a copy of the tape was prepared which was used for preparing transcript and carrying out further analysis. The transcript of the CVR conversation is given in Appendix 2.

3.4.4.2 Shannon Air Traffic Control Tape

A copy of this tape that contains all radio communications between the aircraft and Shannon was provided to the Indian Authorities by the Air Traffic Control Authorities, Shannon. The recording also included the short series of unusual sounds that occurred about the time of the accident.

3.4.4.3 When the CVR and the ATC tapes were played it was found that some adjustment in speed was necessary so as to synchronize the two. This adjustment was independently carried out by different experts who analysed the CVR tapes.

3.4.4.4 Digitial Flight Data Recorder Tape

The Lockheed representative had brought a Lockheed Model 235 Copy

Recorder from his plant. This unit copies all the 25 hours of data from the recorder by running it at high speed for only two passes of the tape, an operation lasting only 16 minutes. A copy tape was made by this procedure before embarking on the standard Air India recovery procedure to serve as a back-up tape in the event of physical damage to the original tape in subsequent playback.

3.4.4.5 Air India playback equipment for the DFDR required that the tape be re-installed in another DFDR in which it was driven at high speed. In the standard playback procedure, the tape was first run to the beginning of Track 1 through 6 sequentially on to a computer tape followed by a repeat of Track 1. The computer tape was then taken to Air India's main computing facility where selected information was printed out in engineering units.

3.4.4.6 The first printouts showed that the accident was recorded on Track 1, as indicated by the latching relays, and suggested a rather abrupt end to the recording. There was a loss in bit synchronization in word 26 of the last Subframe 3 of data that was followed by a normal Subframe 4. Prior to the loss in bit synchronization, all measurements appeared normal. Plans were made to borrow the high speed oscillograph recorder previously used to studythe final CVR signals from BARC to examine the end of the recorded serial digital signal in detail.

3.4.4.7 Meanwhile, the critical section of the tape and the heads of the playback recorder were re-cleaned and a second transfer of data on to the computer tape was made. Printouts from this computer tape showed no significant difference from the first one.

3.4.4.8 The recorder was then opened and the tape positioned about 1.5 inches before the final resting place of the tape that was clearly indicated by head imprints on the magnetic oxide coating side. A high speed oscillograph record of a few seconds of data was made and visually decoded. It was found that the recorded GMT was 21 hr 16 min. This time corresponded to 15 min or about 333 inches of the tape after start of the oldest recording downstream of the accident.

3.4.4.9 The tape was then re-positioned using a Lockheed analogue playback unit, that had a display of the recorded time and a stopwatch was used to locate the accident timing. Two oscillograph copies of the end of the serial digital data were made, the second one having more data preceding the end. Visual reading of the traces confirmed that recording became erratic and irrecoverable at the end of Word 26 in Subframe 3 at the recorded time of 07 h : 14m : 35s. The erratic signal continued for about 0.27 inches of the tape before switching back to the data recorded 25 hours earlier.

3.4.4.10 Examination of the printouts confirmed a suspicion that the complete Subframe 4 of data following the partial Subframe 3, was data from 32 seconds earlier that had not been cleared from the data buffer in the computer and that Word 26 of the Subframe 3 was the last normal measurement provided by the recorder.

3.4.4.11 The end of recording occurred at the point on the tape at which some damage had been observed during the cleaning process. It was apparent that, after the end of the recording, the tape had run on for 336 inches before finally coming to rest.

3.4.4.12 A copy tape of the DFDR tape was made at Bombay and taken to Ottawa. Data from the accident flight, the preceeding Toronto-to-Montreal flight and part of the cruise conditions of the earlier flight to Toronto were transcribed on to the computer tape. The tape was edited to minimize errors and converted to engineering units using standards calibration. Time histories of all parameters for periods of interest were plotted. In addition, chart records were made of all parameters in raw data form for the total duration of the last lap of the flight.

3.4.4.13 The DFDR read out shows that the aircraft was cruising at an altitude of 31,000 ft. and a computed air speed of 296 knots till it suddently stopped recording at 07:14:35 GMT recorded time.

3.4.5 Reports received by the Court

3.4.5.1 The CVR was taken to B.A.R.C. This tape was played by the CVR group a number of times and hard copies of the time information were also prepared using an ultra violet (UV) Recorder. The group consisted of Mr. Satendra Singh, Regional Controller of Air Safety of D.G.C.A., Mr. S.N. Seshadri of BARC, Mr. Paul C. Turner of NTSB, USA, Mr. John G. Young of NTSB, USA and Mr. P. dE Niverville of CASB, Canada. On 18th July, 1985 this group made the following observations after playing the aforesaid tape (UV recording of CVR is at Fig. 1) :-

"The first visible rising signal volume was observed on channel number three the CAM channel It reaches a maximum in about 50 milliseconds. At this time noticeable disturbances are observable on the other three channels. A smaller disturbance is observable on channels 2 and 4 earlier than observable on channel 1. A major disturbance is observed to begin approx. ninety milliseconds following the initial observation on channel number 3 (CAM), on channels 1,2 and 4. Following this point at 75 milliseconds the CAM signal subsides to a lower level but much higher than observed ambient (prior to disturbance) where it remains for approximately 375 milliseconds from initiation when it ceases. Channel four goes off at the same time. Channel 1 goes off twenty five milliseconds earlier. Channel two is inconclusive and had a different pattern. All four channels exhibit a disturbance at approx. 450 milliseconds. The cockpit voice recorder power then shuts off at 650 milliseconds.

The Shannon area control centre tape made the night of the accident was examined and printed. It shows a signal was received at approximately the time the aircraft disappeared from radar. It isn't conclusive at this time that the signal originated from the accident aircraft. The signal was received in pulses for approximately five seconds."

3.4.5.2 The tape was again played on 19th July, 1985 and a further report was prepared which was signed by the aforesaid persons and Mr. B. Caiger of NRC, Canada. In this report it was stated as follows:-

"The Shannon area control centre tape was again printed at .05"/second per inch speed from approximately 22 sec. before the first broadcast from the accident aircraft at 0709.58 until Radio carrier with indecipherable modulation can be heard at 0714:01. The print contains a time encoded signal.

A similar print was made from the CVR channel 4 (Co-Pilot's) of the same audio as received on the ATC tape. Although the tape speed is different, the events when corrected for tape speed errors occur at the same time. It appears that the ATC recording contains the beginning of the aircraft breaking until power is lost to the transmitter since channel one and channel four (Capt + Co-pilot's radio) appear to contain a transmitted signal on the CVR. It is probable that the ATC signal at 0714:01 coincides with the final quarter second of CVR radio channels".

3.4.5.3 On the date i.e. 19th July, 1985, Mr. Paul Turner of NTSB also gave an additional report which is to the following effect :-

"During my observations of numerous cockpit voice recorders I have heard and observed a number of aircraft breakages due to various causes. In this case the explosive sound on the CAM channels occurs prior to any electrical disturbance observable on the selector panel signals. Electrical disturbances can generally be seen prior to audio signal when explosive sounds originate at any significant measureable distance from the microphone (15 feet) and in the area where there is significant electrical systems. It is my opinion that an explosive event occurred close to the cockpit. The CAM signal which follows the explosive event shows a very much higher noice level than cockpit ambient 85 db, indicating to me the cockpit area was penetrated and opened to the atmosphere. The selector panel signals show signatures similar to those of an aircraft breaking up and are apparantly caused by electrical systems disturbance (circuit breaker blowing, fuse switching etc.). The lack of Mayday call and apparent inadvertant signal from the cockpit crew incapacitation. The transmitter coming on due to breakup is phenomena observed previously.

This contains only my personal opinion and in no way should be considered a final determination of cause without corroborating evidence".

3.4.5.4 Copies of the tapes were also sent to some of the participants who wanted to carry out independent analysis.

3.4.5.5 With regard to DFDR the Court received reports from Dr. Caroll Roberts of NTSB and report dated 11th November of Mr. B. Caiger.

3.4.5.6 With regard to CVR the Court received reports from Mr. B.

Caiger dated 11th November, 1985, report dated November, 1985 of Mr. R.A. Davis, Head, Flight Recorder Section, Accidents Investigation Branch, Farnborough, U.K., report dated 31st August, 1985 of Mr. S.N. Seshadri of BARC, Bombay.

3.4.6 Court Observations

3.4.6.1 Digital Flight Data Recorder

The reports of Dr. Caroll Roberts and Mr. Caiger which also coincide with the report submitted by Mr. Satendra Singh disclose that the DFDR showed no evidence of abnormal values of any of the many parameters being monitored upto a point at which the recorded data signal became irregular for a fraction of a second and recording ceased. Both the DFDR and the CVR stopped at the same time.

3.4.6.2 The short period of irregular digital data that occupied only 0.27 inches of tape, most probably indicates that the recorder was subjected to a sharp angular acceleration in the left wing down sense about the aircraft longitudinal axis.

3.4.6.3 According to Mr. Caiger's report the possibility that the digital recorder was subjected to a sharp disturbance more rapid than violent motion of the aircraft lends some credence to the possibility of a detonatiaon of an explosive device in the aircraft. The other alternative, according to Mr. Caiger, which could have led to this was that the Flight Data Acquisition Unit in the main electronics bay .or its power supply were suddenly disturbed. As the Lockheed Quick Access Recorder was not recovered from the wreckage, this possibility could not be investigated further. A perusal of the DFDR print out, however, shows that whereas there was a speed limit of 290 knots (.81 Mach) of the aircraft due to carriage of the 5th pod engine, in actual fact the aircraft's speed during cruise varied from 287 to 296 knots. Mr. H.S. Khola asked the Boeing Airplane Company to examine the effect of aircraft cruising at a speed of 296 knots with a 5th pod engine installed on it. The Boeing company sent a reply, inter alia, stating as follows:

"The operating speed limit of Air India 747-237B, JT9D-7J with fifth engine pod was 290 knots indicated airspeed, with an altitude limit of 35,200 feet. Flight testing of this model airplane configuration was successfully accomplished to a dive speed of 386 knots calibrated airspeed and 0.92 Mach number, with no adverse effects.

In the event that the operating speed placard was exceeded an increase in perceptible vibration levels would be felt. As the dive Mach number (0.92) is approached the buffet vibration would increase to level that could become objectional to the flight crew, but would not he bazardous".

3.4.6.4 It would thus be clear that if no adverse effects could have been noticed with a dive speed of 386 knots calibrated airspeed and 0.92 Mach number, there was little likelihbood of the aircraft having been subjected to any adverse effect by reason of the speed varying from 287 to 296 knots while it was cruising at a height of about 31,000 feet.

3.4.6.5 Cockpit Voice Recorder

The Court received four reports of the CVR tape analysis. These reports were of Mr. B. Caiger, Mr. R.A. Davis, Mr. S.N. Seshadri and Mr. Paul C. Turner. Whereas the first three experts appeared and deposed in Court, Mr. Paul Turner did not come.

3.4.6.6. There were certain aspects of the report of Mr. Turner which required clarification. After the Court had failed to secure his presence, it sent a questionnaire to Mr. Turner for his answers thereto. It is indeed unfortunate that till now no reply has been received. It is in this background that the report dated 13th November, 1985 of Mr. Turner and the reports of other experts have to be judged and analysed.

3.4.6.7 Mr. B. Caiger's Report and Deposition

Mr. Caiger has said in his report that the Cockpit Area Microphone signal was studied in detail. According to him, in an aircraft, sound can be transmitted by multiplicity of paths. If an explosive device was located close to the microphone then the short wave from the disturbance would cause a sharp rise in pressure which was not noticed. From more remote location, however, structurally transmitted sounds could reach the microphone first and induce more complex signals. According to Mr. Caiger, at this time he did not have any evidence from occurrences of this nature that would permit any meaningful comparisons or conclusions.

3.4.6.8 Mr. Caiger obtained from the manufacturers details of Automatic Gain Control (AGC) on the cockpit area microphone. According to the information so provided it was indicated that the decrease in amplitude of the recorded noise over about 33 msec after the peak level was reached 40 msec from the start of the disturbance is most probably due to the AGC and that the actual envelope of the pressure levels at the microphone continued to increase until 90 msec from the start before establishing at about four times the recorded level until the 160 msec point when the recorded amplitude started to decrease rapidly. Mr. Caiger could not find any explanation for this marked reduction. Mr. Caiger further recorded that the large amplitude lower frequency signature, that immdediately followed this reduction, is similar to signatures observed by the manufacturer when there was an abrupt break in the line from the cockpit area microphone pre-amplifier output to the voice recorder. No similar signature was observed in tests on the crew audio channels when the appropriate lines to the recorder were similarly interrupted.

3.4.6.9 The observation of Mr. Caiger with regard to ATC tape was as follows :-

"The ATC recording that followed the cockpit area microphone sounds appears at first to contain a series of short intermittant sounds. Closer study reveals that the background noise only returns to its steady level for about 160 msec immediately after the first low level noise and again for about 85 msec just over halfway through the 5.4 sec duration of the recordings. At the end of all routine radio transmissions, a damped sine wave transmitter keying signature is observed with a frequency in the region of 450 Hz. In the accident recordings, only two of these are observed".

"Listening to the sounds, it also appears that a human cry occurs near the end of the recordings. Spectral analysis of these sounds and comparison with voice limitations reveals that the accident sounds do not contain all the pitch harmonic frequencies normally associated with such voice sounds. The origin of all the sounds has not been identified."

3.4.6.10 From the aforesaid investigation Mr. Caiger concluded that :-

"From the voice and data recorders, Air India Flight 182 was proceeding normally enroute from Montreal to London, England at an altitude of 31,000 feet and a computed airspeed of 296 knots when the cockpit area microphone detected a sudden loud sound the cause of which has not yet been identified. The sound continued for about 0.35 seconds, and then almost immediately, the line from the cockpit area microphone to the cockpit voice recorder at the rear of the pressure cabin was most probably broken. This was followed by a loss of electrical power to the recorder".

"The initial waveform of the cockpit area microphone signal is not consistant with the sharp pressure rise expected with detonation of an explosive device close to the flight deck but, with the multiplicity of paths by which sound may be conducted from other regions of the aircraft, we cannot at this time exclude the possibility that it originated from such a device elsewhere in the aircraft".

"Within 1 to 2 seconds of the first detection of the loud sound on the cockpit area microphone, a series of unidentified noises were recorded on the Shannon ATC tape. These extended over a period of 5.4 seconds and are assumed to have origniated from VT-EFO. They gave the impression of abnormal conditions on the flight deck".

3.4.6.11 In his evidence in court, Mr. Caiger explained about Automatic Gain Control. He stated that the CAM channel of the CVR had an Automatic Gain Gontrol in a pre-amplifier that is installed close to the microphone. This AGC is designed to prevent excessively loud signals from saturating the microphone and the associated electronics. He further stated that from the tests conducted by the manufacturers it could be concluded that most likely at 45 msec. point the AGC came into effect which gradually reduced the signal over the next 33 msec. before letting it stabilise at a roughly constant value. This figure of 33 msec. was taken by Mr. Caiger not by carrying out any experiment himself but it was provided to him by the manufacturers. He also stated that there was no positive indication of structural failure being evident from the flight recorders. Mr. Caiger was asked to explain as to what was the reason for loud sound to which reference had been made in his report. In answer to the said question from the Court he said that there could be a number of reasons. The detonation of an explosive device not close to the microphone was one possibility, the occurrence of some type of structural failure was another possibility. He was further of the opinion that at the present stage of development in structural acoustics, he did not think it was possible to come up with any reasonable estimate of the location of either explosive device or some type of possible structural failure. When asked for his opinion about the sequence of events which he could determine by looking at the sound spectrum, he said as follows: "From the study that we have made which have of course been augmented by studies done by several other groups it would appear that there was a very sharp bang that was detected by the CAM. Approximately one-third of a second after this happened the line from the CAM to the CVR was disconnected but intermitant power supply was still being sent to the voice recorder for approximately one and a half seconds. During this 1-1/2 seconds period sounds were being transmitted from the 'Kanishka' aircraft that tend to suggest that the aircraft was in some distress. Though it is difficult to be specific about the basis on which we assesss the state of the aircraft, this signal ceased after a period of 5.4 seconds and we have no more audio information concerning the aircraft from that point onwards."

3.4.6.12 Mr. R.A. Davis's Report and Deposition

Mr. R.A. Davis in his report on the analysis of CVR has stated that he did not have with him a faithful copy of the original CVR tape. The tape supplied to his contained signals which warranted investigation but any measurement could be hampered by a decreased signal to noise ratio due to the copying process. Mr. Davis however analysed the tape which admittedly according to him was not of good quality. Mr. Davis in his report states that he carried out a spectrum analysis of the different channels of the CVR. The spectra did contain the sound of a bang. He however, could not find any significant low frequency content in the spectrum which according to him, would have been expected if the sound was of a high explosive detonation.

3.4.6.13 While carrying out detailed study of the tape he also looked out for any evidence of various audio warning signals which may have been buried in the noise. One such audio warning which could have been detected was that of pressurisation warning. Mr. Davis stated that this warning possessed a very defined frequency spectrum which was not present in the signal of the CVR of Kanishka. With regard to this he, however, stated that absence of this signal was not surprising as any decompression would take a finite time before reaching the warning level. Mr. Davis further observed that the presence of warnings due to attititude display disagreement, excessive speed and fire were investigated but with negative results.

3.4.6.14 During the course of investigations, Mr. Davis had compared Kanishka CVR recording with the recordings of an explosive decompression on a DC-10, a bomb in the freight hold of a B-737 and a gun shot on the flight deck of a B-737. According to Mr. Davis the spectrum of VCR tape of B-737 showed a much low frequency content with very little content at upper frequencies. This bomb, in the forward baggage hold of B-737, had exploded while the aircraft was at a low level and therefore the CVR did not have the sound accompanied with that of depressurization. That aircraft had landed safely. Mr. Davis, however, observed that if Kanishka's accident was caused by detonation of a high explosive device, then the spectra should have shown large low frequency content, but this was absent. He further opined that, even if there was a possibility of a bomb remote from the flight deck and of a low power, even then the characteristics of a bomb would still be apparent in the time record. He also analysed the spectrum of the sound of the hand gun shot on a B-737 flight deck and according to him the said signal was sharp edged and did not compare with that of Kanishka's signal.

3.4.6.15 Mr. Davis also analysed the sounds recorded on the ATC tape. He concluded that the sounds emanated from Air India's Kanishka aircraft. According to him the transmission from the ATC is "chopped" until at approximately 2.7 seconds into the transmission a loud noise lasting about 200 milliseconds is heard. This is followed about 0.5

seconds later by a sound which increases in volume. This sound was similar to that heard in other accidents where there had been a rapid increase in airspeed.

In the noise which continues until the end of the transmission is heard a crying sound. This was originally thought to be a human cry. He, however, noted that a human cry would contain more harmonics than was noticed in this case. It was also reported by Mr. Davis that knocking sounds which were heard during the transmission were initially thought to be due to hand-held microphone vibration. This was discounted because of the frequency of the sounds. He noticed that almost identical sounds were heard on the DC-10 CVR after the decompression had occured and the source of that sound had not been identified. On the DC-10 the pressurization audio warning commenced 2.2 seconds after the decompression. Analysing the ATC tape Mr. Davis observed that no such warning was identified during the open microphone transmission.

3.4.6.16 In conclusion, Mr. Davis reported as follows :-

"It is considered that from the CVR and ATC recordings supplied for analysis, there is no evidence of a high explosive device having detonated on AI 182.

"There is strong evidence to suggest that a sudden explosive decompression occurred but the cause has not been identified.

"Although there is no evidence of a high-explosive device, the possibility cannot be ruled out that a detonation occurred in a location remote from the flight deck and was not detected on the microphone. Such a situation would be most unusual, if not unique, in that we have never failed to detect sounds of structural failure, decompression, explosives etc., on any accident CVR, even though the event occurred at the rear of the aircraft. If such a device was used on AI 182 it is considered that it would have to be a very small device in order not to be detected (unlikely in itself). Such a device would be unlikely to cause the sudden total destruction which occurred in this instance. It is considered that a device of sufficient power to produce this effect could not fail to be detected on the CVR. The B-747 explosions referred to earlier, blew holes several feet wide in the structure but the crew were still able to control and operate the aircraft.

"It must be concluded that without positive evidence of an explosive device from either the wreckage or pathological examinations, some other cause has to be established for the accident".

3.4.6.17 In reply to a question it was stated by Mr. Davis, when he was examined in Court, that it was true that there was no evidence that rapid decompression was caused by any structural failure. In an answer to another question, as to whether in his opinion there is a low frequency content present in every situation whereever there has been a high explosive device detonated, Mr. Davis answered in the affirmative, he however added that "But we do not have sufficient numbers to indicate that that would always be the case". Mr. Davis, however, agreed that DC-10 aircraft was quite dissimilar to Boeing 747, and the sound of an explosive decompression in the aft cargo hold of a DC-10 would not be identical to an explosive decompression in the aft cargo hold of a Boeing 747.

3.4.6.18 Mr. Davis further agreed that he was looking for low frequencies in Kanishka tape, but he did not know what type of low frequencies should be looked out for because there was no available data anywhere in the world for the sound of a bomb explosion in a Boeing 747. Mr. Davis was however emphatic in saying that he could not measure the distance of the origin of the sound from the cockpit area mike. In his report, and also in the earlier part of the examination, Mr. Davis had referred to the absence of low frequency component in the spectrum and had sought to conclude that such absence showed that there was no detonation of a high explosive device. In an answer to the question put by the Court however, Mr. Davis appeared to have altered his stand. This is evident from the following deposition of Mr. Davis :-

"Court Ques Am I to understand that there must necessarily be a low frequency whenever an explosion occurs?

Ans. No. What we thought was there would be. There was only one sample of explosion in B-737. But we would need more accidents of that nature to able to say that yes we must have a low frequency component.

Court Ques: Am I to understand that the absence of a low frequency component would not therefore necessarily mean that the sound was not that of an explosion?

Ans. Because of the absence of a low frequency component we would not be able to say positively that there was an explosion or it was not explosion."

Court Ques : Would the frequency of a particular type of sound change depending upon the environment in which that sound occurs?

Ans Yes.

Court Ques If an event results in low frequency sounds in one type of environment, can it mean that the same event can result in a high frequency sound in a different environment?

Ans. That must be possible".

3.4.6.19 Mr. S.N. Seshadri's Report and Deposition

A detailed analysis of the CVR and the ATC tapes was also carried out by Mr. S.N. Seshadri at BARC. For the purposes of comparison, CVR tapes of Iranian Air Force Boeing 747 accident as well as that of Indian Airlines Boeing 737 accident were also analysed at BARC.

3.4.6.20 The original CVR tape of Kanishka was played on a 4 channel tape recorder modified to run at 1-7/8" per second. The output of this tape recorder was copied faithfully on an eight channel HP 3968A instrumentation tape recorder. Channels 1 to 4 were used for recording the CVR data and channels 5 for recording a time marker. For further processing and signal analysis this copy of the original tape was used.

3.4.6.21 The observations of the data so recorded, as contained in the said report inter-alia are as follows :

"Repeated and careful listening to all the four channels revealed the presence of explosive sounds on all these channels occuring nearly at the end at the same time. Speech information is present on channels 3 and 4 during the last few minutes. Channel 1 does not contain any speech data during this period. Channel 2 contains indecipherable speech data about 20 to 25 seconds before the explosive sound".

"It was decided to analyse in detail the tape data during the final few seconds within which significant audio and electrical changes were observed to be present. Data from all the four channels were displayed on a Tektronix 2-channel storage oscilloscope Model 466 for initial observations. Based on this study the relevant portion of the tape was selected for more intensive snalysis. Simultanious ultraviolet recording of all the four channels on this portion of the tape was next carried out". The following observations are relevant.

1. Channel 3, which corresponds to the area mike shows the first indication of a rising audio signal. This instant is termed, for conveniece, as zero time reference. The signal level rises from the ambient level in the cockpit by about 18.5 db in approximately 45 milliseconds. The signal then starts falling and stablises at a level about 10 db higher than the ambient level before zero time. The signal continues to remain at this level for about 275 milliseconds. The total duration of the signal from zero reference is thus about 360 milliseconds.

2. Channels 1 and 2, which are the radio channels of the pilot and the flight engineer respectively, show start of electrical disturbance signals 45 milliseconds from zero time at which the audio signal on channel 3 is at its maximum. These signals, which have do minant frequencies in the range of 70 to 210 Hz, persist for about 100 milliseconds on both channels. Subsequent to this, channel 1, shows an audio burst lasting about 200 milliseconds. Channel 2 shows a delayed audio burst lasting 25 milliseconds, 220 milliseconds from zero time, or in other words, 175 milliseconds after the peak signal from channel 3. A low amplitude tail appears after this burst and lasts around 40 milliseconds. Channel 4 which is the co-pilot's radio channel shows an electrical disturbance commencing at 85 milliseconds from zero time and lasting around 60 milliseconds. The frequency distribution during this period is similar to those on channels 1 and 2. This is followed by an audio burst of 230 milliseconds duration. The frequency spectra of the audio portions of channels 1,2 and 4 are reasonably similar."

3.4.6.22 "Correlation of Events of ATC Shannon Tape and Channel 4 of CVR tape :

"It was observed that during the last few minutes before the stoppage of the CVR, information recorded on the ATC tape and channel 4 of the CVR tape are identical. However, the ATC tape contains a series of audio bursts approximately corresponding to the instant at which a single explosive sound is recorded on channel 4. Thus a doubt arose whether the series of audio bursts recorded on the ATC tape had originated from channel 4 of Kanishka CVR since these are not recorded on the CVR tape. In order to obtain an answer to this it was necessary to check with very good accuracy the simultaneity of the explosive sound on channel 4 and the series of audio bursts on the ATC. The procedure followed for the same is given below.

"The ATC Shannon tape and the CVR tape were run on two independent tape recorders. It was found that the speeds of the two tapes were mismatched. In order to match speeds the earliest speech signal on both the tapes.

"Seven seventy that checks maintain three five zero" was used as the reference point. The speech signals which mostly contain the conversation between the co-pilot and ATC Shannon lasts for about 146 seconds. Channel four was kept ready for starting exactly at the reference point. The ATC was next played starting well before the reference point. The tape recorder playing channel 4 was started manually exactly at the time when the reference point on the ATC was audible. By noting the time of ending of the conversation on both the tapes which corresponds to

"Right Sir squaking two zero zero five one eight two" the speed of the recorder playing the ATC tape was corrected by pitch control to approach the speed of CVR tape. The process was repeated a number of times till audibly the speeds were matched. The two tapes were next synchronously played and both the channels were simultaneously recorded on a third recorder to a point well after the explosive sound on channel 4. This tape was used for all further analysis.

"The first significant observation was that the explosive sound on channel 4 coincided with the beginning of the series of audio bursts on the ATC tape as heard by the ear. It was thus clear that both the recordings correspond to those generated by Kanishka during its last moments.

"To confirm this preliminary conclusion which was judged solely by the ear, accurate instrumented tests were carried out. The two channels were simultaneously recorded on an ultraviolet recorder at the four speeds, 0.1"/sec, 1"/sec, 10"/sec and 160"/sec for study of synchronism as well as frequency details. It was noticed that the two waveforms were not exactly suynchronised though by the ear they appeared to be so. In order to find out exactly the difference in synchronisation the following tests were done:

UV recordings at 16" per second were taken at three representative points relating to the communication of ATC with Kanishka. These points correspond to speech portions at 070838 "Five eh Squawking and eh Air India", at 070958 "Right Sir Squawking" and near the blast on channel 4. It was found that the ATC was running slightly faster. At the first point the ATC was leading by 90 milliseconds, and at the second point by 130 milliseconds. The time interval between these points is about 80 sec. By extrapolating this lead to the time of the blast which occurs about 243 sec. from the second point, it is clear that the lead of the ATC with respect to channel 4 at this point will be given by 130 + (130-90) (243/80) which is approximately 250 milliseconds. This error is very small."

"Thus one can conclude that the sounds recorded on the ATC Shannon tape are those which emanated from Kanishka during its last seconds."

3.4.6.23 "Frequency Analysis:

Mr. Seshadri also carried out frequency analysis of the CVR and the ATC tapes. His opinion with regard to the same was the follows:

"Significant audio and electrical disturbances were observed in the final few seconds of the CVR tape. It was therefore decided to analyse all the four channels for their frequency contents at the various places in this pertinent region. For Fourier analysis of each signal, digitized time data of 200 milliseconds duration was processed. The frequency analysis was carried out using Bruel & Kjaer model 2033, high resolution signal analyser. Frequency spectrum was computed over a base band of 2 KHz with a resolution of 5 Hz.

3.4.6.24 "The frequency analysis of electrical disturbances in channels 1,2 and 4 indicate presence of low frequencies in the region of 20 Hz to 600 Hz. The dominant frequencies are in the range of 70 Hz to 210 Hz.

3.4.6.25 "The frequency spectrum of the background noise in channel 3 just before the explosive sound has a broad band spectrum with some dominant frequencies in the region of 650 Hz to 1550 Hz. At the bang, many additional frequencies appear. The frequency spectrum of bang on channel 3 indicates an increase in the bandwidth.

3.4.6.26 "The frequency spectrum of channel 1 at the bang position indicates a fairly broad spectrum with dominant frequencies in the range of 150 Hz to 1 KHz. Channel 2 displays a frequency spectrum at the bang position in which low frequencies are dominant. It has a significant frequency range between 20 Hz to about 1 KHz. The frequency spectrum of channel 4 at the bang is wide-band with a broad peak in the range of 150 Hz to 800 Hz.

3.4.6.27 "At the beginning of the crackling sound, the frequency spectrum shows narrow band peaks around 1.6 KHz. About 90 and 300 milliseconds later, the spectrum changes with additional peaks appearing around 400 Hz, 600 Hz and 1150 Hz. Frequency analysis was also carried out at 600, 800 and 1000 milliseconds before the start of the crackling sound."

3.4.6.28 The conclusions which were arrived at by Mr. Seshadri on the basis of what he had heard and after studying the various spectra were as follows:

"The signal in channel 3 of the CVR which corresponds to the cockpit Area Mike shows the first signs of an audio disturbance. The signal time data of 200 milliseconds duration was processed. The frequency analysis was carried out using Bruel & Kjaer model 2033, high resolution signal analyser. Frequency spectrum was computed over a base band of 2 KHz with a resolution of 5 Hz.

3.4.6.24 "The frequency analysis of electrical disturbances in channels 1,2 and 4 indicate presence of low frequencies in the region of 20 Hz to 600 Hz. The dominant frequencies are in the range of 70 Hz to

210 Hz.

3.4.6.25 "The frequency spectrum of the background noise in channel 3 just before the explosive sound has a broad band spectrum with some dominant frequencies in the region of 650 Hz to 1550 Hz. At the bang, many additional frequencies appear. The frequency spectrum of bang on channel 3 indicates on increase in the bandwidth.

3.4.6.26 "The frequency spectrum of channel 1 at the bang position indicates a fairly broad spectrum with dominant frequencies in the range of 150 Hz to 1 KHz. Channel 2 displays a frequency spectrum at the bang position in which low frequencies are dominant. It has a significant frequency range between 20 Hz to about 1 KHz. The frequency spectrum of channel 4 at the bang is wide-band with a broad peak in the range of 150 Hz to 800 Hz.

3.4.6.27 "At the beginning of the crackling sound, the frequency spectrum shows narrow band peaks around 1.6 KHz. About 90 and 300 milliseconds later, the spectrum changes with additional peaks appearing around 400 Hz, 600 Hz and 1150 Hz. Frequency analysis was also carried out at 600, 800 and 1000 milliseconds before the start of the crackling sound."

3.4.6.28 The conclusions which were arrived at by Mr. Seshadri on the basis of what he had heard and after studying the various spectra were as follows:

"The signal in channel 3 of the CVR which corresponds to the cockpit Area Mike shows the first signs of an audio disturbance. The signal peaks to its maximum of 18.5 db above ambient level in about 45 milliseconds. A loud audible blast is heard when this channel is played at this point. An analysis of the frequency spectra before this loud blast and during the blast shows a definite change in the frequency composition. From all the above results it can be concluded that an explosion occurred in the aircraft. The exact position in the aircraft at which the explosion occurred is likely to be about 40 to 50 feet from the Cockpit judging from the rise time of 45 milliseconds.

3.4.6.29 "Explosive sounds on all the four radio channels preceded by electrical disturbance reinforce the evidence provided by channel 3.

3.4.6.30 The synchronised recording and detailed analysis of the ATC and channel 4 confirm that the sounds recorded in the ATC Shannon tape are undoubtedly attributable to the transmissions from AI 182 Kanishka during its last moments. The sounds indicate possible breaking up of the aircraft in mid air and the air blast which follows a decompression. A very detailed UV recording does not indicate the presence of a second explosion."

3.4.6.31 "Copies of CVR tapes of well understood air crashes pertaining to an Indian Airlines Boeing 737 in 1979 and Iranian Air Force Boeing 747 in 1976 were analysed for possible reference in connection with the analysis of the CVR tape of Kanishka.

3.4.6.32 "A definite explosion near the Cockpit was the cause of the crash of the Indian Airlines Boeing 737. An explosive sound recorded on the Cockpit Area Mike shows a rise time of about 8 milliseconds which corresponds to a distance of about 8 feet. This indicates that the rise time is a measure of the distance from the Cockpit Area Mike at which an explosion has occurred.

3.4.6.33 "The Iranian Air Force Boeing 747 broke up in mid air. Analysis of the CVR tape clearly indicates that the frequency spectra of the electrical disturbances are similar to those obtained for Kanishka. Thus the series of audio bursts recorded on the ATC Shannon tape have been most probably generated by the break-up of kanishka in midair.

3.4.6.34 Mr. Seshadri was also examined in Court on 27th January, 1986. In his deposition he very succintly explained some aspects of the work which was done by him. He also dealt with the aspect of AGC to which reference has been made by Mr. R.A. Davis and Mr. Paul Turner in their reports. The relevant part of the testimony in this connection is as follows :-

"We wanted to make sure that the CVR recording and the ATC corresponded to the same aircraft Kanishka. When we played the tapes for the first time we found that there was a difference of about 1 second. Though this figure may be tolerable because of the accuracy of the tape speeds, we wanted to investigate further to make really sure that the ATC corresponded to Kanishka. For this purpose we had simultaneously "recorded channel 4 of the CVR and the ATC on a single tape on 2 channels after synchronising the common speech signals to the best of our ability by the ear. We started with the first speech which was available on both the tapes, namely, "770 that checks maintain 350". This was a conversation with the TWA aircraft which is available on both channel 4 and the ATC. The last sound which is recorded common to CVR and ATC is the speech of the co-pilot who says "right Sir, squaking 2005 182". After this recording though by the ear the explosive sounds on the ATC. as well as the CVR seemed to match, we wanted to check it in more detail. For this purpose we had detailed UV recordings of different portions of the synchronised tapes pertaining to the conversation between ATC and Kanishka. This was done and we noticed that the ATC was running slightly fast. We had about 80 seconds reference time of conservation from Air India Boeing Kanishka and the ATC for reference and we had to extrapolate the information in this section for another 243 seconds at which time the explosive sound occurs. During the beginning of this 80 seconds reference period, we find that the ATC was leading by 90 milli-seconds and at the end of 80 seconds the lead of ATC was 130 milli-seconds. Thus, in 80 seconds, the ATC had gained 40 milliseconds.

"This extrapolated to 243 seconds and gives a figure of 250milliseconds. This is how we arrived at the conclusion that both are synchronised within 250 milliseconds. I would like to bring to the notice of the Court that we have taken great pains to confirm this information by reapeating the tests a number of times. We did not take the 400 cycle signal available on the tape as the time reference. We took for reference the bunching of signals produced by the conversation and the gaps in between the convervation which are very clear on both tapes. Hence we are sure that our results are right. The UV recording which was made has been filed along with my report.

"The main channel which was examined was the CAM channel. This was agreed to by all the experts who were present during the first analysis of the tape at the BARC between 16th and 20th July, 1985. One of the most noticeable things is that channel 3 which corresponds to cockpit area shows the first sign of disturbance. Let us say for reference that the disturbance starts at 0 time. In about 45 milliseconds the signal rises to a peak value which is approximately 18.5 db above the ambient level before the commencement of the signal. After this point the signal decays roughly exponentially in about 40 milliseconds to be almost a steady level which is 10 db above the ambient level before the explosive sound. From this we could draw conclusions. Assuming that an explosion occurred on the aircraft. The explosion produces a shock wave with a steep wave front which travels in air as well as through the aluminium body and the speed of travel will depend upon the distance of the explosive from the point of observation. It will depend on the cube root of the explosive and it will also depend on the ratio of the distance to the cube root of the weight of the explosive. The shock wave is very fast. It can travel at about 10 times the speed of sound. Also when the shock wave hits the aluminium body of the aircraft the vibrating panels which are defined by the stringers and longerons transmit the sound to the CAM location. Because the speed of sound in aluminium is about 19,200 feet per second which is 16 to 18 times that of the speed of sound in air and the shock velocity is also about 10 to 12 times. This signal will be received

"first by the CAM. Nevertheless the shock wave gets attenuated diffracted and refracted during its travels to the cockpit. Hence the signal received at the cockpit will be an attenuated signal and this small signal we have taken as instantaneous with the time of explosion. As the time passes the sound waves travel from the explosion site reinforcing the sound in the cockpit area thereby there is a rise time. Then when all the complete sound information is transmitted we get the peak of the signal and thus the rise time corresponds to the delay between the first rise in signal to the peak as compared to the speed of sound. One may ask the question what is the speed of sound because the aircraft has an explosion and is exposed to the outside environment but since the de-pressurization of the aircraft through the explosive fracture will take a minimum of a few seconds, we can reasonably assume that the pressure of the air in the aircraft corresponds to about 5000 to 6000 feet of altitude. At this presure and temperature, the sound velocity is roughly 1000 feet per second and from the 45 milliseconds delay we concluded that the explosion should have occurred about 40 to 50 feet from the cockpit. A question may be asked that the decay of the signal might be due to the AGC of the CVR coming into action. Mr. Turner, who is an acknowledged expert in the field of CVR has reported that Messrs Fairchild tested the cockpit voice recorders with a 10 db rise and fall of signals at the threshold of AGC and they got a result indicating a decay time of 33 milliseconds. The fall in the waveform of Channel 3 is about 40 milliseconds and is well near 33 milliseconds, so an argument may be advanced that the sound continued to remain steady and the fall in the signal level was effected by the AGC. In order to confirm this we tested the Cockpit Voice Recorder which was identical to the one which was on Kanishka by applying 1 KHz waveform of rectuangular modulation. To our surprise, we found that the decay time roughly was 130 milliseconds as compared to 33 milliseconds given by Mr. Turner. We repeated the tests with an initial background and without any background at all. We further tested with ramp waveforms, in other words, "slowly rising and falling waveforms of triangular shape with modulations of 1000 cycle carrier. This also confirms our finding. In order to clarify how the tests were performed so that others can judge whether it was a realistic test, I will explain the procedure. The modulated waveform was produced by a signal generator. This was fed to an amplifier. The amplifier output was fed to a loudspeaker. The output of the amplifier was checked to ensure that there was no distortion. Thus the signal going into the loudspeaker is the same modulated signal which has been applied at the input of the amplifier. This sound coming from the loudspeaker was recorded on the CVR through the CAM in the laboratory. This is how the test was performed. We were given a CVR tape by the Department of Civil Aviation purported to be that of an explosion which occurred on a Boeing 737 aircraft which crash- landed at Madras. We did the CVR analysis of this aircraft. We first recorded the output of the CVR of Indian Airlines CAM channel on a UV recorder. We found the rise time to be very small. This was of the order of a few milliseconds, about 8 milliseconds or so. We have been told that the explosion occurred just by the side of the front toilet i.e. just behind the cockpit. This to some extent confirms that the rise time is related to the distance of the explosion from the detecting CAM. The next thing that we did was the frequency analysis of this waveform. Mr. Davis has indicated in his report that if an explosion occurs on board the aircraft there should be low frequencies present. When we analysed the frequencies of the Kaniskha aircraft Channel 3, we did not find very low frequencies in case of an explosion abroad the aircraft. When we analysed the Boeing 737 tape we did not find any low frequencies in the signals. The report of Mr. Davis also provides the frequency analysis of a pistol shot which has been fired in the cockpit of the aeroplane. This also shows no low frequency components. So our conclusion, that it is not essential for low frequencies to be present in case of an explosion abroad an aircraft, was confirmed. I will go a step further to say that the frequency received by an area mike which responds to an explosive action abroad the aircraft will contain frequencies of the structure of the defracted " and dragging shock wave, the resonant frequencies of the aluminium panels defined by the longerons and the stiffening channel members and also some frequencies which may be of objects that the shock wave encounters in its path. It is, therefore, impossible to calculate the frequency spectrum that one would expect in the cockpit due to an explosion taking place in the aircraft".

3.4.6.35 In answer to a question Mr. Seshadri categorically stated that the word "explosion" in his report meant "a bomb, a very fast device".

3.4.6.36 Mr. Paul C. Turner's Report

Lastly, a reference may be made to the report dated 13th November, 1985 of Mr. Paul C. Turner. The evaluation of Mr. Turner of the analysis done by him of the CVR and the ATC tapes, as contained in the said report, was as follows:-

"With the foregoing as background, we can make several observations. The CVR record on the CAM channel, captain's channel and flight engineer's channel show that they were all affected at about the same time; the copilot's perhaps 20 milliseconds later. Major disturbances which are recognized as electrical system disturbances can be seen to begin about 60 milliseconds after the initial disturbance. This approximates the time it would take for the electrical system protective circuitry to become active.

3.4.6.37 "A steep wave front which would be indicative of a shock wave cannot be seen on the CAM channel sound spectrum; however, the spectrum analaysis shows that impulse type sounds occurred at the beginning of the event recorded on the CAM channel of the CVR. Since audio signals propagate through aluminium approximately 16 times the speed of sound in air, the CAM channel would probably have been affected by structurally transmitted noise before being affected by airborne noise. The geometry of the aircraft was such that structure borne disturbances could be recorded before the airborne transmitted information appeared at the cockpit microphone and an air transmitted shock wave or steep wave front may not be evident on the CVR.

3.4.6.38 The captain's and copilot's selector box channels recorded signals which appeared to be electrically inducted and similar to those seen on the Huete Boeing 747 breakups. These are then followed by a signal resembling audio frequency noises similar to an open microphone in a noisy environment or the opening of a receiver squelch. Both effects have been seen during aircraft breakups. The audio noise on the captain's and copilot's channels appears to have come from a different source. The flight engineer's channel does not contain audio noise. A spectral diagram of the copilot's and captain's channel noises just show broad band noise across the spectrum. The signal frequncies extend beyond the frequency range of a microphone both on the high and the low end. It does not fit the normal microphone envelope. Spectral diagrams of the event on the CAM channel show the normal microphone preamplifier envelope summed with wide band signal of unspecified origin. Since the signal quits abruptly with a doublet, it indicates that the interference was added upstream of the CVR and was not just reflected in the CVR power supply.

3.4.6.39 "The CVR record shows a signal stayed on for about 200 milliseconds when it appears that the power may have been interrupted to both the radio channel and the CAM channel of the CVR at the same time. It further appears that the signals to the CVR were probably interrupted at 360 milliseconds from the initial disturbance possibly by severance of the signal wires. It further appears from the action of the erase head and record that the main electrical system began to fail at this point and the CVR bus voltage value dropped to a value below 70 volts but not below 20 volts. This fluctuating voltage continued intermittently for a minimum of 1-1/4 seconds at which time the voltage evidently dropped to some value below 20 volts and the recorder ceased to operate. The power for operation of the No. 1 VHF transmitter can be explained by the operation of the standby bus and battery and connection of the No. 1 VHF radio to this standby bus.

3.4.6.40 "The necking down of the signal to a low value shows that no signal was coming to the CVR from the CAM preamplifier. The lack of a signal on the radio channels, which do not need to be erased before being recorded, further suggest that the wires were severed or

"that the transmission to Cork began after what appeared to be the loss of the primary electrical system approximately 1-1/2 seconds following the event. Standby power would have become available upon loss of the primary power, the number one VHF would have become available, and CVR would have ceased to operate.

3.4.6.41 "The action of the erase circuitry in the CVR suggests that the fluctuating voltage seen was coming from the main electrical system bus. Anything else causing this fluctuating voltage down stream of the CVR circuit breaker would probably blow it.

3.4.6.42 "The signal received in Ireland indicated that a radio, most probably this aircraft's No. 1 VHF transmitter, stayed operational for about 5.4 seconds following the event at which time the entire aircraft electrical system ceased to function. This assumes that the No. 1 transmitter ceased to operate due to standby bus failure.

3.4.6.43 "In the conclusion, it appears that a catastrophic event occurred on Kanishka. It was reflected in all channels of the CVR and the CVR power supply at the same time. The main electrical bus began to fail within 0.35 second and the standby bus survived for only 6 seconds more at which time the aircraft's electrical system ceased to function. It appears that the event occurred in a manner to affect the cockpit area microphone operation severely and to force operation of the automatic gain control on the CVR. This loud noise continued for the life of the aircraft's main electrical system as reflected in the CVR.

3.4.6.44 "The mechanism of how the ATC transmission was made from Kanishka to Cork is unclear. The sound was not recorded on the CVR, indepentent studies by Canadian and British investigators have the Cork ATC call originating approximately 1-1/2 seconds following the event on the CVR. This is about the time that standby power would have become available to the No. 1 VHF.

3.4.6.45 "This report should be viewed as an accident investigation tool only and used in conjunction with other evidence gathered during the investigation.

3.4.6.46 "The United States Noard/Space Command has confirmed that there was no incoming space debris in the vicinity of Ireland on June 23, 1985."

3.4.6.47 It is pertinent to note that according to Mr. Turner there was "catastrophic event" which had occurrred on Kanishka. He has, however, not elucidated as to what this event was.

3.4.6.48 After the receipt of the report, the Court requested the NTSB that Mr. Turner should come and depose. It is unfortunate that permission was not granted to him. Faced with this situation and as it was thought necessary that some clarification was called for, the Court sent a telex to Mr. Turner whereby he was asked to give replies to the queries contained therein. He was requested that the reply be sent by 27th January 1986. A copy of the telex was also forwarded to the American Embassy at New Delhi for sending the same to NTSB by way of confirmation. Previously all communications addressed to NTSB were being routed through American Embassy. No reply has been received by the Court till this day either from NTSB or from Mr. Paul Turner. According to paragraph 5.14 of Annex 13 the State is required, on request from the State conducting the investigation of an accident, to provide to that State with all the relevant information available to it. It was, therefore, obligatory on the NTSB to have seen that the information sought for by the Court by way of answers to the queries was supplied.

3.4.6.49 Court Evaluation

From the reports of all the experts and the testimonies of M/s Caiger, Davis and Seshadri it is clear, and it is agreed to by all of them, that there was a breakup of the aircraft in mid-air. The experts also agreed that the sounds recorded on the ATC Shannon tape at 0714:01 Z emanated from the Kanishka aircraft.

3.4.6.50 Mr. Caiger has not said either in the report or in his statement as to what was the cause of the bang. Mr. Davis, on the other hand, is categorical in stating in his report that there was explosive decompression (meaning rapid decompression) on the aircraft. He has, however,
stated in the report that there is no evidence of an explosive device. The main reason for his coming to this conclusion is that he had not been able to find low frequencies in the spectra of the CVR of Kanishka. Mr. Seshadri, on the other hand is equally vehement in concluding that an explosive device had detonated in the front cargo hold of Kanishka.

3.4.6.51 It may be that the frequency spectrum of Kanishka CVR did not contain low frequencies but, as has been admitted by Mr. Davis himself in answer to a Court question, it is not necessary that in the case of every detonation there must necessarily be low frequencies in the spectrum. Frequency spectra of 'Kanishka CVR before 'bang' and at the 'bang' position are shown in Figs. 2 & 3, indicating presence of additional high frequncies at the bang. Indeed in the case of Indian Airlines Boeing 737, which admittedly was a case where there was an explosion of a device within about 8 feet of the CAM, the frequency analysis showed absence of low frequencies. Frequency spectrum of Indian Airlines Boeing 737 CVR is shown at Fig. 4. Merely, because therefore, there were no low frequencies present would not mean that there was no detonating device on board the Kanishka. The CVR of Indian Airlines Boeing 737 has not been analysed either by Mr. Caiger or Mr. Davis. The analysis was, however, conducted by Mr. Seshadri and as is evident from his report, there were marked similarities between the spectra of Indian Airlines 737 and Air India's Kanishka CVR. One of the important reasons for coming to this conclusion, which has been indicated by Mr. Seshadri, is the rise time of the bang signal. From the analysis of the Indian Airlines Boeing 737 tape it was observed that it had taken 8 milliseconds for the peak to be reached. It was also seen that the explosive device was approximately 8 feet away from the cockpit area mike. Keeping this in view Mr. Seshadri observed that in the case of Kanishka the peak of the bang signal was reached in about 40 milliseconds. He, therefore, concluded that the origin of the bang sound was about 40 feet away from the cockpit area mike.

3.4.6.52 It would be pertinent to note that even according to the report of Mr. Davis the rise time in the case of Kanishka, which has been given for the peak is about 40 milliseconds. He, however, does not attach much importance to this because according to him after about 40 ms automatic gain control would become effective.

3.4.6.53 Mr. Davis has no personal experience of the time which it would take for the Automatic Gain Control to take effect. He has got the figures from the manufacturer. Mr. Davis admitted that the time which it will take for the AGC to be effective is not indicated in any published document of the manufacturer.

3.4.6.54 Mr. Seshadri, however, personally carried out the experiments on a Boeing 747 by using an instrument similar to what was on board Kanishka. From the testimony of Mr. Seshadri it is apparent that the results which he got were different. As per his testimony, for the AGC to be effective it will take 130 ms. If this be so then it may be possible to conclude that in the case of Kanishka the peak was reached in 40 ms. and thereafter the signal decayed and the signal was in no way effected by the AGC.

3.4.6.55 A reference may also be made, at this stage, the frequency spectrum of the sound of the hand gun which was fired on a boeing 737 flight deck. Frequency spectrum prepared by Mr. R.A. Davis is shown at Fig. 5. He has stated that the rise time for reaching the peak is almost instantaneous. Same is the case with regard to the frequency spectrum prepared by him of a bomb in a B-737 aircraft where the bomb had been placed in the freight hold which is shown in Fig. 6. A perusal of that spectrum also shows that the peak was reached in approximately 5 ms. The forward freight hold compartment of Boeing 737 is much more than five feet away from the cockpit area mike. If the theory of Mr. Seshadri was to be applied then as per the frequency analysis of this Boeing 737 bomb, the distance from the area mike could not have been more than 5 ft. It is, however, known, as per the report of Davis, that the bomb was actually in the freight hold which would mean not nearer than about 25 feet.

3.4.6.56 From what has been stated in the various reports, as well as in the testimony of the 3 experts who apperared in the Court, the only safe conclusion which can be drawn is that possibly enough study has not been done, due to lack of adequate data, which can lead one to the conclusion as to the exact nature of the sound and the distance from which it originated.

3.4.6.57 The fact that a bang was heard is evident to the ear when the CVR as well as the ATC tapes are played. The bang could have been caused by a rapid decompression but it could also have been caused by an explsoive device. One fact which has, however, to be noticed is that the sound from the explosion must necessarily emanate a few milliseconds or seconds earlier than the sound of rapid decompression because the explosion must necessarily occur before a hole is made, which results in decompression. In the event of there being an explosive detonation then the sound from there must reach the area mike first before the sound of decompression is received by it. The sound may travel either through the air or through the structure of the aircraft, but if there is no explosion of a device, but there is nevertheless an explosive decompression for some other reason, then it is that sound which will reach the area mike. To my mind it will be difficult to say, merely by looking at the spectra of the sound, that the bang recorded on the CVR tape was from an explosive device.

3.4.6.58 There are various hypothesis and theories which the experts have to investigate before any acceptable conclusions are arrived at. It so happens that in the present case we have the opinions of four experts, but they do not agree with one another on some material aspects. Two of the experts, namely, Mr. Caiger and Mr. Davis are categorical in saying that it is not possible to measure the distance of the origin of the sound on the cockpit area mike, whereas Mr. Seshadri has come to a different conclusion. Mr. Paul Turner in his report dated 13th November, 1985 in silent on this aspect, though in his earlier report dated 19th July, 1985 he had categorically said that there was an explosive device close to the cockpit.

3.4.6.59 With regard to the nature of the sound also we have 3 different opinions. Mr. Caiger is unable to give the nature of the sound, Mr. Davis says it is rapid decompression while Mr. Seshadri says it is a sound of an explosive device followed by decompression.

3.4.6.60 In the absence of any other technical literature on the subject, it is not possible for this Court to come to the conclusion as to which of the Experts is right. The only conclusion which can, however, be arrived at is that the aircraft had broken in midair and that there has been a rapid decompression in the aircraft. Just as it is not possible to say that the spectrum discloses that the bang is due to an explosive device similarly, and as has also been admitted by Mr. Caiger and Mr. Davis, it is not possible to say that the bang is due to break up of a structure.

3.4.6.61 The bang could have been due to either of the aforesaid two causes i.e. a bomb explosion or the sound emanating due to rapid decompression. The advantage of carrying out the said analysis is that a number of possible causes of the accident are eliminated. On the other hand, if the analysis is viewed in conjunction with other evidence on the record it is further possible to determine the exact nature or cause of the bang. In the present case the bang, as already noticed, could have been due to the sound originating from the detonation of a device or by reason of rapid decompression. Other evidence on the record, however, clearly indicates that the accident occurred due to a bomb having exploded in the forward cargo hold of Kanishka. The spectra analysis and the conclusions of Mr. S.N. Seshadri are corroborated by other evidence.

TESTS AND RESEARCH

3.5.1 During the course of investigation a number of groups were formed to study and analyse evidence and data which was available. Materials like CVR, ATC and DFDR tapes were also given to the various participants.

3.5.2 The groups as well as other experts studied and analysed the material with them and submitted their reports which have been referred to earlier.

3.5.3 The experts examining the CVR tapes did carry out a number of tests. Different graphs and traces were prepared and the sound was analysed by them. The result of their analysis has been referred to in Chapter 3.4 on Flight Recorders.

3.5.4. The metallurgical examination of some of the recovered pieces was carried out at BARC. The examination of some of the pieces showed different types of damages having been recorded on the targets such as petalling and curling round the holes, spikes etc. The said team carried out certain explosion experiments. Their report on the experiments so carried out has already been set-out in paragraph 3.2 above.

3.5.5 The Indian Air Force has set up an Institute of Aviation Medicine at Bangalore. The Court visited the said Institute on 9th December 1985. During that visit an experiment was conducted in the explosive decompression and high altitude chamber to demonstrate what actually happens during explosive decompression and subsequently on exposure to hypoxia.

3.5.6 Subjects were taken to 8,000 feet in the explosive decompression chamber with oxygen. They were exposed to an altitude of 25,000 feet within one second. During the course of this explosion a loud bang was heard and inside the chamber there was misting and drop in temperature. After this the chamber was allowed to run at 22,000 feet for roughly two minutes and an experiment to show the adverse affects of hypoxia on the subjects was done. In this experiment, subjects were asked to write a given sentence while their oxygen supply was cut off. It was observed that initially the subjects kept on writing the sentence correctly and then after about 120 seconds they started making errors while writing the sentence and finally they stopped writing. At this stage oxygen was re-started and within a few seconds, the subjects started writing their sentence once again. The experiment was completed at this stage and the altitude chamber was brought down to ground level.

3.5.7 The subjects were taken out and were asked questions as to what did they feel. They explained that at the time of explosive decompression, they heard a loud bang, felt cold and saw misting inside the chamber. They also found air escaping from their lungs. On further enquiry about the experiment pertaining to hypoxia, they said that they felt light headed and after that they did not know what happened till they once again noticed that they were writing on a piece of paper.

SECURITY

3.6.1 The evidence and the statements filed on record show that Canadian Security arrangements in place prior to 23rd June, 1985 met the international requirements for civil air transportation. However, before this date, the emphasis was on preventing the boarding of weapons including explosive devices in hand baggage. Hence, the screening of checked baggage was only undertaken in conditions of a heightened threat as was the case with respect to Air India flights.

3.6.2 Air India, as required by Canadian regulation, had a security programme. Because of the threat level assessed against the Airline, Air India had more extensive security measures than almost any other Canadian or international airline. These measures were generally in accordance with the recommended procedures of the ICAO Security Manual for special risk flights. Air India had also requested and had received and arranged for extra security for the month of June, 1985. For Air India flight 181/182, Air India provided a security officer from its New York Office to oversee the security at Toronto and Montreal.

3.6.3 As it became apparent during the course of investigation that security would be an important aspect whilch would require the attention of the Court, Mr. Rodney Wallis, Director, Facilitation and Security, International Air Transport Association was good enough to appear in Court on 24th January, 1986. His testimony on certain aspects of security was recorded in camera by the Court on that date. The expert evidence has been taken into consideration while formulating some of the recommendations.

INTERNATIONAL COOPERATION

3.7.1 The manner in which persons and organisations from five different countries combined their resources and efforts in connection with this accident is an object lesson in international cooperation.

3.7.2 From the time the accident occurred, till the conclusion of the investigation proceedings by the Court in Delhi, there has been a consistent interplay amongst different persons and organisations. When all the persons got together, for the first time, at Cork the group was very heterogeneous. Each one had his own point of view, which did not necessarily coincide with that of another. At times, the atmosphere was charged with a bit of tension which continued even when the Court was constituted to investigate into the accident.

3.7.3 It was noticed that not only were the participants a bit apprehensive and suspicious but, during the course of investigation, there were also occasions when there appeared some acrimony between a few of them.

3.7.4 In such a sensitive situation, careful handling was called for. The participants' honesty of purpose could not be doubted. All that was wanted was that there should be an effort to try and understand the point of view of all the persons. This is precisely what the Court tried to do.

3.7.5 It is indeed fortunate that the efforts of the Court, in this regard, succeeded. After the Court had decided that it was not the purpose or the function of the investigation to affix responsibility for any lapse which may have been committed, one could see the general relieving of tension. With the passage of time there was a gradual building up of the confidence of the participants in the conduct of the investigation. The participants' interest for air safety transcended all barriers and any apprehension or suspicion, which was present in the minds of some, was soon dispelled. In its place there grew a deep sense of urgency, anxiety and cooperation in an effort to see that all the participants rendered utmost assistance for the satisfactory completion of the task in hand.

3.7.6 The main beneficiary of this international cooperation was not only the Court investigating the accident but it was the cause of air safety which benefited the most. Countries and Organisations went out of the way to help each other, financially and otherwise, even when they were not obliged to do so. Money and services were readily and voluntarily offered and usually the requirements of the Court were always fulfilled.

3.7.7 As the accident had occurred only about 100 miles off the coast of Ireland, the centre of activity, initially, was centred at Cork. The Government of Ireland, and the Irish people in particular, acted as though they regarded this as a national disaster. Not only did they render every assistance with regard to the search and rescue operation, hospital facilities, police etc. but the people acted as if one of their own kith and kin had died. In the situation which existed they were pillars of strength to the relatives of the deceased. Not only did complete strangers comfort such relatives but, more often than not, they even joined in their grief. The residents of Cork did everything possible to try and mitigate the sorrow of the victims' relatives. Everyone did their small bit, even the children of Cork queued up to place flowers at the coffins of the victims.

3.7.8 The Representatives of the Government of Canada also came to the scene, at the initial stages itself, and rendered full help and cooperation till the last. The major brunt of the mapping and the salvage operations was borne by Canada. Willingly and without any demur it incurred huge expenses, which must have been to the tune of a few million dollars, in carrying out these operations. It rendered full help and assitance to the Court whenever called upon to do so. For example, it offorded full facilities and help to the team which had been sent to Canada by the Court in August, 1985. It was only with the help of the Canadian Government, and the CASB and RCMP in particular, that the Court was able to obtain evidence and information relating to the accident. Without Canadian help the conduct of the investigation would have only been speculative in nature.

3.7.9 On their own, and without any request from the Court or from the Government of India, the Government of United States decided to lend a helping hand in the salvage operations. This was done at a very critical juncture when financial help and expertise were required so as to salvage the important critical pieces of the wreckage. It arranged for the services of a salvage expert and it also made necessary arrangements for the deployment of a second ship, duly fitted with necessary equipment to enable it to salvage some of the heavier pieces of the wreckage. The Court understands that the amount which was contributed in meeting the expenses by the United States was to the tune of U.S. $ 700,000.

3.7.10 The Government of United Kingdom also provided ship and helicopters in connection with the search and rescue operations. Even during the time when salvage operations were being carried out it was the British Helicopters which assisted in transporting personnel to and from the ship which were engaged in the salvage operations. The A.I.B. at Farnborough, on being asked by the Court to do so, carried out a very detailed analysis of the CVR and the ATC tapes.

3.7.11 Being the state of Registry of the aircraft and also the state holding the investigation, the major brunt of the work fell on the shoulders of officers of the Government of India and BARC. They acted as coordinators who had to oversee the work being carried out by persons belonging to diverse organisations and coming from different countries. Young engineers of Air India took turns in going aboard the ships and manning the Control Centre at Cork. They worked in conjunction with the engineers of Boeing and CASB and the crew members of the ships during the salvage operations. Without their enthusiastic participation the progress of the salvage operations would have been severely hampered.

3.7.12 The Scientists from BARC and National Aeronautical Laboratory, Bangalore were ever ready and willing to work together with the experts from abroad. Whenever called upon to do so, they rendered whatever assistance which was desired by the Court and the other participants.

3.7.13 It was seen that when the persons, coming from different countries and backgrounds, worked together with sincerety and honesty of purpose then they functioned smoothly and harmoniously, and usually arrived at an agreed solution or finding. These days it is indeed rare to see such a degree of international cooperation between different persons, organisations and countries.

ANALYSIS AND CONCLUSIONS

4.1 From the evidence which is available what has now to be determined is as to what caused the accident.

4.2 Finding the cause of the accident is usually a deduction from known set of facts. In the present case known facts are not very many, but there are a number of possible events which might have happened which could have led to the crash.

4.3 The first task is to try and marshal the facts which may have a bearing as to the cause of the accident.

4.4 It is undisputed, and there is ample evidence on the record to prove it, that Air India's Kanishka had a normal and uneventful flight out of Montreal. The aircraft had been in air for about five hours and was cruising smoothly at an altitude of 31,000 feet. The readout from the CVR shows that there was no emergency on board till the catastrophic event had occurred. This is corroborated by the printout available from the DFDR. The event occurred at approximately 0714 Z and that brought the aircraft down, and it probably hit the surface of the sea within a distance of 5 miles. The time within which the plane came down at such a steep angle could not have been more than very few minutes. There was a sudden snapping of the communication between the aircraft and the ground. The aircraft had also suddenly disappeared from the radar.

4.5 It is evident that an event had occurred at 31,000 feet which had brought down 'Kanishka'. What could have possibly happened to it? The aircraft was apparently incapacitated and this was due either to it having been hit from outside; or due to some structural failure; or due to the detonation of an explosive device within the aircraft.

4.6 Evidence indicates that after the event had occurred, though the pilots did not or were not in a position to communicate with the ground, they nevertheless appeared to have taken some action. According to Mr. Laflamme, witness No. 12, the examination of the wreckage showed that spoilers had been deployed and this must have been done with a view to enter into emergency descent. He has further speculated that such an emergency descent would support or perhaps cause a rupture in the forward area or a partial damage to the hydraulic system or damage to the control system which created such a condition that the pilots were not able to control the flight. The wreckage fruther showed that the jack screw for the stabilizer trim was found in the nose-up position and it was hard to explain how this got there merely as a result of impact with the water. The trim being in that position could only have been due to the pilot selecting it or as a result of a situation created by an explosion. In that position, and at a high aircraft speed, there would have been an extremely high g-loading on the aircraft.

4.7 It can further be speculated that if an explosion takes place in the forward cargo compartment, the oxygen stream might have been damaged so that when the pilots donned their masks as part of the emergency drill for explosive decompression, they were not breathing enriched oxygen and the time of useful consciousness at about 31,000 feet would be significantly less than 30 seconds under high stress and if the pilots became unconscious as a result of this, then the aircraft would have got out of control which would explain the subsequent events.

4.8 None of the participants have produced any evidence which could lead one to the conclusion, that there was any external hit to the aircraft. In fact in the report dated 13th November, 1985, Mr. Paul Turner has stated as follows:

"The United States Norad/Space Command has confirmed that there was no incoming space debris in the vicinity of Ireland on June 23, 1985."

4.9 Thus we are left with only two of the possibilities viz., structural failure or accident having been caused due to a bomb having been placed inside the aircraft.

4.10 After going through the entire record we find that there is circumstantial as well as direct evidence which directly points to the cause of the accident as being that of an explosion of a bomb in the forward cargo hold of the aircraft. At the same time there is complete lack of evidence to indicate that there was any structural failure.

4.11 The circumstantial and direct evidence which leads to the aforesaid conclusion is as follows :

A. Connection with an explosion at Narita Airport :

On 23rd June, 1985 there was an explosion at the Narita Airport. The explosion occurred when a bomb exploded in a suit case which was to be interlined to Air India's Flight No. 301 from Tokyo to Bangkok. The following events, which had occurred prior to this explosion, clearly establish the connection between the two incidents :

(i) On 19 June 1985, at approximately 1800 PDT (0100 GMT, 20 June), a CP Air reservations agent in Vancouver received a telephone call from a male with a slight Indian accent. He identified himself as Mr. Singh and informed the agent that he was making bookings for two different males also with the surname of Singh. One booking was made in the name of Jaswand Singh with CP 086 from Vacouver to Dorval on 22 June 1985 to link with AI 182 departing from Mirabel. The other booking was to Bangkok using CP 003 from Vancouver to Tokyo and AI 301 from Tokyo to Bangkok. This booking was made in the name of Mohinderbel Singh. A local telephone contact number was given and the call lasted about one-half hour.

(ii) On the same date at approxmimately 1920 PDT (0220 GMT), another reservations agent for CP Air was contacted and requested to change the booking for Jaswand Singh. The confirmed flight on CP 086 was cancelled and a reservation was made on CP 060 from Vancouver to Toronto, and a request to be wait-listed on AI 181/182 from Toronto to Delhi was made.

(iii) On 20 June, 1985 at about 1210 PDT (1910 GMT), a male appearing to be of Indian origin purchased the tickets with cash from a CP Air Ticket office in Vancouver. The booking in the name of Mohinderbel Singh was changed to L. Singh and the booking using the name of Jaswand Singh changed to 'M. Singh'. The telephone contact number was also changed. The final itinerary was as follows :

(a) M. Singh - CP 060 Vancouver - Toronto Confirmed Scheduled to depart Vancouver at 0900 PDT, 22 June 1985

- AI 181 Toronto - Montreal Wait-listed Scheduled to depart Toronto at 1835 EDT, 22nd June, 1985

- AI 182 Montreal - Delhi Wait-listed Scheduled to depart Montreal at 2020 EDT, 22nd June, 1985

(b) L. Singh - CP 003 Vacouver - Tokyo Confirmed Scheduled to depart Vancouver at 1315 PDT, 22 June, 1985

- Air India 301 Tokyo - Bangkok Confirmed Scheduled to depart Tokyo at 1705 time in Tokyo, local 23 June, 1985

(iv) On 22 June, 1985 at about 0630 PDT (1330 GMT), a caller identifying himself as Mr. Manjit Singh called the CP Air reservations office. The caller spoke with a heavy Indian accent and wanted to know if his booking on AI 181/182 was confirmed. The caller was informed by the agent that the was still wait-listed out of Toronto and offered to make alternate arrangements to Delhi. The caller stated that he would rather go to the airport and take his chances. The caller also asked if he could send his luggage from Vancouver to Delhi and was told he could not check his baggage past Toronto unless his flight was confirmed.

(v) On Saturday morning, 22 June, 1985, a CP Air passenger agent worked check-in position number 26 at the CP AIR ticket counter, Vancouver International Airport, and recalls dealing with a passenger of Indian origin booked on CP 060 and then on to Delhi. The passenger stated that he wanted his bag tagged right to Delhi from Vancouver. After checking the computer, the agent explained that since he was not confirmed past Toronto his baggage could not be interlined. The passenger insisted and, as the line-up were long, the agent relented and interlined his suitcase. The flight manifest for CP 060 shows that 'M. Singh' checked in through this passenger agent, was assigned seat 10B, and checked one piece of baggage.

(vi) The flight manifest for CP 003 shows that on the same day the person using the name of 'L. Singh' with an interline ticket to Bangkok also checked through the same counter, was assigned seat 38H, and checked one piece of baggage.

(vii) A check of CP Air's records and interviews with passengers on flights CP 003 and CP 060 indicates that the persons identifying themselves as 'M. Singh' and 'L. Singh' did not board these respective flights.

(viii) In a statement of William Long, annexed to the affidavit of I.G. Pole, Police Officer, City of Toronto, he has stated that on 22nd June, 1985 he was employed as a driver whose responsibility was to deliver interlined baggage between terminal 2 to Terminal 1 and vice versa at Toronto. He has further stated that he had picked up 4 bags from Terminal 1 which were destined for terminal 2 Air India. Three of these bags were from U.S. Air originating from New York city. Regarding the last bag he stated as follows :

"The fourth bag destined for Air India was, I distinctly remember looking at the baggage tag and it was pink with the CP logo in blue and letters saying CP on it there were also numbers but I can't remember the number, from CP Air and I remember it was from Vancouver. On the bottom of the tag it said vancouver using the initials YVR and the flight number which I can't remember. The bag was destined for India. When I arrived at the CP Air belt there were a number of bags from other airlines on the belt included in these were the three U.S. Air bags destined for Air India. As I was finishing loading the carts, a CP Air station attendant who had been unloading bags from containers, I noticed as I checked once more for anymore bags, drop another bag on the conveyer belt. This was the bag destined for Air India. It was dark brown Samsonite Hard sided Type 01A on the Baggage Identification Chart. After they were loaded onto the cart I took them over to Air Canada domestic belt at Gate 89-91".

To further questions posed to him, Long stated that this bag from CP Air weighed approximately 70 lbs and there was something which rattled inside the bag. He could not say what it was but he said that "it sounded small". When specifically asked whether he thought there was something big inside the bag, he answered in the affirmative, and added that he did not know what was in it but it was heavy. There was discrepancy in the time when he is alleged to have picked up the bags which he had indicated in his schedule when compared with CP Air Vancouver flight which had arrived at 1622 hours. When this was pointed out to Long, he answered "I could have may be got the time wrong, it was during the busy period. It could have been an estimate time. But I do remember the bag came off CP air. It could have been 16:34 Hrs. I don't know."

(ix) The aircraft departed from Toronto for Mirable and London with the suitcase unaccompained by the passenger who had checked it in at Vancouver. Similarly, CP Air 003 departed Toronto for Tokyo with the baggage of one passenger 'L. Singh' to be interlined to Air India flight AI 301 to Bangkok even though 'L Singh' had not boarded that flight.

(x) The linking of the two occurrences namely the blast at Narita Airport and the Air India accident becomes startingly evident if we look at the following chronology of events:

CPA 003 (VANCOUVER-TOKYO) CPA 060 (VANCOUVER-TORONTO) Connection to Connecting to Air India 301 Air India 182 WESTBOUND EASTBOUND All Times GMT Thurs 20 June, 1985 0057 A male called C.P. Air Reservations in Vancouver and after discussing a number of routings, booked a one-way ticket and CPA 060 to Toronto with connections to Air India 182 under the name of Jaswand SINGH. A return ticket was also booked on CPA 003 to Tokyo connecting with Air India 301 to Bangkok in the name of Mohinderbel SINGH.

1912 A male attended the CP Air Ticket Office in Vancouver. He paid $ 3005.00 in cash for the above tickets after changing the ticket of Mohinderbel SINGH to L. SINGH and changing from a return to a one-way ticket. He changed the Jaswand SINGH ticket to M. SINGH.

Saturday 22 June A Mr. SINGH called Reservations and got 1330 confirmation on his one-way ticket to Toronto with luggage to be sent through to India. M. SINGH checked in with seat 10B confirmed to 1550 Toronto. Wanted suitcase interlined to AI 182. Agent relents. 1618 CPA 060 departed Vancouver 18 minutes late. M. SINGH not in assigned seat. L. SINGH checked in for CPA 003 and one suitcase interlined to Air India 301. Assigned seat 38H. CPA 060 arrived Toronto 2022 12 minutes late. Some passengers and baggage interlined to AI 181.

CPA 003 departed 17 min. late for Tokyo. L. SINGH not in 2037 assigned seat. Sunday 23 June Air India 181 departed 0015 Toronto for Mirabel 1 hour 40 minutes late. 0100 Air India arrived Mirabel. 0218 Air India 182 departed Mirabel 1 hour 38 minutes late. CPA 003 arrived Narita Airport, Tokyo. Arrived 14 minutes early 0541 Baggage cart explodes in transit area. 2 killed, 4 injured, 0619 0714 Air India 182 disappeared from Radar

Air India 301 departed Narita. 0805 0815 Air India 182 Scheduled arrival Heathrow (fuel stop).

(xi) It would indeed to too much of a coincidence that two persons, whose tickets were bought at the same time and who had checked in under the names of 'L. Singh' and 'M. Singh' missed their respective flights, more so when 'M. Singh' had insisted at the check in counter at Vancouver that he should be interlined, even though his seat from Toronto on AI 181/182 was not confirmed, and his baggage (one suitcase) accepted and be routed through to Delhi. If there had been some reason for 'gate no-show' by both of them, one would ordinarily have expected both, or at least one of them, to have made efforts, at that time or thereafter, either to ask for refund of money or they should have contacted the airline staff at the Airport and asked that they should be put on another flight.

(xii) A large amount of money had been spent on the purchase of the two tickets and a question which comes to mind is as to why was this money spent if both the tickets were to be wasted and no one was to travel on them, after having checked in and obtained boarding cards. Furthermore, no effort has been made by any of these two persons to try and lodge a claim for the baggage which they had checked in.

(xiii) The aforesaid facts clearly indicate the connection between the travel plans of so called 'L. Singh' and 'M. Singh'. In fact the manner in which the reservations were changed to the names of 'M. Singh' and 'L. Singh' shows the anxiety of some one to hide behind the identity of persons who bore notorious names.

(xiv) The interlined baggage exploded at Narita Airport and there is strong probability that the suticase from Vancouver, which was interlined to AI 182, contained a device similar to the one which had exploded at Narita Airport on 23 June, 1985.

B. CVR and DFDR both stopped simultaneously:

There was simultaneous interruption of electrical power to the flight recorders. The electrical supply could have been interrupted either because of the cables being cut or because of total electric failure. Power supply wires to the CVR and the DFDR run under the passenger cabin ceiling on the left and the right hand side. The supply of electricity through these cables originates from the MEC compartment, which is in front of the forward cargo hold. If the CVR and the DFDR had stopped due to the breakage of electrical supply wires as a result of possible explosion in the aft cargo hold there would have had to be an instantaneous break of almost the entire section of fuselage, because both these recorders had stoped simultaneously. In such a catastrophic event it is not possible that the bottom skin panels of the aft cargo compartment would remain undistorted, or would have no rupture or holes in them. Furthermore, in such an event the tail portion of the aircraft would have been found in the beginning of the wreckage trail, but this was not so. On the other hand, and explosion in the forward cargo compartment would have resulted in damage to the electrical buses located in the MEC and that would, in turn, result in cutting off the electrical power supply causing simultaneous stoppage of the recorders.

C. The ATC Transponder Stopped Transmitting :

The transponder is located at the bottom of the one of the forward rakes immediately forward of the front cargo compartment. Signals from this also stopped being received by the secondary radar at Shannon. Keeping in view that the CVR and the DFDR had stopped simultaneously at about the same time, when the signals from ATC transponder had also ceased, it is reasonable to presume that there must have been a complete breackdown of electrical supply which had affected all the three units. The only event which could have caused such a damage to paralyse the entire MEC compartment could only have been an explosion in the forward cargo hold. It was not possible that any rapid decompression caused by a structural failure could have disrupted the entire electricl power supply from the MEC compartment. In known cases of aircraft being subjected to rapid decompression there has never been such an instantaneous and total stoppage of electrical power and in fact aircrafts have been known to have continued to fly and communicate with the ground even after decompression.

D. Non-supply of Oxygen :

Oxygen supply cylinders are located in the ceiling of the forward cargo compartment. Any rupture of the only pipeline which supplies oxygen to the passengers would result in there being no surge of oxygen flow, which alone drops the oxygen masks. The inspection of the wreckage shows that there is no indication of the oxygen masks ever having dropped. A rupture of this pipeline, simultaneously with power rupture, could only have been caused if there had been a detonation of the explosive device in the front cargo hold.

E. Damage in air :

The examination of the floating and the other wreckage shows that the right hand wing leading edge, the No. 3 engine fan cowl, right hand inboard mid flap leading edge and the leading edge of the right hand stabilizer were damaged in flight. This damage could have occurred only if objects had been ejected from the front portion of the aircraft when it was still in the air. The cargo door of the front cargo compartment was also found ruptured from above. This also indicates that the explosion perhaps occurred in the forward cargo compartment causing the objects to come out and thereby damaging the components on the right hand side.

F. Evidence of Overpressurization :

The examination of the structural panels and the other parts of the forward cargo compartment and the aft cargo compartment, recovered from the sea bed, indicates that overpressure condition had occurred in both the cargo compartments. The failure of the passenger cabin floor panels in upward direction also indicates that overpressure was created in both the compartments. It cannot be disputed that whenever an explosive detonates very high pressure shockwaves are formed which travel in all directions and high speed fragments of the container, or the loose material, also move away from the source of explosion. It is, therefore, clear that there was overpressurization in the cargo compartments which resulted in such rupture of the cabin floor panels.

G. Holes in the front cargo hold panels

While the skin panels of the aft cargo compartment are fairly straight and undamaged, the panels of the front cargo compartment are ruptured and have a large number of holes. This shows that there was occurrence of an event in the front cargo compartment and not in the aft cargo compartment.

H. Buckling of Seats :

The seats towards the rear of the aircraft had only the aft legs buckled, whereas the seats towards the front had both the front and the aft legs buckled. This indicated that the whole floor was subjected to a vertical force and was more severe towards the front. Moreover, the upper deck storage cabin was found among floating wreckage. The bottom of this cabin was pushed up in the shape of a dome with no evidence of impact damage. This deformation was indicative of having been caused, possibly, as a result of a shockwave.

I. Metallurgical Examination Results :

A metallurgical examination, especially of Targets 362 and 399, clearly confirms that there was an explosion in the forward cargo compartment. Microscopy around some of the holes discloses that they have such characteristics like twinning which can be present only if the holes had been puntured due to the detonation of an explosive device.

J. CVR Tape Analysis :

The report of CVR tape analysis by Mr. S.N. Seshadri also corroborates the aforesaid evidence i.e. that there was a bomb in the forward cargo hold of the aircraft.

RECOMMENDATIONS

5.1 ICAO, IATA and the States should :-

(a) undertake an ongoing review of established aviation security standards to prevent the placement of explosive substances on board commercial aircraft;

(b) establish a programme of monitoring the implimentation of security measures in airports around the world, in cooperation with the Governments concerned. For each airport studied, it should report its findings and recomend any improvements that may be required;

(c) consider establishing a group of civil aviation experts to investigate serious breaches of security. The purpose of these investigations would be to determine the facts of an incident so that necessary measures could be developed and implemented world wide to prevent similar breaches in the future.

Note : As it may take some time for ICAO and IATA to implement these recommendations, at least those countries which have international air traffic should take up effective measures without delay.

5.2 ICAO should :-

(a) develop a model clause on security that could be used in the bilateral air agreements that govern the exchange of air traffic rights between countries;

(b) consider establishing standards for the training of security personnel.

5.3 IATA should develop practical procedures for reconciliation of interlined passengers and their baggage at intermediate airports.

5.4 Interlining of checked-in baggage should not be done if a passenger does not have a confirmed reservation on the onward carrier flight.

5.5 The baggage of interlined passengers should be matched with passengers by the onward carriers before loading the baggage on the aircraft.

5.6 Whenever a Government becomes aware of particular high risk security threat it should notify not only the airline at risk, but also all connecting airlines in order that extra precaution can be taken at potential points of introduction of interline baggage into the system.

5.7 When an Airline is aware of a high security threat it should communicate the same to the host state as well as, if possible and prudent, to the other airlines operating there.

5.8 Passenger count should be done at boarding gate and in case of 'no gate show' of a passenger, his baggage must be off-loaded.

5.9 All checked-in baggage, whether it has been screened by X-ray machine or not, should be personally matched and identified with the passengers boarding an aircraft. Any baggage which is not so identified should be off-loaded. This is advisable as examination of the baggage with the help of an X-ray machine has its own limitations and is not fool proof. Some explosives hidden in Radios, Cameras etc. may not be readily detected by such a machine. In fact an explosive not placed in a metallic container will not be detectable by an X-ray machine. Similarly, a plastic explosive can be given an innocuous shape or form so as to avoid detection by an X-Ray. Reliance on an X-Ray machine alone may in fact provide a false sense of security.

5.10 Effectiveness of the instrument known as PD-4 is highly questionable. It is not advisable to rely on it.

5.11 All unaccompanied baggage should be placed on the aircraft after their contents have been physically checked. In the alternative, it should be loaded only after it has been placed in a decompression chamber and the host state is satisfied that the baggage is clean and the shipper has been identified.

5.12 Airlines should have effective backup security equipment or procedures available in case of machanical break down of security equipment.

5.13 All hand baggage, including that of the crew, should be opened and the contents physically checked even if the said baggage has been x-rayed. This will no doubt be a bit time consuming and laborius but if security is to be meaningful, then slight inconvenience has to be endured in order to ensure a safer flight.

5.14 The manufacturers of aircraft should take effective steps for protecting sensitive parts of the aircraft from explosive damage.

5.15 Studies should be undertaken to determine the feasibility of physically separating the avionics bay and emergency oxygen systems from the cargo area in aircraft so that these sensitive and essential areas of the aircraft cannot be damaged or destroyed by a relatively small explosive deivce concealed in luggage.

5.16 The seats should have safety belts which can act as restraint for the upper part of the body e.g. like a shoulder harness with inertial restraint.

5.17 The seats in the aircraft should be so designed so as to incorporate shock absorbing systems within the seat and they should be manufactured by using material which does not break easily.

5.18 In addition to the cockpit voice recorder, there should be in the cockpit a video/scanning camera which would record the movements and the audio sounds in the cockpit. This will not only assist in ascertaining as to how the pilots act during as emergency but, in the case of hijacking, would also assist in the identification of the hijackers.

5.19 The CVR should record all the conservation and sounds in the cockpit for the entire duration of the flight, and not merely for the last 30 minutes.

5.20 The CVR and the DFDR should be powered from two alternative sources of energy.

5.21 The oxygen for the flight crew should be supplied from two different sources i.e. in the event of an emergency the pilot and the co-pilot must don the oxygen mask and the oxygen must be supplied from different source.

5.22 Suitable provisions should be incorporated in Annex 13 which would give power to an Investigator to record evidence outside the country of investigation and also to summon witness from abroad. It should also be mandatory on the contracting States to give information

sought for by an Investigator.
(B. N. KIRPAL)
February 26, 1986 COURT
We agree with the conclusions and recommendations stated above.
ASSESSORS
(V. Ramachandran) (J.S. Gharia)
(J.S. Dhillon) (J.K. Mehra)
(B.K. Bhasin)

ACKNOWLEDGEMENTS

When I was appointed as the Court to investigate into the accident, the magnitude of the task involved was known. With the help, assistance and cooperation of a team of dedicated workers, the work was, however, completed in not too long time. The assistance received from those who helped me cannot be too highly praised.

From amongst my Assessors, Captian B.K. Bhasin was the only one who was permanently stationed in Delhi. We met for the first time on 15th July, 1985 and little did I realise then that, by the time our work would be over, how much I would be depending upon him. Not only was his advice on the technical aspects of flying and air safety invaluable but, whenever any difficulty or a problem arose, I invariably turned to him for assistance and advice which I readily got. I found him having a very practical and positive approach to all the problems but, at the same time, he very rightly was not prepared to compromise on any principal issues.

The only interest Dr. V. Ramachandran appeared to have was to do his work to perfection. No praise can be too high for the manner in which this Metallurgist from landlocked Bangalore volunteered and boarded the salvage ships which were carrying out operations in the cold and choppy waters of Atlantic Ocean. He sarificed all comforts and went to sea with a view to be present on board the ships at the time when salvaged pieces of wreckage were brought on board. His deep knowledge of metallurgy greatly assisted the examination of the salvaged pieces of wreckage. In this connection the entire metallurgical examination was planned and organised by him.

Whenever any information was required concerning explosives, Mr. J.S. Gharia was ever eager and in a position to provide the information.

Mr. J.K. Mehra looked into the engineering aspect of the accident and he spent a lot of time in going through various Air-India Maintenance Manuals. He always made discussions very lively and interesting.

Captain J.S. Dhillon came out of his retirement and provided useful information to the Court on some aspects of flying.

This work would never have been satisfactorily completed without the help and assistance received by the Court from late Mr. S.N. Seshadri of Bhabha Atomic Research Centre. From the time when the CVR was first played by him at BARC on 16 July, 1985 till the very end, he most willingly and pleasantly undertook any assignment which was given to him by the Court. It was a great national loss when he suddenly passed away on 2nd February, 1986, only a few days after he had deomonstrated his brilliance when his testimony, regarding the analysis of the CVR tape, was recorded by me in the Court.

I am also grateful to the other Scientists and staff of B.A.R.C. who rendered considerable assistance to the Court. The facilities made available by Dr. P.K. Iyengar, Director, B.A.R.C. with regard to the finalisation and completion of the report cannot be easily forgotten. In the absence of late Mr. S.N. Seshadri, with whom I had developled a personal rapport, Dr. Ashok Mohan and Mr. V.K. Chadda met with all our requirements in the finalisation and preparation of the Report. Dr. Asundi of BARC and the other Metallurgists of that Organisation and of the National Aeronautical Laboratory also spent a considerable amount of their time and energy in successfully carrying out metallurgical tests and examination of the salvaged pieces.

During the investigation I had to visit Ireland on two occasions. I immediately realised the extent of help, assistance and guidance which was being rendered to all of us by Mr. Kiran Doshi, the Indian Ambassador to Ireland. There was no problem to which he did not have a solution. On my visit to Dublin not only did I enjoy the hospitality of Kiran and his wife Razia but it also gave an opportunity to personally meet Mr. Mitchel, the Minister of Communications, and senior officials of his Ministry, and to express my gratitude to them for all the help and assistance which the Government and people of Ireland had, most willingly, rendered.

At Tokyo the Indian Ambassador and members of his staff looked after all our needs and arranged meetings with the Japanese officials whom we wanted to meet.

As representatives of the Court in Cork, Mr. P.R. Chandrasekhar and Mr. C.D. Kolhe did a commendable job. They kept me informed of the progress which was taking place at Cork and, whenever required to do so, they took vital decisions while coordinating the mapping and salvage operations.

Mr. H.S. Khola, Director of Air Safety, New Delhi willingly carried out all the directions of the Court. Special mention must also be made of Mr. Satendra Singh, Regional Controller of Air Safety, Bombay, who worked day and night when the flight recorders were first opened and the copies of the tapes made and the data analysed.

I have also to express my gratitude to the Counsel who assisted the Court in the Investigation. Without their help and cooperation, it would not have been possible to complete the work in 7-1/2 months.

On my trip to Bombay, the Staff and Management of Centaur Hotel made my stay very comfortable. It was like a home away from home.

The work done during the salvage operarations by four young engineers of Air-India was highly commendable and valuable. All of them namely, Mr. Balasubramanium, Mr. L.S. Carvalho, Mr. G.D. Nayar and Mr. A.K. Sheode, worked round the clock even during adverse climatic conditions.

The Registrar of the Delhi High Court, Ms. Usha Mehra spared no efforts in rendering every assistance whenever the same was required. She ably marshalled all the resources available in the High Court in order to ensure the smooth and efficient functioning of my office. My own personal staff in particular, headed by Mr. V.P. Ahuja, Court Master and Mr. Balram Chopra, Private Secretary, as usual, rose to the occasion. While Mr. Ahuja kept complete control of hundreds of documents and affidavits which had been filed, Mr. Chopra besides bearing the brunt of the typing work, very ably supervised the work of other Stenographers. It was most fortunate that I was able to persuade Mr. S.N. Sharma to accept the trying job of being the Secretary to the Court. His vast experience in such Investigations, he had been a Secretary in three such Investigations earlier, made my task much lighter. Moreover, as an Aircraft Engineer, he was always ready to explain technical intricacies involved in the case. Without his help I could not have completed my work within the stipulated time.

(B. N. KIRPAL)

26th February, 1986 COURT

Air Accidents Investigation Branch
Aircraft Accident Report No 2/90 (EW/C1094)

Report on the accident to
Boeing 747-121, N739PA
at Lockerbie, Dumfriesshire, Scotland
on 21December 1988

Contents

Operator: Pan American World Airways
Aircraft Type: Boeing 747-121
Nationality: United States of America
Registration: N 739 PA
Place of Accident Lockerbie, Dumfries, Scotland
Latitude 55¡ 07' N
Longitude 003¡ 21' W
Date and Time (UTC): 21 December 1988 at 19.02:50 hrs
All times in this report are UTC
SYNOPSIS

The accident was notified to the Air Accidents Investigation Branch at 19.40

hrs on the 21 December 1988 and the investigation commenced that day. The members of the AAIB team are listed at Appendix A.

The aircraft, Flight PA103 from London Heathrow to New York, had been in level cruising flight at flight level 310 (31,000 feet) for approximately seven minutes when the last secondary radar return was received just before 19.03 hrs. The radar then showed multiple primary returns fanning out downwind. Major portions of the wreckage of the aircraft fell on the town of Lockerbie with other large parts landing in the countryside to the east of the town. Lighter debris from the aircraft was strewn along two trails, the longest of which extended some 130 kilometres to the east coast of England. Within a few days items of wreckage were retrieved upon which forensic scientists found conclusive evidence of a detonating high explosive. The airport security and criminal aspects of the accident are the subject of a separate investigation and are not covered in this report which concentrates on the technical aspects of the disintegration of the aircraft.

The report concludes that the detonation of an improvised explosive device led directly to the destruction of the aircraft with the loss of all 259 persons on board and 11 of the residents of the town of Lockerbie. Five recommendations are made of which four concern flight recorders, including the funding of a study to devise methods of recording violent positive and negative pressure pulses associated with explosions. The final recommendation is that Airworthiness Authorities and aircraft manufacturers undertake a systematic study with a view to identifying measures that might mitigate the effects of explosive devices and improve the tolerance of the aircraft's structure and systems to explosive damage.

1. FACTUAL INFORMATION

1.1 History of the Flight

Boeing 747, N739PA, arrived at London Heathrow Airport from San Francisco and parked on stand Kilo 14, to the south-east of Terminal 3. Many of the passengers for this aircraft had arrived at Heathrow from Frankfurt, West Germany on a Boeing 727, which was positioned on stand Kilo 16, next to N739PA. These passengers were transferred with their baggage to N739PA which was to operate the scheduled Flight PA103 to New York Kennedy. Passengers from other flights also joined Flight PA103 at Heathrow. After a 6 hour turnround, Flight PA103 was pushed back from the stand at 18.04 hrs and was cleared to taxy on the inner taxiway to runway 27R. The only relevant Notam warned of work in progress on the outer taxiway. The departure was unremarkable.

Flight PA103 took-off at 18.25 hrs. As it was approaching the Burnham VOR it took up a radar heading of 350¡ and flew below the Bovingdon holding point at 6000 feet. It was then cleared to climb initially to flight level (FL) 120 and subsequently to FL 310. The aircraft levelled off at FL 310 north west of Pole Hill VOR at 18.56 hrs. Approximately 7 minutes later, Shanwick Oceanic Control transmitted the aircraft's oceanic clearance but this transmission was not acknowledged. The secondary radar return from Flight PA103 disappeared from the radar screen during this transmission. Multiple primary radar returns were then seen fanning out downwind for a considerable distance. Debris from the aircraft was strewn along two trails, one of which extended some 130 km to the east coast of England. The upper winds were between 250¡ and 260¡ and decreased in strength from 115 kt at FL 320 to 60 kt at FL 100 and 15 to 20 kt at the surface.

Two major portions of the wreckage of the aircraft fell on the town of Lockerbie; other large parts, including the flight deck and forward fuselage section, landed in the countryside to the east of the town. Residents of Lockerbie reported that, shortly after 19.00 hrs, there was a rumbling noise like thunder which rapidly increased to deafening proportions like the roar of a jet engine under power. The noise appeared to come from a meteor-like object which was trailing flame and came down in the north-eastern part of the town. A larger, dark, delta shaped object, resembling an aircraft wing, landed at about the same time in the Sherwood area of the town. The delta shaped object was not on fire while in the air, however, a very large fireball ensued which was of short duration and carried large amounts of debris into the air, the lighter particles being deposited several miles downwind. Other less well defined objects were seen to land in the area.

1.2 Injuries to persons

Injuries	Crew	Passengers	Others
Fatal	16	243	11
Serious	-	-	2
Minor/None	-	-	3

CLICK HERE TO RETURN TO INDEX

1.3 Damage to aircraft

The aircraft was destroyed

1.4 Other damage

The wings impacted at the southern edge of Lockerbie, producing a crater whose volume, calculated from a photogrammetric survey, was approximately 560 cubic metres. The weight of material displaced by the wing impact was estimated to be well in excess of 1500 tonnes. The wing impact created a fireball, setting fire to neighbouring houses and carrying aloft debris which was then blown downwind for several miles. It was subsequently established that domestic properties had been so seriously damaged as a result of fire and/or impact that 21 had to be demolished and an even greater number of homes required substantial repairs. Major portions of the aircraft, including the engines, also landed on the town of Lockerbie and other large parts, including the flight deck and forward fuselage section, landed in the countryside to the east of the town. Lighter debris from the aircraft was strewn as far as the east coast of England over a distance of 130 kilometres.

1.5 Personnel information

1.5.1 Commander: Male, aged 55 years
Licence: USA Airline Transport Pilot's Licence
Aircraft ratings: Boeing 747, Boeing 707, Boeing 720, Lockheed L1011 and Douglas DC3
Medical Certificate: Class 1,valid to April 1989, with the limitation that the holder shall wear lenses that correct for distant vision and possess glasses that correct for near vision

Flying experience:
Total all types: 10,910 hours
Total on type: 4,107 hours
Total last 28 days 82 hours
Duty time: Commensurate with company requirements
Last base check: 11 November 1988
Last route check: 30 June 1988
Last emergencies check: 8 November 1988

1.5.2 Co-pilot: Male, aged 52 years
Licence: USA Airline Transport Pilot's Licence
Aircraft ratings: Boeing 747, Boeing 707, Boeing 727
Medical Certificate: Class 1, valid to April 1989, with the limitation that the holder shall possess correcting glasses for near vision

Flying experience:
Total all types: 11,855 hours
Total on type: 5,517 hours
Total last 28 days: 51 hours
Duty time: Commensurate with company requirements
Last base check: 30 November 1988
Last route check: Not required
Last emergencies check: 27 November 1988

1.5.3 Flight Engineer: Male, aged 46 years
Licence: USA Flight Engineer's Licence
Aircraft ratings: Turbojet
Medical certificate: Class 2, valid to June 1989, with the limitation that the holder shall wear correcting glasses for near vision
Flying experience:
Total all types: 8,068 hours
Total on type: 487 hours
Total last 28 days: 53 hours
Duty time: Commensurate with company requirements
Last base check: 30 October 1988
Last route check: Not required
Last emergencies check: 27 October 1988

1.5.4 Flight Attendants: There were 13 Flight Attendants on the aircraft, all of whom met company proficiency and medical requirements

1.6 Aircraft information

1.6.1 Leading particulars
Aircraft type: Boeing 747-121
Constructor's serial number: 19646
Engines: 4 Pratt and Whitney JT9D-7A turbofan

1.6.2 General description

The Boeing 747 aircraft, registration N739PA, was a conventionally designed long range transport aeroplane. A diagram showing the general arrangement is shown at Appendix B, Figure B-1 together with the principal dimensions of the aircraft.

The fuselage of the aircraft type was of approximately circular section over most of its length, with the forward fuselage having a diameter of 21† feet where the cross-section was constant. The pressurised section of the fuselage (which included the forward and aft cargo holds) had an overall length of 190 feet, extending from the nose to a point just forward of the tailplane. In normal cruising flight the service pressure differential was at the maximum value of 8.9 pounds per square inch. The fuselage was of conventional skin, stringer and frame construction, riveted throughout, generally using countersunk flush riveting for the skin panels. The fuselage frames were spaced at 20 inch intervals and given the same numbers as their stations, defined in terms of the distance in inches from the datum point close to the nose of the aircraft [Appendix B, Figure B-2]. The skin panels were joined using vertical butt joints and horizontal lap joints. The horizontal lap joints used three rows of rivets together with a cold bonded adhesive.

Accommodation within the aircraft was predominately on the main deck, which extended throughout the whole length of the pressurised compartment. A separate upper deck was incorporated in the forward part of the aircraft. This upper deck was reached by means of a spiral staircase from the main deck and incorporated the flight crew compartment together with additional passenger accommodation. The cross-section of the forward fuselage differed considerably from the near circular section of the remainder of the aircraft, incorporating an additional smaller radius arc above the upper deck section joined to the main circular arc of the lower cabin portion by elements of straight fuselage frames and flat skin.

In order to preserve the correct shape of the aircraft under pressurisation loading, the straight portions of the fuselage frames in the region of the upper deck floor and above it were required to be much stiffer than the frame portions lower down in the aircraft. These straight sections were therefore of very much more substantial construction than most of the curved sections of frames lower down and further back in the fuselage. There was considerable variation in the gauge of the fuselage skin at various locations in the forward fuselage of the aircraft.

The fuselage structure of N739PA differed from that of the majority of Boeing

747 aircraft in that it had been modified to carry special purpose freight containers on the main deck, in place of seats. This was known as the Civil Reserve Air Fleet (CRAF) modification and enabled the aircraft to be quickly converted for carriage of military freight containers on the main deck during times of national emergency. The effect of this modification on the structure of the fuselage was mainly to replace the existing main deck floor beams with beams of more substantial cross-section than those generally found in passenger carrying Boeing 747 aircraft. A large side loading door, generally known as the CRAF door, was also incorporated on the left side of the main deck aft of the wing.

Below the main deck, in common with other Boeing 747 aircraft, were a number of additional compartments, the largest of which were the forward and aft freight holds used for the storage of cargo and baggage in standard air-transportable containers. These containers were placed within the aircraft hold by means of a freight handling system and were carried on a system of rails approximately 2 feet above the outer skin at the bottom of the aircraft, there being no continuous floor, as such, below these baggage containers. The forward freight compartment had a length of approximately 40 feet and a depth of approximately 6 feet. The containers were loaded into the forward hold through a large cargo door on the right side of the aircraft.

1.6.3 Internal fuselage cavities

Because of the conventional skin, frame and stringer type of construction, common to all large public transport aircraft, the fuselage was effectively divided into a series of 'bays'. Each bay, comprising two adjacent fuselage frames and the structure between them, provided, in effect, a series of interlinking cavities bounded by the frames, floor beams, fuselage skins and cabin floor panels etc. The principal cavities thus formed were:

(i) A semi-circular cavity formed in between the fuselage frames in the lower lobe of the hull, i.e. from the crease beam (at cabin floor level) on one side down to the belly beneath the containers and up to the opposite crease beam, bounded by the fuselage skin on the outside and the containers/cargo liner on the inside [Appendix B, Figure B-3, detail A].

(ii) A horizontal cavity between the main cabin floor beams, the cabin floor panels and the cargo bay liner. This extended the full width of the fuselage and linked the upper ends of the lower lobe cavity [Appendix B, Figure B-3, detail B].

(iii) A narrow vertical cavity between the two containers [Appendix B,

Figure B-3, detail C].
(iv) A further narrow cavity around the outside of the two containers, between the container skins and the cargo bay liner, communicating with the lower lobe cavity [Appendix B, Figure B-3, detail D].
(v) A continuation of the semi-circular cavity into the space behind the cabin wall liner [Appendix B, Figure B-3, detail E]. This space was restricted somewhat by the presence of the window assembly, but nevertheless provided a continuous cavity extending upwards to the level of the upper deck floor. Forward of station 740, this cavity was effectively terminated at its upper end by the presence of diaphragms which formed extensions of the upper deck floor panels; aft of station 740, the cavity communicated with the ceiling space and the cavity in the fuselage crown aft of the upper deck.

All of these cavities were repeated at each fuselage bay (formed between pairs of fuselage frames), and all of the cavities in a given bay were linked together, principally at the crease beam area [Appendix B, Figure B-3, region F]. Furthermore, each of the set of bay cavities was linked with the next by the longitudinal cavities formed between the cargo hold liner and the outer hull, just below the crease beam [Appendix B, Figure B-3, detail F]; i.e. this cavity formed a manifold linking together each of the bays within the cargo hold.

The main passenger cabin formed a large chamber which communicated directly with each of the sub floor bays, and also with the longitudinal manifold cavity, via the air conditioning and cabin/cargo bay de-pressurisation vent passages in the crease beam area. (It should be noted that a similar communication did not exist between the upper and lower cabins because there were no air conditioning/depressurisation passages to bypass the upper deck floor.)

1.6.4 Aircraft weight and centre of gravity

The aircraft was loaded within its permitted centre of gravity limits as follows:

Loading: lb kg
Operating empty weight 366,228 166,120
Additional crew 130 59
243 passengers (1) 40,324 18,291
Load in compartments:
1 11,616 5,269
2 20,039 9,090

3 15,057 6,830
4 17,196 7,800
5 2,544   1,154
Total in compartments (2) 66,452 30,143
Total traffic load   106,776 48,434
Zero fuel weight 472,156 214,554
Fuel (Take-off) 239,997 108,862
Actual take-off weight(4)   713,002 323,416
Maximum take-off weight 733,992 332,937

Note 1:
Calculated at standard weights and including cabin baggage.

Note 2:
Despatch information stated that the cargo did not include dangerous goods, perishable cargo, live animals or known security exceptions.

1.6.5 Maintenance details

N739PA first flew in 1970 and spent its whole service life in the hands of Pan American World Airways Incorporated. Its Certificate of Airworthiness was issued on 12 February 1970 and remained in force until the time of the accident, at which time the aircraft had completed a total of 72,464 hours flying and 16,497 flight cycles. Details of the last 4 maintenance checks carried out during the aircraft's life are shown below:

DATE   SERVICE HOURS   CYCLES
27 Sept 88   C Check (Interior upgrade)   71,502 16,347
2 Nov 88 B Service Check 71,919 16,406
27 Nov 88 Base 1 72,210 16,454
13 Dec 88 Base 2 72,374 16,481

The CRAF modification programme was undertaken in September 1987. At the same time a series of modifications to the forward fuselage from the nose back to station 520 (Section 41) were carried out to enable the aircraft to continue in service without a continuing requirement for structural inspections in certain areas.

All Airworthiness Directives relating to the Boeing 747 fuselage structure between stations 500 and 1000 have been reviewed and their applicability to this aircraft checked. In addition, Service Bulletins relating to the structure in this area were also reviewed. The applicable Service Bulletins, some of which implement the Airworthiness Directives are listed below together with their subjects. The dates, total aircraft times and total aircraft cycles at which each relevant inspection was last carried out have been reviewed and their status on aircraft N739PA at the time of the accident has been established.

N739PA Service Bulletin compliance:

SB 53-2064 Front Spar Pressure Bulkhead Chord Reinforcement and Drag Splice Fitting Rework.
Modification accomplished on 6 July 1974.
Post-modification repetitive inspection IAW (in accordance with) AD 84-18-06 last accomplished on 19 November 1985 at 62,030 TAT hours (Total Aircraft Time) and 14,768 TAC (Total Aircraft Cycles).
SB 53-2088 Frame to Tension Tie Joint Modification - BS760 to 780.
Repetitive inspection IAW AD 84-19-01 last accomplished on 19 June 1985 at 60,153 hours TAT and 14,436 TAC.
SB 53-2200 Lower Cargo Doorway Lower Sill Truss and Latch Support Fitting Inspection Repair and Replacement.
Repetitive inspection IAW AD 79-17-02 R2 last accomplished 2 November 1988 at 71,919 hours TAT and 16,406 TAC.
SB 53-2234 Fuselage - Auxiliary Structure - Main Deck Floor - BS 480 Floor Beam Upper Chord Modification.
Repetitive inspection per SB 53A2263 IAW AD 86-23-06 last accomplished on 26 September 1987 at 67,376 hours TAT and 15,680 TAC.
SB 53-2237 Fuselage - Main Frame - BS 540 thru 760 and 1820 thru 1900 Frame Inspection and Reinforcement.
Repetitive inspection IAW AD 86-18-01 last accomplished on 27 February 1987 at 67,088 hours TAT and 15,627 TAC.
SB 53-2267 Fuselage - Skin - Lower Body Longitudinal Skin Lap Joint and Adjacent Body Frame Inspection and Repair.
Terminating modification accomplished 100% under wing-to-body fairings and approximately 80% in forward and aft fuselage sections on 26 September 1987 at 67,376 hours TAT and 15,680 TAC.
Repetitive inspection of unmodified lap joints IAW AD 86-09-07 R1 last accomplished on 18 August 1988 at 71,043 hours TAT and 16,273 TAC.
SB 53A2303 Fuselage - Nose Section - station 400 to 520 Stringer 6 Skin Lap Splice Inspection, Repair and Modification.
Repetitive inspection IAW AD 89-05-03 last accomplished on 26 September 1987 at 67,376 hours TAT and 15,680 TAC.

This documentation, when viewed together with the detailed content of the above service bulletins, shows the aircraft to have been in compliance with the requirements laid down in each of those bulletins. Some maintenance items were outstanding at the time the aircraft was despatched on the last flight, however, none of these items relate to the structure of the aircraft and none had any relevance to the accident.

1.7 Meteorological Information

1.7.1 General weather conditions

An aftercast of the general weather conditions in the area of Lockerbie at about 19.00 hrs was obtained from the Meteorological Office, Bracknell. The synoptic situation included a warm sector covering northern England and most of Scotland with a cold front some 200 nautical miles to the west of the area moving eastwards at about 35 knots. The weather consisted of intermittent rain or showers. The cloud consisted of 4 to 6 oktas of stratocumulus based at 2,200 feet with 2 oktas of altocumulus between 15,000 and 18,000 feet. Visibility was over 15 kilometers and the freezing level was at 8,500 feet with a sub-zero layer between 4,000 and 5,200 feet.

1.7.2 Winds

There was a weakening jet stream of around 115 knots above Flight Level 310. From examination of the wind profile (see below), there appeared to be insufficient shear both vertically and horizontally to produce any clear air turbulence but there may have been some light turbulence.

Flight Level	Wind
320	260¡/115 knots
300	260¡/ 90 knots
240	250¡/ 80 knots
180	260¡/ 60 knots
100	250¡/ 60 knots
050	260¡/ 40 knots
Surface	240¡/ 15 to 20 gusting 25 to 30 knots

1.8 Aids to navigation

Not relevant.

1.9 Communications

The aircraft communicated normally on London Heathrow aerodrome, London control and Scottish control frequencies. Tape recordings and transcripts of all radio telephone (RTF) communications on these frequencies were available.

At 18.58 hrs the aircraft established two-way radio contact with Shanwick Oceanic Area Control on frequency 123.95 MHz. At 19.02:44 hrs the clearance delivery officer at Shanwick transmitted to the aircraft its oceanic route clearance. The aircraft did not acknowledge this message and made no subsequent transmission.

1.9.1 ATC recording replay

Scottish Air Traffic Control provided copy tapes with time injection for both Shanwick and Scottish ATC frequencies. The source of the time injection on the tapes was derived from the British Telecom "TIM" signal.

The tapes were replayed and the time signals corrected for errors at the time of the tape mounting.

1.9.2 Analysis of ATC tape recordings

From the cockpit voice recorder (CVR) tape it was known that Shanwick was transmitting Flight PA103's transatlantic clearance when the CVR stopped. By synchronising the Shanwick tape and the CVR it was possible to establish that a loud sound was heard on the CVR cockpit area microphone (CAM) channel at 19.02:50 hrs ±1 second.

As the Shanwick controller continued to transmit Flight PA103's clearance instructions through the initial destruction of the aircraft it would not have been possible for a distress call to be received from N739PA on the Shanwick frequency. The Scottish frequency tape recording was listened to from 19.02 hrs until 19.05 hrs for any unexplained sounds indicating an attempt at a distress call but none was heard.

A detailed examination and analysis of the ATC recording together with the flight recorder, radar, and seismic recordings is contained in Appendix C.

1.10 Aerodrome information

Not relevant

1.11 Flight recorders

The Digital Flight Data Recorder (DFDR) and the Cockpit Voice Recorder (CVR) were found close together at UK Ordnance Survey (OS) Grid Reference 146819, just to the east of Lockerbie, and recovered approximately 15 hours after the accident. Both recorders were taken directly to AAIB Farnborough for replay. Details of the examination and analysis of the flight recorders together with the radar, ATC and seismic recordings are contained in Appendix C.

1.11.1 Digital flight data recorder

The flight data recorder installation conformed to ARINC 573B standard with a Lockheed Model 209 DFDR receiving data from a Teledyne Controls Flight Data Acquisition Unit (FDAU). The system recorded 22 parameters and 27 discrete (event) parameters. The flight recorder control panel was located in the flight deck overhead panel. The FDAU was in the main equipment centre at the front end of the forward hold and the flight recorder was mounted in the aft equipment centre.

Decoding and reduction of the data from the accident flight showed that no abnormal behaviour of the data sensors had been recorded and that the recorder had simply stopped at 19.02:50 hrs ±1 second.

1.11.2 Cockpit voice recorder

The aircraft was equipped with a 30 minute duration 4 track Fairchild Model A100 CVR, and a Fairchild model A152 cockpit area microphone (CAM). The CVR control panel containing the CAM was located in the overhead panel on the flight deck and the recorder itself was mounted in the aft equipment centre.

The channel allocation was as follows:-

Channel 1 Flight Engineer's RTF.
Channel 2 Co-Pilot's RTF.
Channel 3 Pilot's RTF.

Channel 4   Cockpit Area Microphone.

The erase facility within the CVR was not functioning satisfactorily and low level communications from earlier recordings were audible on the RTF channels. The CAM channel was particularly noisy, probably due to the combination of the inherently noisy flight deck of the B747-100 in the climb and distortion from the incomplete erasure of the previous recordings. On two occasions the crew had difficulty understanding ATC, possibly indicating high flight deck noise levels. There was a low frequency sound present at irregular intervals on the CAM track but the source of this sound could not be identified and could have been of either acoustic or electrical origin.

The CVR tape was listened to for its full duration and there was no indication of anything abnormal with the aircraft, or unusual crew behaviour. The tape record ended, at 19.02:50 hrs ±1 second, with a sudden loud sound on the CAM channel followed almost immediately by the cessation of recording whilst the crew were copying their transatlantic clearance from Shanwick ATC.

1.12 Wreckage and impact information

1.12.1 General distribution of wreckage in the field

The complete wing primary structure, incorporating the centre section, impacted at the southern edge of Lockerbie. Major portions of the aircraft, including the engines, also landed in the town. Large portions of the aircraft fell in the countryside to the east of the town and lighter debris was strewn to the east as far as the North Sea. The wreckage was distributed in two trails which became known as the northern and southern trails respectively and these are shown in Appendix B, Figure B-4. A computer database of approximately 1200 significant items of wreckage was compiled and included a brief description of each item and the location where it was found

Appendix B, Figures B-5 to B-8 shows photographs of a model of the aircraft on which the fracture lines forming the boundaries of the separate items of structure have been marked. The model is colour coded to illustrate the way in which the wreckage was distributed between the town of Lockerbie and the northern and southern trails.

1.12.1.1 The crater

The aircraft wing impacted in the Sherwood Crescent area of the town leaving a crater approximately 47 metres (155 feet) long with a volume calculated to be 560 cubic metres.

The projected distance, measured parallel from one leading edge to the other wing tip, of the Boeing 747-100 was approximately 143 feet, whereas the span is known to be 196 feet. This suggests that impact took place with the wing structure yawed. Although the depth of the crater varied from one end to the other, its widest part was clearly towards the western end suggesting that the wing structure impacted whilst orientated with its root and centre section to the west.

The work carried out at the main crater was limited to assessing the general nature of its contents. The total absence of debris from the wing primary structure found remote from the crater confirmed the initial impression that the complete wing box structure had been present at the main impact.

The items of wreckage recovered from or near the crater are coloured grey on the model at Appendix B, Figures B-5 to B-8.

1.12.1.2 The Rosebank Crescent site

A 60 feet long section of fuselage between frame 1241 (the rear spar attachment) and frame 1960 (level with the rear edge of the CRAF cargo door) fell into a housing estate at Rosebank Crescent, just over 600 metres from the crater. This section of the fuselage was that situated immediately aft of the wing, and adjoined the wing and fuselage remains which produced the crater. It is colour coded yellow on the model at Appendix B, Figures B-5 to B-8. All fuselage skin structure above floor level was missing except for the following items:

Section containing 3 windows between door 4L and CRAF door;
The CRAF door itself (latched) apart from the top area containing the hinge;
Window belt containing 8 windows aft of 4R door aperture
Window belt containing 3 windows forward of 4R door aperture;
Door 4R.

Other items found in the wreckage included both body landing gears, the right wing landing gear, the left and right landing gear support beams and the cargo door (frames 1800-1920) which was latched. A number of pallets, luggage containers and their contents were also recovered from this site.

1.12.1.3 Forward fuselage and flight deck section.

The complete fuselage forward of approximately station 480 (left side) to station 380 (right side) and incorporating the flight deck and nose landing gear was found as a single piece [Appendix B, Figure B-9] in a field approximately 4 km miles east of Lockerbie at OS Grid Reference 174808. It was evident from the nature of the impact damage and the ground marks that it had fallen almost flat on its left side but with a slight nose-down attitude and with no discernible horizontal velocity. The impact had caused almost complete crushing of the structure on the left side. The radome and right nose landing gear door had detached in the air and were recovered in the southern trail.

Examination of the torn edges of the fuselage skin did not indicate the presence of any pre-existing structural or material defects which could have accounted for the separation of this section of the fuselage. Equally so, there were no signs of explosive blast damage or sooting evident on any part of the structure or the interior fittings. It was noted however that a heavy, semi-eliptical scuff mark was present on the lower right side of the fuselage at approximately station 360. This was later matched to the intake profile of the No 3 engine.

The status of the controls and switches on the flight deck was consistent with normal operation in cruising flight. There were no indications that the crew had attempted to react to rapid decompression or loss of control or that any emergency preparations had been actioned prior to the catastrophic disintegration.

1.12.1.4 Northern trail

The northern trail was seen to be narrow and clearly defined, to emanate from a point very close to the main impact crater and to be orientated in a direction which agreed closely with the mean wind aftercast for the height band from sea level to 20,000 ft. Also at the western end of the northern trail were the lower rear fuselage at Rosebank Crescent, and the group of Nos. 1, 2 and 4 engines which fell in Lockerbie.

The trail contained items of structure distributed throughout its length, from the area slightly east of the crater, to a point approximately 16 km east, beyond which only items of low weight / high drag such as insulation, interior trim, paper etc, were found. For all practical purposes this trail ended at a range of 25 km.

The northern trail contained mainly wreckage from the rear fuselage, fin and the inner regions of both tailplanes together with structure and skin from the upper half of the fuselage forward to approximately the wing mid-chord position. A number of items from the wing were also found in the northern trail, including all 3 starboard Kreuger flaps, most of the remains of the port Kreuger flaps together with sections of their leading edge attachment structures, one portion of outboard aileron approximately 10 feet long, the aft ends of the flap-track fairings (one with a slide raft wrapped around it), and fragments of glass reinforced plastic honeycombe structure believed to be from the flap system, i.e. fore-flaps, aft-flaps, mid-flaps or adjacent fairings. In addition, a number of pieces of the engine cowlings and both HF antennae (situated projecting aft from the wing-tips) were found in this trail.

All items recovered from the northern trail, with the exception of the wing, engines, and lower rear fuselage in Rosebank Crescent, are coloured red on the model of the aircraft in Appendix B, Figures B-5 to B-8.

1.12.1.5 Southern trail

The southern trail was easily defined, except within 12 km of Lockerbie where it tended to merge with the northern trail. Further east, it extended across southern Scotland and northern England, essentially in a straight band as far as the North Sea. Most of the significant items of wreckage were found in this trail within a range of 30 km from the main impact crater. Items recovered from the southern trail are coloured green on the model of the aircraft at Appendix B, Figures B-5 to B-8.

The trail contained numerous large items from the forward fuselage. The flight deck and nose of the aircraft fell in the curved part of this trail close to Lockerbie. Fragments of the whole of the left tailplane and the outboard portion of the right tailplane were distributed almost entirely throughout the southern trail. Between 21 and 27 km east of the main impact point (either side of Langholm) substantial sections of tailplane skin were found, some bearing distinctive signs of contact with debris moving outwards and backwards relative to the fuselage. Also found in this area were numerous isolated sections of fuselage frame, clearly originating from the crown region above the forward upper deck.

1.12.1.6 Datum line

All grid references relating to items bearing actual explosive evidence, together with those attached to heavily distorted items found to originate immediately adjacent to them on the structure, were plotted on an Ordnance Survey (OS) chart. These references, 11 in total, were all found to be distributed evenly about a mean line orientated 079¡(Grid) within the southern trail and were spread over a distance of 12 km. The distance of each reference from the line was measured in a direction parallel to the aircraft's track and all were found to be within 500 metres of the line, with 50% of them being within 250 metres of the line. This line is referred to as the datum line and is shown in Appendix B, Figure B-4.

1.12.1.7 Distribution of wreckage within the southern trail

North of the datum line and parallel to it were drawn a series of lines at distances of 250, 300, 600 and 900 metres respectively from the line, again measured in a direction parallel to the aircraft's track. The positions on the aircraft structure of specific items of wreckage, for which grid references were known with a high degree of confidence, within the bands formed between these lines, are shown in Appendix B, Figures B-10 to 13. In addition, a separate assessment of the grid references of tailplane and elevator wreckage established that these items were distributed evenly about the 600 metre line.

1.12.1.8 Area between trails

Immediately east of the crater, the southern trail converged with the northern trail such that, to an easterly distance of approximately 5 km, considerable wreckage existed which could have formed part of either trail. Further east, between 6 and 11 km from the crater, a small number of sections and fragments of the fin had fallen outside the southern boundary of the northern trail. Beyond this a large area existed between the trails in which there was no wreckage.

1.12.2 Examination of wreckage at CAD Longtown

The debris from all areas was recovered by the Royal Air Force to the Army Central Ammunition Depot Longtown, about 20 miles from Lockerbie. Approximately 90% of the hull wreckage was successfully recovered, identified, and laid out on the floor in a two-dimensional reconstruction [Appendix B, Figure B-14]. Baggage container material was incorporated into a full three-dimensional reconstruction. Items of wreckage added to the reconstructions was given a reference number and recorded on a computer database together with a brief description of the item and the location where it was found.

1.12.2.1 Fuselage

The reconstruction revealed the presence of damage consistent with an explosion on the lower fuselage left side in the forward cargo bay area. A small region of structure bounded approximately by frames 700 & 720 and stringers 38L & 40L, had clearly been shattered and blasted through by material exhausting directly from an explosion centred immediately inboard of this location. The material from this area, hereafter referred to as the 'shatter zone', was mostly reduced to very small fragments, only a few of which were recovered, including a strip of two skins [Appendix B, Figure B-15] forming part of the lap joint at the stringer 39L position.

Surrounding the shatter zone were a series of much larger panels of torn fuselage skin which formed a 'star-burst' fracture pattern around the shatter zone. Where these panels formed the boundary of the shatter zone, the metal in the immediate locality was ragged, heavily distorted, and the inner surfaces were pitted and sooted - rather as if a very large shotgun had been fired at the inner surface of the fuselage at close range. In contrast, the star-burst fractures, outside the boundary of the shatter zone, displayed evidence of more typical overload tearing, though some tears appeared to be rapid and, in the area below the missing panels, were multi-branched. These surrounding skin panels were moderately sooted in the regions adjacent to the shatter zone, but otherwise were lightly sooted or free of soot altogether. (Forensic analysis of the soot deposits on frame and skin material from this area confirmed the presence of explosive residues.) All of these skin panels had pulled away from the supporting structure and had been bent and torn in a manner which indicated that, as well as fracturing in the star burst pattern, they had also petalled outwards producing characteristic, tight curling of the sheet material.

Sections of frames 700 and 720 from the area of the explosion were also recovered and identified. Attached to frame 720 were the remnants of a section of the aluminium baggage container (side) guide rail, which was heavily distorted and displayed deep pitting together with very heavy sooting, indicating that it had been very close to the explosive charge. The pattern of distortion and damage on the frames and guide rail segment matched the overall pattern of damage observed on the skins.

The remainder of the structure forming the cargo deck and lower hull was, generally, more randomly distorted and did not display the clear indications of explosive processes which were evident on the skin panels and frames nearer the focus of the explosion. Nevertheless, the overall pattern of damage was consistent with the propagation of explosive pressure fronts away from the focal area inboard of the shatter zone. This was particularly evident in the fracture and bending characteristics of several of the fuselage frames ahead of, and behind station 700.

The whole of the two-dimensional fuselage reconstruction was examined for general evidence of the mode of disintegration and for signs of localised damage, including overpressure damage and pre-existing damage such as corrosion or fatigue. There was some evidence of corrosion and dis-bonding at the cold-bond lap joints in the fuselage. However, the corrosion was relatively light and would not have compromised significantly the static strength of the airframe. Certainly, there was no evidence to suggest that corrosion had affected the mode of disintegration, either in the area of the explosion or at areas more remote. Similarly, there were no indications of fatigue damage except for one very small region of fatigue, involving a single crack less than 3 inches long, which was remote from the bomb location. This crack was not in a critical area and had not coincided with a fracture path.

No evidence of overpressure fracture or distortion was found at the rear pressure bulkhead. Some suggestion of 'quilting' or 'pillowing' of skin panels between stringers and frames, indicative of localised overpressure, was evident on the skin panels attached to the larger segments of lower fuselage wreckage aft of the blast area. In addition, the mode of failure of the butt joint at station 520 suggested that there had been a rapid overpressure load in this area, causing the fastener heads to 'pop' in the region of stringers 13L to 16L, rather than producing shear in the fasteners. Further evidence of localised overpressure damage remote from the source of the explosion was found during the full three-dimensional reconstruction, detailed later in paragraph 1.12.3.2.

An attempt was made to analyse the fractures, to determine the direction and sequence of failure as the fractures propagated away from the region of the explosion. It was found that the directions of most of the fractures close to the explosion could be determined from an analysis of the fracture surfaces and other features, such as rivet and rivet hole distortions. However, it was apparent that beyond the boundary of the petalled region, the disintegration process had involved multiple fractures taking place simultaneously - extremely complex parallel processes which made the sequencing of events not amenable to conventional analysis.

1.12.2.2 Wing structure and adjacent fuselage area

On completion of the initial layout at Longtown it became evident that, in the area from station 1000 to approximately station 1240 the only identifiable fuselage structure consisted of elements of fuselage skin, stringers and frames from above the cabin window belts. The wreckage from in and around the crater was therefore sifted to establish more accurately what sections of the aircraft had produced the crater. All of the material was highly fragmented, but it was confirmed that the material comprised mostly wing structure, with a few fragments of fuselage sidewall and passenger seats. The badly burnt state of these fragments made it clear that they were recovered from the area of the main impact crater, the only scene of significant ground fire. Amongst these items a number of cabin window forgings were recovered with sections of thick horizontal panelling attached having a length equivalent to the normal window spacing/frame pitch. This arrangement, with skins of this thickness, is unique to the area from station 1100 to 1260. It is therefore reasonable to assume that these fragments formed parts of the missing cabin sides from station 1000 to station 1260, which must have remained attached to the wing centre section at the time of its impact. Because of the high degree of fragmentation and the relative insignificance of the wing in terms of the overall explosive damage pattern, a reconstruction of the wing material was not undertaken. The sections of the aircraft which went into the crater are colour coded grey in Appendix B, Figures B-5 to B-8.

1.12.2.3 Fin and aft section of fuselage

Examination of the structure of the fin revealed evidence of in-flight damage to the leading edge caused by the impact of structure or cabin contents. This damage was not severe or extensive and the general break-up of the fin did not suggest either a single readily defined loading direction, or break-up due to the effects of leading edge impact. A few items of fin debris were found between the northern and southern trails.

A number of sections of fuselage frame found in the northern trail exhibited evidence of plastic deformation of skin attachment cleats and tensile overload failure of the attachment rivets. This damage was consistent with that which would occur if the skin had been locally subjected to a high loading in a direction normal to its plane. Although this was suggestive of an internal overpressure condition, the rear fuselage revealed no other evidence to support this possibility. Examination of areas of the forward fuselage known to have been subjected to high blast overpressures revealed no comparable evidence of plastic deformation in the skin attachment cleats or rivets, most skin attachment failures appearing to have been rapid.

Calculations made on the effects of internal pressure generated by an open ended fuselage descending at the highest speed likely to have been experienced revealed that this could not generate an internal pressure approaching that necessary to cause failure in an intact cabin structure.

1.12.2.4 Baggage containers

During the wreckage recovery operation it became apparent that some items, identified as parts of baggage containers, exhibited damage consistent with being close to a detonating high explosive. It was therefore decided to segregate identifiable container parts and reconstruct any that showed evidence of explosive damage. It was evident, from the main wreckage layout, that the explosion had occurred in the forward cargo hold and, although all baggage container wreckage was examined, only items from this area which showed the relevant characteristics were considered for the reconstruction. Discrimination between forward and rear cargo hold containers was relatively straightforward as the rear cargo hold wreckage was almost entirely confined to Lockerbie, whilst that from the forward hold was scattered along the southern wreckage trail.

All immediately identifiable parts of the forward cargo containers were segregated into areas designated by their serial numbers and items not identified at that stage were collected into piles of similar parts for later assessment. As a result of this, two adjacent containers, one of metal construction the other fibreglass, were identified as exhibiting damage likely to have been caused by the explosion. Those parts which could be positively identified as being from these two containers were assembled onto one of three simple wooden frameworks, one each for the floor and superstructure of the metal container and one for the superstructure of the fibreglass container. From this it was positively determined that the explosion had occurred within the metal container (serial number AVE 4041 PA), the direct effects of this being evident also on the forward face of the adjacent fibreglass container (serial number AVN 7511 PA) and on the local airframe on the left side of the aircraft in the region of station 700. It was therefore confirmed that this metal container had been loaded in position 14L in agreement with the aircraft loading records. While this work was in progress a buckled section of the metal container skin was found by an AAIB Inspector to contain, trapped within its folds, an item which was subsequently identified by forensic scientists at the Royal Armaments Research and Development Establishment (RARDE) as belonging to a specific type of radio-cassette player and that this had been fitted with an improvised explosive device (IED).

The reconstruction of these containers and their relationship to the aircraft structure is described in detail in Appendix F. Examination of all other components of the remaining containers revealed only damage consistent with ejection into the high speed slipstream and/or ground impact, and that only one device had detonated within the containers on board the aircraft.

1.12.3 Fuselage three-dimensional reconstruction

1.12.3.1 The reconstruction

The two-dimensional reconstruction successfully established that there had been an explosion in the forward hold; its location was established and the general damage characteristics in the vicinity of the explosion were determined. However, the mechanisms by which the failure process developed from local damage in the immediate vicinity of the explosion to the complete structural break-up and separation of the whole forward section of the fuselage, could not be adequately investigated without recourse to a more elaborate reconstruction.

To facilitate this additional work, wreckage forming a 65 foot section of the fuselage (approximately 30 feet each side of the explosion) was transported to AAIB Farnborough, where it was attached to a specially designed framework to form a fully three-dimensional reconstruction [Appendix B, Figures B-16 and B-17] of the complete fuselage between stations 360 & 1000 (from the separated nose section back to the wing cut out). The support framework was designed to provide full and free access to all parts of the structure, both internally and externally. Because of height constraints, the reconstruction was carried out in two parts, with the structure divided along a horizontal line at approximately the upper cabin floor level. The previously reconstructed containers were also transported to AAIB Farnborough to allow correlation of evidence with, and partial incorporation into, the fuselage reconstruction.

Structure and skin panels were attached to the supporting framework by their last point of attachment, to provide a better appreciation of the modes and direction of curling, distortion, and ultimate separation. Thus, the panels of skin which had petalled back from the shatter zone were attached at their outer edges, so as to identify the bending modes of the panels, the extent of the petalled region, and also the size of the resulting aperture in the hull. In areas more remote from the explosion, the fracture and tear directions were used together with distortion and curling directions to determine the mode of separation, and thus the most appropriate point of attachment to the reconstruction. Cabin floor beam segments were supported on a steel mesh grid and a plot of the beam fractures is shown at Appendix B, Figure B-18.

The cargo container base elements were separated from the rest of the container reconstruction and transferred to the main wreckage reconstruction, where the re-assembled container base was positioned precisely onto the cargo deck. To assist in the correlation of the initial shatter zone and petalled-out regions with the position of the explosive device, the boundaries of the skin panel fractures were marked on a transparent plastic panel which was then attached to the reconstruction to provide a transparent pseudo-skin showing the positions of the skin tear lines. This provided a clear visual indication of the relationship between the skin panel fractures and the explosive damage to the container base, thus providing a more accurate indication of the location of the explosive device.

1.12.3.2 Summary of explosive features evident

The three-dimensional reconstruction provided additional information about the region of tearing and petalling around the shatter zone. It also identified a number of other regions of structural damage, remote from the explosion, which were clearly associated with severe and rapidly applied pressure loads acting normal to the skin's internal surface. These were sufficiently sharp-edged to pre-empt the resolution of pressure induced loads into membrane tension stresses in the skin: instead, the effect was as though these areas of skin had been struck a severe 'pressure blow' from within the hull.

The two types of damage, i.e. the direct blast/tearing/petalling damage and the quite separate areas of 'pressure blow' damage at remote sites were evidently caused by separate mechanisms, though it was equally clear that each was caused by explosive processes, rather than more general disintegration.

The region of petalling was bounded (approximately) by frames 680 and 740, and extended from just below the window belt down nearly to the keel of the aircraft [Appendix B, Figure B-19, region A]. The resulting aperture measured approximately 17 feet by 5 feet. Three major fractures had propagated beyond the boundary of the petalled zone, clearly driven by a combination of hull pressurisation loading and the relatively long term (secondary) pressure pulse from the explosion. These fractures ran as follows:

(i) rearwards and downward in a stepped fashion, joining the stringer 38L lap joint at around station 840, running aft along stringer 38L to around

station 920, then stepping down to stringer 39L and running aft to terminate at the wing box cut-out [Appendix B, Figure B-19, fracture 1].
(ii) downwards and forward to join the stringer 44L lap joint, then running forward along stringer 44L as far as station 480 [Appendix B, Figure B-19, fracture 2].
(iii) downwards and rearward, joining the butt line at station 740 to run under the fuselage and up the right side to a position approximately 18 inches above the cabin floor level [Appendix B, Figures B-19 and B-20, fracture 3].

The propagation of tears upwards from the shatter zone appeared to have taken the form of a series of parallel fractures running upwards together before turning towards each other and closing, forming large flaps of skin which appear to have separated relatively cleanly.

Regions of skin separation remote from the site of the explosion were evident in a number of areas. These principally were:

(i) A large section of upper fuselage skin extending from station 500 back to station 760, and from around stringers 15/19L up as far as stringer 5L [Appendix B, Figures B-19 and B-20, region B], and probably extending further up over the crown. This panel had separated initially at its lower forward edge as a result of a pressure blow type of impulse loading, which had popped the heads from the rivets at the butt joint on frame 500 and lifted the skin flap out into the airflow. The remainder of the panel had then torn away rearwards in the airflow.
A region of 'quilting' or 'pillowing', i.e. spherical bulging of skin panels between frames and stringers, was evident on these panels in the region between station 560 and 680, just below the level of the upper deck floor, indicative of high internal pressurisation loading [Appendix B, Figure B-19, region C].
(ii) A smaller section of skin between stations 500 and 580, bounded by stringers 27L and 34L [Appendix B, Figure B-19, region D], had also been 'blown' outwards at its forward edge and torn off the structure rearwards. A characteristic curling of the panel was evident, consistent with rapid, energetic separation from the structure.
(iii) A section of thick belly skin extending from station 560, stringers 40R to 44R, and tapering back to a point at stringer 45R/station720 [Appendix B, Figure B-19 and B-20, region E], had separated from the structure as a result of a very heavy 'pressure blow' load at its forward end which had popped the heads off a large number of substantial skin fasteners. The panel had then torn away rearwards from the structure, curling up tightly onto itself as it did so -

indicating that considerable excess energy was involved in the separation process (over and above that needed simply to separate the skin material from its supporting structure).
(iv) A panel of skin on the right side of the aircraft, roughly opposite the explosion, had been torn off the frames, beginning at the top edge of the panel situated just below the window belt and tearing downwards towards the belly [Appendix B, Figure B-20, region F]. This panel was curled downwards in a manner which suggested significant excess energy.

Appendix B, Figure B-21 shows a plot of the fractures noted in the fuselage skins between stations 360 and 1000.

The cabin floor structure was badly disrupted, particularly in the general area above the explosion, where the floor beams had suffered localised upward loading sufficient to fracture them, and the floor panels were missing. Elsewhere, floor beam damage was mainly limited to fractures at the outer ends of the beams and at the centreline, leaving sections of separated floor structure comprising a number of half beams joined together by the Nomex honeycomb floor panels.

1.12.3.3 General damage features not directly associated with explosive forces.

A number of features appeared to be a part of the general structural break-up which followed on from the explosive damage, rather than being a part of the explosive damage process itself. This general break-up was complex and, to a certain extent, random. However, analysis of the fractures, surface scores, paint smears and other features enabled a number of discreet elements of the break-up process to be identified. These elements are summarised below.

(i) Buckling of the window belts on both sides of the aircraft was evident between stations 660 and 800. That on the left side appeared to be the result of in-plane bending in a nose up sense, followed by fracture. The belt on the right side had a large radius curve suggesting lateral deflection of the fuselage possibly accompanied by some longitudinal compression. This terminated in a peeling failure of the riveted joint at station 800.
(ii) On the left side three fractures, apparently resulting from in-plane bending/buckling distortion, had traversed the window belt [Appendix B, Figure B-21, detail G]. Of these, the forward two had broken through the window apertures and the aft fracture had exploited a rivet line at the region of reinforcement just forward of the L2 door aperture. On the right side, the window belt had peeled rearwards, after buckling had occurred, separating

from the rest of the fuselage, following rivet failure, at the forward edge of the R2 door aperture.
(iii) All crown skins forward of frame 840 were badly distorted and a number of pieces were missing. It was clearly evident that the skin sections from this region had struck the empennage and/or other structure following separation.
(iv) The fuselage left side lower lobe from station 740 back to the wing box cut-out, and from the window level down to the cargo deck floor (the fracture line along stringer 38L), had peeled outwards, upwards and rearwards - separating from the rest of the fuselage at the window belt. The whole of this separated section had then continued to slide upwards and rearwards, over the fuselage, before being carried back in the slipstream and colliding with the outer leading edge of the right horizontal stabiliser, completely disrupting the outer half. A fragment of horizontal stabiliser spar cap was found embedded in the fuselage structure adjacent to the two vent valves, just below, and forward of, the L2 door [Appendix B, Figure B-22].
(v)   A large, clear, imprint of semi-eliptical form was apparent on the lower right side at station 360 which had evidently been caused by the separating forward fuselage section striking the No 3 engine as it swung rearwards and to the right (confirmed by No 3 engine fan cowl damage).

1.12.3.4 Tailplane three-dimensional reconstruction

The tailplane structural design took the form of a forward and an aft torque box. The forward box was constructed from light gauge aluminium alloy sheet skins, supported by closely pitched, light gauge nose ribs but without lateral stringers. The aft torque box incorporated heavy gauge skin/stringer panels with more widely spaced ribs. The front spar web was of light gauge material. Leading edge impacts inflicted by debris would therefore have had the capacity to reduce the tailplane's structural integrity by passing through the light gauge skins and spar web into the interior of the aft torque box, damaging the shear connection between top and bottom skins in the process and thereby both removing the bending strength of the box and opening up the weakened structure to the direct effects of the airflow.

Examination of the rebuilt tailplane structure at AAIB Farnborough left little doubt that it had been destroyed by debris striking its leading edges. In addition, the presence on the skins of smear marks indicated that some unidentified soft debris had contacted those surfaces whilst moving with both longitudinal and lateral velocity components relative to the aircraft.

The reconstructed left tailplane [Appendix B, Figure B-23] showed evidence that disruption of the inboard leading edge, followed respectively by the forward torque box, front spar web and main torque box, occurred as a result of frontal impact by the base of a baggage container. Further outboard, a compact object appeared to have struck the underside of the leading edge and penetrated to the aft torque box. In both cases, the loss of the shear web of the front spar appeared to have permitted local bending failure of the remaining main torque box structure in a tip downwards sense, consistent with the normal load direction. For both events to have occurred it would be reasonable to assume that the outboard damage preceded that occurring inboard.

The right tailplane exhibited massive leading edge impact damage on the outboard portion which also appeared to have progressed to disruption of the aft torsion box. A fragment of right tailplane spar cap was found embedded in the fuselage structure adjacent to the two vent valves, just below, and forward of, the L2 door and it is clear that this area of forward left fuselage had travelled over the top of the aircraft and contributed to the destruction of the outboard right tailplane.

1.12.4 Examination of engines

All four engines had struck the ground in Lockerbie with considerable velocity and therefore sustained major damage, in particular to most of the fan blades. The No 3 engine had fallen 1,100 metres north of the other three engines, striking the ground on its rear face, penetrating a road surface and coming to rest without any further change of orientation i.e. with the front face remaining uppermost. The intake area contained a number of loose items originating from within the cabin or baggage hold. It was not possible initially to determine whether any of the general damage to any of the engine fans or the ingestion noted in No 3 engine intake occurred whilst the relevant engines were delivering power or at a later stage.

Numbers 1, 2 and 3 engines were taken to British Airways Engine Overhaul Limited for detailed examination under AAIB supervision in conjunction with a specialist from the Pratt and Whitney Engine Company. During this examination the following points were noted:

(i) No 2 engine (situated closest to the site of the explosion) had evidence of blade "shingling" in the area of the shrouds consistent with the results of major airflow disturbance whilst delivering power. (This effect is produced when random bending and torsional deflection occurs, permitting the mid-span shrouds to disengage and repeatedly strike the adjacent aerofoil surfaces of the blades). The interior of the air intake contained paint smears and other evidence suggesting the passage of items of debris. One such item of significance was a clear indentation produced by a length of cable of diameter and strand size similar to that typically attached to the closure curtains on the baggage containers.

(ii) No 3 engine, identified on site as containing ingested debris from within the aircraft, nonetheless had no evidence of the type of shingling seen on the blades of No 2 engine. Such evidence is usually unmistakable and its absence is a clear indication that No 3 engine did not suffer a major intake airflow disturbance whilst delivering significant power. The intake structure was found to have been crushed longitudinally by an impact on the front face although, as stated earlier, it had struck the ground on its rear face whilst falling vertically.

(iii) All 3 engines had evidence of blade tip rubs on the fan cases having a combination of circumference and depth greater than hitherto seen on any investigation witnessed on Boeing 747 aircraft by the Pratt and Whitney specialists. Subsequent examination of No 4 engine confirmed that it had a similar deep, large circumference tip rub. These tip-rubs on the four engines were centred at slightly different clock positions around their respective fan cases.

The Pratt and Whitney specialists supplied information which was used to interpret the evidence found on the blades and fan cases including details of engine dynamic behaviour necessary to produce the tip rub evidence. This indicated that the depth and circumference of tip rubs noted would have required a marked nose down change of aircraft pitch attitude combined with a roll rate to the left.

Pratt and Whitney also advised that:

(i) Airflow disruption such as that presumed to have caused the shingling observed on No 2 engine fan blades was almost invariably the result of damage to the fan blade aerofoils, resulting from ingestion or blade failure.

(ii) Tip rubs of a depth and circumference noted on all four engines could be expected to reduce the fan rotational energy on each to a negligible value within approximately 5 seconds.

(iii) Airflow disruption sufficient to cause the extent of shingling noted on the fan blades of No 2 engine would also reduce the rotational fan energy to a negligible value within approximately 5 seconds.

1.13 Medical and pathological information

The results of the post mortem examination of the victims indicated that the majority had experienced severe multiple injuries at different stages, consistent with the in-flight disintegration of the aircraft and ground impact. There was no pathological indication of an in-flight fire and no evidence that any of the victims had been injured by shrapnel from the explosion. There was also no evidence which unequivocally indicated that passengers or cabin crew had been killed or injured by the effects of a blast. Although it is probable that those passengers seated in the immediate vicinity of the explosion would have suffered some injury as a result of blast, this would have been of a secondary or tertiary nature.

Of the casualties from the aircraft, the majority were found in areas which indicated that they had been thrown from the fuselage during the disintegration. Although the pattern of distribution of bodies on the ground was not clear cut there was some correlation with seat allocation which suggested that the forward part of the aircraft had broken away from the rear early in the disintegration process. The bodies of 10 passengers were not recovered and of these, 8 had been allocated seats in rows 23 to 28 positioned over the wing at the front of the economy section. The fragmented remains of 13 passengers who had been allocated seats around the eight missing persons were found in or near the crater formed by the wing. Whilst there is no unequivocal proof that the missing people suffered the same fate, it would seem from the pattern that the missing passengers remained attached to the wing structure until impact.

1.14 Fire

Of the several large pieces of aircraft wreckage which fell in the town of Lockerbie, one was seen to have the appearance of a ball of fire with a trail of flame. Its final path indicated that this was the No 3 engine, which embedded itself in a road in the north-east part of the town. A small post impact fire posed no hazard to adjacent property and was later extinguished with water from a hosereel. The three remaining engines landed in the Netherplace area of the town. One severed a water main and the other two, although initially on fire, were no risk to persons or property and the fires were soon extinguished.

A large, dark, delta shaped object was seen to fall at about the same time in the Sherwood area of the town. It was not on fire while in the air, however, a fireball several hundred feet across followed the impact. It was of relatively short duration and large amounts of debris were thrown into the air, the lighter particles being carried several miles downwind, while larger pieces of burning debris caused further fires, including a major one at the Townfoot Garage, up to 350 metres from the source. It was determined that the major part of both wings, which included the aircraft fuel tanks, had formed the crater. A gas main had also been ruptured during the impact.

At 19.04 hrs the Dumfries Fire Brigade Control received a call from a member of the public which indicated that there had been a "huge boiler explosion" at Westacres, Lockerbie, however, subsequent calls soon made it clear that it was an aircraft which had crashed. At 19.07 hrs the first appliances were mobile and at 1910 hrs one was in attendance in the Rosebank area. Multiple fires were identified and it soon became apparent that a major disaster had occurred in the town and the Fire Brigade Major Incident Plan was implemented. During the initial phase 15 pumping appliances from various brigades were deployed but this number was ultimately increased to 20.

At 22.09 hrs the Firemaster made an assessment of the situation. He reported that there was a series of fires over an area of the town centre extending 1† by € mile. The main concentration of the fire was in the southwest of the town around Sherwood Park and Sherwood Crescent. Appliances were in attendance at other fires in the town, particularly in Park Place and Rosebank Crescent. Water and electricity supplies were interrupted and water had to be brought into the town.

By 02.22 hrs on 22 December, all main seats of fire had been extinguished and the firemen were involved in turning over and damping down. At 04.42 hrs small fires were still occurring but had been confined to the Sherwood Crescent area.

1.15 Survival aspects

1.15.1 Survivability

The accident was not survivable.

1.15.2 Emergency services

A chronology of initial responses by the emergency services is listed below:-

Time Event
19.03 hrs Radio message from Police patrol in Lockerbie to Dumfries and Galloway Constabulary reporting an aircraft crash at Lockerbie.
19.04 hrs Emergency call to Dumfries and Galloway Fire Brigade.
19.37 hrs First ambulances leave for Dumfries and Galloway Royal Infirmary with injured town residents. (2- serious; 3- minor)
19.40 hrs Sherwood Park and Sherwood Crescent residents evacuated to Lockerbie Town Hall.
20.25 hrs Nose section of N739PA discovered at Tundergarth (approximately 4 km east of Lockerbie).

During the next few days a major emergency operation was mounted using the guidelines of the Dumfries and Galloway Regional Peacetime Emergency Plan. The Dumfries and Galloway Constabulary was reinforced by contingents from Strathclyde and Lothian & Borders Constabularies. Resources from HM Forces were made available and this support was subsequently authorised by the Ministry of Defence as Military Aid to the Civil Power. It included the provision of military personnel and a number of helicopters used mainly in the search for and recovery of aircraft wreckage. It was apparent at an early stage that there were no survivors from the aircraft and the search and recovery of bodies was mainly a Police task with military assistance.

Many other agencies were involved in the provision of welfare and support services for the residents of Lockerbie, relatives of the aircraft's occupants and personnel involved in the emergency operation.

1.16 Tests and research

An explosive detonation within a fuselage, in reasonably close proximity to the skin, will produce a high intensity spherically propagating shock wave which will expand outwards from the centre of detonation. On reaching the inner surface of the fuselage skin, energy will partially be absorbed in shattering, deforming and accelerating the skin and stringer material in its path. Much of the remaining energy will be transmitted, as a shock wave, through the skin and into the atmosphere but a significant amount of energy will be returned as a reflected shock wave, which will travel back into the fuselage interior where it will interact with the incident shock to produce Mach stem shocks - re-combination shock waves which can have pressures and velocities of propagation greater than the incident shock.

The Mach stem phenomenon is significant because it gives rise (for relatively small charge sizes) to a geometric limitation on the area of skin material which the incident shock wave can shatter, irrespective of charge size, thus providing a means of calculating the standoff distance of the explosive charge from the fuselage skin. Calculations suggest that a charge standoff distance of aproximately 25 inches would result in a shattered region approximately 18 to 20 inches in diameter, comparable to the size of the shattered region evident in the wreckage. This aspect is covered in greater detail in [Appendix G].

1.17 Additional information

1.17.1 Recorded radar information

Recorded radar information on the aircraft was available from 4 radar sites. Initial analysis consisted of viewing the recorded information as it was shown to the controller on the radar screen from which it was clear that the flight had progressed in a normal manner until secondary surveillance radar (SSR) was lost.

The detailed analysis of the radar information concentrated on the break-up of the aircraft. The Royal Signals and Radar Establishment (RSRE) corrected the radar returns for fixed errors and converted the SSR returns to latitude and longitude so that an accurate time and position for the aircraft could be determined. The last secondary return from the aircraft was recorded at 19.02:46.9 hrs, identifying N739PA at Flight Level 310, and at the next radar return there is no SSR data, only 4 primary returns. It was concluded that the aircraft was, by this time, no longer a single return and, considering the approximately 1 nautical mile spread of returns across track, that items had been ejected at high speed probably to both right and left of the aircraft.

Each rotation of the radar head thereafter showed the number of returns increasing, with those first identified across track having slowed down very quickly and followed a track along the prevailing wind line. The radar evidence then indicated that a further break-up of the aircraft had occurred and formed a parallel wreckage trail to the north of the first. From the absence of any returns travelling along track it was concluded that the main wreckage was travelling almost vertically downwards for much of the time.

A detailed analysis of the recorded radar information, together with the radar, ATC and seismic recordings is contained in Appendix C.

1.17.2 Seismic data

The British Geological Survey has a number of seismic monitoring stations in Southern Scotland. Stations close to Lockerbie recorded a seismic event measuring 1.6 on the Richter scale and, with appropriate corrections for the times of the waves to reach the sensors, it was established that this occurred at 19.03:36.5 hrs ±1 second. A further check was made by triangulation techniques from the information recorded by the various sensors.

An analysis of the seismic recording, together with the radar, ATC and radar information is contained in Appendix C.

1.17.3 Trajectory analysis

A detailed trajectory analysis was carried out by Cranfield Institute of Technology in an effort to provide a sequence for the aircraft disintegration. This analysis comprised several separate processes, including individual trajectory calculations for a limited number of key items of wreckage and mathematical modelling of trajectory paths adopted by a series of hypothetical items of wreckage encompassing the drag/weight spectrum of the actual wreckage.

The work carried out at Cranfield enabled the reasons for the two separate trails to be established. The narrow northern trail was shown to be created by debris released from the aircraft in a vertical dive between 19,000 and 9,000 feet overhead Lockerbie. The southern trail, longer and straight for most of its length, appeared to have been created by wreckage released during the initial disintegration at altitude whilst the aircraft was in level flight. Those items falling closest to Lockerbie would have been those with higher density which would travel a significant distance along track before losing all along-track velocity, whilst only drifting a small distance downwind, owing to the high speed of their descent. The most westerly items thus showed the greatest such effect. The southern trail therefore had curved boundaries at its western end with the curvature becoming progressively less to the east until the wreckage essentially fell in a straight band. Thus wreckage in the southern trail positioned well to the east could be assumed to have retained negligible velocity along aircraft track after separation and the along-track distribution could be used to establish an approximate sequence of initial disintegration.

The analysis calculated impact speeds of 120 kts for the nose section weighing approximately 17,500 lb and 260 kts for the engines and pylons which each weighed about 13,500 lb. Based on the best available data at the time, the analysis showed that the wing (approximately 100,000 lb of structure containing an estimated 200,000 lb of fuel) could have impacted at a speed, in theory, as high as 650 kts if it had 'flown' in a streamlined attitude such that the drag coefficient was minimal. However, because small variations of wing incidence (and various amounts of attached fuselage) could have resulted in significant increases in drag coefficient, the analysis also recognized that the final impact speed of the wing could have been lower.

1.17.4 Space debris re-entry

Four items of space debris were known to have re-entered the Earth's atmosphere on 21 December 1988. Three of these items were fragments of debris which would not have survived re-entry, although their burn up in the upper atmosphere might have been visible from the Earth's surface. The fourth item landed in the USSR at 09.50 hrs UTC.

2 ANALYSIS

2.1 Introduction

The airport security and criminal aspects of the destruction of Boeing 747 registration N739PA near Lockerbie on 21 December 1988 are the subjects of a separate investigation and are not covered in this report. This analysis discusses the technical aspects of the disintegration of the aircraft and considers possible ways of mitigating the effects of an explosion in the future.

2.2 Explosive destruction of the aircraft

The geographical position of the final secondary return at 19.02:46.9 hrs was calculated by RSRE to be OS Grid Reference 15257772, annotated Point A in Appendix B, Figure B-4, with an accuracy considered to be better than ±300 metres This return was received 3.1±1 seconds before the loud sound was recorded on the CVR at 19.02:50 hrs. By projecting from this position along the track of 321¡(Grid) for 3.1±1 seconds at the groundspeed of 434 kts, the position of the aircraft was calculated to be OS Grid Reference 14827826, annotated Point B in Appendix B, Figure B-4, within an accuracy of ±525 metres. Based on the evidence of recorded data only, Point B therefore represents the geographical position of the aircraft at the moment the loud sound was recorded on the CVR.

The datum line, discussed at paragraph 1.12.1.6, was derived from a detailed analysis of the distribution of specific items of wreckage, including those exhibiting positive evidence of a detonating high performance plastic explosive. The scatter of these items about the datum line may have been due partly to velocities imparted by the force of the detonating explosive and partly by the difficulty experienced in pinpointing the location of the wreckage accurately in relatively featureless terrain and poor visibility. However, the random nature of the scatter created by these two effects would have tended to counteract one another, and a major error in any one of the eleven grid references would have had little overall effect on the whole line. There is, therefore, good reason to have confidence in the validity of the datum line.

The items used to define the datum line, included those exhibiting positive evidence of a detonating high performance plastic explosive, would have been the first pieces to have been released from the aircraft. The datum line was projected westwards until it intersected the known radar track of the aircraft in order to derive the position of the aircraft along track at which the explosive items were released and therefore the position at which the IED had detonated. This position was OS grid reference 146786 and is annotated Point C in Appendix B, Figure B-4. Point C was well within the circle of accuracy (±525 metres) of the position at which the loud noise was heard on the CVR (Point B). There can, therefore, be no doubt that the loud noise on the CVR was directly associated with the detonation of the IED and that this explosion initiated the disintegration process and directly caused the loss of the aircraft.

2.3 Flight recorders

2.3.1 Digital flight data recordings

A working group of the European Organisation for Civil Aviation Electronics (EUROCAE) was, during the period of the investigation, formulating new standards (Minimum Operational Performance Requirement for Flight Data Recorder Systems, Ref:- ED55) for future generation flight recorders which would have permitted delays between parameter input and recording (buffering) of up to € second. These standards are intended to form the basis of new CAA specifications for flight recorders and may be adopted worldwide.

The analysis of the recording from the DFDR fitted to N739PA, which is detailed in Appendix C, showed that the recorded data simply stopped. Following careful examination and correlation of the various sources of recorded information, it was concluded that this occurred because the electrical power supply to the recorder had been interrupted at 19.02:50 hrs ±1 second. Only 17 bits of data were not recoverable (less that 23 milliseconds) and it was not possible to establish with any certainty if this data was from the accident flight or was old data from a previous recording.

The analysis of the final data recorded on the DFDR was possible because the system did not buffer the incoming data. Some existing recorders use a process whereby data is stored temporarily in a memory device (buffer) before recording. The data within this buffer is lost when power is removed from the recorder and in currently designed recorders this may mean that up to 1.2 seconds of final data contained within the buffer is lost. Due to the necessary processing of the signals prior to input to the recorder, additional delays of up to 300 milliseconds may be introduced. If the accident had occurred when the aircraft was over the sea, it is very probable that the relatively few small items of structure, luggage and clothing showing positive evidence of the detonation of an explosive device would not have been recovered. However, as flight recorders are fitted with underwater location beacons, there is a high probability that they would have been located and recovered. In such an event the final milliseconds of data contained on the DFDR could be vital to the successful determination of the cause of an accident whether due to an explosive device or other catastrophic failure. Whilst it may not be possible to reduce some of the delays external to the recorder, it is possible to reduce any data loss due to buffering of data within the data acquisition unit.

It is, therefore, recommended that manufacturers of existing recorders which use buffering techniques give consideration to making the buffers non-volatile, and hence recoverable after power loss. Although the recommendation on this aspect, made to the EUROCAE working group during the investigation, was incorporated into ED55, it is also recommended that Airworthiness Authorities re-consider the concept of allowing buffered data to be stored in a volatile memory.

CLICK HERE TO RETURN TO INDEX

2.3.2 Cockpit voice recorders

The analysis of the cockpit voice recording, which is detailed in Appendix C, concluded that there were valid signals available to the CVR when it stopped at 19.02:50 hrs ±1 second because the power supply to the recorder was interrupted. It is not clear if the sound at the end of the recording is the result of the explosion or is from the break-up of the aircraft structure. The short period between the beginning of the event and the loss of electrical power suggests that the latter is more likely to be the case. In order to respond to events that result in the almost immediate loss of the aircraft's electrical power supply it was therefore recommended during the investigation that the regulatory authorities consider requiring CVR systems to contain a short duration (i.e. no greater than 1 minute) back-up power supply.

2.3.3 Detection of explosive occurrences

In the aftermath of the Air India Boeing 747 accident (AI 182) in the North Atlantic on 23 June 1985, RARDE were asked informally by AAIB to examine means of differentiating, by recording violent cabin pressure pulses, between the detonation of an explosive device within the cabin (positive pulse) and a catastrophic structural failure (negative pulse). Following the Lockerbie disaster it was considered that this work should be raised to a formal research project. Therefore, in February 1989, it was recommended that the Department of Transport fund a study to devise methods of recording violent positive and negative pressure pulses, preferably utilising the aircraft's flight recorder systems. This recommendation was accepted.

Preliminary results from the trials indicate that, if a suitable sensor can be developed, its output will need to be recorded in real time and therefore it may require wiring to the CVR installation. This will further strengthen the requirement for battery back up of the CVR electrical power supply.

2.4 IED position within the aircraft

From the detailed examination of the reconstructed luggage containers, discussed at paragraph 1.12.2.4 and in Appendix F, it was evident that the IED had been located within a metal container (serial number AVE 4041 PA), near its aft outboard quarter as shown in Appendix F, Figure F-13. It was also clear that the container was loaded in position 14L of the forward hold which placed the explosive charge approximately 25 inches inboard from the fuselage skin at frame 700. There was no evidence to indicate that there was more than one explosive charge.

2.5 Engine evidence

To produce the fan blade tip rub damage noted on all engines by means of airflow inclined to the axes of the nacelles would have required a marked nose down change of aircraft pitch attitude combined with a roll rate to the left while all of the engines were attached to the wing.

The shingling damage noted on the fan blades of No 2 engine can only be attributed to airflow disturbance caused by ingestion related fan blade damage occurring when substantial power was being delivered. This is readily explained by the fact that No 2 engine intake is positioned some 27 feet aft and 30 feet outboard of the site of the explosion and that the interior of the intake exhibited a number of prominent paint smears and general foreign object damage. This damage included evidence of a strike by a cable similar to that forming part of the closure curtain of a typical baggage container. It is inconceivable that an independent blade failure could have occurred in the short time frame of this event. By similar reasoning, the absence of such shingling damage on blades of No 3 engine was a reliable indication that it suffered no ingestion until well into the accident sequence.

The combination of the position of the explosive device and the forward speed of the aircraft was such that significant sized debris resulting from the explosion would have been available to be ingested by No 2 engine within milliseconds of the explosion. In view of the fact that the tip rub damage observed on the fan case of No 2 engine is of similar magnitude to that observed on the other three engines it is reasonable to deduce that a manoeuvre of the aircraft occurred before most of the energy of the No 2 engine fan was lost due to the effect of ingestion (seen only in this engine). Since this shingling effect could only readily be produced as a by-product of ingestion whilst delivering considerable power, it is reasonable to assume that this was also occurring before loss of major fan energy due to tip rubbing took place. Hence both phenomena must have been occurring simultaneously, or nearly so, to produce the effects observed and must have occupied a time frame of substantially less than 5 seconds. The onset of this time period would have been the time at which debris from the explosion first inflicted damage to fan blades in No 3 engine and, since the fan is only approximately 40 feet from the location of the explosive device, this would have been an insignificant time interval after the explosion.

It was therefore concluded from this evidence that the wing with all of the engines attached had achieved a marked nose down and left roll attitude change well within 5 seconds of the explosion.

2.6 Detachment of forward fuselage

Examination of the three major structural elements either side of the region of station 800 on the right side of the fuselage makes it clear that to produce the curvature of the window belt and peeling of the riveted joint at the R2 door aperture requires the door pillar to be securely in position and able to react longitudinal and lateral loads. This in turn requires the large section of fuselage on the right side between stations 760 and 1000 (incorporating the right half of the floor) to be in position in order to locate the lower end of the door pillar. Thus both these sections must have been in position until the section from station 560 to 800 (right side) had completed its deflection to the right and peeled from the door pillar. Separation of the forward fuselage must thus have been complete by the time all three items mentioned above had fallen free.

CLICK HERE TO RETURN TO INDEX

2.7 Speed of initial disintegration

The distribution of wreckage in the bands between the datum line and the 250, 300, 600 and 900 metre lines was examined in detail. The positions of these items of structure on the aircraft are shown in Appendix B, Figures B-10 to B-13. It should be noted that the position on the ground of these items, although separated by small distances when measured in a direction along aircraft track, were distributed over large distances when measured along the wreckage trail. All were recovered from positions far enough to the east to be in that part of the southern trail which was sufficiently close, theoretically, to a straight line for any curvature effect to be neglected.

The wreckage found in each of the bands enabled an approximate sequence of break-up to be established. It was clear that as the distance travelled from the datum line increased, items of wreckage further from the station of the IED were encountered. The items shown on the diagram as falling on the 250 metre band also include those fragments of lower forward fuselage skin having evidence of explosive damage and presumed to have separated as a direct result of the blast. However, a few portions of the upper forward fuselage were also found within the 250 metre band, suggesting that these items had also separated as a result of the blast.

By the time the 300 metre line was reached much of the structure from the right side in the region of the explosive device had been shed. This included the area of window belt, referred to in paragraph 2.6 above, which gave clear indications that the forward structure had detached to the right and finally peeled away at station 800. It also included the areas of adjacent structure immediately to the rear of station 800 about which the forward structure would have had to pivot. By the time the 600 metre line was reached, there was clearly insufficient structure left to connect the forward fuselage with the remainder of the aircraft. Wreckage between the 600 and 900 metre lines consisted of structure still further from the site of the IED.

There is evidence that a manoeuvre occurred at the time of the explosion which would have produced a significant change of the aircraft's flight path, however, it is considered that the change in the horizontal velocity component in the first few seconds would not have been great. The original groundspeed of the aircraft was therefore used in conjunction with the distribution of wreckage in the successive bands to establish an approximate time sequence of break-up of the forward fuselage. Assuming the original ground speed of 434 Kts, the elapsed flight times from the datum to each of the parellel lines were calculated to be:

Distance (metres)	250	300	600	900
Time (seconds)	1.1	1.3	2.7	4.0

Thus, there is little doubt that separation of the forward fuselage was complete within 2 to 3 seconds of the explosion.

The separate assessment of the known grid references of tailplane and elevator wreckage in the southern trail revealed that those items were evenly distributed about the 600 metre line and therefore that most of the tailplane damage occurred after separation of the forward fuselage was complete.

2.8 The manoeuvre following the explosion

The engine evidence, timing and mode of disintegration of the fuselage and tailplane suggests that the latter did not sustain significant damage until the forward fuselage disintegration was well advanced and the pitch/roll manoeuvre was also well under way.

Examination of the three dimensional reconstruction makes it clear that both main and upper deck floors were disrupted by the explosion. Since pitch control cables are routed through the upper deck floor beams and the roll control cables through the main deck beams, there is a strong possibility that movement of the beams under explosive forces would have applied inputs to the control cables, thus operating control surfaces in both axes.

2.9 Secondary disintegration

The distribution of fin debris between the trails suggests that disintegration of the fin began shortly before the vertical descent was established. No single mode of failure was identified and the debris which had struck the leading edge had not caused major disruption. The considerable fragmentation of the thick panels of the aft torque box was also very different from that noted on the corresponding structure of the tailplanes. It was therefore concluded that the mode of failure was probably flutter.

The finding, in the northern trail, of a slide raft wrapped around a flap track fairing suggests that at a later stage of the disintegration the rear of the aircraft must have experienced a large angle of sideslip. The loss of the fin would have made this possible and also subjected the structure to large side loads. It is possible that such side loading would have assisted the disintegration of the rear fuselage and also have caused bending failure of the pylon attachments of the remaining three engines.

2.10 Impact speed of components

The trajectory analysis carried out by Cranfield Institute of Technology calculated impact speeds of 120 kts for the nose section, and 260 kts for the engines and pylons. These values were considered to be reliable because the drag coefficients could be estimated with a reasonable degree of confidence. Based on the best available data at the time, the analysis also showed that the wing could have impacted at a speed, in theory, as high as 650 kts if it had flown in a streamlined attitude such that the drag coefficient was minimal. However, it was also recognized that relatively small changes in the angle of incidence of the wing would have produced a significant increase in drag with a consequent reduction in impact speed. Refinement of timing information and radar data subsequent to the Cranfield analysis has enabled a revised estimate to be made of the mean speed of the wing during the descent.

The engine evidence indicated that there had been a large nose down attitude change of the aircraft early in the event. The Cranfield analysis also showed that the rear fuselage had disintegrated while essentially in a vertical descent between 19,000 and 9,000 feet over Lockerbie. Assuming that, following the explosion, the wing followed a straight line descending flight profile from 31,000 feet to 19,000 feet directly overhead Lockerbie and then descended vertically until impact, the wing would have travelled the minimum distance practicable. The ground distance between the geographical position at which the disintegration started (Figure B-4, Point B) and the crater made by the wing impact was 2997 ±525 metres (9833 ±1722 feet). The time interval between the explosion and the wing impact was established in Appendix C as 46.5 ±2 seconds. Based on the above times and distances the mean linear speed achieved by the wing would have been about 440 kts.

The impact location of Nos 1, 2, and 4 engines closely grouped in Lockerbie was consistent with their nearly vertical fall from a point above the town. If they had separated at about 19,000 feet and the wing had then flown as much as one mile away from the overhead position before tracking back to impact, the total flight path length of the wing would not have required it to have achieved a mean linear speed in excess of 500 kts.

Any speculation that the flight path of the wing could have been longer would have required it to have undergone manoeuvres at high speed in order to arrive at the 19,000 feet point. The manoeuvres involved would almost certainly have resulted in failure of the primary wing structure which, from distribution of wing debris, clearly did not occur. Alternatively the wing could have travelled more than one mile from Lockerbie after reaching the 19,000 feet point, but this was considered unlikely. It is therefore concluded that the mean speed of the wing during the descent was in the region of 440 to 500 kts.

2.11 Sequence of disintegration

Analysis of wreckage in each of the bands, taken in conjunction with the engine evidence and the three-dimensional reconstruction, suggests the following sequence of disintegration:

(i) The initial explosion triggered a sequence of events which effectively destroyed the structural integrity of the forward fuselage. Little more then remained between stations 560 and 760 (approximately) than the window belts and the cabin sidewall structure immediately above and below the windows, although much of the cargo-hold floor structure appears to have remained briefly attached to the aircraft. [Appendix B, Figure B-24]
(ii) The main portion of the aircraft simultaneously entered a manoeuvre involving a marked nose down and left roll attitude change, probably as a result of inputs applied to the flying control cables by movement of structure.
(iii) Failure of the left window belt then occurred, probably in the region of station 710, as a result of torsional and bending loads on the fuselage imparted by the manoeuvre (i.e. the movement of the forward fuselage relative to the remainder of the aircraft was an initial twisting motion to the right, accompanied by a nose up pitching deflection).
(iv) The forward fuselage deflected to the right, pivoting about the starboard window belt, and then peeled away from the structure at station 800. During this process the lower nose section struck the No 3 engine intake causing the engine to detach from its pylon. This fuselage separation was apparently

complete within 3 seconds of the explosion.
(v) Structure and contents of the forward fuselage struck the tail surfaces contributing to the destruction of the outboard starboard tailplane and causing substantial damage to the port unit. This damage occurred approximately 600 metres track distance after the explosion and therefore appears to have happened after the fuselage separation was complete.
(vi) Fuselage structure continued to break away from the aircraft and the separated forward fuselage section as they descended.
(vii) The aircraft maintained a steepening descent path until it reached the vertical in the region of 19,000 feet approximately over the final impact point. Shortly before it did so the tail fin began to disintegrate.
(viii) The mode of failure of the fin is not clear, however, flutter of its structure is suspected.
(ix) Once established in the vertical dive, the fin torque box continued to disintegrate, possibly permitting the remainder of the aircraft to yaw sufficiently to cause side load separation of Nos 1, 2 and 4 engines, complete with their pylons.
(x) Break-up of the rear fuselage occurred during the vertical descent, possibly as a result of loads induced by the yaw, leaving a section of cabin floor and baggage hold from approximately stations 1241 to 1920, together with 3 landing gear units, to fall into housing at Rosebank Terrace.
(xi) The main wing structure struck the ground with a high yaw angle at Sherwood Crescent.

2.12 Explosive mechanisms and the structural disintegration

The fracture and damage pattern analysis was mainly of an interpretive nature involving interlocking pieces of subtle evidence such as paint smears, fracture and rivet failure characteristics, and other complex features. In the interests of brevity, this analysis will not discuss the detailed interpretation of individual fractures or damage features. Instead, the broader 'damage picture' which emerged from the detailed work will be discussed in the context of the explosive mechanisms which might have produced the damage, with a view to identifying those features of greatest significance.

It is important to keep in mind that whilst the processes involved are considered and discussed separately, the timescales associated with shock wave propagation and the high velocity gas flows are very short compared with the structural response timescales. Consequently, material which was shattered or broken by the explosive forces would have remained in place for a sufficiently long time that the structure can be considered to have been intact throughout much of the period that these explosive propagation phenomena were taking place.

2.12.1 Direct blast effect

2.12.1.1 Shock wave propagation

The direct effect of the explosive detonation within the container was to produce a high intensity spherically propagating shock wave which expanded from the centre of detonation close to the side of the container, shattering part of the side and base of the container as it passed through into the gap between the container and the fuselage skin. In breaking out of the container, some internal reflection and Mach stem interaction would have occurred, but this would have been limited by the absorptive effect of the baggage inboard, above, and forward of the charge. The force of the explosion breaking out of the container would therefore have been directed downwards and rearwards.

The heavy container base was distorted and torn downwards, causing buckling of the adjoining section of frame 700, and the container sides were blasted through and torn, particularly in the aft lower corner. Some of the material in the direct path of the explosive pressure front was reduced to shrapnel sized pieces which were rapidly accelerated outwards behind the primary shock front. Because of the overhang of the container's sloping side, fragments from both the device itself and the container wall impacted the projecting external flange of the container base edge member, producing micro cratering and sooting. Metallurgical examination of the internal surfaces of these craters identified areas of melting and other features which were consistent only with the impact of very high energy particles produced by an explosion at close quarters. Analysis of material on the crater surfaces confirmed the presence of several elements and compounds foreign to the composition of the edge member, including material consistent with the composition of the sheet aluminium forming the sloping face of the container.

On reaching the inner surface of the fuselage skin, the incident shock wave energy would partially have been absorbed in shattering, deforming and accelerating the skin and stringer material in its path. Much of its energy would have been transmitted, as a shock wave, through the skin and into the atmosphere [Appendix B, Figure B-25], but a significant amount of energy would have been returned as a reflected shock wave, back into the cavity between the container and the fuselage skin where Mach stem shock waves would have been formed. Evidence of rapid shattering was found in a region approximately bounded by frames 700 & 720 and stringers 38L & 40L, together with the lap joint at 39L.

The shattered fuselage skin would have taken a significant time to move, relative to the timescales associated with the primary shock wave propagation. Clear evidence of soot and small impact craters were apparent on the internal surfaces of all fragments of container and structure from the shatter zone, confirming that the this material had not had time to move before it was hit by the cloud of shrapnel, unburnt explosive residues and sooty combustion products generated at the seat of the explosion.

Following immediately behind the primary shock wave, a secondary high pressure wave - partly caused by reflections off the baggage behind the explosive material but mainly by the general pressure rise caused by the chemical conversion of solid explosive material to high temperature gas - emerged from the container. The effect of this second pressure front, which would have been more sustained and spread over a much larger area, was to cause the fuselage skin to stretch and blister outwards before bursting and petalling back in a star-burst pattern, with rapidly running tear fractures propagating away from a focus at the shatter zone. The release of stored energy as the skin ruptured, combined with the outflow of high pressure gas through the aperture, produced a characteristic curling of the skin 'petals' - even against the slipstream. For the most part, the skins which petalled back in this manner were torn from the frames and stringers, but the frames and stringers themselves were also fractured and became separated from the rest of the structure, producing a very large jagged hole some 5 feet longitudinally by 17 feet circumferentially (upwards to a region just below the window belt and downwards virtually to the centre line).

From this large jagged hole, three of the fractures continued to propagate away from the hole instead of terminating at the boundary. One fracture propagated longitudinally rearwards as far as the wing cut-out and another forwards to station 480, creating a continuous longitudinal fracture some 43 feet in length. A third fracture propagated circumferentially downwards along frame 740, under the belly, and up the right side of the fuselage almost as far as the window belt - a distance of approximately 23 feet.

These extended fractures all involved tearing or related failure modes, sometimes exploiting rivet lines and tearing from rivet hole to rivet hole, in other areas tearing along the full skin section adjacent to rivet lines, but separate from them. Although the fractures had, in part, followed lap joints, the actual failure modes indicated that the joints themselves were not inherently weak, either as design features or in respect of corrosion or the conditions of the joints on this particular aircraft.

Note: The cold bond process carried out at manufacture on the lap joints had areas of disbonding prior to the accident. This disbonding is a known feature of early Boeing 747 aircraft which, by itself, does not detract from the structural integrity of the hull. The cold bond adhesive was used to improve the distribution of shear load across the joint, thus reducing shear transfer via the fasteners and improving the resistance of the joint to fatigue damage; the fasteners were designed to carry the full static loading requirements of the joint without any contribution from the adhesive. Thus, the loss of the cold bond integrity would only have been significant if it had resulted in the growth of fatigue cracks, or corrosion induced weaknesses, which had then been exploited by the explosive forces. No evidence of fatigue cracking was found in the bonded joints. Inter-surface corrosion was present on most lap joints but only one very small region of corrosion had resulted in significant material thinning; this was remote from the critical region and had not played any part in the break-up.

The cracks propagating upwards as part of the petalling process did not extend beyond the window line. The wreckage evidence suggests that the vertical fractures merged, effectively closing off the fracture path to produce a relatively clean bounding edge to the upper section of the otherwise jagged hole produced by the petalling process. There are at least two probable reasons for this. Firstly the petalling fractures above the shattered zone did not diverge, as they had tended to do elsewhere. Instead, it appears that a large skin panel separated and peeled upwards very rapidly producing tears at each side which ran upwards following almost parallel paths. However, there are indications that by the time the fractures had run several feet, the velocity of fracture had slowed sufficiently to allow the free (forward) edge of the skin panel to overtake the fracture fronts, as it flexed upwards, and forcibly strike the fuselage skin above, producing clear witness marks on both items. Such a tearing process, in which an approximately rectangular flap of skin is pulled upwards away from the main skin panel, is likely to result in the fractures merging. Secondly, this merging tendency would have been reinforced in this particular instance by the stiff window belt ahead of the fractures, which would have tended to turn the fractures towards the horizontal.

It appears that the presence of this initial ('clean') hole, together with the stiff window belt above, encouraged other more slowly running tears to break into it, rather than propagating outwards away from the main hole.

2.12.1.2 Critical crack considerations

The three very large tears extending beyond the boundary of the petalled region resulted in a critical reduction of fuselage structural integrity.

Calculations were carried out at the Royal Aerospace Establishment to determine whether these fractures, growing outwards from the boundary of the petalled hole, could have occurred purely as a result of normal differential pressure loading of the fuselage, or whether explosive forces were required in addition to the pressurisation loads.

Preliminary calculations of critical crack dimensions for a fuselage skin punctured by a 20 by 20 inches jagged hole indicated that unstable crack growth would not have occurred unless the skin stress had been substantially greater than the stress level due to normal pressurisation loads alone. It was therefore clear that explosive overpressure must have produced the gross enlargement of the initially small shattered hole in the hull. Furthermore, it was apparent from the degree of curling and petalling of the skin panels within the star-burst region that this overpressure had been relatively long term, compared with the shock wave overpressure which had produced the shatter zone. A more refined analysis of critical crack growth parameters was therefore carried out in which it was assumed that the long term explosive overpressure was produced by the chemical conversion of solid explosive material into high temperature gas.

An outline of the fracture propagation analysis is given at Appendix D. This analysis, using theoretical fracture mechanics, showed that, after the incident shock wave had produced the shatter zone, significant explosive overpressure loads were needed to drive the star-burst fractures out to the boundary of the petalled skin zone. Thereafter, residual gas overpressure combined with fuselage pressurisation loads were sufficient to produce the two major longitudinal cracks and a single major circumferential crack, extending from the window belt down to beyond the keel centreline.

2.12.1.3 Damage to the cabin floor structure

The floor beams in the region immediately above the baggage container in which the explosive had detonated were extensively broken, displaying clear indications of overload failure due to buckling caused by localised upward loading of the floor structure.

No direct evidence of bruising was found on the top panel of the container. It therefore appears that the container did not itself impact the floor beams, but instead the floor immediately above the container was broken through as a result of explosive overpressure as gases emerged from the ruptured container and loaded the floor panels. Data on floor strengths, provided by Boeing, indicated that the cabin floor (with the CRAF modification) would fail at a uniform static differential pressure of between 3.5 and 3.9 psi (high pressure below the cabin floor), and that the floor panel to floor beam attachments would not fail before the floor beams. Whilst there is no direct evidence of the pressure loading on the floor structure immediately following detonation, there can be no doubt that in the region of station 700 it would have exceeded the ultimate failure load by a large margin.

2.12.2 Indirect explosive damage (damage at remote sites)

All of the damage considered in the foregoing analysis, and the mechanisms giving rise to that damage, resulted from the direct impact of explosive shock waves and/or the short-term explosive overpressure on structure close to the source of the explosion. However, there were several regions of skin separation at sites remote from the explosion (see para 1.12.3.2) which were much more difficult to understand. These remote sites formed islands of indirect explosive damage separated from the direct damage by a sea of more generalised structural failure characterised by the progressive aerodynamic break-up of the weakened forward fuselage. All of these remote damage sites were consistent with the impact of very localised pressure impulses on the internal surfaces of the hull -effectively high energy 'pressure blows' against the inner surfaces produced by explosive shock waves and/or high pressure gas flows travelling through the interior spaces of the hull.

The propagation of explosive shock waves and supersonic gas flows within multiple, interlinking, cavities having indeterminate energy absorption and reflection properties, and ill-defined structural response, is extremely complex. Work has been initiated in an attempt to produce a three-dimensional computer analysis of the shock wave and supersonic flow propagation inside the fuselage, but full theoretical analysis is beyond present resources.

Because of the complexity of the problem, the following analysis will be restricted to a qualitative consideration of the processes which were likely to have taken place. Whilst such an approach is necessarily limited, it has identified a number of propagation mechanisms which appear to have been of fundamental importance to the break-up of Flight PA103, and which are likely to be critical in any future incident involving the detonation of high explosive inside an aircraft hull.

2.12.2.1 Shock wave propagation through internal cavities

When Mach stem shocks are produced not only are the shock pressures very high but they propagate at very high velocity parallel to the reflecting surface. In the context of the lower fuselage structure in the region of Mach stem formation, it can readily be seen that the Mach stem will be perfectly orientated to enter the narrow cavity formed between the outer skin and the cargo liner/containers, bounded by the fuselage frames [Appendix B, Figure B-25]. This cavity enables the Mach stem shock wave to propagate, without causing damage to the walls (due to the relatively low pressure where the Mach stem sweeps their surface), and reach regions of the fuselage remote from the source of the explosion. Furthermore, energy losses in the cavity are likely to be less than would occur in the 'free' propagation case, resulting in the efficient transmission of explosive energy. The cavity would tend to act like a 'shock tube', used for high speed aerodynamic research, confining the shock wave and keeping it running along the cavity axis, with losses being limited to kinetic heating due to friction at the walls.

Paragraph 1.6.3 contains a general description of the structural arrangements in the area of the cargo hold. Before proceeding further and considering how the shock waves might have propagated through this network of cavities, it should be pointed out that the timescale associated with the propagation of the shock waves is very short compared with the timescale associated with physical movement and separation of skin and structure fractured or damaged by the shock. Therefore, for the purpose of assessing the shock propagation through the cavities, the explosive damage to the hull can be ignored and the structure regarded as being intact. A further simplification can usefully be made by considering the structure to be rigid. This assumption would, if the analysis were quantitative, result in over-estimations of the shock strengths. However, for the purposes of a purely qualitative assessment, the assumption should be valid, in that the general trends of behaviour should not be materially altered.

It has already been argued that the shock wave emerging from the container was, in part, reflected back off the inner surface of the fuselage skin, forming a Mach stem shock wave which would then have tended to travel into the semi-circular lower lobe cavity. The Mach stem waves would have propagated away through this cavity in two directions:

(i) under the belly, between the frames [Appendix B, Figure B-3, detail A], and
(ii) up the left side, expanding into the cavity formed by the longitudinal

manifold chamber where it joins the lower lobe cavity.
As the shock waves travelled along the cavity, little attenuation or other change of characteristic was likely to have occurred until the shocks passed the entrances to other cavities, or impinged upon projections and other local changes in the cavity. A review of the literature dealing with propagation of blast waves within such cavities provides useful insights into some of the physical mechanisms involved.

As part of a research program carried out into the design of ventilation systems for blast hardened installations intended to survive the long duration blast waves following the detonation of nuclear weapons, the propagation of blast waves along the primary passages and into the side branches of ventilation ducts was studied. The research showed that 90¡ bends in the ducts produced very little attenuation of shock wave pressure; a series of six right angle bends produced only a 30% pressure attenuation, together with an extension of the shock duration. It is therefore evident that the attenuation of shock waves propagating through the fuselage cavities, all of which were short with hardly any right angle turns, would have been minimal.

It was also demonstrated that secondary shock waves develop within the entrance to any side branch from the main duct, produced by the interaction of the primary shock wave with the geometric changes in the duct walls at the side-branch location. These secondary shock waves interact as they propagate into the side branch, combining together within a relatively short distance (typically 7 diameters) to produce a single, plane shock wave travelling along the duct axis. In a rigid, smooth walled structure, this mechanism produces secondary shock overpressures in the side branch of between 30% and 50% of the value of the primary shock, together with a corresponding attenuation of the primary shock wave pressure by approximately 20% to 25%.

This potential for the splitting up and re-transmission of shock wave energy within the lower hull cavities is of extreme importance in the context of this accident. Though the precise form of the interactions is too complex to predict quantitatively, it is evident that the lower hull cavities will serve to convey the overpressure efficiently to other parts of the aircraft. Furthermore, the cavities are not of serial form, i.e. they do not simply branch (and branch again) in a divergent manner, but instead form a parallel network of short cavities which reconnect with each other at many different points, principally along the crease beams. Thus, considerable scope exists for: the additive recombination of blast waves at cavity junctions; for the sustaining of the shock overpressure over a greater time period; and, for the generation of multiple shocks produced by the delay in shock propagation inherent in the different shock path (i.e.

cavity) lengths.

Whilst it has not been possible to find a specific mechanism to explain the regions of localised skin separation and peel-back (i.e. the 'pressure blow' regions referred to in para 2.12.2), they were almost certainly the result of high intensity shock overpressures produced locally in those regions as a result of the additive recombination of shock waves transmitted through the lower hull cavities. It is considered that the relatively close proximity of the left side region of damage just below floor level at station 500, [Appendix B, Figure B-19, region D] to the forward end of the cargo hold may be significant insofar as the reflections back from the forward end of the hold would have produced a local enhancement of the shock overpressure. Similarly, 'end blockage effects' produced by the cargo door frame might have been responsible for local enhancements in the area of the belly skin separation and curl-back at station 560 [Appendix B, Figure B-19 and B-20, region E].

The separation of the large section of upper fuselage skin [Appendix B, Figure B-19 and B-20, detail B] was almost certainly associated with a local overpressure in the side cavities between the main deck window line and the upper deck floor, where the cavity is effectively closed off. It is considered that the most probable mechanism producing this region of impulse overpressure was a reflection from the closed end of the cavity, possibly combined with further secondary reflections from the window assembly, the whole being driven by reflective overpressures at the forward end of the longitudinal manifold cavity caused by the forward end of the cargo hold. The local overpressure inside the sidewall cavity would have been backed up by a general cabin overpressure resulting from the floor breakthrough, giving rise to an increased pressure acting on the inner face of the cabin side liner panels. This would have provided pseudo mass to the panels, effectively preventing them from moving inwards and allowing them to react the impulse pressure within the cavity, producing the region of local high pressure evidenced by the region of quilting on the skin panels [Appendix B, Figure B-19, region C].

2.12.2.2 Propagation of shock waves into the cabin

The design of the air-conditioning/depressurisation-venting systems on the Boeing 747 (and on most other commercial aircraft) is seen as a significant factor in the transmission of explosive energy, as it provides a direct connection between the main passenger cabin and the lower hull at the confluence of the lower hull cavities below the crease beam. The floor level air conditioning vents along the length of the cabin provided a series of apertures through which explosive shock waves, propagating through the sub floor cavities, would have radiated into the main cabin.

Once the shock waves entered the cabin space, the form of propagation would have been significantly different from that which occurred in the cavities in the lower hull. Again, the precise form of such radiation cannot be predicted, but it is clear that the energy would potentially have been high and there would also (potentially) have been a large number of shock waves radiating into the cabin, both from individual vents and in total, with further potential to recombine additively or to 'follow one another up' producing, in effect, sustained shock overpressures.

Within the cabin, the presence of hard, reflective, surfaces are likely to have been significant. Again, the precise way in which the shock waves interacted is vastly beyond the scope of current analytical methods and computing power, but there clearly was considerable potential for additive recombination of the many different shock waves entering at different points along the cabin and the reflected shock waves off hard surfaces in the cabin space, such as the toilet and galley compartments and overhead lockers. These recombination effects, though not understood, are known phenomena. Appendix B, Figure B-26 shows how shock waves radiating from floor level might have been reflected in such a way as produce shock loading on a localised area of the pressure hull.

2.12.2.3 Supersonic gas flows

The gas produced by the explosive would have resulted in a supersonic flow of very high pressure gas through the structural cavities, which would have followed up closely behind the shock waves. Whilst the physical mechanisms of propagation would have been different from those of the shock wave, the end result would have been similar, i.e. there would have been propagation via multiple, linked paths, with potential for additive recombination and successive pressure pulses resulting from differing path lengths. Essentially, the shock waves are likely to have delivered initial 'pressure blows' which would then have been followed up immediately by more sustained pressures resulting from the high pressure supersonic gas flows.

2.13 Potential limitation of explosive damage

Quite clearly the detonation of high explosive material anywhere on board an aircraft is potentially catastrophic and the most effective means of protecting lives is to stop such material entering the aircraft in the first place. However, it is recognised that such risks cannot be eliminated entirely and it is therefore essential that means are sought to reduce the vulnerability of commercial aircraft structures to explosive damage.

The processes which take place when an explosive detonates inside an aircraft fuselage are complex and, to a large extent, fickle in terms of the precise manner in which the processes occur. Furthermore, the potential variation in charge size, position within the hull, and the nature of the materials in the immediate vicinity of the charge (baggage etc) are such that it would be unrealistic to expect to neutralise successfully the effect of every potential explosive device likely to be placed on board an aircraft. However, whilst the problem is intractable so far as a total solution is concerned, it should be possible to limit the damage caused by an explosive device inside a baggage container on a Boeing 747 or similar aircraft to a degree which would allow the aircraft to land successfully, albeit with severe local damage and perhaps resulting in some loss of life or injuries.

In Appendix E the problem of reducing the vulnerability of commercial aircraft to explosive damage is discussed, both in general terms and in the context of aircraft of similar size and form to the Boeing 747. In that discussion, those damage mechanisms which appear to have contributed to the catastrophic structural failure of Flight PA103 are identified and possible ways of reducing their damaging effects are suggested. These suggestions are intended to stimulate thought and discussion by manufacturers, airworthiness authorities, and others having an interest in finding solutions to the problem; they are intended to serve as a catalyst rather than to lay claim to a definitive solution.

2.14 Summary

It was established that the detonation of an IED, loaded in a luggage container positioned on the left side of the forward cargo hold, directly caused the loss of the aircraft. The direct explosive forces produced a large hole in the fuselage structure and disrupted the main cabin floor. Major cracks continued to propagate from the large hole under the influence of the service pressure differential. The indirect explosive effects produced significant structural damage in areas remote from the site of the explosion. The combined effect of the direct and indirect explosive forces was to destroy the structural integrity of the forward fuselage, allow the nose and flight deck area to detach within a period of 2 to 3 seconds, and subsequently allow most of the remaining aircraft to disintegrate while it was descending nearly vertically from 19,000 to 9,000 feet.

The investigation has enabled a better understanding to be gained of the explosive processes involved in such an event and to suggest ways in which the effects of such an explosion might be mitigated, both by changes to future design and also by retrospective modification of aircraft. It is therefore recommended that Regulatory Authorities and aircraft manufacturers undertake a systematic study with a view to identifying measures that might mitigate the effects of explosive devices and improve the tolerance of the aircraft structure and systems to explosive damage.

3. CONCLUSIONS

(a) Findings

(i) The crew were properly licenced and medically fit to conduct the flight.

(ii) The aircraft had a valid Certificate of Airworthiness and had been maintained in compliance with the regulations.

(iii) There was no evidence of any defect or malfunction in the aircraft that could have caused or contributed to the accident.

(iv) The structure was in good condition and the minimal areas of corrosion did not contribute to the in-flight disintegration.

(v) One minor fatigue crack approximately 3 inches long was found in the fuselage skin but this had not been exploited during the disintegration.

(vi) An improvised explosive device detonated in luggage container serial number AVE 4041 PA which had been loaded at position 14L in the forward hold. This placed the device approximately 25 inches inboard from the skin on the lower left side of the fuselage at station 700.

(vii) The analysis of the flight recorders, using currently accepted techniques, did not reveal positive evidence of an explosive event.

(viii) The direct explosive forces produced a large hole in the fuselage structure and disrupted the main cabin floor. Major cracks continued to propagate from the large hole under the influence of the service pressure differential.

(ix) The indirect explosive effects produced significant structural damage in areas remote from the site of the explosion.

(x) The combined effect of the direct and indirect explosive forces was to destroy the structural integrity of the forward fuselage.

(xi) Containers and items of cargo ejected from the fuselage aperture in the forward hold, together with pieces of detached structure, collided with the empennage severing most of the left tailplane, disrupting the outer half of the right tailplane, and damaging the fin leading edge structure.
(xii) The forward fuselage and flight deck area separated from the remaining structure within a period of 2 to 3 seconds.
(xiii) The No 3 engine detached when it was hit by the separating forward fuselage.
(xiv) Most of the remaining aircraft disintegrated while it was descending nearly vertically from 19,000 to 9,000 feet.
(xv) The wing impacted in the town of Lockerbie producing a large crater and creating a fireball.

(b) Cause

The in-flight disintegration of the aircraft was caused by the detonation of an improvised explosive device located in a baggage container positioned on the left side of the forward cargo hold at aircraft station 700.

4. SAFETY RECOMMENDATIONS

The following Safety Recommendations were made during the course of the investigation :

4.1 That manufacturers of existing recorders which use buffering techniques give consideration to making the buffers non-volatile, and the data recoverable after power loss.
4.2 That Airworthiness Authorities re-consider the concept of allowing buffered data to be stored in a volatile memory.
4.3 That Airworthiness Authorities consider requiring the CVR system to contain a short duration, i.e. no greater than 1 minute, back-up power supply to enable the CVR to respond to events that result in the almost immediate loss of the aircraft's electrical power supply.
4.4 That the Department of Transport fund a study to devise methods of recording violent positive and negative pressure pulses, preferably utilising the aircraft's flight recorder systems.
4.5 That Airworthiness Authorities and aircraft manufacturers undertake a systematic study with a view to identifying measures that might mitigate the effects of explosive devices and improve the tolerance of aircraft structure and

systems to explosive damage.

APPENDIX A

PERSONNEL CONDUCTING THE INVESTIGATION

The following Inspectors of the Air Accidents Investigation Branch conducted the investigation:

Mr M M Charles	Investigator-in-Charge
Mr D F King	Principal Inspector (Engineering)
Mr P F Sheppard	Assistant Principal Inspector (Engineering)
Mr A N Cable	Senior Inspector (Engineering)
Mr R G Carter	Senior Inspector (Engineering)
Mr P T Claiden	Senior Inspector (Engineering)
Mr P R Coombs	Senior Inspector (Engineering)
Mr S R Culling	Senior Inspector (Engineering)
Miss A Evans	Senior Inspector (Engineering)
Mr B M E Forward	Senior Inspector (Operations)
Mr P N Giles	Senior Inspector (Operations)
Mr S W Moss	Senior Inspector (Engineering)
Mr R Parkinson	Senior Inspector (Engineering)

Mr J D Payling	Senior Inspector (Operations)
Mr C G Pollard	Senior Inspector (Engineering)
Mr C A Protheroe	Senior Inspector (Engineering)
Mr A H Robinson	Senior Inspector (Engineering)
Mr A P Simmons	Senior Inspector (Engineering)
Mr R G Vance	Senior Inspector (Engineering)
Mr R StJ Whidborne	Senior Inspector (Operations)

The Air Accidents Investigation Branch would like to thank the following organisations from the United Kingdom, United States of America, France, and Canada who participated in the investigation:

Air Line Pilot's Association International

Boeing Commercial Airplane Company

British Airways

British Army

British Geological Survey

Bureau Enquete Accidents

Canadian Aviation Safety Bureau

Civil Aviation Authority

Cranfield Institute of Technology

Federal Aviation Administration

Federal Bureau of Investigation

Independent Union of Flight Attendants

National Transportation Safety Board

Pan American World Airways

Police Service

Royal Aerospace Establishment

Royal Air Force

Royal Armaments Research and Development Establishment

Royal Navy

Royal Ordnance

Royal Signals and Radar Establishment

United Technologies International Operations (Pratt and Whitney)

The Air Accidents Investigation Branch would also like to acknowledge the excellent work of the Dumfries & Galloway Regional Council and to thank all the many voluntary organisations who gave such unstinting support to the investigation.

APPENDIX C

ANALYSIS OF RECORDED DATA

1. Introduction

This appendix describes and analyses the different types of recorded data which were examined during the investigation of the accident to Boeing 747 registration N739PA at Lockerbie on 21 December 1988.
The recorded data consists of that from the Cockpit Voice Recorder (CVR), the Digital Flight Data Recorder (DFDR), Air Traffic Control (ATC) radio telephony (RTF), ATC radar, and British Geological Survey seismic records. The time correlation of the records is also discussed.

2. Digital flight data recorder

The flight data recorder installation conformed to ARINC 573B standard with a Lockheed Model 209 DFDR receiving data from a Teledyne Controls Flight Data Acquisition Unit (FDAU). The system recorded 22 analogue parameters and 27 discrete (event) parameters. The flight recorder control panel was located in the flight deck overhead panel. The FDAU was in the main equipment centre at the front end of the forward hold and the flight recorder was mounted in the aft equipment centre.

2.1 DFDR strip and examination

Internal inspection of the DFDR showed that there was considerable disruption to the control electronics circuits. The crash protection was removed and the plastic recording tape was found detached from its various guide rollers and tangled in the tape spools. There was no tension in the negator springs. This indicated that the tape had probably moved since electrical power was removed from the recorder. The position of the tape in relation to the record/replay heads was marked with a piece of splicing tape in order to quantify the movement. To ensure that no additional damage was caused to the tape it was necessary to cut the negator springs to separate the upper and lower tape reels.

The crinkling and stretching of the tape and the damage to the control electronics meant that the tape had to be replayed outside the recorder. AAIB experience has shown that the most efficient method of replaying stretched Lockheed recorder tapes is to re-spool the tape into a known serviceable recorder, in this case a Plessey 1584G.

2.2 DFDR replay

The 25 hour duration of the DFDR was satisfactorily replayed. Data relating to the accident flight was recorded on track 2. The only significant defect in the recording system was that normal acceleration was inoperative. There was one area on the tape, 2 minutes from the end, where data synchronisation was lost for 1 second.

Decoding and reduction of the data from the accident flight showed that no abnormal behaviour of the data sensors had been recorded. The recorded data simply stopped. Figure C-1 is a graphical representation of the main flight parameters.

2.3 DFDR analysis

In order to ensure that all recorded data from the accident flight had been decoded and to examine the quality of the data at the end of the recording, a section of tape, including both the most recently recorded data and the oldest data (data from 25 hours past), was replayed through an ultra-violet (UV) strip recorder. The data was also digitised and the resulting samples used to reconstruct the tape signal on a VDU.

Both methods of signal representation were used to determine the manner by which the recorder stopped. There was no gap between the most recently recorded data and the 25 hour old data. This showed that the recorder stopped while there was an incoming data stream from the FDAU. The recorder, therefore, stopped because its electrical supply was disconnected. The tape signal was examined for any transients or noise signals that would have indicated the presence of electrical disturbances prior to the recorder stopping. None was found and this indicated that there had been a quick clean break of the electrical supply.

The last seconds of data were decoded independently using both the UV record and the digitised signal. Only 17 bits of data were not recoverable (less that 23 milliseconds) and it was not possible to establish with any certainty if this data was from the accident flight or if it was old data from a previous recording.

A working group of the European Organisation for Civil Aviation Electronics (EUROCAE) was, during the period of the investigation, formulating new standards (Minimum Operational Performance Requirement for Flight Data Recorder Systems, Ref:- ED55) for future generation flight recorders which would have permitted delays between parameter input and recording (buffering) of up to ? second.
These standards are intended to form the basis of new CAA specifications for flight recorders and may be adopted worldwide.

The analysis of the final data recorded on the DFDR was possible because the system did not buffer the incoming data. Some existing recorders use a process whereby data is stored temporarily in a memory device (buffer) before recording. The data within this buffer is lost when power is removed from the recorder and in currently designed recorders this may mean that up to 1.2 seconds of final data contained within the buffer is lost. Due to the necessary processing of the signals prior to input to the recorder, additional delays of up to 300 milliseconds may be introduced. If the accident had occurred when tha aircraft was over the sea, it is very probable that the relatively few small items of structure, luggage and clothing showing positive evidence of the detonation of an explosive device would not have been recovered. However, as flight recorders are fitted with underwater location beacons, there is a high probability that they would have been located and recovered. In such an event the final milliseconds of data contained on the DFDR could be vital to the successful determination of the cause of an accident whether due to an explosive device or other catastrophic failure. Whilst it may not be possible to reduce some of the delays external to the recorder, it is possible to reduce any data loss due to buffering of data within the data acquisition unit.

It is, therefore, recommended that manufacturers of existing recorders which use buffering techniques give consideration to making the buffers non-volatile, and hence recoverable after power loss. Although the recommendation on this aspect, made to the EUROCAE working group during the investigation, was incorporated into ED55, it is also recommended that Airworthiness Authorities re-consider the concept of allowing buffered data to be stored in a volatile memory.

3. Cockpit voice recorder (CVR)

The aircraft was equipped with a 30 minute duration 4 track Fairchild Model A100 CVR, and a Fairchild model A152 cockpit area microphone (CAM). The CVR control panel containing the CAM was located in the overhead panel on the flight deck and the recorder itself was mounted in the aft equipment centre.

The channel allocation was as follows:-

Channel 1	Flight Engineer's RTF.
Channel 2	Co-Pilot's RTF.
Channel 3	Pilot's RTF.
Channel 4	Cockpit Area Microphone.

3.1 CVR strip and examination

To gain access to the recording tape it was necessary to cut away the the outer case and saw through part of the crash protected enclosure. No damage to the tape transport or the recording tape was found. The endless loop of tape was cut and the tape transferred to the replay equipment. The electronic modules in the CVR were crushed and there was evidence of long term overheating of the dropper resistors on the power supply module. The CAM had been crushed breaking internal wiring and damaging components on the printed circuit board.

3.2 CVR replay

The erase facility within the CVR was not functioning satisfactorily and low level communications from earlier recordings was audible on the RTF channels. The CAM channel was particularly noisy, this was probably due to the combination of the inherently noisy cockpit of the B747-100 in the climb and distortion from the incomplete erasure of the previous recordings. On two occasions the crew had difficulty understanding ATC, possibly indicating high cockpit noise levels. There was a low frequency sound present at irregular intervals on the CAM track but the source of this sound could not be identified as of either acoustic or electrical in origin.

The CVR tape was listened to for its full duration and there was no indication of anything abnormal with the aircraft, or unusual in crew behaviour. The tape record ended with a sudden loud sound on the CAM channel followed almost immediately by the cessation of recording. The sound occurred whilst the crew were copying their transatlantic clearance from Shanwick ATC.

3.3 Analysis of the CVR record

3.3.1 The stopping of the recorder

To determine the mechanism that stopped the recorder a bench test rig was constructed utilizing an A100 CVR and an A152 CAM. Figures C-2 to C-5 show the effect of shorting, earthing or disconnecting the CAM signal wires. Figure C-8 shows the CAM channel signal response to the event which occurred on Flight PA103. From this it can be seen that there are no characteristic transients similar to those caused by shorting or earthing the CAM signal wires. Neither does the signal stop cleanly and quickly as shown in Figure C-5, indicating that the CAM signal wires were not interrupted. The UV trace shows the recorded signal decaying in a manner similar to that shown in Figure C-6, which demonstrates the effect of disconnecting electrical power from the recorder. The tests were repeated on other CVRs with similar results and it is therefore concluded that Flight PA103's CVR stopped because its electrical power was removed.

Figures C-9A to C-9D show the recorded signals for the Air India B747 (AI 182) accident in the North Atlantic on 23 June 1985. These show that there is a large transient on the CAM track indicating earthing or shorting of the CAM signal wires and that recorder power-down is more prolonged, indicating attempts to restore the electrical power supply either by bus switching or healing of the fault. The Flight PA103 CVR shows no attempts at power restoration with the break being clean and final.

In order to respond to events that result in the almost immediate loss of the aircraft's electrical power supply it was therefore recommended during the investigation that the regulatory authorities consider requiring CVR systems to contain a short duration (i.e. no greater than 1 minute) back-up power supply.

3.3.2 Information concerning the event

Figure C-8 is an expanded UV trace of the final milliseconds of the CVR record. Three tracks have been used, the flight engineer's RTF channel which contained similar information to the P2's channel has been replaced with a timing signal. Individual sections of interest are identified by number. On the bottom trace, the P1 RTF track, section 1 is part of the Shanwick transatlantic clearance. During this section the loud sound on the CAM channel is evident.

Examination of the DFDR event recordings shows that the Shanwick oceanic clearance was being received on VHF2, the aerial for which is on the underside of the fuselage close to the seat of the explosion.
Section 2 identifies a transient, on the P1 channel, typical of an end of ATC transmission transient for this CVR. The start and finish of most of the recorded ATC transmissions were analysed and they produce a similar signature to the three shown in Figure C-10. The signature

on the P1 channel more closely resembles the end of transmission signature and it is open to conjecture that this transient was caused by the explosion damaging the aerial feeder and/or its supporting structure.

Section 3 shows what is considered to be a high speed power supply transient which is evident on all the RTF channels and is probably on the CAM channel, but cannot be identified because of the automatic gain control (AGC), limiting the audio event. This transient is considered to coincide with the loss of electrical power to the CVR. Section 5 identifies the period to the end of recording and this agrees well with tests carried out by AAIB and independently by Fairchild as part of the AI 182 investigation. The typical time from removal of the electrical supply until end of recording is 110 milliseconds.

During the period identified as section 4 it is considered that the disturbances on the RTF channels are electrical transients probably channelled through the communications equipment. Section 6 identifies the 170 millisecond period from the point when the sound was first heard on the CAM until the recording stopped.

The CAM unit is of the old type which has a frequency response of 350 to 3500 Hz. The useable duration of the signal is probably confined to the first 60 milliseconds of the final 170 milliseconds and even during this period the AGC is limiting the signal. In the remaining time the sound is being distorted because power to the recorder has been disconnected. The ambient cockpit noise may have been high enough to have caused the AGC to have been active prior to the event and in this event the full volume of the sound would not be audible. Distortion from the incomplete erasure of the last recording may form part of the recorded signal.

It is not clear if the recorded sound is the result of the explosion or is from the break-up of the aircraft structure. The short period between the beginning of the event and the loss of electrical power suggests that the latter is more likely to be the case.

Additionally some of the frequencies present on the recording were not present in the original sound, but are the result of the rise in total harmonic distortion caused by the increased amplitude of the incoming signal. Outputs from a frequency analysis of the recorded signal for the same frequency of input to the CVR, but at two input amplitudes, are shown in

Figures C-11 and C-12. These illustrate the effects on harmonic distortion as the signal level is increased. Finally the recorded signal does not lend itself to analysis by a digital spectrum analyser as it is, in a large measure, aperiodic and most digital signal analysis algorithms are unable to deal with a short duration signal of this type, however, it is hoped that techniques being developed in Canada will enable more information to be deduced from the end of the recording.

In the aftermath of the Air India Boeing 747 accident (AI 182) in the North Atlantic on 23 June 1985 the Royal Armaments Research and Development Establishment (RARDE) were asked informally by AAIB to examine means of differentiating, by recording violent cabin pressure pulses, between the detonation of an explosive device within the cabin (positive pulse) and a catastrophic structural failure (negative pulse). Following the Lockerbie disaster it was considered that this work should be raised to a formal research project. Therefore, in February 1989, it was recommended that the Department of Transport fund a study to devise methods of recording violent positive and negative pressure pulses, preferably utilising the aircraft's flight recorder systems.

Preliminary results from these trials indicates that if a suitable sensor can be developed its output will need to be recorded in real time and therefore it may require wiring into the CVR installation. This will further strengthen the requirement for battery back up of the CVR electrical power supply.

4. Flight recorder electrical system

4.1 CVR/DFDR electrical wiring.

The flight recorders were located in the left rear fuselage just forward of the rear pressure bulkhead. Audio information to the CVR ran along the left hand side of the aircraft, at stringer 11. Electrical power to the CVR followed a similar route on the right hand side of the aircraft crossing to the left side above the rear passenger toilets. DFDR electrical power and signal information followed the same route as the CVR audio information.

4.2 Flight recorder power supply

The DFDR, CVR and the transponders were all powered from the essential alternating current (AC) bus. This bus was capable of being powered by any generator, however, in normal operation the selector switch on the flight engineers panel is selected to "normal" connecting the essential bus to number 4 generator. When the cockpit of Flight PA103 was examined the selector switch was found in the normal position.

4.3 Aircraft alternating current power supplies

AC electrical power to the aircraft was provided by 4 engine driven generators, see Figure C-13. Each generator was driven at constant speed through a constant speed drive (CSD) and connected to a separate bus-bar through a generator control breaker (GCB). The 4 generators were connected to a parallel bus-bar (sync bus) by individual bus tie breakers (BTBs). Control and monitoring of the AC electrical system was achieved through the flight engineer's instrument panel. In normal operation the generators operated in parallel, i.e with the BTBs closed.

4.4 Fault conditions

Analysis of the CVR CAM channel signal indicated that approximately 60 milliseconds after the sound on the CAM channel an electrical transient was recorded on all 4 channels and that approximately 110 milliseconds later the CVR had ceased recording. Within the accuracy of the available timing information it is believed that the incoming VHF was lost at the same time, indicating an AC power supply fault.

The AC electrical system was protected from faults in individual systems or equipment by fuses or circuit breakers. Faults in the generators or in the distribution bus-bars and feeders were dealt with automatically by opening of the GCBs and opening or closing of the BTBs. In the event of fault conditions causing the disconnection of all 4 generators electrical power for essential services, including VHF radio, was provided by a battery located in the cockpit.

The short time interval of 55 milliseconds after which the AC supply to the flight recorders was lost limits the basis on which a fault path analysis of the AC electrical system can be undertaken. On the available information only a differential (feeder) fault could have isolated the bus-bar this quickly, with the generator field control relay taking 20 milliseconds to trip. However, in normal operation, the generators would have been operating in parallel and the essential AC bus-bar would have been supplied via the number 4 BTB from the sync bus. If the fault conditions had continued, a further 40 to 100 milliseconds would have elapsed before the BTB opened. If the BTB was open prior to the fault it would have attempted to close and restore the supply to the essential bus. Any automatic switching causes electrical transients to appear on the CVR and data losses on the FDR. Both the CVR and the FDR indicate that a clean break of the AC supply occurred with no electrical transients associated with BTBs open or closing in an attempt to restore power. In the absence of any additional information only two possibilities are apparent:

i) That all 4 generators were simultaneously affected causing a total loss of AC electrical power. The feeders for the left and right side generators run on opposite sides of the aircraft under the passenger cabin floor. The only situation envisaged that could cause simultaneous loss of all 4 generators is the disruption of the passenger cabin floor across its entire width.

ii) That disruption of the main equipment centre, housing the control units for the AC electrical system, caused the loss of all AC power. However, again it would have to affect both the left and right sides of the aircraft as the control equipment is located at left and right extremes of the main equipment centre.

The nature of the event may also produce effects that are not understood. It is also to be noted that a sudden loss of electrical power to the flight recorders has been reported in other B747 accidents, e.g. Air India, AI 182.

5. Seismic data

The British Geological Survey has a number of seismic monitoring stations in Southern Scotland. Stations close to Lockerbie recorded a seismic event caused by the wing section crashing on Lockerbie. The seismic monitors are time correlated with the British Telecom Rugby standard. Using this and calculating the time for the various waves to reach the recording stations it was possible for the British Geological Survey to conclude that the event occurred at 19.03:36.5 hrs ± 1 second.

Attempts were made to correlate various smaller seismic events with other wreckage impacts. However, this was not conclusive because the nearest recording station was above ground and due to the high winds at the time of the accident had considerable noise on the trace. In addition, little of the other wreckage had the mass or impact velocity to stimulate the sensors.

6. Time correlation

6.1 Introduction

The sources of each time encoded recording were asked to provide details of their time standard and any known errors in the timings on their recordings. Although the resolution of the recorded time sources is high it was not possible to attach an accuracy of better than ±1 second due to possible errors in synchronising the recorded time with the associated standard. The following time sources were available and used in determining the significant events in the investigation:-

i) ATC

ATC communications were recorded along with a time signal. The time source for the ATC tape was the British Telecom "Tim" signal. Any error in setting the time when individual tapes are mounted was logged.

ii) Recorded rada data

A time signal derived from the British Telecom "Rugby" standard was included on radar recordings. The Rugby and Tim times were assumed to be of equal accuracy for timing purposes.

iii) The DFDR had UTC recorded.

The source of this time was the flight engineer's clock. This clock was set manually and therefore this time was subject to a significant fixed error as well any inaccuracy in the clock.

iv) The CVR had no time signal.

However, the CVR was correlated with the ATC time through the RTF and with the DFDR, by correlating the press to talk events on the FDR with the press to talk signature on the CVR.

v) Seismic recordings

Seismic recordings included a timing signal derived from the British Telecom Rugby standard.

6.2 Analysis and correlation of times

The Scottish and Shanwick ATC tapes were matched with each other and with the CVR tape. The CVR recording speed was adjusted by peaking its recorded 400 Hz AC power source frequency. This correlation served as a double check on any fixed errors on the ATC recordings and to fix events on the CVR to UTC. The timing of the sound on the CAM channel of the CVR was made simpler because Shanwick was transmitting when it occurred. From this it was possible to determine that the sound on the CVR occurred at 19.02:50 hrs ±1 second.

With the CVR now tied to the Tim standard it was possible to match the RTF keying on the CVR with the RTF keying events on the FDR. These events on the FDR were sampled and recorded once per second, it was therefore possible for a 1 second delay to be present on the FDR. This potential error was reduced by obtaining the best fit between a number of RTF keyings and a time correlation between the FDR and CVR of ±? second was achieved. From this it was determined, within this accuracy, that electrical power was removed from the CVR and FDR at the same time.

From the recorded radar data it was possible to determine that the last recorded SSR return was at 19.02:46.9 hrs and that by the next rotation of the radar head a number of primary returns, some left and right of track, were evident. Time intervals between successive rotations of the radar head became more difficult to use as the head painted more primary returns.

The point at which aircraft wreckage impacted Lockerbie was determined using the time recorded by seismic activity detectors. A seismic event measuring 1.6 on the Richter scale was detected and, with appropriate time corrections for times of the waves to reach the sensors, it was established that this occurred at 19.03:36.5 hrs ±1 second. A further check was made by triangulation techniques from the information recorded by the various sensors.

7. Recorded radar information

7.1 Introduction

Recorded radar information on the aircraft was available from from 4 radar sites. Initial analysis consisted of viewing the recorded information as it was shown to the controller on the radar screen, from this it was clear that the flight had progressed in a normal manner until Secondary Surveillance Radar (SSR) was lost. There was a single primary return received by both Great Dun Fell and Claxby radars approximately 16 seconds before SSR returns were lost. The Lowther Hill and St. Annes radars did not see this return. The Great Dun Fell radar recording was watched for 1 hour both before and after this single return for any signs of other spurious returns, but none was seen. The return was only present for one paint and no explanation can be offered for its presence.

7.2 Limitations of recorded radar data

Before evaluating the recorded radar data it is important to highlight limitations in radar performance that must be taken into account when interpreting primary radar data. The radar system used for both primary and secondary radar utilised a rotating radar transmitter/receiver (Head). This means that a return was only visible whilst the radar head was pointing at the target, commonly called painting or illuminating the target. In the case of this accident the rotational speeds of the radar heads varied from approximately 10 seconds for the Lowther Hill Radar to 8 Seconds for the Great Dun Fell Radar.

Whilst it was possible to obtain accurate positional information within a resolution of 0.09¡ of bearing and ± 1/16 nautical mile range for an aircraft from SSR, incorporating mode C height encoding, primary radar provided only slant range and bearing and therefore positional information with respect to the ground was not accurate.

The structural break-up of an aircraft releases many items which were excellent radar reflectors eg. aluminium cladding, luggage containers, sections of skin and aircraft structure. These and other debris with reflective properties produce "clutter" on the radar by confusing the radar electronics in a manner similar to chaff ejected by military aircraft to avoid radar detection.

Even when the target is not masked by clutter repetitive detection of individual targets may not be possible because detection is a function of the target effective area which, for wreckage with its irregular shape, is not constant but fluctuates wildly. These factors make it impossible to follow individual returns through successive sweeps of the radar head.

7.3 Analysis of the radar data

The detailed analysis of the radar information concentrated on the break-up of the aircraft. The Royal Signals and Radar Establishment (RSRE) corrected the radar returns for fixed errors and converted the SSR returns to latitude and longitude so that an accurate time and position for the aircraft could be determined. This information was correlated with the CVR and ATC times to establish a time and position for the aircraft at the initial disintegration.

For the purposes of this analysis the data from Great Dun Fell Radar has been presented. Figures C-14 to C-23 show a mosaic picture of the radar data i.e. each figure contains the information on the preceding figure together with more recently recorded information. Figure C-14 shows the radar returns from an aircraft tracking 321¡(Grid) with a calculated ground speed of 434 kts. Reading along track (towards the top left of Figure C-14) there are 6 SSR returns with the sixth and final SSR return shown decoded: squawk code 0357 (identifying the aircraft as N739PA); mode C indicating FL310; and the time in seconds (68566.9 seconds from 00:00, i.e. 19.02:46.9 hrs).

At the next radar return there is no SSR data, only 4 primary returns. One return is along track close to the expected position of the aircraft if it had continued at its previous speed and heading. There are 2 returns to the left of track and 1 to the right of track. Remembering the point made earlier about clutter, it is unlikely that each of these returns are real targets. It can, however, be concluded that the aircraft is no longer a single return and, considering the approximately 1 nautical mile spread of returns across track, that items have been ejected at high speed probably to both right and left of the aircraft. Figure C-15 shows the situation after the next head rotation. There is still a return along track but it has either slowed down or the slant range has decreased due to a loss of altitude.

Each rotation of the radar head thereafter shows the number of returns increasing with those first identified across track in Figure C-14 having slowed down very quickly and followed a track along the prevailing wind line. Figure C-20 shows clearly that there has been a further break-up of the aircraft and subsequent plots show a rapidly increasing number of returns, some following the wind direction and forming a wreckage trail parallel to and north of the original break-up debris. Additionally it is possible that there was some break-up between these points with a short trail being formed between the north and south trails. From the absence of any returns travelling along track it can be concluded that the main wreckage was travelling almost vertically downwards for much of the time.

The geographical position of the final secondary return at 19.02:46.9 hrs was calculated by RSRE to be OS Grid Reference 15257772, annotated Point A in Appendix B, Figure B-4, with an accuracy considered to be better than ±300 metres This return was received 3.1±1 seconds before the loud sound was recorded on the CVR at 19.02:50 hrs. By projecting from this position along the track of 321¡(Grid) for 3.1±1 seconds at the groundspeed of 434 kts, the position of the aircraft was calculated to be OS Grid Reference 14827826, annotated Point B in Appendix B, Figure B-4, within an accuracy of ±525 metres. Based on the evidence of recorded data only, Point B therefore represents the geographical position of the aircraft at the moment the loud sound was recorded on the CVR.

8. Conclusions

The almost instant destruction of Flight PA103 resulted in no direct evidence on the cause of the accident being preserved on the DFDR. The CVR CAM track contained a loud sound 170 milliseconds before recording ceased. Sixty milliseconds of this sound were while power was applied to the recorder; after this period the amplitude decreased. It cannot be determine whether the decrease was because of reducing recorder drive or if the sound itself decreased in amplitude. Analysis of both flight recorders shows that they stopped because the electrical supply was removed and that there were valid signals available to both recorders at that time.

The most important contribution to the investigation that the flight recorders could make was to pinpoint the time and position of the event. As the timescale involved was so small in relation to the resolution and accuracy of many of the recorded time sources it was necessary to analyse collectively all the available recordings. From the analysis of the CVR, DFDR, ATC tapes, radar data and the seismic records it was concluded that the loud sound on the CVR occurred at 19.02:50 hrs ±1 second and wreckage from the aircraft crashed on Lockerbie at 19.03:36.5 hrs

±1 second, giving a time interval of 46.5 ±2 seconds
between these two events. When the loud sound was recorded on the CVR, the geographical position of the aircraft, based on the evidence of recorded data, was calculated to be within 525 metres of OS Grid Reference 14827826.

Eight seconds after the sound on the CVR the Great Dun Fell radar showed 4 primary radar returns. The returns indicated a spread of wreckage in the order of 1 nautical mile across track. On successive returns of the radar, two parallel wreckage trails are seen to develop with the second trail, to the north, becoming evident 30 to 40 seconds after the first.

APPENDIX D

CRITICAL CRACK CALCULATIONS

It was assumed that the fuselage rupture and associated star-burst petalling process was driven by an expanding 'bubble' of high pressure gas, produced by the conversion of solid explosive material into gas products. As the explosive gas pressures reduced due to dissipation through the structure and external venting, the service differential pressure loading would have taken over from the explosive pressures as the principal force driving the skin fractures.

The high temperature gas would initially have been confined within the container where, because of the low volume, the pressure would have been extremely high (too high for containment) and the gas bubble would have expanded violently into the cavities of the fuselage between the outer skin and the container. This gas bubble would have continued to expand, with an accompanying fall in pressure due to the increasing volume combined with a corresponding drop in temperature.

The precise nature of the gas expansion process could not be determined directly from the evidence and it was therefore necessary to make a number of assumptions about its behaviour, based on the geometry of the hull and the area of fuselage skin which the high pressure bubble would have ruptured. Essentially, it was assumed that the gas bubble would expand freely in the circumferential direction, into the cavity between the fuselage skin and the container. In contrast, the freedom for the bubble to expand longitudinally would have been restricted by the presence of the fuselage frames, which would have partially blocked the passage of gas in the fore and aft directions. However, the pressures acting on the frames would have been such that they would have buckled and failed, allowing the gas to vent into the next 'bay', producing failure of the next frame. This sequential frame-failure process would have continued until the pressure had fallen to a level which the frames could withstand. During the period of frame failure and the associated longitudinal expansion of the gas bubble, this expansion rate was assumed to be half that of the circumferential rate.

It was assumed that venting would have taken place through the ruptured skin and that the boundary of the petalled hole followed behind the expanding gas bubble, just inside its outer boundary, i.e. the expanding gas bubble would have stretched and 'unzipped' the skins as it expanded. This process would have continued until the gas bubble had expanded/vented to a level where the pressure was no longer able to drive the petalling mechanism because the skin stresses had reduced to below the natural strength of the material.

The following structural model was assumed:

(i) The pressurised hull was considered to be a cylinder of radius 128 inches, divided into regular lengths by stiff frames.

(ii) The contributions of the stringers and frames beyond the petalled region were considered to be the equivalent of a reduction of stress in the skins by 20%, corresponding to an increase in skin thickness from 0.064 inches to 0.080 inches.

(iii) Standing skin loads were assumed to be present due to the service differential pressure, i.e.. it was assumed that no significant venting of internal cabin pressure occurred within the relevant timescale.

(iv) The mechanism of bubble pressure load transfer into the skins was:

a) Hoop direction -conventional membrance reaction into hoop stresses b)

Longitudinal direction - reaction of pressures locally by the frames, restrained by the skins.

The critical crack calculations were based upon the generalised model of a plate under biaxial loading in which there was an elliptical hole with sharp cracks emanating from it. This is a good approximation of the initial condition, i.e.. the shattered hole, and an adequate representation of the subsequent phase, when the hole was enlarging in its star-burst, petalling, mode.

The analyses of critical crack dimensions in the circumferential and longitudinal directions were based on established Fracture Resistance techniques. The method utilises fracture resistance data for the material in question to establish the critical condition at which the rate of energy released by the crack just balances the rate of energy absorbed by the material in the cracking process, i.e. the instantaneous value of the parameter Kr, commonly referred to as the fracture toughness Kc. From this, the relationship between critical stress and crack length can be determined.

Using conventional Linear Elastic Fracture Mechanics (LEFM) with fracture toughness data from RAE experimental work and published geometric factors relating to cracks emanating from elliptical holes, the stress levels required to drive cracks of increasing lengths in both circumferential and longitudinal directions were calculated. The skin stresses at sequential stages of the expanding gas bubble/skin petalling process were then calculated and compared with these data.

The results of the analysis indicated that, once the large petalled hole had been produced by explosive gas overpressure, the hoop stresses generated by fuselage pressurisation loads acting alone would have been sufficient to drive cracks longitudinally for large distances beyond the boundaries of the petalled hole. Thus, with residual gas overpressure acting as well, the 43 feet (total length) longitudinal fractures observed in the wreckage are entirely understandable. The calculations also suggested that the hoop fractures, due to longitudinal stresses in the skins, would have extended beyond the boundary of the petalled hole, though the excess stress driving the fractures in this direction would have been much smaller than for the longitudinal fractures, and the level of uncertainty was greater due to the difficulty of producing an accurate model reflecting the diffusion of longitudinal loads into the skins. Nevertheless, the results suggested that the circumferential cracks would extend downwards just beyond the keel, and upwards as far as the window belt - conclusions which accord reasonably well with the wreckage evidence.

APPENDIX E

POTENTIAL REMEDIAL MEASURES

1. Introduction

In the following discussion, those damage mechanisms which appear to have contributed to the catastrophic structural failure of Flight PA103 are identified and possible ways of reducing their damaging effects are suggested. These suggestions are intended to stimulate thought and discussion by manufacturers, airworthiness authorities, and others having an interest in finding solutions to the problem; they are intended to serve as a catalyst rather than to lay claim to a definitive solution. On the basis of the Flight PA103 investigation, damage is likely to fall into two categories: direct explosive damage, and indirect explosive damage.

2. Direct explosive damage

The most serious aspect of the direct explosive damage on the structure is the large, jagged aperture in the pressure hull, combined with frame and stringer break-up, which results from the star-burst rupture of the fuselage skin. Because of its uncontrolled size and position, and the naturally radiating cracks which form as part of the petalling process, the skin's critical crack length (under pressurisation loading) is likely to be exceeded, resulting in unstable crack propagation away from the boundary of the aperture. Such cracks can lead to a critical loss of structural integrity at a time when additional loads are likely to be imposed on the structure due to reflected blast pressure and/or aircraft aerodynamic and inertial loading.

A further complicating factor is that the size of this aperture is likely to be sufficiently large to allow complete cargo containers and other debris to be ejected into the airstream, with a high probability of causing catastrophic structural damage to the empennage.

3. Indirect explosive damage

Indirect explosive damage (channelling or ducting of explosive energy in the form of both shock waves and supersonic gas flows) is likely to occur because of the network of interlinked cavities which exist, in various forms, in all large commercial aircraft, particularly below cabin floor level. This channeling mechanism can produce critical damage at significant distances from the source of the explosion.

In addition to the structural damage, aircraft flight control and other critical systems will potentially be disrupted, both by the explosive forces and as a result of structural break-up and distortions. The discussion which follows focuses on possible means of limiting structural damage of the kind which occurred on Flight PA103. Undoubtedly, such measures will also have beneficial effects in limiting systems damage. However, system vulnerability can further be reduced by applying, wherever possible, those techniques used on military aircraft to reduce vulnerability to battle damage; multiplexed, multiply redundant systems using distributed hardware to minimise risk of a single area of damage producing major system disruption. Fly by wire flight control systems potentially offer considerable scope to achieve these goals, but the same distributed approach would also be required for the electronic and other equipment which, in current aircraft, tends to be concentrated into a small number of 'equipment centres'.

4. Remedial measures to reduce structural damage

Whilst pure containment of the explosive energy is theoretically possible, in an aviation context such a scheme would not be viable. Any unsuccessful attempt to contain the explosive will probably produce greater devastation than the original (uncontained) explosion since all the explosive energy would merely be stored until the containment finally ruptured, when the stored energy would be released together with massive fragmentation of the containment.

However, a mixed approach involving a combination of containment, venting, and energy absorption should provide useful gains provided that a systematic rather than piecemeal approach is adopted, and that the scheme also addresses blast channelling. The following scheme is put forward for discussion, primarily as means of identifying, by example, how the various elements of the problem might be approached at a conceptual level and to provide a stimulus for debate. No detailed engineering solutions are offered, but it is firmly believed that the requirements of such a scheme could be met from a technical standpoint. The proposed scheme is based on the need to counter a threat similar to that involving Flight PA103, i.e. a high explosive device placed within a baggage container, however, the principles should be applicable to other aircraft types.

Such a scheme might comprise several 'layers' of defence. The first two layers, one within the other, are essentially identical and provide partial containment of the explosive energy and the redirection of blast out from the compartment via pre-determined vent paths. Although the containment is temporary, it must provide an effective barrier to uncontrolled venting, preventing the escape of blast except via the pre-designated paths.

The third layer comprises a pre-determined area of fuselage skin, adjoining the outer end of the vent path, designed to rupture or burst in a controlled manner, providing a large vent aperture which will not tend to crack or rupture beyond the designated boundaries.

A fourth layer of protection has two elements, both intended to limit the propagation of shock waves through the internal cavities in the hull. The first element comprises the closure of any gaps between the vent apertures in the two innermost containment layers and the vent aperture in the outer skin. This effectively provides an exhaust duct connecting the inner and outer vent apertures to minimise leakage into the intervening structure and cavities around the cargo hold. The second element comprises the incorporation of an energy absorbing lining material within all the cavities in the lower hull, to absorb shock energy, limit shock reflection and limit the propagation of pressure waves which might enter the cavities, for example because of containment layer breakthrough.

5 Possible application to Boeing 747 type aircraft

5.1 Container Modification

The obvious candidates for the inner containment layer are the baggage containers themselves. Existing containers are of crude construction, typically comprising aluminium sheet sides and top attached to an aluminium frame with a fabric reinforced access curtain, or have sides and top of fibreglass laminate attached to a robust aluminium base section.

These containers are stacked in the aircraft in such a manner that on three sides (except for the endmost containers) the baggage within the adjoining containers provides an already highly effective energy absorbing barrier. If the container is modified so that loading access is via the outboard side of the container rather than at the end, i.e. the curtain is put on the faces shown in Figure E-1, then only the top and base are 'unbacked' by other containers, leaving the outboard face as a vent region.

The proposal is therefore that a modified container is developed in which the access is changed from the end to the outside face only, and which is modified to improve the resistance to internal pressures and thus encourage venting via the new access curtain only. How the container is actually modified to achieve the containment requirement is a matter of detail design, but two approaches suggest themselves, both involving the use of composite type materials. The first approach is to adopt a scheme for a rigid container which relies on a combination of energy absorption and burst strength to prevent uncontrolled breakout of explosive energy. The second approach is to use a 'flexible' container, i.e. rigid enough for normal use, but sufficiently flexible to allow gross deformation of shape without rupture. This, particularly if used with a backing blanket made from high performance material to resist fragmentation, could deform sufficiently to allow the container to bear against, and partially crush, adjoining containers. In this way, the shock energy transmission should be significantly reduced and the inherent energy absorption capability and mass of the baggage in adjoining containers could be utilised, whilst still retaining the high pressure gas for long enough to allow venting via the side face. Clearly, care would need to be taken to ensure that the container vent aperture remained as undistorted as possible, to ensure minimal leakage at the interface.

5.2 Cargo bay liner

The existing cargo bay liner is a thin fibreglass laminate which lines the roof and sidewalls of the cargo hold. There is no floor as such; instead, the containers are supported on rails running fore and aft on the tops of the fuselage frame lower segments. In a number of areas, there are zipped fabric panels let into the liner to provide access to equipment located behind. The liner 'ceiling' is suspended on plastic pillars approximately 2 centimeters below the bottom of the main cabin floor beams.

The purpose of the liner is solely to act as a general barrier to protect wiring looms and systems components.

The proposal is to produce a new liner designed to provide the second level of containment, essentially at 'floor' and 'roof' level only [Figure E-1]. The dimensional constraints are such that potentially quite thick material could be incorporated (leaving aside the weight problem), permitting not only a rigid liner design, but semi-rigid or flexible linings backed by energy absorbing blanket materials.

The liner would be designed to provide an additional barrier at the base and roof of the containers, which unlike the sides, are not protected by adjoining containers. The outside ends of these barrier elements must effectively seal against the vent apertures in the containers, to minimise leakage into the fuselage cavities.

5.3 Structural blow-out regions.

The final element in the containment/venting part of the scheme is a line of blow-out regions in the fuselage skins, coinciding exactly with the positions of the vent apertures in the cargo containers and cargo bay liner. These should extend along the length of the cargo hold, zoned in such a way that rupture due to rapid overpressure will occur in a controlled manner. The primary function of the blow-out regions would be to provide immediate pressure relief by allowing the inevitable skin rupture to take place only within pre-determined zones, limiting the extent of the skin tearing by means of careful stiffness control at the boundary of the blow-out regions.

The structural requirements of such panels are perhaps the most difficult challenge to meet, particularly for existing designs. However, it is believed that by giving appropriate consideration to the directionality of fastening strengths, and the use of external tear straps, it should be possible to design the structure to carry the normal service loads whilst creating a pre-disposition to rupturing in a controlled manner in response to gross pressure impulse loading.

The implementation of such features will need carefully balanced design in order to provide local stiffening, sufficient to control and direct the tear processes, without creating stiffness discontinuities which could lead to fatigue problems during extended service. However, the degree of reinforcement needed at the blow-out aperture need only be sufficient to limit tearing and to sustain the aircraft long enough to complete the flight unpressurised.

All aircraft have pre-existing strength discontinuities, despite the efforts of the designers to eliminate them. By choosing the positions of butt joints, lap joints, anti-tear straps and similar structural features in future designs, so as to incorporate them into the boundary of the blow-out panel region, the natural "tear here" tendencies of such features could possibly be turned to advantage. In the case of current generation aircraft, the positions of existing lines of weakness at such features will determine the optimum position for structural blow-out areas, and hence the positions of the container and cargo bay liner blow-out panels. A limited amount of local structural reinforcement (e.g. in the form of external anti-tear straps), carried out as part of a modification program, could perhaps fine tune the tearing properties of existing lines of weakness, potentially producing significant improvements.

5.4 Closure of cavities

There are four main classes of cavity which will need to be addressed on the Boeing 747, and most other modern aircraft. These are:

(i) The channels formed between fuselage frames

(ii) The cross-ship cavities between cabin floor beams

(iii) Longitudinal 'manifold' cavities on each side of the cargo deck, running fore and aft in the space behind the upper sidewall areas of the cargo bay liner.

(iv) Air conditioning vents along the bottom of the cabin side-liner panels, which connect the side cavities below cabin floor level with the main passenger cabin.

If the containment barriers (i.e. modified cargo containers and cargo hold liner) can be made to prevent blast breakthrough into these cavities directly, then the only area where transfer can occur is at the interface between the container/cargo hold liner vent apertures and the fuselage skins at the blow-out region. This short distance will need to be sealed in order to form a short 'exhaust duct' between the container vent aperture and the fuselage skin. Since the shock and general explosive pressure will act mainly along the vent-duct axis, the pressure loading on the vent duct walls should not be excessive.

5.5 Attenuation of shock waves in structural cavities

To prevent the 'ducting' of any blast which does enter the fuselage cavities, either because of partial penetration of the containment barriers or leakage at the vent duct interfaces, the scheme requires the provision of lightweight energy absorbing material within the cavities to limit reflection and propagation of pressure waves within the cavities, and radiation of shock waves into the cabin from the conditioning air vents. Materials such as vermiculite, which are of low density yet have excellent explosive energy absorption properties, may have application in this area, perhaps in lieu of the existing insulation material.

Since the existing cavities often serve as part of the air conditioning outflow circuit, some consideration will need to be given to finding an alternative route. However, the flow rates are small compared with the total cross-sectional flow potential of the cavities and this function could be served by separate air conditioning ducts, or perhaps by restricting access to one or two cavities only (thus limiting the risk), or by using some form of blast valve to close off the air conditioning vents. Similarly, the requirement to vent pressure from the cabin in the event of a cargo bay decompression would also need to be addressed.

APPENDIX F

BAGGAGE CONTAINER EXAMINATION, RECONSTRUCTION AND RELATIONSHIP TO THE AIRCRAFT STRUCTURE

1. Introduction

During the wreckage recovery operation it became apparent that some items, identified as parts of baggage containers, exhibited blast damage. It was confirmed by forensic scientists at the Royal Armaments Research and Development Establishment (RARDE), after detailed physical and chemical examination, that these items showed conclusive evidence of a detonating high performance plastic explosive. It was therefore decided to segregate identifiable container parts and reconstruct any that showed evidence from the effect of Improvised Explosive Device (IED). It was evident, from the main wreckage layout that the IED had been located in the forward cargo hold and, although all baggage container wreckage was examined, only items from the forward hold showing the relevant characteristics were considered for the reconstruction. This Appendix documents the reconstruction of two particular containers and, from their position within the forward fuselage, defines the location of the IED.

2 Container Arrangement

Information supplied by Pan Am showed that this aircraft had been loaded with 12 baggage containers and two cargo pallets in the forward hold located as shown in Figure F-1. Three containers were recorded as being of the glass fibre reinforced plastic type (those at positions 11L, 13L and 21L) with the remaining 9 being of metal construction.

3. Container Description

All the baggage containers installed in the forward cargo hold were of the LD3 type (lower deck container, half width - cargo) and designated with the codes AVE, for those constructed from aluminum alloy, and AVA or AVN for those constructed from fibreglass. Each container was specifically identified with a four digit serial number followed by the letters PA and this nine digit identifier was present at the top of three sides of each container in black letters/numbers approximately 5 inches tall. Detail drawings and photographs of a typical metal container are shown in Figure F-2. Each container was essentially a 5 feet cube with a 17 inch extension over its full length to the left of the access aperture. In order to fit within the section of the lower fuselage this extension had a sloping face at its base joining the edge of the container floor to the left vertical sidewall at a position some 20 inches above the floor. The access aperture on the AVE type container was covered by a blue reinforced plastic curtain, fixed to the container at its top edge, braced by two wires and central and lower edge cross bars which engaged with the aperture structure. The strength of this type of container superstructure was provided by the various extruded section edge members, attached to a robust floor panel, with a thin aluminum skin providing baggage containment and weatherproofing.

4. Container Identification

Discrimination between forward and rear cargo hold containers was relatively straightforward as the rear cargo hold wreckage was almost entirely confined to the town of Lockerbie and was characteristically different from that from the forward hold, in that it was generally severely crushed and covered in mud. The forward hold debris, by comparison, was mostly recovered from the southern wreckage trail some distance from Lockerbie and had mainly been torn into relatively large sections.

All immediately identifiable parts of the forward cargo containers were segregated into areas designated by their serial numbers and items not identified at that stage were collected into piles of similar parts for later assessment. As a result of this two containers, one metal and one fibreglass, were identified as exhibiting damage likely to have been caused by the IED. From the Pan Am records the metal container of these two had been positioned at position 14L, and the fibreglass at position 21L (adjacent positions, 4th and 5th from the front of the forward cargo hold on the left side). The serial numbers of these containers were respectively AVE 4041 PA and AVN 7511 PA.

5. Container Reconstruction

Those parts which could be positively identified as being from containers AVE 4041 PA and AVN 7511 PA were assembled onto one of three wooden frameworks; one each for the floor and superstructure of container 4041, and one for the superstructure of container 7511. Figures F-3 to F-9 show the reconstruction of container 4041 and Figure F-10 shows the reconstructed forward face of container 7511.
Approximately 85% of container 4041 was identified, the main missing sections being the aft half of the sloping face skin and all of the curtain. Two items were included which could not be fracture or tear matched to container 4041, however, they showed the particular type of blast damage exhibited only by items from this container.

While this work was in progress a buckled section of skin from container 4041 was found by an AAIB Inspector to contain, trapped within its folds, an item which was subsequently identified by forensic scientists at the Royal Armaments Research and Development Establishment (RARDE) as belonging to a specific type of radio-cassette player and that this had been fitted with an improvised explosive device.

Examination of all other component parts of the remaining containers from the front and rear cargo holds did not reveal any evidence of blast damage similar to that found on containers 4041 and 7511.

6. Wreckage Distribution

Those items which were positively identified as parts of container 4041 or 7511, and for which a grid reference was available, were found to have fallen close to the southern edge of the southern wreckage trail. This indicated that one of the very early events in the aircraft break-up sequence was the blast damage to, and ejection of, parts of these two containers.

7. Fuselage Reconstruction

In order to gain a better understanding of the failure sequence, that part of the aircraft's fuselage encompassing the forward cargo hold was reconstructed at AAIB Farnborough. After all available blast damaged pieces of structure had been added, the floor of container 4041 was installed as near to its original position as the deformation of the wreckage would allow and this is shown in Figure F-11. The presence of this floor panel in the fuselage greatly assisted the three-dimensional assessment of the IED location. Witness marks between this floor and the aircraft structure, tie down rail, roller rail and relative areas of blast damage left no doubt that container 4041 had been located at position 14L at the time of detonation.

8. Analysis

The general character of damage that could be seen on the reconstructions of containers 4041 and 7511 was not of a type seen on the wreckage of any of the other containers examined. In particular, the reconstruction of the floor of container 4041 revealed an area of severe distortion, tearing and blackening localised in its aft outboard quarter which, together with the results of the forensic examination of items from this part of the container, left no doubt that the IED had detonated within this container.

Within container 4041 the lack of direct blast damage (of the type seen on the outboard floor edge member and lower portions of the aft face structural members) on most of the floor panel in the heavily distorted area suggested that this had been protected by, presumably, a piece of luggage. The downward heaving of the floor in this area was sufficient to stretch the floor material, far enough to be cut by cargo bay sub structure, and distort the adjacent fuselage frames. This supported the view that the item of baggage containing the IED had been positioned fairly close to the floor but not actually placed upon it. The installation of the floor of container 4041 into the fuselage reconstruction (Figure F-11) showed the blast to have been centered almost directly above frame 700 and that its main effects had not only been directed mostly downwards and outboard but also rearwards. The blast effects on the aircraft skin were onto stringer 39L but centered at station 710 (Figure F-12). Downwards crushing at the top, and rearwards distortion of frame 700 was apparent as well as rearwards distortion of frame 720.

With the two container reconstructions placed together it became apparent that a relatively mild blast had exited container 4041 through the rear lower face to the left of the curtain and impinged at an angle on the forward face of container 7511. This had punched a hole, Figure F-10, approximately 8 inches square some 10 inches up from its base and removed the surface of this face inboard from the hole for some 50 inches. Radiating out from the hole were areas of sooting, and other black deposits, extending to the top of the container. No signs were present of any similar damage on other external or internal faces of container 7511 or the immediately adjacent containers 14R and 21R.

The above assessment of the directions of distortion, comparison of damage to both containers, and the related airframe damage adjacent to the container position, enabled the most probable lateral and vertical location of the IED to be established as shown in Figure F-13, centered longitudinally on station 700.

9. Conclusions

Throughout the general examination of the aircraft wreckage, direct evidence of blast damage was exhibited on the airframe only in the area bounded, approximately, by stations 700 and 720 and stringers 38L and 40L. Blast damage was found only on pieces of containers 4042 and 7511, the relative location and character of which left no doubt that it was directly associated with airframe damage. Thus, these two containers had been loaded in positions 14L and 21L as recorded on the Pan Am cargo loading documents. There was also no doubt that the IED had been located within container 14L, specifically in its aft outboard quarter as indicated in Figure F-13, centered on station 700.

Blast damage to the forward face of container 7511 was as a direct result of hot gases/fragments escaping from the aft face of container 4041. No evidence was seen to suggest that more than one IED had detonated on Flight PA103.

APPENDIX G

MACH STEM SHOCK WAVE EFFECTS

1. Introduction

An explosive detonation within a fuselage, in reasonably close proximity to the skin, will produce a high intensity shock wave which will propagate outwards from the centre of detonation. On reaching the inner surface of the fuselage skin, energy will partially be absorbed in shattering, deforming and accelerating the skin and stringer material in its path. Much of the remaining energy will be transmitted, as a shock wave, through the skin and into the atmosphere but a significant amount of energy will be returned as a reflected shock wave, which will travel back into the fuselage interior where it will interact with the incident shock to produce Mach stem shocks - re-combination shock waves which can have pressures and velocities of propagation greater than the incident shock.

The Mach stem phenomenon is significant for two reasons. Firstly, it gives rise (for relatively small charge sizes) to a geometric limitation on the area of skin material which the incident shock wave can shatter. This geometric limitation occurs irrespective of charge size (within the range of charge sizes considered realistic for the Flight PA103 scenario), and thus provides a means of calculating the standoff distance of the explosive charge from the fuselage skin. Secondly, the Mach stem may have been a significant factor in transmitting explosive energy through the fuselage cavities, producing damage at a number of separate sites remote from the source of the explosion.

2. Mach stem shock wave formation

A Mach stem shock is formed by the interaction between the incident and reflected shock waves, resulting in a coalescing of the two waves to produce a new, single, shock wave. If an explosive charge is detonated in a free field at some standoff distance from a reflective surface, then the incident shock wave expands spherically until the wave front contacts the reflective surface, when that element of the wave surface will be reflected back (Figure G-1). The local angle between the spherical wave front and the reflecting surface is zero at the point where the reflecting surface intersects the normal axis, resulting in wave reflection directly back towards the source and maximum reflected overpressure at the reflective surface. The angle between the wave front and the reflecting surface at other locations increases with distance from the normal axis, producing a corresponding increase in the oblique angle of reflection of the wave element, with a corresponding reduction in the reflected overpressure. (To a first order of approximation, explosive shock waves can be considered to follow similar reflection and refraction paths to light waves, ref: "Geometric Shock Initiation of Pyrotechnics and Explosives", R Weinheimer, McDonnel Douglas Aerospace Co.) Beyond some critical (conical) angle about the normal axis, typically around 40 degrees, the reflected and incident waves coalesce to form Mach stem shock waves which, effectively, bisect the angle between the incident and reflected waves, and thus travel approximately at right angles to the normal axis, i.e.parallel with the reflective surface (detail "A", figure G-1).

3. Estimation of charge standoff distance from the fuselage skin

Within the constraint of the likely charge size used on Flight PA103, calculations suggested that the initial Mach stem shock wave pressure close to the region of Mach stem formation (i.e. the shock wave face-on pressure, acting at right angles to the skin), was likely to be more than twice that of the incident shock wave, with a velocity of propagation perhaps 25% greater. However, the Mach stem out-of-plane pressure, i.e.the pressure felt by the reflecting surface where the Mach stem touches it, would have been relatively low and insufficient to shatter the skin material. Therefore, provided that the charge had sufficient energy to produce skin shatter within the conical central region where no Mach stems form, the size of the shattered region would be a function mainly of charge standoff distance, and charge weight would have had little influence. Consequently, it was possible to calculate the charge standoff distance required to produce a given size of shattered skin from geometric considerations alone. On this basis, a charge standoff distance of approximately 25 to 27 inches would have resulted in a shattered region of some 18 to 20 inches in diameter, broadly comparable to the size of the shattered region evident on the three-dimensional wreckage reconstruction.

Whilst the analytical method makes no allowance for the effect of the IED casing, or any other baggage or container structure interposed between the charge and the fuselage skin, the presence of such a
barrier would have tended to absorb energy rather than re-direct the transmitted shock wave; therefore its presence would have been more critical in terms of charge size than of position. Certainly, the standoff
distance predicted by this method was strikingly similar to the figure of 25 inches derived independently from the container and fuselage reconstructions.

EXPLOSIVE DECOMPRESSION-- LOSS OF CARGO DOOR IN FLIGHT UNITED AIRLINES FLIGHT 811 BOEING 747-122, N4713U HONOLULU, HAWAII FEBRUARY 24, 1989

Adopted: March 18, 1992 Notation 5059C

Abstract: This report explains the explosive decompression resulting from the loss of a cargo door in flight on United Airlines flight 811, a Boeing 747-122, near Honolulu, Hawaii, on February 24, 1989. The safety issues discussed in the report are the design and certification of the B-747 cargo doors, the operation and maintenance to assure the continuing airworthiness of the doors, and emergency response. Recommendations concerning these issues were made to the Federal Aviation Administration, the State of Hawaii, and the U.S. Department of Defense.

CONTENTS

EXECUTIVE SUMMARY

On February 24, 1989, United Airlines flight 811, a Boeing 747-122, experienced an explosive decompression as it was climbing between 22,000 and 23,000 feet after taking off from Honolulu, Hawaii, en route to Sydney, Australia with 3 flightcrew, 15 flight attendants, and 337 passengers aboard.

The airplane made a successful emergency landing at Honolulu and the occupants evacuated the airplane. Examination of the airplane revealed that the forward lower lobe cargo door had separated in flight and had caused extensive damage to the fuselage and cabin structure adjacent to the door. Nine of the passengers had been ejected from the airplane and lost at sea.

A year after the accident, the Safety Board was uncertain that the cargo door would be located and recovered from the Pacific Ocean. The Safety Board decided to proceed with a final report based on the available evidence without the benefit of an actual examination of the door mechanism. The original report was adopted by the Safety Board on April 16, 1990, as NTSB/AAR-90/01.

Subsequently, on July 22, 1990, a search and recovery operation was begun by the U.S. Navy with the cost shared by the Safety Board, the Federal Aviation Administration, Boeing Aircraft Company, and United Airlines. The search and recovery effort was supported by Navy radar data on the separated cargo door, underwater sonar equipment, and a manned submersible vehicle. The effort was successful, and the cargo door was recovered in two pieces from the ocean floor at a depth of 14,200 feet on September 26 and October 1, 1990.

Before the recovery of the cargo door, the Safety Board believed that the door locking mechanisms had sustained damage in service prior to the accident flight to the extent that the door could have been closed and appeared to have been locked, when in fact the door was not fully latched. This belief was expressed in the report and was supported by the evidence available at the time. However, upon examination of the door, the damage to the locking mechanism did not support this hypothesis. Rather, the evidence indicated that the latch cams had been backdriven from the closed position into a nearly open position after the door had been closed and locked. The latch cams had been driven into the lock sectors that deformed so that they failed to prevent the back-driving.

Thus, as a result of the recovery and examination of the cargo door, the Safety Board's original analysis and probable cause have been modified. This report incorporates these changes and supersedes NTSB/AAR-90/01.

The issues in this investigation centered around the design and certification of the B-747 cargo doors, the operation and maintenance to assure the continuing airworthiness of the doors, cabin safety, and emergency response.

The National Transportation Safety Board determines that the probable cause of this accident was the sudden opening of the forward lower lobe cargo door in flight and the subsequent explosive decompression. The door opening was attributed to a faulty switch or wiring in the door control system which permitted electrical actuation of the door latches toward the unlatched position after initial door closure and before takeoff. Contributing to the cause of the accident was a deficiency in the design of the cargo door locking mechanisms, which made them susceptible to deformation, allowing the door to become unlatched after being properly latched and locked. Also contributing to the accident was a lack of timely corrective actions by Boeing and the FAA following a 1987 cargo door opening incident on a Pan Am B-747.

As a result of this investigation, the Safety Board issued safety recommendations concerning cargo doors and other nonplug doors on pressurized transport category airplanes, cabin safety, and emergency response.

WASHINGTON, D.C. 20594

AIRCRAFT ACCIDENT REPORT

EXPLOSIVE DECOMPRESSION-- LOSS OF CARGO DOOR IN FLIGHT UNITED AIRLINES FLIGHT 811 BOEING 747-122, N4713U HONOLULU, HAWAII FEBRUARY 24, 1989

1. FACTUAL INFORMATION

1.1 History of the Flight

On February 24, 1989, United Airlines (UAL) flight 811, a Boeing 747-122 (B-747), N4713U, was being operated as a regularly scheduled flight from Los Angeles, California (LAX) to Sydney, Australia (SYD), with intermediate stops in Honolulu, Hawaii (HNL) and Auckland, New Zealand (AKL).

The flightcrew assigned to the LAX/HNL route segment reported no difficulty during their flight.

A flightcrew change occurred when flight 811 arrived at HNL. The oncoming captain stated that he and his crew reported to UAL operations 1 hour and 15 minutes prior to the flight's scheduled departure time from HNL. The crew had completed a 34-hour layover (rest period) in HNL.

The captain reviewed the flight plan, the weather, pertinent NOTAMs, and maintenance records, and signed the Instrument Flight Rules (IFR) clearance before boarding the airplane.

Flight 811 departed HNL gate 10 at 0133 Honolulu Standard Time (HST), 3 minutes after the scheduled departure time, with 3 flight crewmembers, 15 cabin crewmembers, and 337 passengers. The flightcrew attributed the short delay to cabin crew problems with arming the 5L cabin door emergency exit slide and the normal securing of the 2L door after a somewhat extended passenger boarding process. The second officer stated that all cabin and cargo door warning lights were out prior to the airplane's departure from the gate. He said that he dimmed the annunciator panel lights at his station while the airplane was departing the gate area.

The captain was at the controls when the flight was cleared for takeoff on HNL runway 8R at 0152:49 HST. The auxiliary power unit (APU), which was used during the takeoff, was shutdown shortly after making the initial power reduction to climb thrust. The flightcrew reported the airplane's operation to be normal during the takeoff and during the initial and intermediate segments of the climb. The flightcrew observed en route thunderstorms both visually and on the airplane's weather radar, so they requested and received clearance for a deviation to the left of course from the HNL Combined Center Radar Approach

Control (CERAP). The captain elected to leave the passenger seat belt sign "on."

The flightcrew stated that the first indication of a problem occurred while the airplane was climbing between 22,000 and 23,000 feet at an indicated airspeed (IAS) of 300 knots. They heard a sound, described as a "thump," which shook the airplane. They said that this sound was followed immediately by a "tremendous explosion." The airplane had experienced an explosive decompression. They said that they donned their respective oxygen masks but found no oxygen available. The airplane cabin altitude horn sounded and the flightcrew believed the passenger oxygen masks had deployed automatically.

The captain immediately initiated an emergency descent, turned 180(to the left to avoid a thunderstorm, and proceeded toward HNL. The first officer informed CERAP that the airplane was in an emergency descent and appeared to have lost power in the No. 3 engine. The appropriate 7700 emergency code was placed in the airplane's radar beacon transponder and an emergency was declared with CERAP at approximately 0220 HST. The No. 3 engine was shut down shortly after commencing the descent because of heavy vibration, no N1 compressor indication, low exhaust gas temperature (EGT), and low engine pressure ratio (EPR).

The second officer then left the cockpit to inspect the cabin area and returned to inform the captain that a large portion of the forward right side of the cabin fuselage was missing. The captain subsequently shut down the No. 4 engine because of high EGT and no N1 compressor indication, accompanied by visible flashes of fire. The flightcrew initiated fuel dumping during the descent to reduce the airplane landing weight.

The airplane was cleared for an approach to HNL runway 8L. The final approach was flown at 190 to 200 knots with the No. 1 and No. 2 engines only. During flap extension, the flightcrew observed an indication of asymmetrical flaps as the flap position approached 5(. The flightcrew decided to extend inboard trailing edge flaps to 10(for the landing. The right outboard leading edge flaps did not extend during the flap lowering sequence. The airplane touched down on the runway, approximately 1,000 feet from the approach end, and came to a stop about 7,000 feet later. The captain applied idle reverse on the Nos. 1 and No. 2 engines and employed moderate to heavy braking to stop the airplane. At 0234 (HST), HNL tower was notified by the flightcrew that the airplane was stopped and an emergency evacuation had commenced on the runway.

After the accident, UAL ramp service personnel, who had been involved with the cargo loading and unloading of flight 811 before takeoff from HNL, stated that they had opened and closed the forward cargo door electrically. They said that they had observed no damage to the cargo door. The ramp service personnel said that they had verified that the forward cargo door was flush with the fuselage of the airplane, that the master door latch handle was stowed, and that the pressure relief doors were flush with the exterior skin of the cargo door.

The dispatch mechanic stated that, in accordance with UAL procedures, he had performed a "circle check" prior to the airplane's departure from the HNL gate. This check included verification that the cargo doors were flush with the fuselage of the airplane, that the master latch lock handles were stowed, and that the pressure relief doors were flush or within 1/2 inch of the cargo door's exterior skin. He said a flashlight was used during this inspection.

The second officer stated that, in accordance with UAL Standard Operating Procedures (SOP) he had performed an operational check of the door warning annunciator lights as part of his portion of the cockpit preparation. The second officer also stated that he used a flashlight while performing an exterior inspection, again in accordance with UAL procedures. The exterior inspection was conducted while ramp service personnel were performing cargo loading operations and the cargo doors were open. He stated that he had observed no abnormalities or damage.

1.2 Injuries to Persons

Injuries Flightcrew Cabincrew Passengers Others Serious *Lost in flight. An extensive air and sea search for the passengers was unsuccessful.

1.3 Damage to the Airplane

The primary damage to the airplane consisted of a hole on the right side in the area of the forward lower lobe cargo door, approximately 10 by 15 feet large. The cargo door fuselage cutout lower sill and side frames were intact but the door was missing (see figures 1 and 2). An area of fuselage skin measuring about 13 feet lengthwise by 15 feet vertically, and extending from the upper sill of the forward cargo door to the upper deck window belt, had separated from the airplane at a location above the cargo door extending to the upper deck windows. The floor beams adjacent to and inboard of the cargo door area had been fractured and buckled downward.

Examination of all structure around the area of primary damage disclosed no evidence of preexisting cracks or corrosion. All fractures were typical of fresh overstress breaks.

Debris had damaged portions of the right wing, the right horizontal stabilizer, the vertical stabilizer and engines Nos. 3 and 4. No damage was noted on the left side of the airplane, including engines Nos. 1 and 2.

The right wing had sustained impact damage along the leading edge between the No. 3 engine pylon and the No. 17 variable camber leading edge flap. Slight impact damage to the No. 18 leading edge flap was noted.

There was a break and scuff in the wing leading edge aft of engine No. 4 and a scuff in the wing leading edge outboard of engine No. 4. There was a large indentation (to a depth of nearly 8 inches) in the area just above the outboard landing light, and the landing light covers were broken. There was a small puncture in the upper surface of the No. 14 krueger flap and impact damage to the wing leading edge just aft of the No. 14 krueger flap. There was a gash on the upper wing surface aft of the No. 14 krueger flap and leading edge, as well as punctures to the wing leading edge aft of the number 16 krueger flap. The under wing surface aft of the krueger flaps also sustained impact damage.

The right wing also had sustained damage at the wing-to-body fairing and two flap track canoe fairings.1 Wing-to-body fairing damage was limited to surface scraping forward of and below the wing. The outboard surface of the No. 6 flap track canoe fairing revealed a slightly more significant gouge mark. The most severe damage was evident on the inboard surface of the No. 8 flap track canoe fairing, where three separate punctured areas were observed. The trailing edge flaps were not damaged.

The leading edge of the right horizontal stabilizer had several dents. The most severe dents, located 8 to 10 feet from the stabilizer root, were approximately 3 inches wide and 1 inch deep. No punctures were found. The vertical stabilizer had multiple small and elongated indentations with a maximum depth of 1/2 inch near the right base of the leading edge. A small gouge and two small scrapes were noted at midspan of the upper rudder.

A piece of cargo container was found lodged between the No. 3 engine pylon (inboard) and the wing underside. The piece of metal had severed the pneumatic duct for the leading edge flaps. Various nicks and punctures were evident on the inboard side of the No. 3 engine pylon. The No. 4 engine pylon had a small puncture near the leading edge of the wing.

The external surfaces of the No. 3 engine inlet cowl assembly exhibited foreign object damage including small tears, scuffs and a large outwardly directed hole. The entire circumference of all the acoustic (sound attenuator) panels installed on the inlet section of the cowl had been punctured, torn, or dented. None of the No. 3 engine cases were penetrated by objects, nor was there evidence of fire damage to any visible engine components and accessories. The

leading edges of all fan blade airfoils on the No. 3 engine exhibited extensive foreign object damage.

External damage to the No. 4 engine inlet and core cowls was confined to the inboard side of the inlet cowl assembly. The damage consisted of one major scuff mark, four lesser scuff marks and one crescent- shaped cut. The sound attenuator panels that were installed in the inlet area of the inlet cowl assembly had not been penetrated. The No. 4 engine fan blade airfoils had sustained both soft and hard object damage from foreign objects.

The cargo door separation resulted in the loss of fuselage shell structure above the cargo door, along with main cabin floor structure below seats 8GH through 12GH (see figure 3). The missing floor area extended inboard from the interior of the right side fuselage wall to the inboard seat track of seats 8GH through 12GH.

The supply and fill lines from the flightcrew oxygen bottle, and the supply line for the passenger oxygen system had been broken below the cabin floor inboard of the missing cargo door.

The two cabin pressurization out-flow valves, located on the underside of the fuselage, aft of the rear cargo compartment, were found fully open. The two over-pressure relief valves located on the forward left side of the airplane were found in the normal closed position. These valves were removed and bench tested. (See section 1.16.3, Pressurization System.) The majority of the cabin floor-to-cargo compartment blowout panels were found activated. The blowout panels are designed to relieve excess

pressure differential following an explosive decompression to prevent catastrophic damage to the cabin floor structures.
The estimated damage to the airplane was $14,000,000, based on UAL's costs to repair it.

1.4 Other Damage

No other property damage resulted from this accident.

1.5 Personnel Information

The crew consisted of 3 flight crewmembers (the captain, the first officer, and the second officer) and 15 cabin crewmembers. (See appendix B.)

1.6 Aircraft Information

1.6.1 General

On February 24, 1989, the United Airlines B-747 fleet consisted of 31 airplanes, including: 2 B-747-222B, 11 B-747-SP, 5 B-747-123, and 13 B-747-122 series airplanes. N4713U was equipped with four Pratt & Whitney model JT9D engines.
The accident airplane, serial No. 19875, registered in the United States as N4713U, was manufactured as a Boeing 747-122 transport category airplane by the Boeing Commercial Airplane Company (Boeing), Seattle, Washington, a Division of the Boeing Company. N4713U, the 89th B-747 built by Boeing, was manufactured in accordance with Federal Aviation Administration (FAA) type certificate No. A20WE, as approved on December 30, 1969. The airplane was certificated in accordance with the provisions of 14 CFR Part 25, effective February 1, 1965.
The maximum calculated takeoff weight for flight 811 was 706,000 pounds. The flight plan data showed an actual takeoff weight of 697,900 pounds. The center of gravity (CG) for takeoff was computed at 20.4 percent mean aerodynamic chord (MAC). The forward and aft CG limits were 12 and 29.7 percent MAC, respectively.
At the time of the accident, N4713U had accumulated 58,815 total flight hours and 15,028 flight cycles. N4713U had not been

involved in any previous accident. Records indicated that the airplane had been inspected and maintained in accordance with the General Maintenance Program as defined in UAL Operations Specifications and in accordance with the FAA approved Aircraft and Powerplants Reliability Program. The records indicated that all required inspection and maintenance actions had been completed within specified time limits and all applicable airworthiness directives (AD) had been accomplished or were in the process of being accomplished, with the exception of AD 88-12-04, which was applicable to the B-747 lower lobe cargo door, and which had only been complied with partially. (See section 1.6.8 for explanation).

1.6.2 Cargo Door Description and Operation

Both the forward and aft lower cargo doors are similar in appearance and operation. They are located on the lower right side of the fuselage and are outward-opening. The door opening is approximately 110 inches wide by 99 inches high, as measured along the fuselage.

Electrical power for operation of the cargo door switches and actuators is supplied from the ground handling bus, which is powered by either external power or the APU. See figure 17 for a diagram of the cargo door electrical circuitry. The engine generators cannot provide power to the ground handling bus. APU generator electrical power to the ground handling bus is interrupted when an engine generator is brought on line after engine start. The APU generator "field" switch can be reengaged by the flightcrew, if necessary on the ground, to power the ground handling bus. The air/ground safety relay automatically disconnects the APU generator from the ground handling bus, if it is energized, when the airplane becomes airborne and the air/ground relay senses that the airplane is off the ground.

The cargo door and its associated hardware are designed to carry circumferential (hoop) loads arising from pressurization of the airplane. These loads are transmitted from the piano hinge at the top of the door, through the door itself, and into the eight latches located along the bottom of the door. The eight latches consist of eight latch pins attached to the lower door sill and eight latch cams attached to the bottom of the door. The cargo door also has two midspan latches located along the fore and aft sides of the door. These midspan latches primarily serve to keep the sides of the door aligned with the fuselage. There are also four door stops which limit inward movement of the door. There are two pull-in hooks located on the fore and aft lower portion of the door, with pull-in hook pins on the sides of the door frame. (See figure 4 for cargo door components).

The cargo doors on the B-747 have a master latch lock handle installed on the exterior of the door. The handle is opened and closed manually. The master latch lock handle simultaneously controls the operation of the latch lock sectors, which act as locks for the latch cams, and the two pressure relief doors located on the door. Figure 5 depicts a lock sector and latch cam in an unlocked and locked condition.

Figure 4.--Boeing 747 lower lobe forward cargo door.

Figure 5.--Cargo door latch cam and lock sector in unlocked and locked ositions.

The door has three electrical actuators for opening/closing and latching of the door. One actuator (main actuator) moves the door from the fully open position to the near closed position, and vice versa. A second actuator (pull-in hook actuator) moves the pull-in hooks closed or open, and the third actuator (latch actuator) rotates the latch cams from the unlatched position to the latched position, and vice versa. The latch actuator has an internal clutch, which slips to limit the torque output of the actuator.

Normally, the cargo doors are operated electrically by means of a switch located on the exterior of the fuselage, just forward of the door opening. The switch controls the opening and closing and the latching of the door. If at any time the switch is released, the switch will return to a neutral position, power is removed from all actuators, and movement of the actuators ceases.

In order to close the cargo door, the door switch is held to the "closed" position, energizing the closing actuator, and the door moves toward the closed position. After the door has reached the near closed position, the hook position switch transfers the electrical control power to the pull- in hook actuator, and the cargo door is brought to the closed position by the pull-in hooks. When the pull-in hooks reach their fully closed position, the hook-closed switch transfers electrical power to the latch actuator. The latch actuator rotates the eight latch cams, mounted on the lower portion of the door, around the eight latch pins, attached to the lower door sill. At the same time, the two midspan latch cams, located on the sides of the door rotate around the two midspan latch pins located on the sides of the door frame. When the eight latch cams and the two mid-span cams reach their fully closed position, electrical power is removed from the latch actuator by the latch-closed switch. This completes the electrically powered portion of the door closing operation. The door can also be operated in the same manner electrically by a switch located inside the cargo compartment adjacent to the door.

The final securing operation is the movement of lock sectors across the latch cams. These are manually moved in place across the open mouth of each of the eight lower cams through mechanical linkages to the master latch lock handle. The position of the lock sectors is indicated indirectly by noting visually the closed position of the two pressure relief doors located on the upper section of each cargo door. The pressure relief doors are designed to relieve any residual pressure differential before the cargo doors are opened after landing, and to prevent pressurization of the airplane should the airplane depart with the cargo doors not properly secured. The pressure relief doors are mechanically linked to the movement of the lock sectors. This final procedure also actuates the master latch lock switch, removing electrical control power from the opening and closing control circuits, and also extinguishes the cockpit cargo door warning light through a switch located on one of the pressure relief doors. Opening the cargo door is accomplished by reversing the above procedure.

The B-747 cargo door has eight (8) view ports located beneath the latch cams for direct viewing of the position of the cams by means of alignment stripes. Procedures for using these view ports for verifying the position of the cams were not in place or required by Boeing, the FAA, or UAL (see 1.17.5 for additional information).

Closing the door manually is accomplished through the same sequence of actions without electrical power. The door actuator mechanisms are manually driven to a closed and latched position by the use of a one-half inch socket driver. The door can also be opened manually with the use of the socket driver. There are separate socket drives for the door raising/lowering mechanism, the pull-in hooks, and the latches.

Operating procedures for the normal electrical operation of the forward and aft cargo doors are outlined in the UAL Maintenance Manual (MM). Authorization for deferral of maintenance on the door power system is contained in the UAL B-747 Minimum Equipment List (MEL). In addition, operating procedures for dispatching aircraft with an inoperative door electrical power system (manual operation) are specified in the operator's MEL.

The UAL MM differs from Boeing's recommended MM. UAL had modified Boeing printed material or replaced pages with their own methods and procedures for conducting maintenance functions. The modifications to the manufacturer's MM were accepted by the FAA through "approval" by the FAA Principal Maintenance Inspector (PMI). Electrical cargo door open/close operations in the UAL and Boeing MM's are approximately the same, except the final "Caution" statement differs in methods to ensure that the latch cams are closed:

United Airlines Maintenance Manual

CAUTION DO NOT FORCE HANDLE. LATCH CAMS NOT FULLY CLOSED COULD CAUSE HANDLE MECHANISM SHEAR RIVET TO SHEAR.

Boeing Airplane Company Maintenance Manual

CAUTION DO NOT FORCE HANDLE. IF RESISTANCE IS FELT, CHECK LATCH ALIGNMENT STRIPES THROUGH VIEWING PORTS IN DOOR. LATCH CAMS NOT FULLY CLOSED COULD CAUSE HANDLE MECHANISM SHEAR RIVET TO SHEAR.

The following step in Boeing's MM does not appear in the UAL MM: "Check that the Cargo Door Warning Light on flight engineer panel goes out." The UAL flightcrew checklist includes a check of the warning light as part of the cockpit procedures for dispatch.

Prior to the issuance of AD-88-12-04 (see 1.6.8), UAL ramp service personnel only operated the cargo doors electrically. Manual operation was accomplished only by maintenance personnel. AD-88-12-04 required the additional procedure of recycling the master latch lock handle following manual operation of the latch actuator.

1.6.3 UAL Boeing 747 Special Procedures--Doors

The Safety Board's investigation revealed that UAL had published a "special maintenance procedure" in the UAL MEL for manual operation of the cargo door. The Maintenance Manual Special Procedures, 5-8-2-52, dated January 1988, were incorporated into UAL's MEL for use by maintenance controllers and work foremen in issuing instructions or procedures to mechanics. The procedure allowed the use of a special 1/2-inch socket drive wrench as the primary tool for use in manually opening or closing the cargo door. The document further authorized, as an alternate tool, an air-driven torque-limiting screwdriver. UAL procedures required approval by San Francisco Line Maintenance and the station maintenance coordinator before an air-driven screwdriver could be used to operate the doors of a B-747 airplane with an inoperative cargo door power system.

At the Safety Board's public hearing, the FAA PMI and the FAA B-747 maintenance inspector for UAL testified that prior to the accident they were unaware of an FAA authorization for UAL's use of an air-driven torque-limiting screwdriver on B-747 cargo doors. However, the FAA's approval for the use of the tool was noted in the MEL section of the airline's maintenance manual. The original approval had occurred before the current inspectors assumed their respective positions. Both testified that they had not reviewed UAL's B-747 MEL because they assumed that the previous inspectors had reviewed it.

According to UAL, the calibration/adjustment for the torque-limited air-driven screwdrivers was tested every six months. Safety Board investigators found no records for the calibration/adjustment of the power tools used to manually open and close UAL B-747 cargo doors.

The Safety Board received statements from UAL supervisory maintenance personnel at all UAL stations and contract facilities for B-747 operations indicating that air-driven screwdrivers had not been used by maintenance personnel to open or close the forward cargo door on N4713U in the months prior to the accident.

1.6.4 UAL Maintenance Program

Airplanes operated by UAL are maintained under an FAA-approved continuous airworthiness maintenance program, as required by 14 CFR Part 121, Subpart L. The requirements of the UAL maintenance program are detailed in their Operations Specifications, dated November 21, 1988. Generally, UAL has an overall in-house capability to perform virtually all of the maintenance required on its own airframes and powerplants. All of the required major airframe and powerplant maintenance for N4713U had been performed at the UAL maintenance facility in San Francisco, California.

UAL's maintenance and inspection program is scheduled either at specific flight hour or calendar intervals. These maintenance and inspection programs are designated as: Service No. 1, Service No. 2, or A, B, C, MPV, and D Checks.

The work scope of Service Checks consists of a general inspection of the airplane and engines, including servicing of consumable fluids, oxygen, and tire pressures. The Service No. 1 check involves an inspection at each maintenance facility where the airplane lands. The Service No. 2 check is performed at a maintenance facility where the airplane is scheduled for at least 12 hours of ground time. The maximum time interval between Service No. 2 Checks is not to exceed 65 flight hours.

The "A" Check is performed at intervals not to exceed 350 flight hours. This check includes an extended inspection of the cockpit, cabin, cargo compartments, landing gear, tires, and brakes. It does not include a detailed inspection of the cargo doors.

The Phase Check ("B" Check) is scheduled on a calendar basis, not to exceed 131 days. The scope of the "B" Check contains items of inspection such as interior safety equipment and functional verification of various aircraft systems and components. It does not include a detailed inspection of the cargo doors.

The "C" Check is heavy maintenance oriented and is scheduled on a calendar basis, every 13 months. The "C" Check work scope is substantial and includes:

structural inspection items;

corrosion repair;

prevention and inspection of critical flight control systems; and,

a detailed inspection of the cargo doors.
The Mid-Period Visit (MPV) Check is a heavy maintenance inspection that is scheduled at intervals not to exceed 5 years. Items requiring scheduled overhaul are contained in the check as well as inspections of the airplane structure and interior.
The D Check, completes the routine scheduled B-747 maintenance plan and is scheduled at intervals not to exceed 9 years. The work scope is very similar to the MPV Check and consists of heavy maintenance to the airplane structure, landing gear, interior, and airplane systems, including the cargo doors.

1.6.5 Maintenance Records Review

A review of the airplane's history indicated that the forward and aft cargo doors were the original doors and neither had been removed for repair or replaced for cause. There was no record of major repair to either door or adjacent airplane structure.
The forward cargo door's forward mid-span latch pin had been removed because of gouging of the pin surface, during the last "C" check on
November 28, 1988. According to the available maintenance documents, including the most recent "D" check, a full cargo door rigging check had not been accomplished. UAL maintenance personnel indicated that no rigging of the forward or aft cargo doors was required during the following checks:

1. "D" check accomplished April 1984;
2. "C" checks accomplished November 11, 1987, and November 28, 1988; and,
3. "B" checks accomplished March 21, 1988 and July 27, 1988;

The records prior to the "D" check in 1984 and the "C" check accomplished in November 1987 were not required to be retained. This procedure complies with FAR 121.380.
The logbook of N4713U was reviewed and all numbered pages were in sequential order with none missing. The airplane had been released for flight by UAL, HNL Maintenance, in accordance

with UAL procedures. The Los Angeles to HNL segment of flight 811, on February 23, 1989, generated four logbook discrepancy entries. All items were cleared by HNL maintenance and none were related to the cargo door. No new deferred items were generated and no current deferred items were corrected. The Maintenance Release document for flight 811 indicated that all deferred items were in accordance with the UAL Minimum Equipment List (MEL) and none referenced the forward cargo door.

UAL stores its maintenance information in an "electronic logbook," entitled Aircraft Maintenance Information System (AMIS). This system tracks on a daily and worldwide basis the flightcrew defect reports, all nonroutine maintenance defects, and maintenance corrective actions for the UAL airplane fleet. The system follows an Airline Transport Association (ATA) chapter format. According to UAL, the AMIS information is used as part of UAL's FAA approved maintenance reliability program affording the capability to assess trends at any given time.

A complete history of N4713U was reviewed for the following ATA Chapters:

Chapter-00-Miscellaneous

No significant items associated with the cargo door systems.

Chapter-21-Air Conditioning and Pressurization

An entry, dated August 19, 1988, indicated "Auto and Standby pressure controllers were erratic." UAL maintenance cleared this item as "Checked per Maintenance Manual Chapter (MM) 21-31-00.

Chapter-31-Instruments (Not related to any specific system)

No significant items associated with the cargo door systems.

Chapter-52-Doors (Cargo door section only)

During the period September 7, 1988, through November 1, 1988, a series of five discrepancies on the forward cargo door's electrical opening and closing system were noted. Ground handling personnel were required to operate the door by the manual system. On November 1, 1988, UAL maintenance corrective action for this discrepancy was signed off as, "replaced power unit [lift mechanism] per Maintenance Manual Chapter 52-34-02.

An expanded AMIS history of the N4713U forward cargo door system was prepared beginning December 1, 1988, and continuing until the date of the accident. The history tracked the airplane by each flight and station transited.

During the period December 5, 1988, through December 23, 1988, eight defect reports regarding the opening and closing of the forward cargo door were entered into the system. The reported defects involved problems with the cargo door not always operating with the normal electrical system. Appendix E contains the details of the writeups and corrective actions.

During the period December 23, 1988, through February 23, 1989, two forward cargo door discrepancies were noted on N4713U. On January 3, 1989, the discrepancy was, "Manual lock seals broken." The corrective action was signed off as, "recycled [door] per placard on door and documented. No door problems." On January 15, 1989, the discrepancy was, "cargo door seal, lower aft corner is torn and loose from retainer." The corrective action was "repaired seal." There were no further recorded discrepancies.

On February 23, 1989, a written discrepancy noted "Aft cargo door damaged aft lower corner." The corrective action listed, "Interim repair per (EVA) LM-8-433. Accomplish permanent repair within 60 flight hours."

Chapter-53-Structures (Fuselage)

During the period March 1988, through February 24, 1989, one defect was noted for each of the forward and aft cargo doors on N4713U.

Forward Cargo Door.--On September 6, 1988, the discrepancy was, "Approximately six inches of forward cargo door jamb damaged center of lower side sealing surface." The corrective action was, "Installed doubler and sealed area."

Aft Cargo Door.--On April 22, 1988, the discrepancy was, "Aft cargo door rear sill latch does not spring up to lock." The corrective action was, "Replaced latch."

1.6.6 Service Difficulty Report Information

A review was made of the Service Difficulty Reports (SDRs) for ATA Chapter 52 for all UAL Boeing 747 airplanes. Thirty-nine SDRs were recorded over the period January 31, 1983, through March 21, 1989. The following summarizes data concerning the forward and aft cargo doors:

cases of corrosion;

cases of cracking;

cases of door open (false) indications;

cases where cabin did not pressurize;

cases of cabin pressure loss; and

case of dent caused by ground equipment.

None of the noted SDR cases were recorded for N4713U.

1.6.7 Service Letters and Service Bulletins

Boeing issues information to its customers via Service Letters (SL's) and Service Bulletins (SB's) to inform operators of reported and anticipated difficulties with various airplane models. Twelve SL's provided guidance for maintenance or information applicable to the B-747 cargo doors. Twenty-nine SB's provided guidance for maintenance or information applicable to the B-747 cargo door.

SB-747-52-2097, "Pressure Relief Door Shroud Installation--Lower Lobe and Side Cargo Doors," was issued on June 27, 1975. Revision 1 to SB-747-52-2097 was issued November 14, 1975. In general, the SB recommended the installation of shrouds on the inboard sides of the cargo door pressure relief door openings. The purpose of the shrouds was to prevent the possibility of the pressure relief doors being rotated (blown) to the closed position during the pressurization cycle. This condition could only occur if the master latch lock handle had been left open and the flightcrew failed to note the cargo door open warning before takeoff.

UAL records for N4713U indicated that SB-747-52-2097 had been complied with and the shrouds had been installed on the forward and aft cargo doors. However, examination of the aft cargo door on N4713U revealed that the shrouds were not in place. UAL could not find records to verify if the shrouds had been installed or if they had been removed from either door.

1.6.8 Airworthiness Directives

There had been 141 Airworthiness Directives (ADs) issued that were applicable to the accident airplane. Two ADs were pertinent to the cargo door. AD 79-17-02-R2 ("Inspection of Fore and Aft Lower Cargo Door Sill Latch Support Fittings,") required an inspection every 1,700 flight hours. The second, AD 88-12-04 ("To Insure That Inadvertent Opening Of The Lower Cargo Door Will Not Occur In Flight,") issued on May 13, 1988, required an initial one time inspection of the cargo door latch locking mechanisms within 30 days of issuance of the AD, and certain repetitive inspections until terminating action for the AD was taken.

The circumstances of a Pan American World Airways (Pan Am), Boeing 747-122 cargo door opening in flight (see 1.17.1 for details) led to the issuance of Boeing Alert Service Bulletins (ASB) 52A2206 on April 8, 1987, and 52A2209 on August 27, 1987, entitled, "Doors - Cargo Doors Lower Lobe Forward and Aft Cargo Doors, Latch Locking System Tests, Operation and Modification." Tests and investigation revealed that latch lock sectors would, in some instances, not restrain the latch cams from being driven open manually or electrically. Movement of the latch cams without first moving the lock sectors to the stowed [unlocked] position would cause bending, gouging, and breaking of the sectors. The FAA issued AD-88-12-04 to make the provisions of SB's 52A2206 and 52A2209 mandatory.

The terminating action for AD 88-12-04 called for installing steel doublers to add strength to the lock sectors to prevent the latch cams from being able to be driven to the open position manually or electrically with the sectors in the locked position. AD 88-12-04 also required that, if the door could not be operated normally (electrically), a trained and qualified mechanic was to open and close the door manually, rather than ramp service personnel. Further, the AD required an inspection of the lock sectors for damage once a cargo door was restored to electrical operation after any malfunction had required manual operation of the door. The amount of time allowed for completing the terminating action portion of AD 88-12-04 was either 18 months or 24 months, from the issue date of the AD, depending on the Boeing 747 model series. Terminating action for the AD had not been accomplished on N4713U prior to the accident, nor was it required since, for this airplane, the deadline for compliance with the terminating action was January 1990. According to UAL, N4713U was scheduled for completion of the terminating action in April 1989, when the airplane was scheduled for other heavy maintenance.

During the Safety Board's investigation it was determined that a clerical error was made by UAL personnel, while attempting to expedite the processing of an advanced copy of a Notice of Proposed Rulemaking (NPRM 87-NM-148-AD), preceding AD 88-12-04. The error involved the omission of one line of text during the typing of the document. Because of that error, the portion of the text of the NPRM (and the final text of the AD) was left out of UAL's maintenance procedures. The omitted text required an inspection of the B-747 cargo door lock sectors every time a cargo door was restored to normal (electrical) operation after manual operation was required.

The UAL maintenance internal auditing system, including quality assurance personnel, did not detect the omission until after the accident. UAL personnel stated that, for unknown reasons, no one within the maintenance or quality assurance programs had reviewed the final AD language for comparison with the UAL maintenance procedure.

A review by Safety Board investigators of forms used by UAL to verify compliance with applicable FAA AD's issued indicated that all of the applicable mandatory ADs were satisfied within their specified time limits. The list provided by UAL to the FAA as part of the FAA's oversight responsibilities showed compliance with AD-88-12-04, with the exception of the terminating action.

Section 1.17.3 contains information relevant to the B-747 cargo door corrective actions taken since the accident.

1.7 Meteorological Information

The accident occurred in night visual meteorological conditions. No adverse weather was experienced, although the flight did have to deviate around thunderstorms during the descent.

1.8 Aids to Navigation

There were no navigational problems.

1.9 Communications

There were no radio communication difficulties between flight 811 and air traffic control (ATC). Members of the flightcrew did not have any difficulty in verbally communicating with each other; however, attempts to communicate with the cabin crewmembers by interphone were unsuccessful following the explosive decompression.

1.10 Aerodrome Information

After the explosive decompression, the airplane returned to HNL, a 14 CFR Part 139 certificated airport on the island of Oahu, Hawaii. The airport is located about 4 miles west of Honolulu, Hawaii.

HNL is a "joint use" airport that is used by the State of Hawaii, the U.S. Air Force, general aviation, commercial, air carrier, air taxi, and military aircraft. Aircraft Rescue and Fire Fighting (ARFF) services are provided by State and Hickam Air Force Base ARFF units. Prior to the emergency landing at Honolulu, flight 811 requested that all available rescue and medical equipment to be on hand when they landed. When the crash alarm was broadcast, all civilian and military fire units responded and were in position in 1-minute at pre-designated stations at runway 8 left.

The Safety Board's investigation revealed that there was no direct radio communications between the State Airport vehicles and Hickam ARFF vehicles. Because there were no direct radio communications, the Chief of the airport's units had to drive his vehicle to the vehicle of the Chief of the Hickam units to coordinate the positioning of ARFF units prior to the landing of United 811.

The Hickam vehicles are painted olive drab camouflage. During the response, the Chief of the State ARFF vehicles observed a near collision between a State and a Hickam vehicle. He attributed this to the camouflaged Hickam vehicle not being visually conspicuous in spite of the fact that each of the vehicles had a red rotating beacon operating. The response took place on a moonless night and in light rain.

1.11 Flight Recorders

The airplane was equipped with a Sundstrand model 573 digital type Flight Data Recorder (DFDR) and a Sundstrand model AV557-B Cockpit Voice Recorder (CVR).

Examination of the data plotted from the DFDR indicated that the flight was normal from liftoff to the accident. The recorder operated normally during the period. However, the decompression event caused a data loss of approximately 2 1/2 seconds. When the data resumed being recorded, all values appeared valid with the exception of the pitch and roll parameters. Lateral acceleration showed a sharp increase immediately following the decompression. Vertical acceleration showed a sharp, rapid change just after the decompression and a slight increase as the airplane began its descent.

The CVR revealed normal communication before the decompression. At 0209:09:2 HST, a loud bang could be heard on the CVR. The loud bang was about 1.5 seconds after a "thump" was heard on the CVR for which one of the flightcrew made a comment. The electrical power to the CVR was lost for approximately 21.4 seconds following the loud bang. The CVR returned to normal operation at 0209:29 HST, and cockpit conversation continued to be recorded in a normal manner.

1.12 Wreckage and Impact Information

An extensive air and surface search of the ocean conducted immediately following the accident failed to locate the portions of the airplane lost during the explosive decompression. However, the Safety Board, as well as other parties to the investigation, pursued several avenues to search for and recover the cargo door. Navy radar near Honolulu tracked debris that fell from the airplane when the cargo door was lost. Refinement of the radar data led to a probable "splashdown" point in the ocean. Further assistance from the Navy regarding the ocean currents and drift information led to a probable location of the cargo door and associated debris on the ocean floor.

The undersea search operation was begun on July 22, 1990, using the Orion, a state-of-the-art Navy side-scanning sonar "fish." Searching in the area selected by analysis of radar data and undersea currents, the Orion located a debris field on its first pass over the 14,200-foot-deep ocean floor. The second pass located a significant sonar target, which later analysis indicated was probably the cargo door. Since the Orion is only capable of searching, the debris field was marked with transponders for use during the subsequent recovery phase.

On September 14, 1990, the recovery ship Laney Chouest sailed from Pearl Harbor with the manned, deep-sea submersible Sea Cliff. Safety Board, FAA, Boeing, and UAL engineering staff assisted the recovery team aboard the Laney Chouest. After four dives in the area previously identified as the debris field, only pieces of cargo container and other small debris from the airplane had been recovered. (It appears that the significant target identified by the Orion was a piece of cargo container rather than the cargo door.) On the following dive, however, the lower portion of the cargo door was located and recovered. The fuselage structure above the cargo door was located and raised to the surface on the sixth dive, but heavy seas prevented its recovery. The upper portion of the door was recovered during the Sea Cliff's seventh dive on October 1, 1990. Afterward, it was decided that no further effort could be justified to recover the fuselage structure above the cargo door, and the recovery mission was terminated.

Following recovery of the cargo door, each piece was sprayed with a corrosion inhibitor. The ship promptly returned to Pearl Harbor, and the retrieved door portions were removed and examined before being shipped to Seattle, Washington, for detailed examinations under the supervision of Safety Board staff.

Visual examinations on the recovery ship and in Pearl Harbor confirmed that the cargo door lock sectors were in the locked position and that the latch cams were in the nearly open position. Figure 6 depicts the position of the lock sectors and cams as recovered from the ocean. There was no evidence of progressive fractures in the door structure.

The cost for the search mission was $193,000, and the cost for the recovery mission was $250,000. These costs were shared by the Safety Board, the FAA, UAL, and Boeing. Section 1.16 contains information on the examination of the recovered wreckage.

1.13 Medical and Pathological Information

Appendix D contains a list of injuries.

1.14 Fire

There was no fire in the cabin or fuselage. The fires in engines No. 3 and 4 were extinguished after the engines were shut down.

1.15 Survival Aspects

The fatal injuries were the result of the explosive nature of the decompression, which swept nine of the passengers from the airplane.

At 0210, the FAA notified the U.S. Coast Guard that a United Airlines, Inc., B-747, with a possible bomb on board, had experienced an explosion and was returning to HNL. The Coast Guard Cutter, Cape Corwin, departed Maui at 0248 to search the area for debris and the missing passengers. Ultimately, 4 shore commands, 13 surface/air units, and approximately 1,000 persons took part in the combined search and rescue (SAR) operation. The search was t™ erminated at 1200 on February 26, 1989, without recovery of any passenger bodies.

The flight attendants had approximately 20 minutes to prepare the cabin and the passengers for an imminent ocean ditching, and subsequently, for an emergency evacuation. During the 20 minutes they attended to injured flight attendants and passengers, attached the face masks to their emergency oxygen bottles, helped each other don life preservers, helped numerous passengers don life preservers, held up safety cards and life vests to call attention to these items for passengers to use, briefed "helper" passengers to assist in the evacuation, cleared debris away from the exit doors and aisles, closed the doors of the storage compartment above doors 2 left and 2 right, prepared the cabin for an emergency evacuation, and told the passengers to brace for impact.

Several problems were experienced by the flight attendants and the passengers following the decompression, while preparing for a possible ditching, and preparing for the emergency evacuation.

These problems included difficulties encountered by flight attendants in connecting face masks to their portable oxygen bottles, the lack of a sufficient number of megaphones, limited visibility from a flight attendant seat, overhead storage compartment doors opening, and donning and fastening life preservers.

Federal Aviation Regulation 14 CFR 25.1447 (c)(4) requires that "portable oxygen equipment must be immediately available for each cabin attendant." Those portable oxygen bottles on N4713U, which were readily available, were not immediately usable because the masks were not attached to the regulators. The flight attendants reported difficulties in attaching the masks to the regulators.

The aft purser ran back to the flight attendant jumpseat at door 5-left for a portable oxygen bottle. However, she found no bottle at this location (none was installed). She then ran back to the 4-left jumpseat, by which time she was "light headed." After the aft purser reached jumpseat 4-left, flight attendant No. 14, who was already sitting there, placed an oxygen mask on her face. The aft purser further stated, "considering the fact that in this case there was no other available source of oxygen, you can't imagine how horrible I felt going back there needing oxygen but finding no oxygen bottle at 5-left. It was terrifying."

A portable emergency oxygen bottle was not required to be stowed at the flight attendant seat at exit 5-right; however, one was stowed in the right coat closet behind the flight attendant seat. In addition, the left side closet and rest rooms were physically separated from the right side closet and rest rooms. This arrangement requires a flight attendant, who was seated at exit 5-left to walk around to the right side of the cabin to obtain the oxygen bottle.

Communication between the flight attendants and passengers was very difficult because of the high ambient noise level in the cabin after the decompression, even though the public address (PA) system was operational. Flight attendants were located at each of the 10 exit doors, yet there were only two megaphones required to be on the airplane; one located at door 1-left and another located a 4-left.

The flight attendants, who were responsible for each of these two doors, used the megaphones to broadcast commands to passengers in their immediate areas and to other flight attendants in preparation for the landing and subsequent evacuation. The other 13 flight attendants (including the one deadheading flight attendant) had to shout, use hand signals, and show passengers how to prepare for the evacuation by holding up passenger safety cards, so passengers could review the information and also know how to put on their life preservers.

As soon as the decompression occurred, the flight attendant in the upper deck business class section went to her jumpseat and donned her oxygen mask, life preserver, and restraint system. While she waited for instructions, and because of intense cabin noise she had to communicate with passengers by holding up a safety card and a life preserver. Passengers sitting in the front rows, in turn, showed safety cards and life preservers to other passengers seated behind them. Eventually everyone understood that they were to read the safety card and put on their preservers. However, the 5 foot 3 1/2 inch flight attendant stated that her jumpseat was so low that she could not directly observe the passengers in the 4th row (last).

A two door overhead stowage compartment that had formerly stored a life raft was located above each exit door. These compartments contained blankets and passenger carry-on luggage. At doors 2-left and 2-right the doors of each compartment had opened downward and blocked each exit. Also the contents of the compartments fell to the floor at the exits. The doors had to be closed before the evacuation because they

partially blocked the exit.
The chief purser was not able to tighten the life preserver's two straps around her waist and needed the deadheading flight attendant to tighten them for her. Several flight attendants and passengers had difficulties connecting the two straps around their waists. One flight attendant helped about 36 passengers don their preservers.
Safety Board investigators and United Airlines personnel examined several life preservers from each of the types of preservers produced by five manufacturers. The strap of one manufacturer's preserver was very difficult to tighten around the waist while another from the same manufacturer was easy to tighten. The two vests had different strap material and strap adjustment fittings. Also, the straps are very difficult, if not impossible, to tighten when they are pulled at an acute angle from the wearer's body, i.e. from about 45 to 70 degrees. Holding the hands and straps closer to the waist facilitates easier adjustment of the straps.

1.16 Tests and Research

1.16.1 Cargo Door Hardware Examinations

1.16.1.1 Before Recovery of the Door

The following forward cargo door closing and latching components were returned to the Safety Board's Materials Laboratory for analysis after they were documented in place on the airplane:
Two pull-in hook pins, one from the lower end of the forward side of the door body cutout forward frame, and one from the lower end of the aft side of the body cutout aft frame, with housings;
Two mid-span pins, one from the forward side of the door body cutout forward frame, and one from the aft side of the door body cutout aft frame.
All components were initially examined while installed on the

airplane. All eight forward cargo door latch pins, with housings, were removed for further laboratory examination. Also, for comparison, one of the latch pins, with housing, from the aft cargo door was also removed. For orientation purposes, the eight lower latch pin assemblies are referred to by number, with the No. 1 latch pin being the most forward on the lower door sill, and the No. 8 pin being the most aft. When referencing a circumferential location on the latch pins or mid-span pins, a clock position was used. The clock code was oriented looking forward with 12 o'clock being straight up and 9 o'clock being directly inboard.

Based on the orientation of the latching mechanisms, the fully unlatched latching cams would first contact the latch pins from about the 1:15 o'clock position to the 7:15 position as the door was closed. As the cams are being latched around the pins, they would rotate approximately 80(, making contact with the pins from about the 4:15 position to the 10:15 position (See figure 7).

Detailed examination of the exposed surface of the pins (the portion of the pins extending from the housings) revealed various types of wear and damage. In general, all of the forward door cargo latch pins had smooth wear over the entire portion of the pin area contacted by the cams during normal closing and opening of the door. The pins also had distinct roughened (smeared) areas between the 6:15 and the 7:30 positions (See figure 8). The roughened areas had evidence of "heat tinting" and transfer of cam material to the surface of the pins. On pins 1 and 8 the roughened areas extended past the pin bottom to the 5:00 position. The 7:30 position approximately corresponds to the area on the pin where the lower surface of the cam would be relative to the pin when the latch cams are in the unlatched or nearly unlatched position.

The forward pull-in hook pin was not significantly bent, but the structure to which it was attached was deformed outward, so the hook pin was deflected significantly outward. Three of the four bolts holding the aft pull-in hook pin had sheared, so the hook pin was also deflected outward. Both hook pin ends were damaged, but neither pin was significantly deformed along its length. There was significant heat tinting on the damaged area of the forward hook pin. Boeing engineering calculations determined that the pull-in hook pins would fail at a 3.5 psi differential cabin pressure with the latch cams unlatched.

The forward mid-span latch pin was relatively undamaged. The aft mid-span latch pin had definite areas of damage. Both pins had wear areas where the cams would contact the pins during latching.

1.16.1.2 After Recovery of the Door

The documentation of the recovered cargo door was divided into four areas: 1) door structure, 2) master latch lock system, 3) latch system, and 4) hook system. A description of the recovered door follows.

1. Door Structure:

The cargo door had fractured longitudinally near the mid-span lap joint near stringer 34R, just beneath the mid-span torque tubes. Except for an area of missing skin between frames 2 and 3 and a portion of frame webs where the upper latch lock torque tube had torn out, the frames and skin of the upper door piece mated to the lower door piece.2 Several areas of the upper door skin along the longitudinal fracture were bent back. In addition, a large area of lower door skin between frame 6 and the aft door edge had peeled downward from the fracture line. The two door pieces are shown together in Figures 9 and 10.

Examinations of the fracture surfaces of the skin and frames revealed no evidence of pre-existing cracks. All fractures were typical of overstress separation.

Seven of the eight lock sector slots in the lower beam showed evidence of contact and scraping by the lock sectors. Only the No.

1 lock sector slot was undamaged, although the bracket forward and above the No. 1 slot did appear to have been damaged by contact from the lock sector (slots numbered 1-8, forward-aft). The direction of the scraping on the slots could not be determined conclusively.

The decal covering the latch actuator manual drive port was found broken circumferentially around the edge of the port cover, which was loose and rotated from its normal position (See figure 11). There was an impression in the decal similar to a Phillips-head screw slot in line with the center of the retainer screw securing the cover. There was also a 0.06-inch-long linear slit from 10 to 4 o'clock approximately centered over the retainer screw head (See figures 12 and 13). There was no rotational tearing and no loss of decal material in the area covering the screw head location. During examinations of the door at Boeing, it was noted that the retainer bracket on the inside of the latch actuator manual drive port cover was bowed outward; the port cover was not deformed. The retainer bracket on the inside of the hook actuator manual drive port cover was similarly bowed outward, and the port cover was bowed outward.

The hinge that attaches the cargo door to the fuselage is comprised of several hinge sections--those attached along the upper edge of the cargo door and those along the fuselage just above the cargo door cutout--interconnected with hinge pins. The hinge pins and all hinge sections from N4713U's forward cargo door were intact; all hinge sections rotated relatively easily. All attach bolts from the hinge sections on the door remained attached; conversely, no bolts remained attached to the hinge sections on the fuselage. Several areas on the hinge sections, such as the fuselage hinge sections, showed evidence of contact from the door during overtravel (See figure 14). In addition, the fuselage forward hinge sections

were slightly bent. The upper flange of the door, to which the door hinges are attached, was not deformed. The forward cargo door can rotate open 143 degrees before the hinge would deform, permitting the door to contact the fuselage above.

Examination of the outer skin contour of the upper door piece revealed that it had been crushed inward. There were also many areas on the outer skin where blue and red paint transfer marks could be seen. These marks were generally forward of the aft pressure-relief door, and the blue marks were located above the red marks. The UAL paint pattern incorporates red and blue stripes along the fuselage above the cargo door. Figure 15 is a plot of the documented paint marks on the upper door piece.

There was no evidence of the pressure relief door shrouds found on the forward door; however, most of the inner door lining to which the shrouds attach was missing.

2. Master Latch Lock System:

All eight lock sectors were found in the locked position--actually past the fully locked position. They had been pulled through the lock sector slots in the lower beam of the cargo door. (When they are fully locked, the lock sectors should be recessed in the lower beam approximately 3/8 inch). All lock sectors had deflected off the high shoulder of the latch cams due to interference with the partially unlatched cams. Prior to disassembly of the components, the interference between the cams and the lock sectors was removed by rotating the cams to the latched position.

Examination of the lock sectors disclosed that the bottom of the lower arm of each lock sector was gouged. For seven of the eight lock sectors, the distance from the main gouge area to the location of the interference between the latch cam and the lock sector was approximately 0.75 inch. (The No. 2 lock sector was corroded and had fractured at the location of the large gouge common to the other seven lock sectors. Consequently, it was not in contact with the No. 2 latch cam when the door was retrieved).

The master latch lock handle housing and trigger were found relatively flush with the door outer skin. The top of the handle was recessed approximately 0.50 inch inward from flush, and the bottom of the handle was protruding approximately 0.40 inch outward from flush (See figure 16). This

Figure 15.--Documented paint marks on outer skin of upper door piece. Dashed line is approximately 8 degrees from horizontal.

position of the handle indicates that the lock sectors were in a position past fully locked. The fuse pin was found in three pieces but was heavily corroded. The handle housing was undamaged. Two of the three connecting rods between the master latch lock handle and the lock sector torque tube were bowed slightly, but they were otherwise intact. No deformation was observed on any section of the lock sector torque tube, although one of the six bearings assembled on the torque tube had been damaged. The No. 3 bearing inner race and its torque tube locator sleeve were displaced forward approximately 0.20 inch from the bearing housing centerline. The outer race was broken and pushed forward out of the housing.

The lower two connecting rods between the lock sector torque tube and the torque tube below the pressure-relief doors were undamaged; however, the upper connecting rod had separated at the upper, tapered end. The torque tube below the pressure-relief doors were missing, and the pressure-relief door connecting rods had separated at the lower, tapered end. The remaining portion of each rod was undamaged, but the forward pressure-relief door was jammed open into the cutout.

3. Latch System:

All eight lower latch cams were found in a nearly unlatched position, and all of them were binding against the lock sectors except the No. 2 cam (lock sector No. 2 had broken). Latch cams 1-6 were approximately 62 degrees from the fully latched position, and cams 7 and 8 were approximately 70 degrees from fully latched. Full rotation of the latch cams is 80 degrees.

Several of the lower latch cams contained compression and smearing damage on the lower lip of the latch cam cavity ("lower" relative to an open cam). This damage is consistent with the forceful movement of the cams across the latch pins.

The four rods between the latch actuator torque tube and the four bellcranks containing the latch cams were attached and undamaged. No section of the latch actuator torque tube was damaged, and the bearings/supports along the tube were intact. The latch actuator was removed and later disassembled. No anomalies were found.

4. Pull-in Hook System:

The forward and aft pull-in hooks were found near the closed position. Both of them exhibited wear patterns consistent with contact with the pull-in hook pins during door operation. For both the forward and aft hooks, the inboard edge of the pull-in hook channel contained compression and smearing damage consistent with a forceful movement of the hooks over the pins while the hooks were in the closed or nearly closed position.

1.16.2 Forward Cargo Door Electrical Component Examinations

1.16.2.1 Before Recovery of the Door

Several electrical components associated with the operation of the forward cargo door were examined on the airplane and were then removed for further testing. These components included the No. 2 ground handling power bus relay, the air/ground safety relay, the No. 1 auxiliary power circuit breaker, and the outside and inside door control switches. All of these components were tested for both single faults and intermittent failures. The test results showed that all of the switches/relays were functional, although a loose wire connection was found on the outside door control switch. This loose wire connection showed evidence of overheated insulation on the two terminal lugs that attach to terminal No. 5, and there was evidence of a burn (arc point) on the top of the screw head for terminal No. 5. Terminal No. 5 is associated with power for the door "close" cycle, and not the door "open" cycle.

An electrical continuity check was performed on the cockpit cargo door warning light system components that remained with the airplane. This check confirmed the integrity of the circuit from the door area to the cockpit. The examination of the two bulbs that comprise the forward cargo door warning light revealed that one bulb was inoperative. The other bulb, which is in parallel with the inoperative bulb, was found operative. The illumination of the display legend, which reads "FWD CARGO DR" on the flight engineer's panel, was discernible with one bulb inoperative. A functional check of the circuit, which allows the cockpit warning lights to be dimmed during night operations, was also performed. The check consisted of removing the card containing this circuit and installing it in another B-747. The test was satisfactory in that the dim/bright circuit functioned properly.

1.16.2.2 After Recovery of the Door Switches--General

The cargo door was recovered with all of its position sensing switches installed in their proper locations. The electrical junction box was found attached to the door but damaged. The switches recovered and examined were: S2 Master Latch Lock; S3 Door Warning; S4 Latch Close; S5 Hook Position; S6 Fwd Mid-Span Latch Open; S7 Door Close; S8 Hook Close; and S9 Aft Mid-Span Latch Open. Figure 17 provides a diagram of the cargo door's electrical circuitry.

Five of the eight position-sensing switches installed on the door had evidence of external damage to the switch housing. The damage on four switches (S2,S3,S4,S8) consisted of primarily compression dimpling on the housing. The S5 switch exhibited mechanical impact damage on the switch housing and mounting bracket. The striker assembly for switch S8 was loose (2 of 3 rivet fasteners sheared). The electrical wiring recovered with the door exhibited signs of tensile separation from overload at all failure points examined.

Each switch was photographed and its installed position was documented. Electrical continuity readings were taken with an ohmmeter across the poles of each switch at the first point of wire separation as found on the door. After the readings were recorded, all switches were removed from the door so that photographs and x-rays of each switch could be taken. Electrical continuity readings were retaken.

Disassembly of each switch consisted of: (1) drilling two holes in the switch housing to release trapped water from the switch (2) cutting a small window in the switch housing to examine the internal basic switches (3) removing the housing, (4) removing the internal bracket, and (5) removing basic switch covers.

During the drilling step, water was released from every switch when the holes were drilled in the switch housing. The water was filtered into a glass container. The quantity was not measured but appeared to be less than 5 mL. The residue from the filtered water trapped on the filter media had a blue-green color.

After the switch housing was removed, an ohmmeter was connected across the 1-2 poles of the switches that would not transfer electrical continuity (S2,S3,S4,S6,S7) when actuated. The rivets were then drilled out of the internal bracket. After the last of the two rivets were drilled out, the switch contacts

Figure 17b.--Diagram of cargo door electrical circuitry.

transferred to the other pole on S2, S3, and S4. On S6, the used3 basic switch was held closed by its plunger. S7 transferred after the switch housing and water inside were removed.

During removal of the basic switch covers, a trend was noted in the discoloration of some of the basic switches. The used switch had a reddish-brown coloration. The unused switch was not discolored.

Each switch was found to be wired correctly to its poles and through its contacts within the basic switches. All contacts operated with light finger pressure after removal of the basic switch covers. There was no evidence of pitting, excessive corrosion, or heat distress in the contacts of any of the switches. The following sections detail pertinent observations concerning each switch.

The S2 master latch lock is given particular significance because of its function to protect against inadvertent door operation and is thus described in more detail. It is a single-pole double-throw (SPDT) switch used to sense the unlocked position of the door lock sectors. The switch is mounted in the aft lower corner of the door. A bracket attached to the No. 7 lock sector depresses the switch when the door lock sectors are rotated to their unlocked position. When the bracket attached to the lock sector contacts the switch plunger and depresses it, the circuit path through the switch is closed and 28VDC electrical control power to the door is established. When the force on the plunger is relaxed, the circuit is opened and 28VDC electrical control circuit is removed.

The wires leading to the S2 switch had been cut by the team after the recovery in an attempt to test continuity through the switch. The door recovery team reported that it found continuity through the 1-3 contacts but not through the 1-2 contacts. The switch plunger was actuated by the recovery team. The recovery team noted that the switch did not transfer continuity during these tests. The operation of the switch plunger would normally transfer continuity. Subsequent detailed examination of the S2 switch confirmed the findings of the recovery team.

The area around the upper face of the internal bracket was bent toward the basic switches and had evidence of corrosion residue. The bracket was found broken. The switch contacts transferred from the 1-3 actuated position to the 1-2 nonactuated position when the bracket was removed. Scanning electron

microscope examination of the fracture surfaces revealed evidence of overload and corrosion.
The external switch housing was dented. The final examination performed on the switch consisted of removing the plastic covers on the basic switches. Prior to removal of the basic switch covers, it was noted that the cover to the used basic switch was cracked. The contacts functioned normally when exercised by light finger pressure.
Microscopic examination revealed a black discoloration near one of the lower contact posts of the used basic switch. Energy dispersive spectrometric examination of the residue disclosed the presence of gold, iron, magnesium, sodium, and chlorine. No mechanical or electrical anomalies were detected with the basic switch contacts.
Additional testing was performed by Boeing on switches of a similar design to those used on the accident airplane's cargo door. The testing was conducted to identify conditions that would result from salt water immersion at a pressure depth of 14,200 feet for 18 months. The testing verified that external damage to the switch housing occurred at pressure depths of 7,000 feet and greater. Switch seal leakage and subsequent internal corrosion was also noted. None of the testing performed by Boeing duplicated internal switch damage that caused basic switch contact closure or internal damage to the switch support bracket.
Wiring:
The electrical wiring recovered with the cargo door was documented in place before being removed for further tests. About 40 percent or 112 feet of wire from the original length of approximately 274 feet was recovered and examined. Of this amount, about 46 feet of wire installed in the aircraft forward of the cargo door was not examined. Most of the wires leading from the door to the fuselage were not recovered. There was no visible external evidence of burning, arcing, or heat distress in any of the

wires removed. Several areas of wire insulation damage were found.

Thirty five wires were identified that could provide a possible short circuit path that could drive the latch actuator open with or without failures of other door electrical components if the ground handling bus was energized. The wires were schematically coded by function. Wires coded (-..-..-) were denoted for wiring that provides open command logic to the latch actuator. Wires coded (--.--.--.) were denoted for additional wiring enabled by an activated (failed) S2 switch. Wires coded (-o-o-o-o) were denoted for wiring providing 28VDC power from the C285 circuit.

Potential short circuit paths were identified for the cargo door that could provide 28VDC to the latch actuator control circuit relay. These potential short circuit paths can cause the latch actuator to drive the latches toward their open position if 115VAC power is available to the latch actuator motor. The potential short circuit paths include two bare wires shorting against each other, bare wire-to-metal structure-to-bare wire contact, wire to conductive fluid (such as water) to wire, or a combination of the aforementioned.

Conductive contact of (-o-o-o-o) or (--.--.--) coded wire with (-..-..-) coded wire could potentially result in providing a 28VDC circuit path to the latch actuator open circuit. Direct wire-to-wire paths are coded in Figure 17 as defined above. The two-wire short circuit paths are identified as wire pairs consisting of wire 101-20 shorting with any of the following wires; 108-20, 121-20, 122-20, 124-20, 135-20, or 136-20.

If the S2 master latch lock switch fails in the "Not Locked" position, there are additional wire pairs that provide short circuit paths. These are coded in Figure 17 as (--.--.--) to (-..-..-..) wire pairs.

Short Circuit Wire Damage Simulation Tests:

Tests were conducted by Boeing and United to simulate typical examples of bare wire short circuiting to determine the extent of visible wire damage that would be expected in the 28VDC cargo door control circuit.

United performed tests on BMS 13-42 wire, the wire type used in the B-747 cargo door control circuit. Visible electrical short circuit damage on bare BMS 13-42 wire surfaces was difficult to create at 28VDC. Surface damage was considered visible when detected by microscopic examination at 15X magnification. United testing simulated the relay coil resistance variations that would be found during typical in-service conditions. A current of 1.0 A at 28VDC created visible surface damage on momentary bare wire-to-bare wire contact. Multiple contacts at 1.0 A provided a more positive indication. A single momentary contact between two bare BMS 13-42 wires with 0.160 A at 28VDC did not create visible surface damage. Contact between a BMS 13-42 bare wire and Alclad 2024-T3 metal (airplane and cargo door structure) with 0.160A at 28VDC did not create visible surface damage.

Boeing performed wire tests on BMS 13-48 20 gauge wire. The test setup used the MS27418-2B door latch actuator control relay in parallel with the 60B00311-2 door restraint solenoid, the actual electrical loads used in the B-747 cargo door latch actuator control circuit. A single momentary contact of a bare 28VDC power wire, with a bare wire connecting to the relay of the solenoid, showed small pithead area developed at the point of wire contact that was visible without magnification.

Wire Examination Procedure:

All of the recovered wires were examined in the Safety Board's Materials Laboratory on a mylar sheet to simulate their installed positions. Labels were used to identify the coded wires using the manufacturer's original wire identification numbers imprinted on each wire's insulation. Wire pairs for direct electrical short circuiting were located in two common wire bundles installed on the cargo door. One common wire bundle was associated with the

P3 plug connector, the other with the P4 plug junction box. The wire bundles were examined visually for areas of obvious insulation damage. Each individual wire was also examined with a stereo-microscope. Representative wire damage features were photographed.

Wire Damage Found:

Seven wires numbered 101-20, 102-20, 105-20, 107-20, 108-20, 122-20, and 135-20 had visible damage located near a 3.8 inch position as measured from the P3 plug pin tips. This common position on the wire corresponds to a 360-degree loop in the wire bundle, which is located immediately below the junction box. Figures 18 and 19 show typical wire damage. Wire 122-20 had an open insulation area approximately 0.25 inch long. The other four wires had flattened insulation damage areas.

In the P4 plug connector wire bundle, three wires displayed insulation damage. Wires 113-20, 121-20, and 124-20 had transverse insulation nicks, which exposed bare conductors. All three had insulation nicks 3 inches from the P4 plug pin tips; wires 121-20 and 124-20 had additional insulation nicks 34 inches from the plug pin tips. The two P4 insulation damage locations corresponded to wire bundle clamp positions.

1.16.3 Pressurization System

The pressure relief valves located on the left side of the fuselage in the forward cargo compartment were removed from the airplane and subjected to bench tests at the UAL maintenance facility in San Francisco, California. No significant anomalies were discovered and both valves performed within specified tolerances.

1.16.4 General Inspection of Other UAL Airplanes

During the on-scene phase of the investigation, the Safety Board investigators examined six other B-747 airplanes while they were on the ground at HNL (four UAL airplanes and two operated by other carriers) to observe routine cargo door operations and to assess the condition of latching components. Generally, the door operations were normal. During the examination of latch pins on these airplanes, it was noted that most had a smooth wear ridge at the 9:00 position (looking forward) or were undamaged. All wear areas on the pins were smooth.

During electrical operation of the aft cargo door on one of the other UAL B-747 airplanes (N4718U), the pull-in hooks did not pull the door fully closed and the latch cams completed the closure. During operation of the latch cams, the bottom of the door moved, first circumferentially downward and then inboard. This additional movement was approximately 1/4 inch. A definite "thunking" noise was discernible as the door moved to its closed position at the end of cam rotation. On one occasion, the door would not open under electrical power. The door was "kicked" by a UAL mechanic, power was reapplied, and the door opened properly. Examination of the door by UAL mechanics, disclosed that the riveted plate holding the aft pull-in hook switch striker was loose.

All eight lower latch pins for the forward cargo door on N4718U exhibited a smooth ridge near the 9:00 position. Pins No. 1 and 2 also showed a smooth ridge at the 6:30 position with a smooth wear area between the 6:30 and 9:00 position. The forward and aft midspan cams of both forward and aft cargo doors had a heavy gouge mark corresponding to the end of the midspan latch pin. N4718U was subsequently removed from service for repair of the aft cargo door latching mechanisms.

1.17 Additional Information

1.17.1 Previous Cargo Door Incident

On March 10, 1987, a Pan American Airways B-747-122, N740PA, operating as flight 125 from London to New York, experienced an incident involving the forward cargo door. According to Pan Am and Boeing officials who investigated this incident, the flightcrew experienced pressurization problems as the airplane was climbing through about 20,000 feet. The crew began a descent and the pressurization problem ceased about 15,000 feet. The crew began to climb again, but about 20,000 feet, the cabin altitude began to rise rapidly again. The flight returned to London.

When the airplane was examined on the ground, the forward cargo door was found open about 1 1/2 inches along the bottom with the latch cams unlatched and the master latch lock handle closed. The cockpit cargo door warning light was off.

According to the persons who examined the airplane, the cargo door had been closed manually and the manual master latch lock handle was stowed, in turn closing the pressure relief doors and extinguishing the cockpit cargo door warning light. Subsequent investigation on N740PA revealed that the latch lock sectors had been damaged and would not restrain the latch cams from being driven open electrically or manually. It was concluded by Boeing and Pan Am that the ground service person who closed the cargo door apparently had back-driven (opened) the latches manually after the door had been closed and locked. The damage to the sectors, and the absence of other mechanical or electrical failures supported this conclusion.

Further testing of the door components from N740PA and attempts to recreate the events that led to the door opening in flight revealed that the lock sectors, even in their damaged condition, prevented the master latch lock handle from being stowed, until the latch cams had been rotated to within 20 turns (using the manual 1/2 inch socket drive) of being fully closed. A full cycle, from closed to open, is about 95 turns with the manual drive system.

1.17.2 FAA Surveillance of UAL Maintenance

The Denver, Colorado, FAA Flight Standards District Office (FSDO) holds the operating certificate for United Airlines, Inc. The FAA FSDO in San Francisco, California, has the primary surveillance and oversight

responsibility for UAL maintenance.
The FAA's PMI has the responsibility to oversee an airline's compliance with Federal Regulations with respect to maintenance, preventive maintenance, and alteration programs. The PMI determines the need for, and then establishes work programs for, surveillance and inspection of the airline to assure adherence to the applicable regulations. A portion of the PMIs position description reads as follows:
Provides guidance to the assigned air carrier in the development of required maintenance manuals and recordkeeping systems. Reviews and determines adequacy of manuals associated with the air carrier's maintenance programs and revisions thereto. Assures that manuals and revisions comply with regulatory requirements, prescribe safe practices, and furnish clear and specific instructions governing maintenance programs. Approves operations specifications and amendments thereto.
Determines if overhaul and inspection time limitations warrant revision.
Determines if the air carrier's training program meets the requirements of the FARs, is compatible with the maintenance program, is properly organized and effectively conducted, and results in trained and competent personnel.
Directs the inspection and surveillance of the air carrier's continuous airworthiness maintenance program. Monitors all phases of the air carrier's maintenance operation, including the following: maintenance, engineering, quality control, production control, training, and reliability programs.
At the Safety Board's public hearing on this accident, the PMI for United Airlines at the time of the flight 811 accident stated that he was trained as an FAA air carrier inspector and had been assigned to United Airlines since November 25, 1985. In addition to attending the normal FAA indoctrination course, he had received training in accident investigation, compliance

enforcement, nondestructive testing, enforcement, and composite materials. To qualify for the position of PMI, he had completed a 3-week management training course at Lawton, Oklahoma. This was supplemented by a 2-week course on management training systems.

According to the PMI, FAA surveillance of UAL B-747 maintenance activities was organized around the daily work schedule of the FAA air safety inspector, specifically assigned to the UAL B-747 fleet by the PMI. The schedule for surveillance is normally prepared a year in advance by the FAA computerized Work Planning Management System (WPMS). Each FAA inspector is assigned specific responsibilities in the surveillance and monitoring of the airplane fleet to which he is assigned.

The PMI stated that assigned inspectors conducted surveillance of the UAL airplanes while they were in light or heavy maintenance and when they were released to service or in the process of preparing for a flight. Postflight surveillance was also performed. He said, as a routine, the inspectors visually inspected the airplanes and reviewed the airplane log records either during en route checks, while in flight, or upon termination of various flights. He said that inspectors conduct spot ramp inspections; however, they do not routinely observe ramp service operations as part of the surveillance program.

He said that FAA inspectors are not required to inspect the airplanes, but merely are to observe ramp service activities. Deficiencies or malfunctions were to be noted. The assigned inspector or the PMI would then report these observations to the UAL quality assurance liaison person or directly to UAL management.

The PMI stated that the FAA had conducted five special surveillance inspections of UAL in the previous 3 years and 5 months. The last special inspection, an MEL Survey Inspection, was completed in 1988. That inspection primarily addressed how many deferred maintenance items were being carried or deferred on each aircraft during a specified time period.

The PMI stated that his office does not approve the method by which the carrier complies with an AD, unless specified in the AD. However, a scheduled surveillance method was in place to review the carrier's AD compliance process and the ADs applicable to certain fleets. Each assigned inspector had a schedule for performing this oversight in his work program. The PMI or his staff review a monthly report from the carrier listing ADs applicable to a particular fleet and their compliance. The FAA's surveillance of the carrier's AD compliance process involved a review of this list, not actual shop visits to verify compliance.

The inspector assigned to the UAL B-747 fleet stated that approximately 30 percent of his time was spent on actual ramp maintenance surveillance. Other activities included: en route inspections, station inspections, meetings, classes and administrative paper work. Spot ramp inspections were scheduled as a normal routine, as well as by mandate in a particular AD.

The PMI stated that foreign contract maintenance bases were inspected once a year at a minimum. The PMI had the prerogative to use geographical surveillance inspectors (inspectors from other FAA offices), or inspectors from his office more familiar with UAL maintenance procedures to conduct inspections or investigations.

The PMI and the B-747 maintenance inspector assigned to UAL testified that, prior to this accident, they were not aware of any problems involving the operation of B-747 cargo doors, including the problems reported with N4713U during December 1988. The PMI testified that he could always use more inspectors to "conduct more in-depth surveillance and monitor UAL's fleet more adequately."

The extensive documentation of maintenance performed on UAL B-747 airplanes was forwarded to the PMI's official library by US mail. The data were ultimately channeled to the B-747 maintenance inspector. The PMI and maintenance inspector testified that the voluminous paperwork and work schedules precluded their monitoring the information to determine trends on problem areas.

1.17.3 Corrective Actions

On March 31, 1989, the FAA issued telegraphic (AD) ADT 89-05-54. This AD superseded AD 88-12-04 and required certain procedures to be accomplished when operating the cargo doors. These included: confidence checks of the door mechanical and electrical systems, inspections of the door locking mechanisms, and repairs if necessary. The AD also accelerated the schedule for terminating action to place steel doublers on the latch lock sectors, and it reinstituted the procedures for using the eight view ports to verify the position of the latch cams, after the door is latched and locked.

The FAA, in conjunction with the Air Transport Association, the manufacturers, and other interested parties, are collectively working to address the human factor issues in the readability and understandability of ADs and SBs by line maintenance personnel. They are also reviewing the entire range of design, maintenance, and operation of outward opening doors to develop advisory information for pertinent parties.

FAA representatives stated at the Safety Board's public hearing that the FAA is increasing their operations and airworthiness inspector staffing by approximately 1,000 new hires in the next 3 fiscal years.

The PMI for UAL at the time of the accident stated at the Safety Board's public hearing that, as a result of the accident, "we have intensified our surveillance on the cargo door activities to the point where the assigned inspectors and inspectors who are not assigned to that particular fleet, 747s, are doing night surveillance, early morning surveillance, and we have intensified our surveillance on the cargo door in watching the operation of the cargo door to comply with the Airworthiness Directive."

On August 23, 1989, the Safety Board issued three safety recommendations (A-89-92 through -94) to the FAA. The recommendations urged the FAA to:

Issue an Airworthiness Directive (AD) to require that the manual drive units and electrical actuators for Boeing 747 cargo doors have torque limiting devices to ensure that the lock sectors, modified per AD-88-12-04, cannot be overridden during mechanical or electrical operation of the latch cams.

Issue an Airworthiness Directive (AD) for non-plug cargo doors on all transport category airplanes requiring the installation of positive indicators to ground personnel and flightcrews confirming the actual position of both the latch cams and locks, independently.

Require that fail-safe design considerations for non-plug cargo doors on present and future transport category airplanes account for conceivable human errors in addition to electrical and mechanical malfunctions.

Section 4.0 contains the FAA's response to the recommendations and the status of the followup actions.

On October 12, 1989, the FAA issued NPRM 89-NM-148-AD, which proposed the amendment of ADT-89-05-54. The proposed revisions would require modification of the warning systems for the forward and aft cargo door, and the main deck cargo door, if installed. The modifications would provide visual warnings to flightcrew and ground crew when the doors are not fully closed, the latch cams are not rotated to the closed position, or the lock sectors are not in the locked position. Further, the source for the warning signal would monitor the position of the latch cams. Public comments for the NPRM were due by

December 27, 1989.

Boeing has completed tests that have verified the integrity of the upgraded latch lock sectors to prove that the latch cams cannot be back-driven through the lock sectors mechanically or electrically. Boeing also has been conducting tests on the B-747 cargo door to evaluate the effects of unrepaired damage and abuse on the latch/lock system. The tests, which determined the allowable damage limits on the latch lock system and mechanism support structures, were completed in March 1990. Additionally, Boeing conducted tests to evaluate any unlatching tendencies under cabin pressure loads. These tests were completed in November 1990 and included the measurement of loads in the latch system as the latch cams are rotated incrementally from the fully latched position to the unlatched position under pressurization loads.

The first series of tests included electrical backdriving of the latch cams into the lock sectors (both steel and steel reinforced were tested) with a modified latch actuator (the maximum output torque of the modified latch actuator was roughly twice that of a normal, torque-limiting latch actuator.) During these tests, the maximum cam rotation was 22.2 degrees against steel reinforced lock sectors and 18.8 degrees against the all-steel lock sectors.

During the second set of tests, which measured the effects of internal pressure loads on partially unlatched cams, it was discovered that pressurization did not create any significant loads in the latch mechanism with the door fully closed and the latch cams positioned up to 45 degrees from the fully latched position.

Both series of tests show that if the latch cams were somehow electrically backdriven by a latch actuator that had no torque-limiting ability, the steel or steel-reinforced lock sectors would limit the amount of cam rotation such that the partially unlatched cams would still prevent pressure loads from forcing the door open.

1.17.4 Boeing 747 Cargo Door Certification

Title 14 CFR 25.783, Amendment 25-15, effective October 24, 1967, was the original certification basis for Boeing 747 cargo doors. Specifically, Part 25.783(e) and (f) applied to doors for which the initial opening movement is outward (non-plug type doors). Those rules specified that:

(e) There must be a provision for direct visual inspection of the locking mechanism by crewmembers to determine whether external doors, for which the initial opening movement is outward (including passenger, crew, service, and cargo doors), are fully locked. In addition, there must be a visual means to signal to appropriate crewmembers when normally used external doors are closed and fully locked.

(f) Cargo and service doors not suitable for use as an exit in an emergency need only meet paragraph (e) of this section and be safeguarded against opening in flight as a result of mechanical failure.

Amendment 25-23, effective May 8, 1970, added the following text to paragraph (f): "...or failure of a single structural element." Amendment 25-23 did not apply to the initial certification basis for the B-747.

Amendment 25-54, effective October 14, 1980, expanded Part 25.783 (e), (f), and (g) to read:

(e) There must be a provision for direct visual inspection of the locking mechanism to determine if external doors, for which the initial opening movement is not inward (including passenger, crew, service and cargo doors), are fully closed and locked. The provision must be discernible under operational lighting conditions by appropriate crewmembers using a flashlight or equivalent lighting source. In addition, there must be a visual warning means to signal the appropriate flight crewmembers if any external door is not fully closed and locked. The means must be designed such that any failure or combination of failures that would result in an erroneous closed and locked indication is improbable for doors for which the initial opening movement is not inward.

(f) External doors must have provisions to prevent the initiation of pressurization of the airplane to an unsafe level if the door is not fully closed and locked. In addition, it must be shown by safety analysis that inadvertent opening is extremely improbable.

(g) Cargo and service doors not suitable for use as an exit in an emergency need only meet paragraph (e) of this section and be safeguarded against opening in flight as a result of mechanical failure or failure of a single structural element.

At the Safety Board's public hearing, the FAA and the Boeing representatives acknowledged that during certification of the Boeing 747 the loss of a lower lobe cargo door was not considered to be an "acceptable event." Therefore, redundant mechanical devices and operational procedures were incorporated to protect against loss of the door in flight. Initial FAA certification approval of the Boeing cargo door design and operation included the installation and use of eight view ports on the door for ground personnel to observe the alignment of paint stripes on the latch cams with arrows on the latch pin support fitting, thereby complying with the requirements of 14 CFR 25.783(e), which require a ". . . provision for direct visual inspection of the door locking mechanism ...," to determine if the door is closed and locked.

In correspondence dated November 24, 1969, and May 15, 1970, Boeing requested that the FAA approve the use of a visual inspection of the pressure relief doors of the cargo doors as an alternate method for determining the locked condition of the door. This design also provided a visual indication to the flightcrew via the cargo door warning light on the flight engineer's warning light annunciator panel. Boeing's request stated that this means of compliance "... provides a simpler check whereby only the pressure relief doors need to be checked ...," by

the ground crew, in lieu of actually observing the latch cams and alignment stripes through the eight view ports. Boeing also provided a Failure Analysis to support its request. The conclusion of the Failure Analysis reads: "Any failure, mechanical or electrical, within the latching system which results in open latches will always be indicated by open pressure relief doors." The FAA approved their alternate method on June 8, 1970. Subsequently, the procedures for maintaining the view ports and the alignment stripes in a serviceable condition,
which had been included in the UAL MM were removed. Also, the provision for observing the alignment stripes as part of the door closing procedure were not required for B-747 airline operators.

At the Safety Board's public hearing, a Boeing witness, in answer to a question relative to Boeing's possible consideration of modifications or design changes to the B-747 cargo door indication system to install a position switch directly on the latch cams, stated, "We are looking into the best possible designs that would provide indication on the cams and door closed, both exterior to the aircraft and in the flight deck. We are going to look into that.... However, we want to achieve the required indication in the most reliable method and we have not yet determined what that will be, or any changes (that) are necessary, or would make it more reliable than the way the system operates currently."

1.17.5 Advisory Circular AC 25.783-1

Advisory Circular (AC) 25.783-1 was issued December 10, 1986, on the subject, "Fuselage Doors, Hatches, and Exits." AC 25.783-1 set forth the acceptable means of compliance with the provisions of Part 25 of the FAR's dealing with the certification of fuselage doors. Specifically, it provides for an acceptable method for showing compliance with the provisions of Part 25.783, Amendment 25-54.

Neither the provisions of Part 25.783, Amendment 25-54, nor the guidelines of AC 25.783-1 were part of the certification basis of the Boeing 747.

1.17.6 Uncommanded Cargo Door Opening--UAL B-747, JFK Airport

On June 13, 1991, UAL maintenance personnel were unable to electrically open the aft cargo door on a Boeing 747-222B, N152UA, at JFK Airport, Jamaica, New York. The airplane was one of two used exclusively on nonstop flights between Narita, Japan, and JFK. This particular airplane had accumulated 19,053 hours and 1,547 cycles at the time of the occurrence.

The airplane was being prepared for flight at the UAL maintenance hangar when an inspection of the circuit breaker panel revealed that the C-288 (aft cargo door) circuit breaker had popped. The circuit breaker, located in the electrical equipment bay just forward of the forward cargo compartment, was reset, and it popped again a few seconds later. A decision was made to defer further work until the airplane was repositioned at the gate for the flight. The airplane was then taxied to the gate, and work on the door resumed.

The aft cargo door was cranked open manually, the C-288 circuit breaker was reset, and it stayed in place. The door was then closed electrically and cycled a couple of times without incident. With the door closed, one of the two "cannon plug" (multiple pin) connectors was removed from the J-4 junction box located on the upper portion of the interior of the door. The wiring bundle from the junction box to the fuselage was then manipulated while readings were taken on the cannon plug pins using a volt/ohmmeter. Fluctuations in electrical resistance were noted. When the plug was reattached to the J-4 junction box, the door began to open with no activation of the electrical door open switches. The C-288 circuit breaker was pulled, and the door operation ceased. When the circuit breaker was reset, the door continued to the full open position, and the lift actuator motor continued to run for several seconds until the circuit breaker was again pulled. At this time, a flexible conduit, which covered a portion of the wiring bundle, was slid along the bundle toward the J-4 junction box, revealing several wires with insulation breaches and damage. UAL personnel notified the Safety Board of the occurrence, and the airplane was examined at JFK by representatives of the Safety Board, United Airlines, and Boeing. After the wires in the damaged area were electrically isolated, electrical operation of the door was normal when the door was unlocked. When the door was locked (master latch lock handle closed), activation of the door control switches had no effect on the door. This indicated that the S2 master latch lock switch was operating as expected (removing power from the door when it was locked). After the on-site examinations, the wiring bundle was cut from the airplane and taken to the Safety Board's materials laboratory for further examination.

The wiring bundle with the damaged wires contained all electric control wires (28 volt DC) and power wires (115 volt AC) that pass between the fuselage and the aft cargo door. From the forward side of the J-4 junction box, the bundle progresses in the forward direction, just above the forward pressure relief door, then upward, following the forward lift actuator arms. The bundle then enters an empty space between two floor beams, where the bundle has an approximate 180-degree bend when the door is closed. From this location, the wiring bundle progresses inboard, through a fore-to-aft intercostal between two floor beams. The wiring bundle then splits, with wires going in several directions.

The bundle is covered by the flexible conduit approximately from the lower end of the lift actuator arms to the fore-to-aft intercostal between the floor beams.

The conduit covering the wiring bundle is intended to prevent the wire bundle from being damaged during opening and closing of the door and during cargo handling operations. The conduit is a sealed flexible interconnector consisting of a convoluted helical brass innercore covered by a bronze braid. The innercore is soldered at every other convolute, and should be capable of withstanding pressures exceeding 1,000 pounds per square inch (psi). Boeing has indicated that the conduit is an evolutionary improvement and that it has been installed on all B-747 airplanes produced since 1981 (from line number 489 on). Airplane N152UA was delivered in April 1987.

Airplanes produced prior to 1981, including N4713U, used a bungee retraction system, to retract the cargo door wire bundle. Guidelines for the replacement of the bungee sys tem with the flexible conduit were covered in Boeing Service Bulletin 747-752-2170, dated August 1981. The service bulletin was prompted by reports that the wire bundle bungee retraction system had not retracted the wire bundle sufficiently to prevent trapping the bundle between the cargo door and the door frame. UAL did not perform the retrofit on N4713U, which was line number 89, nor was the company required to do so.

Examination of the wires in the damaged area on the wiring bundle revealed that four of the wires were similar in appearance, with insulation breaches that progressed through to the underlying conductor. Adjacent to the breach on these four wires, the insulation was blackened, as if it had been burned. Another wire contained an extensive breach but no evidence of burned insulation. The damaged area was located on the bundle at a position approximately corresponding to a conduit support bracket and attached standoff pin on the upper arm of the forward lift actuator mechanism. This support bracket was found bent in the forward direction. In addition, mechanical damage was noted on adjacent components in this area.

A second damaged area was noted on the wiring bundle at a position approximately corresponding to the conduit swivel clamp at the elbow between the two arms of the forward lift actuator mechanism. Wires in this area were missing portions of their exterior coating, but no breaches to the underlying conductors were noted.

The exterior braid on the conduit contained minor rub marks and was slightly kinked at a position corresponding to the area on the wires with breached insulation. Additional examinations revealed that the innercore of the conduit contained multiple circumferential cracks in the areas corresponding to the damage areas on the wires. The cracks were in the convoluted innercore directly adjacent to the inside diameter of the conduit.

The lock sectors, latch cams, and latch pins from the aft cargo door were examined on the incident airplane and were generally in excellent condition. There was no evidence to suggest that the cams had ever been electrically (or manually) driven into or through the lock sectors.

Boeing also informed the Safety Board that, in May of 1991, a B-747 operated by Quantas was found to have chafing of the wires in the wire bundle to the aft cargo door. This airplane also had a flexible conduit protecting the wires, and the chafing was located approximately at the standoff pin on the bracket at the upper arm of the forward lift actuator.

The Safety Board determined that the chafing of the wires on the airplane involved in the JFK occurrence was caused by, or was greatly accelerated by, the circumferential cracks in the conduit and that the cracks in the conduit were caused either by repeated flexing of the conduit as the cargo door opens and shuts or by unusual stresses on the conduit generated concurrently with damage to the conduit guide bracket and attached standoff pin on the upper end of the forward lift actuator upper arm.

A portion of the wire bundle for the forward cargo door on many B-747 airplanes is also covered by a flexible conduit that is very similar to the conduit for the aft cargo door. However, there are substantial differences between the orientation of the flexible conduits for the two doors, and the Safety Board has not become aware of problems associated with the flexible conduit for the forward door.

Nevertheless, because of the concerns about the chafed wires and possible electrical short circuits, on August 28, 1991, the Safety Board recommended that the FAA:

Issue an Airworthiness Directive applicable to all Boeing 747 airplanes with a flexible conduit protecting the wiring bundle between the fuselage and aft cargo door to require an expedited inspection of:

(1) the wiring bundle in the area normally covered by the conduit for the presence of damaged insulation (using either an electrical test method or visual examination);

(2) the conduit support bracket and attached standoff pin on the upper arm of the forward lift actuator mechanism;

(3) the flexible conduit for the presence of cracking in the convoluted innercore.

Wires with damaged insulation should be repaired before further service. Damage to the flexible conduit, conduit support bracket and standoff pin should result in an immediate replacement of the conduit as well as the damaged parts. The inspection should be repeated at an appropriate cyclic interval. (Class II, Priority Action) (A-91-83)

Evaluate the design, installation, and operation of the forward cargo door flexible conduits on Boeing 747 airplanes so equipped and issue, if warranted, an Airworthiness Directive for inspection and repair of the flexible conduit and underlying wiring bundle, similar to the provisions recommended in A-91-83. (Class II, Priority Action) (A-91-84)

The FAA responded to these safety recommendations on November 1, 1991, stating that it agreed with the intent of the recommendations and that the issuance of an NPRM was being considered to address the issues in the safety recommendations. The Safety Board replied on November 27, 1991, classifying each of the recommendations as "Open--Acceptable Response," pending the completion of the rulemaking process. Since that exchange of correspondence, the FAA has published an NPRM which is now being reviewed by the Safety Board. Safety Recommendations A-91-83 and -84 will continue to be classified as "Open--Acceptable Response" until an acceptable final rule is published.

2. ANALYSIS

2.1 General

This analysis is based on the facts gathered during the initial investigation phase, without the benefit of the evidence from the cargo door, updated to include the findings from the subsequent examinations of the door after it was recovered.

The flightcrew and flight attendants were trained and qualified in accordance with the applicable Federal regulations and UAL standards and requirements. There were no air traffic control or weather factors related to the cause of this accident.

The airplane had been properly maintained, with the exception of certain requirements pertaining to the cargo doors. Those discrepancies will be discussed in detail in this analysis.

The evidence examined by the Safety Board during its investigation revealed conclusively that this accident was precipitated by the sudden loss of the forward lower lobe cargo door, which led to an explosive decompression. There was no evidence of preexisting metal fatigue or corrosion in the structure surrounding the cargo door. All breaks were the result of overload at the time of the loss of the door. There was no evidence of a bomb or similar device that caused an explosion on the airplane.

The explosive decompression of the cabin when the cargo door separated caused the nine fatalities. The floor structure and seats where the nine fatally injured passengers had been seated were subjected to the destructive forces of the decompression and the passengers were lost through the hole in the fuselage. Their remains were not recovered. Most of the injuries sustained by the survivors were caused by the events associated with the decompression, such as baro-trauma to ears, and cuts and abrasions from the flying debris in the cabin. Other injuries were incurred during the emergency evacuation.

The loss of power to the Nos. 3 and 4 engines was caused by foreign object damage when debris were ejected from the cargo compartment and cabin during the explosive decompression. The debris also caused damage to the right wing leading edge flap pneumatic ducting, and other areas along the right side and empennage of the airplane.

During the approach to HNL, all of the leading edge flaps had extended, except the outboard sections 22 through 26 on the right wing. The reason that they failed to extend probably was the damage to the pneumatic duct caused by the ejected debris. The pneumatic pressure probably was too low to actuate the most outboard flaps to the extended position.

The failure of the flightcrew and passenger oxygen systems was caused by structural deformation and damage to the supply lines in the area adjacent to the cargo door and failed fuselage structure.

The Safety Board's analysis of this accident concentrated on the reasons for the loss of the cargo door and the events that led to its loss in flight. The analysis included an evaluation of the design, certification, and approval processes for the B-747 cargo doors, and the operational, maintenance, and inspection processes for the doors. Also, the analysis included an evaluation of the historical events that had occurred over the past months and years that eventually led to this accident.

2.2 Loss of the Cargo Door

The calculated pressure differential at the time of the loss was about 6.5 psi, which would have exerted a load on a properly closed and locked door that was substantial, but well within design limits.

There was no evidence of a structural problem with the cargo door that could have caused it to fail from metal fatigue or corrosion. Although the cargo door was recovered in two pieces on the floor of the ocean, there was no evidence of a preseparation structural failure of the door. All fractures and damage found on the door were determined to be the result of the sudden opening of the door rather than the cause. The evidence showed that the door was intact when it flew open violently and that its integrity was compromised when it struck the upper fuselage structure and most likely when it struck the water. The fracture in the cargo door occurred just below the midspan latch cams. Paint marks on the outer surface of the door that matched upper fuselage structure paint pattern, damage to the latch pins, pull-in hooks and hook pins, as well as damage to the floor structure near the upper door hinge area were consistent evidence that the door was intact when it flew open.

The evidence was also conclusive that the failure of the door did not result from the failure of the structure surrounding the door. The damage to the cabin floor beam structure, adjacent to the cargo door hinge area, showed that decompression loads in the cabin broke the beams downward when pressure was released from the cargo compartment. The fuselage skin above the door was torn away during the decompression as the door separated violently from the airplane. Unfortunately, the upper skin structure was not recovered from the sea.

There are no reasonable means by which the door could open in flight with the cams properly closed and locked. If the lock sectors were in proper condition, and were properly situated over the closed latch cams, the lock sectors had sufficient strength to prevent the cams from vibrating to the open position during ground operation and flight. Thus, the only ways in which the cargo door could open while in flight involve the placement of the cams in a partially latched or unlatched position. Either the latching mechanisms were forced open electrically through the lock sectors after the door was secured, or the door was not properly latched and locked before departure. Then the door opened when the pressurization loads reached a point at which the latches could not hold.

2.3 Partially Closed Door

Examination of the eight latch pins that had been removed from the lower sill of the forward cargo door revealed smooth wear patterns where the latch cams had normally rotated around the pins. These wear patterns indicate that interference had existed during normal operation between the cams and the pins over an extended period of time. All eight pins also had roughened areas from approximately the 6:15 position to the 7:30 position (clock references are as looking forward, 9:00 being directly inboard). The 7:30 position corresponds closely to the area where the lower surface of the cam first contacts the pin as the door reaches the nearly closed position, before the cams are rotated to the latched position.

The hoop stresses generated by pressurization of the airplane create a bearing load against the cam/pin contacting points. Even if the cams are in the unlatched position, and the airplane is pressurized, this bearing load could act as a frictional latch between the cams and the pins and would tend to keep the door in the closed position.

Transferred cam material and heat tinting of the pin surface was found to extend from the point where the cam-to-pin interface at the near fully open position of the latch cams (7:30 position) to a position corresponding to the bottom of the pin (6:15 position).

This evidence was found on the roughened areas on all of the pins. The heat tinting and metal transfer are indicative of the high stress and rapid movement of the cam across the pin when the door separation occurred. Therefore, the location of this evidence indicates the probable location of the cams just before, and at the time of, separation of the door. The Safety Board concludes that these markings and their location on the pins resulted from a very fast, high bearing stress, separation of the cams across the pins, when the cams were in or very close to the unlatched position. Further, examination of the recovered cargo door confirmed that the latch cams were in a nearly unlatched position at the time the separation occurred. The lock sectors were found in the locked position jammed against the cams. Therefore, the cargo door latch cams had been closed, the master latch lock handle had been closed, and the lock sectors had moved to the locked position. Subsequently, the cams had been back-driven to the near-open position, deforming the lock sectors.

The pull-in hooks and pull-in hook pins would also counteract the pressurization loads in the outward direction, providing that the latch cams were not engaged on the latch pins and carrying the pressurization loads. However, Boeing studies showed that the pull-in hooks would fail at a pressure differential of about 3.5 psi, assuming that the cams are in the unlatched position and that there is no bearing load on the pins. Therefore, based on the probable pressure differential of about 6.5 psi just before the door separated, it is concluded that forces other than the pull-in hooks/pins were holding the door closed. Since the flightcrew and passengers reported no pressurization difficulties until the explosive decompression, it is reasonable to conclude that the door was being held closed by the bearing stresses of the cam-to-pin interfaces as well as by the pull-in hooks.

The Safety Board believes that the approximate 1.5 to 2.0 seconds between the first sound (a thump) and the second very loud noise recorded on the CVR at the time of the door separation was probably the time difference between the initial failure of the latches at the bottom of the door, and the subsequent separation of the door, explosive decompression, and destruction of the cabin floor and fuselage structure. The door did not fail and separate instantaneously; rather, it first opened at the bottom and then flew open violently. As the door separated, it tore away the hinge and surrounding structure as the pressure in the cabin forced the floor beams downward in the area of the door to equalize with the loss of pressure in the cargo compartment.

Three possible theories to explain why the latch cams could have been in a partially latched condition during flight are examined: (1) they were never closed fully before the door was "locked" before takeoff. (2) they were backdriven manually after the door had been fully latched and locked or (3) they were back-driven electrically after the door had been fully latched and locked.

2.4 Incomplete Latching of the Door During Closure

The Safety Board considered the possibility that the master latch lock handle had not been closed before the airplane departed the gate, and the possibility that the shrouds recommended by SB-747-52-2097 for the cargo door pressure relief doors were not installed on the forward door. If this were the case, it is possible that this condition allowed the pressure relief doors to be rotated closed when the airplane pressurized.

The Safety Board believes that these events were very unlikely based on the statements of the ramp personnel, line maintenance personnel, and the flightcrew. The ramp and maintenance personnel would have to have missed seeing the master latch lock handle in the unstowed position and the pressure relief doors open before departure. Also, the flightcrew would have to have missed seeing the cockpit cargo door warning light indication.

The examination of the recovered forward cargo door did not provide confirmation that the pressure relief door shrouds were actually installed on the forward door, although UAL records showed that they had been installed on both cargo doors of N4713U, in accordance with SB-747-52-2097. However, the shrouds were found not to be installed on the aft door, contrary to UAL records, and therefore may not have been installed on the forward door. Without the shrouds, the pressure relief doors could have rotated shut during the pressurization cycle. Because the closure of the pressure relief doors would back-drive the lock sectors, this scenario would presume previous damage to the sectors, which would permit the sectors to move over the unlatched cams.

Before recovery of the cargo door, the Safety Board believed that the lock sectors might have been damaged some time prior to the accident flight to the extent that they could have been moved to the locked position even though the latching cams were not fully closed.

During closure of the door, the latch actuator may not be able to rotate the cams to the fully closed position because of excessive binding forces between the latch cams and pins. This could occur if the cargo door is misaligned (out of rig) or if the pull-in hooks do not pull the door in far enough to properly engage the cams around the pins. There is sufficient evidence of wear on the pins and from the previous discrepancies with the door to indicate that the door was misaligned and not properly rigged.

The smooth wear areas found on the pins from N4713U are signs of heavy contact (interference) between the cams and pins during numerous past closings and openings of the door. This wear, other evidence from the door, and the maintenance history of the door, suggest strongly that the door was out of rig during the weeks and months before the accident.

The wear pattern damage to the pull-in hook pins also showed interference during the normal ground operations prior to the accident. This is further evidence of an out-of-rig door. It is also possible that the excessive binding force acting over a period of time precipitated a failure of the latch actuator. Regardless of the reason(s), the conditions of the latch pins and pull-in hook pins showed prolonged out-of-rig operation.

Most of the previous discrepancies with the forward cargo door on N4713U during December 1988 involved problems with closing the door electrically. These problems always occurred when the airplane was fully or nearly fully loaded, just before departure. The trouble-shooting and corrective actions by UAL maintenance, which on some occasions only involved cycling the door and finding it functional, were performed when the airplane was not fully loaded, during overnight maintenance inspections. The flexing of the fuselage with a full load of fuel, cargo, and passengers could have caused distortion of the door frame and resulted in misalignment between the cams and pins. In this case, the pull-in hooks may not have pulled the door fully in before the cam actuator attempted to latch the door. The wear evidence on the latch pins from N4713U suggests that this event had been occurring before the accident.

Safety Board investigators also witnessed this event during inspection and operation of the aft door on another UAL B-747, N4718U, in HNL. It was noted that the door on N4718U was not being pulled in fully by the pull-in hooks, so the latch cams completed the closing cycle with significant interference and "thunking" sounds. In fact, the out-of-rig door on N4718U failed to operate electrically at one point during its examination.

By design, any attempt to close the master latch lock handle and move undamaged lock sectors into place would not be successful unless the cams were rotated to near the fully latched position. This condition was substantiated by Boeing tests. Even with severely damaged lock sectors, as found on the Pan Am B-747, if the cams were more than 20 turns from the fully closed position on the Pan Am airplane, the master latch lock handle could not be stowed. Examination of the recovered N4713U door indicated that the door lock sectors were generally intact and jammed against the cams that had been back-driven into the lock sectors. Consequently, if the latch cams had been in the nearly unlatched position as found on the recovered door at the time the cargo handler attempted to move the master latch lock handle, the interference between the cams and the lock sectors would have prevented the master latch lock handle from moving to the closed position. Furthermore, this interference would have prevented the closure of the pressure relief doors as the airplane pressurized, irrespective of the possible absence of the pressure relief door shrouds. This conclusion is supported by extensive testing of the latch/lock mechanisms following the recovery of the door.

Therefore, based upon the examination of the lock sectors and the tests that were conducted, the Safety Board concludes that the latches were fully closed and that the locking handle was placed in the stowed position after the cargo was loaded.

2.5 Manual Unlatching of the Door Following Closure

It is possible that the cams could have been manually back-driven (about 95 turns) after the door had been secured; however, the UAL ramp personnel involved with dispatching the flight stated that the door was operated electrically. Furthermore, it seems unlikely that the ramp personnel would have driven the manual latch actuator 95 turns toward the open position after the door was fully latched.

The placard/seal located over the latch actuator manual drive on the recovered door was found with damage that initially suggested it had been previously compromised. If this were the case, it would indicate that someone may have used the manual drive to operate the door latches on an earlier flight or possibly immediately before the accident flight. However, the Safety Board

believes that an insertion of a screw driver and rotation of the plate retaining screw would have caused rotational tearing around the circumference of the screw head. There was no such tear. Rather, the damage to the placard/seal was more consistent with that which would occur from impact and underwater pressure
forces. Therefore, the evidence strongly suggests that manual operation of the latch actuator by ground service personnel after the door was properly closed is unlikely.

2.6 Electrical Unlatching of the Door Following Closure

2.6.1 Conditions or Malfunctions Required to Support Hypothesis

It was determined in 1987, after the Pan Am incident, that the locking sectors for B-747's, including those installed on N4713U, could be overcome by the force of the latch cam actuator, electrically or mechanically. If the latch cam actuator had been energized for some reason with the originally designed unstrengthened lock sectors installed, the latch actuator motor was capable of driving the latch cams open through properly positioned lock sectors, whether they were damaged or undamaged. Therefore, the locking sectors installed as original equipment for B-747's, and those installed on N4713U, would not perform the locking function as intended by the design. They would not "lock" the latches in place as implied by the name "lock sectors."

The investigation has shown that there are several conditions that must be met before the latch actuator will electrically drive the latch cams to the unlatched position on the B-747 after the door has been properly closed and locked. First, the ground handling power bus must be energized by having external power connected, or the APU must be operating and the APU generator field switch in the cockpit must be set to power the bus via the No. 2 ground handling power relay. Second, the air/ground relay must be in the "airplane on the ground" position. These two conditions are normally present when the airplane is on the ground before engine startup. Third, there must be a signal to the door open position in one of the two door open/close switches. Fourth, the S2 master latch lock switch, which cuts off power to the door actuators when the handle is stowed, must sense "not locked."

Therefore, it would take several independent conditions and some failures to provide for electrical power to be available to drive the door open electrically once it is closed and locked. The number of conditions and combinations depend upon the phase of operation of the airplane.

While the airplane was on the ground, before engine startup, with the master latch lock handle stowed, the external power connected (or with the APU running), and the ground handling bus powered, an "open" signal to the cargo door latch actuator would have occurred if any of the following combinations of conditions had been met: (1) a malfunction of the S2 master latch lock switch and the placement by someone of one of the door control switches to the "open" position; (2) a malfunction of the S2 master latch lock switch and certain short circuits; or (3) a two-wire short circuit path consisting of wire 101-20 shorting with any of the following wires: 108-20, 121-20, 122-20, 124-20, 135-20, or 136-20.

While the airplane was on the ground, after engine startup, and with the cargo door master latch lock handle stowed and the APU running, an "open" signal to the door latch actuator would have occurred if the following conditions had been met: (1) an energized ground handling bus resulting from the flightcrew reenergizing the APU generator field or failure of the No. 2 ground handling power relay; (2) a malfunction of the S2 master latch lock switch; (3) a malfunction of either of the door open/close switches or the placement of the switch in the "open" position by someone. An "open" signal would have also occurred had certain wire short circuits been present with condition (1) alone, or with conditions (1) and (2).

Regardless of the cause, electrical power to the latch actuator would have had to persist for the time necessary to rotate the cams to the nearly open position. If the electrical power had been applied for a longer time, the latch cams could have opened fully and caused the pull-in hooks to rotate open, a situation that would have prevented the airplane from pressurizing after takeoff. However, it is also possible that the latch actuator stalled before they opened fully because of the forces of the interference between the lock sectors and the cams as they were back-driven.

After takeoff, electrical operation of the door latch actuator would have required: (1) the APU to be running; (2) malfunction of the air/ground relay, (3) malfunction of the No. 2 ground handling power relay; and (4) malfunction of the S2 master latch lock switch and one of the cargo door open/close switches or a short circuit of the aforementioned wire pairs. Although the flightcrew could conceivably energize the ground handling bus from the APU by actuating the APU generator "field" switch, there was no evidence that they did so.

Thus, regardless of the phase of operation, either a wiring short circuit or a failure of the S2 master latch lock switch combined with some other anomaly or action would be required to cause the latches to move toward the open position. Before the recovery of the door, the Safety Board was able to examine two of the electrical relays and the door open/close switches from N4713U that would have to have failed to allow electrical operation of the cargo door in flight, with the APU running. These were the No. 2 ground handling power relay, the air/ground relay, and the internal and external door open/close switches. The examination of the relays and switches revealed no evidence of a single fault or conditions that might have caused an intermittent failure mode. The arcing noted on the No. 5 terminal of the outside door control switch was on the door "close" circuit and could not have been related to a short to the open mode. Further, because the flightcrew did not note a cargo door warning light, and the fact that the airplane was able to be pressurized, confirms that the master latch lock handle was in the closed position before takeoff. This position would actuate the master latch lock switch to disconnect power to the door opening actuators.

According to the flightcrew testimony and the pilots' comments recorded on the CVR during the flight, the APU was shut down shortly after takeoff and remained in that condition. Engine generators cannot power the ground handling bus from which the cargo door actuating mechanisms are powered. Once the APU was shut down, there was no power available to any of the cargo door electrical components. Therefore, an electrical actuation of the latch cam actuator at the time of the door loss was not possible.

The Safety Board believes that there is another reason why the opening of the door could not have been caused by electrical actuation shortly before the explosive decompression. Because the door carries the structural loads (hoop stresses) through its hinge and latches, the latch cams would be heavily loaded against the latch pins when the airplane was pressurized to the 6.5 psi differential pressure that was calculated to have been present at the time of the decompression. In that case, the torque limiter within the actuator would probably slip well before the actuator could achieve the torque necessary to drive the cams open against the frictional lock produced by the high bearing stresses resulting from pressurization.

2.6.2 Electrical Switches and Wiring Examinations--Recovered Door

All cargo door position sensing switches (S2 through S9) were found installed in their proper position. The cargo door recovery team found the S2 master latch lock switch in the "not-locked" position immediately after the door was aboard the recovery ship. This position would be consistent with the master latch lock handle being open. Further tests of the S2 switch revealed damage that probably resulted from the pressures under the sea. The only notable exception was a broken internal bracket that may have affected the operation of the switch prior to the accident. Other similar switches did not exhibit this failure. It is therefore possible that the S2 master latch lock switch failed prior to the accident, allowing more possibilities for electrical short circuits to power the latch actuator. Nevertheless, despite extensive testing, it could not be determined whether the S2 switch was functional before the accident.

The examination of 35 wires that remained with the recovered cargo door revealed several areas of damaged insulation that could have permitted an electrical short circuit to power the latch actuator. However, no evidence was noted of arcing that was indicative of short circuits. Furthermore, a significant number of the wires that had the potential for allowing for short circuits to power the latch actuator were not recovered. Testing conducted by Boeing and by UAL was inconclusive regarding whether a short circuit would have left detectable evidence of arcing. Therefore, the Safety Board was unable to determine whether the latch actuator was inadvertently powered by a short circuit in the cargo door wires.

The incident involving a UAL Boeing 747 at JFK Airport on June 13, 1991, confirmed that electrical short circuits in the cargo door wiring could cause the door to open. In this case, the short circuits were in the fuselage-to-cargo door wiring bundle where the bundle was covered by a flexible conduit. Although N4713U did not have a flexible conduit installed at the forward door position, its wiring was routed over the top of the door hinge where exposure to damage could occur. That portion of the wiring from N4713U was not recovered from the sea. The wires located at the door hinge area are more susceptible to in-service damage from movement during the open/close cycle, as compared with the wires mounted on the door that are normally static.

Following the incident at JFK, UAL directed that the circuit breaker that terminates power to the cargo doors be pulled after the door is closed and before departure of every B-747 flight. UAL obtained approval for this practice from the FAA and requested Boeing and the FAA to make such a practice part of the approved manual for the airplane. Neither Boeing nor the FAA acted on UAL's request.

Nevertheless, the Safety Board believes that the FAA should initiate rulemaking to include design considerations for nonplug transport category aircraft cargo doors that would deactivate the electrical circuitry to the door actuators after the doors are closed and locked. The catastrophic nature of the loss of a cargo door dictates the need to provide additional redundancies and fail-safe features in the door mechanisms to supplement the hardware safety features.

2.6.3 Possibility of Electrical Malfunction

Due to the lack of physical evidence, the Safety Board was unable to conclude that an electrical short caused the cargo door actuator to move the latch cams to the nearly open position, allowing the door to separate when the cabin pressure exceeded the load-carrying capability of the door latches. Neither could this possibility be eliminated. A momentary actuation of the door open switch by someone on the ground in the presence of a faulty S2 switch could also have caused the latches to open through the closed lock sectors. However, no evidence has been found that someone actuated the switch after the door was initially closed and locked.

The Safety Board concludes that it was not possible for the cargo door to have opened electrically at the time of the loss of the door. There was no power to the ground handling bus to power the actuator, even if there had been an electrical short. Further, the Safety Board concludes that it is highly improbable that an electrical short could have caused the latches to open after the airplane was airborne. Although the ground handling bus could conceivably have been powered, failures of other components that were tested as functional would also have been necessary.
The Safety Board believes that the electrical operation of the latch actuators from the fully closed and locked position most likely occurred before the engines were started when the ground handling bus was powered. The precise source of the electrical actuation could not be determined. Once the engines were started, the possibility of an electrical short decreases significantly because the ground handling bus is disengaged from the APU when the engines start. There was no evidence that the flightcrew reengaged the ground handling bus.
Because the preaccident condition of the S2 master latch lock switch could not be determined, it could also not be determined whether its proper functioning would have prevented the accident. The Safety Board did not determine whether damaged cargo door wires or a malfunctioning S2 switch could have been found by UAL maintenance had they been more aggressive in troubleshooting the cargo door problem in the weeks prior to the accident.

2.7 Design, Certification, and Continuing Airworthiness Issues

The Safety Board's analysis of this accident went beyond the conclusions about how the door failed. The Safety Board also examined the initial design and certification of the B-747 cargo door, and the continuing airworthiness system that should have prevented this accident, to identify the breakdowns in this system that led to the accident. As is the case with most aviation accidents, there are many factors that led up to the actual failure of the door on flight 811.

The Safety Board found that there were multiple opportunities during the design, certification, operation, and maintenance of the forward cargo door for N4713U for persons to have taken actions that could have precluded the accident involving flight 811. The circumstances that led to this accident exemplify the need for human factors considerations in the promulgation of regulations, the application of regulatory policies, the design of airplane systems, and the quality of airline operational and maintenance practices.

The first opportunity to prevent this accident occurred during the design and certification of the B-747 cargo door mechanical systems, when the design was chosen and approved, which allowed for the overriding of the lock sectors by either mechanical or electrical actuation. It is apparent that the original design was not tested sufficiently to verify that the locking sectors in fact "locked" the latch cams in the closed position. This shortcoming should have become apparent during the initial certification testing and approval process. Later, it should have become apparent when Boeing applied for, and the FAA granted, an alternative method of compliance with the certification regulations (25.783 [e]) that permitted the elimination of operational practices that included a visual verification of the cargo door latch positions via view ports in the doors.

The failure mode analysis performed by Boeing, and the FAA's acceptance of its content in granting the exemption, probably were based on the assumption that the lock sectors would always prevent the master latch lock handle from being in a stowed position when the latch cams were not fully closed. This assumption was not valid, as evidenced by the findings in 1987 following the Pan Am incident that the lock sectors could not prevent the latch cams from being driven from the fully latched position with the master latch lock handle stowed, while a false indication was provided to the flightcrew that the cargo door was properly latched and locked. At the time that Boeing sought approval of the alternative compliance, Boeing and the FAA should have reviewed the design and required testing of the door latch/lock mechanisms to verify their integrity. Thus, the procedure for direct viewing of the latches via the view ports before the airplane could be dispatched should not have been eliminated without adequate verification that the lock sectors were totally effective.

The next opportunity for the FAA and Boeing to have reexamined the original assumptions and conclusions about the B-747 cargo door design and certification was after the findings of the Turkish Airline DC-10 accident in 1974 near Paris, France. The concerns for the DC-10 cargo door latch/lock mechanisms and the human and mechanical failures, singularly and in combination, that led to that accident, should have prompted a review of the B-747 cargo door's continuing airworthiness. In the Turkish Airlines case, a single failure by a ramp service agent, who closed the door, in combination with a poorly designed latch/lock system, led to a catastrophic accident. The revisions to the DC-10 cargo door mechanisms mandated after that accident apparently were not examined and carried over to the design of the B-747 cargo doors.

Specifically, the mechanical retrofit of more positive locking mechanisms on the DC-10 cargo door to preclude an erroneous locked indication to the flightcrew, and the incorporation of redundant sensors to show the position of the latches/locks, were not required to be retrofitted at that time for the B-747. Of similar concern is the fact that the cargo doors for the L-1011 required redundant latch/lock indication sensors at initial certification, during the approximate same time frame the DC-10 and B-747

were certificated.
More recently, when Boeing and the FAA learned about the circumstances of the Pan Am cargo door opening incident in March 1987, more timely and positive corrective actions should have been taken. The Safety Board believes that the findings of that incident investigation should have called into question the assumptions and conclusions about the original design and certification of the B-747 cargo door, especially the alternative method for verifying that the door was latched and locked that was sought by Boeing and was granted by the FAA. Since a B-747 cargo door opening in flight was considered to be an "unacceptable event", once a door did come open in flight, the FAA and Boeing should have acted much quicker to prevent another failure.
It took nearly 16 months from the date of the Pan Am Incident (March 10, 1987) until the FAA issued AD-88-12-04 (July 1, 1988). And then, the AD allowed 18 or 24 months, depending on the model B-747, from the date of its issuance for compliance with the terminating actions of the AD. The fact that Boeing had issued an Alert SB as a result of the Pan Am incident is an indication of the apparent urgency with which Boeing treated this issue. Alert SB's are issued for "safety of flight" reasons, while regular SB's deal with "reliability" and not necessarily safety of flight items. Despite this, the terminating action, issued as
revision 3 to the Alert SB, on August 27, 1987, was not mandated by the FAA for 11 months.
The Safety Board found no evidence that the FAA or Boeing reassessed the original design and certification conclusions regarding the safety of the B-747 cargo door during this period.
Several opportunities for preventive action were also missed by UAL during this period. First, UAL delayed the completion of the terminating actions of Alert SB 52A2206 (Rev 3 and AD-88-12-04. In fact, there was no evidence that UAL had intended to comply

with the terminating action of the Alert SB, until it was mandated by the FAA.

It is understandable that an airline would not take its aircraft out of service to incorporate revisions that do not appear to be safety critical. Although by definition an Alert SB is safety related, there was no implication from Boeing's and FAA's actions regarding this matter that urgency was required. The airlines rely on the airframe manufacturers and the FAA to evaluate the need for urgent airworthiness actions that might take airplanes out of revenue service. In this case, UAL had scheduled completion of its B-747 fleet modifications in accordance with the terminating actions for AD-88-12-04 before the final allowable date; however, the schedule was based on other heavy maintenance schedules to prevent unnecessary down-time of its airplanes.

UAL personnel stated after the UAL 811 accident that its personnel did not fully appreciate the importance, or safety implications, of the terminating actions, or they would have incorporated the improvements much earlier. The usual difficulties in setting short suspense dates for performing terminating actions in AD's, such as parts availability, did not seem to exist in this case, because the parts were not complex components and probably could have been fabricated fairly quickly in-house by most airlines.

Human performance certainly contributed to UAL's failure to incorporate an important inspection step into its maintenance program as mandated by AD-88-12-04. When UAL obtained an advance draft copy of the forthcoming NPRM that eventually led to the AD, the airline began preparing its work orders to implement the forthcoming the AD requirements into its B-747 fleet (30 airplanes at the time). UAL developed its maintenance work sheets from the text of the draft NPRM, which was virtually identical to the text of the final rule. As a result of a clerical error, one of the important inspection steps required by the AD was omitted.

Apparently, UAL maintenance personnel never compared the work sheets they received with the actual requirements of the AD, or if they did, the omission was not detected. FAA inspectors responsible for oversight of UAL's maintenance program also did not detect this error because normal surveillance of AD compliance merely involved verifying the correctness of UAL's paperwork that listed the applicable AD's and compliance dates. The inspectors did not actually verify UAL's compliance action by shop visits, or by comparison of work sheets with AD provisions. These omissions by the UAL maintenance and quality assurance personnel, and the limitations of the FAA surveillance procedures were probably significant in setting the stage for the events that led to the actual cause of the door separation from N4713U.

Another matter of concern is the quality of UAL's trend analysis program. There was no indication that the repeated discrepancies with the forward cargo door on N4713U "raised a flag" within the UAL maintenance department. A quality assurance or trend analysis program should have detected an adverse trend and should have prompted efforts to resolve the repeated problems. If it had, any faults in the door electrical system or damage to mechanical components might have been detected.

In summary, the Safety Board concludes that there were several opportunities wherein Boeing, the FAA, and UAL could have taken action during the initial design and certification of the B-747 cargo door, as well as during the operation and maintenance of the cargo door installed on N4713U, to ensure the continuing airworthiness of the cargo door. The Safety Board further concludes that these deficiencies and oversights contributed to the cause of this accident.

2.8 Survival Aspects

The Hickam ARFF units and the airport's ARFF units operated on separate radio networks and thus they could not communicate directly on-scene by radio. This situation required them to communicate by voice. Although the two ARFF services had a common radio frequency (as per the Airport Emergency Plan), procedures for its use had not yet been developed. The Safety Board believes that such communication procedures should be expeditiously developed.

The use of camouflage paint schemes on military ARFF vehicles may be appropriate for military purposes; however, the Safety Board believes that camouflage is not appropriate for ARFF vehicles that are operated at a joint- use airport. It is obvious that these vehicles must be conspicuous to be seen by other responding vehicles and by persons who are involved in the accident, such as airport and airline personnel, crew and passengers, and off-airport firefighting and rescue vehicles.

The National Fire Protection Association Standards recommend for primary firefighting, rapid intervention and combined agent vehicles, that, "Paint finish shall be selected for maximum visibility and shall be resistant to damage from firefighting agents."4 Furthermore, Federal Aviation Regulation 14 CFR 139.319 (f) (2) requires emergency vehicles, "Be painted or marked in colors to enhance contrast with the background environment and optimize daytime and nighttime visibility and identification." Further guidance for the high visibility color of ARFF vehicles is provided in a Federal Aviation Administration Advisory Circular where the vehicle paint color is specified as, "lime yellow" Dupont No. 7744 UH or its equivalent.5

Because flight attendants are vital to the safety and survival of the passengers following a decompression, measures should be taken to prevent flight attendants from being incapacitated by hypoxia. The Safety Board believes that oxygen masks should be attached to the emergency oxygen bottles to avoid any delay in their use in order to be in compliance with the intent of 14 CFR 25.1447 (c)(4).

Therefore, the FAA should direct its inspector staff to survey B-747 airplanes for compliance with 14 CFR 25.1447(c)(4), and correct deficiencies found.

In this accident, the use of megaphones was vital because of the inability to be heard over the public address (PA) system. Title 14CFR 121.309 (f)(1) requires one megaphone on each airplane with a seating capacity of more that 60 and less that 100 passengers; 14 CFR 121.309 (f)(2) requires two megaphones in the cabins on each airplane with a seating capacity of more than 99 passengers. As this decompression demonstrated, additional megaphones are necessary on wide-body and large narrow-body airplanes to ensure communication in the cabin during emergencies when the PA system is inoperative.

Had there been a need for an immediate evacuation, or a water ditching, rapid egress would not have been possible at doors 2-left and 2-right because they were blocked by open storage compartments and spilled contents. The possibility also exists that a compartment door could release during a hard landing or turbulence and swing down and injure a flight attendant. Thus, the Safety Board believes that improved latches should be installed and the downward movement of stowage compartments doors should be restricted to prevent the doors from striking a seated flight attendant or block the exit door.

The Safety Board believes that the problems with life preserver donning and adjustment demonstrated in this accident should be addressed by the FAA. The straps and fittings on life preservers need to be evaluated to determine where improvements can be made, and clearer donning instructions should be developed.

TSO-C13d, Life Preservers 1/3/83 prescribes the minimum performance standards for life preservers. With regard to donning, the TSO requires:

Donning. It must be demonstrated that an adult, after receiving only the customary preflight briefing on the use of life preservers, can don the life preserver within 15 seconds unassisted while seated. It must be demonstrated that an adult can install the life preserver on another adult, a child, or an infant within 30 seconds unassisted. The donning demonstration is begun with the unpackaged life preserver in hand.

Based on flight attendant interviews and information obtained from passengers these donning times were exceeded in many instances.

The Safety Board has made numerous recommendations to the FAA in the past regarding needed improvements in life preserver donning instructions, donning procedures, and timing of donning.6 The FAA has adopted most of the Safety Board's recommendations in its April 23, 1986, revision to TSO-C13e, Life Preservers, which now requires the wearer to be able to secure the preserver with no more than one attachment and make no more than one adjustment for fit. Also, donning tests are required for age groups of users starting with 20-29 years and ending with 60-69 years. At least 60% of the test subjects in each age group must be able to don then life preserver within 25 seconds unassisted with their seatbelts fastened starting with the life preserver in its storage package. TSO-C13e contains requirements that would have eliminated some of the problems that passengers had in this accident in correctly donning and adjusting their life preservers.

The Safety Board has recommended (A-85-35 through-37) to the FAA to amend 14 CFR 121, 125, and 135 to require air carriers to install life preservers that meet TSO-C13e within a reasonable time. The FAA adopted TSO-C13e on April 23, 1986, and originally had specified an effective date of April 23, 1988, after which all newly manufactured life preservers approved under the TSO system would have to meet the requirements of TSO-C13e. The objective of the cut off date was to introduce life preservers into the fleets with the higher performance level as specified in

TSO-C13e by assuring that replacement articles met the higher standards. On March 3, 1988, the FAA rescinded the cut off date to seek further public comments of fleet retrofit in accord with the proposed rulemaking. See Section 4.0 for FAA action and status of the recommendations.

3. CONCLUSIONS

3.1 Findings

1. There were no flightcrew or cabincrew factors in the cause of the accident or injuries.
2. There were no air traffic control or weather factors in the cause of the accident.
3. The airplane had not been maintained in accordance with the provisions of AD-88-12-04 that required an inspection of the cargo door locking mechanisms after each time the door was operated manually and restored to electrical operation. However, this circumstance was determined not to be a factor in the accident.
4. All but one of the electrical components remaining with the airplane or found with the cargo door that were necessary to have malfunctioned in order to cause an inadvertent electrical opening of the cargo door after dispatch were found to function properly.
5. The forward cargo door lock sectors were found in the locked position (actually in an "over-locked" position) and jammed against the latch cams. The latch cams were found in the nearly open position.
6. The latch actuator manual drive port seal was found damaged from the forces involved in the separation of the door and did not indicate that the drive port had been used to open the door latches manually before the accident.
7. Electrical continuity tests indicated that the S2 master latch lock switch was in the "not locked" position when it was recovered with the cargo door. Because it had sustained damage from being submerged in the sea, its preaccident condition could not be determined.

8. An S2 switch functioning as found after recovery would permit electrical power to the door during ground operation so that additional failure modes or activation of the door control switch could result in movement of the latching cams.

9. All other switches associated with operation of the cargo door were found damaged from being submerged in the sea; however, they were determined to be properly installed and probably functional.

10. Short circuit paths in the cargo door circuit were identified that could have led to an uncommanded electrical actuation of the latch actuator; this situation occurred most likely before engine start, although limited possibilities for an uncommanded electrical actuation exist after engine start while an airplane is on the ground with the APU running.

11. It was not possible for electrical short circuits to command the cargo door to open at the time of the loss of the door, and it is highly improbable that such an event occurred when the airplane was airborne during the short period while the APU was running.

12. Insulation breaches were found on recovered portions of the cargo door wires that could have allowed short circuiting and power to the latch actuator, although no evidence of arcing was noted. All of the wires were not recovered, and tests showed that arcing evidence may not be detectable.

13. An uncommanded movement of cargo door latches that occurred on another UAL B-747 on June 13, 1991, was attributed to insulation damage and a consequent short between wires in the wiring bundle between the fuselage and the moveable door. Because the S2 switch functioned properly on that airplane, movement of the latches would not have occurred after the door was locked.

14. UAL's maintenance trend analysis program was inadequate to detect an adverse trend involving the cargo door on N4713U.

This circumstance was determined not to be a factor in the accident.
15. FAA oversight of the UAL maintenance and inspection program did not ensure adequate trend analysis and adherence to the provisions of airworthiness directives. This circumstance was determined not to be a factor in the accident.
16. The smooth wear patterns on the latch pins of the forward cargo door installed on N4713U were signs that the door was not properly aligned (out of rig) for an extended period of time, causing significant interference during the normal open/close cycle.
17. The rough heat-tinted wear areas on the latch pins of the forward cargo door installed on N4713U marked the positions of the cams at the time the door opened in flight.
18. The design of the B-747 cargo door locking mechanisms did not provide for the intended "fail-safe" provisions of the locking and indicating systems for the door.
19. Boeing's Failure Analysis, which was the basis upon which the FAA granted an alternative method of compliance with the provisions of 14 CFR 25.783(e), was not valid as evidenced by the findings of the Pan Am incident in 1987, and the accident involving flight 811.
20. Boeing and the FAA did not take immediate action to require the use of the cam position view ports following the Pan Am incident, and did not include this requirement in the provisions of the Alert Service Bulletins or AD-88-12-04.
21. There were several opportunities for the manufacturer and the FAA to have taken action during the service life of the Boeing 747 that might have prevented this accident.
22. The fact that the crash fire rescue vehicles responding to this accident did not use a common radio frequency led to problems in communication among the responding vehicles.
23. The camouflage paint scheme of the military fire rescue

units led to reduced visibility of these units and resulted in at least one near-collision.

24. Megaphones were used in flight to communicate with passengers because of the high ambient noise level. However, more megaphones would have afforded better communication in all parts of the cabin.

25. Some flight attendants and passengers had difficulties tightening straps of their life preservers around their waists because of the fabric used, the design of the adjustment fittings, and the angle the straps were pulled.

26. Articles that fell to the floor from stowage bins above the L-2 and R-2 exits and galley service items had to be cleared away from the exits before the emergency evacuation could be initiated.

3.2 Probable Cause

The National Transportation Safety Board determines that the probable cause of this accident was the sudden opening of the forward lower lobe cargo door in flight and the subsequent explosive decompression. The door opening was attributed to a faulty switch or wiring in the door control system which permitted electrical actuation of the door latches toward the unlatched position after initial door closure and before takeoff. Contributing to the cause of the accident was a deficiency in the design of the cargo door locking mechanisms, which made them susceptible to deformation, allowing the door to become unlatched after being properly latched and locked. Also contributing to the accident was a lack of timely corrective actions by Boeing and the FAA following a 1987 cargo door opening incident on a Pan Am B-747.

4. RECOMMENDATIONS

As a result of the investigation, including evidence from the recovered cargo door and a June 13, 1991, incident involving the uncommanded electrical operation of a cargo door on a UAL Boeing 747 at JFK Airport, the National Transportation Safety

Board recommends that the FAA:

Require that the electrical actuating systems for nonplug cargo doors on transport-category aircraft provide for the removal of all electrical power from circuits on the door after closure (except for any indicating circuit power necessary to provide positive indication that the door is properly latched and locked) to eliminate the possibility of uncommanded actuator movements caused by wiring short circuits. (Class II, Priority Action) (A-92-21)

As a result of this investigation, on August 23, 1989, the Safety Board issued the following safety recommendations to the FAA:

Issue an Airworthiness Directive (AD) to require that the manual drive units and electrical actuators for Boeing 747 cargo doors have torque limiting devices to ensure that the lock sectors, modified per AD-88-12-04, cannot be overridden during mechanical or electrical operation of the latch cams. (Class II, Priority Action)(A-89-92)

Issue an Airworthiness Directive (AD) for non-plug cargo doors on all transport category airplanes requiring the installation of positive indicators to ground personnel and flightcrews confirming the actual position of both the latch cams and locks, independently. (Class II, Priority Action)(A-89-93)

Require that fail-safe design considerations for non-plug cargo doors on present and future transport category airplanes account for conceivable human errors in addition to electrical and mechanical malfunctions. (Class II, Priority Action)(A-89-94)

The FAA responded to Safety Recommendations A-89-92 through -94 on November 3, 1989. During its evaluation of Safety Recommendation A-89-92, the FAA determined that Boeing 747 cargo doors with lock sectors, modified in compliance with AD 88-12-04, cannot be overridden during mechanical or
least one torque-limiting device. The Safety Board has reviewed AD 88-12-04 and has confirmed the FAA's findings. Based on this,

Safety Recommendation A-89-92 has been classified as "Closed--Reconsidered."

The FAA responded to Safety Recommendations A-89-93 and -94 describing action to review all outward opening (nonplug) doors and all jetpowered transport-category airplanes to determine what, if any, modifications are needed to ensure that these doors will not open in flight. The FAA pointed out that the door latch indicating system is to be only part of the review and that door designs will be evaluated against criteria specified in 14 CFR 25.783 as amended by Amendment 25-54, and the policy material published in Advisory Circular 25.783.1, adopted in 1980 and will take into account human factors involved in the routine operation of closing and locking doors to ensure that the latch and lock systems are fail-safe. Further, to emphasize the importance of human factors, the FAA has developed a training program for FAA certification personnel to enhance their knowledge of human factors in aircraft design. This training program will be offered to approximately 100 certification personnel during the next year. Based on this response, Safety Recommendations A-89-93 and -94 have been classified as "Open--Acceptable Action." The Safety Board believes it necessary to point out that this hazard exists for any pressurized aircraft using nonplug doors and that the FAA should not be limiting this review to only those transports which are jetpowered.

On November 29, 1990, Boeing issued service bulletin number 747-52-2224 applicable to all 747-100, 747-200, and 747-300 airplanes to add a new "door latch" switch to all 747 cargo doors. In addition to the door warning switch that monitors the position of the pressure relief doors, the new door latch switch is activated by the latch cam bellcrank to separately sense the position of the latch cams. The existing "door closed" switch is also replaced with a double pole switch. The additional pole is used to separately sense the position of the door. Another single pole switch is also added to redundantly sense the position of the door. If any of these switches are not actuated, the warning light on the flight engineer's panel and a new light added to pilot's glareshield panel will be illuminated. The modification also requires installation of new cargo door control panels on the forward and aft lower cargo doors. The new panel incorporates an additional light to indicate proper door locking.

The FAA mandated the incorporation of this service bulletin within 18 months by AD 90-09-06, Amendment 39-6581, effective May 29, 1990.

Also, as a result of this accident, on May 4, 1990, the National Transportation Safety Board issued the following safety recommendations to the FAA:

Amend 14 CFR 25.1447(c)(4) to require that face masks be attached to the regulators of portable emergency oxygen bottles. (Class II, Priority Action) (A-90-54)

Require, in accordance with the requirements of 14 CFR 25.1447 (c)(4), that a portable oxygen bottle be located at the flight attendant stations at exit door 5 right and at exit door 5 left in B-747 airplanes. (Class II, Priority Action) (A-90-55)

Require that no articles be placed in storage compartments that are located over emergency exit doors. (Class II, Priority Action) (A-90-56)

Amend 14 CFR 121.309(f) to require a readily accessible megaphone at each seat row at which a flight attendant is stationed. (Class II, Priority Action) (A-90-57)

Take corrective action to improve direct visibility to passengers from the upper level flight attendant jumpseat in the B-747 airplanes using eye reference data contained in Federal Aviation Administration report FAA-AM-75-2 "Anthropometry of Airline Stewardesses." (Class II, Priority Action) (A-90-58)

Issue an Airworthiness Directive to require that stronger latches be installed in oversized storage compartments that formerly held liferafts on all B-747 airplanes and also limit the distance that these compartments can be opened. (Class II, Priority Action) (A-90-59)

Demonstrate for each make and model of life preserver that it can be donned, adjusted, and tightened within the elapsed time required by TSO-C13d. Direct particular attention to the ease with which straps pass through adjustment fittings when the straps are pulled at all possible angles. (Class II, Priority Action) (A-90-60)

Establish a cutoff date of [within 1 year of this recommendation letter] after which all life preservers manufactured for passengercarrying aircraft would be required to meet the specifications of TSO-C13e. (Class II, Priority Action) (A-90-61)

The FAA first responded to these safety recommendations in a July 26, 1990, letter. Further responses to various safety recommendations in the group came in letters dated October 26, 1990 (A-90-59); May 13, 1991 (A-90-58); September 23, 1991 (A-90-55, -56, and -59); and March 9, 1992 (A-90-59). The current status of each safety recommendation is:

A-90-54: "Open--Acceptable Response," pending outcome of potential rulemaking initiative by the FAA.

A-90-55: "Open--Unacceptable Response," pending a review by the FAA of B-747 airplanes for compliance with portable oxygen bottle placement and securement requirements and for modifications that do not meet the intent of the type certification.

A-90-56: "Open--Unacceptable Response," pending a reexamination by the FAA of the potential for contents of compartments spilling out during an emergency and obstructing passengers.

A-90-57: "Open--Unacceptable Response," pending the FAA's review of its position regarding a requirement for multiple megaphones on passenger airplanes.

A-90-58: "Closed--Reconsidered" as a result of the Safety Board's acceptance of the FAA position that the cabin jumpseat design on

B-747's does not constitute an unsafe condition.
A-90-59: "Open--Acceptable Response," pending the issuance of an Airworthiness Directive to require stronger latches on oversized storage compartments on B-747 airplanes.
A-90-60: "Open--Acceptable Response," pending the implementation of the latest iteration of TSO-C13.
A-90-61: "Open--Unacceptable Response," pending inclusion in TSO-C13 (latest iteration) of a cutoff date after which all life preservers manufactured for passenger-carrying aircraft would be required to meet the specifications of the TSO.
The FAA's March 9, 1992, response to Safety Recommendation A-90-59 included the final AD addressing this issue. The AD does meet the intent of the recommendation, which is now classified as "Closed--Acceptable Action."
Also as a result of this accident, on May 4, 1990, the Safety Board reiterated the following recommendations to the FAA:
A-85-35
Amend 14 CFR 121 to require that all passenger-carrying air carrier aircraft operating under this Part be equipped with approved life preservers meeting the requirements of the most current revision of TSO-C13 within a reasonable time after the adoption of the current revision of the TSO; ensure that 14 CFR 25 is consistent with the amendments to Part 121.
A-85-36
Amend 14 CFR 125 to require that all passenger-carrying air carrier aircraft operating under this Part be equipped with approved life preservers meeting the requirements of the most current revision of TSO-C13 within a reasonable time after the adoption of the current revision of the TSO; amend Part 125 to require approved flotation-type seat cushions (TSO-C72) on all such aircraft; ensure that 14 CFR 25 is consistent with the amendments of Part 125.
A-85-37

Amend 14 CFR 135 to require that all passenger-carrying air carrier aircraft operating under this Part be equipped with approved life preservers meeting the requirements of the most current revision of TSO-C13 within a reasonable time after the adoption of the current revision of the TSO; Amend Part 135 to require approved floatation-type seat cushions (TSO-C72) on all such aircraft; ensure that 14 CFR SFAR No. 23 is consistent with the amendments to Part 135.

In a November 28, 1988, letter to the FAA, the Safety Board recommended that a cutoff date January 1, 1989, be reestablished. Based on this accident, the Safety Board's again urges the FAA to establish a cutoff date by which life preservers meeting TSO-C13e would be introduced into the fleets within a reasonable time (A-85-36). The Safety Board recognizes that the FAA has complied with the part of this recommendation pertaining to the flotation-type seat cushions.

Safety Recommendations A-85-35 and -37 are being held in an "Open--Acceptable Action" status pending the publication of the final rule. Safety Recommendation A-85-36 is being held in an "Open--Unacceptable Action" status because Part 125 operations were not included in the FAA rulemaking action.

As a result of its investigation, on May 4, 1990, the Safety Board also recommended that the State of Hawaii, Department of Transportation, Airports Division:

Develop, in cooperation with the Department of Defense, procedures for direct radio communication between aircraft rescue and fire fighting vehicles operated by the State of Hawaii and Hickam Air Force Base that would be used when responding to airport emergencies at Honolulu International Airport. (Class II, Priority Action) (A-90-62)

Additionally, as a result of its investigation, on May 4, 1990, the Safety Board recommended that the Department of Defense:

Develop, in cooperation with the State of Hawaii Department of

Transportation, procedures for direct radio communication between aircraft rescue and firefighting vehicles operated by Hickam Air Force Base and the State of Hawaii that would be used when responding to airport emergencies at Honolulu International Airport. (Class II, Priority Action) (A-90-63)

Comply with Federal Regulation 14 CFR 139.319(f)(2) and the guidance contained in Federal Aviation Administration Advisory Circular 150/5220-14 by using high visibility color for aircraft rescue and firefighting vehicles that operate at Honolulu International Airport. (Class II, Priority Action) (A-90-64)

The Department of Defense responded to Safety Recommendations A-90-63 and -64 on August 17, 1990, citing the establishment of emergency radio communication ability between ARFF vehicles operated by Hickam Air Force Base and the State of Hawaii at Honolulu International Airport. Based on this action, Safety Recommendation A-90-63 was classified as "Closed--Acceptable Action" on December 12, 1990. With the establishment of the communications system as recommended, the Safety Board now classifies Safety Recommendation A-90-62 as "Closed--Acceptable Action."

Also, with regard to Safety Recommendation A-90-64, the Department of Defense pointed out that the Air Force has initiated a program to rep™ aint the vehicles over a 3-year period to spread out funding concerns. This safety recommendation is being held as "Open--Acceptable Response," pending the completion of the repainting program in 1993.

5. APPENDIXES

APPENDIX A

INVESTIGATION AND HEARING

1. Investigation

The Washington Headquarters of the National Transportation Safety Board was notified of the United Airlines accident within a short time after the occurrence. A full investigation team departed Washington, D.C. at 1400 eastern daylight time on the same day and arrived in Honolulu at 0030 Hawaiian standard time the next day.

The team was composed of the following investigation groups: Operations, Structures/Systems, Maintenance Records, Metallurgy, and Survival Factors. In addition, specialist reports were prepared relevant to the CVR, FDR and radar plots.

Parties to the field investigation were United Airlines, the FAA, the Boeing Commercial Airplane Company, the Air Line Pilots Association, the International Association of Machinists, and the Association of Flight Attendants.

2. Public Hearing

A 3-day public hearing was held in Seattle, Washington, beginning on April 25, 1989. Parties represented at the hearing were the FAA, United Airlines, the Boeing Commercial Airplanes Company, the Air Line Pilots Association, and the International Association of Machinists.

APPENDIX B

PERSONNEL INFORMATION

Captain David Cronin

Captain David Cronin, 59, was hired by UAL on December 10,

1954. The captain holds Airline Transport Pilot (ATP) Certificate No. 1268493 with airplane multiengine land ratings and commercial privileges in airplane single-engine land, sea and gliders. The captain is type rated in the B747, DC10, DC8, B727, Convair (CV) 440, CV340, CV240 and the learjet. The captain was issued a first class medical certificate on November 1, 1988, with no limitations.

The captain's initial operating experience (IOE) check out in the B747 occurred in December, 1985. The captain's latest line and proficiency checks in the B747 were completed in August and December, 1988, respectively. Training in ditching and evacuation was included with the proficiency check. The captain had flown a total of about 28,000 hours, 1,600 to 1,700 hours of which were in the B747. During the 24-hour, 72-hour and 30-day periods, prior to the accident, the captain had flown: 1 hour, 5 minutes; 13 hours, 35 minutes; and 76 hours, 18 minutes, respectively.

First Officer Gregory Slader

First Officer Gregory Slader, 48, was hired by UAL on June 15, 1964. The first officer holds ATP Certificate No. 1528630 with airplane multiengine land ratings and commercial privileges in airplane single-engine land. The first officer is type rated in B747, DC10, B727, and B737. The first officer was issued a first class medical certificate on February 14, 1989, with no limitations.

The first officer's initial operating experience (IOE) check out in the B747 occurred in August, 1987. The first officer's latest proficiency check in the B747 was completed in October, 1988. Training on ditching and evacuation was included with the proficiency check. The first officer had flown a total of about 14,500 hours, 300 hours of which were in the B747. During the 24-hours, 72-hour and 30-day periods prior to the accident, the first officer had flown: 1 hour, 5 minutes; 13 hours, 35 minutes; and 46 hours, 25 minutes, respectively.

Second Officer Randal Thomas

Second Officer Randal Thomas, 46, was hired by UAL on May 22, 1969. The second officer holds Flight Engineer Certificate No. 1947041 for turbo jet powered airplanes, issued July 18, 1969. The second officer holds commercial pilot certificate No. 1585899 with ratings and limitations of airplane single and multiengine land with instrument privileges. The second officer was issued a first class medical certificate on December 6, 1988, with no limitations. The second officer's IOE check out in the B747 occurred in March, 1987. The second officer's latest proficiency check in the B747 was completed in October, 1988. Training in ditching and evacuation was included with the proficiency check. He had flown a total of about 20,000 hours, about 1,200 hours of which were as second officer on the B747. During his 24-hour, 72-hour and 30 day-periods, prior to the accident, the second officer had flown: 1 hour, 5 minutes; 13 hours, 35 minutes; and 46 hours, 25 minutes, respectively.

Flight Attendant and Chief Purser Laura Brentlinger

Flight attendant Laura Brentlinger, 38, was employed by UAL in May 1982; and had completed B747 recurrent training on September 19, 1988.

Flight Attendant and AFT Purser Sarah Shanahan

Flight attendant Sarah Shanahan, 42, was employed by UAL in August 1967; and had completed B747 recurrent training on October 10, 1988.

Flight Attendant Richard Lam

Flight attendant Richard Lam, 41, was employed by UAL on April 1970; and had completed B747 recurrent training on September 16, 1988.

Flight Attendant John Horita

Flight attendant John Horita, 44, was employed by UAL in June 1970; and had completed B747 recurrent training on November 1, 1988.

Flight Attendant Curtis Christensen

Flight attendant Curtis Christensen, 34, was initially employed by PAA in May 1978. He was subsequently employed by UAL in February 1986 when UAL purchased PAA Pacific Division. Flight attendant Chrisensen had completed B747 recurrent training on December 12, 1988.

Flight Attendant Tina Blundy

Flight attendant Tina Blundy, 36, was employed by UAL in May 1973; and had completed B747 recurrent training on October 28, 1988.

Flight Attendant Jean Nakayama

Flight attendant Jane Nakayama, 37, was employed by UAL in August 1973; and had completed B747 recurrent training on December 6, 1988.

Flight Attendant Mae Sapolu

Flight attendant Mae Sapolu, 38, was initially employed by Pan American Airlines (PAA) in March 1973. She was subsequently employed by UAL in February 1986; when UAL purchased PAA Pacific Division. Flight attendant Sapolu completed B747 recurrent training on October 13, 1988.

Flight Attendant Robyn Nakamoto

Flight attendant Robyn Nakamoto, 26, was employed by UAL in April, 1986, and transferred to the Inflight Service Division in May, 1988. She was initially trained on the B747 in May 1988; and had not attended recurrent training.

Flight Attendant Edward Lythgoe

Flight attendant Edward Lythgoe, 37, was employed by UAL in December 1978; and had completed B747 recurrent training on October 21, 1988.

Flight Attendant Sharol Preston

Flight attendant Sharol Preston, 39, was employed by UAL in July 1970; and had completed B747 recurrent training on July 29, 1988.

Flight Attendant Ricky Umehira

Flight attendant Ricky Umehira, 35, was employed by UAL in

November 1983; and had completed B747 recurrent training on November 15, 1988.

Flight Attendant Darrell Blankenship

Flight attendant Darrell Blankenship, 28, was employed by UAL in February 1984; and had completed B747 recurrent training on February 10, 1988.

Flight Attendant Linda Shirley

Flight attendant Linda Shirley, 30, was employed by UAL in March 1979; and had completed B747 recurrent training on November 3, 1989.

Flight Attendant Ilona Benoit

Flight attendant Ilona Benoit, 48, was initially employed by PAA in November 1969. She was subsequently employed by UAL in February 1986; and had completed B747 recurrent training on November 17, 1988.

Lead Ramp Serviceman Paul Engalla

Lead ramp serviceman Paul Engalla was employed by UAL in 1959. Because of his extensive ramp service experience, Mr. Engalla was selected as a ramp service trainer in 1986.

Ramp Serviceman Daniel Sato

Ramp serviceman Daniel Sato was employed by UAL in May 1987. Company records indicate that his proficiency in the opening and closing of B747 cargo doors and the operation of container loads was attained in September 1988.

Ramp Serviceman Brian Kitaoka

Ramp serviceman Brian Kitaoka was employed by UAL in November 1986. Company records indicate that his proficiency in the operation of container loaders was attained in November 1987. His proficiency in the opening and closing of B747 cargo doors was attained in October 1988.

Dispatch Mechanic Steve Hajanos

Dispatch mechanic Steve Hajanos was employed as an airplane mechanic by UAL on October 30, 1986. He holds FAA Airplane and Powerplants Certificate No. 362583850, issued November 14, 1981. He was formerly employed by Aloha Airlines as a maintenance supervisor and by World Airways as a mechanic and maintenance supervisor. He began his aviation career as an airplane mechanic in the United States Air Force.

APPENDIX D

INJURY INFORMATION

Flight Crewmember.--The second officer sustained minor superficial brush burns to both elbows and forearms, during the evacuation.

Cabin Crewmembers.--The cabin crewmembers sustained the following injuries during the evacuation:

Flight attendant No. 1 sustained a strained left shoulder;

Flight attendant No. 2 sustained acute thoracic and lumbosacral

strain;
Flight attendant No. 3 sustained a mild right bicep strain;
Flight attendant No. 4 sustained a left elbow contusion, left shoulder dislocation, and mild lumbosacral strain;
Flight attendant No. 5 sustained a left calf contusion;
Flight attendant No. 6 sustained a mild left elbow bruise;
Flight attendant No. 7 sustained mild left arm and lower back strain;
Flight attendant No. 8 sustained a soft tissue injury to the back;
Flight attendant No. 9 sustained abrasions to both palms and the left knee;
Flight attendant No. 10 sustained a fracture of the left tenth rib;
Flight attendant No. 11 sustained a minimal injury to the right middle finger PIP joint and left first MP joint;
Flight attendant No. 12 sustained a pulled muscle on the left side of the neck;
Flight attendant No. 13 sustained a comminuted fracture of the right ulna and radius;
Flight attendant No. 14 sustained a mild thoracic back strain;
Flight attendant No. 15 sustained a non-displaced fracture of C-6, a cerebral concussion, a fracture of the proximal right humerus, and multiple lacerations;
A flight attendant, flying as a passenger, sustained mild lumbosacral strain, a laceration of the right little finger, and a left elbow abrasion.
Passengers.--Nine Passengers who were seated in seats 8H, 9FGH, 10GH, 11GH, and 12H, were ejected from the fuselage and were not found; and thus, are assumed to have been fatally injured in the accident.
Passengers seated in the indicated seats sustained the following injuries:
Seat
7C - Barotrauma to both ears

9C - Half-inch laceration to the upper left arm, superficial abrasions to left arm and hand, barotrauma to both ears
9E - Superficial abrasions and contusions to the left hand, mild barotrauma to both ears
10B - Superficial abrasions to the left elbow and left middle finger
10E - Superficial abrasions to the torso and left forearm, bruising of the left hand and fingers
11E - Laceration on the right ankle tendon, multiple bruises
11F - Slight contusion of the right shoulder
13D - Barotrauma to both ears
13E - Bleeding in both ears
13H - Contusion to the left periorbital area
14A - Laceration in the parietal occipital area, barotrauma to both ears
15J - Comminuted fracture of the lateral epicondyle of the left distal humerus (about 5mm separation)
16B - Superficial abrasions to the right arm
16J - Barotrauma to both ears
16K - Right temporal abrasions
26A - Barotrauma to both ears
26B - barotrauma to both ears
26H - Barotitis to both ears, low back pain, irritation to the right eye due to foreign bodies
27A - Barotrauma to the right ear
28J - Superficial abrasions and a contusion to the left hand, mild barotrauma to both ears

1The flap track canoe fairings are numbered 1 through 8, from left outboard to right outboard.

2For ease in reference, the following numbering was used to relate forward cargo door frames to fuselage body stations (BS): frame 1--BS 567.10, frame 2--BS 580.95, frame 3--BS 596.75, frame 4--BS 608.15, frame 5--BS 623.96, frame 6--BS 636.02, frame 7--BS

651.50, frame 8--BS 662.90.
3 The "used" switch is the switch through which electricity passes; the "unused" switch does not have electricity pass through it.

Subject: **AARs**

Dear Jaswinder,

The crown gave us 26 CD ROMs of information that they have gathered over the past 15 years. The CD's contain scanned images of documents they have collected. I am in the process of converting those images to text documents. Once this process is done the defence team will better be able to do searches using standard boolean expressions.

Terrific. I have the three AAR of AI 182, PA 103, and UAL 811 electronically and use the 'search' function all the time. The AAR of TWA 800 is very large and not suitable for emailing but is on

NTSB web site.

Let me send you the three AAR for reference, I'll use three separate email.

I am also in the process of creating a web site with forum that will alow us to communicate over the internet. I am looking into different ways to make sure the site is secure.

Well, sir, put in www.airindiaflight182.com into your browser and see where you go. Voila! Explosive decompression for AI 182. If you want to get rid of the banner ad on the bottom, just go direct to www.corazon.com

I own that domain and the defence can use it. Making it secure and creating the site would require professionals above my league.

I assume you got my pictures, I just want to confirm we can send and receive .jpg between us.

Narinder is coming down to my house tomorrow for another discussion about plans.

I really believe we are getting some where. It is time for the defence to take the initiative. Let the Crown disprove the wiring/cargo door/explosive decompression explanation (they can't) as we try to disprove the 'bomb' explanation, (we can).

Sincerely,
Barry

Subject: **Re: Morale booster, no bomb.**

Mr. Malik is not permitted to receive any food from the outside. His family
is vegetarian - so chocolates with no eggs please.

as

Got it, chocolate, no eggs is OK.

Is there anything official that Garstang changed to Aft instead of forward? Is that the point of view of Garstang or the TSB? Any reason for his changing. This is potentially very difficult. I can't rebut phantoms.

If it's aft, then the charges need to be refiled because the charges are based on the official report which says forward.

If forward, the charges need to be dismissed because all baggage from Vancouver, including the 'bomb', when into the aft compartment.

If aft, a new report by TSB needs to be written and approved explaining the new evidence which reverses the overwhelming evidence of explosion in forward compartment.

Sincerely,
Barry

Subject: **Legally Blonde**

Thank you for the message regarding the appraisal. I forwarded your message on to Andy so he is current. I appreciate how you are handling all the various aspects of this transaction, and admire your calm manner after experiencing so much turbulence.

We mailed the contract to Mrs. Titus this afternoon, so that she will receive it on her return home.

Thanks for all your assistance and immediate response to these matters.

All the best, Randa

Dear Randa,

Message received. Standing by for email about deal.

Legally Blonde is good, very funny, not very true, but what the heck...

Needs a sequel, "Illegally Brunette."

Cheers,

Barry

Subject: Shorted wiring/forward cargo door rupture/ explosive decompression/inflight breakup

Very intriguing Can you tell me more about it?????Andy Swartz

Well.....

Assume: that I believe my conclusions although they may be considered wrong by others; that if the discovery were easy, it would have been done long ago by others, that my conclusions are politically devastating to several countries, that I can document every statement I make, it's never been refuted, and you will not believe it at first blush.

I claim that four Boeing 747s have had fatal accidents caused by faulty wiring causing the forward cargo door to open in flight leading to explosive decompression. The state of the world today is that all four were thought to be bombs planted by terrorists. One accident was shown to be a cargo door event hours later, one accident had the bomb explanation ruled out 17 months later, and for the two remaining, the bomb explanation remains the official explanation. Conspiracy thinking rules, unfortunately.

I offer the mechanical explanation with no conspiracy involved and it's rejected as too weird.

The rewards come in when offered by governments and an individual for explanations for the fatal accidents. As it stands now, the rewards are offered for informants to give up terrorists who are assumed to be the culprits. I know the culprit and the explanation and it's wiring coupled with a design defect of outward opening non plug cargo doors. I have written thousands of pages about the events and contacted hundreds of persons in authority with mostly futile results.

There is an upcoming trial in February 02 in Vancouver BC for three accused of planting a bomb in Air India Flight 182. I know they did not do it, because nobody 'did it'. I've met two of the attorneys for one of the accused, Mr. Malik. They remain unconvinced. The evidence picks the flight numbers and they are all controversial of course, Air India Flight 182, Pan Am Flight 103, United Airlines Flight 811, and Trans World Airlines Flight 800.

The trigger event for action is another fatal accident that fits the pattern. The event is almost inevitable and could happen anytime. We will both know it was a shorted wiring/forward cargo door rupture/explosive decompression/inflight breakup event when it is reported that a Boeing 747 came apart in the air suddenly and the explanation will be 'bomb'; the CVR will show a sudden loud sound followed by an abrupt power cut to the recorders; and engine number three will show foreign object damage plus much other significant matching evidence.

I've been at this for 12 years. It's a good story with life and death implications. When you consider it, consider this, I have been in a sudden night fiery fatal jet airplane crash and I am talking about sudden night fiery fatal jet airplane crashes. I've been there and I know what I'm talking about.

Subject: **Circuit breakers**

You are correct. I have no doubt you have the ability to prbably handle the
action by yourself. You certainly have the courage to do so. The problem is

the massive legal maneuvers to be expected by the other side. In any event
good luck and I sincerely thank you for considering me as your counsel. Andy
Swartz 9/1/01

Well, I did not mean to be arrogant and was later afraid my comment appeared to be so.

There would be no 'massive legal maneuvers' by either side until the next one explodes. I am looking ahead.

I would not be a party as victim or family member, Kriendler and Wolk and Granito III have that area sewed up.

It's even a stretch to claim a reward for explaining a crash when what the reward people want is the blood of a terrorist, not the red paint smears which shows the door opened up and outward and smashed against the fuselage transferring paint.

I've stayed away from the legal arena on this wiring/cargo door thing precisely for the reasons you state, massive maneuvers.

Well, thanks anyway and for at least considering it. If you will follow the upcoming trial of the three accused 'terrorists' for the 'bombing' of Air India Flight 182, you may see the wiring/cargo door explanation surface. One of the accused, Mr. Malik, is a millionaire businessman and has hired two attorneys, Crossin and Donaldson, who may know about crime and bank robberies, but nothing about why planes crash.

For information, if the below 10/11/00 event had happened in flight instead of on the ground, there would have been another inflight decompression leading to fatalities. The door stayed closed in flight because the circuit breakers had been pulled by the crew. The FAA specifically ordered crews to leave the CB in. The crew disobeyed the FAA and saved their lives.

My position based on facts, data, and evidence is the below sequence occurred for the other three controversial accidents which have been blamed on something not so damning for all concerned such as terrorists or mystery fuel tank explosions.

Well, maybe later. Life is so funny.

Cheers,
Barry

ORDER: 8300.10

APPENDIX: 4

BULLETIN TYPE: Flight Standards Information Bulletin (FSIB)
for Airworthiness (FSAW)

BULLETIN NUMBER: FSAW 93-50

BULLETIN TITLE: Inappropriate Use of Circuit Breakers
During B-747 Lower Lobe Cargo Door Operation

EFFECTIVE DATE: 06-02-94

---

1. SUBJECT. This FSIB informs inspectors of unsafe procedures
being used by some operators to close and lock the lower lobe cargo doors of the Boeing 747 (B-747) series aircraft.

2. BACKGROUND.

A. This bulletin was developed after an inquiry by a foreign airworthiness authority into the special procedures used by a specific operator to close and lock the lower lobe cargo doors of B-747 series aircraft. The special procedure included in the operator's maintenance manual called for manual tripping of the cargo door control circuit breakers and the section 2 ground handling bus circuit breaker in order to further remove the possibility of power being applied accidentally to the cargo door control circuitry.

B. The manual tripping of the circuit breakers in special cargo door lock procedures is unnecessary and decreases the reliability of the circuit breakers to perform their intended function. Frequent switching of the breakers could cause them to trip before the point of rated voltage or not to trip at all. Both cases could have adverse effects (such as the following) in relation to the safe operation of the cargo doors:

(1) Circuit breakers that trip before the point of rated voltage would cause increased manual operation of the cargo doors.

(2) Manual operation could introduce additional failure conditions, such as out-of-sequence operation and overdriving of the cargo door mechanisms.

(3) Service history has shown that manual operation of the cargo doors is more prone to cause damage; for example, the failure of a breaker to trip at the point of rated voltage could lead to failed components and fire.

C. The revision to the B-747 cargo door lock sectors warning system, in airplanes compliant with Airworthiness Directive (AD)
90-09-06, provides an increased level of integrity so that manual tripping of the circuit breakers is not necessary to prevent the possibility of an uncommanded opening of the cargo doors. Furthermore, power to the cargo door is automatically removed by
the Master Latch Lock System upon first motion of the Master Latch Lock Switch away from the fully unlocked position.

3. ACTION. Principal maintenance inspectors (PMI) having certificate management responsibilities for operators of Boeing 747 series aircraft should ensure that this information is brought to the attention of their respective operators. Any operators using this procedure should be discouraged from its continued use.

4. INQUIRIES. This FSIB was developed by SEA.AEG. Any questions regarding this information should be directed to AFS-510 at (703) 661-0333, extension 5018.

5. EXPIRATION. This FSIB will expire on 05-31-95.

/s/
Edgar C. Fell

From AAR 92/02 United Airlines Flight 811

1.17.6 Uncommanded Cargo Door Opening--UAL B-747, JFK Airport

On June 13, 1991, UAL maintenance personnel were unable to electrically open the aft cargo door on a Boeing 747-222B, N152UA, at JFK Airport, Jamaica, New York. The airplane was one of two used exclusively on nonstop flights between Narita, Japan, and JFK. This particular airplane had accumulated 19,053 hours and 1,547 cycles at the time of the occurrence.

The airplane was being prepared for flight at the UAL maintenance hangar when an inspection of the circuit breaker panel revealed that the C-288 (aft cargo door) circuit breaker had popped. The circuit breaker, located in the electrical equipment bay just forward of the forward cargo compartment, was reset, and it popped again a few seconds later. A decision was made to defer further

work until the airplane was repositioned at the gate for the flight. The airplane was then taxied to the gate, and work on the door resumed.

The aft cargo door was cranked open manually, the C-288 circuit breaker was reset, and it stayed in place. The door was then closed electrically and cycled a couple of times without incident. With the door closed, one of the two "cannon plug" (multiple pin) connectors was removed from the J-4 junction box located on the upper portion of the interior of the door. The wiring bundle from the junction box to the fuselage was then manipulated while readings were taken on the cannon plug pins using a volt/ohmmeter. Fluctuations in electrical resistance were noted. When the plug was reattached to the J-4 junction box, the door began to open with no activation of the electrical door open switches. The C-288 circuit breaker was pulled, and the door operation ceased. When the circuit breaker was reset, the door continued to the full open position, and the lift actuator motor continued to run for several seconds until the circuit breaker was again pulled. At this time, a flexible conduit, which covered a portion of the wiring bundle, was slid along the bundle toward the J-4 junction box, revealing several wires with insulation breaches and damage.

UAL personnel notified the Safety Board of the occurrence, and the airplane was examined at JFK by representatives of the Safety Board, United Airlines, and Boeing. After the wires in the damaged area were electrically isolated, electrical operation of the door was normal when the door was unlocked. When the door was locked (master latch lock handle closed), activation of the door control switches had no effect on the door. This indicated that the S2 master latch lock switch was operating as expected (removing power from the door when it was locked). After the on-site examinations, the wiring bundle was cut from the airplane and taken to the Safety Board's materials laboratory for further examination.

The wiring bundle with the damaged wires contained all electric control wires (28 volt DC) and power wires (115 volt AC) that pass between the fuselage and the aft cargo door. From the forward side of the J-4 junction box, the bundle progresses in the forward direction, just above the forward pressure relief door, then upward, following the forward lift actuator arms. The bundle then enters an empty space between two floor beams, where the bundle has an approximate 180-degree bend when the door is closed. From this location, the wiring bundle progresses inboard, through a fore-to-aft intercostal between two floor beams. The wiring bundle then splits, with wires going in several directions.

The bundle is covered by the flexible conduit approximately from the lower end of the lift actuator arms to the fore-to-aft intercostal between the floor beams.

The conduit covering the wiring bundle is intended to prevent the wire bundle from being damaged during opening and closing of the door and during cargo handling operations. The conduit is a sealed flexible interconnector consisting of a convoluted helical brass innercore covered by a bronze braid. The innercore is soldered at every other convolute, and should be capable of withstanding pressures exceeding 1,000 pounds per square inch (psi). Boeing has indicated that the conduit is an evolutionary improvement and that it has been installed on all B-747 airplanes produced since 1981 (from line number 489 on). Airplane N152UA was delivered in April 1987.

Airplanes produced prior to 1981, including N4713U, used a bungee retraction system, to retract the cargo door wire bundle. Guidelines for the replacement of the bungee system with the flexible conduit were covered in Boeing Service Bulletin 747-752-2170, dated August 1981. The service bulletin was prompted by reports that the wire bundle bungee retraction system had not retracted the wire bundle sufficiently to prevent trapping the bundle between the cargo door and the door frame. UAL did not perform the retrofit on N4713U, which was line number 89, nor was the company required to do so.

Examination of the wires in the damaged area on the wiring bundle revealed that four of the wires were similar in appearance, with insulation breaches that progressed through to the underlying conductor. Adjacent to the breach on these four wires, the insulation was blackened, as if it had been burned. Another wire contained an extensive breach but no evidence of burned insulation. The damaged area was located on the bundle at a position approximately corresponding to a conduit support bracket and attached standoff pin on the upper arm of the forward lift actuator mechanism. This support bracket was found bent in the forward direction. In addition, mechanical damage was noted on adjacent components in this area.

A second damaged area was noted on the wiring bundle at a position approximately corresponding to the conduit swivel clamp at the elbow between the two arms of the forward lift actuator mechanism. Wires in this area were missing portions of their exterior coating, but no breaches to the underlying conductors were noted.

The exterior braid on the conduit contained minor rub marks and was slightly kinked at a position corresponding to the area on the wires with breached insulation. Additional examinations revealed that the innercore of the conduit contained multiple circumferential cracks in the areas corresponding to the damage areas on the wires. The cracks were in the convoluted innercore directly adjacent to the inside diameter of the conduit.

The lock sectors, latch cams, and latch pins from the aft cargo door were examined on the incident airplane and were generally in excellent condition. There was no evidence to suggest that the cams had ever been electrically (or manually) driven into or through the lock sectors.

Boeing also informed the Safety Board that, in May of 1991, a B-747 operated by Quantas was found to have chafing of the wires in the wire bundle to the aft cargo door. This airplane also had a flexible conduit protecting the wires, and the chafing was located approximately at the standoff pin on the bracket at the upper arm of the forward lift actuator.

The Safety Board determined that the chafing of the wires on the airplane involved in the JFK occurrence was caused by, or was greatly accelerated by, the circumferential cracks in the conduit and that the cracks in the conduit were caused either by repeated flexing of the conduit as the cargo door opens and shuts or by unusual stresses on the conduit generated concurrently with damage to the conduit guide bracket and attached standoff pin on the upper end of the forward lift actuator upper arm.

A portion of the wire bundle for the forward cargo door on many B-747 airplanes is also covered by a flexible conduit that is very similar to the conduit for the aft cargo door. However, there are substantial differences between the orientation of the flexible conduits for the two doors, and the Safety Board has not become aware of problems associated with the flexible conduit for the forward door.

Nevertheless, because of the concerns about the chafed wires and possible electrical short circuits, on August 28, 1991, the Safety Board recommended that the FAA:

Issue an Airworthiness Directive applicable to all Boeing 747 airplanes with a flexible conduit protecting the wiring bundle between the fuselage and aft cargo door to require an expedited inspection of:

(1) the wiring bundle in the area normally covered by the conduit for the presence of damaged insulation (using either an electrical test method or visual examination);

(2) the conduit support bracket and attached standoff pin on the upper arm of the forward lift actuator mechanism;

(3) the flexible conduit for the presence of cracking in the convoluted innercore.

Wires with damaged insulation should be repaired before further service. Damage to the flexible conduit, conduit support bracket and standoff pin should result in an immediate replacement of the conduit as well as the damaged parts. The inspection should be repeated at an appropriate cyclic interval. (Class II, Priority Action) (A-91-83)

Evaluate the design, installation, and operation of the forward cargo door flexible conduits on Boeing 747 airplanes so equipped and issue, if warranted, an Airworthiness Directive for inspection and repair of the flexible conduit and underlying wiring bundle, similar to the provisions recommended in A-91-83. (Class II, Priority Action) (A-91-84)

The FAA responded to these safety recommendations on November 1, 1991, stating that it agreed with the intent of the recommendations and that the issuance of an NPRM was being considered to address the issues in the safety recommendations.

The Safety Board replied on November 27, 1991, classifying each of the recommendations as "Open--Acceptable Response," pending the completion of the rulemaking process. Since that exchange of correspondence, the FAA has published an NPRM which is now being reviewed by the Safety Board. Safety Recommendations A-91-83 and -84 will continue to be classified as "Open--Acceptable Response" until an acceptable final rule is published.

Subject: **Contact! Air India Flight 182**

Dear Mr. Hamilton, 15 October, 2001

Well, yours is an important email. Thanks for contact.

I have briefly reviewed your report, and it does raise several issues that do not appear to have been addressed in any of the other reports, and which I want to examine more closely.

Exactly right.

My report is dense because it is supposed to be, most scientific reports are when supported by documentation. For informal purposes, please email me with questions and I can answer them briefly without all the quotations. Or call by phone.

I know your clients are innocent because they did not do it, because nobody 'did it'. It was not evil persons but a mechanical event that has happened before and since. And it's all documented and available for inspection for those willing to be objective and scientific.

Just for openers:

The CASB says explosion of unknown type in forward cargo compartment of Air India Flight 182.
The Indians in the Kirpal report state explosion by bomb in the forward cargo compartment.
The RCMP with Garstang of TSB state explosion by bomb in aft cargo compartment.
AAIB opines explosion of unknown cause but not bomb, in the forward cargo compartment.
Smith, that's me, says explosion of explosive decompression when forward cargo door inadvertently opens inflight at the forward cargo compartment.
TSB is neutral.

All Vancouver baggage loaded in aft cargo compartment.
All Montreal baggage loaded into forward cargo compartment.

Can you see the problems for the prosecution? Where was exactly the explosion? What was the source? If in aft, how can CASB and Indians be so wrong? If forward, then Vancouver baggage could not have held bomb and accused are innocent.

TSB, CASB, Indians, RCMP, and this independent investigator all have conflicting answers.

I believe mine to be the most correct and invite rebuttal or questions.

From your point of view: Was it a bomb or not? If you believe a bomb then leave me out of it and continue on the conspiracy lunacy that sweeps the world.

If not a bomb, what was it? Then include me and we can go through the ways airplanes can come apart in the air as Air India Flight 182 did.

My model for the shorted wiring/forward cargo door rupture/ explosive decompression/inflight breakup explanation for Air India Flight 182 is United Airlines Flight 811, AAR available upon request. It's happened before, Mr. Hamilton.

Please keep in mind, Air India Flight 182 was an airplane crash, not a bank robbery. If we start with that premise, everything will make sense.

I await your enquiries. The sooner the better.

Cheers,
John Barry Smith

Dear Mr. Smith:

I do not appear to have a mailing address for you, so I am sending you this email message instead.

I am one of the lawyers working on the defence team for Ajaib Singh Bagri, one of the three men charged with the Air India Flight 182 crash. Jaswinder Parmar suggested that I write to you, as I am reviewing the forensic evidence.

I have a copy of your report dated April 9, 2001, and the appendices. As you would expect, I have many reports that have been generated during the RCMP investigation and the various inquiries since 1985. I am working my way through them chronologically, and will be reading your's very closely within the next few weeks.

I have briefly reviewed your report, and it does raise several issues that do not appear to have been addressed in any of the other reports, and which I want to examine more closely.

When I have had an opportunity to read your report and appendices carefully, I expect that I will want to be in touch with you again, to discuss some specific issues.

Thank you for the interest you have expressed in our case. I will be in touch with you again, as my review of the reports continues.

Sincerely,

Keith Hamilton

Subject: **Forensics**

Dear Mr. Hamilton, 17 Oct 01

Forensics...forensics in an airplane crash. I interpret that to mean examination and evaluation of all physical evidence.

Well, there's not that much. 5% of the wreckage recovered. Lots of 35 MM film and video.

The most valuable of all the evidence is the rare direct testimony of the actual event on the CVR. That is gold. We can hear it but we can't see it. Then the FDR. The CVR and FDR are the heart of the physical evidence. They were put there to enable investigators to reconstruct what happened in the event of an accident. It happened and they did their job.

They state to the CASB, the AAIB and me that no bomb exploded anywhere on Air India Flight 182 and that the explosion that caused the inflight breakup was unknown or of a cause yet to be determined.

I have continued that out to determine the cause of the explosion in the forward cargo compartment was one of explosive decompression, just like as what happened four years later to United Airlines Flight 811.

No bomb, no bad guys, no crime, no criminals. Just a mechanical cause that is a probable cause that causes much grief among many powerful institutions that don't like being blamed for innocent deaths especially if the blame can be shifted. We might do the same if in their positions.

So, Mr. Hamilton, you are being compensated by the Crown? You are one side of the adversarial British type judicial system and being paid by the other side? Weird. Do you feel a conflict of interest?

What is your interest? Are you a neutral scientist? Strategy attorney? Spy for RCMP?

Ah, "Paranoia strikes deep, into your life it will creep."

Let's agree we are the good guys, I'm trying for aviation safety to get bad wiring and poor cargo doors fixed and you are trying to create justice by evaluating fairly and objectively real facts, data, and evidence.

I've been doing this persuasion thing for six years and I'm very poor at it. So, now I just say whatever I want assuming it makes no difference because the correct answer is in the twisted metal, bent plastic, crushed seats, dented panels, torn skin, magnetic tapes, and cargo manifests.

The answer is no bomb, no missile, no center tank explosion, no midair, but the same thing that did the Comet in, explosive decompression at high altitude. Ka-Boom! That is on the Air India Flight 182 CVR and the effect is immediately shown on the FDR.

The cause of the explosive decompression in the Comet was metal fatigue around a squarish window. The cause for Air India Flight 182, in my humble but expert opinion, was shorted wiring/ forward cargo door rupture/explosive decompression which caused the inflight breakup.

Wiring is the final culprit, then outward opening/non plug cargo doors, then the physical laws of pressure differential at altitude; 8.9 PSI for Air India Flight 182 at 35000 feet MSL at almost 300 Knots IAS.

So, choice for the public: Exciting story of agents and bombs, and timers, and terrorism here and there and politics everywhere; or boring mechanical problem that brought down an airliner and happened since, was supposed to have been fixed with stronger metal, but wasn't.

Of course the prevailing belief for Air India Flight 182 was bomb, bomb by terrorists, bomb by Sikh terrorists, bomb by Sikh terrorist Bagri. And even more so right now. Few will listen to a story about a plane crash that was not a terrorist act even though it was thought to be for 16 years.

But, the prevailing wisdom is wrong and time showed it to be so when four years after Air India Flight 182, another similar event in a Boeing 747 occurred that did not come apart but almost, but was able to land with its CVR and FDR intact which matched Air India Flight 182.

The CVR and FDR for Air India Flight 182 and United Airlines Flight 811 match in many significant points and those are the heart of any aviation accident investigation.

I have had email correspondence with Mr. Bill Tucker of TSB, Director General of Investigations. Would you like to see those? He is an ally, I believe. He may correspond with you, I've asked him to conduct a supplemental AAR from the TSB for Air India Flight 182 since it is prudent to have an official version ready during a trial. He has declined so far giving budget and staff overload reasons.

I've put a recent uncommanded cargo door opening on a Boeing 747 below. It's still happening as it did on June 23, 1985 with Air India Flight 182 and February 23, 1989 with United Airlines Flight 811. (I also contend it happened for two other controversial Boeing 747 crashes.) So, there is an urgency from my point of view of preventing future catastrophic events since there are about 1000 Boeing 747s in active service that are affected.

If you rule out circumstantial evidence such as Narita and try to find any direct evidence of bomb, there is none.

If you rule out circumstantial evidence of a bomb, there is much evidence to explain the mechanical alternative, the shorted wiring/forward cargo door rupture/explosive decompression/ inflight breakup explanation.

If the defense team believes it was a bomb that broke apart Air India Flight 182 and are looking for ways to squabble about were it was, how big, how did it get there, who put it, and why, please tell me. You will do what the PA 103 team did, agree it was a bomb but their clients did not put it there. One of the three Sikhs will be convicted in the political judgment such as PA 103.

If you submit that there was no bomb and no crime and no criminals, the Crown must establish a crime has been committed and they can't do that if you offer a plausible mechanical explanation with precedent that makes more sense and has more evidence.

Cross examine me if you wish, Mr. Hamilton. My explanation stands firm. It can not be shaken although I encourage attempts at rebuttal or refutation. It's not because of me and my charm, it's because of the facts, data, evidence, forensic evidence.

I'll be glad to go over any of the forensic evidence with you, Mr. Hamilton, and the sooner the better.

Sincerely,
Barry

Aircraft Model : 747422

Engine Manufacturer : PWA
Engine Group : 4056
Engine Model : PW4056
Part/Defect Location : CARGO DOOR
Part Condition : MALFUNCTIONED
Submitter Code : Carrier
Operator Desig. : UALA
Precautionary Procedure : NONE
Nature : OTHER
Stage of Flight : INSP/MAINT
District Office Region : Western/Pacific US office #29
A/C N Number : 199UA
Aircraft Serial No. : 28717

Discrepancy/Corrective Action:FWD CARGO DOOR OPENED BY ITSELF WHEN CB PUSHED IN. ON ARRIVAL, CIRCUIT BREAKERS WERE PUSHED IN, WHEN PRESSURE RELIEF DOOR HANDLE WAS OPENED THE DOOR LATCHES OPENED AND THEN THE DOOR OPENED ON ITS OWN. COULD NOT DUPLICATE PROBLEM AFTER INITIAL OPENING.

From NTSB AAR 92/02 United Airlines Flight 811

1.17.6 Uncommanded Cargo Door Opening--UAL B-747, JFK Airport

On June 13, 1991, UAL maintenance personnel were unable to electrically open the aft cargo door on a Boeing 747-222B, N152UA, at JFK Airport, Jamaica, New York. The airplane was one of two used exclusively on nonstop flights between Narita, Japan, and JFK. This particular airplane had accumulated 19,053

hours and 1,547 cycles at the time of the occurrence.
The airplane was being prepared for flight at the UAL maintenance hangar when an inspection of the circuit breaker panel revealed that the C-288 (aft cargo door) circuit breaker had popped. The circuit breaker, located in the electrical equipment bay just forward of the forward cargo compartment, was reset, and it popped again a few seconds later. A decision was made to defer further work until the airplane was repositioned at the gate for the flight. The airplane was then taxied to the gate, and work on the door resumed.
The aft cargo door was cranked open manually, the C-288 circuit breaker was reset, and it stayed in place. The door was then closed electrically and cycled a couple of times without incident. With the door closed, one of the two "cannon plug" (multiple pin) connectors was removed from the J-4 junction box located on the upper portion of the interior of the door. The wiring bundle from the junction box to the fuselage was then manipulated while readings were taken on the cannon plug pins using a volt/ohmmeter. Fluctuations in electrical resistance were noted. When the plug was reattached to the J-4 junction box, the door began to open with no activation of the electrical door open switches. The C-288 circuit breaker was pulled, and the door operation ceased. When the circuit breaker was reset, the door continued to the full open position, and the lift actuator motor continued to run for several seconds until the circuit breaker was again pulled. At this time, a flexible conduit, which covered a portion of the wiring bundle, was slid along the bundle toward the J-4 junction box, revealing several wires with insulation breaches and damage.

Subject: Request from RCMP AITF

Keith Hamilton,
Defence Counsel

Dear Mr. Hamilton, 14 Nov 01

Below is a request from RCMP AITF Sgt Blachford to come to California to meet and discuss my report in some detail, taking at least a day to do so. He is asking when and where I would prefer to meet and states it will take at least a day to review my report.

I am going to reply back soon that in my home office is a good place and the sooner the better. Would you like to join us for a discussion of the shorted wiring/forward cargo door rupture/ explosive decompression/inflight breakup for Air India Flight 182? I think you should. What times and dates or places are convenient for you? I've notified Jaswinder of my offer to you.

I'll meet you at the Monterey Airport, or, if you drive, as I did in March to Vancouver, call me and I'll set you up with lodging. An alternative meeting place is possible.

I've also invited a representative of TSB to join us.

It seems the mood has changed in the past few days and now the first speculation of a cause of an airliner crash is mechanical failure instead of a terrorist act (such as believed in 1985). It looks like facts, data, and evidence, are taking priority now and that is good. There are lots of those for support of a mechanical cause for Air India Flight 182 and would look forward to laying them out for you.

Cheers,

John Barry Smith

Subject: **So close, have the other attorneys contact me, I can prove no bomb anywhere, forward or aft.**

Reyat defence was to argue against blast
Thursday, February 27, 2003
By Robert Matas

VANCOUVER -- If his trial had gone ahead, Inderjit Singh Reyat was preparing to challenge the widely held assumption that Air-India Flight 182 was destroyed by a bomb at the rear of the aircraft.

Under a plea-bargain deal with the prosecution, Mr. Reyat was sentenced to five years in prison for manslaughter. The deal was announced shortly before John Garstang, an expert on analyzing wreckage scatter, was to be questioned at a pretrial hearing.

Court documents that now can be reported show that Mr. Reyat's lawyers had told the court as early as November, 2001, that they were reviewing several contradictory reports on the cause of the disaster and the location of the bomb.

Most of the Boeing 747 wreckage remains on the ocean floor, despite two RCMP dives. By weight, only 3 to 4 per cent of the aircraft has been retrieved.

An aggressive effort failed to find the remains of many of the 329 people on the flight. Only 131 bodies, including 30 children, were recovered and taken to Cork, Ireland, for autopsies.

An insurance-arbitration report for Lloyd's of London on a civil dispute over the cause of the crash notes that neither the bodies nor the wreckage provided clues to the cause of the crash.

"None of the recovered parts of the aircraft showed any sign whatsoever of damage from explosives," Lord Roskill wrote in a report dated March 21, 1988. "None of the 131 bodies . . . showed any sign of death having been caused by explosive injuries or by shrapnel."

Lord Roskill said he was faced with a situation in which neither side in the dispute could point to a recovered part of the aircraft or a body to establish conclusively whether the plane was brought down by a bomb blast or structural failure.

Lord Roskill, after noting that the suitcase believed to be housing a bomb was placed in the aft cargo compartment, concluded that a bomb exploded in the cargo hold at the back of the plane.

His findings contradict the conclusions of Canadian experts and a judicial inquiry in India.

The Canadian Aviation Safety Board found that an "explosion" occurred in the plane's forward cargo compartment. "This evidence is not conclusive. However, the evidence does not support any other conclusion," the agency stated in a submission to the judicial inquiry in India.

Mr. Justice B. N. Kirpal of the High Court of Delhi was more direct. Circumstantial and direct evidence directly points to "an explosion of a bomb in the forward cargo hold" as the cause of the incident, he wrote in a February, 1986, report.

At the Air-India trial in Vancouver, documents show that the prosecution preferred Lord Roskill's analysis to those of the Canadian experts and the Kirpal Commission's.

The prosecution was prepared to show at trial that a bomb exploded at the rear, in the cargo compartment where a suitcase from Vancouver was placed.

The court heard that the prosecution had a list of 49 potential witnesses to testify about the wreckage and 39 potential witnesses to testify about the analysis of injuries to the passengers.

At least 16 forensic experts were available to present evidence on the characteristics of a bomb, and 86 potential witnesses could be called to explain how the bomb was placed at the rear.

Mr. Reyat's lawyers told the court that conflicting opinions about whether the crash could be conclusively attributed to a bomb in the rear of the aircraft was "a very live issue" for the trial. "Although many murder cases involve one, two or perhaps more competing expert battles, a case involving scores of such experts is virtually unknown," the defence counsel said.

Dear Mr. Donaldson, Sunday, February 19, 2006 at 8:54 AM

John Barry Smith here, the formerly long haired American who sat in your office in December 2001 with model airplanes and talked about the shorted wiring/ruptured open cargo door/ explosive decompression/inflight breakup explanation for Air

India Flight 182 and Pan Am 103.

You asked intelligent questions until Mr. Dave Crossin came in, took over the meeting, and then proceeded to tell me all about it, giving his best courtroom charm. I sensed an open mind in your questions although the premise was startling: No bomb for Pan Am 103.

Mr. Crossin was lucky and charming, he ran into an honest judge; his clients walked and more power to him. He never disputed a bomb brought down the plane, just that his clients did not do it. He was right about that, they did not do it, nobody did.

Well, I'm still here and the evidence still stands. Nobody bombed AI 182, it was a mechanical problem. In the upside down world of today, when an experienced pilot who has survived a fatal jet airplane crash reports that a fatal jet airplane crash was caused by a mechanical problem with precedent, he is labeled weird and his explanation unworthy of evaluation.

I still trust in the hard evidence and its ability to speak for me....eventually.

Mr. Reyat is now being tossed about. I can't really address the Narita event or any other involvement he had with whomever, but.....I do know that no bomb brought down AI 182 and that has to mean something to his case since he is alleged to have provided the bomb.

If you would like to chat about AI 182 and its reasonable and plausible explanation for the explosive decompression, I'm here where I've always been with a new email address, barry@qp6.com. I'll be glad to answer any questions you might have and let's leave the conspiracy nonsense for the conspiracy experts, the police and the media.

I would add that for PA 103 there has been a startling development: The police chief said the evidence was faked. PDF attached.

Regardless of the prosecutorial misconduct or the ineptness of the investigations, the evidence in the CVR and twisted metal for these crashes is what counts since it is immune from emotional interpretations and political considerations.

Subject: **Re: Refer John Hill to me, please**

Dear Sundeep, Wednesday, February 22, 2006 at 10:17 PM

Look at that, exactly five years to the day you emailed me, coincidence!

I understand why you would wish to avoid any dealings with Reyat, but I was asking for a referral to a fellow attorney to me regarding a case he has undertaken. I assume you made attorney in the past five years and if so, congratulations. Well done.

A Sikh friend sent the below to me recently:

3. A Sikh is prohibited from arguing with people who believe in foolish dogma and who insist on making ridiculous arguments. For example, some people insist that a prophet must perform miracles. People have turned sticks into snakes, heal the sick, walk through fire, etc., routinely on the stage everyday. The Gurus did not believe in engaging in such circus show just to

make people believe in them. People attracted in this manner will follow someone out of fear of punishment or, hope of a reward. Such people can not endure the rigors of the actual practice of God's Love, which should endure even in the face of adversity. Such people cannot understand why anyone would love God even if there were no reward forthcoming at all.

Sundeep, I do not believe in foolish dogma. I believe in facts, data and evidence plus my experience of flying airplanes for forty five years. AI 182 was not bombed by anybody, it was a mechanical problem. The problem of faulty wiring leading to a cargo door opening flight exists today and puts all passengers in Boeing 747s at risk. I am trying to get the wiring replaced and the doors fixed.

Just because Mr. Malik was set free after being unjustly held in prison for four years does not mean that the case is closed. The mystery remains for the police and the victim's families. Until that mystery in their minds is resolved, the press, the police, and the population will continue to believe that some Sikhs unknown committed a horrendous crime against innocents. That terrible reputation is a heavy burden to bear for a religion of twenty million.

I tried again and again on the web to find John Hill's number or email address to no avail. I've mailed a letter to Ian Donaldson.

I'll keep on trying. Any suggestions or advice would be welcomed.

Hi Barry!

My name is Sundeep Kaur, I am helping Aniljit Singh and Mr. Malik with legal research, etc.

YOu sent three reports to Aniljit Singh and he has asked me to print them up, I was wondering if you could send those reports to me as attachments so that i can do that. It is easier for us to review hard copies of reports than on the computer. This would be much appreciated.

Thanks in advance.

Ian Donaldson, QC
Vancouver County
Donaldson Jett⁄
490 - 1090 Homer Street
Vancouver, BC V6B 2W9

Dear Mr. Donaldson, Saturday, June 10, 2006

Thank you for your letter of 5 June 2006 replying to my previous letter and enclosing the Acte D'Accusation of Mr. Inderjit Singh Reyat for twenty seven acts of "...swearing falsely and attempt to mislead the Court that he did not know or recall any details of the alleged conspiracy..."

At first blush, I ask, what conspiracy? Oh, that conspiracy, the one that culminated in the successful blowing up of Air India Flight 182...by a bomb...by bombers that Reyat knew...and Reyat supplied materials for the bomb....that successfully blew up Air India Flight 182...after an alleged conspiracy (but lied about knowing in court...under oath!).. (This alleged conspiracy was not the one to blow up Parliament, that was Guy Fawkes and Reyat is no Fawkes.)

At second blush, I note that every one of the twenty seven charges listed by the Crown has the 'alleged conspiracy' words included as an integral part of the charge. Specifically Mr. Reyat is accused of lying about the bombing of Air India Flight 182, lying about the bomb parts, lying about the bombers, and lying about the plot to blow it up. I would forcibly argue that Mr. Reyat and Air India Flight 182 are inextricably entwined and any information/analysis/conclusion about that airplane crash is relevant to his defence. The Crown prosecution certainly thinks that the details of Air India Flight 182 are relevant to his prosecution for perjury since they include the basic reference to it in every charge against him.

But let's get organized, first, the past, then a short detour to the present, then an analogy, then the future and lastly the present again.

As I reflected on the tone of my previous letter I hoped I did not appear petulant when complaining about manners in our relationship and I hoped that I was not upsetting by appearing to be arrogant when discussing legalities. I should have added then but state now that we are on the same side in that we are allies. Not friends or business partners but allies with common causes: Justice and citizen safety. Well, allies sometimes squabble, it's natural in grasping for the same plums on the tree.

Regarding the coffee incident. It was not you but Mr. Crossin who had the coffee, a thermos or pot as I recall. Aniljit was sitting on my right, you were opposite me at your desk and Mr. Crossin was on your right in a chair. After an hour Mr. Crossin got up and came back with some coffee and offered it to you but none to Aniljit or me. You accepted and the conversation (actually mostly Mr. Crossin talking) continued. I remember because I was thirsty after an hour or so. It is also at that moment when I knew my case was lost. I had driven twenty hours non stop from Carmel Valley to Vancouver the day before just to meet "Malik's attorneys" and it was all for naught, very deflating. The questions that were asked of me and my shorted wiring/ruptured open forward cargo door/explosive decompression/inflight breakup explanation that indicate an open mind of the listener were not being asked. Statements were made that indicated a closed mind, mainly about bomb, bomb, bomb, and bombers.

Regarding your correspondence as an 'indignity': I'm sorry, I was being selfish. To be brief is fair when the clock is ticking for billing and also a good habit, one I have not yet acquired.

Short detour to the present of your letter:

ID>It is not a central point, nor indeed is it any part, of the current prosecution against Mr. Reyat that there was a bomb on the airplane.

JBS>Polite response with respect disagreement, sir: I gainsay it is not a central point. Rude reply: Hell yes it is! Central. Right in the middle. Essential. Important so much so it is listed on the first page in the first paragraph of the Indictment and included in every single one of the charges, "...alleged conspiracy...". What exactly is the 'alleged conspiracy? It was to put a 'bomb on the airplane.' The central point of the current prosecution is there was a 'bomb on the airplane' based upon a conspiracy to put it there, a conspiracy Mr. Reyat is accused of lying about.

If no 'alleged conspiracy' to bomb Air India Flight 182 because there was no bomb then he could not lie when 'he did not know or recall details...' of it (Quadruple negative, whew). If no bomb, then no bombers; if no bombers, then no alleged conspiracy. If no alleged conspiracy, then no one can lie about it (or tell the truth about it). If no lies about it, then no perjury about the conspiracy. (There might be lies by Mr. Reyat about other matters, but he is not charged with those, only about the 'alleged conspiracy." Charges dropped...but first, no bomb? That's a tough nut to crack. I can do that, I have done that, I can show you how.

But more on those charges later; now I would like to give an analogy to avoid the emotional buzz words of bombs and Sikhs and flight numbers and mass murder of 329.

A man is walking along a street as he usually does every day. During his walk he falls down on the ground. The police and a physician arrive on the scene. The physician examines the prostrate man and declares he's dead but the physician doesn't know why. The police investigate and conclude he is dead because he was shot in the head by a rifle shot from two men seeking revenge. The press reports the man was murdered by rifle shot by terrorist thugs involved in a conspiracy.

The medical team that had the responsibility to keep the victim alive is relieved it was a murder and not health related implying negligence. The family of the dead man is relieved that it was not some genetic fault in the family that would shame them. The media is relieved the victim's death is interesting as a murder conspiracy and not a boring normal death. The government is relieved that they are not at fault for negligent oversight of his medical care and can now blame political enemies for the murder. The victim's friends are relieved because now they have someone to vent their anger at to assuage their grief.

The two accused terrorist men go on trial for murder and conspiracy. Another man accused of being in the conspiracy is separated out and accepts a deal for a lesser sentence and understands he may be called as a witness against the other two. This third man agrees to the lesser charge and goes on the witness stand but gives confusing, contradictory, misleading, evasive and nonsense statements about the conspiracy to murder the dead man. There is never any discussion by the defence for the two men that the victim was not murdered, just that he was murdered but not by the two accused.

The two accused of the murder and conspiracy are acquitted. The family, media, government, and friends are outraged that the killers go free. They all demand a government inquiry into how the case was bungled. The loser prosecution team submits that it was because of the perjured testimony of a witness who betrayed them and lied about the murder conspiracy under oath, implying that if the witness had spoken the truth, a conviction of the two murderers was assured. The witness is now accused of perjury by the prosecutors for his confusing, evasive, and misleading statements about that murder conspiracy.

And then, and then, the defence attorney for the accused witness is made aware by a correspondent (who, while not a physician, is well informed about medical matters) that there may in fact have been no murder and thus no murder conspiracy. An alternative explanation for the demise of the victim is offered: The death of the man was in fact a heart attack based on genetic defects in the family line and poor living habits. Proof is offered; precedents are cited.

The attorney replies that the cause of death for the victim is irrelevant; his client is not charged with the murder, just swearing falsely under oath about the conspiracy to murder.

The correspondent replies that if there is no conspiracy, then any accusations regarding it are of no practical importance or moot. The attorney deliberates.

The correspondent responds with advice to look at the victim. Check out the victim. Who was he? Was he a crime figure who might likely be murdered? Was he in a bad neighborhood and might be shot? Was he having an affair, was he in debt, what was his history?

And then the attorney finds out that in fact the victim was an old man with a history of heart problems and had three identical brothers fall down on the same road about the same time of day with the same weather conditions with two twins dying and one twin surviving although requiring a long recuperation period.

The one brother who lived through the heart attack had the same bruises, scrapes, and tears on him as the dead victims who were thought to have been murdered. The same sounds came out of all four brothers' mouths as they suffered the injury and fell down. All four brothers' injuries were initially thought to have been murders by rifle by terrorists. One brother's death remains officially cause unknown, one death a murder by rifle, one death was changed to brain stroke and the injury of the one brother who lived was caused by partial heart failure by natural causes of aging and genetics.

The possibility then exists that the victim was not murdered but was in fact a health related issue and plausible, it has precedent, and there is ample proof it was a heart attack. There was no murder, nor murder conspiracy, nor witness to lie about a non existent crime. His client is innocent. No one murdered the victim, he died from a natural internal problem called a heart attack.

The physicians are asked again for an opinion on their previous evaluation which stated the victim was dead of unknown causes and now can use the benefit of hindsight and the subsequent deaths of the victims' brothers under similar circumstances for a valid update.

The police are asked to provide all the photographs of the death scene for evaluation of bruises, blood, and scrapes on the victim.

And then...

My analogy skips to the imagined wishful thinking future and substitutes actual details:

After the Transportation Safety Board of Canada examines the previous accident reports and matches them to United Airlines Flight 811, they report internally that their initial assessment in 1986 was correct that an explosive decompression in the forward cargo compartment occurred in Air India Flight 182 but the unknown probable cause can now be updated as a mechanical electrical event, and that a bomb explosion therefore was ruled out.

The Crown Prosecutors and the Gendarmerie royale du Canada (GRC), after getting together with the TSB investigators, decide that based upon this new evaluation of excluded bomb and likely mechanical caused event, now based upon incontrovertible matching facts of a similar accident, to drop perjury charges against a witness. The reason given will be that the expense of a new trial does not warrant the punishment of a man who has already spent fifteen years in jail. The Crown would rather face the wrath of the victims' families than the unraveling of their entire case which would show they have been chasing ghosts for twenty one years at great expense in time and manpower.

Charges of perjury involving a conspiracy to bomb an airliner are dropped: The accused witness Reyat is happy, his attorney is happy, I am not happy. I'm happy that justice is done but the main goal was missed, aviation safety with the repair of faulty wiring and the correction of the design defect in the cargo doors of early model Boeing 747s. The hazards remain in the five hundred plus type airliners in service carrying and exposing hundreds of thousands of passengers and crew to a life and death hazard; explosive decompression in flight when the shorted wiring ruptures open the cargo door inflight at high altitude.

I would then ask you, Mr. Donaldson, after you write to TSB requesting an update to a twenty year old accident report on an airplane crash your client is accused of lying under oath about an 'alleged conspiracy' to blow up; after you request all the evidence of the airplane crash now held by RCMP, after the officials of those agencies get together and decide their case for a bombing and thus a conspiracy to bomb is weak and probably not provable, after they decide it is in the best interests (sic) of justice to drop the perjury charges against Reyat, that you go further with three possible actions.

1. I ask that you represent Mr. Malik for damages against him by the Crown for malicious prosecution since I know that the RCMP Air India Task Force representative Sgt Bart Blatchford knew about the shorted wiring/ruptured open forward cargo door/explosive decompression/ inflight breakup explanation before his trial and did not pursue the investigation; or:

2. You represent the families of the victims who died in Air India Flight 182 since they received a fraction of the money due them in a mechanically caused accident; or:

3. You arrange to get me into the John Major Commission of Inquiry into Air India Flight 182 now going on. I would use the opportunity to explain the shorted wiring/ruptured open forward cargo door/explosive decompression/inflight breakup explanation and answer any questions.

I ask these actions in order to get the official updated version of the probable cause of Air India Flight 182 by TSB into the record, into the public mind, into the government safety organizations around the world that monitor their airlines that fly early model Boeing 747s in order to get the manufacturer to repair the defects.

In my future predictions, one man was set free from risk of prison while I am trying to free literally hundreds of thousands from risk of death.

And then my crystal ball becomes cloudy and I revert back to the present, your 5 June 2006 letter to me.

The Crown>Indictment "...Reyat did commit perjury...by swearing falsely and attempt to mislead the Court that he did not know or recall any details of the alleged conspiracy...that:"

JBS>Note that all of the charges start out in lower case as they are the suffixes to the preliminary statement ending in '...alleged conspiracy...that:" The key to the successful defence of Mr. Reyat is in Count 1 as quoted above. "...of the alleged conspiracy..." It is their undoing. The Crown went a prosecution too far. Why include the words, "alleged conspiracy" for all the charges? It was to make the charges have practical importance. Without those conspiracy words, the charges are petty but the conspiracy allegation brings in mass murder, terror, and horrible evil thereby elevating the charges to important. Note also the mismatch of tense of 'swearing' and 'attempt'. This indictment is poorly written, the grammar has errors, the charges are confusing, the meanings are ambiguous, and one charge is downright nonsense.

ID>During his testimony, the Crown says that some of the statements {of the alleged conspiracy} made by Mr. Reyat were untrue. (Inserts of {of the alleged conspiracy} clarify your word "statements" and are quoted exactly from the Indictment. I will add further clarifying words in parenthesis as we go on.)

JBS>He may have made untrue statements but they were not about a conspiracy since there was none. No bomb, no bombers, no conspiracy, and no lying statement about it. If Reyat lied about his memories of the names of his friends from years ago, then let the Crown accuse him of that. They have not done that; they have accused him of misleading and making false statements of the 'alleged conspiracy' which included names of friends. Get rid of the conspiracy and it will get rid of the accusation of perjury about it.

ID>Whether the airplane crashed due to mechanical error or not, the issues at his trial will be whether the statements {of the alleged conspiracy} (to successfully blow up an airliner) that he made were true or false, or more particularly, whether the Crown can prove his statements {of the alleged conspiracy} (to successfully blow up an airliner) were false.

JBS>The Crown can never prove anybody made misleading statements about a conspiracy when there was no conspiracy. There are millions of Canadians out there who had nothing to do with Air India Flight 182 and dozens who have lied in court, why is it that Mr. Reyat is on trial if he had nothing to do with it? He is on trial because he is accused of having a lot to do with it. Regarding your phrase, "...or more particularly, whether the Crown can prove his statements {of the alleged conspiracy} were false", that refers to a strategy I call the Crossin Defence.

The Crossin Defence: It's where you do not prove your client is innocent. It's where you do not present an alternative culprit that could have committed the crime for which your client is accused. It's where you just poke holes in the Crown's case enough so that reasonable doubt is created in the mind of the judge or jury. It's a full defensive posture with no offence. The Crossin Defence is based upon the belief that the defence is more cunning and can avoid, deflect, or repel any offensive action by the clumsy Crown without fatal injury. In the current system of British based law and poorly worded indictments, that's good enough...for a not guilty verdict. It also requires an honest judge or impartial jury.

It's also the best type of defence to defend the guilty. The innocent deserve better. They deserve to be exonerated of the false charges. They need to be shown to be innocent which is a higher quality vindication than 'not guilty'. But if the accused did not do the crime, then who did it? And was it a crime after all? The innocent deserve to have the true culprit identified or to show the charges lacked merit since no crime occurred.

Mr. Reyat is innocent of perjury of a conspiracy and also innocent in any assistance in the bombing of Air India Flight 182. I know that and he deserves the exoneration of the accusations. That exoneration can be achieved by showing there was no bombing and also revealing the true culprit, in this case a manufacturing defect of faulty wiring and a design defect of a non plug cargo door. One byproduct of this exoneration will be the resurrection of the honor of a religion of twenty million world wide. Another consequence will be improved safety in current and future airliners.

ID>You will note from the indictment that the Crown does not allege anything to do with the cause of that event.

JBS>Whaaa? The Crown alleges that Reyat had everything to do with that event, the successful bombing of Air India Flight 182 because of a conspiracy. The Crown alleges he knew the conspirators, he provided the materials for the bomb, he practiced with the bomb, he harbored the conspirators; (and he lied about all of it!) The only thing he didn't do was put the bomb in the suitcase. If the Crown suspected that, they would not have severed him from Misters Malik and Bagri.

ID>Even if a witness's false statements {of the alleged conspiracy} (to successfully blow up an airliner which killed 329 passengers and crew) under oath are "not of any practical importance", and the Crown can prove beyond reasonable doubt that they are false then a perjury charge may be maintained.

JBS>Maintained but not convicted by a jury that says "What's the big deal, he protected his buddies who were acquitted of a crime and it turns out no crime anyway. Not guilty and stop wasting our time." The worst case guilty scenario would be a vastly reduced sentence for lying about what his friends' names were, his friends that were not part of an alleged conspiracy to blow up an airliner since there was no bomb, bombers, or conspiracy.

ID>Our client is not charged with assisting in the deaths of any person, but simply with giving false statements {of the alleged conspiracy} (to successfully blow up an airliner which killed 329 passengers and crew, including many women and children) under oath when called as a witness.

JBS> He certainly is accused, possibly indirectly, with assisting in the death of a person, in fact, 329 persons. He was asked at trial to effectively admit he was a co-conspirator. He declined. The Crown says he lied. Your client is charged simply with giving false statements of the alleged conspiracy to successfully blow up an airliner which killed 329 persons and refusing to admit he was part of the plot.

The Crown asserts in so many words: If he had not provided the materials for the bomb and practiced with it with Mr. X (those conspiracy boys do love their Mr. Xs, who always seem to die or remain missing) then there would have been no bombing and thus no deaths. If he had gone to the police and informed on his mates, the airliner would not have blown up. If he had not lied about his involvement in the alleged conspiracy to blow up an airliner or two, his guilty friends would have been convicted. Because he lied, two mass murderers of passengers in an airliner went free. He must be punished for those lies about the alleged conspiracy (to successfully blow up an airliner which killed 329 passengers and crew, including many women and children). The perjury charges are vindictive harassment by sore loser prosecutors. The prosecutors don't realize they lost convictions of bombers because no bombers exist to convict.

Again I say, no bomb, no bombers, no conspiracy, no perjury about the alleged conspiracy, no conviction, no punishment.

If there were no bomb, bombers or conspiracy, it is impossible to give false statements about the alleged conspiracy. He is innocent...but first it needs to be proved there was no bomb, bombers and thus no conspiracy. I can do that to your satisfaction. For the satisfaction of the RCMP and Crown, the TSB opinion is probably required. TSB must be asked for the updated opinion by you.

ID>You will see the statements {of the alleged conspiracy} (to successfully blow up an airliner which killed 329 passengers and crew, including many women and children making it the worst mass murder in Canadian history) alleged to be false.

JBS>Let's look at them all. But first, another analogy: If a man is accused of adultery by having an affair with a woman and I, as a witness, testify he was with me one assignation night and I'm lying (he was somewhere else) and thus accused of perjury about the adultery, if there were no affair in truth then there was no perjury about the adultery because I did not lie about an event that did not take place. If the Crown wants to accuse me of lying about where my friend was one night, then let them charge me for that. I am innocent about lying about an alleged adulterous affair since there was none.

JBS>Facts:

1. Talwinder Singh Parmar is dead and Mr. X is nowhere to be found and thus, fortunately for the defence and unfortunately for the prosecution, they are unable to be cross examined.

2. Air India Flight 182 crashed on June 23, 1985.

Assumptions:

A. The Babbar Khalsa is a terrorist group of Sikh extremists banned by the Canadian government.

B. Mr. Parmar was chief of the Babbar Khalsa, an organization of Sikh separatists.

C. Investigators believe the Air India bombing was masterminded by Talwinder Singh Parmar, leader of the extremist Babbar Khalsa group that advocates creating a Sikh state called Khalistan in India's Punjab region. Parmar was killed by Indian police in 1992.

JBS> All of the twenty seven charges of perjury against Mr. Reyat are prefaced in Count 1 by this edited statement: "...Reyat did commit perjury...by swearing falsely and attempt to mislead the Court that he did not know or recall any details of the alleged conspiracy...that:"

All of the twenty seven charges then start out in lower case as they are the suffixes to the preliminary statement ending in '...alleged conspiracy...that:"

Every complete charge thus includes the words 'alleged conspiracy". The conspiracy referenced in the Indictment is the one to successfully blow up an airliner which killed 329 passengers and crew, including many women and children making it the worst mass murder in Canadian history.

For example: Charge 5 would read in its entirety if standing alone: "...Reyat did commit perjury...by swearing falsely and attempt to mislead the Court that he did not know or recall any details of the alleged conspiracy...that Parmar asked him to make one explosive device."

The words "know" and "recall' appear to be redundant with the proper one word being 'recall'. A clearer accusation might read: Charge 5: "Reyat did commit perjury by swearing falsely and attempting to mislead the Court by stating he did not recall any details of the alleged conspiracy that resulted in the bombing of Air India Flight 182, for example, that Parmar asked him to make one explosive device."

Charge 1. he (Reyat) did not know....

Charge 2. he did not know...

Charge 3. he had no idea...

Charge 4. he could not recall what Parmar..

Charge 5. Parmar asked him...

Charge 6. the only reason Parmar...

Charge 7. Parmar did not say...

Charge 8. most of his conversations with Parmar...

Charge 9. Parmar never asked...

Charge 10. the two test devices that he built and tested for Parmar...

Charge 11. during the two tests...

Charge 12. after Parmar asked him...

Charge 13. before the second test, an associate of Parmar ("Mr. X")...

Charge 14. he never learned Mr. Xs name...

Charge 15. after the second test, neither Mr. X nor Parmar...

Charge 16. after the second test, Parmar returned to the ferry in Nanaimo but Mr. X...

Charge 17. he gave Mr. X... and had 'no idea' why Mr. X...

Charge 18. ...he never discussed doing so with Parmar or Mr. X;

Charge 19. although he believed at the time that Mr. X intended....he did not know why Mr. X intended...

Charge 20. Mr. X asked him....

Charge 21. while Mr. X and he ... Mr. X spent...but Mr. X did not say why....

Charge 22. he gave Mr. X...anticipating that Mr. X may want...

Charge 23. Mr. X never discussed...

Charge 24. before Mr. X left his home, Mr. X's phone number...

Charge 25. he introduced Mr. X...

Charge 26. he never asked Parmar...

Charge 27. he told either Parmar or Mr. X that....he never asked Parmar or Mr. X....

Perjury: (For the USA) In order for a person to be found guilty of perjury the government must prove: the person testified under oath before; at least one particular statement was false; and the person knew at the time the testimony was false.

The three elements of a perjury charge: 1: Testify under oath. 2. Statement was false to start with. 3. The person knew at the time of testimony the statement was false.

The first element is proven, Mr. Reyat testified under oath. The third element may or may not be true since Mr. Reyat may have known to himself he was lying.

But...the second of three elements of the perjury charges is impossible to fulfill for all charges related to Parmar or Mr. X (4 through 10, 12 through 27, total 23 charges) because the statement has to be false to fulfill element two and the only persons to confirm the falsehood are dead or missing. Charges relating to the state of mind of Parmar or Mr. X can only be confirmed by them thus it is impossible to confirm a statement about their state of mind being false or true. For instance, if Reyat were asked under oath what was Parmar's favorite color of turban and Reyat replies white when in fact Reyat knows he is lying because Parmar stated one time how he loves his black turban, there is no way to prove Reyat is lying if Parmar, the only authoritative source of his state of mind, is dead. If there is other supporting evidence of a Reyat lie, then present it, such as tape recordings or videotapes. Any other evidence is probably hearsay and inadmissible anyway.

For instance, Charge 20 essentially states that "Reyat did commit perjury by swearing falsely and attempt to mislead the Court by stating he did not recall any details of the alleged conspiracy that resulted in the bombing of Air India Flight 182 such that Mr. X asked him for a Micronta clock after seeing one installed in Reyat's car." The only person who could confirm that Reyat made a false statement that he could not recall the conversation is Mr. X who could contradict Mr.

Reyat and testify he did indeed ask Mr. Reyat for a Micronta clock... Without Mr. X, there is no proof that Mr. Reyat made a false statement about a clock and thus no perjury charge is proven. Twenty three charges are thus bogus and not provable without the testimony of the only persons who can prove they were false to start with, Parmar and Mr. X.

I once had a Superior Court judge tell me why murder charges are so hard to prove, it's because the victim was not there to rebut the exculpatory testimony of the accused. In Mr. Reyat's case, let the Crown produce Parmar or Mr. X and prove the second element in the twenty three charges that the statements by Mr. Reyat are false. And if they can't produce the rebutting evidence, then the assumption is that the statements by Mr. Reyat are not false.

(Mr. X is alleged to be a terrorist. It can be assumed he would not give his real name or details on his identity, habits, or location to strangers or fellow conspirators. To charge somebody for perjury for not revealing a name which is probably false anyway is unreasonable.)

Regarding charges 1 through 3: These are mind reading charges, thought crimes against a thoughtful person made by the Thought Police. The Crown assumes it knows what Mr. Reyat knows or should know, what he thinks or should remember. Many supposedly educated citizens are woefully ignorant about basic knowledge that is required for daily living. For Mr. Reyat to claim he did not know about a political splinter group or its leader is reasonable and to claim he should have known is doubtful. For Mr. Reyat to claim he had no idea what was going on politically in a country six thousand miles away which undergoes political change weekly is certainly plausible. To claim Mr. Reyat, a mill worker, is assumed to know the internal politics of a foreign country is doubtful. The Crown can never prove the statement that "Mr. Reyat did not know the name of a leader of a political splinter group" is false because the only one who knows what goes on in Mr. Reyat's mind is Mr. Reyat. Are there witnesses who can rebut Mr. Reyat's claimed ignorance of Indian politics? Bring them on. There is none. What is Mr. Reyat's IQ? What is his reading level? Is he a political science professor at McGill? Did Mr. Reyat lead seminars on Sikh separatist movements?

Are his students available for testimony as to Mr. Reyat's political knowledge? Can the average juror even name the previous four opposition leaders in Canadian government starting from twenty years ago?

Charges 1 through 3 are not provable for element two because only Mr. Reyat knows what Mr. Reyat knows and if he says he didn't know this or that, then it has to be assumed he did not know this or that. If Mr. Reyat says his favorite color is red, then it's red if there is no one to contradict him even if there is no red in his wardrobe, his car is not red, his house is not red, and his wife is not a redhead. And tomorrow if he says he hates red, then he hates red even though he wears red pants, his car is red, his house is red and his wife is...still blond.

Charges 4 through 10, 12 through 27 are not provable for element two because the only two persons who could confirm or discredit Reyat statements about the alleged conspiracy being false are dead or missing. And of course, Mr. Reyat can change his mind about what his mind remembers. If he made previous incriminating statements and then remembers differently under oath on the witness stand, well, that's what goes on inside people's heads all the time, selective memory and reinterpretations of history. Many eyewitnesses make false statements under oath while believing them to be true.

Charge 11: "during the two tests he used gunpowder rather than dynamite to ensure that no one got hurt."
What is the false statement? There was only one test? He was not present at the test? He did use dynamite after all? Someone got hurt? He couldn't remember what he used as the explosive? Regardless, since Mr. Reyat is the only one available about what did or did not happen on that day, his testimony can not be reliably discredited.

Charge number 8: It's interesting as it makes no sense. "most of his conversation with Parmar in the weeks prior to the June 22, 1985 concerned the conversion of Parmar's car to propane." What is the word 'the' doing in the sentence? It's as if the writer meant, "... most of his conversation with Parmar in the weeks prior to the June 22, 1985 (sic) bombing of Air India Flight 182 concerned the conversion..."

Regardless, this charge is a direct reference to Air India Flight 182 and determines the end date of any interest in Mr. Reyat's contacts with the parties named in the other charges.

To conclude:

1. All of the perjury charges against Mr. Reyat include the phrase 'alleged conspiracy' which directly refers to the alleged conspiracy of bombers to successfully bomb Air India Flight 182 on February 23, 1985.

2. Any information, data, or evidence about Air India Flight 182 is thus directly relevant to the perjury charges. Any request for such evidence or information for disclosure is justified. Acquiring that evidence is warranted for a comprehensive defence.

3. All of the perjury charges are not provable for the second element required: a statement was false to start with. The only persons who can prove the statements were false to start with are dead or missing or Mr. Reyat himself. (Perjury is hard to prove, if it were easy, prosecutors would be charging it often.)

4. If the 'alleged' conspiracy were shown to be not proven, then all the charges are not proven because each charge includes reference to the alleged conspiracy. Note the second dictionary meaning of 'alleged', doubtful plot indeed.

alleged [adj.]
PRON: /&'lΔjd/
1. Declared but not proved; "alleged abuses of housing benefits" --Wall Street Journal.
2. Doubtful or suspect; "these alleged experts are no help"; SYN. so-called, supposed.

conspiracy [n.]
PRON: /k&n'spir&sE/
FORMS: conspiracies
1. A group of conspirators banded together to achieve some harmful or illegal purpose; SYN. confederacy.

2. A plot to carry out some harmful or illegal act (especially a political plot); SYN. cabal.
3. A secret agreement between two or more people to perform an unlawful act; SYN. confederacy.

Recommendations:

1. Requests for all relevant data and evidence about Air India Flight 182 such as conspiracy related interviews, photographs of twisted metal, and cockpit voice recorder transcripts should be made to those agencies by an authorized attorney.

2. The request to the TSB should request an updated investigation by an objective official. Any TSB official seconded to the Air India Task Force should be excluded as he represented the Crown prosecution and has been biased.

3. The request to RCMP for photographic evidence and videos might indicate that Mr. Malik and Mr. Bagri were acquitted as well as stating the physical condition of the decades old evidence is irrelevant.

Mr. Donaldson, this winding long trail has ended, I hope you ended up here with me, even through the backtracks. There are shortcuts in there someplace, I imagine. Please request TSB and RCMP to provide disclosure about Air India Flight 182 to you, please ask me about the crash, you should know why airplanes crash sooner or later or at least one big one.

Best Regards,

Dear Sundeep, Wednesday, June 21, 2006

Do you have any information on how I can contact Air-India inquiry administrator Sheila-Marie Cook? I want to apply for standing so I can appear before the Commission of Inquiry.

Regards,

John Barry Smith
541 Country Club Drive

barry@qp6.com

At 11:37 AM -0700 6/21/06,
She said she expects to hear from interested parties after June 21.
The first three hearing dates are July 18, 19 and 20, which will be to hear from people who would like standing at the inquiry and who would like to have funded legal representation.
Judge Major said he will begin putting other witnesses on notice in July that they are going to be subpoenaed to testify after the inquiry formally begins hearing evidence in late September.

Air India inquiry begins this week

Kim Bolan, CanWest News Service
Published: Monday, June 19, 2006

VANCOUVER - The judicial inquiry into the Air-India bombing will have done its job if victims' families feel like they are real Canadians despite the fact that many immigrated to Canada from India, retired Supreme Court Justice John Major says.

Close to 80 relatives are expected in Ottawa on Wednesday when Judge Major officially opens the long-awaited inquiry into the June, 1985, terrorist bombings with a brief statement outlining the terms of reference.

Judge Major said in an interview this week he is looking forward to helping bring resolutions to outstanding questions related to the unprecedented terrorist attack that was plotted and hatched in British Columbia and left 331 people dead.

Judge Major has held meetings across the country with victims' families -- many of whom have lobbied for 20 years for a public inquiry into Canada's worst mass murder.

Their lobby only picked up steam when two B.C. Sikh separatists -- Ripudaman Singh Malik and Ajaib Singh Bagri -- were acquitted in March, 2005, of all charges related to the bombings after a 19-month trial.

"If this commission can give them a sense that they are really Canadians despite the colour of their skin and that mistakes were made but they won't be made a second time, most of them -- from what they have said -- would feel that something's been accomplished," Judge Major said. "Accomplishing the second is easier than the first."

Judge Major said the simple act of then-prime minister Brian Mulroney sending a letter of condolence to Indian prime minister Rajiv Gandhi after the bombings pained family members, who were almost entirely Canadians or living in Canada. "They are owed some form of explanation for a letter of condolence going to India," he said.

But the bigger issue for Judge Major, who retired last year as chief justice of the Supreme Court of Canada, is reassuring Canadians such an act of terror could not be carried out again.

"The big interest is, 'could this happen again?' and I think that brings some public interest to the inquiry beyond what the tragedy is. Where are we with security?" he said. "I don't know how forthcoming the CSIS and the RCMP will be because they generally feel they are prejudicing the safety if they disclose too much, but we will see."

Part of his mandate -- as outlined when the inquiry was formally announced by Prime Minister Stephen Harper on May 1 -- is to look at whether a lack of information-sharing between agencies hampered the investigation into Sikh extremists prior to the bombing and during the subsequent bombing probe.

Judge Major said both the RCMP and CSIS "have expressed the willingness to co-operate fully."

"We will want to hear from the Department of Transport and they are doing their report. So, so far, there seems to be a willingness to see this thing through and hopefully reach some sensible conclusions," Judge Major said. "The mandate says that we are not to find fault and we don't make any awards."

Corporal Tom Seaman said the RCMP does not yet know who will be called as a witness. But he said the force is on board with the inquiry, even though the criminal investigation into the bombings continues.

Air India inquiry begins this week

Kim Bolan, CanWest News Service
Published: Monday, June 19, 2006

Judge Major said he has not heard from either of the two men acquitted about wanting to appear before the inquiry. Mr. Malik recently told journalists he was prepared to participate if asked to do so.
But then, nobody has yet made their intentions known, Air-India inquiry administrator Sheila-Marie Cook said on Friday.
She said she expects to hear from interested parties after June 21.
The first three hearing dates are July 18, 19 and 20, which will be to hear from people who would like standing at the inquiry and who would like to have funded legal representation.
Judge Major said he will begin putting other witnesses on notice in July that they are going to be subpoenaed to

testify after the inquiry formally begins hearing evidence in late September.

"If the witnesses volunteer, they don't have to be subpoenaed," he said.

Mr. Major said most of the staff is already in place.

The lead counsel is Mark Freiman, a partner with McCarthy Tetrault in Toronto and a former deputy attorney-general of Ontario.

Lata Pada, a Mississauga, Ont. dancer, who lost her husband and two teenage daughters in the 1985 terrorist attack, will be in Ottawa as the inquiry is officially launched. It is the same day the only man convicted in the bombing -- Inderjit Singh Reyat -- is to make another court appearance after being charged with perjury for his testimony at the Air-India trial.

Ms. Pada said she thinks the inquiry is particularly timely given the recent arrests in Ontario of suspected Islamic terrorists.

"I think the Air-India inquiry can certainly be a watershed moment in assessing Canada's preparedness for terrorist attacks," she said. "Air-India was really the precursor to everything we are seeing today with terrorism."

Ideally, whatever comes out at the inquiry should "serve to inform policy changes," Ms. Pada said. "We'll be watching it with keen interest."

Ms. Pada wants to make sure victims' families get independent counsel financed by the inquiry to represent their interests.

"There is a commitment and we hope that they keep that commitment," she said.

Dave Hayer, Surrey's Liberal Member of the Legislative Assembly, will also be in Ottawa, representing his late father Tara, who had agreed to be a witness in the Air-India case when he was assassinated in November, 1998.

Dave Hayer has been an advocate for victims' rights ever since, and has strong opinions about what more could be done to deal with terrorism cases and protect witnesses who risk a lot to testify.

"There should be some justice done for all the people killed in the Air-India bombing. Most of them -- 280 -- were Canadians. There were 20 Americans on the plane. We want to make sure that something like this never happens again," Mr. Hayer said. "And we want to make sure our judicial system has the tools to deal with cases like this."

Commission of Inquiry into the Investigation of the Bombing
of Air India Flight 182
Honourable John C. Major, Q.C. Commissioner
Sheila-Marie Cook, Executive Director and Commission Secretary
Mark J. Freiman, Commission's Lead Counsel
Michel Dorval, Commission's Co-Counsel

P.O. Box 1298, Station B
Ottawa, Ontario K1P 5R3
CANADA

Dear Commissioner Honourable John C. Major, Q.C. and esteemed Staff, Sunday, June 25, 2006

As required by the Rules of Procedure and Practice I hereby apply for standing as a 'person' by way of this motion supported by affidavit.

1. John Barry Smith
541 Country Club Drive
Carmel Valley, California 93924
1 831 659 3552

barry@ntsb.org
http://www.montereypeninsulaairport.com

2. I seek standing as a person for a portion of the mandate of the Inquiry.

3. The areas in which I have a clearly ascertainable interest and perspective which would enhance the work of the Commissioner and the reasons in support thereof are:

a. Aviation Safety in general. I am a survivor of a sudden fiery fatal jet airplane crash which has motivated me to become an independent aviation accident investigator to prevent similar accidents. In that role I have reviewed over a thousand aviation accident reports and hundreds in detail. My perspective is that of one who has been on scene before, during, and after the event, heard the explosions, felt the fires, suffered the injury, witnessed the fatality, smelled the ashes, and experienced the emotions caused by a sudden fiery fatal jet airplane crash.

b. Air India Flight 182 in specific. My ascertainable interest is demonstrated by my Smith AAR (Aviation Accident Report) for Air India Flight 182, a 249 page exhaustive evaluation of the facts, data, and evidence regarding that event. The AAR is a result of ten years of research and will be presented, if standing is granted, at Stage 2 of the inquiry. (Available upon request)

4. If required, I will make an oral submission in mid July in Ottawa.

Dear Commission Members, please permit me at this time to direct you to a significant error in the basic premise for the establishment of the Commission of Inquiry which, if I may be so bold to suggest, should be corrected as soon as possible to prevent undermining the credibility of your Commission.

1. Please note that the Prime Minister states that the public inquiry is a route to obtain answers to the tragedy of Air India Flight 182. He does not limit the inquiry to investigating any one cause, such as a bombing, but rightfully calls it a tragedy and implies any reasonable explanation will be considered as there are several non-bombing reasons for an aircraft to explode in flight.

From the Commission website: "Opening Statement" June 21, 2006, Background,
"In announcing the launch of this Inquiry, the Prime Minister, the Right Honourable Stephen Harper, stated that a public inquiry is the only route left to obtaining answers to how the tragedy of June 23, 1985 occurred when Air India Flight 182 exploded over the Atlantic Ocean."

2. The above is correct and yet several sentences later the grievous error is stated:
"Opening Statement" June 21, 2006, Background,
"Yet, it was not until the following January that the Canadian Aviation Safety Board concluded that the destruction of this aircraft was caused by a bomb."

Not so. Absolutely incorrect. Terribly misleading. The Canadian Aviation Safety Board made no such conclusion. The below is the actual conclusion in 4.1.5.

Aviation Occurrence Report of the Canadian Aviation Safety Board for Air India Flight 182 of January 22, 1986

"4.0 CONCLUSIONS
The Canadian Aviation Safety Board respectfully submits as follows:
4.1 Cause-Related Findings
1. At 0714 GMT, 23 June 1985, and without warning, Air India Flight 182 was subjected to a sudden event at an altitude of 31,000 feet resulting in its crash into the sea and the death of all on board.
2. The forward and aft cargo compartments ruptured before water impact.
3. The section aft of the wings of the aircraft separated from the forward portion before water impact.
4. There is no evidence to indicate that structural failure of the aircraft was the lead event in this occurrence.
5. There is considerable circumstantial and other evidence to indicate that the initial event was an explosion occurring in the forward cargo compartment. This evidence is not conclusive. However, the evidence does not support any other conclusion."

Dear Commission Members, the above Canadian accident expert opinion is correct. There was an explosion in the forward cargo compartment. The cause is left unstated and, in fact, the internal text of the report generally rules out a bomb as the cause of the explosion and suggests a mechanically caused explosive decompression.

The Indian Report, on the other hand:
Report of the Honourable Mr. Justice B.N. Kirpal of the High Court of Delhi of February 26, 1986:
"Analysis and Conclusions
4.1 From the evidence which is available what has now to be determined is as to what caused the accident.
4.5 It is evident that an event had occurred at 31,000 feet which had brought down 'Kanishka'. What could have possibly happened to it? The aircraft was apparently incapacitated and this was due either to it having been hit from outside; or due to some structural failure; or due to the detonation of an explosive device within the aircraft.
4.9 Thus we are left with only two of the possibilities viz., structural failure or accident having been caused due to a bomb having been placed inside the aircraft.
4.10 After going through the entire record we find that there is circumstantial as well as direct evidence which directly points to the cause of the accident as being that of an explosion of a bomb in the forward cargo hold of the aircraft. At the same time there is complete lack of evidence to indicate that there was any structural failure."

Dear Commission Members, a Canadian Commission of Inquiry should use the Canadian aviation accident experts' opinions as a starting frame of reference, not that of an Indian Judge's opinion, (a criminal judge with no aviation accident investigation experience.) To claim that the Canadian Aviation Safety Board concluded that the destruction of this aircraft was caused by a bomb is absolutely incorrect and injects a dangerous bias into the supposedly objective proceedings so much so that the title is even incorrect: "Commission of Inquiry into the Investigation of the Bombing of Air India Flight 182". The title could be corrected to "Commission of Inquiry into the Investigation of the Tragedy of Air India Flight 182".

(The bombing statement error is understandable after twenty years of constant media and police opinions about terrorists everywhere and desires for grieving family members for revenge. However, there are no conspiracies to hide any truths, just passionate persons acting in their own perceived best interests.)

Please note that both of the quotes from the documents referenced above are specifically allowed by the Commission's Terms of Reference:

Terms of Reference: "...the Commissioner to conduct the Inquiry as he considers appropriate with respect to accepting as conclusive or giving weight to the findings of other examinations of the circumstances surrounding the bombing of Air India Flight 182, including
the report of the Honourable Mr. Justice B.N. Kirpal of the High Court of Delhi of February 26, 1986,
the Aviation Occurrence Report of the Canadian Aviation Safety Board into the crash involving Air India Flight 182 of January 22, 1986"

The points for my presentation at the Inquiry shall be:
1. The Canadian Aviation Safety Board conclusion of 1986 was correct and the Indian finding was wrong.
2. The verdict in the Canadian trial of the two accused as not guilty was correct. The criminal justice system did not fail the families or all Canadians. There were no bombs, no bombers, no conspiracies, no crimes, no criminals, no guilt.
3. Based upon the benefit of 20 years of hindsight and several similar early model Boeing 747 accidents and in particular United Airlines Flight 811, the actual probable cause of Air India Flight 182 is the shorted wiring/ruptured open forward cargo door/explosive decompression/inflight breakup explanation.
4. A request by the Commission to the Transportation Safety Board (Air) for an updated version of the Aviation Occurrence Report for Air India Flight 182 would be prudent and wise. The older report is now over twenty years old. Safety related explanations are constantly being updated after new accidents. There have subsequently been several similar early model Boeing 747s that have suffered a fatal inflight explosive decompression in the forward cargo compartment after a sudden loud sound on the cockpit voice recorder followed by an abrupt

power cut to the flight recorders.

In summary:
I apply for standing in the Inquiry as a person with an ascertainable interest and perspective. I have demonstrated with this letter a review of the Commission's mandates, a close observation of its premises, the detection of a serious error of fact, a suggested correction, provided confirming documentation quotes, and referenced supporting documents. I will do the same in principle at the Inquiry for the wiring/cargo door explanation.

From the Commission Opening Statement of Commissioner John Major: "We can, however, attempt to understand how this happened and to recommend safeguards and systemic changes to prevent future threats to our national security and intrusions into the lives of so many innocent people."

Yes, sir, we certainly can, and must, attempt to understand how this {Air India Flight 182} happened, recommend safeguards and changes to prevent future threats and intrusions. Please assign me as a person with standing the opportunity to explain how.

Attached below:
Relevant excerpts from the Commission's website,
Relevant excerpts from Canadian and Indian AAR for Air India Flight 182.

OPENING STATEMENT
June 21, 2006

In announcing the launch of this Inquiry, the Prime Minister, the Right Honourable Stephen Harper, stated that a public inquiry is the only route left to obtaining answers to how the tragedy of June 23, 1985 occurred when Air India Flight 182 exploded over the Atlantic Ocean. The aircraft was flying at an altitude of 31,000 feet (9500 m) just south of Ireland, when all 329 on board were killed. Eighty-two of those victims were children and 280 were Canadian citizens.

Yet, it was not until the following January that the Canadian Aviation Safety Board concluded that the destruction of this aircraft was caused by a bomb.

STANDING

10. A person may be granted full or partial standing as a party by the Commissioner if the Commissioner is satisfied that the person is directly and substantially affected by the mandate of the Inquiry or portions thereof.

12. Any person wishing to be granted standing must apply by way of a motion in writing supported by affidavit on or before July 7, 2006, or at the discretion of the Commissioner at any other date, which must include the following information:

1. name, address, telephone and fax numbers, and e-mail addresses of the person;
2. whether the person seeks standing as a party or as an intervenor for all or a portion of the mandate of the Inquiry;
3. the areas and issues where the person is directly and substantially affected or where the person has a clearly ascertainable interest or perspective which would enhance the work of the Commissioner and the reasons in support thereof;

13. Applicants for standing will be permitted to make oral submissions not exceeding 15 minutes at a public standing hearing in Ottawa, on July 18-20, 2006 at the Bytown Pavilion, Victoria Hall, 111 Sussex Drive, Ottawa, Ontario, or at the discretion of the Commissioner at any other date.

14. The Commissioner will determine any special conditions under which a person may participate and those parts of the Inquiry in which a person granted standing may

B. DEFINITIONS

2. In the Rules, unless otherwise provided, the following words mean:
10. Person: an individual, group, government or agency or other entity.

EVIDENCE

26. The Commissioner may receive any evidence or information which he considers to be helpful in fulfilling his mandate whether or not such evidence or information would be admissible in court.

* . Testimony in Stage 2 of the Inquiry
1. Preparation of Documentary Evidence

30. As soon as possible after being granted standing, parties and intervenors shall provide to the Commission all documents having any bearing on the subject matter of the Inquiry.

Commission of Inquiry into the Investigation of the
Bombing of Air India Flight 182
P.O. Box 1298, Station B
Ottawa, Ontario K1P 5R3
CANADA

Telephone: (613) 992-1834
Fax: (613) 995-3506

TERMS OF REFERENCE

the Commissioner to conduct the Inquiry as he considers appropriate with respect to accepting as conclusive or giving weight to the findings of other examinations of the circumstances surrounding the bombing of Air India Flight 182, including

the report of the Honourable Mr. Justice B.N. Kirpal of the High Court of Delhi of February 26, 1986,

the Aviation Occurrence Report of the Canadian Aviation Safety Board into the crash involving Air India Flight 182 of January 22, 1986,

that the Commissioner be authorized to grant to any other person who satisfies him that he or she has a substantial and direct interest in the subject-matter of the Inquiry an opportunity for appropriate participation in the Inquiry;

To conclude only that the criminal justice system has to date failed the families of Air India victims falls short of the problem. It failed all Canadians. The system failed all Canadians.

It is not possible to undo what happened in 1985. We can, however, attempt to understand how this happened and to recommend safeguards and systemic changes to prevent future threats to our national security and intrusions into the lives of so many innocent people.

AAR for Air India Flight 182 excerpts:

"4.0 CONCLUSIONS
The Canadian Aviation Safety Board respectfully submits as follows:
4.1 Cause-Related Findings
1. At 0714 GMT, 23 June 1985, and without warning, Air India Flight 182 was subjected to a sudden event at an altitude of 31,000 feet resulting in its crash into the sea and the death of all on board.
2. The forward and aft cargo compartments ruptured before water impact.
3. The section aft of the wings of the aircraft separated from the forward portion before water impact.
4. There is no evidence to indicate that structural failure of the aircraft was the lead event in this occurrence.
5. There is considerable circumstantial and other evidence to indicate that the initial event was an explosion occurring in the forward cargo compartment. This evidence is not conclusive. However, the

evidence does not support any other conclusion."

Kirpal Report:
ANALYSIS AND CONCLUSIONS
4.1 From the evidence which is available what has now to be determined is as to what caused the accident.
4.5 It is evident that an event had occurred at 31,000 feet which had brought down 'Kanishka'. What could have possibly happened to it? The aircraft was apparently incapacitated and this was due either to it having been hit from outside; or due to some structural failure; or due to the detonation of an explosive device within the aircraft.
4.9 Thus we are left with only two of the possibilities viz., structural failure or accident having been caused due to a bomb having been placed inside the aircraft.
4.10 After going through the entire record we find that there is circumstantial as well as direct evidence which directly points to the cause of the accident as being that of an explosion of a bomb in the forward cargo hold of the aircraft. At the same time there is complete lack of evidence to indicate that there was any structural failure.
http://www.majorcomm.ca/en/index.asp

On May 1, 2006, an Order in Council was issued defining the terms of reference for the Commission of Inquiry into the Investigation of the Bombing of Air India Flight 182. The Honourable John C. Major, Q.C., was appointed Commissioner under Part 1 of the Inquiries Act.

The Inquiry will be conducted in two stages. During the first stage, the Commissioner will hear voluntary testimony from the families of the victims. Stage two will deal with matters set out in clause (b) of the Order in Council. For the Order in Council text, please visit the Terms of Reference.

Sheila-Marie Cook is the Executive Director and Commission Secretary. Mark J. Freiman is the Commission's Lead Counsel. Michel Dorval is the Commission's Co-Counsel.

RULES OF PROCEDURE AND PRACTICE

A. THE INQUIRY

1. This Inquiry shall be conducted in accordance with the Inquiries Act and the Terms of Order in Council P.C. 2006-293 and without restricting the generality of the foregoing will, when appropriate, follow the following guidelines.

The Commission proceedings will start with the voluntary testimony of the victims of the bombing of Air India Flight 182 ("Stage 1"). The balance of the Inquiry ("Stage 2") will inquire in phases into the matters set out in clauses (b)(i)-(vii) of the Terms of Reference of the Commission, PC 2006-293.

B. DEFINITIONS

2. In the Rules, unless otherwise provided, the following words mean:

1. Commission: the Commission of Inquiry into the Investigation of the Bombing of Air India Flight 182, established by Order in Council, PC 2006-293;

2. Commissioner: The Honourable John C. Major, Q.C., appointed by Order in Council, PC 2006-293;

3. Commission Counsel: Counsel appointed by the Commissioner to aid and assist the Commissioner in the Inquiry. Commission Counsel shall have standing throughout the Inquiry;

4. Commission Offices: the offices of the Commission are located at 222 Queen Street, Ottawa, Ontario, K1P 5V9;

5. Documents: records made or stored in physical or electronic form and include written, electronic, audiotape, videotape, digital reproductions, photography, maps, graphs, microfiche or any other data and information recorded or shared by means of any device;

6. Family: relatives of the victims of the Bombing of Air India Flight 182 or others to the discretion of the Commissioner;

7. Inquiry: the Commission;

8. Intervenor: a person granted status as an intervenor by the Commissioner;

9. Party: a person granted full or partial standing as a party by the Commissioner;

10. Person: an individual, group, government or agency or other entity.

C. GENERAL

3. The Commissioner may amend these Rules or dispense with compliance with them as he deems necessary to ensure that the Inquiry is thorough, fair and timely.

4. All parties, intervenors, witnesses and their counsel shall be deemed to undertake to adhere to the Rules, and may raise any issue of non-compliance with the Commissioner.

5. The Commissioner shall deal with a breach of these Rules as he sees fit including, but not restricted to, revoking the standing of a party, and imposing restrictions on the further participation in or attendance at (including exclusion from) the hearings by any party, intervenor, counsel, individual, or member of the media.

6. Subject to the Inquiries Act, the conduct of and the procedure to be followed on the Inquiry is under the control and discretion of the Commissioner.

7. Hearings will be convened in Ottawa unless otherwise directed in the discretion of the Commissioner

8. Insofar as he needs to hear evidence, the Commissioner is committed to a process of public hearings to the greatest extent possible. However, the Terms of Reference direct the Commissioner to take all steps necessary to prevent disclosure of information that, if it were disclosed to the public could, in the opinion of the Commissioner, be injurious to international relations, national defence or national security. The procedure which will govern hearings where such issues may arise is addressed in the section on "National Security Confidentiality".

9. Applications may also be made to proceed in camera for reasons of personal confidentiality, referred to as "Personal Confidentiality" in these Rules. Such applications should be made in writing at the earliest possible opportunity.

D. STANDING

10. A person may be granted full or partial standing as a party by the Commissioner if the Commissioner is satisfied that the person is directly and substantially affected by the mandate of the Inquiry or portions thereof.

11. A person may be granted standing as an intervenor by the Commissioner if the Commissioner is satisfied that the person represents clearly ascertainable interests and perspectives essential to the Commissioner's mandate, which the Commissioner considers ought to be separately represented before the Inquiry, in which event the intervenor may participate in a manner to be determined by the Commissioner.

12. Any person wishing to be granted standing must apply by way of a motion in writing supported by affidavit on or before July 7, 2006, or at the discretion of the Commissioner at any other date, which must include the following information:

1. name, address, telephone and fax numbers, and e-mail addresses of the person;

2. whether the person seeks standing as a party or as an intervenor for all or a portion of the mandate of the Inquiry;

3. the areas and issues where the person is directly and substantially affected or where the person has a clearly ascertainable interest or perspective which would enhance the work of the Commissioner and the reasons in support

thereof;

4. the names of the lawyers, if any representing the person, together with the lawyer's address, telephone number, e-mail address and fax number.

13. Applicants for standing will be permitted to make oral submissions not exceeding 15 minutes at a public standing hearing in Ottawa, on July 18-20, 2006 at the Bytown Pavilion, Victoria Hall, 111 Sussex Drive, Ottawa, Ontario, or at the discretion of the Commissioner at any other date.

14. The Commissioner will determine any special conditions under which a person may participate and those parts of the Inquiry in which a person granted standing may participate.

15. From time to time, the Commissioner may, in his discretion, at any time grant to or rescind standing from a person, or modify the status or conditions of the standing of a person.

16. The Commissioner will determine on what terms and in which parts of the Inquiry a party or intervenor may participate, and the nature and extent of such participation.

17. The Commissioner may direct that a number of applications share in a single grant of standing.

18. Counsel representing witnesses called to testify before the Commission may participate during the hearing of such evidence as provided in these Rules.

E. FUNDING

19. For the purposes of the Inquiry, parties who would not otherwise be able to participate may seek funding by way of a motion in writing, with supporting affidavit(s), to be

filed with the Commission on or before August 16, 2006, or at the discretion of the Commissioner at any other date. Funding will be recommended at the Commissioner's discretion in accordance with paragraph (h) of the Terms of Reference. There will be no oral hearing with respect to funding.

20. Where the Commissioner's funding recommendation is accepted, funding shall be in accordance with approved Treasury Board guidelines respecting rates of remuneration and reimbursement and the assessment of accounts.

F. RIGHT TO COUNSEL

21. Witnesses have the right to consult counsel at their own expense unless funding for said costs is ordered by the Commissioner as provided in these Rules. Anyone interviewed by or on behalf of Commission Counsel is entitled to have one personal counsel present for the interview to represent his or her interests.

G. HEARING AND DECORUM

22. In so far as it needs to consider evidence under the Inquiry, the Commission is committed to a process of public hearings.

23. However, applications may be made by a party asking that the Commissioner issue an order that any portion of the proceedings be in camera, or issue an order prohibiting the disclosure, publication or communication of any testimony, document, personal information or evidence. Such applications shall be made in writing, supported by affidavit(s), at the earliest opportunity. The evidence and submissions on such applications may be presented in private or in public, or a combination of both, at the discretion of the Commissioner, according to these Rules, which are applicable to in camera matters with appropriate

modifications.

24. The Commissioner may, at his discretion, issue an order that any portion of the proceedings be in camera, or issue an order prohibiting the disclosure, publication or communication of any testimony, document, personal information or evidence.

25. The Commission will set the dates, hours and places of its hearings. Unless otherwise directed by the Commissioner in his discretion, hearings will start at 9:30 a.m. and end at 4:30p.m., from Monday to Friday, inclusive, and will take place in Ottawa at the Bytown Pavilion, Victoria Hall, 111 Sussex Drive, Ottawa, Ontario or at such other place as the Commissioner determines.

H. EVIDENCE

26. The Commissioner may receive any evidence or information which he considers to be helpful in fulfilling his mandate whether or not such evidence or information would be admissible in court.

27. The Commissioner, in his discretion, may accept as conclusive or give such weight as he deems appropriate to the findings of the examinations of the circumstances surrounding the bombing of Air India Flight 182 set out in paragraph (a) of the Commission's Terms of Reference, Order in Council, PC 2006-293.

* 1. Commencement of the Inquiry (Stage 1)

28. Family of the victims of the bombing of Air India Flight 182 who participate in Stage 1 of the Inquiry will not be required to give their testimony upon oath or upon affirmation and shall not be subject to cross-examination.

29. The Commissioner, in his discretion, may make such

further Rules as he deems appropriate with respect to the conduct of Stage 1 of the Inquiry. The Rules with respect to evidence in the balance of the Inquiry (Stage 2) will not apply to Stage 1, unless specifically so ordered by the Commissioner.

* 2. Testimony in Stage 2 of the Inquiry
    1. Preparation of Documentary Evidence

30. As soon as possible after being granted standing, parties and intervenors shall provide to the Commission all documents having any bearing on the subject matter of the Inquiry.

31. Where a party objects to the production of any document on the grounds of privilege, the document shall be produced in its original unedited form to Commission Counsel who will review and determine the validity of the privilege claim. The party, intervenor and/or counsel may be present during the review process. In the event the party or intervenor claiming privilege disagrees with Commission Counsel's determination, the Commissioner, on application, may either inspect the impugned document(s) and make a ruling, or may direct the issue to be resolved by the Federal Court.

32. Upon the request of Commission Counsel, parties and intervenors shall provide originals of relevant documents.

33. Documents received from a party, intervenor, or any other organization or individual, shall be treated as confidential by the Commission unless and until they are made part of the public record or the Commissioner otherwise declares. This does not preclude Commission Counsel from producing a document to a proposed witness prior to the witness giving his or her testimony, as part of

the investigation being conducted, all subject to National Security Confidentiality.

2. Witness Interviews

34. Commission Counsel may interview people who have information or documents which have any bearing upon the subject matter of the Inquiry. People who are interviewed are entitled, but not required, to have a legal counsel present at their expense unless otherwise ordered by the Commissioner, as provided in these Rules.

35. If Commission Counsel determines that a person will be called as a witness following an interview, Commission Counsel will prepare a statement of the witness' anticipated evidence. Commission Counsel will provide a copy of the statement of anticipated evidence to the witness for review before the witness testifies before the Commission. Where a statement of anticipated evidence is released to persons with party status prior to the testimony of a witness, the statement will be deemed confidential and unless otherwise ordered by the Commissioner shall be not be disclosed to third parties until after the completion of the testimony of the witness in question.

3. Witnesses

36. All government entities, agencies and officials and all witnesses shall co-operate fully with the Commission and shall make available all documents and witnesses relevant to the mandate of the Commission.

37. Witnesses who testify will give their evidence at a hearing under oath or upon affirmation unless otherwise ordered by the Commissioner in his discretion.

38. Commission Counsel may issue and serve a subpoena or summons upon each witness before he or she testifies.

Witnesses may be called more than once.

39. Witnesses who are not represented by counsel for parties are entitled to have their own counsel present while they testify, subject to National Security Confidentiality. Counsel for a witness will have standing only for the purpose of that witness' testimony to make any objections thought appropriate and for other purposes as directed by the Commissioner in his discretion.

40. Parties and intervenors are encouraged to advise Commission Counsel of the names, addresses and telephone numbers of all witnesses they wish to have called and, if possible, to provide summaries of the information the witnesses may have.

41. If the proceedings are televised, applications may be made for an order that the evidence of a witness not be televised or broadcast.

4. Commission Dossier

42. At the commencement of any phase of Stage 2 of the Inquiry, Commission Counsel may present to the Commissioner a statement of evidence, facts or conclusions together with the sources or basis for the evidence, facts or conclusions that Commission Counsel proposes that the Commissioner adopt for purposes of the Commission's findings or conclusions with respect to that phase of Stage 2 (a "Commission Dossier").

43. Commission Counsel may call witnesses or experts to support or supplement the Commission Dossier.

44. A person who has been granted party status with respect to a phase of Stage 2 with respect to which Commission Counsel has presented a Commission Dossier may cross-examine witnesses called with respect to the Dossier. A person granted status as a party or as an

intervenor may propose witnesses to be called with respect to the Dossier. Where Commission Counsel declines to call a witness proposed by a person with party or intervenor status, that person may follow the procedure as set out in Rule 49.

5. Oral Examination

45. In the ordinary course Commission Counsel will call and question witnesses who testify at the Inquiry. Counsel for a party may apply to the Commissioner to lead a particular witnesses' evidence in chief. If counsel is granted the right to do so, examination shall be confined to the normal rules governing the examination of one's own witness in court proceedings, unless otherwise directed by the Commissioner.

46. Commission Counsel have a discretion to refuse to call or present evidence.

47. The order of examination in the ordinary course will be as follows:

1. Commission Counsel will lead the evidence from the witnesses. Except as otherwise directed by the Commissioner, Commission Counsel is entitled to ask both leading and non-leading questions;

2. parties will then have an opportunity to cross-examine the witness to the extent of their interest. The order of cross-examination will be determined by the parties and, if they are unable to reach agreement, by the Commissioner;

3. after cross-examinations, counsel for a witness may then examine the witness. Except as otherwise directed by the Commissioner, counsel for the witness is entitled to ask both leading and none-leading questions;

4. Commission Counsel shall have the right to re-

examine last.

48. After a witness has been sworn, affirmed, or otherwise qualified at the commencement of giving evidence, no counsel other than Commission Counsel may speak to such witness about the evidence that he or she has given until the evidence of such witness is complete except with the permission of the Commissioner. Commission Counsel may not speak to any witness about his or her evidence while the witness is being cross-examined by other counsel.

49. When Commission Counsel indicate that they have called the witnesses whom they intend to call in relation to a particular issue, a party may then apply to the Commissioner for leave to call a witness whom the party believes has the evidence relevant to that issue. If the Commissioner is satisfied that the evidence of the witness is needed, Commission Counsel shall call the witness, subject to Rule 47.

6. Use of Documents at Hearings

50. In advance of a witness' testimony, Commission Counsel will endeavour to provide to parties and intervenors with an interest in the subject matter of the proposed evidence, a statement of that witness' anticipated evidence and associated documents, subject to the Rules regarding National Security Confidentiality, and subject to receipt of an undertaking that all such documents or information will be used solely for the purpose of the Inquiry. In addition, the Commissioner may require that documents provided, and all copies made, be returned to the Commission if not tendered in evidence. Counsel are entitled to provide such documents or information to their respective clients only on terms consistent with the undertakings given, and upon the clients entering into written undertakings to the same effect. These undertakings will be of no force regarding any document or information once it has become an exhibit. The

Commissioner may, upon application, release any party or intervenor in whole or in part from the provisions of the undertaking in respect of any particular document or other information.

51. Parties shall provide Commission counsel with any documents that they intend to file as exhibits or otherwise refer to during the hearings at the earliest opportunity, and in any event shall provide such documents to Commission counsel no later than two business days before the document will be referred to or filed.

52. Before using a document for purposes of cross-examination, counsel shall provide a copy to the witness and to all parties having an interest in the subject matter of the proposed evidence not later than two business days prior to the commencement of that witness' testimony.

7. National Security Confidentiality

53. As contemplated by paragraph (m) of the Terms of Reference, Order in Council, P.C. 2006-293, the Attorney General of Canada may apply from time to time to have certain evidence heard in camera to prevent public disclosure of information on grounds of National Security Confidentiality. The Commissioner will conduct proceedings to determine the disposition of such applications in accordance with paragraph (m) (i-v) of the Terms of Reference subject to such additional procedures consistent with the Terms of Reference as the Commissioner may at his discretion direct.

8. Personal Confidentiality

54. Upon application, the Commissioner may make an order for a grant of "Personal Confidentiality", aimed at protecting the identity of any person. For the purposes of the Inquiry, Personal Confidentiality shall include the right of any person to have his or her identity disclosed only by way of non-identifying initials, and, if the Commissioner so

rules, the right to testify before the Commission in camera, together with any other privacy measures which the Commissioner grants.

55. Upon application, the Commissioner may make an order to conduct hearings in camera when he is of the opinion that intimate financial, personal or other matters are of such a nature, having regard to the circumstances, that the desirability of avoiding disclosure outweighs the desirability of adhering to the general principle that the hearings should be open to the public.

56. A person who is granted Personal Confidentiality will not be identified in the public records and transcripts of the hearing except by non-identifying initials, and the public transcripts may be redacted to exclude any identifying details. Any reports of the Commission referring to a person who has been granted Personal Confidentiality will use non-identifying initials only, and may exclude reference to identifying details.

57. Media reports relating to a person granted Personal Confidentiality shall avoid references that might reveal the identity of the person. No photographic or other reproduction of a person granted confidentiality shall be made either during the person's testimony or upon his or her entering and leaving the site of the Inquiry.

58. Any witness who is granted Personal Confidentiality may either swear an oath or affirm to tell the truth using the non-identifying initials given for the purpose of the witness's testimony.

59. Any party, intervenor or witness may apply to the Commissioner to have intimate financial or personal information which is not relevant to the subject matter of the Inquiry redacted from documents proposed to be introduced into evidence.

60. All media representatives shall be deemed to undertake to adhere to the Rules respecting Personal Confidentiality. A breach of these Rules by a media representative shall be dealt with by the Commissioner as he sees fit.

9. Access to Evidence

61. All evidence shall be categorized and marked P for public sittings and C for sittings in camera

62. Copies of the P transcript of evidence will be made available on the Inquiry's website. One copy of the P transcript and the P exhibits of the public hearings will be made available for public review at the Commission offices.

63. Only those persons authorized by the Commission, in writing, shall have access to C transcripts and exhibits.

I. CONSULTATION PAPERS, POLICY FORUMS, PUBLIC CONSULTATIONS

64. The Commissioner, in his discretion, may authorize the commissioning of Consultation Papers, and/or the convening of Expert Policy Forums or Public Consultations for use in the preparation of Commission Dossiers.

65. The Commissioner, in his discretion, may receive evidence at any stage of Phase 2 of public hearings from one or more panels of expert witnesses. The Commissioner may modify the Rules for cross-examination of witnesses as he deems appropriate, so as to allow persons with standing in relation to the relevant phase of Stage 2 to participate appropriately in relation to the evidence of the panel in question.

66. Persons with an interest in any phase of Stage 2 may, prior to the commencement of that phase, may make a

submission in writing about any matter relevant to that phase, including specific proposals for the recommendations to be made by the Commissioner with respect to that phase.

67. The Commissioner may convene public and private consultations to hear submissions with respect to any matter raised in any phase of Stage 2 of the Inquiry. The participants in such consultations may include any persons whom the Commissioner concludes will contribute to the process.

J. MEDIA COVERAGE

68. The Commission may authorize the tape recording and live broadcasting of the public hearings by a designated media representative who will provide such recording and live feed to all other media pursuant to a pooling agreement. If the media cannot agree on a pooling agreement, they may apply to the Commissioner for a decision.

69. Representatives of the media who have signed the pooling agreement have the same rights in connection with the utilization of the tape recording and live broadcasting feed of the public hearings as the designated media representative.

70. The designated media representative authorized to tape record and broadcast the public hearings shall provide a copy of such recording to the Commission's Registrar, not later than three days after the recorded hearing.

71. Cameras and microphones will be located at pre-determined places in the hearing rooms. Only fixed cameras and the lighting system in the hearing room will be allowed.

72. No media scrums, interviews, or reporting will be allowed in the hearing rooms or within a prescribed distance from the hearing room entrances.

73. Media representatives will have to abide by the Commission's directives.

74. Whenever the Commission decides pursuant to Rules 8, 9, 53, 54 and 55 to proceed in camera, or issue a publication, disclosure or communication ban, the designated media representative must, to the satisfaction of the Commission, take all necessary measures to ensure that all tape recording or sound recording machines have been turned off.

75. No other forms or means of recording, re-broadcasting or photographing beyond those permitted by these Rules will be allowed in the hearing rooms.

76. Notwithstanding Rule 75, the Commission may allow, at his discretion at times and under conditions set by him, one photographer to take pictures in the hearing room with the understanding that he make available his negatives to representatives of the media pursuant to a pooling agreement of the kind described in Rule 68 above.

Ottawa, Ontario
CANADA

Her Excellency the Governor General in Council, on the recommendation of the Prime Minister, hereby directs that a Commission do issue under Part I of the Inquiries Act and under the Great Seal of Canada appointing the Honourable John C. Major, Q.C., as Commissioner to conduct an inquiry into the investigation of the bombing of Air India Flight 182 (the "Inquiry"), which Commission shall direct

1. the Commissioner to conduct the Inquiry as he considers appropriate with respect to accepting as conclusive or giving weight to the findings of other examinations of the circumstances surrounding the bombing of Air India Flight 182, including

    1. the report of the Honourable Bob Rae entitled Lessons to Be Learned of November 23, 2005,

    2. proceedings before the superior courts of British Columbia,

    3. the 1991–1992 Security Intelligence Review Committee review of Canadian Security Intelligence Service activities in regard to the destruction of Air India Flight 182,

    4. the report of the Honourable Mr. Justice B.N. Kirpal of the High Court of Delhi of February 26, 1986,

    5. the Aviation Occurrence Report of the Canadian Aviation Safety Board into the crash involving Air India Flight 182 of January 22, 1986,

    6. the 1985 report of Blair Seaborn entitled Security Arrangements Affecting Airports and Airlines in Canada, and

    7. the reports prepared by the Independent Advisory Panel assigned by the Minister of Transport to review the provisions of the Canadian Air Transport Security Authority Act, the operations of the Canadian Air Transport Security Authority and other matters relating to aviation security;

2. the Commissioner to conduct the Inquiry specifically for the purpose of making findings and recommendations

with respect to the following, namely,

1. if there were deficiencies in the assessment by Canadian government officials of the potential threat posed by Sikh terrorism before or after 1985, or in their response to that threat, whether any changes in practice or legislation are required to prevent the recurrence of similar deficiencies in the assessment of terrorist threats in the future,

2. if there were problems in the effective cooperation between government departments and agencies, including the Canadian Security Intelligence Service and the Royal Canadian Mounted Police, in the investigation of the bombing of Air India Flight 182, either before or after June 23, 1985, whether any changes in practice or legislation are required to prevent the recurrence of similar problems of cooperation in the investigation of terrorism offences in the future,

3. the manner in which the Canadian government should address the challenge, as revealed by the investigation and prosecutions in the Air India matter, of establishing a reliable and workable relationship between security intelligence and evidence that can be used in a criminal trial,

4. whether Canada's existing legal framework provides adequate constraints on terrorist financing in, from or through Canada, including constraints on the use or misuse of funds from charitable organizations,

5. whether existing practices or legislation provide adequate protection for witnesses against intimidation in the course of the investigation or prosecution of terrorism cases,

6. whether the unique challenges presented by the

prosecution of terrorism cases, as revealed by the prosecutions in the Air India matter, are adequately addressed by existing practices or legislation and, if not, the changes in practice or legislation that are required to address these challenges, including whether there is merit in having terrorism cases heard by a panel of three judges, and

7. whether further changes in practice or legislation are required to address the specific aviation security breaches associated with the Air India Flight 182 bombing, particularly those relating to the screening of passengers and their baggage;

3. the Commissioner to conduct the Inquiry under the name of the Commission of Inquiry into the Investigation of the Bombing of Air India Flight 182;

4. that the Commissioner be authorized to adopt any procedures and methods that he may consider expedient for the proper conduct of the Inquiry, and to sit at any times and in any places in or outside Canada that he may decide;

5. that the Commissioner be authorized to conduct consultations in relation to the Inquiry as he sees fit;

6. that the Commissioner be authorized to grant to the families of the victims of the Air India Flight 182 bombing an opportunity for appropriate participation in the Inquiry;

7. that the Commissioner be authorized to recommend to the Clerk of the Privy Council that funding be provided, in accordance with approved guidelines respecting rates of remuneration and reimbursement and the assessment of accounts, to ensure the appropriate participation of the families of the victims of the Air India Flight 182 bombing;

8. that the Commissioner be authorized to grant to any other person who satisfies him that he or she has a substantial and direct interest in the subject-matter of the Inquiry an opportunity for appropriate participation in the Inquiry;

9. that the Commissioner be authorized to recommend to the Clerk of the Privy Council that funding be provided, in accordance with approved guidelines respecting rates of remuneration and reimbursement and the assessment of accounts, to ensure the appropriate participation of any party granted standing under paragraph (h), to the extent of the party's interest, where in the Commissioner's view the party would not otherwise be able to participate in the Inquiry;

10. that the Commissioner be authorized to rent any space and facilities that may be required for the purposes of the Inquiry, in accordance with Treasury Board policies;

11. the Commissioner to use the automated litigation support program specified by the Attorney General of Canada and to rely, to the greatest extent possible, on documents that have been previously identified for use in Canadian criminal proceedings arising from the bombing of Air India Flight 182, and to consult with records management officials within the Privy Council Office on the use of standards and systems that are specifically designed for the purpose of managing records;

12. that the Commissioner be authorized to engage the services of any experts and other persons referred to in section 11 of the Inquiries Act, at rates of remuneration and reimbursement approved by the Treasury Board;

13. the Commissioner, in conducting the Inquiry, to take all steps necessary to prevent disclosure of information which, if it were disclosed, could, in the opinion of the

Commissioner, be injurious to international relations, national defence or national security and to conduct the proceedings in accordance with the following procedures, namely,

1. on the request of the Attorney General of Canada, the Commissioner shall receive information in camera and in the absence of any party and their counsel if, in the opinion of the Commissioner, the disclosure of that information could be injurious to international relations, national defence or national security,

2. the Commissioner may release a part or a summary of the information received in camera, if, in the opinion of the Commissioner, its disclosure would not be injurious to international relations, national defence or national security, and shall provide the Attorney General of Canada with an opportunity to make submissions regarding international relations, national defence or national security prior to any release of a part or a summary of information received in camera,

3. if the Commissioner concludes that, contrary to the submissions of the Attorney General of Canada referred to in subparagraph (ii), disclosure of a part or a summary of information received in camera would not be injurious to international relations, national defence or national security, he shall so notify the Attorney General of Canada, which notice shall constitute notice under section 38.01 of the Canada Evidence Act,

4. the Commissioner shall provide the Attorney General of Canada with an opportunity to make submissions regarding international relations, national defence or national security with respect to any reports that are intended for release to the public prior to submitting such reports to the Governor in Council, and

5. if the Commissioner concludes that, contrary to the

submissions of the Attorney General of Canada referred to in subparagraph (iv), disclosure of information contained in reports intended for release to the public would not be injurious to international relations, national defence or national security, he shall so notify the Attorney General of Canada, which notice shall constitute notice under section 38.01 of the Canada Evidence Act;

14. that nothing in that Commission shall be construed as limiting the application of the provisions of the Canada Evidence Act;

15. the Commissioner to follow established security procedures, including the requirements of the Government Security Policy, with respect to persons engaged pursuant to section 11 of the Inquiries Act and the handling of information at all stages of the Inquiry;

16. the Commissioner to perform his duties without expressing any conclusion or recommendation regarding the civil or criminal liability of any person or organization;

17. the Commissioner to perform his duties in such a way as to ensure that the conduct of the Inquiry does not jeopardize any ongoing criminal investigation or criminal proceeding;

18. the Commissioner to file the papers and records of the Inquiry with the Clerk of the Privy Council as soon as reasonably possible after the conclusion of the Inquiry;

19. the Commissioner to submit a report or reports, simultaneously in both official languages, to the Governor in Council; and

20. the Commissioner to ensure that members of the public can, simultaneously in both official languages, communicate with, and obtain services from it, including

transcripts of proceedings if made available to the public.

Dear Mr. Donaldson Wednesday, August 23, 2006

Attached are submissions 4 through 12 which were sent to, received, and acknowledged by the Commission of Inquiry. I've also sent all 12 submissions to RCMP, Attorney General, Transport Canada and Transportation Safety Board. Do you think the Prime Minister would be overkill?

I see the hearing to set a trial date for Mr. Reyat was delayed from 2 August to early September. Why?

From your silence I have to guess you are not going with the 'no bomb, no bombers, no conspiracies, no perjury' defense but probably the 'well, I forgot, that's my story and I'm sticking to it' defense.

It seems funny to me to have to defend someone from a conspiracy charge in which the client was involved with two men who were found not guilty of conspiracy.

Anyway, I'm trying to see your point of view.

1. Requesting bomb report on the Narita event from Japanese authorities is too much trouble, takes too long, and probably written in Japanese anyway
2. Requesting a Canadian aviation safety board that investigates airplane crashes and who has never given its opinion would be a waste of time as they are very busy and understaffed and the report would be too technical to understand anyway.
3. Using the 'no bomb, no conspiracy' defense would undermine efforts of your colleague/friend Dave Crossin since Ole Dave never argued or disputed:
  a. that since all the Vancouver baggage was loaded into the aft cargo compartment

of Air India Flight 182 and the explosion occurred in the forward compartment, the Vancouver guys were innocent.
b. the cause was a bomb since the CASB did not conclude it was a bomb, only an explosion for which there are many causes.
c. the switch from forward compartment explosion which was believed for fifteen years and then suddenly switched to aft cargo compartment when all the evidence in the CASB and Kirpal reports specifically ruled out an explosion of any cause back there.

With a defense counsel like that, who agrees with the Crown it was a bomb and let's just explode it anywhere, who needs prosecutors?

But, he did earn his money, he got verdicts of not guilty and that's what counts in the end as far as the defense for two men goes. Maybe you were involved with the decision not to dispute the bombing conclusion made by the police and ignore the opinions of the people who actually investigate aircraft crashes.

In effect, those decisions have made it much harder to defend Mr. Reyat....who unbeknownst to him, the bomb making materials were used to ....bring down the World Trade Center...

Sheer cunning genius by some Crown prosecutor to have a suspect sign a document saying that unbeknownst to him, something bad happened and he was involved, knowing the media and public would take that as a confession.

However, unbeknownst to Mr. Reyat the
items that he acquired were used by another person or persons to help
make an explosive device that, on or about Jun. 23, 1985, destroyed Air
India Flight 182, killing all 329 people on board."

By STAFF
The Toronto Star, Feb. 11, 2003

"Text of the agreed statement of facts submitted in B.C. Supreme Court
when Inderjit Singh Reyat pleaded guilty Feb. 10 to 329 counts of
manslaughter in the 1985 bombing of Air India Flight 182:"

"In May and Jun. 1985, in the province of British Columbia, Mr. Reyat
acquired various materials for the purpose of aiding others in the
making of the explosive devices. Mr. Reyat was told and believed that
the explosive devices would be transported to India in order to blow up
property such as a car, a bridge or something 'heavy.' Although Mr.
Reyat acquired materials for this purpose, he did not make or arm an
explosive device, nor did he place an explosive device on an airplane,

nor does he know who did or did not do so. At no time did Mr. Reyat intend by his actions to cause death to any person or believe that such consequences were likely to occur. However, unbeknownst to Mr. Reyat the items that he acquired were used by another person or persons to help make an explosive device that, on or about Jun. 23, 1985, destroyed Air India Flight 182, killing all 329 people on board."

Well, my advice still stands:
a. Go with science, not emotion, to explain an airplane crash.
b. Seek information such as Japanese report on the Narita event and the TSB Air opinion on Air India Flight 182 to get expert opinion you respect other than news reports.
c. Appear before the Commission of Inquiry to present your contributions to the cheating done by the Crown in the prosecutions of Malik and Bagri.

Pan Am Flight 103
SCCRC appeal Abdelbaset Ali Mohmed al-Megrahi Awaiting ruling.
Crown appeal for longer sentence for Abdelbaset Ali Mohmed al-Megrahi. Status unknown

Discussion:

Early model Boeing 747s are machines. We say they die when they crash but they were never really alive, now were they? We anthropomorphize. Let me continue with the analogy.

Four early model Boeing 747s were assumed to have been murdered with the killers caught and tried. Some went free and some went to jail. I am here to say to you that there was no murder, no crime, no killers and innocent men are in prison for a crime that was nonexistent but that a machine failed because of a mechanical part, wiring. That safety hazard persists.

It's as if a person falls down dead. The police, the media, the man's family, the courts, the prosecution, and the defence all agree, yes, it was a shot to the head that killed him but we'll argue about who and where and when he was shot. Several men are arrested, and at the trial the defence states that yes, the victim was shot in the head but their clients did not do it. All the while some physicians who examined the dead person are saying, no, it was not a gunshot to the head but a heart attack, while other physicians say we don't know how he died but we may find out later.

And then another man fall down dead at same spot and it's the brother of the previous dead man. Same thing happens, most non physicians say gunshot to head but the autopsy cause of death determined by government physicians claim natural causes. Several more men are accused and tried. The defence agreed with the prosecution as to cause of death as gunshot but their clients did not pull the trigger.

And then another brother falls down dead under similar circumstances...first guesses were gunshot to head but later proven wrong.

And then another brother falls down dead under similar circumstances...first guesses were gunshot to head but later proven wrong.

All four brothers share the same exact DNA and the evidence discovered at their deaths is generally the same. Two brothers are conclusively proven to have died of heart attacks and the deaths of the other two remain controversial.

And all the while, the people who know why people fall down dead are saying, not a gunshot to the head but heart attack, probably caused by poor diet.

Too bizarre an analogy? No. It's happening in your lives and has happened for years.

Gentlemen, do you have time to examine a reasonable alternative explanation for the aircraft crashes for which your clients are accused of being involved in? I would think your clients have time as they have the rest of their lives to think about it, live with it, and integrate the accusations into their lives inside or outside of prison.

How does a four time serial killer called faulty wiring get away with it?

1. The deaths happen over a period of years, 1985 through 1996. Memories are short. Personnel change. Documents are thrown away, misplaced, or lost. Witnesses forget.
2. The deaths happen many thousands of miles apart from each

other, such as Ireland, New York, Lockerbie, and Hawaii.
3. The deaths involve many agencies; RCMP, Scotland Yard, FBI, CIA, CSIS, TSB, NTSB, CASB, AAIB, Indian Civil Aviation Agency, and all the way to the top political leaders. The agencies do not cooperate or communicate fully, they defend their area of investigation, they are secretive, and they have many administrative senior officials directing them. Each agency looks closely at its lone tree/brother/aircraft in the forest/family of four while ignoring the other three.
4 The deaths involve objects that look different at first glance such as different colors in their livery, different names in their titles, and different nicknames.
5. The deaths involve victims who are not wealthy, important, connected to authority, or famous.
6. The deaths involve different complex legal jurisdictions in faraway places such as India, Canada, UK, and USA.
7. The deaths involve billions of dollars which means people get funny when they get around money.

A. The killer is well loved, well connected, wealthy, powerful, and not a suspect and anybody raising suspicion is scorned.
B. The killer has killed before but is still above suspicion having said to have reformed.
C. The killer's freedom is necessary for the financial well being of thousands of workers.

1. The accused are relatively poor, different color skin and language than the accusers, and have in the past expressed violent thoughts.
2. The accused reinforce the prejudices of the accusers.
3. The accused get the suspicion off the real killer.

There are no conspiracies among the agencies, courts, media, or public to hide or protect the real killer or to convict the innocent. All involved really believe the real killer is not guilty and the accused are guilty based upon the public's own self interest. The well meaning accusers all believe in a vast international conspiracy by the accused to commit mass murder and like all zealots, refuse to consider down to earth explanations for such mass grief causing events. The hysteria feeds on itself with the stories gaining myth status with constant repeating, embellishment and modifications.

The real killer is faulty wiring, a small failure which brings down huge machines, early model Boeing 747s, by exploiting the design flaws of non plug cargo doors and no locking sectors on the midspan latches. The dead brothers/machines are Air India Flight 182, Pan Am Flight 103, United Airlines Flight 811, and TWA Flight 800.

Details:

The innocent accused are:

Air India Flight 182
Inderjit Singh Reyat now in prison.
Ripudaman Singh Malik acquitted but trying to clear his reputation.
Ajaib Singh Bagri acquitted,

Pan Am Flight 103 accused
Abdelbaset Ali Mohmed al-Megrahi now in prison
Al-Amin Khalifa Fhimah, acquitted.

United Airlines Flight 811
A ground crewman accused of killing nine passengers by

negligence in improper latching of the forward cargo door before takeoff. He was proven innocent years later when the cargo door was found to be properly latched but the inadvertent opening was caused by an electrical problem in the wiring or switch.

TWA Flight 800
US Navy by firing a missile which blew up the aircraft.
Disproved by lack of evidence after two years.
Unknown terrorists who placed bomb in aircraft. Disproved after seventeen months of attempts to confirm by FBI.

The deaths are respectively 329, 270, 9, and 230 for a total of eight hundred thirty eight fatalities. That's a mass killing in four events over eleven years and thousands of miles apart involving the governments of four countries. (And it can happen again and it may have with China Airlines Flight 611 in 2003 but more evidence is needed to rule out or rule in so that early model Boeing 747 inflight breakup is not considered in this report.)

And the four victims are virtually identical. They are early model Boeing 747s. There are tens of thousand of airliners out there in hundreds of model and submodels but there are currently about five hundred Boeing 747-100 and 747-200 aircraft still in service of which only four have the below similar evidence after inflight breakups.

The similarities in the circumstances and of the wreckage of those events are many: larger version at http://www.montereypeninsulaairport.com/

How can it be that the court systems of two countries had partial failure and partial success in determining who did what?

That's where you gentlemen come in. You are the defence. You are the professionals who represent the mature society's belief that it could make mistakes and therefore offers an opportunity to present alternative explanations and alternative culprits.

That opportunity has not been realized in the past. For the record: In the several trials in two countries against several men accused of being involved in the killing of 838 men women and children, the defence has never said, "It was not gunshots that killed the four brothers". The defence never claimed it was a heart attack, just that their clients never pulled the trigger of the guns.

Enough of the analogy already...

Defence Strategy:

The defence for Inderjit Singh Reyat, Ripudaman Singh Malik, Ajaib Singh Bagri, Abdelbaset Ali Mohmed al-Megrahi, Al-Amin Khalifa Fhimah, never once said that Air India Flight 182 or Pan Am Flight 103 was not brought down by bombs but by something else. The defence essentially stipulated to the cause of the crashes as bombs and quibbled over a few feet of where it was in the aircraft and challenged the Crown to prove who planted the bombs.

And the defence followed that strategy all the while knowing (assuming they did their homework) that the actual government experts in aviation crash investigations were saying they did not know the cause, or the cause was an explosive decompression and that one UK crash expert even refuted the bomb cause. The defence knew that similar type aircraft had similar type fatal accidents in 1989 and 1996 and the cause was electrical, not a bomb explosion. The defence uncritically believed the police story and that of the Crown prosecutors, the media, the public, and the anguished victim's families, while ignoring the one group who knew what they were talking about, the Canadian Aviation Safety Board investigators, the UK Air Accidents Investigation Board investigators, the National Transportation Safety Board investigators, and the Indian accident investigators.

The defence was caught up in the hateful revenge seeking hysteria of the moment which was kept hot by those that wanted to believe it for their own self interest motives. Everybody loves the bomb explanation except for a few and we know who they are, they are the clients you represent or have represented. The accused probably believe the crashes were caused by bomb explosion but they know and I know they had nothing to do with those tragic events.

For Air India Flight 182 the location of the explosion was in the forward cargo compartment for fifteen years. That conclusion is amply supported by hard wreckage evidence and yet on the day of the trial the location switched to the aft bulk cargo compartment, a location conclusively ruled out by earlier investigators. The defence never disputed the move of the explosion from forward to aft compartments.

For Pan Am Flight 103 the AAIB investigator of the wreckage observed that the cause of the soot in the container alleged to have held a powerful, spherical and loud bomb was actually: "Where these panels formed the boundary of the shatter zone, the metal in the immediate locality was ragged, heavily distorted, and the inner surfaces were pitted and sooted - rather as if a very large shotgun had been fired at the inner surface of the fuselage at close range." The defence never objected to the premise of a bomb explosion which was shown by evidence to be mild, directed, and silent, three physical impossibilities for a bomb but natural for a 'very large shotgun' in the luggage which was safe unless a huge explosive decompression were to occur nearby were a cargo door to rupture open inflight.

Emotion trumped science. Wishful thinking ruled the day. Pleasant explanations based on grief salving emotions were believed while unpleasant explanations supported by hard evidence that could be touched, seen, and listened to was rejected without consideration.

Esteemed attorneys, barristers, solicitors, members of the bar, I'm sure you have heard of the saying, "The best defense is a strong offense." Well, now is the time to go on the offense, become offensive, risk scorn, accept ridicule, take charge and present to the world at large and the courts in specific the reality scientific explanation for those airplane crashes to counter the conspiracy nonsense with its Mr. Xs and bombs flying around the world in multiple aircraft sometimes detonating and sometimes not.

I'm asking that you consider the hard evidence that supports the science explanation for the aircraft crashes your clients are accused of being involved in. They are innocent, they did not do it because nobody did it. It was a mechanical problem, a problem which still exists which involves my interest in aviation safety. I wish to have the hazards of faulty wiring and non plug cargo doors removed and repaired.

More Discussion and Quotes:

Speaking legally as an amateur, I understand there are several types of evidence possible; circumstantial, indirect, hearsay, and direct. All can be very persuasive. The best evidence is direct evidence. For Air India Flight 182, Pan Am Flight 103, United Airlines Flight 811, and TWA Flight 800 there is only once source of direct evidence and much of circumstantial such as altitude and time of day and indirect such as wreckage debris pattern and twisted metal. Hearsay is for the conspiracy guys.

The one source for the best evidence which is direct and irrefutable is the cockpit voice recorder and the flight data recorder. They were there. Those recorders were put there to do precisely what they did, record for later evaluation events which took place in the cockpit and in the aircraft at large. They tell us directly what went on in the final minutes.

And what does the best and indisputable direct evidence show as to what the cause of Air India Flight 182 and Pan Am Flight 103 and two others?

Chart 12 above from NTSB public docket for TWA Flight 800 showing the sudden loud sound from the CVRs in graphical format. Air India is Air India Flight 182, PanAm is Pan Am Flight 103, and United is United Airlines Flight 811. (Philippine Air was a Boeing 737 that had a fuel tank explode on the ground and not a Boeing 747 exploding in the air as the others.)

The graph shows a sudden loud sound followed by an abrupt power cut to the flight data recorders, a rare event separately, and extremely rare to have both together.

The sudden loud sound was analyzed very carefully by the government analysts for frequency, duration, limiting, and rise and fall time.

The conclusion reached by all the analysts in the UK, USA, Canada and India is that the sudden loud sound is not a bomb explosion sound, nor a missile exploding sound, but that of an explosive decompression sound. The bomb sound was ruled out because necessary low frequencies were not present and the rise time was too slow. There was no bomb sound in the cockpit at the initial event time for Air India Flight 182, Pan Am Flight 103, United Airlines Flight 811, and TWA Flight 800.

If not a bomb sound, then what was the cause of the sudden loud sound?

Air India Flight 182
"Mr. R.A. Davis, Head, Flight Recorder Section, Accidents Investigation Branch, Farnborough, U.K. 3.4.6.16 In conclusion, Mr. Davis reported as follows :- "It is considered that from the CVR and ATC recordings supplied for analysis, there is no evidence of a high explosive device having detonated on AI 182. There is strong evidence to suggest that a sudden explosive decompression occurred but the cause has not been identified. It must be concluded that without positive evidence of an explosive device from either the wreckage or pathological examinations, some other cause has to be established for the accident".

2.10.2 Analysis by Accidents Investigation Branch (AIB), United Kingdom
The AIB analysis was restricted to the CVR and the Shannon ATC tape. An analysis of the CVR audio found no significant very low frequency content which would be expected from the

sound created by the detonation of a high explosive device. A comparison with CVRs recording an explosive decompression* on a DC-10, a bomb in the cargo hold of a B737, and a gun shot on the flight deck of a B737 was made. Considering the different acoustic characteristics between a DC-10 and a B747, the AIB analysis indicates that there were distinct similarities between the sound of the explosive decompression on the DC-10 and the sound recorded on the AI 182 CVR. *Explosive decompression is an aviation term used to mean a sudden and rapid loss of cabin pressurization.

(Gentlemen, note the DC-10 explosive decompression above referenced in the Air India Flight 182 CVR analysis was probably the Turkish Airlines DC-10 fatal event when the aft cargo door blew open causing an explosive decompression which destroyed the flight controls leading to the crash.)

Pan Am Flight 103
"It is not clear if the sound at the end of the recording is the result of the explosion or is from the break-up of the aircraft structure. The short period between the beginning of the event and the loss of electrical power suggests that the latter is more likely to be the case."

United Airlines Flight 811
"The Safety Board believes that the approximate 1.5 to 2.0 seconds between the first sound (a thump) and the second very loud noise recorded on the CVR at the time of the door separation was probably the time difference between the initial failure of the latches at the bottom of the door, and the subsequent separation of the door, explosive decompression, and destruction of the cabin floor and fuselage structure. The door did not fail and separate instantaneously; rather, it first opened at the

bottom and then flew open violently. As the door separated, it tore away the hinge and surrounding structure as the pressure in the cabin forced the floor beams downward in the area of the door to equalize with the loss of pressure in the cargo compartment."

TWA Flight 800
"The TWA flight 800 CVR recorded noise characteristics that were most similar to those recorded by the CVRs on board the United flight 811 and Philippine Airlines airplanes."

Summary:

The Pan Am Flight 103 sudden loud sound is 'more likely' to be the case for the break-up of the aircraft structure, not a bomb sound.

The United Airlines Flight 811 sudden loud sound is indisputably and irrefutably the explosive decompression sound when the forward cargo door burst open because that aircraft barely landed at Honolulu.

The TWA Flight 800 sudden loud sound is most similar to United Airlines Flight 811 as that both were early model Boeing 747s.

United Airlines Flight 811 is the model that fits the other three, it is the victim of the killer wiring that was able to make it back to Honolulu to point to the culprit, the electrical system of wiring or a switch. Just as it was only after United Airlines Flight 811 that the cause of the sound on Air India Flight 182 was identified, it was only after TWA Flight 800 that the true extent of the pervasive and dangerous Poly X wiring in all early model Boeing 747s was made known. To put it another way: If United Airlines Flight 811 had been caused by a bomb explosion, all causes would be bombs, if United Airlines Flight 811 were a missile attack, all four events would be missile attacks, but the cause was electrical thus all were electrical.

(United Airlines Flight 811 is the case law analogy; it was a similar case that was tried and proven beyond doubt to be a certain cause and that cause may be applied to other similar cases.)

The best evidence for these similar events in similar aircraft is the direct evidence which is the cockpit voice recorder which recorded the sudden loud sound which when analyzed indicated an explosive decompression from a ruptured open forward cargo door and not a bomb explosion sound. That's science, that's real, that's confirmable, and it's corroborated by government sound analysts.

Human Nature Conjecture:

Why has the shorted wiring/unlatch motor on/ruptured open forward cargo door/explosive decompression/inflight breakup explanation for Air India Flight 182, Pan Am Flight 103, and TWA Flight 800 not been advanced before in the public's mind?

I would hope I would not but I might very well have reacted as others have if my job, my reputation, my income, and my freedom depended upon the bomb explosion explanation being the accepted one and the wiring/cargo door explanation rejected. There is no conspiracy, just people acting in their own perceived best interests. What are they?

1. The manufacturer wants the blame for the loss of the aircraft and life to be placed upon factors out its control and not on its design errors of non plug cargo doors and absent locking sectors in the midspan latches. The manufacturer does not want to have to spend millions to correct the manufacturing faults in the wiring nor modify the cargo doors.
2. The airline wants the blame placed on others such as airport screening personnel and not on itself for not finding the frayed wires to the cargo door unlatch motor. The aircrews want to believe the event was a rare occurrence and do not want to believe that every minute they fly in early model Boeing 747s the aircraft can come apart in flight in seconds when the cargo door blows open as it did in United Airlines Flight 811.
3. The police, the RCMP, the FBI, Scotland Yard and prosecutors all welcome the inclusion of the high profile catastrophes into their jurisdiction so they can solve the crime and increase their budgets and staff to counter the threats. They would reject the mechanical cause as their general involvement would end.
4. The court system welcomes the chance to establish justice by punishing the criminals asserted by the law enforcement agencies. Vast amounts of bailiffs, new court facilities, numerous attorneys, and much tax money goes into trials while a mechanical cause is relegated to settlement meetings between insurance attorneys.
5. The victims' families have turned their grief to anger to hate and want someone to vent their emotion of revenge against. They would prefer to believe their loved ones died in some vast international conspiracy which is part of a worldwide larger force instead of a trivial event such as bare wire shorting to metal and turning on a motor which is supposed to remain off while in flight.
6. The media such as TV, radio, and newspapers much prefer an

emotional human tragedy interesting story to tell rather than a scientific story which requires education into basic laws of nature such as gravity, lift, thrust, drag, and pressure differential. Emotional stories require feelings which everyone has while science stories require education which is absent in many viewers, listeners, and readers. The media tells people what they want to hear and that is exciting, illogical, conspiracy stories, not boring mechanical proofs.

7. The government oversight agencies want to shift the blame of the crashes to foreign terrorists slipping through lax airport security and not their own failures as regulators and monitors of safety issues. The wiring/cargo door explanation reveals their failure to order the airlines and manufacturer to fix the documented problem of faulty wiring causing cargo doors to open in early model Boeing 747s such as Pan Am Flight 125 in 1987, United airlines preflight in 1991, and United Airlines Flight 811 in 1989.

8. The public demands revenge for a great loss of human life which was preventable. Dying in a bombed airplane crash offends two basic instincts of all humans at birth, a startle reflex shown by arms stretched wide and the falling reflex shown by grasping hands. The public pays money to hear what it wants and rejects that which is unpleasant. The bombing explanation reinforces their prejudices of xenophobia and racism; it implies the event was a one off affair and not likely to reappear if only security were tighter. The bombing story gives an opportunity for revenge; it gives an exciting tale of intrigue, spying, shootouts, and chase scenes. The wiring/cargo door explanation is dry, has lots of charts and statistics, and implies the faulty wiring and dangerous non plug cargo doors are industry wide, not fixed, and the problems could reappear the next time they fly as a passenger.

I say again, there are no conspiracies among the principals, only people acting in their own perceived best interests which is essentially, "It's not my fault, nor my company's fault, nor my government's, nor the police, nor the airline, nor the media, nor the courts' fault; it's the fault of those revenge seeking turbaned terrorists over there."

And to support that blame shifting exculpatory bomb explosion explanation, vast illogical and science defying fantasies had to be devised and repeated until the myth of the Lockerbie bombing and the bombing of Air India Flight 182 was implanted into the public psyche. Debunking will be very difficult as myths are generated and believed by a people needing them.

However......zealots defeat their cause eventually. Conspiracy guys are zealots. The continued controversies with Air India Flight 182 and Pan Am Flight 103 are evidence that something is not right and thus the trials, the appeals, the inquiries continue.

Summing Up:

This is your opportunity, gentlemen of the law and the defence. You have been given the power to present the other side of the criminal prosecutions. You have authority to request certain documents and interview certain people. You have the responsibility to prevent innocent men from being punished unfairly.

You can:
1. Request all reports on the Narita explosion from RCMP and the Japanese police.
2. Request all reports on the staged Boeing 747 bomb explosion at Bruntingthorpe from Scotland Yard and AAIB.

3. Request all copies of the film and photographs of the wreckage of Air India Flight 182 and Pan Am Flight 103 now held by law enforcement and withheld from the public.
4. Request updated supplements from TSB and AAIB to the CASB AOR for Air India Flight 182 and the AAIB AAR for Pan Am Flight 103 based upon the twenty and sixteen year age of those reports and the subsequent similar accidents of United Airlines Flight 811 and TWA Flight 800 after which much was learned why early model Boeing 747s come apart in the air. The new findings for those similar events were not bomb explosions but electrical switch or faulty Poly X wiring.
5. Conduct interviews with previous AAIB and CASB officials to have them explain why they believe Air India Flight 182 and Pan Am Flight 103 were not bomb explosions but mechanical problems, as they have officially claimed in their reports.
6. Present the wiring/cargo door explanation to the aviation media in TV, newsletters, and magazines for their evaluations for credibility or rejection by their experienced and skeptical staff.
7. Seek expert outside opinion as to the actual causes of the aircraft crashes. There are many independent aviation accident investigators, such as myself, available for counsel.
8. Review my extensive websites at http://www.montereypeninsulaairport.com and http://www.ntsb.org. I suggest you download my many pdf files to include my three aircraft accident reports for Air India Flight 182, Pan Am Flight 103, and United Airlines Flight 811 which give details and supporting documents for the wiring/cargo door explanation.

The current emphasis is on the human victims and those accused of the deaths. The actual victims are the aircraft. If a dog drowns and the fleas it carries drown also, it can be said the fleas are victims although they were just along for the ride. So it is with the passengers. If the plane had not crashed, they would not be victims. Air India Flight 182 and Pan Am Flight 103 were airplane crashes first and always; they were the anthropomorphized victims. The emphasis needs to be why the airplanes crashed first and that was not done at any of the trials nor in the media. The assumption was the cause was a bomb explosion and that assumption is wrong as proven by evidence, not emotion.

Conclusion:

There were no bombs on Air India Flight 182 nor on Pan Am Flight 103. There were no crimes and no criminals and no conspiracies. There was and is a mechanical problem which exists to this day, aging and failing Poly X wiring which exploits design errors of non plug cargo doors and omitted midspan locking sectors allowing an explosive decompression when the forward cargo door ruptures open in flight.

To know the cause of Air India Flight 182 and Pan Am Flight 103, you must know the details of United Airlines Flight 811, the model and irrefutably explained event. All of those official AARs are available at http://ntsb.org.

I appeal to you all to consider my suggested actions to confirm or rule out the wiring/cargo door mechanical explanation for the aircraft crash you are involved in. Please present my arguments to your clients for their consideration. They can be proven innocent which is a lot better than not guilty. Please communicate with each other although in different jurisdictions and time zones. Please realize you are similar in language and culture and you represent clients who are different from that culture, you are similar in being involved with similar type accident scenes with similar type vehicles under similar circumstances; you are similar in being part of a similar type British based justice system with its adversary relationships and discovery and disclosure rules for evidence. I implore you to reject conspiracy nonsense and consider a down to earth explanation with precedent.

My interest is aviation safety for millions first and justice for a few second. I believe your interests are reversed as it should be. Let us work together to accomplish both our goals.

I am available for consultations to clarify or further explain my mechanical premises for the crashes. Call, write, or email anytime.

Sometimes it's good to ask questions for which you do not already know the answers.

==================================

On May 1, 2006, an Order in Council was issued defining the terms of reference for the Commission of Inquiry into the

Investigation of the Bombing of Air India Flight 182. The Honourable John C. Major, Q.C., was appointed Commissioner under Part 1 of the Inquiries Act.

===================================

Air India bomb maker's perjury trial set for May
Canadian Press
VANCOUVER Ñ Convicted Air India bomb-maker Inderjit Singh Reyat will go to trial next May on perjury charges.
Lawyers appeared in B.C. Supreme Court to set the date although they will return next month to confirm it before Associate Chief Justice Patrick Dohm.
Mr. Reyat was charged with perjury after his testimony in the trial of two men co-accused in the Air India case.
Ripudaman Singh Malik and Ajaib Singh Bagri were acquitted in March 2005 of murder and conspiracy charges in the 1985 bombing of Air India Flight 182 that killed 329 people.
The indictment filed against Mr. Reyat in B.C. Supreme Court lists 27 times where he allegedly misled the court during his testimony in September 2003.
Mr. Reyat is currently serving a five-year sentence for manslaughter as part of a plea agreement for the deaths of those killed after the bomb exploded aboard the plane on June 23, 1985.
He could spend a maximum of 14 years in prison if convicted of perjury.
Before that, Mr. Reyat served 10 years for a blast at Tokyo's Narita airport the same day as Flight 182.

====================================

By STAFF

The Toronto Star, Feb. 11, 2003

"Text of the agreed statement of facts submitted in B.C. Supreme Court
when Inderjit Singh Reyat pleaded guilty Feb. 10 to 329 counts of
manslaughter in the 1985 bombing of Air India Flight 182:"

"In May and Jun. 1985, in the province of British Columbia, Mr. Reyat
acquired various materials for the purpose of aiding others in the
making of the explosive devices. Mr. Reyat was told and believed that
the explosive devices would be transported to India in order to blow up
property such as a car, a bridge or something 'heavy.' Although Mr.
Reyat acquired materials for this purpose, he did not make or arm an
explosive device, nor did he place an explosive device on an airplane,
nor does he know who did or did not do so. At no time did Mr. Reyat
intend by his actions to cause death to any person or believe that such
consequences were likely to occur. However, unbeknownst to Mr. Reyat the
items that he acquired were used by another person or persons to help
make an explosive device that, on or about Jun. 23, 1985, destroyed Air
India Flight 182, killing all 329 people on board."

======================================

Acquitted Air India suspect wins role in public inquiry

Ripudaman Singh Malik leaves B.C. Supreme Court in Vancouver with supporters after he was found not guilty on March 16, 2005 in the bombing of Air India flight 182 in 1985.

By Jim Brown, Canadian Press
Published: Tuesday, July 25, 2006
OTTAWA - A man once a prime suspect in the Air India bombing has won the right to limited participation in a public inquiry into the tragedy.
Ripudaman Singh Malik was granted intervenor status Tuesday by former Supreme Court judge John Major, the head of the inquiry.
In a brief written ruling, Major cautioned that Malik's interventions will be limited to challenging "any evidence that directly and adversely affects his reputation."
Any submissions by Malik or his lawyers will have to be made in writing, at least to start. They will have to apply for leave if they want to go further and participate in oral statements and examination of witnesses.
Malik and Ajaib Singh Bagri were acquitted last year -- after an18-month trial -- of criminal charges stemming from the downing of Air India Flight 182 by a terrorist bomb off the coast of Ireland in 1985.
The bombing, believed to be work of Sikh extremists campaigning for a separate homeland in northern India, took the lives of 329 passengers, most of them Canadian citizens of Indian origin or descent.
It was the worst terrorist attack ever mounted from Canadian

soil, and the worst involving civil aviation anywhere in the world until the 9-11 attacks in the United States in 2001.
Malik's lawyers had argued, in a written brief last week, that their client needed legal standing at the inquiry to protect his reputation and respond to any evidence that 'may impugn his character."
They also warned that Malik may want to ask for some evidence to be heard behind closed doors "where he anticipates prejudice to his reputation or other intimate matters."
Major is required, under the inquiry's terms of reference, to hear some evidence in private if it endangers national security as defined by the federal government.
He can consider other requests to hold closed hearings, but commission counsel Mark Freiman has noted it would be unusual to do so.
Major has granted full standing at the inquiry to seven organizations and individuals, including the federal government, Air India and a number of family members who lost loved ones in the bombing.
Another nine groups and individuals, including Malik, will be permitted to play more limited roles.
Among them are a number of organizations with no direct link to the Air India tragedy, but that want to have a say on more general questions of anti-terrorist policy.
They include the Canadian Jewish Congress, B'nai Brith, the Canadian Council on American Islamic Relations and the Canadian Muslim Civil Liberties Association.
Major will examine a range of issues, including investigative turf wars between the RCMP and CSIS, airline security, better protection of witnesses in terrorist cases, and the possibility of holding high-profile trials before a three-judge panel rather than a single jurist.
Testimony is to begin in September and run through next April. A

report is due in September 2007.

==

Lockerbie bomber appeal dates set
Abdelbaset Ali Mohmed al-Megrahi
Megrahi was convicted of the Lockerbie bombing in 2001
The appeal launched by Lockerbie bomber Abdelbaset Ali Mohmed al-Megrahi over his 27-year minimum prison sentence is to be heard in July, it has emerged.

An appeal by the Crown Office arguing for a longer sentence for the Libyan will also be heard at the same time.

The Crown will claim the minimum period Megrahi must serve is too lenient.

A panel of five judges will hear the case on 11 and 12 July, although it has not yet been decided whether it will take place in Edinburgh or Glasgow.

The High Court in Glasgow is closer to Greenock Prison, where Megrahi is currently being held, if he wants to be present is likely to be used for security reasons.

The Libyan was found guilty in 2001 of killing 270 people in the 1988 bombing of PanAm flight 103.

He has claimed the 27-year minimum sentence is too long, having been told at his original trial that he should serve at least 20 years.

However, the Crown will argue that the maximum punishment period that courts can impose in murder cases should be raised and with it the length of time Megrahi should remain in prison before he can apply for release on parole.

The appeals will not affect the work of the Scottish Criminal Cases Review Commission which has been studying the case for almost two years to see if there was a miscarriage of justice.
It said it would announce its decision in the summer.
==

Lockerbie bomb appeal lined up for summer
JOHN ROBERTSON LAW CORRESPONDENT

THE appeal launched by the Lockerbie bomber against the length of his sentence is due to be heard this summer, it emerged yesterday.
Abdelbaset Ali Mohmed al-Megrahi's legal bid against his 27-year minimum prison sentence will be considered by a panel of five judges on 11 and 12 July, the Scottish Executive said.

At the same time, a counter-appeal by the Crown Office arguing that the sentence was unduly lenient will also be heard.

Tony Kelly, Megrahi's solicitor, questioned the fixing of the hearing. "I find it illogical, when we are still waiting to hear whether there is to be an appeal against conviction," he said.

Megrahi has had an application before the Scottish Criminal Cases Review Commission since September 2003. It investigates possible miscarriages of justice and has the power to refer a case to the Court of Criminal Appeal, even if an appeal has previously been heard and refused, as happened to Megrahi.

Mr Kelly did not know when the commission might decide on a referral, but said the process must be in its closing stages. A successful appeal against conviction would make an appeal against sentence unnecessary.

"So what is the point in holding this hearing at this stage?" asked Mr Kelly.

A court spokesman said that as an appeal against sentence had been lodged and was outstanding, it was right to press on with it. He added: "There might be a referral from the commission, but there might not be."

Megrahi was convicted in 2001 of bombing Pan Am flight 103 and killing 270 people.
A fellow Libyan, Al-Amin Khalifa Fhimah, was acquitted.

==

EXECUTIVE SUMMARY

On February 24, 1989, United Airlines flight 811, a Boeing 747-122, experienced an explosive decompression as it was climbing between 22,000 and 23,000 feet after taking off from Honolulu, Hawaii, en route to Sydney, Australia with 3 flightcrew, 15 flight attendants, and 337 passengers aboard.
The airplane made a successful emergency landing at Honolulu and the occupants evacuated the airplane. Examination of the airplane revealed that the forward lower lobe cargo door had separated in flight and had caused extensive damage to the fuselage and cabin structure adjacent to the door. Nine of the passengers had been ejected from the airplane and lost at sea.
A year after the accident, the Safety Board was uncertain that the

cargo door would be located and recovered from the Pacific Ocean. The Safety Board decided to proceed with a final report based on the available evidence without the benefit of an actual examination of the door mechanism. The original report was adopted by the Safety Board on April 16, 1990, as NTSB/AAR-90/01.

Subsequently, on July 22, 1990, a search and recovery operation was begun by the U.S. Navy with the cost shared by the Safety Board, the Federal Aviation Administration, Boeing Aircraft Company, and United Airlines. The search and recovery effort was supported by Navy radar data on the separated cargo door, underwater sonar equipment, and a manned submersible vehicle. The effort was successful, and the cargo door was recovered in two pieces from the ocean floor at a depth of 14,200 feet on September 26 and October 1, 1990.

Before the recovery of the cargo door, the Safety Board believed that the door locking mechanisms had sustained damage in service prior to the accident flight to the extent that the door could have been closed and appeared to have been locked, when in fact the door was not fully latched. This belief was expressed in the report and was supported by the evidence available at the time. However, upon examination of the door, the damage to the locking mechanism did not support this hypothesis. Rather, the evidence indicated that the latch cams had been backdriven from the closed position into a nearly open position after the door had been closed and locked. The latch cams had been driven into the lock sectors that deformed so that they failed to prevent the back-driving.

Thus, as a result of the recovery and examination of the cargo door, the Safety Board's original analysis and probable cause have been modified. This report incorporates these changes and supersedes NTSB/AAR-90/01.

The issues in this investigation centered around the design and

certification of the B-747 cargo doors, the operation and maintenance to assure the continuing airworthiness of the doors, cabin safety, and emergency response.
The National Transportation Safety Board determines that the probable cause of this accident was the sudden opening of the forward lower lobe cargo door in flight and the subsequent explosive decompression. The door opening was attributed to a faulty switch or wiring in the door control system which permitted electrical actuation of the door latches toward the unlatched position after initial door closure and before takeoff. Contributing to the cause of the accident was a deficiency in the design of the cargo door locking mechanisms, which made them susceptible to deformation, allowing the door to become unlatched after being properly latched and locked. Also contributing to the accident was a lack of timely corrective actions by Boeing and the FAA following a 1987 cargo door opening incident on a Pan Am B-747.
As a result of this investigation, the Safety Board issued safety recommendations concerning cargo doors and other nonplug doors on pressurized transport category airplanes, cabin safety, and emergency response.

Messrs. Murray L. Smith and Brent B. Olthuis
Smith Barristers,
Suite 1300 - 355 Burrard Street,
Vancouver, BC, V6C 2G8

Dear Mr. Olthuis and Mr. Smith, Thursday, October 5, 2006

Thank you Mr. Olthuis for your prompt and polite reply to my email regarding the shorted wiring/unlatch motor on/ruptured open forward cargo door/explosive decompression/inflight breakup explanation for Air India Flight 182.

I would have hoped I would have become inured to polite brushoffs after having received so many over the years by the conspiracy believing good folk out there, but no, it still rankles somewhat. But...a polite brushoff is better than no brushoff.

If I had emailed you stating the cause of Air India Flight 182 was a midair with a Pluto flying saucer by revenge seeking Plutonians mad because we demoted their planet I think your response would have been the same; to paraphrase:

"Here, Mr. Malik, look at this email, this is good for a chuckle, and Mr. Smith, there is nothing we can do at this stage as judges and newspapers said it was a bomb, and our client can't do much talking anyway, and your flying saucer story does not help our client so we can't use it. But..thanks anyway for a juicy story, it could be true!"

The only difference between my science based wiring cargo door email and the nonsense crazy conspiracy story is you would have asked questions about the flying saucer such as, what color was it, how fast was it going, and was there a money trail between the Iranians and the Plutonians?

The science explanation with supporting documentation gets nary a query.

Surprise me please by saying you read the pdf file I sent about my submissions to the Commission of Inquiry into the Bombing of Air India Flight 182. Perused it? Scanned? Glanced. http://www.ntsb.org and http://wwwmontereypeninsulaairport.com are two good websites with pictures, text, and diagrams to assist the visitor.

Surprise me please by saying you sent that pdf file to Mr. Malik. Sikhs revere writing and respect the thoughts when well written. The Sikh holy temples do not house bones, teeth, or weapons but books. My SmithAAR for Air India Flight 182 is thicker than most books and better documented. I have attached to this email my Smith AAR182. It's full of technical stuff since, after all, Air India Flight 182 was an airplane crash, first and always. Mr. Malik will understand both documents I'm sure.

I wrote to Mr. Malik while he was in prison awaiting trial. I met Mrs. Malik, a lovely lady. We chatted for an hour in the Malik's office in Vancouver. I met their sons, we went to a Vancouver hockey game, I had dinner at their house and met their families. There are only two people on the planet that know for certain that Mr. Malik had nothing to do with Air India Flight 182, me and him. Mr. Malik believe it was a bomb but he knows he did not plant it. I know he did not plant anything because nobody did. It was a mechanical problem, and has happened since with United Airlines Flight 811. Associating with suspected airplane terrorists was a little scary for me but it had to be done for the sake of aviation safety and justice.

Let Mr. Malik read my submissions to the Commission he has applied to appear before and then either have him suggest you followup on the mechanical explanation with me or let him direct you to tell me he is not interested.

My key point of persuasion is that saying at the hearing he is a good family man and a judge said he is not guilty will not restore his reputation nor that of his religion. The only way he can do that is to either show up with two confessed non-Sikh terrorists with videotape of them making the bombs and putting them in the planes or to be proven innocent which is a lot different than not guilty. He can be proven innocent and thus exonerated by the wiring/cargo explanation because it clears everybody, nobody did it. Mr. Malik and the Sikhs would be vindicated by exoneration through science not convicted by myth.

Mr. Olthuis, let me go over your reply for specifics:

At 8:47 AM -0700 10/5/06, Brent Olthuis wrote:
Mr. Smith:

Thank you for your correspondence, which we have brought to the attention of our client.

Thank you, I'm sure he will be interested, especially in the fourteen submissions in the pdf file which lay out the wiring/cargo door case for Air India Flight 182 and debunk the bomb explanation.

We write to let you know that we are unable to do anything at this stage with the information you provide.

Ah. A scientific explanation with documentation that vindicates your client, fulfills your goal of restoring his reputation and ....nothing can be done? Not even a question or two? The good thing about science is that premises and allegations can be substantiated or refuted, unlike crazy conspiracy nonsense that relies on emotional conversations from years ago. Everything I say about Air India Flight 182 can be corroborated.

Let me help you go through the mental reactions to the no bomb explanation for Air India Flight 182 after twenty one years of hearing about the bomb explanation week after week:

No Bomb!

1. No.
2. You are wrong.
3. You are crazy.
4. Go away.
5. I'm ignoring you.
6. Attack.
7. Ask a real question to check it out.
8. Take action on new knowledge acquired.

You implied number one, were polite and did not state numbers two and three, hoping for number four with your email, and considering number five after reading this email which may provoke number six. I invite number seven. Number eight stands not within the prospect of belief.

First, the mandate of the Commission in our opinion does not extend into a questioning of the prevailing theory that a bomb brought down the plane.

Not true. Well, in your opinion it is true. In my opinion the mandate does extend. Shall we duel with mandates and quotes? In my submissions I refute Commissioner Major's premise that a Commission of Inquiry about a plane crash can not inquire about that plane crash.

Let me quote Prime Minister Harper and Commissioner Major:

Speech excerpts - Prime Minister Harper announces inquiry into Air India bombing:
"A full public inquiry is required. This inquiry will be launched immediately and led by an outstanding Canadian, retired Supreme Court Justice John Major. He has agreed to serve as Commissioner for this inquiry and I have every confidence that he will conduct a thorough and compassionate investigation into the events surrounding this tragedy. This inquiry is about analyzing the evidence that has come to light since 1985 and applying it to the world we live in today."
The Prime Minister desires a full, thorough, and compassionate public inquiry into the events surrounding Air India Flight 182 by analyzing the evidence that has come to light since 1985.
Commissioner Major, from transcript of 18 July 2006, Hearing on Standing: The Commissioner: "Yes. Well, I will confirm that. The nature of this Commission was to be very broad in the evidence that it heard, in order to put to rest the various theories, rumours and neglect that have occurred since the explosion in 1985."

For the record: There has never been any official refutation of the bomb explanation in any of the trials of those accused of participating in it. The bomb explanation has been stipulated by the defence. The Crown has never had to defend the allegation that it was not a bomb, just where it was and who put it there.

To review:
1. The CASB was correct, there was an explosion and they did not yet understand the cause because the answer only became apparent four years later with United Airlines Flight 811.

2. Justice Josephson was correct, the two accused did not put a bomb on board, nobody did.
3. There were no lapses in security that led to Air India Flight 182's bombing that need to be rectified because there was no bombing.
4. The Mounties did not get their man because there were no men to get.
5. There will be closure for the families when they can clearly understand through science what happened and why.
6. A divisive issue of anger, hate, and revenge will be removed from the Canadian psyche.
7. This Commission of Inquiry can examine and put to rest the various theories, rumours and neglect that have occurred since the explosion in 1985 if it is very broad in the evidence it hears.

Indeed, this is probably the reason that your standing application turned out as it did.

Hmmmm....I was denied standing and yet B'nai Brith, Canada Canadian Civil Liberties Association (CCLA), Canadian Coalition Against Terror (C-CAT), Canadian Council on American Islamic Relations, Canadian Muslim Civil Liberties Association (CMCLA), Canadian Coalition for Democracies, and the Canadian Jewish Congress were granted standing, where is the logic in that?

In addition I was personally involved in a strict reading of the mandate in the Term of Reference:

I was personally investigated by the RCMP Air India Task Force during their investigation of the bombing of Air India Flight 182. I was personally questioned by the TSB about the events surrounding the bombing of Air India Flight 182. I received erroneous information from Securitas of the TSB. The two agencies did not cooperate based upon the information I gave them. Details in Smith Submission 8: Specific Term of Reference: Non Cooperation.

To sum up regarding the term of reference of non cooperation that I am personally involved in which justifies my request for grant of standing: There was noncooperation between TSB Air and the RCMP AITF regarding relevant and important visual evidence in the form of videotapes and 35 MM color film of the wreckage of Air India Flight 182. The Canadian air accident investigating board was denied visual evidence of an airplane crash by the police authorities who claimed an exemption to law to justify the denial.

Further, as you may be aware, Commissioner Major gave our client only a limited standing before the Commission: Mr. Malik has the status of an intervener, and even then has only the ability to respond (in writing) to evidence that directly and adversely affects his reputation.

Jackpot! Every time there is a reference to a 'bombing', which is every fifteen minutes, the reputation of Mr. Malik is impugned because the belief in Canada is strong that he was the bomber and the only reason he is free is because of bungling by the RCMP and CSIS, so much so that a special Commission of Inquiry was created to explain the bungling that let two callous mad killers go free. Every time some witness mentions 'bomb', object and ask how does he know it was a bomb? Is he an expert in aircraft accident investigations such as the Canadian Aviation Safety Board investigators who did not conclude it was a bomb?

Aviation Occurrence Report of the Canadian Aviation Safety Board for Air India Flight 182 of January 22, 1986
"4.0 CONCLUSIONS
The Canadian Aviation Safety Board respectfully submits as follows:
4.1 Cause-Related Findings
1. At 0714 GMT, 23 June 1985, and without warning, Air India Flight 182 was subjected to a sudden event at an altitude of 31,000 feet resulting in its crash into the sea and the death of all on board.
5. There is considerable circumstantial and other evidence to indicate that the initial event was an explosion occurring in the forward cargo compartment. This evidence is not conclusive. However, the evidence does not support any other conclusion."

The witnesses may refer to the 'explosion' in Air India Flight 182 that brought the aircraft down, that is correct. To give the cause of the explosion as a bomb is unsubstantiated by the witness and the Crown experts. The bomb explanation is even refuted by hard evidence of the cockpit voice recorder, the only direct evidence available:

"Mr. R.A. Davis, Head, Flight Recorder Section, Accidents Investigation Branch, Farnborough, U.K. 3.4.6.16 In conclusion, Mr. Davis reported as follows :- "It is considered that from the CVR and ATC recordings supplied for analysis, there is no evidence of a high explosive device having detonated on AI 182. There is strong evidence to suggest that a sudden explosive decompression occurred but the cause has not been identified. It must be concluded that without positive evidence of an explosive device from either the wreckage or pathological examinations, some other cause has to be established for the accident".

Any witness who claims a bombing of Air India Flight 182 is presuming to know more than the Crown and UK experts in aircraft accidents. Any judge, police, or attorney who says it was a bomb incorrectly presumes that also.

As your information does not directly touch on Mr. MalikÕs reputation and does not do so adversely,

What does that mean? My information does directly touch on Mr. Malik's reputation, it proves his innocence, it exonerates him, it vindicates him, it restores him and his religion to its former stature.

What does "...does not do so adversely,..." mean? My information does not adversely affect Mr. Malik's reputation? Well, I should say so, we agree.

we are not in a position to use or refer to it.

Ah, the polite stage four, go away.

That said, we thank you again for your assistance.

What assistance?

Here's the thing, Mr. Olthuis, until you can show me you understand the basic foundations of the wiring/cargo door explanation by asking a few questions, I will assume your mind is closed and holds tight the bombing explanation. That's not proper for an attorney at the start of a year long case. I have shown you by a few quotes that the bombing explanation and your excluding mandate of the Commission are disputed or in error. That is proper for this independent aviation accident investigator.

I will let Mr. Malik decide whether my logic and reasoning make sense. He pays the piper (you, not me); he gets to call the tune. Please show him this email, my SmithAAR182.pdf, and my Smithsubmission1-14 to the Commission of Inquiry.

If he tells me to go away, I will. If he indicates he would like to pursue the wiring/cargo door explanation, then we will. The telling clue to his direction will be if he starts to ask questions.

Thanks again, really, for your prompt and polite reply; I've tried to respond to it with a little humor, some history, a few facts, and lots of disguised pleading.

(Might you or Mr. Smith be pilots? Would I actually be talking with someone who knows why airplanes fly and why they don't? How sweet that would be. If you don't know why airplanes crash I can show you. I've been in one that did and lived to tell about it.)

Subject: Air India Flight 182 mechanical probable cause.

Messrs. Murray L. Smith and Brent B. Olthuis
Smith Barristers,
Suite 1300 - 355 Burrard Street,
Vancouver, BC, V6C 2G8

Dear Mr. Smith and Mr. Olthuis, Wednesday, October 4, 2006

My name is John Barry Smith and I have evidence which will completely exonerate your client from suspicion and restore his reputation as well as that of his religion.

There was no bomb on Air India Flight 182, and therefore no bombers, no conspiracy, no crime, and no criminals. The cause was a mechanical systems failure, faulty wiring shorted on the forward cargo door unlatch motor which caused an explosive decompression leading to the inflight breakup.

Further details to substantiate the wiring/cargo door explanation are at http://www.ntsb.org and http://www.montereypeninsulaairport.com. The SmithAAR for Air India Flight 182 is available for download also which gives exhaustive details.

Mr. Malik previously was interested in the mechanical explanation in the early part of 2001 and I traveled to Vancouver to speak to his attorneys, Mr. Crossin and Mr. Donaldson, at Mr. Malik's request. I failed to impress. Let's hope I do better this time.

I recently went to Ottawa to try to achieve standing in front of the Commissioner of the Commission of Inquiry into the Bombing of Air India Flight 182. I was promised fifteen minutes of oral submission but was cut off after four. It appears I again failed to impress.

Well, never give up, especially since the evidence in the form of cockpit voice recorders, flight data recorders, twisted metal, and damaged engines supports a mechanical explanation over the conspiracy nonsense so emotionally tinged that up is down and inside out. In aviation matters I always defer to reality.

For the record: The only official Canadian aircraft accident investigator's opinion about the probable cause of Air India Flight 182 did not conclude it was a bomb, only an explosion. There are many potential causes for an explosion in the pressurized hull of an early model Boeing 747, the rarest of which is a bomb.

Aviation Occurrence Report of the Canadian Aviation Safety Board for Air India Flight 182 of January 22, 1986 "4.0 CONCLUSIONS The Canadian Aviation Safety Board respectfully submits as follows: 4.1 Cause-Related Findings 5. There is considerable circumstantial and other evidence to indicate that the initial event was an explosion occurring in the forward cargo compartment."

The TSB (Air) has never given an official opinion.

In fact, the UK AAIB investigator ruled out a bomb in the original report: "Mr. R.A. Davis, Head, Flight Recorder Section, Accidents Investigation Branch, Farnborough, U.K. 3.4.6.16 In conclusion, Mr. Davis reported as follows :- "It is considered that from the CVR and ATC recordings supplied for analysis, there is no evidence of a high explosive device having detonated on AI 182. There is strong evidence to suggest that a sudden explosive decompression occurred but the cause has not been identified. It must be concluded that without positive evidence of an explosive device from either the wreckage or pathological examinations, some other cause has to be established for the accident".

The cause Mr. Davis alluded to only became apparent four years later with United Airlines Flight 811, the model for the inflight breakups for early model Boeing 747s.

I have asked TSB and the Commissioner to request TSB (Air) to provide an updated supplement to the twenty year old Aviation Occurrence Report to the Commission for their consideration. That reasonable request would certainly be within your rights to ask for.

The Commissioner granted me leave to provide material to the Commission and I have done so. A pdf file of my fourteen additional submissions is attached to this email. Those submissions lay out the framework that debunks the bomb theory and substantiates the mechanical explanation.

There is an error of fact on the Commission Website which harms your client. It is the highly prejudicial error that states the CASB concluded it was a bomb; they did not. ("Yet, it was not until the following January that the Canadian Aviation Safety

Board concluded that the destruction of this aircraft was caused by a bomb.") I have repeatedly asked the Commissioner to correct the error but he has not.

In the past few months of dealing with the Canadian government about Air India Flight 182 I realize what you are up against. You have Crown prosecutors who cheat, a Commissioner who lies, a police force who is confused and creative with facts, a media who loves intrigue and danger, and family members and a public lusting for revenge. Into that stew of emotion all I ask is that you check out a lead that is down to earth, offers confirmable evidence, follows rigid rules of logic, and offers reasonable explanations for tragic events.

You might tell Mr. Malik I followed his trial and offer him congratulations on his release. I have known he was innocent since he was arrested years ago. As was Mr. Bagri.

I've also been in written communication with Mr. Donaldson but may have offended him with my unkind comments about Mr. Crossin.

Regardless, if Mr. Malik wants his reputation restored, he will have to do better than a not guilty verdict by the honest Justice Josephson. The way to do that is to resort to science, not myth.

The shorted wiring/unlatch motor on/ruptured open forward cargo door/explosive decompression/inflight breakup explanation is science.

I am available for follow up questions or to clarify aspects of the explanation.

Vancouver BC V5W 3A4   Telephone: 604.321.3232

Dear Mr. Unterman, Thursday, March 22, 2007

My name is John Barry Smith. Mr. Malik is aware of my explanation for Air India Flight 182 which absolves him and his religion of any responsibility. ItÕs called the shorted wiring/unlatch motor on/ruptured open forward cargo door/explosive decompression/inflight breakup explanation. ItÕs mechanical with precedent and relies on science for confirmation. It is not a conspiracy story with a secret Mr. X and wild shootouts.
The phrase, Òmalicious prosecutionÓ was the exact phrase I used in speaking personally with Mr. Dave Crossin and Ian Donaldson in late 2001 at the request of Mr. Malik, who paid my

expenses to Vancouver from Carmel Valley. I met his family and friends. I knew then and know now Mr. Malik is innocent because nobody put a bomb on Air India Flight 182, there was no bomb, no crime, no criminals. The cause is mechanical and has happened since with United Airlines Flight 811 in 1989.

If you want to talk about why airplanes such as a Boeing 747 crash I can explain it to you. If you want to talk about conspiracies of Sikhs or Mounties or the press to injure your client, then, well, read the newspapers. If you respect science and reason, contact me. If you like exciting stories with intrigue, revenge, and betrayal, well, keep on assuming what the RCMP and prosecutors want you to assume, bomb!

Sgt Bart Blachford of RCMP Air India Task Force and Mr. Bill Tucker (now retired) of TSB (Air) have visited me in my home to discuss the wiring/cargo door explanation. The authorities have known for years that Malik and Bagri could not have placed a bomb in Air India Flight 182 because all the bags loaded in Vancouver went into the aft cargo compartment and the explosion occurred in the forward cargo compartment.

In addition, there has never been an official Crown aviation investigation conclusion of a bomb at all. The press and the current Commission of Inquiry into the Bombing of Air India Flight 182 incorrectly state the CASB concluded it was a bomb. The Canadian Aviation Safety Board made no such bombing conclusion.

Aviation Occurrence Report of the Canadian Aviation Safety Board for Air India Flight 182 of January 22, 1986
"4.0 CONCLUSIONS
The Canadian Aviation Safety Board respectfully submits as

follows:
4.1 Cause-Related Findings
1. At 0714 GMT, 23 June 1985, and without warning, Air India Flight 182 was subjected to a sudden event at an altitude of 31,000 feet resulting in its crash into the sea and the death of all on board.
5. There is considerable circumstantial and other evidence to indicate that the initial event was an explosion occurring in the forward cargo compartment. This evidence is not conclusive. However, the evidence does not support any other conclusion."

Mr. Unterman, there was an explosion in the forward cargo compartment, a powerful explosive decompression, just like what happened four years later with a similar sudden loud sound on the CVR:
United Airlines Flight 811:

"The CVR revealed normal communication before the decompression. At 0209:09:2 HST, a loud bang could be heard on the CVR. The loud bang was about 1.5 seconds after a "thump" was heard on the CVR for which one of the flightcrew made a comment. The electrical power to the CVR was lost for approximately 21.4 seconds following the loud bang. The CVR returned to normal operation at 0209:29 HST, and cockpit conversation continued to be recorded in a normal manner.
NTSB Accident Report 92-02 Page 25
Air India Flight 182:
"From the CVR and DFDR, AI 182 was proceeding normally en route from Montreal to London at an altitude of 31,000 feet and an indicated airspeed of 296 knots when the cockpit area microphone detected a sudden loud sound. The sound continued

for about 0.6 seconds, and then almost immediately, the line from the cockpit area microphone to the cockpit voice recorder at the rear of the pressure cabin was most probably broken. This was followed by a loss of electrical power to the recorder."
Canadian Aviation Safety Board Air India 23 June 1985, page 21

Please relay my congratulations to Mr. Malik, he got lucky and ran into a competent judge, Justice Josephson. I respect his decision for redress of grievance. I have known he was innocent since he was arrested many years ago.

Malik says he lost reputation, savings

VANCOUVER -- He was once a wealthy and well-respected British
Columbia businessman, but after he was charged in relation to the
murder of 329 people in the bombing of Air-India Flight 182,
Ripudaman Singh Malik lost his reputation and his savings.

Now, seven years after he was charged along with Ajaib Singh Bagri,
of Kamloops, and two years after both men were acquitted on all
counts, Mr. Malik has filed a writ against the Attorneys-General of
B.C. and Canada.

In a filing in the Supreme Court of British Columbia, Mr. Malik
claims unspecified damages "for malicious prosecution, wrongful
imprisonment, breach of the Plantiff's Charter rights, Conspiracy to
Injure, negligent performance of duty and damage to the Plantiff's

reputation in connection with the Plaintiff's wrongful
prosecution."

David Unterman, Mr. Malik's lawyer and a member of the South Fraser Law Group, declined to comment yesterday.

The Globe and Mail

B.C. Attorney-General Wally Oppal, who is away from work to undergo surgery, was not available for comment, but a government spokesman said the writ would have to be studied before any response could be made.

Mr. Malik and Mr. Bagri were both arrested in October, 2000, some 15 years after the RCMP began investigating the bomb blast that downed Air-India Flight 182 off the coast of Ireland on June 23, 1985, killing all aboard.

The prosecution contended the bomb was contained in baggage that was loaded aboard the flight in Vancouver and that Mr. Malik and Mr. Bagri were key players in Canada's worst act of terrorism.

The two men were jointly charged with first-degree murder, of conspiring to commit murder and of conspiring to cause bombs to be placed onboard aircraft. They were also jointly charged with a second

count of first-degree murder in relation to the explosion of
another
bomb, in the luggage terminal at Narita airport in Japan.

Mr. Malik and Mr. Bagri were denied bail and remained in jail
until
March, 2005, when Mr. Justice Ian Bruce Josephson acquitted
them both.

"Justice is not achieved . . . if persons are convicted on anything
less than the requisite standard of proof beyond a reasonable
doubt,"
he stated.

During the lengthy trial Mr. Malik said that his savings, of
several
millions, had been exhausted and he obtained about $6-million in
funding from the Crown. The government has been trying to
recover
those funds, but Mr. Malik has pleaded poverty.

Unterman, David H., Barrister & Solicitor,
South Fraser Law
200 - 6330 Fraser Street
Vancouver BC V5W 3A4   Telephone: 604.321.3232
Dear Mr. Unterman, Thursday, March 22, 2007

Well, as usual, after writing my previous letter I realize what I should have said...so here goes...

"Malicious" is a funny word; it's so subjective.

"Malicious from legal Encyclopedia.

Involving malice; characterized by wicked or mischievous motives or intentions.

An act done maliciously is one that is wrongful and performed willfully or intentionally, and without legal justification."

It seems to me that every acquitted person would file a malicious prosecution lawsuit if it were easy to show maliciousness.

I can show you that the prosecution of Mr. Malik was done willfully and intentionally and without legal justification. Any prosecution of anyone would have been malicious since no one brought Air India Flight 182 down and the evidence from Canadian and UK aircraft investigators supports my assertion.

The Canadian Aviation Safety Board respectfully submits as follows:
Ò4.1 Cause-Related Findings
5. There is considerable circumstantial and other evidence to indicate that the initial event was an explosion occurring in the forward cargo compartment.Ó
That finding from CASB is absolutely correct. It also does not conclude the destruction of the aircraft was caused by a bomb. It is specific on the location. There are several alternative explanations for that confirmed explosion, from fire in the cargo

hold or hull rupture at a door, or bomb in baggage go boom. I agree there was an explosion in the forward cargo compartment, all the experts agreed on that point in 1986 for solid reasons.

The Canadian and United Kingdom government experts in aircraft accident investigation for Air India Flight 182 did not state the cause was a bomb and in fact, the UK expert stated in 1986 it was not a bomb and gave strong evidence for his conclusion.

Mr. R.A. Davis, Head, Flight Recorder Section, Accidents Investigation Branch, Farnborough, U.K. 3.4.6.16 In conclusion, Mr. Davis reported as follows :- "It is considered that from the CVR and ATC recordings supplied for analysis, there is no evidence of a high explosive device having detonated on AI 182. There is strong evidence to suggest that a sudden explosive decompression occurred but the cause has not been identified. It must be concluded that without positive evidence of an explosive device from either the wreckage or pathological examinations, some other cause has to be established for the accident".

That 'other cause' was established by me in 1996 based on an event in 1989, UAL 811, plus other accidents. (And there is good reason why it is called an ÔexplosiveÕ decompression. It is an explosion that mimics a bomb.)
The Canadian crash experts (CASB) called Air India Flight 182 a 'crash'. It was. The word ÔbombÕ was never used in relation with Air India Flight 182 in their entire CASB report. ÒBombÓ was used only once in reference to a different aircraft and event for comparison purposes. There was no match.

Mr. Unterman, are you perchance a pilot? Might you understand why airplanes fly and why they don't? Would you understand terms such as lift, drag, thrust, PSI, TAS?

The RCMP and CSIS were chasing ghosts, that's why they could not get a conviction, not sloppy administrative work and non cooperation between agencies.

If you are going to turn over stones not yet turned over, why not turn over one that absolutely clears your client of any wrongdoing, which takes him from 'not guilty' to 'innocent', one that restores his religion to the stature it deserves and removes a blot of evil which will last centuries if not corrected?

The shorted wiring/unlatch motor on/ruptured open forward cargo door/explosive decompression/inflight breakup explanation does all that.

Mr. Malik has been given standing before the Commission of Inquiry into the Bombing of Air India Flight 182. What a great opportunity to clear his name. If you want a specific lie that the Crown has used to prejudice the case against Mr. Malik I can refer you the the Commission website in which they state a terribly biased 'fact' which is incorrect. I pointed the error out to Commissioner Major personally at the hearing in July in Ottawa, I have written to the Commission often, but they will not correct the error of fact which has persisted for eight months. That is malicious.

From Commission website: Background

'In announcing the launch of this Inquiry, the Prime Minister, the Right Honourable Stephen Harper, stated that a public inquiry is the only route left to obtaining answers to how the tragedy of June 23, 1985 occurred when Air India Flight 182 exploded over the Atlantic Ocean. The aircraft was flying at an altitude of 31,000 feet (9500 m) just south of Ireland, when all 329 on board were killed. Eighty-two of those victims were children and 280 were Canadian citizens.

Many issues remain unresolved relating back to that 1985 terrorist attack on Air India flight 182 that began in Canada but never reached its destination. In the middle of the night, more than 300 Canadians, some of Indian ancestry, lost their lives in a senseless act of unprecedented violence over the skies of Ireland. Yet, it was not until the following January that the Canadian Aviation Safety Board concluded that the destruction of this aircraft was caused by a bomb. This massive murder was the most insidious episode of cowardice and inhumanity in our history at the time, and its death toll has been surpassed only by the September 11, 2001 attacks on the World Trade Centre in New York. The Air India destruction remains among the worst aviation disasters in Canadian and world history.'

Below is excerpt in my letter to the Commission August 1, 2006 regarding a statement on the Commission website http://www.majorcomm.ca/en/index.asp:

"My first point is to repeat my observation made to the Commission in
writing and in person several weeks ago that a grievous error of fact
persists every day in the Commission's Opening Statement on the official website: June 21, 2006, Background:

"Yet, it was not until the following January that the Canadian Aviation Safety Board concluded that the destruction of this aircraft
was caused by a bomb."

Not so. Absolutely incorrect. Terribly misleading. That error leads
to a hysterical rant such as the next statement by the Commission:
"This massive murder was the most insidious episode of cowardice and
inhumanity in our history at the time,..."

The Canadian Aviation Safety Board made no such bombing conclusion.

Aviation Occurrence Report of the Canadian Aviation Safety Board for
Air India Flight 182 of January 22, 1986
"4.0 CONCLUSIONS
The Canadian Aviation Safety Board respectfully submits as follows:
4.1 Cause-Related Findings
1. At 0714 GMT, 23 June 1985, and without warning, Air India
Flight 182 was subjected to a sudden event at an altitude of 31,000
feet resulting in its crash into the sea and the death of all on board.
5. There is considerable circumstantial and other evidence to
indicate that the initial event was an explosion occurring in the
forward cargo compartment. This evidence is not conclusive. However,
the evidence does not support any other conclusion."

When an error as serious as the false statement about the Canadian
accident experts calling the explosion a bomb is allowed to

persist,
the erroneous deductions are compounded over time. The Prime Minister
even repeated the error to Parliament. There are several reasons with
precedent for an explosion in the forward cargo compartment of a
Boeing 747 with a bomb being a very unlikely cause and a mechanically
caused explosive decompression very likely. To continue to misquote
the Canadian Safety Board and call their conclusion a bombing is bewilderingly deceptive."

Mr. Unterman, on my website at www.ntsb.org is a link to a pdf file of my many submissions to the Commission of Inquiry. They will give you a overview of the entire wiring/cargo door explanation for Air India Flight 182. I would mail it but the pdf file is over a hundred pages and you have not made your email address public. In this day and age I find this mailing and stamping things quaint.

I'm hoping you do not assume something that all other criminal attorneys have assumed: Evil exists in human hearts and a tragedy such as Air India Flight 182 could only be caused by criminals...which require their services.

I would hope you are not emotional when it comes to reality but fact based. I'm hoping you respect science and not myth for truth. I know what happened to Air India Flight 182 and I can explain it to you. It's mechanical, the hazard of faulty wiring still exists in over five hundred early model Boeing 747s still in service today. My motive is aviation safety and there is danger out there still.

Below is United Airlines Flight 811. The same thing happened years earlier to Air India Flight 182. The evidence matches.

OPENING STATEMENT
June 21, 2006

1. INTRODUCTION

Today, we begin the public proceedings of The Commission of Inquiry into the Investigation of the Bombing of Air India Flight 182, which was established by Order in Council P.C. 2006-293, issued on May 1, 2006 pursuant to Part I of the Inquiries Act.

Following the Terms of Reference contained in the Order in Council, this Commission's mandate is to hold hearings, either in public or in camera, anywhere inside or outside Canada in order to provide a report on the following questions:

* The extent to which potential threats posed by Sikh terrorism prior to 1985 have been resolved, and any legislative and procedural changes that are still needed;
* The extent to which any systemic problems in the inter-agency cooperation in the investigation of the bombing of Air India Flight 182 have been resolved and any legislative and procedural changes that are still needed;
* How best to establish a reliable and workable relationship between security intelligence and evidence that can be used in a criminal trial;

* Whether Canada's existing legal framework provides adequate constraints on terrorist financing in, from or through Canada;
* Whether existing practices or legislation provide adequate protection for witnesses against intimidation in the context of terrorism cases;
* The sufficiency of our existing system to meet the unique challenges presented in prosecuting terrorism cases; and any changes that might be required, in particular the merits in having terrorism cases heard by a panel of three judges; and
* The question of whether further changes in practice or legislation are required to address the specific aviation security breaches associated with the Air India Flight 182 bombing, particularly those relating to the screening of passengers and their baggage.

This Inquiry has broad powers of subpoena, but is not a court of law. We cannot find guilt nor make any award. We are authorized to call witnesses from any place to testify before us in order to establish facts that will support conclusions and recommendations as to how the system should have or could have functioned. That will help us determine how we can assure the families who have spent more than twenty years seeking answers that the Canadian system has been or can be fixed.

The Air India tragedy or its like must never be repeated. To ensure that, we have to conduct a thorough investigation of the areas specified by the Terms of Reference established in the Order in Council. Our mandate requires answers to how the criminal investigation process in relation to terrorist activities should be conducted and how evidence is gathered and shared among authorities. It will be necessary to review airport and other transportation security measures adopted subsequent to

June 1985. We must understand how our system can uncover sources and prevent the flow of funds that have been used to finance terrorist activities. Also to be examined is the adequacy of our system to protect witnesses in terrorism cases and the merits of having terrorism cases heard by panels comprised of three judges. Some of these matters may be heard in camera for reasons of national security. I will deal with the details of procedural matters later.

Background

In announcing the launch of this Inquiry, the Prime Minister, the Right Honourable Stephen Harper, stated that a public inquiry is the only route left to obtaining answers to how the tragedy of June 23, 1985 occurred when Air India Flight 182 exploded over the Atlantic Ocean. The aircraft was flying at an altitude of 31,000 feet (9500 m) just south of Ireland, when all 329 on board were killed. Eighty-two of those victims were children and 280 were Canadian citizens.

Many issues remain unresolved relating back to that 1985 terrorist attack on Air India flight 182 that began in Canada but never reached its destination. In the middle of the night, more than 300 Canadians, some of Indian ancestry, lost their lives in a senseless act of unprecedented violence over the skies of Ireland. Yet, it was not until the following January that the Canadian Aviation Safety Board concluded that the destruction of this aircraft was caused by a bomb. This massive murder was the most insidious episode of cowardice and inhumanity in our history at the time, and its death toll has been surpassed only by the September 11, 2001 attacks on the World Trade Centre in New York. The Air India destruction remains among the worst aviation disasters in Canadian and world history.

More than 20 years have passed since this terrible tragedy, and while Canadians have not forgotten what took place, there has been a tendency to see the issues that surround this incident as a problem related to politics in India - as part of the fight for an independent Sikh homeland. This result circumvents the fact that this was and is a Canadian tragedy. Yet, after prolonged criminal investigations and public reviews both here and in other countries, the families of the victims remain in a state of limbo. Their concerns are largely unresolved and it is not yet possible for them to achieve any peace of mind with knowing what happened and why it should not happen again. Many of these citizens have expressed disappointment at the length of time taken and the results to date in the criminal justice system. But our Inquiry is not mandated to comment upon such proceedings. Nor is it appropriate to revisit the past to assess evidence while the courts continue to hear cases on these matters.

This Inquiry will not focus on dissecting the past. It will look to how we can establish parameters for the future - to help shape a system that contains sufficient safeguards to prevent tragedies from occurring. We must collect evidence that provides guidance on systemic changes to prevent terror attacks against Canadians, whether on land or sea, in airspace, or anywhere else.

To conclude only that the criminal justice system has to date failed the families of Air India victims falls short of the problem. It failed all Canadians. The system failed all Canadians. Certainly, the majority of grief and suffering was borne within the families of the victims, but all Canadians suffered a loss in June 1985. The personal losses and unspeakable tragedies are the most immediate and visible aspect of our loss. The systemic weaknesses that have been identified are less visible, but potentially as fatal, as what happened.

This Inquiry will provide recommendations to public policy and procedural questions that can continue to repair the system that allowed such horrific acts to take place. The courts have attempted, and continue to attempt, to address issues relating to criminal justice. It is hoped that this Inquiry can help to achieve justice on a broader scale.

It is not possible to undo what happened in 1985. We can, however, attempt to understand how this happened and to recommend safeguards and systemic changes to prevent future threats to our national security and intrusions into the lives of so many innocent people.

The Inquiry

The Terms of Reference for this Inquiry call for me, as Commissioner, to accept as conclusive or take into account as appropriate the findings of various other investigations into the circumstances surrounding the bombing of Air India Flight 182, including:

The report entitled Lessons to be Learned submitted November 23, 2005 by The Honourable Bob Rae;

Proceedings before the superior courts of British Columbia;

The 1991-1992 Security Intelligence Review Committee review of Canadian Security Intelligence Service activities with respect to Air India Flight 182;

The report of The Honourable Mr. Justice B. N. Kirpal of the High Court of Delhi of February 26, 1986;

The Aviation Occurrence Report of the Canadian Aviation Safety Board into the crash involving Air India Flight 182 of January 22, 1986;

The 1985 report of Blair Seaborn on Security Arrangements Affecting Airports and Airlines in Canada; and

The reports prepared by the Independent Advisory Panel assigned by the Minister of Transport to review the provisions and operation of the Canadian Air Transport Security Authority Act and to review the actions taken since 1985 to address the specific aviation security breaches associated with the Air India flight 182 bombing.

Prior to the formal initiation of this Inquiry, I met with many of those Canadians who lost loved ones in that terrorist act. Their grief, anger and bereavement were palpable. I reported my impressions to the Prime Minister.

To recognize the significance of their losses and the critical importance that this Inquiry has to them, I am pleased that many of them are present today to witness the beginning of this public Inquiry. Although it must be painful for them, I hope that they can take some comfort in the fact that the quest for truth is today renewed.

I should note that the Commission of Inquiry is independent from the Government of Canada. The only obligations upon us are to comply with the Terms of Reference, and to abide by the legal requirement to act fairly. As Commissioner, I will be guided only by the evidence, documentation and representations reviewed by me in the course of this Inquiry.

Organization

I will now tell you a bit about myself and the senior staff who will be working with me in managing the Commission's work.

I am John C. Major, and have recently retired from my position as a Justice of the Supreme Court of Canada, where I served from November 1992 to December 2005. Following my retirement from the Court, I returned to private law practice in Calgary with the firm of Bennett Jones LLP.

The management of the overall operations of this Commission will be the responsibility of Mrs. Sheila-Marie Cook, whom I have appointed to be Executive Director and Commission Secretary. Mrs. Cook has extensive experience with major public inquiries and Royal Commissions. Her reputation gives me confidence that everything will be done in a timely and effective manner to support our hearings and the eventual production of our final report.

The public hearings will be held in Ottawa. The Commission has set up premises at 222 Queen Street, and hearings will take place in the Victoria Hall of the Bytown Pavilion at 111 Sussex Drive where we are launching this Inquiry today.

The Commission's Senior Lead Counsel will be Mr. Mark J. Freiman, who is a partner in the Toronto office of McCarthy Tetrault LLP. He has extensive experience in law and public policy and is a former Deputy Attorney General in the Province of Ontario.

Michel Dorval, a senior partner in the Montreal firm of Waxman, Dorval and Associates will be the Commission's Co-Counsel. He was Crown prosecutor for the Attorney General of Quebec and the Senior Independent Chairperson for the Solicitor General of Canada (Quebec region).

Together, they will have the primary responsibility for preparing the Commission's legal and investigative activities, and will, with the assistance of others, see to the orderly presentation of evidence.

2. RULES OF PROCEDURE AND PRACTICE

The Commission proceedings will start with the voluntary testimony of the victims of the bombing of Air India Flight 182 ("Stage 1"). The balance of the Inquiry ("Stage 2") will inquire in phases into the matters set out in clauses (b)(i)-(vii) of the Terms of Reference of the Commission, PC 2006-293. Appendix II to this statement provides a tentative schedule of the Commission's proceedings.

It is important for all parties to consult and review the full Rules, which are contained in Annex A.

Section B of the Rules provides various definitions about the Commission and its operations. I would like to point out four such definitions today:

Rule B 2(f) defines "Family" as relatives of the victims of the Bombing of Air India Flight 182 or others in the discretion of the Commissioner. Rule B 2(h) defines an intervenor as a person granted status as an intervenor by the Commissioner. Rule B 2(i) defines a party as a person granted full or partial standing as a party by the Commissioner. And Rule B 2(j) defines person as an individual, group, government or agency or other entity.

Under section C of the Rules, I point out C 3, which states that the Commissioner may amend these Rules or dispense with compliance of them as he deems necessary to ensure that the Inquiry is thorough, fair and timely. And Rule C 4 states that all parties, intervenors, witnesses and their counsel shall be deemed to undertake to adhere to the Rules, and may raise any issue of non-compliance with the Commissioner.

Section D of the Rules deals with standing. Rule D 10 states that the Commissioner may grant a person full or partial standing as a party if the Commissioner is satisfied that the person is directly and/or substantially affected by the mandate of the Inquiry or portions thereof. Rule D 11 provides that a person may be granted standing as an intervenor by the Commissioner if the Commissioner is satisfied that the person represents clearly ascertainable interests and perspectives essential to the Commissioner's mandate and which the Commissioner considers to be separately represented before the Inquiry. If granted status, that intervenor may participate in a manner to be determined by the Commissioner.

Any person wishing to be granted standing must apply by a motion in writing supported by an affidavit on or before July 7, 2006, or at the discretion of the Commissioner at any other date, but such motion must include information specified in Rule D 12.

Applicants for standing will be permitted to make oral submissions not exceeding 15 minutes at a public standing hearing in Ottawa, on July 18-20, 2006 in the Bytown Pavilion, where we are meeting today, or at the discretion of the Commissioner at any other place or date.

Section F of the Rules establishes a final date of August 16, 2006 for parties who would not otherwise be able to participate to seek funding by way of a motion in writing, with supporting affidavit (s), to be filed with the Commission. At the discretion of the Commissioner another date may be allowed. Funding will be recommended at the Commissioner's discretion in accordance with paragraph (h) of the Terms of Reference. There will be no oral hearing with respect to funding.

Section H of the Rules deals with evidence brought before the Commission. Of particular importance, upon commencement of the Inquiry (Stage 1), family of the victims of the bombing of Air India Flight 182 who participate in Stage 1 of the Inquiry will not be required to give their testimony upon oath or upon affirmation and shall not be subject to cross-examination. Rule H 29 states that the Commissioner, in his discretion, may make such further Rules as he deems appropriate with respect to the conduct of Stage 1 of the Inquiry. The Rules with respect to evidence in the balance of the Inquiry (Stage 2) will not apply to Stage 1, unless specifically so ordered by the Commissioner.

Rules 30 through 63 provide important criteria for testimony in Stage 2 of the Inquiry. These Rules cover: the preparation of documentary evidence; witness interviews; witnesses; Commission Dossier (which will comprise a statement of evidence, facts or conclusions together with the sources or basis for the evidence, facts or conclusions that Commission Counsel proposes that the Commissioner adopt for purposes of the Commission's findings or conclusions with respect to that phase of Stage 2); oral examination; the use of documents at hearings; in camera proceedings for reasons of national security or personal confidentiality; and access to evidence.

Section I of the Rules deals with the Commissioner's discretion to authorize the commissioning of Consultation Papers, and/or the convening of Expert Policy Forums or Public Consultations for use in the preparation of Commission Dossiers. Section J of the Rules establishes parameters for media coverage throughout the Commission's hearings.

3. FUNDING

The Government has agreed to provide assistance, in the form of contribution payments, to ensure the appropriate participation of Families, Parties and Intervenors in accordance with the following principles and criteria, and subject to the Commissioner's recommendations:

Commission Counsel has the primary responsibility for representing the public interest at the Inquiry, including the responsibility to ensure that all interests that bear on the public interest are brought to the Commissioner's attention.

The aim of the contribution payments is to: provide Families an opportunity for appropriate participation in the Inquiry, and assist the Parties and Intervenors to the extent of their interest where, in the Commissioner's view, they would not otherwise be able to participate in the Inquiry, but is not intended to indemnify all costs.

The Terms and Conditions define "Families" as the Families of the victims of the Air India Flight 182 bombing as determined by the Commissioner. A "Party" is defined as a Recipient with a substantial and direct interest in the subject matter of the factual Inquiry; and an "Intervenor" will be a Recipient with limited participation who would attend the hearings as required for particular aspects of the Inquiry.

4. CONCLUSION

I reiterate my earlier comment that this Inquiry is neither connected to nor involved with ongoing police investigations or court proceedings. Where appropriate, however, we are empowered to seek access to relevant material resulting from such investigations or proceedings if not precluded, by law. Any such actions will be taken in such a way as not to jeopardize any of those proceedings.

I think that some words from Bob Rae's report sum up the raison d'∆tre of this Inquiry and what it must achieve:

"Let it be said clearly: the bombing of the Air India flight was the result of a conspiracy conceived, planned and executed in Canada. Most of its victims were Canadians. This is a Canadian catastrophe, whose dimension and meaning must be understood by all Canadians."
