# Design Progression

## Chassis

### Design Considerations

- Maneuverable yet **robust**
- Can traverse **barriers**
- Fits the 13-inch **gap** between terrain and wall

### Iteration 1: Strafer Chassis

- The original 2022 straffer chassis provided by goBILDA

Pros	Cons
<ul style="list-style-type: none"> <li>- <b>Maneuverable</b> - 5.4 ft/s</li> <li>- Plentiful <b>space</b> - 13 in.</li> </ul>	<ul style="list-style-type: none"> <li>- Could not <b>traverse</b> the pipes</li> <li>- Could not fit the 13-inch <b>gap</b></li> </ul>

### Iteration 2: Thirteen Inch Chassis

- Reduced width to **12.5 inches** by cutting center channel

Pros	Cons
<ul style="list-style-type: none"> <li>- Fits the 13-inch <b>gap</b></li> <li>- <b>Maneuverable</b> - 5.4 ft/sec</li> <li>- Increased turn speed</li> </ul>	<ul style="list-style-type: none"> <li>- Very little <b>space</b></li> <li>- Could not <b>traverse</b> the terrain - gets stuck</li> </ul>

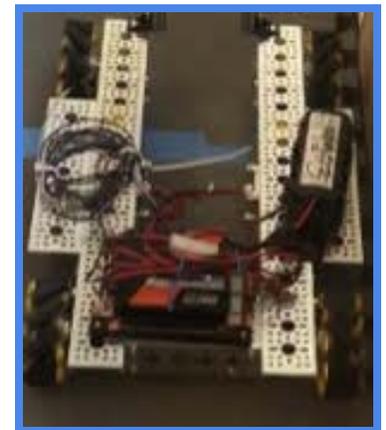

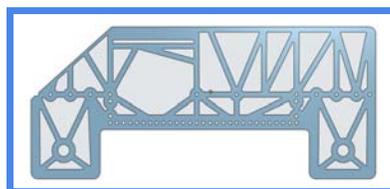

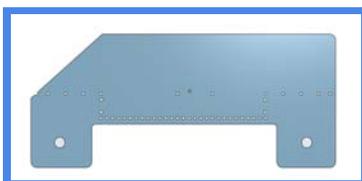

### Iteration 3: Raised Thirteen Inch Chassis

- Raised chassis **48 millimeters** by mounting motors **vertically**

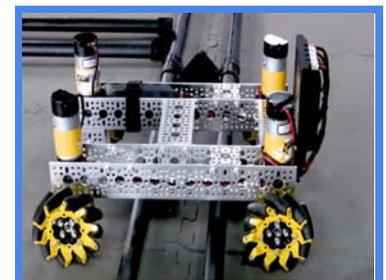

Pros	Cons
<ul style="list-style-type: none"> <li>- Fits the 13-inch <b>gap</b></li> <li>- <b>Maneuverable</b> - 5.4 ft/s</li> <li>- Can <b>traverse</b> barrier</li> </ul>	<ul style="list-style-type: none"> <li>- Very little <b>space</b> - 8 inches</li> </ul>

### Addition: Side Plates

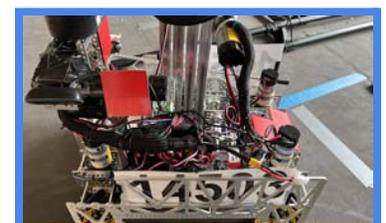

- Implemented for **protection** after facing defense in the Texas Cup
- **CNC cut side plates** out of **6061 aluminum**
- **Pocketing** removes excess material for a **53% weight decrease**
- Used sponsorship from **Send Cut Send** to manufacture

Iteration 2: 13-Inch Chassis

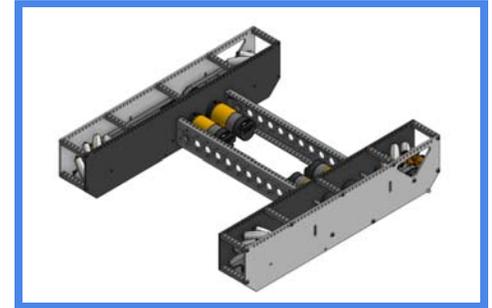

Iteration 3: Raised Chassis

Addition: Side Plates

## Computer-Aided Design (CAD)

Something that we discovered is very important in the design process was **CAD drawings**, so we prioritized adding those in as a visual representation of our design process. We drew out **multiple iterations** of each design aspect using **CAD** for mechanisms such as our odometry, transfer, ramp, wheel guards, and team scoring element. Overall, CAD has been **crucial** in our design process. You can see examples of our CAD drawings throughout our portfolio. The software we used is **Fusion 360** and **Onshape**. Additionally, to make sure that our CNC side plates could withstand the rigors of gameplay, we used **MathCad** to **conduct stress tests** on the aluminum.

Custom Belt-Driven Chassis in CAD

## Intake

### Design Considerations

- Quick and **smooth** pick-up
- Only intake **one freight** at a time
- Wide **range**

### Iteration 1: Zip Ties

- Wrapped axle with **zip ties** that were able to grip freight and propel it into our robot at **high speeds**

Pros	Cons
<ul style="list-style-type: none"> <li>- Could pick up balls and light blocks <b>very fast</b></li> <li>- An extremely <b>wide range</b> of pickup</li> </ul>	<ul style="list-style-type: none"> <li>- Could not haul in <b>heavier cubes</b></li> <li>- Intakes 4+ freight</li> </ul>

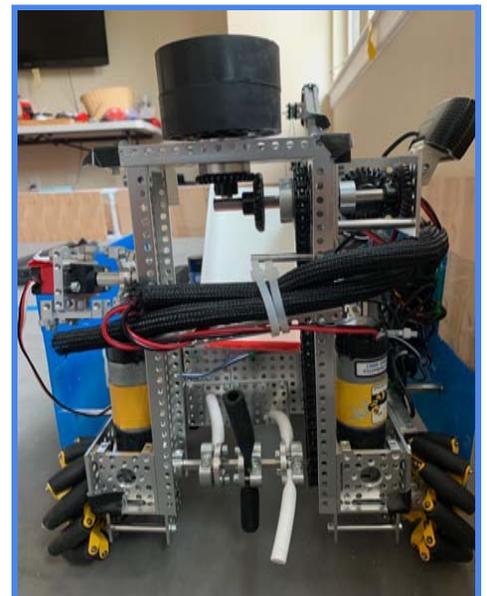

Iteration 1: Zip-Ties

### Iteration 2: Surgical Tubing

- Change material to **surgical tubing**
- **Narrower** intake area for single intake
- **Chain-driven** rotation

Pros	Cons
<ul style="list-style-type: none"> <li>- Picks up freight from <b>tight spaces</b> quickly</li> <li>- Picks up <b>weighted</b> freight</li> <li>- Only intakes one block</li> </ul>	<ul style="list-style-type: none"> <li>- <b>Bends</b> over time and needs to be replaced</li> </ul>

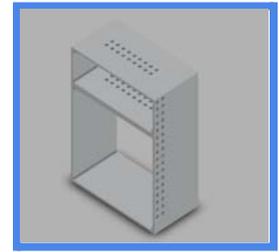

Iteration 2: Surgical Tubing

## Transfer/Outtake

### Design Considerations

- Easy to **replace**
- Efficient to **outtake**
- Can score on both alliance and shared hub **easily**
- Keeps one mineral at a time
- Prevents mineral **lodging**

Iteration 4: CAD Box + Guide + Stopper

### Four Design Iterations

Iteration	Improvements	Problems
<b>1 - goBILDA Box</b>	<ul style="list-style-type: none"> <li>- Fits <b>balls and spheres</b></li> <li>- Smooth transition</li> </ul>	<ul style="list-style-type: none"> <li>- <b>Messy</b> and unstable</li> </ul>
<b>2 - CAD Box</b>	<ul style="list-style-type: none"> <li>- Neat/<b>clean</b> look (3D-printed)</li> <li>- Optimal hole patterns</li> </ul>	<ul style="list-style-type: none"> <li>- Blocks exit inconsistently</li> </ul>
<b>3 - CAD Box + Guide</b>	<ul style="list-style-type: none"> <li>- Uses a <b>guide</b> to funnel mineral</li> </ul>	<ul style="list-style-type: none"> <li>- Can hold more than one block at a time</li> </ul>
<b>4 - CAD Box + Guide + Stopper</b>	<ul style="list-style-type: none"> <li>- Only holds <b>one block</b> at a time</li> </ul>	<ul style="list-style-type: none"> <li>- Wasn't able to deposit shared hub consistently</li> </ul>
<b>5 - Enclosed CAD Box + Ramp Deposit</b>	<ul style="list-style-type: none"> <li>- Fast shared hub cycle time in order to adapt to Worlds gameplay</li> </ul>	<ul style="list-style-type: none"> <li>- Center of rotation is high</li> </ul>

### Current Design (Iteration 5)

Attached to stationary linear slide for **manipulation** and scoring  
**Stopper** to prevent intaking of more than one mineral  
 Small ridge to prevent the mineral from falling out.  
**Torque servo** on the back to drop the freight once ready  
**Internal** guides to allow for accurate deposition

### Lessons Learned

- Center of rotation is very high leads to a longer time for the freight to fall out
- Can break easily - have **replacements** ready; 3D printing is not always consistent

Iteration 5: Enclosed CAD box + ramp deposit

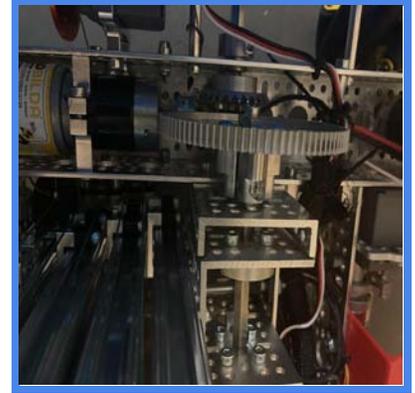

## Lift

### Design Considerations

- Fast **extension** and **retraction**
- **Adaptability** to different deposit positions
- Reduction in **drive time**

### Iteration 1: Angling Linear Slide

- Added a **high torque** motor to **angle** the slides to any desired position
- The **gearbox** to angle the linear slide has as much torque as a **Honda Civic (180 lb\*ft)**
- **Encoders** for easier autonomous and teleop automation

Iteration 1: Angling Linear Slide (Gearbox)

Pros	Cons
<ul style="list-style-type: none"> <li>- Fast <b>extension</b> and <b>retraction</b></li> <li>- Extension of <b>3.5 ft</b></li> <li>- <b>6 second</b> cycle time</li> </ul>	<ul style="list-style-type: none"> <li>- Not very efficient for fast shared hub cycles</li> <li>- Took too much space on the robot</li> </ul>

### Iteration 2: Fixed Linear Slide

- A **stationary** linear slide at a 55° angle
- Carries the freight, stored in the transfer, from the intake to the shipping hub
- Faster than before using shovel mech as outtake

Pros	Cons
<ul style="list-style-type: none"> <li>- Fast <b>extension</b> and <b>retraction</b></li> <li>- Extension of over <b>3.5 feet</b></li> <li>- <b>5 second</b> cycle time</li> </ul>	<ul style="list-style-type: none"> <li>- Limited <b>adaptability</b> - could only deposit from one single position</li> </ul>

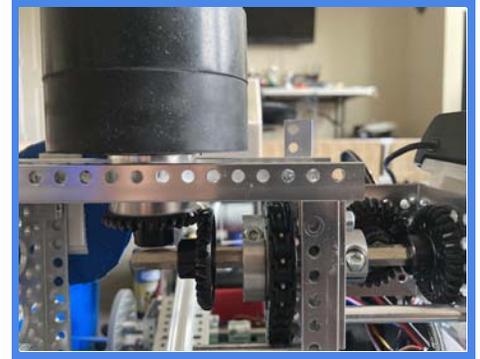

Iteration 2: Fixed Linear Slide

## Duck Mechanism

### Iteration 1: Super-Speed Servo + Gecko Wheel

Pros	Cons
<ul style="list-style-type: none"> <li>- Compact and <b>efficient</b></li> <li>- <b>Grips</b> carousel well</li> </ul>	<ul style="list-style-type: none"> <li>- Too <b>slow</b> and low-torque</li> </ul>

### Iteration 2: Intake Motor + Gecko Wheel

- Uses **miter-gears** to transmit motor power **perpendicularly**
- **Intake motor** powers both our intake and the duck mechanism with a complex **gear + chain system**
- Saves **space and weight**, both of which are limited
- Motor connects to a **double gecko wheel** with a wide area to account for inconsistencies

### Iteration 2: Intake Motor + Gecko Wheel

### Application: Physics of Optimal Motor Speed

- Used the **coefficient of static friction** between the duck and carousel along with **centripetal force** analysis to find the **optimal angular velocity** of our duck wheel

**FINDING COEFFICIENT OF STATIC FRICTION**

$\sum F_x = F_{gx} - F_f = 0$      $\sum F_y = F_n - F_g = 0$   
 $F_{gx} = F_f$      $F_n = F_g$   
 $F_{gx} = \mu_s F_n$      $F_n = mg \cos \theta$   
 $\mu_s mg \sin \theta = \mu_s mg \cos \theta$   
 $\mu_s = \frac{\sin \theta}{\cos \theta} = \tan \theta$   
 $\theta = 21.3^\circ \rightarrow \mu_s = 0.39$

**Centripetal Force Analysis:**

$\sum F_c = F_f = \frac{mv_0^2}{r_0}$      $\sum F_y = F_n - F_g = 0$   
 $\mu_s F_n = \frac{mv_0^2}{r_0}$      $F_n = F_g = mg$   
 $r_0 \cdot \mu_s \cdot mg = \frac{mv_0^2}{r_0}$   
 $v_0 = \sqrt{\mu_s g r_0}$

**Velocity and Angular Velocity Relationships:**

$v_{DUCK} = \omega_{DUCK} \cdot r_{DUCK} \rightarrow \omega_{DUCK} = \frac{v_{DUCK}}{r_{DUCK}}$   
 $\omega_{DUCK} = \omega_{CAROUSEL}$   
 $v_{CAROUSEL} = \omega_{CAROUSEL} \cdot r_{CAROUSEL}$   
 $v_{CAROUSEL} = \frac{v_{DUCK} \cdot r_{CAROUSEL}}{r_{DUCK}}$   
 $v_{WHEEL} = v_c = \frac{v_0 \cdot r_c}{r_0} = \omega_{W} \cdot r_w$   
 $\omega_{W} = \frac{v_0 \cdot r_c}{r_0 \cdot r_w}$

**Final Calculation:**

$\omega_{W} = \frac{r_c \cdot \sqrt{\mu_s g r_0}}{r_0 \cdot r_w}$   
 $\omega_{W} = \frac{0.19 \text{ m} \cdot \sqrt{0.39 \cdot 9.8 \frac{\text{m}}{\text{s}^2} \cdot 0.05 \text{ m}}}{0.05 \text{ m} \cdot 0.07 \text{ m}}$   
 $\omega_{W} = 23.7 \frac{\text{rad}}{\text{s}}$   
 $\frac{23.7 \frac{\text{rad}}{\text{s}} \cdot 1 \text{ rev}}{2\pi \text{ rad}} \cdot \frac{60 \text{ s}}{1 \text{ min}} = 226 \text{ RPM}$

## Team Scoring Element

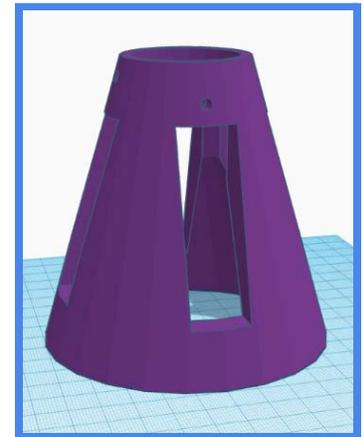

### Design Considerations

- **Lightweight**
- Easy to **grab** and place
- Can work with other **alliance partners**

### Iteration 1: 3D Design

- **Hollow cone** with a **hole** for an arm to pass through
- Funnel-shaped to allow **room for error**

Pros	Cons
<ul style="list-style-type: none"> <li>- Works effortlessly with <b>alliance partner's</b> capstones</li> <li>- Fits <b>perfectly</b> onto alliance hub</li> </ul>	<ul style="list-style-type: none"> <li>- <b>Heavy</b></li> <li>- <b>Difficult</b> to grab</li> </ul>

Iteration 1: 3D Design

### Iteration 2: Magnetism

- **Lightweight** cardboard cylinder with a **magnetic** layer on top
- Painted **red** to aid with vision (see OpenCV)

Pros	Cons
<ul style="list-style-type: none"> <li>- Extremely <b>light</b></li> <li>- <b>Magnetic</b> - easy to grab</li> <li>- Easy to replace</li> </ul>	<ul style="list-style-type: none"> <li>- <b>Sometimes</b> difficult when placing TSE on top of another team</li> <li>- Can be run over and be <b>crushed</b></li> </ul>

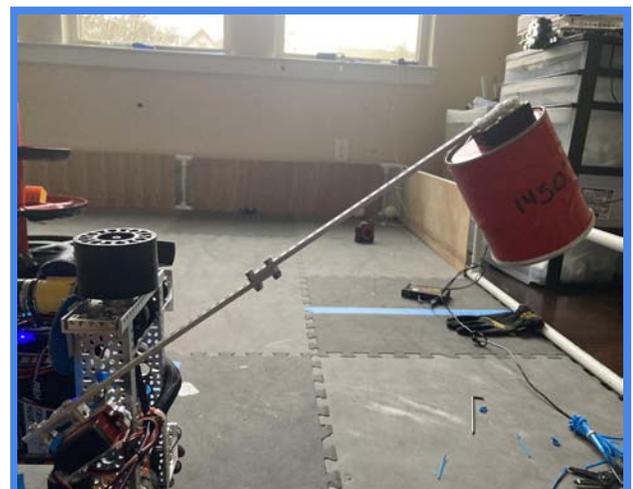

Iteration 2: Magnetism

### Retrieval Mechanism: Magnet

- **Magnet** at the tip of the arm that attracts to a magnetic plate on **TSE**
- Long rod attached at a high, **fixed pivot point** on the robot to reach the top of the hub
- Extremely efficient - **10-second cycle** time per TSE capped

Capping Example

Retrieval Mechanism: Magnet

# Programming

## Odometry

Odometry is a system that uses **dead wheels** to track a robot's position on the field. These odometry wheels are spring-loaded to the floor and spin as the robot moves. By **attaching an E8T encoder** to these wheels and noting the wheels' **circumferences**, we can track exactly how much the robot has moved in a certain direction. With one or two wheels parallel to the robot's motion and one perpendicular, the odometry wheels track the exact coordinate position **in terms of X and Y**. **Heading**, or orientation, is tracked through different methods.

Odometry makes our autonomous significantly more **accurate** because it tracks the **actual** movement of the robot, rather than the **hypothetical** movement. For example, if the robot hits the wall, the odometry wheels will not move because the robot is not; however, in a time-based code, the programming would **assume** that the robot was actually moving during that period.

The calculations show use of **mathematics** to robotics to localize the robot with **trigonometry**.

$$\begin{pmatrix} \Delta x \\ \Delta y \\ \varphi \end{pmatrix} = \begin{pmatrix} \cos(\theta_0) & -\sin(\theta_0) & 0 \\ \sin(\theta_0) & \cos(\theta_0) & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} \frac{\sin(\varphi)}{\varphi} & \frac{\cos(\varphi)-1}{\varphi} & 0 \\ \frac{1-\cos(\varphi)}{\varphi} & \frac{\sin(\varphi)}{\varphi} & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} \Delta x_c \\ \Delta x_\perp \\ \varphi \end{pmatrix}$$

Trigonometric Kinematics

### Iteration 1: Three Odometry Wheels - Math of Localization/Odometry

- Three dead wheels: two **parallel** (vertical), one **perpendicular** (horizontal)
- Heading calculated through **trigonometric mapping** of the difference between parallels

### Setback (Problem): Fragility

- Encoders were **fragile** - break approximately every month
- **Expensive** to replace - \$30 each

### Iteration 2 (Solution): Two Odometry Wheels + Rev Hub IMU

- Two dead wheels: one **parallel** (vertical), one **perpendicular** (horizontal)
- REV Control Hub **built-in IMU** measures the robot's heading, or orientation
- More accurate because of fewer magnifications of dead wheel **encoder drift** than three wheels
- Needs fewer **odometry pods**, so we don't need as many replacement parts

### Iteration 3: Retractable Odometry

- Need to **traverse barriers** without damaging the fragile odometry pods
- Solution: lift odometry using **servos** at the beginning of teleop, when it is not needed

Standard

Retracted

## Roadrunner

This year, in order to increase our accuracy and potential in autonomous, we decided to use a library called **Roadrunner**. Roadrunner is a **motion profiling** library that uses localization to accurately determine the robots **X, Y and theta** coordinates. In addition, Roadrunner implements **velocity** and **acceleration** control which allows the robot to maintain a constant acceleration and accurate velocity throughout the path despite **battery voltage**.

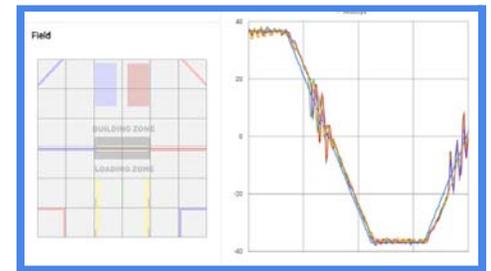

Roadrunner has many different controls that add to the accuracy of the paths. They include a **heading PID**, which accurately corrects the theta angle of the robot, and we also have **translational PID**, which accurately corrects the X and Y coordinates of the robot. The motions also utilize **feedforward** control, allowing for more accuracy with movement (velocity). Roadrunner, when paired with **odometry**, makes our autonomous system very **powerful** overall.

## Vision

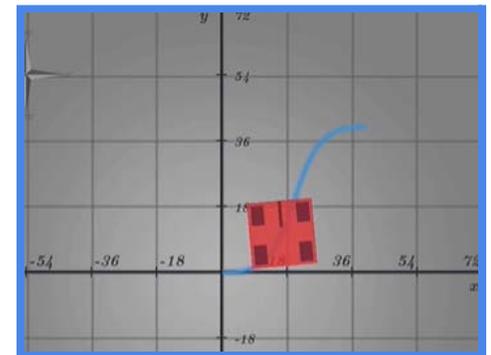

### OpenCV (Computer Vision)

After trying various methods, we found out that **OpenCV** is the most efficient to code, and it is also the most accurate autonomous **computer vision** system. It has a **100% accuracy** rate in detecting the position of the TSE. We used it for determining where to place the starting freight, which then affected the **movements** of the rest of our program.

The unique challenge this year involved detecting our **own team scoring element** rather than a game piece. Because of this, we had to design a custom-built OpenCV pipeline entirely **from scratch** to specifically match the TSE. Our pipeline draws **three small squares** on each of the three possible positions of the team scoring element on the barcode. In each square, it extracts the **Cr** (red) channel from each pixel using the **YCrCb color scheme** and averages the Cr values for all pixels within that square. This results in three numbers representing the **redness degree** of each possible TSE position, no matter the amount of **light** present. By determining which spot is the most red, we can determine which contains our **TSE**. Although this is tuned specifically to our own TSE, in order to **collaborate** with alliances and be able to **cap** both elements, we have made our vision system such that it can detect **any color of TSE**
