

# Procurement 3.0 Portal

# Developer Setup

# Procurement 3.0 Developer Setup

## Summary

This document provides information concerning how a developer could set up the Procurement 3.0 Portal solution in various development environments. **This document is not a user guide.** It is not intended for OTS client or external consumption.

***This document contains information about internal architecture and processes.  
Please safeguard this document accordingly!***

## Notes on Style (of this document)

- Hyperlinks to the definitions appear throughout the document. The first instance of a definition of each page will link back to the definitions that follow.
- References to figures are linked to the figure and appear in bold type.
- Phrases may be linked to other documents in the Google drive repository.
- Nouns protected by copyright bear the registered trademark symbol, and ownership is acknowledged in a footnote.

## Definitions

API	Application Programming Interface – the rules/syntax through which programming actions are to be performed.
CSS	Cascading Style Sheets
EUC	End User Computing, an organization in the Office of Technical Services (OTS)
GIT	Software versioning system integrated with Microsoft® Visual Studio.
GUI or UI	Graphical User Interface: the portion of an application that is exposed to the user; the primary user experience.
IDE	Integrated Development Environment; software like Microsoft® Visual Studio® and SQL Server Management Studio®.
IIS	Microsoft® Internet Information Server – the engine behind Microsoft Web Servers and services.
ISM	XXXXXXXXXX; used as a “back end” of P3P.
POC	Proof-of-concept. An application designated as a proof-of-concept is a research project meant to determine if a specific goal may be achieved.
P3P	Procurement 3.0 Portal.
RDBMS	Relational Database Management System; commonly, the “back end” of a Web application.
REST	Representational State Transfer; an architectural style for building web services based on the idea of representing resources using HTTP methods and URIs.
SSMS	Microsoft® SQL Server Management Studio®.

# Procurement Portal Application Series

T-SQL                      Structured Query Language (SQL), a programming language used in manipulating relational database management systems. Microsoft's version is Transact-SQL, or T-SQL. Oracle's version is "Procedural Language extensions to SQL," or PL/SQL.

## Key Locations

DB SERVER	XXXXXXXXXXXX
DEV SHARE	<u>XXXXXXXXXXXXXXXXXXXX</u>
GIT	<u>XXXXXXXXXXXX</u>
ISM DB (DEV)	XXXXXXXXXXXX
P3P DB (DEV)	XXXXXXXXXXXX

## Background

The Procurement 3.0 Portal (P3P) began as a proof-of-concept application, with no requirements to build against – just its objective (detailed later). This tasking was received in 2021. The project had no visibility outside of our EUC application development team and certain members of the EUC management hierarchy. The system, still in development due partly to other priorities, represents a significant departure from the standard EUC portfolio.

The idea was to replace the operator-facing forms with a fresh, new UI that takes cues from modern, ubiquitous ecommerce platforms in concept and interface (see Figure 1), but maintaining the critical ISM business objects and workflows on the back end.

To date, development of the P3P has been the product of a single developer (the author of this document). Happily, the concept is now proven, and so the project will soon mature away from its POC status.

More information about the background of the P3P may be found in the [Technical Overview](#).<sup>1</sup>

*Figure 1. The Landing Page of the P3P application.*

XXXXXXXXXX

The system was initially called XXXXXXXX, which is why so many objects have that in their names. The [Web application in IIS](#) is named “XXXXXXX,” and all of the back-end objects in the [RDBMS](#) have “XXXXXXX” in their names (*spoiler alert*: The folder containing the precompiled code is called “XXXXXXXXXXXXXXXX.”)

## Development

[P3P](#) is architected as a standard Web application with Microsoft® .NET® presentation and business logic connected to a Microsoft SQL Server® RDBMS.<sup>2 3</sup> The presentation logic includes some client-side code (JavaScript, jQuery [libraries](#)) and is styled using [CSS](#). P3P has an application database and connects to the ISM database as needed, primarily through [T-SQL](#) stored procedures. Arguably, the heart of the system lay in its ability to [communicate](#) with ISM via XXXXXX [REST API](#).

---

<sup>1</sup> There are actually a few items in this document borrowed from the Technical Overview document.

<sup>2</sup> Microsoft, .NET, SQL Server, SQL Server Management Studio, Office 365, Visual Studio, and ASP.NET are all registered trademarks of Microsoft Corporation.

<sup>3</sup> The application was initially coded in straight HTML with CSS and JavaScript (using Notepad!), with REST capabilities handled in the latter. The decision to port the REST code to .NET was a function of concern for security.

## Notes on Coding Format

- Code should be consistent and precise, and well factored.
- Objects should be disposed of as a matter of good practice.
- Each routine should be preceded by an XML summary that describes the routine (lines 381 – 388 in [Figure 2](#)).<sup>4</sup>
- The Microsoft® standard of using prefixes to identify variable types should be used generally (commonly e.g., “str”, “int”, “dec”, “obj”; lines 394 – 401 in [Figure 2](#)).
- Comments should also be included to describe processes within routines; they allow developers new to the project the ability to follow along without having to decipher the intent or actions of the process, which gets them “up to speed” more quickly and ultimately saves the organization money.
- Comments should also be included to help distinguish properties from variables (line 416 in [Figure 2](#)).
- Comments should also appear at the close of every logic block in both T-SQL stored procedures and in .NET code. Notice at lines 425 and 426 in [Figure 2](#) there are comments following the two End If statements that contain substantial code within the respective logic blocks.

## Git

The application code is protected by Git. It is also backed up over the network at regular intervals. The “local” repo I use is located on a network drive.<sup>5 6</sup>

Database code is also protected by Git, though the process is much more “manual” –

---

<sup>4</sup> I’m working to include these throughout the application code. I started including them late in the development process.

<sup>5</sup> In most respects, having my “local” repo on a network drive is nice because it benefits from the aforementioned backup scheme and keeps code off of my local machine, but it also means that everything I do requires network resources. The most common byproduct of this choice is lag (I am a remote worker).

<sup>6</sup> If you’re unfamiliar with Git, visit <https://git-scm.com>.

Periodically, I'll create scripts of the database objects, then place them into a repo via the Web interface.

## Setup Requirements

Following is a list of requirements before development on P3P may begin.

1. An account on the XXXXX domain with elevated privileges, which permits access to [the DEV share](#)
2. An account capable of accessing the [DB server](#)
3. Installation of Visual Studio and [SSMS](#) software on your device
4. Installation of [Git](#) software on your device.

These are addressed in greater detail later, though I'd like to suggest you get really adept with Git – especially on how to pull, push, and merge.

## .NET Development

Because no specifications on system design were provided, I chose to build the system in ASP.NET® because the [ISM](#) application it was “shadowing” was hosted in a Microsoft® .NET® environment.

To set up Visual Studio for the P3P solution:

- Download and install Visual Studio 2019 or later if you haven't already. The install may require the assistance of the OTS Help Desk.
- Open Windows Explorer and click on “This PC” in the left hand navigation.

- Create a network location and point it to the [DEV share](#). See [Figure 3](#).
- Open the network location using your account with elevated privileges.
- Open Visual Studio.
- On the form that appears following the splash screen, click Open a Project or Solution (Note: with a new install, your form may not look exactly like this). See [Figure 4](#).
- You should be able to find the DEV share now in the left-hand navigation, under This PC, XXX ([Figure 5](#)). Click that.
- Open the XXXXXXXXXXXX folder (also [Figure 5](#)).
- Click on Project.sln.

You will always need to open the DEV share before attempting to open the project in Visual Studio. Opening the DEV share allows Visual Studio to “see” the drive where the solution is.

To set up Visual Studio for the P3P Git Remote Repo:

- Follow the procedure outlined in [Procurement-3.0-Set-Up-Remote-Git-Repo 202412-30.pdf](#).

### T-SQL Development

Because [ISM](#) uses Microsoft® SQL Server® as its [RDBMS](#), it made perfect sense to create objects to support the new application in the ISM database, then later move those objects out to an independent database with SELECT access to certain ISM database objects.

P3P does not write anything to any ISM DB object. It only ever reads information from ISM.

The database component makes extremely heavy use of stored procedures because they are far more efficient than standard [T-SQL](#) queries.

*All communication between the business logic and the database occurs through the **database class**. An instance of the class is created, the method is executed and results from the database are returned as applicable.*

The tool for managing the database development for P3P is [SSMS](#).

## Procurement Portal Application Series

```
381     ''' <summary>
382     ''' Retrieves the data necessary to build OrderData.ItemList,
383     ''' then updates the OrderData record. Make sure OrderData_SummaryCreate() is called first.
384     ''' Requires plaintext version of SessionID as input.
385     ''' Outputs the number of rows updated.
386     ''' Called from Page_Load().
387     ''' </summary>
388     ''' <returns>Integer</returns>
389     Private Function OrderData_ItemListCreate() As Integer
390
391         Dim db As New Database()
392         Dim ds As New DataSet()
393
394         Dim intRecordsUpdated As Integer = 0
395         Dim strOrderDataID As String = String.Empty
396         Dim strAgency As String = String.Empty
397         Dim strProcurementType As String = String.Empty
398         Dim strOrderedBy As String = String.Empty
399         Dim strDateOrdered As String = String.Empty
400         Dim strItem As String = String.Empty
401         Dim strOutput As String = String.Empty
402
403         ds = db.Database_OrderData_SummaryCreate(SessionID)
404
405         If ds IsNot Nothing Then
406             If ds.Tables(0) IsNot Nothing Then
407
408                 With ds.Tables(0)
409                     strOrderDataID = .Rows(0)("OrderDataID").ToString()
410                 End With
411
412                 For Each row As DataRow In ds.Tables(0).Rows
413                     strItem &= row.Item("Item") & vbCrLf
414                 Next
415
416                 'OrderDataID is a property
417                 If strOrderDataID <> String.Empty Then
418                     OrderDataID = strOrderDataID
419                 End If
420
421                 If strOutput <> String.Empty Then
422                     intRecordsUpdated = db.Database_OrderData_ItemListInsert(OrderDataID, strItem)
423                 End If
424
425             End If 'ds.Tables(0) IsNot Nothing
426         End If 'ds IsNot Nothing
427
428         db.Dispose()
429
430         Return intRecordsUpdated
431     End Function
```

Figure 2: A typical routine. Notice the XML Summary and the standardized variable naming convention. Also Notice the comments after the long If-End If blocks.

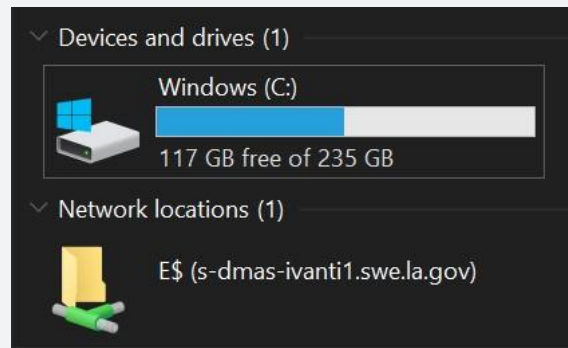

Figure 3. The DEV share as a network location in Windows Explorer.

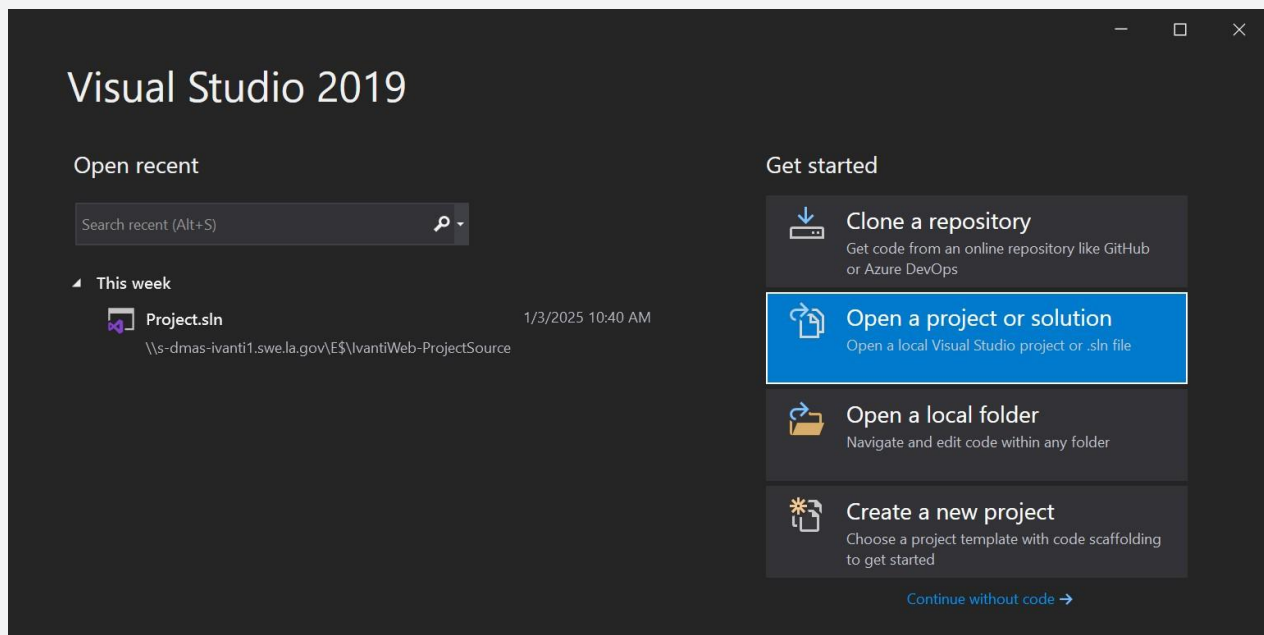

Figure 4. Visual Studio 2019's "Get Started" form.

Figure 5. IvantiWeb-ProjectSource ("graylighted") has the source code for the project. Duh.

## To set up SSMS for access to the P3P database:

- Submit a ticket to the OTS Help Desk asking for an account on the [DB server](#), with SELECT rights on XXXXXXXX, and full rights on ProcurementPortal. Rights on any environments above DEV (discussed shortly) are not yet required.
- Download and install SSMS version 20 or later if you haven't already. The install may require the assistance of the OTS Help Desk.
- Once you have received credentials, connect to the DB server as follows (these fields are on the Login tab; no other information is required on any other tab; see [Figure 6](#)):

Server Name: XXXXXXXXXXXX

- Authentication: SQL Server Authentication
- Login: {*Your credential*}
- Password: {*Your credential*}
- Encryption: Mandatory
- Trust server certificate: Checked

Figure 6. Connect to the DEV instance of SQL Server

## Environments

Technically, there are four environments: The **local** environment is where the application is primarily built and debugged. After testing, code is promoted to the **development** environment. Here the application is launched from the ISM development environment and may be launched by any person with ISM access. The **testing** and **production** environments complete the four, although the application isn't in either of those environments yet.

*The application's Web.Config file contains an Environment variable in its AppSettings. This node is chiefly responsible for telling the application what environment the instance is operating in. This is important because access is cued in part from this value. Care must be taken to ensure the Web.Config is not overwritten when code is pushed up from a lower environment.*
