Specifies whether to use the low-priority-geographies algorithm. If false, the low-priority-geographies algorithm is not used. The default value is false.

low-priority-port
Defines how to use the low-priority-port eviction strategy.

enabled
Specifies whether to use the low-priority-port algorithm. If false, the low-priority-port algorithm is not used. The default value is false.

ports
Provides a list of ports considered low-priority candidates to evict.

app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

port-number
Specifies the port number considered low-priority. The number provided can be either a number (e.g., 80) or a name (e.g., http).

protocol
Specifies the protocol considered low-priority. The default value is any.

low-priority-route-domain
Defines how to use the low-priority-route-domain eviction strategy.

enabled
Specifies whether to use the low-priority-route-domain algorithm. If false, the low-priority-route-domain algorithm is not used. The default value is false.

names
Specifies a list of route domain names considered to be low-priority candidates to evict.

low-priority-virtual-server
Defines how to use the low-priority-virtual-server eviction strategy.

enabled
Specifies whether to use the low-priority-virtual-server algorithm. If false, the low-priority-virtual-server algorithm is not used. The default value is false.

names
Specifies a list of virtual server names considered to be low-priority candidates to evict.

BIG-IP 2015-07-14 ltm eviction-policy(1)

ltm global-settings connection

NAME

connection - Configures the global settings that pertain to connections for the BIG-IP(r) and VIPRION(r) local traffic management systems.

MODULE

ltm global-settings

SYNTAX

Configure the connection component within the ltm global-settings module using the syntax shown in the following sections.

MODIFY

modify connection

options:

adaptive-reaper-hiwater [integer]
adaptive-reaper-lowater [integer]
auto-last-hop [disabled | enabled]
default-vs-syn-challenge-threshold [infinite | integer]
global-flow-eviction-policy [name]
global-syn-challenge-threshold [infinite | integer]
synccookies-threshold [integer]
vlan-keyed-conn [disabled | enabled]
vlan-syn-cookie [disabled | enabled]

DISPLAY

list connection

list connection [option name]

show running-config connection

show running-config connection [option name]

options:

all-properties
non-default-properties
one-line

DESCRIPTION

You can use the connection component to modify how the system processes connections.

EXAMPLES

modify connection auto-last-hop disabled

Specifies that the system does not automatically map the last hop for pools.

list connection

Displays the global settings for how the system processes connections.

OPTIONS

adaptive-reaper-hiwater

IMPORTANT This command has been deprecated (as of 11.6.0). Please use ltm eviction-policy instead. Specifies, in a percentage, the memory usage at which the system stops establishing new connections. Once the system meets the reaper high-water mark, the system does not establish new connections until the memory usage drops below the reaper low-water mark. The adaptive reaper settings help mitigate the effects of a denial-of-service attack.

The available range is 85 - 100. The default value is 95. To disable the adaptive reaper, set the high-water mark to 100.

adaptive-reaper-lowater

IMPORTANT This command has been deprecated (as of 11.6.0). Please use ltm eviction-policy instead. Specifies, in percent, the memory usage at which the system silently purges stale connections, without sending reset packets (RST) to the client. If the memory usage remains above the low-water mark after the purge, then the system starts purging established connections closest to their service timeout.

The available range is 70 - 100. The default value is 85. To disable the adaptive reaper, set the low-water mark to 100.

auto-last-hop

Specifies that the system automatically maps the last hop for pools. The default value is enabled.

default-vs-syn-challenge-threshold

Specifies the default value of per-virtual server SYN Cookie activation threshold per chassis. The default value is infinite. The valid range is 128 - 1024K or infinite (encoded as 0).

global-flow-eviction-policy

Specifies the flow eviction policy to use when approaching memory usage limits. The settings in the policy determine the adaptive reaper high and low water marks, and help determine which client connections to terminate when memory limits have exceeded the "low-water" threshold in the eviction policy. The settings help mitigate the effects of a denial-of-service attack.

global-syn-challenge-threshold

Specifies the default value of the global SYN Cookie activation threshold per TMM. The default value is 64K. The valid range is 2048 - 4096K or infinite (encoded as 0).

synccookies-threshold

This option is deprecated in version 13.0.0 and is replaced by default-vs-syn-challenge-threshold. Specifies the number of new or untrusted TCP connections that can be established before the system activates the SYN Cookies authentication method for subsequent TCP connections. The default value is 16384.

vlan-keyed-conn

Enables or disables VLAN-keyed connections. You use VLAN-keyed connections when traffic for the same connection must pass through the system several times, on multiple pairs of VLANs (or in different VLAN groups). The default value is enabled.

vlan-syn-cookie

Enables or disables the hardware per-VLAN SYN cookie protection on platforms with supported firmware. The default value is enabled.

BIG-IP 2016-09-06 ltm global-settings connection(1)

ltm global-settings general

NAME
general - Configures the general properties for the BIG-IP(r) and VIPRION(r) local traffic management systems.

MODULE
ltm global-settings

SYNTAX
Configure the general component within the ltm global-settings module using the syntax shown in the following sections.

MODIFY
modify general
options:
gratuitous-arp-rate [integer value: 0 ~ 2147483647]
l2-cache-timeout [integer value: 0 ~ 2147483647]
maintenance-mode [disabled | enabled]
mgmt-auto-lasthop [disabled | enabled]
share-single-mac [unique | global | vmw-compat]
snat-packet-forward [disabled | enabled]

DISPLAY
list general
list general [option name]
show running-config general
show running-config general [option name]
options:
all-properties
non-default-properties
one-line

DESCRIPTION
You can use the general component to modify how the system processes local traffic.

EXAMPLES
modify general maintenance-mode enabled
Places the Local Traffic Manager system in maintenance mode.

list general
Displays the general properties of the local traffic management system.

OPTIONS
gratuitous-arp-rate
Specifies how fast gratuitous ARPs can be sent. If it is 0, then gratuitous ARPs are sent without pause. Otherwise, it specifies how many gratuitous ARPs can be sent every second. The default value is 0. The range is 0 (zero) to 2147483647."

l2-cache-timeout
Specifies, in seconds, the amount of time that records remain in the Layer 2 forwarding table, when the MAC address of the record is no longer detected on the network.

The default value is 300 seconds. The range is 0 (zero) to 2147483647 seconds.

maintenance-mode
Specifies, when enabled, that the unit is in maintenance mode. In maintenance mode, the system stops accepting new connections and slowly finishes off existing connections.

The default value is disabled.

mgmt-auto-lasthop
Specifies, when enabled, that auto-lasthop should be used for incoming traffic to the management port. That means return traffic will be sent to the MAC address that originated the traffic rather than looked up using the routing and ARP/NDP tables.

The default value is enabled.

share-single-mac
Specifies the Media Access Control address (MAC address) that the system assigns to a VLAN. The default value is unique, which indicates that a VLAN uses a unique MAC address from the pool of mac addresses assigned to each hardware platform. The global value indicates that all of the VLANs on the system use the same MAC address. The vmw-compat value indicates that the MAC address of a vlan is allocated in a manner compatible with VMware(tm) vSwitch, and restricts vlans to a single interface, with no trunks allowed. Changing the value of this feature requires a manual restart of all TMOS daemons.

snat-packet-forward
Enables or disables SNAT packet forwarding. The default value is enabled.

BIG-IP 2017-06-28 ltm global-settings general(1)

ltm global-settings rule

NAME

rule - Configures the iRule properties for the BIG-IP(r) and VIPRION(r) local traffic management systems.

MODULE

ltm global-settings

SYNTAX

Configure the rule component within the ltm global-settings module using the syntax shown in the following sections.

MODIFY

```
modify rule
options:
  rule-aborted-log-ratio [integer value: 0 ~ 2147483647]
```

DISPLAY

```
list rule
list rule [option name]
show running-config rule
show running-config rule [option name]
options:
  all-properties
  non-default-properties
  one-line
```

DESCRIPTION

You can use the rule component to modify how the system processes iRule conditions.

EXAMPLES

```
modify rule rule-aborted-log-ratio 5
Instructs the system to generate one log message for every 5
aborted iRule executions.
```

```
list rule
Displays the iRule properties of the local traffic management
system.
```

OPTIONS

rule-aborted-log-ratio
Specifies the ratio of log messages generated when iRule executions are aborted. If set to 1, every aborted execution is logged. If set higher, every n aborted executions will result in one log message. If set to 0, no message is generated when executions are aborted.

Note, this setting is per TMM across all iRules; the implication is that if the value is set to a number greater than 1 in order to reduce the rate of log messages, all aborted rule executions are affected.

If there are multiple rules that could cause this condition where one rule is causing an excessive amount of such logs (and this condition is considered non important), and another rule where this condition signifies a problem, and the ratio is set to a large number, the occurrence of this condition for the second rule could be lost.

The default value is 1. The range is 0 (zero) to 2147483647.

ltm global-settings traffic-control

NAME

traffic-control - Configures the global settings that pertain to traffic control for the BIG-IP(r) and VIPRION(r) local traffic management systems.

MODULE

ltm global-settings

SYNTAX

Configure the traffic-control component within the ltm global-settings module using the syntax shown in the following sections.

MODIFY

modify traffic-control

options:

accept-ip-options [disabled | enabled]
accept-ip-source-route [disabled | enabled]
allow-ip-source-route [disabled | enabled]
continue-matching [disabled | enabled]
max-icmp-rate [integer value: 0 ~ 2147483647]
max-reject-rate [integer value: 1 ~ 1000]
max-reject-rate-timeout [integer value: 0 ~ 300]
min-path-mtu [integer value: 68 ~ 1500]
path-mtu-discovery [disabled | enabled]
port-find-linear [integer value: 0 ~ 61439]
port-find-random [integer value: 0 ~ 1024]
port-find-threshold-warning [disabled | enabled]
port-find-threshold-trigger [integer value: 1 ~ 12]
port-find-threshold-timeout [integer value: 0 ~ 300]
reject-unmatched [disabled | enabled]

DISPLAY

list traffic-control
list traffic-control [option name]
show running-config traffic-control
show running-config traffic-control [option name]
options:
all-properties
non-default-properties
one-line

DESCRIPTION

You can use the traffic-control component to modify how the system processes local traffic.

EXAMPLES

modify traffic-control accept-ip-options enabled
Specifies that the system accepts IPv4 packets with IP options.

list traffic-control
Displays the local traffic control global settings.

OPTIONS

accept-ip-options

Specifies whether the system accepts IPv4 packets with IP options. The default value is disabled.

accept-ip-source-route

Specifies whether the system accepts IPv4 packets with IP source route options that are destined for Traffic Management Microkernel (TMM). The default value is disabled.

To enable this option, you must also enable the accept-ip-options option.

allow-ip-source-route

Specifies whether the system allows IPv4 packets with IP source route options enabled to be routed through Traffic Management Microkernel (TMM). The default value is disabled.

To enable this option, you must also enable the accept-ip-options option.

continue-matching
Specifies whether the system matches against a less-specific virtual server when the more-specific one is disabled. When continue-matching is disabled, the default value, the system drops connections that request a disabled virtual server. In this case, the system rejects or drops packets depending on the value of the reject-unmatched option.

max-icmp-rate
Specifies the maximum rate per second at which the system issues Internet Control Message Protocol (ICMP) errors. The default value is 100 errors per second. The range is from 0 (zero) to 2147483647 errors per second. This option is useful for preventing ICMP-message storms.

max-reject-rate
Specifies the maximum rate per second at which the system issues reject packets (TCP RST or ICMP port unreachable). The default value is 250 per second. The range is from 1 to 1000 per second.

max-reject-rate-timeout
Specifies the time in seconds which the system ignores icmp port unreachable and tcp rst ratelimits on becoming active after a failover. The default value is 30 seconds. The range is from 0 to 300 seconds.

min-path-mtu
Specifies the minimum packet size that can traverse the path without suffering fragmentation, also known as path Maximum Transmission Unit(MTU). The default value is 296. The range is from 68 to 1500.

path-mtu-discovery
Specifies, when enabled, that the system discovers the maximum transmission unit (MTU) that it can send over a path, without fragmenting TCP packets. The default value is enabled.

port-find-linear
Specifies the maximum of ports to linearly search for outbound connections. The default value is 16. The range is from 0 to 61439.

port-find-random
Specifies the maximum of ports to randomly search for outbound connections. The default value is 16. The range is from 0 to 1024.

port-find-threshold-warning
Specifies if the ephemeral port-exhaustion threshold warning is to be monitored. The default is enabled.

port-find-threshold-trigger
Specifies the threshold warning's trigger which is the value of random port attempts when attempting to find an unused outbound port for a connection. The default is 8. The valid range is 1 - 12.

port-find-threshold-timeout
Specifies the threshold warning's timeout. This is the time in seconds since the last trigger value was hit and will drop the tuple if not hit. The default is 30 (1/2 minute) with range from 0 - 300.

reject-unmatched
Specifies, when enabled, that the system returns a TCP RESET or ICMP_UNREACH packet if no virtual servers on the system match the destination address of the incoming packet. When this option is disabled, the system silently drops the unmatched packet. The default value is enabled.

Iitm ifile

NAME

ifile - Configures an iFile.

MODULE

ltm

SYNTAX

Configure the iFile component within the ltm module using the syntax shown in the following sections.

CREATE/MODIFY

```
create ifile [name]
modify ifile [name]
```

options:

```
app-service [[string] | none]
description [string]
file-name [ifile file object name]
```

```
edit ifile [ [name] | [glob] | [regex] ] ... ]
```

options:

```
all-properties
non-default-properties
one-line
```

DISPLAY

```
list ifile
```

```
list ifile [ [ [name] | [glob] | [regex] ] ... ]
```

```
show running-config ifile
```

```
show running-config ifile [ [ [name] | [glob] | [regex] ] ... ]
```

options:

```
all-properties
non-default-properties
one-line
```

DELETE

```
delete ifile [name]
```

DESCRIPTION

You can use the iFile component to configure an iFile. The iFile can then be referenced from an iRule, to allow loading an external file into an iRule.

EXAMPLES

```
create ifile my_ifile file-name ifile_file_object_name
```

Creates an iFile named `my_ifile`, that gets its contents from the file object `ifile_file_object_name`.

```
list ifile all-properties
```

Displays all of the properties of all of the iFiles.

```
delete ifile my_ifile
```

Deletes the iFile named `my_ifile`.

OPTIONS

app-service

Specifies the name of the application service to which the iFile belongs. The default value is `none`. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the iFile. Only the application service can modify or delete the iFile.

description

User defined description.

file-name

The name of the iFile File Object that this iFile uses.

SEE ALSO

    non-default-properties

reset-stats lsn-log-profile
reset-stats lsn-log-profile [ [name] | [glob] | [regex] ] ... ]

DISPLAY
list lsn-log-profile
list lsn-log-profile [ [name] | [glob] | [regex] ] ... ]
show running-config lsn-log-profile
show running-config lsn-log-profile [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties
    one-line

DELETE
delete lsn-log-profile [name | all]

```

DESCRIPTION

A LSN log profile allows fine grain control of the logging for LSN translation events. When attached to an LSN pool, you can control the events to enable logging, and the elements in the log entry.

EXAMPLES

```

create ltm lsn-log-profile my_lsn_log_profile end-inbound-session {
action enabled } end-outbound-session { action enabled }

```

Creates the LSN log profile `my_lsn_log_profile` that generates log entries for both inbound and session when the translation session ends.

```

delete lsn-log-profile my_lsn_log_profile

```

Deletes the LSN log profile named `my_lsn_log_profile`.

OPTIONS

app-service
Specifies the name of the application service to which this object belongs. The default value is none.

Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete this object. Only the application service can modify or delete this object.

csv-format
When enabled, use CSV log format for log entries. The default value is disabled.

events
The type of LSN translation events available for logging control.

start-outbound-session
Event for start of outbound translation session, when the outbound flow is created.

end-outbound-session
Event for end of outbound translation session, when the outbound flow is deleted.

start-inbound-session
Event for start of incoming connection to a translated address.

end-inbound-session
Event for end of incoming connection to a translated address.

quota-exceeded
Event for when client exceeded allocated resource limit.

errors

Event for when LSN encountered errors while attempting translation for clients.

subscriber-id
When enabled, the subscriber ID associated with a subscriber IP address will be printed in the logs.

action
Specify the logging action to be taken when a particular event is encountered.

enabled
Logging is enable for the event, whether translation is from the primary pool member or backup pool member.

backup-allocation-only
Logging is enable for the event, when translation is take from backup pool member only.

disabled
Logging is disable for the event.

elements
Optional elements that can be added to the log message.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

DELETE
delete lsn-pool [name | all]

```

DESCRIPTION

A large-scale NAT (LSN) pool is a set of networks and port numbers that the BIG-IP system uses as public-side addresses and ports. When you assign an LSN pool to a virtual server, the virtual server's clients have their private addresses (and/or ports) translated to a public address and/or port from the LSN pool. The public-side addresses and ports in the LSN pool are called translation addresses and ports.

EXAMPLES

```
create lsn-pool my_lsn_pool1 mode napt persistence { mode address-port
timeout 600 } members add { 10.10.10.0/24 10.10.20.0/24 } translation-
port-range 4000:5000 client-connection-limit 100
```

Creates the LSN pool `my_lsn_pool1` that contains the translation addresses in the range of (members) `10.10.10.0/24` and `10.10.20.0/24`, translation port range `4000-5000`, with a client connection limit of 100 connections per client. The translated address and port are persisted for 600 seconds. This LSN pool operates in NAT mode (Network Address and Port Translation mode), which is the default mode if not specified.

```
delete lsn-pool my_lsn_pool1
```

Deletes the LSN pool named `my_lsn_pool1`.

OPTIONS

app-service

Specifies the name of the application service to which this object belongs. The default value is none.

Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete this object. Only the application service can modify or delete this object.

backup-members

Specifies translation IP addresses available in the backup pool which is used by DNAT translation mode if DNAT mode translation fails and falls back to NAT mode. This is a collection of IP prefixes with their prefix lengths.

client-connection-limit

The maximum number of simultaneous translated connections a client or subscriber is allowed to have.

description

User defined description.

egress-interfaces

The set of interfaces on which the source address translation is allowed or disallowed. If `egress-interfaces-enabled` is specified, the source address translation is allowed only on the specified set of interfaces. If `egress-interfaces-disabled` is specified, source address translation is disabled on specified interfaces.

egress-interfaces-disabled

Source address translation is not allowed on the interfaces specified in the `egress-interfaces` set.

egress-interfaces-enabled

Source address translation is allowed on the interfaces specified in the `egress-interfaces` set.

`glob` Displays the items that match the `glob` expression. See `help glob` for a description of `glob` expression syntax.

hairpin-mode
Enable or disable hairpinning for incoming connections.

When a client sends a packet to another client in the same private network, hairpin mode sends the packet directly to the destination client's private address; the BIG-IP system immediately translates the packet's public-side destination address. Rather than going out to the public network and coming back later for translation, the packet takes a hairpin turn at the BIG-IP device.

icmp-echo
Enable or disable ICMP echo on translated addresses.

inbound-connections
Modifies the inbound-connection mode for incoming connections to translation endpoints. A translation endpoint is the public-side address and port (X':x') for a private-side address (X:x). You can allow one of three algorithms for managing inbound connections:

Automatic
creates inbound mappings automatically from outbound traffic and allows inbound connections. Consider an outbound mapping from X:x to X':x'. If a connection comes from X:x through X':x', the BIG-IP system automatically creates a reverse mapping from X':x' back to X:x. A public-side station can respond through the X':x' address. This allows the BIG-IP system to provide Endpoint Independent Filtering (EIF) as defined in section 5 of RFC 4787
().

Explicit
only allows inbound connections for mappings that are explicitly created by another party, such as iRules or a PCP request. For example, if a PCP request creates a mapping of X:x to X':x' and the client at X:x uses it, an external caller can respond to the client through X':x'. However, if a client at M:m automatically makes a NAT'ed connection through M':m', the BIG-IP does not support an inbound connection from M':m' back to M:m.

Disabled
disables inbound connections to translation end-points (X':x'). If there is a mapping of X (a private-side IP address) to X' (a public-side IP), connections can only go out from X through X'. If a public-side recipient tries to answer at the client's public-side X' address, the BIG-IP system does not map X' back to X. The inbound connection never happens.

Port Control Protocol (PCP) is not supported if you use this setting.

log-publisher
Specify the name of the log publisher which logs translation events. See help sys log-config for more details on the logging sub-system. Use the "sys log-config publisher" component to set up a log publisher.

log-profile
Specify the name of the LSN log profile which controls the logging of translation events. See help ltm lsn-log-profile for more details on the logging profile sub-system. Use the "ltm lsn-log-profile profile" component to set up a LSN log profile.

members
Specifies the set of translation IP addresses available in the pool. This is a collection of IP prefixes with their prefix lengths. All public-side addresses come from the subnets you enter in this property.

mode Specifies which kind of translation address mapping is performed when an address is translated. Available options are NATP, Deterministic, and PBA.

NAPT (Network Address Port Translation) assigns translation addresses and ports in round-robin fashion. The algorithm first cycles through translation addresses and then through translation ports.

Deterministic (DNAT) is a reversible translation method. A given client address and port always translates to a particular public address and port from the LSN pool. This method has the following restrictions:

it is only available for NAT44 translations,
it does not support connections through DS-Lite tunnels,
subscriber connections must be received over a VLAN with the property, cmp-hash, set to "source ip,"
the egress to the Internet must be over a VLAN with the property, cmp-hash, set to "dest ip,"
any virtual server ("ltm virtual") that uses this LSN pool must have a source property set to an IP prefix containing fewer than 231 addresses. For example, the source cannot be 0.0.0.0/0.

PBA (Port Block Allocation) assigns 'blocks' of the translation addresses and ports to individual clients. All client connections are restricted to the allocated port blocks. Only block allocations and deallocations are logged in order to reduce the volume of logs.

subscriber connections must be received over a VLAN with the property, cmp-hash, set to "source ip,"
the egress to the Internet must be over a VLAN with the

property, `cmp-hash`, set to "dest ip,"

You can access your VLAN configurations through the "net vlan" component. You can find the VLANs used by your virtual server by showing or listing the "ltm virtual" component.

`name` Specifies a unique name for the `lsn-pool` component. This option is required for the commands `create`, `delete`, and `modify`.

`persistence`

Configure the persistence settings for LSN translation entries. Persistence is the preservation of a public-side IP address for a client from session to session.

`persistence.mode`

Configure the persistence mode for LSN translation entries. You can enter `address`, `address-port`, or `none`.

`address`

causes the BIG IP software to attempt to keep the IP address persistent but not necessarily the port. If a client's private IP address:port combination is `X:x`, it's public-side address may be `X':a` in one session, `X':b` in the next session, `X':c` in a third session, and so on.

`address-port`

causes the BIG IP software to attempt to keep the IP address and port persistent. If a client's private IP address:port combination is `X:x`, and it's public-side address is `X':x'` in the first session, it remains `X':x'` in all future sessions.

This is called "Endpoint Independent Mapping" in RFC 4787
().

This is the only supported setting for PCP, which you configure with the `pcp` property.

`none` prevents the BIG IP software from attempting any IP address or port persistence. An `address:port` combination of `X:x` is never guaranteed to have the same public-side address or port in two sessions.

`persistence.timeout`

After the most-recent session where `address:port X:x` translated to `X':x'` on the public side, a timer begins. If the timer expires before `X:x` has another session, `X'` or `x'` may be used as the public side of another `address:port`. Use this parameter to set the timeout (in seconds) for address and port persistence.

`pcp` A Port Control Protocol (PCP) client can set (or at least learn) its own translation (public-side) IP address and/or port. It can also set the address and/or port of a third-party client. PCP is defined in RFC 6887 (see).

`pcp.profile`

Specifies the PCP profile to use for this LSN pool. This PCP profile defines the settings to use for communication with PCP clients. Use the `create ltm profile pcp` command to create a new PCP profile.

PCP requires a profile (defined with this property) and either a `pcp.selfip` or a `pcp.dslite` tunnel where clients can send their PCP requests.

If you remove this profile option, you must specifically remove any `pcp.selfip` or `pcp.dslite` tunnel, too.

`pcp.selfip`

Specifies the PCP Server self-IP address for this LSN pool. The virtual server's clients send their PCP packets to this address. Use the `create net self` command to create a self-IP address, then use that address for this parameter. Choose a self-IP address in a VLAN that is reachable by the virtual server's clients.

`pcp.dslite`

Specifies a DS-LITE tunnel for PCP packets. Whenever a client sends a PCP packet through this tunnel, the BIG-IP device uses the PCP profile you choose with the `pcp.profile` property.

A DS-LITE tunnel places each IPv4 packet into the payload of an IPv6 packet. The IPv6 packet carries the IPv4 packet between customer equipment and the BIG-IP system, which then removes the IPv4 packet, uses NAT to translate its IPv4 addresses, and sends it to its destination.

You cannot use this property if the `mode` property is set to `Deterministic`.

`port-block-allocation`

Configures the port block settings for PBA mode.

`port-block-allocation.block-idle-timeout`

Configures the time after the last connection using the block is freed that the block assignment expires. The default value is 3600 seconds.

`port-block-allocation.block-lifetime`

Configures the timeout after which the block is no longer used for new port allocations. The block becomes a zombie block. The default is 0 which corresponds to an infinite timeout.

`port-block-allocation.block-size`

Configures the number of ports in a block. The default value is 64.

port-block-allocation.client-block-limit
Configures the number of blocks that can be assigned to a single subscriber IP address. The default value is 1.

port-block-allocation.zombie-timeout
Configures the timeout after which connections using the zombie block are killed. After connections are killed zombie block is freed after **port-block-allocation.block-idle-timeout**. This parameter is unused unless the **port-block-allocation.block-lifetime** is set. The default value is 0 which corresponds to infinite timeout.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (**@[regular expression]**) to indicate that the identifier is a regular expression. See help **regex** for a description of regular expression syntax.

route-advertisement
Specifies whether route advertisement is enabled or disabled for translated IP addresses.

translation-port-range
Specifies the range of port numbers available for use with translation IP addresses.

failure-cause
Displays the failure-cause table for this lsn-pool. There are many different possible failure causes and only the failures that occur will be displayed. This information can be useful for determining why a translation is failing.

ltm message-routing diameter peer

NAME
peer - Configures a peer for routing Diameter protocol messages.

MODULE
ltm message-routing diameter

SYNTAX
Configure the peer component within the ltm message-routing diameter module using the syntax shown in the following sections.

CREATE/MODIFY
create peer [name]
modify peer [name]
options:
 app-service [[string] | none]
 auto-initialization [enabled | disabled]
 auto-initialization-interval [integer]
 connection-mode [per-peer | per-blade | per-tmm | per-client]
 description [string]
 number-connections [integer]
 pool [name]
 ratio [integer]
 transport-config [transport-config]

edit peer [[[name] | [glob] | [regex]] ...]
options:
 all-properties

DISPLAY
list peer
list peer [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 one-line

DELETE
delete peer [name]

DESCRIPTION

You can use the peer component to manage a named Diameter peer. A peer

specifies the pool for the Diameter router to use as the destination for Diameter routes. You can also use the peer component to specify how many connections the parser creates to a remote host and what transport the parser uses to establish the connection.

EXAMPLES

```
create peer my_peer { pool my_pool transport { type virtual name my_vip
}
```

Creates a Diameter peer named `my_peer` which uses the settings of `my_vip` to establish a connection with a pool member from pool `my_pool`.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

auto-initialization

If enabled, the BIGIP will automatically create outbound connections to the active pool members in the specified pool using the configuration of the specified `transport-config`. For auto-initialization to attempt to create a connection, the peer must be included in a route that is attached to a router instance. For each router instance that the peer is contained in, a connection will be initiated. The auto-initialization logic will verify at a configurable interval if the a connection exists between the BIG-IP and the pool members of the pool. If a connection does not exist, it will attempt to reestablish one. The default is disabled.

auto-initialization-interval

Specifies the interval (in milliseconds) that attempts to initiate a connection occur. Valid ranges are from 500ms to 65535ms. The default is 5000ms.

connection-mode

Specifies how the number of connections per host is limited. Note a host (specified in the referred pool) may exist more than one peer object, and those peer objects may have different settings for `connection-mode` and `number-connections`. Thus, these settings specify how messages routed through this peer are distributed between a set of connections, not the maximum number of connections to a specified host. The default value is `per-peer`.

per-blade

Specifies the number of connections to a remote host per blade in the cluster.

per-client

Specifies the number of connections to a remote host per client connection.

per-peer

Specifies the number of connections to a remote host.

per-tmm

Specifies the number of connections to a remote host per TMM in the system.

description

User defined description.

number-connections

Specifies the distribution of connections between the BIG-IP system and a remote host. The default value is 1.

`pool` Specifies the name of the pool to which the Diameter parser routes messages.

ratio

Specifies the ratio the Diameter router uses to select a peer from a list of peers for the ltm message-routing diameter route. The default value is 1.

transport-config

Specifies the name of the transport configuration (ltm message-routing diameter transport-config) the message router uses to create an outgoing connection.

SEE ALSO

show router [[[name] | [glob] | [regex]] ...]
options:
 (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
 field-fmt

DELETE
delete router [name]

DESCRIPTION
You can use the router component to manage a Diameter router profile.

EXAMPLES
create router my_router_profile defaults-from router

Creates a Diameter router profile named my_router_profile using the system defaults.

create router my_router_profile routes add { route1 route2 }

Creates a Diameter profile named my_router_profile with two static routes.

OPTIONS
app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from
Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is router.

description
User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

ha-message-sweeper-interval
Specifies the maximum time in milliseconds that a message will be held on the standby device as it waits for the active device to route the message. Messages on the standby device held for longer than the configurable sweeper interval, will be dropped. The

default value is 1000 milliseconds.

ignore-peer-port

If selected (enabled), any connection from a configured peer will be suitable for routing a message to, regardless of its remote port number. The default value is enabled.

max-pending-bytes

Specifies the maximum number of bytes contained within pending messages that will be held while waiting for a connection to a peer to be created. Once reached any additional messages to the peer will be flagged as undeliverable and returned to the originator.

max-pending-messages

Specifies the maximum number of pending messages that will be held while waiting for a connection to a peer to be created. Once reached any additional messages to the peer will be flagged as undeliverable and returned to the originator.

max-retries

This attribute sets the maximum number of time a message may be resubmitted for rerouting by the MR::retry iRule command. The default value is 1.

mirrored

If enabled, connection created on the active device of the traffic-group specified, will be mirrored on the standby device. Messages processed on the active device will also be mirrored and perform equivalent processing on the standby device.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

routes

Specifies a list of static routes. The ordering of the route entries is insignificant.

supported-applications

Defines the list of application ID values that will be supported. If a message is received with an Auth-Application-ID or Acct-Application-ID AVP that does not match any of the values in this list, it will be dropped and the connection will be reset. A value of 0 will match all application IDs. The default value is none.

traffic-group

Specifies the traffic group on which the router is active. The default traffic group is inherited from the containing folder.

inherited-traffic-group

Read-only property that indicates if the traffic-group is inherited from the parent folder.

transaction-timeout

Specifies the maximum time (in seconds) between a request and its response. A provisional response restarts the timer. The default value is 10 seconds. Note: This may not affect all transactions. The scenarios where the system waits for response (eg. a final response for REGISTER request), are impacted by dropping any persistent data maintained for the request.

use-local-connection

Enables or disables a preference for local connections established by the ingress TMM over connections established by other TMM's when selecting the egress connection to destination peer. By default this attribute is enabled.

SEE ALSO

DELETE
delete session [name]
```

DESCRIPTION You can use the session component to manage a Diameter session profile.

EXAMPLES

```
create session my_session_profile defaults-from session

Creates a Diameter session profile named my_session_profile using the
system defaults.

create session my_session_profile { reset-on-timeout disabled }

Creates a Diameter profile named my_session_profile that will not reset
the connection when watchdog failure exceed maximum-watchdog-failures.
```

OPTIONS

```
acct-application-id
Specifies as an integer the Accounting identifier for specific
application, as specified in RFC 6733. This value will be
appended at the end of array-acct-application-id in capabilities
exchange messages if it doesn't already exist in it.

app-service
Specifies the name of the application service to which the object
belongs. The default value is none. Note: If the strict-updates
```

option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

array-acct-application-id
Specifies as a whitespace separated list of integers the Accounting identifier(s) for specific application(s), as specified in RFC 6733.

array-auth-application-id
Specifies as a whitespace separated list of integers the Authentication and Authorization identifier(s) for specific application(s), as specified in RFC 6733.

auth-application-id
Specifies as an integer the Authentication and Authorization identifier for specific application, as specified in RFC 6733. This value will be appended at the end of array-auth-application-id in capabilities exchange messages if it doesn't already exist in it.

defaults-from
Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is `diametersession`.

description
User defined description.

dest-host-rewrite
Specifies the destination host AVP to which the specified value on the egress will be rewritten.

dest-realm-rewrite
Specifies the destination realm AVP to which the specified value on the egress will be rewritten.

discard-unroutable
When selected (enabled), messages that do not match any known route will be silently discarded. When disabled, unroutable messages are routed back to the connection where they came from. The default value is enabled.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

handshake-timeout
Specifies the number of seconds before the peer handshake times out. The default is 10 seconds.

host-ip-address
Specifies the value that will be used in the Host-IP-Address AVP sent in Capabilities-Exchange-Request and Capabilities-Exchange-Answer messages. When unset (default), the Diameter router will use the virtual server's IP address.

max-message-size
Specifies the maximum number of bytes acceptable in a Diameter message. The default value is 0 which indicates that there is no message size restriction for this session. Note: Message size is also restricted by the database variable "diameter.message.maxlen"; the smallest value is used as a maximum. Messages exceeding this size are silently discarded.

max-retransmissions
Specifies the maximum number of retransmissions of a Diameter message. The default value is 0.

max-watchdog-failures
Specifies the maximum number of device watchdog failures that the traffic management system can receive before it tears down the connection. After the system receives this number of device watchdog failures, it closes the connection. The default value is 1.

origin-host
Specifies the identifier of the originating server in the form `siteserver.f5.com`. Must specify the origin-host.

origin-host-rewrite
Specifies the value to rewrite to the Origin-Host AVP on egress.

origin-realm
Specifies the Origin-Realm AVP data. Must specify the origin-realm.

origin-realm-rewrite
Specifies the value to rewrite to the Origin-Realm AVP on egress.

persist-avp
Specifies the Diameter AVP that is used for persistence. The format is `avp[index]` for a single AVP or `a[x]:b[y]:c[z]:d[w]` for a grouped AVP. There may be at most 4 AVPs in a group. The AVP name is used as the session-key; it may be an ASCII string or numeric ID in the range 1 to 4294967295 (AVP code can be specified instead of AVP name). Note: The default value is "SESSION-ID[0]". A grouped-avp can be specified with the following syntax:
`grouped-avp-name[index]:nested-avp1[index1]:nested-avp2[index2]`, where "nested-avp1" and "nested-avp2" are the AVPs in the grouped AVP.

persist-timeout
Specifies the timeout value (in seconds) for persistence entries. The default value is 180. Note: Its recommended to have the

persist-timeout to be greater than transaction timeout, specified in the Diameter router configuration, as the lesser of the two is used when creating the persist record on receiving of the first Diameter request message. Upon receiving of the response for the first Diameter request message the persistence record is updated with the persist-timeout value. For any subsequent responses received the persist timeout is updated for the persist record.

persist-type Specifies the type of the persistence. The options are:
avp Persist based on avp in the message.

custom

Persist based on a custom key set using iRule.

none Persistence is disabled.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reset-on-timeout

When enabled, the system resets the connection when the number of watchdog failures exceeds the value of max-watchdog-failures. The default value is enabled.

retransmission-timeout

Specifies the timeout between retransmissions of a Diameter message. The default value is 0 indicating that retransmissions are disabled.

route-unconfigured-peers

When enabled, all connections will be allowed. When disabled, connections from peers whose IP addresses cannot be found in a statically configured route will be rejected. The default value is enabled.

vendor-id

Specifies the vendor identification number assigned to your diameter server by the Internet Assigned Numbers Authority (IANA). The default value is 3375.

vendor-specific-vendor-id

Specifies the vendor ID number that will be sent in Vendor-Specific-Application-ID AVPs. A value of 0 disables the feature. If this value is set, exactly one of either vendor-specific-acct-app-id or vendor-specific-auth-app-id must also be specified. The default value is 0.

vendor-specific-acct-app-id

Specifies the accounting application ID number that will be sent in Vendor-Specific-Application-ID AVPs. A value of 0 disables the feature. If this value is set, vendor-specific-vendor-id must be set and vendor-specific-auth-app-id must be unset. The default value is 0.

vendor-specific-auth-app-id

Specifies the authentication/authorization application ID number that will be sent in Vendor-Specific-Application-ID AVPs. A value of 0 disables the feature. If this value is set, vendor-specific-vendor-id must be set and vendor-specific-acct-app-id must be unset. The default value is 0.

watchdog-timeout

Specifies the watchdog timeout in seconds. This setting specifies the number of seconds that a connection is idle before the device watchdog request is sent. A value of 0 means BIG-IP will not send a device watchdog request to either client or server side. The default value is 10 seconds.

BIG-IP ltm2message-routing diameter profile session(1)

ltm message-routing diameter route

NAME

route - Configures a static route for use in Diameter protocol message routing.

MODULE
ltm message-routing diameter

SYNTAX
Configure the route component within the ltm message-routing diameter module using the syntax shown in the following sections.

CREATE/MODIFY

```
create route [name]
modify route [name]
options:
  app-service [[string] | none]
  application-id [integer]
  description [string]
  destination-realm [[string] | none]
  origin-realm [[string] | none]
  peer-selection-mode [ratio | sequential]
  peers { [none | [peer_name ... ] ] }
  virtual-server [virtual-server_name]
```

```
edit route [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
```

DISPLAY

```
list route
list route [ [ [name] | [glob] | [regex] ] ... ]
show running-config route
show running-config route [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  one-line
```

DELETE

```
delete route [name]
```

DESCRIPTION

You can use the route component to define origin and destination realms, virtual server, peers, and peer selection mode of a message routing Diameter static route.

EXAMPLES

```
create route my_route
```

Creates a route instance named my_route using the system defaults.

```
create route my_route peers { peer1 peer2 }
```

Creates a route instance named my_route that will use two peers for forwarding messages.

OPTIONS

app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

application-id
Specifies the application-id to match in the Diameter message. Default value 0 matches every application-id.

description
User defined description.

destination-realm
When specified, match the Destination-Realm AVP value in the message. Default value of "" specifies all destination-realms may be routed.

origin-realm
When specified, match the Origin-Realm AVP value in the message. Default value of "" specifies all origin-realms may be routed.

peer-selection-mode
Specifies the mode of selecting a peer from a list of peers. The options are:

ratio
Peers are selected based on their weights in comparison with other peers.

sequential
Peers are selected in the order listed. All traffic will route the first peer unless all pool members in the peer are marked down.

peers
Specifies an ordered list of peers to use for forwarding messages.

virtual-server
Restricts routing for this route to connections originating on the specified virtual server. The default value is none which means the route is not restricted and messages originating on any connection may be routed to the route.

BIG-IP 2016-031tm message-routing diameter route(1)

ltm message-routing diameter transport-config

NAME

transport-config - Configures a Diameter transport-config instance for routing Diameter message protocol messages.

MODULE

ltm message-routing diameter

SYNTAX

Configure the transport-config component within the ltm message-routing diameter module using the syntax shown in the following sections.

CREATE/MODIFY

```
create transport-config [name]
modify transport-config [name]
options:
  app-service [[string] | none]
  description [string]
  source-port [integer]
  profiles [add | delete | replace-all-with] {
    [profile name ...] {
context [all | clientside | serverside]    read-only attribute for v12.0.0 or greater.
    }
  }
  rules { [none | [rule_name ... ] }
  source-address-translation {
    options:
  pool [ [pool_name] | none]
  type [ automap | snat | none ]
}
```

```
edit transport-config [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list transport-config
list transport-config [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete transport-config [name]
```

DESCRIPTION

You can use the transport-config component to define the profiles, rules, and source-address-translation of an outgoing connection.

EXAMPLES

```
create transport-config my_transport-config
```

Creates a transport-config instance named my_transport-config using the system defaults.

```
create transport-config my_transport-config { profiles add {
my_diameter my_tcp } }
```

Creates a transport-config instance named my_transport-config that will use two profiles, my_diameter and my_tcp, to create and configure an outgoing connection. The outgoing connection is automatically configured with the router instance that created the connection.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

profiles

Specifies a list of profiles that the outgoing connection uses to use to direct and manage traffic. The default value is none.

rules
Specifies a list of iRules, separated by spaces, that customize the transport configuration to direct and manage traffic. The default value is none.

source-address-translation
Specifies the type of source address translation enabled for the transport configuration, as well as the pool that the source address translation uses.

pool Specifies the name of a SNAT pool used by the specified transport configuration.

type Specifies the type of source address translation associated with the specified transport configuration.

The options are:

automap
Specifies the use of self IP addresses for transport configuration server source address translation.

none Specifies no source address translation is used by the transport configuration.

snat Specifies the use of a SNAT pool of translation addresses for virtual server source address translation.

source-port
Specifies the source port to be used for the connection being created. If no value is specified an ephemeral port is chosen. The default value is 0.

SEE ALSO

create, delete, edit, glob, list, ltm virtual, modify, regex, tmsh, ltm message-routing diameter route

BIG-IP ltm message-routing diameter transport-config(1)

ltm message-routing generic peer

NAME
peer - Configures a peer for routing generic message protocol messages.

MODULE
ltm message-routing generic

SYNTAX
Configure the peer component within the ltm message-routing generic module using the syntax shown in the following sections.

CREATE/MODIFY

```
create peer [name]
modify peer [name]
options:
  app-service [[string] | none]
  auto-initialization [ enabled | disabled ]
  auto-initialization-interval [integer]
  connection-mode [ per-peer | per-blade | per-tmm | per-client ]
  description [string]
  number-connections [integer]
  pool [name]
  ratio [integer]
  transport-config [ transport-config ]
```

```
edit peer [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list peer
list peer [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete peer [name]
```

DESCRIPTION

You can use the peer component to manage a named generic message peer. A peer specifies the pool for the generic message parser to use as the destination for generic message routes. You can also use the peer component to specify how many connections the parser creates to a remote host and what transport the parser uses to establish the connection.

EXAMPLES

```
create peer my_peer { pool my_pool transport { type virtual name my_vip } }
```

Creates a generic message peer named `my_peer` which uses the settings of `my_vip` to establish a connection with a pool member from pool `my_pool`.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

auto-initialization

If enabled, the BIGIP will automatically create outbound connections to the active pool members in the specified pool using the configuration of the specified transport-config. For auto-initialization to attempt to create a connection, the peer must be included in a route that is attached to a router instance. For each router instance that the peer is contained in, a connection will be initiated. The auto-initialization logic will verify at a configurable interval if the a connection exists between the BIG-IP and the pool members of the pool. If a connection does not exist, it will attempt to reestablish one. The default is disabled.

auto-initialization-interval

Specifies the interval (in milliseconds) that attempts to initiate a connection occur. Valid ranges are from 500ms to 65535ms. The default is 5000ms.

connection-mode

Specifies how the number of connections per host is limited. Note a host (specified in the referred pool) may exist more than one peer object, and those peer objects may have different settings for connection-mode and number connections. Thus, these settings specify how messages are routed through this peer are distributed between a set of connections, not the maximum number of connections to a specified host. The default value is per-peer.

per-peer

Specifies the number of connections to a remote host.

per-blade

Specifies the number of connections to a remote host per blade in the cluster.

per-tmm

Specifies the number of connections to a remote host per TMM in the system.

per-client

Specifies the number of connections to a remote host per client connection.

description

User defined description.

number-connections

Specifies the distribution of connections between the BIG-IP system and a remote host. The default value is 1.

pool Specifies the name of the pool to which the generic parser routes messages.

ratio

Specifies the ratio the generic message parser uses to select a peer from a list of peers for the ltm message-routing generic route. The default value is 1.

transport-config

Specifies the name of the transport configuration (ltm message-routing generic transport-config) the message router uses to create an outgoing connection.

ltm message-routing generic protocol

NAME
protocol - Configures a generic message protocol component for parsing generic messages.

MODULE
ltm message-routing generic

SYNTAX
Configure the protocol component within the ltm message-routing generic module using the syntax shown in the following sections.

CREATE/MODIFY
create protocol [name]
modify protocol [name]
options:
defaults-from [[name] | none]
description [string]
disable-parser [yes | no]
max-egress-buffer [integer]
max-message-size [integer]
message-terminator [string]
no-response [yes | no]

edit protocol [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties

reset-stats protocol
reset-stats protocol [[[name] | [glob] | [regex]] ...]

DISPLAY
list protocol
list protocol [[[name] | [glob] | [regex]] ...]
show running-config protocol
show running-config protocol [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties
one-line
partition

show protocol
show protocol [[[name] | [glob] | [regex]] ...]
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
field-fmt

DELETE
delete protocol [name]

DESCRIPTION
You can use the protocol component to implement a named generic message parser for use with the message routing framework. You can create a protocol component, and then add it to a virtual server. You do this when you want to separate a stream of bytes, from a connection to a peer, into messages for routing. This also enables a set of iRule commands to create, populate, and route messages.

EXAMPLES
create protocol my_protocol defaults-from genericmsg

Creates a message protocol component named my_protocol using the system defaults.

create protocol my_protocol { welcome-message hello }

Creates a protocol instance named my_protocol that sends a welcome message of "hello" to any new connection.

OPTIONS
defaults-from
Specifies the protocol that you want to use as the parent protocol. The new protocol inherits all of the settings and values from the specified parent protocol. The default value is genericmsg.

description
User defined description.

disable-parser
When set to yes, the generic message parser is disabled. The parser ignores all incoming packets and does not directly send message data. This mode supports iRule script protocol implementations that generate messages from the incoming transport stream and send messages on the outgoing transport stream.

max-egress-buffer
Specifies the maximum size of the send buffer in bytes. If the number of bytes in the send buffer for a connection exceeds this value, the generic message parser stops receiving outgoing messages from the router until the size of the buffer drops below this setting. The default value is 32768.

max-message-size
Specifies the maximum size of a received message. If a message exceeds this size, the connection is reset. The default value is 32768.

message-terminator
Specifies the string of characters used to terminate a message. If the message-terminator parameter is empty, the generic message parser does not separate the input stream into messages. The default value is \n.

no-response
When set to yes, matching of responses to requests is disabled. The default value is no.

BIG-IP 2014-ltmmessage-routing generic protocol(1)

ltm message-routing generic route

NAME

route - Configures a static route the generic message parser uses to route generic message protocol messages.

MODULE

ltm message-routing generic

SYNTAX

Configure the route component within the ltm message-routing generic module using the syntax shown in the following sections.

CREATE/MODIFY

```
create route [name]
modify route [name]
  options:
    app-service [[string] | none]
    description [string]
    destination-address [string]
    peer-selection-mode [ sequential | ratio ]
    peers { [peer-name] }
    source-address [string]

edit route [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties

reset-stats route
reset-stats route [ [name] | [glob] | [regex] ] ... ]
```

DISPLAY

```
list route
list route [ [name] | [glob] | [regex] ] ... ]
```

DELETE

```
delete route [name]
```

DESCRIPTION

You can use the route component to manage a generic message static route.

EXAMPLES

```
create route my_route
```

Creates a static route named my_route that uses a wildcard value for the source-address and destination-address parameters. This acts as a default route.

```
create route my_route { destination-address helpdesk peers add { peer1 peer2 } }
```

Creates a static route named my_route that contains two peers, peer1 and peer2. Messages routed with a destination-address of helpdesk are routed to a pool member contained in peer1 or peer2, based on the specified peer-selection-mode.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

destination-address

Specifies the destination address of the route. If this parameter is not present, the generic message parser considers the destination-address as a wildcard that matches all message destination addresses. The default value is none.

description

User defined description.

peer-selection-mode

Specifies the method the generic message parser uses to select a peer from the specified list of peers. The default value is sequential.

sequential

Specifies that the generic message parser selects the first peer in the list of peers. If the protocol retransmits the message, the generic message parser uses another pool member in the first peer. If all pool members in a peer are unavailable, the generic message parser uses the next peer in the list.

ratio

Specifies that the generic message parser selects a peer from a list of peers based on the relative ratio values of each peer. For example if three peers have ratios of 1, 1, and 2, the first 2 peers have a 25% (1/4) probability of being selected and the third peer has a 50% (2/4) probability of being selected.

peers

Specifies a list of peers.

source-address

Specifies the source address of the route. If this parameter is not present, the generic message parser considers the source-address as a wildcard that matches all message sources addresses. The default value is none.

SEE ALSO

create, delete, edit, glob, list, ltm virtual, modify, regex, reset-stats, tmsh, ltm message-routing generic peer ltm message-routing generic router

show router [ [ [name] | [glob] | [regex] ] ... ]
  options:
    (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
    field-fmt

DELETE
delete router [name]

```

DESCRIPTION

You can use the router component to manage a generic message router instance. All virtual servers containing the same router instance share the same route table and can route messages between peers.

EXAMPLES

```

create router my_router defaults-from messengerouter

Creates a message router instance named my_router using the system
defaults.

create router my_router { routes add { route1 route2 } }

Creates a router instance named my_router that contains two static
routes, route1 and route2.

```

OPTIONS

app-service
Specifies the name of the application service to which the router belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the router. Only the application service can modify or delete the router.

defaults-from
Specifies the profile that you want to use as the parent profile. The new profile inherits all of the settings and values from the specified parent profile. The default value is messengerouter.

description
User defined description.

ignore-client-port
If set to yes, the system ignores the remote port on clientside connections (connections where the peer connected to the BIG IP system) when searching for an existing connection. The default value is no.

irule-scope-message
If set to yes, iRule events for this message-routing protocol are scoped to the message executing (that is each message has its own execution context). This allows multiple messages to process iRules concurrently without suspending commands blocking each other or variables being shared. If set to no, all iRule events for this protocol are scoped to the connection flow (that is all share a single execution context per flow) and therefore are forced to execute one at a time even though they are processing independent messages (this is the legacy mode). The default value is no. Some existing iRules need to be adjusted to use the per-message scope.

ha-message-sweeper-interval
Specifies the maximum time in milliseconds that a message will be held on the standby device as it waits for the active device to route the message. Messages on the standby device held for longer than the configurable sweeper interval, will be dropped. The default value is 1000 milliseconds.

inherited-traffic-group
Read-only property that indicates if the traffic-group is inherited from the parent folder.

max-pending-bytes
Specifies the maximum number of bytes of pending messages that the router instance holds while waiting for a connection to a peer to be created. Once reached, any additional messages to the peer are flagged as undeliverable and returned to the originator. The default value is 32768.

max-pending-messages
Specifies the maximum number of pending messages that the router instance holds while waiting for a connection to a peer to be created. Once reached, any additional messages to the peer are flagged as undeliverable and returned to the originator. The default value is 64.

max-retries

This attribute sets the maximum number of time a message may be resubmitted for rerouting by the MR::retry iRule command. The default value is 1.

mirrored

If enabled, connection created on the active device of the traffic-group specified, will be mirrored on the standby device. Messages processed on the active device will also be mirrored and perform equivalent processing on the standby device.

traffic-group

Specifies the traffic group on which the router is active. The default traffic group is inherited from the containing folder.

inherited-traffic-group

Read-only property that indicates if the traffic-group is inherited from the parent folder.

use-local-connection

If true, the router will route a message to an existing connection on the same TMM as the message was received on. If an existing connection is not found, it will route the message through an existing connection based on a deterministic algorithm that may be on another TMM. If a matching existing connection is not found, it will create a connection on the current TMM. Setting this flag may limit the number of connections that are created to a peer.

routes

Specifies a list of static routes for the router instance to use.

ltm message-routing generic transport-config

NAME

transport-config - Configures a message transport-config instance for routing generic message protocol messages.

MODULE

ltm message-routing generic

SYNTAX

Configure the transport-config component within the ltm message-routing generic module using the syntax shown in the following sections.

CREATE/MODIFY

```
create transport-config [name]
modify transport-config [name]
options:
  app-service [[string] | none]
  description [string]
  source-port [integer]
  profiles [add | delete | replace-all-with] {
    [profile_name ...] {
  context [all | clientside | serverside]      read-only attribute for v12.0.0 or greater.
    }
  }
  rules { [none | [rule_name ... ] ] }
  source-address-translation {
    options:
  pool [ [pool_name] | none]
  type [ automap | snat | none ]
}

edit transport-config [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list transport-config
list transport-config [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

one-line
partition

DELETE
delete transport-config [name]

DESCRIPTION
You can use the transport-config component to define the profiles, rules, and source-address-translation of an outgoing connection.

EXAMPLES
create transport-config my_transport-config

Creates a transport-config instance named my_transport-config using the system defaults.

create transport-config my_transport-config { profiles add { my_genericmsg my_tcp } }

Creates a transport-config instance named my_transport-config that will use two profiles, my_genericmsg and my_tcp, to create and configure an outgoing connection. The outgoing connection is automatically configured with the router instance that created the connection.

OPTIONS
app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description
User defined description.

source-port
Specifies the source port to be used for the connection being created. If no value is specified an ephemeral port is chosen. The default value is 0.

profiles
Specifies a list of profiles that the outgoing connection uses to direct and manage traffic. The default value is none.

rules
Specifies a list of iRules, separated by spaces, that customize the transport configuration to direct and manage traffic. The default value is none.

source-address-translation
Specifies the type of source address translation enabled for the transport configuration, as well as the pool that the source address translation uses.

pool Specifies the name of a SNAT pool used by the specified transport configuration.

type Specifies the type of source address translation associated with the specified transport configuration.

The options are:

automap
Specifies the use of self IP addresses for transport configuration server source address translation.

none Specifies no source address translation is used by the transport configuration.

snat Specifies the use of a SNAT pool of translation addresses for virtual server source address translation.

DELETE
 delete peer [name]

DESCRIPTION
 You can use the peer component to manage a named MQTT peer. A peer specifies the pool for the MQTT router to use as the destination for MQTT routes. You can also use the peer component to specify how many connections the parser creates to a remote host and what transport the parser uses to establish the connection.

EXAMPLES
 create peer my_peer { pool my_pool transport { type virtual name my_vip } }
 } }
 Creates a MQTT peer named my_peer which uses the settings of my_vip to establish a connection with a pool member from pool my_pool.

OPTIONS
 app-service
 Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description
 User defined description.

pool Specifies the name of the pool to which the MQTT parser routes messages.

transport-config
 Specifies the name of the transport configuration (ltm message-routing mqtt transport-config) the message router uses to create an outgoing connection.

options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt
```

DELETE

```
delete router [name]
```

DESCRIPTION

You can use the router component to manage a MQTT router profile.

EXAMPLES

```
create router my_router_profile defaults-from router
```

Creates a MQTT router profile named my_router_profile using the system defaults.

```
create router my_router_profile route routel
```

Creates a MQTT router profile named my_router_profile with a static route.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is router.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

max-pending-bytes

Specifies the maximum number of bytes contained within pending messages that will be held while waiting for a connection to a peer to be created. Once reached any additional messages to the peer will be flagged as undeliverable and returned to the originator.

max-payload-pending-bytes

Specifies the maximum number of payload bytes contained within pending messages that will be held before exerting flow control and eventually closing the TCP window.

max-pending-messages

Specifies the maximum number of pending messages that will be held while waiting for a connection to a peer to be created. Once reached any additional messages to the peer will be flagged as undeliverable and returned to the originator.

max-retries

This attribute sets the maximum number of time a message may be resubmitted for rerouting by the MR::retry iRule command. The default value is 1.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

route

Specifies a static route.

traffic-group

Specifies the traffic group on which the router is active. The default traffic group is inherited from the containing folder.

inherited-traffic-group

Read-only property that indicates if the traffic-group is inherited from the parent folder.

use-local-connection

Enables or disables a preference for local connections established by the ingress TMM over connections established by other TMM's when selecting the egress connection to destination peer.

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

field-fmt

DELETE

delete session [name]

DESCRIPTION

You can use the session component to manage a MQTT session profile.

EXAMPLES

```
create session my_session_profile defaults-from session
```

Creates a MQTT session profile named `my_session_profile` using the system defaults.

OPTIONS

`app-service`

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

`defaults-from`

Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is `session`.

`description`

User defined description.

`clientid-prefix`

Specifies the client-id prefix that will be used when sending the `CONNECT` message to the broker.

`keepalive-int`

Specifies the keepalive interval that will be used when sending the `CONNECT` message to the broker.

`peered-session-mode`

Set this option to peer a client session with server session. When either side terminates the peered session will terminate immediately.

`proxy-topic-prefix`

Specifies a prefix that will be added to topic of messages that belong to the proxy.

`client-will-handling-mode`

Specifies the will handling mode to control will action for ungraceful shutdown of the client session.

`server-will-handling-mode`

Specifies the will handling mode to control will action for ungraceful shutdown of proxy's session with the broker.

`glob` Displays the items that match the glob expression. See help `glob` for a description of glob expression syntax.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

`partition`

Displays the administrative partition within which the component resides.

SEE ALSO

`create`, `delete`, `edit`, `glob`, `list`, `ltm virtual`, `modify`, `regex`, `reset-stats`, `show`, `tmsh`

BIG-IP 2ltm-message-routing mqtt profile session(1)

ltm message-routing mqtt route

NAME

`route` - Configures a static route for use in MQTT message routing.

MODULE

`ltm message-routing mqtt`

SYNTAX

Configure the route component within the `ltm message-routing mqtt` module using the syntax shown in the following sections.

```

CREATE/MODIFY
create route [name]
modify route [name]
options:
  app-service [[string] | none]
  description [string]
  peer [peer_name]
  virtual-server [virtual-server_name]

edit route [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list route
list route [ [ [name] | [glob] | [regex] ] ... ]
show running-config route
show running-config route [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

show route
show route [ [ [name] | [glob] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt

DELETE
delete route [name]

```

DESCRIPTION
 You can use the route component to define the URI's, virtual server, peers and peer selection mode of a message routing MQTT static route.

EXAMPLES

```

create route my_route

Creates a route instance named my_route using the system defaults.

create route my_route peer peer1

Creates a route instance named my_route that will use peer1 for forwarding messages.

```

OPTIONS

```

app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description
User defined description.

peer Specifies a peer to use for forwarding messages.

virtual-server
Specifies the virtual server on which connections will be routed to this route. If the virtual server is unset, messages originating on any connection may be routed to the route.

```

SEE ALSO

BIG-IP 2018-07-16 ltm message-routing mqtt route(1)

ltm message-routing mqtt transport-config

NAME
 transport-config - Configures a mqtt transport-config instance for routing mqtt message protocol messages.

MODULE
 ltm message-routing mqtt

SYNTAX

Configure the transport-config component within the ltm message-routing mqtt module using the syntax shown in the following sections.

CREATE/MODIFY

```
create transport-config [name]
modify transport-config [name]
options:
  app-service [[string] | none]
  description [string]
  source-port [integer]
  profiles [add | delete | replace-all-with] {
    [profile_name ...] {
context [all | clientside | serverside]      read-only attribute for v12.0.0 or greater.
    }
  }
  rules { [none | [rule_name ... ] ] }
  source-address-translation {
    options:
  pool [ [pool_name] | none]
  type [ automap | snat | none ]
}
```

```
edit transport-config [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list transport-config
list transport-config [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete transport-config [name]
```

DESCRIPTION

You can use the transport-config component to define the profiles, rules, and source-address-translation of an outgoing connection.

EXAMPLES

```
create transport-config my_transport-config
```

Creates a transport-config instance named my_transport-config using the system defaults.

```
create transport-config my_transport-config { profiles add { my_mqttmsg
my_tcp } }
```

Creates a transport-config instance named my_transport-config that will use two profiles, my_mqttmsg and my_tcp, to create and configure an outgoing connection. The outgoing connection is automatically configured with the router instance that created the connection.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

source-port

Specifies the source port to be used for the connection being created. If no value is specified an ephemeral port is chosen. The default value is 0.

profiles

Specifies a list of profiles that the outgoing connection uses to use to direct and manage traffic. The default value is none.

rules

Specifies a list of iRules, separated by spaces, that customize the transport configuration to direct and manage traffic. The default value is none.

source-address-translation

Specifies the type of source address translation enabled for the transport configuration, as well as the pool that the source address translation uses.

pool Specifies the name of a SNAT pool used by the specified transport configuration.

type Specifies the type of source address translation associated with the specified transport configuration.

The options are:

automap

Specifies the use of self IP addresses for transport configuration server source address translation.

none Specifies no source address translation is used by the transport configuration.

snat Specifies the use of a SNAT pool of translation addresses for virtual server source address translation.

BIG-IP ltm8message-routing mgmt transport-config(1)

ltm message-routing sip peer

NAME

peer - Configures a peer for routing SIP message protocol messages.

MODULE

ltm message-routing sip

SYNTAX

Configure the peer component within the ltm message-routing sip module using the syntax shown in the following sections.

CREATE/MODIFY

```
create peer [name]
modify peer [name]
options:
  connection-mode [ per-peer | per-blade | per-tmm | per-client ]
  app-service [[string] | none]
  auto-initialization [ enabled | disabled ]
  auto-initialization-interval [integer]
  connection-mode [ per-peer | per-blade | per-tmm | per-client ]
  description [string]
  number-connections [integer]
  pool [name]
  ratio [integer]
  transport-config [ transport-config ]
```

```
edit peer [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list peer
list peer [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete peer [name]
```

DESCRIPTION

You can use the peer component to manage a named SIP peer. A peer specifies the pool for the SIP router to use as the destination for SIP routes. You can also use the peer component to specify how many connections the parser creates to a remote host and what transport the parser uses to establish the connection.

EXAMPLES

```
create peer my_peer { pool my_pool transport { type virtual name my_vip } }
```

Creates a SIP peer named my_peer which uses the settings of my_vip to establish a connection with a pool member from pool my_pool.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

auto-initialization

If enabled, the BIGIP will automatically create outbound connections to the active pool members in the specified pool using the configuration of the specified transport-config. For auto-initialization to attempt to create a connection, the peer must be included in a route that is attached to a router instance. For each router instance that the peer is contained in, a connection

will be initiated. The auto-initialization logic will verify at a configurable interval if the a connection exists between the BIG-IP and the pool members of the pool. If a connection does not exist, it will attempt to reestablish one. The default is disabled.

auto-initialization-interval
Specifies the interval (in milliseconds) that attempts to initiate a connection occur. Valid ranges are from 500ms to 65535ms. The default is 5000ms.

connection-mode
Specifies how the number of connections per host is limited. Note a host (specified in the referred pool) may exist more than one peer object, and those peer objects may have different settings for connection-mode and number_connections. Thus, these settings specify how messages routed through this peer are distributed between a set of connections, not the maximum number of connections to a specified host. The default value is per-peer.

per-peer
Specifies the number of connections to a remote host.

per-blade
Specifies the number of connections to a remote host per blade in the cluster.

per-tmm
Specifies the number of connections to a remote host per TMM in the system.

per-client
Specifies the number of connections to a remote host per client connection.

description
User defined description.

number-connections
Specifies the distribution of connections between the BIG-IP system and a remote host. The default value is 1.

pool Specifies the name of the pool to which the SIP parser routes messages.

ratio
Specifies the ratio the SIP router uses to select a peer from a list of peers for the ltm message-routing sip route. The default value is 1.

transport-config
Specifies the name of the transport configuration (ltm message-routing sip transport-config) the message router uses to create an outgoing connection.

DELETE
delete router [name]

```

DESCRIPTION

You can use the router component to manage a SIP router profile.

EXAMPLES

```

create router my_router_profile defaults-from router

Creates a SIP router profile named my_router_profile using the system
defaults.

create router my_router_profile routes add { route1 route2 }

Creates a SIP profile named my_router_profile with two static routes.

```

OPTIONS

app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from
Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is router.

description
User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

log-publisher
Specify the name of the log publisher which logs translation events. See help sys log-config for more details on the logging sub-system. Use the "sys log-config publisher" component to set up a log publisher.

log-profile
Specify the name of the ALG log profile which controls the logging of ALG . See help ltm alg-log-profile for more details on the logging profile sub-system. Use the "ltm alg-log-profile profile" component to set up a ALG log profile.

max-pending-bytes
Specifies the maximum number of bytes contained within pending messages that will be held while waiting for a connection to a peer to be created. Once reached any additional messages to the peer will be flagged as undeliverable and returned to the originator.

max-pending-messages

Specifies the maximum number of pending messages that will be held while waiting for a connection to a peer to be created. Once reached any additional messages to the peer will be flagged as undeliverable and returned to the originator.

max-retries

This attribute sets the maximum number of time a message may be resubmitted for rerouting by the MR::retry iRule command. The default value is 1.

mirrored

If enabled, connection created on the active device of the traffic-group specified, will be mirrored on the standby device. Messages processed on the active device will also be mirrored and perform equivalent processing on the standby device.

Important: Changing traffic groups, with Connection Mirroring enabled, drops all mirrored connections and loses all persistence data. If you change traffic groups, mirroring must restart.

operation-mode

Specifies the behavior of the routing instance. The options are:

load-balancing

Messages will be load balanced.

application-level-gateway

The virtual will act as a forwarding virtual, forwarding messages to the server of peer identified as the destination address of the incoming connection. The messages will be inspected so that associated media flows can be created.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

routes

Specifies a list of static routes. The ordering of the route entries is insignificant.

session.transaction-timeout

Specifies the maximum time (in seconds) between a request and its response. A provisional response restarts the timer. This may not affect all transactions. The scenarios where the system waits for response (eg. a final response for REGISTER request), are impacted by dropping any persistent data maintained for the request.

session.max-session-timeout

This attribute is valid when the operation-mode is application-level-gateway. Specifies the maximum duration (in seconds) the media for a call remains active. After this period call media is terminated.

traffic-group

Specifies the traffic group on which the router is active. The default traffic group is inherited from the containing folder.

inherited-traffic-group

Read-only property that indicates if the traffic-group is inherited from the parent folder.

media-proxy.max-media-sessions

This attribute is valid when the operation-mode is application-level-gateway. Specifies the maximum number of media sessions that are allowed per call.

media-proxy.media-inactivity-timeout

This attribute is valid when the operation-mode is application-level-gateway. Specifies the maximum duration (in seconds) that a media flow is active with no RTP packets. After this period the media flow is removed. This attribute is applicable only to RTP packets. Inactivity time applicable to RTCP packets is max-session-timeout.

max-global-registrations

This attribute is valid when the operation-mode is application-level-gateway. Specifies the maximum number of registrations allowed. If the limit is reached the registrations are dropped. A default value of 0 indicates the limit is ignored."

nonregistered-subscriber-callout

This attribute is valid when the operation-mode is application-level-gateway with translation. Enables non-registered subscriber to initiate calls. Non-registered subscribers will not be able to receive incoming calls. The default value is enabled.

concurrent-sessions-per-subscriber

This attribute is valid when the operation-mode is application-level-gateway. Specifies the maximum number of concurrent calls allowed per subscriber. It denotes the concurrent From-URI in the call matching the registration key. If the limit exceeds then the call is dropped. Default value of 0 indicates that the limit is ignored."

registration-timeout

This attribute is valid when the operation-mode is application-level-gateway with LSN source-address-translation. Specifies the

maximum duration (in seconds) that a registration entry remains active while a response has not been received from the registrar. After this period the registration entry is removed from the registration table, unless the registrar has responded. A default value of 0 means this timeout is ignored and the Expires header value is used.

`dialog_establishment_timeout`
This attribute is valid when the operation-mode is application-level-gateway. Specifies the timeout (in seconds) that represents the Timer B as per RFC 3261, the INVITE transaction timeout. The `dialog-establishment-timeout` is used by the Call Table. The default value is 32 seconds.

`use-local-connection`
Enables or disables a preference for local connections established by the ingress TMM over connections established by other TMM's when selecting the egress connection to destination peer.

BIG-IP 2011tmmessage-routing sip profile router(1)

ltm message-routing sip profile session

NAME

`session` - Configures a Session Initiation Protocol (SIP) Session profile.

MODULE

`ltm message-routing sip profile`

SYNTAX

Configure the session component within the `ltm message-routing sip profile` module using the syntax shown in the following sections.

CREATE/MODIFY

```
create session [name]
modify session [name]
options:
  app-service [[string] | none]
  custom-via [[via-header] | none]
  defaults-from [[name] | none]
  description [string]
  do-not-connect-back [disabled | enabled]
  generate-response-on-failure [disabled | enabled]
  honor-via [disabled | enabled]
  insert-record-route-header [disabled | enabled]
  insert-via-header [disabled | enabled]
  maintenance-mode [disabled | enabled]
  loop-detection [disabled | enabled]
  loop-detection-mode [Loose | Strict]
  max-forwards-check [disabled | enabled]
  max-msg-header-count [integer]
  max-msg-header-size [integer]
  max-msg-size [integer]
  persistence {
    persist-key [Call-ID | Custom | Src-Addr]
    persist-timeout [integer]
    persist-type [session | none]
  }
  enable-sip-firewall [no | yes]

edit session [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

reset-stats session
reset-stats session [ [name] | [glob] | [regex] ] ... ]
```

DISPLAY

```
list session
list session [ [name] | [glob] | [regex] ] ... ]
show running-config session
show running-config session [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

one-line
partition

```
show session
show session [ [ [name] | [glob] | [regex] ] ... ]
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
field-fmt
```

```
DELETE
delete session [name]
```

DESCRIPTION
You can use the session component to manage a SIP session profile.

EXAMPLES

```
create session my_session_profile defaults-from session
```

Creates a SIP session profile named `my_session_profile` using the system defaults.

```
create session my_session_profile { insert-record-route-header enabled
}
```

Creates a SIP profile named `my_session_profile` with insertion of record-route header in requests which establish a dialog.

OPTIONS

app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

custom-via Specifies the value the system uses for the Sent-by field of the Via header when the Insert Via Header setting is enabled. Note: The value that you enter must include a format of SIP/SIP-version/protocol, followed by a Sent-By value. For example, SIP/2.0/TCP www.siterequest.com:4343 or SIP/2.0/SCTP 10.10.4.32.

defaults-from
Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is `session`.

description
User defined description.

do-not-connect-back
Enables or disables whether a connection to a request originator is re-established (if it no longer exists) in order to deliver a response. When disabled, responses that cannot be forwarded using an existing connection are dropped.

generate-response-on-failure
Enables or disables sending failure response messages such as 4xx, 5xx and 6xx, when a SIP request is being dropped. Note: Where it is specified "silently" discarded/dropped, no error response is generated. In any case, a dropped message (request/response) is tracked by the Messages Dropped Statistic.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

honor-via
Enables or disables honoring any via which is not inserted by the system for routing the response. This attribute has no effect if the associated siprouter profile's operation mode attribute is set to `"application level gateway"`.

insert-record-route-header
Enables or disables the insertion of a record-route header in requests that establish dialog. When enabled, along with the URI, the custom parameters may be added to facilitate the routing of subsequent requests within this call to avoid route lookup. The record route URI is the local-IP and port of flows that are used for forwarding the message. This attribute has no effect if the associated siprouter profile's operation mode attribute is set to `"application level gateway"`.

insert-via-header
Enables or disables insertion of top via. When enabled, custom parameters to help route the response back are inserted, along with sent-by field of via. The source address:port of the flow forwarding the request is filled as value for sent-by field of the via unless a custom via value is specified. The custom parameters inserted to help routing, helps improve performance as it facilitates routing without any lookup. The via is inserted at egress side of the flow, after the SIP_REQUEST_SEND event. This attribute has no effect if the associated siprouter profile's operation mode attribute is set to `"application level gateway"`.

maintenance-mode
Enables or disables maintenance mode. When enabled, SIP response `"503 Service Unavailable"` will be sent for incoming SIP request. SIP response will be dropped.

loop-detection
Enables or disables loop-detection checking. When a loop is detected, the request is discarded. An error response is sent, if configured. A request is detected as seen before (forwarded/spiraled/looped) only if self inserted via is found in the message and the value of its branch param plays a key role in detecting loop versus spiral. Hence enabling via insertion becomes

a requirement to do loop detection check. This attribute has no effect if the associated siprouter profile's operation mode attribute is set to \"application level gateway\".

loop-detection-mode

Loop detection logic generates a unique hash per transaction based on several attributes including Cseq, To, From, Call-ID, Route, Request-URI and Chassis serial number. Loop-detection-mode value of Loose will skip \"To\" attribute in the hash calculation.

max-forwards-check

Enables or disables checking on max-forwards. The max-forwards header field serves to limit the number of hops a request can transit on the way to its destination. If 0, the request is discarded. An error response is sent, if configured. This attribute has no effect if the associated siprouter profile's operation mode attribute is set to \"application level gateway\".

max-msg-header-count

Indicates the maximum count of expected SIP message header fields. A message that exceeds this limit is silently discarded.

max-msg-header-size

Indicates the maximum SIP message header size (in bytes). A message which exceeds this size is silently discarded.

max-msg-size

Indicates the maximum number acceptable SIP message size (in bytes). A message which exceeds this size is silently discarded.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

persistence

Configure the persistence settings.

persistence.persist-key

Specifies the method which should be used to extract the key value that is used to persist on. The options are:

Call-ID

Persist based on the \"Call-ID\" header field value in the message.

Custom

Persist based on the custom key specified using an iRule.

Src-Addr

Persist based on originating IP address in the message.

The default option is Call-ID.

persistence.persist-timeout

Specifies the timeout value of persistence entries in seconds. Upon receiving of the response for the initial SIP Request message, the persistence record is updated with the persist-timeout value.

persistence.persist-type

Specifies the type of the persistence to be used for the specified \"persist-key\" attribute value. The options are:

session

Persistence is enabled guaranteeing that messages containing a given persistence key will be delivered to the same peer.

none Persistence is disabled.

The default option is session.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

enable-sip-firewall

Indicates whether to enable the Application Firewall Security policy. When enabled, the configured AFM security features will apply to the virtual server(s) using this SIP session profile.

ltm message-routing sip route

NAME
route - Configures a static route for use in Session Initiation Protocol (SIP) message routing.

MODULE
ltm message-routing sip

SYNTAX
Configure the route component within the ltm message-routing sip module using the syntax shown in the following sections.

CREATE/MODIFY
create route [name]
modify route [name]
options:
app-service [[string] | none]
description [string]
from-uri [string]
peer-selection-mode [ratio | sequential]
peers { [none | [peer_name ...] }
request-uri [string]
to-uri [string]
virtual-server [virtual-server_name]

edit route [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties

DISPLAY
list route
list route [[[name] | [glob] | [regex]] ...]
show running-config route
show running-config route [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties
one-line
partition

show route
show route [[[name] | [glob] | [regex]] ...]
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
field-fmt

DELETE
delete route [name]

DESCRIPTION
You can use the route component to define the URI's, virtual server, peers and peer selection mode of a message routing SIP static route.

EXAMPLES
create route my_route

Creates a route instance named my_route using the system defaults.

create route my_route peers { peer1 peer2 }

Creates a route instance named my_route that will use two peers for forwarding messages.

OPTIONS
app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description
User defined description.

from-uri
Specifies the patterns to be matched against the From field of a SIP message. This URI will be matched as a case insignificant method. It should be in the form of user@domain. The "sip:" prefix should not be present. Any additional modifiers (for example port or transport) should also not be present. It may begin with a wildcard, "*". If empty, it will be treated as if the entire URI was a wildcard (matching all From-URIs).

peer-selection-mode
Specifies the mode of selecting a peer from a list of peers. The options are:

ratio
Peers are selected based on their weights in comparison with other peers.

sequential
Peers are selected in the order listed. All traffic will route the first peer unless all pool members in the peer are marked down.

peers
Specifies an ordered list of peers to use for forwarding messages.

request-uri
Specifies the patterns to be matched against the request-uri field of a SIP message. This URI will be matched as a case insensitive method. It should be in the form of user@domain. The "sip:" prefix should not be present. Any additional modifiers (for example port or transport) should also not be present. It may begin with a wildcard, * "*". If empty, it will be treated as if the entire URI was a * wildcard (matching all Request-URIs).

to-uri
Specifies the patterns to be matched against the To field of a SIP message. This URI will be matched as a case insensitive method. It should be in the form of user@domain. The "sip:" prefix should not be present. Any additional modifiers (for example port or transport) should also not be present. It may begin with a wildcard, "*". If empty, it will be treated as if the entire URI was a wildcard (matching all To-URIs).

virtual-server
Specifies the virtual server on which connections will be routed to this route. If the virtual server is unset, messages originating on any connection may be routed to the route.

SEE ALSO

BIG-IP 2016-03-14 ltm message-routing sip route(1)

ltm message-routing sip transport-config

NAME

transport-config - Configures a sip transport-config instance for routing sip message protocol messages.

MODULE

ltm message-routing sip

SYNTAX

Configure the transport-config component within the ltm message-routing sip module using the syntax shown in the following sections.

CREATE/MODIFY

```
create transport-config [name]
modify transport-config [name]
options:
  app-service [[string] | none]
  description [string]
  source-port [integer]
  profiles [add | delete | replace-all-with] {
    [profile_name ...] {
context [all | clientside | serverside]      read-only attribute for v12.0.0 or greater.
    }
  }
  rules { [none | [rule_name ... ] }
  source-address-translation {
    options:
  pool [ [pool_name] | none]
  type [ automap | snat | none ]
}
```

```
edit transport-config [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list transport-config
list transport-config [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

partition

DELETE
delete transport-config [name]

DESCRIPTION

You can use the transport-config component to define the profiles, rules, and source-address-translation of an outgoing connection.

EXAMPLES

```
create transport-config my_transport-config
```

Creates a transport-config instance named my_transport-config using the system defaults.

```
create transport-config my_transport-config { profiles add { my_sipmsg  
my_tcp } }
```

Creates a transport-config instance named my_transport-config that will use two profiles, my_sipmsg and my_tcp, to create and configure an outgoing connection. The outgoing connection is automatically configured with the router instance that created the connection.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

source-port

Specifies the source port to be used for the connection being created. If no value is specified an ephemeral port is chosen. The default value is 0.

profiles

Specifies a list of profiles that the outgoing connection uses to use to direct and manage traffic. The default value is none.

rules

Specifies a list of iRules, separated by spaces, that customize the transport configuration to direct and manage traffic. The default value is none.

source-address-translation

Specifies the type of source address translation enabled for the transport configuration, as well as the pool that the source address translation uses.

pool Specifies the name of a SNAT pool used by the specified transport configuration.

type Specifies the type of source address translation associated with the specified transport configuration.

The options are:

automap

Specifies the use of self IP addresses for transport configuration server source address translation.

none Specifies no source address translation is used by the transport configuration.

snat Specifies the use of a SNAT pool of translation

addresses for virtual server source address translation.

BIG-IP 2ltm-message-routing sip transport-config(1)

ltm monitor diameter

NAME

diameter - Configures a monitor for Diameter protocol resources.

MODULE

ltm monitor

SYNTAX

Configure the diameter component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

```
create diameter [name]
modify diameter [name]
options:
  acct-application-id [ [integer] | none ]
  app-service [[string] | none]
  auth-application-id [ [integer] | none ]
  defaults-from [name]
  description [string]
  host-ip-address [ [ip address] | none]
  interval [integer]
  manual-resume [enabled | disabled]
  origin-host [ [ip address] | none]
  origin-realm [ [hostname] | none]
  product-name [name]
  time-until-up [integer]
  timeout [integer]
  up-interval [integer]
  vendor-id [integer]
  vendor-specific-acct-application-id [ [integer] | none]
  vendor-specific-auth-application-id [ [integer] | none]
  vendor-specific-vendor-id [ [integer] | none]

edit diameter [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list diameter
list diameter [ [ [name] | [glob] | [regex] ] ... ]
show diameter [ [ [name] | [glob] | [regex] ] ... ]
show running-config diameter
show running-config diameter [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete diameter [name]
```

Note: You cannot delete default monitors.

DESCRIPTION

You can use the diameter component to configure a custom monitor, or you can use the default Diameter monitor that the Local Traffic Manager provides. This type of monitor checks the health of Diameter protocol resources.

EXAMPLES

```
create diameter my_diameter defaults-from diameter
```

Creates a monitor named `my_diameter` that inherits properties from the default Diameter monitor.

```
list diameter
```

Displays the properties of all of the Diameter monitors.

OPTIONS

acct-application-id
Specifies the ID of the accounting portion of a Diameter application. If you specify this option, you must also specify a value for the `auth-application-id` option. The default value is `none`.

Note that the `acct-application-id` and `auth-application-id` attribute-value-pair (AVP), and the `vendor-specific-auth-application-id` and `vendor-specific-acct-application-id` AVP are mutually exclusive. You can only specify one of these AVPs.

app-service
Specifies the name of the application service to which the monitor belongs. The default value is `none`. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

auth-application-id
Specifies the ID of the authentication and authorization portion of a Diameter application. If you specify this option, you must also specify a value for the `acct-application-id` option. The default value is `none`.

Note that the `acct-application-id` and `auth-application-id` attribute-value-pair (AVP), and the `vendor-specific-auth-application-id` and `vendor-specific-acct-application-id` AVP are mutually exclusive. You can only specify one set of these AVPs.

defaults-from
Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is `firepass`.

description
User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

host-ip-address

Specifies the IP address of the sender of the Diameter message for the Diameter protocol peer discovery feature. The default value is none.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 10 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

origin-host

Specifies the IP address from which the Diameter message originates. The default value is the fully-qualified domain name of the BIG-IP system.

origin-realm

Specifies the realm in which the host from which the Diameter message originates resides. The default value is f5.com.

partition

Displays the administrative partition within which the component resides.

product-name

Specifies the vendor-assigned name of the Diameter application. The value of this option must remain constant across firmware revisions for the same product. The default value is F5 BIGIP Diameter Health Monitoring.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

vendor-id

Specifies the IANA SMI Network Management Private Enterprise Code assigned to the vendor of the Diameter application. The default value is 3375.

vendor-specific-acct-application-id

Specifies the ID of the vendor-specific accounting portion of a Diameter application. If you specify this option, you must also specify a value for the vendor-specific-auth-application-id option. The default value is none.

Note that the acct-application-id and auth-application-id attribute-value-pair (AVP), and the vendor-specific-auth-application-id and vendor-specific-acct-application-id AVP are mutually exclusive. You can only specify one of these AVPs.

vendor-specific-auth-application-id

Specifies the ID of the vendor-specific authentication and authorization portion of a Diameter application. If you specify this option, you must also specify a value for the vendor-specific-acct-application-id option. The default value is none.

Note that the acct-application-id and auth-application-id attribute-value-pair (AVP), and the vendor-specific-auth-application-id and vendor-specific-acct-application-id AVP are mutually exclusive. You can only specify one of these AVPs.

vendor-specific-vendor-id
Specifies the ID of a vendor-specific Diameter application. The system uses this ID to advertise support for the application. The default value is none.

BIG-IP 2017-04-05 ltm monitor diameter(1)

ltm monitor dns

NAME

dns - Configures a Domain Name System (DNS) monitor.

MODULE

ltm monitor

SYNTAX

Configure the dns component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

create dns [name]

modify dns [name]

options:

accept-rcode [no-error | anything]

adaptive [enabled | disabled]

adaptive-divergence-type [relative | absolute]

adaptive-divergence-value [integer]

adaptive-limit [integer]

adaptive-sampling-timespan [integer]

answer-contains [query-type | any-type | anything]

app-service [[string] | none]

defaults-from [name]

description [string]

destination [[ipv4 address[:port]] | [ipv6 address[.port]]]

interval [integer]

manual-resume [enabled | disabled]

qname [string]

qtype [a | aaaa]

recv [none | [string]]

reverse [enabled | disabled]

time-until-up [integer]

timeout [integer]

transparent [disabled | enabled]

up-interval [integer]

edit dns [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list dns

list dns [[[name] | [glob] | [regex]] ...]

show dns [[[name] | [glob] | [regex]] ...]

show running-config dns

show running-config dns [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

test-result

DELETE

delete dns [name]

Note: You cannot delete default monitors.

RUN

run dns [name] [destination [[ipv4 address[:port]] | [ipv6 address[.port]]]]

STOP

stop dns [name]

DESCRIPTION

You can use the dns component to configure a custom monitor. This type of monitor verifies the DNS service by attempting to send DNS requests generated using the parameters provided to a pool, pool member, or virtual server and validating the DNS response.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create dns my_dns defaults-from dns qname www.test.com
```

Creates a monitor named my_dns that inherits properties other than qname from the default DNS monitor.

```
list dns
```

Displays the properties of all of the DNS monitors.

```
run dns my_dns destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_dns against a target node at 10.10.10.10:80.

```
stop dns my_dns
```

Cancels a one-shot test of the custom monitor my_dns in progress.

```
show dns my_dns test-result
```

Displays the result of the most recent one-shot test of the custom monitor my_dns.

OPTIONS

accept_rcode
Specifies the RCODE required in the response for an 'up' status. The default value is no-error.

The options are:

no-error
Specifies that the status of the node will be marked up if the received dns message has RCODE = NOERROR.

anything
Specifies that the status of the node will be marked up irrespective of the RCODE in the dns message received.

adaptive
Specifies whether the adaptive feature is enabled for this monitor. Not all monitors support the adaptive feature.

adaptive-divergence-type
Specifies whether the adaptive-divergence-value is relative or absolute.

adaptive-divergence-value
Specifies how far from mean latency each monitor probe is allowed to be. If adaptive-divergence-type is relative, this value is a percentage deviation from mean (e.g. 50 would indicate the probe is allowed to exceed the mean latency by 50%.) If adaptive-divergence-type is absolute, this value is an offset from mean in milliseconds (e.g. 250 would indicate the probe is allowed to exceed the mean latency by 250 ms.) A probe that exceeds latency is counted the same as a probe that is not received, so in the typical scenario, it will require three missed latencies in a row to mark a pool member or node down (i.e. a 15-second interval with a 46-second timeout, would require three missed probes before the pool member or node would be marked down.)

adaptive-limit
Specifies the hard limit, in milliseconds, which the probe is not allowed to exceed, regardless of the divergence value. For example, if this value is 500, then the probe latency may not exceed 500 ms even if that would still fall within the divergence value.

adaptive-sampling-timespan
Specifies the size of the sliding window, in seconds, which records probe history. For example, if this value is 300, then a sliding window of the last five minutes' probe history will be used for calculating probe mean latency and standard deviation.

answer_contains
Specifies the record types required in the answer section of the response in order to mark the status of a node up. The default value is query-type.

The options are:

query-type
Specifies that the response should contain at least one answer of which the resource record type matches the qtype.

any-type
Specifies that the dns message should contain at least one

answer.

anything
Specifies that an empty answer section is enough to mark the status of the node up.

app-service
Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

defaults-from
Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is dns.

description
User defined description.

destination
Specifies the IP address and service port of the resource that is the destination of this monitor. Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

***:port**
Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port
Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

IP address:port (with the transparent option enabled)
Specifies to perform a health check on the server at the IP address and port you specify, route the check through the IP address and port supplied by the pool member, and mark the pool member (the gateway) up or down accordingly.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval
Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume
Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition
Displays the administrative partition within which the component resides.

qname
Specifies the query name that the monitor send a DNS query for. The default value is Enter a query name.

qtype
Specifies the query type of that the monitor sends a query. The default value is a.

The options are:

a Specifies that the monitor will send a DNS query of type A.

aaaa Specifies that the monitor will send a DNS query of type AAAA.

recv Specifies the ip address that the monitor looks for in the dns response's resource record sections. The ip address should be specified in the dotted-decimal notation or ipv6 notation. The default value is none. If no recv value is specified, then the dns message will be checked against accept_rcode and answer_contains monitor parameters respectively.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reverse

Specifies whether the monitor operates in reverse mode. When the monitor is in reverse mode, a successful receive string match marks the monitored object down instead of up. You can use this mode only if you configure `recv` option.

The default value is disabled, which specifies that the monitor does not operate in reverse mode. The enabled value specifies that the monitor operates in reverse mode.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds. If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

transparent

Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

`ltm monitor`

SYNTAX

Configure the external component within the `ltm monitor` module using the syntax in the following sections.

CREATE/MODIFY

```
create external [name]
modify external [name]
options:
  args [ [arguments] | none]
  app-service [[string] | none]
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[.port] ] ]
  interval [integer]
  manual-resume [enabled | disabled]
  run [none | [external monitor] ]
  time-until-up [integer]
  timeout [integer]
  user-defined [ [name] [value] | [name] none ]
  up-interval [integer]
```

```
edit external [ [ [name] | [glob] | [regex] ] ... ]
options:
```

all-properties
non-default-properties

DISPLAY

```
list external
list external [ [ [name] | [glob] | [regex] ] ... ]
show external [ [ [name] | [glob] | [regex] ] ... ]
show running-config external
show running-config external [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
  test-result
```

DELETE

```
delete external [name]
```

Note: You cannot delete default monitors.

RUN

```
run external [name] [ destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ] ]
```

STOP

```
stop external [name]
```

DESCRIPTION

You can use the external component to configure a custom monitor, or you can use the default external monitor that the Local Traffic Manager provides. Using this type of monitor, you can use your own programs to monitor services.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create external my_external defaults-from external
```

Creates a monitor named my_external that inherits properties from the default external monitor.

```
list external
```

Displays the properties of all of the external monitors.

```
run external my_external destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_external against a target node at 10.10.10.10:80.

```
stop external my_external
```

Cancels a one-shot test of the custom monitor my_external in progress.

```
show external my_external test-result
```

Displays the result of the most recent one-shot test of the custom monitor my_external.

OPTIONS

args Specifies any command-line arguments that the external program requires. The default value is none.

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is external.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

: Specifies to perform a health check on the address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the

specified custom monitor.

`glob` Displays the items that match the `glob` expression. See `help glob` for a description of `glob` expression syntax.

`interval`

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the `up-interval` option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

`manual-resume`

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the `manual-resume` option is disabled.

Note that if you set the `manual-resume` option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, `modify`, `run` and `stop`.

`partition`

Displays the administrative partition within which the component resides.

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See `help regex` for a description of regular expression syntax.

`run` Specifies the external monitor file to be executed by the external monitor. The default value is none.

`test-result`

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

`time-until-up`

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

`timeout`

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

`up-interval`

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 zero, which specifies that the system uses the value of the `interval` option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the `interval` option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

`user-defined`

Specifies any user-defined command-line arguments and variables that the external program requires. Use the following syntax to specify a user defined parameter.

```
modify external my_external user-defined my_param_name  
my_param_value
```

Use the following syntax to remove a user defined parameter.

```
modify external my_external user-defined my_param_name none
```

ltm monitor firepass

NAME
firepass - Configures a FirePass(r) monitor.

MODULE
ltm monitor

SYNTAX
Configure the firepass component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

create firepass [name]

modify firepass [name]

options:

app-service [[string] | none]

cipherlist [list]

concurrency-limit [integer]

defaults-from [name]

description [string]

destination [[ipv4 address[:port]] | [ipv6 address[:port]]]

interval [integer]

max-load-average [integer]

password [password]

time-until-up [integer]

timeout [integer]

up-interval [integer]

username [[name] | none]

edit firepass [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list firepass

list firepass [[[name] | [glob] | [regex]] ...]

show firepass [[[name] | [glob] | [regex]] ...]

show running-config firepass

show running-config firepass [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

test-result

DELETE

delete firepass [name]

Note: You cannot delete default monitors.

RUN

run firepass [name] [destination [[ipv4 address[:port]] | [ipv6 address[:port]]]]

STOP

stop firepass [name]

DESCRIPTION

You can use the firepass component to configure a custom monitor, or you can use the default Firepass monitor that the Local Traffic Manager provides. This type of monitor checks the health of FirePass systems.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create firepass my_firepass defaults-from firepass
```

Creates a monitor named my_firepass that inherits properties from the default Firepass monitor.

```
list firepass
```

Displays the properties of all of the Firepass monitors.

```
run firepass my_firepass destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_firepass against a target node at 10.10.10.10:80.

```
stop firepass my_firepass
```

Cancels a one-shot test of the custom monitor my_firepass in progress.

```
show firepass my_firepass test-result
```

Displays the result of the most recent one-shot test of the custom monitor my_firepass.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

cipherlist

Specifies the list of ciphers for this monitor. The default value is HIGH:!ADH.

concurrency-limit

Specifies the maximum percentage of licensed connections currently in use under which the monitor marks the FirePass system up. The default value is 95.

For example, a value of 95 percent means that the monitor marks the FirePass system up until 95 percent of licensed connections are in use. When the number of in-use licensed connections exceeds 95 percent, the monitor marks the FirePass system down.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is firepass.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

: Specifies to perform a health check on the address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

max-load-average

Specifies the number that the monitor uses to mark the FirePass system up or down. The system compares the value of this option to a one-minute average of the FirePass system load. When the FirePass system-load average falls within the specified value, the monitor marks the FirePass system up. When the average exceeds the value, the monitor marks the system down.

The default value is 12.0.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

password

Specifies the password, if the monitored target requires authentication. The default value is none.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval
Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username
Specifies the username, if the monitored target requires authentication. The default value is gtmuser.

ltm monitor ftp

NAME
ftp - Configures a File Transfer Protocol (FTP) monitor.

MODULE
ltm monitor

SYNTAX
Configure the ftp component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY
create ftp [name]
modify ftp [name]
options:
 app-service [[string] | none]
 debug [no | yes]
 defaults-from [name]
 description [string]
 destination [[ipv4 address[:port]] | [ipv6 address[.port]]]
 filename [[filename] | none]
 interval [integer]
 manual-resume [enabled | disabled]
 mode [passive | port]
 password [none | [password]]
 time-until-up [integer]
 timeout [integer]
 up-interval [integer]
 username [name]

edit ftp [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 non-default-properties

DISPLAY
list ftp
list ftp [[[name] | [glob] | [regex]] ...]
show ftp [[[name] | [glob] | [regex]] ...]
show running-config ftp
show running-config ftp [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 non-default-properties
 one-line
 partition
 test-result

DELETE
delete ftp [name]

Note: You cannot delete default monitors.

```
RUN
run ftp [name] [ destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ] ] ]
STOP
stop ftp [name]
```

DESCRIPTION

You can use the ftp component to configure a custom monitor, or you can use the default FTP monitor that the Local Traffic Manager provides. This type of monitor verifies the FTP service by attempting to download a specific file to the /var/tmp directory on the system. Once downloaded successfully, the file is not saved.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create ftp my_ftp defaults-from ftp
```

Creates a monitor named my_ftp that inherits properties from the default FTP monitor.

```
list ftp
```

Displays the properties of all of the FTP monitors.

```
run ftp my_ftp destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_ftp against a target node at 10.10.10.10:80.

```
stop ftp my_ftp
```

Cancels a one-shot test of the custom monitor my_ftp in progress.

```
show ftp my_ftp test-result
```

Displays the result of the most recent one-shot test of the custom monitor my_ftp.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks.

The default value is no. The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is ftp.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

: Specifies to perform a health check on the address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

filename

Specifies the full path and file name of the file that the system attempts to download. The health check is successful if the system

can download the file. The default value is none.

`glob` Displays the items that match the glob expression. See help `glob` for a description of glob expression syntax.

`interval`

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the `up-interval` option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

`manual-resume`

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the `manual-resume` option is disabled.

Note that if you set the `manual-resume` option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

`mode` Specifies the data transfer process (DTP) mode. The default value is passive.

The options are:

`passive`

Specifies that the monitor sends a data transfer request to the FTP server. When the FTP server receives the request, the FTP server then starts and establishes the data connection.

`port` Specifies that the monitor starts and establishes the data connection with the FTP server.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, `modify`, `run` and `stop`.

`password`

Specifies the password, if the monitored target requires authentication. The default value is none.

`partition`

Displays the administrative partition within which the component resides.

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@`[regular expression]) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

`test-result`

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

`time-until-up`

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

`timeout`

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

`up-interval`

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 zero, which specifies that the system uses the value of the `interval` option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the `interval` option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

`username`

Specifies the username, if the monitored target requires authentication. The default value is none.

ltm monitor gateway-icmp

NAME

gateway-icmp - Configures a Gateway Internet Control Message Protocol (ICMP) monitor.

MODULE

ltm monitor

SYNTAX

Configure the gateway-icmp component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

```
create gateway-icmp [name]
```

```
modify gateway-icmp [name]
```

options:

```
adaptive [enabled | disabled]
```

```
adaptive-divergence-type [relative | absolute]
```

```
adaptive-divergence-value [integer]
```

```
adaptive-limit [integer]
```

```
adaptive-sampling-timespan [integer]
```

```
app-service [[string] | none]
```

```
defaults-from [name]
```

```
description [string]
```

```
destination [ [ ipv4 address[:port] ] | [ ipv6 address[.port] ] ]
```

```
interval [integer]

```

```
test-result
```

DELETE

```
delete gateway-icmp [name]
```

Note: You cannot delete default monitors.

RUN

```
run gateway-icmp [name] [ destination [ [ ipv4 address[:port] ] | [ ipv6 address[.port] ] ] ]
```

STOP

```
stop gateway-icmp [name]
```

DESCRIPTION

You can use the gateway-icmp component to configure a custom monitor, or you can use the default Gateway ICMP monitor that the Local Traffic Manager provides. This type of monitor monitors a pool that implements gateway fail-safe for high availability.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create gateway-icmp my_icmp defaults-from gateway_icmp
```

Creates a monitor named my_icmp that inherits properties from the default Gateway ICMP monitor.

```
list gateway-icmp
```

Displays the properties of all of the Gateway ICMP monitors.

```
run gateway-icmp my_gateway-icmp destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_gateway-icmp against a

target node at 10.10.10.10:80.

stop gateway-icmp my_gateway-icmp

Cancels a one-shot test of the custom monitor my_gateway-icmp in progress.

show gateway-icmp my_gateway-icmp test-result

Displays the result of the most recent one-shot test of the custom monitor my_gateway-icmp.

OPTIONS

adaptive

Specifies whether the adaptive feature is enabled for this monitor. Not all monitors support the adaptive feature.

adaptive-divergence-type

Specifies whether the adaptive-divergence-value is relative or absolute.

adaptive-divergence-value

Specifies how far from mean latency each monitor probe is allowed to be. If adaptive-divergence-type is relative, this value is a percentage deviation from mean (e.g. 50 would indicate the probe is allowed to exceed the mean latency by 50%). If adaptive-divergence-type is absolute, this value is an offset from mean in milliseconds (e.g. 250 would indicate the probe is allowed to exceed the mean latency by 250 ms.) A probe that exceeds latency is counted the same as a probe that is not received, so in the typical scenario, it will require three missed latencies in a row to mark a pool member or node down (i.e. a 15-second interval with a 46-second timeout, would require three missed probes before the pool member or node would be marked down.)

adaptive-limit

Specifies the hard limit, in milliseconds, which the probe is not allowed to exceed, regardless of the divergence value. For example, if this value is 500, then the probe latency may not exceed 500 ms even if that would still fall within the divergence value.

adaptive-sampling-timespan

Specifies the size of the sliding window, in seconds, which records probe history. For example, if this value is 300, then a sliding window of the last five minutes' probe history will be used for calculating probe mean latency and standard deviation.

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is gateway_icmp.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

IP address:port (with the transparent option enabled)

Specifies to perform a health check on the server at the IP address and port specified in the monitor, routing the check through the IP address and port supplied by the pool member. The pool member (the gateway) is marked up or down accordingly.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume
Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition
Displays the administrative partition within which the component resides.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

test-result
Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up
Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

transparent
Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

up-interval
Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

  non-default-properties
  one-line
  partition
  test-result

DELETE
delete http [name]

    Note: You cannot delete default monitors.

RUN
run http [name] [ destination [ [ ipv4 address[:port] ] | [ ipv6 address[.port] ] ] ]

STOP
stop http [name]

DESCRIPTION
    You can use the http component to configure a custom monitor, or you
    can use the default HTTP monitor that the Local Traffic Manager
    provides. This type of monitor verifies the HTTP service by attempting
    to receive specific content from a Web page.

    You can test a custom monitor configuration against a specified target
    destination by using the run command, and view the results of such a
    test by using the show command with the test-result option.

    The following user roles (in addition to the root user) have
    permissions to run and stop an ltm monitor test:

    admin, application-editor, manager, operator, resource-admin

EXAMPLES
    create http my_http defaults-from http

    Creates a monitor named my_http that inherits properties from the
    default HTTP monitor.

    list http

    Displays the properties of all of the HTTP monitors.

    run http my_http destination 10.10.10.10:80

    Runs a one-shot test of the custom monitor my_http against a target
    node at 10.10.10.10:80.

    stop http my_http

    Cancels a one-shot test of the custom monitor my_http in progress.

    show http my_http test-result

    Displays the result of the most recent one-shot test of the custom
    monitor my_http.

OPTIONS
    adaptive
    Specifies whether the adaptive feature is enabled for this
    monitor. Not all monitors support the adaptive feature.

    adaptive-divergence-type
    Specifies whether the adaptive-divergence-value is relative or
    absolute.

    adaptive-divergence-value
    Specifies how far from mean latency each monitor probe is allowed
    to be. If adaptive-divergence-type is relative, this value is a
    percentage deviation from mean (e.g. 50 would indicate the probe

```

is allowed to exceed the mean latency by 50%.) If adaptive-divergence-type is absolute, this value is an offset from mean in milliseconds (e.g. 250 would indicate the probe is allowed to exceed the mean latency by 250 ms.) A probe that exceeds latency is counted the same as a probe that is not received, so in the typical scenario, it will require three missed latencies in a row to mark a pool member or node down (i.e. a 15-second interval with a 46-second timeout, would require three missed probes before the pool member or node would be marked down.)

adaptive-limit

Specifies the hard limit, in milliseconds, which the probe is not allowed to exceed, regardless of the divergence value. For example, if this value is 500, then the probe latency may not exceed 500 ms even if that would still fall within the divergence value.

adaptive-sampling-timespan

Specifies the size of the sliding window, in seconds, which records probe history. For example, if this value is 300, then a sliding window of the last five minutes' probe history will be used for calculating probe mean latency and standard deviation.

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is http.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

IP address:port (with the transparent option enabled)

Specifies to perform a health check on the server at the IP address and port specified in the monitor, routing the check through the IP address and port supplied by the pool member. The pool member (the gateway) is marked up or down accordingly.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

ip-dscp

Specifies the differentiated services code point (DSCP). DSCP is a 6-bit value in the Differentiated Services (DS) field of the IP header. It can be used to specify the quality of service desired for the packet. The valid range for this value is 0 to 63 (hex 0x0 to 0x3f). The default value is zero.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition

Displays the administrative partition within which the component resides.

password

Specifies the password if the monitored target requires

authentication. The default value is none.

`recv` Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in an HTML file on your site. The text string can be regular text, HTML tags, or image names, and the associated operation is not case-sensitive. If you do not specify a value for both the `send` and `recv` options, the monitor performs a simple service check and connect only.

`recv-disable`
Specifies a text string that the monitor looks for in the returned resource. If the text string is matched in the returned resource, the corresponding node or pool member is marked session disabled. The default value is none.

You specify a `recv-disable` string in the same way that you specify a `recv` string.

If you specify a `recv-disable` string, you must also specify a `recv` string. You cannot specify a `recv-disable` string, if the reverse option is enabled.

`regex`
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@`[regular expression]) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

`reverse`
Specifies whether the monitor operates in reverse mode. When the monitor is in reverse mode, a successful check marks the monitored object down instead of up. You can use the this mode only if you configure both the `send` and `recv` options.

The default value is disabled, which specifies that the monitor does not operate in reverse mode. The enabled value specifies that the monitor operates in reverse mode.

`send` Specifies the text string that the monitor sends to the target object.

The default setting is `GET /`, which retrieves a default HTML file for a web site. To retrieve a specific page from a web site, specify a fully-qualified path name, for example, `GET /www/company/index.html`.

Since the string may have special characters, the system may require that the string be enclosed with single quotation marks.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the `recv` option and ignores the option even if not null.

`test-result`
Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

`time-until-up`
Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

`timeout`
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

`transparent`
Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

`up-interval`
Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

`username`
Specifies the username, if the monitored target requires authentication. The default value is none.

RUN

```
run https [name] [ destination [ [ ipv4 address[:port] ] | [ ipv6 address[.port] ] ] ]
```

STOP

```
stop https [name]
```

DESCRIPTION

You can use the https component to configure a custom monitor, or you can use the default HTTPS monitor that the Local Traffic Manager provides. This type of monitor verifies the HTTPS service by attempting to receive specific content from a Web page protected by Secure Socket Layer (SSL) security.

Note that one of the pre-configured HTTPS monitors is named https_443, which performs a health check on a server using the IP address supplied

by the pool member and port 443.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create https my_https defaults-from https
```

Creates a monitor named my_https that inherits properties from the default HTTPS monitor.

```
list https
```

Displays the properties of all of the HTTPS monitors.

```
run https my_https destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_https against a target node at 10.10.10.10:80.

```
stop https my_https
```

Cancels a one-shot test of the custom monitor my_https in progress.

```
show https my_https test-result
```

Displays the result of the most recent one-shot test of the custom monitor my_https.

OPTIONS

adaptive

Specifies whether the adaptive feature is enabled for this monitor. Not all monitors support the adaptive feature.

adaptive-divergence-type

Specifies whether the adaptive-divergence-value is relative or absolute.

adaptive-divergence-value

Specifies how far from mean latency each monitor probe is allowed to be. If adaptive-divergence-type is relative, this value is a percentage deviation from mean (e.g. 50 would indicate the probe is allowed to exceed the mean latency by 50%.) If adaptive-divergence-type is absolute, this value is an offset from mean in milliseconds (e.g. 250 would indicate the probe is allowed to exceed the mean latency by 250 ms.) A probe that exceeds latency is counted the same as a probe that is not received, so in the typical scenario, it will require three missed latencies in a row to mark a pool member or node down (i.e. a 15-second interval with a 46-second timeout, would require three missed probes before the pool member or node would be marked down.)

adaptive-limit

Specifies the hard limit, in milliseconds, which the probe is not allowed to exceed, regardless of the divergence value. For example, if this value is 500, then the probe latency may not exceed 500 ms even if that would still fall within the divergence value.

adaptive-sampling-timespan

Specifies the size of the sliding window, in seconds, which records probe history. For example, if this value is 300, then a sliding window of the last five minutes' probe history will be used for calculating probe mean latency and standard deviation.

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

cert Deprecated since v13.1.0. Use ssl-profile instead. Specifies a file object for a client certificate that the monitor sends to the target SSL server. The default value is none.

cipherlist

Deprecated since v13.1.0. Use ssl-profile instead.

compatibility

Deprecated since v13.1.0. Use ssl-profile instead. Specifies, when enabled, that the SSL options setting (in OpenSSL) is set to ALL. The default value is enabled.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is https.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

. Specifies to perform a health check on the IP address and

port supplied by a pool member.

***:port**
Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port
Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

IP address:port (with the transparent option enabled)
Specifies to perform a health check on the server at the IP address and port specified in the monitor, routing the check through the IP address and port supplied by the pool member. The pool member (the gateway) is marked up or down accordingly.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval
Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

ip-dscp
Specifies the differentiated services code point (DSCP). DSCP is a 6-bit value in the Differentiated Services (DS) field of the IP header. It can be used to specify the quality of service desired for the packet. The valid range for this value is 0 to 63 (hex 0x0 to 0x3f). The default value is zero.

key Deprecated since v13.1.0. Use ssl-profile instead. Specifies the RSA private key if the monitored target requires authentication. The key must be surrounded by quotation marks, for example, key \"client.key\". Note that if you specify a key, you must also specify a value for the cert option. The default value is none.

manual-resume
Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition
Displays the administrative partition within which the component resides.

password
Specifies the password if the monitored target requires authentication. The default value is none.

recv Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in an HTML file on your site. The text string can be regular text, HTML tags, or image names, and the associated operation is not case-sensitive. If you do not specify a value for both the send and recv options, the monitor performs a simple service check and connect only.

recv-disable
Specifies a text string that the monitor looks for in the returned resource. If the text string is matched in the returned resource, the corresponding node or pool member is marked session disabled. The default value is none.

You specify a recv-disable string in the same way that you specify a recv string.

If you specify a recv-disable string, you must also specify a recv string. You cannot specify a recv-disable string, if the reverse option is enabled.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reverse
Specifies whether the monitor operates in reverse mode. When the monitor is in reverse mode, a successful check marks the monitored object down instead of up. You can use the this mode only if you configure both the send and recv options.

The default value is disabled, which specifies that the monitor

does not operate in reverse mode. The enabled value specifies that the monitor operates in reverse mode.

send Specifies the text string that the monitor sends to the target object.

The default setting is GET /, which retrieves a default HTML file for a web site. To retrieve a specific page from a web site, specify a fully-qualified path name, for example, GET /www/company/index.html.

Since the string may have special characters, the system may require that the string be enclosed with single quotation marks.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if not null.

ssl-profile
Specifies the server side SSL profile that this monitor will use to ping the monitored node or target.

test-result
Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up
Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

transparent
Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

up-interval
Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username
Specifies the username, if the monitored target requires authentication. The default value is none.

DELETE
delete icmp [name]

```

Note: You cannot delete default monitors.

```

RUN
run icmp [name] [destination [ip address]]

```

```

STOP
stop icmp [name]

```

DESCRIPTION

You can use the icmp component to configure a custom monitor, or you can use the default ICMP monitor that the Local Traffic Manager provides.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create icmp my_icmp defaults-from icmp
```

Creates a monitor named my_icmp that inherits properties from the default ICMP monitor.

```
list icmp
```

Displays the properties of all of the ICMP monitors.

```
run icmp my_icmp destination 10.10.10.10
```

Runs a one-shot test of the custom monitor my_icmp against a target node at IP address 10.10.10.10.

```
stop icmp my_icmp
```

Cancels a one-shot test of the custom monitor my_icmp in progress.

```
show icmp my_icmp test-result
```

Displays the result of the most recent one-shot test of the custom monitor my_icmp.

OPTIONS

adaptive
Specifies whether the adaptive feature is enabled for this monitor. Not all monitors support the adaptive feature.

adaptive-divergence-type
Specifies whether the adaptive-divergence-value is relative or absolute.

adaptive-divergence-value
Specifies how far from mean latency each monitor probe is allowed to be. If adaptive-divergence-type is relative, this value is a percentage deviation from mean (e.g. 50 would indicate the probe is allowed to exceed the mean latency by 50%). If adaptive-divergence-type is absolute, this value is an offset from mean in milliseconds (e.g. 250 would indicate the probe is allowed to exceed the mean latency by 250 ms.) A probe that exceeds latency is counted the same as a probe that is not received, so in

the typical scenario, it will require three missed latencies in a row to mark a pool member or node down (i.e. a 15-second interval with a 46-second timeout, would require three missed probes before the pool member or node would be marked down.)

adaptive-limit

Specifies the hard limit, in milliseconds, which the probe is not allowed to exceed, regardless of the divergence value. For example, if this value is 500, then the probe latency may not exceed 500 ms even if that would still fall within the divergence value.

adaptive-sampling-timespan

Specifies the size of the sliding window, in seconds, which records probe history. For example, if this value is 300, then a sliding window of the last five minutes' probe history will be used for calculating probe mean latency and standard deviation.

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is icmp.

description

User defined description.

destination

Specifies the IP address of the resource that is the destination of this monitor. The default value is *.

Possible values are:

- * Specifies to perform a health check on the IP address of the node.

IP address

Specifies to perform a health check on the IP address that you specify, and mark the associated node up or down accordingly.

IP address (with the transparent option enabled)

Specifies to perform a health check on the IP address that you specify, route the check through the IP address of the associated node, and mark the IP address of the associated node up or down accordingly.

This option is required for the command run, unless an IP address is specified in the destination option for the custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

transparent

Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

BIG-IP 2017-04-05 ltm monitor icmp(1)

ltm monitor imap

NAME

imap - Configures an Internet Message Access Protocol (IMAP) monitor.

MODULE

ltm monitor

SYNTAX

Configure the imap component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

```
create imap [name]
modify imap [name]
options:
  app-service [[string] | none]
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[.port] ] ]
  folder [ [name] | none]
  interval [integer]
  manual-resume [enabled | disabled]
  password [none | [password] ]
  time-until-up [integer]
  timeout [integer]
  up-interval [integer]
  username [ [name] | none]
```

```
edit imap [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list imap
list imap [ [ [name] | [glob] | [regex] ] ... ]
show imap [ [ [name] | [glob] | [regex] ] ... ]
show running-config imap
show running-config imap [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
  test-result
```

DELETE

```
delete imap [name]
```

Note: You cannot delete default monitors.

RUN
run imap [name] [destination [[ipv4 address[:port]] | [ipv6 address[:port]]]]

STOP
stop imap [name]

DESCRIPTION

You can use the imap component to configure a custom monitor, or you can use the default IMAP monitor that the Local Traffic Manager provides. This type of monitor verifies IMAP by attempting to open a specified mail folder on a server. This monitor is similar to the POP3 monitor.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create imap my_imap defaults-from imap
```

Creates a monitor named my_imap that inherits properties from the default IMAP monitor.

```
list imap
```

Displays the properties of all of the IMAP monitors.

```
run imap my_imap destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_imap against a target node at 10.10.10.10:80.

```
stop imap my_imap
```

Cancel a one-shot test of the custom monitor my_imap in progress.

```
show imap my_imap test-result
```

Displays the result of the most recent one-shot test of the custom monitor my_imap.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks.

The default value is no. The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is imap.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

folder

Specifies the name of the folder on the IMAP server that the monitor tries to open. The default value is INBOX.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 10 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition

Displays the administrative partition within which the component resides.

password

Specifies the password if the monitored target requires authentication. The default value is none.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username

Specifies the username, if the monitored target requires authentication. The default value is none.

BIG-IP 2017-08-16 ltm monitor imap(1)

ltm monitor inband

inband - Configures an Inband (passive) monitor.

MODULE

ltm monitor

SYNTAX

Configure the inband component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

```
create inband [name]
modify inband [name]
options:
  app-service [[string] | none]
  defaults-from [name]
  description [string]
  failure-interval [integer]
  failures [integer]
  response-time [integer]
  retry-time [integer]
```

```
edit inband [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list inband
list inband [ [ [name] | [glob] | [regex] ] ... ]
show inband [ [ [name] | [glob] | [regex] ] ... ]
show running-config inband
show running-config inband [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete inband [name]
```

Note: You cannot delete default monitors.

DESCRIPTION

You can use the inband component to configure a custom monitor, or you can use the default Inband monitor that the Local Traffic Manager provides. With this type of monitor the BIG-IP(r) system can perform passive monitoring as part of client requests.

EXAMPLES

```
create inband my_inband defaults-from inband
```

Creates a monitor named my_inband that inherits properties from the default Inband monitor.

```
list inband
```

Displays the properties of all of the Inband monitors.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is inband.

description

User defined description.

failure-interval

Specifies an interval, in seconds. If the number of failures specified in the failures option occurs within this interval, the system marks the pool member as being unavailable. The default value is 30.

failures

Specifies the number of failures that the system allows to occur, within the time period specified in the failure-interval option, before marking a pool member unavailable. The default value is 3, which means that the system marks the pool member unavailable at the fourth failure. The multiple tmm processes use a per-process number to calculate failures, depending on the specified load. For example, for the Round Robin load balancing method, if there are N tmm processes and M pool members, and the Failures setting is set to L, then up to N*M*L+1 failures can occur before the system marks the node as down.

Specifying a value of 0 (zero) disables this option.

A failure can be either a failure to connect or a failure of the pool member to respond within the time specified in the response-time option.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition
Displays the administrative partition within which the component resides.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

response-time
Specifies an amount of time, in seconds. If the pool member does not respond with data after the specified amount of time has passed, the number of failures in this interval increments by 1. Specifying a value of 0 (zero) disables this option.

retry-time
Specifies the amount of time in seconds after the pool member has been marked unavailable before the system retries to connect to the pool member. Specifying a value of 0 (zero) disables this option.

SEE ALSO

create, delete, edit, glob, list, modify, regex, show, tmsh

BIG-IP 2017-04-05 ltm monitor inband(1)

ltm monitor ldap

NAME

ldap - Configures a Lightweight Directory Access Protocol (LDAP) monitor.

MODULE

ltm monitor

SYNTAX

Configure the ldap component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

```
create ldap [name]
modify ldap [name]
options:
  app-service [[string] | none]
  base [none | [string] ]
  chase-referrals [no | yes]
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[.port] ] ]
  filter [ [LDAP key] | none]
  interval [integer]
  mandatory-attributes [no | yes]
  manual-resume [enabled | disabled]
  password [none | [password] ]
  security [none | ssl | tls]
  time-until-up [integer]
  timeout [integer]
  up-interval [integer]
  username [ [name] | none]
```

```
edit ldap [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list ldap
list ldap [ [ [name] | [glob] | [regex] ] ... ]
show ldap [ [ [name] | [glob] | [regex] ] ... ]
show running-config ldap
show running-config ldap [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
  test-result
```

DELETE

delete ldap [name]

Note: You cannot delete default monitors.

RUN

run ldap [name] [destination [[ipv4 address[:port]] | [ipv6 address[:port]]]]

STOP

stop ldap [name]

DESCRIPTION

You can use the ldap component to configure a custom monitor, or you can use the default LDAP monitor that the Local Traffic Manager provides. This type of monitor verifies the LDAP service by attempting to authenticate the specified user.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

create ldap my_ldap defaults-from ldap

Creates a monitor named my_ldap that inherits properties from the default LDAP monitor.

list ldap

Displays the properties of all of the LDAP monitors.

run ldap my_ldap destination 10.10.10.10:80

Runs a one-shot test of the custom monitor my_ldap against a target node at 10.10.10.10:80.

stop ldap my_ldap

Cancels a one-shot test of the custom monitor my_ldap in progress.

show ldap my_ldap test-result

Displays the result of the most recent one-shot test of the custom monitor my_ldap.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

base Specifies the location in the LDAP tree from which the monitor starts the health check. A sample value is dc=bigip-test,dc=net. The default value is none.

chase-referrals

Specifies whether the monitor upon receipt of an LDAP referral entry chases that referral. The default value is yes.

The options are:

no Specifies that the system will treat a referral entry as a normal entry and refrain from querying the remote LDAP server(s) pointed to by the referral entry.

yes Specifies that the system upon receiving any referral entry from the monitored LDAP server query, the system will then query the corresponding LDAP server(s) pointed to by the LDAP query. If the query for the referral is unsuccessful the system will mark the monitored LDAP server down.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is ldap.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

: Specifies to perform a health check on the address and port supplied by a pool member.

***:port**
Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port
Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

filter
Specifies an LDAP key for which the monitor searches. A sample value is `objectclass=*`. The default value is none.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval
Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 10 seconds.

Important: F5 Networks recommends that when you configure this option and the `up-interval` option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

mandatory-attributes
Specifies whether the target must include attributes in its response to be considered up. The default value is no.

The options are:

no Specifies that the system performs only a one-level search (based on the value of the filter option), and does not require that the target returns any attributes.

yes Specifies that the system performs a sub-tree search, and if the target returns no attributes, the target is considered down.

manual-resume
Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition
Displays the administrative partition within which the component resides.

password
Specifies the password if the monitored target requires authentication. The default value is none.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

security
Specifies the secure communications protocol that the monitor uses to communicate with the target. The default value is none. The options are:

none Specifies that the system does not use a security protocol for communications with the target.

ssl Specifies that the system uses the SSL protocol for communications with the target.

tls Specifies that the system uses the TLS protocol for communications with the target.

test-result
Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up
Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is

considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval
Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username
Specifies the username, if the monitored target requires authentication. The default value is none.

BIG-IP 2017-08-16 ltm monitor ldap(1)

ltm monitor module-score

NAME
module-score - Configures a Module Score monitor that monitors the performance of a pool or node, rather than the health of the pool or node.

MODULE
ltm monitor

SYNTAX
Configure the module-score component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY
create module-score [name]
modify module-score [name]
options:
app-service [[string] | none]
debug [no | yes]
defaults-from [name]
description [string]
interval [integer]
pool [name]
snmp-community [none | [string]]
snmp-ip-address [[ip address] | none]
snmp-port [port]
snmp-version [string]
time-until-up [integer]
timeout [integer]
up-interval [integer]

edit module-score [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties

DISPLAY
list module-score
list module-score [[[name] | [glob] | [regex]] ...]
show module-score [[[name] | [glob] | [regex]] ...]
show running-config module-score
show running-config module-score [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties
one-line
partition

DELETE
delete module-score [name]

Note: You cannot delete default monitors.

DESCRIPTION
You can use the module-score component to configure a custom monitor,

or you can use the default Module Score monitor that the Local Traffic Manager provides. This type of monitor enables global and local traffic management systems to load balance in a proportional manner to local traffic management virtual servers associated with the Web Accelerator(tm) and Application Security Manager modules. When you configure a Module Score type of monitor, the local traffic management system uses SNMP to pull the gtm_score values from the downstream virtual servers and set the dynamic ratios on the associated upstream local traffic management pool members or nodes.

More specifically, the Module Score monitor retrieves the gtm_score values from the virtual server and the gtm_vs_score values associated with the virtual server. Then, if a pool name is not specified, this monitor sets the dynamic ratio on the node that is associated with the virtual server.

The BIG-IP(r) system uses the lowest non-zero value of the gtm_vs_score values to set the dynamic ratio. If all gtm_vs_score values are zero, then the gtm_score value is used to set the dynamic ratios. If you specify a pool name in the monitor definition, then the dynamic ratio is set on the pool member.

Note: If you want to distribute traffic to a cluster of WebAccelerator or Application Security Manager virtual servers, you must create a separate custom Module Score monitor for each back-end Local Traffic Manager system.

EXAMPLES

```
create module-score my_module-score defaults-from module_score
```

Creates a monitor named my_module-score that inherits properties from the default Module Score monitor.

```
list module-score
```

Displays the properties of all of the Module Score monitors.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is module_score.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 10 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

pool Specifies a Local Traffic Manager pool name. Use this option if you want the system to set dynamic ratios on a pool member instead of on the associated node for the pool member. The default value is none.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

snmp-community

Specifies the identifier for the SNMP community. The default value is public.

snmp-ip-address

Specifies the IP address of the SNMP server. The default value is

none.

snmp-port
Specifies the port associated with the SNMP server. The default value is 161.

snmp-version
Specifies the SNMP version in use by the system. The default value is v2c.

time-until-up
Specifies the amount of time in seconds after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 30 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval
Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

BIG-IP 2017-04-05 ltm monitor module-score(1)

ltm monitor mqtt

NAME
mqtt - Configures a Message Queuing Telemetry Transport (MQTT) monitor.

MODULE
ltm monitor

SYNTAX
Configure the mqtt component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

```
create mqtt [name]
modify mqtt [name]
options:
  app-service [[string] | none]
  clientid [ [name] | none]
  defaults-from [name]
  description [string]
  destination [ip address][port]
  interval [integer]
  manual-resume [enabled | disabled]
  mqtt-version [[string] | none]
  password [none | [password] ]
  time-until-up [integer]
  timeout [integer]
  up-interval [integer]
  username [ [name] | none]
```

```
edit mqtt [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list mqtt
list mqtt [ [ [name] | [glob] | [regex] ] ... ]
show mqtt [ [ [name] | [glob] | [regex] ] ... ]
```

```
show running-config mqtt
show running-config mqtt [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
DELETE
delete mqtt [name]
```

Note: You cannot delete default monitors.

DESCRIPTION

You can use the mqtt component to configure a custom monitor, or you can use the default mqtt monitor that the Local Traffic Manager provides. This type of monitor verifies the mqtt service by attempting to establish mqtt connection with mqtt server.

EXAMPLES

```
create mqtt my_mqtt defaults-from mqtt
```

Creates a monitor named my_mqtt that inherits properties from the default mqtt monitor.

```
list mqtt
```

Displays the properties of all of the mqtt monitors.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

clientid

Specifies the client identifier to send to MQTT server. The default value is empty.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is mqtt.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

IP address:port (with the transparent option enabled)

Specifies to perform a health check on the server at the IP address and port specified in the monitor, routing the check through the IP address and port supplied by the pool member. The pool member (the gateway) is marked up or down accordingly.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

mqtt-version

Specifies a version to communicate with MQTT server. Default value is 3.1.1.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component

resides.

password

Specifies the password if the monitored target requires authentication. The default value is none.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username

Specifies the username, if the monitored target requires authentication. The default value is none.

BIG-IP 2017-09-05 ltm monitor mqtt(1)

ltm monitor mssql

NAME

mssql - Configures a Microsoft(r) Windows(r) Structured Query Language (MSSQL) monitor.

MODULE

ltm monitor

SYNTAX

Configure the mssql component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

create mssql [name]

modify mssql [name]

options:

app-service [[string] | none]

count [integer]

database [[name] | none]

debug [no | yes]

defaults-from [name]

description [string]

destination [[ipv4 address[:port]] | [ipv6 address[:port]]]

interval [integer]

manual-resume [enabled | disabled]

password [none | [password]]

recv [none | [string]]

recv-column [none | [string]]

recv-row [none | [string]]

send [none | [string]]

time-until-up [integer]

timeout [integer]

```

up-interval [integer]
username [[name] | none]

edit mssql [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list mssql
list mssql [ [ [name] | [glob] | [regex] ] ... ]
show mssql [ [ [name] | [glob] | [regex] ] ... ]
show running-config mssql
show running-config mssql [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
  test-result

DELETE
delete mssql [name]

```

Note: You cannot delete default monitors.

```

RUN
run mssql [name] [ destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ] ]

```

```

STOP
stop mssql [name]

```

DESCRIPTION

You can use the mssql component to configure a custom monitor, or you can use the default Microsoft Windows SQL monitor that the Local Traffic Manager provides. This type of monitor verifies Microsoft Windows SQL-based services.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create mssql my_mssql defaults-from mssql
```

Creates a monitor named my_mssql that inherits properties from the default MSSQL monitor.

```
list mssql
```

Displays the properties of all of the MSSQL monitors.

```
run mssql my_mssql destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_mssql against a target node at 10.10.10.10:80.

```
stop mssql my_mssql
```

Cancels a one-shot test of the custom monitor my_mssql in progress.

```
show mssql my_mssql test-result
```

Displays the result of the most recent one-shot test of the custom monitor my_mssql.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

count

Specifies the number of monitor probes after which the connection to the database will be terminated. Count value of zero indicates that the connection will never be terminated. The default value is zero.

database

Specifies the name of the database with which the monitor attempts to communicate. The default value is none.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from
Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is mssql.

description
User defined description.

destination
Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port
Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port
Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval
Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 30 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume
Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition
Displays the administrative partition within which the component resides.

password
Specifies the password if the monitored target requires authentication. The default value is none.

recv Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in a field in your database. If you do not specify a value for both the send and recv options, the monitor performs a simple service check and connect only.

recv-column
Specifies the column in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

recv-row
Specifies the row in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

send Specifies the SQL query that the monitor sends to the target database, for example, SELECT count(*) FROM mytable.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if not null.

test-result
Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up
Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid

response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 91 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username

Specifies the username, if the monitored target requires authentication. The default value is none.

ltm monitor mysql

NAME

mysql - Configures a MySQL(r) monitor.

MODULE

ltm monitor

SYNTAX

Configure the mysql component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

```
create mysql [name]
modify mysql [name]
options:
  app-service [[string] | none]
  count [integer]
  database [ [name] | none]
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[.port] ] ]
  interval [integer]
  manual-resume [enabled | disabled]
  password [none | [password] ]
  recv [none | [string] ]
  recv-column [none | [string] ]
  recv-row [none | [string] ]
  send [none | [string] ]
  time-until-up [integer]
  timeout [integer]
  up-interval [integer]
  username [[name] | none]
```

```
edit mysql [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list mysql
list mysql [ [ [name] | [glob] | [regex] ] ... ]
show mysql [ [ [name] | [glob] | [regex] ] ... ]
show running-config mysql
show running-config mysql [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

one-line
partition
test-result

DELETE
delete mysql [name]

Note: You cannot delete default monitors.

RUN
run mysql [name] [destination [[ipv4 address[:port]] | [ipv6 address[.port]]]]

STOP
stop mysql [name]

DESCRIPTION

You can use the mysql component to configure a custom monitor, or you can use the default MySQL monitor that the Local Traffic Manager provides. This type of monitor verifies MySQL-based services.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create mysql my_mysql defaults-from mysql
```

Creates a monitor named my_mysql that inherits properties from the default MySQL monitor.

```
list mysql
```

Displays the properties of all of the MySQL monitors.

```
run mysql my_mysql destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_mysql against a target node at 10.10.10.10:80.

```
stop mysql my_mysql
```

Cancels a one-shot test of the custom monitor my_mysql in progress.

```
show mysql my_mysql test-result
```

Displays the result of the most recent one-shot test of the custom monitor my_mysql.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

count

Specifies the number of monitor probes after which the connection to the database will be terminated. Count value of zero indicates that the connection will never be terminated. The default value is zero.

database

Specifies the name of the database with which the monitor attempts to communicate. The default value is none.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is mysql.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

. Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP

address supplied by the pool member and the port you specify.

IP address:port
Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval
Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 30 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume
Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition
Displays the administrative partition within which the component resides.

password
Specifies the password if the monitored target requires authentication. The default value is none.

recv Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in a field in your database. If you do not specify a value for both the send and recv options, the monitor performs a simple service check and connect only.

recv-column
Specifies the column in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

recv-row
Specifies the row in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

send Specifies the SQL query that the monitor sends to the target database, for example, SELECT count(*) FROM mytable.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if not null.

test-result
Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up
Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 91 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval
Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username
Specifies the username, if the monitored target requires authentication. The default value is none.

BIG-IP 2017-08-16 ltm monitor mysql(1)

ltm monitor nntp

NAME
nntp - Configures a Network News Transfer Protocol (NNTP) monitor.

MODULE
ltm monitor

SYNTAX
Configure the nntp component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY
create nntp [name]
modify nntp [name]
options:
app-service [[string] | none]
debug [no | yes]
defaults-from [name]
description [string]
destination [[ipv4 address[:port]] | [ipv6 address[.port]]]
interval [integer]
manual-resume [enabled | disabled]
newsgroup [[name] | none]
password [none | [password]]
time-until-up [integer]
timeout [integer]
up-interval [integer]
username [[name] | none]

edit nntp [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties

DISPLAY
list nntp
list nntp [[[name] | [glob] | [regex]] ...]
show nntp [[[name] | [glob] | [regex]] ...]
show running-config nntp
show running-config nntp [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties
one-line
partition
test-result

DELETE
delete nntp [name]

Note: You cannot delete default monitors.

RUN
run nntp [name] [destination [[ipv4 address[:port]] | [ipv6 address[.port]]]]

STOP
stop nntp [name]

DESCRIPTION

You can use the nntp component to configure a custom monitor, or you can use the default NNTP monitor that the Local Traffic Manager provides. This type of monitor verifies the Usenet News protocol service by attempting to retrieve a newsgroup identification string from the server.

You can test a custom monitor configuration against a specified target

destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create nntp my_nntp defaults-from nntp
```

Creates a monitor named my_nntp that inherits properties from the default NNTP monitor.

```
list nntp
```

Displays the properties of all of the NNTP monitors.

```
run nntp my_nntp destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_nntp against a target node at 10.10.10.10:80.

```
stop nntp my_nntp
```

Cancels a one-shot test of the custom monitor my_nntp in progress.

```
show nntp my_nntp test-result
```

Displays the result of the most recent one-shot test of the custom monitor my_nntp.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is nntp.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

***:port**

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for

load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

newsgroup
Specifies the name of the newsgroup that you are monitoring, for example alt.car.mercedes. The default value is none.

partition
Displays the administrative partition within which the component resides.

password
Specifies the password if the monitored target requires authentication. The default value is none.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

test-result
Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up
Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval
Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username
Specifies the username, if the monitored target requires authentication. The default value is none.

BIG-IP 2017-08-16 ltm monitor nntp(1)

ltm monitor none

NAME
none - Disables monitoring for a node or pool member.

MODULE
ltm monitor

SYNTAX
Apply the none monitor using the syntax in the following sections. The "none" attribute is indicated when viewing the listed node.

MODIFY
modify ltm node [[[name] | [glob] | [regex]] ...] monitor none

DISPLAY
list ltm node monitor

DESCRIPTION

To disable monitoring on the node or pool member, set the monitor to none.

EXAMPLES

```
modify ltm pool [name] monitor none
```

Apply a none monitor on a pool.

```
modify ltm pool members modify { [name] { monitor none } }
```

Apply a none monitor on a pool member.

```
modify ltm node [name] monitor none
```

Apply a none monitor on a node.

```
list ltm node monitor
```

Displays the monitor applied to all nodes.

```
list ltm node [name] monitor
```

Displays the monitor applied to a specific node.

```
list ltm pool p1 members { all { monitor } }
```

Displays the monitor applied to all pools' members.

```
list ltm pool [name] members { monitor }
```

Displays the monitor applied to a pool's members.

```

```
STOP
stop oracle [name]
```

DESCRIPTION

You can use the oracle component to configure a custom monitor, or you can use the default Oracle monitor that the Local Traffic Manager provides. This type of monitor verifies Oracle database services.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create oracle my_oracle defaults-from oracle
```

Creates a monitor named my_oracle that inherits properties from the default Oracle monitor.

```
list oracle
```

Displays the properties of all of the Oracle monitors.

```
run oracle my_oracle destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_oracle against a target node at 10.10.10.10:80.

```
stop oracle my_oracle
```

Cancels a one-shot test of the custom monitor my_oracle in progress.

```
show oracle my_oracle test-result
```

Displays the result of the most recent one-shot test of the custom monitor my_oracle.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

count

Specifies the number of monitor probes after which the connection to the database will be terminated. Count value of zero indicates that the connection will never be terminated. The default value is zero.

database

Specifies the name of the database with which the monitor attempts to communicate. The proper format for database name is ::. The default value is none.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is oracle.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

***:port**
Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port
Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval
Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 30 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume
Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition
Displays the administrative partition within which the component resides.

password
Specifies the password if the monitored target requires authentication. The default value is none.

recv Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in a field in your database. If you do not specify a value for both the send and recv options, the monitor performs a simple service check and connect only.

recv-column
Specifies the column in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

recv-row
Specifies the row in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

send Specifies the SQL query that the monitor sends to the target database, for example, SELECT count(*) FROM mytable.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if not null.

test-result
Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up
Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 91 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down

without waiting for the timeout interval to expire.

up-interval
Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username
Specifies the username, if the monitored target requires authentication. The default value is none.

ltm monitor pop3

NAME

pop3 - Configures a Post Office Protocol (POP3) monitor.

MODULE

ltm monitor

SYNTAX

Configure the pop3 component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

```
create pop3 [name]
modify pop3 [name]
options:
  app-service [[string] | none]
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[.port] ] ]
  interval [integer]
  manual-resume [enabled | disabled]
  password [none | [password] ]
  time-until-up [integer]
  timeout [integer]
  up-interval [integer]
  username [ [name] | none]
```

```
edit pop3 [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list pop3
list pop3 [ [ [name] | [glob] | [regex] ] ... ]
show pop3 [ [ [name] | [glob] | [regex] ] ... ]
show running-config pop3
show running-config pop3 [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
  test-result
```

DELETE

```
delete pop3 [name]
```

Note: You cannot delete default monitors.

RUN

```
run pop3 [name] [ destination [ [ ipv4 address[:port] ] | [ ipv6 address[.port] ] ] ]
```

STOP

```
stop pop3 [name]
```

DESCRIPTION

You can use the pop3 component to configure a custom monitor, or you can use the default POP3 monitor that the Local Traffic Manager provides. This type of monitor verifies the POP3 service by attempting to connect to a pool, pool member, or virtual server, log on as the specified user, and log off.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create pop3 my_pop3 defaults-from pop3
```

Creates a monitor named my_pop3 that inherits properties from the default POP3 monitor.

```
list pop3
```

Displays the properties of all of the POP3 monitors.

```
run pop3 my_pop3 destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_pop3 against a target node at 10.10.10.10:80.

```
stop pop3 my_pop3
```

Cancels a one-shot test of the custom monitor my_pop3 in progress.

```
show pop3 my_pop3 test-result
```

Displays the result of the most recent one-shot test of the custom monitor my_pop3.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks.

The default value is no. The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is pop3.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume
Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition
Displays the administrative partition within which the component resides.

password
Specifies the password if the monitored target requires authentication. The default value is none.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

test-result
Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up
Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval
Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username
Specifies the username, if the monitored target requires authentication. The default value is none.

show running-config postgresql [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties
    one-line
    partition
    test-result

```

DELETE

```
delete postgresql [name]
```

Note: You cannot delete default monitors.

RUN

```
run postgresql [name] [ destination [ [ ipv4 address[:port] ] | [ ipv6 address[.port] ] ] ]
```

STOP

```
stop postgresql [name]
```

DESCRIPTION

You can use the postgresql component to configure a custom monitor, or you can use the default PostgreSQL monitor that the Local Traffic Manager provides. This type of monitor verifies PostgreSQL-based services.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create postgresql my_postgresql defaults-from postgresql
```

Creates a monitor named my_postgresql that inherits properties from the default PostgreSQL monitor.

```
list postgresql
```

Displays the properties of all of the PostgreSQL monitors.

```
run postgresql my_postgresql destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_postgresql against a target node at 10.10.10.10:80.

```
stop postgresql my_postgresql
```

Cancels a one-shot test of the custom monitor my_postgresql in progress.

```
show postgresql my_postgresql test-result
```

Displays the result of the most recent one-shot test of the custom monitor my_postgresql.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

count

Specifies the number of monitor probes after which the connection to the database will be terminated. Count value of zero indicates that the connection will never be terminated. The default value is zero.

database

Specifies the name of the database with which the monitor attempts to communicate. The default value is none.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is postgresql.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 30 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition

Displays the administrative partition within which the component resides.

password

Specifies the password if the monitored target requires authentication. The default value is none.

recv Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in a field in your database. If you do not specify a value for both the send and recv options, the monitor performs a simple service check and connect only.

recv-column

Specifies the column in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

recv-row

Specifies the row in the database where the system expects the specified Receive String to be located. Specify this option only if you configure the send and recv options. The default value is none.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression])

to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

send Specifies the SQL query that the monitor sends to the target database, for example, SELECT count(*) FROM mytable.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if not null.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 91 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username

Specifies the username, if the monitored target requires authentication. The default value is none.

BIG-IP 2017-08-16 ltm monitor postgresql(1)

ltm monitor radius-accounting

NAME

radius-accounting - Configures a RADIUS accounting monitor for the BIG-IP(r) Local Traffic Manager.

MODULE

ltm monitor

SYNTAX

Configure the radius-accounting component within the ltm monitor module using the syntax shown in the following sections.

CREATE/MODIFY

```
create radius-accounting [name]
modify radius-accounting [name]
options:
  app-service [[string] | none]
  debug [no | yes]
  defaults-from [ [name] | none]
  description [string]
  destination [ip address]
  interval [integer]
  manual-resume [disabled | enabled]
  nas-ip-address [ip address]
  secret [string]
  time-until-up [integer]
  timeout [integer]
  up-interval [integer]
  username [none | [string] ]
```

```
edit radius-accounting [ [ [name] | [glob] | [regex] ] ...]
options:
  all-properties
  non-default-properties

DISPLAY
list radius-accounting
list radius-accounting [ [ [name] | [glob] | [regex] ] ...]
show radius-accounting [ [ [name] | [glob] | [regex] ] ...]
show running-config radius-accounting
show running-config radius-accounting [ [ [name] | [glob] |
[regex] ] ...]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
DELETE
delete radius-accounting [name]
```

Note: You cannot delete default monitors.

DESCRIPTION

You can use the radius-accounting component to configure a custom monitor, or you can use the default RADIUS accounting monitor that the Local Traffic Manager provides. This type of monitor provides information about the usage of the RADIUS service for accounting purposes.

EXAMPLES

```
create radius-accounting my_radius_acct defaults-from radius_accounting
```

Creates a monitor named my_radius_acct that inherits properties from the default RADIUS accounting monitor.

```
list radius-accounting
```

Displays the properties of all of the RADIUS accounting monitors.

OPTIONS

app-service
Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

debug
Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from
Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is radius.

description
User defined description.

destination
Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

***:port**
Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port
Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval
Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 10 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume
Specifies whether the system automatically changes the status of a

resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

nas-ip-address
Specifies the network access server IP address that the system uses to identify itself to the RADIUS server. Using this option, multiple BIG-IP(r) systems can appear as a single network access device to the RADIUS server. The default value is none.

partition
Displays the administrative partition within which the component resides.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

secret
Specifies the secret the monitor needs to communicate with the resource. The default value is none.

time-until-up
Specifies the amount of time in seconds after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval
Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username
Specifies the username, if the monitored target requires authentication. The default value is none.

BIG-IP 2017-04-05 ltm monitor radius-accounting(1)

ltm monitor radius

NAME
radius - Configures a Remote Access Dial-in User Service (RADIUS) monitor.

MODULE
ltm monitor

SYNTAX
Configure the radius component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY
create radius [name]

```

modify radius [name]
  options:
    app-service [(string) | none]
    debug [no | yes]
    defaults-from [name]
    description [string]
    destination [ [ ipv4 address[:port] ] | [ ipv6 address[.port] ] ]
    interval [integer]
    manual-resume [enabled | disabled]
    nas-ip-address [ [ip address] | none]
    password [none | [password] ]
    secret [none | [secret] ]
    time-until-up [integer]
    timeout [integer]
    up-interval [integer]
    username [ [name] | none]

edit radius [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties

DISPLAY
list radius
list radius [ [ [name] | [glob] | [regex] ] ... ]
show radius [ [ [name] | [glob] | [regex] ] ... ]
show running-config radius
show running-config radius [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties
    one-line
    partition
    test-result

DELETE
delete radius [name]

```

Note: You cannot delete default monitors.

RUN

```
run radius [name] [ destination [ [ ipv4 address[:port] ] | [ ipv6 address[.port] ] ] ]
```

STOP

```
stop radius [name]
```

DESCRIPTION

You can use the radius component to configure a custom monitor, or you can use the default RADIUS monitor that the Local Traffic Manager provides. This type of monitor verifies the RADIUS service by attempting to authenticate the specified user.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

```
admin, application-editor, manager, operator, resource-admin
```

EXAMPLES

```
create radius my_radius defaults-from radius
```

Creates a monitor named my_radius that inherits properties from the default RADIUS monitor.

```
list radius
```

Displays the properties of all of the RADIUS monitors.

```
run radius my_radius destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_radius against a target node at 10.10.10.10:80.

```
stop radius my_radius
```

Cancels a one-shot test of the custom monitor my_radius in progress.

```
show radius my_radius test-result
```

Displays the result of the most recent one-shot test of the custom monitor my_radius.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is radius.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 10 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

nas-ip-address

Specifies the network access server IP address that the system uses to identify itself to the RADIUS server. With this option, multiple BIG-IP systems can appear as a single network access device to the RADIUS server. The default value is none.

partition

Displays the administrative partition within which the component resides.

password

Specifies the password if the monitored target requires authentication. The default value is none.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

secret

Specifies the secret the monitor must use when contacting the resource. The default value is none.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username

Specifies the username, if the monitored target requires authentication. The default value is none.

BIG-IP 2017-08-16 ltm monitor radius(1)

ltm monitor real-server

NAME

real-server - Configures a RealServer(r) monitor.

MODULE

ltm monitor

SYNTAX

Configure the real-server component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

```
create real-server [name]
modify real-server [name]
options:
  app-service [[string] | none]
  defaults-from [name]
  description [string]
  interval [integer]
  metrics [ [metrics] | none]
  time-until-up [integer]
  timeout [integer]
```

```
edit real-server [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list real-server
list real-server [ [ [name] | [glob] | [regex] ] ... ]
show real-server [ [ [name] | [glob] | [regex] ] ... ]
show running-config real-server
show running-config real-server [ [ [name] | [glob] | [regex] ] ... ]
options:
  agent
  all-properties
  command
  method
  non-default-properties
  one-line
  partition
```

DELETE

```
delete real-server [name]
```

Note: You cannot delete default monitors.

DESCRIPTION

You can use the real-server component to configure a custom monitor, or you can use the default RealServer monitor that the Local Traffic Manager provides. This type of monitor checks the performance of a pool, pool member, or virtual server that is running the RealServer data collection agent, and then dynamically load balances traffic accordingly.

EXAMPLES

```
create real-server my_real-server defaults-from real_server
```

Creates a monitor named my_real-server that inherits properties from the default RealServer monitor.

list real-server

Displays the properties of all of the RealServer monitors.

OPTIONS

agent

Displays the agent for the monitor. The default agent is Mozilla/4.0 (compatible: MSIE 5.0; Windows NT). You cannot modify the agent.

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

command

Displays the command that the system uses to obtain the metrics from the resource. See the documentation for this resource for information on available commands. You cannot modify the command.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is real-server.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies the frequency at which the system issues the monitor check. The default value is 5 seconds.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

method

Displays the GET method. You cannot modify the method.

metrics

Specifies the performance metrics that the commands collect from the target. The default value is ServerBandwidth:1.5, CPUPercentUsage, MemoryUsage, TotalClientCount.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

SEE ALSO

create, delete, edit, glob, list, modify, regex, show, tmsh

BIG-IP 2017-04-05 ltm monitor real-server(1)

NAME
rpc - Configures a Remote Procedure Call (RPC) monitor.

MODULE
ltm monitor

SYNTAX
Configure the rpc component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY
create rpc [name]
modify rpc [name]
options:
app-service [[string] | none]
debug [no | yes]
defaults-from [name]
description [string]
destination [[ipv4 address[:port]] | [ipv6 address[:port]]]
interval [integer]
manual-resume [enabled | disabled]
mode [tcp | udp]
program-number [[integer] | none]
time-until-up [integer]
timeout [integer]
up-interval [integer]
version-number [[integer] | none]

edit rpc [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties

DISPLAY
list rpc
list rpc [[[name] | [glob] | [regex]] ...]
show rpc [[[name] | [glob] | [regex]] ...]
show running-config rpc
show running-config rpc [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties
one-line
partition
test-result

DELETE
delete rpc [name]

Note: You cannot delete default monitors.

RUN
run rpc [name] [destination [[ipv4 address[:port]] | [ipv6 address[:port]]]]

STOP
stop rpc [name]

DESCRIPTION
You can use the rpc component to configure a custom monitor, or you can use the default RPC monitor that the Local Traffic Manager provides. This type of monitor queries the RPC server, and verifies the availability of a given program.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES
create rpc my_rpc defaults-from rpc
Creates a monitor named my_rpc that inherits properties from the default RPC monitor.
list rpc
Displays the properties of all of the RPC monitors.
run rpc my_rpc destination 10.10.10.10:80
Runs a one-shot test of the custom monitor my_rpc against a target node at 10.10.10.10:80.
stop rpc my_rpc
Cancels a one-shot test of the custom monitor my_rpc in progress.
show rpc my_rpc test-result
Displays the result of the most recent one-shot test of the custom monitor my_rpc.

OPTIONS
app-service
Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks.

The default value is no. The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is rpc.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 10 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

mode Specifies the protocol that the monitor uses to communicate with the target. The default value is tcp.

The options are:

tcp Specifies that the monitor uses the TCP protocol to communicate with the target object.

udp Specifies that the monitor uses the UDP protocol to communicate with the target object.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition

Displays the administrative partition within which the component resides.

program-number

Specifies the number of the program for which you want the monitor to verify availability. The default value is none.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

version-number

Specifies the number of the version for which you want the monitor to verify availability. The default value is none.

SEE ALSO

create, delete, edit, glob, list, modify, regex, run, show, stop, tmsh

BIG-IP 2017-08-16 ltm monitor rpc(1)

ltm monitor sasp

NAME

sasp - Configures a Server Application State Protocol (SASP) monitor.

MODULE

ltm monitor

SYNTAX

Configure the sasp component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

create sasp [name]

modify sasp [name]

options:

app-service [[string] | none]
defaults-from [name]
description [string]
interval [integer]
mode [pull | push]
primary-address [ip address]
protocol [tcp | udp]
secondary-address [[ip address] | none]
service [none | [port]]
time-until-up [integer]
timeout [integer]

edit sasp [[[name] | [glob] | [regex]] ...]

options:

all-properties
non-default-properties

DISPLAY

list sasp

list sasp [[[name] | [glob] | [regex]] ...]

show sasp [[[name] | [glob] | [regex]] ...]

show running-config sasp

show running-config sasp [[[name] | [glob] | [regex]] ...]

options:

all-properties
non-default-properties
one-line
partition

DELETE

delete sasp [name]

Note: You cannot delete default monitors.

DESCRIPTION

You can use the `sasp` component to configure a custom monitor, or you can use the default FTP monitor that the Local Traffic Manager provides. This type of monitor verifies the availability of IBM Group Workload Managers network resources.

EXAMPLES

```
create sasp my_sasp defaults-from sasp
```

Creates a monitor named `my_sasp` that inherits properties from the default SASP monitor.

```
list sasp
```

Displays the properties of all of the SASP monitors.

OPTIONS

`app-service`

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

`defaults-from`

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is `sasp`.

`description`

User defined description.

`glob` Displays the items that match the `glob` expression. See help `glob` for a description of `glob` expression syntax.

`interval`

Specifies the frequency at which the system issues the monitor check. The default value is `auto`.

`mode` Specifies whether the load balancer should send Get Weight Request messages (pull) or receive Send Weights messages (push) from the GWM. The default mode is `push`.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

`partition`

Displays the administrative partition within which the component resides.

`primary-address`

Specifies the IP address of the primary Group Workload Manager.

`protocol`

Specifies the protocol that the monitor uses to communicate with the target. The default value is `tcp`.

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@`[regular expression]) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

`secondary-address`

Specifies the IP address of the secondary Group Workload Manager.

`service`

Specifies the port through which the SASP monitor communicates with the Group Workload Manager. The default port is 3860.

`time-until-up`

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

`timeout`

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 100 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

SEE ALSO

`create`, `delete`, `edit`, `glob`, `list`, `modify`, `regex`, `show`, `tmsh`

COPYRIGHT

ltm monitor scripted

NAME
scripted - Configures a Scripted monitor.

MODULE
ltm monitor

SYNTAX
Configure the scripted component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

```
create scripted [name]
modify scripted [name]
options:
  app-service [[string] | none]
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[.port] ] ]
  filename [ [filename] | none]
  interval [integer]
  manual-resume [enabled | disabled]
  time-until-up [integer]
  timeout [integer]
  up-interval [integer]
```

```
edit scripted [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list scripted
list scripted [ [ [name] | [glob] | [regex] ] ... ]
show scripted [ [ [name] | [glob] | [regex] ] ... ]
show running-config scripted
show running-config scripted [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
  test-result
```

DELETE

```
delete scripted [name]
```

Note: You cannot delete default monitors.

RUN

```
run scripted [name] [ destination [ [ ipv4 address[:port] ] | [ ipv6 address[.port] ] ] ]
```

STOP

```
stop scripted [name]
```

DESCRIPTION

You can use the scripted component to configure a custom monitor, or you can use the default scripted monitor that the Local Traffic Manager provides.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create scripted my_scripted defaults-from scripted
```

Creates a monitor named my_scripted that inherits properties from the default scripted monitor.

```
list scripted
```

Displays the properties of all of the scripted monitors.

```
run scripted my_scripted destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_scripted against a target node at 10.10.10.10:80.

```
stop scripted my_scripted
```

Cancels a one-shot test of the custom monitor my_scripted in progress.

```
show scripted my_scripted test-result
```

Displays the result of the most recent one-shot test of the custom monitor my_scripted.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks.

The default value is no. The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is scripted.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

filename

Specifies the name of a file in the /config/eav/ directory on the system. The user-created file contains the send and expect data that the monitor uses for the monitor check. The default value is none.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 10 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

SEE ALSO

BIG-IP 2017-08-16 ltm monitor scripted(1)

ltm monitor sip

NAME

sip - Configures a Session Initiation Protocol (SIP) monitor.

MODULE

ltm monitor

SYNTAX

Configure the sip component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

```
create sip [name]
modify sip [name]
options:
  app-service [[string] | none]
  cert [ [cert list] | none]
  cipherlist [string]
  compatibility [enabled | disabled]
  debug [ no | yes]
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[.port] ] ]
  filter [any | none | status]
  filter-neg [any | none | status]
  headers [ [new line separated headers] | none]
  interval [integer]
  key [ [key] | none]
  manual-resume [enabled | disabled]
  mode [sips | tcp | tls | udp]
  request [none | [string] ]
  time-until-up [integer]
  up-interval [integer]
  username [ [name] | none]
```

```
edit sip [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list sip
list sip [ [ [name] | [glob] | [regex] ] ... ]
show sip [ [ [name] | [glob] | [regex] ] ... ]
show running-config sip
show running-config sip [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
  test-result
```

DELETE

```
delete sip [name]
```

Note: You cannot delete default monitors.

```
RUN
run sip [name] [ destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ] ] ]
STOP
stop sip [name]
```

DESCRIPTION

You can use the sip component to configure a custom monitor, or you can use the default SIP monitor that the Local Traffic Manager provides. This type of monitor checks the status of SIP Call-ID services on a device. The SIP protocol enables real-time messaging, voice, data, and video.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create sip my_sip defaults-from sip
```

Creates a monitor named my_sip that inherits properties from the default SIP monitor.

```
list sip
```

Displays the properties of all of the SIP monitors.

```
run sip my_sip destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_sip against a target node at 10.10.10.10:80.

```
stop sip my_sip
```

Cancels a one-shot test of the custom monitor my_sip in progress.

```
show sip my_sip test-result
```

Displays the result of the most recent one-shot test of the custom monitor my_sip.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

cert Specifies a fully-qualified path for a client certificate that the monitor sends to the target SSL server. The default value is none.

cipherlist

Specifies the list of ciphers for this monitor. The default value is DEFAULT:+SHA:+3DES:+KEDH.

compatibility

Specifies, when enabled, that the SSL options setting (in OpenSSL) is set to ALL. The default value is enabled.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks.

The default value is no. The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is sip.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

filter

Specifies the SIP status codes that the target can return to be considered up. By default the system always accepts status codes whose value is in the 100, 200 or 300s.

The options are:

any Specifies that the monitor accepts any SIP status codes.

none Specifies that the monitor does not accept any other SIP status codes. This is the default value.

status

Specifies one or more status codes that you want to add to the monitor.

filter-neg

Specifies the SIP status codes that the target can return to be considered down. By default the system always accepts status codes according to sip-monitor.filter. After checking that, the status code is checked against this key. If a code is also in sip-monitor.filter, the node is marked up.

The options are:

any Specifies that the monitor rejects all SIP status codes that are not in sip-monitor.filter.

none Specifies that the monitor does not specifically reject any other SIP status codes. This is the default value.

status

Specifies one or more status codes that you want to add to the monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

headers

Specifies the set of SIP headers in the SIP message that is sent to the target. Separate each header with a new line. The default value is none.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

key Specifies the key if the monitored target requires authentication. The default value is none.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

mode Specifies the protocol that the monitor uses to communicate with the target. The default mode is udp. The options are:

sips Specifies that the monitor uses SIPS to communicate with the target.

tcp Specifies that the monitor uses TCP to communicate with the target.

tls Specifies that the monitor uses TLS to communicate with the target, and the SIP URI is SIPS.

udp Specifies that the monitor uses UDP to communicate with the target.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

request

Specifies the SIP request line in the SIP message that is sent to the target. The default value is none.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

BIG-IP 2017-08-16 ltm monitor sip(1)

ltm monitor smb

NAME

smb - Configures a Server Message Bloc (SMB)/Common Internet File System (CIFS) monitor.

MODULE

ltm monitor

SYNTAX

Configure the smb component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

```
create smb [name]
modify smb [name]
options:
  app-service [[string] | none]
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]
  get [none | [filename] ]
  interval [integer]
  manual-resume [enabled | disabled]
  password [none | [password] ]
  server [ [NETBIOS name] | none]
  service [ [[name] | [integer]] | none]
  time-until-up [integer]
  timeout [integer]
  up-interval [integer]
  username [ [name] | none]

edit smb [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties
```

DISPLAY

```
list smb
list smb [ [ [name] | [glob] | [regex] ] ... ]
show smb [ [ [name] | [glob] | [regex] ] ... ]
show running-config smb
```

```
show running-config smb [ [ name ] | [ glob ] | [ regex ] ] ... ]
```

```
options:  
all-properties  
non-default-properties  
one-line  
partition  
test-result
```

DELETE

```
delete smb [name]
```

Note: You cannot delete default monitors.

RUN

```
run smb [name] [ destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ] ]
```

STOP

```
stop smb [name]
```

DESCRIPTION

You can use the smb component to configure a custom monitor, or you can use the default SMB monitor that the Local Traffic Manager provides. This type of monitor verifies the availability of an SMB/CIFS server. You can use this type of monitor to either check the availability of the server as a whole, the availability of a specific service on the server, or the availability of a specific file used by a service.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create smb my_smb defaults-from smb
```

Creates a monitor named my_smb that inherits properties from the default SMB monitor.

```
list smb
```

Displays the properties of all of the SMB monitors.

```
run smb my_smb destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_smb against a target node at 10.10.10.10:80.

```
stop smb my_smb
```

Cancels a one-shot test of the custom monitor my_smb in progress.

```
show smb my_smb test-result
```

Displays the result of the most recent one-shot test of the custom monitor my_smb.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is smb.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

get Specifies a file associated with a service. The default value is none.

The monitor uses the relative path to the service itself when attempting to locate the file. You are not required to specify a value for this option; however, if you elect to use this option you must also specify a value for the service option.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval
Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 10 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume
Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition
Displays the administrative partition within which the component resides.

password
Specifies the password if the monitored target requires authentication. The default value is none.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

server
Specifies the NetBIOS name of the SMB/CIFS server for which this monitor checks for availability. You must specify a server for this monitor to function. The default value is none.

service
Specifies a specific service on the SMB/CIFS for which you want to verify availability. The default value is none.

test-result
Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up
Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval
Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username
Specifies the user name if the monitored target requires authentication. The default value is none.

ltm monitor smtp

NAME
smtp - Configures a Simple Mail Transport Protocol (SMTP) monitor.

MODULE
ltm monitor

SYNTAX
Configure the smtp component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY
create smtp [name]
modify smtp [name]
options:
app-service [[string] | none]
debug [no | yes]
defaults-from [name]
description [string]
destination [[ipv4 address[:port]] | [ipv6 address[.port]]]
domain [[name] | none]
interval [integer]
manual-resume [enabled | disabled]
time-until-up [integer]
timeout [integer]
up-interval [integer]

edit smtp [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties

DISPLAY
list smtp
list smtp [[[name] | [glob] | [regex]] ...]
show smtp [[[name] | [glob] | [regex]] ...]
show running-config smtp
show running-config smtp [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties
one-line
partition
test-result

DELETE
delete smtp [name]

Note: You cannot delete default monitors.

RUN
run smtp [name] [destination [[ipv4 address[:port]] | [ipv6 address[.port]]]]

STOP
stop smtp [name]

DESCRIPTION
You can use the smtp component to configure a custom monitor, or you can use the default SMTP monitor that the Local Traffic Manager provides. This type of monitor checks the status of a pool, pool member, or virtual server by issuing standard SMTP commands.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES
create smtp my_smtp defaults-from smtp

Creates a monitor named my_smtp that inherits properties from the default SMTP monitor.

list smtp

Displays the properties of all of the SMTP monitors.

```
run smtp my_smtp destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_smtp against a target node at 10.10.10.10:80.

```
stop smtp my_smtp
```

Cancels a one-shot test of the custom monitor my_smtp in progress.

```
show smtp my_smtp test-result
```

Displays the result of the most recent one-shot test of the custom monitor my_smtp.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is smtp.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

. Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

domain

Specifies the domain name to check, for example, bigipinternal.com. The default value is none.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression])

to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

ltm monitor snmp-dca-base

NAME

snmp-dca-base - Configures a base Simple Network Management Protocol (SNMP) Data Center Audit monitor.

MODULE

ltm monitor

SYNTAX

Configure the snmp-dca-base component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

create snmp-dca-base [name]

modify snmp-dca-base [name]

options:

app-service [[string] | none]

community [[name] | none]

cpu-coefficient [[integer] | none]

defaults-from [name]

description [string]

interval [integer]

time-until-up [integer]

timeout [integer]

user-defined [[name] [value] | [name] none]

version [[integer] | none]

edit snmp-dca-base [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list snmp-dca-base

list snmp-dca-base [[[name] | [glob] | [regex]] ...]

show snmp-dca-base [[[name] | [glob] | [regex]] ...]

show running-config snmp-dca-base

show running-config snmp-dca-base [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties
one-line
partition

DELETE

delete snmp-dca-base [name]

Note: You cannot delete default monitors.

DESCRIPTION

You can use the snmp-dca-base component to configure a custom monitor, or you can use the default base SNMP DCA monitor that the Local Traffic Manager provides. This type of monitor checks the performance of a server running an SNMP agent such as UC Davis. Use this monitor only when you want the load balancing destination to be based solely on user data, and not CPU, memory or disk use.

EXAMPLES

```
create snmp-dca-base my_snmp-dca-base defaults-from snmp_dca_base
```

Creates a monitor named my_snmp-dca-base that inherits properties from the default base SNMP DCA monitor.

```
list snmp-dca-base
```

Displays the properties of all of the base SNMP DCA monitors.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

community

Specifies the community name that the BIG-IP system must use to authenticate with the host server through SNMP. The default value is public.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is snmp_dca_base.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies the frequency at which the system issues the monitor check. The default value is 10 seconds.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 30 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

user-defined

Specifies any user-defined command-line arguments and variables that the external program requires. Use the following syntax to specify a user defined parameter.

```
modify external my_external user-defined my_param_name  
my_param_value
```

Use the following syntax to remove a user defined parameter.

```
modify external my_external user-defined my_param_name none
```

version

Specifies the version of SNMP that the host server uses. The default value is none.

SEE ALSO

create, delete, edit, glob, list, modify, regex, show, tmsh

show running-config snmp-dca [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties
one-line
partition

DELETE
delete snmp-dca [name]

Note: You cannot delete default monitors.

DESCRIPTION
You can use the snmp-dca component to configure a custom monitor, or you can use the default SNMP DCA monitor that the Local Traffic Manager provides. This type of monitor checks the performance of a server running an SNMP agent such as UC Davis, for the purpose of load balancing traffic to that server.

EXAMPLES
create snmp-dca my_snmp-dca defaults-from snmp_dca

Creates a monitor named my_snmp-dca that inherits properties from the default SNMP DCA monitor.

list snmp-dca

Displays the properties of all of the SNMP DCA monitors.

OPTIONS
agent-type
Specifies the type of agent. The default value is ucd.

app-service
Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object,

you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

community

Specifies the community name that the BIG-IP system must use to authenticate with the host server through SNMP. The default value is public.

cpu-coefficient

Specifies the coefficient that the system uses to calculate the weight of the CPU threshold in the dynamic ratio load balancing algorithm. The default value is 1.5.

cpu-threshold

Specifies the maximum acceptable CPU usage on the target server. The default value is 80 percent.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is snmp_dca.

description

User defined description.

disk-coefficient

Specifies the coefficient that the system uses to calculate the weight of the disk threshold in the dynamic ratio load balancing algorithm. The default value is 2.0.

disk-threshold

Specifies the maximum acceptable disk usage on the target server. The default value is 90 percent.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies the frequency at which the system issues the monitor check. The default value is 10 seconds.

memory-coefficient

Specifies the coefficient that the system uses to calculate the weight of the memory threshold in the dynamic ratio load balancing algorithm. The default value is 1.0.

memory-threshold

Specifies the maximum acceptable memory usage on the target server. The default value is 70 percent.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 30 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

user-defined

Specifies attributes for a monitor that you define. The default value is none.

version

Specifies the version of SNMP that the host server uses. The default value is none.

SEE ALSO

ltm monitor soap

NAME
soap - Configures a Simple Object Access Protocol (SOAP) monitor.

MODULE
ltm monitor

SYNTAX
Configure the soap component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY
create soap [name]
modify soap [name]
options:
app-service [[string] | none]
debug [no | yes]
defaults-from [name]
description [string]
destination [[ipv4 address[:port]] | [ipv6 address[.port]]]
expect-fault [no | yes]
interval [integer]
manual-resume [enabled | disabled]
method [string]
namespace [[name] | none]
parameter-name [[name] | none]
parameter-type [bool | int | long | string]
parameter-value [none | [integer] | [string]]
password [none | [password]]
protocol [http | https]
return-type [bool | char | double | int | long | short | string]
return-value [none | [integer] | [string]]
soap-action [string]
time-until-up [integer]
timeout [integer]
up-interval [integer]
url-path [none | [string]]
username [[name] | none]

edit soap [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties

DISPLAY
list soap
list soap [[[name] | [glob] | [regex]] ...]
show soap [[[name] | [glob] | [regex]] ...]
show running-config soap
show running-config soap [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties
one-line
partition
test-result

DELETE
delete soap [name]

Note: You cannot delete default monitors.

RUN
run soap [name] [destination [[ipv4 address[:port]] | [ipv6 address[.port]]]]

STOP
stop soap [name]

DESCRIPTION
You can use the soap component to configure a custom monitor, or you can use the default SOAP monitor that the Local Traffic Manager provides. This type of monitor tests a Web service based on SOAP.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES
create soap my_soap defaults-from soap

Creates a soap monitor that inherits values from the system default SOAP monitor.

list soap

Displays the properties of all of the SOAP monitors.

```
run soap my_soap destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_soap against a target node at 10.10.10.10:80.

```
stop soap my_soap
```

Cancels a one-shot test of the custom monitor my_soap in progress.

```
show soap my_soap test-result
```

Displays the result of the most recent one-shot test of the custom monitor my_soap.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the type of monitor you want to use to create the new monitor. The default value is soap.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

expect-fault

Specifies whether the value of the method option causes the monitor to expect a SOAP fault message. The default value is no.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

method

Specifies the method by which the monitor contacts the resource.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

namespace

Specifies the name space for the Web service you are monitoring, for example, http://example.com/. The default value is none.

parameter-name

If the method has a parameter, specifies the name of that parameter. The default value is none.

parameter-type
Specifies the parameter type. The default value is bool.

parameter-value
Specifies the value for the parameter. The default value is none.

partition
Displays the administrative partition within which the component resides.

password
Specifies the password if the monitored target requires authentication. The default value is none.

protocol
Specifies the protocol that the monitor uses to communicate with the target, http or https. The default value is http.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

return-type
Specifies the type for the returned parameter. The default value is bool.

return-value
Specifies the value for the returned parameter. The default value is none.

soap-action
Specifies the value for the SOAPAction header. The default value is the empty string.

test-result
Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up
Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds. If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

url-path
Specifies the URL for the Web service that you are monitoring, for example, /services/myservice.aspx. The default value is none.

up-interval
Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

username
Specifies the user name if the monitored target requires authentication. The default value is none.

BIG-IP 2017-08-16 ltm monitor soap(1)

NAME
tcp-echo - Configures a Transmission Control Protocol (TCP) Echo monitor.

MODULE
ltm monitor

SYNTAX
Configure the tcp-echo component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY
create tcp-echo [name]
modify tcp-echo [name]
options:
 adaptive [enabled | disabled]
 adaptive-divergence-type [relative | absolute]
 adaptive-divergence-value [integer]
 adaptive-limit [integer]
 adaptive-sampling-timespan [integer]
 app-service [[string] | none]
 defaults-from [name]
 description [string]
 destination [[ipv4 address[:port]] | [ipv6 address[.port]]]
 interval [integer]
 manual-resume [enabled | disabled]
 time-until-up [integer]
 timeout [integer]
 transparent [disabled | enabled]
 up-interval [integer]

edit tcp-echo [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 non-default-properties

DISPLAY
list tcp-echo
list tcp-echo [[[name] | [glob] | [regex]] ...]
show tcp-echo [[[name] | [glob] | [regex]] ...]
show running-config tcp-echo
show running-config tcp-echo [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 non-default-properties
 one-line
 partition
 test-result

DELETE
delete tcp-echo [name]

Note: You cannot delete default monitors.

RUN
run tcp-echo [name] [destination [[ipv4 address[:port]] | [ipv6 address[.port]]]]

STOP
stop tcp-echo [name]

DESCRIPTION
You can use the tcp-echo component to configure a custom monitor, or you can use the default TCP Echo monitor that the Local Traffic Manager provides. This type of monitor checks the status of a resource, using TCP Echo.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES
create tcp-echo my_tcp-echo defaults-from tcp_echo

Creates a monitor named my_tcp-echo that inherits properties from the default TCP Echo monitor.

list tcp-echo

Displays the properties of all of the TCP Echo monitors.

run tcp-echo my_tcp-echo destination 10.10.10.10:80

Runs a one-shot test of the custom monitor my_tcp-echo against a target node at 10.10.10.10:80.

stop tcp-echo my_tcp-echo

Cancels a one-shot test of the custom monitor my_tcp-echo in progress.

show tcp-echo my_tcp-echo test-result

Displays the result of the most recent one-shot test of the custom monitor my_tcp-echo.

OPTIONS
adaptive
Specifies whether the adaptive feature is enabled for this monitor. Not all monitors support the adaptive feature.

adaptive-divergence-type
Specifies whether the adaptive-divergence-value is relative or absolute.

adaptive-divergence-value
Specifies how far from mean latency each monitor probe is allowed to be. If adaptive-divergence-type is relative, this value is a percentage deviation from mean (e.g. 50 would indicate the probe is allowed to exceed the mean latency by 50%.) If adaptive-divergence-type is absolute, this value is an offset from mean in milliseconds (e.g. 250 would indicate the probe is allowed to exceed the mean latency by 250 ms.) A probe that exceeds latency is counted the same as a probe that is not received, so in the typical scenario, it will require three missed latencies in a row to mark a pool member or node down (i.e. a 15-second interval with a 46-second timeout, would require three missed probes before the pool member or node would be marked down.)

adaptive-limit
Specifies the hard limit, in milliseconds, which the probe is not allowed to exceed, regardless of the divergence value. For example, if this value is 500, then the probe latency may not exceed 500 ms even if that would still fall within the divergence value.

adaptive-sampling-timespan
Specifies the size of the sliding window, in seconds, which records probe history. For example, if this value is 300, then a sliding window of the last five minutes' probe history will be used for calculating probe mean latency and standard deviation.

app-service
Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

defaults-from
Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is tcp_echo.

description
User defined description.

destination
Specifies the IP address of the resource that is the destination of this monitor. The default value is *.

Possible values are:

* Specifies to perform a health check on the IP address of the node.

IP address
Specifies to perform a health check on the IP address that you specify, and mark the associated node up or down accordingly.

IP address (with the transparent option enabled)
Specifies to perform a health check on the IP address that you specify, route the check through the IP address of the associated node, and mark the IP address of the associated node up or down accordingly.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval
Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume
Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition
Displays the administrative partition within which the component resides.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

test-result
 Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up
 Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout
 Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

transparent
 Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

up-interval
 Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

BIG-IP 2017-08-16 ltm monitor tcp-echo(1)

ltm monitor tcp-half-open

NAME
 tcp-half-open - Configures a Transmission Control Protocol (TCP) Half Open monitor.

MODULE
 ltm monitor

SYNTAX
 Configure the tcp-half-open component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY
 create tcp-half-open [name]
 modify tcp-half-open [name]
 options:
 app-service [[string] | none]
 defaults-from [name]
 description [string]
 destination [[ipv4 address[:port]] | [ipv6 address[:port]]]
 interval [integer]
 manual-resume [enabled | disabled]
 time-until-up [integer]
 timeout [integer]
 transparent [disabled | enabled]
 up-interval [integer]

edit tcp-half-open [[name] | [glob] | [regex] ...]
 options:
 all-properties
 non-default-properties

DISPLAY
 list tcp-half-open
 list tcp-half-open [[name] | [glob] | [regex] ...]
 show tcp-half-open [[name] | [glob] | [regex] ...]
 show running-config tcp-half-open

```
show running-config tcp-half-open [ [ name ] | [ glob ] |
[ regex ] ] ... ]
```

```
options:
  all-properties
  non-default-properties
  one-line
  partition
  test-result
```

DELETE

```
delete tcp-half-open [name]
```

Note: You cannot delete default monitors.

RUN

```
run tcp-half-open [name] [ destination [ [ ipv4 address[:port] ] | [ ipv6 address[.port] ] ] ]
```

STOP

```
stop tcp-half-open [name]
```

DESCRIPTION

You can use the `tcp-half-open` component to configure a custom monitor, or you can use the default TCP Half Open monitor that the Local Traffic Manager provides.

For more information about configuring monitors, refer to the Configuration Guide for BIG-IP(r) Local Traffic Manager(r).

You can test a custom monitor configuration against a specified target destination by using the `run` command, and view the results of such a test by using the `show` command with the `test-result` option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create tcp-half-open my_tcp-half-open defaults-from tcp_half_open
```

Creates a monitor named `my_tcp-half-open` that inherits properties from the default TCP Half Open monitor.

```
list tcp-half-open
```

Displays the properties of all of the TCP Half Open monitors.

```
run tcp-half-open my_tcp-half-open destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor `my_tcp-half-open` against a target node at `10.10.10.10:80`.

```
stop tcp-half-open my_tcp-half-open
```

Cancels a one-shot test of the custom monitor `my_tcp-half-open` in progress.

```
show tcp-half-open my_tcp-half-open test-result
```

Displays the result of the most recent one-shot test of the custom monitor `my_tcp-half-open`.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is `tcp_half_open`.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is `*:*`.

Possible values are:

`*:*` Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

IP address:port (with the `transparent` option enabled)
Specifies to perform a health check on the server at the IP address and port you specify, route the check through the IP address and port supplied by the pool member, and mark the pool member (the gateway) up or down accordingly.

This option is required for the command `run`, unless an IP address and service port are specified in the `destination` option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

transparent

Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

```

DESCRIPTION

You can use the tcp component to configure a custom monitor, or you can use the default TCP monitor that the Local Traffic Manager provides.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create tcp my_tcp defaults-from tcp
```

Creates a monitor named my_tcp that inherits properties from the default TCP monitor.

```
list tcp
```

Displays the properties of all of the TCP monitors.

```
run tcp my_tcp destination 10.10.10.10:80
```

Runs a one-shot test of the custom monitor my_tcp against a target node at 10.10.10.10:80.

```
stop tcp my_tcp
```

Cancels a one-shot test of the custom monitor my_tcp in progress.

```
show tcp my_tcp test-result
```

Displays the result of the most recent one-shot test of the custom monitor my_tcp.

OPTIONS

adaptive

Specifies whether the adaptive feature is enabled for this monitor. Not all monitors support the adaptive feature.

adaptive-divergence-type
Specifies whether the adaptive-divergence-value is relative or absolute.

adaptive-divergence-value
Specifies how far from mean latency each monitor probe is allowed to be. If adaptive-divergence-type is relative, this value is a percentage deviation from mean (e.g. 50 would indicate the probe is allowed to exceed the mean latency by 50%). If adaptive-divergence-type is absolute, this value is an offset from mean in milliseconds (e.g. 250 would indicate the probe is allowed to exceed the mean latency by 250 ms.) A probe that exceeds latency is counted the same as a probe that is not received, so in the typical scenario, it will require three missed latencies in a row to mark a pool member or node down (i.e. a 15-second interval with a 46-second timeout, would require three missed probes before the pool member or node would be marked down.)

adaptive-limit
Specifies the hard limit, in milliseconds, which the probe is not allowed to exceed, regardless of the divergence value. For example, if this value is 500, then the probe latency may not exceed 500 ms even if that would still fall within the divergence value.

adaptive-sampling-timespan
Specifies the size of the sliding window, in seconds, which records probe history. For example, if this value is 300, then a sliding window of the last five minutes' probe history will be used for calculating probe mean latency and standard deviation.

app-service
Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

defaults-from
Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is tcp.

description
User defined description.

destination
Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is *.*.

Possible values are:

: Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port
Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port
Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

IP address:port (with the transparent option enabled)
Specifies to perform a health check on the server at the IP address and port you specify, route the check through the IP address and port supplied by the pool member, and mark the pool member (the gateway) up or down accordingly.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval
Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

ip-dscp
Specifies the differentiated services code point (DSCP). DSCP is a 6-bit value in the Differentiated Services (DS) field of the IP header. It can be used to specify the quality of service desired for the packet. The valid range for this value is 0 to 63 (hex 0x0 to 0x3f). The default value is zero.

manual-resume
Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required

for the commands create, delete, modify, run and stop.

partition
Displays the administrative partition within which the component resides.

recv Specifies the text string that the monitor looks for in the returned resource. The default value is none.

The most common receive expressions contain a text string that is included in an HTML file on your site. The text string can be regular text, HTML tags, or image names. If you do not specify a value for both the send and recv options, the monitor performs a simple service check and connect only.

recv-disable
Specifies a text string that the monitor looks for in the returned resource. If the text string is matched in the returned resource, the corresponding node or pool member is marked session disabled. The default value is none.

You specify a recv-disable string in the same way that you specify a recv string.

If you specify a recv-disable string, you must also specify a recv string. You cannot specify a recv-disable string, if the reverse option is enabled.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reverse
Specifies whether the monitor operates in reverse mode. When the monitor is in reverse mode, a successful check marks the monitored object down instead of up. You can use the this mode only if you configure both the send and recv options.

The default value is disabled, which specifies that the monitor does not operate in reverse mode. The enabled value specifies that the monitor operates in reverse mode.

send Specifies the text string that the monitor sends to the target object. The default setting is GET /, which retrieves a default HTML file for a web site.

To retrieve a specific page from a web site, specify a fully-qualified path name, for example, GET /www/company/index.html. Since the string may have special characters, the system may require that the string be enclosed with single quotation marks.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if not null.

test-result
Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up
Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

transparent
Specifies whether the monitor operates in transparent mode. Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

up-interval
Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

BIG-IP 2017-08-16 ltm monitor tcp(1)

ltm monitor udp

NAME

udp - Configures a User Datagram Protocol (UDP) monitor.

MODULE

ltm monitor

SYNTAX

Configure the udp component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

```
create udp [name]
modify udp [name]
options:
  adaptive [enabled | disabled]
  adaptive-divergence-type [relative | absolute]
  adaptive-divergence-value [integer]
  adaptive-limit [integer]
  adaptive-sampling-timespan [integer]
  app-service [[string] | none]
  debug [no | yes]
  defaults-from [name]
  description [string]
  destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ]
  interval [integer]
  manual-resume [enabled | disabled]
  recv [none | [string] ]
  recv-disable [none | [string] ]
  reverse [enabled | disabled]
  send [none | [string] ]
  time-until-up [integer]
  timeout [integer]
  transparent [disabled | enabled]
  up-interval [integer]
```

```
edit udp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list udp
list udp [ [ [name] | [glob] | [regex] ] ... ]
show udp [ [ [name] | [glob] | [regex] ] ... ]
show running-config udp
show running-config udp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
  test-result
```

DELETE

```
delete udp [name]
```

Note: You cannot delete default monitors.

RUN

```
run udp [name] [ destination [ [ ipv4 address[:port] ] | [ ipv6 address[:port] ] ] ]
```

STOP

```
stop udp [name]
```

DESCRIPTION

You can use the udp component to configure a custom monitor, or you can use the default UDP monitor that the Local Traffic Manager provides. This type of monitor verifies the UDP service by attempting to send UDP packets to a pool, pool member, or virtual server and receiving a reply.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

```
create udp my_udp defaults-from udp
```

Creates a monitor named my_udp that inherits properties from the

default UDP monitor.

list udp

Displays the properties of all of the UDP monitors.

run udp my_udp destination 10.10.10.10:80

Runs a one-shot test of the custom monitor my_udp against a target node at 10.10.10.10:80.

stop udp my_udp

Cancels a one-shot test of the custom monitor my_udp in progress.

show udp my_udp test-result

Displays the result of the most recent one-shot test of the custom monitor my_udp.

OPTIONS

adaptive

Specifies whether the adaptive feature is enabled for this monitor. Not all monitors support the adaptive feature.

adaptive-divergence-type

Specifies whether the adaptive-divergence-value is relative or absolute.

adaptive-divergence-value

Specifies how far from mean latency each monitor probe is allowed to be. If adaptive-divergence-type is relative, this value is a percentage deviation from mean (e.g. 50 would indicate the probe is allowed to exceed the mean latency by 50%.) If adaptive-divergence-type is absolute, this value is an offset from mean in milliseconds (e.g. 250 would indicate the probe is allowed to exceed the mean latency by 250 ms.) A probe that exceeds latency is counted the same as a probe that is not received, so in the typical scenario, it will require three missed latencies in a row to mark a pool member or node down (i.e. a 15-second interval with a 46-second timeout, would require three missed probes before the pool member or node would be marked down.)

adaptive-limit

Specifies the hard limit, in milliseconds, which the probe is not allowed to exceed, regardless of the divergence value. For example, if this value is 500, then the probe latency may not exceed 500 ms even if that would still fall within the divergence value.

adaptive-sampling-timespan

Specifies the size of the sliding window, in seconds, which records probe history. For example, if this value is 300, then a sliding window of the last five minutes' probe history will be used for calculating probe mean latency and standard deviation.

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

no Specifies that the system does not redirect error messages and additional information related to this monitor.

yes Specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is udp.

description

User defined description.

destination

Specifies the IP address and service port of the resource that is the destination of this monitor. Possible values are:

*: * Specifies to perform a health check on the IP address and port supplied by a pool member.

*:port

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

IP address:port

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

IP address:port (with the transparent option enabled)

Specifies to perform a health check on the server at the IP address and port you specify, route the check through the IP

address and port supplied by the pool member, and mark the pool member (the gateway) up or down accordingly.

This option is required for the command run, unless an IP address and service port are specified in the destination option for the specified custom monitor.

`glob` Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

`interval`
Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

`manual-resume`
Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

`name` Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

`partition`
Displays the administrative partition within which the component resides.

`recv` Specifies the text string that the monitor looks for in the returned resource. The default value is none.

`recv-disable`
Specifies a text string that the monitor looks for in the returned resource. If the text string is matched in the returned resource, the corresponding node or pool member is marked session disabled. The default value is none.

The recv-disable string may be specified the same way a recv string may be specified.

If the recv-disable string is configured, the recv string must be non-empty. The recv-disable string may not be configured if reverse mode is enabled.

`regex`
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

`reverse`
Specifies whether the monitor operates in reverse mode. When the monitor is in reverse mode, a successful check marks the monitored object down instead of up. You can use the this mode only if you configure both the send and recv options.

The default value is disabled, which specifies that the monitor does not operate in reverse mode. The enabled value specifies that the monitor operates in reverse mode.

`send` Specifies the text string that the monitor sends to the target object. The default value is GET /, which retrieves a default HTML file for a web site.

To retrieve a specific page from a web site, specify a fully-qualified path name, for example, GET /www/company/index.html. Since the string may have special characters, the system may require that the string be enclosed with single quotation marks.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if it is not null. The default value is none.

`test-result`
Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

`time-until-up`
Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

`timeout`
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds. If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

`transparent`
Specifies whether the monitor operates in transparent mode.

Monitors in transparent mode can monitor pool members through firewalls. The default value is disabled.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

BIG-IP 2017-08-16 ltm monitor udp(1)

ltm monitor virtual-location

NAME

virtual-location - Configures a Virtual Location monitor.

MODULE

ltm monitor

SYNTAX

Configure the virtual-location component within the ltm monitor module using the syntax shown in the following sections.

CREATE/MODIFY

```
create virtual-location [name]
modify virtual-location [name]
options:
  app-service [[string] | none]
  debug [no | yes]
  defaults-from [name]
  description [string]
  interval [integer]
  pool [name]
  time-until-up [integer]
  timeout [integer]
  up-interval [integer]
```

```
edit virtual-location [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list virtual-location
list virtual-location [ [name] | [glob] | [regex] ] ... ]
show virtual-location [ [name] | [glob] | [regex] ] ... ]
show running-config virtual-location
show running-config virtual-location
    [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete virtual-location [name]
```

Note: You cannot delete default monitors.

DESCRIPTION

The Virtual Location monitor will determine if a pool member which has a virtual IP is currently a local pool member with its arp entry existing on a local VLAN, or, a remote pool member with its ARP entry existing on a tunnel VLAN. If the pool member is local it will set the pool member's priority to 2. If the pool member is remote it will set the priority to 1 (a lower priority). The Virtual Location will always return up as the availability for the pool member. It is necessary to use an additional monitor to check the availability status of the pool member.

You can use the virtual-location component to configure a custom monitor, or you can use the default Virtual Location monitor that the

Local Traffic Manager provides.

EXAMPLES

```
create virtual-location my_virtual-location defaults-from
virtual_location pool aPool
```

Creates a monitor named my_virtual-location that inherits properties from the default Virtual Location monitor.

```
list virtual-location
```

Displays the properties of all of the Virtual Location monitors.

OPTIONS

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

debug

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. The default setting is no. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The options are no (specifies that the system does not redirect error messages and additional information related to this monitor.) and yes (specifies that the system redirects error messages and additional information to the /var/log/monitors/--.log file.)

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is virtual_location.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 5 seconds.

Important: F5 Networks recommends that when you configure this option and the up-interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

pool Specifies the pool for the target pool member. This is a required argument.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

BIG-IP 2016-03-14 ltm monitor virtual-location(1)

ltm monitor wap

NAME

wap - Configures a Wireless Application Protocol (WAP) monitor.

MODULE

ltm monitor

SYNTAX

Configure the wap component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

create wap [name]

modify wap [name]

options:

accounting-node [none | [RADIUS server name]]
accounting-port [[integer] | none]
app-service [[string] | none]
call-id [none | [RADIUS server 11 digit phone number]]
debug [no | yes]
defaults-from [name]
description [string]
destination [[ipv4 address[:port]] | [ipv6 address[.port]]]
framed-address [none | [RADIUS framed IP address]]
interval [integer]
manual-resume [enabled | disabled]
recv [none | [string]]
secret [none | [password]]
send [none | [string]]
server-id [none | [RADIUS NAS-ID]]
session-id [none | [RADIUS session ID]]
time-until-up [integer]
timeout [integer]
up-interval [integer]

edit wap [[[name] | [glob] | [regex]] ...]

options:

all-properties
non-default-properties

DISPLAY

list wap

list wap [[[name] | [glob] | [regex]] ...]

show wap [[[name] | [glob] | [regex]] ...]

show running-config wap

show running-config wap [[[name] | [glob] | [regex]] ...]

options:

all-properties
non-default-properties
one-line
partition
test-result

DELETE

delete wap [name]

Note: You cannot delete default monitors.

RUN

run wap [name] [destination [[ipv4 address[:port]] | [ipv6 address[.port]]]]

STOP

stop wap [name]

DESCRIPTION

You can use the wap component to configure a custom monitor, or you can use the default WAP monitor that the Local Traffic Manager provides. This type of monitor requests the URL specified in the send option, and finds the string specified in the recv option somewhere in the data returned by the URL response.

You can test a custom monitor configuration against a specified target destination by using the run command, and view the results of such a test by using the show command with the test-result option.

The following user roles (in addition to the root user) have permissions to run and stop an ltm monitor test:

admin, application-editor, manager, operator, resource-admin

EXAMPLES

create wap my_wap defaults-from wap

Creates a monitor named `my_wap` that inherits properties from the default WAP monitor.

`list wap`

Displays the properties of all of the WAP monitors.

`run wap my_wap destination 10.10.10.10:80`

Runs a one-shot test of the custom monitor `my_wap` against a target node at 10.10.10.10:80.

`stop wap my_wap`

Cancels a one-shot test of the custom monitor `my_wap` in progress.

`show wap my_wap test-result`

Displays the result of the most recent one-shot test of the custom monitor `my_wap`.

OPTIONS

`accounting-node`

Specifies the RADIUS server that provides authentication for the WAP target. Note that if you configure the `accounting-port` option, but you do not configure the `this` option, the system assumes that the RADIUS server and the WAP server are the same system.

`accounting-port`

Specifies the port that the monitor uses for RADIUS accounting. The default value is none. A value of 0 (zero) disables RADIUS accounting.

`app-service`

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

`call-id`

Specifies the 11-digit phone number for the RADIUS server. The default value is none.

`debug`

Specifies whether the monitor sends error messages and additional information to a log file created and labeled specifically for this monitor. You can use the log information to help diagnose and troubleshoot unsuccessful health checks. The default value is no.

The options are:

`no` Specifies that the system does not redirect error messages and additional information related to this monitor.

`yes` Specifies that the system redirects error messages and additional information to the `/var/log/monitors/--.log` file.

`defaults-from`

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is `wap`.

`description`

User defined description.

`destination`

Specifies the IP address and service port of the resource that is the destination of this monitor. The default value is `*:*`.

Possible values are:

`*:*` Specifies to perform a health check on the IP address and port supplied by a pool member.

`*:port`

Specifies to perform a health check on the server with the IP address supplied by the pool member and the port you specify.

`IP address:port`

Specifies to mark a pool member up or down based on the response of the server at the IP address and port you specify.

This option is required for the command run, unless an IP address and service port are specified in the `destination` option for the specified custom monitor.

`glob` Displays the items that match the glob expression. See `help glob` for a description of glob expression syntax.

`framed-address`

Specifies the RADIUS framed IP address. The default value is none.

`interval`

Specifies, in seconds, the frequency at which the system issues the monitor check when either the resource is down or the status of the resource is unknown. The default value is 10 seconds.

Important: F5 Networks recommends that when you configure this option and the `up-interval` option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

manual-resume

Specifies whether the system automatically changes the status of a resource to up at the next successful monitor check. The default value of the manual-resume option is disabled.

Note that if you set the manual-resume option to enabled, you must manually mark the resource as up before the system can use it for load balancing connections.

name Specifies a unique name for the component. This option is required for the commands create, delete, modify, run and stop.

partition

Displays the administrative partition within which the component resides.

recv Specifies the text string that the monitor looks for in the returned resource. The most common receive expressions contain a text string that is included in an HTML file on your site. The text string can be regular text, HTML tags, or image names. If you do not specify both a value for both the send and recv options, the monitor performs a simple service check and connect only. The default value is none.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

secret

Specifies the password the monitor needs to access the resource. The default value is none.

send Specifies the text string that the monitor sends to the target object. The default setting is GET /, which retrieves a default HTML file for a web site.

To retrieve a specific page from a web site, specify a fully-qualified path name, for example, GET /www/company/index.html. Since the string may have special characters, the system may require that the string be enclosed with single quotation marks.

If this value is null, then a valid connection suffices to determine that the service is up. In this case, the system does not need the recv option and ignores the option even if it is not null. The default value is none.

server-id

Specifies the RADIUS NAS-ID for this system when configuring a RADIUS server. The default value is none.

session-id

Specifies the RADIUS session identification number when configuring a RADIUS server. The default value is none.

test-result

Displays the result of the most recent one-shot test of the specified monitor(s), if any such test has been performed since BIG-IP was started.

time-until-up

Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout

Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 31 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

up-interval

Specifies, in seconds, the frequency at which the system issues the monitor check when the resource is up. The default value is 0 (zero), which specifies that the system uses the value of the interval option whether the resource is up or down.

Important: F5 Networks recommends that when you configure this option and the interval option, whichever value is greater be a multiple of the lesser value to allow for an even distribution of monitor checks among all monitors.

ltm monitor wmi

NAME
wmi - Configures a Windows Management Infrastructure (WMI) monitor.

MODULE
ltm monitor

SYNTAX
Configure the wmi component within the ltm monitor module using the syntax in the following sections.

CREATE/MODIFY

```
create wmi [name]
modify wmi [name]
options:
  agent [string]
  app-service [[string] | none]
  command [ [command] | none ]
  defaults-from [name]
  description [string]
  interval [integer]
  metrics [ [value] | none]
  password [none | [password] ]
  time-until-up [integer]
  timeout [integer]
  url [none | [URL] ]
  username [ [name] | none]
```

```
edit wmi [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list wmi
list wmi [ [ [name] | [glob] | [regex] ] ... ]
show wmi [ [ [name] | [glob] | [regex] ] ... ]
show running-config wmi
show running-config wmi [ [ [name] | [glob] | [regex] ] ... ]
options:
  agent
  all-properties
  method
  non-default-properties
  one-line
  partition
  post
```

DELETE

```
delete wmi [name]
```

Note: You cannot delete default monitors.

DESCRIPTION

You can use the wmi component to configure a custom monitor, or you can use the default WMI monitor that the Local Traffic Manager provides. This type of monitor checks the performance of a pool, pool member, or virtual server that is running the WMI data collection agent, and then dynamically load balances traffic accordingly.

EXAMPLES

```
create wmi my_wmi defaults-from wmi
```

Creates a monitor named my_wmi that inherits properties from the default WMI monitor.

```
list wmi
```

Displays the properties of all of the WMI monitors.

OPTIONS

agent

Displays the agent for the monitor. The default agent is Mozilla/4.0 (compatible: MSIE 5.0; Windows NT).

app-service

Specifies the name of the application service to which the monitor belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the monitor. Only the application service can modify or delete the monitor.

command

Specifies the command that the system uses to obtain the metrics from the resource. See the documentation for this resource for information on available commands.

defaults-from

Specifies the name of the monitor from which you want your custom monitor to inherit settings. The default value is wmi.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interval
Specifies the frequency at which the system issues the monitor check. The default value is 5 seconds.

method
Displays the GET method. You cannot modify the method.

metrics
Specifies the performance metrics that the commands collect from the target. The default value is LoadPercentage, DiskUsage, PhysicalMemoryUsage:1.5, VirtualMemoryUsage:2.0.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition
Displays the administrative partition within which the component resides.

password
Specifies the password if the monitored target requires authentication. The default value is none.

post Specifies the mechanism that the monitor uses for posting. The default value is RespFormat=HTML.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

time-until-up
Specifies the amount of time, in seconds, after the first successful response before a node is marked up. A value of 0 (zero) causes a node to be marked up immediately after a valid response is received from the node. The default value is 0 (zero).

timeout
Specifies the number of seconds the target has in which to respond to the monitor request. The default value is 16 seconds.

If the target responds within the set time period, it is considered up. If the target does not respond within the set time period, it is considered down. Also, if the target responds with a RESET packet, the system immediately flags the target as down without waiting for the timeout interval to expire.

url Specifies the URL that the monitor uses. The default value is /scripts/f5Isapi.dll.

username
Specifies the user name if the monitored target requires authentication. The default value is none.

SEE ALSO

BIG-IP 2017-04-05 ltm monitor wmi(1)

ltm nat

NAME
nat - Configures network address translation (NAT) for the Local Traffic Manager.

MODULE
ltm

SYNTAX
Configure the nat component within the ltm module using the syntax in the following sections.

CREATE/MODIFY
create nat [name]
modify nat [name]

```

options:
  app-service [[string] | none]
  arp
  auto-lasthop [default | enabled | disabled ]
  description [string]
  [enabled | disabled]
  originating-address [ip address]
  translation-address [ip address]
  traffic-group [[string] | default | non-default | none]
  vlans [enabled | disabled]
  vlans-disabled
  vlans-enabled
reset-stats nat
reset-stats nat [ [ [name] | [glob] | [regex] ] ... ]

edit nat [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties

DISPLAY
list nat
list nat [ [ [name] | [glob] | [regex] ] ... ]
show running-config nat
show running-config nat [ [ [name] | [glob] |
  [regex] ] ... ]
  options:
    all-properties
    non-default-properties
    one-line
    partition

show nat
show nat [name]
  options:
    (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
    field-fmt

DELETE
delete nat [name]

```

DESCRIPTION

A network address translation (NAT) defines a mapping between an originating IP address and an IP address that you specify.

A primary reason for defining a NAT is to allow one of the servers in the server array behind the traffic management system to start communication with a computer in front of, or external to, the system.

EXAMPLES

```
create nat new_nat translation-address 10.0.140.100 originating-address
11.0.0.100
```

The node behind the system with the IP address 10.0.140.100 has a presence in front of the BIG-IP(r) System as IP address 11.0.0.100.

```
delete nat new_nat
```

Permanently deletes the NAT from the system configuration.

Additional Restrictions

The nat component has the following additional restrictions:

- o A virtual server cannot use the IP address specified in the NAT.
- o A NAT should not use an IP address of a BIG-IP system.
- o A NAT cannot use an originating or translated IP address defined for and used by a SNAT or another NAT.
- o You must delete a NAT before you can redefine it.

OPTIONS

app-service

Specifies the name of the application service to which the NAT belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the NAT. Only the application service can modify or delete the NAT.

arp Enables or disables Address Resolution Protocol (ARP).

description

User defined description.

[enabled | disabled]

Enables or disables the NAT. The default value is enabled.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

inherited-traffic-group

Indicates if the traffic-group is inherited from the parent folder. This property is read only.

originating-address

Specifies the IP address from which traffic is being initiated.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

traffic-group
Specifies the traffic group of the failover device group on which the NAT is active. The default traffic group is inherited from the containing folder.

translation-address
Specifies the IP address that is translated or mapped, and the IP address to which it is translated or mapped. This option is required when creating a NAT. This option may not be changed after the nat has been created.

unit Specifies the unit in a redundant system. Derived from traffic-group. This property is read only.

vlan
Specifies a list of existing VLANs on which access to the NAT is enabled or disabled. A NAT is accessible on all VLANs by default.

vlan-disabled
Indicates the NAT is disabled on the list of VLANs.

vlan-enabled
Indicates the NAT is enabled on the list of VLANs.

ltm node

NAME
node - Configures node addresses and services.

MODULE
ltm

SYNTAX
Configure the node component within the ltm module using the syntax in the following sections.

```
CREATE/MODIFY
create node [name]
modify node [name]
options:
  address [ip address]
  app-service [[string] | none]
  connection-limit [integer]
  description [string]
  [down | up]
  dynamic-ratio [integer]
  fqdn {
name [string]
address-family [ipv4 | ipv6]
autopopulate [enabled | disabled]
down-interval [integer]
interval [integer]
}
  logging [enabled | disabled]
  monitor [ [name] | none]
  rate-limit [integer]
  ratio [integer]
  session [user-enabled | user-disabled]
  state [user-down | user-up]
  metadata
    [add | delete | modify] {
[metadata_name ... ] {
  value [ "value content" ]
  persist [ true | false ]
}
}

reset-stats node
reset-stats node [ [ip address] | [glob] | [regex] ] ... ]

edit node [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

mv node [ [[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-name]] ]
```

options:
to-folder

DISPLAY
list node
list node [[[name] | [glob] | [regex]] ...]
show running-config node
show running-config node [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties

partition
show node
show node [name]
options:
all-properties
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
field-fmt

DELETE
delete node [name]

DESCRIPTION
Displays information about nodes, and sets attributes of nodes and node IP addresses.

EXAMPLES
list node all-properties
Displays all of the properties of all of the nodes.
modify node all monitor none
Removes all monitor associations from nodes.
create node myNode address 10.10.10.15
Creates a node named myNode with an IP address of 10.10.10.15.
modify node myNode monitor none
Removes all monitor associations from the node, myNode.
show node
Displays statistics and status for all nodes in the system configuration.
show node all-properties
Displays statistics and status for all nodes in the system configuration. If the system includes Packet Velocity(r) ASIC (PVA) and PVA Assist capabilities, this command displays status and statistics for that feature.
mv /ltm node /Common/10.10.10.15 to-folder /Common/all_nodes
Moves the node 10.10.10.15 to a folder named all_nodes, where all_nodes has already been created under /Common.
Note: If you wish to change the name of the node, you must use the nodes same IP Address or a name that does not represent an IP Address that does not match the address configured on the node.
Please refer to the mv manual page for additional examples on how to use the mv command.

OPTIONS

address
Specifies the IP address of the node.

app-service
Specifies the name of the application service to which the node belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the node. Only the application service can modify or delete the node.

connection-limit
Specifies the maximum number of connections that a node or node address can handle. The default value is 0 (zero).

description
Specifies a user-defined description.

[down | up]
Marks the node up or down. The default value is down.

dynamic ratio
Sets the dynamic ratio number for the node. The ratio weights are based on continuous monitoring of the servers and are therefore continually changing. The default value is 1.

Dynamic Ratio load balancing can currently be implemented on RealNetworks RealServer platforms, on Windows platforms equipped with Windows Management Instrumentation (WMI), or on a server equipped with either the UC Davis SNMP agent or Windows 2000 Server SNMP agent.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

metadata

Associates user defined data, each of which has a name and value pair and persistence. The default value is persistent, which saves the data to the config file.

`fqdn` Specifies the attributes for defining a fully qualified domain name for the node.

`name` Specifies the fully-qualified domain name of the node.

`address-family`
Specifies whether the `fqdn` should consider IPv4, IPv6, or IP-agnostic address family.

`autopopulate`
Specifies whether a node defined by a fully-qualified domain name should automatically scale to the set of IP addresses returned by the DNS query. If disabled, only one ephemeral node is generated from the first IP address returned by DNS. The default is disabled.

`interval`
Specifies the interval to instantiate DNS queries on a fully-qualified domain name. The default is the TTL.

`down-interval`
Specifies the interval for the domain name resolution operation when a DNS query fails.

`logging`
Specifies whether the monitor applied should log its actions. Logs are stored in `/var/log/monitors/` and are regularly rotated and compressed. The default value is disabled. This option isn't a part of configuration and will reset to disabled on load. This option doesn't sync.

`monitor`
Specifies the name of the monitor that you want to associate with the node. The default value is none.

`partition`
Displays the administrative partition in which the node object resides.

`rate-limit`
Specifies the maximum number of connections per second allowed for a node or node address. The default value is 'disabled'.

`ratio`
Specifies the fixed ratio value used for a node during Ratio load balancing. The default value is 1.

`regex`
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

`session`
Establishing a session with a node is establishing the ability of the client to persist to the node when making new connections. When a node is session disabled, clients that have already established sessions with the node may create new connections, but a client that has not already established a session may not create a new one (or make a connection which would create a new session). This feature is used to gently drain connections from a node, typically as part of a maintenance operation. The default value is user-enabled.

`state`
Specifies the current state of the node. Use `user-down` to indicate that the node may not handle any new connections. Use `user-up`, after using `user-down`, to indicate that the node may accept new connections.

`to-folder`
This is used with the `mv` command to specify a folder in which to move the node to.

Note: nodes can be moved to any folder under `/Common`, but dependencies upon it may restrict moving it out of `/Common`.

DESCRIPTION

You can use the cookie component to configure cookie persistence for the BIG-IP(r) system. Cookie persistence uses an HTTP cookie stored on a client's computer to allow the client to connect to the same server previously visited at a web site.

A persistence profile is a profile that enables persistence when you assign the profile to a virtual server. Using a persistence profile avoids having to write an iRule to implement a type of persistence. You can either use the default profile, or create a custom profile based on the default.

EXAMPLES

```
list cookie
```

Displays all cookie persistence profiles.

```
create cookie cookie_persistence defaults-from cookie
```

Creates a custom cookie persistence profile named `cookie_persistence` that inherits its settings from the default cookie persistence profile.

```
mv cookie /Common/my_cookie_profile to-folder /Common/my_folder
```

Moves a custom cookie persistence profile named `my_cookie_profile` to a folder named `my_folder`, where `my_folder` has already been created and exists within `/Common`.

OPTIONS

always-send

Send the cookie persistence entry on every reply, even if the entry has previously been supplied to the client. The default value is disabled.

app-service

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

cookie-name

Specifies a unique name for the cookie. This option is required.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is cookie, the system default cookie persistence profile.

description

User defined description.

cookie-encryption

Specifies the way in which cookie format will be used: disabled: generate old format, unencrypted, preferred: generate encrypted cookie but accept both encrypted and old format, and required: cookie format must be encrypted. Default is required.

cookie-encryption-passphrase

Specifies a passphrase to be used for cookie encryption.

expiration

Specifies the cookie expiration date in the format d:h:m:s, h:m:s, m:s or seconds. (hours 0-23, minutes 0-59, seconds 0-59). The time period must be less than 24856 days.

You can use "session-cookie" (0 seconds) to indicate that the cookie expires when the browser closes.

encrypt-cookie-poolname

Specifies whether the pool-name in the inserted BigIPServer default cookie should be encrypted. The default value is disabled.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

httponly

Specifies whether the httponly attribute should be enabled or disabled for the inserted cookies. The default value is enabled.

secure

Specifies whether the secure attribute should be enabled or disabled for the inserted cookies. The default value is enabled.

hash-length

Specifies the cookie hash length. The length is the number of bytes to use when calculating the hash value. The default value is 0 (zero) bytes.

hash-offset

Specifies the cookie hash offset. The offset is the number of bytes in the cookie to skip before calculating the hash value. The default value is 0(zero) bytes.

match-across-pools

Specifies, when enabled, that the system can use any pool that contains this persistence record. The default value is disabled.

match-across-services

Specifies, when enabled, that all persistent connections from a client IP address, which go to the same virtual IP address, also go to the same node. The default value is disabled.

match-across-virtuals

Specifies, when enabled, that all persistent connections from the same client IP address go to the same node. The default value is disabled.

method

Specifies the type of cookie processing that the system uses. The default value is insert.

mirror

Specifies whether the system mirrors persistence records to the high-availability peer. This option is applicable only when the value of the method option is hash. The default value is disabled.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

override-connection-limit

Specifies, when enabled, that the pool member connection limits are not enforced for persisted clients. Per-virtual connection limits remain hard limits and are not disabled. The default value is disabled.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

timeout

Specifies the duration of the persistence entries. The default value is 180 seconds.

to-folder
cookie persistence profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

DELETE

delete dest-addr [name]

options:

all

DESCRIPTION

You can use the dest-addr component to configure a destination address affinity persistence profile for the BIG-IP(r) system. Also known as sticky persistence, destination address affinity persistence supports TCP and UDP protocols, and directs session requests to the same server based solely on the destination IP address of a packet.

A persistence profile is a profile that enables persistence when you assign the profile to a virtual server. Using a persistence profile means that you do not have to write an iRule to implement a type of persistence. You can either use the default profile, or create a custom

profile based on the default.

EXAMPLES

```
list dest-addr
```

Displays all destination address affinity persistence profiles.

```
create dest-addr da_persistence defaults-from dest-addr
```

Creates a custom destination address affinity persistence profile named `da_persistence` that inherits its settings from the default destination address affinity persistence profile.

```
mv dest-addr /Common/my_dest-addr_profile to-folder /Common/my_folder
```

Moves a custom destination address persistence profile named `my_dest-addr_profile` to a folder named `my_folder`, where `my_folder` has already been created and exists within `/Common`.

OPTIONS

`app-service`

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

`defaults-from`

Specifies the existing profile from which the system imports settings for the new profile. The default value is `dest_addr`, the system default destination address affinity persistence profile.

`description`

User defined description.

`glob` Displays the items that match the `glob` expression. See `help glob` for a description of `glob` expression syntax.

`hash-algorithm`

Specifies the system uses hash persistence load balancing. The default value is `default` (no hash persistence).

The options are:

`carp` Specifies to use the Cache Array Routing Protocol (CARP) to select the pool member for LB. The input to CARP is the hash value of destination address.

`default`

no hash persistence.

`mask` Specifies an IP mask. This is the mask used by simple persistence for connections. The default value is `::`.

`match-across-pools`

Specifies, when enabled, that the system can use any pool that contains this persistence record. The default value is disabled.

`match-across-services`

Specifies, when enabled, that all persistent connections from a client IP address, which go to the same virtual IP address, also go to the same node. The default value is disabled.

`match-across-virtuals`

Specifies, when enabled, that all persistent connections from the same client IP address go to the same node. The default value is disabled.

`mirror`

Specifies whether the system mirrors persistence records to the high-availability peer. The default value is disabled.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

`override-connection-limit`

Specifies, when enabled, that the pool member connection limits are not enforced for persisted clients. Per-virtual connection limits remain hard limits and are not disabled. The default value is disabled.

`partition`

Displays the administrative partition within which the component resides.

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See `help regex` for a description of regular expression syntax.

`timeout`

Specifies the duration of the persistence entries. The default value is 180 seconds.

`to-folder`

`dest-addr` persistence profiles can be moved to any folder under `/Common`, but configuration dependencies may restrict moving the profile out of `/Common`.

BIG-IP 2014-01-14 ltm persistence dest-addr(1)

ltm persistence global-settings

NAME

global-settings - Configures persistence for the BIG-IP(r) system.

MODULE

ltm persistence

SYNTAX

Configure the global-settings component within the ltm persistence module using the syntax in the following sections.

MODIFY

modify global-settings [option name]

options:

description [string]
dest-addr-limit-mode [timeout | maxcount]
dest-addr-max [integer]
proxy-group [string]

edit global-settings [[[name] | [glob] | [regex]] ...]

options:

all-properties
non-default-properties

DISPLAY

list global-settings

list global-settings [[[name] | [glob] | [regex]] ...]

show running-config global-settings

show running-config global-settings

[[[name] | [glob] | [regex]] ...]

options:

all-properties
non-default-properties
one-line

DESCRIPTION

You can use the global-settings component within the ltm persistence module to configure persistence for the system.

For information about configuring session persistence for a virtual server, see the man pages for the following components: ltm persistence hash, ltm persistence msrdp, ltm persistence sip, ltm persistence source-addr, ltm persistence ssl, and ltm persistence universal.

EXAMPLES

list global-settings

Displays the global persistence configuration.

modify global-settings dest-addr-limit-mode maxcount

Sets the value of the option dest-addr-limit-mode to maxcount, which indicates that a persistence session is limited by the maximum number of requests to the destination address.

OPTIONS

description

User defined description.

dest-addr-limit-mode

Specifies that a persistence session is limited by either the number of seconds before the persistence entry times out, or by a maximum number of requests to the destination address. The default value is timeout.

dest-addr-max

Specifies the maximum number of entries that the persistence table can contain at any one time, when the value of the option dest-addr-limit-mode is maxcount. The default value is 2048 entries.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

proxy-group

Specifies a group of servers that are configured to process all of the requests from a single source address during a persistence session. The default value is aol.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

list, ltm virtual, modify, regex, show, tmsh

COPYRIGHT

options:

all

DESCRIPTION

You can use the hash component to configure a hash persistence profile for the BIG-IP(r) system. Hash persistence can also be activated from an existing iRule.

A persistence profile is a profile that enables persistence when you assign the profile to a virtual server. Using a persistence profile means that you do not have to write an iRule to implement a type of persistence. You can either use the default profile, or create a custom profile based on the default.

EXAMPLES

list hash

Displays all hash persistence profiles.

create hash hash_persistence defaults-from hash

Creates a custom hash persistence profile named hash_persistence that inherits its settings from the default hash persistence profile.

mv hash /Common/my_hash_profile to-folder /Common/my_folder

Moves a custom hash persistence profile named my_hash_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is hash, the system default cookie persistence profile.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

hash-algorithm

Specifies the algorithm the system uses for hash persistence load balancing. The default value is default.

The options are:

carp Specifies to use the Cache Array Routing Protocol (CARP) to select the pool member for LB.

default

Specifies to use indexing of pool members to select the pool member for LB.

hash-buffer-limit

Specifies the maximum buffer length the system collects to locate the hashing pattern for hash persistence load balancing. The default value is 0 (zero).

hash-end-pattern

Specifies the string that describes the ending location of the hash pattern that the system uses to perform hash persistence load balancing. The default value is none.

hash-length

Specifies the length of data within the packet in bytes that the system uses to calculate the hash value when performing hash persistence load balancing. The default value is 0 (zero) bytes.

hash-offset

Specifies the start offset within the packet from which the system begins the hash when performing hash persistence load balancing. The default value is 0 (zero).

hash-start-pattern

Specifies the string that describes the start location of the hash pattern that the system uses to perform hash persistence load balancing. The default value is none.

match-across-pools

Specifies, when enabled, that the system can use any pool that contains this persistence record. The default value is disabled.

match-across-services

Specifies, when enabled, that all persistent connections from a client IP address, which go to the same virtual IP address, also go to the same node. The default value is disabled.

match-across-virtuals

Specifies, when enabled, that all persistent connections from the same client IP address go to the same node. The default value is disabled.

mirror

Specifies whether the system mirrors persistence records to the high-availability peer. The default value is disabled.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

override-connection-limit

Specifies, when enabled, that the pool member connection limits are not enforced for persisted clients. Per-virtual connection limits remain hard limits and are not disabled. The default value is disabled.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

rule Specifies a rule name, if you are using a rule for universal persistence.

timeout

Specifies the duration of the persistence entries. The default value is 180 seconds.

to-folder

hash persistence profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

SEE ALSO

create, delete, edit, glob, list, ltm virtual, modify, mv, regex, show, tmsh

ltm persistence host

NAME

host - Configures a host persistence profile.

MODULE

ltm persistence

SYNTAX

Configure the host component within the ltm persistence module using the syntax in the following sections.

MODIFY

```
create host [name]
modify host [name]
options:
  all
  app-service [[string] | none]
  defaults-from [name]
  description [string]
  match-across-pools [enabled | disabled]
  match-across-services [enabled | disabled]
  match-across-virtuals [enabled | disabled]
  mirror [enabled | disabled]
  override-connection-limit [enabled | disabled]
  timeout [integer]
```

```
edit host [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```
mv host [ [[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-name]] ]
options:
  to-folder
```

DISPLAY

```
list host
list host [ [ [name] | [glob] | [regex] ] ... ]
show running-config host
show running-config host [name]
options:
  all
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete host [name]
options:
  all
```

DESCRIPTION

You can use the host component to configure a host persistence profile for the BIG-IP(r) system. Host persistence uses the HTTP Host header

passed in a HTTP request to determine which pool member to pick. Host persistence can also be activated from an existing iRule.

A persistence profile is a profile that enables persistence when you assign the profile to a virtual server. Using a persistence profile means that you do not have to write an iRule to implement a type of persistence. You can either use the default profile, or create a custom profile based on the default.

EXAMPLES

```
list host
```

Displays all host persistence profiles.

```
create host host_persistence defaults-from host
```

Creates a custom host persistence profile named `host_persistence` that inherits its settings from the default host persistence profile.

```
mv host /Common/my_host_profile to-folder /Common/my_folder
```

Moves a custom host persistence profile named `my_host_profile` to a folder named `my_folder`, where `my_folder` has already been created and exists within `/Common`.

OPTIONS

`app-service`

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

`defaults-from`

Specifies the existing profile from which the system imports settings for the new profile. The default value is `host`, the system default host persistence profile.

`description`

User defined description.

`match-across-pools`

Specifies, when enabled, that the system can use any pool that contains this persistence record. The default value is disabled.

`match-across-services`

Specifies, when enabled, that all persistent connections from a client IP address, which go to the same virtual IP address, also go to the same node. The default value is disabled.

`match-across-virtuals`

Specifies, when enabled, that all persistent connections from the same client IP address go to the same node. The default value is disabled.

`mirror`

Specifies whether the system mirrors persistence records to the high-availability peer. The default value is disabled.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

`override-connection-limit`

Specifies, when enabled, that the pool member connection limits are not enforced for persisted clients. Per-virtual connection limits remain hard limits and are not disabled. The default value is disabled.

`partition`

Displays the administrative partition within which the component resides.

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See `help regex` for a description of regular expression syntax.

`timeout`

Specifies the duration of the persistence entries. The default value is 180 seconds.

`to-folder`

host persistence profiles can be moved to any folder under `/Common`, but configuration dependencies may restrict moving the profile out of `/Common`.

SEE ALSO

options:
all
all-properties
non-default-properties
one-line
partition

DELETE
delete msrdp [name]
options:
all

DESCRIPTION
You can use the msrdp component to configure an MSRDP persistence profile for the BIG-IP(r) system. MSRDP persistence provides an efficient way of load balancing traffic and maintaining persistent sessions between Windows clients and servers that are running the Microsoft Terminal Services service. The recommended scenario for enabling the MSRDP persistence feature is to create a load balancing pool that consists of members running Windows .NET Server 2003, Enterprise Edition, or later, where all members belong to a Windows cluster and participate in a Windows session directory.

A persistence profile is a profile that enables persistence when you assign the profile to a virtual server. Using a persistence profile means that you do not have write an iRule to implement a type of persistence. You can either use the default profile, or create a custom profile based on the default.

EXAMPLES
list msrdp
Displays all MSRDP persistence profiles.
create msrdp msrdp_persistence defaults-from msrdp
Creates a custom MSRDP persistence profile named msrdp_persistence that inherits its settings from the default MSRDP persistence profile
mv msrdp /Common/my_msrdp_profile to-folder /Common/my_folder
Moves a custom MSRDP persistence profile named my_msrdp_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS
app-service
Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object,

you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is msrdp, the system default cookie persistence profile.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

has-session-dir

Specifies whether the Microsoft terminal services are configured with a session directory, so the system does not load balance the initial connection. The default value is yes.

match-across-pools

Specifies, when enabled, that the system can use any pool that contains this persistence record. The default value is disabled.

match-across-services

Specifies, when enabled, that all persistent connections from a client IP address, which go to the same virtual IP address, also go to the same node. The default value is disabled.

match-across-virtuals

Specifies, when enabled, that all persistent connections from the same client IP address go to the same node. The default value is disabled.

mirror

Specifies whether the system mirrors persistence records to the high-availability peer. The default value is disabled.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

override-connection-limit

Specifies, when enabled, that the pool member connection limits are not enforced for persisted clients. Per-virtual connection limits remain hard limits and are not disabled. The default value is disabled.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

timeout

Specifies the duration of the persistence entries. The default value is 300 seconds.

to-folder

msrdp persistence profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

SEE ALSO

BIG-IP 2014-01-14 ltm persistence msrdp(1)

ltm persistence persist-records

NAME

persist-records - Displays or deletes persistence records.

MODULE

ltm persistence

SYNTAX

Configure the persist-records component within the ltm persistence

module using the syntax in the following sections.

DISPLAY

show persist-records

options:

client-addr [ip address]
key [string]
mode [cookie | destination-address | hash | msrdp | sip |
source-address | ssl-session-id | universal]
node-addr [ip address]
node-port [integer]
pool [string]
save-to-file [filename]
virtual [string]

DELETE

delete persist-records

options:

client-addr [ip address]
key [string]
mode [cookie | destination-address | hash | msrdp | sip |
source-address | ssl-session-id | universal]
node-addr [ip address]
node-port [integer]
pool [string]
virtual [string]

DESCRIPTION

You can use the persist-records component to either display or delete records of persistent connections.

EXAMPLES

show persist-records

Displays all persistent connections on the BIG-IP(r) system.

delete persist-records client-addr 172.19.255.1

Deletes all persistent connections that originate from the client IP address, 172.19.255.1.

OPTIONS

client-addr

Specifies the IP address of the client from which the persistent connections you want to view or delete persist.

key Specifies a string that the system is using to persist the connections you want to view or delete.

mode Specifies the type of persistence of the connections you want to view or delete. The options are:

cookie

Cookie persistence uses an HTTP cookie stored on a client's computer to allow the client to connect to the same server previously visited at a web site.

destination-address

Also known as sticky persistence, destination address affinity persistence supports TCP and UDP protocols, and directs session requests to the same server based solely on the destination IP address of a packet.

hash Hash persistence is based on an existing iRule.

msrdp

MSRDP persistence provides an efficient way of load balancing traffic and maintaining persistent sessions between Windows(r) clients and servers that are running the Microsoft(r) Terminal Services service. The recommended scenario for enabling the MSRDP persistence feature is to create a load balancing pool that consists of members running Windows .NET Server 2003, Enterprise Edition, or later, where all members belong to a Windows cluster and participate in a Windows session directory.

sip Session Initiation Protocol (SIP) persistence is a type of persistence available for server pools. You can configure SIP persistence for proxy servers that receive SIP messages sent through UDP. The BIG-IP system currently supports persistence for SIP messages sent through UDP, TCP, or SCTP.

source-address

Also known as simple persistence, source address affinity persistence supports TCP and UDP protocols, and directs session requests to the same server based solely on the source IP address of a packet. When you specify a source address as the mode of persistence, you must specify an IP address using the client-addr option.

ssl-session-id

SSL persistence is a type of persistence that tracks non-terminated SSL sessions, using the SSL session ID. Even when the client's IP address changes, the system still recognizes the connection as being persistent based on the session ID. Note that the term, non-terminated SSL sessions, refers to sessions in which the system does not perform the tasks of SSL certificate authentication and encryption/re-encryption.

universal

Universal persistence allows you to write an expression that defines what to persist on in a packet. The expression, written using the same expression syntax that you use in iRules(r), defines some sequence of bytes to use as a session

identifier.

node-addr
Specifies the IP address of the node with which the client sessions that you want to view or delete remain persistent.

node-port
Specifies the port number of the node with which the client sessions that you want to view or delete remain persistent.

pool Specifies the pool member with which the client sessions that you want to view or delete remain persistent.

save-to-file
Specifies the file which persist-records information can be save to. With this option, it can write a file larger than 2GB.

virtual
Specifies the virtual server with which the client sessions that you want to view or delete remain persistent.

SEE ALSO

delete, show, tmsh

COPYRIGHT

  match-across-virtuals [enabled | disabled]
  mirror [enabled | disabled]
  override-connection-limit [enabled | disabled]
  sip-info [Call-ID | From | none | SIP-ETag | Subject | To]
  timeout [integer]
```

```
edit sip [ [name] | [glob] | [regex] ] ... ]
```

options:

all-properties
non-default-properties

```
mv sip [ [[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-name]
```

options:

to-folder

DISPLAY

```
list sip
list sip [ [name] | [glob] | [regex] ] ... ]
show running-config sip
show running-config sip [ [name] | [glob] | [regex] ] ... ]
options:
  all
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete sip [name]
options:
  all
```

DESCRIPTION

You can use the sip component to configure a SIP persistence profile for the BIG-IP(r) system. SIP persistence is a type of persistence available for server pools. You can configure SIP persistence for proxy servers that receive SIP messages sent through UDP. The BIG-IP system currently supports persistence for SIP messages sent through UDP, TCP, or SCTP.

A persistence profile is a profile that enables persistence when you assign the profile to a virtual server. Using a persistence profile means that you do not have write an iRule to implement a type of persistence. You can either use the default profile, or create a custom profile based on the default.

EXAMPLES

```
list sip
```

Displays all SIP persistence profiles.

```
create sip sip_persistence defaults-from sip_info
```

Creates a custom SIP persistence profile named sip_persistence that inherits its settings from the default SIP persistence profile.

```
mv sip /Common/my_sip_profile to-folder /Common/my_folder
```

Moves a custom SIP persistence profile named my_sip_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is sip_info, the system default cookie persistence profile.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

match-across-pools

Specifies, when enabled, that the system can use any pool that contains this persistence record. The default value is disabled.

match-across-services

Specifies, when enabled, that all persistent connections from a client IP address, which go to the same virtual IP address, also go to the same node. The default value is disabled.

match-across-virtuals

Specifies, when enabled, that all persistent connections from the same client IP address go to the same node. The default value is disabled.

mirror

Specifies whether the system mirrors persistence records to the high-availability peer. The default value is disabled.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

override-connection-limit

Specifies, when enabled, that the pool member connection limits are not enforced for persisted clients. Per-virtual connection limits remain hard limits and are not disabled. The default value is disabled.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

sip-info

Specifies the SIP header field on which you want SIP sessions to persist. The default value is none.

timeout

Specifies the duration of the persistence entries. The default value is 180 seconds.

to-folder

sip persistence profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

DESCRIPTION
You can use the source-addr component to configure a source address affinity persistence profile for the BIG-IP(r) system. Also known as simple persistence, source address affinity persistence supports TCP and UDP protocols, and directs session requests to the same server based solely on the source IP address of a packet.

A persistence profile is a profile that enables persistence when you assign the profile to a virtual server. Using a persistence profile means that you do not have to write an iRule to implement a type of persistence. You can either use the default profile, or create a custom profile based on the default.

EXAMPLES
list source-addr

Displays all source address affinity persistence profiles.

create source-addr simple_persistence defaults-from source_addr

Creates a custom source address affinity persistence profile named simple_persistence that inherits its settings from the default source

address affinity persistence profile.

```
mv source-addr /Common/my_source-addr_profile to-folder  
/Common/my_folder
```

Moves a custom source address persistence profile named my_source-addr_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is source_addr, the system default cookie persistence profile.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

hash-algorithm

Specifies the system uses hash persistence load balancing. The default value is default (no hash persistence).

The options are:

carp Specifies to use the Cache Array Routing Protocol (CARP) to select the pool member for LB. The input to CARP is the hash value of source address.

default

no hash persistence.

map-proxies

Enables or disables the map proxies attribute. The default value is disabled.

This attribute controls whether a source address will first be checked against an IP data-group/class to determine whether it is a well-known proxy address. If it matches the IP class, then the source address will be mapped to a single IP address for the purposes of persistence. The default well known proxy class is based on a pre-defined data-group "aol" which represents the AOL(r) company's previously-published list of proxies. Using this feature enables you to use client/source IP address persistence with a simple persist mask, but forces all clients matching the IP class to persist to the same server. The IP data-group/class may also be changed using either the map-proxy-class profile attribute or globally by changing the DB variable Persist.WellKnownProxyClass. Also, the IP address used for mapping a single source IP address for persistence may also be specifically set using the map-proxy-address profile attribute.

map-proxy-address

Specifies the single IP address to use when the source address matches the proxy data-group/class. The default value is any which results in the default behavior of using one of the IP addresses from the proxy data-group/class. Note: This mapped IP address does not have to be contained in the IP data-group/class. It may actually be any IP address since it is only used for keying the persistence record.

map-proxy-class

Specifies the data-group/class to use for determining whether a source address is from a proxy. The default value is none which will result in map_proxies using the class defined by the DB variable Persist.WellKnownProxyClass.

mask Specifies an IP mask. This is the mask used by simple persistence for connections. The default value is ::.

match-across-pools

Specifies, when enabled, that the system can use any pool that contains this persistence record. The default value is disabled.

match-across-services

Specifies, when enabled, that all persistent connections from a client IP address, which go to the same virtual IP address, also go to the same node. The default value is disabled.

match-across-virtuals

Specifies, when enabled, that all persistent connections from the same client IP address go to the same node. The default value is disabled.

mirror

Specifies whether the system mirrors persistence records to the high-availability peer. The default value is disabled.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

override-connection-limit

Specifies, when enabled, that the pool member connection limits are not enforced for persisted clients. Per-virtual connection limits remain hard limits and are not disabled. The default value

is disabled.

partition
Displays the administrative partition within which the component resides.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

timeout
Specifies the duration of the persistence entries. The default value is 180 seconds.

to-folder
source-addr persistence profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

ltm persistence ssl

NAME

ssl - Configures a Secure Socket Layer (SSL) persistence profile.

MODULE

ltm persistence

SYNTAX

Configure the ssl component within the ltm persistence module using the syntax in the following sections.

MODIFY

```
create ssl [name]
modify ssl [name]
options:
  all
  app-service [[string] | none]
  defaults-from [name]
  description [string]
  match-across-pools [ enabled | disabled]
  match-across-services [enabled | disabled]
  match-across-virtuals [enabled | disabled]
  mirror [enabled | disabled]
  override-connection-limit [enabled | disabled]
  timeout [integer]
```

```
edit ssl [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```
mv ssl [ [[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-name] ]
options:
  to-folder
```

DISPLAY

```
list ssl
list ssl [ [ [name] | [glob] | [regex] ] ... ]
show running-config ssl
show running-config ssl [ [ [name] | [glob] | [regex] ] ... ]
options:
  all
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete ssl [name]
options:
  all
```

DESCRIPTION

You can use the `ssl` component to configure a destination address affinity persistence profile for the BIG-IP(r) system. SSL persistence is a type of persistence that tracks non-terminated SSL sessions, using the SSL session ID. Even when the client's IP address changes, the system still recognizes the connection as being persistent based on the session ID. Note that the term, non-terminated SSL sessions, refers to sessions in which the system does not perform the tasks of SSL certificate authentication and encryption/re-encryption.

A persistence profile is a profile that enables persistence when you assign the profile to a virtual server. Using a persistence profile means that you do not have to write an `iRule` to implement a type of persistence. You can either use the default profile, or create a custom profile based on the default.

EXAMPLES

```
list ssl
```

Displays all SSL persistence profiles.

```
create ssl ssl_persistence defaults-from ssl
```

Creates a custom SSL persistence profile named `ssl_persistence` that inherits its settings from the default SSL persistence profile.

```
mv ssl /Common/my_ssl_profile to-folder /Common/my_folder
```

Moves a custom SSL persistence profile named `my_ssl_profile` to a folder named `my_folder`, where `my_folder` has already been created and exists within `/Common`.

OPTIONS

`app-service`

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

`defaults-from`

Specifies the existing profile from which the system imports settings for the new profile. The default value is `ssl`, the system default cookie persistence profile.

`description`

User defined description.

`glob` Displays the items that match the `glob` expression. See `help glob` for a description of `glob` expression syntax.

`match-across-pools`

Specifies, when enabled, that the system can use any pool that contains this persistence record. The default value is disabled.

`match-across-services`

Specifies, when enabled, that all persistent connections from a client IP address, which go to the same virtual IP address, also go to the same node. The default value is disabled.

`match-across-virtuals`

Specifies, when enabled, that all persistent connections from the same client IP address go to the same node. The default value is disabled.

`mirror`

Specifies whether the system mirrors persistence records to the high-availability peer. The default value is disabled.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

`override-connection-limit`

Specifies, when enabled, that the pool member connection limits are not enforced for persisted clients. Per-virtual connection limits remain hard limits and are not disabled. The default value is disabled.

`partition`

Displays the administrative partition within which the component resides.

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an `@` sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See `help regex` for a description of regular expression syntax.

`timeout`

Specifies the duration of the persistence entries. The default value is 300 seconds.

`to-folder`

`ssl` persistence profiles can be moved to any folder under `/Common`, but configuration dependencies may restrict moving the profile out of `/Common`.

non-default-properties

mv universal [[[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-name]]]
options:
to-folder

DISPLAY
list universal
list universal [[name] | [glob] | [regex]] ...]
show running-config universal
show running-config universal [[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties
one-line
partition

DELETE
delete universal [name]

DESCRIPTION
You can use the universal component to configure a universal persistence profile for the BIG-IP(r) system. With universal persistence you can write an expression that defines what to persist on in a packet. The expression, written using the same expression syntax that you use in iRules(r), defines some sequence of bytes to use as a session identifier.

A persistence profile is a profile that enables persistence when you assign the profile to a virtual server. Using a persistence profile means that you do not have to write an iRule to implement a type of persistence. You can either use the default profile, or create a custom profile based on the default.

EXAMPLES
list universal
Displays all universal persistence profiles.

create universal uni_persistence defaults-from universal
Creates a custom universal persistence profile named uni_persistence that inherits its settings from the default universal persistence profile.

mv universal /Common/my_universal_profile to-folder /Common/my_folder
Moves a custom universal persistence profile named my_universal_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

app-service
Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from
Specifies the existing profile from which the system imports settings for the new profile. The default value is universal, the system default cookie persistence profile.

description
User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

match-across-pools
Specifies, when enabled, that the system can use any pool that contains this persistence record. The default value is disabled.

match-across-services
Specifies, when enabled, that all persistent connections from a client IP address, which go to the same virtual IP address, also go to the same node. The default value is disabled.

match-across-virtuals
Specifies, when enabled, that all persistent connections from the same client IP address go to the same node. The default value is disabled.

mirror
Specifies whether the system mirrors persistence records to the high-availability peer. The default value is disabled.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

override-connection-limit
Specifies, when enabled, that the pool member connection limits are not enforced for persisted clients. Per-virtual connection limits remain hard limits and are not disabled. The default value is disabled.

partition
Displays the administrative partition within which the component resides.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

rule Specifies an iRule name when you are using a rule for universal persistence.

timeout
Specifies the duration of the persistence entries. The default value is 180 seconds.

to-folder
universal persistence profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

ltm policy-strategy

NAME
policy-strategy - Configures policy-strategy for Centralized Policy Manager.

MODULE
ltm

DESCRIPTION

The policy-strategy component stores the different matching strategies employed by LTM Policy engine. Strategy comes into play when a policy has multiple rules, and the behavior of the policy can be customized as the situation requires.

There are 3 pre-defined matching strategies: "first-match", "all-match", and "best-match". A "first-match" strategy terminates the matching engine on the first condition that matches and executes that rule's actions. An "all-match" strategy will execute the actions for all conditions that match.

The "best-match" strategy is intended for situations when multiple conditions match simultaneously, and allows for the more specific match to win. For example, one rule may match the http-uri hostname while another may match the http-uri extension. The system has a built-in table defining combinations of event, operand, and selector, and an associated precedence value for each combination. When multiple rules match in a "best-match" situation, then the condition with the lowest ordinal value of event-operand-selector precedence is declared to be the most specific, and its actions are executed.

Generally policy-strategy should not require additions or changes. However, it could make sense to create user-defined policy-strategy when a "best-match" strategy is desired, but the built-in precedence table does not reflect the organization's idea of which operand-selector combinations are most specific.

For additional details, refer to Local Traffic Policy documentation on the AskF5 knowledge base at <http://support.f5.com>.

CREATE/MODIFY

```
create policy-strategy [name]
modify policy-strategy [name]
options:
  [ strategy | [ all-match | best-match | first-match ] ]
  operands [add | delete | modify | replace-all-with] {
ORDINAL {
  [OPERAND] [EVENT] [SELECTOR]
}
}
  [ app-service [VALUE | none]]
  [ partition VALUE ]
```

where

strategy
Specifies the match method: all-match, best-match, or first-match.

operands
Define a combination of event, operand, selector, and associate it with an ordinal precedence value.

ORDINAL
Integer precedence value, lower value indicates a higher precedence.

OPERAND
Entity to compare, see some examples in Precedence Table below, or ltm_policy documentation for list with descriptions.

EVENT
Framework event like request or response, default is "request" if not specified.

SELECTOR
More specific part of operand, default is "all" if not specified. See some examples in the Precedence Table below, or ltm_policy documentation for list and descriptions.

app-service
Specifies the name of the application service to which the policy strategy belongs. The default value is "none" if not specified. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the policy strategy. Only the application service can modify or delete the policy strategy.

DISPLAY

```
list policy-strategy
list policy-strategy [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete policy-strategy [name]
```

EXAMPLES

```
create policy-strategy my_strategy strategy first-match
```

Creates the policy strategy my_strategy which matches the first rule selected.

Precedence Table

```
Ordinal Event Operand Selector
```

ltm policy

NAME

policy - Configures a policy for Centralized Policy Manager.

MODULE

ltm

SYNTAX

Create or modify LTM Policies within the ltm module, using the syntax shown in the following sections.

Policies exist in 2 forms, draft and published. Only draft policies can be modified, and only published policies can be applied to a virtual

server. A draft policy can be turned into a published policy using the publish command. A draft copy can be obtained from a published policy using modify [name] create-draft. Draft policies are placed in a Drafts folder.

For additional details, refer to Local Traffic Policy documentation on the AskF5 knowledge base at <http://support.f5.com>.

```
CREATE/MODIFY
create policy Drafts/[name]
modify policy Drafts/[name]
options:
  strategy [STRING | none]
  copy-from [name | Drafts/name]
  create-draft
  rules [add | delete | modify | replace-all-with] {
STRING {
  ordinal          NUMBER |
  app-service STRING |
  conditions [add | delete | modify | replace-all-with] {
    NUMBER { CONDITION_SPEC [[CONDITION_SPEC] ...] }
  } |
  actions [add | delete | modify | replace-all-with] {
    NUMBER { ACTION_SPEC [[ACTION_SPEC] ...] }
  }
}
}
}

[controls [add | delete | modify | replace-all-with] {
  CONTROLS_ASPECT [[CONTROLS_ASPECT] ...]
}]

[requires [add | delete | modify | replace-all-with] {
  REQUIRES_ASPECT [[REQUIRES_ASPECT] ...]
}]

PUBLISH
publish policy name

DISPLAY
  list policy
  list policy [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

  show policy
  show policy [name]
options:
  all-properties
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  detail
  field-fmt

DELETE
delete policy [name]
```

Note: Before a policy can be deleted, it must be removed from all virtual servers holding a reference to it.

DESCRIPTION

An LTM Policy is a set of rules which can be attached to a virtual server to efficiently process traffic. Similar in concept to iRules, Policies can inspect requests and responses, and perform programmed actions.

The controls and requires aspects for a policy are automatically set by the system based on an inspection of the conditions and actions specified in LTM Policy rules. User should not specify either of these.

EXAMPLES

```
create policy Drafts/my_policy
  strategy my_strategy
```

Creates a Local Traffic Manager policy in the Drafts folder named my_policy. The strategy determining policy actions is my_strategy. Draft policies may be modified, but cannot be applied to a virtual server until they are published.

```
create ltm policy Drafts/new_policy copy-from published_policy
create ltm policy Drafts/new_policy copy-from Drafts/old_policy
```

Creates a Local Traffic Manager policy based on an existing published policy, and from an existing draft policy, respectively.

```
modify ltm policy new_policy create-draft
```

Creates a draft policy of an existing published policy.

```
publish ltm policy Drafts/my_policy
```

Takes a policy that was created or modified in the Drafts folder, and publishes it. Published policies can then be applied to a virtual server.

```
delete policy my_policy
```

Deletes the policy named my_policy.

```
show policy
```

Displays statistics and status for all Local Traffic Manager policies in the system configuration.

show policy all-properties

Displays statistics and status for all Local Traffic Manager policies in the system configuration.

Note that if the system includes Packet Velocity(r) ASIC (PVA) and PVA Assist capabilities, this command displays status and statistics for that feature.

list policy my_policy

Displays properties of the policy named my_policy.

app-service - Specifies the name of the application service to which the policy belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the policy. Only the application service can modify or delete the policy.

CONTROLS_ASPECT is one or more of the following:

none - Associated with unrestricted actions that are always available, like logging.

forwarding - Enables many options for Forwarding connections to the back end.

caching - Caching enable or disable on a per-request basis.

compression - Actions which enable / disable compression and decompression. Virtual server will need to have an appropriate compression profile applied.

acceleration - Enable or disable Web Acceleration

asm - Enable or disable Application Security Management

avr - Enable or disable Application Visibility Reporting

l7dos - Enable or disable Layer 7 Denial-of-Service protection

classification - Used by the Traffic classification engine

request-adaptation - Enable or disable Request Adaptation

response-adaptation - Enable or disable Response Adaptation

client-ssl - Enable or disable SSL connection on the client side

server-ssl - Enable or disable SSL connection on the server side

websocket - Actions related to WebSockets

REQUIRES_ASPECT is one or more of the following:

none - Associated with conditions that are always available, like cpu-usage, with no specific profiles required to be attached to a virtual server

http - Makes available HTTP-protocol conditions. A profile that communicates using the HTTP protocol needs to be attached to a virtual server with this policy.

http-explicit - Makes available HTTP Explicit Proxy specific conditions. An HTTP Explicit Proxy profile needs to be attached to a virtual server with this policy.

http-connect - Makes available HTTP Connect specific conditions. An HTTP Connect profile needs to be attached to a virtual server with this policy.

tcp - A TCP profile needs to be attached to a virtual with this policy. Makes available TCP-specific conditions.

client-ssl - A Client-SSL profile needs to be attached to a virtual with this policy.

server-ssl - A Server-SSL profile needs to be attached to a virtual with this policy.

classification - A classification profile needs to be attached to a virtual with this policy.

Data Types

BOOLEAN - [true* | false]

NUMBER - signed 32-bit integer

STRING - Bare_string -or- "quoted string"

TCLSTRING - A STRING optionally containing Tcl command substitutions to be evaluated at runtime. If string begins with the 4-character prefix "tcl:", then the prefix is removed and the rest of the string is passed to the Tcl interpreter. If no prefix, then whole string is treated as a plain string with no Tcl interpreter overhead. Examples:

log request message "tcl:This is Tcl-enabled and the URI is [HTTP::uri]"

log request message "This is just a plain old string"

IP_ADDRESS - IPv4 or IPv6 address

Comparison operators

Core to defining conditions is the need to compare quantities at run time against pre-defined values. LTM Policy allows you to specify single or multiple values in a comparison.

NUMBER_COMPARISON

```
[not] [equals* | less | greater | less-or-equal | greater-or-equal]
values { VAL1 [[VAL2] ...]}
```

Sample numeric comparisons:

```
not greater values { 1024 } # no more than 1024
values { 80 443 8080 } # compare against 80, 443, or 8080, equals implied
```

STRING_COMPARISON

```
[not] [equals* | starts-with | ends-with | contains]
values { VAL1 [[VAL2] ...]} [case-insensitive* | case-sensitive ]
```

Sample string comparisons:

```
equals values { Abel bAkEr chArLiE } # case-insensitive match of 3 candidates
values { Abel bAkEr chArLiE } # same as above, equals implied
ends-with values { html txt } # match if string ends with either candidate
contains values { "jj83Q@#@AFRT@==" } case-sensitive # match value, case must match
```

*default if not specified

CONDITION_SPEC

A CONDITION SPEC, or condition specification, is where you can tell the system the specific attributes you would like to inspect and use as a trigger for action.

Conditions are associated with an event, so conditions can be evaluated at different times during a request-response cycle.

Below is a list of all supported conditions, the events during which they can be evaluated, additional qualifiers, and parameters.

http-uri

Inspect the URI on a request and match on various parts or the entire URI (since 11.4.0)

Specifying http-uri in a condition automatically adds "requires {http}" to the policy.

```
http-uri [proxy-request* | request | proxy-connect]
[all STRING_COMPARISON
 [normalized BOOL]
]
[scheme STRING_COMPARISON
 [normalized BOOL]
]
[host STRING_COMPARISON
 [normalized BOOL]

 [normalized BOOL]
]
[urlcat
 [normalized BOOL]
]
```

where

all - match on the full URI
normalized - Convert URI to standard form for consistent comparison.
scheme - match on the scheme, e.g. http, https, ftp,

file

normalized - Convert URI to standard form for consistent comparison.
host - match on the hostname in the URI
normalized - Convert URI to standard form for consistent comparison.
port - match on the port number in the URI
normalized - Convert URI to standard form for consistent comparison.

path - match on the URI path
 normalized - Convert URI to standard form for
 consistent comparison.
 extension - match on the file extension in the URI,
 e.g. jpg, html, cgi
 normalized - Convert URI to standard form for
 consistent comparison.
 query-string - match against text in the query string
 normalized - Convert URI to standard form for
 consistent comparison.
 query-param - match value of the named query parameter
 from the query string
 name - Specify the name of the particular query
 parameter whose value is to be used
 normalized - Convert URI to standard form for
 consistent comparison.
 unnamed-query-param - match the value of a query
 parameter by a numeric index instead of by name
 index - The numeric order of the query parameter
 whose value is to be used, starting at 1. Negative
 values indicate counting right to left.
 normalized - Convert URI to standard form for
 consistent comparison.
 path-segment - Match a part of the URI path by a
 numeric index
 index - The numeric order of a segment in the
 path, starting at 1. Negative values indicate
 counting right to left.
 normalized - Convert URI to standard form for
 consistent comparison.
 urlcat - Run URI through a categorization engine. List
 of categories - 'tmsh list sys url-db url-category'
 normalized - Convert URI to standard form for
 consistent comparison.

tcp

Inspect and match on various TCP properties of a connection (since 11.5.0)

Specifying tcp in a condition automatically adds "requires {tcp}" to the policy.

```

tcp [client-accepted* | ssl-client-hello |
ssl-client-serverhello-send | ssl-server-hello |
ssl-server-handshake | server-connected |
request | response | proxy-request | proxy-connect |
proxy-response | ws_request | ws_response |
classification-detected]
  [address IP_COMPARISON
  [internal BOOL]
  [local BOOL]
  ]
  [port NUMBER_COMPARISON
  [internal BOOL]
  [local BOOL]
  ]
  [mss NUMBER_COMPARISON
  [internal BOOL]
  ]
  [rtt NUMBER_COMPARISON
  [internal BOOL]
  ]
  [vlan STRING_COMPARISON
  [internal BOOL]
  ]
  [vlan_id NUMBER_COMPARISON
  [internal BOOL]
  ]
  [route_domain NUMBER_COMPARISON
  [internal BOOL]
  ]

```

where

address - Match on IP address. By default the IP
 address is the one associated with the external
 interface, remote end of the connection.
 internal - Internal specifies the IP address of
 the endpoint on the "internal" side of the
 connection.
 local - Local specifies the IP address of the
 local side of the connection, i.e. not the remote
 side.
 port - Match on port number. By default the port is
 the one associated with the external interface, remote
 end of the connection.
 internal - Internal specifies the port of the
 endpoint on the "internal" side of the connection.
 local - Local specifies the port of the local side
 of the connection, i.e. not the remote side.
 mss - Compare the TCP maximum segment size on the
 external network interface.
 internal - Refers to the maximum segment size on
 the internal interface.
 rtt - Inspect the round trip time on the external
 network interface.
 internal - Refers to the round trip time on the
 internal interface.
 vlan - Compare traffic with specified vlan on the
 external network interface.
 internal - Refers to the vlan on the internal
 interface.
 vlan_id - Compare traffic with specified vlan-id

number on the external network interface.
internal - Refers to the vlan_id on the internal interface.
route_domain - Compare traffic with specified route domain number on the external network interface.
internal - Specifies the route domain on the internal interface.

Examples

```
tcp address matches values { 141.202.53.16 }
tcp address internal matches values { 192.168.63.1 192.168.63.121 }
tcp port matches values { 8080 3128 }
```

client-ssl

Inspect properties of the SSL connection on the client side of the device. (since 11.4.0)

Specifying client-ssl in a condition automatically adds "requires {client-ssl}" to the policy.

```
client-ssl [proxy-request* | request | proxy-connect |
proxy-response | response]
[protocol STRING_COMPARISON]
[cipher STRING_COMPARISON]
[cipher-bits NUMBER_COMPARISON]
```

where

protocol - Compare SSL protocol name
cipher - Cipher name
cipher-bits - cipher strength in number of bits

http-method

Inspect the request's HTTP method, e.g. GET, POST, HEAD (since 11.4.0)

Specifying http-method in a condition automatically adds "requires {http}" to the policy.

```
http-method [request* | proxy-request]
all STRING_COMPARISON
```

Example

```
http-method all values { POST }
```

http-version

Inspect the version of an HTTP request or response (since 11.4.0)

Specifying http-version in a condition automatically adds "requires {http}" to the policy.

```
http-version [proxy-request* | request | proxy-connect |
proxy-response | response]
[all STRING_COMPARISON]
[protocol STRING_COMPARISON]
[major NUMBER_COMPARISON]
[minor NUMBER_COMPARISON]
```

where

all - Compare against full version string
protocol - HTTP protocol
major - Numeric major part of HTTP version
minor - Numeric minor part of HTTP version

Examples

```
http-version all contains values { HTTP/1.1 }
http-version protocol values { HTTP }
http-version major values { 1 }
http-version minor greater-or-equal values { 0 }
```

http-status

Inspect the HTTP response's status (since 11.4.0)

Specifying http-status in a condition automatically adds "requires {http}" to the policy.

```
http-status [proxy-response* | response]
[all STRING_COMPARISON]
[code NUMBER_COMPARISON]
[text STRING_COMPARISON]
```

where

all - Compare against full HTTP status response including both code and text
code - Numeric HTTP response status code
text - HTTP response status string, e.g. "Authentication Required"

Examples

```
http-status response values { "HTTP/1.1 200 OK" }
http-status response code values { 401 }
http-status response text contains values { "Authentication Required" }
```

http-host

Match against an HTTP request's Host: header (since 11.4.0)

Specifying http-host in a condition automatically adds "requires {http}" to the policy.

```
http-host [proxy-request* | request | proxy-connect]
  [all STRING_COMPARISON]
  [host STRING_COMPARISON]
  [port NUMBER_COMPARISON]
```

where

- all - Compare against full Host header string
- host - compare against hostname
- port - compare against port number

Examples

```
http-host values { example.com }
http-host host values { ns1.example.com ns2.example.com }
http-host port values { 80 443 3128 8080 }
```

http-header

Match against any HTTP header (since 11.4.0)

Specifying http-header in a condition automatically adds "requires {http}" to the policy.

```
http-header [proxy-request* | request | proxy-connect |
proxy-response | response]
  all STRING_COMPARISON
  name STRING
```

Example

```
http-header response name Content-type starts-with values { text/ }
```

http-referer

Inspect HTTP Referer: header or specific parts of the URI value. (since 11.4.0)

Specifying http-referer in a condition automatically adds "requires {http}" to the policy.

```
http-referer [proxy-request* | request | proxy-connect]
  [all STRING_COMPARISON
  [normalized BOOL]
  ]
  [scheme STRING_COMPARISON
  [normalized BOOL]
  ]
  [host STRING_COMPARISON
  [normalized BOOL]
  ]
  [port NUMBER_COMPARISON
  [normalized BOOL]
  ]
  [path STRING_COMPARISON
  [normalized BOOL]
  ]
  [extension STRING_COMPARISON
  [normalized BOOL]
  ]
  [query-string STRING_COMPARISON
  [normalized BOOL]
  ]
  [path-segment STRING_COMPARISON
  index NUMBER
  [normalized BOOL]
  ]
  [query-param STRING_COMPARISON
  name STRING
  [normalized BOOL]
  ]
  [unnamed-query-param STRING_COMPARISON
  index NUMBER
  [normalized BOOL]
  ]
  [urlcat
  [normalized BOOL]
  ]
  ]
```

where

- all - entire URI, e.g. http://example.com/path/to/page.cgi?a=b&c=d
- normalized - Convert URI to standard form for consistent comparison.
- scheme - e.g. http, https, ftp
- normalized - Convert URI to standard form for consistent comparison.
- host - DNS hostname or IP address
- normalized - Convert URI to standard form for consistent comparison.
- port - numeric port number, e.g. 80
- normalized - Convert URI to standard form for consistent comparison.
- path - URI path, e.g. /path/to

normalized - Convert URI to standard form for consistent comparison.
 extension - document extension, e.g. cgi
 normalized - Convert URI to standard form for consistent comparison.
 query-string - full query string, e.g. a=b&c=d
 normalized - Convert URI to standard form for consistent comparison.
 path-segment - path segment by numerical index
 index - Identify a segment of a path by its numerical order starting at 1. Negative values indicate counting right to left.
 normalized - Convert URI to standard form for consistent comparison.
 query-param - value of query param by name
 name - Identify a query string parameter by its name
 normalized - Convert URI to standard form for consistent comparison.
 unnamed-query-param - value of query parameter by numerical index
 index - Identify a query string parameter by its numerical order starting at 1. Negative values indicate counting right to left.
 normalized - Convert URI to standard form for consistent comparison.
 urlcat - Run URI through a categorization engine. List of categories - 'tmsh list sys url-db url-category'
 normalized - Convert URI to standard form for consistent comparison.

Examples

```
http-referer request all contains values { cgi }
http-referer request all scheme values { http https }
http-referer request all host values { example.com 127.0.0.1 }
http-referer request all port values { 80 8080 }
http-referer request all path contains values { /cgi-bin/ }
http-referer request all extension contains values { xml xhtml xsd }
http-referer request all query-string contains values { __utmz }
http-referer path-segment index 2 values { to }
http-referer query-parameter name foo contains values { bar }
http-referer request unnamed-query-param index 1 values { a }
```

http-cookie

Inspect an HTTP request's Cookie: header (since 11.4.0)

Specifying http-cookie in a condition automatically adds "requires {http}" to the policy.

```
http-cookie [proxy-request* | request | proxy-connect]
  all STRING_COMPARISON
  name STRING
```

Example

```
http-cookie name User values { xyz123 }
```

http-set-cookie

Inspect an HTTP response's Set-Cookie: header (since 11.4.0)

Specifying http-set-cookie in a condition automatically adds "requires {http}" to the policy.

```
http-set-cookie [proxy-response* | response]
  [value STRING_COMPARISON
  name STRING
  ]
  [version STRING_COMPARISON
  name STRING
  ]
  [path STRING_COMPARISON
  name STRING
  ]
  [domain STRING_COMPARISON
  name STRING
  ]
  [expiry STRING_COMPARISON
  name STRING
  ]
  ]
```

where

value - value of the named cookie named by the parameter
 version - version of the named cookie
 path - path of the named cookie
 domain - value of the domain specified by the named cookie

expiry - Time when validity of named cookie expires, in RFC 6265 format (Wdy, DD Mon YYYY HH:MM:SS GMT)

Examples

```
http-set-cookie response value name Cust-Id values { org177 org187 org197 }
http-set-cookie response version name mycook values { 1.1 }
http-set-cookie response path name mycook values { /private/cgi-bin/ }
http-set-cookie response domain name mycook values { example.com }
http-set-cookie response expiry name MyCookie contains values { "Wed, 09 Jun 2021" }
```

http-basic-auth

Inspect an HTTP request's username/password specified for Basic authentication. (since 11.4.0)

Specifying http-basic-auth in a condition automatically adds "requires {http}" to the policy.

```
http-basic-auth [proxy-request* | request | proxy-connect]
  [username STRING_COMPARISON]
  [password STRING_COMPARISON]
```

where

```
username - basic authentication username
password - basic authentication password
```

Example

```
http-basic-auth password not values { password }
```

http-proxy

Inspect properties of the HTTP Explicit Proxy feature (since 13.1.0)

Specifying http-proxy in a condition automatically adds "requires {http-explicit}" to the policy.

```
http-proxy [request*]
  [address IP_COMPARISON]
  [port NUMBER_COMPARISON]
  [route-domain NUMBER_COMPARISON]
```

where

```
address - The resolved IP address
```

Examples

```
http-proxy address equals values { 10.0.0.1 }
http-proxy port matches values { 80 }
http-proxy route-domain matches values { 2 }
```

http-connect

Inspect properties of the HTTP Proxy Connect feature (since 13.1.0)

Specifying http-connect in a condition automatically adds "requires {http-connect}" to the policy.

```
http-connect [client-accepted* | ssl-client-hello |
ssl-client-serverhello-send | ssl-server-hello |
ssl-server-handshake | server-connected |
proxy-request | request | proxy-connect |
proxy-response | response]
  [host STRING_COMPARISON]
  [port NUMBER_COMPARISON]
```

where

```
host - The host sent to the remote proxy
```

Examples

```
http-proxy-connect host matches values { http://example.com }
http-proxy-connect port matches values { 80 }
```

ssl-extension

Inspect SSL extensions being negotiated during HELLO phase. (since 11.4.0)

This condition is available to all policies.

```
ssl-extension [ssl-client-hello* | ssl-server-hello]
  [server-name STRING_COMPARISON]
  [npn STRING_COMPARISON]
  [index NUMBER]
]
  [alpn STRING_COMPARISON]
  [index NUMBER]
]
```

where

```
server-name - server name indication
npn - next protocol negotiation
alpn - application layer protocol negotiation
```

Example

```
ssl-extension ssl-client-hello server-name values { secure43.example.org }
```

ssl-cert

Inspect properties of an SSL certificate. (since 11.4.0)

Specifying ssl-cert in a condition automatically adds "requires {server-ssl}" to the policy.

```
ssl-cert [ssl-server-handshake*]
common-name STRING_COMPARISON
[index NUMBER]
```

where

common-name - hostname covered by the SSL certificate

geoup

Specify a condition based upon properties of the geographical location of the IP address, such as continent code, country code, city, region, or organization. The default is to inspect the external interface, remote endpoint. (since 11.5.0)

This condition is available to all policies.

```
geoup [client-accepted* | ssl-client-hello |
ssl-client-serverhello-send | ssl-server-hello |
ssl-server-handshake | server-connected |
proxy-request | request | proxy-connect |
proxy-response | response]
[continent STRING_COMPARISON
 [internal BOOL]
 [local BOOL]
]
[country-code STRING_COMPARISON
 [internal BOOL]
 [local BOOL]
]
[country-name STRING_COMPARISON
 [internal BOOL]
 [local BOOL]
]
[region-code STRING_COMPARISON
 [internal BOOL]
 [local BOOL]
]
[region-name STRING_COMPARISON
 [internal BOOL]
 [local BOOL]
]
[org STRING_COMPARISON
 [internal BOOL]
 [local BOOL]
]
[isp STRING_COMPARISON
 [internal BOOL]
 [local BOOL]
]
```

where

continent - Two-character continent code: AF, AN, AS, OC, EU, NA, SA
country-code - Two-character country code as defined in ISO-3166-2
country-name - Full name of country
region-code - Abbreviation of State, Province, or country-specific region
region-name - Full name of State, Province, or country-specific region
org - Organization associated with address
isp - Internet Service Provider associated with address

Examples

```
geoup continent values { NA }
geoup country-code values { us }
geoup country-name values { "United States" }
geoup region-code values { NY CA TX }
geoup region-name values { Washington Oregon Idaho }
geoup organization values { "Acme Widgets" }
geoup isp values { "Fastcast Networks" "Responsive Cable Inc." }
```

cpu-usage

Specify a condition based upon CPU usage percentage for the past 15 seconds, 1 minute or 5 minutes intervals. (since 11.5.0)

This condition is available to all policies.

```
cpu-usage [client-accepted* | ssl-client-hello |
ssl-client-serverhello-send | ssl-server-hello |
ssl-server-handshake | server-connected |
proxy-request | request | proxy-connect |
proxy-response | response]
[last-15secs NUMBER_COMPARISON]
[last-1min NUMBER_COMPARISON]
[last-5mins NUMBER_COMPARISON]
```

where

last-15secs - CPU usage ratio % over the past 15 seconds, 0-100
last-1min - CPU usage ratio % over the past minute, 0-100
last-5mins - CPU usage ratio % over the past 5 minutes, 0-100

Examples

```
cpu-usage request last-15secs 8
cpu-usage response last-1min 10
cpu-usage last-5mins 12
```

http-user-agent

Specify a condition based upon User Agent sub-string, i.e. version, browser type, or mobile device make and model. (since 11.4.0)

Specifying http-user-agent in a condition automatically adds "requires {http}" to the policy.

```
http-user-agent [proxy-request* | request]
  [device-make STRING_COMPARISON]
  [device-model STRING_COMPARISON]
  [browser-type STRING_COMPARISON]
  [browser-version STRING_COMPARISON]
  [ua-token STRING_COMPARISON]
  name STRING
]
```

where

```
device-make - Make of device
device-model - Model of device
browser-type - Browser name/type
browser-version - Browser version string
ua-token - Sub version string associated with
specified parameter
```

Examples

```
http-user-agent device-make values { Samsung ASUS }
http-user-agent device-model values { DroidX }
http-user-agent request browser-type values { Mozilla }
http-user-agent request browser-version values { "37.0.2049.0" }
http-user-agent user-agent-token name Mozilla values { 9.0 }
```

websocket

Specify a condition based upon properties of a websockets connection. (since 12.1.0)

Specifying websocket in a condition automatically adds "requires {websocket}" to the policy.

```
websocket [ws_request* | ws_response]
  [protocol STRING_COMPARISON]
  [extension STRING_COMPARISON]
  [version STRING_COMPARISON]
  [ws_key STRING_COMPARISON]
```

where

```
protocol - value of the Sec-WebSocket-Protocol header
extension - value of the Sec-WebSocket-Extensions
header
version - value of the Sec-WebSocket-Version header
ws_key - value of the masking-key
```

classification

Specify a condition based on flow's classification results. (since 13.0.0)

Specifying classification in a condition automatically adds "requires {classification}" to the policy.

```
classification [classification-detected*]
  [application STRING_COMPARISON]
  [application-id ]
  [application-risk ]
  [category STRING_COMPARISON]
  [category-id ]
  [url-category STRING_COMPARISON]
  [url-category-id ]
```

where

```
application - Classification Application Name
application-id - Classification Application ID
application-risk - Classification Application Risk
category - Application's category name
category-id - Application's category ID
url-category - URL's category name
url-category-id - URL's category ID
```

Examples

```
application values { cnn youtube }
application-id values { 1245 }
application-risk greater-or-equal values { 3 }
category values { News And Media }
category-id values { 16666 }
url-category starts-with values { News }
url-category-id values { 25555 }
```

iprep

Perform a reputation lookup on IP address (since 13.1.0)

This condition is available to all policies.

```
iprep [client-accepted* | proxy-request | request |
server-connected]
  all
  [internal BOOL]
  [local BOOL]
```

Example

```
iprep all values { "Spam Sources" "Denial of Service" }
```

ACTION_SPEC

An ACTION_SPEC, or action specification, is where you can tell the system the specific programmed actions you would like to take.

Actions are associated with an event, and depending on the action, can be set to run at different times during the request-response cycle.

Below is a list of all supported actions, the events during which they can be executed, their specific sub-actions, and parameters (if any).

ltm-policy

Provides the ability to disable LTM Policy processing on a request by request basis. (since 11.4.0)

This action is available to all policies.

```
ltm-policy [client-accepted* | ssl-client-hello |
ssl-client-serverhello-send | ssl-server-hello |
ssl-server-handshake | server-connected |
proxy-request | request | proxy-connect |
proxy-response | response]
  disable*
```

http

Provides the ability to enable or disable Big Ip's HTTP filter processing (since 11.4.0)

This action is available to all policies.

```
http [client-accepted* | proxy-request | request |
response | server-connected]
  [enable*]
  [disable]
```

http-uri

Modify the request's URI or path or query string. Setting URI value overrides path and query-string setting. (since 11.4.0)

This action is available to all policies.

```
http-uri [proxy-request* | request | proxy-connect]
  replace*
  [value TCLSTRING]
  [path TCLSTRING]
  [query-string TCLSTRING]
```

http-host

Modify the request's Host: header (since 11.4.0)

This action is available to all policies.

```
http-host [proxy-request* | request | proxy-connect]
  replace*
  value TCLSTRING
```

http-header

Modify HTTP header in request or response (since 11.4.0)

This action is available to all policies.

```
http-header [proxy-request* | request | proxy-connect |
proxy-response | response]
  [replace*
  name STRING
  value TCLSTRING
  ]
  [insert
  name STRING
  value TCLSTRING
  ]
  [remove
  name STRING
  ]
```

http-referer

Modify the request's Referer: header (since 11.4.0)

This action is available to all policies.

```
http-referer [proxy-request* | request | proxy-connect]
  [replace*
  [value TCLSTRING]
  ]
  [insert
  value TCLSTRING
  ]
```

[remove]

where

replace - Replace request's Referer: header.
value - New value for request's Referer: header.
Values beginning with "tcl:" are treated as Tcl
command substitutions and expanded before use.

insert - Insert an HTTP Referer: header into the
request
value - New value for request's Referer: header.
Values beginning with "tcl:" are treated as Tcl
command substitutions and expanded before use.
remove - Remove the HTTP Referer: header from the
request

http-cookie

Modify the request's Cookie: header (since 11.4.0)

This action is available to all policies.

```
http-cookie [proxy-request* | request | proxy-connect]
[insert*
  name STRING
  [value TCLSTRING]
]
[remove
  name STRING
]
```

where

insert - Insert an HTTP Cookie: header into the
request
name - Name of the cookie being inserted into
request's Cookie: header.
value - New value for the cookie in the request's
Cookie: header. Values beginning with "tcl:" are
treated as Tcl command substitutions and expanded
before use.
remove - Remove the HTTP Cookie: header from the
request
name - Name of the cookie being inserted into
request's Cookie: header.

Examples

```
http-cookie request insert name "Source-IP" value "tcl:[IP::remote_addr]"
http-cookie remove name "X-Tracker"
```

http-set-cookie

Modify the response's Set-Cookie: header (since 11.4.0)

This action is available to all policies.

```
http-set-cookie [response*]
[insert*
  name STRING
  value TCLSTRING
  [domain TCLSTRING]
  [path TCLSTRING]
]
[remove
  name STRING
]
```

where

insert - Insert an HTTP Set-Cookie: header into the
response
name - Name of the cookie being inserted into
response's Set-Cookie: header.
value - New value for the cookie in the response's
Set-Cookie: header. Values beginning with "tcl:"
are treated as Tcl command substitutions and
expanded before use.
domain - Value for the domain attribute of a
cookie in Set-Cookie header. Tcl command
substitutions are allowed for this field.
path - Value for the path attribute of a cookie in
Set-Cookie header. Tcl command substitutions are
allowed for this field.
remove - Remove the HTTP Cookie: header from the
request
name - Name of the cookie to be removed from
response's Set-Cookie: header.

http-reply

Redirect an HTTP request to a different URL (since 11.4.0)

Specifying http-reply in an action automatically adds "controls
{forwarding}" to the policy.

```
http-reply [proxy-request* | request | response]
redirect*
  location TCLSTRING
  [code NUMBER]
```

where

redirect - Redirect an HTTP request to a different URL
location - The new URL for which a redirect response will be sent. A Tcl command substitution can be used for this field.
code - Optional HTTP response code for redirect. Default value is 302 if not specified. Valid values are in the range of 300-399.

log

Write messages to local or remote system log (since 11.4.0)

This action is available to all policies.

```
log [client-accepted* | ssl-client-hello |
ssl-client-serverhello-send | ssl-server-hello |
ssl-server-handshake | server-connected |
proxy-request | request | proxy-connect |
proxy-response | response | ws_request |
ws_response | classification-detected]
write*
  [message TCLSTRING]
  [facility STRING]
  [priority STRING]
  [ip_address STRING]
  [port NUMBER]
```

where

write - Write a message to the system log files, local or remote
message - The message to write to the system log. A Tcl command substitution is allowed here.
facility - Standard syslog facility associated with message, such as auth, kern, daemon, user.
priority - Standard syslog priority associated with message, such as emerg, alert, err, warning, notice, info, debug.
ip_address - For remote logging, the IP address of the remote syslog server.
port - For remote logging, the port number of the remote syslog server.

Examples

```
log request message "tcl:This is Tcl-enabled and the URI is [HTTP:uri]"
log request message "This is just a plain old string"
log request message "Something serious is happening!" priority alert
```

pem

Classify traffic (since 11.4.0)

Specifying pem in an action automatically adds "controls {classification}" to the policy.

```
pem [ssl-client-hello* | ssl-client-serverhello-send |
ssl-server-hello | ssl-server-handshake |
proxy-request | request | response]
classify*
  [application STRING]
  [category STRING]
  [protocol STRING]
  [defer BOOL]
  [ssl-session-id BOOL]
```

where

classify - Classify traffic

ce

Classify traffic (since 12.1.0)

Specifying ce in an action automatically adds "controls {ce}" to the policy.

```
ce [ssl-client-hello* | ssl-server-hello |
ssl-server-handshake | request | response]
classify*
  [application STRING]
  [category STRING]
```

where

classify - Classify traffic

cache

Control caching (since 11.4.0)

Specifying cache in an action automatically adds "controls {caching}" to the policy.

```
cache [client-accepted* | proxy-request | request |
response | server-connected]
[enable*
  [pin BOOL]
]
[disable]
```

where

enable - Enable caching for a connection
disable - Disable caching for a connection

compress

Control compression (since 11.4.0)

Specifying compress in an action automatically adds "controls {compression}" to the policy.

```
compress [client-accepted* | proxy-request | request |  
response | server-connected]  
[enable*]  
[disable]
```

where

enable - Enable compression for a connection
disable - Disable compression for a connection

decompress

Control decompression (since 11.4.0)

Specifying decompress in an action automatically adds "controls {compression}" to the policy.

```
decompress [client-accepted* | proxy-request | request |  
response | server-connected]  
[enable*]  
[disable]
```

where

enable - Enable decompression for a connection
disable - Disable decompression for a connection

forward

Many options for controlling where a connection is forwarded (since 11.4.0)

Specifying forward in an action automatically adds "controls {forwarding}" to the policy.

```
forward [client-accepted* | ssl-client-hello |  
ssl-client-serverhello-send | proxy-request |  
request]  
[select*  
[pool STRING]  
[clone-pool STRING]  
[node STRING]  
[snat STRING]  
[snatpool STRING]  
[nexthop STRING]  
[vlan STRING]  
[vlan-id NUMBER]  
[virtual STRING]  
[rateclass STRING]  
]  
[reset]
```

where

select - Select appropriate location for forwarding the connection based on specified parameters. While all of the parameters are marked as optional, at least one must be specified.

pool - Forward connection to the specified pool.

clone-pool - Clone traffic to the specified clone pool.

node - Forward connection to the specified node.

snat - Control snat automap.

snatpool - Forward connection to the specified snat pool.

nexthop - Set the next destination for the connection to the specified endpoint. A vlan or vlan-id must also be specified.

vlan - Forward connection to the specified vlan.

vlan-id - Forward connection to the vlan specified by the vlan-id.

virtual - Forward connection to the specified virtual server.

rateclass - Control rate class properties on the connection.

reset - Deprecated. See target "shutdown connection".

shutdown

Reset connection (since 13.1.0)

This action is available to all policies.

```
shutdown [client-accepted* | ssl-client-hello |  
ssl-client-serverhello-send | ssl-server-hello |  
ssl-server-handshake | server-connected |  
proxy-request | request | proxy-connect |  
proxy-response | response | ws_request |  
ws_response]  
connection*
```

where

connection - Terminate the connection through the Big

IP.

persist

Many options for controlling how a connection is persisted (since 12.0.0)

Specifying persist in an action automatically adds "controls {persistence}" to the policy.

```
persist [client-accepted* | proxy-request | request]
[disable]
[src-addr*
 [netmask STRING]
 [timeout NUMBER]
]
[dest-addr
 [netmask STRING]
 [timeout NUMBER]
]
[cookie-insert
 [name STRING]
 [expiry STRING]
]
[cookie-rewrite
 [name STRING]
 [expiry STRING]
]
[cookie-passive
 [name STRING]
]
[cookie-hash
 name STRING
 [offset NUMBER]
 [length NUMBER]
 [timeout NUMBER]
]
[universal
 key TCLSTRING
 [timeout NUMBER]
]
[hash
 key TCLSTRING
 [timeout NUMBER]
]
[carp
 key TCLSTRING
 [timeout NUMBER]
]
]
```

where

disable - Disable persistence
src-addr - Persist the connection based on the source IP address.
netmask - Network mask, e.g. 192.168.13.23/16 or 10.0.2.15/255.0.0.0.
timeout - Timeout value in seconds.
dest-addr - Persist the connection based on the destination IP address.
netmask - Network mask, e.g. 192.168.13.23/16 or 10.0.2.15/255.0.0.0.
timeout - Timeout value in seconds.
cookie-insert - Persist the connection using cookie insertion method
name - cookie name
expiry - Expiration duration expressed as [Dd] [[HH:]MM:]SS
cookie-rewrite - Persist the connection using cookie rewrite method
name - cookie name
expiry - Expiration duration expressed as [Dd] [[HH:]MM:]SS
cookie-passive - Persist the connection using cookie passive method
name - cookie name
cookie-hash - Persist the connection using cookie hash method
name - cookie name
offset - offset into hash
length - substring length
timeout - Timeout value in seconds.
universal - persistence based on user-defined key
key - The key to use. Tcl command substitution is allowed.
timeout - Timeout value in seconds.
hash - persistence based on hash of the key
key - The key to use. Tcl command substitution is allowed.
timeout - Timeout value in seconds.
carp - hash persistence using Cache Array Routing Protocol (CARP) algorithm
key - The key to use. Tcl command substitution is allowed.
timeout - Timeout value in seconds.

wam

Control web acceleration (since 11.4.0)

Specifying wam in an action automatically adds "controls {wam}" to the policy.

```
wam [client-accepted* | proxy-request | request]
```

```
[enable*]
[disable]
```

where

```
enable - Enable web acceleration for a connection
disable - Disable web acceleration for a connection
```

asm

Control web security (since 11.4.0)

Specifying asm in an action automatically adds "controls {asm}" to the policy.

```
asm [client-accepted* | proxy-request | request]
    [enable*
     policy STRING
    ]
[disable]
```

where

```
enable - Enable web security for a connection
policy - name of security policy to enable
disable - disable web security for the connection
```

l7dos

Enable or disable Layer 7 Denial-of-Service processing (since 11.4.0)

Specifying l7dos in an action automatically adds "controls {l7dos}" to the policy.

```
l7dos [client-accepted* | proxy-request | request]
      [enable*
       from-profile STRING
      ]
[disable]
```

where

```
enable - turn on Layer 7 DOS protection
from-profile - name of DOS profile to enable
disable - turn off Layer 7 DOS protection
```

avr

Enable or disable Application Visibility and Reporting (since 11.4.0)

Specifying avr in an action automatically adds "controls {avr}" to the policy.

```
avr [client-accepted* | proxy-request | request]
    [enable*]
[disable]
```

where

```
enable - turn on reporting
disable - turn off reporting
```

tcl

Set a Tcl variable in runtime environment (since 11.4.0)

This action is available to all policies.

```
tcl [client-accepted* | ssl-client-hello |
ssl-client-serverhello-send | ssl-server-hello |
ssl-server-handshake | server-connected |
proxy-request | request | proxy-connect |
proxy-response | response]
    set-variable*
    name STRING
    expression STRING
```

where

```
set-variable - set a Tcl variable in the runtime
environment
name - name of variable
expression - Tcl expression to evaluate
```

Example

```
tcl set-variable expression tcl:[HTTP::uri] name my_uri
```

request-adapt

Enable or disable request adaptation, optionally sending traffic to specified internal virtual server (since 11.4.0)

Specifying request-adapt in an action automatically adds "controls {request-adaptation}" to the policy.

```
request-adapt [client-accepted* | server-connected |
proxy-request | request | response]
    [enable*
     [internal-virtual STRING]
    ]
[disable]
```

where

enable - turn on request adaptation
internal-virtual - which internal virtual server
disable - turn off request adaptation

response-adapt

Enable or disable response adaptation, optionally sending traffic to specified internal virtual server (since 11.4.0)

Specifying response-adapt in an action automatically adds "controls {response-adaptation}" to the policy.

```
response-adapt [client-accepted* | server-connected |  
proxy-request | request | response]  
[enable*  
 [internal-virtual STRING]  
 ]  
[disable]
```

where

enable - turn on response adaptation
internal-virtual - which internal virtual server
disable - turn off response adaptation

tcp-nagle

Enable or disable Nagle's algorithm on a connection, or allow BIG-IP to determine the best setting. (since 11.4.0)

This action is available to all policies.

```
tcp-nagle [client-accepted* | request]  
[enable*  
 [auto-mode BOOL]  
 ]  
[disable]
```

where

enable - turn on Nagle
auto-mode - turn on Auto Nagle
disable - turn off Nagle

server-ssl

Enable or disable encrypted connections to backend servers (since 11.4.0)

Specifying server-ssl in an action automatically adds "controls {server-ssl}" to the policy.

```
server-ssl [client-accepted* | proxy-request | request |  
proxy-connect | proxy-response | server-connected]  
[enable*]  
[disable]
```

where

enable - encrypted connection to backend
disable - plaintext connection to backend

client-ssl

Enable or disable encrypted connections to client (since 13.1.0)

Specifying client-ssl in an action automatically adds "controls {client-ssl}" to the policy.

```
client-ssl [client-accepted*]  
[enable*]  
[disable]
```

where

enable - encrypted connection to client
disable - plaintext connection to client

ssl-intercept

Switch the SSL Intercept feature between bypass and intercept modes (since 13.1.0)

Specifying ssl-intercept in an action automatically adds "controls {ssl-intercept}" to the policy.

```
ssl-intercept [ssl-client-serverhello-send*]  
[enable*]  
[disable]
```

where

enable - SSL Intercept feature is in intercept mode
disable - SSL Intercept feature is in bypass mode

websocket

Enable or disable websocket processing (since 12.1.0)

Specifying websocket in an action automatically adds "controls {websocket}" to the policy.

```
websocket [client-accepted* | ws_request | ws_response |
proxy-request | request | proxy-connect |
proxy-response | response | server-connected]
[enable*]
[disable]
```

where

enable - turn on websocket filter
disable - turn off websocket filter

classification

Perform classification/enforcement of the connection (since 13.0.0)

Specifying classification in an action automatically adds "controls {classification}" to the policy.

```
classification [ssl-client-hello* | ssl-client-serverhello-send |
ssl-server-hello | ssl-server-handshake |
proxy-request | request | response | classification-detected]
[drop]
[reject]
```

where

drop - Silently drop connection
reject - Gracefully close connection

server-ssl-profile

Dynamic selection of SSL server profile (since 13.1.0)

Specifying server-ssl-profile in an action automatically adds "controls {server-ssl}" to the policy.

```
server-ssl-profile [server-connected*]
select*
name STRING
```

http-proxy

Enable or Disable the HTTP Explicit Proxy (since 13.1.0)

This action is available to all policies.

```
http-proxy [proxy-request*]
[enable*]
[disable]
```

where

enable - turn on the HTTP Explicit Proxy feature
disable - turn off the HTTP Explicit Proxy feature

http-uri-rewrite

Enable or Disable the rewriting of HTTP URI's into proxy form (since 13.1.0)

This action is available to all policies.

```
http-uri-rewrite [client-accepted* | ssl-client-hello |
ssl-server-hello | ssl-server-handshake |
proxy-request | request | server-connected]
[enable*]
[disable]
```

where

enable - turn on rewriting the URI into proxy form
disable - turn off rewriting the URI into proxy form

http-connect

Control the HTTP Proxy Connect feature (since 13.1.0)

This action is available to all policies.

```
http-connect [client-accepted* | ssl-client-hello |
proxy-request | request | server-connected |
proxy-connect | proxy-response]
[enable*]
[disable]
[replace
[port NUMBER]
[host STRING]
]
[retry]
```

where

enable - turn on the HTTP Proxy Connect feature
disable - turn off the HTTP Proxy Connect feature
retry - retry the HTTP CONNECT

DELETE
delete pool [name]

```

Note: You must remove all references to a pool before you can delete the pool.

DESCRIPTION

You can use this pool component to configure the pool definitions on the Local Traffic Manager. A load balancing pool is a logical set of devices, such as Web servers, that you group together to receive and process traffic.

EXAMPLES

```

create pool my_pool members add { 10.2.3.11:http 10.2.3.12:http }

Creates a Local Traffic Manager pool named my_pool with two members,
10.2.3.11 and 10.2.3.12, using the default values for the pool and pool
members.

delete pool my_pool

Deletes the pool named my_pool.

show pool

Displays statistics and status for all Local Traffic Manager pools in
the system configuration.

show pool all-properties

Displays statistics and status for all Local Traffic Manager pools in
the system configuration.

Note that if the system includes Packet Velocity(r) ASIC (PVA) and PVA
Assist capabilities, this command displays status and statistics for
that feature.

list pool my_pool

Displays properties of the pool named my_pool.

mv /ltm pool /Common/my_pool to-folder /Common/some_folder

Moves an LTM pool named my_pool and all of its Pool Members to the
folder named some_folder, where some_folder has already been created
under /Common.

Please refer to the mv manual page for additional examples on how to
use the mv command.

```

OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

allow-nat Specifies whether the pool can load balance network address translation (NAT) connections. The default value is yes.

allow-snat Specifies whether the pool can load balance secure network address translation (SNAT) connections. The default value is yes.

app-service Specifies the name of the application service to which the pool belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the pool. Only the application service can modify or delete the pool.

autoscale-group-id Deprecated since v13.1.0. Specifies the autoscale-group id as

reported by Amazon Web Services(AWS).

description
User defined description.

gateway-failsafe-device
Specifies that the pool is a gateway failsafe pool in a redundant configuration. The gateway-failsafe-device identifies the device that depends on the gateway. If the monitor associated with the pool reports that the gateway is down, the device goes to the standby state. The default value for this string is empty, the feature is not configured.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

traffic-acceleration-status
Displays the current Traffic-Acceleration status. Indicates whether the pool is in-use by or dedicated to a virtual server that uses a traffic-acceleration profile.

ignore-persisted-weight
Discounts the weight of connections made to pool members selected through persistence, rather than as a result of the algorithm configured on the pool. If the connection's weight is ignored, then it is not treated as a 'pick' for that pool member, and does not influence subsequent pool member load balancing decisions.

This option only impacts pools configured with one of the following load balancing modes: observed-member, observed-node, predictive-member, predictive-node, ratio-least-connections-member, ratio-least-connections-node, ratio-member, or ratio-node.

The default value is no, which results in persisted pool member connections being accounted for during load balancing calculations.

ip-tos-to-client
Specifies the Type of Service (ToS) level to use when sending packets to a client. The default value is 65535 (pass-through).

ip-tos-to-server
Specifies the ToS level to use when sending packets to a server. The default value is 65535 (pass-through).

link-qos-to-client
Specifies the Link Quality of Service (QoS) level to use when sending packets to a client. The default value is 65535 (pass-through).

link-qos-to-server
Specifies the Link QoS level to use when sending packets to a server. The default value is 65535 (pass-through).

load-balancing-mode
Specifies the modes that the system uses to load balance name resolution requests among the members of this pool. The default value is round-robin.

The options are:

dynamic-ratio-member
Specifies that the system distributes connections based on various aspects of real-time server performance analysis, such as the number of current connections per node or the fastest node response time.

This mode is similar to the dynamic-ratio-node mode, except that weights are based on continuous monitoring of the servers and are therefore continually changing.

dynamic-ratio-node
Specifies that the system distributes connections based on various aspects of real-time server performance analysis, such as the number of current connections per node or the fastest node response time.

This mode is similar to the dynamic-ratio-member mode, except that weights are based on continuous monitoring of the servers and are therefore continually changing.

fastest-app-response
Specifies that the system passes a new connection based on the fastest response of all currently active nodes in a pool. This mode might be particularly useful in environments where nodes are distributed across different logical networks.

fastest-node
Specifies that the system passes a new connection based on the fastest response of all pools of which a server is a member. This mode might be particularly useful in environments where nodes are distributed across different logical networks.

least-connections-member
Specifies that the system passes a new connection to the node that has the least number of current connections in the pool. This mode works best in environments where the servers or other equipment you are load balancing have similar capabilities.

This dynamic load balancing mode distributes connections based on various aspects of real-time server performance analysis, such as the current number of connections per node

or the fastest node response time.

least-connections-node

Specifies that the system passes a new connection to the node that has the least number of current connections out of all pools of which a node is a member. This mode works best in environments where the servers or other equipment you are load balancing have similar capabilities.

This dynamic load balancing mode distributes connections based on various aspects of real-time server performance analysis, such as the number of current connections per node, or the fastest node response time.

least-sessions

Specifies that the system passes a new connection to the node that has the least number of current sessions. This mode works best in environments where the servers or other equipment you are load balancing have similar capabilities.

This dynamic load balancing mode distributes connections based on various aspects of real-time server performance analysis, such as the number of current sessions.

observed-member

Specifies that the system ranks nodes based on the number of connections. Nodes that have a better balance of fewest connections receive a greater proportion of the connections.

This mode differs from the least-connections-member mode, which measures connections only at the moment of load balancing, while the observed-member mode tracks the number of Layer 4 connections to each node over time and creates a ratio for load balancing.

This dynamic load balancing mode works well in any environment, but may be particularly useful in environments where node performance varies significantly.

observed-node

Specifies that the system ranks nodes based on the number of connections. Nodes that have a better balance of fewest connections receive a greater proportion of the connections.

This mode differs from least-connections-node mode, which measures connections only at the moment of load balancing, while the observed-node mode tracks the number of Layer 4 connections to each node over time and creates a ratio for load balancing.

This dynamic load balancing method works well in any environment, but may be particularly useful in environments where node performance varies significantly.

predictive-member

Uses the ranking method used by the observed-member mode, except that the system analyzes the trend of the ranking over time, determining whether a node's performance is improving or declining. The nodes in the pool with better performance rankings that are currently improving, rather than declining, receive a higher proportion of the connections. This dynamic load balancing mode works well in any environment.

predictive-node

Uses the ranking method used by the observed-node mode, except that the system analyzes the trend of the ranking over time, determining whether a node's performance is improving or declining. The nodes in the pool with better performance rankings that are currently improving, rather than declining, receive a higher proportion of the connections. This dynamic load balancing mode works well in any environment.

queue-depth-limit

Specifies the maximum number of connections that may simultaneously be queued to go to any member of this pool. The default is zero which indicates there is no limit.

queue-on-connection-limit

Enable or disable queuing connections when pool member or node connection limits are reached. When queuing is not enabled, new connections are reset when connection limits are met. The default value is disabled.

queue-time-limit

Specifies the maximum time, in milliseconds, a connection will remain enqueued. The default is zero which indicates there is no limit.

ratio-least-connections-member

Specifies that the system weights connections to each pool member based on the value of the ratio weight defined for each pool member. If a ratio weight is unspecified, it will be treated as a default value of '1'.

ratio-least-connections-node

Specifies that the system weights connections to each pool member based on the value of the ratio weight defined for the pool member's node. If a ratio weight is unspecified, it will be treated as a default value of '1'.

ratio-member

Specifies that the number of connections that each machine receives over time is proportionate to a ratio weight you define for each machine within the pool.

ratio-node

Specifies that the number of connections that each machine receives over time is proportionate to a ratio weight you define for each machine across all pools of which the server is a member.

ratio-session

Specifies that the number of sessions that each machine receives over time is proportionate to a ratio weight that you define for each machine within the pool.

round-robin

Specifies that the system passes each new connection request to the next server in line, eventually distributing connections evenly across the array of machines being load balanced. This mode works well in most configurations, especially if the equipment that you are load balancing is roughly equal in processing speed and memory.

weighted-least-connections-member

Specifies that the system passes a new connection to the pool member that is handling the lowest percentage of the specified maximum number of concurrent connections allowed. This mode works best in environments where the servers or other equipment you are load balancing have different but quantified capability limits.

This mode requires that you specify a value for the connection-limit option for all members of the pool, but does not require all servers or other equipment you are load balancing to have similar capabilities.

weighted-least-connections-node

Specifies that the system passes a new connection to the node that is handling the lowest percentage of the specified connection limit. This mode works best in environments where the servers or other equipment you are load balancing have different but quantified capability limits.

This mode requires that you specify a value for the connection-limit option for all nodes, but does not require all servers or other equipment you are load balancing to have similar capabilities.

members

Adds, deletes, or replaces a set of pool members, by specifying a node name and service port in the format [node name/port]. If a node by the specified name does not exist, it will be created. You can configure the following options for a pool member:

address

Specifies the IP address of a pool member if a node by the name specified does not already exist.

app-service

Specifies the name of the application service to which the pool member belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the pool member. Only the application service can modify or delete the pool member.

connection-limit

Specifies the maximum number of concurrent connections allowed for a pool member. The default value is 0 (zero).

description

User defined description.

dynamic-ratio

Specifies a range of numbers that you want the system to use in conjunction with the ratio load balancing method. The default value is 1.

fqdn Specifies the attributes for defining a fully qualified domain name for the node.

name Specifies the fully-qualified domain name of the node.

address-family

Specifies whether the fqdn should consider IPv4, IPv6, or IP-agnostic address family.

autopopulate

Specifies whether a node defined by a fully-qualified domain name should automatically scale to the set of IP addresses returned by the DNS query. If disabled, only one ephemeral node is generated from the first IP address returned by DNS. The default is disabled.

interval

Specifies the interval to instantiate DNS queries on a fully-qualified domain name. The default is the TTL.

down-interval

Specifies the interval for the domain name resolution operation when a DNS query fails.

inherit-profile

Specifies whether the pool member inherits the encapsulation profile from the parent pool. The default value is enabled. If you disable inheritance, no encapsulation takes place, unless you specify another encapsulation profile for the pool

member using the profiles attribute.

logging

Specifies whether the monitor applied should log its actions. Logs are stored in /var/log/monitors/ and are regularly rotated and compressed. The default value is disabled. This option isn't a part of configuration and will reset to disabled on load. This option doesn't sync.

monitor

Specifies the health monitors that are configured to monitor the pool member. The default value is default, the system monitors the pool member using the monitors specified for the pool.

You can specify:

- o A single monitor, for example, modify pool mypool members modify { pool_member_1:80 { monitor http } }.
- o Multiple monitors, for example, modify pool mypool members modify { pool_member_1:80 { monitor http and https } }.
- o A minimum number of monitors, for example, modify pool mypool members modify { pool_member_1:80 { monitor min 1 of { http https } } }.
- o No monitor rule or remove a monitor rule, for example, modify pool mypool members modify { pool_member_1:80 { monitor none } }.

profiles

Specifies the encapsulation profile to use for the pool member, when the inherit-profile attribute is disabled. The default value is none.

priority-group

Specifies the priority group within the pool for this pool member. Valid values are 0 through 65535. The system sends traffic to groups in order of priority. The default value is 0.

rate-limit

Specifies the maximum number of connections per second allowed for a pool member. The default value is 'disabled'.

ratio

Specifies the weight of the pool member for load balancing purposes. The default value is 1.

session

Establishing a session with a pool member is establishing the ability of the client to persist to the pool member when making new connections. When a pool member is session disabled, clients that have already established sessions with the pool member may create new connections, but a client that has not already established a session may not create a new one (or make a connection which would create a new session). This feature is used to gently drain connections from a node, typically as part of a maintenance operation. The default value is user-enabled.

The value of this property can be set by system or by user. If the value is set by system, the property will not be displayed in "Edit" command. But, users can add this field in if they need to modify this property. The values which user can set for this property are user-enabled and user-disabled.

state

user-down forces the pool member offline, overriding monitors. user-up reverts the user-down. When user-up, this displays the monitor state.

metadata

Associates user-defined data, each of which has name and value pair and persistence. The default value is persistent, which saves the data to the config file.

min-active-members

Specifies the minimum number of members that must be up for traffic to be confined to a priority group when using priority-based activation. The default value is 0 (zero). An active member is a member that is up (not marked down) and is handling fewer connections than its connection limit.

min-up-members

Specifies the minimum number of pool members that must be up; otherwise, the system takes the action specified in the min-up-members-action option.

Use this option for gateway pools in a redundant system where a unit number is applied to the pool. This indicates that the pool is configured only on the specified unit.

min-up-members-action

Specifies the action to take if min-up-members-checking is enabled, and the number of active pool members falls below the number specified in the min-up-members option. The default value is failover. The options are:

reboot

Specifies that when the min-up-members-checking option is enabled, and the number of active pool members is less than

the number specified in the min-up-members option, the system restarts.

restart-all

Specifies that when the min-up-members-checking option is enabled, and the number of active pool members is less than the number specified in the min-up-members option, the system restarts.

failover

Specifies, for a redundant system, that when the min-up-members-checking option is enabled, and the number of active pool members is less than the number specified in the min-up-members option, the system fails over.

min-up-members-checking

Enables or disables the min-up-members feature. If you enable this feature, you must also specify a value for both the min-up-members and min-up-members-action options.

monitor

Specifies the health monitors that the system uses to determine whether it can use this pool for load balancing. The monitor marks the pool up or down based on whether the monitor is successful. The default value is none.

You can specify:

- o A single monitor, for example, modify pool mypool monitor http.

- o Multiple monitors, for example, modify pool mypool monitor http and https.

- o A minimum number of monitors, for example, modify pool mypool monitor min 1 of {http and https}.

- o No monitor rule or remove a monitor rule, for example, modify pool mypool monitor none.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the pool resides.

profiles

Specifies the profile to use for encapsulation. The default value is none, which indicates no encapsulation.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reselect-tries

When set to the default value of 0 (zero) the system does not attempt to load balance to another pool member after a passive failure. A passive failure is a pool member connection failure.

When set to any other value, the system attempts to load balance to another pool member after a passive failure, and if that attempt also results in a passive failure, the system repeats the process until the specified number of reselection tries is reached.

reset-stats

Resets the statistics for the specified component to 0 (zero).

service-down-action

Specifies the action to take if the service specified in the pool is marked down. The options are:

drop Specifies that the system drops connections when a the service is marked down.

none Specifies that the system takes no action when a the service is marked down. This is the default value.

reselect

Specifies that the system reselects a node for the next packet that comes in on a Layer 4 connection, if the service of the existing connection is marked down.

reset

Specifies that the system resets when a the service is marked down.

slow-ramp-time

Specifies, in seconds, the ramp time for the pool. This provides the ability to cause a pool member that has just been enabled, or marked up, to receive proportionally less traffic than other members in the pool. The proportion of traffic the member accepts is determined by how long the member has been up in comparison to the value of the slow-ramp-time option for the pool.

For example, if the load-balancing-mode of a pool is round-robin and it has a slow-ramp-time of 60 seconds, when a pool member has been up for only 30 seconds, the pool member receives approximately half the amount of new traffic as other pool members that have been up for more than 60 seconds. After the pool member has been up for 45 seconds, it receives approximately three

quarters of the new traffic.

The slow-ramp-time option is particularly useful when used with the least-connections-member load balancing mode. The default value is 10.

to-folder

This is used with the mv command to specify a folder in which to move the pool and its members to.

Note: pools can be moved to any folder under /Common, but dependencies upon it may restrict moving it out of /Common.

```

DESCRIPTION
 Use the analytics component to create, modify, display, or delete an analytics profile for use with analytics functionality.

EXAMPLES
 create analytics my_analytics_profile defaults-from analytics

Creates a custom analytics profile named my_analytics_profile that inherits its settings from the system default analytics profile.

```
list analytics
```

Displays the properties of all analytics profiles.

OPTIONS
 app-service
 Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

alerts
 Adds, deletes, or replaces a set of analytics alerts. You can configure the following options for an analytics alert:

app-service
 Specifies the name of the application service to which the alert belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the alert. Only the application service can modify or delete the alert.

granularity
 Specifies a granularity level on which the alert is defined.

The options are:

application
 Specifies that an alert is triggered for applications for which a threshold is breached.

pool-member

Specifies that an alert is triggered for pool members for which a threshold is breached.

virtual-server

Specifies that an alert is triggered for virtual servers for which a threshold is breached.

metric

Specifies a metric on which the alert is defined.

The options are:

average-page-load-time

Specifies that an alert is triggered when the average time it takes for the client to respond to a request breaches the defined threshold.

average-request-throughput

Specifies that an alert is triggered when the average number of bits per second the system processed, based on requests only, breaches the defined threshold.

average-response-throughput

Specifies that an alert is triggered when the average number of bits per second the system processed, based on responses only, breaches the defined threshold.

average-server-latency

Specifies that an alert is triggered when the average time it takes for the web server to respond to a request breaches the defined threshold.

average-tps

Specifies that an alert is triggered when the average number of transactions per second breaches the defined threshold.

max-page-load-time

Specifies that an alert is triggered when the longest time it takes for the client to respond to a request breaches the defined threshold.

max-request-throughput

Specifies that an alert is triggered when the maximum number of bits per second the system processed, based on requests only, breaches the defined threshold.

max-response-throughput

Specifies that an alert is triggered when the maximum number of bits per second the system processed, based on requests only, breaches the defined threshold.

max-server-latency

Specifies that an alert is triggered when the longest time it takes for the web server to respond to a request breaches the defined threshold.

max-tps

Specifies that an alert is triggered when the largest number of transactions per second breaches the defined threshold.

name Specifies a unique name for an alert. This option is required for the commands create, delete, and modify.

sample-period

Specifies that the alert metric is triggered when the conditions that trigger the alert last a defined amount of time, measured in seconds. The default value is 300.

threshold

Specifies the threshold that must be breached in order for the system to generate alert.

threshold-relation

Specifies whether the metric value must be below or above the metric.

The options are:

above

Specifies that an alert is issued if metric current value is above the threshold.

below

Specifies that an alert is issued if metric current value is below the threshold.

captured-traffic-external-logging

Enables or disables the external logging of captured traffic.

captured-traffic-internal-logging

Enables or disables the internal logging of captured traffic.

collect-page-load-time

Enables or disables the collection of the page load time statistics. The page load time is the round-trip latency between client end-users and the servers, that is, the round-trip time between an end-user's request for a page until the time the response finishes loading.

collect-geo

Enables or disables the collection of the names of the countries from where the traffic was sent.

collect-http-throughput

Enables or disables the collection of throughput statistics. This property has been deprecated. As of v11.3.0, HTTP throughput is always collected.

collect-http-timing-metrics

Enables or disables the collection of HTTP timing metrics.

collect-ip

Enables or disables the collection of client IPs statistics.

collect-max-tps-and-throughput

Enables or disables the collection of maximum TPS and throughput for all collected entities.

collect-methods

Enables or disables the collection of HTTP methods statistics.

collect-response-codes

Enables or disables the collection of response codes returned by the servers.

collect-server-latency

Enables or disables the collection of server latency statistics. This property has been deprecated. As of v11.3.0, server latency is always collected.

collect-subnets

Enables or disables the collection of client side subnets.

collect-url

Enables or disables the collection of requested URL statistics.

collect-user-agent

Enables or disables the collection of user agents.

collect-user-sessions

Enables or disables the collection of the unique user sessions.

collected-stats-external-logging

Enables or disables the external logging of the collected statistics.

collected-stats-internal-logging

Enables or disables the internal logging of the collected statistics.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is analytics.

description

User defined description.

external-logging-publisher

Specifies the external logging publisher used to send statistical data to one or more destinations.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

notification-by-email

Enables or disables sending the analytics alerts by email.

notification-by-snmp

Enables or disables sending the analytics alerts by SNMP traps. notification-by-syslog must be enabled.

notification-by-syslog

Enables or disables logging of the analytics alerts into the Syslog.

notification-email-addresses

Specifies which email addresses receive alerts by email when notification-by-email is enabled.

partition

Displays the administrative partition within which the component resides.

publish-irule-statistics

Enables or disables publishing analytics statistics for iRules.

sampling

Enables or disables transaction sampling. This attribute can be set in the default profile only. The default value is disabled.

session-cookie-security

Specifies the condition for adding a secure attribute to the session cookie. The options are:

always

The secure attribute is always added to the session cookie.

never

The secure attribute is never added to the session cookie.

ssl-only

The secure attribute is only added to the session cookie when the virtual server has a client-SSL profile. This is the default value.

session-timeout-minutes

Specifies the number of minutes of user non-activity before the system considers the session to be over.

smtp-config

Specifies the SMTP configuration to be used with analytics.

subnet-masks

Adds, deletes, or replaces predefined subnet addresses. This options defines the display names given to certain subnet addresses seen in the client IP subnets report.

subnet

Subnet address. IPv4 addresses will be masked by 255.255.255.0. IPv6 addresses will be masked by ffff:ffff:ffff:ffff:: .

countries-for-stat-collection

Manage a list of 10 predefined countries that are used for collecting AVR statistics

ips-for-stat-collection

Manage a list of 10 predefined IP addresses that are used for collecting AVR statistics.

subnets-for-stat-collection

Manage a list of 10 predefined URLs that are used for collecting AVR statistics.

urls-for-stat-collection

Manage a list of 10 predefined subnet addresses that are used for collecting AVR statistics. IPv4 addresses will be masked by 255.255.255.0. IPv6 addresses will be masked by ffff:ffff:ffff:ffff:: .

traffic-capture

Adds, deletes, or replaces an analytics traffic capture definition. You can configure the following options for an analytics traffic capture:

app-service

Specifies the name of the application service to which the analytics traffic capture belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the analytics traffic capture. Only the application service can modify or delete the analytics traffic capture.

captured-protocols

Specifies whether the system captures traffic data sent using all protocols, or only one type of protocol.

The options are:

all Specifies that the system captures traffic data sent using all protocols.

http Specifies that the system captures traffic data sent using http protocol.

https Specifies that the system captures traffic data sent using https protocol.

client-ips

Adds, deletes, or replaces a set of client IP addresses from/to which captured traffic is sent.

dos-activity

Specifies whether the system captures traffic data mitigated by DoS Layer 7 Enforcer or regardless of DoS activity.

The options are:

any Specifies that system does not filter traffic data by DoS activity.

mitigated-by-dos17

Specifies that the system captures only traffic data mitigated by DoS Layer 7 Enforcer.

methods

Adds, deletes, or replaces a set of HTTP methods used to send requests from which traffic is captured.

name Specifies a unique name for an analytics traffic capture. This option is required for the commands create, delete, and modify.

node-addresses

Adds, deletes, or replaces a set of node addresses from/to which captured traffic is sent.

request-captured-parts

Specifies what parts of the request data the system captures.

The options are:

all Specifies that the system captures all the parts of the

request data.

body Specifies that the system captures the body of the request data.

headers Specifies that the system captures the HTTP headers of the request data.

none Specifies that the system does not capture the request data.

request-content-filter-search-part Specifies which part of the request is filtered by a specific string.

The options are:

all Specifies that the system filters all the parts of the request data.

body Specifies that the system filters the body of the request data.

headers Specifies that the system filters the HTTP headers of the request data.

none Specifies that system does not filter the request data.

uri Specifies that the system filters the URI path component, including the query string, of the request data.

request-content-filter-search-string Specifies the string by which a request data is filtered, or none.

response-captured-parts Specifies what parts of the response data the system captures.

The options are:

all Specifies that the system captures all the parts of the response data.

body Specifies that the system captures the body of the response data.

headers Specifies that the system captures the HTTP headers of the response data.

none Specifies that the system does not capture the response data.

response-codes Adds, deletes, or replaces a set of HTTP response codes from which traffic is captured.

response-content-filter-search-part Specifies which part of the response is filtered by a specific string.

The options are:

all Specifies that the system filters all the parts of the response data.

body Specifies that the system filters the body of the response data.

headers Specifies that the system filters the HTTP headers of the response data.

none Specifies that system does not filter the response data.

response-content-filter-search-string Specifies the string by which the response data is filtered, or none.

url-path-prefixes Adds, deletes, or replaces a set of URL path prefixes on which traffic can be captured (both to and from).

user-agent-substrings Adds, deletes, or replaces a set of user agent substrings on which traffic can be captured (both to and from).

virtual-servers Adds, deletes, or replaces a set of virtual servers from/to which captured traffic is sent.

ltm profile certificate-authority

NAME
certificate-authority - Defines the settings necessary to authenticate the client certificate.

MODULE
ltm profile

SYNTAX
Configure the certificate-authority within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY
create certificate-authority [name]
modify certificate-authority [name]
options:
 authenticate-depth
 ca-file
 crl-file
 default-name
 description
 update-crl

edit certificate-authority [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 non-default-properties

DISPLAY
list certificate-authority
list certificate-authority [[[name] | [glob] | [regex]] ...]
 app-service
 partition

show certificate-authority
show certificate-authority [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 field-fmt
non-default-properties
 one-line

DESCRIPTION
Use the certificate-authority component to modify or display a certificate-authority profile.

EXAMPLES
create ltm profile certificate-authority mycaprofile { ca-file ca.crt }

Creates a certificate authority profile named mycaprofile using the system defaults.

modify ltm profile certificate-authority mycaprofile { authenticate-depth 3 }

Modifies the authenticate-depth setting to 3 for the certificate authority profile named mycaprofile.

OPTIONS
 app-service
Displays the application service to which the object belongs. The default value is none.

Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

 authenticate-depth
Specifies the authenticate depth. This is the client certificate chain maximum traversal depth.

 ca-file
Specifies the certificate authority file name or, you can use default for the default certificate authority file name. Configures certificate verification by specifying a list of client or server certificate authorities that the traffic management system trusts.

 crl-file
Specifies the certificate revocation list file name. You can use default for the default certificate revocation file name.

defaults-from
Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified.

description
User defined description.

name Specifies the profile instance name. This option is required for the modify command.

partition
Specifies the administrative partition within which the profile resides.

regex
Specifies the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

update-crl
Automatically updates the CRL file.

SEE ALSO

edit, glob, list, modify, regex, show, tmsh,

ltm profile classification

NAME
classification - Configures a classification profile.

MODULE
ltm profile

SYNTAX
Configure the classification profile within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY

create classification [name]
modify classification [name]

options:

defaults-from [[name] | none]
description [string]
app-detection [on | off]
urlcat [on | off]
irule-event [on | off]
log-publisher [string]
preset [string]

edit classification [[[name] | [glob] | [regex]] ...]

options:

all-properties
non-default-properties

DISPLAY

list classification
list classification [[[name] | [glob] | [regex]] ...]
show running-config classification
show running-config classification [[[name] | [glob] | [regex]] ...]

options:

all-properties
non-default-properties
one-line
partition

DELETE

delete classification [name]

DESCRIPTION

Use the classification component to create, modify, delete or display a classification profile.

EXAMPLES

```
create classification my_cl { irule-event off preset /Common/ce }
```

Creates classification profile named my_cl with Classification Engine configuration /Common/ce and iRule event disabled.

```
edit classification my_cl
Edits the classification profile named my_cl.

list classification my_cl
Displays the properties of the my_cl classification profile.

delete classification my_cl
Deletes the my_cl classification profile.
```

OPTIONS

```
description
User defined description.

app-detection
Enables / Disables Application Detection feature.

urlcat
Enables / Disables URL categorization feature.

irule-event
Enables / disables CLASSIFICATION_DETECTED iRule event generation.

log-publisher
Specifies the log publisher name

preset
Specifies Classification Engine configuration. Refer to ltm
classification ce for more details
```

SEE ALSO

```
edit, list, ltm virtual, ltm classification, ltm classification ce,
modify, regex, reset-stats, show, tmsh
```

COPYRIGHT

ltm profile client-ldap

```
NAME
client-ldap - Configures an Client LDAP profile.

MODULE
ltm profile

SYNTAX
Configure the client-ldap component within the ltm profile module using
the syntax shown in the following sections.

CREATE/MODIFY
create client-ldap [name]
modify client-ldap [name]
options:
  app-service [[string] | none]
  defaults-from [ [name] | none]
  description [string]
  activation-mode [ none | allow | require ]

edit client-ldap [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list client-ldap
list client-ldap [ [ [name] | [glob] | [regex] ] ... ]
show running-config client-ldap
show running-config client-ldap [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DELETE
delete client-ldap [name]
```

DESCRIPTION

```
You can use the client-ldap component to create, modify, display, or
delete an Client LDAP profile with which you can manage Client LDAP
traffic.
```

EXAMPLES

```
create client-ldap my_clientldap_profile defaults-from clientldap
```

Creates a custom Client LDAP profile named `my_clientldap_profile` that inherits its settings from the system default Client LDAP profile.

```
list client-ldap
```

Displays the properties of all Client LDAP profiles.

OPTIONS

`app-service`

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

`defaults-from`

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is `smtp`.

`description`

User defined description.

`glob` Displays the items that match the glob expression. See `help glob` for a description of glob expression syntax.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See `help regex` for a description of regular expression syntax.

`activation-mode`

Sets the activation-mode `STARTTLS`. The options are `NONE`, `ALLOW`, or `REQUIRE`. The default value is `REQUIRE`.

DESCRIPTION

You can use the client-ssl component to create, modify, or delete a custom Client SSL profile, or display a custom or default Client SSL profile.

Client-side profiles allow the traffic management system to handle authentication and encryption tasks for any SSL connection coming into a traffic management system from a client system.

EXAMPLES

```
create client-ssl my_clientssl_profile
```

Creates a clientssl profile named my_clientssl_profile using the system defaults.

```
create clientssl my_clientssl_profile authenticate-depth number
```

Creates a Client SSL profile named my_clientssl_profile using the system defaults, except that a user is authenticated with depth number.

```
mv client-ssl /Common/my_client-ssl_profile to-folder /Common/my_folder
```

Moves a custom client-ssl profile named my_client-ssl_profile to a folder named my_folder, where my_folder has already been created and exists within /Common. =head1 OPTIONS

alert-timeout

Specifies the maximum time period in seconds to keep the SSL session active after alert message is sent, or indefinite. The default value is indefinite.

allow-non-ssl

Enables or disables non-SSL connections. Specify enabled when you want non-SSL connections to pass through the traffic management system as clear text. The default value is disabled.

allow-dynamic-record-sizing

Enables or disables dynamic application record sizing. Specify enabled when you want to allow dynamic record sizing. The default value is disabled.

app-service

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

authenticate

Specifies how often the system authenticates a user. The default value is once.

authenticate-depth

Specifies the authenticate depth. This is the client certificate chain maximum traversal depth. The default value is 9.

bypass-on-client-cert-fail

Enables or disables SSL forward proxy bypass on failing to get client certificate that server asks for. When enabled and the SSL handshake cannot be completed because of failure to get the client certificate, SSL traffic bypasses the BIG-IP system untouched, without decryption/encryption. The default value is disabled. Conversely, you can specify enabled to use this feature.

bypass-on-handshake-alert

Enables or disables SSL forward proxy bypass on receiving handshake_failure, protocol version or unsupported extension alert message during the serverside SSL handshake. When enabled and there is an SSL handshake_failure, protocol version or unsupported extension alert during the serverside SSL handshake, SSL traffic bypasses the BIG-IP system untouched, without decryption/encryption. The default value is disabled. Conversely, you can specify enabled to use this feature.

c3d-drop-unknown-ocsp-status

Specifies the BIG-IP action when the OCSF responder returns unknown status. The default value is drop, which causes the connection to be dropped. Conversely, you can specify ignore, which causes the connection to ignore the unknown status and continue.

c3d-ocsp

Specifies the SSL client certificate constrained delegation OCSF object that the BIG-IP SSL should use to connect to the OCSF responder and check the client certificate status.

ca-file

Specifies the certificate authority (CA) file name. Configures certificate verification by specifying a list of client or server CAs that the traffic management system trusts. The default value is none.

cache-size

Specifies the SSL session cache size. For client-side profiles only, you can configure timeout and size values for the SSL session cache. Because each profile maintains a separate SSL session cache, you can configure the values on a per-profile basis. The default value is 262144.

cache-timeout

Specifies the SSL session cache timeout value. This specifies the number of usable lifetime seconds of negotiated SSL session IDs. The default value is 3600 seconds. Acceptable values are integers greater than or equal to 0 and less than or equal to 86400.

cert This option is deprecated and is maintained here for backward compatibility reasons. Please check cert-key-chain option to add certificate, key, passphrase and chain to the profile.

cert-extension-includes

Specifies the extensions of the web server certificates to be included in the generated certificates using SSL Forward Proxy. For example, { basic-constraints }. The default value is none. The extensions are:

authority-key-identifier

Authority Key Identifier provides a means of identifying the public key corresponding to the private key used to sign a certificate.

basic-constraints

Basic Constraints are used to indicate whether the certificate belongs to a CA.

certificate-policies

Certificate Policies contain a sequence of one or more policy information terms.

crl-distribution-points

CRL Distribution Points identify how CRL information is obtained.

extended-key-usage

Extended Key Usage is used, typically on a leaf certificate, to indicate the purpose of the public key contained in the certificate.

fresh-crl

Fresh CRL (a.k.a Delta CRL Distribution Point) identifies how delta CRL information is obtained.

issuer-alternative-name

As with subject-alternative-name, Issuer Alternative Name is used to associate Internet style identities with the certificate issuer.

key-usage

Key Usage provides a bitmap specifying the cryptographic operations which may be performed using the public key contained in the certificate; for example, it could indicate that the key should be used for signature but not for encipherment.

subject-alternative-name

Subject Alternative Name allows identities to be bound to the subject of the certificate. These identities may be included in addition to or in place of the identity in the subject field of the certificate.

subject-directory-attributes

Subject Directory Attributes are used to convey identification attributes (for example, nationality) of the subject.

subject-key-identifier

Subject Key Identifier provides a means of identifying certificates that contains a particular public key.

destination-ip-blacklist

Specifies the data group name of destination ip blacklist when SSL forward proxy bypass feature is enabled.

destination-ip-whitelist

Specifies the data group name of destination ip whitelist when SSL forward proxy bypass feature is enabled.

forward-proxy-bypass-default-action

Specifies the SSL forward proxy bypass default action. The default option is intercept.

hostname-blacklist

Specifies the data group name of hostname blacklist when SSL forward proxy bypass feature is enabled.

hostname-whitelist

Specifies the data group name of hostname whitelist when SSL forward proxy bypass feature is enabled.

inherit-certkeychain

This is read only value used internally.

cert-key-chain

Adds, deletes, or replaces a set of certificate, key, passphrase, chain (usage specifies whether this item is used for Server or CA, where Server is the default and CA is for SSL forward proxy). client-ssl profile requires at least one cert/key pair to work. Multiple cert/key types can be associated to a client-ssl profile using following options:

cert Specifies the name of the certificate installed on the traffic management system for the purpose of terminating or initiating an SSL connection. You can specify the default certificate name, which is default.crt.

chain

Specifies or builds a certificate chain file that a client can use to authenticate the profile. The default value is none.

key Specifies the name of a key file that you generated and installed on the system. When selecting this option, type a key file name or use the default value default.key.

passphrase

Specifies the key passphrase, if required. The default value is none.

cert-lifespan

Specifies the lifespan of the certificate generated using the SSL forward proxy feature. The default value is 30.

cert-lookup-by-ipaddr-port

Specifies whether to perform certificate look up by IP address and port number.

chain

This option is deprecated and is maintained here for backward compatibility reasons. Please check cert-key-chain option to add certificate, key, passphrase and chain to the profile.

cipher-group

Specifies a cipher group. If the cipher group is not blank or none, the ciphers string will be used.

ciphers

Specifies a cipher name. The default value is DEFAULT, which uses the default ciphers.

client-cert-ca

Specifies the client cert certificate authority name. The default value is none.

crl-file

Specifies the certificate revocation list file name. The default value is none.

allow-expired-crl

Use the specified CRL file even if it has expired. The default value is disabled.

defaults-from

This setting specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is clientssl.

description

User defined description.

generic-alert

Enables or disables generic-alert. The default option is enabled, which causes the SSL profile to use generic alert number. Conversely, you can specify disabled to cause SSL profile to use alert number defined in RFC5246/RFC6066 strictly.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

handshake-timeout

Specifies the handshake timeout in seconds. The default value is 10 seconds.

key This option is deprecated and is maintained here for backward compatibility reasons. Please check cert-key-chain option to add certificate, key, passphrase and chain to the profile.

maximum-record-size

Specifies the profile's maximum record size. The range is 128 - 16384. The default value is 16384.

mod-ssl-methods

Enables or disables ModSSL method emulation. Enable this option when OpenSSL methods are inadequate, for example, when you want to use SSL compression over TLSv1. The default value is disabled.

mode Specifies the profile mode, which enables or disables SSL processing. The default value is enabled.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

options

Enables options, including some industry-related workarounds. Enter options inside braces, for example, {dont-insert-empty-fragments microsoft-sess-id-bug}.

The default value is dont-insert-empty-fragments no-tls1.3. The

options are:

all-bugfixes

This option enables the following industry-related defect workarounds: microsoft-sess-id-bug, netscape-challenge-bug, netscape-reuse-cipher-change-bug, sslref2-reuse-cert-type-bug, microsoft-big-ssl3-buffer, msie-ssl2-rsa-padding, ssleay-080-client-dh-bug, tls-d5-bug, tls-block-padding-bug, and dont-insert-empty-fragments.

It is usually safe to use this option to enable the defect workaround options when compatibility with broken implementations is desired. It is usually safe to use this option to enable the defect workaround options when compatibility with broken implementations is desired. Note that if you edit the configuration in the Web-based configuration utility, the system expands the all-bugfixes syntax into each individual option.

cipher-server-preference

When choosing a cipher, this option uses the server's preferences instead of the client references. If this option was not set, the SSL server would follow the client's references. When this option is set, the SSLv3/TLSv1 server chooses by using its own references.

Note: This option has no effect. The BIG-IP system always behaves as if the option is active, even when you disable it.

dont-insert-empty-fragments

Disables a countermeasure against an SSL 3.0/TLS 1.0 protocol vulnerability affecting CBC ciphers. These ciphers cannot be handled by certain broken SSL implementations. This option has no effect for connections using other ciphers.

ephemeral-rsa

Uses ephemeral (temporary) RSA keys when doing RSA operations. According to the specifications, this is done only when an RSA key can be used for signature operations only (namely under export ciphers with restricted RSA key length). By setting this option, you specify that you want to use ephemeral RSA keys always. This option breaks compatibility with the SSL/TLS specifications and may lead to interoperability problems with clients. Therefore, F5 Networks does not recommend this option. Use ciphers with ephemeral Diffie-Hellman (EDH) key exchange instead. This option is ignored for server-side SSL.

microsoft-big-ssl3-buffer

Enables a workaround for communicating with older Microsoft(r) applications that use non-standard SSL record sizes.

microsoft-sess-id-bug

Handles a Microsoft session ID problem.

msie-ssl2-rsa-padding

Enables a workaround for communicating with older Microsoft applications that use non-standard RSA key padding. This option is ignored for server-side SSL.

netscape-ca-dn-bug

Handles a defect regarding the system crashing or hanging. If the system accepts a Netscape Navigator(r) browser connection, demands a client cert, has a non-self-signed CA that does not have its CA in Netscape, and the browser has a certificate, the system crashes or hangs.

netscape-challenge-bug

Handles the Netscape challenge problem.

netscape-demo-cipher-change-bug

Manipulates the SSL server session resumption behavior to mimic that of certain Netscape servers (see the Netscape reuse cipher change bug workaround description). Note that F5 Networks does not recommend this option for normal use. It is ignored for server-side SSL.

netscape-reuse-cipher-change-bug

Handles a defect within Netscape-Enterprise/2.01 (<https://merchant.neape.com>), only appearing when connecting through SSLv2/v3 then reconnecting through SSLv3. In this case, the cipher list changes.

First, a connection is established with the RC4-MD5 cipher list. If it is then resumed, the connection switches to using the DES-CBC3-SHA cipher list. However, according to RFC 2246, (section 7.4.1.3, cipher suite) the cipher list should remain RC4-MD5.

As a workaround, you can attempt to connect with a cipher list of DES-CBC-SHA:RC4-MD5 and so on. For some reason, each new connection uses the RC4-MD5 cipher list, but any re-connection attempts to use the DES-CBC-SHA cipher list. Thus Netscape, when reconnecting, always uses the first cipher in the cipher list.

no-session-resumption-on-renegotiation

When performing renegotiation as an SSL server, this option always starts a new session (that is, session resumption requests are only accepted in the initial handshake). The system ignores this option for server-side SSL.

no-ssl

Do not use any version of the SSL protocol.

no-ssl2

Do not use the SSLv2 protocol.

`no-sslv3`
Do not use the SSLv3 protocol.

`no-tls`
Do not use any version of the TLS protocol.

`no-tls1`
Do not use the TLSv1.0 protocol.

`no-tls1.1`
Do not use the TLSv1.1 protocol.

`no-tls1.2`
Do not use the TLSv1.2 protocol.

`no-tls1.3`
Do not use the TLSv1.3 protocol.

`no-dtls`
Do not use any version of the DTLS protocol.

`passive-close`
Specifies how to handle passive closes.

`none` Disables all workarounds. Note that F5 Networks does not recommend this option.

`notify-cert-status-to-virtual-server`
Specifies whether to propagate the status of the certificates of this clientssl profile to the virtual servers that are using this clientssl profile.

`ocsp-stapling`
Specifies whether to enable OCSP stapling.

`pkcs1-check-1`
This debugging option deliberately manipulates the PKCS1 padding used by SSL clients in an attempt to detect vulnerability to particular SSL server vulnerabilities. Note that F5 Networks does not recommend this option for normal use. The system ignores this option for client-side SSL.

`pkcs1-check-2`
This debugging option deliberately manipulates the PKCS1 padding used by SSL clients in an attempt to detect vulnerability to particular SSL server vulnerabilities. Note that F5 Networks does not recommend this option for normal use. The system ignores this option for client-side SSL.

`single-dh-use`
Creates a new key when using temporary/ephemeral DH parameters. This option must be used to prevent small subgroup attacks, when the DH parameters were not generated using strong primes (for example, when using DSA-parameters). If strong primes were used, it is not strictly necessary to generate a new DH key during each handshake, but F5 Networks recommends it. Enable the Single DH Use option whenever temporary or ephemeral DH parameters are used.

`ssleay-080-client-dh-bug`
Enables a workaround for communicating with older SSLeay-based applications that specify an incorrect Diffie-Hellman public value length. This option is ignored for server-side SSL.

`sslref2-reuse-cert-type-bug`
Handles the SSL reuse certificate type problem.

`tls-block-padding-bug`
Enables a workaround for communicating with older TLSv1-enabled applications that use incorrect block padding.

`tls-d5-bug`
This option is a workaround for communicating with older TLSv1-enabled applications that specify an incorrect encrypted RSA key length. This option is ignored for server-side SSL.

`tls-rollback-bug`
Disables version rollback attack detection. During the client key exchange, the client must send the same information about acceptable SSL/TLS protocol levels as it sends during the first hello. Some clients violate this rule by adapting to the server's answer. For example, the client sends an SSLv2 hello and accepts up to SSLv3.1 (TLSv1), but the server only processes up to SSLv3. In this case, the client must still use the same SSLv3.1 (TLSv1) announcement. Some clients step down to SSLv3 with respect to the server's answer and violate the version rollback protection. The system ignores this option for server-side SSL.

`partition`
Displays the administrative partition within which the profile resides.

`passphrase`
This option is deprecated and is maintained here for backward compatibility reasons. Please check cert-key-chain option to add certificate, key, passphrase and chain to the profile.

`peer-cert-mode`
Specifies the peer certificate mode. The default value is ignore.

`peer-no-renegotiate-timeout` Specifies the timeout in seconds when the server sends Hello Request and waits for ClientHello before it sends Alert with fatal alert. You can also specify indefinite. The default is 10 seconds.

`proxy-ca-cert`

Specifies the name of the certificate file that is used as the certification authority certificate when SSL forward proxy feature is enabled. The certificate should be generated and installed by you on the system. When selecting this option, type a certificate file name. (This option is deprecated since v14.0.0, suggest to use cert-key-chain with usage CA to add SSL forward proxy CA key/cert.)

proxy-ca-key

Specifies the name of the key file that is used as the certification authority key when SSL forward proxy feature is enabled. The key should be generated and installed by you on the system. When selecting this option, type a key file name. (This option is deprecated since v14.0.0, suggest to use cert-key-chain with usage CA to add SSL forward proxy CA key/cert.)

proxy-ca-passphrase

Specifies the passphrase of the key file that is used as the certification authority key when SSL forward proxy feature is enabled. When selecting this option, type the passphrase corresponding to the selected proxy-ca-key. (This option is deprecated since v14.0.0, suggest to use cert-key-chain with usage CA to add SSL forward proxy CA key/cert.)

proxy-ssl

Enabling this option requires a corresponding server ssl profile with proxy-ssl enabled to perform transparent SSL decryption. This allows further modification of application traffic within an SSL tunnel while still allowing the server to perform necessary authorization, authentication, auditing steps.

proxy-ssl-passthrough

Enabling this option requires a corresponding server ssl profile with proxy-ssl-passthrough enabled. This allows Proxy SSL to passthrough the traffic when ciphersuite negotiated between the client and server is not supported. The default option is disabled.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

renegotiate-max-record-delay

Specifies the maximum number of SSL records that the traffic management system can receive before it renegotiates an SSL session. After the system receives this number of SSL records, it closes the connection. This setting applies to client profiles only. The default value is indefinite.

renegotiate-period

Specifies the number of seconds required to renegotiate an SSL session. The default value is indefinite.

renegotiate-size

Specifies the size of the application data, in megabytes, that is transmitted over the secure channel. If the size of the data is higher than this value, the traffic management system must renegotiate the SSL session. The default value is indefinite.

renegotiation

Specifies whether renegotiations are enabled. The default value is enabled. When renegotiations are disabled, and the system is acting as an SSL server, and a COMPAT or NATIVE cipher is negotiated, the system will abort the connection. Additionally, when renegotiations are disabled, and the system is acting as an SSL client, the system will ignore the server's HelloRequest messages.

retain-certificate

APM module requires storing certificate in SSL session. When set to false, certificate will not be stored in SSL session. The default value is true.

secure-renegotiation

Specifies the secure renegotiation mode. The default value is require. When secure renegotiation is required, any client attempting to renegotiate that does not support secure renegotiation will have its connection aborted. When secure renegotiation is set to require-strict, any client attempting to connect that does not support secure renegotiation will have its initial handshake denied. When secure renegotiation is set to request, unpatched clients will be permitted to renegotiate. This setting is NOT recommended however, as it is subject to active man-in-the-middle attacks.

max-renegotiations-per-minute

Specifies the maximum number of renegotiation attempts allowed in a minute. The default value is 5.

max-active-handshakes

Specifies the maximum number allowed SSL active handshakes. The default value is 0.

max-aggregate-renegotiation-per-minute

Specifies the maximum number of aggregate renegotiation attempts allowed in a minute. The default value is indefinite.

server-name

Specifies the server names to be matched with SNI (server name indication) extension information in ClientHello from a client connection. Wildcard is supported by using wildcard character "*" to match multiple names.

sni-default

When true, this profile is the default SSL profile when the server name in a client connection does not match any configured server names, or a client connection does not specify any server name at all.

sni-require

When this option is enabled, a client connection that does not specify a known server name or does not support SNI extension will be rejected.

ssl-sign-hash

Specifies SSL sign hash algorithm which is used to sign and verify SSL Server Key Exchange and Certificate Verify messages for the specified SSL profiles. The default value is sha1.

strict-resume

Enables or disables strict-resume. The default option is disabled, which causes the SSL profile to resume an uncleanly shut down SSL session. Conversely, you can specify enabled to prevent an SSL session from being resumed after an unclean shutdown.

unclean-shutdown

By default, the SSL profile performs unclean shutdowns of all SSL connections, which means that underlying TCP connections are closed without exchanging the required SSL shutdown alerts. If you want to force the SSL profile to perform a clean shutdown of all SSL connections, set this option to disabled.

session-mirroring

Enables or disables the mirroring of sessions to high availability peer. By default, this setting is disabled, which causes the system to not mirror ssl sessions.

session-ticket

Enables or disables session-ticket. The default option is disabled, which causes the SSL profile not to use session ticket per RFC 5077. Conversely, you can specify enabled to cause SSL profile to use session ticket per RFC 5077.

session-ticket-timeout

Specifies the session ticket timeout. The default value is 0 which means cache timeout is used.

source-ip-blacklist

Specifies the data group name of source ip blacklist when SSL forward proxy bypass feature is enabled.

source-ip-whitelist

Specifies the data group name of source ip whitelist when SSL forward proxy bypass feature is enabled.

ssl-c3d

Enables or disables SSL client certificate constrained delegation. The default option is disabled. Conversely, you can specify enabled to use the SSL client certificate constrained delegation.

ssl-forward-proxy

Enables or disables SSL forward proxy feature. The default option is disabled. Conversely, you can specify enabled to use the SSL Forward Proxy Feature.

ssl-forward-proxy-bypass

Enables or disables SSL forward proxy bypass feature. The default option is disabled. Conversely, you can specify enabled to use the SSL Forward Proxy Bypass Feature.

ssl-forward-proxy-verified-handshake

Specifies, when enabled, that in SSL forward proxy mode, the system should always do a TLS handshake with the server first before doing the client handshake. When disabled, the system will do the server handshake first only if it has not previously forged and cached the server certificate; once the server certificate is ready, the system will always handshake first with the client. The default value is disabled.

to-folder

client-ssl profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

MODULE
ltm profile

SYNTAX
Configure the dhcpv4 profile within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY

```
create dhcpv4 [name]
modify dhcpv4 [name]
options:
  app-service [[string] | none]
  defaults-from {[name] | none]
  mode [relay | forwarding]
  description [string]
  idle-timeout [ [integer] | indefinite ]
  default-lease-time [integer]
  lease-query-max-retry [integer]
  lease-query-only [true | false]
  transaction-timeout [integer]
  authentication {
    options:
  enabled [true | false]
  virtual [[string] | none]
  user-name {
    options:
    format [mac-address | mac-and-relay-option | relay-option | tcl-snippet]
    suboption-id1 [integer]
    suboption-id2 [integer]
    separator1 [[string] | none]
    separator2 [[string] | none]
    tcl [[string] | none]
  }
  subscriber-discovery {
    options:
  enabled [true | false]
  subscriber-id {
    options:
    format [mac-address | mac-and-relay-id | tcl-snippet]
    suboption-id1 [integer]
    suboption-id2 [integer]
    separator1 [[string] | none]
    separator2 [[string] | none]
    tcl [[string] | none]
  }
  relay-agent-id {
    options:
  add [true | false]
  remove [true | false]
  suboption {
    options:
    id1 [integer]
    id2 [integer]
    value1 [string | none]
    value2 [string | none]
  }
  ttl-value [integer]
  ttl-dec-value [ by-0 | by-1 | by-2 | by-4 ]
  max-hops [integer]
}
edit dhcpv4 [ [name] ... ]
options:
  all-properties
  non-default-properties

DELETE
delete dhcpv4 [name]
```

DESCRIPTION

You can use the dhcpv4 profile to manage DHCPv4 network traffic.

EXAMPLES

```
create dhcpv4 my_dhcpv4_profile defaults-from dhcpv4
```

Creates a custom DHCPv4 profile named `my_dhcpv4_profile` that inherits its settings from the system default DHCPv4 profile.

```
list dhcpv4 all-properties
```

Displays all properties for all DHCPv4 profiles.

```
create dhcpv4 new_dhcpv4_profile {
mode relay
idle-timeout 120
transaction-timeout 45
default-lease-time 3600
ttl-value 0
ttl-dec-value by-2
max-hops 4
subscriber-discovery {
  enabled true
  subscriber-id {
    format mac-and-relay-option
    suboption-id1 1
    separator1 -
  }
}
authentication {
  enabled true
  virtual new_authen_vs
  user-name {
    format mac-and-relay-option
    suboption-id1 1
    separator1 -
  }
}
relay-agent-id {
  add false
  remove true
}
}
```

Creates a DHCPv4 profile named `new_dhcpv4_profile` with `idle-timeout` value of <120 seconds>, `transaction-timeout` of <45 seconds>, `default-lease-time` of 3600 seconds, `ttl-dec-value` of 2 and `max-hops` of 4. The BIG-IP virtual will work in relay mode, with subscriber discovery enabled and configured with the `subscriber-id` format set to `mac-and-relay-option` and configured to use only suboption 1 (the first suboption ID) of the relay-agent info option (option 82) and to use the - to concatenate the MAC address to the first suboption ID. The authentication is enabled and its `user-name` equals the `subscriber-id` and the authentication virtual name is `new_authen_vs`. It also does not add relay agent option 82 but removed it (if exists) from the server-to-client messages.

OPTIONS

`app-service`

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

`default-lease-time`

Provides the default value in seconds of DHCPv4 lease time in case it was missing in the client-server exchange. The default is 86400.

`defaults-from`

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile. The default value is `dhcpv4`.

`description`

User defined description.

`lease-query-max-retry`

Specifies the maximum number of retries for a DHCPv4 lease query request.

`lease-query-only`

Specifies if a DHCPv4 virtual that uses this profile can be used for DHCP lease query only or for DHCP discovery as well.

`mode`

Specifies the operation mode of the DHCP virtual. If the virtual to run in relay mode, then it means that it is acting as a standard DHCPv4 relay agent. This means that the relay will change some of the DHCPv4 packet fields before sending it to either the client or server. The forwarding mode is similar to relay except that the virtual will not modify the standard fields, instead it will forward the message from client to server and vice-versa. The default is `relay`.

`idle-timeout`

Specifies the number of seconds that a connection is idle before the connection is eligible for deletion. The default value is 60 seconds.

`transaction-timeout`

Specifies DHCPv4 transaction timeout, in seconds. The transactions should complete within the timeout specified. If a transaction does not complete for any reason, it is removed. The

default value is 45 seconds.

authentication
Manages the subscriber authentication attributes.

enabled
To enable or disable subscriber authentication. If enabled, then user has to fill the following fields. Default is false.

virtual
Specifies the authentication virtual server name.

user-name
Manages the authentication user name's attributes. The user-name is what will be used to authenticate the DHCP client.

format
Specifies the user-name format. The options are: MAC address, MAC + relay-agent option, relay-agent option or tcl-snippet. The concatenation symbol is defined as separator1.

suboption-id1
The relay-agent option (option 82) first suboption ID. The default is 1.

suboption-id2
The relay-agent option (option 82) second suboption ID. The default is 2.

separator1
A string that is used to concatenate the MAC address and the relay-agent info option (option 82) to create the authentication user-name. The default is @.

separator2
A string that is used to concatenate the relay-agent info option (option 82) suboptions 1 and 2 to create the authentication user-name. The default is @.

tcl-snippet
A tcl snippet to format the user name. This value will be taken into account only if the format value was chosen to be tcl-snippet.

subscriber-discovery
Manages the subscriber discovery attributes.

enabled
To enable or disable subscriber discovery. If enabled, then user has to fill the following fields. Default is false.

subscriber-id
Manages the subscriber-id attributes. The subscriber-id is used by SPM to create, delete and update subscriber sessions.

format
Specifies the subscriber-id format. The options are: MAC address, MAC + relay-agent option, relay-agent option or tcl-snippet. The concatenation symbol is defined as separator1.

suboption-id1
The relay-agent info option (option 82) first suboption ID. The default is 1.

suboption-id2
The relay-agent info option (option 82) second suboption ID. The default is 2.

separator1
A string that is used to concatenate the MAC address and the relay-agent info option (option 82) to create the subscriber-id. The default is @.

separator2
A string that is used to concatenate the relay-agent info option (option 82) suboptions 1 and 2 to create the subscriber-id. The default is @.

tcl-snippet
A tcl snippet to format the subscriber-id. This value will be taken into account only if the format value was chosen to be tcl-snippet.

relay-agent-id
Manages the relay agent information option (option 82) attributes. As a relay, the DHCP virtual can insert this option.

add Specifies if the user wants the DHCP relay agent to insert option 82 or not. Default is false.

remove
Specifies if the user wants the DHCP relay agent to remove option 82 from the server-to-client traffic or not. Default is false.

suboptions
Manages the inserted relay agent information option (option 82) suboptions. We allow only two suboptions to be inserted.

id1 An integer to represent the first suboption ID. Default is 1.

value1
A string to represent the first suboption value.

id2 An integer to represent the second suboption ID. Default is 2.

value2
A string to represent the second suboption value.

t11-value
Specifies the ttl absolute value that the user may want to set for each outgoing DHCP packet. Default is 0; and in this case, we use the ttl-dec-value field.

t11-dec-value
Specifies the amount that the DHCP virtual will use to decrement the ttl for each outgoing DHCP packet. Default is by-1.

max-hops
Specifies the maximum number of relay agents that the DHCPv4 messages pass through before they are discarded. The default is 4.

```

```

DELETE
delete dhcpv6 [name]

```

DESCRIPTION

You can use the dhcpv6 profile to manage DHCPv6 network traffic.

EXAMPLES

```
create dhcpv6 my_dhcpv6_profile defaults-from dhcpv6
```

Creates a custom DHCPv6 profile named my_dhcpv6_profile that inherits its settings from the system default DHCPv6 profile.

```
list dhcpv6 all-properties
```

Displays all properties for all DHCPv6 profiles.

```

create dhcpv6 new_dhcpv6_profile {
mode relay
idle-timeout 120
transaction-timeout 45
default-lease-time 3600
subscriber-discovery {
  enabled true
  subscriber-id {
format mac-and-option37
separator1 @
  }
}
authentication {
  enabled true
  virtual new_authen_vs
  user-name {
format mac-and-option37
separator1 @
  }
}
remote-id-option {
  add false
  remove true
}
subscriber-id-option {
  add false
  remove true
}
}

```

Creates a DHCPv6 profile named new_dhcpv6_profile with idle-timeout value of <120 seconds>, transaction-time out of <45 seconds> and default-lease-time of 3600 seconds. The BIG-IP virtual will work in relay mode, with subscriber discovery enabled and configured with the subscriber-id format set to mac-and-option37 (remote-id relay agent option) and to use the @ to concatenate both MAC address and option 37. The authentication is enabled and its user-name equals the subscriber-id and the authentication virtual name is new_authen_vs. It also does not add either option 37 or options 38 (remote-id option and subscriber-id option) but remove them (if exists) from the server-to-client messages.

OPTIONS

```
app-service
```

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

```
default-lease-time
```

Provides the default value in seconds of DHCPv6 lease time in case it was missing in the client-server exchange. The default is 86400.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile. The default value is dhcpv6.

description

User defined description.

lease-query-max-retry

Specifies the maximum number of retries for a DHCPv6 lease query request.

lease-query-only

Specifies if a DHCPv6 virtual that uses this profile can be used for DHCP lease query only or for DHCP discovery as well.

mode Specifies the operation mode of the DHCP virtual. If the virtual to run in relay mode, then it means that it is acting as a standard DHCPv6 relay agent. This means that the relay will encapsulate the original messages into one of the relay messages before it send it to the server or the client. In the forwarding mode, the virtual will just forward the message to either the server or the client. The default is relay.

idle-timeout

Specifies the number of seconds that a connection is idle before the connection is eligible for deletion. The default value is 60 seconds.

transaction-timeout

Specifies DHCPv6 transaction timeout, in seconds. The transactions should complete within the timeout specified. If a transaction does not complete for any reason, it is removed. The default value is 45 seconds.

authentication

Manages the subscriber authentication attributes.

enabled

To enable or disable subscriber authentication. If enabled, then user has to fill the following fields. Default is false.

virtual

Specifies the authentication virtual server name.

user-name

Manages the authentication user name's attributes. The user-name is what will be used to authenticate the DHCP client.

format

Specifies the user-name format. The options are: MAC address, option37, MAC + option37, option38, MAC + option38, option37 + option38, mac + option37 + option38 tcl-snippet. The concatenation symbols are defined as separator1 and separator2.

separator1

A string that is used to concatenate the MAC address and the first two strings of the authentication user-name. The default is @.

separator2

A string that is used to concatenate the MAC address and the second two strings of the authentication user-name. The default is @.

tcl-snippet

A tcl snippet to format the user name. This value will be taken into account only if the format value was chosen to be tcl-snippet.

subscriber-discovery

Manages the subscriber discovery attributes.

enabled

To enable or disable subscriber discovery. If enabled, then user has to fill the following fields. Default is false.

subscriber-id

Manages the subscriber-id attributes. The subscriber-id is used by SPM to create, delete and update subscriber sessions.

format

Specifies the user-name format. The options are: MAC address, option37, MAC + option37, option38, MAC + option38, option37 + option38, mac + option37 + option38 tcl-snippet. The concatenation symbols are defined as separator1 and separator2.

separator1

A string that is used to concatenate the first two strings of the subscriber-id. The default is @.

separator2

A string that is used to concatenate the second two strings of the subscriber-id. The default is @.

tcl-snippet

A tcl snippet to format the subscriber-id. This value will be taken into account only if the format value was chosen to be tcl-snippet.

remote-id-option

Manages the DHCPv6 relay agent remote-id option (option 37)

attributes. As a relay, the DHCP virtual can insert or remove this option.

add Specifies if the user wants the DHCP relay agent to insert option 37 or not. Default is false.

remove
Specifies if the user wants the DHCP relay agent to remove option 37 from the server-to-client traffic or not. Default is false.

enterprise-number
Specifies the enterprise number of the inserted remote-id option (option 37).

value
A string to represent the remote-id option value.

subscriber-id-option
Manages the DHCPv6 relay agent subscriber-id option (option 38) attributes. As a relay, the DHCP virtual can insert or remove this option.

add Specifies if the user wants the DHCP relay agent to insert option 38 or not. Default is false.

remove
Specifies if the user wants the DHCP relay agent to remove option 38 from the server-to-client traffic or not. Default is false.

value
A string to represent the subscriber-id option value.

    global

DELETE
delete diameter [name]

DESCRIPTION
  You can use the diameter component to configure a profile to manage
  Diameter network traffic.

EXAMPLES
  create diameter my_diameter_profile defaults-from diameter

  Creates a Diameter profile named my_diameter_profile that inherits its
  settings from the system default Diameter profile.

  list diameter

  Displays the properties of all Diameter profiles.

  mv diameter /Common/my_diameter_profile to-folder /Common/my_folder

  Moves a custom diameter profile named my_diameter_profile to a folder
  named my_folder, where my_folder has already been created and exists
  within /Common.

OPTIONS
  app-service
  Specifies the name of the application service to which the profile
  belongs. The default value is none. Note: If the strict-updates
  option is enabled on the application service that owns the object,
  you cannot modify or delete the profile. Only the application
  service can modify or delete the profile.

  connection-prime
  When enabled, and the system receives a capabilities exchange
  request from the client, the system will establish connections and
  perform handshaking with all the servers prior to sending the
  capabilities exchange answer to the client. The default value is
  disabled.

  defaults-from
  Specifies the profile that you want to use as the parent profile.
  Your new profile inherits all settings and values from the parent
  profile specified. The default value is diameter.

  description
  User defined description.

  destination-realm
  This attribute has been deprecated as of BIG-IP v11.3.0. Specifies
  the realm to which messages are routed. A value of none indicates
  that the destination-realm option is disabled. The default value
  is none.

  You can specify a fully qualified domain name as an ASCII string.
  For more information about this option, see RFC 3588 section 6.6.

  glob Displays the items that match the glob expression. See help glob
  for a description of glob expression syntax.

  handshake-timeout
  Specifies the handshake timeout in seconds. This setting specifies
  the maximum number of seconds that a connection can be idle after
  the capabilities exchange request was sent to the server. The
  default value is 10. The system will reset the connection after it
  has timed out.

  You can specify a numeric value in the range 0 to 4294967295. The
  recommended value is in the range of 5 to 30

  host-ip-rewrite
  When enabled and the message is a capabilities exchange request or
  capabilities exchange answer, rewrite the host-ip-address
  attribute with the system's egress IP address. The default value
  is enabled.

  max-retransmit-attempts
  Specifies the maximum number of retransmit attempts. This setting
  specifies the maximum number of attempts that BIG-IP will take to
  retransmit the request messages if it does not receive the
  corresponding answer messages. If retransmit is unsuccessful,

```

after maximum attempts, BIG_IP will send an error response. The default value is 1.

You can specify a numeric value in the range 0 to 4294967295. The recommended value is in the range of 1 to 10

max-watchdog-failure

Specifies the maximum number of device watchdog failures that the traffic management system can take before it tears down the connection. After the system receives this number of device watchdog failures, it closes the connection. The default value is 10.

You can specify a numeric value in the range 0 to 4294967295.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

origin-host

This attribute has been deprecated as of BIG-IP v11.3.0. Please use, origin-host-to-client or origin-host-to-server. Specifies the origin host of BIG-IP. The origin-host is used to overwrite the server's actual origin host attribute when it responds to the client. A value of none indicates that origin-host is disabled. The default value is none.

You can specify an ASCII string as a FQDN. See RFC 3588 section 6.3.

origin-host-to-client

Specifies the origin host to client of BIG-IP. The origin-host-to-client is used to overwrite the server's actual origin host attribute when it responds to the client. A value of none indicates that origin-host-to-client is disabled. The default value is none.

You can specify an ASCII string as a FQDN. See RFC 3588 section 6.3.

origin-host-to-server

Specifies the origin host to server of BIG-IP. The origin-host-to-server is used to overwrite the client's actual origin host attribute when it responds to the server. A value of none indicates that origin-host-to-server is disabled. The default value is none.

You can specify an ASCII string as a FQDN. See RFC 3588 section 6.3.

origin-realm

This attribute has been deprecated as of BIG-IP v11.3.0. Please use, origin-realm-to-client or origin-realm-to-server. Specifies the origin realm of BIG-IP. The origin-realm is used to overwrite the server's actual origin realm attribute when it responds to the client. A value of none indicates that origin-realm is disabled. The default value is none.

You can specify an ASCII string as a FQDN. See RFC 3588 section 6.4.

origin-realm-to-client

Specifies the origin realm of BIG-IP. The origin-realm-to-client is used to overwrite the server's actual origin realm attribute when it responds to the client. A value of none indicates that origin-realm-to-client is disabled. The default value is none.

You can specify an ASCII string as a FQDN. See RFC 3588 section 6.4.

origin-realm-to-server

Specifies the origin realm to server of BIG-IP. The origin-realm-to-server is used to overwrite the client's actual origin realm attribute when it responds to the server. A value of none indicates that origin-realm-to-server is disabled. The default value is none.

You can specify an ASCII string as a FQDN. See RFC 3588 section 6.4.

overwrite-destination-host

This attribute has been deprecated as of BIG-IP v11.3.0. When you enable this option, the system replaces the value of the destination host field in the Diameter header with the BIG-IP(r) pool member address. When you disable this option, the system does not modify the destination host field. The default value is enabled.

parent-avp

Specifies the name of the Diameter attribute that the system uses to indicate if the persist-avp option is embedded in a grouped avp. A value of none indicates that the value of the persist-avp option is not embedded in a grouped avp. The default value is none.

You can specify an ASCII string or a numeric ID in the range 1 to 4294967295. Acceptable strings can be found in RFC 3588 section 4.5.

partition

Displays the administrative partition within which the profile resides.

persist-avp

Specifies the name of the Diameter attribute that the system

persists on. A value of none indicates that persistence is disabled. The default value is session-id.

You can specify an ASCII string or a numeric ID in the range 1 to 4294967295. Acceptable strings can be found in RFC 3588 section 4.5.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reset-on-timeout

When it is enabled and the watchdog failures exceed the max watchdog failure, the system resets the connection. The default value is enabled.

retransmit-timeout

Specifies the retransmit timeout in seconds. This setting specifies the number of seconds to retransmit the request messages if BIG-IP does not receive the corresponding answer messages. The default value is 10.

You can specify a numeric value in the range 0 to 4294967295. The recommended value is in the range of 5 to 30

to-folder

diameter profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

watchdog-timeout

Specifies the watchdog timeout in seconds. This setting specifies the number of seconds that a connection is idle before the device watchdog request is sent. The default value is 0, which means BIG-IP will not send a device watchdog request to either client or server side.

You can specify a numeric value in the range 0 to 4294967295. The recommended value is in the range of 6 to 30

BIG-IP 2015-07-22 ltm profile diameter(1)

ltm profile dns-logging

NAME

dns-logging - Configures a domain name service logging (DNS Logging) profile.

MODULE

ltm profile

SYNTAX

Configure the dns-logging component within the ltm profile module using the syntax in the following sections.

CREATE/MODIFY

create dns-logging [name]

modify dns-logging [name]

options:

description [string]

enable-query-logging [no | yes]

enable-response-logging [no | yes]

include-complete-answer [no | yes]

include-query-id [no | yes]

include-source [no | yes]

include-timestamp [no | yes]

include-view [no | yes]

log-publisher [name]

edit dns-logging [[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

mv dns-logging [[[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [fol

options:
to-folder

DISPLAY
list dns-logging
list dns-logging [[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties
one-line
partition

DELETE
delete dns-logging [name]

DESCRIPTION
You can use this component to create, modify, display, or delete a DNS logging profile, to enable query or response logging, and to define the format of messages themselves.

EXAMPLES
list dns-logging
Displays the properties of all DNS logging profiles.
create dns-logging my_dns_log_profile enable-query-logging yes log-publisher my_pub include-query-id yes
Creates a DNS logging profile with query logging enabled. Messages will be sent to publisher my_pub. Messages will contain the query ID.
mv dns-logging /Common/my_dns_logging_profile to-folder /Common/my_folder
Moves a custom dns-logging profile named my_dns_logging_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS
description
User defined description.
enable-query-logging
Log the contents of DNS queries. The default value for this option is yes.
enable-response-logging
Log the contents of DNS responses. The default value is no.
glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.
include-complete-answer
Selects whether all the resource records are included in response log messages. The default value is yes (complete-answer).
include-query-id
Selects whether the query id sent by the client is included in the query and response log messages. The default value is no.
include-source
Selects whether the message originator is included in the query and response log messages. The default value is yes.
include-timestamp
Selects whether the time stamp of the message is included in the query and response log messages. The default value is yes. You may or may not need this depending on whether the destination log servers prepend a time stamp to messages.
include-view
Selects whether the view is included in the query log messages. The default value is yes.
log-publisher
Specifies the log publisher used to deliver messages to one or more destinations. This option must be specified.
regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.
to-folder
dns-logging profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

SEE ALSO
create, delete, edit, glob, list, modify, mv, regex, ltm profile dns, tmsh

 show running-config dns
 show running-config dns [[[name] | [glob] | [regex]] ...]
 options:
 all-properties
 non-default-properties
 one-line
 partition

DELETE
 delete dns [name]

DESCRIPTION
 You can use this component to create, modify, display, or delete a DNS profile to define how the BIG-IP system handles DNS traffic. You can also display and reset DNS profile statistics.

EXAMPLES
 create dns my_dns_profile defaults-from dns
 Creates a DNS profile named my_dns_profile that inherits its settings from the system default DNS profile.

list dns
 Displays the properties of all DNS profiles.

mv dns /Common/my_dns_profile to-folder /Common/my_folder
 Moves a custom dns profile named my_dns_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

avr-dnsstat-sample-rate

Sets AVR DNS statistics rate. The default value is 0, which means AVR DNS statistics is disabled. If the sampling rate is set to 1, each query will be sent to the analytics database. If the sampling rate is set to an integer N, every Nth query will be sent and the analytics database will count it N times. When sampling rate is greater than one, the statistics will be inaccurate if the traffic volume is low. However, when the traffic volume is high, the system performance will benefit from sampling and the inaccuracy will be negligible. Also be aware that analytics database has its own internal sampling mechanism. The sampling rate does not apply to DNS firewall statistics. AVR DNS statistics contain query name, query type, virtual server IP and client IP.

cache

Specifies the user-created cache that the system uses to cache DNS responses. When you select a cache for the system to use, you must also enable the DNS cache setting.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is dns.

description

User defined description.

dns64

Sets DNS64 mapping mode. The default value is disabled.

dns64-additional-section-rewrite

Sets DNS64 additional section rewriting. For AAAA and A records in additional section, this field specifies how they are being rewritten. The default value is disabled.

dns64-prefix

Specifies DNS64 mapping IPv6 prefix.

dns-security

Indicates the DNS security profile the system uses.

edns0-client-subnet-insert

Indicates, when enabled, that the system should set the edns0 client subnet option to the source address for queries that do not already contain a client subnet option. Also specifies that the system should remove the client subnet option from responses to clients that did not send a client subnet option in their most recent query.

enable-cache

Indicates whether the system caches DNS responses. The default value is no.

enable-dnssec

Indicates whether to perform DNS Security Extension (DNSSEC) operations on the DNS packet, for example, respond to DNSKEY queries; add RRSIGs to response.

enable-dns-express

Indicates whether the dns-express service is enabled. The service handles zone transfers from the primary DNS server.

enable-dns-firewall

Indicates whether DNS firewall capability is enabled. The default value is no.

enable-gtm

Indicates whether the Global Traffic Manager handles DNS resolution for DNS queries and responses that contain Wide IP names. The default value is yes.

enable-hardware-query-validation

On supported platforms, indicates whether the hardware will accelerate query validation. The default value is no.

enable-hardware-response-cache

On supported platforms, indicates whether the hardware will cache responses. The default value is no.

enable-logging

Indicates whether to enable high speed logging for DNS queries and responses or not. Default value is no. When it is set to yes, a DNS profile must be configured with a log-profile.

enable-rapid-response

On supported platforms, indicates whether to allow queries to be answered by Rapid Response. The default value is no. When enabled, if the query name matches a GTM Wide IP name and GTM is enabled on this profile, the DNS query will bypass Rapid Response.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

log-profile

Specifies the DNS logging profile used to configure what events get logged and their message format.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition
Displays the administrative partition within which the profile resides.

process-rd
Indicates whether to process client-side DNS packets with Recursion Desired set in the header. The default value is yes. If set to no, processing of the packet will be subject to the unhandled-query-action option.

process-xfr
Indicates whether the system answers zone transfer requests for a DNS zone created on the system. The default value is no. The enable-dns-express and process-xfr settings affect how the system responds to zone transfer requests.

rapid-response-last-action
Specifies what action to take when Rapid Response is enabled and the incoming query has not matched a DNS-Express Zone. Default is drop. Option allow sends non-matching queries up the regular packet processing path. All other options result in a response returned immediately to the client: truncate (truncate), nxdomain (non-existent name), noerror (no data), refuse (REFUSED return code).

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

to-folder
dns profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

unhandled-query-action
Specifies the action to take when a query does not match a Wide IP or a DNS Express Zone. The default value is allow.

use-local-bind
Indicates whether non-GTM and non-dns-express requests should be forwarded to the local BIND.

ltm profile fasthttp

NAME
fasthttp - Configures a Fast HTTP profile.

MODULE
ltm profile

SYNTAX
Modify the fasthttp component within the ltm profile module using the syntax shown in the following sections.

```
CREATE/MODIFY
create fasthttp [name]
modify fasthttp [name]
options:
  app-service [[string] | none]
  client-close-timeout [integer]
  connpool-idle-timeout-override [integer]
  connpool-max-reuse [integer]
  connpool-max-size [integer]
  connpool-min-size [integer]
  connpool-replenish [disabled | enabled]
  connpool-step [integer]
  defaults-from [ [name] | none]
  description [string]
  force-http-10-response [disabled | enabled]
  hardware-syn-cookie [disabled | enabled]
  header-insert [none | [string] ]
```

```
http-11-close-workarounds [disabled | enabled]
idle-timeout [integer]
insert-xforwarded-for [disabled | enabled]
layer-7 [disabled | enabled]
max-header-size [integer]
max-requests [integer]
mss-override [integer]
receive-window-size [65535 - 2^31 bytes for window scale enabling]
reset-on-timeout [disabled | enabled]
server-close-timeout [integer]
server-sack [disabled | enabled]
server-timestamp [disabled | enabled]
unclean-shutdown [disabled | enabled]
```

```
mv fasthttp [ [[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder options:
to-folder
```

  global
```

```
DELETE
delete fasthttp [name]
```

DESCRIPTION

You can use this component to create, modify, display, or delete a Fast HTTP profile. This profile provides the ability to accelerate certain HTTP connections such as banner ads.

EXAMPLES

```
create fasthttp my_fast_http_profile defaults-from fasthttp
```

Creates a Fast HTTP profile named `my_fast_http_profile` that inherits its settings from the system default Fast HTTP profile.

```
mv fasthttp /Common/my_fasthttp_profile to-folder /Common/my_folder
```

Moves a custom fasthttp profile named `my_fasthttp_profile` to a folder named `my_folder`, where `my_folder` has already been created and exists within `/Common`.

```
show fasthttp
```

Displays fasthttp profile statistics in the system default units.

OPTIONS

app-service
Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

client-close-timeout
Specifies the number of seconds after which the system closes a client connection, when the system either receives a client FIN packet or sends a FIN packet. This option overrides the `idle-timeout` option. The default value is 5.

server-sack
Specifies whether to support server sack option in cookie response by default. The default value is disabled.

server-timestamp
Specifies whether to support server timestamp option in cookie response by default. The default value is disabled.

receive-window-size
Specifies the window size to use, minimum and default to 65535 bytes, the maximum is 2^31 for window scale enabling.

connpool-idle-timeout-override
Specifies the number of seconds after which a server-side connection in a OneConnect(tm) pool is eligible for deletion, when the connection has no traffic. This option overrides the `idle-timeout` option. The default value is 0 (zero) seconds, which disables the override setting.

connpool-max-reuse
Specifies the maximum number of times that the system can re-use a current connection. The default value is 0 (zero).

connpool-max-size

Specifies the maximum number of connections to a load balancing pool. A value of 0 (zero) specifies that a pool can accept an unlimited number of connections. The default value is 2048.

connpool-min-size

Specifies the minimum number of connections to a load balancing pool. The default value of 0 (zero) specifies that there is no minimum.

connpool-replenish

When enabled, the system replenishes the number of connections to a load balancing pool to the number of connections that existed when the server closed the connection to the pool. The default value is enabled.

When disabled, the system replenishes the connection that was closed by the server, only when there are fewer connections to the pool than the number of connections set in the connpool-min-size option.

connpool-step

Specifies the increment at which the system makes additional connections available, when all available connections are in use. The default value is 4.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is fasthttp.

description

User defined description.

force-http10-response

Specifies whether to rewrite the HTTP version in the status line of the server to HTTP 1.0 to discourage the client from pipelining or chunking data. The default value is disabled.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

hardware-syn-cookie

This option is deprecated in version 13.0.0 because it is not a fully functioning feature. Specifies whether or not to use hardware SYN Cookie when cross system limit. The default value is enabled

header-insert

Specifies a string that the system inserts as a header in an HTTP request. If the header exists already, the system does not replace it. The default value is none.

http11-close-workarounds

Enables or disables HTTP 1.1 close workarounds. The default value is disabled.

idle-timeout

Specifies the number of seconds after which a connection is eligible for deletion, when the connection has no traffic. The default value is 300 seconds.

insert-xforwarded-for

Specifies whether the system inserts the XForwarded For header in an HTTP request with the client IP address, to use with connection pooling.

The options are:

disabled

Specifies that the system does not insert the XForwarded For header.

enabled

Specifies that the system inserts the XForwarded For header with the client IP address.

layer7

When enabled, the system parses HTTP data in the stream. Disable this option if you want to use the performance HTTP profile to shield against denial-of-service attacks against non-HTTP protocols. The default value is enabled.

max-header-size

Specifies the maximum amount of HTTP header data that the system buffers before making a load balancing decision. The default value is 32768.

max-requests

Specifies the maximum number of requests that the system can receive on a client connection, before the system closes the connection. The default value of 0 specifies that requests are not limited.

mss-override

Specifies a maximum segment size (MSS) override for server connections. The default value is 0 (zero), which corresponds to an MSS of 1460. You can specify any integer between 536 and 1460.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reset-on-timeout

When enabled, the system sends a TCP RESET packet when a connection times out, and deletes the connection. The default value is enabled.

server-close-timeout

Specifies the number of seconds after which the system closes a client connection, when the system either receives a client FIN packet or sends a FIN packet. This option overrides the value of the idle-timeout option. The default value is 5.

to-folder

fasthttp profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

unclean-shutdown

Specifies how the system handles closing a connection. The options are:

disabled

Prevents an unclean shutdown of a client connection. This is the default value.

enabled

Specifies to permit an unclean shutdown of a client connection.

fast Specifies that the system sends a RESET packet to close the connection only if the client attempts to send further data after the response has completed.

DELETE
delete fastL4 [name]

```

DESCRIPTION

You can use this component to create, modify, display, or delete a Fast Layer 4 profile. The Fast L4 profile is the default profile that the system uses when you create a basic configuration for non-UDP (User Datagram Protocol) traffic.

Any changes you make to an active Fast L4 profile (one that is in use by a virtual server) take effect after the value of the idle-timeout option has passed. That means new connections are affected by the profile change immediately. However, for the new values to take effect, old connections need to be either aged out or closed. =head1 EXAMPLES

```
create fastl4 my_fastl4_profile defaults-from fastl4
```

Creates a custom Fast Layer 4 profile named `my_fastl4_profile` that inherits its settings from the system default Fast L4 profile.

```
mv fastl4 /Common/my_fastl4_profile to-folder /Common/my_folder
```

Moves a custom fastl4 profile named `my_fastl4_profile` to a folder named `my_folder`, where `my_folder` has already been created and exists within `/Common`.

Please refer to the mv manual page for examples on how to use the mv command.

```
show fastl4
```

Displays statistics for all Fast Layer 4 profiles.

OPTIONS

`app-service`
Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

`defaults-from`
Specifies the profile that you want to use as the parent profile.

Your new profile inherits all settings and values from the parent profile specified. The default value is fastl4.

description
User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

hardware-syn-cookie
This option is deprecated in version 13.0.0 and is replaced by syn-cookie-enable. Enables or disables hardware SYN cookie support when PVA10 is present on the system. The default value is disabled.

Note that when you set the hardware-syn-cookie option to enabled, you may also want to set the following bigdb database variables using the db component, based on your requirements:

pva.SynCookies.Full.ConnectionThreshold (default: 500000)
pva.SynCookies.Assist.ConnectionThreshold (default: 500000)
pva.SynCookies.ClientWindow (default: 0)
idle-timeout
Specifies the number of seconds that a connection is idle before the connection is eligible for deletion. The default value is 300 seconds. You can also specify immediate or indefinite.

When you specify an idle-timeout for the Fast L4 profile, for the profile to work properly, the value needs to be greater than the bigdb database variable Pva.Scrub_time_in_msec.

ip-tos-to-client
Specifies an IP Type of Service (ToS) number for the client-side. This option specifies the ToS level that the traffic management system assigns to IP packets when sending them to clients. The default value is 65535, which indicates, do not modify.

ip-tos-to-server
Specifies an IP ToS number for the server side. This option specifies the ToS level that the traffic management system assigns to IP packets when sending them to servers. The default value is 65535, which indicates, do not modify.

keep-alive-interval
Specifies the keep-alive probe interval, in seconds. The default value is disabled (0 seconds).

ip-df-mode
Describe the Don't Fragment (DF) bit setting in the IP Header of the outgoing TCP packet. The available settings are: Pmtu: Set the outgoing IP Header DF bit based on IP pmtu setting(tm.pathtudiscovery). Preserve: Set the outgoing Packet's IP Header DF bit to be same as incoming IP Header DF bit. Set: Set the outgoing packet's IP Header DF bit. Clear: Clear the outgoing packet's IP Header DF bit. The default setting is Preserve.

ip-ttl-mode
Describe the outgoing TCP packet's IP Header TTL mode. The available Modes are: Proxy: Set the outgoing IP Header TTL value to 255/64 for ipv4/ipv6 respectively. Preserve: Set the outgoing IP Header TTL value to be same as the incoming IP Header TTL value. Decrement: Set the outgoing IP Header TTL value to be one less than the incoming TTL value. Set: Set the outgoing IP Header TTL value to a specific value(as specified by ip-ttl-v{4|6}). The default mode is Proxy.

ip-ttl-v4
Specify the outgoing packet's IP Header TTL value for IPv4 traffic. Maximum TTL value that can be specified is 255. The default is 255.

ip-ttl-v6
Specify the outgoing packet's IP Header TTL value for IPv6 traffic. Maximum TTL value that can be specified is 255. The default is 64.

link-qos-to-client
Specifies a Link Quality of Service (QoS) (VLAN priority) number for the client side. This option specifies the QoS level that the system assigns to packets when sending them to clients. The default value is 65535, which indicates, do not modify.

link-qos-to-server
Specifies a Link QoS (VLAN priority) number for the server side. This option specifies the QoS level that the system assigns to packets when sending them to servers. The default value is 65535, which indicates, do not modify.

priority-to-client
Specifies internal packet priority for the client side. This option specifies the internal packet priority that the system assigns to packets when sending them to clients. The default value is 65535, which indicates, do not modify.

priority-to-server
Specifies internal packet priority for the server side. This option specifies the internal packet priority that the system assigns to packets when sending them to servers. The default value is 65535, which indicates, do not modify.

loose-close
Specifies that the system closes a loosely-initiated connection when the system receives the first FIN packet from either the

client or the server. The default value is disabled.

loose-initialization
Specifies that the system initializes a connection when it receives any Transmission Control Protocol (TCP) packet, rather than requiring a SYN packet for connection initiation. The default value is disabled.

mss-override
Specifies a maximum segment size (MSS) override for server connections. Note that this is also the MSS advertised to a client when a client first connects.

The default value is 0 (zero), which disables this option. You can specify an integer from 256 to 9162.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition
Displays the administrative partition within which the component resides.

pva-acceleration
Specifies the Packet Velocity(r) ASIC acceleration policy. The default value is full. In 12.1, dedicated mode is the new low latency policy which replaces guaranteed. The full and partial mode has same effect for ePVA platforms.

pva-dynamic-client-packets
Specifies the number of client packets before dynamic ePVA hardware re-offloading occurs. The valid value is 0-10. The default value is 2.

pva-dynamic-server-packets
Specifies the number of server packets before dynamic ePVA hardware re-offloading occurs. The valid value is 0-10. The default value is 2.

pva-offload-dynamic
Specifies whether PVA flow dynamic offloading is enabled or not. The default is enabled.

For a flow or flow(s) in a connection to be offloaded to ePVA hardware, both the client (pva-dynamic-client-packets) and server (pva-dynamic-server-packets) flow packets setting need to be satisfied. If only one direction packets need to be taken into consideration, the other direction packets should set to zero.

pva-offload-state
Specifies at what stage the ePVA performs hardware offload. The default value is embryonic and implies at TCP CSYN or the first client UDP packet. establish implies TCP 3WAY handshaking or UDP CS round trip are confirmed.

pva-flow-aging
Specifies if automatic aging from ePVA flow cache upon inactive and idle for a period, default to enabled.

pva-flow-evict
Specifies if this flow can be evicted upon hash collision with a new flow learn snoop request, defaults to enabled.

reassemble-fragments
Specifies whether to reassemble fragments. The default value is disabled.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reset-on-timeout
Specifies whether you want to reset connections on timeout. The default value is enabled.

rtt-from-client
Enables or disables the TCP timestamp options to measure the round trip time to the client. The default value is disabled.

rtt-from-server
Enables or disables the TCP timestamp options to measure the round trip time to the server. The default value is disabled.

server-sack
Specifies whether to support server sack option in cookie response by default. The default value is disabled.

server-timestamp
Specifies whether to support server timestamp option in cookie response by default. The default value is disabled.

receive-window-size
Specifies the window size to use, minimum and default to 65535 bytes, the maximum is 2^{31} for window scale enabling.

software-syn-cookie
This option is deprecated in version 13.0.0 and is replaced by syn-cookie-enable. Enables or disables software SYN cookie support when PVA10 is not present on the system. The default value is disabled.

syn-cookie-enable

Enables syn-cookies capability on this virtual server. For the details on the threshold at which syn-cookies are triggered please see default-vs-syn-challenge-threshold and global-syn-challenge-threshold or the tcp-half-open vector in the DoS profile. The default is enabled.

syn-cookie-mss

Specifies a maximum segment size (MSS) for server connections when SYN Cookie is enabled. Note that this is also the MSS advertised to a client when a client first connects.

The default value is 0 (zero), which disables this option. You can specify an integer from 256 to 9162.

name =item syn-cookie-whitelist

Specifies whether or not to use a SYN Cookie WhiteList when doing software SYN Cookies. This means not doing a SYN Cookie for the same src IP address if it has been done already in the previous tm.flowstate.timeout (30) seconds. The default value is disabled.

tcp-close-timeout

Specifies a TCP close timeout in seconds. You can also specify immediate or indefinite. The default value is 5 seconds.

tcp-generate-isn

Specifies whether you want to generate TCP sequence numbers on all SYNs that conform with RFC1948, and allow timestamp recycling. The default value is disabled.

tcp-handshake-timeout

Specifies a TCP handshake timeout in seconds. You can also specify immediate or indefinite. The default value is 5 seconds.

tcp-time-wait-timeout

Specifies a TCP time_wait timeout in milliseconds. The default value is 0 milliseconds.

tcp-strip-sack

Specifies whether you want to block the TCP SackOK option from passing to the server on an initiating SYN. The default value is disabled.

tcp-timestamp-mode

Specifies how you want to handle the TCP timestamp. The default value is preserve.

tcp-wscale-mode

Specifies how you want to handle the TCP window scale. The default value is preserve.

late-binding

Specifies whether to enable or disable intelligent selection of a back-end server pool. The default value is disabled. With this option enabled, an iRule can read a Layer 7 (FIX) packet to select a server pool, and then can send the FIX stream down to the ePVA. The ePVA then manages the FIX stream at a low latency, for as long as the stream persists. To keep the latency low, the BIG-IP software does not examine any more Layer-7 data in that FIX stream.

If you enable this option, you also need a FIX profile in the Performance FastL4 Virtual Server configuration.

explicit-flow-migration

Specifies whether to have the iRule code determine exactly when the FIX stream drops down to the ePVA hardware. The default value is disabled.

The explicit flow migration state indicates whether connections are automatically migrated into the ePVA hardware (disabled), or the iRule must explicitly migrate them with the BIGTCP::release_flow command (enabled).

client-timeout

Specifies late binding client timeout in seconds. This is the number of seconds allowed for a client to transmit enough data to select a server pool. If this timeout expires, the timeout-recovery option dictates whether to drop the connection or fallback to the normal FastL4 load-balancing method to pick a server pool. The default timeout is 30 seconds.

timeout-recovery

Specifies late binding timeout recovery mode. This is the action to take when late binding timeout occurs on a connection. This could be disconnect if only the L7 iRule actions are acceptable to pick a server or fallback if the normal FastL4 load-balancing methods are acceptable to pick a server. The default action is to disconnect.

to-folder

fastl4 profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

ltm profile fix

NAME
fix - Configures an Financial Information eXchange Protocol (FIX) profile.

MODULE
ltm profile

SYNTAX
Configure the fix component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY
create fix [name]
modify fix [name]
options:
app-service [[string] | none]
defaults-from [[name] | none]
description [string]
error-action [drop_connection | dont_forward]
full-logon-parsing [true | false]
message-log-publisher [publisher]
quick-parsing [true | false]
statistics-sample-interval [integer]
report-log-publisher [publisher]
response-parsing [true | false]
sender-tag-class {[sender-id] [class name]}...}

edit fix [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties

reset-stats fix
reset-stats fix [[[name] | [glob] | [regex]] ...]

DISPLAY
list fix
list fix [[[name] | [glob] | [regex]] ...]
show running-config fix
show running-config fix [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties
one-line
partition

show fix
show fix [[[name] | [glob] | [regex]] ...]
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
field-fmt

DELETE
delete fix [name]

DESCRIPTION
You can use the fix component to manage an Financial Information eXchange Protocol profile.

EXAMPLES
create fix my_fix defaults-from fix

Creates an financial information exchange protocol profile named my_fix using the system defaults.

create fix my_fix { }

Creates an financial information exchange protocol profile named my_fix.

app-service
Specifies the name of the application service to which this object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this object. Only the application service can modify or delete this object.

defaults-from
Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is none.

description
User defined description.

error-action
Specifies the error handling method.

full-logon-parsing
Enable or disable logon message is always fully parsed.

message-log-publisher
Specifies the publisher for message logging.

quick-parsing
Enable or disable quick parsing which parses the basic standard fields and validates message length and checksum.

statistics-sample-interval
Specifies the sample interval in seconds of the message rate.

response-parsing
Enable or disable response parsing which parses the messages from FIX server.

report-log-publisher
Specifies the publisher for error message and status report.

partition
Specifies the administrative partition within which the profile resides.

sender-tag-class
Specifies the tag substitution map between sender id and tag substitution data group.

ltm profile ftp

NAME
ftp - Configures an FTP profile.

MODULE
ltm profile

SYNTAX
Configure the ftp component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY
create ftp [name]
modify ftp [name]
options:
app-service [[string] | none]
defaults-from [[name] | none]
description [string]
port [name]
allow-ftps [disabled | enabled]
ftps-mode [disallow | allow | require]
enforce-tls-session-reuse [disabled | enabled]
allow-active-mode [disabled | enabled]
security [disabled | enabled]
translate-extended [disabled | enabled]
inherit-parent-profile [disabled | enabled]
log-publisher [log publisher name | none]
log-profile [log profile name | none]

mv ftp [[[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-name] options:
to-folder

edit ftp [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties

DISPLAY
list ftp

```
list ftp [ [name] | [glob] | [regex] ] ... ]
show running-config ftp
show running-config ftp [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
DELETE
delete ftp [name]
```

DESCRIPTION

Use this command to create, modify, display, or delete an FTP profile with which you can manage FTP traffic.

EXAMPLES

```
create ftp my_ftp_profile defaults-from ftp
```

Creates a custom FTP profile named `my_ftp_profile` that inherits its settings from the system default FTP profile.

```
list ftp
```

Displays the properties of all FTP profiles.

```
mv ftp /Common/my_ftp_profile to-folder /Common/my_folder
```

Moves a custom ftp profile named `my_ftp_profile` to a folder named `my_folder`, where `my_folder` has already been created and exists within `/Common`.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is `ftp`.

description

User defined description.

`glob` Displays the items that match the glob expression. See `help glob` for a description of glob expression syntax.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

partition

Displays the administrative partition within which the component resides.

`port` Specifies a service for the data channel port used for this FTP profile. The default port is `ftp-data`.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@regular expression`) to indicate that the identifier is a regular expression. See `help regex` for a description of regular expression syntax.

allow-ftsps

Deprecated since v14.0.0. Use `ftsps-mode` instead. Allow explicit FTPS negotiation. The default value is disabled.

ftsps-mode

Specifies the policy for explicit FTPS negotiation on FTP command channel, including `disallow`, `allow` and `require`. The default is `disallow`.

Mode disabled

Detects explicit FTPS negotiation, and AUTH TLS command will be dropped.

Mode

Bypasses explicit FTPS negotiation through the BIGIP.

Mode allow

Allows FTPS negotiation, and will intercept TLS if SSL forward proxy is configured on the virtual server.

Mode require

Requires FTPS negotiation to protect the FTP data transfers.

enforce-tls-session-reuse

Enforce data connection to reuse TLS session. The default value is disabled.

allow-active-mode

Allow FTP active transfer mode. The default value is enabled.

security

Enables or disables secure FTP traffic for the BIG-IP(r) Application Security Manager. You can set the security option only if the system is licensed for the BIG-IP Application Security Manager. The default value is disabled.

to-folder

ftp profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

translate-extended

This option is enabled by default, and thus, automatically translates RFC2428 extended requests EPSV and EPRT to PASV and PORT when communicating with IPv4 servers.

inherit-parent-profile

Enables the FTP data channel to inherit the TCP profile used by the control channel. If disabled, the data channel uses FastL4 (BigProto) only.

log-publisher

Specify the name of the log publisher which logs translation events. See help sys log-config for more details on the logging sub-system. Use the "sys log-config publisher" component to set up a log publisher.

log-profile

Specify the name of the ALG log profile which controls the logging of ALG. See help ltm alg-log-profile for more details on the logging profile sub-system. Use the "ltm alg-log-profile profile" component to set up a ALG log profile.

SEE ALSO

```

```
list gtp [ [ [name] | [glob] | [regex] ] ... ]
```

```
show running-config gtp
```

```
show running-config gtp [ [ [name] | [glob] | [regex] ] ... ]
```

options:

```
all-properties
```

```
non-default-properties
```

```
one-line
```

```
partition
```

```
show gtp
```

```
show gtp [ [ [name] | [glob] | [regex] ] ... ]
```

options:

```
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
```

```
field-fmt
```

DELETE
delete gtp [name]

DESCRIPTION
You can use the gtp component to manage a GTP profile.

EXAMPLES
create gtp my_gtp_profile defaults-from gtp
Creates a GTP profile named my_gtp_profile using the system defaults.
create gtp my_gtp_profile { ingress-max 1000 }
Creates a GTP profile named my_gtp_profile that specifies the maximum number of messages that can be held in the ingress queue is 1000.
mv gtp /Common/my_gtp_profile to-folder /Common/my_folder
Moves a custom gtp profile named my_gtp_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS
app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.
defaults-from
Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is gtp.
description
User defined description.
glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.
ingress-max
Specifies the maximum number of messages that can be held in ingress queue. If it is 0, then it is unlimited. The default value is 0.
name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.
partition
Displays the administrative partition within which the component resides.
regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

ltm profile html

NAME
html - Configures an HTML profile.

MODULE
ltm profile

SYNTAX
Configure the html component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY
create html [name]
modify html [name]

```

options:
  defaults-from [ [name] | none]
  content-detection [disabled | enabled]
  content-selection
    [add | delete | replace-all-with] {
[content-type] ...
    }
  content-selection none
  rules
    [add | delete | replace-all-with] {
[html-rule] ...
    }
  rules none

mv html [ [[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-name]
options:
  to-folder

reset-stats html
reset-stats html [ [ [name] | [glob] | [regex] ] ... ]

DISPLAY
list html
list html [ [ [name] | [glob] | [regex] ] ... ]
show running-config html
show running-config html [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

show html
show html [ [ [name] | [glob] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt
  global

DELETE
delete html [name]

DESCRIPTION
Use this command to create, modify, display, or delete an HTML profile
with which you can manage HTML traffic.

EXAMPLES
create html my_html_profile defaults-from html

Creates a custom HTML profile named my_html_profile that inherits its
settings from the system default HTML profile.

list html

Displays the properties of all HTML profiles.

mv html /Common/my_html_profile to-folder /Common/my_folder

Moves a custom HTML profile named my_html_profile to a folder named
my_folder, where my_folder has already been created and exists within
/Common.

Please refer to the mv manual page for examples on how to use the mv
command.

OPTIONS
  defaults-from
Specifies the profile that you want to use as the parent profile.
Your new profile inherits all settings and values from the parent
profile specified. The default value is html.

  description
User defined description.

  glob
Displays the items that match the glob expression. See help glob
for a description of glob expression syntax.

  name
Specifies a unique name for the component. This option is required
for the commands create, delete, and modify.

  partition
Displays the administrative partition within which the component
resides.

  content-detection
Scans initial HTTP payload to look for HTML signatures and enables
HTML profile if HTML-like patterns are detected.

  content-selection
Matches content-type from response header against a list of
content-types and enables HTML profile if a match is found.

  rules
Specifies a list of HTML (content rewrite) rules, separated by
spaces, that are used for parsing and patching HTML.

  to-folder
html profiles can be moved to any folder under /Common, but
configuration dependencies may restrict moving the profile out of
/Common.

SEE ALSO
create, delete, glob, list, ltm virtual, modify, mv, reset-stats, show,
tmsh

  non-default-properties
  one-line
  partition
```

```
show http-compression
show http-compression [ [ [name] | [glob] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt
  global
```

```
DELETE
delete http-compression [name]
```

DESCRIPTION

You can use the http-compression component to create, modify, display, or delete an HTTP Compression profile.

The BIG-IP(r) system installation includes the following default HTTP Compression-type profiles:

- o http-compression
- o wan-optimized-compression

The default HTTP Compression profile contains values for properties related to managing compression settings.

You can create a new HTTP Compression-type profile using an existing profile as a parent profile, and then you can change the values of the properties to suit your needs.

EXAMPLES

```
create http-compression my_hc_profile defaults-from http-compression
```

Creates a custom HTTP Compression profile named my_hc_profile that inherits its settings from the system default HTTP Compression profile.

```
mv http-compression /Common/my_httpcompression_profile to-folder
/Common/my_folder
```

Moves a custom http-compression profile named my_httpcompression_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

allow-http10
Enables or disables compression of HTTP/1.0 server responses. The default value is disabled.

app-service
Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

browser-workarounds
Deprecated since v13.1.0. Enables or disables browser workarounds. The default value is disabled.

- o If the client browser is Netscape Navigator(r) version 4.0x, compression is turned off. Netscape advertises that the browser can handle compression gracefully. In this case, F5 Networks disables compression entirely for that class of browser.

- o If the client browser is Netscape Navigator version 4.x (4.10 and later) and the server response Content-Type is not either text/html or text/plain compression is turned off. This class of Netscape browsers can handle plain text and HTML just fine, but there are known issues with other types of content.

- o If the client browser is Microsoft(r) Internet Explorer (any version), the server response Content-Type is either text/css or application/x-javascript, and the client connection is over SSL, compression is turned off. The Microsoft article ID for this problem is 825057.

- o If the client browser is Microsoft Internet Explorer (any version), the server response Content-Type is either text/css or application/x-javascript, and the server sets the header Cache-Control to no-cache, compression is turned off. The Microsoft article ID for this problem is 327286.

buffer-size
Specifies the maximum number of uncompressed bytes that the system buffers before determining whether to compress the response. Useful when the headers of a server response do not specify the length of the response content. The default value is 4096.

content-type-exclude
Specifies a string list of HTTP Content-Type responses that you do not want the system to compress. The default value is none.

content-type-include
Specifies a string list of HTTP Content-Type responses that you want the system to compress. The default value is { text/application/ (xml|x-javascript) }.

cpu-saver
Enables or disables the CPU saver feature. When the CPU saver is enabled, the system monitors the percent of CPU usage and adjusts compression rates automatically when the CPU usage reaches the percentage defined in the compress-cpu-saver-low and compress-cpu-saver-high options. The default value is enabled.

cpu-saver-high

Specifies the percent of CPU usage at which the system starts automatically decreasing the amount of content being compressed, as well as the amount of compression that the system is applying. The default value is 90.

`cpu-saver-low`

Specifies the percent of CPU usage at which the system resumes content compression at the user-defined rates. The default value is 75.

`defaults-from`

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is `httpcompression`.

`description`

User defined description.

`gzip-level`

Specifies a value that determines the amount of memory that the system uses when compressing a server response. The default value is 1.

`gzip-memory-level`

Specifies the amount of memory (in kilobytes) that the system uses when compressing a server response. The system rounds the value up to the nearest power of two. The default value is 8. The maximum value is 256.

`gzip-window-size`

Specifies the number of kilobytes in the window size that the system uses when compressing a server response. The system rounds the value up to the nearest power of two. The default value is 16k. The maximum value is 128k.

`keep-accept-encoding`

Specifies where data compression is performed. When enabled, the target server, rather than the BIG-IP local traffic management system, performs data compression. The default value is disabled.

`method-prefer`

Specifies the type of compression that the system prefers. The default value is `gzip`.

`min-size`

Specifies the minimum length in bytes of a server response that is acceptable for compression. The length in bytes applies to content length only, not headers. The default value is 1024.

`partition`

Displays the administrative partition within which the profile resides.

`selective`

Enables or disables selective compression mode. Note that the data compression feature compresses HTTP server responses, and not client requests. The default value is disabled.

`to-folder`

http-compression profiles can be moved to any folder under `/Common`, but configuration dependencies may restrict moving the profile out of `/Common`.

`uri-exclude`

Disables compression on a specified list of HTTP Request-URI responses. Use a regular expression to specify a list of URIs you do not want to compress. The default value is none.

`uri-include`

Enables compression on a specified list of HTTP Request-URI responses. Use a regular expression to specify a list of URIs you want to compress. The default value is `{ .* }`.

`vary-header`

Enables or disables the insertion of a Vary header into cacheable server responses. The default value is enabled.

DELETE
delete http [name]

```

DESCRIPTION

You can use the http component to create, modify, display, or delete an HTTP profile.

The BIG-IP(r) system installation includes the following default HTTP-type profiles:

http

The default HTTP profile contains values for properties related to managing HTTP traffic.

You can create a new HTTP-type profile using an existing profile as a parent profile, and then you can change the values of the properties to suit your needs.

EXAMPLES

```
create http my_http_profile defaults-from http
```

Creates a custom HTTP profile named my_http_profile that inherits its settings from the system default HTTP profile.

```
mv http /Common/my_http_profile to-folder /Common/my_folder
```

Moves a custom HTTP profile named my_http_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

Please refer to the mv manual page for examples on how to use the mv command.

OPTIONS

accept-xff

Enables or disables trusting the client IP address, and statistics from the client IP address, based on the request's XFF (X-forwarded-for) headers, if they exist.

app-service

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

basic-auth-realm

Specifies a quoted string for the basic authentication realm. The system sends this string to a client whenever authorization fails. The default value is none.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is http.

description

User defined description.

encrypt-cookie-secret

Specifies a passphrase for the cookie encryption. The default value is none.

encrypt-cookies

Specifies to encrypt specific cookies that the BIG-IP system sends to a client system. The default value is none.

enforcement

Specifies protocol enforcement options for the HTTP profile:

excess-client-headers

Specifies the pass-through behavior when max-header-count is exceeded by the client. The default is disabled which rejects

the connection.

excess-server-headers

Specifies the pass-through behavior when max-header-count is exceeded by the server. The default is disabled which rejects the connection.

unknown-method

Specifies the behavior when an unknown method is seen. The default is allow which allows all methods, (known or unknown).

known-methods

Specifies the HTTP methods known by the HTTP filter. Combine with the unknown-method field to control behavior when unusual methods are parsed.

max-header-size

Specifies the maximum header size. The default value is 32768.

max-header-count

Specifies the maximum number of headers in HTTP request or response that will be handled. If client or server sends request or response with the number of headers greater than specified, the connection will be dropped. The default value is 64.

max-requests

Specifies the number of requests that the system accepts on a per-connection basis. The default value is 0 (zero), which means the system does not limit the number of requests per connection.

oversize-client-headers

Specifies the pass-through behavior when max-header-size is exceeded by the client. The default is disabled which rejects the connection.

oversize-server-headers

Specifies the pass-through behavior when max-header-size is exceeded by the server. The default is disabled which rejects the connection.

pipeline

Enables or disables HTTP/1.1 pipelining. If pass-through is chosen, then the HTTP filter will switch to pass through mode (and be disabled) if pipelined data is seen. The default value is allow, which means that clients can make requests even when prior requests have not received a response. In order for this to succeed, however, destination servers must include support for pipelining.

to-folder

http profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

truncated-redirects

Specifies the pass-through behavior when a redirect lacking the trailing carriage-return and line feed pair at the end of the headers is parsed. The default is disabled, which will silently drop the invalid HTTP.

unknown-method

Specifies the behavior (allow, reject, or pass-through) when an unknown HTTP method is parsed. The default is to allow unknown methods.

fallback-host

Specifies an HTTP fallback host. The default value is none.

With HTTP redirection, you can redirect HTTP traffic to another protocol identifier, host name, port number, or URI path. For example, if all members of a targeted pool are unavailable (that is, the members are disabled, marked as down, or have exceeded their connection limit), the system can redirect the HTTP request to the fallback host, with the HTTP reply Status Code 302 Found.

fallback-status-codes

Specifies one or more three-digit status codes that can be returned by an HTTP server. The default value is none.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

header-erase

Specifies the header string that you want to erase from an HTTP request. The default value is none.

header-insert

Specifies a quoted header string that you want to insert into an HTTP request. The default value is none.

The HTTP header being inserted can include a client IP address. Including a client IP address in an HTTP header is useful when a connection goes through a secure network address translation (SNAT) and you need to preserve the original client IP address. When you assign the configured HTTP profile to a virtual server, the system then inserts the header specified by the profile into any HTTP request that the system sends to a pool or pool member.

insert-xforwarded-for

Enables or disables insertion of an X-Forwarded-For header. The

default value is disabled.

When using connection pooling, which allows clients to make use of other client requests' server connections, you can insert the X-Forwarded-For header and specify a client IP address.

lws-separator

Specifies the linear white space separator that the system uses between HTTP headers when a header exceeds the maximum width specified in the lws-width option. The valid value should be none, or, any combination of cr(carriage return), lf(line feed), or sp(space). The default value is none.

lws-width

Specifies the maximum number of columns that a header that is inserted into an HTTP request can have. The default value is 80.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

oneconnect-transformations

Specifies whether the system performs HTTP header transformations for the purpose of keeping server-side connections open. The default value is enabled. This feature requires configuration of a OneConnect(tm) profile.

partition

Displays the partition within which the component resides.

redirect-rewrite

Specifies which of the application HTTP redirects the system rewrites to HTTPS. The options are:

all Specifies to rewrite all application redirects to HTTPS.

matching

Specifies to rewrite to HTTPS only application redirects that match the original URI exactly.

nodes

If the URI contains a node IP address, instead of a host name, specifies that the system rewrites the node IP address to the virtual server IP address.

none Specifies that the system does not rewrite to HTTPS any application HTTP redirects. This is the default value.

Use this feature when an application is generating HTTP redirects that send the client to HTTP (a non-secure channel) when you want the client to continue accessing the application using HTTPS (a secure channel). This is a common occurrence when using client SSL processing on a BIG-IP system.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

request-chunking

Specifies how to handle chunked and unchunked requests. The default value is preserve. The options are described under response-chunking.

response-chunking

Specifies how to handle chunked and unchunked responses. The default value is selective. The options are:

unchunk

If the request or response is chunked, this option unchunks the request or response, processes the HTTP content, and passes the request or response on as unchunked. The Keep-Alive value for the Connection header is not supported, and therefore the system sets the value of the header to close.

If the request or response is unchunked, the LTM system processes the HTTP content and passes the request or response on untouched.

rechunk

If the request or response is chunked, the system unchunks the request or response, processes the HTTP content, re-adds the chunk trailer headers, and then passes on the request or response as chunked. Any chunk extensions are lost.

If the request or response is unchunked, the system adds transfer encoding and chunking headers on egress.

preserve

If the request or response is chunked or unchunked, the system leaves the request or response chunked, processes the HTTP content, and passes the request or response on untouched.

selective

If the request or response is chunked, the system unchunks the request or response, processes the HTTP content, re-adds the chunk trailer headers, and then passes on the request or response as chunked. Any chunk extensions are lost.

If the request is unchunked, the system processes the HTTP content, and then passes on the request or response untouched.

response-headers-permitted
Specifies headers that the BIG-IP system allows in an HTTP response. The default value is none.

explicit-proxy
Specifies explicit settings for the HTTP profile:

enabled
Specifies whether the explicit proxy service is enabled or disabled. The default it is no.

dns-resolver
Specifies the dns-resolver object that will be used to resolve hostnames in proxy requests. The default is dns-resolver.

ipv6 Specifies the relative order of IPv4 and IPv6 DNS resolutions for URIs. The default is no, which will try a IPv4 lookup before a IPv6.

tunnel-name
Specifies the tunnel that will be used for outbound proxy requests. This enables other virtual servers to receive connections initiated by the proxy service. The default is http-tunnel.

route-domain
Specifies the route-domain that will be used for outbound proxy requests. The default is 0.

default-connect-handling
Specifies the behavior of the proxy service for CONNECT requests. If set to deny, CONNECT requests will only be honored if there is another virtual server listening for the requested outbound connection. If set to allow outbound connections will be made regardless of other virtual servers. The default is deny.

host-names
Specifies the which host names are to be treated as local. Proxy requests made for those hosts will be treated as regular HTTP requests and will be sent to the configured default pool.

connect-error-message
Specifies the error message that will be returned to the browser when a proxy request can't be completed because of a failure to establish the outbound connection.

dns-error-message
Specifies the error message that will be returned to the browser when a proxy request can't be completed because of a failure to resolve the hostname in the request.

bad-request-message
Specifies the error message that will be returned to the browser when a proxy request can't be completed because the request was malformed.

bad-response-message
Specifies the error message that will be returned to the browser when a proxy request can't be completed because the response was malformed.

sflow
Specifies sFlow settings for the HTTP profile:

poll-interval
Specifies the maximum interval in seconds between two pollings. The default value is 0. To enable this setting, you must also set the poll-interval-global setting to no.

poll-interval-global
Specifies whether the global HTTP poll-interval setting, which is available under sys sflow global-settings module, overrides the object-level poll-interval setting. The default value is yes.

The available values are:

no Specifies to use the object-level poll-interval setting.

yes Specifies to use the global HTTP poll-interval setting.

sampling-rate
Specifies the ratio of packets observed to the samples generated. For example, a sampling rate of 2000 specifies that 1 sample will be randomly generated for every 2000 packets observed. The default value is 0. To enable this setting, you must also set the sampling-rate-global setting to no.

sampling-rate-global
Specifies whether the global HTTP sampling-rate setting, which is available under sys sflow global-settings module, overrides the object-level sampling-rate setting. The default value is yes.

The available values are:

no Specifies to use the object-level sampling-rate setting.

yes Specifies to use the global HTTP sampling-rate setting.

via-host-name
Specifies the hostname that will be used in the Via: HTTP header. See **via-request** and **via-response** for how the Via: header will be handled. If either **via-request** or **via-response** are set to **append**, then this is required.

via-request
Specifies how you want to process Via: HTTP header in requests sent to OWS. The default setting is **remove**. The available values are:

append
The value from **via-host-name** is appended to the Via: HTTP header.

preserve
Via: HTTP header is preserved without changes.

remove
Via: HTTP header is removed from the request.

via-response
Specifies how you want to process Via: HTTP header in responses sent to clients. The default setting is **remove**. The available values are the same as in **via-request**.

server-agent-name
Specifies the string used as the server name in traffic generated by LTM. The default value is **BigIP**.

alternative-xff-names
Specifies alternative XFF headers instead of the default **X-forwarded-for** header.

hsts Specifies HSTS settings for the HTTP profile:

mode Specifies if the HSTS settings are enabled or disabled. The default is **disabled**.

maximum-age
Specifies the maximum age to be sent in the HSTS header. The default is **16070400**.

include-subdomains
Specifies if the **includeSubdomains** directive is sent in the HSTS header. The default is **enabled**.

preload
Specifies if the **preload** directive is sent in the HSTS header. The default is **disabled**.

  field-fmt
  global
```

DELETE

```
delete http2 [name]
```

DESCRIPTION

You can use the http2 component to create, modify, display, or delete a HTTP/2 profile.

The BIG-IP(r) system installation includes the following default HTTP/2-type profiles:

http2

The default HTTP/2 profile contains values for properties related to managing HTTP/2 traffic.

You can create a new HTTP/2-type profile using an existing profile as a parent profile, and then you can change the values of the properties to suit your needs.

EXAMPLES

```
create http2 my_http2_profile defaults-from http2
```

OPTIONS

activation-modes

Specifies what will cause a connection to be treated as a HTTP/2 connection. The value alpn specifies that the TLS application-layer-protocol-negotiation will be used to determine whether HTTP/2 should be activated. Clients that use TLS, but only support HTTP will work as-if HTTP/2 is not present. The value always specifies that all connections are assumed to be HTTP/2 connections. The default value is { alpn }.

concurrent-streams-per-connection

Specifies how many concurrent requests are allowed to be outstanding on a single HTTP/2 connection.

connection-idle-timeout

Specifies how many seconds a HTTP/2 connection is left open idly before it is shutdown.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is http2.

description

User defined description.

frame-size

Specifies the size of the data frames, in bytes, that HTTP/2 will send to the client. Larger frame sizes will improve network utilization, but may affect concurrency. The default value is 2048.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

insert-header

Specifies whether an HTTP header that indicates the use of HTTP/2 should be inserted in the request going to the back-end server. The default value is disabled.

insert-header-name

Specifies the name of the HTTP header controlled by insert-header. The default value is "X-HTTP2".

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

receive-window

Specifies the receive window, in KB. The receive window is a mechanism used by HTTP/2 to perform flow control. The receive window allows HTTP/2 to stall individual upload streams when needed. This mechanism is available only for HTTP/2 version 3. The default value is 32.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

write-size

Specifies the total size of combined data frames, in bytes, HTTP/2 will send in a single write. This controls the size of the TLS records when HTTP/2 is used over SSL. A large write size will cause HTTP/2 to buffer more data, but will improve network utilization. The default value is 16384.

header-table-size

Specifies the size of the header table, in bytes. The HTTP/2 protocol compresses http headers to save bandwidth. A larger table will allow better compression, at the cost of more memory usage. The default value is 4096 bytes. This is currently unused.

BIG-IP 2017-02-10 ltm profile http2(1)

ltm profile icap

NAME

icap - Configures an Internet Content Adaptation Protocol (ICAP) profile.

MODULE

ltm profile

SYNTAX

Configure the icap component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY

```
create icap [name]
modify icap [name]
options:
  defaults-from [ [name] | none]
  description [string]
  header-from [string]
  host [string]
  preview-length [integer]
  referer [string]
  uri [string]
  user-agent [string]
```

```
edit icap [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```
mv icap [ [[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-name]] ]
options:
  to-folder
```

```
reset-stats icap
reset-stats icap [ [ [name] | [glob] | [regex] ] ... ]
```

DISPLAY

```
list icap
list icap [ [ [name] | [glob] | [regex] ] ... ]
show running-config icap
show running-config icap [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
show icap
show icap [ [ [name] | [glob] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt
```

DELETE

```
delete icap [name]
```

DESCRIPTION

You can use the icap component to manage an Internet Content Adaptation Protocol profile.

EXAMPLES

```
create icap my_icap defaults-from icap
```

Creates an internet content adaptation protocol profile named `my_icap` using the system defaults.

```
create icap my_icap { uri icap://mycompany.com/ad_insertion/ }
```

Creates an internet content adaptation protocol profile named `my_icap` that uses `icap://mycompany.com/ad_insertion/` as the ICAP URI.

```
mv icap /Common/my_icap_profile to-folder /Common/my_folder
```

Moves a custom icap profile named `my_icap_profile` to a folder named `my_folder`, where `my_folder` has already been created and exists within `/Common`.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is `icap`.

description

User defined description.

header-from

Specifies the header-from attribute to use in the ICAP header. Please refer to RFC 3507 section 4.3.2.

host Specifies the host attribute to use in the ICAP header. Please refer to RFC 3507 section 4.3.2i.

preview-length

Specifies the ICAP data preview size. Please refer to RFC 3507 section 4.5.

referer

Specifies the referer attribute to use in the ICAP header. Please refer to RFC 3507 section 4.3.2.

to-folder

icap profiles can be moved to any folder under `/Common`, but configuration dependencies may restrict moving the profile out of `/Common`.

uri Specifies the ICAP URI to use in the ICAP header. Please refer to RFC 3507 section 4.2. Macro expansion has been implemented for all attributes values in the ICAP header. If an ICAP header attribute value contains `${SERVER_IP}`, the macro will be replaced with the IP address of the ICAP server selected from the internal virtual server's pool. If an ICAP header attribute contains `${SERVER_PORT}`, the macro will be replaced with the port of the ICAP server selected from the internal virtual server's pool. For example, the URI attribute in an ICAP profile could be set to `icap://${SERVER_IP}:${SERVER_PORT}/videoOptimization`.

user-agent

Specifies the user-agent attribute to use in the ICAP header. Please refer to RFC 3507 section 4.3.2.

BIG-IP 2013-12-31 ltm profile icap(1)

ltm profile iiop

NAME

`iiop` - Configures an Internet Inter-Orb Protocol (IIOP) profile.

MODULE

`ltm profile`

SYNTAX

Configure the `iiop` component within the `ltm profile` module using the syntax shown in the following sections.

CREATE/MODIFY

```
create iiop [name]
modify iiop [name]
options:
  abort-on-timeout [disabled | enabled]
```

```
app-service [[string] | none]
defaults-from [name]
description [string]
persist-object-key [disabled | enabled]
persist-request-id [disabled | enabled]
timeout [integer]
```

```
edit iiop [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```
reset-stats iiop
reset-stats iiop [name]
```

```
DISPLAY
list iiop
list iiop [ [ [name] | [glob] | [regex] ] ... ]
show running-config iiop
show running-config iiop [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
show iiop
show iiop [ [ [name] | [glob] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt
  global
```

```
DELETE
delete iiop [name]
```

DESCRIPTION

You can use the iiop component to manage IIOP network traffic. The system parses the incoming TCP stream, disaggregates it into IIOP messages, and performs load balancing and persistence based on the parameters you set.

EXAMPLES

```
create iiop my_iiop_profile defaults-from iiop
```

Creates an IIOP profile named `my_iiop_profile` that inherits its settings from the system default IIOP profile named `iiop`.

```
list iiop all-properties
```

Displays all properties for all IIOP profiles.

OPTIONS

abort-on-timeout
Specifies whether the system aborts the connection if there is no response received within the time specified in the `timeout` option. The default value is disabled.

app-service
Specifies the name of the application service to which the profile belongs. The default value is `none`. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from
Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is `iiop`.

description
User defined description.

glob Displays the items that match the glob expression. See help `glob` for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

partition
Displays the administrative partition within which this profile resides.

persist-object-key
Specifies whether to persist connections based on the object key in the IIOP request. The default value is disabled.

persist-request-id
Specifies whether to persist connections based on the request ID in the IIOP request. The default value is enabled.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

timeout
Specifies the request timeout. The system uses this value when the `abort-on-timeout` option is enabled. The default value is 30 seconds.

ltm profile ilx

NAME

ilx - Configures an ILX profile.

MODULE

ltm profile

SYNTAX

Configure the ilx component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY

```
create ilx [name]
modify ilx [name]
options:
  app-service [[string] | none]
  defaults-from [[name] | none]
  description [string]
  plugin [string]
```

```
edit ilx [ [name] | [glob] | [regex] ] ... ]
```

options:

```
all-properties
non-default-properties
```

DISPLAY

```
list ilx
list ilx [ [name] | [glob] | [regex] ] ... ]
show running-config ilx
show running-config ilx [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete ilx [name]
```

DESCRIPTION

You can use the ilx component to create, modify, display, or delete an ILX profile. An ILX profile is used to associate an ILX Plugin (see ilx plugin) with a virtual server. When a client connects to a virtual server the data from the client and server will be routed to the ILX plugin allowing the plugin to inspect and manage traffic. An ILX profile is compatible with the following virtual server profiles: clientssl, http, http-compression, serverssl, stream, tcp and web-acceleration. A plugin may be associated with at most one ILX profile. An ILX profile may be associated with multiple virtual servers.

The BIG-IP(r) system installation includes the following default ILX profiles:

ilx

EXAMPLES

```
create ilx my_ilx_profile defaults-from ilx
```

Creates a custom ILX profile named my_ilx_profile that inherits its settings from the system default ILX profile.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile. The default value is ilx.

description

User defined description.

mpi-channel
Displays the communication channel used by the TMM and Node.js process.

partition
Displays the administrative partition within which the profile resides.

plugin
The name of an ILX Plugin, see also ilx plugin.

STATS

Connections
The number of current active connections

Connections Max Active
The maximum number of active connections at one time

Connection Aborts
The number of aborted connections (due to plugin error)

Connection Rejects
The number of aborted connections (due to TMM error)

Backlogged Messages
Messages queued to be sent from TMM to plugin

Backlogged Bytes
Bytes queued to be sent from TMM to plugin

Received Message Count
Messages received by TMM from plugin

Transmitted Message Count
Messages sent from TMM to plugin

Received Payload Bytes
Payload bytes received by TMM from plugin

Transmitted Payload Bytes
Payload bytes sent from TMM to plugin

SEE ALSO

BIG-IP 2017-05-24 ltm profile ilx(1)

ltm profile imap

NAME
imap - Configures an IMAP profile.

MODULE
ltm profile

SYNTAX
Configure the imap component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY
create imap [name]
modify imap [name]
options:
app-service [[string] | none]
defaults-from [[name] | none]
description [string]
activation-mode [none | allow | require]

edit imap [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties

DISPLAY
list imap
list imap [[[name] | [glob] | [regex]] ...]
show running-config imap
show running-config imap [[[name] | [glob] | [regex]] ...]
options:
all-properties

non-default-properties

DELETE
delete imap [name]

DESCRIPTION

You can use the imap component to create, modify, display, or delete an IMAP profile with which you can manage IMAP traffic.

EXAMPLES

```
create imap my_imap_profile defaults-from imap
```

Creates a custom IMAP profile named `my_imap_profile` that inherits its settings from the system default IMAP profile.

```
list imap
```

Displays the properties of all IMAP profiles.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is `imap`.

description

User defined description.

`glob` Displays the items that match the `glob` expression. See `help glob` for a description of `glob` expression syntax.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@`[regular expression]) to indicate that the identifier is a regular expression. See `help regex` for a description of regular expression syntax.

activation-mode

Sets the `activation-mode` `STARTTLS`. The options are `NONE`, `ALLOW`, or `REQUIRE`. The default value is `REQUIRE`.

SEE ALSO

`create`, `delete`, `edit`, `glob`, `list`, `ltm virtual`, `modify`, `regex`, `reset-stats`, `show`, `sys provision`, `tmsh`

COPYRIGHT

BIG-IP 2017-08-23 ltm profile imap(1)

ltm profile ipother

NAME

`ipother` - Configures a generic IP profile for non-TCP and non-UDP traffic.

MODULE

`ltm profile`

SYNTAX

Configure the `ipother` component within the `ltm profile` module using the syntax shown in the following sections.

CREATE/MODIFY

```
create ipother [name]
modify ipother [name]
```

options:

```
app-service [[string] | none]
defaults-from [[name] | none]
description [string]
idle-timeout [immediate | indefinite | integer]
```

```
edit ipother [ [name] | [glob] | [regex] ] ... ]
options:
all-properties
```

non-default-properties

```
reset-stats ipother
reset-stats ipother [ [name] | [glob] | [regex] ] ... ]

DISPLAY
list ipother
list ipother [ [name] | [glob] | [regex] ] ... ]
show running-config ipother
show running-config ipother
  [ [name] | [glob] | [regex] ] ... ]
  options:
  all-properties
  non-default-properties
  one-line
  partition

show ipother
show ipother [ [name] | [glob] | [regex] ] ... ]
  options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt
  global

DELETE
delete ipother [name]
```

DESCRIPTION

You can use the ipother component to manage non-TCP and non-UDP network traffic. If you want to manage TCP or UDP traffic, then use the appropriate TCP or UDP LTM profiles.

EXAMPLES

```
create ipother my_ipother_profile defaults-from ipother
```

This creates a custom IP-OTHER profile that is named `my_ipother_profile` which inherits its settings from the system default IP-OTHER profile.

```
list ipother all-properties
```

Displays all properties for all IP-OTHER profiles.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile. The default value is ipother.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

idle-timeout

Specifies the number of seconds that a connection is idle before the connection is eligible for deletion. The default value is 60 seconds.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the profile resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

create, delete, edit, glob, ltm profile, ltm virtual, modify, show, regex, reset-stats, tmsh

ltm profile ipsecalg

NAME
ipsecalg - Configures a IPsecALG profile.

MODULE
ltm profile

SYNTAX
Configure the ipsecalg component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY
create ipsecalg [name]
modify ipsecalg [name]
options:
 app-service [[string] | none]
 defaults-from [[name] | none]
 description [string]
 idle-timeout [integer]
 pending-ike-connection-limit [integer]
 initial-connection-timeout [integer]
 log-publisher [log publisher name | none]
 log-profile [log profile name | none]

mv ipsecalg [[[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder options:
 to-folder

edit ipsecalg [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 non-default-properties

DISPLAY
list ipsecalg
list ipsecalg [[[name] | [glob] | [regex]] ...]
show running-config ipsecalg
show running-config ipsecalg [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 non-default-properties
 one-line
 partition

DELETE
delete ipsecalg [name]

DESCRIPTION
Use this command to create, modify, display, or delete an IPsecALG profile with which you can manage IPsecALG traffic.

EXAMPLES
create ipsecalg my_ipsecalg_profile defaults-from ipsecalg
Creates a custom IPsecALG profile named my_ipsecalg_profile that inherits its settings from the system default IPsecALG profile.
list ipsecalg
Displays the properties of all IPsecALG profiles.
mv ipsecalg /Common/my_ipsecalg_profile to-folder /Common/my_folder
Moves a custom IPsecALG profile named my_ipsecalg_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS
app-service
Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.
defaults-from
Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is ipsecalg.
description
User defined description.
glob
Displays the items that match the glob expression. See help glob for a description of glob expression syntax.
name
Specifies a unique name for the component. This option is required for the commands create, delete, and modify.
partition
Displays the administrative partition within which the component resides.
regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.
to-folder

ipsealg profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

idle-timeout

Specifies an idle timeout in seconds. This setting specifies the number of seconds that a connection is idle before the connection is eligible for deletion. The default value is 3600 seconds.

pending-ike-connection-limit

Specifies the the maximum number of unacknowledged IKE connections a client can have before being denied further requests to prevent a single client from flooding all the connections trying to establish the connections. The default value is 5 connections per client.

initial-connection-timeout

Specifies an initial connection timeout in seconds. This is the max number of seconds to wait for a response from the server for the IKE/IPsec request. The default value is 3 seconds.

log-publisher

Specify the name of the log publisher which logs translation events. See help sys log-config for more details on the logging sub-system. Use the "sys log-config publisher" component to set up a log publisher.

log-profile

Specify the name of the ALG log profile which controls the logging of ALG events. See help ltm alg-log-profile for more details on the logging profile sub-system. Use the "ltm alg-log-profile profile" component to set up an ALG log profile.

SEE ALSO

create, delete, edit, glob, list, ltm virtual, modify, mv, regex, reset-stats, show, tmsh

COPYRIGHT

BIG-IP 2017-01-20 ltm profile ipsealg(1)

ltm profile mapt

NAME

map-t - Configures a MAP-T tunnel profile.

MODULE

net tunnels

SYNTAX

Configure the map-t component within the ltm profile module using the syntax in the following sections.

CREATE/MODIFY

create map-t [name]

modify map-t [name]

options:

app-service [[string] | none]

defaults-from [[name] | none]

description [string]

ip6-prefix [ipv6 address/netmask]

ip4-prefix [ipv4 address/netmask]

ea-bits-length [integer]

port-offset [integer]

br-prefix [ipv6 address/netmask]

edit map-t [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list map-t

list map-t [[[name] | [glob] | [regex]] ...]

show running-config map-t

show running-config map-t [[[name] | [glob] | [regex]] ...]

options:

all-properties

app-service

non-default-properties

one-line

partition

DELETE

delete map-t [all | [name]]

DESCRIPTION

You can use the map-t component to create a MAP-T profile that you associate with an LTM Virtual. A map-t profile allows you to define NAT parameters which will allow legacy IPV4 servers to connect to an IPV6 network.

EXAMPLES

```
create map-t my_map
```

Creates a MAP-T profile called my_map.

```
list map-t all-properties
```

Displays all the properties of all the MAP-T profiles.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is mapt.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create and modify.

partition

Displays the administrative partition within which this component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

ip6-prefix

Specifies the Rule IPv6 Prefix and netmask using CIDR notation, such as 2014::/48. The default prefix length is 48.

ip4-prefix

Specifies the Rule IPv4 Prefix and netmask using CIDR notation, such as 192.0.0.0/8. The default prefix length is 8.

ea-bits-length

Specifies the Rule EA (Embedded Address) Length of the MAP-T domain. The default is 40 (IPv4 32 bits + PSID 8 bits).

port-offset

Specifies the port offset bits length of the MAP-T domain. The default is 6.

br-prefix

Specifies the BR (Border Relay) IPv6 prefix and netmask using CIDR notation, such as 2023::/96. The default prefix length is 96.

psid Specify PSID value for MAP-T. The default is zero.

draft-mode

Allow BIGIP to work with non rfc compliant CE devices which map BR prefix at a wrong offset. The default is to disable draft mode.

br-pfx-ignore

Allow BIGIP to work with non rfc compliant CE devices which ignore BR prefix lengths. The default is to disable.

SEE ALSO

create, delete, edit, glob, list, modify, net tunnels tunnel, regex, show, tmsh

COPYRIGHT

ltm profile mblb

NAME
mblb - Configures an MBLB profile (experimental).

MODULE
ltm profile

SYNTAX
Configure the mblb component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY
create mblb [name]
modify mblb [name]
options:
 app-service [[string] | none]
 defaults-from [[name] | none]
 description [string]
 isolate-abort [disabled | enabled]
 isolate-expire [disabled | enabled]
 isolate-server [disabled | enabled]
 isolate-client [disabled | enabled]
 egress-high [# of messages]
 egress-low [# of messages]
 ingress-high [# of messages]
 ingress-low [# of messages]
 min-conn [# of connections]
 tag-ttl [# of seconds]
 shutdown-timeout [# of seconds]

edit mblb [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 non-default-properties

DISPLAY
list mblb
list mblb [[[name] | [glob] | [regex]] ...]
show running-config mblb
show running-config mblb [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 non-default-properties

DELETE
delete mblb [name]

DESCRIPTION
Use this command to create, modify, display, or delete an MBLB profile with which you can customize MBLB behavior.

EXAMPLES
create mblb my_mblb_profile defaults-from mblb

Creates a custom MBLB profile named my_mblb_profile that inherits its settings from the system default MBLB profile.

list mblb

Displays the properties of all MBLB profiles.

OPTIONS
app-service
Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from
Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is mblb.

description
User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

isolate-abort
Specify whether to isolate abort event propagation.

isolate-expire
Specify whether to isolate expiration event propagation.

isolate-server
Specify whether to isolate serverside shutdown event propagation. This also dominate serverside abort/expiration event propagation.

isolate-client

Specify whether to isolate clientside shutdown event propagation. This also dominate clientside abort/expiration event propagation.

egress-high
Specify the high water mark for egress message queue. The default value is 50.

egress-low
Specify the low water mark for egress message queue. The default value is 5.

ingress-high
Specify the high water mark for ingress message queue. The default value is 50.

ingress-low
Specify the low water mark for ingress message queue. The default value is 5.

min-conn
Specify the minimum number of serverside connections. The default value is 0.

tag-ttl
Specify the TTL (time to live) for message TAG. The default value is 60.

shutdown-timeout
Delays sending FIN when BIGIP receives the first FIN packet from either the client or the server. Value of 0 means send FIN immediately otherwise the minimum of tcp idle timeout and shutdown timeout is used. The default value is 5 seconds

SEE ALSO

BIG-IP 2014-07-10 ltm profile mblb(1)

ltm profile mqtt

NAME
mqtt - Configures an MQTT profile.

MODULE
ltm profile

SYNTAX
Configure the mqtt component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY

```
create mqtt [name]
modify mqtt [name]
options:
  app-service [[string] | none]
```

```
edit mqtt [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```
mv mqtt [ [[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-name]] ]
options:
  to-folder
```

```
reset-stats mqtt
reset-stats mqtt [ [ [name] | [glob] | [regex] ] ... ]
```

DISPLAY

```
list mqtt
list mqtt [ [ [name] | [glob] | [regex] ] ... ]
show running-config mqtt
show running-config mqtt [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
show mqtt
```

```
show mqttd [ [ [name] | [glob] | [regex] ] ... ]
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
field-fmt
global
```

```
DELETE
delete mqttd [name]
```

DESCRIPTION

You can use the mqttd component to create, modify, display, or delete an MQTT profile.

The BIG-IP(r) system installation includes the following default MQTT-type profiles:

mqttd

The default MQTT profile contains values for properties related to managing MQTT traffic.

You can create a new MQTT-type profile using an existing profile as a parent profile, and then you can change the values of the properties to suit your needs.

EXAMPLES

```
create mqttd my_mqttd_profile defaults-from mqttd
```

Creates a custom MQTT profile named my_mqttd_profile that inherits its settings from the system default MQTT profile.

```
mv mqttd /Common/my_mqttd_profile to-folder /Common/my_folder
```

Moves a custom MQTT profile named my_mqttd_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

Please refer to the mv manual page for examples on how to use the mv command.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

ltm profile mssql

NAME mssql - Configures a profile to manage mssql(tds) database traffic.

MODULE ltm profile

SYNTAX Configure the mssql component within the ltm profile module using the syntax in the following sections.

CREATE/MODIFY

```
create mssql [name]
modify mssql [name]
options:
app-service [[string] | none]
defaults-from [name]
description [[string] | none]
read-pool [string]
read-write-split-by-user [disabled | enabled]
read-write-split-by-command [disabled | enabled]
user-can-write-by-default [true | false]
user-list [add | delete | none | replace-all-with] {
[user names...]
}
write-persist-timer [number]
write-pool [string]
```

```

edit mssql [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties

reset-stats mssql
reset-stats mssql [ [ [name] | [glob] | [regex] ] ... ]

DISPLAY
list mssql
list mssql [ [ [name] | [glob] | [regex] ] ... ]
show running-config mssql
show running-config mssql [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties
    one-line
    partition

show mssql
show mssql [ [ [name] | [glob] | [regex] ] ... ]
  options:
    (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
    field-fmt
    global

DELETE
delete mssql [name]

```

DESCRIPTION

You can use the mssql component to configure a profile to manage mssql(tds) database traffic.

EXAMPLES

```
create mssql my_mssql_profile defaults-from mssql
```

Creates a mssql profile named my_mssql_profile that inherits its settings from the system default mssql profile.

```
list mssql
```

Displays the properties of all mssql profiles.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is mssql.

partition

Displays the administrative partition within which the profile resides.

read-pool

Specifies the pool of MS SQL database servers to which the system sends ready-only requests.

read-write-split-by-command

When enabled, the system decides which pool to send the client requests the by the content in the message. It can only be enabled when read-write-split-by-user is disabled.

read-write-split-by-user

When enabled, the system decides which pool to send the client requests the by user name. It can only be enabled when read-write-split-by-command is disabled.

user-can-write-by-default

Specifies whether users have write access by default. When set to true, all users have write access, except those added to the users list.

user-list

Specifies the users who have read-only access to the MS SQL if user-can-write-by-default is true, or the users who have write access to the MS SQL database if user-can-write-by-default is false.

write_persist_timer

Specify how many minimum time in milliseconds the connection will be persisted to write-pool after connection switch to write pool.

write-pool

Specifies the pool of MS SQL database servers to which the system sends requests that are not read-only.

SEE ALSO

create, delete, edit, glob, list, ltm virtual, modify, regex, reset-stats, show, tmsb

ltm profile netflow

NAME
netflow - Configures a NETFLOW profile.

MODULE
ltm profile

SYNTAX
Configure the netflow component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY
create netflow [name]
modify netflow [name]
options:
app-service [[string] | none]
defaults-from [[name] | none]
description [string]
netflow-version [enumerated]

edit netflow [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties

mv netflow [[[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-
options:
to-folder

reset-stats netflow
reset-stats netflow [[[name] | [glob] | [regex]] ...]

DISPLAY
list netflow
list netflow [[[name] | [glob] | [regex]] ...]
show running-config netflow
show running-config netflow [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties
one-line
partition

show netflow
show netflow [[[name] | [glob] | [regex]] ...]
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
field-fmt

DELETE
delete netflow [name]

DESCRIPTION
You can use the netflow component to manage a NETFLOW profile.

EXAMPLES
create netflow my_netflow_profile defaults-from netflow

Creates a NETFLOW profile named my_netflow_profile using the system defaults.

create netflow my_netflow_profile { netflow-version version-5 }

Creates a NETFLOW profile named my_netflow_profile that specifies the maximum number of messages that can be held in the ingress queue is 1000.

mv netflow /Common/my_netflow_profile to-folder /Common/my_folder

Moves a custom netflow profile named my_netflow_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS
app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from
Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is netflow.

description
User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

netflow-version
Specifies the expected netflow version for a profile.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition
Displays the administrative partition within which the component resides.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

create, delete, edit, glob, list, ltm virtual, modify, mv, regex, reset-stats, show, tmsh

ltm profile ntlm

NAME
ntlm - Configures a Microsoft(r) Windows(r) NT Local Area Network (LAN) manager profile.

MODULE
ltm profile

SYNTAX
Configure the ntlm component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY
create ntlm [name]
modify ntlm [name]
options:
app-service [[string] | none]
defaults-from [name]
description [string]
insert-cookie-domain [domain]
insert-cookie-name [cookie name]
insert-cookie-passphrase [passphrase]
key-by-cookie [disabled | enabled]
key-by-cookie-name [cookie name]
key-by-domain [disabled | enabled]
key-by-ip-address [disabled | enabled]
key-by-target [disabled | enabled]
key-by-user [disabled | enabled]
key-by-workstation [disabled | enabled]

edit ntlm [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties

DISPLAY
list ntlm
list ntlm [[[name] | [glob] | [regex]] ...]
show running-config ntlm
show running-config ntlm [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties
one-line
partition

DELETE
delete ntlm [name]

DESCRIPTION

You can use the ntlm component to create a Microsoft Windows NT LAN manager (NTLM) profile to manage servers on the LAN that are running

Windows NT.

EXAMPLES

```
create ntlm my_ntlm_profile defaults-from ntlm
```

Creates a Microsoft Windows NT LAN manager profile named my_ntlm_profile that inherits its settings from the system default NTLM profile named ntlm.

```
list ntlm all-properties
```

Displays all properties for all NTLM profiles.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is ntlm.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

insert-cookie-domain

Specifies an optional domain for the inserted cookie. The default is none, which causes no domain to be configured for the inserted cookie.

insert-cookie-name

Specifies a cookie name that the system inserts in the cookie. The default value is NTLMconnpool.

insert-cookie-passphrase

Specifies a cookie passphrase that the system inserts in the cookie. The default value is mypassphrase.

key-by-cookie

Specifies whether the system uses the existing cookie as the key. The default value is disabled.

key-by-cookie-name

Specifies whether the system uses the value of the insert-cookie-name option as the key. The default value is mycookie.

key-by-domain

Specifies whether the system uses the NTLM domain as the key. The default value is disabled.

key-by-ip-address

Specifies whether the system uses the client IP address as the key. The default value is disabled.

key-by-target

Specifies whether the system uses the NTLM target as the key. The default value is disabled.

key-by-user

Specifies whether the system uses the NTLM user as the key. The default value is enabled.

key-by-workstation

Specifies whether the system uses the NTLM workstation as the key. The default value is disabled.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

create, delete, edit, glob, list, ltm virtual, modify, regex, reset-stats, show, tmsb

show running-config one-connect [[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties
one-line
partition

show one-connect
show one-connect [[name] | [glob] | [regex]] ...]
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
field-fmt
global

DELETE
delete one-connect [name]

DESCRIPTION
You can use the one-connect component to create a OneConnect profile that optimizes connections by improving client performance and

increasing server capacity.

EXAMPLES

```
create one-connect my_OC_profile defaults-from oneconnect
```

Creates a OneConnect profile named `my_OC_profile` that inherits its settings from the system default OneConnect profile named `oneconnect`.

```
list one-connect all-properties
```

Displays all properties for all OneConnect profiles.

```
mv one-connect /Common/my_oneconnect_profile to-folder  
/Common/my_folder
```

Moves a custom one-connect profile named `my_oneconnect_profile` to a folder named `my_folder`, where `my_folder` has already been created and exists within `/Common`.

OPTIONS

`app-service`

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

`defaults-from`

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is `oneconnect`.

`description`

User defined description.

`glob` Displays the items that match the glob expression. See `help glob` for a description of glob expression syntax.

`idle-timeout-override`

Specifies the number of seconds that a connection is idle before the connection flow is eligible for deletion. The default value is disabled.

`share-pools`

Indicates that connections may be shared not only within a virtual server, but also among similar virtual servers (e.g. those that differ only in destination address). When enabled, all virtual servers that use the same One Connect and other internal network profiles can share connections.

`max-age`

Specifies the maximum age, in number of seconds, of a connection in the connection reuse pool. For any connection with an age higher than this value, the system removes that connection from the reuse pool. The default value is 86400.

`max-reuse`

Specifies the maximum number of times that a server connection can be reused. The default value is 1000.

`max-size`

Specifies the maximum number of connections that the system holds in the connection reuse pool. If the pool is already full, then the server connection closes after the response is completed. The default value is 10000.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

`partition`

Displays the partition within which the component resides.

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See `help regex` for a description of regular expression syntax.

`source-mask`

Specifies a source IP mask. The default value is 0.0.0.0.

The system applies the value of this option to the source address to determine its eligibility for reuse. A mask of 0.0.0.0 causes the system to share reused connections across all clients. A host mask (all 1's in binary), causes the system to share only those reused connections originating from the same client IP address.

`limit-type`

Connection limits with OneConnect are different from straight TCP connection limits. Three options are supported: "none" (the default), "idle", and "strict". When the limit is "none", simultaneous in-flight requests and responses over TCP connections to a pool member are counted toward the limit (this being the historical handling). There may be more TCP connections open to support new requests than there can be simultaneous in-flight requests and responses. This is particularly true when SNAT pools and narrow source address masks are used. When the limit is "idle", idle connections will be dropped as the TCP connection limit is reached. For short intervals, during the overlap of the idle connection being dropped and the new connection being established, the TCP connection limit may be exceeded. When the limit is "strict", the TCP connection limit is honored with no exceptions. This means that idle connections will prevent new TCP connections from being made until they expire, even if they could

otherwise be reused. This is not a recommended configuration except in very special cases with short expiration timeouts.

to-folder
one-connect profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

```
show pcp
show pcp [ [name] | [glob] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt
```

DELETE

```
delete pcp [name]
```

DESCRIPTION

You can use the pcp component to specify Port Control Protocol attributes for a profile that can be used in an LSN pool.

EXAMPLES

```
create pcp my_pcp_profile defaults-from pcp
```

Creates a custom PCP profile named my_pcp_profile that inherits its settings from the system default pcp profile.

```
list pcp all-properties
```

Displays all properties for all PCP profiles.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is pcp, a profile that is shipped in the software.

description

User defined description.

announce-after-failover

Specifies that the BIG-IP software should send an unsolicited ANNOUNCE response to all PCP clients when there is a failover. The unsolicited ANNOUNCE response goes over a link-local multi-cast address, and it contains a new EPOCH time. This signals to the PCP clients that they should renew all of their active mappings.

announce-multicast

Whenever the BIG-IP system reboots, or if there is any possibility that the system lost its PCP-mapping state, it sends an unsolicited ANNOUNCE response to all of its PCP clients. It sends the response over a link-local multi-cast address, and it contains a new EPOCH time. The PCP clients react by renewing all of their active IP mappings. To compensate for possible packet loss (since the multi-cast address is link-local), you can use this property to set the number of multi-cast re-sends. Default is 10 re-sends.

map-filter-limit

A PCP client can request a "filter" for a mapping entry, where the filter limits the number of external endpoints that can use the IP map. The filter request contains the particular IP address and port for the endpoint (or subnet of endpoints), as well as a prefix length. Enter the maximum number of filters (allowed subnets) that clients are allowed to set for each PCP mapping. Default is 1.

map-limit-per-client

Specifies the maximum number of PCP mappings per client. Default is 65535 (unlimited).

Use run util lsndb to see the currently-active set of PCP mappings on the system. See "util lsndb" for details on the LSN DB utility.

map-recycle-delay

After a IP mapping times out (that is, its lifetime expires), there is a further delay before the public-side address and port can be used by another PCP client. Use this property to set the recycle delay. Default is 60 (seconds).

Use run util lsndb to see the currently-active set of PCP mappings on the system. See "util lsndb" for details on the LSN DB utility.

max-mapping-lifetime

When a PCP client requests an IP mapping from a BIG IP system, it also requests a "lifetime" for the mapping. The mapping expires at the end of that lifetime. This property is the maximum number of seconds allowed for a mapping lifetime. Default is 86400 (seconds), or 1 day.

Use run util lsndb to see the currently-active set of PCP mappings on the system. See "util lsndb" for details on the LSN DB utility.

min-mapping-lifetime

Specifies the minimum number of seconds allowed for a mapping lifetime. Default is 600 (seconds), or 10 minutes.

Use run util lsndb to see the currently-active set of PCP mappings on the system. See "util lsndb" for details on the LSN DB utility.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex (regex) for a description of regular expression syntax.

rule Specifies the iRule that is associated with this pcp profile. An iRule can read packets and possibly filter them based on whatever programming logic you design. For example, an iRule could reject all PCP mapping requests using a specific port, or pass an ANNOUNCE request through a specific port. An iRule gives you the flexibility to filter, process, or log the PCP packets that fit this profile.

Select an iRule from the menu of existing iRules. To create a new one, use the create ltm rule command (see "ltm rule").

third-party-allowed-subnets

Specifies the PCP clients that can make MAP requests on behalf of other clients. Enter a collection of IP prefixes (IPv4 or IPv6) with their prefix lengths. If a PCP client outside of any of these subnets attempts a PCP mapping, the BIG-IP software rejects the mapping.

You can shorten any IPv6 addresses as defined in RFC 2373 (see).

This list is only used if the third-party-option is also enabled.

If the list is empty and the third-party-option is enabled, any PCP client can create mappings for third parties.

third-party-option

Allows PCP clients to make MAP requests on behalf of other clients, using the THIRD_PARTY flag in the PCP request. You can set this property to enabled or disabled. If you enable this property, we recommend using the third-party-subnets option to limit the the clients that can use the THIRD_PARTY flag; it is a potential security risk. The default is disabled.

BIG-IP 2016-03-14 ltm profile pop3(1)

ltm profile pop3

NAME

pop3 - Configures a POP3 profile.

MODULE

ltm profile

SYNTAX

Configure the pop3 component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY

```
create pop3 [name]
modify pop3 [name]
options:
  app-service [[string] | none]
  defaults-from [ [name] | none]
  description [string]
  activation-mode [ none | allow | require ]
```

```
edit pop3 [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list pop3
list pop3 [ [ [name] | [glob] | [regex] ] ... ]
show running-config pop3
show running-config pop3 [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DELETE

```
delete pop3 [name]
```

DESCRIPTION

You can use the pop3 component to create, modify, display, or delete a POP3 profile with which you can manage POP3 traffic.

EXAMPLES

```
create pop3 my_pop3_profile defaults-from pop3
```

Creates a custom POP3 profile named my_pop3_profile that inherits its settings from the system default POP3 profile.

```
list pop3
```

Displays the properties of all POP3 profiles.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from
Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is pop3.

description
User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

activation-mode
Sets the activation-mode for STARTTLS. The options are NONE, ALLOW, or REQUIRE. The default value is REQUIRE.

SEE ALSO

DELETE
delete pptp [name]

DESCRIPTION

You can use the ptp component to manage a PPTP profile.

EXAMPLES

```
create ptp my_ptp_profile defaults-from ptp
```

Creates a PPTP profile named my_ptp_profile using the system defaults.

```
create ptp my_ptp_profile { log-server-ip disabled }
```

Creates a PPTP profile named my_ptp_profile with server address logging disabled.

```
modify ptp my_ptp_profile description "This is a PPTP Profile"
```

Modifies the description attribute of a PPTP profile named my_ptp_profile.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is ptp.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

publisher-name

Specifies the name of the log publisher for PPTP events.

include-destination-ip

Specifies whether the log messages for call establishment/disconnect include the server's ip address. The default value is disabled. When disabled the ip address will be displayed as 0.0.0.0.

csv-format

When enabled, use CSV log format for log entries. The default value is disabled.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

ltm profile qoe

NAME

qoe - Configures a Quality of Experience (QoE) Monitoring profile.

MODULE

ltm profile

SYNTAX

Configure the qoe component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY

```
create qoe [name]
modify qoe [name]
```

```

options:
  app-service [[string] | none]
  defaults-from [name]
  description [[string] | none]
  video [true | false]

reset-stats qoe
reset-stats qoe [ [ [name] | [glob] | [regex] ] ... ]

DISPLAY
list qoe
list qoe [ [ [name] | [glob] | [regex] ] ... ]
show running-config qoe
show running-config qoe [ [ [name] | [glob] | [regex] ] ... ]
  options:

DELETE
delete qoe [name]

DESCRIPTION
  You can use the qoe component to monitor Video Quality of Experience.

EXAMPLES
  create qoe my_qoe defaults-from qoe

  Creates an quality of experience profile named my_qoe.

  create qoe my_qoe { video true }

  video
  Specifies to monitor the QoE MOS score of video streams with the
  format of MP4 or FLV.

SEE ALSO

```

ltm profile radius

```

NAME
  radius - Configures a RADIUS profile for network traffic load
  balancing.

MODULE
  ltm profile

SYNTAX
  Configure the radius component within the ltm profile module using the
  syntax shown in the following sections.

CREATE/MODIFY
create radius [name]
modify radius [name]
  options:
    app-service [[string] | none]
    clients [add | delete | modify | replace-all-with] {
      [ip address] ...
    }
    clients none
    defaults-from [name]
    description [string]
    persist-avp [ [string] | [integer] | none]
    pem-protocol-profile-radius [ [pem_protocol_profile_radius_name] | none]
    subscriber-discovery [ disabled | enabled ]

mv radius [ [[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-n
  options:
    to-folder

edit radius [ [ [name] | [glob] | [regex] ] ... ]

show radius [[[name] | [glob] | [regex]] ...]
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
field-fmt
global

DELETE
delete radius [name]

DESCRIPTION
You can use the radius component to manage RADIUS network traffic.

EXAMPLES
create radius my_radius_server

Creates a RADIUS profile named my_radius_server that inherits its settings from the system default RADIUS profile.

delete radius my_radius_server

Deletes the RADIUS profile named my_radius_server.

mv radius /Common/my_radius_profile to-folder /Common/my_folder

Moves a custom radius profile named my_radius_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS
app-service
Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

clients
Specifies host and network addresses from which clients can connect. The default value is none, which indicates that any client can connect.

defaults-from
Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile. The default value is radiusLB.

description
User defined description.

glob
Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name
Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition
Displays the administrative partition within which the component resides.

pem-protocol-profile-radius
Specifies PEM protocol profile to be used when subscriber discovery is enabled. PEM protocol profile defines mapping of RADIUS AVPs to subscriber ID and other PEM subscriber session attributes.

persist-avp
Specifies the name of the RADIUS attribute on which traffic persists. Acceptable values are ASCII strings from section 5 of RFC 2865 or numeric codes (1-255). The default value is none, which indicates that persistence is disabled.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

subscriber-discovery
Specifies whether to enable PEM subscriber discovery based on the content of RADIUS packets. The options are disabled and enabled. The default value is disabled, which indicates that it will not extract subscriber information from RADIUS packets.

to-folder
radius profiles can be moved to any folder under /Common, but

configuration dependencies may restrict moving the profile out of /Common.

BIG-IP 2016-03-14 ltm profile radius(1)

ltm profile ramcache

NAME

ramcache - Manages the BIG-IP(r) system RAM cache.

MODULE

ltm profile

SYNTAX

Configure the ramcache component within the ltm profile module using the syntax shown in the following sections.

DISPLAY

```
show ramcache
show ramcache [ [ [name] | [glob] | [regex] ] ... ]
options:
  exact
  host [string]
  max-response [integer]
  uri [string]
```

DELETE

```
delete ramcache [name]
```

DESCRIPTION

You can use the ramcache component to delete the entries in or show information about the BIG-IP(r) system RAM cache.

EXAMPLES

```
show ramcache
```

Displays information about the entries in the BIG-IP system RAM cache.

```
delete ramcache
```

Deletes the entries in the BIG-IP system RAM cache.

OPTIONS

exact

Displays the exact number of entries in the RAM cache.

host Displays the host from which the entry was cached.

max-response

Displays the maximum number of entries in the RAM cache. The default value is 0 (zero), which is equivalent with no max-response value being specified. Without the max-response option the system will limit the number of entries to 10 per Traffic Management Microkernel (TMM).

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

uri Displays the URI from which the entry was cached.

SEE ALSO

delete, show, tmsh

ltm profile request-adapt

NAME
request-adapt - Configures a HTTP request adaptation profile.

MODULE
ltm profile

SYNTAX
Configure the request-adapt component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY

```
create request-adapt [name]
modify request-adapt [name]
options:
  defaults-from [ [name] | none ]
  enabled [ yes | no ]
  internal-virtual [ [name] | none ]
  preview-size [integer]
  service-down-action [ ignore | reset | drop ]
  timeout [integer]
  allow-http-10 [ yes | no ]

edit request-adapt [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

mv request-adapt [ [[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [f
options:
  to-folder

reset-stats request-adapt
reset-stats request-adapt [ [ [name] | [glob] | [regex] ] ... ]
```

DISPLAY

```
list request-adapt
list request-adapt [ [ [name] | [glob] | [regex] ] ... ]
show running-config request-adapt
show running-config request-adapt [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

show request-adapt
show request-adapt [ [ [name] | [glob] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt
```

DELETE
delete request-adapt [name]

DESCRIPTION
You can use the request-adapt component to manage a HTTP request adaptation profile.

EXAMPLES

```
create request-adapt my_req_adapt defaults-from request-adapt
```

Creates a HTTP request adaptation profile named my_req_adapt using the system defaults.

```
create request-adapt my_req_adapt { enabled yes }
```

Creates a HTTP request adaptation profile named my_req_adapt that is enabled for adapting HTTP requests.

```
mv request-adapt /Common/my_requestadapt_profile to-folder /Common/my_folder
```

Moves a custom request-adapt profile named my_requestadapt_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

defaults-from
Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is requestadapt.

enabled
Enables adaptation of HTTP requests. If set to yes, HTTP requests will be forwarded to the specified internal virtual server for adaptation. The default value is yes.

internal-virtual
Specifies the name of the internal virtual server to use for adapting the HTTP request.

preview-size

Specifies the maximum size of the preview buffer. The preview buffer is used to hold a copy of the HTTP request header and data sent to the internal virtual server in case the adaptation server reports that it does not need to adapt the HTTP request. Setting the preview-size to 0, disables buffering the request and should only be done if the adaptation server will always return with a modified HTTP request or the original HTTP request. The default value is 1024.

service-down-action

Specifies the action to take if the internal virtual server does not exist or returns an error. The default value is ignore.

The options are:

ignore

Ignore the error and send the unmodified HTTP request to a HTTP server selected from this virtual server's pool.

drop Drop the connection.

reset

Reset the connection.

timeout

Specifies a timeout in milliseconds. If the internal virtual server does not return a result within the specified time, a timeout error will occur. If preview-size is 0, the countdown will start after the entire content has been sent for adaptation. A 0 value disables the timeout. The default value is 0.

to-folder

request-adapt profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

allow-http-10

Specifies whether to forward HTTP version 1.0 requests for adaptation. By default only HTTP version 1.1 requests are forwarded. Version 1.0 is not supported. While it should work in most cases, it might be necessary to restrict adaptation on a site-specific basis. The default value is no.

ltm profile request-log

NAME

request-log - Configures a Request-Logging profile.

MODULE

ltm profile

SYNTAX

Configure the request-log component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY

```
create request-log [name]
```

```
modify request-log [name]
```

options:

```
app-service [[string] | none]
```

```
defaults-from [[name] | none]
```

```
description [string]
```

```
log-request-logging-errors [disabled | enabled]
```

```
log-response-by-default [disabled | enabled]
```

```
log-response-logging-error [disabled | enabled]
```

```
proxy-close-on-error [disabled | enabled]
```

```

options:
  to-folder
```

```
DISPLAY
list request-log
list request-log [ [ [name] | [glob] | [regex] ] ... ]
show running-config request-log
show running-config request-log
  [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
show request-log
show request-log [ [ [name] | [glob] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt
  global
```

```
DELETE
delete request-log [name]
```

DESCRIPTION
You can use the request-log component to manage request-log network traffic.

EXAMPLES

```
create request-log my_reqlog_profile defaults-from request-log
```

Creates a custom request-log profile named `my_reqlog_profile` that inherits its settings from the system default request-log profile.

```
list request-log all-properties
```

Displays all properties for all request-log profiles.

```
mv request-log /Common/my_requestlog_profile to-folder /Common/my_folder
```

Moves a custom request-log profile named `my_requestlog_profile` to a folder named `my_folder`, where `my_folder` has already been created and exists within `/Common`.

OPTIONS

`app-service`
Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

`defaults-from`
Specifies the default values from this profile.

`description`
User defined description.

`log-request-logging-errors`
Enables secondary logging should the primary lack sufficient available bandwidth. This mechanism is best used to send an alert to a completely separate destination.

`log-response-by-default`
Indicates if response logging may be overridden via `iRule`. This field determines the default response action.

`log-response-logging-errors`
Enables secondary logging should the primary lack sufficient available bandwidth. This mechanism is best used to send an alert to a completely separate destination.

`partition`
Displays the administrative partition within which the profile resides.

`proxy-close-on-error`
Specifies, if enabled, that the logging profile will close the connection after sending its proxy-response.

`proxy-respond-on-logging-error`
Specifies that the logging profile respond directly (for example, with an HTTP 502) if the logging fails.

`proxy-response`
Specifies the response to send on logging errors.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

request-log-error-pool

Specifies the name of the pool from which to select log servers.

request-log-error-protocol

Specifies the HighSpeedLogging protocol to use when logging.

request-log-error-template

Specifies the template to use when generating log messages. Shell style escapes (for example, \$foo and/or \${foo}) are used to import transaction-specific values.

request-log-pool

Specifies the name of the pool from which to select log servers.

request-log-protocol

Specifies the HighSpeedLogging protocol to use when logging.

request-log-template

Specifies the template to use when generating log messages. Shell style escapes (for example, \$foo and/or \${foo}) are used to import transaction-specific values.

request-logging

Enables or disables logging before the response is returned to the client.

response-log-error-pool

Specifies the name of the pool from which to select log servers.

response-log-error-protocol

Specifies the HighSpeedLogging protocol to use when logging.

response-log-error-template

Specifies the template to use when generating log messages. Shell style escapes (for example, \$foo and/or \${foo}) are used to import transaction-specific values.

response-log-pool

Specifies the name of the pool from which to select log servers.

response-log-protocol

Specifies the HighSpeedLogging protocol to use when logging.

response-log-template

Specifies the template to use when generating log messages. Shell style escapes (for example, \$foo and/or \${foo}) are used to import transaction-specific values.

response-logging

Enables or disables logging before the response is returned to the client.

to-folder

request-log profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

SEE ALSO

```

```

DELETE
delete response-adapt [name]

```

DESCRIPTION

You can use the response-adapt component to manage a HTTP response adaptation profile.

EXAMPLES

```
create response-adapt my_req_adapt defaults-from response-adapt
```

Creates a HTTP response adaptation profile named my_req_adapt using the system defaults.

```
create response-adapt my_req_adapt { enabled yes }
```

Creates a HTTP response adaptation profile named my_req_adapt that is enabled for adapting HTTP responses.

```
mv response-adapt /Common/my_responseadapt_profile to-folder
/Common/my_folder
```

Moves a custom responseadapt profile named my_responseadapt_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is responseadapt.

enabled

Enables adaptation of HTTP responses. If set to yes, HTTP responses will be forwarded to the specified internal virtual server for adaptation. The default value is yes.

internal-virtual

Specifies the name of the internal virtual server to use for adapting the HTTP response.

preview-size

Specifies the maximum size of the preview buffer. The preview buffer is used to hold a copy of the HTTP response header and data sent to the internal virtual server in case the adaptation server reports that it does not need to adapt the HTTP response. Setting the preview-size to 0, disables buffering the response and should only be done if the adaptation server will always return with a modified HTTP response or the original HTTP response. The default value is 1024.

service-down-action

Specifies the action to take if the internal virtual server does not exist or returns an error. The default value is ignore.

The options are:

ignore

Ignore the error and send the unmodified HTTP response to a HTTP server selected from this virtual server's pool.

drop Drop the connection.

reset

Reset the connection.

timeout
Specifies a timeout in milliseconds. If the internal virtual server does not return a result within the specified time, a timeout error will occur. If preview-size is 0, the countdown will start after the entire content has been sent for adaptation. A 0 value disables the timeout. The default value is 0.

to-folder
response-adapt profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

allow-http-10
Specifies whether to forward HTTP version 1.0 responses for adaptation. By default only HTTP version 1.1 responses are forwarded. Version 1.0 is not supported. While it should work in most cases, it might be necessary to restrict adaptation on a site-specific basis. The default value is no.

edit rewrite [ [ [name] | [glob] ] ... ]
options:
  all-properties
  non-default-properties

DELETE
delete rewrite [name]

DESCRIPTION
Use the rewrite component to configure a Rewrite Profile in URI
Translation or Portal (Access) mode.

EXAMPLES
URI Translation Mode
Create a profile
create my_uri_rewrite rewrite-mode uri-translation

Add a rule to rewrite URIs
modify my_uri_rewrite uri-rules add { my_rule { client { path
/client/ } server { path /server/ } } }

modify my_uri_rewrite uri-rules add { my_rule { client { scheme
http host www.client.com path / } server { scheme http host
www.server.com path / } } }

Add a rule to rewrite Set-Cookie headers
modify my_uri_rewrite set-cookie-rules add { my_rule { client {
domain client.com path / } server { domain server.com path / }
} }

Portal (Access) Mode
Create a profile
create my_portal_rewrite rewrite-mode portal

Configure the client to cache all files
modify my_portal_rewrite client-caching-type cache-all

Set the rewrite list and bypass list
modify my_portal_rewrite rewrite-list add {
*://www.myportal.com/* http://abc*.com/* } bypass-list add {
*://external_web.com/* }

Configure split-tunneling
modify my_portal_rewrite split-tunneling true

OPTIONS
app-service
Specifies the name of the application service to which the
object belongs. The default value is none. Note: If the strict-
updates option is enabled on the application service that owns
the object, you cannot modify or delete the object. Only the
application service can modify or delete the object.

bypass-list
Specifies a list of URIs that are bypassed inside a web page
when the page is accessed using Portal Access. The default is
none.

client-caching-type
Specifies one of four options for client caching. When the
Client Cache setting for a web application resource is set to
default, the system uses the setting configured in the Rewrite
profile. If the Client Cache option is configured for any other
setting, the web application resource item caching
configuration overwrites the setting in the Rewrite profile.
The default is cache-css-js. The options are:

cache-all
Do not modify cache headers on backend servers.

cache-css-js
Cache only the CSS file and Java Script.

cache-img-css-js
Cache only images, the CSS file and Java Script.

no-cache
Eliminate caching.

defaults-from
Specifies the profile from which the Rewrite profile inherits
properties. Explicitly specified properties override inherited

```

properties.

java-ca-file
Specifies a CA against which to verify signed Java applets signatures. The default value is ca-bundle.crt.

java-crl
Specifies a CRL against which to verify signed Java applets signature certificates. The default value is none.

java-sign-key
Specifies a private key for re-signing of signed Java applets after patching. The default value is default.key.

java-sign-key-passphrase
Specifies a passphrase for the private key to be encrypted with. The default value is none. Note: your passphrase will be encrypted and displayed under the label java-sign-key-passphrase-encrypted.

java-signer
Specifies a certificate to use for re-signing of signed Java applets after patching. The default value is default.crt.

location-specific
Specifies whether or not this object contains one or more attributes with values that are specific to the location where the BIG-IP device resides. The location-specific attribute is either true or false. When using policy sync, mark an object as location-specific to prevent errors that can occur when policies reference objects, such as authentication servers, that are specific to a certain location. The default value is none.

rewrite-list
Specifies a list of URIs that are rewritten inside a web page when the page is accessed using Portal Access. The default value is none.

rewrite-mode
Specifies the mode of rewriting. uri-translation is a rules-based rewrite mode. portal is for use with Portal Access.

set-cookie-rules
Used with uri-translation mode. Specifies the rules for rewriting HTTP Set-Cookie headers. Each rule has a name and a client and server domain and path. The name may be any alphanumeric string and must be unique. The path must be an absolute directory path and not a relative path or a file path. If the domain and path of the Set-Cookie header in the HTTP response match the domain and path of the server side of a rule, they will be rewritten to the domain and path of client side of that rule. Set-Cookie rules take precedence over URI rules when rewriting Set-Cookie headers.

split-tunneling
Specifies whether the profile provides for split tunneling. The default is false.

uri-rules
Used with uri-translation mode. Specifies the rules for rewriting request and response headers and response bodies. These rules affect the following.

request headers
URI, Host, Referer

response headers
Content-Location, Link, Location, Refresh, Set-Cookie

response body
HTML, CSS

Each rule has a name, a type, and a client and server URI. The name may be any alphanumeric string and must be unique. The type may be "request", "response", or "both": "request" rules affect request headers only, "response" rules affect response headers and bodies only, and "both" rules affect both. URIs must include a path; scheme, host, and port are optional. If a URI must contain a scheme or host, it must include both. If it must include a port, it must also include a scheme and host. Paths may be absolute directory paths only. They may not be relative paths or file paths. If a URI in a request header matches the client side URI of a rule, it will be rewritten to the server side URI of that rule. If a URI in a response header or body matches the server side URI of a rule, it will be rewritten to the client side URI of that rule. When rewriting Set-Cookie headers, the host and path of the server side URI are used to match the domain and path of the header. The client side host and path replace that header's domain and path if a match is found. Set-Cookie rules take precedence over URI rules when rewriting Set-Cookie headers.

DELETE
delete rtsp [name]

DESCRIPTION
You can use the rtsp component to manage a profile that you use to control RTSP traffic.

EXAMPLES
create rtsp my_rtsp_profile defaults-from rtsp

Creates a custom RTSP profile named my_rtsp_profile that inherits its settings from the system default RTSP profile.

list rtsp all-properties

Displays all properties for all RTSP profiles.

mv rtsp /Common/my_rtsp_profile to-folder /Common/my_folder

Moves a custom rtsp profile named my_rtsp_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS
app-service

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

check-source

When enabled the system uses the source attribute in the transport header to establish the target address of the RTP stream, and before the response is forwarded to the client, updates the value of the source attribute to be the virtual address of the BIG-IP system. When disabled the system does not change the source attribute. The default value is enabled.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is rtsp.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

idle-timeout

Specifies the number of seconds that a connection is idle before the connection is eligible for deletion. The default value is 300 seconds.

max-header-size

Specifies the maximum size of an RTSP request or response header that the RTSP filter accepts before dropping the connection. The default value is 4096 bytes.

max-queued-data

Specifies the maximum amount of data that the RTSP filter buffers before dropping the connection. The default value is 32768 bytes.

multicast-redirect

Specifies whether to enable or disable multicast redirect. When enabled, the client can select the destination to which to stream data. The default value is disabled.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

proxy

Specifies whether the RTSP filter is associated with an RTSP proxy configuration. The default value is none.

proxy-header

When the proxy option is set, specifies the name of the header in the RTSP proxy configuration that is passed from the client-side virtual server to the server-side virtual server. Note that the name of the header must begin with X-. The default value is none.

To use the proxy-header option, you must specify a value for the proxy option.

real-http-persistence

Specifies whether to enable or disable real HTTP persistence. When enabled, the RTSP filter automatically persists Real Networks RTSP over HTTP using the RTSP port. The default value is enabled. If you disable this parameter, you can override the default behavior with an iRule.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

rtcp-port

Specifies the number of the port to use for the Real Time Control Protocol (RTCP) service. The default value is 0 (zero). RTCP allows monitoring of real-time data delivery.

rtp-port

Specifies the number of the port to use for the RTP service. The default value is 0 (zero).

session-reconnect

Specifies whether to enable or disable session reconnect. When enabled, the RTSP filter persists the control connection, which is being resumed, to the correct server. The default value is disabled.

to-folder

rtsp profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

unicast-redirect

Specifies whether to enable or disable unicast redirect. When enabled, the client can select the destination to which to stream data. The default value is disabled.

log-publisher

Specify the name of the log publisher which logs translation

events. See help sys log-config for more details on the logging sub-system. Use the "sys log-config publisher" component to set up a log publisher.

log-profile

Specify the name of the ALG log profile which controls the logging of ALG. See help ltm alg-log-profile for more details on the logging profile sub-system. Use the "ltm alg-log-profile profile" component to set up a ALG log profile.

DELETE

delete sctp [name]

DESCRIPTION

You can use the sctp component to manage a profile for SCTP traffic.

EXAMPLES

```
create sctp my_sctp_profile defaults-from sctp
```

Creates a custom SCTP profile named `my_sctp_profile` that inherits its settings from the system default SCTP profile.

```
list sctp all-properties
```

Displays all properties for all SCTP profiles.

```
mv sctp /Common/my_sctp_profile to-folder /Common/my_folder
```

Moves a custom sctp profile named `my_sctp_profile` to a folder named `my_folder`, where `my_folder` has already been created and exists within `/Common`.

OPTIONS

`app-service`

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

`cookie-expiration`

Specifies how many seconds the cookie is valid. The default value is 60 seconds.

`defaults-from`

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is `sctp`.

`description`

User defined description.

`glob` Displays the items that match the glob expression. See help `glob` for a description of glob expression syntax.

`heartbeat-interval`

Specifies the number of seconds to wait before sending a heartbeat chunk. The default value is 30 seconds.

`heartbeat-max-burst`

Specifies the number of heartbeat packets to be sent in a single burst. The default value is 1.

`idle-timeout`

Specifies the number of seconds without traffic before a connection is eligible for deletion. The default value is 300 seconds.

`in-streams`

Specifies the number of inbound streams. The default value is 2.

`init-max-retries`

Specifies the maximum number of retries to establish a connection. The default value is 4.

`ip-tos`

Specifies the Type of Service (ToS) that is set in packets sent to the peer. The default value is 0.

`link-qos`

Specifies the Link Quality of Service (QoS) that is set in sent packets. The default value is 0.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

`out-streams`

Specifies the number of outbound streams. The default value is 2.

`partition`

Displays the administrative partition within which the component resides.

`proxy-buffer-high`

Specifies the proxy buffer level after which the system closes the receive window. The default value is 16384.

`proxy-buffer-low`

Specifies the proxy buffer level after which the system opens the receive window. The default value is 4096.

`receive-chunks`

Specifies the size (in chunks) of the `rx_chunk` buffer. The default value is 256.

receive-ordered
When enabled, the default, the system delivers messages to the application layer in order.

receive-window-size
Specifies the size (in bytes) of the receive window. Prorate this value to the receive-chunks value. The default value is 65535.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reset-on-timeout
When enabled, the default, the system resets the connection when the connection times out.

secret
Specifies the internal secret string used for HTTP Message Authenticated Code (HMAC) cookies.

send-buffer-size
Specifies the size in bytes of the buffer. The default value is 65536.

max-burst
Specifies the maximum number of data packets to send in a single burst. The default value is 4.

send-max-retries
Specifies the maximum number of time the system tries again to send the data. The default value is 8.

send-partial
When enabled, the default, the system accepts partial application data.

tcp-shutdown
When enabled, the system emulates the closing of a TCP connection. The default value is enabled.

to-folder
sctp profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

transmit-chunks
Specifies the size of the tx_chunk buffer. The default value is 256.

ltm profile server-ldap

NAME
server-ldap - Configures an Server LDAP profile.

MODULE
ltm profile

SYNTAX
Configure the server-ldap component within the ltm profile module using the syntax shown in the following sections.

```
CREATE/MODIFY
create server-ldap [name]
modify server-ldap [name]
options:
  app-service [[string] | none]
  defaults-from [ [name] | none]
  description [string]
  activation-mode [ none | allow | require ]
  ss-activation-mode [ none | allow | require ]

edit server-ldap [ [ [name] | [glob] | [regex] ] ... ]
options:
```

```

    all-properties
    non-default-properties

DISPLAY
list server-ldap
list server-ldap [ [ [name] | [glob] | [regex] ] ... ]
show running-config server-ldap
show running-config server-ldap [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties

DELETE
delete server-ldap [name]

DESCRIPTION
You can use the server-ldap component to create, modify, display, or
delete an Server LDAP profile with which you can manage Server LDAP
traffic.

EXAMPLES
create server-ldap my_serverldap_profile defaults-from serverldap

Creates a custom Server LDAP profile named my_serverldap_profile that
inherits its settings from the system default Server LDAP profile.

list server-ldap

Displays the properties of all Server LDAP profiles.

OPTIONS
app-service
Specifies the name of the application service to which the profile
belongs. The default value is none. Note: If the strict-updates
option is enabled on the application service that owns the object,
you cannot modify or delete the profile. Only the application
service can modify or delete the profile.

defaults-from
Specifies the profile that you want to use as the parent profile.
Your new profile inherits all settings and values from the parent
profile specified. The default value is smtp.

description
User defined description.

glob Displays the items that match the glob expression. See help glob
for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required
for the commands create, delete, and modify.

regex
Displays the items that match the regular expression. The regular
expression must be preceded by an at sign (@[regular expression])
to indicate that the identifier is a regular expression. See help
regex for a description of regular expression syntax.

activation-mode
Sets the activation-mode for STARTTLS. The options are NONE,
ALLOW, or REQUIRE. The default value is NONE.

SEE ALSO
create, delete, edit, glob, list, ltm virtual, modify, regex, reset-
stats, show, sys provision, tmsh

DESCRIPTION

You can use the server-ssl component to manage a server SSL profile.

Server-side profiles enable the traffic management system to handle encryption tasks for any SSL connection being sent from a local traffic management system to a target server. A server-side SSL profile acts as a client by presenting certificate credentials to a server when authentication of the local traffic management system is required. You implement this type of profile by using the default profile, or by creating a custom profile based on the Server SSL profile template and modifying its settings.

EXAMPLES

```
create server-ssl my_serversssl_profile defaults-from serversssl
```

Creates a custom Server SSL profile named `my_serversssl_profile` that inherits its settings from the system default profile `serversssl`.

```
list server-ssl all-properties
```

Displays all properties for all Server SSL profiles.

```
mv server-ssl /Common/my_serversssl_profile to-folder /Common/my_folder
```

Moves a custom server-ssl profile named `my_serversssl_profile` to a folder named `my_folder`, where `my_folder` has already been created and exists within `/Common`.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

alert-timeout

Specifies the maximum time period in seconds to keep the SSL session active after alert message is sent, or indefinite. The default value is indefinite.

allow-expired-crl

Use the specified CRL file even if it has expired. The default value is disabled.

authenticate

Specifies the frequency of authentication. The default value is once.

authenticate-depth

Specifies the client certificate chain maximum traversal depth. The default value is 9.

authenticate-name

Specifies a Common Name (CN) that is embedded in a server certificate. The system authenticates a server based on the specified CN. The default value is none.

bypass-on-client-cert-fail

Enables or disables SSL forward proxy bypass on failing to get client certificate that server asks for. When enabled and the SSL handshake cannot be completed because of failure to get the client certificate, SSL traffic bypasses the BIG-IP system untouched, without decryption/encryption. The default value is disabled. Conversely, you can specify enabled to use this feature.

bypass-on-handshake-alert

Enables or disables SSL forward proxy bypass on receiving handshake failure, protocol version or unsupported extension alert message during the serverside SSL handshake. When enabled and there is an `SSL handshake failure`, `protocol version` or `unsupported extension` alert during the serverside SSL handshake, SSL traffic bypasses the BIG-IP system untouched, without decryption/encryption. The default value is disabled. Conversely, you can specify enabled to use this feature.

c3d-ca-cert

Specifies the name of the certificate file that is used as the certification authority certificate when SSL client certificate constrained delegation is enabled. The certificate should be generated and installed by you on the system. When selecting this option, type a certificate file name.

c3d-ca-key

Specifies the name of the key file that is used as the certification authority key when SSL client certificate constrained delegation is enabled. The key should be generated and installed by you on the system. When selecting this option, type a key file name.

c3d-ca-passphrase

Specifies the passphrase of the key file that is used as the certification authority key when SSL client certificate constrained delegation is enabled. When selecting this option, type the passphrase corresponding to the selected `c3d-ca-key`.

c3d-cert-extension-custom-oids

Specifies the custom extension OID of the client certificates to be included in the generated certificates using SSL client certificate constrained delegation.

c3d-cert-extension-includes

Specifies the extensions of the client certificates to be included in the generated certificates using SSL client certificate constrained delegation. For example, { basic-constraints }. The default value is { basic-constraints extended-key-usage key-usage subject-alternative-name }. The extensions are:

basic-constraints

Basic constraints are used to indicate whether the certificate belongs to a CA.

extended-key-usage

Extended Key Usage is used, typically on a leaf certificate, to indicate the purpose of the public key contained in the certificate.

key-usage

Key Usage provides a bitmap specifying the cryptographic operations which may be performed using the public key contained in the certificate; for example, it could indicate that the key should be used for signature but not for encipherment.

subject-alternative-name

Subject Alternative Name allows identities to be bound to the subject of the certificate. These identities may be included in addition to or in place of the identity in the subject field of the certificate.

c3d-cert-lifespan

Specifies the lifespan of the certificate generated using the SSL client certificate constrained delegation. The default value is 24.

ca-file

Specifies the certificate authority file name. Configures certificate verification by specifying a list of client or server CAs that the traffic management system trusts. The default value is none.

cache-size

Specifies the SSL session cache size. For client profiles only, you can configure timeout and size values for the SSL session cache. Because each profile maintains a separate SSL session cache, you can configure the values on a per-profile basis. The default value is 262144.

cache-timeout

Specifies the SSL session cache timeout value, which is the usable lifetime seconds of negotiated SSL session IDs. The default value is 3600 seconds. Acceptable values are integers greater than or equal to 0 and less than or equal to 86400.

cert Specifies the name of the certificate installed on the traffic management system for the purpose of terminating or initiating an SSL connection. The default value is none.

chain

Specifies or builds a certificate chain file that a client can use to authenticate the profile. The default value is none.

cipher-group

Specifies a cipher group. If the cipher group is not blank or none, the ciphers string will be used.

ciphers

Specifies a cipher name. The default value is DEFAULT.

crl Specifies the name of crl validator for validating status of server certificate. Specifying none disables crl validation of server certificate. The default value is none.

crl-file

Specifies the certificate revocation list file name. The default value is none.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is serverssl.

description

User defined description.

expire-cert-response-control

Specifies the BIGIP action when the server certificate has expired. The default value is drop, which causes the connection to be dropped. Conversely, you can specify ignore to cause the connection to ignore the error and continue.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

handshake-timeout

Specifies the handshake timeout in seconds. The default value is 10.

key Specifies the key file name. Specifies the name of the key

installed on the traffic management system for the purpose of terminating or initiating an SSL connection. The default value is none.

mod-ssl-methods

Enables or disables ModSSL methods. The default value is disabled.

Enable this option when OpenSSL methods are inadequate. For example, you can enable ModSSL method emulation when you want to use SSL compression over TLSv1.

mode Enables or disables SSL processing. The default value is enabled.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

ocsp Specifies the name of ocsp profile for purpose of validating status of server certificate. Specifying none disables ocsp validation of server certificate. The default value is none.

options

Enables options, including some industry-related workarounds. Enter options inside braces, for example, { dont-insert-empty-fragments microsoft-sess-id-bug}. The default value is dont-insert-empty-fragments no-tls1.3.

all-bugfixes

This option enables the following industry-related defect workarounds: microsoft-sess-id-bug, netscape-challenge-bug, netscape-reuse-cipher-change-bug, sslref2-reuse-cert-type-bug, microsoft-big-ssl3-buffer, msie-ssl2-rsa-padding, ssleay-080-client-dh-bug, tls-d5-bug, tls-block-padding-bug, and dont-insert-empty-fragments.

It is usually safe to use this option to enable the defect workaround options when compatibility with broken implementations is desired. Note that if you edit the configuration in the browser-based Configuration utility, the system expands the all-bugfixes syntax into each individual option.

cipher-server-preference

When choosing a cipher, this option uses the server's preferences instead of the client references. When this option is not set, the SSL server always follows the client's references. When this option is set, the SSLv3/TLSv1 server chooses by using its own references. Due to the different protocol, for SSLv2 the server sends its list of preferences to the client and the client always chooses.

dont-insert-empty-fragments

Disables a countermeasure against a SSL 3.0/TLS 1.0 protocol vulnerability affecting CBC ciphers. These ciphers cannot be handled by certain broken SSL implementations. This option has no effect for connections using other ciphers.

ephemeral-rsa

Uses ephemeral (temporary) RSA keys when doing RSA operations. According to the specifications, this is only done when an RSA key can be used for signature operations (namely under export ciphers with restricted RSA key length). By setting this option, you specify that you always want to use ephemeral RSA keys. This option breaks compatibility with the SSL/TLS specifications and may lead to interoperability problems with clients. Therefore, F5 Networks does not recommend this option. Use ciphers with EDH (ephemeral Diffie-Hellman) key exchange instead. This option is ignored for server-side SSL.

max-active-handshakes

Specifies the maximum number allowed SSL active handshakes. The default value is 0.

microsoft-big-ssl3-buffer

Enables a workaround for communicating with older Microsoft(r) applications that use non-standard SSL record sizes.

microsoft-sess-id-bug

Handles a Microsoft session ID problem.

msie-ssl2-rsa-padding

Enables a workaround for communicating with older Microsoft applications that use non-standard RSA key padding. This option is ignored for server-side SSL.

netscape-ca-dn-bug

Handles a defect regarding the system crashing or hanging. If the system accepts a Netscape Navigator(r) browser connection, demands a client cert, has a non-self-signed CA that does not have its CA in Netscape, and the browser has a certificate, the system crashes or hangs.

netscape-challenge-bug

Handles the Netscape challenge problem.

netscape-demo-cipher-change-bug

Manipulates the SSL server session resumption behavior to mimic that of certain Netscape servers (see the Netscape reuse cipher change bug workaround description). Note that F5 Networks does not recommend this option for normal use. It is ignored for server-side SSL.

netscape-reuse-cipher-change-bug

Handles a defect within Netscape-Enterprise/2.01 (<https://merchant.neape.com>), appearing only when connecting through SSLv2/v3, and then reconnecting through SSLv3. In this case, the cipher list changes.

First, a connection is established with the RC4-MD5 cipher list. If it is then resumed, the connection switches to using the DES-CBC3-SHA cipher list. However, according to RFC 2246, (section 7.4.1.3, cipher suite) the cipher list is RC4-MD5.

As a workaround, you can attempt to connect with a cipher list of DES-CBC-SHA:RC4-MD5 and so on. For some reason, each new connection uses the RC4-MD5 cipher list, but any re-connection attempts to use the DES-CBC-SHA cipher list. Thus Netscape, when reconnecting, always uses the first cipher in the cipher list.

no-session-resumption-on-renegotiation
When performing renegotiation as an SSL server, this option always starts a new session (that is, session resumption requests are accepted only in the initial handshake). The system ignores this option for server-side SSL.

no-ssl
Do not use any version of the SSL protocol.

no-sslv2
Do not use the SSLv2 protocol.

no-sslv3
Do not use the SSLv3 protocol.

no-tls
Do not use any version of the TLS protocol.

no-tls1
Do not use the TLSv1.0 protocol.

no-tls1.1
Do not use the TLSv1.1 protocol.

no-tls1.2
Do not use the TLSv1.2 protocol.

no-tls1.3
Do not use the TLSv1.3 protocol. Note that this is for future expansion. Currently TLSv1.3 has not been implemented for server side SSL, so removing this will have no effect and log a warning message.

no-dtls
Do not use any version of the DTLS protocol.

passive-close
Specifies how to handle passive closes.

none Disables all workarounds. Note that F5 Networks does not recommend this option.

pkcs1-check-1
This debugging option deliberately manipulates the PKCS1 padding used by SSL clients in an attempt to detect vulnerability to particular SSL server vulnerabilities. Note that F5 Networks does not recommend this option for normal use. The system ignores this option for client-side SSL.

pkcs1-check-2
This debugging option deliberately manipulates the PKCS1 padding used by SSL clients in an attempt to detect vulnerability to particular SSL server vulnerabilities. Note that F5 Networks does not recommend this option for normal use. The system ignores this option for client-side SSL.

single-dh-use
Creates a new key when using temporary/ephemeral DH parameters. This option must be used to prevent small subgroup attacks, when the DH parameters were not generated using strong primes (for example, when using DSA-parameters). If strong primes were used, it is not strictly necessary to generate a new DH key during each handshake, but F5 Networks recommends it. Enable the Single DH Use option whenever temporary or ephemeral DH parameters are used.

ssleay-080-client-dh-bug
Enables a workaround for communicating with older SSLeay-based applications that specify an incorrect Diffie-Hellman public value length. This option is ignored for server-side SSL.

sslref2-reuse-cert-type-bug
Handles the SSL reuse certificate type problem.

tls-block-padding-bug
Enables a workaround for communicating with older TLSv1-enabled applications that use incorrect block padding.

tls-d5-bug
This option is a workaround for communicating with older TLSv1-enabled applications that specify an incorrect encrypted RSA key length. This option is ignored for server-side SSL.

tls-rollback-bug
Disables version rollback attack detection. During the client

key exchange, the client must send the same information about acceptable SSL/TLS protocol levels as it sends during the first hello. Some clients violate this rule by adapting to the server's answer. For example, the client sends an SSLv2 hello and accepts up to SSLv3.1 (TLSv1), but the server only processes up to SSLv3. In this case, the client must still use the same SSLv3.1 (TLSv1) announcement. Some clients step down to SSLv3 with respect to the server's answer and violate the version rollback protection. The system ignores this option for server-side SSL.

partition

Displays the administrative partition within which the component resides.

passphrase

Specifies the key passphrase, if required. The default value is none.

peer-cert-mode

Specifies the peer certificate mode. The default value is ignore.

proxy-ssl

Enabling this option requires a corresponding client ssl profile with proxy-ssl enabled to perform transparent SSL decryption. This feature allows further modification of application traffic within an SSL tunnel while still allowing the server to perform necessary authorization, authentication, auditing steps.

proxy-ssl-passthrough

Enabling this option requires a corresponding client ssl profile with proxy-ssl-passthrough enabled. This allows Proxy SSL to passthrough the traffic when ciphersuite negotiated between the client and server is not supported. The default option is disabled.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

renegotiate-period

Specifies the number of seconds from the initial connect time after which the system renegotiates an SSL session. The default value is indefinite, which means that you do not want the system to renegotiate SSL sessions.

Each time the session renegotiation is successful, a new connection is started. Therefore, the system attempts to renegotiate the session again, in the specified amount of time following a successful session renegotiation. For example, setting the renegotiate-period option to 3600 seconds triggers session renegotiation at least once an hour.

renegotiate-size

Specifies a throughput size, in megabytes, of SSL renegotiation. This option forces the traffic management system to renegotiate an SSL session based on the size, in megabytes, of application data that is transmitted over the secure channel. The default value is indefinite, which specifies that you do not want a throughput size.

renegotiation

Specifies whether renegotiations are enabled. The default value is enabled. When renegotiations are disabled, the system is acting as an SSL server, and a COMPAT or NATIVE cipher is negotiated, the system will abort the connection. Additionally, when renegotiations are disabled and the system is acting as an SSL client, the system will ignore the server's HelloRequest messages.

retain-certificate

APM module requires storing certificate in SSL session. When set to false, certificate will not be stored in SSL session. The default value is true.

generic-alert

Enables or disables generic-alert. The default option is enabled, which causes the SSL profile to use generic alert number. Conversely, you can specify disabled to cause SSL profile to use alert number defined in RFC5246/RFC6066 strictly.

secure-renegotiation

Specifies the secure renegotiation mode. The default value is require-strict. When secure renegotiation is set to require, any connection to an unpatched server will be aborted. For server-ssl, there is no difference between require and require-strict secure renegotiation. When secure renegotiation is set to request, connections to unpatched servers will be permitted. This setting is NOT recommended however, as it is subject to active man-in-the-middle attacks.

server-name

Specifies the server name to be included in SNI (server name indication) extension during SSL handshake in ClientHello.

session-mirroring

Enables or disables the mirroring of sessions to high availability peer. By default, this setting is disabled, which causes the system to not mirror ssl sessions.

session-ticket

Enables or disables session-ticket. The default option is disabled, which causes the SSL profile not to use session ticket

per RFC 5077. Conversely, you can specify enabled to cause SSL profile to use session ticket per RFC 5077.

sni-default

When true, this profile is the default SSL profile when the server name in a client connection does not match any configured server names, or a client connection does not specify any server name at all.

sni-require

When this option is enabled, connections to a server that does not support SNI extension will be rejected.

ssl-c3d

Enables or disables SSL Client certificate constrained delegation. The default option is disabled. Conversely, you can specify enabled to use the SSL client certificate constrained delegation.

ssl-forward-proxy

Enables or disables ssl-forward-proxy feature. The default option is disabled. Conversely, you can specify enabled to use the SSL Forward Proxy Feature.

ssl-sign-hash

Specifies SSL sign hash algorithm which is used to sign and verify SSL Server Key Exchange and Certificate Verify messages for the specified SSL profiles. The default value is sha1.

ssl-forward-proxy-bypass

Enables or disables ssl-forward-proxy-bypass feature. The default option is disabled. Conversely, you can specify enabled to use the SSL Forward Proxy Bypass Feature.

ssl-forward-proxy-verified-handshake

Specifies, when enabled, that in SSL forward proxy mode, the system should always do a TLS handshake with the server first before doing the client handshake. When disabled, the system will do the server handshake first only if it has not previously forged and cached the server certificate; once the server certificate is ready, the system will always handshake first with the client. The default value is disabled.

strict-resume

Enables or disables the resumption of SSL sessions after an unclean shutdown. The default value is disabled, which indicates that the SSL profile refuses to resume SSL sessions after an unclean shutdown.

to-folder

server-ssl profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

unclean-shutdown

Specifies, when enabled, that the SSL profile performs unclean shutdowns of all SSL connections, which means that underlying TCP connections are closed without exchanging the required SSL shutdown alerts. If you want to force the SSL profile to perform a clean shutdown of all SSL connections, you can disable this option.

untrusted-cert-response-control

Specifies the BIGIP action when the server certificate has untrusted CA. The default value is drop, which causes the connection to be dropped. Conversely, you can specify ignore to cause the connection to ignore the error and continue.

BIG-IP 2018-03-20 ltm profile server-ssl(1)

ltm profile sip

NAME

sip - Configures a Session Initiation Protocol (SIP) profile.

MODULE

ltm profile

SYNTAX

Configure the sip component within the ltm profile module using the syntax shown in the following sections.

```
CREATE/MODIFY
create sip [name]
modify sip [name]
options:
  alg-enable [disabled | enabled]
  app-service [[string] | none]
  community [ [community name] | none]
  defaults-from [ [name] | none]
  description [string]
  dialog-aware [disabled | enabled]
  dialog-establishment-timeout [integer]
  enable-sip-firewall [no | yes]
  insert-record-route-header [disabled | enabled]
  insert-via-header [disabled | enabled]
  max-media-sessions [integer]
  max-registrations [integer]
  max-sessions-per-registration [integer]
  max-size [integer]
  registration-timeout [integer]
  rtp-proxy-style [symmetric | restricted-by-ip-address | any-location]
  secure-via-header [disabled | enabled]
  security [disabled | enabled]
  sip-session-timeout [integer]
  terminate-on-bye [disabled | enabled]
  user-via-header [ [via-header] | none]
  log-publisher [log publisher name | none]
  log-profile [log profile name | none]

edit sip [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

mv sip [ [[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-name] ]
options:
  to-folder

reset-stats sip
reset-stats sip [ [ [name] | [glob] | [regex] ] ... ]

DISPLAY
list sip
list sip [ [ [name] | [glob] | [regex] ] ... ]
show running-config sip
show running-config sip [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

show sip
show sip [ [ [name] | [glob] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt

DELETE
delete sip [name]
```

DESCRIPTION

You can use the sip component to manage a SIP profile.

EXAMPLES

```
create sip my_sip_profile defaults-from sip

Creates a SIP profile named my_sip_profile using the system defaults.

create sip my_sip_profile { terminate-bye disabled }

Creates a SIP profile named my_sip_profile that leaves a connection
open following the completion of a BYE transaction.

mv sip /Common/my_sip_profile to-folder /Common/my_folder

Moves a custom sip profile named my_sip_profile to a folder named
my_folder, where my_folder has already been created and exists within
/Common.
```

OPTIONS

alg-enable
Enables or disables the SIP ALG (Application Level Gateway) feature. The default value is disabled. Note: for a SIP profile with ALG enabled to function correctly, the virtual which uses the profile must have destination and mask set to 0.0.0.0 for IPv4, or :: for IPv6. Additionally, the virtual must have source-address-translation enabled.

app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

community
Specifies the community to which you want to assign the virtual server that you associate with this profile. The default value is none.

defaults-from
Specifies the profile that you want to use as the parent profile. Your new profile inherits all of the settings and values from the specified parent profile. The default value is sip.

description
User defined description.

dialog-aware
Enables or disables the ability for the system to be aware of unauthorized use of the SIP dialog. The default value is disabled.

dialog-establishment-timeout
Indicates the timeout value for dialog establishment in a sip session. The default value is 10 seconds.

enable-sip-firewall
Indicates whether to enable SIP firewall functionality or not. Default value is no.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

insert-record-route-header
Enables or disables the insertion of a Record-Route header, which indicates the next hop for the following SIP request messages. The default value is disabled.

insert-via-header
Enables or disables the insertion of a Via header, which indicates where the message originated. The response message uses this routing information. The default value is disabled.

max-media-sessions
Indicates the maximum number of SDP media sessions that the BIG-IP system accepts. The default value is 6.

max-registrations
Indicates the maximum number of registrations, the maximum allowable REGISTER messages can be recorded that the BIG-IP system accepts. The default value is 100.

max-sessions-per-registration
Indicates the maximum number of calls or sessions can be made by a user for a single registration that the BIG-IP system accepts. The default value is 50.

max-size
Specifies the maximum SIP message size that the BIG-IP system accepts. The default value is 65535 bytes.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition
Displays the administrative partition within which the component resides.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

registration-timeout
Indicates the timeout value for a sip registration. The default value is 3600 seconds.

rtp-proxy-style
Indicates the style in which the RTP will proxy the data. When a dialog is established, the necessary SDP data needs to know where the RTP flows are directed. The default value is symmetric. The options available are:

symmetric
Indicates the use of a bidirectional related flow.

restricted-by-ip-address
Indicates the use of ephemeral listeners to support fixed client IP, listener is restricted to connections coming from a particular source.

any-location
Indicates the use of ephemeral listeners to support wildcard, connections are allowed to come from anyway.

secure-via-header
Enables or disables the insertion of a Secure Via header, which indicates where the message originated. When you are using SSL/TLS (over TCP) to create a secure channel with the server node, use this setting to configure the system to insert a Secure Via header into SIP requests. The default value is disabled.

security
Enables or disables security for the SIP profile. The default value is disabled.

sip-session-timeout
Indicates the timeout value for a sip session. The default value is 300 seconds.

terminate-on-bye
Enables or disables the termination of a connection when a BYE transaction finishes. Use this parameter with UDP connections

only, not with TCP connections. The default value is enabled.

to-folder
sip profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

user-via-header
Enables or disables the insertion of a Via header specified by a system administrator. The default value is none.

log-publisher
Specify the name of the log publisher which logs translation events. See help sys log-config for more details on the logging sub-system. Use the "sys log-config publisher" component to set up a log publisher.

log-profile
Specify the name of the ALG log profile which controls the logging of ALG. See help ltm alg-log-profile for more details on the logging profile sub-system. Use the "ltm alg-log-profile profile" component to set up a ALG log profile.

ltm profile smtp

NAME
smtp - Configures an SMTP profile.

MODULE
ltm profile

SYNTAX
Configure the smtp component within the ltm profile module using the syntax shown in the following sections. The smtp profile is available when the asm module is enabled. You enable the asm module via provisioning commands, which are described in help sys provision.

CREATE/MODIFY
create smtp [name]
modify smtp [name]
options:
app-service [[string] | none]
defaults-from [[name] | none]
description [string]
security [disabled | enabled]

edit smtp [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties

DISPLAY
list smtp
list smtp [[[name] | [glob] | [regex]] ...]
show running-config smtp
show running-config smtp [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties

DELETE
delete smtp [name]

DESCRIPTION
You can use the smtp component to create, modify, display, or delete an SMTP profile with which you can manage SMTP traffic.

EXAMPLES
create smtp my_smtp_profile defaults-from smtp

Creates a custom SMTP profile named my_smtp_profile that inherits its settings from the system default SMTP profile.

list smtp

Displays the properties of all SMTP profiles.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is smtp.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

security

Enables or disables secure SMTP traffic for the BIG-IP(r) Application Security Manager. The default value is disabled.

SEE ALSO

BIG-IP 2013-11-06 ltm profile smtp(1)

ltm profile smtps

NAME

smtps - Configures an SMTPs profile.

MODULE

ltm profile

SYNTAX

Configure the smtps component within the ltm profile module using the syntax shown in the following sections. The smtps profile is available when the asm module is enabled. You enable the asm module via provisioning commands, which are described in help sys provision.

CREATE/MODIFY

create smtps [name]

modify smtps [name]

options:

app-service [[string] | none]

defaults-from [[name] | none]

description [string]

activation-mode [none | allow | require]

edit smtps [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list smtps

list smtps [[[name] | [glob] | [regex]] ...]

show running-config smtps

show running-config smtps [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DELETE

delete smtps [name]

DESCRIPTION

You can use the smtps component to create, modify, display, or delete

an SMTPs profile with which you can manage SMTPs traffic.

EXAMPLES

```
create smtps my_smtps_profile defaults-from smtps
```

Creates a custom SMTPs profile named `my_smtps_profile` that inherits its settings from the system default SMTPs profile.

```
list smtps
```

Displays the properties of all SMTPs profiles.

OPTIONS

`app-service`

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

`defaults-from`

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is `smtp`.

`description`

User defined description.

`glob` Displays the items that match the glob expression. See help `glob` for a description of glob expression syntax.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

`activation-mode`

Sets the activation-mode for STARTTLS. The options are `NONE`, `ALLOW`, or `REQUIRE`. The default value is `NONE`.

ltm profile socks

NAME

`socks` - Configures a SOCKS profile.

MODULE

`ltm profile`

SYNTAX

Configure the `socks` component within the `ltm profile` module using the syntax shown in the following sections.

CREATE/MODIFY

```
create socks [name]
```

```
modify socks [name]
```

options:

```
protocol-versions {  
  [ [socks4] | [socks4a] | [socks5] ] ... ]  
}
```

```
dns-resolver [dns-resolver]
```

```
ipv6 [no | yes]
```

```
tunnel-name [tunnel]
```

```
route-domain [route-domain]
```

```
default-connect-handling [deny | allow]
```

```
edit socks [ [ [name] | [glob] | [regex] ] ... ]
```

options:

```
all-properties
```

```
non-default-properties
```

```
reset-stats socks
```

```
reset-stats socks [ [ [name] | [glob] | [regex] ] ... ]
```

```
DISPLAY
list socks
list socks [ [ [name] | [glob] | [regex] ] ... ]
show running-config socks
show running-config socks [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
show socks
show socks [ [ [name] | [glob] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt
  global
```

```
DELETE
delete socks [name]
```

DESCRIPTION

You can use the socks component to create, modify, display, or delete an SOCKS profile.

The BIG-IP(r) system installation includes the following default SOCKS-type profiles:

socks

The default SOCKS profile contains values for properties related to managing SOCKS traffic.

You can create a new SOCKS-type profile using an existing profile as a parent profile, and then you can change the values of the properties to suit your needs.

EXAMPLES

```
create socks my_socks_profile defaults-from socks
```

Creates a custom SOCKS profile named `my_socks_profile` that inherits its settings from the system default SOCKS profile.

OPTIONS

`protocols-versions`
Specifies the SOCKS protocol versions that are supported. The value is one or more off:

`socks4`
Specifies protocol support for SOCKS version 4.

`socks4a`
Specifies protocol support for SOCKS version 4A (like version 4, but with hostname support).

`socks5`
Specifies protocol support for SOCKS version 5 (with hostname and IPv6 support).

The default value specifies all available protocols.

`dns-resolver`
Specifies the dns-resolver object that will be used to resolve hostnames in connect requests. The default is dns-resolver.

`ipv6` Specifies the relative order of IPv4 and IPv6 DNS resolutions for URIs. The default is no, which will try a IPv4 lookup before a IPv6.

`tunnel-name`
Specifies the tunnel that will be used for outbound connect requests. This enables other virtual servers to receive connections initiated by the proxy service. The default is socks-tunnel.

`route-domain`
Specifies the route-domain that will be used for outbound connect requests. The default is 0.

`default-connect-handling`
Specifies the behavior of the proxy service for connect requests. If set to deny, connect requests will only be honored if there is another virtual server listening for the requested outbound connection. If set to allow outbound connections will be made regardless of other virtual servers. The default is deny.

ltm profile splitsessionclient

NAME
splitsessionclient - Configures a Splitsessionclient profile.

MODULE
splitsessionclient profile

SYNTAX
Configure the splitsessionclient component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY
create splitsessionclient [name]
modify splitsessionclient [name]
options:
 peer-ip
 peer-port
 http-header
 local-peer
 session-lookup-type

DISPLAY
list splitsessionclient
list splitsessionclient [[name] | [glob] | [regex]] ...]
show running-config splitsessionclient
show running-config splitsessionclient [[name] | [glob] | [regex]] ...]
options:
 all-properties
 non-default-properties
 one-line
 partition

show splitsessionclient
show splitsessionclient [[name] | [glob] | [regex]] ...]
options:
 (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
 field-fmt
 global

DELETE
delete splitsessionclient [name]

DESCRIPTION
Use this command to create, modify, display, or delete a Splitsessionclient profile.

EXAMPLES
create splitsessionclient my_splitsessionclient_profile defaults-from splitsessionclient

OPTIONS

peer-ip
Specifies the IP address of the Splitsession peer that the Out-of-band connection is made to if the splitsession peer (server) is remote. There is no default value for this field. If the peer is remote, splitsession-default-serverssl and splitsession-default-tcp profiles are used by the Splitsession client for the encrypted Out-of-band channel. If the splitsession peer is local, this value must be any.

peer-port
Specifies the port of the Splitsession peer that the Out-of-band connection is made to if the peer is remote. There is no default value for this field. If the peer is remote, splitsession-default-serverssl and splitsession-default-tcp profiles are used by the Splitsession client for the encrypted Out-of-band channel. If the splitsession peer is local, this value must be 0.

http-header
Specifies the HTTP header for signaling between the splitsession client and server. The default value is none.

local-peer
Specifies if the splitsession peer is local or remote. The default value is remote.

session-lookup-type
Specifies the session DB lookup method type, including flow, session-flow and http-header. Lookup type flow uses the 5-tuple flow key as the index to lookup the session DB, session-flow uses 5-tuple flow key plus the splitsessionclient profile name, and http-header depends on an HTTP header value. The default value is flow.

defaults-from
Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is none.

description
User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

ltm profile splitsessionserver

NAME splitsessionserver - Configures a Splitsessionserver profile.

MODULE splitsessionserver profile

SYNTAX Configure the splitsessionserver component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY

```
create splitsessionserver [name]
modify splitsessionserver [name]
```

options:

```
listen-ip
listen-port
http-header
local-peer
splitsessionclient
session-lookup-type
```

DISPLAY

```
list splitsessionserver
list splitsessionserver [ [name] | [glob] | [regex] ] ... ]
show running-config splitsessionserver
show running-config splitsessionserver [ [name] | [glob] | [regex] ] ... ]
```

options:

```
all-properties
non-default-properties
one-line
partition
```

```
show splitsessionserver
show splitsessionserver [ [name] | [glob] | [regex] ] ... ]
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
field-fmt
global
```

DELETE

```
delete splitsessionserver [name]
```

DESCRIPTION

Use this command to create, modify, display, or delete a Splitsessionserver profile.

EXAMPLES

```
create splitsessionserver my_splitsessionserver_profile defaults-from
splitsessionserver
```

OPTIONS

listen-ip

Specifies the IP address that the Splitsession server listens on for the Out-of-band connection if the splitsession client is remote. There is no default value for this field. If the peer is remote, splitsession-default-clientssl and splitsession-default-tcp profiles are used by the Splitsession server for the encrypted Out-of-band channel. If the splitsession peer is local, this value must be any.

listen-port

Specifies the port that the Splitsession server listens on for the Out-of-band connection if the splitsession client is remote. There is no default value for this field. If the peer is remote, splitsession-default-clientssl and splitsession-default-tcp profiles are used by the Splitsession server for the encrypted Out-of-band channel. If the splitsession peer is local, this value must be 0.

http-header

Specifies the HTTP header for signaling between the splitsession client and server. The default value is none.

local-peer

Specifies if the splitsession peer is local or remote. The default value is remote.

splitsessionclient

Specifies splitsessionclient profile associated with this splitsessionserver in local deployment.

session-lookup-type

Specifies the session DB lookup method type, including flow, session-flow and http-header. Lookup type flow uses the 5-tuple flow key as the index to lookup the session DB, session-flow uses 5-tuple flow key plus the splitsessionclient profile name, and http-header depends on an HTTP header value. The default value is flow.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is none.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

[ [ [name] | [glob] | [regex] ] ... ]
```

```
options:
```

```
all-properties
non-default-properties
one-line
partition
```

```
show statistics
```

```
show statistics [ [ [name] | [glob] | [regex] ] ... ]
```

```
options:
```

```
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
field-fmt
```

```
DELETE
```

```
delete statistics [all | name]
```

```
DESCRIPTION
```

You can use the statistics component to create, modify, display, or delete a Statistics profile that provides user-defined statistical counters.

```
EXAMPLES
```

```
create statistics my_stats_profile defaults-from stats
```

Creates a Statistics profile name `my_stats_profile` that inherits all settings and values from the profile `stats`.

```
list statistics my_stats
```

Displays the configuration of the profile `my_stats`.

```
list statistics my_stats field1 total_users field2 current_users field3
max_users
```

Creates a Statistics profile named `my_stats` with a total users counter in Field 1 and a current users counter in Field 2. You can then write an iRule to count the total number of connections, and record the current number of connections.

For more information about writing and using iRules(r), see the F5 Networks DevCentral web site at .

```
mv statistics /Common/my_statistics_profile to-folder /Common/my_folder
```

Moves a custom statistics profile named `my_statistics_profile` to a folder named `my_folder`, where `my_folder` has already been created and exists within `/Common`.

```
OPTIONS
```

```
app-service
```

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

```
defaults-from
```

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is `stats`.

description
User defined description.

field1 ... field32
Specifies the name of a counter. You can specify a counter for up to 32 fields. The default value for each field is none.

You can then write an iRule that uses the counter names to gather statistics about the traffic the system is processing.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition
Displays the administrative partition within which the component resides.

to-folder
statistics profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

ltm profile stream

NAME
stream - Configures a Stream profile.

MODULE
ltm profile

SYNTAX
Configure the stream component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY

create stream [name]
modify stream [name]

options:

app-service [[string] | none]
defaults-from [[name] | none]
description [string]
source [none | [string]]
target [none | [string]]
chunking-enabled [disabled | enabled]
chunk-size [integer]

edit stream [[[name] | [glob] | [regex]] ...]

options:

all-properties
non-default-properties

mv stream [[[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-

options:

to-folder

reset-stats stream

reset-stats stream [[[name] | [glob] | [regex]] ...]

DISPLAY

list stream

list stream [[[name] | [glob] | [regex]] ...]

show running-config stream

show running-config stream

[[[name] | [glob] | [regex]] ...]

options:

all-properties
non-default-properties

one-line
partition

show stream
show stream [[[name] | [glob] | [regex]] ...]
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
field-fmt
global

DELETE
delete stream [name]

DESCRIPTION

You can use the stream component to search and replace strings within a data stream, such as a TCP connection.

EXAMPLES

```
create stream my_stream_profile defaults-from stream
```

Creates a custom Stream profile named `my_stream_profile` that inherits its settings from the system default stream profile.

```
list stream all-properties
```

Displays all properties for all Stream profiles.

```
mv stream /Common/my_stream_profile to-folder /Common/my_folder
```

Moves a custom stream profile named `my_stream_profile` to a folder named `my_folder`, where `my_folder` has already been created and exists within `/Common`.

OPTIONS

`app-service`

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

`defaults-from`

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is `stream`.

`description`

User defined description.

`glob` Displays the items that match the glob expression. See help `glob` for a description of glob expression syntax.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

`partition`

Displays the administrative partition within which the component resides.

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@`[regular expression]) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

`source`

Specifies the string that you want to rewrite. The default value is none.

`target`

Specifies the new string, to replace the source string. The default value is none.

`chunking`

Specifies that the stream processor should parse incoming data in chunks. This restricts the maximum amount of additional memory needed by the stream processor. It also limits the maximum length of the value that can be matched to the `chunk-size`. The default value is disabled.

`chunk-size`

The maximum size of the parsed chunk.

`to-folder`

Stream profiles can be moved to any folder under `/Common`, but configuration dependencies may restrict moving the profile out of `/Common`.

SEE ALSO

DELETE
delete tcp [name]

```

DESCRIPTION

You can use the `tcp` component to manage TCP network traffic. Many of the options are standard `YSCTL`-types of options, while others are unique to the traffic management system. For most of the options, the default values usually meet your needs. The specific options that you might want to change are: `reset-on-timeout`, `idle-timeout`, `ip-tos-to-client`, and `link-qos-to-client`.

The system installation includes these default TCP-type profiles: `tc`, `tcp-cell-optimized`, `tcp-lan-optimized`, and `tcp-wan-optimized`. You can modify the settings of these profiles, or create new TCP-type profiles using any of these existing profiles as parent profiles.

EXAMPLES

```
create tcp my_tcp_profile defaults-from tcp
```

Creates a custom TCP profile named `my_tcp_profile` that inherits its settings from the system default `tcp` profile.

```
list tcp all-properties
```

Displays all properties for all TCP profiles

OPTIONS

`abc` When enabled, increases the congestion window by basing the increase amount on the number of previously unacknowledged bytes that each acknowledgement code (ACK) includes. The default value is enabled.

`ack-on-push`
When enabled, significantly improves performance to Microsoft(r) Windows(r) and MacOS peers, who are writing out on a very small send buffer. The default value is enabled.

`app-service`
Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

`auto-proxy-buffer-size`
Specifies, when enabled, that the system uses the network measurements to set the optimal proxy buffer size. The default value is disabled.

`auto-receive-window-size`
Specifies, when enabled, that the system uses the network measurements to set the optimal receive window size. The default value is disabled.

`auto-send-buffer-size`
Specifies, when enabled, that the system uses the network measurements to set the optimal send buffer size. The default value is disabled.

`close-wait-timeout`
Specifies the number of seconds that a connection remains in a `LAST-ACK` (last acknowledgement code) state before quitting. A value of 0 (zero) represents a term of forever (or until the `maxrtx` of the `FIN` state). The default value is 5 seconds.

`cmetrics-cache`
Specifies, when enabled, the default value, that the system uses a cache for storing congestion metrics.

`cmetrics-cache-timeout`
Specifies the time, in seconds, for which entries in the

congestion metrics cache are valid. The default value is 0, which defers to the sys db variable route.metrics.timeout.

congestion-control

Specifies the algorithm to use to share network resources among competing users to reduce congestion. The default value is high-speed.

The options are:

cdg Specifies that the system use a Caia Delay-Gradient congestion control algorithm, where congestion inferences are made based on a gradient of RTT over time. Improves inferences made about packet loss and whether they are due to congestion or other factors. The use of a shadow window improves coexistence with loss-based TCP flows.

chd Specifies that the system use a Caia-Hamilton delay-based congestion control algorithm, where delay-based congestion window operations are performed only once per RTT. Tolerates packet losses that are likely to be unrelated to congestion. Uses a shadow window to help regain lost transmission opportunities when competing with loss-based TCP flows.

cubic Specifies that the system uses a component optimized for high latency, high bandwidth connections as the TCP congestion control algorithm.

high-speed

Specifies that the system uses a more aggressive, loss-based algorithm.

illinois

Specifies that the system uses a hybrid of both delay and loss as the TCP congestion control algorithm.

new-reno

Specifies that the system uses a modification to the Reno algorithm that responds to partial acknowledgements when SACKs are unavailable.

none

Specifies that the system does not use a network-congestion-control mechanism, even when congestion occurs.

reno

Specifies that the system uses an implementation of the TCP Fast Recovery algorithm, which is based on the implementation in the BSD Reno release.

scalable

Specifies that the system uses a TCP algorithm modification that adds a scalable, delay-based and loss-based component into the Reno algorithm.

vegas

Specifies that the system uses a delay-based component as the TCP congestion control algorithm.

westwood

Specifies that the system uses the Westwood+ bandwidth estimation component as the TCP congestion control algorithm.

woodside

Specifies that the system uses a hybrid of both delay and loss as the TCP congestion control algorithm.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile. The default value is tcp.

deferred-accept

Specifies, when enabled, that the system defers allocation of the connection chain context until the system has received the payload from the client. This option is useful for dealing with 3-way handshake denial-of-service (DOS) attacks. The default value is disabled.

delay-window-control

When enabled, the system uses an estimate of queueing delay as a measure of congestion, in addition to the normal loss-based control, to control the amount of data sent. The default value is disabled.

delayed-acks

Specifies, when enabled, the default value, that the traffic management system allows coalescing of multiple acknowledgement (ACK) responses.

description

User defined description.

dsack

When enabled, specifies the use of the SACK option to acknowledge duplicate segments. The default is disabled.

early-retransmit

Specifies, when enabled, that the system uses early retransmit recovery (as specified in RFC 5827) to reduce the recovery time for connections that are receive-buffer or user-data limited. The default value is disabled.

ecn Specifies, when enabled, that the system uses the TCP flags CWR and ECE to notify its peer of congestion and congestion counter-

measures. The default value is disabled.

enhanced-loss-recovery
Specifies whether the system uses enhanced loss recovery to recover from random packet losses more effectively. The default value is disabled.

fast-open
Specifies, when enabled, that the system supports TCP Fast Open, which allows a client to include the first packet of data with the SYN to reduce latency. The default value is disabled. This option has no effect on server-side TCP profiles.

fast-open-cookie-expiration
Specifies the number of seconds that a "Fast Open Cookie" delivered to a client is valid for SYN packets from that client. The default value is 21600 seconds (6 hours). A value of 0 (zero) means use the default. The maximum value is 1000000 seconds.

fin-wait-timeout
Specifies the number of seconds that a connection is in the FIN-WAIT-1 or closing state before quitting. The default value is 5 seconds. A value of 0 (zero) represents a term of forever (or until the maxrtx of the FIN state).

fin-wait-2-timeout
Specifies the number of seconds that a connection is in the FIN-WAIT-2 state before quitting. The default value is 300 seconds. A value of 0 (zero) represents a term of forever (or until the maxrtx of the FIN state).

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

hardware-syn-cookie
This option is deprecated in version 13.0.0 and is replaced by syn-cookie-enable. Specifies whether or not to use hardware SYN Cookie when cross system limit. The default value is disabled.

idle-timeout
Specifies the number of seconds that a connection is idle before the connection is eligible for deletion. The default value is 300 seconds.

init-cwnd
Specifies the initial congestion window size for connections to this destination. The actual window size is this value multiplied by the MSS (Maximum Segment Size) for the same connection. The default value is 3. The range is from 0 to 64.

init-rwnd
Specifies the initial receive window size for connections to this destination. The actual window size is this value multiplied by the MSS (Maximum Segment Size) for the same connection. The default value is 3. The range is from 0 to 64.

ip-df-mode
Describe the IP Header Don't Fragment (DF) bit setting in the outgoing TCP packet. The available settings are: Pmtu: Set the outgoing IP Header DF bit based on IP pmtu setting(tm.pathmtudiscovery). Preserve: Set the outgoing Packet's IP Header DF bit to be same as incoming IP Header DF bit. Set: Set the outgoing packet's IP Header DF bit. Clear: Clear the outgoing packet's IP Header DF bit. The default setting is Preserve.

ip-ttl-mode
Describe the outgoing TCP packet's IP Header TTL mode. The available Modes are: Proxy: Set the outgoing IP Header TTL value to 255/64 for ipv4/ipv6 respectively. Preserve: Set the outgoing IP Header TTL value to be same as the incoming IP Header TTL value. Decrement: Set the outgoing IP Header TTL value to be one less than the incoming TTL value. Set: Set the outgoing IP Header TTL value to a specific value(as specified by ip-ttl-v[4|6]). The default mode is Proxy.

ip-ttl-v4
Specify the outgoing packet's IP Header TTL value for IPv4 traffic. Maximum TTL value that can be specified is 255. The default is 255.

ip-ttl-v6
Specify the outgoing packet's IP Header TTL value for IPv6 traffic. Maximum TTL value that can be specified is 255. The default is 64.

ip-tos-to-client
Specifies the Type of Service (ToS) level that the traffic management system assigns to TCP packets when sending them to clients. The default value is 0 (zero).

keep-alive-interval
Specifies the keep-alive probe interval, in seconds. The default value is 1800 seconds.

limited-transmit
Specifies, when enabled, the default value, that the system uses limited transmit recovery revisions for fast retransmits (as specified in RFC 3042) to reduce the recovery time for connections on a lossy network.

link-qos-to-client
Specifies the Link Quality of Service (QoS) level that the system assigns to TCP packets when sending them to clients. The default

value is 0 (zero).

max-retrans

Specifies the maximum number of retransmissions of data segments that the system allows. The default value is 8.

md5-signature

Specifies, when enabled, that the system uses RFC2385 TCP-MD5 signatures to protect TCP traffic against intermediate tampering. The default value is disabled.

md5-signature-passphrase

Specifies a plain text passphrase which may be between 1 and 80 characters in length, and is used in a shared-secret scheme to implement the spoof-prevention parts of RFC2385. The default value is none.

minimum-rto

Specifies the minimum TCP retransmission timeout in milliseconds. The default value is 1000 milliseconds.

mptcp

Specifies, when enabled, that the system will accept MPTCP connections. When passthrough MPTCP connections are not terminated by this virtual. The default value is disabled.

mptcp-csum

Specifies, when enabled, that the system will calculate the checksum for MPTCP connections. The default value is disabled.

mptcp-csum-verify

Specifies, when enabled, that the system verifies checksum for MPTCP connections. The default value is disabled.

mptcp-debug

This option is DEPRECATED v12.0.0 onwards and is maintained here for backward compatibility reasons. Specifies, when enabled, that the system provides debug logs and statistics for MPTCP connections. The default value is disabled.

mptcp-fallback

Specifies, MPTCP fallback mode. The default value is reset.

The options are:

accept

Specifies accept on fallback.

active-accept

Specifies active accept on fallback.

reset

Specifies that the connection is reset on fallback.

retransmit

Specifies retransmit on fallback.

mptcp-join-max

Specifies the max number of MPTCP connections that can join to given one. The default value is 5.

mptcp-nojoindssack

Specifies, when enabled, no DSS option is sent on the JOIN ACK. The default value is disabled.

mptcp-rtomax

Specifies, the number of RTOs before declaring subflow dead. The default value is 5.

mptcp-rxmitmin

Specifies the minimum value (in msec) of the retransmission timer for these MPTCP flows. The default value is 1000.

mptcp-subflowmax

Specifies the maximum number of MPTCP subflows for a single flow. The default value is 6.

mptcp-makeafterbreak

Specifies, when enabled, that make-after-break functionality is supported, allowing for long-lived MPTCP sessions. The default value is disabled.

mptcp-timeout

Specifies, the timeout value to discard long-lived sessions that do not have an active flow, in seconds. The default value is 3600.

mptcp-fastjoin

Specifies, when enabled, FAST join, allowing data to be sent on the MP_JOIN SYN, which can allow a server response to occur in parallel with the JOIN. The default value is disabled.

nagle

Specifies, when enabled, that the system applies Nagle's algorithm to reduce the number of short segments on the network. The default value is disabled. When auto, the use of Nagle's algorithm is decided based on network conditions.

Note that for interactive protocols such as Telnet, rlogin, or SSH, F5 Networks recommends disabling this setting on high-latency networks, to improve application responsiveness.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition
Displays the administrative partition within which the profile resides.

pkt-loss-ignore-burst
Specifies the probability of performing congestion control when multiple packets in a row are lost, even if the `pkt-loss-ignore-rate` was not exceeded. Valid values are 0 (zero) through 32. The default value is 0 (zero), which means that the system performs congestion control, if any packets are lost. Higher values decrease the chance of performing congestion control.

pkt-loss-ignore-rate
Specifies the threshold of packets lost per million at which the system should perform congestion control. Valid values are 0 (zero) through 1,000,000. The default value is 0 (zero), which means that the system performs congestion control, if any packet loss occurs. If you set the ignore rate to 10 and packet loss for a TCP connection is greater than 10 per million, congestion control occurs.

proxy-buffer-high
Specifies the highest level at which the receive window is closed. The default value is 49152.

proxy-buffer-low
Specifies the lowest level at which the receive window is closed. The default value is 32768.

proxy-mss
Specifies, when enabled, that the system advertises the same mss to the server as was negotiated with the client. The default value is enabled.

proxy-options
Specifies, when enabled, that the system advertises an option, such as a time-stamp to the server only if it was negotiated with the client. The default value is enabled.

push-flag
When default, specifies that the system sets PUSH flag when sending the last segment in the send buffer. When none, specifies that the system never sets PUSH flag for TCP packets. When one, specifies that the system sets one PUSH flag for the FIN segment. When auto, specifies that the system sets PUSH flag based on the application/network conditions. The default value is default.

rate-pace
Specifies, when enabled, that the system will rate pace TCP data transmissions. The default value is disabled.

rate-pace-max-rate
If not 0, sets the maximum rate in bytes per second that TCP data transmission will be paced to. If set to 0, no maximum is enforced. The default value is 0.

receive-window-size
Specifies the size of the receive window, in bytes. The default value is 65535 bytes.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See `help regex` for a description of regular expression syntax.

reset-on-timeout
Specifies whether to reset connections on timeout. The default value is enabled.

rexmt-thresh
Specifies the number of duplicate ACKs (retransmit threshold) to start fast recovery. The default value is 3. The range is from 3 to 255.

selective-acks
Specifies, when enabled, the default value, that the system negotiates RFC2018-compliant Selective Acknowledgements with peers.

selective-nack
Specifies whether Selective Negative Acknowledgment is enabled or disabled. The default value is enabled.

send-buffer-size
Specifies the size of the buffer, in bytes. The default value is 65535 bytes.

slow-start
Specifies, when enabled, the default value, that the system uses larger initial window sizes (as specified in RFC 3390) to help reduce round trip times. Note that disabling this attribute causes the setting for `cmetrics-cache` to be ignored.

syn-cookie-enable
Specifies the default (if no DoS profile is associated) number of embryonic connections that are allowed on any virtual server, before SYN Cookie challenges are enabled for that virtual server. The default is enabled.

syn-cookie-whitelist
Specifies whether or not to use a SYN Cookie WhiteList when doing software SYN Cookies. This means not doing a SYN Cookie for the same src IP address if it has been done already in the previous

tm.flowstate.timeout (30) seconds. The default value is disabled.

syn-max-retrans
Specifies the maximum number of retransmissions of SYN segments that the system allows. The default value is 3.

syn-rto-base
Specifies the initial RTO (Retransmission TimeOut) base multiplier for SYN retransmission, in milliseconds. This value is modified by the exponential backoff table to select the interval for subsequent retransmissions. The default value is 3000.

tail-loss-probe
Specifies whether the system uses tail loss probe to reduce the number of retransmission timeouts. The default value is disabled.

tcp-options
Specifies the option numbers that will be accessible from iRules (TCP::option) for the flow. The format of each entry should be:
"{

ltm profile tcpanalytics

NAME
tcp-analytics - Configures a TCP Analytics profile.

MODULE
ltm profile

SYNTAX
Configure the tcp-analytics component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY
create tcp-analytics [name]
modify tcp-analytics [name]
options:
collected-by-client-side [disabled | enabled]

field-fmt
global

DELETE
delete tcp-analytics [name]

DESCRIPTION

You can use the tcp-analytics component to generate detailed TCP statistics for virtuals that have a TCP or FastL4 profile, if AVR is provisioned. The options specify where the data is collected and stored, and which connection identifiers ("entities") users can query the data with.

In general, storing more entities increases the ability to drill down to specific connections. However, if AVR hits its memory limits it will begin to aggregate new connections and reduce this resolution. If a virtual serves a very high number of IP addresses, for example, it is best to store data using collect-remote-host-subnet, or use the TCP::analytics iRule to enhance collection for a set of IP addresses of

interest.

The system installation includes the default profile tcp-analytics. You can modify the settings of this profile, or create new TCP analytics profiles using it as a parent profile.

EXAMPLES

```
create ltm profile tcp-analytics my_tcpanalytics_profile defaults-from tcp-analytics
```

Creates a custom TCP profile named my_tcpanalytics_profile that inherits its settings from the system default tcp-analytics profile.

```
list ltm profile tcp-analytics all-properties
```

Displays all properties for all TCP profiles

OPTIONS

collected-by-client-side

When enabled, client side connections collect TCP analytics data unless directed otherwise by iRule. If false, client side connections only collect data if directed by iRule. The default value is enabled.

collected-by-server-side

When enabled, server side connections collect TCP analytics data unless directed otherwise by iRule. If false, server side connections only collect data if directed by iRule. The default value is disabled.

collected-stats-external-logging

When enabled, TCP statistics are logged on a remote machine determined by external-logging-publisher. The default value is disabled.

collected-stats-internal-logging

When enabled, TCP statistics are logged on the local BIG-IP. The default value is enabled.

collect-city

When enabled, AVR stores the city (from the GeoIP database) for the remote IP address of the connection with TCP statistics. See SOL11176 on support.f5.com for more on GeoIP. The default value is disabled.

collect-continent

When enabled, AVR stores the continent (from the GeoIP database) for the remote IP address of the connection with TCP statistics. See SOL11176 on support.f5.com for more on GeoIP. The default value is enabled.

collect-country

When enabled, AVR stores the country (from the GeoIP database) for the remote IP address of the connection with TCP statistics. See SOL11176 on support.f5.com for more on GeoIP. The default value is enabled.

collect-nexthop

When enabled, AVR stores the nexthop ethernet address of the connection with TCP statistics. The default value is disabled.

collect-post-code

When enabled, AVR stores the postcode (from the GeoIP database) for the remote IP address of the connection with TCP statistics. See SOL11176 on support.f5.com for more on GeoIP. The default value is disabled.

collect-region

When enabled, AVR stores the region (from the GeoIP database) for the remote IP address of the connection with TCP statistics. See SOL11176 on support.f5.com for more on GeoIP. The default value is disabled.

collect-remote-host-ip

When enabled, AVR stores the remote host IP address with TCP statistics. The default value is disabled.

collect-remote-host-subnet

When enabled, AVR stores the remote host IP subnet (24-bit) with TCP statistics. The default value is enabled.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile. The default value is tcp-analytics.

description

User defined description.

external-logging-publisher

The name of the publisher to accept external logging.

show running-config tftp [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties
one-line
partition

DELETE
delete tftp [name]

DESCRIPTION
Use this command to create, modify, display, or delete an TFTP profile with which you can manage TFTP traffic.

EXAMPLES
create tftp my_tftp_profile defaults-from tftp
Creates a custom TFTP profile named my_tftp_profile that inherits its settings from the system default TFTP profile.
list tftp
Displays the properties of all TFTP profiles.
mv tftp /Common/my_tftp_profile to-folder /Common/my_folder
Moves a custom tftp profile named my_tftp_profile to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS
app-service
Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.
defaults-from
Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is tftp.
description
User defined description.
glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.
name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition
Displays the administrative partition within which the component resides.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

to-folder
tftp profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

idle-timeout
Specifies an idle timeout in seconds. This setting specifies the number of seconds that a connection is idle before the connection is eligible for deletion. The default value is 300 seconds.

log-publisher
Specify the name of the log publisher which logs translation events. See help sys log-config for more details on the logging sub-system. Use the "sys log-config publisher" component to set up a log publisher.

log-profile
Specify the name of the ALG log profile which controls the logging of ALG events. See help ltm alg-log-profile for more details on the logging profile sub-system. Use the "ltm alg-log-profile profile" component to set up an ALG log profile.

ltm profile traffic-acceleration

NAME
traffic-acceleration - Configures a Traffic Acceleration profile.

MODULE
ltm profile

SYNTAX
Configure the traffic-acceleration component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY
create traffic-acceleration [name]
modify traffic-acceleration [name]
options:
 app-service [[string] | none]
 defaults-from [[name] | none]
 description [string]
 idle-timeout [integer]
 tcp-handshake-timeout [integer]
 time-wait-timeout [integer]

edit traffic-acceleration [[name] | [regex]]
options:
 all-properties
 non-default-properties

reset-stats traffic-acceleration
reset-stats traffic-acceleration [[name] | [regex]]

DISPLAY
list traffic-acceleration
list traffic-acceleration [[name] | [regex]]
show running-config traffic-acceleration
show running-config traffic-acceleration [[name] | [regex]]
options:
 all-properties
 non-default-properties
 one-line
 partition

show traffic-acceleration

```
show traffic-acceleration [ [name] | [regex] ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt
  global
```

```
DELETE
delete traffic-acceleration [name]
```

DESCRIPTION

You can use this component to create, modify, display, or delete a Traffic Acceleration profile.

Any changes you make to an active Traffic Acceleration profile (one that is in use by a virtual server) take effect after the value of the idle-timeout option has passed. That means new connections are affected by the profile change immediately. However, for the new values to take effect, old connections need to be either aged out or closed.

EXAMPLES

```
create traffic-acceleration my_profile defaults-from traffic-
acceleration
```

Creates a custom Traffic Acceleration profile named my_profile that inherits its settings from the system default Traffic Acceleration profile.

```
show traffic-acceleration
```

Displays statistics for all Traffic Acceleration profiles.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is traffic-acceleration.

description

User defined description.

idle-timeout

Specifies the number of milliseconds that a connection is idle before the connection is eligible for deletion. The default value is five minutes or 300000 milliseconds. Minimum is 0 meaning the connection does not timeout. The maximum is 2147483647 (0x7FFFFFFF) milliseconds.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

tcp-handshake-timeout

Specifies a TCP handshake timeout in milliseconds. The default value is 5000 milliseconds. Minimum is 0 meaning there is no timeout. The maximum is 65535 milliseconds.

time-wait-timeout

Specifies a TCP time wait timeout in milliseconds. The default value is 2000 milliseconds. The minimum is 1 millisecond. The maximum is 65535 milliseconds.

SEE ALSO

```

ltm profile udp

NAME

udp - Configures a User Datagram Protocol (UDP) profile.

```

MODULE
    ltm profile

SYNTAX
    Configure the udp component within the ltm profile module using the
    syntax shown in the following sections.

CREATE/MODIFY
create udp [name]
modify udp [name]
options:
    allow-no-payload [disabled | enabled]
    app-service [[string] | none]
    buffer-max-bytes [integer]
    buffer-max-packets [integer]
    datagram-load-balancing [disabled | enabled]
    defaults-from [[name] | none]
    description [string]
    idle-timeout [immediate | indefinite | integer]
    ip-tos-to-client [[integer] | pass-through]
    link-qos-to-client [[integer] | pass-through]
    no-checksum [disabled | enabled]
    proxy-mss [disabled | enabled]
    ip-ttl-mode [proxy | preserve | decrement | set]
    ip-ttl-v4 [integer]
    ip-ttl-v6 [integer]
    ip-df-mode [pmtu | preserve | set | clear]
    send-buffer-size [integer]

edit udp [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties

mv udp [ [[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-name]
options:
    to-folder

reset-stats udp
reset-stats udp [ [ [name] | [glob] | [regex] ] ... ]

DISPLAY
list udp
list udp [ [ [name] | [glob] | [regex] ] ... ]
show running-config udp
show running-config udp
[ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties
    one-line
    partition

show udp
show udp [ [ [name] | [glob] | [regex] ] ... ]
options:
    (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
    field-fmt
    global

DELETE
delete udp [name]

DESCRIPTION
    You can use the udp component to manage UDP network traffic.

EXAMPLES
create udp my_udp_profile defaults-from udp

Creates a custom UDP profile named my_udp_profile that inherits its
settings from the system default UDP profile.

list udp all-properties

Displays all properties for all UDP profiles.

mv udp /Common/my_udp_profile to-folder /Common/my_folder

Moves a custom udp profile named my_udp_profile to a folder named
my_folder, where my_folder has already been created and exists within
/Common.

OPTIONS
    allow-no-payload
    Provides the ability to allow the passage of datagrams that
    contain header information, but no essential data. The default is
    disabled.

    app-service
    Specifies the name of the application service to which the profile
    belongs. The default value is none. Note: If the strict-updates
    option is enabled on the application service that owns the object,
    you cannot modify or delete the profile. Only the application
    service can modify or delete the profile.

    buffer-max-bytes
    Specifies ingress buffer byte limit. The default value is 655350.
    Maximum allowed value is 16777215.

    buffer-max-packets
    Specifies ingress buffer packet limit. The default value is 0.
    Maximum allowed value is 255.

    datagram-load-balancing

```

Provides the ability to load balance UDP datagram by datagram. The default is disabled.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile. The default value is udp.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

idle-timeout

Specifies the number of seconds that a connection is idle before the connection is eligible for deletion. The default value is 60 seconds.

ip-tos-to-client

Specifies the Type of Service level that the traffic management system assigns to UDP packets when sending them to clients. The default value is 0 (zero).

ip-ttl-mode

Describe the outgoing UDP packet's TTL mode. Modes are: Proxy: Set the IP TTL of ipv4 to the default value of 255 and ipv6 to the default value of 64. Preserve: Set the IP TTL to the original packet TTL value. Decrement: Set the IP TTL to the original packet TTL value minus 1. Set: Set the IP TTL with the specified values in ip-ttl-v4 and ip-ttl-v6 values in the same profile.

ip-df-mode

Describe the Don't Fragment (DF) bit setting in the outgoing UDP packet. Pmtu: Set the outgoing UDP packet DF bit based on the ip pmtu setting. Preserve: Preserve the incoming UDP packet Don't Fragment bit. Set: Set the outgoing UDP packet DF bit. Clear: Clear the outgoing UDP packet DF bit.

link-qos-to-client

Specifies the Quality of Service level that the system assigns to UDP packets when sending them to clients. The default value is 0 (zero).

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

no-checksum

Enables or disables checksum processing. Note that if the datagram is IPv6, the system always performs checksum processing. The default value is disabled.

partition

Displays the administrative partition within which the profile resides.

proxy-mss

Specifies, when enabled, that the system advertises the same mss to the server as was negotiated with the client. The default value is disabled.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

send-buffer-size

Specifies send buffer byte limit. The default value is 655350. The range is from 536 to 16777215.

to-folder

udp profiles can be moved to any folder under /Common, but configuration dependencies may restrict moving the profile out of /Common.

    (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
    field-fmt
    global

  DELETE
delete web-acceleration [name]

```

DESCRIPTION

You can use the web-acceleration component to create, modify, display, or delete an Web Acceleration profile.

The BIG-IP(r) system installation includes the following default Web Acceleration-type profiles:

```

web-acceleration
optimized-caching
optimized-acceleration

```

The default Web Acceleration profile contains values for properties related to managing WA Cache.

You can create a new Web Acceleration-type profile using an existing profile as a parent profile, and then you can change the values of the properties to suit your needs.

EXAMPLES

```

create web-acceleration my_wa_profile defaults-from web-acceleration

```

Creates a custom Web Acceleration profile named `my_wa_profile` that inherits its settings from the system default Web Acceleration profile.

OPTIONS

`applications`

Configures a list of applications assigned to this profile. Assigning at least one application enables WA functionality. The default value of none specifies that WA is not enabled.

`app-service`

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

`cache-aging-rate`

Specifies how quickly the system ages a cache entry. The aging rate ranges from 0 (slowest aging) to 10 (fastest aging). The default value is 9.

`cache-client-cache-control-mode`

Specifies which cache disabling headers sent by clients the system ignores. The default value is all.

`cache-insert-age-header`

When enabled, inserts Age and Date headers in the response. The default value is enabled.

`cache-max-age`

Specifies how long the system considers the cached content to be valid. The default value is 3600 seconds.

`cache-max-entries`

Specifies the maximum number of entries that can be in the WA cache. The default value is 10000.

`cache-object-max-size`

Specifies the largest object that the system considers eligible for caching. The default value is 50000 bytes.

`cache-object-min-size`

Specifies the smallest object that the system considers eligible for caching. The default value is 500 bytes.

`cache-size`

Specifies the maximum size, in megabytes, for the WA cache. When the cache reaches the maximum size, the system starts removing the oldest entries. The default value is 100 megabytes.

`cache-uri-exclude`

Configures a list of Uniform Resource Identifiers (URIs) to

exclude from the WA Cache. The default value is none and specifies that no URI will be excluded.

cache-uri-include

Configures a list of URIs that are cacheable. The default value is .* and specifies that all URIs are cacheable.

cache-uri-include-override

Configures a list of URIs that should be cached in the WA cache even though they would normally not be cached due to constraints defined by cache-object-max-size or others. The default value is none. URIs on the cache-uri-include-override list are cacheable even if they are not on the cache-uri-include list.

cache-uri-pinned

Configures a list of URIs that are kept in the WA cache regardless their max-age or expiry settings. The default value is none. URIs on the cache-uri-pinned list are cacheable even if they are not on the cache-uri-include list.

metadata-cache-max-size

Specifies the maximum size of the metadata cache. The metadata cache applies only when there is an application applied to the profile, and does not include the content cache.

defaults-from

Configures the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is webacceleration.

description

User defined description.

partition

Displays the administrative partition within which the profile resides.

partition

DELETE

delete web-security [name]

DESCRIPTION

You can use the web-security component to create, modify, display, or

delete an Web Security profile.

The BIG-IP(r) system installation includes the following default Web Security-type profiles:

websecurity

The default Web Security profile contains values for properties related to managing web security.

You can create a new Web Security-type profile using an existing profile as a parent profile, and then you can change the values of the properties to suit your needs.

EXAMPLES

```
create web-security my_asm_profile defaults-from web-security
```

Creates a custom Web Security profile named `my_asm_profile` that inherits its settings from the system default Web Security profile.

OPTIONS

`defaults-from`

Configures the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is none.

`partition`

Displays the administrative partition within which the profile resides.

SEE ALSO

ltm profile websocket

NAME

websocket - Configures a WebSocket protocol profile.

MODULE

websocket profile

SYNTAX

Configure the websocket component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY

```
create websocket [name]
modify websocket [name]
options:
  masking [preserve | unmask | remask | selective]
```

DISPLAY

```
list websocket
list websocket [ [ [name] | [glob] | [regex] ] ... ]
show running-config websocket
show running-config websocket [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
show websocket
show websocket [ [ [name] | [glob] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt
  global
```

DELETE

```
delete websocket [name]
```

DESCRIPTION

Use this command to create, modify, display, or delete a WebSocket profile.

EXAMPLES

```
create websocket my_websocket_profile defaults-from websocket
```

OPTIONS

masking
Specifies the masking operation for WebSocket frames.

preserve
Maintains the mask of the packet received from the client.

unmask
Removes the mask from the packet and remasks it using the same mask when sending the traffic to the server.

remask
Removes the mask received from the client and the system generates a new, random mask when sending the traffic to the server.

selective
Preserves the mask of the packet received, and makes no changes unless an Application Security Policy is associated with the virtual server.

defaults-from
Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is none.

description
User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

create, delete, edit, glob, list, ltm profile fasthttp, ltm virtual, modify, regex, reset-stats, show, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2016-03-14 ltm profile websocket(1)

ltm profile xml

NAME

xml - Configures an XML profile.

MODULE

ltm profile

SYNTAX

Configure the xml component within the ltm profile module using the syntax shown in the following sections.

CREATE/MODIFY

```
create xml [name]
modify xml [name]
options:
  app-service [[string] | none]
  defaults-from [ [name] | none]
  description [string]
  namespace-mappings [ [none] |
[ { { mapping-namespace namespace1 mapping-prefix prefix1 } } ]
  xpath-queries [ none |
[ add | delete | replace_all_with { queries } ] ]
  multiple-query-matches [enabled | disabled]
```

```
edit xml [ [ [name] | [glob] | [regex] ] ... ]
```

options:

all-properties
non-default-properties

```
mv xml [ [[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-name]
```

options:

to-folder

DISPLAY

```
list xml
list xml [ [ [name] | [glob] | [regex] ] ... ]
show running-config xml
show running-config xml [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
DELETE
delete xml [name]
```

DESCRIPTION

Use this command to create, modify, display, or delete an XML profile with which you can use XML functionality.

EXAMPLES

```
create xml my_xml_profile defaults-from xml
```

Creates a custom XML profile named `my_xml_profile` that inherits its settings from the system default XML profile.

```
list xml
```

Displays the properties of all XML profiles.

```
mv xml /Common/my_xml_profile to-folder /Common/my_folder
```

Moves a custom xml profile named `my_xml_profile` to a folder named `my_folder`, where `my_folder` has already been created and exists within `/Common`.

OPTIONS

`app-service`
Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

`defaults-from`
Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is `xml`.

`description`
User defined description.

`glob` Displays the items that match the glob expression. See help `glob` for a description of glob expression syntax.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

`partition`
Displays the administrative partition within which the component resides.

`namespace-mappings`
Specifies a list of mappings between namespaces and prefixes to be used in the XPath queries of the profile.

`regex`
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

`to-folder`
xml profiles can be moved to any folder under `/Common`, but configuration dependencies may restrict moving the profile out of `/Common`.

`xpath-queries`
Specifies the list of XPath queries that are used by the profile. A match of any of the queries will trigger the `XML_CONTENT_BASED_ROUTING iRule` event.

`multiple-query-matches`
Enables or disables multiple matches for a single XPath query.

SEE ALSO

`create`, `delete`, `edit`, `glob`, `list`, `ltm virtual`, `modify`, `mv`, `regex`, `reset-stats`, `show`, `tmsb`

COPYRIGHT

ltm rule-profiler

MODULE
ltm

SYNTAX
Configure the rule-profiler component within the ltm module using the syntax shown in the following sections.

CREATE/MODIFY
create rule-profiler [name]
modify rule-profiler [[name] ...]

DISPLAY
list rule-profiler
list rule-profiler [[[name] | [glob] | [regex]] ...]

DELETE
delete rule-profiler [name]

HELP help rule-profiler
DESCRIPTION

You can use the rule-profiler component to configure execution tracing of iRules attached to virtual servers. A rule-profiler comprises a set of matching filters that help limit the profiling information output, a log publisher that directs the output to the intended destination and properties for controlling the state of the profiler and the amount of time the profiler will be active for.

EXAMPLES

```
list rule-profiler
```

Displays all iRule Profiler objects.

```
delete rule-profiler my_profiler
```

Deletes the iRule Profiler named my_profiler.

```
rule-profiler my_profiler {  
vs-filter { vs_test }  
rule-filter { rl http }  
event-filter { HTTP_REQUEST }
```

```
period 1000  
publisher my_tracer_pub  
occ-mask 30  
state disabled  
}
```

Creates an iRule Profiler named my_profiler.

```
modify rule-profiler my_profiler state enabled
```

Enables the rule-profiler causing matching profiling occurrences to be published by the publisher associated with the rule-profiler.

OPTIONS

description
User defined description.

period
Specifies the period (in milliseconds) that a rule-profiler can be active for. When set to 0, the profiler is disabled. Default value is 0.

state
Specifies the state of the rule-profiler. When set to enabled and the profiler consequently started, matching occurrence records are emitted via the configured log publisher. Default value is disabled.

start
Start profiling. After this command, at the point of the first filter match, profiling and timer counting start.

stop Stop profiling. After this command, the profiling stops.

vs-filter
Specifies the name of virtual server(s) for which occurrence records can be emitted. If this property is left empty, all virtual servers will be considered a match. Default is empty list.

rule-filter
Specifies the name of iRule(s) for which occurrence records can be emitted. If this property is left empty, all executing iRules will be considered a match. Default is empty list.

event-filter
Specifies the name of iRule Events for which occurrence records can be emitted. If this property is left empty, all iRule Events will be considered a match. Default is empty list.

occ-mask
Specifies the types of occurrences of interest to the user. This is a value set comprised by adding the desired occurrence type. The types are defined as follows:

o event

Specifies that profiling information is emitted at the entry point to the TCL subsystem, as close as possible to the occurrence of the external event, and at completion of the execution, just before the TCL subsystem returns to the LTM profile/filter code.

- o rule

Specifies that profiling information is emitted at the entry point to the execution of a single iRule handler for the event, and once the TCL VM completes execution of the single event handler. This bit is useful when there are multiple rules handling the same event.

- o rule-vm

Specifies that profiling information is emitted once the TCL VM is about to execute the byte code for an iRule script, and once it completed executing the byte code.

- o cmd-vm

Specifies that profiling information is emitted when the TCL VM is beginning the internal setup preceding the invocation of a TCL command (eg. HTTP::uri) and once the internal setup is being torn down.

- o cmd

Specifies that profiling information is emitted once the TCL VM is about to invoke a TCL command (eg. HTTP::uri) and once the command execution completes.

- o var-mod

Specifies that profiling information is emitted when the TCL VM is changing the value of an iRule variable.

- o bytecode

Specifies that profiling information is emitted when the TCL VM is executing a byte code instruction.

SEE ALSO

create, delete, list, modify, tmsh

BIG-IP 2017-05-12 ltm rule-profiler(1)

ltm rule

NAME

rule - Configures an iRule for traffic management system configuration.

MODULE

ltm

SYNTAX

Configure the rule component within the ltm module using the syntax shown in the following sections.

CREATE/MODIFY

```
create rule [name]
edit rule [name]
modify rule [ [name] | [glob] | [regex] ] ... ]
```

Note: When using tmsh, you can only create iRules using the editor, which starts when you use the create or edit commands. You cannot create an iRule directly on the command line. The vim editor applies the autoindent and smartindent options. You can toggle on/off paste mode using the F12 key.

Note: You can also edit user metadata associated with an iRule. See the example section for more information.

DISPLAY

```
list rule
list rule [ [name] | [glob] | [regex] ] ... ]
show running-config rule
show running-config rule [ [name] | [glob] | [regex] ] ... ]
options:
all-properties
```

non-default-properties

```
show rule
show rule [ [ [name] | [glob] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt
```

```
mv rule [ [[source-name] [destination-name]] | [[name] to-folder [folder-name]] | [[name...name] to-folder [folder-name]] ]
options:
  to-folder
```

```
DELETE
delete rule [name]
```

```
GENERATE
generate rule [name]
options:
  checksum
  signature
```

```
HELP help rule help rule [ command | event | namespace ] [name]
DESCRIPTION
```

You cannot edit the system rules that come with the BIG-IP system. However, you can open a system rule in the editor and use it as a template to create a new rule.

To create a new rule using a system rule as a template:

1. Enter the command sequence `edit rule [system rule name]`. `tmsh` opens the system rule in an editor.
 2. Change the name of the rule in the editor.
 3. Edit the rule and exit the editor.
- `tmsh` checks for syntax errors, and if there are none, it saves the new rule.

For more information about `iRules(r)`, see <http://devcentral.f5.com/>.

EXAMPLES

```
list rule
```

Displays all `iRules`.

```
delete rule my_irule
```

Deletes the `iRule` named `my_irule`.

```
rule my_irule {
when RULE_INIT {
}
}
priority 1

when SERVER_CONNECTED {
}
timing on
check strict
}
```

Creates an `iRule` named `my_irule`.

```
generate rule my_irule checksum
```

Generates a checksum for the rule definition and adds the checksum to the rule.

```
generate rule my_irule signature signing-key my_key
```

Generates a signature for the rule definition using the specified private key and adds the signature to the rule.

Note: For a rule that includes a checksum or signature to successfully load, the rule definition contents must match the stored checksum or signature. To modify the rule definition and still retain the checksum or signature, the `ignore-verification` attribute must be set to `true`. This is done by editing the rule and adding the `ignore-verification` attribute, which allows the modified rule to load and changes the verification status to `Not Verified`:

```
rule my_irule {
when RULE_INIT {
definition-checksum 7c0dba9aa53e8959042c6cfe041d3d11
ignore-verification true }
}
```

Modifies an existing `iRule` named `my_irule` by adding a new metadata and modifying an existing metadata:

```
modify rule my_irule {
when RULE_INIT {
definition-checksum 7c0dba9aa53e8959042c6cfe041d3d11
metadata replace-all-with {
  my_meta { persist false
    value "hello"
  }
  my_meta2 { persist false
    value "hello 2"
  }
}
}
}
```

The metadata attribute is the user defined key/value pair. Metadata has the following format:

```
metadata
[add | delete | modify] {
```

```
[metadata_name] {
value [ "value content" ]
persist [ true | false ]
} }>
```

Deletes a metadata from an iRule:

```
modify rule my_irule {
when RULE_INIT {}
definition-checksum 7c0dba9aa53e8959042c6cfe041d3d11
metadata delete { my_meta } }
```

```
mv /ltm rule /Common/my_rule to-folder /Common/some_folder
```

Moves an iRule named my_rule to the folder named some_folder, where some_folder has already been created under /Common.

Note: Please note that you may not move an iRule that has an explicit usage of a configuration object, such as a pool.

OPTIONS

checksum

Generates a checksum for the rule definition and adds the checksum to the rule. This option is used only with the generate command.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the create, delete, and modify commands.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

signature

Generates a signature for the rule definition using the specified private key and adds the signature to the rule as a property. This option is used only with the generate command.

signing-key

Specifies the private key to use for signing the rule. This is used only with the signature option.

meta-data

Specifies the user-defined key/value pair associated with the rule. See the example section for usage format.

app-project

Specifies the dev plugin this rule belongs to. This is a read-only attribute.

SEE ALSO

create, delete, edit, generate, glob, list, modify, mv, regex, show, tmsh

BIG-IP 2015-10-07 ltm rule(1)

ltm snat-translation

NAME

snat-translation - Configures an explicit secure network address translation (SNAT) translation address.

MODULE

ltm

SYNTAX

Configure the snat-translation component within the ltm module using the syntax shown in the following sections.

CREATE/MODIFY

```
create snat-translation [all | [name] ]
modify snat-translation [all | [name] ]
options:
address [ip address]
arp [disabled | enabled]
app-service [[string] | none]
connection-limit [integer]
```

```

description [string]
[disabled | enabled]
ip-idle-timeout [indefinite | [integer] ]
tcp-idle-timeout [indefinite | [integer] ]
udp-idle-timeout [indefinite | [integer] ]
traffic-group [[string] | default | non-default | none]

edit snat-translation [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list snat-translation
list snat-translation [ [ [name] | [glob] | [regex] ] ... ]
show running-config snat-translation
show running-config snat-translation [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line

show snat-translation
show snat-translation [ [ [name] | [glob] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt

DELETE
delete snat-translation [all | [name] ]

DESCRIPTION
  Explicitly defines the properties of a SNAT translation address.

EXAMPLES
  modify snat-translation all arp disabled

  Disables Address Resolution Protocol (ARP) on all SNAT translation
  addresses.

  list snat-translation all-properties

  Displays all properties of all SNAT translation addresses.

OPTIONS
  address
  The translation IP address.

  arp Indicates whether the system responds to ARP requests or sends
  gratuitous ARPs. The default value is enabled.

  app-service
  Specifies the name of the application service to which this object
  belongs. The default value is none. Note: If the strict-updates
  option is enabled on the application service that owns the object,
  you cannot modify or delete this object. Only the application
  service can modify or delete this object.

  connection-limit
  Specifies the number of connections a translation address must
  reach before it no longer initiates a connection. The default
  value of 0 (zero) indicates that the option is disabled.

  description
  User defined description.

  disabled
  Disables SNAT translation.

  enabled
  Enables SNAT translation. The default value is enabled.

  glob Displays the items that match the glob expression. See help glob
  for a description of glob expression syntax.

  traffic-acceleration-status
  Displays the current traffic-acceleration status. Indicates
  whether the SNAT address is (indirectly via a SNAT pool) in-use by
  or dedicated to a virtual server that uses a traffic-acceleration
  profile.

  ip-idle-timeout
  Specifies the number of seconds that IP connections initiated
  using a SNAT address are allowed to remain idle before being
  automatically disconnected. The default value is indefinite.

  regex
  Displays the items that match the regular expression. The regular
  expression must be preceded by an at sign (@[regular expression])
  to indicate that the identifier is a regular expression. See help
  regex for a description of regular expression syntax.

  tcp-idle-timeout
  Specifies the number of seconds that TCP connections initiated
  using a SNAT address are allowed to remain idle before being
  automatically disconnected. The default value is indefinite.

  udp-idle-timeout
  Specifies the number of seconds that UDP connections initiated
  using a SNAT address are allowed to remain idle before being
  automatically disconnected. The default value is indefinite.

  unit Read-only property that specifies the unit in a redundant system.
  Derived from traffic-group.

```

traffic-group
Specifies the traffic group of the failover device group on which the SNAT is active. The default traffic group is inherited from the containing folder.

inherited-traffic-group
Read-only property that indicates if the traffic-group is inherited from the parent folder.

SEE ALSO

create, delete, edit, glob, list, modify, ltm snat, ltm snatpool, regex, show, tmsb

ltm snat

NAME
snat - Configures secure network address translation (SNAT).

MODULE
ltm

SYNTAX
Configure the snat component within the ltm module using the syntax shown in the following sections.

```
CREATE/MODIFY
create snat [name]
modify snat [name]
options:
  (automap | none)
  auto-lasthop [default | enabled | disabled ]
  app-service [[string] | none]
  description [string]
  mirror { [disabled | enabled | none] }
  origins
    [add | delete | replace-all-with] {
  [address ... | address/mask ... ]
  }
  snatpool [ name ]
  source-port [change | preserve | preserve-strict ]
  translation [translation name ... ]
  vlans
    [add | delete | replace-all-with] {
  [vlan name ... ]
  }
  vlans [ default | none]
  [vlans-disabled | vlans-enabled ]
  metadata
    [add | delete | modify] {
  [metadata_name ... ] {
  value [ "value content" ]
  persist [ true | false ]
  }
  }
}
```

```
edit snat [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```
DISPLAY
list snat
list snat [ [ [name] | [glob] | [regex] ] ... ]
show running-config snat
show running-config snat [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

```
show snat
show snat [ [ [name] | [glob] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  detail
  field-fmt
```

```
DELETE
delete snat [name]
```

DESCRIPTION

You can use the `snat` component to configure a SNAT. A SNAT defines the relationship between an externally visible IP address, SNAT IP address, or translated address, and a group of internal IP addresses, or originating addresses, of individual servers at your site.

EXAMPLES

```
create snat my_snat origins add { 10.1.1.3 } translation
mySnatTranslation
```

Creates the SNAT `my_snat` that translates the address of connections that originate from the address `10.1.1.3` to the translation address `mySnatTranslation`.

```
list snat all-properties
```

Displays all properties for all SNATs.

OPTIONS

automap

Specifies that the system translates the source IP address to an available self IP address when establishing connections through the virtual server. You can use this option only if you do not use the `snatpool` and `translation` options.

Note that when you use the `edit` command to create a new `snat`, by default `automap` is enabled. If you do not want to use `automap`, you must turn this feature off by using the `none` option.

app-service

Specifies the name of the application service to which this object belongs. The default value is `none`. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete this object. Only the application service can modify or delete this object.

description

User defined description.

`glob` Displays the items that match the `glob` expression. See `help glob` for a description of `glob` expression syntax.

mirror

Enables or disables mirroring of SNAT connections. The default value is `none`.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

origins

Specifies a set of IP addresses and subnets from which connections originate. This option is required.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an `@` sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See `help regex` for a description of regular expression syntax.

snatpool

Specifies the name of a SNAT pool. You can only use this option if you do not use the `automap` and `translation` options.

source-port

Specifies whether the system preserves the source port of the connection. The default value is `preserve`.

The options are:

change

Use this setting to obfuscate internal network addresses.

preserve

Specifies to preserve the source port of the connection.

preserve-strict

Use this value only for UDP under very special circumstances such as `nPath` or `transparent` (that is, no translation of any other L3/L4 field), where there is a 1:1 relationship between virtual IP addresses and node addresses, or when clustered multi-processing (CMP) is disabled.

translation

Specifies the name of a translated IP address. Note that translated addresses are outside the traffic management system. You can use this option only if you do not use the `automap` and `snatpool` options.

vlan

Specifies the name of the VLAN to which you want to assign the SNAT. The default value is `none`.

vlan-disabled

Disables the SNAT for all specified VLANs. When the `"vlan"` value is set to `"none"`, the `"vlan-disabled"` option enables the SNAT on all VLANs.

vlan-enabled

Enables the SNAT for all specified VLANs. When the `"vlan"` value is set to `"none"`, the `"vlan-enabled"` option disables the SNAT on all VLANs.

metadata

Associates user defined data, each of which has name and value pair and persistence. Persistent(default) means the data will be saved into config file.

SEE ALSO

BIG-IP 2016-03-14 ltm snat(1)

ltm snatpool

NAME snatpool - Configures a secure network address translation (SNAT) pool.

MODULE ltm

SYNTAX Configure the snatpool component within the ltm module using the syntax shown in the following sections.

CREATE/MODIFY
create snatpool [name]
modify snatpool [name]
options:
app-service [[string] | none]
description [string]
members
[add | delete | replace-all-with] {
[ip address ...]
}
members [default | none]
edit snatpool [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties
reset-stats snatpool
reset-stats snatpool [[[name] | [glob] | [regex]] ...]
DISPLAY
list snatpool
list snatpool [[[name] | [glob] | [regex]] ...]
show running-config snatpool
show running-config snatpool [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties
one-line
show snatpool
show snatpool [[[name] | [glob] | [regex]] ...]
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
detail
field-fmt
DELETE
delete snatpool [name]

DESCRIPTION

A SNAT pool is a pool of translation addresses that you can map to one or more original IP addresses. Translation addresses in a SNAT pool are not self-IP addresses. You can simply create a SNAT pool and then assign it as a resource directly to a virtual server. This eliminates the need for you to explicitly define original IP addresses to which to map translation addresses.

EXAMPLES

```
create snatpool my_snat_pool1 members add { 11.12.11.24 11.12.11.25 }
```

Creates the SNAT pool my_snat_pool1 that contains the translation addresses (members) 11.12.11.24 and 11.12.11.25.

```
delete snatpool my_snat_pool1
```

Deletes the SNAT pool named my_snat_pool1.

OPTIONS

app-service
Specifies the name of the application service to which this object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this object. Only the application service can modify or delete this object.

description
User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

traffic-acceleration-status
Displays the current traffic-acceleration status. Indicates whether the SNAT pool is in-use by or dedicated to a virtual server that uses a traffic-acceleration profile.

members
Specifies translation IP addresses of the pools in the SNAT pool.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

BIG-IP 2016-10-07 ltm snatpool(1)

ltm tacdb customdb-file

NAME
customdb-file - Manages a custom TACDB file

MODULE
ltm tacdb

SYNTAX
List the customdb-file component within the ltm tacdb module using the syntax in the following sections.

CREATE
create customdb-file [name]
options:
source-path [string]
app-service [name]

DEPRECATED: Though this command is visible, this is not meant to be used by the users. The daemons use it internally.

DISPLAY
list customdb-file [[name] | all | [property]]
options:
all-properties
one-line
partition

DELETE
delete customdb-file [[name] | all]

DEPRECATED: Though this command is visible, this is not meant to be used by the users. The daemons use it internally.

DESCRIPTION
The customdb-file is created internally using the URL specified in ltm tacdb customdb.

EXAMPLES
create customdb-file new { source-path file:/shared/images/new.txt }

Creates a new customdb file object, "new" from the source file /shared/images/new.txt

list customdb-file [fileobj-name]

Lists the attributes of customdb file object, "new" from the source file /shared/images/new.txt

OPTIONS

create

Creates a new file object for custom tacdb.

delete

Deletes the file object that you specify next.

source-path

Specifies the location from where the TACDB file object sources the file.

app-service

Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

description

User defined description for this customdb file object.

partition

Displays the administrative partition within which the component resides.

SEE ALSO

edit, list, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2015-05-12 ltm tacdb customdb-file(1)

ltm tacdb customdb

NAME

customdb - Configures a custom tacdb to be used for file loads. A customdb includes a URL (including local file paths) from where TACDB files are loaded. These files contain TAC code information.

MODULE

ltm tacdb

SYNTAX

Configure the customdb component within the ltm tacdb module using the syntax in the following sections.

CREATE/MODIFY

```
create customdb [name]
modify customdb [[name] | all]
options:
  url [string]
  poll-interval [integer]
  user [string]
  password [string]
  priority [ high | low ]
  app-service [name]
  description [string]
```

DISPLAY

```
list customdb [[name] | all | [property]]
options:
  all-properties
  non-default-properties
  one-line
  partition
  recursive
```

DELETE

```
delete customdb [[name] | all]
```

```
LOAD load customdb [name]
```

DESCRIPTION

You can use the customdb component to define a custom tacdb

EXAMPLES

```
create customdb new { url file:/shared/images/new.txt }
```

Creates a new custom tacdb, "new" with TAC code information in the file specified by url.

delete customdb new

Deletes the custom tacdb that has been specified.

load customdb new

Trigger a manual download of the custom tacdb from the location pointed to and load it into memory.

OPTIONS

url Specifies the url to fetch the file containing the TACDB information.

poll-interval
Specifies the time interval in seconds at which the URL needs to be polled. The initial default value 0 disables polling. The literal "default" value is 300 seconds (5 minutes).

priority
Specifies the priority whether the customdb is higher or lower than built-in/licensed TACDB.

app-service
Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

description
User defined description for this customdb.

partition
Displays the administrative partition within which the component resides.

SEE ALSO

edit, list, modify, tmsh

COPYRIGHT

F5 Networks and BIG-IP (c) Copyright 2008, 2012-2016. All rights reserved.

BIG-IP 2017-05-17 ltm tacdb customdb(1)

ltm tacdb licenseddb

NAME
licenseddb - Configures a licensed tacdb to be used for file loads.

MODULE
ltm tacdb

SYNTAX
Configure the licenseddb component within the ltm tacdb module using the syntax in the following sections.

MODIFY
modify licenseddb [licensed-tacdb | all]
options:
poll-interval [integer]

LOAD
load licenseddb [licensed-tacdb]

DISPLAY
list licenseddb [licensed-tacdb | all | [property]]
options:
all-properties
non-default-properties
one-line
recursive

DESCRIPTION
You can use the licenseddb component to define polling interval of downloading licensed tacdb

EXAMPLES
modify licenseddb licensed-tacdb poll-interval 2
Modifies polling interval, "2" means two weeks.
load licenseddb licensed-tacdb

Triggers a manual download of the licensed tac-db from the built-in location in the F5 servers and loads it into memory.

OPTIONS

poll-interval
Specifies the time interval in weeks at which the licensed tacdb needs to be polled

SEE ALSO

edit, list, modify, tmsh

ltm tacdb query

NAME

query - Displays the device type and OS to which a TAC code belongs

MODULE

ltm tacdb

SYNTAX

Use the query component within the ltm tacdb module to query the device type and OS the TAC code belongs to.

DISPLAY

show ltm tacdb query [integer]

DESCRIPTION

You can use the query component to query the device type and OS a url belongs to

EXAMPLES

show ltm tacdb query 35333303

Displays the device type and OS "35333303" belongs to.

OPTIONS

integer
Specify the TAC code.

SEE ALSO

show, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2009-2015. All rights reserved.

BIG-IP 2016-03-14 ltm tacdb query(1)

ltm traffic-class

NAME

traffic-class - Configures a traffic class.

MODULE

ltm

SYNTAX

Configure the traffic-class component within the ltm module using the syntax shown in the following sections.

```
CREATE/MODIFY
create traffic-class [name]
modify traffic-class [name]
options:
  app-service [[string] | none]
  classification [string]
  description [string]
  destination-address [ [ip address] | none]
  destination-mask [ [ip address] | none]
  destination-port [ [integer] | [port name] ]
  protocol [any | [protocol] ]
  source-address [ [ip address] | none]
  source-mask [ [ip address] | none]
  source-port [ [integer] | [port name] ]
```

```
edit traffic-class [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

```
DISPLAY
list traffic-class
list traffic-class [ [name] | [glob] | [regex] ] ... ]
show running-config traffic-class
show running-config traffic-class [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

```
DELETE
delete traffic-class [name]
```

DESCRIPTION

You can use the traffic-class component to configure a traffic class, which is a named group of ports, machines, and subnets. You can then assign this traffic class to a virtual server in order to configure the virtual server to achieve specific Quality of Service (QoS) standards.

EXAMPLES

```
create traffic-class my_traffic_class classification "My traffic class."
```

Creates a traffic class named my_traffic_class, which tags matching flows with the tag My traffic class.

```
list traffic-class all-properties
```

Displays all of the properties of all of the traffic classes.

```
delete traffic-class my_traffic_class
```

Deletes the traffic class named my_traffic_class.

OPTIONS

app-service
Specifies the name of the application service to which the traffic class belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the traffic class. Only the application service can modify or delete the traffic class.

classification
Specifies the actual textual tag to be associated with the flow if the traffic class is matched. This option is required.

description
User defined description.

destination-address
Specifies destination IP addresses for the system to use when evaluating traffic flow. If traffic flow matches this value, it is tagged with the value in the classification option. The default value is none.

destination-mask
Specifies a destination IP address mask for the system to use when evaluating traffic flow. If traffic flow matches this value, it is tagged with the value in the classification option. The default value is none.

destination-port
Specifies a destination port for the system to use when evaluating traffic flow. If traffic flow matches this value, it is tagged with the value in the classification option. The default value is 0 (zero).

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

protocol
Specifies a protocol for the system to use when evaluating traffic flow. If traffic flow matches this value, it is tagged with the value in the classification option. The default value is any.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

source-address
Specifies source IP addresses for the system to use when evaluating traffic flow. If traffic flow matches this value, it is tagged with the value in the classification option. The default value is none.

source-mask
Specifies a source IP address mask for the system to use when evaluating traffic flow. If traffic flow matches this value, it is tagged with the value in the classification option. The default value is none.

source-port
Specifies a source port for the system to use when evaluating traffic flow. If traffic flow matches this value, it is tagged with the value in the classification option. The default value is 0 (zero).

SEE ALSO

BIG-IP 2016-03-14 ltm traffic-class(1)

ltm traffic matching criteria

NAME

traffic-matching-criteria - Configures a virtual server matching object that defines how traffic is steered towards the virtual server object for the Local Traffic Manager.

MODULE

ltm

SYNTAX

Configure the traffic-matching-criteria component within the ltm module using the syntax shown in the following sections.

CREATE/MODIFY

```
create traffic-matching-criteria [name]
modify traffic-matching-criteria [name]
options:
  all
  description [string]
  destination-address-list [ [addr_list_name] | none]
  destination-address-inline [ [address] | none]
  destination-port-list [ [port_list_name] | none]
  destination-port-inline [port]
  source-address-list [ [addr_list_name] | none]
  source-address-inline [address]
  source-port-inline [port]
```

```
edit traffic-matching-criteria [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list traffic-matching-criteria
list traffic-matching-criteria [ [ [name] | [glob] | [regex] ] ... ]
show running-config traffic-matching-criteria
show running-config traffic-matching-criteria [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
show traffic-matching-criteria
show traffic-matching-criteria [name]
options:
  hours
  minutes
  seconds
```

DELETE

```
delete traffic-matching-criteria [name]
```

Note: You must remove all references to a traffic-matching-criteria before you can delete the traffic-matching-criteria.

DESCRIPTION

You can use this traffic-matching-criteria component to configure the virtual server matching definitions on the Local Traffic Manager. This defines the criteria used for matching destination and source address/ports for a virtual server.

EXAMPLES

```
create traffic-matching-criteria my_traffic_matching_criteria
destination-address-list dst_addr_list destination-port-list
dst_port_list
```

Creates a Local Traffic Manager traffic-matching-criteria named my_traffic_matching_criteria with dst_addr_list and the dst_port_list for destination matching, from any source.

```
create traffic-matching-criteria my_traffic_matching_criteria source-
address-list src_addr_list source-port-list src_port_list
```

Creates a Local Traffic Manager traffic-matching-criteria named my_traffic_matching_criteria with src_addr_list and the port-list for source matching, to any destination.

```
create traffic-matching-criteria my_traffic_matching_criteria
destination-address-list dst_addr_list destination-port-list
dst_port_list source-address-list src_addr_list1 source-port-list
src_port_list1
```

Creates a Local Traffic Manager traffic-matching-criteria named my_traffic_matching_criteria with src_addr_list and the src_port-list for source matching, and dst_addr_list and dst_port_list for destination matching.

```
delete traffic-matching-criteria my_traffic_matching_criteria
```

Deletes the traffic_matching_criteria named my_traffic_matching_criteria.

```
show traffic-matching-criteria
```

Displays status for all Local Traffic Manager traffic-matching-criteria objects in the system configuration.

```
show traffic-matching-criteria all-properties
```

Displays status for all Local Traffic Manager traffic-matching-criteria objects in the system configuration.

```
list traffic-matching-criteria my_traffic_matching_criteria
```

Displays properties of the traffic-matching-criteria named my_traffic_matching_criteria.

OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

destination-address-list

Specifies the name of destination address list for this virtual server matching object i.e. the addresses on which the virtual server referencing this object will listen for connections. The default value is any.

destination-address-inline

Specifies a single destination address for this virtual server matching object i.e. the address on which the virtual server referencing this object will listen for connections. The default value is none.

destination-port-list

Specifies the name of destination port list for this virtual server matching object i.e. the ports on which the virtual server referencing this object will listen for connections. The default value is any.

destination-port-inline

Specifies a single destination port for this virtual server matching object i.e. the port on which the virtual server referencing this object will listen for connections. The default value is none.

source-address-list

Specifies the source address list for this virtual server matching object i.e. the addresses from which the virtual server referencing this object will accept traffic. The default value is any.

source-address-inline

Specifies a single source address list for this virtual server matching object i.e. the address from which the virtual server referencing this object will accept traffic. The default value is none.

source-port-list

Specifies the source port list for this virtual server matching object i.e. the ports from which the virtual server referencing this object will accept traffic. The default value is any.

source-port-inline

Specifies a single source port for this virtual server matching object i.e. the port from which the virtual server referencing this object will accept traffic. The default value is none.

description

User defined description.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

ltm urlcat-cloud-cache

NAME

urlcat-cloud-cache - Operating on the cache of cloud lookup result.

MODULE

ltm

SYNTAX

Use the urlcat-cloud-cache component within the ltm module to operating on the cloud cache.

DISPLAY

delete ltm urlcat-cloud-cache url all

DESCRIPTION

You can use the urlcat-cloud-cache component to operating on the cache.

EXAMPLES

delete ltm urlcat-cloud-cache url all

Delete all the cache entries currently in cloud cache.

OPTIONS

all Use all to delete all the cache entries currently in cloud cache.

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

ltm urlcat-query

NAME

urlcat-query - Displays the category to which a url belongs

MODULE

ltm

SYNTAX

Use the urlcat-query component within the ltm module to query the category the url belongs to.

DISPLAY

show ltm urlcat-query [string]

DESCRIPTION

You can use the urlcat-query component to query the category a url belongs to

EXAMPLES

```
show ltm urlcat-query www.google.com
```

Displays the category "www.google.com" belongs to.

OPTIONS

string
Specify the urlname.

SEE ALSO

show, tmsh

ltm virtual-address

NAME

virtual-address - Configures virtual addresses.

MODULE

ltm

SYNTAX

Configure the virtual-address component within the ltm module using the syntax shown in the following sections.

CREATE/MODIFY

```
create virtual address [name]
```

```
modify virtual address [name]
```

options:

```
address [ip address]
```

```
app-service [[string] | none]
```

```
arp [enabled | disabled]
```

```
auto-delete [true | false]
```

```
connection-limit [integer]
```

```
description [string]
```

```
enabled [yes | no]
```

```

DELETE
delete virtual-address [all | [name]]

DESCRIPTION

You can use the virtual-address component to enable, disable, display, and delete virtual addresses. You can also list the virtual address configuration, and view statistics for a specific virtual address.

Note that tmsh only displays virtual addresses when you explicitly request them. For example:

To display the properties of virtual addresses or a specific virtual address from the ltm module, use the command sequences list virtual-address and list virtual-address [name], respectively.

To display statistics for virtual addresses or a specific virtual address from the ltm module, use the command sequence show virtual-address and show virtual-address [name], respectively.

EXAMPLES

```
create virtual-address myVirtualAddr address 10.10.10.20 enabled yes
```

Creates a virtual address 10.10.10.20, with a name of myVirtualAddr.

```
create virtual-address myVirtualAddr address 10.10.10.20 enabled yes  
traffic-group /Common/traffic-group-1
```

Creates a virtual address 10.10.10.20, with a name of myVirtualAddr, that is assigned to traffic-group-1.

```
modify virtual-address myVirtualAddr enabled no
```

Disables the virtual address myVirtualAddr.

```
delete virtual-address myVirtualAddr
```

Deletes the virtual address myVirtualAddr.

```
list virtual-address myVirtualAddr all-properties
```

Lists the configuration information for the virtual address, myVirtualAddr.

```
show virtual-address myVirtualAddr
```

Displays statistics and status for the virtual-address myVirtualAddr.

```
show virtual-address myVirtualAddr all-properties
```

Displays statistics and status for the virtual named myVirtualAddr.

Note that if the system includes Packet Velocity(r) ASIC (PVA) and PVA Assist capabilities, this command displays status and statistics for that feature.

```
mv /ltm virtual-address /Common/10.10.10.20 to-folder  
/Common/all_virtual_addresses
```

Moves the virtual-address 10.10.10.20 to a folder named all_virtual_addresses.

Note: If you wish to change the name of the virtual-address, you must use the configured IP Address or a name that does not represent a different IP Address than the one configured.

Please refer to the mv manual page for additional examples on how to use the mv command.

OPTIONS

address
The virtual IP address.

arp Enables or disables ARP for the specified virtual address. The default value is enabled.

app-service
Specifies the name of the application service to which the virtual address belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the virtual address. Only the application service can modify or delete the virtual address.

auto-delete
Indicates if the virtual address will be deleted automatically on deletion of the last associated virtual server or not. The default value is true.

connection-limit
Sets a concurrent connection limit for one or more virtual servers. The default value is 0, meaning "no limit."

description
User defined description.

enabled
Specifies whether the specified virtual address is enabled. The default value is yes.

floating

Read-only property derived from traffic-group. A floating virtual address is a virtual address for a VLAN that serves as a shared address by all devices of a BIG-IP traffic-group.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

icmp-echo

Specifies whether the virtual address should reply to ICMP echo requests. The default value is enabled.

enabled or always

ICMP echo reply will be sent in response to ICMP echo requests.

disabled

ICMP echo reply will not be sent in response to ICMP echo requests.

selective

ICMP echo reply will be sent in response to ICMP echo requests, when availability status is true.

any ICMP echo reply will be sent in response to ICMP echo requests, when any of the contributing virtual server is available.

all ICMP echo reply will be sent in response to ICMP echo requests when all of the contributing virtual server is available.

mask Sets the netmask for one or more network virtual servers only. This setting is required for network virtual servers. The default value is 255.255.255.255.

partition

Displays the administrative partition within which the virtual address resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

route-advertisement

Specifies the route advertisement setting for the virtual address. The default value is disabled.

enabled or selective

Route is advertised when virtual-address is available.

disabled

Route is not advertised.

always

Route is advertised regardless of the availability status.

any Route is advertised when any of the contributing virtual server is available.

all Route is advertised when all of the contributing virtual server is available.

server-scope

Specifies the server that uses the specified virtual address. The default value is any.

spanning

Enables or disables spanning for the specified virtual address. The default value is disabled.

unit Read-only property that specifies the unit in a redundant system. Based on traffic-group.

traffic-group

Specifies the traffic group on which the virtual address is active. The default traffic group is inherited from the containing folder.

inherited-traffic-group

Read-only property that indicates if the traffic-group is inherited from the parent folder.

metadata

Associates user defined data, each of which has name and value pair and persistence. Persistent(default) means the data will be saved into config file.

SEE ALSO

create, delete, edit, glob, list, ltm virtual, modify, mv, regex, reset-stats, show, tmssh

DELETE
delete virtual [name]

```

DESCRIPTION

You can use the virtual component to create, delete, modify properties on, and display information about virtual servers. Virtual servers are externally visible IP addresses that receive client requests. Rather than sending the requests directly to the destination IP address specified in the packet header, it sends the requests to any of several content servers that make up a load balancing pool. Virtual servers also apply various behavioral settings to multiple traffic types, enable persistence for multiple traffic types, and direct traffic according to user-written iRules(r).

Note: After you configure a Global Traffic Manager listener, when you use the tab completion feature within the ltm module, the listener displays as one of the virtual servers in the Configuration Items section.

EXAMPLES

```
create virtual myV2 { destination 11.11.11.12:any persist replace-all-
with { source_addr } } pool myPool}
```

Creates a virtual server named myV2, which uses the source address persistence method.

```
modify virtual vs_f14_http4 profiles replace-all-with { profile-udp }
```

Replaces the profile associated with the virtual server vs_f14_http4.

Note: To replace the profile associated with a virtual server, you must enclose the name of the new profile in curly brackets.

```
delete virtual myV4 myV5 myV6
```

Deletes the virtual servers named myV4, myV5, and myV6.

```
show virtual myV4
```

Displays statistics and status for the virtual named myV4.

```
show virtual myV4 all-properties
```

Displays statistics and status for the virtual named myV4.

Note: If the system includes Packet Velocity(r) ASIC (PVA) and PVA

Assist capabilities, this command displays status and statistics for that feature.

```
mv /ltm virtual /Common/my_vip to-folder /Common/some_folder
```

Moves a virtual server named `my_vip` to the folder named `some_folder`, where `some_folder` has already been created under `/Common`.

Note: Please note that you may not move a virtual server that is associated with CGNAT configuration items, such as LSN pools.

OPTIONS

`all` Specifies that you want to modify all of the existing components of the specified type.

`address-status`

Specifies whether the virtual will contribute to the operational status of the associated virtual-address. The default value is 'yes'.

`app-service`

Specifies the name of the application service to which the virtual server belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the virtual server. Only the application service can modify or delete the virtual server.

`auth` Specifies a list of authentication profile names, separated by spaces, that the virtual server uses to manage authentication.

`clone-pools`

Specifies a pool or list of pools that the virtual server uses to replicate either client or server traffic. You must specify a value of either `clientside` or `serverside` for the `context` option for each clone pool. Typically, this option is used for intrusion detection.

`cmp-enabled`

Enables or disables clustered multi-processor (CMP) acceleration. This feature applies to certain platforms only. The default value is `yes`.

`connection-limit`

Specifies the maximum number of concurrent connections you want to allow for the virtual server. The default value of 0 (zero) allows for an unlimited number of concurrent connections.

`context`

Specifies that the pool is either a `clientside` or `serverside` clone pool.

Note: Because validation occurs outside of TMSH, you will receive an error when you modify the `context` for profiles in a virtual server.

`dhcp-relay`

Specifies a virtual server that relays all received dhcp requests to all pool members. If there is no pool, the received request get dropped. If you specify the `dhcp-relay` option, you cannot use the `ip-forward` or `l2-forward` or `reject` options.

`description`

User defined description.

`destination`

Specifies the name of the virtual address and service on which the virtual server listens for connections.

The format for "ipv4" is `a.b.c.d[:port]`. The format for an "ipv6" address is `a:b:c:d:e:f:g:h[:port]`.

The default value is `any:any`.

`(enabled | disabled)`

Specifies the state of the virtual server. The default value is `enabled`.

Note: When you disable a virtual server, the virtual server no longer accepts new connection requests. However, it allows current connections to finish processing before going to a down state.

`fallback-persistence`

Specifies a fallback persistence profile for the virtual server to use when the default persistence profile is not available. The default value is `none`.

`flow-eviction-policy`

Specifies a flow eviction policy for the virtual server to use, to select which flows to terminate when the number of connections approaches the connection limit on the virtual server. The default value is `none`.

`fw-enforced-policy`

Specifies an enforced firewall policy. `fw-enforced-policy` rules are enforced on a virtual server.

`fw-enforced-policy-rules`

Specifies firewall rules enforced on ltm virtual via referenced `fw-enforced-policy`.

`fw-staged-policy`

Specifies a staged firewall policy. `fw-staged-policy` rules are not enforced while all the visibility aspects namely statistics, reporting and logging function as if the `fw-staged-policy` rules

were enforced on a virtual server.

fw-staged-policy-rules
Specifies firewall rules staged on ltm virtual via referenced fw-staged-policy.

security-nat-rules
Specifies security nat rules associated with ltm virtual via referenced security-nat-policy.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

gtm-score
Specifies a score that is associated with the virtual server. Global Traffic Manager (GTM) can rely on this value to load balance traffic in a proportional manner.

traffic-acceleration-status
Displays the current traffic-acceleration status. The virtual server is considered traffic-acceleration-dedicated if it uses a traffic-acceleration profile.

ip-forward
Specifies a virtual server that has no pool members to load balance, but instead, forwards the packet directly to the destination IP address specified in the client request. If you specify the ip-forward option, you cannot use the l2-forward or reject options. The translate-address and translate-port attributes are disabled by the system, any attempt to change them will have no effect.

ip-protocol
Specifies the IP protocol for which you want the virtual server to direct traffic. Sample protocol names are TCP and UDP. The default value is any.

Note: You do not use this setting when creating an HTTP class virtual server.

internal
Specifies an internal virtual server that handles requests for a parent virtual server, such as content adaptation. Internal virtual servers do not receive external connections, instead they are specified by name by profiles in the parent virtual server (see ltm profile request-adapt and ltm profile response-adapt). Since internal virtual servers do not listen for external connections, not all attributes are used for internal virtual servers. The destination, mask, translate-address, translate-port, vlans, vlans-disabled and vlans-enabled attributes are set by the system, any attempt to change them will have no effect.

l2-forward
Specifies a virtual server that shares the same IP address as a node in an associated VLAN. You create this type of virtual server when you want to create a VLAN group. If you specify the l2-forward option, you cannot use the ip-forward or reject options.

last-hop-pool
Specifies the name of the last hop pool that you want the virtual server to use to direct reply traffic to the last hop router. The default value is none.

mask Specifies the netmask for a network virtual server only. This setting is required for a network virtual server.

The netmask clarifies whether the host bit is an actual zero or a wildcard representation. The default value is 255.255.255.255 for IPv4 or ffff:ffff:ffff:ffff:ffff:ffff:ffff:ffff for IPv6.

mirror
Enables or disables mirroring. You can use mirroring to maintain the same state information in the standby unit that is in the active unit, allowing transactions such as FTP file transfers to continue as though uninterrupted. The default value is none.

mobile-app-tunnel
Deprecated since v13.1.0.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

nat64
Enable or disable NAT64. The default value is disabled. NAT64 is a service that automatically translate IPv6 traffic into IPv4.

partition
Displays the name of the administrative partition within which the virtual server resides.

per-flow-request-access-policy
Specifies the name of the per-request access policy to be used with the virtual server. The default value is none.

persist
Specifies a list of profiles separated by spaces that the virtual server uses to manage connection persistence. The default value is none.

To enable persistence, typically you specify a single profile. However, you can specify multiple profiles in conjunction with iRules(r) that define a persistence strategy based on incoming traffic. In the case of multiple profiles, the default option

specifies which profile you want the virtual server to use if an iRule does not specify a persistence method. When you specify multiple profiles, the default value of the default property is no. You can set the value of the default property to yes for only one of the profiles.

policies

Manage LTM Policies applied to the virtual server. LTM Policies define a set of conditions and actions that can be used to inspect, modify, direct traffic, and enable/disable features on the fly, similar to iRules. LTM Policies do not require programming. See also ltm policy.

pool Specifies a default pool to which you want the virtual server to automatically direct traffic. The default value is none.

port-misuse

Used to show or reset port misuse policy statistics for the virtual server.

fw-context-stat

Used to show or reset firewall statistics for the virtual server.

profiles

Specifies a list of profiles for the virtual server to use to direct and manage traffic. The default value is fastL4.

rate-class

Specifies the name of an existing rate class that you want the virtual server to use to enforce a throughput policy for incoming network traffic. The default value is none.

rate-limit

Specifies the maximum number of connections per second allowed for a virtual server. The default value is 'disabled'.

rate-limit-mode

Indicates whether the rate limit is applied per virtual object, per source address, per destination address, or some combination thereof. The default value is 'object', which does not use the source or destination address as part of the key.

rate-limit-dst-mask

Specifies a mask, in bits, to be applied to the destination address as part of the rate limiting. The default value is '0', which is equivalent to using the entire address - '32' in IPv4, or '128' in IPv6.

rate-limit-src-mask

Specifies a mask, in bits, to be applied to the source address as part of the rate limiting. The default value is '0', which is equivalent to using the entire address - '32' in IPv4, or '128' in IPv6.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

related-rules

Specifies a list of iRules, separated by spaces, that customize the behavior of secondary channels (for instance the data channel on FTP) opened on behalf of the virtual server. The default value is none.

reject

Specifies that the BIG-IP(r) system rejects any traffic destined for the virtual server IP address. If you specify the reject option, you cannot use the ip-forward or l2-forward options.

rules

Specifies a list of iRules, separated by spaces, that customize the virtual server to direct and manage traffic. The default value is none.

security-nat-policy

Configures the following options to specify which Security NAT Policy is to be used to match the incoming traffic and perform source/destination translation (address/port) using the first-match rule criteria:

policy

Specifies the name of the Security NAT Policy to be used (see security nat policy).

use-route-domain-policy

Specifies whether to use the virtual server's route domain context's Security NAT policy. If enabled AND the virtual server does not have a NAT policy configured, route domain's security NAT policy is used.

use-device-policy

Specifies whether to use the security device context NAT policy (see security device-context). If enabled AND both virtual server as well as route domain do not have a NAT policy configured, NAT policy configured at security device (a.k.a global) level is used.

service-down-immediate-action

Specifies the immediate action the BIG-IP system should respond with upon the receipt of the initial client's SYN packet if the availability status of the virtual server is Offline or Unavailable. This is supported for the virtual server of Standard

type and TCP protocol. The default value is none.

service-policy

Specifies a service policy for the virtual server. If set, it will enforce the service policy for incoming network traffic. The service policy can be used to validate if incoming traffic conforms to a set of application protocols.

snat Specifies whether SNAT automap is enabled for the virtual server. The default value is none. This attribute is DEPRECATED. Use source-address-translation { type (automap / none) }

snatpool

Specifies the name of an existing SNAT pool that you want the virtual server to use to implement selective and intelligent SNATs. This attribute is DEPRECATED. Use source-address-translation { type snatpool pool pool_name }

source

Specifies an IP address or network from which the virtual server will accept traffic.

The format for an "ipv4" address is a.b.c.d[/prefixlen]. The format for an "ipv6" address is a:b:c:d:e:f:g:h[/prefixlen].

source-address-translation

Specifies the type of source address translation enabled for the virtual server as well as the pool that the source address translation will use.

pool Specifies the name of a LSN or SNAT pool used by the specified virtual server.

type Specifies the type of source address translation associated with the specified virtual server.

The options are:

automap

Specifies the use of self IP addresses for virtual server source address translation.

lsn Specifies the use of a LSN pool of translation addresses for virtual server source address translation.

none Specifies no source address translation to be used by the virtual server.

snat Specifies the use of a SNAT pool of translation addresses for virtual server source address translation.

source-port

Specifies whether the system preserves the source port of the connection. The default value is preserve.

The options are:

change

Obfuscates internal network addresses.

preserve

Preserves the source port of the connection.

preserve-strict

Use this value only for UDP under very special circumstances, such as nPath or transparent (that is, no translation of any other L3/L4 field), where there is a 1:1 relationship between virtual IP addresses and node addresses, or when clustered multi-processing (CMP) is disabled.

traffic-classes

Specifies a list of traffic classes that are associated with the virtual server. The default value is none.

translate-address

Enables or disables address translation for the virtual server. Disable address translation for a virtual server if you want to use the virtual server to load balance connections to any address. This option is useful when the system is load balancing devices that have the same IP address. The default value is disabled.

translate-port

Enables or disables port translation. Disable port translation for a virtual server, if you want to use the virtual server to load balance connections to any service. The default value is disabled.

transparent-nextthop

Specifies the egress interface for traffic and enables layer 2 (MAC) address preservation. Layer 2 address preservation disables layer 3 (IP/IPv6) address translation.

vlan

Specifies a list of VLANs on which the virtual server is either enabled or disabled. The default value is none. The options vlans-disabled and vlans-enabled indicate whether the virtual server is disabled or enabled on the list of specified VLANs.

vlans-disabled

Disables the virtual server on the VLANs specified in the vlans option. This is the default setting.

vlans-enabled

Enables the virtual server on the VLANs specified in the vlans option.

vs-index
Displays a unique index assigned to this virtual server.

metadata
Associates user defined data, each of which has name and value pair and persistence. Persistent(default) means the data will be saved into config file.

ip-intelligence-categories
Used to show/ reset statistics on IP intelligence white/ black lists categories.

mgmt

mgmt shared settings api-status availability

NAME

availability - Configures the accessibility of the elements that have one of the specified API lifecycle states.

MODULE

mgmt shared settings api-status

SYNTAX

Configure the availability component within the mgmt shared settings api-status module using the syntax shown in the following sections.

MODIFY

```
modify availability
options:
  deprecatedApiAllowed [true | false]
  earlyAccessApiAllowed [true | false]
  testOnlyApiAllowed [true | false]
```

DISPLAY

```
list availability
options:
  deprecatedApiAllowed
  earlyAccessApiAllowed
  testOnlyApiAllowed
```

DESCRIPTION

There are six F5 API lifecycle states namely: internal, testOnly, earlyAccess, generalAccess, deprecated, noStatus. These states are described at the end of this page. For the commands, command properties in deprecated, earlyAccess and testOnly states the availability can be configured by the user.

The availability settings indicate if the commands or properties within a command are accessible to the user. For example: if the deprecatedApiAllowed property is set to false; then it implies that the commands and properties with deprecated status are not available to user. i.e. These elements will not be available for create, modify, delete commands. For list action, the elements will not displayed at the command line.

Warnings will be generated at stderr and /var/log/ltm based on the mgmt::shared::settings::api-status::log::resource and resource-property settings.

If these settings are modified in the tmsh interactive mode then, the user has to exit the tmsh interactive mode and re-enter for the settings to be effective.

OPTIONS

deprecatedApiAllowed
Determines the accessibility of commands, properties in deprecated state. The default value is true.

earlyAccessApiAllowed
Determines the accessibility of commands, properties in

earlyAccess state. The default value is true.

testOnlyApiAllowed
Determines the accessibility of commands, properties in testOnly state. The default value is false.

The remaining properties are read-only and are not user modifiable.

F5 API lifecycle policy

The F5 API lifecycle consists of five states, namely: internal, testOnly, earlyAccess, generalAccess, deprecated, noStatus. These states can be described as follows:

internal

Internal routing not exposed through public interface

testOnly

Enabled only when test variable configured. Used internally for test cases that require special-case workers to complete functional testing for features not exposed in public API.

earlyAccess

Experimental and susceptible to change in future releases. Used for new features that haven't had time to be solidified.

generalAccess

API that satisfies the API general access release policy.

deprecated

Resource still exists in the API but indicates that there is an preferred alternative or that it may be removed in the future based on deprecation policy.

noStatus

For backward compatibility for APIs not categorized. At some point this status will be disallowed and build time break will occur if resource not categorized with appropriate flag.

In the write-up above the terms command, command::properties are used in place of API to describe the behavior of the mgmt::shared::settings::api-status::availability settings.

SEE ALSO

mgmt shared settings api-status log resource, mgmt shared setting api-status log resource-property

BIG-IP mgmt0shared1settings api-status availability(1)

mgmt shared settings api-status log resource-property

NAME

resource-property - Configures the logging of api-status message for the properties that have one of the specified API lifecycle states.

MODULE

mgmt shared settings api-status log

SYNTAX

Configure the resource-property component within the mgmt shared settings api-status log module using the syntax shown in the following sections.

MODIFY

modify resource-property

options:

deprecatedApiAllowed [true | false]
earlyAccessApiAllowed [true | false]
testOnlyApiAllowed [true | false]

DISPLAY

list resource-property

options:

deprecatedApiAllowed
earlyAccessApiAllowed
testOnlyApiAllowed

DESCRIPTION

There are six F5 API lifecycle states namely: internal, testOnly, earlyAccess, generalAccess, deprecated, noStatus. These states are described at the end of this page. For the properties in deprecated, earlyAccess and testOnly states the log::resource-property can be configured by the user.

The resource settings indicate if the user attempt to access the command would generate a [api-status-warning]. These warning will be generated at stderr and /var/log/ltn. For example: if the deprecatedApiAllowed property is set to true; then it implies that the accessing the command with deprecated status will generate an [api-status-warning].

Warnings will always be generated regardless of the log::resource-property setting if the property is not available as per the mgmt::shared::settings::api-status::log::availability setting

If these settings are modified in the tmsh interactive mode then, the user has to exit the tmsh interactive mode and re-enter for the settings to be effective.

OPTIONS

deprecatedApiAllowed

Determines if the [api-status-warning] messages will be generated for the properties with deprecated state. The default value is true.

earlyAccessApiAllowed

Determines if the [api-status-warning] messages will be generated for the properties with earlyAccess state. The default value is true.

testOnlyApiAllowed

Determines if the [api-status-warning] messages will be generated for the properties with testOnly state. The default value is true.

The remaining properties are read-only and are not user modifiable.

F5 API lifecycle policy

The F5 API lifecycle consists of five states, namely: internal, testOnly, earlyAccess, generalAccess, deprecated, noStatus. These states can be described as follows:

internal

Internal routing not exposed through public interface

testOnly

Enabled only when test variable configured. Used internally for test cases that require special-case workers to complete functional testing for features not exposed in public API.

earlyAccess

Experimental and susceptible to change in future releases. Used for new features that haven't had time to be solidified.

generalAccess

API that satisfies the API general access release policy.

deprecated

Resource still exists in the API but indicates that there is an preferred alternative or that it may be removed in the future based on deprecation policy.

noStatus

For backward compatibility for APIs not categorized. At some point this status will be disallowed and build time break will occur if resource not categorized with appropriate flag.

In the write-up above the term property is used in place of API to describe the behavior of the mgmt::shared::settings::api-status::log::resource-property settings.

BIG-IP mgmt shared settingslapi-status log resource-property(1)

mgmt shared settings api-status log resource

NAME

resource - Configures the logging of api-status message for the commands that have one of the specified API lifecycle states.

MODULE

mgmt shared settings api-status log

SYNTAX

Configure the resource component within the mgmt shared settings api-status log module using the syntax shown in the following sections.

MODIFY

modify resource

options:

```
deprecatedApiAllowed [true | false]
earlyAccessApiAllowed [true | false]
testOnlyApiAllowed [true | false]
```

DISPLAY

list resource

options:

```
deprecatedApiAllowed
earlyAccessApiAllowed
testOnlyApiAllowed
```

DESCRIPTION

There are six F5 API lifecycle states namely: internal, testOnly, earlyAccess, generalAccess, deprecated, noStatus. These states are described at the end of this page. For the commands, command properties in deprecated, earlyAccess and testOnly states the resource can be configured by the user.

The resource settings indicate if the user attempt to access the command would generate a [api-status-warning]. These warning will be generated at stderr and /var/log/ltn. For example: if the deprecatedApiAllowed property is set to true; then it implies that the accessing the command with deprecated status will generate an [api-status-warning].

Warnings will always be generated regardless of the log resource setting if the command is not available as per the mgmt::shared::settings::api-status::log::availability setting

If these settings are modified in the tmsh interactive mode then, the user has to exit the tmsh interactive mode and re-enter for the settings to be effective.

OPTIONS

deprecatedApiAllowed

Determines if the [api-status-warning] messages will be generated for the commands with deprecated state. The default value is true.

earlyAccessApiAllowed

Determines if the [api-status-warning] messages will be generated for the commands with earlyAccess state. The default value is true.

testOnlyApiAllowed

Determines if the [api-status-warning] messages will be generated for the commands with testOnly state. The default value is true.

The remaining properties are read-only and are not user modifiable.

F5 API lifecycle policy

The F5 API lifecycle consists of five states, namely: internal, testOnly, earlyAccess, generalAccess, deprecated, noStatus. These states can be described as follows:

internal

Internal routing not exposed through public interface

testOnly

Enabled only when test variable configured. Used internally for test cases that require special-case workers to complete functional testing for features not exposed in public API.

earlyAccess

Experimental and susceptible to change in future releases. Used for new features that haven't had time to be solidified.

generalAccess

API that satisfies the API general access release policy.

deprecated

Resource still exists in the API but indicates that there is an preferred alternative or that it may be removed in the future based on deprecation policy.

noStatus

For backward compatibility for APIs not categorized. At some point this status will be disallowed and build time break will occur if resource not categorized with appropriate flag.

In the write-up above the terms command is used in place of API to describe the behavior of the mgmt::shared::settings::api-status::log::resource settings.

net

net arp

NAME
arp - Manages entries in the Address Resolution Protocol (ARP) table.

MODULE
net

SYNTAX
Configure the arp component within the net module using the syntax in the following sections.

CREATE/MODIFY

```
create arp [name]
options:
  description [string]
  ip-address [ip address ... ip address]
  mac-address [mac address]

modify arp [name]
options:
  description [string]
  mac-address [mac address]
```

edit arp [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties

DISPLAY

```
list arp
list arp [ [ [name] | [glob] | [regex] ] ... ]
show running-config arp
show running-config arp
[ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line

show arp
show arp [ [ [name] | [glob] | [regex] ] ... ]
options:
  (dynamic | static)
```

DELETE
delete arp [name]

DESCRIPTION
You can use the arp component to add entries to or delete entries from the ARP table.

You can create static ARP entries for IPv4 addresses to link-layer addresses, such as Ethernet media access control (MAC) addresses. You can view and delete static and dynamic ARP entries.

Note that you can use the db component in the sys module to configure how the system handles ARP entries for dynamic timeout, maximum dynamic entries, add reciprocal, and maximum retries. For more information, see sys db.

EXAMPLES

```
create arp myARP ip-address 10.10.10.20 mac-address 00:0b:09:88:00:9a
```

Creates an arp mapping of the IP address 10.10.10.20 to the MAC address 00:0b:09:88:00:9a, and the name of this entry is myARP. Alternatively, the address can be used as the name, like the following example.

```
create arp 10.10.10.20 mac-address 00:0b:09:88:00:9a
```

Creates an arp mapping of IP address 10.10.10.20 to the MAC address 00:0b:09:88:00:9a.

```
modify arp 10.10.10.20 mac-address 00:0b:09:88:00:9b
```

Modifies the ARP mapping of the ARP entry named 10.10.10.20 to the MAC address 00:0b:09:88:00:9b.

```
show arp
```

Displays ARP status and statistics for the system.

```
show arp any%2
```

Displays ARP status and statistics for all IP addresses in route domain 2. A glob expression displays the same result: show arp *%2.

list arp all-properties

Displays all properties for all ARP entries for the system.

list arp non-default-properties

Displays all non-default properties for all ARP entries for the system.

delete arp all

Deletes all ARP entries for the system.

delete arp myARP

Deletes the ARP entry named myARP.

OPTIONS

description

User defined description.

dynamic

Displays the status of dynamic ARP entries.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

ip address

Specifies the IP address, in one of the following formats, for which you want to configure an ARP entry:

IPv4 address in dotted-quad notation, for example, 10.10.10.1
host name, for example, www.f5.com

You can also specify a list of IP addresses separated by a single space. For example, this list contains three IP addresses:
10.10.10.20 10.10.10.21 10.10.10.22.

ip-address

The IP address to be mapped. This is optional, and if not present, the name needs to be a string that represents a valid IP address.

mac-address

Specifies a 6-byte ethernet address in not case-sensitive hexadecimal colon notation, for example, 00:0b:09:88:00:9a. You must specify a MAC address when you create an ARP entry.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

static

Displays the status of static ARP entries.

SEE ALSO

create, delete, edit, glob, list, modify, regex, show, tmsh

BIG-IP 2016-03-24 net arp(1)

net bwc policy

NAME

policy - Configures a bandwidth control policy for traffic flow.

MODULE

net bwc

SYNTAX

Configure the policy component within the net bwc module using the syntax in the following sections.

CREATE/MODIFY

create policy [name]

modify policy [name]

options:

app-service [[string] | none]

description [string]

dynamic [enabled]

max-rate [integer]

max-user-rate [integer]

```

max-user-rate-pps [integer]
ip-tos [ integer | pass-through]
link-qos [integer | pass-through]
measure [ disabled ]
log-publisher [[string] | none]
log-period [integer]
categories [none] {
    max-cat-rate [integer]
    max-cat-rate-percentage [integer]
    ip-tos [ integer | pass-through]
    link-qos [integer | pass-through]
    traffic-priority-map [string]
}
traffic-priority-map [string]

edit policy [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties

DISPLAY
list policy
list policy [ [ [name] | [glob] | [regex] ] ... ]
show running-config net policy
show running-config net policy [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties
    one-line

DELETE
delete net policy [all | [name] ]

```

DESCRIPTION

You can use the net bwc policy to create a bandwidth control policy to handle traffic flow, and then associate it with other components such as packet filter, iRule and virtual server. For details on packet filter, virtual server, please refer to the respective documentation.

EXAMPLES

```
create net bwc policy
```

Creates a bwc policy (see below).

```
list net bwc policy all-properties
```

Displays all of the properties of all of the bwc policies.

```
delete net bwc policy
```

Deletes a policy (see below).

Example for static policy:

```
net bwc policy silver_static_policy {
    max-rate 120mbps
}
```

Example for dynamic policy:

```
net bwc policy gold-dynamic-policy {
    categories {
        web {
            description "This is a web test category."
            max-cat-rate 600kbps
            ip-tos 7
            link-qos 5
        }
    }
    description "This is a test."
    dynamic enabled
    max-rate 40gbps
    max-user-rate 1gbps
}
```

Example for dynamic policy with measure enabled:

```
net bwc policy gold-dynamic-policy {
    categories {
        web {
            description "This is a web test category."
            max-cat-rate 600kbps
            ip-tos 7
            link-qos 5
        }
    }
    description "This is a test."
    dynamic enabled
    measure enabled
    log_publisher /Common/my_log_publisher
    log-period 2048
    max-rate 40gbps
    max-user-rate 1gbps
}
```

Example for BWC using packet filter:

```
net bwc policy bwc {
    max-rate 1mbps
}
```

Define packet filter with bwc on it:

```
net packet-filter pfilter {
```

```

action continue
bwc policy bwc
logging enabled
order 2
rule ip
}

```

Example for BWC association with virtual server:

```

ltm virtual l2-for-virtual {
  destination 0.0.0.0:any
  l2-forward
  mask any
  profiles {
    fastL4 { }
  }
  rules {
    bwc_test
  }
  translate-address disabled
  translate-port disabled
  vlans {
    lan
    wan
  }
  vlans-enabled
}
ltm virtual tcp-passthrough {
  destination 0.0.0.0:http
  ip-protocol tcp
  mask any
  profiles {
    tcp { }
  }
  rules {
    bwc_test
  }
  translate-address disabled
  vlans-disabled
}

```

Example for Delete bwc policy:

```
net bwc policy silver_static_policy
```

Example for bwc policy traffic map:

```

net bwc policy bwc-policy-105 {
  categories {
    cat1 {
      max-cat-rate 10mbps
      traffic-priority-map tcl->cat1
    }
    cat2 {
      max-cat-rate 10mbps
      traffic-priority-map tcl->cat2
    }
  }
  dynamic enabled
  max-rate 100mbps
  max-user-rate 10mbps
}

```

Notes: Only static policies are supported for association with packet filter or virtual server components.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

name Specifies a unique name for the policy. This option is required for the commands create, delete, and modify.

description

User defined description.

max-rate

Specifies the maximum bandwidth that traffic is allowed using the policy associated. The range is from 1Mbps to 320Gbps.

Valid units: bps(default), gbps, kbps, mbps.

max-user-rate

Specifies the maximum bandwidth that traffic is allowed using the policy associated. The range is from 5kbps to 2Gbps.

Valid units: bps(default), gbps, kbps, mbps.

max-user-rate-pps

Specifies the limiter in packets per second that traffic is allowed using the associated policy. This does not allocate any fairshare bandwidth. When configured this acts purely as a simple packet limiter. It is packet size and protocol agnostic. It can be configured only on a dynamic policy. When configured along with mbps values, whichever lower limit pps vs mbps is applied. When configured, both need to pass for packets to go through. The default value is 0 (not configured).

traffic-priority-map

Specifies the bwc priority-group to use during congestion. This is

optional and to be configured only as needed. A bwc priority-group can be shared and amongst categories of the same bwc policy but not across bwc policies. When configured on policy or category, the max-user-rate or max-cat-rate as configured would be additionally applied. Thus the lower of all values for max. rates would take effect.

max-cat-rate

Specifies the maximum bandwidth that traffic is allowed using this category with associated policy. The range is from 5Kbps to max-user-rate.

Valid units: bps(default), gbps, kbps, mbps.

max-cat-rate-percentage

Specifies the percentage of the value of the max-cat-rate option of the category, which is associated with the net bwc policy component to which this shaping policy is associated, that is available for this traffic flow. It is the maximum bandwidth as percentage of that traffic is allowed using this category with associated policy. The range is from 1 to 100.

dynamic

Specifies the type for policy to be dynamic type. This option is optional for the commands create, delete, and modify. The default valid is disabled. When dynamic is disabled, the policy type is said to be static, where the maximum rate is enforced for combined traffic using the policy and no fairness bandwidth guarantee for each of the traffic respectively. The default value is: disabled. Note: policy type change modification is a disallowed configuration.

By enabling this option, the policy is dynamic type and requires you to configure max-user-rate-range. This type of policy enforces fairness for all the traffic associated with the policy and also for each traffic within the policy.

ip-tos

Specifies an IP ToS number for the traffic using the net bwc policy. This option specifies the ToS level that the traffic management system assigns to UDP packets when sending them. The default value is pass-through, which indicates, do not modify UDP packets. The valid range for IP ToS value that can be specified is 0 to 63.

Note: If this is specified, bandwidth policy is not enforced. The packets are just marked for a downstream system to process.

link-qos

Specifies a Link QoS (VLAN priority) for the traffic using the net bwc policy. This option specifies the QoS level that the system assigns to UDP packets when sending. The default value is pass-through, which indicates, do not modify UDP packets. The valid range for QoS value is 0 to 7.

Note: If this is specified, bandwidth policy is not enforced. The packets are just marked for a downstream system to process.

measure

Enables or disables bandwidth measurement on all the future instances of bwc policy. Users can override this setting using iRules. If enabling measurement on all instances is not desired then users can keep this setting disabled and use iRules to enable measurement on specific instances of bwc policy.

log_publisher

Specifies the name of the log publisher configured in the system. Bandwidth measurement results will be sent to this log publisher.

log_period

Time interval in milliseconds representing the frequency of generation of bandwidth measurement logs.

categories

This specifies the categories under policy. Note: policy need to be enabled as dynamic to configure categories. Up to a maximum of 32 categories can be configured. All the categories under the dynamic policy share the bandwidth as specified for the category, up to a maximum of max-user-rate. Specify the maximum bandwidth for the category of traffic using max-cat-rate or by max-cat-rate-percentage as a percentage of the maximum user rate. Either only the range or absolute value is required.

Example to configure a dynamic bandwidth policy category using tmsh:

```
root@(localhost)(cfg-sync
Standalone)(Active)(/Common)(tmos.net.bwc policy.gold-dynamic-policy)# categories add { web { max-cat-rate 600kbps
net bwc policy gold-dynamic-policy {
categories {
web {
max-cat-rate 600kbps
}
}
dynamic enabled
max-rate 40gbps
max-user-rate 1gbps
}
}
```

The parameters for dynamic policy and categories:

```
net bwc policy test-policy {
app-service none
```

```

categories {
  web {
    app-service none
    description "This is a web test cat"
    max-cat-rate 600kbps
    max-cat-rate-percentage 0
    ip-tos 6
  }
}
description "This is a test"
dynamic enabled
ip-tos pass-through
link-qos pass-through
max-rate 40gbps
max-user-rate 1gbps
measure enabled
log-publisher /Common/my_log_publisher
log-period 2048
partition Common
}

```

Few Examples using iRule:

Please refer to iRule documentation for complete list of bwc commands.
Below are few examples and do not cover all cases.

Example to associate static bwc policy using iRule:

```

when CLIENT_ACCEPTED {
  BWC::policy attach silver_static_policy
}

```

Example to associate dynamic bwc policy using iRule:

```

when CLIENT_ACCEPTED {
  set mycookie [IP::remote_addr]
  BWC::policy attach gold-dynamic-policy $mycookie
}

```

Example for bwc policy to mark traffic flows using iRule:

```
BWC::mark > >
```

So to assign a policy, color, and mark here is an example rule

```

when CLIENT_ACCEPTED {
  set mycookie [IP::remote_addr]:[TCP::remote_port]
  BWC::policy attach gold_user $mycookie
  BWC::color set gold_user p2p
  BWC::mark set gold_user tos 8 qos 4
}

```

Example for using bwc policy category to color a flow using iRule:

After a flow has been assigned a policy, at some later time when the traffic is classified the user can assign an application to this flow. This uses the bwc config to create a bwc policy with the categories keyword: for example, p2p category below:

```
tmsh create net bwc policy gold_user categories add { p2p { max-cat-rate 8mbps } } max-rate 10mbps max-user-rate 10mbps dynamic enabled
```

The rule args

```
BWC::color
```

So to assign a policy and color here is an example rule

```

when CLIENT_ACCEPTED {
  set mycookie [IP::remote_addr]:[TCP::remote_port]
  BWC::policy attach gold_user $mycookie
  BWC::color set gold_user p2p
}

```

Example for bwc policy rate change using iRule:

After a policy is created, irule can modify the rate for a session or category

The rule args

```
BWC::rate
```

```
BWC::rate
```

So to modify the rate

```

when CLIENT_ACCEPTED {
  set mycookie [IP::remote_addr]:[TCP::remote_port]
  BWC::policy attach gold_user $mycookie
  BWC::color set gold_user p2p
  BWC::mark set gold_user tos 8 qos 4
  BWC::rate $mycookie p2p 1000000bps
}

```

Example for bwc policy to measure the bandwidth using iRule:

```
BWC::measure << | | >
[session_str]>
```

To start the bandwidth measurement for BWC policy

```

when CLIENT_ACCEPTED {
  set mycookie [IP::remote_addr]:[TCP::remote_port]
  BWC::policy attach gold_user $mycookie
}

```

```
BWC::measure start session
}
```

The above iRule will start the measurement of bandwidth on the gold user policy instance. The results will be published to the destination specified in the log_publisher setting for the gold_user bwc policy. The measurement results will be logged every 'log_period' amount of time, which is also specified in the policy settings for gold_user.

Note: Attaching a BWC policy is a pre-requisite for all 'BWC::measure.' iRules. Failing to do so will result in the iRule execution failure which in turn will abort the connection.

To start the bandwidth measurement for a flow inside a BWC policy and tag the results.

```
when CLIENT_ACCEPTED {
  set mycookie [IP::remote_addr]:[TCP::remote_port]
  BWC::policy attach gold_user $mycookie
  BWC::measure identifier MYFLOW flow
  BWC::measure start flow
}
```

The above iRule will start the measurement of bandwidth on the current flow or the flow over which the current iRule is running. The results will be published to the destination specified in the log_publisher setting for the gold_user bwc policy. The measurement results will be logged every 'log_period' amount of time, which is also specified in the policy settings for gold user. Every log message containing the bandwidth result will carry the tag 'MYFLOW'. This helps identify different types of bandwidth results when analyzing the bandwidth measurement results.

To start the bandwidth measurement for a BWC session and get the periodic results.

```
when CLIENT_ACCEPTED {
  set mycookie [IP::remote_addr]:[TCP::remote_port]
  set measureID "MYSESSION"
  BWC::policy attach gold_user $mycookie
  BWC::measure identifier $measureID session
  BWC::measure start session
}
```

```
when SERVER_CONNECTED {
  TCP::collect
  set count 0
}
```

```
when SERVER_DATA {
  if {$count >= 1000 } {
    set rate [BWC::measure get rate session]
    set bytes [BWC::measure get bytes session]

    log local0. "Rate $rate/sec : Bytes $bytes : for address $mycookie"
    set count 0
  }
  TCP::release
  TCP::collect
  incr count
}
```

The above example creates an instance of BWC policy gold user and enables measurement on it upon the iRule event CLIENT_ACCEPTED. It also starts collecting so that it keeps getting notified upon the data arrival. For every 1000 packets a measurement of bandwidth is logged. This is an example that illustrates how to measure bandwidth periodically using iRules. Note that the bandwidth measurement results are still sent to configured log_publisher at every log_period interval.

An example log message that is sent to a log publisher.

```
Apr  2 16:29:04 MYSESSION BWC Measurement: Moving average - 539277
bytes/sec. Total bytes - 7305051
```

Example for bwc policy using pps:

```
BWC::pps
```

```
when CLIENT_ACCEPTED {
  set mycookie [IP::remote_addr]:[TCP::remote_port]
  BWC::policy attach gold_user $mycookie
  BWC::pps 100
}
```

net bwc priority-group

NAME
priority-group - Configures a bandwidth control policy for traffic flow.

MODULE
net bwc

SYNTAX
Configure the priority-group component within the net bwc module using the syntax in the following sections.

CREATE/MODIFY
create priority-group [name]
modify priority-group [name]
options:
 app-service [[string] | none]
 description [string]
 priority-classes [none] {
 description [string]
 weight-percentage [integer]
 }
edit priority-group [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 non-default-properties

DISPLAY
list priority-group
list priority-group [[[name] | [glob] | [regex]] ...]
show running-config net bwc priority-group
show running-config net bwc priority-group [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 non-default-properties
 one-line

DELETE
delete net bwc priority-group [all | [name]]

DESCRIPTION
You can use the net bwc priority-group to create a bandwidth traffic group policy to handle traffic flow, and then associate it with bwc component such as bwc policy/category.

EXAMPLES
create net bwc priority-group

Creates a bwc policy (see below).

list net bwc priority-group all-properties

Displays all of the properties of all of the bwc policies.

delete net bwc priority-group

Deletes a bwc traffic group (see below).

Example for dynamic policy:

net bwc priority-group tc-GOLD {
 priority-classes {
 tc-BLUE {
 weight-percentage 30
 }
 tc-RED {
 weight-percentage 20
 }
 }
}

app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

name Specifies a unique name for the policy. This option is required for the commands create, delete, and modify.

description
User defined description.

weight-percentage
Specifies the percentage of maximum bandwidth that traffic is allowed during congestion using the traffic class associated. The valid range is 5-100.

iRule
Please refer to iRule documentation for iRule to use bandwidth control

policy.

SEE ALSO

create, delete, edit, glob, list, modify, regex, show, tmsh

COPYRIGHT

BIG-IP 2016-05-18 net bwc priority-group(1)

net bwc traffic-group

NAME

traffic-group - Configures a bandwidth control policy for traffic flow.

MODULE

net bwc

SYNTAX

Configure the traffic-group component within the net bwc module using the syntax in the following sections.

CREATE/MODIFY

```
create traffic-group [name]
modify traffic-group [name]
options:
  app-service [[string] | none]
  description [string]
  dynamic [ enabled ]
  priority-classes [none] {
    weight-percentage [integer]
  }
```

```
edit traffic-group [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list traffic-group
list traffic-group [ [name] | [glob] | [regex] ] ... ]
show running-config net bwc traffic-group
show running-config net bwc traffic-group [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

DELETE

```
delete net bwc traffic-group [all | [name] ]
```

DESCRIPTION

You can use the net bwc traffic-group to create a bandwidth traffic group policy to handle traffic flow, and then associate it with bwc component such as bwc policy/category.

EXAMPLES

```
create net bwc traffic-group
```

Creates a bwc policy (see below).

```
list net bwc traffic-group all-properties
```

Displays all of the properties of all of the bwc policies.

```
delete net bwc traffic-group
```

Deletes a bwc traffic group (see below).

Example for dynamic policy:

```
net bwc traffic-group tc-GOLD {
  priority-classes {
    tc-BLUE {
      weight-percentage 30
    }
    tc-RED {
      weight-percentage 20
    }
  }
}
```

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates

option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

name Specifies a unique name for the policy. This option is required for the commands create, delete, and modify.

description
User defined description.

weight-percentage
Specifies the maximum bandwidth that traffic is allowed during congestion using the traffic class associated. The range is from 1Mbps to 320Gbps.

Valid units: bps(default), gbps, kbps, mbps.

dynamic
Specifies the type for traffic group to be dynamic type. This option is optional for the commands create, delete, and modify. The default valid is disabled. When dynamic is disabled, the traffic group type is said to be static. The type of traffic group should match with be bwc policy that would be mapped. Note: policy type change modification is a disallowed configuration.

iRule
Please refer to iRule documentation for iRule to use bandwidth control policy.

net clone-stats

NAME
clone-stats - Display and Reset Clone Statistics.

MODULE
net

SYNTAX
Display and Reset the clone-stats component within the net module using the syntax in the following section.

MODIFY
reset-stats clone-stats

DISPLAY
show clone-stats
options:
(default | field-fmt)

DESCRIPTION
You can use the clone-stats component to display and reset clone statistics. This will help to debug the clone feature.

OPTIONS
For information about the options that you can use with the command show, see help show.

SEE ALSO
reset-stats, show, tmsh

COPYRIGHT

BIG-IP 2017-01-20 net clone-stats(1)

net cmetrics

NAME
cmetrics - Displays and deletes entries in the route metrics table on the BIG-IP(r) system.

MODULE
net

SYNTAX
Use the cmetrics component within the net module to view route metrics or delete a route metric entry using the following syntax.

DISPLAY
show cmetrics
option:
bandwidth
dest-addr [ip address]
hwaddress
mtu
rtt
rttvar
ssthresh
tmm

DELETE
delete cmetrics
option:
dest-addr [IP address]

DESCRIPTION
You can use the cmetrics component to display entries in the route metrics table on the BIG-IP system. Additionally, you can delete a specified route metric entry from the table. The options are display-values and cannot be used for filtering.

Note: You can delete only entries that have no connection references.

EXAMPLES
show cmetrics
Displays all the entries in the route metrics table.

delete cmetrics dest-addr 10.10.1.11
Deletes the entry with destination IP address 10.10.1.11 from the route metrics table.

OPTIONS
bandwidth
Displays the size of the channel in kbps. Computed as cwnd/rtt.

dest-addr
Specifies the destination IP address of the entry that you want to display or delete. You can enter this address in either IPv4 or IPv6 format.

hwaddress
Displays the Media Access Control (MAC) address for the route.

mtu Displays the maximum transmit unit size (in bytes) on the route.

rtt Displays the round-trip time on the route in units of 100ns.

rttvar
Displays the variation in the round-trip time in units of 100ns.

ssthresh
Displays the cached slow-start threshold in bytes.

tmm Displays the identifying number of the tmm (Traffic Management Microkernel).

SEE ALSO
delete, show, tmsh

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

net cos global-settings

NAME
global-settings - Configures the global configuration for class of service (CoS).

MODULE
net cos

SYNTAX
Modify the global-settings component within the net cos module using the syntax shown in the following sections.

CREATE/MODIFY
modify global-settings
options:
feature-enabled
feature-disabled
precedence [dscp-only, 8021p-only]
default-map-dscp
[add | delete | modify | replace-all-with] {
[map-dscp-name] ...
}
default-map-8021p
[add | delete | modify | replace-all-with] {
[map-8021p-name] ...
}
default-traffic-priority [traffic-priority-name]

DISPLAY
list global-settings
options:
all-properties
non-default-properties
one-line
show global-settings

DESCRIPTION
You can use the global-settings component to configure and view information about the global settings of all CoS behavior.

show keyword displays an analysis of the relative weights of the associated traffic-priority objects.

EXAMPLES
modify global-settings default-traffic-priority NORMAL_PRIORITY

Replace the default traffic-priority with traffic-priority NORMAL_PRIORITY.

modify global-settings default-map-8021p add { VOIP }

Add the VOIP 802.1p mapping. The VOIP object specifies the 802.1p field value and associated traffic priority.

OPTIONS
feature-enabled
Enable 8 hardware egress CoS queue feature.

feature-disabled
Disable 8 hardware egress CoS queue feature.

precedence
Specifies the precedence between handling of DSCP and 802.1p. Currently, provided options are dscp-only and 8021p-only.

default-map-dscp
Enables adding and removal of mappings between DSCP field values and traffic priorities. See net cos traffic-priority and net cos map-dscp.

default-map-8021p
Enables adding and removal of mappings between 802.1p field values and traffic priorities.

default-traffic-priority
Specifies the default traffic-priority which is applied to all traffic that does not match a specified DSCP/802.1p field value. This allows the user to specify only the mappings which do not match the default.

SEE ALSO
net cos traffic-priority, net cos map-dscp

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2008-2013, 2016. All rights reserved.

net cos map-8021p

NAME
map-8021p - Configures vlan 8021.p tag to traffic priority mapping.

MODULE
net cos

SYNTAX
Modify the map-8021p component within the net cos module using the syntax shown in the following sections.

CREATE/MODIFY
create map-8021p [name]
modify map-8021p [name]
options:
value [0..7]
traffic-priority [name]

edit map-8021p [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties

DISPLAY
list map-8021p
list map-8021p [[[name] | [glob] | [regex]] ...]

show map-8021p
show map-8021p [[[name] | [glob] | [regex]] ...]
options:
all-properties
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
field-fmt

DELETE
delete map-8021p [name]

DESCRIPTION
The map-8021p object allows users to associate 802.1p field values to relative traffic priority. These objects are associated with active system configuration via net cos global-settings.

EXAMPLES
create map-8021p VOIP value 4 traffic-priority HIGH_PRIORITY

Create the map-8021p named VOIP that associates 802.1p value 4 traffic with traffic-priority named HIGH_PRIORITY.

delete map-8021p VOIP

Delete the map-8021p named VOIP.

OPTIONS
value
Specifies the 802.1p field value.

traffic-priority
Specifies the traffic-priority object associated with traffic matching value.

SEE ALSO
create, delete, edit, glob, list, net cos global-settings, modify, net cos traffic-priority, net cos map-dscp, regex, show, tmsh

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2008-2013. All rights reserved.

BIG-IP 2013-07-01 net cos map-8021p(1)

net cos map-dscp

NAME
map-dscp - Configures IP DSCP field to traffic priority mapping.

MODULE
net cos

SYNTAX

Modify the map-dscp component within the net cos module using the syntax shown in the following sections.

```

CREATE/MODIFY
create map-dscp [name]
modify map-dscp [name]
options:
  value [0..7]
  traffic-priority [name]

edit map-dscp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list map-dscp
list map-dscp [ [ [name] | [glob] | [regex] ] ... ]

show map-dscp
show map-dscp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt

DELETE
delete map-dscp [name]

```

DESCRIPTION

The map-dscp object allows users to associate DSCP field values to relative traffic priority. These objects are associated with active system configuration via net cos global-settings.

EXAMPLES

```

create map-dscp VOIP value 4 traffic-priority HIGH_PRIORITY

Create the map-dscp named VOIP that associates DSCP value 4 traffic
with traffic-priority named HIGH_PRIORITY.

delete map-dscp VOIP

Delete the map-dscp named VOIP.

```

OPTIONS

```

value
Specifies the DSCP field value.

traffic-priority
Specifies the traffic-priority object associated with traffic
matching value.

```

SEE ALSO

create, delete, edit, glob, list, net cos global-settings, modify, net cos traffic-priority, net cos map-dscp, regex, show, tmsb

BIG-IP 2013-07-01 net cos map-dscp(1)

net cos traffic-priority

NAME

traffic-priority - Configures a traffic priority object.

MODULE

net cos

SYNTAX

Modify the traffic-priority component within the net cos module using the syntax shown in the following sections.

```

CREATE/MODIFY
create traffic-priority [name]
modify traffic-priority [name]
options:
  weight [1..127]
  buffer [1..127]

edit traffic-priority [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties

```

```

non-default-properties

DISPLAY
list traffic-priority
list traffic-priority [ [ [name] | [glob] | [regex] ] ... ]

show traffic-priority
show traffic-priority [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt

DELETE
delete traffic-priority [name]

DESCRIPTION
The traffic-priority object allows users to assign relative scheduling
and buffer weightings. These objects are associated to specific traffic
with net cos map-dscp and net cos map-8021p. There can be at most 8
traffic-priorities defined in the system. The DEFAULT_PRIORITY priority
may be deleted or modified as desired.

EXAMPLES
create traffic-priority HIGH_PRIORITY weight 127

Create the traffic-priority HIGH_PRIORITY that has a weight of 127.

delete traffic-priority HIGH_PRIORITY

Delete the traffic-priority named HIGH_PRIORITY.

OPTIONS
weight
Specifies the egress buffer weight. This value is used relative to
other egress traffic-priority objects typical of weighted round-
robin behavior.

buffer
Specifies the relative buffer weight where available egress buffer
space is distributed with consistent relative weight.

SEE ALSO
create, delete, edit, glob, list, net cos global-settings, modify, net
cos map-dscp, net cos map-8021p, regex, show, tmsb

```

net dag-globals

```

NAME
dag-globals - configure global disaggregation settings.

MODULE
net

SYNTAX
Configure the dag-globals component within the net module using the
syntax shown in the following sections.

MODIFY
modify dag-globals
options:
  round-robin-mode [global | local]
  dag-ipv6-prefix-len [integer]
  icmp-hash [icmp | ipicmp]

edit dag-globals
options:
  all-properties
  non-default-properties

DISPLAY
list dag-globals
show running-config dag-globals
options:
  all-properties
  non-default-properties
  one-line

DESCRIPTION

```

Provides the ability to configure global disaggregation settings.

round-robin-mode

Specifies whether the round robin disaggregator (DAG) on a blade can disaggregate packets to all the TMMs in the system or only to the TMMs local to the blade.

dag-ipv6-prefix-len

Specifies whether SPDAG or IPv6 prefix DAG should be used to disaggregate IPv6 traffic when vlan cmp hash is set to src-ip or dst-ip. The default value is 128, using SPDAG.

icmp-hash

Specifies ICMP hash for ICMP echo request and ICMP echo reply in SW DAG. ICMP echo request and ICMP echo reply can be disaggregated based on ICMP id or ICMP id and IP addresses. The default ICMP hash is ICMP id.

BIG-IP 2016-08-12 net dag-globals(1)

net dns-resolver

NAME

resolver - Configures a DNS resolver on the BIG-IP(r) system.

MODULE

net dns-resolver

SYNTAX

Configure the DNS resolver component using the syntax in the following sections.

CREATE/MODIFY

```
create [name]
modify [name]
options:
  answer-default-zones [yes | no]
  app-service [[string] | none]
  cache-size [integer]
  description [string]
  forward-zones [add | delete | modify | replace-all-with] {
    [ [zone-name] ] {
options:
  nameservers [add | delete | replace-all-with] {
    [ [IPv4address:port] | [IPv6address.port] ]
  }
  nameservers none
  }
  forward-zones none
  randomize-query-name-case [yes | no]
  route-domain [name]
  use-ipv4 [yes | no]
  use-ipv6 [yes | no]
  use-tcp [yes | no]
  use-udp [yes | no]
```

DISPLAY

```
list
list [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
show [name]
reset-stats
```

DELETE

```
delete [name]
```

DESCRIPTION

You can use the dns-resolver component to configure and view information about a DNS Resolver object. A DNS resolver performs recursive resolution to fill its cache.

Important: When sizing caches, consider the total amount of memory available and how you wish to allocate memory for DNS caching. Note that cache sizing values are per-TMM process; therefore, a platform with eight TMMs consumes the amount of memory set for the Resolver

object times eight.

Important: DNS Resolver objects use the DNS root nameservers published by InterNIC.

EXAMPLES

list

Displays the properties of the DNS Resolver myRes.

OPTIONS

answer-default-zones

Specifies whether the resolver answers queries for default zones: localhost, reverse 127.0.0.1 and ::1, and AS112 zones. The default value is no.

app-service

Specifies the name of the application service to which this dns-resolver belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this dns-resolver. Only the application service can modify or delete this dns-resolver.

cache-size

Specifies the maximum cache size in bytes of the DNS Resolver object. The default value is 5767168.

The BIG-IP system caches the supporting records in a DNS response in the resource record cache. After the maximum size of the cache is reached, when new or refreshed content is added to the cache, the expired and older content is removed from the cache. A higher maximum size allows more DNS responses to be cached and increases the cache hit percentage. A lower maximum size forces earlier eviction of cached content, but can lower the cache hit percentage.

description

User defined description.

forward-zones

Adds, deletes, modifies, or replaces a set of forward zones on a DNS Resolver, by specifying zone name(s). A given zone name should only use the symbols allowed for a fully qualified domain name (FQDN), namely ASCII letters a through z, digits 0 through 9, hyphen -, and period .. For example site.example.com would be a valid zone name.

A DNS Resolver configured with a forward zone will forward any queries that resulted in a cache-miss (the answer was not available in the cache) and which also match a configured zone name, to the nameserver specified on the zone. If no nameservers are specified on the zone, an automatic SERVFAIL is returned. When a forward zone's nameserver returns a valid response to the DNS Cache, that response is cached and then returned to the requestor.

nameservers

Adds, deletes, modifies, or replaces a set of nameservers in a forward zone on a DNS Resolver. A nameserver is represented by an IP address and port in the format [IPv4:port] or [IPv6.port], for example 10.10.10.10:53 or 2001::1:ff.53, respectively.

If more than one nameserver is listed for a given forward zone, a matching query will be sent to the nameserver that is currently deemed the most responsive (based on RTTs). If no response is received within a certain window of time, the DNS Resolver will resend the query to another nameserver with an increased wait window, until a response is received.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

randomize-query-name-case

Specifies whether the resolver randomizes the case of query names. The default value is yes.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

route-domain

Specifies the route domain the resolver uses for outbound traffic. The default value is the default route domain.

use-ipv4

Specifies whether the resolver sends DNS queries to IPv4 addresses. The default value is yes.

use-ipv6

Specifies whether the resolver sends DNS queries to IPv6 addresses. The default value is yes.

use-tcp

Specifies whether the resolver can send queries over the TCP protocol. The default value is yes.

use-udp

Specifies whether the resolver can send queries over the UDP protocol. The default value is yes.

net f5optics

NAME

f5optics - Manage f5optics package.

MODULE

net

SYNTAX

Manage net f5optics using the syntax in the following section.

INSTALL

```
install f5optics
  options:
    recovery
    slot [ [slot number] | all ]
```

SHOW

```
show f5optics
```

DESCRIPTION

The f5optics package specifies the supported optical PHY modules and their tuning parameters for network interfaces. You can use the f5optics component to manage the f5optics package. The install command will install f5optics with the latest f5optics package under /shared/f5optics/images. Additionally, for a cluster, you can use the slot option to specify either a specific slot or all slots to install the f5optics package.

Notice that the installation will cause network interfaces to be re-initialized on the affected slot(s), hence a temporary traffic interruption.

The show command will display the version information of the installed f5optics package on the appliance, or all the slots in a cluster.

EXAMPLES

```
install net f5optics
```

Install the f5optics package on the appliance, or all the slots in a cluster.

```
install net f5optics slot all
```

Install the f5optics package on all the slots in a cluster.

```
install net f5optics recovery slot all
```

Install the f5optics package on all the slots in a cluster, even if it is not newer than the installed package.

```
install net f5optics slot 2
```

Install the f5optics package on slot 2.

```
show net f5optics
```

Show the f5optics package on the appliance, or all the slots in a cluster.

OPTIONS

recovery

Always install the latest f5optics package, even if it is not newer than the installed package. This is for recovery purposes.

```
slot [ [slot number] | all ]
```

Install the f5optics package on either a specific slot or all slots in a cluster, without changing the active volume of the slot(s).

This option is only available in a clustered environment.

net fdb tunnel

NAME
tunnel - Manages tunnel entries in the Layer 2 Forwarding table.

MODULE
net fdb

SYNTAX
Configure the tunnel component within the net fdb module using the syntax in the following sections.

MODIFY
modify tunnel [tunnel name]
options:
app-service [[string] | none]
records [add | delete | modify | replace-all-with] {
[MAC address] {
app-service [[string] | none]
description [string]
endpoint [IP address]
endpoints [add | delete | modify | replace-all-with] {
[IP address(es)]
}
replicators [add | delete | modify | replace-all-with] {
[IP address(es)]
}
}
records none

DISPLAY
list tunnel
list tunnel [[[tunnel name] | [glob] | [regex]] ...]
show tunnel
show tunnel [[[tunnel name] | [glob] | [regex]] ...]
options:
all-records
dynamic
field-fmt
static

DELETE
delete tunnel [tunnel name]
options:
all-records
dynamic
static

DESCRIPTION
You can use the tunnel component to manage tunnel entries in the Layer 2 Forwarding table.

EXAMPLES
modify tunnel t1 records add { 00:01:02:03:04:05 { endpoint 10.10.0.2 }
}

Creates a tunnel entry for the specified tunnel in the Layer 2 Forwarding table.

modify tunnel t1 records none

Deletes all configured tunnel entries for the specified tunnel in the Layer 2 Forwarding table.

modify tunnel t1 records add { ff:ff:ff:ff:ff:ff { endpoints add { 10.10.0.2 10.10.0.3 10.10.0.4 } } }

Creates a set of endpoints for the specified tunnel in the Layer 2 Forwarding table.

list tunnel

Displays all configured tunnel entries in the Layer 2 Forwarding table.

show tunnel

Displays all dynamic and static tunnel entries in the Layer 2 Forwarding table.

```
delete tunnel t1 all-records
```

Deletes all dynamic and static tunnel entries in the Layer 2 Forwarding table.

OPTIONS

all-records

Applies the command to all dynamic and static tunnel entries in the Layer 2 Forwarding table.

dynamic

Applies the command to all dynamic tunnel entries in the Layer 2 Forwarding table.

static

Applies the command to all static tunnel entries in the Layer 2 Forwarding table.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

net fdb vlan

NAME

vlan - Manages VLAN entries in the Layer 2 Forwarding table.

MODULE

net fdb

SYNTAX

Configure the vlan component within the net fdb module using the syntax in the following sections.

MODIFY

```
modify vlan [vlan name]
options:
  app-service [[string] | none]
  records
    [add | delete | modify | replace-all-with] {
[MAC address] ... {
  app-service [[string] | none]
  description [string]
  trunk [trunk name]
  interface [interface name]
}
}
records none

edit vlan [ [ all | [vlan name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list vlan
list vlan [ [ [vlan name] | [glob] | [regex] ] ... ]
show running-config vlan
show running-config vlan [ [vlan name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
  records

show vlan
show vlan [ [ [vlan name] | [glob] | [regex] ] ... ]
options:
  dynamic
  field-fmt
```

static

```
DELETE
delete vlan
delete vlan [all | [vlan name] ]
options:
  all-records
  dynamic
  static
```

DESCRIPTION

You can use the vlan component to manage entries in VLAN Layer 2 Forwarding tables.

EXAMPLES

```
modify vlan internal records add { 00:0b:09:88:00:9a { interface 1.2 }
}
```

Creates a mapping of the MAC address 00:0b:09:88:00:9a to interface 1.2 on VLAN internal.

```
modify vlan internal records modify { 00:0b:09:88:00:9a { interface 1.1
} }
```

Modifies the mapping of the MAC address 00:0b:09:88:00:9a to interface 1.1 on VLAN internal.

```
show vlan
```

Displays all dynamic and static entries in the Layer 2 Forwarding table.

```
list vlan all-properties
```

Displays all properties for all static entries in the Layer 2 Forwarding table.

```
list vlan non-default-properties
```

Displays all non-default properties for all static entries in the Layer 2 Forwarding table.

```
delete vlan all
```

Deletes all entries in all VLAN Layer 2 Forwarding tables.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

all-records

Deletes, from the specified VLAN, all dynamic and static records.

description

User defined description.

dynamic

Displays or deletes all dynamic entries in the Layer 2 Forwarding table.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

interface

Specifies an interface to which you want to map a MAC address. You must specify either an interface or a trunk when you create an entry in the Layer 2 Forwarding table.

MAC address

Specifies a 6-byte ethernet address in not case-sensitive hexadecimal colon notation, for example, 00:0b:09:88:00:9a. You must specify a MAC address when you create an entry in the Layer 2 Forwarding table.

partition

Displays the administrative partition in which the VLAN resides.

records

Specifies MAC addresses for the VLAN Layer 2 Forwarding table. Specifies MAC addresses that you want to add to, delete from, modify, or replace in the VLAN Layer 2 Forwarding table.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

static

Displays or deletes all static entries in the Layer 2 Forwarding table.

trunk

Specifies a trunk to which you want to map a MAC address. You must specify either an interface or a trunk when you create an entry in the Layer 2 Forwarding table.

net interface-cos

NAME
interface-cos - Displays and resets COS (Class of Service) related statistics for the interfaces.

MODULE
net

SYNTAX
Display cos related statistics within the net module using the following syntax.

MODIFY
reset-stats interface-cos

DISPLAY
show interface-cos
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
global

DESCRIPTION
You can use the interface-cos component to display COS related statistics, including pkts out and bits out for all 8 COS queue.

EXAMPLES
show interface-cos

Displays interface COS related statistics for the system.

For information about the command reset-stats, see help reset-stats.

SEE ALSO
reset-stats, show,

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
field-fmt

DESCRIPTION

You can use the interface component to enable or disable an interface, and to display and set media options, duplex mode, and status for an interface. In addition, you can specify whether the interface participates in the spanning tree protocol (STP) configuration, and set per-interface STP parameters such as link type, edge port status, and automatic edge port detection.

EXAMPLES

modify interface 1.1 enabled
Enables the interface named 1.1.

modify interface 1.2 disabled
Disables the interface named 1.2.

modify interface 1.1 1.2 1.3 stp disable
Disables STP on the interfaces named 1.1, 1.2, and 1.3.

modify interface 1.1 1.2 1.3 stp-auto-edge-port enabled
Sets auto edge detection for STP on the interfaces named 1.1, 1.2, and 1.3.

modify interface 1.1 1.2 1.3 stp-edge-port true
Sets the edge port attribute for STP on the interfaces named 1.1, 1.2, and 1.3.

OPTIONS

description
User defined description.

[disabled | enabled]
Enables or disables the specified interface. The default value is enabled.

flow-control
Specifies how the system controls the sending of PAUSE frames for flow control. The default value is tx-rx.

none Disables flow control.

rx Specifies that the interface honors pause frames from its partner, but does not generate pause frames.

tx Specifies that the interface ignores pause frames from its partner, and generates pause frames when necessary.

tx-rx
Specifies that the interface honors pause frames from its partner, and also generates pause frames when necessary.

force-gigabit-fiber
Enables or disables forcing of gigabit fiber media. If this is enabled for a gigabit fiber interface, the media setting will be forced, and no auto-negotiation will be performed. If it is disabled, auto-negotiation will be performed with just a single gigabit fiber option advertised.

forward-error-correction
Enables or disables IEEE 802.3bm Clause 91 Reed-Solomon Forward Error Correction (RS-FEC) on 100G interfaces. This setting is not valid for LR4 media. This setting must be the same on both ends of the link.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

if-index
Displays the index assigned to this interface. It is a unique identifier assigned for all objects displayed in the SNMP IF-MIB.

mac-address
Displays the 6-byte ethernet address in not case-sensitive hexadecimal colon notation, for example, 00:0b:09:88:00:9a.

media
Specifies the settings for the interface. The possible values are: 10baseT-full, 10baseT-half, 10GbaseER full, 10GbaseLR-full, 10GbaseSR-full, 10GbaseT-full, 10SFP+Cu-full, 40GbaseSR4-full, 40GbaseLR4-full, 100baseTX-half, 100baseTX-full, 1000baseLX full, 1000baseCX-full, 1000baseT-full, 1000baseT-half, 1000baseSX-full, auto, and no-phy.

When you set the media option, the system automatically sets either the media-sfp or media-fixed option, based on whether the interface supports small factor form pluggable (SFP) interfaces, or for combo ports whether SFP is the preferred port.

media-active
Displays the current media setting for the interface.

media-fixed
Specifies the settings for a fixed (non-pluggable) interface. Use this option only with a combo port to specify the media type for the fixed interface, when it is not the preferred port.

media-max
Displays the maximum media value for the interface.

media-sfp
Specifies the settings for an SFP (pluggable) interface. Note that you use this option only with a combo port to specify the media type for the SFP interface, when it is not the preferred port.

module-description
Displays an optics module description about the interface. It is only available on a SFP/SFP+/XFP/QSFP+ unit.

mtu Displays the Maximum Transmission Unit (MTU) of the interface, which is the maximum number of bytes in a frame without IP fragmentation.

name Specifies an interface name, for example 3.1, where 3 is the physical slot number holding the network interface hardware and 1 is the physical port number of that interface on that hardware. Another example is mgmt, the name given to the management interface.

no-mgmt
Ensures that no changes are made to the mgmt interfaces when all is specified. This is especially convenient when disabling all traffic interfaces using the disabled command.

[pending | not-pending]
Pending indicates that the slot with which the interface is associated does not contain a blade. Not-pending indicates that the slot with which the interface is associated is not a cluster member. The default value is pending.

port-fwd-mode
Specifies the port forwarding mode. The default value is l3.

The options are:

l3 Specifies to use the l3 mode. This is the traditional mode of operation of BIGIP, wherein BIGIP forwards traffic between 2 VLANs.

passive
Specifies to use the passive mode. Use this mode to enable the BIGIP to process out of band traffic. In this mode, the BIGIP assumes the received traffic is a copy of real inline traffic, and while it processes it like regular traffic, traffic received on such an interface is never forwarded out.

virtual-wire
Specifies to use the virtual-wire mode. Use this mode to enable the BIGIP to operate like a L2 switch - transparent to the neighboring devices. Packets received on a virtual-wire interface can only be forwarded to another virtual-wire-configured interface. Such traffic retains the L2 header and is forwarded to the same VLAN.

prefer-port
Indicates which side of a combo port the interface uses, if both sides of the port have the potential for external links. The default value is sfp. Do not use this option for non-combo ports.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

sflow
Specifies sFlow settings for the interface:

poll-interval
Specifies the maximum interval in seconds between two pollings. The default value is 0. To enable this setting, you must also set the poll-interval-global setting to no.

poll-interval-global
Specifies whether the global interface poll-interval setting, which is available under sys sflow global-settings module, overrides the object-level poll-interval setting. The default value is yes.

The available values are:

no Specifies to use the object-level poll-interval setting.

yes Specifies to use the global interface poll-interval setting.

serial
Displays the serial number of the pluggable unit on an

interface. It is only available on a SFP/SFP+/XFP/QSFP+ unit.

`stp` Enables or disables STP. If you disable STP, no STP, RSTP, or MSTP packets are transmitted or received on the interface or trunk, and spanning tree has no control over forwarding or learning on the port or the trunk. The default value is enabled.

`stp-auto-edge-port`
Sets the STP automatic edge port detection for the interface. The default value is enabled. When STP automatic edge port detection is set to enabled on an interface, the system monitors the interface for incoming STP, RSTP, or MSTP packets. If no such packets are received for a sufficient period of time (about three seconds), the interface is automatically given edge port status. When automatic edge port detection is set to disabled on an interface, the system does not automatically give the interface the edge port status. Any STP setting set on a per-interface basis applies to all spanning tree instances.

`stp-edge-port`
Sets STP edge port detection. The default value is true.

`stp-link-type`
Specifies the STP link type for the interface. The default value is auto.

The spanning tree system includes important optimizations that can only be used on point-to-point links. That is, on links that connect just two bridges. If these optimizations are used on shared links, incorrect or unstable behavior may result. By default, the implementation assumes that full-duplex links are point-to-point and that half-duplex links are shared.

The options are:

`auto` Specifies that the system determines the spanning tree link type, which is based on the duplex setting.

`p2p` Specifies that the system uses the optimizations for point-to-point spanning tree links. Point-to-point links connect only two spanning tree bridges.

`shared`
Specifies that the system uses the optimizations for shared spanning tree links. Shared links connect two or more spanning tree bridges.

`stp-reset`
Resets STP, which forces a migration check.

`qinq-ethertype`
Specifies the ether-type value used for the packets handled on this port when it is a member in a QinQ vlan. The ether-type can be set to any string containing a valid hexadecimal 16 bits number, or any of the well known ether-types: 0x8100, 0x9100, 0x88a8. Default value is set to 0x8100.

`bundle`
Sets the bundle capability on the port.

`bundle-speed`
Sets the bundle-speed on the port when bundle capability is enabled.

`if-index`
Displays the index assigned to this interface. It is a unique identifier assigned for all objects displayed in the SNMP IF-MIB.

`vendor`
Displays the name of the vendor of the pluggable unit on an interface. It is only available on a SFP/SFP+/XFP/QSFP+ unit.

`vendor-partnum`
Displays the part number programmed by the vendor of the pluggable unit on an interface. It is only available on a SFP/SFP+/XFP/QSFP+ unit.

DELETE
delete ip-address-list [[name] | all]

DESCRIPTION
You can use the ip-address-list component to define reusable lists of addresses.

EXAMPLES
create ip-address-list alist1 addresses add { 10.10.1.1 10.10.1.2
192.168.24.0/24 }

Creates a new address list, "alist1," with two IPv4 addresses and one IPv4 subnet.

```
modify ip-address-list alist1 addresses modify { 10.10.1.1 {  
description "management IP at wwmcd site3" } }
```

Modifies the above address list with a description for the first address.

```
modify ip-address-list alist1 addresses add { 2001:DB8:a::/64 }
```

Modifies the same address list by adding an IPv6 subnet.

```
list ip-address-list alist1  
net ip-address-list alist1 {  
addresses {  
10.10.1.1 {  
description "management IP at wwmcd site3"  
}  
10.10.1.2 { }  
192.168.24.0/24 { }  
2001:db8:a::/64 { }  
}  
}
```

Shows the modified address list.

OPTIONS
addresses
Specifies a list of individual IP addresses and/or subnets. The format for an IPv4 address is a.b.c.d[/prefix]. The general format for an IPv6 address is a:b:c:d:e:f:g:h[/prefix]; you can shorten this by eliminating leading zeros from each field (for example, you can shorten "2001:0db7:3f4a:09dd:ca90:ff00:0042:8329" to "2001:db7:3f4a:9dd:ca90:ff00:42:8329"), and/or by removing the longest contiguous field of zeros (for example, you can shorten "2001:0:0:0:c34a:0:23ff:678" to "2001::c34a:0:23ff:678"). TMSH accepts any valid text representation of IPv6 addresses, as defined in RFC 2373 (see).

The next keyword specifies the action to take with the addresses (add, delete, modify, or replace the current set of addresses).

add Creates a new address list, which you specify next with IP addresses and/or prefixes in curly braces ({}).

delete
Deletes the address(es) that you specify next, in curly braces ({}).

modify
Makes it possible to replace the optional description(s) for the address(es). You can specify a description in a nested set of curly braces after each address.

replace-all-with
Replaces the current set of IP addresses with the address(es) that you specify next, in curly braces ({}).

app-service
Associates this address list with a particular Application Service. An Application Service is a major component of an iApp,

an advanced configuration tool for creating and maintaining similar applications on multiple servers.

description

Is your description for this address list.

BIG-IP 2017-09-05 net ip-address-list(1)

net ipsec-stat

NAME

action - Displays and resets IPsec statistics.

MODULE

ipsec-stat

SYNTAX

Display statistics for the action component within the IPsec module using the syntax in the following section.

DISPLAY

show action

option:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION

You can use the action component to display IPsec statistics. The statistics details are described below:

Cmd Id

Specifies the CPU id for IPsec.

Mode Specifies the IPsec mode (TRANSPORT/TUNNEL).

Proto

Specifies the IPsec Protocol (ESP/AH)..

Packets In

Specifies the number of incoming IPsec packets.

Bytes In

Specifies the number of incoming IPsec bytes.

Packets Out

Specifies the number of outgoing IPsec packets.

Bytes Out

Specifies the number of outgoing IPsec bytes.

EXAMPLES

show action

Displays IPsec statistics.

reset-stats action

Resets the IPsec statistics.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, tmsh

BIG-IP 2017-03-02 net ipsec-stat(1)

net ipsec ike-daemon

NAME
ike-daemon - Configures the Internet Key Exchange (ISAKMP) daemon.

MODULE
net ipsec

SYNTAX
Configure the ike-daemon component within the net ipsec module using the syntax in the following sections.

MODIFY
modify ike-daemon
options:
description [string]
isakmp-natt-port [port number]
isakmp-port [port number]
log-level [error|warning|notify|info|debug|debug2]
natt-keep-alive [seconds]
log-publisher [string]

DISPLAY
list
list ike-daemon
show running-config ike-daemon
options:
all-properties
non-default-properties
one-line

DESCRIPTION
You can use the ike-daemon component to configure global settings for the IKE agent.

EXAMPLES
modify ike-daemon isakmp-port 500

Sets the isakmp port to 500.

OPTIONS
description
User defined description.

isakmp-natt-port
Specifies the port that the IKE daemon uses to accept ISAKMP messages when NAT-Traversal is detected. This is also the port number used to accept UDP-encapsulated ESP traffic for NAT-Traversal. Only 4500 is currently supported.

isakmp-port
Specifies the port that the IKE daemon uses to accept ISAKMP messages. Only 500 is currently supported.

log-level
Specifies the logging level of the IKE daemon. The log file is located at /var/log/racoon.log.

natt-keep-alive
Specifies the interval between sending NAT-Traversal keep-alive packets. The default value is 20 seconds. Set to 0 to disable keep-alive packets.

log-publisher
Specifies the logging publisher. A new log-publisher object can be created via TMSH command tmsh create sys log-config publisher.

SEE ALSO

show running-config ike-peer
show running-config ike-peer [name]
options:
 all-properties
 non-default-properties
 one-line

DELETE
delete ike-peer
delete ike-peer [name]

DESCRIPTION
You can use the ike-peer component to modify the IKE phase 1 parameters for each remote IKE peer. The setting in the default anonymous ike-peer will apply to any peer that does not match a more specific ike-peer directive.

EXAMPLES
create ike-peer SanJose { remote-address 1.2.3.4 preshared-key abc
 phases-auth-method pre-shared-key }

Creates an ike-peer named SanJose that has the IP address of 1.2.3.4 using preshared key as the authentication method.

OPTIONS
app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

ca-cert-file
Specifies the file name, which contains the certificates of the trusted root and intermediate certificate authorities.

crl-file
Specifies the file name of the Certificate Revocation List.

description
User-defined description.

dpd-delay
This option activates the Dead Peer Detection (DPD) and sets the time (in seconds) allowed between two proofs of liveness requests. The default value is 30. When the value is set to 0, it means to disable DPD monitoring, but still negotiate DPD support.

generate_policy

This directive is for the responder. To use it, set passive to true so the IKE peer is only a responder. If the responder does not have any policy in the Security Policy Database (SPD) during phase 2 negotiation, and the directive is set to on, then the racoon daemon chooses the first proposal in the Security Association (SA) payload from the initiator, and generates policy entries from the proposal. It is useful to negotiate with clients whose IP address is allocated dynamically. If an inappropriate policy is installed into the responder's SPD by the initiator, other communications might fail due to a policy mismatch between the initiator and the responder. The initiator ignores this directive. The default value is off.

lifetime

Specifies the lifetime of an IKE SA that will be proposed in the phase 1 negotiations.

mode Specifies the exchange mode for phase 1 when racoon is the initiator, or the acceptable exchange mode when racoon is the responder.

my-cert-file

Specifies the name of my certificate file. The certificate type must match the phasel-auth-method value. Note that there are no default certificates for DSS and ECDSA authentication methods.

my-cert-key-file

Specifies the name of my certificate key file. The certificate key type must match the phasel-auth-method value. Note that there are no default keys for DSS and ECDSA authentication methods.

my-cert-key-passphrase

Specifies the passphrase of the key used for my-cert-key-file. Note that only IKEv2 supports passphrase.

my-id-type

Specifies the identifier type sent to the remote host to use in the phase 1 negotiation.

my-id-value

Specifies the identifier value sent to the remote host to use in the phase 1 negotiation.

nat-traversal

Enables use of the NAT-Traversal IPsec extension (NAT-T). NAT-T allows one or both peers to reside behind a NAT gateway (that is, performing address- or port-translation). The presence of NAT gateways along the path is discovered during the phase 1 handshake, and if found, NAT-T is negotiated. When NAT-T is in charge, all ESP and AH packets of a given connection are encapsulated into UDP datagrams (port 4500, by default). The options are:

force

NAT-T is used regardless of whether NAT is detected between the peers.

off NAT-T is not proposed/accepted. This is the default.

on NAT-T is used when a NAT gateway is detected between the peers.

passive

Specify true if you do not want to be the initiator of the IKE negotiation with this ike-peer.

peers-cert-file

Specifies the peer's certificate for authentication. Deprecated in IKEv2 configuration.

peers-cert-type

Specifies that the only peers-cert-type supported is certfile. Deprecated in IKEv2 configuration.

peers-id-type

Specifies that address, fqdn, asn1dn, user-fqdn, or keyid-tag can be used as peers-id-type.

peers-id-value

Specifies the peer's identifier to be received. If it is not defined, then the IKE agent will not verify the peer's identifier in the ID payload transmitted from the peer. The usage of peers-id-type and peers-id-value is the same as my-id-type and my-id-value except that the individual component values of an asn1dn identifier may be specified as * to match any value (for example, "C=XX, O=MyOrg, OU=*, CN=Mine").

phase1-auth-method

Defines the authentication method used for the phase 1 negotiation. Possible values are: pre-shared-key if using pre-shared-key, and rsa-signature, dss, ecdsa-256, ecdsa-384 or ecdsa-521 if using X.509 certificate-based authentication. Note that dss, ecdsa certificates are supported in IKEv2 only."

phase1-encrypt-algorithm

Specifies the encryption algorithm used for the ISAKMP phase 1 negotiation. This directive must be defined. Possible value is one of following: des, 3des, blowfish, cast128, aes, or camellia for Oakley.

phase1-hash-algorithm

Defines the hash algorithm used for the ISAKMP phase 1 negotiation. This directive must be defined. The algorithm should be one of following: md5, sha1, sha256, sha384, or sha512 for

Oakley.

phase1-perfect-forward-secrecy
Defines the Diffie-Hellman group for key exchange to provide perfect forward secrecy. This directive must be defined in one of Diffie-Hellman groups: modp768, modp1024, modp1536, modp2048, modp3072, modp4096, modp6144 and modp8192, or one of Elliptic-Curve Diffie-Hellman groups: ecp256, ecp384 and ecp521. Note that ECDH is supported in IKEv2 only.

pre-shared-key
Specifies the pre-shared key for ISAKMP SAs. This field is valid only when phase1-auth-method is pre-shared-key.

pre-shared-key-encrypted
Specifies the pre-shared key for ISAKMP SAs. This field is valid only when phase1-auth-method is pre-shared-key. Stores pre-shared-key in encrypted form.

prf Specifies the pseudo-random function to derive keying material for all cryptographic operations.

proxy-support
If this value is enabled, both values of ID payloads in the phase 2 exchange are used as the addresses of end-point of IPsec-SAs. This attribute must be enabled, which is the default value. This field is used only for IKEv1.

remote-address
Specifies the IP address of the IKE remote node. The format required for specifying a route domain ID in an IP address is A.B.C.D%ID. For example, A.B.C.D%2, where the IP address A.B.C.D pertains to route domain 2. The route domain id should be same as the route domain id specified in the source/destination address of the traffic selector associated with this remote node.

replay-window-size
Specifies the replay window size of the IPsec SAs negotiated with the IKE remote node. This window limits the number of out-of-order IPsec packets that can be received relative to the packet with the highest sequence number that has been authenticated so far. Packets with older sequence numbers that are outside this range are rejected. The default value is 64. The valid range is from 4 to 255.

state
Enables or disables this IKE remote node.

traffic-selector
Specifies the names of the traffic-selector objects associated with this ike-peer.

verify-cert If set to true, the identifier sent by the remote host (as specified in its my_identifier statement) is compared with the credentials in the certificate as follows: Type asnldn: the entire certificate subject name is compared with the identifier, e.g. \"C=XX, O=YY, ...\". Type address, fqdn, or user fqdn: The certificate's subjectAltName is compared with the identifier. If the two do not match, the negotiation will fail. The default value is false, which is not to verify the identifier using the peer's certificate.

version
Specifies which version of IKE to be used. The default value is v1. The following versions are available:

v1 Specifies version IKEv1 will be used.
v2 Specifies version IKEv2 will be used.

net ipsec ike-sa

NAME
ike-sa - Displays IKE security associations on the BIG-IP(r) system.

MODULE
net ipsec

SYNTAX

Use the ike-sa component within the ipsec module to manage IKE security associations using the following syntax.

```
DISPLAY
show ike-sa
option:
  all-properties
  peer-ip [IP address]
  peer-name [name]
  route-domain [integer]
  traffic-selector [name]
```

DESCRIPTION
You can use the ike-sa component to display information about IKE security associations in the system.

EXAMPLES
show ike-sa all-properties

Display detail information about IKE security associations.

OPTIONS

- peer-ip
Specifies the peer IP address of the security associations that you want to display.
- peer-name
Specifies the peer name of the security associations that you want to display.
- route-domain
Specifies route domain used for traffic that you want to display. The default value is the default route domain.
- traffic-selector
Specifies the name of the traffic-selector associated with the security associations that you want to display.

SEE ALSO
show

net ipsec ipsec-policy

NAME
ipsec-policy - Configures the IPsec security policy.

MODULE
net ipsec

SYNTAX
Configure the ipsec-policy component within the net ipsec module using the syntax in the following sections.

```
CREATE/MODIFY
create ipsec-policy [name]
modify ipsec-policy [name]
options:
  app-service [[string] | none]
  description [string]
  ike-phase2-auth-algorithm [aes-gcm128 | aes-gcm192 | aes-gcm256 | aes-gmac128 | aes-gmac192 | aes-gmac256 | sha1 |
  ike-phase2-encrypt-algorithm [3des | aes128 | aes192 | aes256 | aes-gcm128 | aes-gcm192 | aes-gcm256 | aes-gmac128
  ike-phase2-lifetime [integer]
  ike-phase2-lifetime-kilobytes [integer]
  ike-phase2-perfect-forward-secrecy [modp1024 | modp1536 | modp2048 | modp3072 | modp4096 | modp6144 | modp768 | mo
  ipcomp [deflate| none | null]
  mode [transport | tunnel | isession | interface]
  protocol [esp]
  tunnel-local-address [ip address]
  tunnel-remote-address [ip address]
```

```
DISPLAY
list ipsec-policy
list ipsec-policy [ [name] | [glob] | [regex] ] ... ]
show running-config ipsec-policy
show running-config ipsec-policy [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  partition
```

DESCRIPTION

An ipsec-policy indicates the ipsec rule and action to be applied to the packets matched by the traffic-selector associated with this ipsec-policy.

EXAMPLES

```
create ipsec ipsec-policy tunnel_policy_sjc_sea { description "ipsec
policy for the sjc-sea ipsec tunnel" mode tunnel tunnel-local-address
1.1.1.1 tunnel-remote-address 2.2.2.2 }
```

Creates the tunnel mode ipsec-policy tunnel_policy_sjc_sea.

```
delete ipsec ipsec-policy tunnel_policy_sjc_sea
```

Deletes the ipsec-policy tunnel_policy_sjc_sea.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

ike-phase2-auth-algorithm

Specifies a payload authentication algorithm for ESP. This attribute is only valid when IKE is used to negotiate Security Associations. The possible options are: aes-gcm128, aes-gcm192, aes-gcm256, aes-gmac128, aes-gmac192, aes-gmac256, sha256, sha384, sha512 and sha1. The default value is aes-gcm128.

Note: Because aes-gcm and aes-gmac are authenticated encryption algorithms, when ike-phase2-auth-algorithm is set to aes-gcm or aes-gmac, ike-phase2-encrypt-algorithm has to be set to the identical algorithm with the same key length. sha256, sha384, sha512 and sha1 can only be used with an encryption algorithm that is NOT an authenticated encryption algorithm.

ike-phase2-encrypt-algorithm

Specifies an encryption algorithm for ESP. This attribute is only valid when IKE is used to negotiate security associations. The default value is aes-gcm128.

Note: Because aes-gcm and aes-gmac are authenticated encryption algorithms, when ike-phase2-encrypt-algorithm is set to one of these algorithms, ike-phase2-auth-algorithm has to be set to the identical algorithm with the same key length.

ike-phase2-lifetime

Specifies the lifetime duration in minutes, for the dynamically-negotiated security associations (SA). This attribute is only valid when IKE is used to negotiate security associations.

ike-phase2-lifetime-kilobytes

Specifies the lifetime duration in kilobytes, for the dynamically-negotiated security associations (SA). This attribute is only valid when IKE is used to negotiate security associations. A value of '0' means the SA will not re-key based on the number of bytes encrypted/decrypted. The minimum recommended value is 1000 kilobytes. This value is not negotiated between peers."

ike-phase2-perfect-forward-secrecy

Defines the group of Diffie-Hellman exponentiations. This attribute is only valid when IKE is used to negotiate Security Associations. The value 'none' indicates that the PFS is disabled for phase2 SA negotiations.

mode Specifies a security protocol mode for use. The options are:

transport

IPsec transport mode is used.

tunnel

IPsec tunnel mode is used.

isession

A special tunnel mode ipsec-policy that is only applicable on wom, remote-endpoint, or local-endpoint.

interface

IPsec interface mode is used.

protocol

Specifies the IPsec protocol: Encapsulating Security Payload (ESP) or Authentication Header (AH).

ipcomp

Specifies the compression algorithm for IPComp. The following codec are available:

none Disable IPComp

deflate

Packets will be encapsulated with IPComp header and Deflate compression algorithm will be applied to the data.

null Packets will be encapsulated with IPComp header but no compression algorithm will be applied to the data.

tunnel-local-address

Specifies the IP address of the local IPsec tunnel endpoint. This

option is only valid when mode is tunnel. The format required for specifying a route domain ID in an IP address is A.B.C.D%ID. For example, A.B.C.D%2, where the IP address A.B.C.D pertains to route domain 2.

tunnel-remote-address
Specifies the IP address of the remote IPsec tunnel endpoint. This option is only valid when mode is tunnel. The format required for specifying a route domain ID in an IP address is A.B.C.D%ID. For example, A.B.C.D%2, where the IP address A.B.C.D pertains to route domain 2.

net ipsec ipsec-sa

NAME
ipsec-sa - Displays IPsec security associations on the BIG-IP(r) system.

MODULE
net ipsec

SYNTAX
Use the ipsec-sa component within the ipsec module to manage IPsec security associations using the following syntax.

DISPLAY
show ipsec-sa
option:
all-properties
src-addr [IP address]
dst-addr [IP address]
route-domain [integer]
spi [integer]
traffic-selector [name]

DESCRIPTION
You can use the ipsec-sa component to display information about IPsec security associations in the system.

EXAMPLES
show ipsec-sa all-properties

Display detail information about IPsec security associations.

OPTIONS
src-addr
Specifies the source IP address of the security associations that you want to display.

dst-addr
Specifies the destination IP address of the security associations that you want to display.

route-domain
Specifies route domain used for traffic that you want to display. The default value is the default route domain.

spi Specifies the SPI of the security associations that you want to display.

traffic-selector
Specifies the name of the traffic-selector object associated with the security associations that you want to display.

SEE ALSO
show, net ipsec traffic-selector, net ipsec ipsec-policy, tmsh

net ipsec manual-security-association

NAME

manual-security-association - Configures the IPsec manual-security-association.

MODULE

net ipsec

SYNTAX

Configure the manual-security-association component within the net ipsec module using the syntax in the following sections.

CREATE/MODIFY

```
create manual-security-association
modify manual-security-association
options:
  app-service [[string] | none]
  description [string]
  auth-algorithm [shal]
  auth-key [key]
  destination-address [ip address]
  encrypt-algorithm [3des|aes128|aes192|aes256|null]
  encrypt-key [key]
  ipsec-policy [name]
  protocol [esp]
  source-address [ip address]
  spi [number]
```

DISPLAY

```
list manual-security-association
show running-config manual-security-association
options:
  app-service
  all-properties
  non-default-properties
  one-line
```

DELETE

```
delete manual-security-association [name]
```

DESCRIPTION

Manually configures Security Association Database(SAD) entries. Because each SA provides data protection only for unidirectional traffic, you must configure a manual-security-association for traffic in each direction to establish a bidirectional IPsec tunnel.

EXAMPLES

```
create ipsec manual-security-association msa_on_dut2_transport_in {
  auth-key test description "manual security association on dut2 for dut1
- transport" destination-address 7.7.7.7 encrypt-key test ipsec-policy
transport_policy_on_dut2 source-address 2.2.2.2 spi 1025 }
```

Creates a manual-security-association object named msa_on_dut2_transport_in to use IPsec to protect traffic from 2.2.2.2 to 7.7.7.7 with the authentication key test and the encryption key test. The ipsec-policy object named transport_policy_on_dut2 is associated with this manually configured security association.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

auth-algorithm

Specifies an authentication algorithm.

auth-key

Specifies the key for the authentication algorithm.

auth-key-encrypted

Displays the encrypted auth-key.

description

User-defined description.

destination-address

Specifies the destination of the security association.

encrypt-algorithm

Specifies an encryption algorithm.

encrypt-key

Specifies the key for the encryption algorithm.

`encrypt-key-encrypted`
Display the encrypted `encrypt-key`.

`ipsec-policy`
Specifies the `ipsec-policy` associated with this `manual-security-association`.

`protocol`
Specifies the IPsec protocol: Encapsulating Security Payload (ESP) or Authentication Header (AH).

`source-address`
Specifies the source address of the security association.

`spi` Specifies the Security Parameters Index. If this is the Security Association(SA) for the outbound traffic, make sure it matches the SPI of the inbound SA configured on the remote site and vice versa. SPI values between 0 and 255 are reserved for the future use by IANA and cannot be used.

net ipsec traffic-selector

NAME
`traffic-selector` - Configures a traffic selector for IPsec.

MODULE
`net ipsec`

SYNTAX
Configure the `traffic-selector` component within the `net ipsec` module using the syntax in the following sections.

CREATE/MODIFY
`create traffic-selector [name]`
`modify traffic-selector [name]`
options:
`action [protect]`
`app-service [[string] | none]`
`description [string]`
`destination-address [ip address/netmask]`
`destination-port [port number]`
`direction [both | in | out]`
`ipsec-policy [name]`
`ip-protocol [protocol number]`
`order [integer]`
`source-address [ip address/netmask]`
`source-port [port number]`

DISPLAY
`list traffic-selector`
`list traffic-selector [name]`
`show traffic-selector`
`show traffic-selector [name]`

DELETE
`delete traffic-selector`
`delete traffic-selector [name]`

DESCRIPTION
You can use the `traffic-selector` component to specify which incoming traffic you want the system to protect with IPsec.

EXAMPLES
`create traffic-selector sjc2sea { source-address 10.10.10.0/24 destination address 20.20.20.0/24 direction both ipsec-policy my_policy}`

Creates a `traffic-selector` named `sjc2sea`, which has the IP address of `10.10.10.0/24` using `ipsec-policy` named `my_policy`.

OPTIONS
`action`
Specifies how the system handles traffic that matches the criteria in the traffic selector. Only `protect` is currently supported.

`app-service`

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description
User defined description.

destination-address
Specifies the destination IP address of the traffic to be matched. The format required for specifying a route domain ID in an IP address is A.B.C.D%ID. For example, A.B.C.D%2, where the IP address A.B.C.D pertains to route domain 2.

destination-port
Specifies the destination port number of the traffic to be matched.

direction
Specifies the direction of traffic to be protected with IPsec. If the direction is both, use source-address and destination-address with respect to the outbound direction. The default value is both.

ip-protocol
Specifies the IP protocol of the traffic to be matched.

ipsec-policy
Specifies the name of the IPsec policy to be enforced on the matched traffic.

order
Specifies the order in which traffic is matched, if traffic can be matched to multiple traffic selectors. Traffic is matched to the traffic selector with the highest priority (lowest order number).

source-address
Specifies the source IP address of the traffic to be matched. The format required for specifying a route domain ID in an IP address is A.B.C.D%ID. For example, A.B.C.D%2, where the IP address A.B.C.D pertains to route domain 2.

source-port
Specifies the source port number of the traffic to be matched.

net lldp-globals

NAME
lldp-globals - configure lldp global settings.

MODULE
net

SYNTAX
Configure the lldp-globals component within the net module using the syntax shown in the following sections.

MODIFY
modify lldp-globals
options:
[disabled | enabled]
max-neighbors-per-port[integer]
reinit-delay[integer]
tx-delay[integer]
tx-hold[integer]
tx-interval[integer]
edit lldp-globals
options:
all-properties
non-default-properties

DISPLAY
list lldp-globals
options:
all-properties
non-default-properties

one-line

DESCRIPTION

Provides the ability to configure global LLDP settings.

[disabled | enabled]

To disable or enable LLDP feature on BIGIP.

max-neighbors-per-port

Specifies maximum neighbors per port BIGIP LLDP feature supports.

reinit-delay

Specifies time delay, in seconds, from when LLDP ports is disabled to a new LLDP initialization.

tx-delay

Specifies the minimum time delay, in seconds, between successive LLDP frame transmissions.

tx-hold

Specifies the multiplier to use to calculate the TTL of transmitted LLDP frame.

tx-interval

Specifies the time interval, in seconds, between LLDP frame transmission to its neighbors.

SEE ALSO

net mroute

NAME
mroute - Displays the multicast routes in the BIG-IP(r) system.

MODULE
net

SYNTAX
Display multicast route (mroute) entries within the net module using the syntax given below.

DISPLAY
show net mroute
options:
source [IP address]
group [multicast group address]

DESCRIPTION
Use the mroute component to display all the multicast routes in the BIG-IP(r) system. Results can be filtered using source option, group option, or both.

EXAMPLES
show net mroute

Displays all the multicast routes in the system.

show net mroute source 10.10.10.1

Displays all the multicast routes in the system whose source IP address is 10.10.10.1.

show net mroute group 224.1.0.13

Displays all the multicast routes in the system whose group multicast address is 224.1.0.13.

show net mroute source 10.10.10.1 group 224.1.0.13

Displays all the multicast routes in the system whose source IP address is 10.10.10.1 and group multicast address is 224.1.0.13.

OPTIONS
source
Specifies the source IP address of the multicast routes that you want to display.

group
Specifies the multicast group address to display. Only a single group may be specified with the group option.

SEE ALSO
show, tmsh

net multicast-globals

NAME
multicast-globals - Global IP multicast configuration options

MODULE
net

SYNTAX
Configure the multicast-globals component within the net module using the syntax shown in the following sections.

MODIFY
modify multicast-globals
options:
route-lookup-timeout [integer value: 0 ~ 2147483647]
max-pending-routes [integer value: 0 ~ 2147483647]
max-pending-packets [integer value: 0 ~ 2147483647]
rate-limit [disabled | enabled]

edit multicast-globals
options:
all-properties
non-default-properties

```

DISPLAY
list multicast-globals
show running-config multicast-globals
  options:
    all-properties
    non-default-properties
    one-line

DESCRIPTION
  Configure global options related to IP multicast traffic processing.

EXAMPLES
modify multicast-globals route-lookup-timeout 2

Specifies the maximum lifetime, in seconds, of an incomplete MFC entry.
The default value is 2.

modify multicast-globals max-pending-routes 256

Specifies the maximum number of incomplete MFC entries any TMM instance
can have at one time. The default value is 256.

modify multicast-globals max-pending-packets 16

Specifies the maximum number of packets queued on behalf of a single
incomplete MFC entry. The default value is 16.

modify multicast-globals rate-limit enabled

When enabled, the packet rate limit configured in the DB variable
switchboard.maxmcastrate is enforced. Otherwise multicast packets are
not rate limited. The default value is enabled.

OPTIONS

net ndp

```

NAME
  ndp - Configures IPv6-to-Ethernet neighbor discovery display and
  control.

MODULE
  net

SYNTAX
  Configure the ndp component within the net module using the syntax in
  the following sections.

  CREATE/MODIFY
  create ndp [name]
  options:
    description [string]
    ip-address [ip address]
    mac-address [MAC address]

  modify ndp [name]
  options:
    description [string]
    mac-address [MAC address]

  edit ndp [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties

  DISPLAY
  list ndp
  list ndp [ [ [name] | [glob] | [regex] ] ... ]
  show running-config ndp
  show running-config ndp
  [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties
    one-line

```

```

show ndp
show ndp [ [ [name] | [glob] | [regex] ] ... ]
options:
  [all | dynamic | field-fmt | static]

DELETE
delete ndp [ [all] | [name]... ]

DESCRIPTION
  Configures the IPv6-to-Ethernet address translation tables used by the
  IPv6 neighbor discovery protocol.

EXAMPLES
create ndp myNdp ip-address fec0:f515::c001 mac-address
00:0B:DB:3F:F6:57

Maps the IPv6 address, fec0:f515::c001, to the MAC address,
00:0B:DB:3F:F6:57, and the name of this entry is myNdp. Alternatively,
the address can be used as the name, like the following example.

create ndp fec0:f515::c001 mac-address 00:0B:DB:3F:F6:57

Maps the IPv6 address, fec0:f515::c001, to the MAC address,
00:0B:DB:3F:F6:57.

show ndp

Displays all static and dynamic IPv6 address-to-MAC address mappings.

OPTIONS
  ip-address
  The IP address that is to be mapped. This is optional, and if not
  present, the name needs to be a string that represents a valid IP
  address.

  description
  User defined description.

  dynamic
  Displays dynamic IPv6 address-to-MAC address mapping.

  glob Displays the items that match the glob expression. See help glob
  for a description of glob expression syntax.

  ip-address
  The IP address that is to be mapped. This is optional, and if not
  present, the name needs to be a string that represents a valid IP
  address.

  mac-address
  Specifies a 6-byte Ethernet address in hexadecimal colon notation
  that is not case-sensitive, for example, 00:0b:09:88:00:9a.

  regex
  Displays the items that match the regular expression. The regular
  expression must be preceded by an at sign (@[regular expression])
  to indicate that the identifier is a regular expression. See help
  regex for a description of regular expression syntax.

  static
  Displays static IPv6 address-to-MAC address mapping.

SEE ALSO
  create, delete, edit, glob, list, modify, regex, show, tmsb

net packet-filter-trusted

```

NAME
  packet-filter-trusted - Modifies or displays trusted allow lists for
  packet filters.

MODULE
  net

SYNTAX
  Configure the packet-filter-trusted component within the net module
  using the syntax in the following sections.

MODIFY
  modify packet-filter-trusted

```

```

options:
  description [string]
  ip-addresses none
  ip-addresses
    [add | delete | replace-all-with] {
[ip address ... ]
    }
  mac-addresses none
  mac-addresses
    [ add | delete | replace-all-with] ] {
[MAC address ...]
    }
  vlans none
  vlans
    [add | delete | replace-all-with] ] {
[vlan name ... ]
    }

```

edit packet-filter-trusted

```

DISPLAY
list packet-filter-trusted
show running-config packet-filter-trusted
options:
  all-properties
  non-default-properties
  one-line

```

DESCRIPTION

Use the packet-filter-trusted component to create a layer of security for the traffic management system using trusted allow lists.

Trusted allow lists are lists of IP addresses, MAC addresses, and VLANs that are exempt from packet filter rules.

Important: By default, packet filtering is disabled. You must enable packet filtering using the Configuration utility. For more information, see the TMOS(r) Management Guide for BIG-IP(r) Systems.

EXAMPLE

Creates a trusted allow list that allows anything listed to bypass the packet filter.

In the following example, you have an administrative laptop that you want to have unrestricted access to the traffic management system. This is a laptop, and therefore it might have a different IP address from time to time. One way to solve the problem is to add a trusted MAC address. This trusted allow list example shows the laptop MAC address as 00:02:3F:3E:2F:FE. Now the laptop can access the traffic management system regardless of what address it boots with or to which VLAN it is connected, as long as it is on the same physical segment as the traffic management system.

Also in this example, the traffic management system is configured for basic firewalling of the private/internal network. This example shows a way to filter incoming traffic and allow outgoing traffic to be unrestricted. To do this, you add trusted VLANs that represent all traffic that originated on the internal network. Another way to do this is to use trusted IP addresses instead, for example, 192.168.26.0/24.

```

modify packet-filter-trusted {
  vlans add { internal1 internal2 }
  mac-addresses add { 00:02:3F:3E:2F:FE }
}

```

OPTIONS

description
User defined description.

ip-addresses
Specifies a list of source IP addresses. Any traffic matching a source IP address in the list is automatically allowed. This simplifies configuration of the packet filter to allow trusted internal traffic to be passed from VLAN to VLAN without a filter rule, including out to the Internet. Processing of traffic by this option occurs before rule list evaluation, making it impossible to override this option and mask out (block) certain types of traffic with a packet filter rule. This option is empty by default.

mac-addresses
Specifies a list of MAC addresses. The system allows any traffic matching a MAC address in the source address list. This simplifies configuration of the packet filter to allow trusted internal traffic to be passed from VLAN to VLAN without a filter rule, including out to the Internet. Processing of traffic by this option occurs before rule list evaluation, making it impossible to override this option and mask out (block) certain types of traffic with a packet filter rule. This option is empty by default.

vlans
Specifies a list of ingress VLANs. Any traffic received on a VLAN that is on the ingress VLAN list is automatically allowed. This simplifies configuration of the packet filter to allow trusted internal traffic to be passed from VLAN to VLAN without a filter rule, including out to the Internet. Processing of traffic by this option occurs before rule list evaluation, making it impossible to override this option and mask out (block) certain types of traffic with a packet filter rule. This option is empty by default.

DELETE
delete packet-filter [all | [name]]

DESCRIPTION
You can use the packet-filter component to create a layer of security for the traffic management system using packet filter rules.

The BIG-IP(r) system packet filters are based on the Berkeley Software Design Packet Filter (BPF) architecture. Packet filter rules are composed of four mandatory attributes and three optional attributes. The mandatory attributes are name, order, action, and rule. The optional attributes are vlan, logging, and rate-class. The rule attribute you choose defines the BPF script to match for the rule.

Important: By default, packet filtering is disabled. You must enable packet filtering using the Configuration utility. For more information, see the TMOS(r) Management Guide for BIG-IP(r) Systems.

EXAMPLES
You can create a set of rules that specify what incoming traffic you want the system to accept and how to accept it. See the examples following.

Example 1: Block spoofed addresses
This example prevents private IP addresses from being accepted on a public VLAN. This is a way of ensuring that no one can spoof private IP addresses through the external VLAN of the system. In this example, the system logs when this happens:

```

create packet-filter spoof_blocker {
order 5
action discard
vlan external
logging enabled
rule " (src net 172.19.255.0/24) "
}

```

Example 2: Allow restricted management access

You can provide restricted SSH and HTTPS access to the traffic management system for management purposes, and keep a log of that access. Note: This not the same management access you can get through the management port/interface (mgmt); that interface is not affected by any packet filter configuration, and if that is the only way you want to allow access to your system, this configuration is not necessary.

In the first rule shown below, SSH is allowed access from a single fixed-address administrative workstation, and each access is logged. In the subsequent rule, browser-based Configuration utility access is allowed from two fixed-address administrative workstations; however, access is not logged.

```

create packet-filter management_ssh {
order 10
action accept
logging enabled
rule " (proto TCP) and (src host 172.19.254.10) and
(dst port 22) "
}

```

```

create packet-filter management_gui {
order 15
action accept
rule " (proto TCP) and (src host 172.19.254.2 or
src host 172.19.254.10) and (dst port 443) "
}

```

Example 3: Allow access to all virtual servers

In this final example, you can verify that all of the virtual servers in your configuration are reachable from the public network. This is critical if you have decided to use a default-deny policy. This example also shows how to rate shape all traffic to the virtual server IP address with a default rate class (that can be overridden by individual virtual servers or iRules(r) later).

Note: This example has a single virtual server IP, and it does not matter what port traffic is destined for. If you want to be more specific, you can specify each service port, as well (for example, HTTP, FTP, telnet).

```

create packet-filter virtuals {
order 20
action accept
vlan external
rate class root
rule " ( dst host 172.19.254.80 ) "
}

```

OPTIONS

You can use these options with the packet-filter component to create packet filter rules:

action

Specifies how the system handles a packet that matches the criteria in the packet filter rule. There is no default; you must specify a value when you create a packet filter rule.

The possible values are:

accept

Indicates that the system accepts the packet, and stops processing additional packet filter rules, if there are any.

continue

Indicates that the system acknowledges the packet for logging or statistical purposes, but makes no decision on how to handle the packet. The system continues to evaluate traffic matching a rule with the Continue action, starting with the next packet filter rule in the list.

discard

Indicates that the system drops the packet, and stops processing additional packet filter rules, if there are any.

reject

Indicates that the system drops the packet, and also sends a reject packet to the sender, indicating that the packet was refused.

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

logging
Enables or disables packet filter logging. If you omit this value, no logging is performed.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

order
Specifies a sort order greater than 0 (zero). No two rules may have the same sort order. There is a single, global list of rules. Each rule in the list has a relative integer order. The system first evaluates the rule with the lowest order value, and then evaluates all other rules based on ascent of the order value assigned to each rule.

For example, if there are 5 rules, numbered 500, 100, 300, 200, 201; the rule evaluation order is 100, 200, 201, 300, 500.

The system compares each packet to be filtered against the list of rules in sequence, starting with the first. Evaluation of the rule list stops on the first match that has an action of accept, discard or reject. A match on a rule with an action of none does not stop further evaluation of the rule list; the system updates the statistics count and generates a log if the rule indicates it, but otherwise rule processing continues with the next rule in the list.

F5 Networks recommends that you sequence rules for effect and efficiency; generally this means:

-- Assign the lowest order to more specific rules, so that the system will evaluate those rules first.

-- The system evaluates one expression with multiple criteria more efficiently than multiple expressions each with a single criterion.

This option is required.

rate-class
Specifies the name of a rate class. The value is the name of any existing rate class. If omitted, no rate filter is applied.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

rule Specifies the BPF expression to match. The rule is mandatory, however you can leave it empty. If empty, the packet filter rule matches all packets.

vlan Specifies the VLAN to which the packet filter rule applies. The value for this option is any VLAN name currently in existence. If you omit this value, the rule applies to all VLANs. If you do not provide a VLAN name when you create a packet-filter, the rule applies to all VLANs.

BIG-IP 2013-10-25 net packet-filter(1)

net packet-tester security

NAME

packet-tester - Shows if packet with given parameters passes through data path, which AFM policies and rules will be applied to the packet, if it will be dropped or not. This is shown for Dos in global and Virtual server context, IP Intelligence and ACL in global, route domain and listener context. You can only use the show command with this component.

MODULE

net

SYNTAX

```
show packet-tester security
dest-addr [IP address]
source-addr [IP address]
dest-port [TCP/UDP port]
source-port [TCP/UDP port]
protocol [protocol]
src-vlan [source vlan name]
check-staged[enable/disable]
trigger-log[enable/disable]
ttl[1 to 255]
syn[SYN TCP FLAG]
ack[ACK TCP FLAG]
rst[RST TCP FLAG]
fin[FIN TCP FLAG]
push[PUSH TCP FLAG]
urg[URG TCP FLAG]
```

DESCRIPTION

With user provided VLAN, source/destination IP addresses, TCP/UDP ports and protocol, the command will craft a packet and insert into data path to match these parameters against user configured DOS, ACL rules and IP intelligence global, route domain, VIP/SelfIP context, and return which policies, rules applied and the final action taken on packet. Both IPv4 and IPv6 addresses and IP/UDP/TCP/SCTP protocols are supported. Detail option with provide which specific policy and rule will be applied to such a packet. This command can be used as a diagnostic tool to trouble-shoot BigIP AFM configuration problem. It provides a faster way to identify which AFM config will have impact to the specified packet stream.

EXAMPLES

```
[root@bigip208:Active:Standalone] rpm # tmsm -s -m show net packet-
tester security dst-addr 41.41.41.41 dst-port 80 src-addr 8.8.8.1 src-
port 99 protocol udp src-vlan /Common/internal detail
```

```

BIG-IP 2016-09-13 net packet-tester security(1)

net port-list

```

NAME
port-list - A port list is a list of IP ports.

MODULE
net

SYNTAX
CREATE/MODIFY
create port-list [name]
modify port-list [[name] | all]
options:
  ports [add | delete | modify | replace-all-with] {
    [ [port] ]
  }
  app-service [name]
  description [string]

edit port-list [[name] | all]
options:
  all-properties
  non-default-properties

DISPLAY
list port-list [[name] | all | [property]]
show running-config port-list [[name] | all | [property]]

DELETE
delete port-list [[name] | all]

DESCRIPTION
You can use the port-list component to define reusable lists of ports.

EXAMPLES
create port-list plist1 ports add { 80 443 }

Creates a new port list, "plist1," with two ports.

modify port-list plist1 description "my port list"

Modifies the above port list with a description.

```

```
modify port-list plist1 ports add { 999 }
```

Modifies the same port list by adding port 999 to it.

```
list port-list plist1
net port-list plist1 {
  ports {
    description "my port list"
    999 { }
    http { }
    https { }
  }
}
```

Shows the modified port list.

OPTIONS

ports
Specifies a list of IP ports.

The next keyword specifies the action to take with the ports (add, delete, modify, or replace the current set of ports).

add Creates a new port list.

delete
Deletes the port(s) that you specify next, in curly braces ({}).

modify
Makes it possible to replace the optional description(s) for the port(s). You can specify a description in a nested set of curly braces after each port.

replace-all-with
Replaces the current set of IP ports with the port(s) that you specify next, in curly braces ({}).

app-service
Associates this port list with a particular Application Service. An Application Service is a major component of an iApp, an advanced configuration tool for creating and maintaining similar applications on multiple servers.

description
Is your description for this port list.

SEE ALSO

edit, list, modify, ltm virtual, tmsh

BIG-IP 2017-09-05 net port-list(1)

net port-mirror

NAME
port-mirror - Configures interface (port) mirroring.

MODULE
net

SYNTAX
Configure the port-mirror component within the net module using the syntax in the following sections.

```
CREATE/MODIFY
create port-mirror [interface_name]
modify port-mirror [interface_name]
options:
  app-service [[string] | none]
  interfaces
    [add | delete | replace-all-with] {
    [interface_name ... ]
    }
  interfaces [default | none]

edit port-mirror [ [ [interface_name] | [glob] | [regex] ] ... ]
options:
  all-properties

DISPLAY
```

```

list port-mirror
list port-mirror
  [ [interface_name] | [glob] | [regex] ] ... ]
show running-config port-mirror
show running-config port-mirror
  [ [interface_name] | [glob] | [regex] ] ... ]
options:
  one-line

DELETE
delete port-mirror [interface_name]

DESCRIPTION
  You can use the port-mirror component to mirror traffic from interfaces
  on a blade to other interfaces on the same blade or another blade.

EXAMPLES
  create port-mirror 1/1.1 interfaces add 1/1.2 1/1.3 1/1.4

  Creates a port mirror from interface 1.1 on blade 1 to interfaces
  1.2, 1.3, 1.4 on the same blade. The system mirrors traffic from
  interfaces 1.2, 1.3, and 1.4 on blade 1 to the interface 1.1 on
  the same blade.

  modify port-mirror 1/1.1 interfaces delete 1/1.3 1/1.4

  Deletes interfaces 1.3 and 1.4 on blade 1 from the existing port
  mirror 1/1.1 on the same blade.

OPTION
  app-service
  Specifies the name of the application service to which the object
  belongs. The default value is none. Note: If the strict-updates
  option is enabled on the application service that owns the object,
  you cannot modify or delete the object. Only the application
  service can modify or delete the object.

  glob Displays the items that match the glob expression. See help glob
  for a description of glob expression syntax.

  interface_name
  Specifies the name of the interface, for example, 1/1.1.

  regex
  Displays the items that match the regular expression. The regular
  expression must be preceded by an at sign (@[regular expression])
  to indicate that the identifier is a regular expression. See help
  regex for a description of regular expression syntax.

SEE ALSO
  create, delete, edit, glob, list, modify, "net interface", regex, show,
  tmsh

options:
  current-module
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DELETE
delete class [all | [name] ]

```

DESCRIPTION

You can use the class component to create a rate class. A rate class lets you specify shaping properties for a specific type of traffic, such as Layer 3 traffic that specifies a certain source, destination, or service. Specifically, a rate class defines the number of bits per second that the system accepts per flow and the number of packets in a queue.

You configure rate shaping by creating a class and then assigning the class to a packet filter, a virtual server, or from within an iRule. When you configure a class, you can associate another class with the class you are configuring using the parent option.

You can also associate drop policies, shaping policies, and queues with a class using the drop-policy, shaping-policy, and queue options of the class component. You can associate pre-configured drop policies and queues with the class, or you can create custom drop policies, queues, and shaping policies, and then associate them with the class.

Note that if you specify a value for the shaping-policy option of the class, the system automatically changes the ceiling-percentage, drop-policy, max-burst, queue, and rate-percentage options of the class to match the values in the specified shaping policy.

EXAMPLES

```

create class my_class rate 10

Creates a class named my_class with a rate of 10.

list class all-properties

Displays all of the properties of all of the classes.

```

OPTIONS

app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

ceiling
Specifies (in bps) how far beyond the value specified for the rate option that traffic can flow. This number sets an absolute limit. No traffic can exceed this rate. The rate class might limit traffic throughput to the value of the rate option when there is high contention among siblings of a parent-child class hierarchy. The default value is the value of the rate option. The minimum value is 296 bps.

ceiling-percentage
Specifies the ceiling of the rate class as a percentage of the ceiling of the associated parent class. This option applies only to rate classes with an associated parent rate class. The default value is 0 (zero), which indicates that the class uses the value of the ceiling option.

description
User defined description.

direction
Specifies the direction of traffic to which the class is applied. The default value is any.

drop-policy
Specifies the name of a drop policy. You can use one of the pre-configured drop policies, or you can create a customized drop policy using the drop-policy component.

The default value is tail, which is the simplest drop policy. The pre-configured drop policies are:

fred Specifies that the system uses Flow-based Random Early Detection to decide whether to drop packets based on the aggressiveness of each flow.

red Specifies that the system uses Random Early Detection to determine whether to drop packets to maintain the average queue length within the specified range.

tail Specifies that the system drops all incoming packets when the queue is full.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

max-burst
Specifies the maximum number of bytes that traffic can burst beyond the value of the rate option. The traffic may not burst higher than the value of the ceiling option. The default value is 0 (zero).

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

parent
Associates another class with this class. The class you are configuring (which when you configure a parent class for it becomes a child class) can borrow bandwidth from the parent class. The parent class can use any of the unused bandwidth of the child class.

queue
Specifies the queuing method. The default value is sfq. The pre-configured options are:

pfifo
The Priority FIFO queuing method queues all traffic under a set of five sub-queues based on the Type of Service (TOS) field of the traffic. Four of the sub-queues correspond to the four possible TOS values (Minimum delay, Maximum throughput, Maximum reliability, and Minimum cost). The fifth sub-queue represents traffic with no TOS value. The Priority FIFO method processes these five sub-queues in a way that preserves the meaning of the TOS value as much as possible. For example, a packet with the TOS value of Minimum cost might yield dequeuing to a packet with the TOS value of Minimum delay.

sfq Stochastic Fair Queuing is a queuing method that further queues packets under a set of many FIFO sub-queues. Selecting a specific sub-queue is based on a hash of the flow address information. SFQ dequeues packets from the set of sub-queues in a Round Robin fashion. The overall effect is that fairness of dequeuing is achieved, because packets from one flow cannot occupy the queues at the exclusion of those of another flow.

Note that if you assign a shaping policy to the class, then the queuing discipline of the class becomes that specified in the shaping policy. If you do not assign a shaping policy to the class, the default queue is sfq.

rate Specifies the guaranteed throughput rate of the traffic handled by this rate class, in bits per second (bps).

rate-percentage
Specifies the rate of the rate class as a percentage of the ceiling of the associated parent class. This option applies only to rate classes with an associated parent rate class. The default value is 0 (zero), which specifies that the system uses the value of the rate option.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

shaping-policy
Specifies the name of a shaping policy. The default value is none.

Note that the system automatically changes the ceiling-percentage, drop-policy, max-burst, queue, and rate-percentage options of this class to match the values in the specified shaping policy.

net rate-shaping color-policer

NAME
color-policer - Configures a policer, which can be applied to other configuration entities to meter or rate-shape traffic using color based classification of packets.

MODULE
net rate-shaping

SYNTAX
Configure the color-policer component within the net rate-shaping module using the syntax in the following sections.

CREATE
create color-policer [name]
modify color-policer [name]
options:
 action [action]
 app-service [[string] | none]
 committed-burst-size [integer]
 description [string]
 committed-information-rate [integer]
 excess-burst-size [integer]

DISPLAY
list color-policer

options:
 all-properties

DELETE
delete color-policer [name]

DESCRIPTION
You can use a color-policer to create a metering/policing configuration to be applied to other configuration entities. For instance, to limit or track out of profile network traffic to a vCMP guest, a color-policer can be added to a vcmp traffic-profile and be applied to any number of vcmp guest objects.

Based on the configuration of color-policer attributes a packet may be counted as either green, yellow, or red. These categories can be tracked for accounting purposes, as well as allowing for out of profile (Red) traffic to be dropped as a rate-shaping or DOS protection technique.

EXAMPLES
list net color-policer

Lists the current configuration of all color-policers.

```
create net color-policer fiftyMbpsLimiter action drop-red committed-  
information-rate 50mbps committed-burst-size 10mb excess-burst-size  
10mb
```

Configures a policer with a committed information rate (CIR) of 50 mbps committed burst size (CBS) of 10 mb, and excess burst size (EBS) of 10 mb. See individual descriptions of options below for more detailed semantics.

OPTIONS

action

One of drop-red or default. Drop-red means that a packet which exceeds the excess burst rate of the policer, and is marked red should be dropped immediately before even attempting to enqueue the packet to/from the guest. Default means that the default behavior for the resulting color packets should be taken, which may vary depending on additional system configuration, and load. For instance, a Red colored packet may be considered lowest priority with respect to QOS queues associated with the guest. Thus, allowing as much traffic through as is available, but increasing the drop probability for packets out of profile in the case that the system is under high enough data-plane traffic load.

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

committed-burst-size

When the data rate exceeds the committed-information-rate then the committed-burst-size (by default specified in bytes) is the burst size below which a packet is marked green, and above which it may be marked yellow, or red.

committed-information-rate

The committed rate of data transfer that is to be given to a metered entity that the policer is associated with. Traffic is marked green as long as it stays below this rate or if bursts above this rate are smaller than the committed-burst-size.

description

User defined description.

excess-burst-size

An additional data burst size to be used on top of the committed-burst-size. A packet is marked yellow if it exceeds the committed-burst-size but not the additional excess-burst-size, and red if it exceeds the excess-burst-size.

net rate-shaping drop-policy

NAME

drop-policy - Configures a custom drop policy for use in rate shaping.

MODULE

net rate-shaping

SYNTAX

Configure the drop-policy component within the net rate-shaping module using the syntax in the following sections.

CREATE/MODIFY

```
create drop-policy [name]
modify drop-policy [name]
options:
  app-service [[string] | none]
  average-packet-size [integer]
  description [string]
  fred-max-active [integer]
  fred-max-drop [integer]
  fred-min-drop [integer]
  inverse-weight [integer]
  max-probability [integer]
  max-threshold [integer]
  min-threshold [integer]
  red-hard-limit [integer]
  type [fred | red | tail]
```

```
edit drop-policy [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list drop-policy
list drop-policy [ [name] | [glob] | [regex] ] ... ]
show running-config drop-policy
show running-config drop-policy [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

DELETE

```
delete drop-policy [all | [name] ]
```

DESCRIPTION

A drop policy tells the system when and how to drop packets when the traffic handling queue is full, if required. The system comes with three pre-configured drop policies: fred, red, and tail.

You can use the drop-policy component to create a custom drop policy, and then associate it with a class using the drop-policy option of the class component. For more information, see net rate-shaping class.

You can also associate a custom drop policy with a shaping policy using the drop-policy option of the shaping-policy component. For more information, see net rate-shaping shaping-policy.

EXAMPLES

```
create drop-policy my_dp
```

Creates a custom drop policy named my_dp.

```
list drop-policy all-properties
```

Displays all of the properties of all of the drop policies.

OPTIONS

app-service
Specifies the name of the application service to which the object

belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

average-packet-size
Specifies the average MTU (maximum transmission unit) size in the range of 0 to 10000 bytes. The default value is 0 (zero).

description
User defined description.

fred-max-active
Specifies the maximum number of flows that can be active for each queue. The range is 0 to 10000. The default value is 0 (zero), which disables active flow limitation.

fred-max-drop
Specifies a hard drop limit in the range of 0 to 400. The default value is 0 (zero). Setting this to a small value does not change the hard drop limit, but a higher number increases the limit.

fred-min-drop
Specifies a hard no drop limit in the range of 0 to 100. The default value is 0 (zero). Setting this to a large value prevents packets from being dropped.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

inverse-weight
Specifies the weight used to calculate the average queue length. Valid values are 0, 64, 128, 256, 512, and 1024. The default value is 0 (zero).

max-probability
Specifies the maximum percentage probability in the range of 0 to 100 according to which packets are dropped when the average queue length is between the minimum and maximum thresholds. The default value is 0 (zero).

max-threshold
Specifies the queue length above which the system drops packets. The default value is 0 (zero).

min-threshold
Specifies the queue length below which the system does not drop packets. The default value is 0 (zero).

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

red-hard-limit
Specifies the maximum queue size in bytes. Additional packets are dropped. The default value is 0 (zero).

This option applies only when the value of the type option is red.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

type Specifies the type of drop policy. The default value is tail.

The options are:

fred Specifies that the system uses Flow-based Random Early Detection to decide whether to drop packets based on the aggressiveness of each flow.

red Specifies that the system uses Random Early Detection to determine whether to drop packets to maintain the average queue length within the specified range.

tail Specifies that the system drops all incoming packets when the queue is full. This is the simplest drop policy.

Note that although you could create a drop policy based on tail, that is already the default value of the drop-policy option in both the shaping-policy and class components.

net rate-shaping queue

NAME

queue - Configures a custom queuing method.

MODULE

net rate-shaping

SYNTAX

Configure the queue component within the net rate-shaping module using the syntax in the following sections.

CREATE/MODIFY

```
create queue [pfifo | sfq]
modify queue [all | pfifo | sfq]
options:
  app-service [[string] | none]
  description [string]
  pfifo-max-size [integer]
  pfifo-min-size [integer]
  sfq-bucket-count [integer]
  sfq-bucket-size [integer]
  sfq-perturbation [integer]
  type [pfifo | sfq]
```

```
edit queue [ [ [all | pfifo | sfq] | [glob] | [regex] ] ... ]
```

options:

```
  all-properties
  non-default-properties
```

DISPLAY

```
list queue
list queue [ [ [all | pfifo | sfq] | [glob] | [regex] ] ... ]
show running-config queue
show running-config queue
  [ [ [all | pfifo | sfq] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

DELETE

```
delete queue [all | [name] ]
```

DESCRIPTION

You can use the queue component to configure a custom queuing method.

EXAMPLES

```
create queue my_q type pfifo
```

Creates a pfifo type queue name my_q.

```
list queue all-properties
```

Displays all of the properties of all of the queue.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

pfifo-max-size

Specifies the size of the largest queue for the pfifo type only. The default value is 0 (zero). Valid units are bytes(default), eb, gb, k, kb, mb, pb, and tb.

pfifo-min-size

Specifies the size of the smallest queue for the pfifo type only. The default value is 0 (zero). Valid units are bytes(default), eb, gb, k, kb, mb, pb, and tb.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

sfq-bucket-count

Specifies the number of buckets into which the queue is divided when you are configuring the sfq type. Valid values are 0, 16, 32, 64, 128, 256, 512, and 1024. The default value is 0 (zero).

sfq-bucket-size

Specifies the bucket size for the sfq type. The default value is 0 (zero). Valid units are bytes(default), eb, gb, k, kb, mb, pb, and tb.

sfq-perturbation
Specifies the interval in seconds at which the system reconfigures the SFQ hash function. This option applies only to the sfq type. The default value is 0 (zero).

type Specifies the queue discipline this custom queue uses. The options are:

pfifo

The Priority FIFO queuing method queues all traffic under a set of five sub-queues based on the Type of Service (TOS) field of the traffic. Four of the sub-queues correspond to the four possible TOS values (Minimum delay, Maximum throughput, Maximum reliability, and Minimum cost). The fifth sub-queue represents traffic with no TOS value. The Priority FIFO method processes these five sub-queues in a way that preserves the meaning of the TOS value as much as possible. For example, a packet with the TOS value of Minimum cost might yield dequeuing to a packet with the TOS value of Minimum delay.

sfq Stochastic Fair Queuing is a queuing method that further queues packets under a set of many FIFO sub-queues. Selecting a specific sub-queue is based on a hash of the flow address information. SFQ dequeues packets from the set of sub-queues in a Round Robin fashion. The overall effect is that fairness of dequeuing is achieved, because packets from one flow cannot occupy the queues at the exclusion of those of another flow.

BIG-IP 2013-04-12 net rate-shaping queue(1)

net rate-shaping shaping-policy

NAME

shaping-policy - Configures a custom rate shaping policy for traffic flow.

MODULE

net rate-shaping

SYNTAX

Configure the shaping-policy component within the net rate-shaping module using the syntax in the following sections.

CREATE/MODIFY

```
create shaping-policy [name]
modify shaping-policy [name]
options:
  app-service [[string] | none]
  ceiling-percentage [integer]
  description [string]
  drop-policy [ [name] | none]
  max-burst [integer]
  queue [ [name] | none]
  rate-percentage [integer]
```

```
edit shaping-policy [ [ [name] | [glob] | [regex] ] ... ]
```

options:

```
all-properties
non-default-properties
```

DISPLAY

```
list shaping-policy
list shaping-policy [ [ [name] | [glob] | [regex] ] ... ]
show running-config shaping-policy
show running-config shaping-policy [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

DELETE

```
delete shaping-policy [all | [name] ]
```

DESCRIPTION

You can use the shaping-policy component to create a custom rate shaping policy to handle traffic flow, and then associate the shaping policy with a class.

Note that if you specify a value for the shaping-policy option of a class, the system automatically changes the ceiling-percentage, drop-policy, max-burst, queue, and rate-percentage options of that class to match the values in the shaping policy.

EXAMPLES

```
create shaping-policy my_sp
```

Creates a shaping policy named my_sp.

```
list shaping policies all-properties
```

Displays all of the properties of all of the shaping policies.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

ceiling-percentage

Specifies the percentage of the value of the ceiling option specified for the parent associated with the class component to which this shaping policy is associated. The default value is 0 (zero).

description

User defined description.

drop-policy

Specifies the name of a drop policy for this traffic flow. The default value is none.

You can use one of the pre-configured drop policies, or you can create a customized drop-policy using the drop-policy component.

The pre-configured drop policies are:

fred Specifies that the system uses Flow-based Random Early Detection to decide whether to drop packets based on the aggressiveness of each flow.

red Specifies that the system uses Random Early Detection to determine whether to drop packets to maintain the average queue length within the specified range.

tail Specifies that the system drops all incoming packets when the queue is full. This is the simplest drop policy.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

max-burst

Specifies the maximum number of bytes that traffic is allowed to burst beyond the value of the rate option of the class component to which this shaping policy is associated. The default value is 0 (zero).

Valid units are byte, bytes(default), eb, gb, k, kb, mb, pb, and tb.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

queue

Specifies the queuing method for this traffic flow. The default value is none. You can create a customized queuing method using the queue component. For more information, see net rate-shaping queue.

The preconfigured queues are:

pfifo

The Priority FIFO queuing method queues all traffic under a set of five sub-queues based on the Type of Service (TOS) field of the traffic. Four of the sub-queues correspond to the four possible TOS values (Minimum delay, Maximum throughput, Maximum reliability, and Minimum cost). The fifth sub-queue represents traffic with no TOS value. The Priority FIFO method processes these five sub-queues in a way that preserves the meaning of the TOS value as much as possible. For example, a packet with the TOS value of Minimum cost might yield dequeuing to a packet with the TOS value of Minimum delay.

sfq Stochastic Fair Queuing is a queuing method that further queues packets under a set of many FIFO sub-queues. Selecting a specific sub-queue is based on a hash of the flow address information. SFQ dequeues packets from the set of sub-queues in a Round Robin fashion. The overall effect is that fairness of dequeuing is achieved, because packets from one flow cannot occupy the queues at the exclusion of those of another flow.

rate-percentage

Specifies the percentage of the value of the rate option of the parent, which is associated with the class component to which this

shaping policy is associated, that is available for this traffic flow. The default value is 0 (zero).

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

net route-domain

NAME

route-domain - Configures route-domains for traffic management.

MODULE

net

SYNTAX

Configure the route-domain component within the net module using the syntax in the following sections.

CREATE/MODIFY

```
create route-domain [ [name] | none]
```

```
options:
```

```
id [integer]
```

```
modify route-domain [name]
```

```
options:
```

```
app-service [[string] | none]
```

```
bwc-policy [string]
```

```
connection-limit [integer]
```

```
description [string]
```

```
flow-eviction-policy [ [eviction policy name] | none ]
```

```
fw-enforced-policy [ [policy_name] | none ]
```

```
fw-staged-policy [ [policy_name] | none ]
```

```
id [integer]
```

```
parent [ [name] | none]
```

```
security-nat-policy [ [policy_name] | none]
```

```
service-policy [ [policy_name] | none ]
```

```
strict [disabled | enabled]
```

```
routing-protocol
```

```
[add | delete | replace-all-with] {
```

```
[protocol name] ...
```

```
}
```

```
vlan
```

```
[add | delete | replace-all-with] {
```

```
[vlan name] ...
```

```
}
```

```
edit route-domain [ [name] | [glob] | [regex] ] ... ]
```

```
options:
```

```
all-properties
```

```
non-default-properties
```

```
reset-stats route-domain [name]
```

```
fw-enforced-policy-rules { [rule name] }
```

```
fw-staged-policy-rules { [rule name] }
```

```
security-nat-rules { [rule name] }
```

```
options:
```

```
fw-context-stat
```

```
ip-intelligence-categories
```

```
port-misuse
```

DISPLAY

```
list route-domain
```

```
list route-domain [ [name] | [glob] | [regex] ] ... ]
```

```
show running-config route-domain
```

```
show running-config route-domain
```

```
[ [name] | [glob] | [regex] ] ... ]
```

```
options:
```

```
all-properties
```

```
one-line
```

```
non-default-properties
```

```
show route-domain [ [ [name] | [glob] | [regex] ] ... ]
```

```
options:
```

```
fw-context-stat  
ip-intelligence-categories  
port-misuse
```

```
DELETE
```

```
delete route-domain [name]
```

DESCRIPTION

Using route domains, you can assign the same IP address to more than one device on a network, as long as each instance of the IP address resides in a separate routing domain.

EXAMPLES

```
create route-domain myRouteDomain id 1 vlans add { my_vlan }
```

Creates a route domain named myRouteDomain with an ID of 1 that includes my_vlan.

```
list route-domain all-properties
```

Displays all properties of all route domains.

OPTIONS

```
app-service
```

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

```
bwc-policy
```

Configures the bandwidth control policy for the route-domain. If set, it will enforce a throughput policy for incoming network traffic.

```
connection-limit
```

Configures the connection limit for the route domain. If set to a value other than zero, this specifies the total number of open connections allowed on this route domain. The default value is 0, unlimited.

```
description
```

User defined description.

```
id
```

Specifies a unique numeric identifier for the route-domain. This option is required during creation; it may not be modified once set.

```
flow-eviction-policy
```

Specifies a flow eviction policy for the route domain to use, to select which flows to evict when the number of connections approaches the connection limit on the route domain. The default value is none.

```
fw-enforced-policy
```

Specifies an enforced firewall policy. fw-enforced-policy rules are enforced on a route-domain.

```
fw-enforced-policy-rules
```

Specifies firewall rules enforced on net route-domain via referenced fw-enforced-policy.

```
fw-staged-policy
```

Specifies a staged firewall policy. fw-staged-policy rules are not enforced while all the visibility aspects namely statistics, reporting and logging function as if the fw-staged-policy rules were enforced on a route-domain.

```
fw-staged-policy-rules
```

Specifies firewall rules staged on net route-domain via referenced fw-staged-policy.

```
security-nat-rules
```

Specifies security nat rules associated with net route-domain via referenced security-nat-policy.

```
parent
```

Specifies the route domain the system searches when it cannot find a route in the configured domain. The default value is None.

If you specify a parent, during route table lookup, if the system cannot find a route in the current route domain, the system searches routes in the parent route domain. If no route is found in the parent route domain, the system searches the parent route domain's parent, and so on, until the system finds either a match or a parent with a value of None. For example, if rd_1 has a parent of rd_0 (in this example, route domain rd_0 has a parent of None), and you include vlan_a in rd_1, when requests arrive for vlan_a, the system looks in rd_1 for a route for the specified destination. If no route is found, the system searches route domain 0. If it still cannot find a route, the request for vlan_a fails. If, using the same example, you set the parent to None, under the same conditions, the system looks in rd_1, and if it cannot find a matching route, the system refrains from searching any other route domain, the request for vlan_a fails.

```
port-misuse
```

Used to show or reset port misuse policy statistics for the route domain.

```
fw-context-stat
```

Used to show or reset firewall statistics for the route domain.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

security-nat-policy

Configures the Security NAT Policy (see security nat policy). If specified, this is the NAT policy used to perform first-match classification for incoming traffic to a virtual server if 'the virtual server itself does not have a NAT policy configured AND security-nat-policy.use-route-domain-policy is enabled on the virtual'.

service-policy

Configures the service policy for the route-domain. If set, it will enforce the service policy for incoming network traffic. The service policy can be used to set specific policy based configurations like flow timers, which applies to the flows that matches the policy specification.

strict

Specifies whether the system allows a connection to span route domains. The default value is enabled.

Note: When you enable this option, the system may find invalid iRules(r) that passed validation.

routing-protocol

Specifies routing protocols, by name, for the system to use in the route domain. The default value is none. Dynamic routing must be licensed to use this option.

vlan

Specifies VLANs, by name, for the system to use in the route domain. The default value is none.

ip-intelligence-categories

Used to show/ reset statistics on IP intelligence white/ black lists categories.

BIG-IP 2017-09-06 net route-domain(1)

net route

NAME

route - Configures a route for traffic management.

MODULE

net

SYNTAX

Configure the route component within the net module using the syntax in the following sections.

CREATE/MODIFY

```
create route [name | ip address/netmask | default | default-inet6]
modify route [name | ip address/netmask | default | default-inet6]
```

options:

```
blackhole
description [string]
gw [ip address]
interface [name]
mtu [integer]
network [ip address/netmask]
pool [name]
```

edit route

```
[ [name | ip address/netmask | default | default-inet6] | [glob] | [regex] ] ... ]
```

options:

```
all-properties
non-default-properties
```

DISPLAY

```
list route
```

```
list route
 [ [name | ip address/netmask | default | default-inet6] | [glob] | [regex] ] ... ]
show running-config route
show running-config route
 [ [name | ip address/netmask | default | default-inet6] | [glob] | [regex] ] ... ]
options:
all-properties
mtu
non-default-properties
one-line
partition

show route
show route
 [ [name | ip address/netmask | default | default-inet6] | [glob] | [regex] ] ... ]
options:
connected
dynamic
field-fmt
lookup [ip address]
static
```

DELETE

```
delete route [name | ip address/netmask | default | default-inet6]
```

DESCRIPTION

You can configure routes for the system, including default routes.

Note that when you use the command edit to create a new route, by default the gw (gateway) option is set. If you do not want to use the gw option, remove that line of syntax in the editor.

EXAMPLES

```
create route myRoute3 network 12.12.4.0/24 interface external
```

Sets the route myRoute3 to the address 12.12.4.0/24 on the interface named external.

```
create route 12.12.3.0/24 gw 10.10.10.254
```

Sets the route to the subnet 12.12.3.0/24 whose gateway IP address is 10.10.10.254.

```
create route default gw 10.10.10.254
```

Sets the default gateway IP address to 10.10.10.254.

```
show route lookup myRoute
```

Displays the route that the system uses to reach the IP address 12.12.3.0.

OPTIONS

Note: The options blackhole, gw, interface, and pool are mutually exclusive. You can use only one of these options at a time, and you must specify at least one of these options when configuring a route.

blackhole

Specifies that the system drops traffic that is addressed to the specified destination.

connected

Displays connected routes.

description

User defined description.

dynamic

Displays dynamic routes.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

gw Specifies a gateway address for the system.

interface

Specifies the tunnel, VLAN or VLAN group to which the system sends traffic.

ip address/netmask

Specifies the destination subnet and mask using CIDR notation, such as 12.12.3.0/24. You can also specify the keyword default or default-inet6.

lookup

Displays the route that the system uses to reach the specified IP address. You can specify only a single IP address with the lookup option.

mtu Sets a specific maximum transition unit (MTU). If you set this option to 0 (zero), the system selects the appropriate MTU for the route, and does not display the MTUs.

network

Specifies the destination subnet and mask using CIDR notation, such as 12.12.3.0/24. You can also specify the keyword default or default-inet6.

partition

Displays the administrative partition within which the route resides.

pool Specifies a pool to which the system sends traffic. This allows the system to send traffic to multiple, load-balanced gateways.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

static
Displays static routes.

net router-advertisement

NAME
router-advertisement - Configures IPv6 prefixes for router advertisement on a VLAN.

MODULE
net

SYNTAX
Modify the router-advertisement component within the net module using the syntax shown in the following sections.

CREATE/MODIFY

```
create router-advertisement [name]
modify router-advertisement [name]
options:
  app-service [[string] | none]
  current-hop-limit [integer]
  description [string]
  disabled | enabled
  max-interval [integer]
  min-interval [integer]
  mtu [integer]
  no-other-config | other-config
  prefixes
  [add | delete | modify | replace-all-with] {
[name] ... {
  app-service [[string] | none]
  autonomous | not-autonomous
  description [string]
  on-link | not-on-link
  preferred-lifetime [integer]
  prefix [ip address]
  prefix-length [integer]
  valid-lifetime [integer]
}
}
  reachable-time [integer]
  retransmit-timer [integer]
  router-lifetime [integer]
  unmanaged | managed
  vlan [name]
```

```
edit router-advertisement [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list router-advertisement
list router-advertisement [ [ [name] | [glob] | [regex] ] ... ]
show running-config router-advertisement
show running-config router-advertisement
[ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

DELETE

```
delete router-advertisement [name]
```

DESCRIPTION

Router advertisements are part of the configuration of BIG-IP(r)

network components. When creating a router advertisement, you must specify a VLAN on the command line.

EXAMPLES

```
create router-advertisement my_ra vlan my_vlan
```

Creates the router advertisement my_ra that includes the VLAN my_vlan.

```
delete router-advertisement my_ra
```

Deletes the router advertisement named my_ra and all associated prefixes.

OPTIONS

Note the following information regarding options for the router-advertisement component:

- o The options disabled and enabled are mutually exclusive.
- o The options no-other-config and other-config are mutually exclusive.
- o The options unmanaged and managed are mutually exclusive.
- o The options autonomous and not-autonomous are mutually exclusive.
- o The options on-link and not-on-link are mutually exclusive.

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

autonomous

Indicates that the Autonomous Flag field in the prefix information option be set to 1. The default value is 1.

current-hop-limit

Defines the hop limit sent in the router advertisement. The default value is 0 (zero).

description

User defined description.

disabled

Disables router advertisement for the VLAN. This is the default.

enabled

Enables router advertisement for the VLAN.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

managed

Indicates that the Managed address configuration flag field in the router advertisement be set to 1.

max-interval

Specifies the maximum time allowed between sending unsolicited multicast Router Advertisements from the interface, in seconds. The default value is 600.

min-interval

Specifies, in seconds, the minimum time allowed between sending unsolicited multicast Router Advertisements from the interface. The default value is 200.

mtu Sets a specific maximum transition unit (MTU) for the VLAN. The default value is 0 (zero).

name Specifies a unique name for the component. This option is required for the create, delete, and modify commands.

no-other-config

Indicates that the Other Configuration flag field in the router advertisement be set to 0 (zero). The default value is 0 zero.

not-autonomous

Indicates that the Autonomous flag field in the prefix information option be set to 0 (zero).

not-on-link

Indicates that the on-link flag field in the prefix information option be set to 0 (zero).

on-link

Indicates that the on-link flag field in the prefix information option be set to 1. The default value is 1.

other-config

Indicates that the Other Configuration flag field in the router advertisement be set to 1.

preferred-lifetime

Specifies, in seconds, the value for the Preferred Lifetime field in the prefix information option. The default value is 604800.

prefix

Specifies the prefix for the prefix information option.

prefix-length

Specifies the length of the prefix for the prefix information

option.

prefixes

Specifies the objects that hold the prefix specific information for the router advertisement.

reachable-time

Specifies the value to be used for the Reachable Time field in the Router Advertisement. The default value is 0 (zero).

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

retransmit-timer

Specifies the value to be used for the Retransmit Timer field in the Router Advertisement. The default value is 0 (zero).

router

Specifies that the router advertisement acts as a router for the VLAN.

router-lifetime

Specifies the value to be used for the Router Lifetime field in the Router Advertisement. The default value is 1800.

unmanaged

Specifies that the Managed address configuration flag field in the router advertisement be set to 0 (zero). The default value is 0 (zero).

valid-lifetime

Specifies, in seconds, the value for the Valid Lifetime field in the prefix information option. The default value is 2592000.

DESCRIPTION None

EXAMPLES

OPTIONS

allow-infinite-hold-time

BGP timer disallow-infinite-hold-time. (default: True)

always-compare-med

option to compare the Multi Exit Discriminator (MED) for paths from neighbors in different autonomous systems. (default: False)

bestpath

as-path-ignore

prevent the router from considering the autonomous system (AS) path length as a factor in the algorithm for choosing a best path route.

compare-confed-asmesh
allow comparing of the confederation AS path length.

compare-originator-id
change the default bestpath selection by not comparing an originator-ID for an identical EBGp path. (default: True)

compare-routerid
compare router IDs for identical eBGP paths.

med
confed
Compare MED among confederation paths.

missing-as-worst
Treat missing MED as the least preferred one.

remove-recv-med
To remove rcvd MED attribute.

remove-send-med
To remove send MED attribute.

tie-break-on-age
always select a preferred older route even when the bestpath.compare-routerid is enabled. (default: True)

client-to-client-reflection
Configure client-to-client route reflection. (default: True)

cluster-id
Route-reflector cluster-id in IP address or 32-bit quantity format.

confederation
identifier
Set routing domain confederation AS.

peers
AS numbers of eBGP peers that are in the same confederation.

dampening
reachability-half-life
Reachability half-life time for the penalty(minutes).

reuse
Value to start reusing a route.

route-map
Route-map to specify the criteria for dampening.

state
Enable route-flap dampening.

suppress
Value to start suppressing a route.

suppress-max
Maximum duration to suppress a stable route(minutes).

unreachability-half-life
Un-reachability half-life time for the penalty(minutes).

default-local-preference
Configure default local preference value (higher=more preferred).
(default: 100)

description
deterministic-med
Pick the best-MED path among paths advertised from the neighboring AS. (default: False)

enabled
enforce-first-as
Enforce the first AS for EBGp routes.

fast-external-failover
Immediately reset session if a link to a directly connected external peer goes down. (default: True)

graceful-restart
graceful-reset
Graceful reset capability.

restart-time
Max time needed for neighbor(s) to restart (seconds).

stalepath-time
Max time to retain stale paths from restarting Neighbor(s) (seconds).

graceful-shutdown
capable
Set router as g-shut capable. (default: False)

local-preference
Set local preference to use during g-shut. (default: 0)

mode Gracefully shutdown this router. (default: False)

hold-time
Globally set or reset the holdtime value for all of the neighbors.
(default: 90)

```
keep-alive
Globally set or reset the keepalive value for all of the
neighbors. (default: 30)

local-as
log-neighbor-changes
Log neighbor up/down and reset reason. (default: False)

profile
route-domain
router-id
Manually override current router identifier (peers will reset).

scan-time
Configure background scan interval (sec). (default: 60)

synchronization
Enable IGP synchronization of internal BGP (iBGP) learned routes.
(default: False)

update-delay
Max time to defer initial route-selection (sec). (default: 120)

view BGP view name.

address-family
auto-summary
enable sending summarized routes by a BGP speaker to its
peers. (default: False)

distance
external
Define administrative distance for routes external to
the AS. (default: 20)

internal
Define administrative distance for routes internal to
the AS. (default: 200)

local
Define administrative distance for local routes.
(default: 200)

network-synchronization
Enable IGP synchronization on network routes.

aggregate-address
as-set
summary-only
redistribute
route-map
distance
access-list
distance
neighbor
advertisement-interval
Minimum interval between sending BGP routing updates.

allow-infinite-hold-time
BGP per neighbor allow-infinite-hold-time. (default: True)

as-origination-interval
Minimum interval between sending AS-origination routing
updates.

capability
dynamic
Advertise dynamic capability to this neighbor. (default:
False)

route-refresh
Advertise route-refresh capability to this neighbor.
(default: True)

capability-negotiate
override
Override capability negotiation result. (default: False)

state
Perform capability negotiation. (default: True)

strict-match
Strict capability negotiation match. (default: False)

collide-established
Include Neighbor in Established State for Collision
Detection.

connect-timer
BGP connect timer. (default: 0)

description
User defined description..

ebgp-multihop
Allow EBGp neighbors not on directly connected networks.
(default: 1)

enabled
enforce-multihop
Enforce EBGp neighbors to perform multihop. (default: False)

fall-over
Fall-over detection - Bidirectional Forwarding Detection
```

(BFD) or BFD Multihop.

- graceful-shutdown
mode Gracefully shut down this neighbor. (default: False)
- timer
Max time needed for Neighbor to shutdown. (default: 60)
- hold-time
Holdtime. (default: 90)
- keep-alive
Keepalive interval. (default: 30)
- local-as
Specify AS number to use with BGP neighbor.
- passive
Don't send open messages to this neighbor. (default: False)
- password
Set password to the neighbor.
- peer-group
port Neighbor's BGP port. (default: 179)
- remote-as
Specify AS number of BGP neighbor.
- restart-time
Max time needed for Neighbor to restart. (default: 0)
- update-source
Source of routing updates.
- version
Set the BGP version to match a neighbor. (default: 4)
- vlan
address-family
activate
Enable the address family for this neighbor. (default: True)
- allow-as-in
Accept as-path with my AS present in it.
- as-override
Override AS path.
- attribute-unchanged
 - as-path
BGP attribute, as-path, is propagated unchanged to this neighbor.
 - med
BGP attribute, med, is propagated unchanged to this neighbor.
 - next-hop
BGP attribute, next-hop, is propagated unchanged to this neighbor.
- capability
 - graceful-restart
The graceful-restart capability. (default: True)
 - orf
prefix-list
Advertise ORF capability to peer. (default: disabled)
- default-originate
 - route-map
Route-map to specify criteria to originate default.
 - state
Originate default route to this neighbor. (default: False)
- distribute-list
 - in
Filter updates to/from this neighbor.
 - out
Filter updates to/from this neighbor.
- filter-list
 - in
Establish BGP filters.
 - out
Establish BGP filters.
- maximum-prefix
 - threshold
Maximum number of prefix threshold value. (default: 0)
 - value
Maximum number of prefix accept from this peer. (default: 0)
 - warning-only
Only give a warning message when the maximum-prefix.threshold limit is exceeded. (default: True)
- next-hop-self

```
    Disable the next hop calculation for this neighbor.
    (default: False)

prefix-list
  in  Filter updates to/from this neighbor.

  out Filter updates to/from this neighbor.

remove-private-as
  Remove private AS number from outbound updates.
  (default: False)

route-map
  in  Apply route map to neighbor.

  out Apply route map to neighbor.

route-reflector-client
  Configure a neighbor as Route Reflector client.
  (default: False)

route-server-client
  Configure a neighbor as Route Server client. (default:
  False)

send-community
  Send community attribute to this neighbor. (default:
  both)

soft-reconfiguration-inbound
  (default: False)

unsuppress-map
  Route-map to selectively unsuppress suppressed routes.

weight
  Set default weight for routes from this neighbor.

  network
  backdoor
  route-map
  peer-group
  advertisement-interval
  Minimum interval between sending BGP routing updates.

  allow-infinite-hold-time
  BGP per neighbor allow-infinite-hold-time. (default: True)

  as-origination-interval
  Minimum interval between sending AS-origination routing
  updates.

  capability
  dynamic
  Advertise dynamic capability to this neighbor. (default:
  False)

  route-refresh
  Advertise route-refresh capability to this neighbor.
  (default: True)

  capability-negotiate
  override
  Override capability negotiation result. (default: False)

state
  Perform capability negotiation. (default: True)

strict-match
  Strict capability negotiation match. (default: False)

  collide-established
  Include Neighbor in Established State for Collision
  Detection.

  connect-timer
  BGP connect timer. (default: 0)

  description
  User defined description..

  ebgp-multihop
  Allow EBGp neighbors not on directly connected networks.
  (default: 1)

  enabled
  enforce-multihop
  Enforce EBGp neighbors to perform multihop. (default: False)

  fall-over
  Fall-over detection - Bidirectional Forwarding Detection
  (BFD) or BFD Multihop.

  graceful-shutdown
  mode Gracefully shut down this neighbor. (default: False)

timer
  Max time needed for Neighbor to shutdown. (default: 60)

  hold-time
  Holdtime. (default: 90)

  keep-alive
  Keepalive interval. (default: 30)
```

local-as
Specify AS number to use with BGP neighbor.

passive
Don't send open messages to this neighbor. (default: False)

password
Set password to the neighbor.

port Neighbor's BGP port. (default: 179)

remote-as
Specify AS number of BGP neighbor.

restart-time
Max time needed for Neighbor to restart. (default: 0)

update-source
Source of routing updates.

version
Set the BGP version to match a neighbor. (default: 4)

address-family
activate
Enable the address family for this neighbor. (default: True)

allow-as-in
Accept as-path with my AS present in it.

as-override
Override AS path.

attribute-unchanged
as-path
BGP attribute, as-path, is propagated unchanged to this neighbor.

med BGP attribute, med, is propagated unchanged to this neighbor.

next-hop
BGP attribute, next-hop, is propagated unchanged to this neighbor.

capability
graceful-restart
The graceful-restart capability. (default: True)

orf
prefix-list
Advertise ORF capability to peer. (default: disabled)

default-originate
route-map
Route-map to specify criteria to originate default.

state
Originate default route to this neighbor. (default: False)

distribute-list
in Filter updates to/from this neighbor.

out Filter updates to/from this neighbor.

filter-list
in Establish BGP filters.

out Establish BGP filters.

maximum-prefix
threshold
Maximum number of prefix threshold value. (default: 0)

value
Maximum number of prefix accept from this peer. (default: 0)

warning-only
Only give a warning message when the maximum-prefix.threshold limit is exceeded. (default: True)

next-hop-self
Disable the next hop calculation for this neighbor. (default: False)

prefix-list
in Filter updates to/from this neighbor.

out Filter updates to/from this neighbor.

remove-private-as
Remove private AS number from outbound updates. (default: False)

route-map
in Apply route map to neighbor.

```

out Apply route map to neighbor.

route-reflector-client
  Configure a neighbor as Route Reflector client.
  (default: False)

route-server-client
  Configure a neighbor as Route Server client. (default:
  False)

send-community
  Send community attribute to this neighbor. (default:
  both)

soft-reconfiguration-inbound
  (default: False)

unsuppress-map
  Route-map to selectively unsuppress suppressed routes.

weight
  Set default weight for routes from this neighbor.

```

DESCRIPTION placeholder

EXAMPLES

OPTIONS

adj-out

Disable BGP ADJ_OUT. (default: True)

aggregate-nexthop-check

Option to perform aggregation only when next-hop matches the specified IP address..

as-local-count

Set the number of times the local-AS (Autonomous System) is to be prepended. (default: 1)

bgp-multiple-instance

Enable to allow BGP views and disallow BGP graceful-restart (peers will reset). (default: False)

defaults-from

description

extended-asn-cap

Enable the router to send 4-octet ASN capabilities. (default: True)

max-paths

ebgp Set number of equal-cost multi-path (ECMP) routes for eBGP.

ibgp Set number of equal-cost multi-path (ECMP) routes for iBGP.

nexthop-trigger

delay

Configure nexthop trigger delay time interval. (default: 5)

state

Enable the nexthop tracking functionality. (default: False)

rfc1771

path-select

Set RFC1771 compatible path selection mechanism. (default: False)

strict

Set the origin path attribute to "IGP" when the origin is a protocol such as RIP, OSPF, or ISIS. (default: False)

router-id

Manually override current router identifier (peers will reset).

        Match entries of IPv6 access-lists.

        prefix-list
        Match entries of IPv6 prefix-lists.

        next-hop
        access-list
        Match entries of IPv6 access-lists.

        prefix-list
        Match entries of IPv6 prefix-lists.

        peer
        access-list
        Match entries of IPv6 access-lists.

metric
    Match metric of route.

origin
    Match BGP origin code.

route-type
    Match route type.

tag Match tag.

vlan Match first hop interface of route.

    set
    aggregator
        address
        set BGP aggregator IP address.

        as set BGP aggregator attribute.

as-path-prepend
    Prepend string for a BGP AS-path attribute.

atomic-aggregate
    BGP atomic aggregate attribute.

community
    additive
        Add to the existing community.

        exact-set
        Do exact setting of communities. (default: False)

        value
        set community number, either in AA:NNO format, or
        number..

```

dampening
 reachability-half-life
 Reachability half-life time for the
 penalty(minutes). (default: 15)

 reuse
 Value to start reusing a route. (default: 750)

 suppress
 Value to start suppressing a route. (default: 2000)

 suppress-max
 Maximum duration to suppress a stable
 route(minutes). (default: 60)

 unreachability-half-life
 Un-reachability half-life time for the
 penalty(minutes). (default: 1)

extcommunity
 rt VPN extended community.

 soo Site-of-Origin extended community.

ip
 next-hop
 address
 IP address of next-hop.

ipv6
 next-hop
 address
 IPv6 local address.

 local
 IPv6 local address.

level
 IP address of next-hop.

local-preference
 BGP local preference path attribute.

metric
 type Metric value.

 value

origin
 set BGP origin code.

originator-id
 set IP address of originator.

tag set tag.

weight
 set BGP weight for routing table.

BIG-IP 2011-01-24 net rst-cause(1)

net self-allow

NAME

self-allow - Configures the default "allow list" for all self IP addresses on the BIG-IP(r) system when the option allow-service of the component self is set to default.

MODULE

net

SYNTAX

Modify the self-allow component within the net module using the syntax shown in the following sections.

MODIFY

```
modify self-allow
  options:
    defaults [all | none]
  defaults
    [add | delete | replace-all-with] {
      [protocol:port] ...
    }
}
```

edit self-allow

```
options:
  all-properties
```

DISPLAY

```
list self-allow
show running-config self-allow
  options:
    all-properties
    defaults
    one-line
```

DELETE

You cannot delete the default allow list.

DESCRIPTION

You can use the self-allow component to modify or display the default allow list for all self IP addresses on the BIG-IP system when the option allow-service of the component self is set to default. The default allow list displays which service and protocol ports allow connections from outside the system. The system refuses connections made to a service or protocol port that is not on the list.

EXAMPLES

```
modify self-allow defaults all
```

Sets the default allow list to all. Then, if the value of the option allow-service of the net self component is default, the system accepts traffic from all protocol port combinations.

```
modify self-allow default replace-all-with { tcp:55 }
```

Sets the default "allow list" for all self IP addresses on the system to TCP on port 55.

```
list self-allow defaults
```

Displays the default "allow list" for all self IP addresses on the system.

OPTIONS

defaults

Specifies to set the default allow list to one of the following:

all Specifies that all protocols and services allow connections from outside the system. Use this option to open the system to complete access.

none Specifies that no protocols or services allow connections from outside the system.

protocol:port
Specifies a list of protocols/services that allow connections from outside the system.

replace-all-with
Specifies to replace the current protocols and services that allow connections from outside the system with the specified protocols and services.

SEE ALSO

DELETE
delete self [name]
```

DESCRIPTION

A self IP address is an IP address that is assigned to the system. Self IP addresses are part of the configuration of the BIG-IP(r) network components. You must define at least one self IP address for each VLAN.

EXAMPLES

```
create self mySelf address 10.10.10.24/16 vlan internal
```

Adds the self IP address 10.10.10.24 to the VLAN named internal. This entry is named mySelf. Alternatively, the name can encompass the IP address and mask fields, like the following example.

```
create self 10.10.10.24/16 vlan internal
```

Adds the self IP address 10.10.10.24 to the VLAN named internal.

```
modify self 10.1.1.1/16 vlan external traffic-group
/Common/traffic-group-1
```

Enables a floating IP address on the external VLAN. The traffic-group option makes this virtual address available to whichever device is active on the given traffic-group. In other words, when the standby device becomes the active device for that traffic-group, it uses this virtual address. Only one of the devices in the traffic-group can use the IP address at any given time.

```
mv /net self /Common/10.10.10.15/24 /Common/myselfIP2
```

Moves/Renames the Self IP from 10.10.10.15/24 to myselfIP2.

Note: If you wish to change the name of the self IP, you may use a name that is the same as the IP Address or a name that does not represent a different IP Address than the one configured. If using prefix-length adornment on the name, it must match the existing prefix-length/netmask for the self IP.

Please refer to the mv manual page for additional examples on how to use the mv command.

Options

```
allow-service
```

Specifies the type of protocol/service that the VLAN handles. If you use this property to allow SSH, HTTP, and/or HTTPS service, administrators can use this self-IP address to log into the BIG-IP system; this makes the current self-IP available as a management-IP address on the VLAN.

The options are:

add Adds the specified protocol/service to the VLAN.

all Specifies that the VLAN handles all protocols/services.

```
app-service
```

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

```
default
```

Specifies that the system uses a pre-defined set of network protocols/services that are commonly required for BIG-IP deployment. You can customize this set of services with the self-allow component.

This is not the default for the allow-service property; none, described below, is the actual default.

```
delete
```

Removes the specified protocol/service from the VLAN.

none Specifies that the VLAN handles no protocols/services. This is the default setting for a self IP address.

```
replace-all-with
```

Replaces the current protocol/service that the VLAN handles with the specified protocol/service.

```
address
```

Specifies the IP address and netmask to be assigned to the system. This is an optional field. If not specified, the name of the entry must appear in the format [ip address/mask].

```
address-source
```

Specifies the source of the self IP. This is an optional field. If not specified, the default value of from-user is used.

The options are:

```
from-management
```

Assigns the self IP with the management IP rather than the provided address or entry name.

```
from-user
```

Assigns the self IP with the provided address or entry name.

fw-context-stat
Used to show or reset firewall statistics for the self IP.

description
User-defined description.

floating
Read-only property based on the traffic-group. A floating self IP address is a self IP address for a VLAN that serves as a shared address by all devices of a BIG-IP traffic-group.

fw-enforced-policy
Specifies an enforced firewall policy. fw-enforced-policy rules are enforced on a self IP address.

fw-enforced-policy-rules
Specifies firewall rules enforced on net self via referenced fw-enforced-policy.

fw-staged-policy
Specifies a staged firewall policy. fw-staged-policy rules are not enforced while all the visibility aspects namely statistics, reporting and logging function as if the fw-staged-policy rules were enforced on a self IP address.

service-policy
Configures the service policy for the self IP address. If set, it will enforce the service policy for incoming network traffic. The service policy can be used to set specific policy based configurations like flow timers, which applies to the flows that matches the policy specification.

fw-staged-policy-rules
Specifies firewall rules staged on net self via referenced fw-staged-policy.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

unit Read-only property that specifies the unit in a redundant system. Based on traffic-group.

traffic-group
Specifies the traffic group of the self IP address. The default traffic group is traffic-group-local-only, the non-floating traffic-group.

inherited-traffic-group
Read-only property that indicates if the traffic-group is inherited from the parent folder.

vlan Specifies the VLAN for which you are setting a self IP address. This option is required.

net service-policy

NAME
service-policy - Configures the service policy.

MODULE
net

SYNTAX
Modify the service policy component within the net module using the syntax shown in the following sections.

CREATE/MODIFY

```

create service-policy [name]
modify service-policy [name]
options:
  description [string]
  port-misuse-policy [[port misuse policy name] | [none]]
  timer-policy [[timer policy name] | [none]]

edit service-policy [[name] | all]
options:
  all-properties
  non-default-properties

DISPLAY
list service-policy
show running-config service-policy
options:
  all-properties
  non-default-properties
  one-line

```

DESCRIPTION

service-policy configuration allows one to specify certain properties that would apply to a flow. Service policy consists of other policy objects like timer policy and port misuse policy objects. The policy can be applied at different contexts, like Global context, virtual server context, route domain context, self-ip context, or a firewall rule. When a service policy is configured both at a context level, as well as on a firewall rule, and a flow matches the rule, the more specific service-policy configuration in the rule will override the service policy setting at the context level. You can use the service-policy component to configure a shareable and reusable set of network service policies which can be associated with a number of configuration objects of the following types: net self, net route-domain, security firewall policy rules, security firewall rule-list rules, ltm virtual. Port misuse policy object is not effective with net self context.

EXAMPLES

```

create net service-policy flow-policy timer-policy idle-flow-policy

list service-policy
net service-policy flow-policy {
  timer-policy idle-flow-policy
}

```

Creates service policy and associates a timer policy configuration object. (see "net timer-policy").

```

modify net service-policy flow-policy port-misuse-policy tcp-port-policy

```

```

list service-policy
net service-policy flow-policy {
  timer-policy idle-flow-policy
  port-misuse-policy tcp-port-policy
}

```

Associates a port misuse policy with service policy. (see "security firewall port-misuse-policy").

```

list service-policy

```

Displays the current service policy configuration.

OPTIONS

```

description
User defined description.

port-misuse-policy
Specify service port misuse policy.

timer-policy
Specify service timer policy.

```

NAME stp-globals - Configures spanning tree protocols on the system.

MODULE net

SYNTAX Configure the stp-globals component within the net module using the syntax shown in the following sections.

MODIFY

```

modify stp-globals
options:
  config-name [configuration name]
  config-revision [integer]
  description [string]
  fwd-delay [integer]
  hello-time [integer]
  max-age [integer]
  max-hops [integer]
  mode [disabled | mstp | passthru | rstp | stp]
  transmit-hold [integer]

```

edit stp-globals

```

options:
  all-properties
  non-default-properties

```

DISPLAY

```

list stp-globals
show running-config stp-globals
options:
  all-properties
  non-default-properties
  one-line

```

DESCRIPTION

Provides the ability to configure spanning tree protocols for the traffic management system. Spanning tree protocols are Layer 2 protocols for preventing bridging loops. The system supports multiple spanning tree protocol (MSTP), rapid spanning tree protocol (RSTP), and spanning tree protocol (STP).

EXAMPLES

```

modify stp-globals mode passthru

```

Sets the STP mode to passthru. Passthru mode forwards spanning tree bridge protocol data units (BPDUs) received on any interface to all other interfaces.

```

modify stp-globals mode disabled

```

Sets the STP mode to disabled. No MSTP, RSTP, or STP packets are transmitted or received on the interface or trunk, and the spanning tree algorithm exerts no control over forwarding or learning on the port or the trunk.

OPTIONS

config-name
Specifies the configuration name (1 - 32 characters in length) only when the spanning tree mode is MSTP. The default configuration name is a string representation of a globally unique MAC address belonging to the traffic management system.

The MSTP standard introduces the concept of spanning tree regions, which are groups of adjacent bridges with identical configuration names, configuration revision levels, and assignments of VLANs to spanning tree instances.

Note: The system default configuration name is a string representation of the globally unique MAC address of the traffic management system in which hyphens replace the colons in the standard MAC address. For example, the default configuration name 00-01-D7-68-11-80, represents the MAC address 00:01:D7:68:11:80.

config-revision
Specifies the revision level of the MSTP configuration only when the value of the mode option is mstp. The specified number must be in the range 0 through 65535. The default value is 0 (zero).

description
User defined description.

fwd-delay
In the original STP, the forward delay parameter controlled the number of seconds for which an interface was blocked from forwarding network traffic after a reconfiguration of the spanning tree topology. This parameter has no effect when RSTP or MSTP are used, as long as all bridges in the spanning tree use the RSTP or MSTP protocol. If any legacy STP bridges are present, then neighboring bridges must fall back to the old protocol, whose reconfiguration time is affected by the value of the fwd-delay option. The default value is 15 seconds, and the valid range is 4 to 30.

hello-time
Specifies the time interval in seconds between the periodic transmissions that communicate spanning tree information to the adjacent bridges in the network. The default value is 2 seconds, and the valid range is 1 - 10. The default value is optimal in virtually all cases. F5 Networks recommends that you do not change the value of the hello-time option.

max-age

Specifies the number of seconds for which spanning tree information received from other bridges is considered valid. The default value is 20 seconds, and the valid range is 6-40 seconds.

max-hops

Specifies the maximum number of hops an MSTP packet can travel before it is discarded. Use this option only when the value of the mode option is mstp. The number of hops must be in the range of 1 to 255 hops. The default number of hops is 20.

mode Specifies one of three spanning tree modes:

disabled

Specifies to discard spanning tree bridge protocol data units (BPDUs) received on any interface.

mstp Specifies multiple spanning tree protocol.

passthru

Forwards spanning tree bridge protocol data units (BPDUs) received on any interface to all other interfaces. Essentially, passthru mode makes the traffic management system transparent to spanning tree BPDUs. This is the system default.

rstp Specifies rapid spanning tree protocol (RSTP) converges to a fully-connected state quickly.

stp The system supports STP mode for legacy systems. If STP is detected in the network, the traffic management system changes to STP mode even when the mode option is set to disabled, mstp, or rstp.

transmit hold

Specifies the absolute limit on the number of spanning tree protocol packets the traffic management system may transmit on a port in any hello-time interval. It is used to ensure that spanning tree packets do not unduly load the network even in unstable situations. The default value is 6 packets, and the valid range is 1 through 10 packets.

BIG-IP 2016-03-14 net stp-globals(1)

net stp

NAME

stp - Configures a Spanning Tree Protocol (STP) instance.

MODULE

net

SYNTAX

Configure the stp component within the net module using the syntax shown in the following sections.

CREATE/MODIFY

```
create stp [all | [name] ]
modify stp [all | [name] ]
options:
  app-service [[string] | none]
  description [string]
  instance-id [integer]
  interfaces [ add | delete | modify | replace-all-with ] {
    [interface name] {
      options:
        app-service [[string] | none]
        external-path-cost [integer]
        internal-path-cost [integer]
        priority [integer]
      }
    }
  interfaces none
  priority [integer]
  trunks [ add | delete | modify | replace-all-with ] {
    [interface name] {
      options:
        app-service [[string] | none]
        external-path-cost [integer]
```

```

internal-path-cost [integer]
priority [integer]
}
}
trunks none
vlans [ add | delete | replace-all-with ] {
    [vlan name ...]
}
vlans none

edit stp [ [ all | [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties

DISPLAY
list stp
list stp [ [ all | [name] | [glob] | [regex] ] ... ]
show stp running-config
show stp running-config [ [ all | [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties
    one-line

DELETE
delete stp [all | [name] ]

```

DESCRIPTION
You can use the stp component to configure an STP instance.

EXAMPLES

```
list stp
```

Displays all STP instances on the system.

```
show running-config stp
```

Displays the running configuration information for all STP instances.

```
delete stp myStp2
```

Removes all members from the STP instance, and then deletes the instance itself.

Note that you cannot delete spanning tree instance 0 (the Common and Internal Spanning Tree). You can only use the command delete in Multiple Spanning Tree Protocol (MSTP) mode.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

external-path-cost

Specifies the external path cost number for either an interface or trunk. The default value is 20000.

Each network interface has an associated path cost within each spanning tree instance. The path cost represents the relative cost of sending network traffic through that interface. In calculating the spanning tree, the algorithm tries to minimize the total path cost between each point of the tree and the root bridge. By manipulating the path costs of different interfaces or trunks it is possible to steer traffic toward paths that are faster, more reliable, and/or more economical. Path costs can take values in the range 1 - 200,000,000. The default path cost for an interface or a trunk is based on the maximum, not actual speed, of the interface or trunk.

In MSTP mode there are two kinds of path cost: external and internal. The external path cost applies only to spanning tree instance 0, the Common and Internal Spanning Tree (CIST). It is used to calculate the cost to reach an adjacent spanning tree region.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

instance-id

The instance ID for this STP instance. In Multiple Spanning Tree Protocol (MSTP) mode, there will be exactly one STP instance with ID 0. The instance ID can be a value between 1 and 255.

internal-path-cost

Specifies the internal path cost number for either an interface or trunk. The default value is 20000.

Each network interface has an associated path cost within each spanning tree instance. The path cost represents the relative cost of sending network traffic through that interface. In calculating the spanning tree, the algorithm tries to minimize the total path cost between each point of the tree and the root bridge. By manipulating the path costs of different interfaces or trunks it is possible to steer traffic toward paths that are faster, more reliable, and/or more economical. Path costs can take values in the range 1 - 200,000,000. The default path cost for an interface

or a trunk is based on the maximum, not actual speed, of the interface or trunk.

In MSTP mode there are two kinds of path cost: external and internal. The internal path costs can be independently set for each spanning tree instance (including instance 0) in MSTP mode. The internal path costs are used to calculate the costs of reaching adjacent bridges within the same spanning tree region.

priority

Specifies the priority number of either a bridge, interface, or trunk. The default value for a bridge is 61440. The default value for both interfaces and trunks is 128.

Each bridge, interface, and trunk in a spanning tree instance has a priority value. The relative values of the priorities control the topology of the spanning tree chosen by the protocol. The bridge with the lowest priority value (numerically) will become the root of the spanning tree. Priority values vary from 0 - 61440 in steps of 4096.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

vlan

Specifies the VLANs that you want to add to, delete from, or replace-all-with for this STP instance.

net timer-policy

NAME

timer-policy - Configures the timer policy.

MODULE

net

SYNTAX

Modify the timer policy component within the net module using the syntax shown in the following sections. A timer-policy is attached to a service-policy and applied either through an ACL rule or policy applied on a context. The list of supported contexts where a timer policy can be applied are: Virtual Server, SelfIP, Route Domain and Global. The precedence of the timer policy is as follows (highest precedence is 1):

1. ACL rule configured on a Virtual Server or SelfIP
2. Policy configured on a Virtual Server or SelfIP
3. ACL rule configured on a Route Domain
4. Policy configured on a Route Domain
5. ACL rule configured through Global Rules
6. Policy configured on Global Service Policy

Note that within the same context, ACL rule based service policy takes first precedence. Among the different contexts, the order of precedence is as follows: Virtual Server, SelfIP, Route Domain, Global.

CREATE/MODIFY

```
create timer-policy [name]
modify timer-policy [name]
options:
  description [string]
  rules [add | delete | modify | replace-all-with] {
    [ rule name ] {
options:
  description [string]
  destination-ports [add | delete | replace-all-with] {
    [ [port] | [port1-port2] ]
  }
  destination-ports none
  ip-protocol [protocol name]
  timers [add | delete | modify | replace-all-with] {
    [ [flow timer type] ] {
value [timeout]
```

```

    }
  }
  timers none
}
rules none

edit timer-policy [[name] | all]
options:
  all-properties
  non-default-properties

DISPLAY
list timer-policy
show running-config timer-policy
options:
  all-properties
  non-default-properties
  one-line

```

DESCRIPTION

You can use the timer-policy component to configure a shareable and reusable set of network timer policies which can be associated with a service policy object.

EXAMPLES

```

create net timer-policy add idle-flow-policy { rules add { r1 { ip-
protocol tcp destination-ports add { 80 8080 } timers add { flow-idle-
timeout { value 120 } } } r2 { ip-protocol udp destination-ports add {
7878 } timers add { flow-idle-timeout { value 300 } } } } }

```

```

list timer-policy
net timer-policy {
  idle-flow-policy {
    rules {
      r1 {
        ip-protocol tcp
        destination-ports {
          http { }
          webcache { }
        }
      }
      timers {
        flow-idle-timeout {
          value 120
        }
      }
    }
    r2 {
      ip-protocol udp
      destination-ports {
        7878 { }
      }
    }
    timers {
      flow-idle-timeout {
        value 300
      }
    }
  }
}
}
}

```

Creates timer policy rules to set specific timeout configuration for tcp ports 80 & 8080 traffic and another entry for protocol udp.

Here is another example to illustrate the rule match behavior for policy with rules configured with 'all-other' for destination-ports and ip-protocol. Consider a policy as listed below.

```

list timer-policy
net timer-policy {
  flow-idle-policy {
    rules {
      r1 {
        ip-protocol tcp
        destination-ports {
          all-other { }
        }
      }
      timers {
        flow-idle-timeout {
          value 120
        }
      }
    }
    r2 {
      ip-protocol udp
      destination-ports {
        9090 { }
      }
    }
    timers {
      flow-idle-timeout {
        value 300
      }
    }
  }
  r3 {
    ip-protocol all-other
    destination-ports {
      all-other { }
    }
  }
  timers {
    flow-idle-timeout {
      value 40
    }
  }
}
}

```

```
}  
}  
}  
}
```

For an incoming flow:-

- a) TCP, any port: Matches rule r1
- b) UDP, port 1010: Matches no rule
- c) ICMP: Matches rule r3

For the above policy, since there is a specific UDP rule for port 9090, a UDP flow with port other than 9090 will not match any rule. If the rule r2 were to be deleted, all UDP traffic will match against the 'all-other' ip-protocol rule r3.

If the user would like to apply a specific timeout for UDP traffic with destination port being anything other than 9090, one can enter rule r4 to the above policy:

```
r4 {  
ip-protocol udp  
destination-ports {  
    all-other { }  
}  
timers {  
    flow-idle-timeout {  
        value 60  
    }  
}  
}
```

```
modify timer-policy idle-flow-policy delete r1
```

Removes the timer policy rule r1.

```
list timer-policy
```

Displays the current timer policy configuration list.

OPTIONS

description
User defined description.

rules
Adds, deletes, or replaces a named timer policy rule.

ip-protocol
Specifies the IP protocol entry for which the timer policy rule is being configured. This could be a layer-4 protocol (such as tcp, udp or sctp). Only flows matching the configured protocol will make use of this rule. Press the key for a full list of valid protocols. Keyword 'all-other' as an ip-protocol entry means, if there are no specific ip-protocol rule that matches the flow, the flow then matches the 'all-other' ip-protocol rule. Please see example above for rule match behavior.

destination-ports
Specifies the destination port or port range to match against the flow. Keyword 'all-other' as a port entry means, if there are no specific port entry rules to match against the flow, the flow then matches the 'all-other' port rule. For eg. if a policy consists of just two rules r1 and r2, with the same protocol 'tcp' but destination port 80 for r1 and port 'all-other' for r2 configured, an incoming flow with port 80 will match r1 and incoming flow with port 9090 will match r2. Without the 'all-other' port rule r2, incoming flow with port 9090 will not match any rule.

timers
Specifies the flow timer configuration for the different timer types.

value
Specifies the timeout value in seconds.

DELETE
delete trunk [all | [name]]

DESCRIPTION
Link Aggregation allows multiple physical links to be treated as one logical link. It is also referred to as trunking.

The main objective of link aggregation is to provide increased bandwidth at a lower cost, without having to upgrade hardware. The bandwidth of the aggregated trunk is the sum of the capacity of individual member links. Thus, it provides an option for linearly incremental bandwidth as opposed to bandwidth options available through physical layer technology. The traffic management system supports link aggregation control protocol (LACP).

When a trunk is created, LACP is disabled by default. In this mode, no control packets are exchanged and the member links carry traffic as long as the physical layer is operational. In the event of physical link failure, an LACP member is removed from the aggregation.

Note that both endpoints of the trunk should have identical LACP configuration to work properly. A mixed configuration where one endpoint is LACP enabled and the other is LACP disabled, is not valid.

EXAMPLES
create trunk my_trunk interfaces add {1.1 1.2 1.3}

Creates a trunk named my_trunk that includes the interfaces 1.1, 1.2, and 1.3.

modify trunk my_trunk lACP enabled

Enable LACP on the trunk named my_trunk.

modify trunk my_trunk lACP-mode active

Enable active LACP mode on the trunk my_trunk.

OPTIONS
app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates

option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

bandwidth

Specifies the operation bandwidth in bytes per second.

cfg-mbr-count

Displays the number of configured members that are associated with this trunk.

description

User defined description.

distribution-hash

Specifies the basis for the hash that the system uses as the frame distribution algorithm. The system uses the resulting hash to determine which interface to use for forwarding traffic.

When frames are transmitted on a trunk, they are distributed across the working member links. The distribution function ensures that the frames belonging to a particular conversation are neither mis-ordered nor duplicated at the receiving end. Distribution is done by calculating a hash value based on source and destination addresses carried in the frame and associating the hash value with a link. All frames with a particular hash value are transmitted on the same link, thereby maintaining frame order.

The options are:

dst-mac

Uses the destination MAC addresses to calculate the hash value.

src-dst-mac

Uses the source, destination, and MAC addresses to calculate the hash value.

src-dst-ipport

Uses the source and destination IP addresses and ports to calculate the hash value.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

id Displays the ID of the trunk.

interfaces

Specifies the interfaces by name separated by spaces that you want to add to the trunk, delete from the trunk, or with which you want to replace all existing interfaces associated with the trunk.

lACP Specifies, when enabled, that the system supports the link aggregation control protocol (LACP), which monitors the trunk by exchanging control packets over the member links to determine the health of the links. If LACP detects a failure in a member link, it removes the link from the link aggregation. LACP is disabled by default, for backward compatibility.

lACP-mode

Specifies the operation mode for LACP if the lACP option is enabled for the trunk. The options are:

active

Specifies that the system periodically transmits LACP packets, regardless of the control value of the peer system.

passive

Specifies that the system periodically transmits LACP packets, unless the control value of the peer system is active.

lACP-timeout

Specifies the rate at which the system sends the LACP control packets. The default value is long.

The options are:

long Specifies that the system exchanges LACP packets every 30 seconds.

short

Specifies that the system exchanges LACP packets every second.

link-select-policy

Sets the LACP policy that the trunk uses to determine which member link (interface) can handle new traffic.

Link aggregation is allowed only when all the interfaces are operating at the same media speed and connected to the same partner aggregation system. When there is a mismatch among configured members due to configuration errors or topology changes (auto-negotiation), link selection policy determines which links become working members and form the aggregation.

The options are:

auto Specifies that the system chooses the lowest numbered operational link as the reference link. All the members that have the same media speed and are connected to the same partner as that of the reference link are declared as working members, and they are aggregated. The other configured members do not carry traffic.

maximum-bandwidth

Specifies that the system adds to the aggregation a subset of links that gives maximum aggregate bandwidth to the trunk.

mac-address

Specifies the media access control (MAC) address, which is associated with the trunk, in not case-sensitive hexadecimal colon notation, for example, 00:0b:09:88:00:9a.

media

Displays the media settings for the trunk.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

stp Enables or disables spanning tree protocols (STP). The default value is enabled.

If you disable STP, the system does not transmit or receive STP, RSTP, or MSTP packets on the trunk, and STP has no control over forwarding or learning on the trunk.

stp-reset

Resets STP, which forces a migration check.

qinq-ethertype

Specifies the ether-type value used for the packets handled on this trunk when it is a member in a QinQ vlan. The ether-type can be set to any string containing a valid hexadecimal 16 bits number, or any of the well known ether-types: 0x8100, 0x9100, 0x88a8. Default value is set to 0x8100.

working-mbr-count

Displays the number of working members associated with this trunk.

net tunnels endpoint

NAME

endpoint - Tunnel endpoint statistics

MODULE

net tunnels

SYNTAX

Show the statistics of tunnel remote endpoints within the net tunnel component using the syntax described in the following sections.

DISPLAY

```
show endpoint tunnel-name [name]
options:
  remote-address [IP address]
```

MODIFY

```
reset-stats endpoint tunnel-name [name]
options:
  remote-address [IP address]
```

DESCRIPTION

The command displays the statistics of tunnel remote endpoints. Currently, the command is only supported for network virtualization tunnels, e.g., VXLAN and NVGRE tunnels.

EXAMPLES

```
show endpoint tunnel-name t1
```

Display the statistics of remote endpoints of tunnel t1.

```
show endpoint tunnel-name t1 remote-address 10.10.0.2
```

Display the statistics of remote endpoint 10.10.0.2 of tunnel t1.

```
reset-stats endpoint tunnel-name t1
```

Reset the statistics of remote endpoints of tunnel t1.

```
reset-stats endpoint tunnel-name t1 remote-address 10.10.0.2
```

Reset the statistics of remote endpoint 10.10.0.2 of tunnel t1.

COPYRIGHT

BIG-IP 2016-09-23 net tunnels endpoint(1)

net tunnels etherip

NAME
etherip - Configures an EtherIP tunnel profile.

MODULE
net tunnels

SYNTAX
Configure the etherip component within the net tunnels module using the syntax in the following sections.

```
CREATE/MODIFY
create etherip [name]
modify etherip [name]
options:
  app-service [[string] | none]
  defaults-from [name]
  description [string]

edit etherip [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list etherip
list etherip [ [ [name] | [glob] | [regex] ] ... ]
show running-config etherip
show running-config etherip [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition

DELETE
delete etherip [ all | [name] ]
```

DESCRIPTION
You can use the etherip component to create an EtherIP profile that you associate with a tunnel using the tunnel component. This will cause ethernet frames to be sent over the tunnel. For more information about creating a tunnel see net tunnel.

EXAMPLES
create etherip my_etherip

Creates an EtherIP profile called my_etherip.

list etherip all-properties

Displays all of the properties of all EtherIP profiles.

OPTIONS
app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from
Specifies the existing profile from which the system imports settings for the new profile. The default value is etherip.

description
User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create and modify.

partition
Displays the administrative partition within which this component resides.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

create, delete, edit, glob, list, modify, net tunnels tunnel, regex, show, tmsh

BIG-IP 2014-03-18 net tunnels etherip(1)

net tunnels fec-stat

NAME
fec-stat - Displays FEC tunnels statistics.

MODULE
net tunnels

SYNTAX
Display statistics for the FEC tunnels using the syntax in the following section.

DISPLAY
show action
option:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION
You can use the fec-stat component to display FEC tunnels statistics. The statistics details are described below:

name Specifies the FEC tunnel name.

profile
Specifies the FEC profile name used for the tunnel.

out_raw_packets
Specifies the number of FEC outgoing raw packets coming from the LAN.

out-raw-bits
Specifies the number of FEC outgoing raw bits coming from the LAN.

out_rdnd_packets
Specifies the number of FEC outgoing redundant packets sent to the WAN.

out_rdnd_bits
Specifies the number of FEC outgoing redundant bits sent to the WAN.

in_raw_packets
Specifies the number of incoming raw packets sent to the LAN.

in-raw-bits
Specifies the number of incoming raw bits sent to the LAN.

in_rdnd_packets
Specifies the number of FEC redundant packets incoming from the WAN.

in_rdnd_bits
Specifies the number of FEC redundant bits incoming from the WAN.

in_rdnd_lost
Specifies the number of FEC redundant packets lost incoming from the WAN.

in_raw_lost

Specifies the number of incoming from WAN raw packets lost.

`rmt_in_rdnd_packets`
Specifies the number of FEC redundant packets from a remote server when incoming from the WAN.

`rmt_in_raw_packets`
Specifies the number of raw packets from remote a server when incoming from the WAN.

`rmt_in_rdnd_lost`
Specifies the number of FEC redundant packets lost from a remote server when incoming from the WAN.

`rmt_in_raw_lost`
Specifies the number of raw packets lost from a remote server when incoming from the WAN.

OPTIONS

For information about the options that you can use with the command `show`, see `help show`.

SEE ALSO

`show`, `fec`, `net tunnels`, `net tunnels fec`, `net tunnels tunnel`, `tmsh`

COPYRIGHT

BIG-IP 2016-03-14 net tunnels fec-stat(1)

net tunnels fec

NAME

`fec` - Configures a Forward Error Correction (FEC) profile.

MODULE

`net tunnels`

SYNTAX

Configure the `fec` component within the `net tunnels` module using the syntax in the following sections.

CREATE/MODIFY

```
create fec [name]
modify fec [name]
options:
  app-service [[string] | none]
  decode-idle-timeout [integer]
  decode-max-packets [integer]
  decode-queues [integer]
  defaults-from [name]
  description [string]
  encode-max-delay [integer]
  keepalive-interval [integer]
  lzo [disabled | enabled]
  repair-adaptive [disabled | enabled]
  repair-packets [integer]
  source-adaptive [disabled | enabled]
  source-packets [integer]
  udp-port [integer]
```

```
edit fec [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  =head2 DISPLAY
```

```
list fec
list fec [ [name] | [glob] | [regex] ] ... ]
show running-config fec
show running-config fec [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition
```

DELETE

```
delete fec [ all | [name] ]
```

DESCRIPTION

You can use the `fec` component to create a FEC profile that you associate with a tunnel using the `tunnel` component. For more information about creating a tunnel see `net tunnel`.

EXAMPLES

```
create fec my_fec
```

Creates a FEC profile called my_fec.

```
list fec all-properties
```

Displays all of the properties of all of the FEC profiles.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is fec.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create and modify.

partition

Displays the administrative partition within which this component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

decode-idle-timeout

Specifies the maximum waiting time for packets in decoding queues. Packets waiting longer than this time are discarded. Range is from 250 to 2000 milliseconds. The default value is 1500 milliseconds.

decode-max-packets

Specifies the maximum number of waiting packets in decoding queues. Range is from 200 to 8000. The default value is 512.

decode-queues

Specifies the number of decoding queues. Valid numbers are 8,16,32,64,128,256,512,1024. The default value is 32.

encode-max-delay

Specifies the maximum waiting time for packet aggregation. Range is from 500 to 5000 microseconds. The default value is 500 microseconds.

keepalive-interval

Specifies the interval between keepalive (statistical data) packets. Range is from 0 to 100 seconds. The default value is 5 seconds.

lzo Controls the use of the LZ0 compression algorithm to compress data packets. The default value is enabled.

repair-adaptive

Controls the use of the adaptive FEC repair technique to modify the number of redundant packets according to actual network conditions. The default value is enabled.

repair-packets

Specifies the number of redundant packets to add. Range is from 0 to 15. The default value is 15. This value should be less than or equal to the value specified for source-packets.

source-adaptive

Controls the use of the adaptive FEC source packets technique to reduce the number of packets for better MTU usage. The default value is enabled.

source-packets

Specifies the number of packets into which the system divides the aggregated payload. Range is from 1 to 15. The default value is 15.

udp-port

Specifies the local port for receiving FEC packets. The default value is 8288.

SEE ALSO

net tunnels geneve

NAME
geneve - Configures a Geneve profile.

MODULE
net tunnels

SYNTAX
Configure the geneve component within the net tunnels module using the syntax in the following sections.

CREATE/MODIFY
create geneve [name]
modify geneve [name]
options:
app-service [[string] | none]
defaults-from [[name] | none]
description [string]
port [integer]
flooding-type [none | multicast | multipoint]

edit geneve [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties

DISPLAY
list geneve
list geneve [[[name] | [glob] | [regex]] ...]
show running-config geneve
show running-config geneve [[[name] | [glob] | [regex]] ...]
options:
all-properties
app-service
non-default-properties
one-line
partition

DELETE
delete geneve [all | [name]]

DESCRIPTION
You can use the geneve component to create a geneve profile that you associate with a tunnel using the tunnel component. For more information about creating a tunnel see net tunnel.

EXAMPLES
create geneve my_geneve

Creates a geneve profile called my_geneve.

list geneve all-properties

Displays all the properties of all the geneve profiles.

OPTIONS
app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from
Specifies the existing profile from which the system imports settings for the new profile. The default value is geneve.

description
User defined description.

glob
Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name
Specifies a unique name for the component. This option is required for the commands create and modify.

partition
Displays the administrative partition within which this component resides.

port
Specifies the local port for receiving geneve packets. The default is 6081.

flooding-type
Specifies the flooding type to use to transmit multicast, broadcast and unknown destination frames. The default is multipoint.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

BIG-IP 2016-03-14 net tunnels geneve(1)

net tunnels gre

NAME

gre - Configures a Generic Router Encapsulation (GRE) profile.

MODULE

net tunnels

SYNTAX

Configure the gre component within the net tunnels module using the syntax in the following sections.

CREATE/MODIFY

```
create gre [name]
modify gre [name]
options:
  app-service [[string] | none]
  defaults-from [name]
  description [string]
  rx-csum [disabled | enabled]
  tx-csum [disabled | enabled]
  encapsulation [standard | nvgre]
  flooding-type [none | multipoint]
```

```
edit gre [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list gre
list gre [ [name] | [glob] | [regex] ] ... ]
show running-config gre
show running-config gre [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition
```

DELETE

```
delete gre [ all | [name] ]
```

DESCRIPTION

You can use the gre component to create a GRE profile that you associate with a tunnel using the tunnel component. For more information about creating a tunnel see net tunnel.

EXAMPLES

```
create gre my_gre
```

Creates a GRE profile called my_gre.

```
list gre all-properties
```

Displays all of the properties of all of the GRE profiles.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is gre.

description
User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create and modify.

partition
Displays the administrative partition within which this component resides.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

rx-csum
Specifies whether the system verifies the checksum on received packets. The default value is disabled.

tx-csum
Specifies whether the system includes a checksum on transmitted packets. The default value is disabled.

encapsulation
Specifies the flavor of GRE header to use for encapsulation. The default value is standard.

flooding-type
Specifies the flooding type to use to transmit broadcast and unknown destination frames. The default is none.

BIG-IP 2014-05-16 net tunnels gre(1)

net tunnels ipip

NAME
ipip - Configures an IP over IP (IPIP) profile.

MODULE
net tunnels

SYNTAX
Configure the ipip component within the net tunnels module using the syntax in the following sections.

CREATE/MODIFY
create ipip [name]
modify ipip [name]
options:
app-service [[string] | none]
defaults-from [name]
description [string]
proto [IPv4 | IPv6]
ds-lite [bool]

edit ipip [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties

DISPLAY
list ipip
list ipip [[[name] | [glob] | [regex]] ...]
show running-config ipip
show running-config ipip [[[name] | [glob] | [regex]] ...]
options:
all-properties
app-service
non-default-properties
one-line
partition

DELETE
delete ipip [all | [name]]

DESCRIPTION

You can use the `ipip` component to create an IPIP profile that you associate with a tunnel using the `tunnel` component. For more information about creating a tunnel see `net tunnel`.

EXAMPLES

```
create ipip my_ipip
```

Creates an IPIP profile called `my_ipip`.

```
list ipip all-properties
```

Displays all of the properties of all of the IPIP profiles.

OPTIONS

`app-service`

Specifies the name of the application service to which the object belongs. The default value is `none`. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

`defaults-from`

Specifies the existing profile from which the system imports settings for the new profile. The default value is `ipip`.

`description`

User defined description.

`glob` Displays the items that match the `glob` expression. See `help glob` for a description of `glob` expression syntax.

`name` Specifies a unique name for the component. This option is required for the commands `create` and `modify`.

`partition`

Displays the partition within which this component resides.

`proto`

Specifies the next header protocol. The default value is `IPv4`.

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an `@` sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See `help regex` for a description of regular expression syntax.

`ds-lite`

Specifies whether the profile is used for a DS-lite deployment. When enabled, an augmented flow lookup is made using the `IPv6` address in the outer header in addition to the inner header addresses for packets coming over this tunnel. The default value is `disabled`.

SEE ALSO

`create`, `delete`, `edit`, `glob`, `list`, `modify`, `net tunnels gre`, `net tunnels tunnel`, `net tunnels wccp`, `regex`, `show`, `tmsh`

BIG-IP 2014-03-18 net tunnels ipip(1)

net tunnels ipsec

NAME

`ipsec` - Configures an IPsec profile.

MODULE

`net tunnels`

SYNTAX

Configure the `ipsec` component within the `net tunnels` module using the syntax in the following sections.

CREATE/MODIFY

```
create ipsec [name]
```

```
modify ipsec [name]
```

options:

```
app-service [[string] | none]
```

```
defaults-from [ [name] | none]
```

```
description [string]
```

```
traffic-selector [name]
```

```

edit ipsec [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties

  DISPLAY
list ipsec
list ipsec [ [ [name] | [glob] | [regex] ] ... ]
show running-config ipsec
show running-config ipsec [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    app-service
    non-default-properties
    one-line
    partition

  DELETE
delete ipsec [ all | [name] ]

DESCRIPTION
  You can use the ipsec component to create an ipsec profile that you
  associate with a tunnel using the tunnel component. For more
  information about creating a tunnel see net tunnel.

EXAMPLES
  create ipsec my_ipsec

  Creates an IPsec profile called my_ipsec.

  list ipsec all-properties

  Displays all the properties of all the IPsec profiles.

OPTIONS
  app-service
  Specifies the name of the application service to which the object
  belongs. The default value is none. Note: If the strict-updates
  option is enabled on the application service that owns the object,
  you cannot modify or delete the object. Only the application
  service can modify or delete the object.

  defaults-from
  Specifies the existing profile from which the system imports
  settings for the new profile. The default value is ipsec.

  description
  User defined description.

  glob Displays the items that match the glob expression. See help glob
  for a description of glob expression syntax.

  name Specifies a unique name for the component. This option is required
  for the commands create and modify.

  partition
  Displays the administrative partition within which this component
  resides.

  traffic-selector
  Specifies the IPsec traffic selector for the IPsec tunnel.

  regex
  Displays the items that match the regular expression. The regular
  expression must be preceded by an at sign (@[regular expression])
  to indicate that the identifier is a regular expression. See help
  regex for a description of regular expression syntax.

SEE ALSO
  create, delete, edit, glob, list, modify, net tunnels tunnel, regex,
  show, tmsh

```

BIG-IP 2015-11-17 net tunnels ipsec(1)

net tunnels lw406

```

NAME
  lw406 - Configures a LW406 tunnel profile.

MODULE
  net tunnels

```

SYNTAX

Configure the lw4o6 component within the net tunnels module using the syntax in the following sections.

CREATE/MODIFY

```
create lw4o6 [name]
modify lw4o6 [name]
options:
  app-service [[string] | none]
  defaults-from [ [name] | none]
  description [string]
  lwtbl-file [string]
  psid-length [integer]
  all-protocols-pass [enabled | disabled]

edit lw4o6 [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list lw4o6
list lw4o6 [ [name] | [glob] | [regex] ] ... ]
show running-config lw4o6
show running-config lw4o6 [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition
```

DELETE

```
delete lw4o6 [ all | [name] ]
```

DESCRIPTION

You can use the lw4o6 component to create a LW4o6 profile that you associate with a tunnel using the tunnel component. For more information about creating a tunnel see net tunnel.

EXAMPLES

```
create lw4o6 my_lw4o6 lwtbl-file name
```

Creates a LW4o6 profile called my_lw4o6, lwtbl-file name have to be created before. For more information about creating a lwtbl-file see sys file lwtunneltbl.

```
list lw4o6 all-properties
```

Displays all the properties of all the LW4o6 profiles.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is lw4o6.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create and modify.

partition

Displays the administrative partition within which this component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

lwtbl-file

Specifies the existing lw4o6 configuration file.

psid-length

Specifies the length of Port Set ID (PSID). The default value is 0.

all-protocols-pass

When enabled and PSID is 0, permits passthrough for all IP sub-protocols. If PSID != 0, value have to be disabled. If it is disabled only TCP/UDP/ICMP traffic can pass lw4o6 tunnel. The default value is disabled."

net tunnels map

NAME

map - Configures a MAP tunnel profile.

MODULE

net tunnels

SYNTAX

Configure the map component within the net tunnels module using the syntax in the following sections.

CREATE/MODIFY

```
create map [name]
```

```
modify map [name]
```

options:

```
app-service [[string] | none]
```

```
defaults-from [ [name] | none]
```

```
description [string]
```

```
ip6-prefix [ipv6 address/prefix length]
```

```
ip4-prefix [ipv4 address/prefix length]
```

```
ea-bits-length [integer]
```

```
port-offset [integer]
```

```
edit map [ [ [name] | [glob] | [regex] ] ... ]
```

options:

```
all-properties
```

```
non-default-properties
```

DISPLAY

```
list map
```

```
list map [ [ [name] | [glob] | [regex] ] ... ]
```

```
show running-config map
```

```
show running-config map [ [ [name] | [glob] | [regex] ] ... ]
```

options:

```
all-properties
```

```
app-service
```

```
non-default-properties
```

```
one-line
```

```
partition
```

DELETE

```
delete map [ all | [name] ]
```

DESCRIPTION

You can use the map component to create a MAP profile that you associate with a tunnel using the tunnel component. For more information about creating a tunnel see net tunnel.

EXAMPLES

```
create map my_map
```

Creates a MAP profile called my_map.

```
list map all-properties
```

Displays all the properties of all the MAP profiles.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is map.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create and modify.

partition

Displays the administrative partition within which this component resides.

regex

Displays the items that match the regular expression. The regular

expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

ip6-prefix

Specifies the IPv6 Prefix using CIDR notation, such as 2014::/48. The default prefix length is 48.

ip4-prefix

Specifies the IPv4 Prefix using CIDR notation, such as 192.0.0.0/8. The default prefix length is 8.

ea-bits-length

Specifies the length in bits of the EA (Embedded Address) of the MAP domain. The default is 32 (IPv4 prefix 24 bits + PSID 8 bits).

port-offset

Specifies the port offset bits length of the MAP domain. The default is 6.

SEE ALSO

BIG-IP 2016-03-14 net tunnels map(1)

net tunnels ppp

NAME

ppp - Configures a PPP profile.

MODULE

net tunnels

SYNTAX

Configure the ppp component within the net tunnels module using the syntax in the following sections.

CREATE/MODIFY

```
create ppp [name]
modify ppp [name]
options:
  app-service [[string] | none]
  defaults-from [ [name] | none]
  description [string]
  lcp-echo-failure [integer]
  lcp-echo-interval [integer]
  vj [disabled | enabled]
```

```
edit ppp [ [ [name] | [glob] | [regex] ] ... ]
```

options:

```
all-properties
non-default-properties
```

DISPLAY

```
list ppp
list ppp [ [ [name] | [glob] | [regex] ] ... ]
show running-config ppp
show running-config ppp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition
```

DELETE

```
delete ppp [ all | [name] ]
```

DESCRIPTION

You can use the ppp component to create a ppp profile that you associate with a tunnel using the tunnel component. For more information about creating a tunnel see net tunnel.

EXAMPLES

```
create ppp my_ppp
```

Creates a PPP profile called my_ppp.

```
list ppp all-properties
```

Displays all the properties of all the PPP profiles.

OPTIONS

app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from
Specifies the existing profile from which the system imports settings for the new profile. The default value is ppp.

description
User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

lcp-echo-failure
Specifies the number of consecutive PPP LCP echo messages that must go unanswered for the server to drop PPP connection. For example, if the server sends number of consecutive PPP LCP Echo Request messages that go unanswered (by Echo Reply), it will close the PPP connection. The default value is 4.

lcp-echo-interval
Specifies the interval, in seconds, between the PPP LCP Echo Request messages that the server sends to the peer (client). The default value is 30.

name Specifies a unique name for the component. This option is required for the commands create and modify.

partition
Displays the administrative partition within which this component resides.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

vj Specifies whether the system uses Van Jacobson Header Compression (also known as VJ compression, or just Header Compression), which is an option in most versions of PPP. VJ is a data compression protocol described in RFC 1144, specifically designed by Van Jacobson to improve TCP/IP performance over slow serial links. The default value is disabled.

net tunnels tcp-forward

NAME

tcp-forward - Configures a tcp-forward tunnel profile.

MODULE

net tunnels

SYNTAX

Configure the tcp-forward component within the net tunnels module using the syntax in the following sections.

CREATE/MODIFY

```
create tcp-forward [name]
modify tcp-forward [name]
options:
  app-service [[string] | none]
  defaults-from [ [name] | none]
  description [string]
```

```
edit [ [name] ... ]
options:
  all-properties
  non-default-properties
```

```

DISPLAY
list tcp-forward
list tcp-forward [ [name] ... ]
show running-config tcp-forward
show running-config tcp-forward [ [name] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition

DELETE
delete tcp-forward [ all | [name] ]

DESCRIPTION
You can use the tcp-forward component to create a TCP-FORWARD profile
that you associate with a tunnel using the tunnel component. For more
information about creating a tunnel see net tunnel.

EXAMPLES
create tcp-forward my_tcp_forward

Creates a TCP_FORWARD profile called my_tcp_forward.

list tcp-forward all-properties

Displays all the properties of all the TCP-FORWARD profiles.

OPTIONS
  app-service
  Specifies the name of the application service to which the object
  belongs. The default value is none. Note: If the strict-updates
  option is enabled on the application service that owns the object,
  you cannot modify or delete the object. Only the application
  service can modify or delete the object.

  defaults-from
  Specifies the existing profile from which the system imports
  settings for the new profile. The default value is tcp-forward.

  description
  User defined description.

  name
  Specifies a unique name for the component. This option is required
  for the commands create and modify.

  partition
  Displays the administrative partition within which this component
  resides.

```

net tunnels tunnel

```

NAME
  tunnel - Configures a tunnel.

MODULE
  net tunnels

SYNTAX
  Configure the tunnel component within the net tunnels module using the
  syntax in the following sections.

  CREATE/MODIFY
  create tunnel [name]
  modify tunnel [name]
  options:
    app-service [[string] | none]
    auto-lasthop [default | enabled | disabled ]
    description [string]
    local-address [ip address]
    secondary-address [ip address]
    mode [bidirectional | inbound | outbound]
    mtu [integer]
    use-pmtu [enabled | disabled ]

```

```

profile [name]
remote-address [ip address]
traffic-group [[traffic group] | none]
tos [integer]
transparent [enabled | disabled ]
idle-timeout [integer]
key [integer]

edit tunnel [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list tunnel
list tunnel [ [ [name] | [glob] | [regex] ] ... ]
show running-config tunnel
show running-config tunnel [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition

DELETE
delete tunnel [ all | [name] ]

```

DESCRIPTION
You can use the tunnel component to configure a tunnel.

EXAMPLES

```

create tunnel my_tunnel local-address 10.10.10.1 remote-address
11.11.11.1 profile gre

Creates a tunnel named my_tunnel between the local IP address
10.10.10.1 and the remote IP address 11.11.11.1.

list tunnel all-properties

Displays all of the properties of all of the tunnels.

```

OPTIONS

app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

auto-lasthop
When enabled, specifies that the system returns packets to the MAC address from which they were sent. The default setting is default, which specifies that the system uses the default route to send back the request.

description
User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

if-index
Displays the index assigned to this tunnel. It is a unique identifier assigned for all objects displayed in the SNMP IF-MIB.

local-address
Specifies a local IP address. This option is required.

secondary-address
Specifies a secondary non-floating IP address when the local-address is set to a floating address. Currently this setting is supported by NVGRE tunnels only.

mode Specifies how the tunnel carries traffic. The default value is bidirectional.

mtu Specifies the maximum transmission unit (MTU) of the tunnel. The default value is 0. When the MTU is set to the default value (of 0), the MTU of the tunnel is computed by the system and is set to the MTU size of the underlying interface minus the encapsulation overhead introduced by the tunneling protocol. The valid range is 0 - 65535.

use-pmtu
Enables or disables the tunnel to use the PMTU (Path MTU) information provided by ICMP NeedFrag error messages. If enabled and the tunnel MTU is set to 0, the tunnel will use the PMTU information. If enabled and the tunnel MTU is fixed to a non-zero value, the tunnel will use the minimum of PMTU and MTU. If disabled, the tunnel will use fixed MTU, or calculate its MTU using tunnel encapsulation configurations.

name Specifies a unique name for the component. This option is required for the commands create, and modify.

partition
Displays the administrative partition within which the component resides.

profile
Specifies the profile that you want to associate with the tunnel. This option is required for the create command.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

remote-address
Specifies a remote IP address. This value is required for the commands create and modify.

traffic-group
Specifies a traffic-group for use with the tunnel. Traffic group determines the ConfigSync behavior of the tunnel object.

tos Specifies a value for insertion into the Type of Service (ToS) octet within the IP header of the encapsulating header of transmitted packets. The default value is preserve. The possible values are 0 (zero) - 255.

transparent
Enables or disables the tunnel to be transparent. If enabled, the user can inspect and/or manipulate the encapsulated traffic flowing through the BIG-IP. A transparent tunnel terminates a tunnel while presenting the illusion that the tunnel transits the device unperturbed i.e. the BIG-IP appears like an intermediate router that simply routes IP traffic through the device. The default value is disabled.

idle-timeout
Specifies an idle timeout for wildcard tunnels in seconds. This setting specifies the number of seconds that a wildcard tunnel connection is idle before the connection is eligible for deletion. The default value is 300 seconds.

key The key field may represent different values depending on the type of the tunnel. For VXLAN it represents the Virtual Network Identifier (VNI). The default value is 0.

BIG-IP 2016-03-14 net tunnels tunnel(1)

net tunnels v6rd

NAME
v6rd - Configures a 6RD profile.

MODULE
net tunnels

SYNTAX
Configure the v6rd component within the net tunnels module using the syntax in the following sections.

CREATE/MODIFY

```
create v6rd [name]
modify v6rd [name]
options:
  app-service [[string] | none]
  defaults-from [ [name] | none]
  description [string]
  v6rdprefix [IPv6 address]
  v6rdprefixlen [integer]
  ipv4prefix [IPv4 address]
  ipv4prefixlen [integer]
```

```
edit v6rd [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list v6rd
list v6rd [ [ [name] | [glob] | [regex] ] ... ]
show running-config v6rd
show running-config v6rd [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
```

non-default-properties
one-line
partition

DELETE

delete v6rd [all | [name]]

DESCRIPTION

You can use the v6rd component to create a v6rd profile that you associate with a tunnel using the tunnel component. For more information about creating a tunnel see net tunnel.

EXAMPLES

```
create v6rd my_v6rd
```

Creates a 6RD profile called my_v6rd.

```
list v6rd all-properties
```

Displays all the properties of all the 6RD profiles.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from

Specifies the existing profile from which the system imports settings for the new profile. The default value is v6rd.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create and modify.

partition

Displays the administrative partition within which this component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

v6rdprefix

Specifies the IPv6 prefix for 6rd domain.

v6rdprefixlen

Specifies the IPv6 prefix length of the 6rd domain. The default is 56.

ipv4prefix

As an extension not mentioned in the RFC5969, it specifies the IPv4 prefix for the Customer-Edge (CE) devices of a 6RD domain at a Border-Relay (BR) in case that the subnet prefixes used by the 6RD devices do not share the same IPv4 prefix. If they do, there is no need to configure this parameter. The default value is 0.0.0.0.

ipv4prefixlen

Also noted as IPv4MaskLen in RFC5969, it specifies the number of identical high-order bits shared by all CE and BR IPv4 addresses in a given 6RD domain. The valid range is from zero to 32. It is a required value for create. It defaults to zero, i.e. the full ipv4 address must be encapsulated.

BIG-IP 2016-03-14 net tunnels v6rd(1)

NAME
vxlan - Configures a VXLAN profile.

MODULE
net tunnels

SYNTAX
Configure the vxlan component within the net tunnels module using the syntax in the following sections.

CREATE/MODIFY
create vxlan [name]
modify vxlan [name]
options:
 app-service [[string] | none]
 defaults-from [[name] | none]
 description [string]
 port [integer]
 flooding-type [none | multicast | multipoint | replicator]
 encapsulation-type [vxlan | vxlan-gpe]

edit vxlan [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 non-default-properties

DISPLAY
list vxlan
list vxlan [[[name] | [glob] | [regex]] ...]
show running-config vxlan
show running-config vxlan [[[name] | [glob] | [regex]] ...]
options:
 all-properties
 app-service
 non-default-properties
 one-line
 partition

DELETE
delete vxlan [all | [name]]

DESCRIPTION
You can use the vxlan component to create a vxlan profile that you associate with a tunnel using the tunnel component. For more information about creating a tunnel see net tunnel.

EXAMPLES
create vxlan my_vxlan
Creates a VXLAN profile called my_vxlan.
list vxlan all-properties
Displays all the properties of all the VXLAN profiles.

OPTIONS
app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from
Specifies the existing profile from which the system imports settings for the new profile. The default value is vxlan.

description
User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create and modify.

partition
Displays the administrative partition within which this component resides.

port Specifies the local port for receiving VXLAN packets. The default is 4789.

flooding-type
Specifies the flooding type to use to transmit multicast, broadcast and unknown destination frames. The default is multicast.

encapsulation-type
Specifies whether the VXLAN header is formatted according to RFC 7348 (vxlan) or with the Generic Protocol Extension (vxlan-gpe). The default is vxlan.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO
create, delete, edit, glob, list, modify, net tunnels tunnel, regex, show, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2016-03-14 net tunnels vxlan(1)

net tunnels wccp

NAME
wccp - Configures a Web-cache coordination protocol (WCCP) GRE profile.

MODULE
net tunnels

SYNTAX
Configure the wccp component within the net tunnels module using the syntax in the following sections.

CREATE/MODIFY

```
create wccp [name]
modify wccp [name]
options:
  app-service [[string] | none]
  defaults-from [name]
  description [string]
  rx-csum [disabled | enabled]
  tx-csum [disabled | enabled]
  wccp-version [1 | 2]
```

```
edit wccp [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list wccp
list wccp [ [name] | [glob] | [regex] ] ... ]
show running-config wccp
show running-config wccp [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition
```

DELETE

```
delete wccp [ all | [name] ]
```

DESCRIPTION

You can use the wccp component to create a WCCP GRE profile that you associate with a tunnel using the tunnel component. For more information about creating a tunnel see net tunnel.

EXAMPLES

```
create wccp my_wccp_gre

Creates a WCCP GRE profile called my_wccp_gre.

list wccp all-properties

Displays all of the properties of all of the WCCP GRE profiles.
```

OPTIONS

app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from
Specifies the existing profile from which the system imports settings for the new profile. The default value is wccpgre.

description
User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create and modify.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

rx-csum

Specifies whether the system verifies the checksum on received packets. The default value is disabled.

tx-csum

Specifies whether the system includes a checksum on transmitted packets. The default value is disabled.

wccp-version

Specifies the version of WCCP that the system uses. The default value is 2.

  non-default-properties
  one-line

show vlan-group
show vlan-group [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt

DELETE
delete vlan-group [name]
```

DESCRIPTION

The vlan-group component defines a VLAN group, which is a grouping of two or more VLANs belonging to the same IP network for the purpose of allowing Layer 2 packet forwarding between those VLANs.

The VLANs between which the packets are to be passed must be on the same IP network, and they must be grouped using the vlan-group component. For example: modify vlan-group network11 members add { internal external }.

EXAMPLES

```
create vlan-group my_vlan-group members add { vlan1 vlan2 }

Creates a VLAN group named my_vlan-group that consists of VLANs named
vlan1 and vlan2.

modify vlan-group proxy-excludes add { 10.10.10.1 }

Sets the global VLAN group proxy exclusion list.

delete vlan-group my_vlan-group

Deletes the VLAN group named my_vlan-group.
```

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

bridge-traffic

When enabled, specifies that the VLAN group forwards all frames, including non-IP traffic. The default value is disabled.

bridge-in-standby

When enabled, specifies that the VLAN group forwards packets, even when the system is the standby unit in a redundant system. This option is designed for deployments in which the VLAN group exists on only one of the units. If that does not match your configuration, using this option may cause adverse effects. The default value is disabled.

bridge-multicast

When enabled, allows bridging of non-Internet Protocol (IP) Address Resolution Protocol (ARP) multicast frames across a VLAN group. An example of when you might want to use this option is

when you are implementing the Spanning Tree Protocol (STP).

description
User-defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

if-index
Displays the index assigned to this VLAN group. It is a unique identifier assigned for all objects displayed in the SNMP IF-MIB.

members
The names of the VLANs that you want to add to or delete from the VLAN group.

migration-keepalive
Specifies whether the system will send keepalive frames (TCP keepalives and empty UDP packets depending on the connection type) when a node is moved from one VLAN group member to another VLAN group member for all existing connections that the system has to that node.

mode Specifies the level of exposure of remote MAC addresses within VLAN groups. The default value is translucent.

The options are:

virtual-wire
Use this option to create a Layer 2 bridge that only forwards traffic between two configured members. Traffic forwarded by such a VLAN group keeps intact the Ethernet header from ingress to egress, thus making this device transparent. A VLAN group configured to be virtual-wire is restricted to two member VLANs.

opaque
Use this option when you have a Cisco router in the network sending CDP packets to the system. Because opaque VLAN groups require a source and destination MAC address, and CDP packets do not contain a source and destination MAC address, the CDP packets are not forwarded through the VLAN group. This mode changes the MAC address to the MAC address assigned to the VLAN group, a proxy ARP with Layer 3 forwarding.

translucent
Uses the real MAC address of the requested host with the locally unique bit toggled. Specifies that the system uses Layer 2 forwarding with locally-unique bit, toggled in ARP response across VLANs.

transparent
Leaves the MAC address unchanged by the traffic management system. Specifies that the system uses Layer 2 forwarding with the original MAC address of the remote system preserved across VLANs.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

proxy-excludes
Specifies the IP addresses that you want to include in the proxy ARP exclusion list. If you use VLAN groups, you must configure a proxy ARP forwarding exclusion list. F5 Networks recommends that you configure this feature if you use VLAN groups with a redundant system. The reason is that both units need to communicate directly with their gateways and the back-end nodes. Creating a proxy ARP exclusion list prevents traffic from being proxied through the active unit due to proxy ARP. This traffic needs to be sent directly to the destination, not proxied.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

DELETE
delete vlan [name]

DESCRIPTION
VLANs are part of the configuration of the BIG-IP(r) network components. VLANs can be based on either ports or tags. When creating a VLAN, a tag value for the VLAN is automatically chosen unless you specify a tag value on the command line.

VLANs can have both tagged and untagged interfaces. You can add an interface to multiple VLANs as a tagged interface. You can add an interface to a single VLAN as an untagged interface. The tagged traffic can be single tagged and double tagged.

Note: To reset the statistics that display when you use the command sequence show vlan, you must reset the statistics for the trunks and interfaces associated with the VLAN.

EXAMPLES
create vlan my_vlan interfaces add { 1.2 1.3 1.4 }

Create the VLAN my_vlan that includes the interfaces 1.2, 1.3, and 1.4.

delete vlan my_vlan

Delete the VLAN named my_vlan.

OPTIONS
app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description
User-defined description.

failsafe
Enables a fail-safe mechanism that causes the active cluster to fail over to a redundant cluster when loss of traffic is detected on a VLAN, and traffic is not restored during the failover timeout period for that VLAN. The default value is disabled.

When you set the VLAN failsafe option to enabled, the default failsafe-action value is restart-all. Therefore, when the fail-safe mechanism is triggered, all the daemons are restarted and the unit fails over.

failsafe-action
Specifies the action for the system to take when the fail-safe mechanism is triggered. The default value is failover-restart-tm.

failsafe-timeout
Specifies the number of seconds that an active unit can run without detecting network traffic on this VLAN before it starts a failover. The default value is 90 seconds.

fwd-mode
Displays the current forwarding mode which is derived from the vlan member port-fwd-mode property. This property is read-only and cannot be modified. See "net interface" for details on port-fwd-mode.

The options are:

13 The VLAN consists of interface member(s) with port-fwd-mode set to 13.

passive
The VLAN consists of interface member(s) with port-fwd-mode set to passive.

virtual-wire
The VLAN consists of interface member(s) with port-fwd-mode set to virtual-wire.

none The VLAN has no interface member.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

if-index
Displays the index assigned to this VLAN. It is a unique identifier assigned for all objects displayed in the SNMP IF-MIB.

interfaces
Specifies a list of tagged or untagged interfaces and trunks that you want to configure for the VLAN. Use tagged interfaces or trunks when you want to assign a single interface or trunk to multiple VLANs.

A tagged interface is one that you assign to a VLAN in a way that causes the system to add a VLAN tag into the header of any frame passing through that interface or trunk.

A trunk is a combination of two or more interfaces and cables configured as one link.

tag-mode
Specifies the tag mode of the interface or trunk associated with. The default value is none.

The available values are:

customer
Specifies tag-mode setting for vlan members that are facing customer network and carry single tagged traffic.

service
Specifies tag-mode setting for vlan members that are facing the service provider networks and carry single tagged traffic.

double
Specifies tag-mode setting for vlan members that are facing the service provider networks and carry double tagged traffic.

none Specifies no tag-mode setting.

learning
Specifies whether switch ports placed in the VLAN are configured for switch learning, forwarding only, or dropped. The default value is enable-forward.

mtu Sets a specific maximum transition unit (MTU) for the VLAN. The default value is 1500. This value does not include the layer2 header.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

sflow
Specifies sFlow settings for the VLAN:

poll-interval
Specifies the maximum interval in seconds between two pollings. The default value is 0. To enable this setting, you must also set the poll-interval-global setting to no.

poll-interval-global
Specifies whether the global VLAN poll-interval setting, which is available under sys sflow global-settings module, overrides the object-level poll-interval setting. The default value is yes.

The available values are:

no Specifies to use the object-level poll-interval setting.

yes Specifies to use the global VLAN poll-interval setting.

sampling-rate
Specifies the ratio of packets observed to the samples generated. For example, a sampling rate of 2000 specifies that 1 sample will be randomly generated for every 2000 packets observed. The default value is 0. To enable this setting, you must also set the sampling-rate-global setting to no.

sampling-rate-global
Specifies whether the global VLAN sampling-rate setting, which is available under sys sflow global-settings module, overrides the object-level sampling-rate setting. The default value is yes.

The available values are:

no Specifies to use the object-level sampling-rate setting.

yes Specifies to use the global VLAN sampling-rate setting.

source-checking
Specifies that only connections that have a return route in the routing table are accepted. The default value is disabled.

tag Specifies a number that the system adds into the header of any frame passing through the VLAN. The value can be 1 through 4094, or 4096. The default is to not use this option, and the system assigns a tag number between 1 to 4094. A VLAN with the special tag 4096 is not used in the packet processing path; rather it assists with virtual-wire configuration, and such VLANs can only have interfaces with the port-fwd-mode property set to virtual-wire.

customer-tag
Specifies a number that the system adds into the header of any double tagged frame passing through the VLAN. The value can be any of the following: 1 through 4094, or none. The default is none.

cmp-hash
Specifies how the traffic on the VLAN will be disaggregated. The traffic disaggregation on the VLAN can be based on source ip, dest ip, or L4 ports. The default cmp hash uses L4 ports.

dag-tunnel
Specifies whether the ip tunnel traffic on the VLAN should be disaggregated based on the inner ip header or outer ip header. The default value is outer.

dag-round-robin
Specifies whether intended stateless traffic on the VLAN should be disaggregated in a round-robin order instead of using static hash. The stateless traffic include nonIP L2 traffic and user-specified UDP protocols. The sys db variable dag.roundrobin.redag allows HSBs to round robin stateless traffic to remote HSBs/blades.

hardware-syncookie
Enables hardware syncookie mode on a VLAN. When enabled, the hardware per-VLAN SYN cookie protection will be triggered when the certain traffic threshold is reached on supported platforms. The default value is disabled.

syncache-threshold
Specifies the number of outstanding SYN packets on the VLAN that will trigger the hardware per-VLAN SYN cookie protection. The default value is set to 6000 packets.

syn-flood-rate-limit
Specifies the max number of SYN flood packets per second received on the VLAN before the hardware per-VLAN SYN cookie

protection is triggered. The default value is set at 1000 packets per second.

show running-config wccp
show running-config wccp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

DELETE

```
delete wccp [name]
```

DESCRIPTION

You can use the wccp component to create and modify WCCPv2 service groups. WCCPv2 is a content-routing protocol developed by Cisco Systems, Inc., which provides a mechanism to redirect traffic flows in real time. A WCCP service in this context is a set of redirection criteria and processing instructions that the BIG-IP(r) system applies to any traffic that a router in the service group redirects to the BIG-IP system.

EXAMPLES

```
list wccp service-wccp all-properties
```

Displays the services and their attributes in the service group named service-wccp.

```
modify server-wccp cache-timeout 40
```

Changes the cache-timeout setting to 40 for the service group named server-wccp.

```
modify server-wccp services modify { 77 {weight 60} }
```

Changes the weight setting to 60 for the service identified as 77 in the service group named server-wccp.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

cache-timeout

Specifies the frequency of control messages between the system and the router. The range is from 1 to 60 seconds. The default value is 10.

description

User-defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

services

Specifies the service group identifier, a number between 51 and 255 that matches a service ID configured on the router.

Adds, deletes, or replaces a set of services. You can configure the following options for a service:

alt-hash-fields

Specifies to the router which traffic attributes to use to determine which BIG-IP system it should forward traffic to for load balancing (traffic-assign mask): destination IP address (dest-ip) or destination port (dest-port) or source IP address (src-ip), or source port (src-port).

app-service

Specifies the name of the application service to which the service belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the service. Only the application service can modify or delete the service.

custom-mask

Specifies the hexadecimal mask used when traffic-assign mask; it should have not more than 6 bits ON.

hash-fields

Specifies to the router which traffic attributes to use to determine which BIG-IP system it should forward traffic to for load balancing (traffic-assign hash): destination IP address (dest-ip), destination port (dest-port), source IP address (src-ip), and/or source port (src-port).

object identifier

Specifies the service group identifier, a number between 51 and 255 that matches a service ID configured on the router.

password

Specifies the password for MD5 authentication or none.

port-type

Specifies whether the WCCP interception of traffic is based on the destination port (dest) or source port (source), or is not specified (none). The default value is none.

ports

Specifies one or more ports (up to 8) on which traffic is redirected.

priority

Specifies the precedence of the service group relative to the other service groups. The range is from 1 to 255. The default value is 100.

protocol

Specifies the protocol of the traffic to be redirected: TCP (tcp) or UDP (udp). The default value is tcp.

redirection

Specifies the method the router uses to redirect traffic: GRE

gre or L2 l2. The default value is gre.

return
Specifies the method used to return passthrough traffic to the router: GRE (gre) or L2 (l2). The default value is gre.

routers
Specifies the IP addresses of the WCCP-enabled routers that redirect traffic.

traffic-assign
Specifies whether load balancing is achieved by a hash algorithm or a mask. If you specify hash, specify one or more attributes using the option hash-fields. If you specify mask, specify one attribute using the option alt-hash-fields

tunnel-local-address
Specifies an IP address on the BIG-IP system to which the WCCP-enabled routers should redirect traffic. Specify a self IP address of an external VLAN on the BIG-IP system.

tunnel-remote-addresses
Specifies the Router Identifier IP address of the router that redirects traffic.

weight
Specifies the relative importance of this traffic in a load-balancing environment. The range is from 1 to 100. The default value is 50.

pem

pem forwarding-endpoint

NAME
forwarding-endpoint - Configures forwarding endpoints for the Policy Enforcement Manager (PEM).

MODULE
pem

SYNTAX
Modify the forwarding-endpoint component within the pem module using the syntax shown in the following sections.

```
CREATE/MODIFY
create forwarding-endpoint [name]
modify forwarding-endpoint [name]
options:
  app-service [[string] | none]
  description [[string] | none]
  persistence {
    options:
  type [destination-ip | disabled | hash | source-ip]
  fallback [destination-ip | disabled | source-ip]
  hash-settings {
    options:
      algorithm [carp ]
      length [integer]
      offset [integer]
      source [tcl-snippet | uri]
      tcl-value [string]
  }
  }
  pool [name]
  snat-pool [name]
  source-port [change | preserve | preserve-strict]
  translate-address [disabled | enabled]
  translate-service [disabled | enabled]

edit forwarding-endpoint [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list forwarding-endpoint
list forwarding-endpoint [ [name] | [glob] | [regex] ] ... ]
show running-config forwarding-endpoint
show running-config forwarding-endpoint [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
DELETE
delete forwarding-endpoint [name]
```

Note: All references to the forwarding-endpoint must be removed before it can be deleted.

DESCRIPTION

forwarding-endpoint is used to specify PEM policy forwarding action(s).

Note: A valid LTM pool with at least one member must be pre-configured before creating a forwarding-endpoint. Please refer to ltm pool for more info about configuring LTM pools.

EXAMPLES

```
create forwarding-endpoint my_endpoint { pool my_pool snatpool
my_snatpool source-port preserved translate-address enabled translate-
service enabled }
```

Creates a Policy Enforcement Manager forwarding endpoint named my_endpoint.

```
delete forwarding-endpoint my_endpoint
```

Deletes the forwarding-endpoint named my_endpoint.

```
list forwarding-endpoint my_endpoint
```

Displays the properties of the forwarding-endpoint named my_endpoint.

OPTIONS

app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, user cannot modify or delete the object. Only the application service can modify or delete the object.

description
Specifies a user-defined description.

persistence
Allows to set a specific persistence method for the pool member selection.

fallback
Specifies the fallback persistence method so that it applies when default persistence fail.

The options are:

destination-ip
Map the destination ip address to a specific pool member so that subsequent traffic sent to this address is directed to the same pool member.

source-ip
Map the source ip address to a specific pool member so that subsequent traffic from this address is directed to the same pool member.

disabled
Specifies that this feature is disabled.

hash-settings
Specifies the settings for the hash persistence method.

algorithm
Specifies the algorithm to calculate the hash value. Currently only the carp algorithm is available.

length
Specifies the length of the source string used to calculate hash value. Default value of length is 1024.

offset
Specifies the offset in bytes from start of the source string to calculate the hash value. Default value of offset is 0.

source
Specifies the source for the string value which is used to calculate hash value.

tcl-value
Specifies the tcl script snippet so that when this script is executed its result used to calculate the hash value.

type Specifies the persistence method.

The options are:

destination-ip
Map the destination ip address to a specific pool member

so that subsequent traffic sent to this address is directed to the same pool member.

hash Map the hash value to a specific pool member so that subsequent traffic with the same hash value is directed to the same pool member.

source-ip Map the source ip address to a specific pool member so that subsequent traffic from this address is directed to the same pool member.

disabled Specifies that this feature is disabled.

pool Specifies the name of an LTM pool where the traffic is going to be directed to. Is used in the PEM policy rule forwarding actions. Note that the pool must be pre-configured before it can be referenced by a forwarding action.

snat-pool Specifies the name of an existing LTM SNAT pool (snatpool) that is used to translate the client IP address to one of the configured IP addresses in that SNAT pool. The Self-IP addresses of the BIG-IP system must not be included in the SNAT pool. The default value is none.

source-port Specifies whether the system preserves the source port of the connection. The default value is preserve.

The options are:

change Specifies that the system changes the source port. This setting is useful for obfuscating internal network address.

preserve Specifies that the system preserves the value configured for the source port, unless the source port from a particular snat is already in use, in which case the system uses a different port.

preserve-strict Specifies that the system preserves the value configured for the source port. If the port is in use, the system does not process the connection. F5 Networks recommends restricting the use of this setting to cases that meet at least one of the following conditions:

The port is configured for UDP traffic.

The system is configured for nPath routing or is running in transparent mode (that is, there is no translation of any other Layer 3 or Layer 4 field).

There is a one-to-one relationship between virtual IP addresses and node addresses, or clustered multiprocessing (CMP) is disabled.

translate-address Specifies, when enabled, that the system translates the original destination address of the virtual server. When disabled, specifies that the system uses the address without translation. The default value is disabled.

translate-service Note that translate-service is really translate-port. It specifies, when enabled, that the system translates the original destination port. When disabled, it specifies that the system uses the original destination port without translation. The default value is disabled.

BIG-IP 2016-01-07 pem forwarding-endpoint(1)

NAME
Analytics - Configures the global settings that pertain to Analytics reporting for Policy Enforcement Manager (PEM).

MODULE
pem global-settings

SYNTAX
Modify the analytics component within the pem global-settings module using the syntax shown in the following sections.

MODIFY

```

modify analytics {
  options:
    mode [disabled | enabled]
    subscriber-aware [disabled | enabled]
    logging {
      hsl {
        endpoint-id [log-publisher]
      }
    }
}

```

edit analytics [[[name] | [glob] | [regex]] ...]

```

options:
  all-properties
  non-default-properties

```

DISPLAY

```

list analytics
list analytics [ [ [name] | [glob] | [regex] ] ... ]
show running-config analytics
show running-config analytics [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

```

DESCRIPTION
You can use the analytics component to configure global settings for analytics reporting.

EXAMPLES

```

modify analytics mode disabled subscriber-aware disabled logging hsl
endpoint-id hsl_endpoint

```

Enables the analytics reporting for PEM and configures logging endpoint as hsl_endpoint.

```

list analytics

```

Displays the configuration for analytics settings.

OPTIONS

mode Specifies the mode for analytics reporting. It can take enable or disable as value.

subscriber-aware
Specifies the subscriber awareness for analytics reporting. It can take enable or disable as value.

logging
You can configure the following option for logging.

hsl You can configure the following options for hsl endpoint.

endpoint-id
Specifies the endpoint name.

SEE ALSO
create, delete, edit, glob, list, modify, pem listener, pem policy, pem profile diameter-endpoint, pem profile spm, pem reporting format-script, pem service-chain-endpoint, pem subscriber, pem subscribers, regex, show, tmsh

pem global-settings insert-content

NAME

insert-content - Configures the global settings that pertain to insert content for Policy Enforcement Manager (PEM).

MODULE
pem global-settings

SYNTAX
Modify the insert-content component within the pem global-settings module using the syntax shown in the following sections.

MODIFY
modify insert-content {
 options:
 max-duration [value]
}

edit insert-content [[[name] | [glob] | [regex]] ...]
 options:
 all-properties
 non-default-properties

DISPLAY
list insert-content
list insert-content [[[name] | [glob] | [regex]] ...]
show running-config insert-content
show running-config insert-content [[[name] | [glob] | [regex]] ...]
 options:
 all-properties
 non-default-properties
 one-line
 partition

DESCRIPTION
You can use the insert-content component to configure global settings for content insert functionality.

EXAMPLES
modify insert-content max-duration 3600

Modifies the content insertion max duration when action is throttled to apply once.

list insert-content

Displays the configuration for insert-content settings.

OPTIONS
mode Specifies the max duration for applying insert content action when frequency Once is used.

SEE ALSO
create, delete, edit, glob, list, modify, pem listener, pem policy, pem profile diameter-endpoint, pem profile spm, pem reporting format-script, pem service-chain-endpoint, pem subscriber, pem subscribers, regex, show, tmsh

pem global-settings quota-mgmt

NAME
quota-mgmt - Configures the global settings that pertain to quota management over Gy for Policy Enforcement Manager (PEM).

MODULE
pem global-settings

SYNTAX
Modify the quota-mgmt component within the pem global-settings module using the syntax shown in the following sections.

MODIFY
modify quota-mgmt
 options:
 default-rating-group [rating-group-name]
 service-context-id [string]

edit quota-mgmt [[[name] | [glob] | [regex]] ...]
 options:
 all-properties
 non-default-properties

```
DISPLAY
list quota-mgmt
list quota-mgmt [ [ name ] | [ glob ] | [ regex ] ] ... ]
show running-config quota-mgmt
show running-config quota-mgmt [ [ name ] | [ glob ] | [ regex ] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

DESCRIPTION
  You can use the quota-mgmt component to configure global settings for
  quota management over Gy.

EXAMPLES
  modify quota-mgmt default-rating-group rg_grp_1 service-context-id
  32251@3gpp.org

  Configures rg_grp_1 as default rating group and service-context-id as
  32251@3gpp.org. rg_grp_1 should be defined before.

  list quota-mgmt

  Displays the configuration for quota-mgmt.

OPTIONS
  default-rating-group
  Specifies the default rating group for quota management over Gy.

  service-context-id
  Specifies the service-context-id to be used for CCR message over
  Gy.

SEE ALSO
  create, delete, edit, glob, list, modify, pem quota-mgmt rating-group,
  pem listener, pem policy, pem profile diameter-endpoint, pem profile
  spm, pem reporting format-script, pem service-chain-endpoint, pem
  subscriber, pem subscribers, regex, show, tmsh

```

BIG-IP 2013-10-23 pem global-settings quota-mgmt(1)

pem global-settings session-mgmt-attributes

```
NAME
  session-mgmt-attributes - Configures the global settings that pertain
  to session management attributes for Policy Enforcement Manager (PEM).

MODULE
  pem global-settings

SYNTAX
  Modify the session-mgmt-attributes component within the pem global-
  settings module using the syntax shown in the following sections.

MODIFY
  modify session-mgmt-attributes
  options:
    clear-on-nas-reboot [enabled | disabled]
    flow-term-on-sess-delete [enabled | disabled]

  edit session-mgmt-attributes
  options:
    clear-on-nas-reboot [enabled | disabled]
    flow-term-on-sess-delete [enabled | disabled]

DISPLAY
  list session-mgmt-attributes
  list session-mgmt-attributes [ name ]
  show running-config session-mgmt-attributes
  show running-config session-mgmt-attributes [ name ]
  options:
    clear-on-nas-reboot
    flow-term-on-sess-delete

DESCRIPTION
  You can use the session-mgmt-attributes component to configure global
  settings for session management attributes.

EXAMPLES
  modify session-mgmt-attributes clear-on-nas-reboot enabled
```

Enable clear-on-nas-reboot so that when accounting-on or accounting-off Radius message is received for a particular NAS address, which indicates NAS reboot, will trigger clearing all PEM sessions associated with the NAS address.

modify session-mgmt-attributes flow-term-on-sess-delete enabled

Enable flow-term-on-sess-delete so that flow will be terminated shortly after session is marked for deletion.

list session-mgmt-attributes

Displays the configuration for session-mgmt-attributes.

OPTIONS

clear-on-nas-reboot

Specifies clear on nas reboot config for session-mgmt-attributes. The default value is disabled.

flow-term-on-sess-delete

Specifies flow termination on session delete config for session-mgmt-attributes. The default value is disabled.

SEE ALSO

BIG-IP pem0global-settings session-mgmt-attributes(1)

pem global-settings subscriber-activity-log

NAME

subscriber-activity-log - Configures the global settings that pertain to subscriber activity log messages for Policy Enforcement Manager (PEM).

MODULE

pem global-settings

SYNTAX

Modify the subscriber-activity-log component within the pem global-settings module using the syntax shown in the following sections.

MODIFY

modify subscriber-activity-log

options:

dynamic-subscriber-ids [add | delete | modify | replace-all-with] { [id_name ...]

}
dynamic-subscriber-ids [none]

publisher [name]

static-subscriber-ids [add | delete | replace-all-with] { [id_name ...]

}
static-subscriber-ids [default | none]

subscriber-ip-addresses [add | delete | modify | replace-all-with] { [ip address/prefixlen ...]

}
subscriber-ip-addresses [none]

edit subscriber-activity-log [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

reset-stats subscriber-activity-log

DISPLAY

list subscriber-activity-log

list subscriber-activity-log [[[name] | [glob] | [regex]] ...]

show running-config subscriber-activity-log

show running-config subscriber-activity-log [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

show subscriber-activity-log

options:

```
all-properties
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
default
field-fmt
```

DESCRIPTION

You can use the subscriber-activity-log component to monitor behavior of the subscribers in the troubleshooting mode by sending activity log messages to one or more destinations. You can add static and dynamic subscribers by IDs, or by subscriber IP addresses. The activity log messages contain the internal information exposing the subscribers behavior.

EXAMPLES

```
modify subscriber-activity-log publisher publ dynamic-subscriber-ids
add { 4081112222 }
```

Adds dynamic subscriber 4081112222 to troubleshooting mode by sending activity log messages to all destinations defined in publ.

```
list subscriber-activity-log
```

Displays the list of the subscribers in troubleshooting mode.

```
show subscriber-activity-log
```

Displays the logging statistics of the subscribers in troubleshooting mode.

```
reset-stats subscriber-activity-log
```

Resets the logging statistics of the subscribers in troubleshooting mode.

OPTIONS

dynamic-subscriber-ids

Specifies a list of dynamic subscriber IDs to be in troubleshooting mode.

publisher

Specifies the external logging publisher used to send activity log messages to one or more destinations.

static-subscriber-ids

Specifies a list of static subscriber IDs to be in troubleshooting mode.

subscriber-ip-addresses

Specifies a list of subscriber IP addresses to be in troubleshooting mode.

SEE ALSO

create, delete, edit, glob, list, modify, pem forwarding-endpoint, pem interception-endpoint, pem listener, pem policy, pem profile diameter-endpoint, pem profile spm, pem reporting format-script, pem service-chain-endpoint, pem subscriber, pem subscribers, regex, show, tmsh

BIG-IP pem0global-settings subscriber-activity-log(1)

pem interception-endpoint

NAME

interception-endpoint - Configures interception endpoints for the Policy Enforcement Manager (PEM).

MODULE

pem

SYNTAX

Modify the interception-endpoint component within the pem module using the syntax shown in the following sections.

CREATE/MODIFY

```
create interception-endpoint [name]
modify interception-endpoint [name]
options:
  app-service [[string] | none]
  persistence [destination-ip | disabled | source-ip]
  pool [name]
```

```
edit interception-endpoint [ [ [name] | [glob] | [regex] ] ... ]
```

```
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list interception-endpoint
list interception-endpoint [ [ [name] | [glob] | [regex] ] ... ]
show running-config interception-endpoint
show running-config interception-endpoint [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete interception-endpoint [name]
```

Note: You must remove all references to an interception-endpoint before you can delete the interception-endpoint.

DESCRIPTION

You can use the interception-endpoint component to configure interception-endpoint definitions for the Policy Enforcement Manager. The interception-endpoint is used to clone all traffic. Note: Before you create a cloning-endpoint you have to create a valid pool. Please refer to ltm pool for more information about how to create a pool.

EXAMPLES

```
create interception-endpoint my_endpoint { pool pool1 }

Creates a Policy Enforcement Manager interception-endpoint named my_endpoint.

delete interception-endpoint my_endpoint

Deletes the interception-endpoint named my_endpoint.

list interception-endpoint my_endpoint

Displays the properties of the interception-endpoint named my_endpoint.
```

OPTIONS

app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

persistence
Specifies the persistence that is based on either the source or destination IP addresses only.

pool Specifies the pool. It is mandatory to specify a pool when creating any interception-endpoint. Before you create an interception-endpoint you have to create a valid pool.

SEE ALSO

create, delete, edit, glob, list, modify, pem forwarding-endpoint, pem listener, pem policy, pem profile diameter-endpoint, pem profile spm, pem reporting format-script, pem service-chain-endpoint, pem subscriber, pem subscribers, regex, show, tmsh

BIG-IP 2013-03-21 pem interception-endpoint(1)

pem irule

NAME
irule - Configures an PEM iRule for traffic management system configuration.

MODULE
pem

SYNTAX
Configure the irule component within the pem module using the syntax shown in the following sections.

```
CREATE/MODIFY
create irule [name]
edit irule [name]
```

```
modify irule [ [ [name] | [glob] | [regex] ] ... ]
```

Note: When using tmsh, you can only create pem iRule using the editor, which starts when you use the create or edit commands. You cannot create an pem iRule directly on the command line. The vim editor applies the autoindent and smartindent options. You can toggle on/off paste mode using the F12 key.

Note: You can also edit user metadata associated with a pem iRule. See the example section for more information.

```
DISPLAY
list irule
list irule [ [ [name] | [glob] | [regex] ] ... ]
show running-config irule
show running-config irule [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

show irule
show irule [ [ [name] | [glob] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt

DELETE
delete irule [name]
```

DESCRIPTION

You can apply pem iRules as an action when the traffic matches the filter criteria defined in pem policy rule. The syntax that you use to write pem iRules is based on the Tools Command Language (Tcl) programming standard. Thus, you can use many of the standard Tcl commands, plus a robust set of extensions that the BIG-IP(r) policy enforcement management system provides to help you customize the actions you want to apply to the traffic.

You cannot edit the system iRules that come with the BIG-IP system. However, you can open a system iRule in the editor and use it as a template to create a new rule.

To create a new pem iRule using a system rule as a template:

1. Enter the command sequence edit irule [system rule name]. tmsh opens the system rule in an editor.
 2. Change the name of the rule in the editor.
 3. Edit the rule and exit the editor.
- tmsh checks for syntax errors, and if there are none, it saves the new rule.

For more information about iRules(r), see <http://devcentral.f5.com/>.

EXAMPLES

```
list irule

Displays all iRules.

delete irule my_irule

Deletes the pem iRule named my_irule.
```

```
create irule my_irule {
  priority 1
  when PEM_POLICY {
  }
}

Creates a pem iRule named my_irule with priority 1.
```

```
modify rule my_irule {
  when RULE_INIT {}
  metadata replace-all-with {
  my_meta {
    persist false
    value "hello"
  }
  my_meta2 {
    persist false
    value "hello 2"
  }
}

Modifies an existing pem iRule named my_irule by adding a new metadata and modifying an existing metadata.

The metadata attribute is the user defined key/value pair. Metadata has the following format:
```

```
metadata
[add | delete | modify] {
[metadata_name] {
  value [ "value content" ]
  persist [ true | false ]
}
}

modify irule my_irule {
  when RULE_INIT {}
  metadata delete { my_meta }
}
```

Deletes a metadata from a pem iRule.

OPTIONS

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the create, delete, and modify commands.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

metadata
Specifies the user-defined key/value pair associated with the rule. See the example section for usage format.

SEE ALSO

pem listener

NAME

listener - Configures listeners for the Policy Enforcement Manager (PEM).

MODULE

pem

SYNTAX

Modify the listener component within the pem module using the syntax shown in the following sections.

CREATE/MODIFY

```
create listener [name]
modify listener [name]
options:
  app-service [[string] | none]
  description [string]
  profile-spm [name]
  profile-subscriber-mgmt [name]
  virtual-servers [name] [add | delete | replace-all-with] {
    [virtual_server_name ... ]
  }
```

```
edit listener [ [ [name] | [glob] | [regex] ]... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list listener
list listener [ [ [name] | [glob] | [regex] ] ... ]
show running-config listener
show running-config listener [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

DELETE

```
delete listener [name]
```

Note: You must remove all references to a listener before you can delete the listener.

DESCRIPTION

You can use the listener component to configure listener definitions for the Policy Enforcement Manager.

EXAMPLES

```
create listener lis1 { profile-spm spm1 virtual-servers add {vs_tcp
vs_udp} }
```

Creates a Policy Enforcement Manager listener named lis1.

delete listener lis1

Deletes the listener named lis1.

list listener lis1

Displays the properties of the listener named lis1.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

profile-spm

Specifies the spm profile name.

profile-subscriber-mgmt

Specifies the subscriber-mgmt profile name.

virtual-servers

Adds, deletes, or replaces a set of virtual servers, by specifying a virtual server name.

SEE ALSO

create, delete, edit, glob, list, modify, pem forwarding-endpoint, pem interception-endpoint, pem policy, pem profile diameter-endpoint, pem profile spm, pem profile subscriber-mgmt, pem reporting format-script, pem service-chain-endpoint, pem subscriber, pem subscribers, regex, show, tmsh

DELETE
delete policy [name]

```

Note: You must remove all references to a policy before you can delete the policy.

DESCRIPTION

You can use this policy component to configure the policy definitions on the Policy Enforcement Manager. A policy is a set of rules which are used to match traffic flow and apply actions. A rule has configuration for filters and actions. All configured filters must match before the actions can be applied to the traffic flow. There are four filters: classification-filter, url-category-filter, flow-info-filter, and tcl-filter. Classification-filter allows for matching the traffic based on the flow L7 features, such as a specific application (for example, Google Mail) or application category (for example, Web). URL-category-filter allows for matching the type of URL, such as adult content. Flow-info-filter allows for matching the traffic using L2-L4 flow parameters. Tcl-filter provides a customized method to match traffic flows using iRule commands. The actions can be steering or/and reporting. Steering allows the user to manipulate the traffic when all configured filters match the flow. The steering options can be forwarded (option forwarding), drop/pass(option gate-status), redirect(option http-redirect), or intercept(option intercept). Reporting allows the user to report the usage to different endpoints by different output formats. The reporting options can be gx or hsl. Policy attribute transactional allow policy enforcement for HTTP traffic for each transaction. Quota allows users to do quota management over Gy by specifying the rating group, which has all the parameters

associated.

EXAMPLES

```
create policy my_policy rules add {
  rule_1 {
    flow-info-filters {
      flow_1 {
        dscp-code 8
      }
      flow_2 {
        dst-port 80
      }
    }
    forwarding {
      endpoint server1
      fallback-action continue
    }
  }
  precedence 1
}
rule_2 {
  reporting {
    dest {
      hsl {
        endpoint-id pem_hsl
        format-script fml
      }
    }
  }
  granularity flow
  volume {
    total 5000
  }
}
precedence 2
}
```

Creates a Policy Enforcement Manager policy named `my_policy` with two rules, `rule_1` and `rule_2`. `rule_1` defines the flow-info-filters so that when the flow with DSCP is 8 or destination port is 80, the traffic will be forwarded to `server1`. `rule_2` defines a flow-based reporting rule which will send flow usage record to `pem_hsl` endpoint using format script defined in `fml` whenever total increases by 5000 bytes.

```
delete policy my_policy
```

Deletes the policy named `my_policy`.

```
list policy my_policy
```

Displays properties of the policy named `my_policy`.

OPTIONS

`app-service`

Specifies the name of the application service to which the policy belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the policy. Only the application service can modify or delete the policy.

`description`

User defined description.

`transactional`

Indicate the policy enable or disable policy enforcement for each HTTP transaction.

`partition`

Displays the administrative partition within which the policy resides.

`rules`

Adds, deletes, or replaces a set of rules, by specifying a rule name. If a rule by the specified name does not exist, it will be created. You can configure the following options for a rule:

`app-service`

Specifies the name of the application service to which the rule belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the rule. Only the application service can modify or delete the rule.

`classification-filters`

Adds, deletes, or replaces a set of classification-filters. You can configure the following options for a classification-filter.

`app-service`

Specifies the name of the application service to which the classification-filter belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the rule. Only the application service can modify or delete the classification-filter.

`application`

Specifies the name of the application where the rule applies to the traffic. The default value is none.

`category`

Specifies the name of the category of applications where the rule applies to the traffic. The default value is none.

operation

The options match and nomatch indicate the traffic flow must match or not match the condition specified in the classification filter. The default value is match.

dscp-marking-downlink

Specifies the action to modify the DSCP code in the downlink packet when the traffic flow matches the rule matching criteria. The range is 0 to 63, or pass-through. The default value is pass-through, indicating the DSCP code of the downlink packet will not be changed when the traffic flow matches the rule.

dscp-marking-uplink

Specifies the action to modify the DSCP code in the uplink packet when the traffic flow matches the rule matching criteria. The range is 0 to 63, or pass-through. The default value is pass-through, indicating the DSCP code of the uplink packet will not be changed when the traffic flow matches the rule.

dtos-tethering

Defines the device type & OS and tethering detection action and its options.

dtos-detect

Specifies the device type & OS detection to be enabled or disabled. Default is disabled

tethering-detect

Specifies the tethering detection to be enabled or disabled. Default is disabled

report

You can configure the following options for dtos and tethering reporting.

dest You can configure the following options for destination.

hsl You can configure the following options for hsl publisher.

publisher

Specifies the publisher name.

format-script

Specifies the format script name to format the HSL output string format.

ran-congestion

Detect congestion in the Radio Access Network.

detect

Enable or disable the ran congestion detection. Default is disabled.

lowerthreshold-bw

Configured lowerthreshold bandwidth for a session in kbps. Session bandwidth below this value will be marked as congested. Default is 1000kbps.

report

You can configure the following options for ran congestion reporting.

dest You can configure the following options for destination.

hsl You can configure the following options for hsl publisher.

publisher

Specifies the publisher name.

format-script

Specifies the format script name to format the HSL output string format.

flow-info-filters

Adds, deletes, or replaces a set of the flow-info-filters. The flow info filter defines the flow conditions (Layer 4) that the traffic should meet (or not meet) for this enforcement policy rule to apply. You can configure the following options for a flow-info-filter.

app-service

Specifies the name of the application service to which the flow-info-filter belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the rule. Only the application service can modify or delete the flow-info-filter.

dscp-code

Specifies the value of DSCP code which matches incoming traffic based on a value in the DSCP field in the IP header. The range is 0 to 63, or disabled. The default value is disabled, indicating that the DSCP code will not be used to filter the packet in the flow-info-filter.

dst-ip-addr

Specifies the destination IP address and prefix length

that the rule applies to. The format is [ip address/prefixlen]. The default value is 0.0.0.0/0.

dst-port

Specifies the destination port against which the packet will be compared. The default value is any.

from-vlan

Specifies the name of the source vlan to match the ingress flow arriving from that vlan.

l2-endpoint

Specifies an L2 endpoint type to be used when matching the traffic flows. The default value is disabled, indicating that L2 endpoint is not used for matching the flows. You can configure the following options:

disabled

Flows are not matched based on the L2 endpoint specification.

vlan The vlan name specified in from-vlan is used to match the traffic flows.

operation

Specifies whether the rule applies to traffic that matches (match) or does not match (nomatch) the traffic flow defined here. The options are match and nomatch. The default value is match.

proto

Specifies the protocol that this rule applies to. The options are any, tcp, and udp. The default value is any.

ip-add-type

Specifies the ip address type (IPv4 or IPv6) that this rule applies to. The options are any, IPv4, and IPv6. The default value is any.

src-ip-addr

Specifies the source IP address and prefix length that the rule applies to. The format is [ip address/prefixlen]. The default value is 0.0.0.0/0.

src-port

Specifies the source port of the network you want the rule to affect. The default value is any.

forwarding

Manages the forwarding action and its attributes.

endpoint

Specifies the forwarding endpoint. The endpoint can be icap, pool or route-to-network. Depending on the type chosen flow can be steered to icap server, pool or to the network.

fallback-action

Specifies whether the connection should continue unchanged or should be dropped in the event the forwarding action fails for any reason. The options are: drop or continue, and the default is drop.

internal-virtual

Specifies the internal virtual server name if the type selected is icap.

icap-type

Defines the ICAP adaptation type: request only adaptation, request and response adaptation or both types of adaptations combined.

type Specifies the type of forwarding action.

gate-status

Specifies, when set to enabled, that the traffic can pass through the system without being changed. Set disabled to drop traffic that this rule applies to. The options are disabled and enabled. The default is enabled.

http-redirect

Manages the HTTP redirect action and its attributes.

redirect-url

Specifies the HTTP redirection URL.

fallback-action

Specifies whether the connection should continue unchanged or should be dropped in the event the forwarding action fails for any reason. The options are: drop or continue, and the default is drop.

intercept

Specifies the name of the intercept endpoint.

l2-marking-downlink

Set Layer-2 Quality of Service Marking in downlink traffic that matches a rule. Setting a L2 QoS Marking affects the packet delivery priority. The range is 0 to 7, or pass-through. The default value is pass-through, indicating the L2 QoS Marking of the packet will not be changed when the packet matches the rule.

l2-marking-uplink

Set Layer-2 Quality of Service Marking in uplink traffic that matches a rule. Setting a L2 QoS marking affects the packet delivery priority. The range is 0 to 7, or pass-through. The default value is pass-through, indicating the L2 QoS Marking of the packet will not be changed when the packet matches the rule.

tcp-optimization-uplink

Set tcp optimization profile to be applied to the uplink traffic that matches a rule. The profile name should be one from the common tcp profile list.

tcp-optimization-downlink

Set tcp optimization profile to be applied to the downlink traffic that matches a rule. The profile name should be one from the common tcp profile list.

tcp-analytics-enable

Specifies the action to enable tcp analytics when the traffic flow matches the rule matching criteria. The options are disabled and enabled. The default is disabled.

modify-http-hdr

Specifies the action to modify the HTTP header when the traffic flow matches the rule matching criteria. You can configure the following options for modifying the HTTP header.

name Specifies the HTTP header name used by the operation option to modify the HTTP header.

operation

Specifies the operation used to modify the HTTP header. The options are insert, none, and remove. The default value is none which indicates that no HTTP header modifications will be made.

value-content

Specifies the HTTP header value content used by the operation option to modify the HTTP header. Based on the selected value-type option, the content format will be interpreted either as a string or a tcl snippet. Note: This field is applicable only when the operation option is set to insert.

value-type

Specifies the type of content format used in the value-content field. The options are string and tcl-snippet. The default value is string which indicates that the value-content field will be interpreted as a string.

insert-content

Specifies the action to insert content into the webpage.

duration

Specifies the periodicity of the insert action. Note: This value is useful only when the frequency is set to once-every.

frequency

Specifies the frequency of the insert content action. It can take values once, once-every, always.

The options are:

always

Specifies if the action need to be applied always on the matched flow.

once Specifies if the action need to be applied once per subscriber.

once-every

Specifies if the action need to be applied once-every time interval configured in duration per subscriber.

position

Specifies the position with respect to the tag name configured. It can take values append, prepend.

value-content

Specifies the value content to be inserted into the webpage. Based on the selected value-type option, the content format will be interpreted either as a string or a tcl-snippet.

value-type

Specifies the type of content format used in the value-content field. The options are string and tcl-snippet. The default value is string which indicates that the value-content field will be interpreted as a string.

tag_name

Specifies the tag name to which the content is either appended or prepended.

precedence

Specifies the precedence for the rule in relation to the other rules. The range is 1 to 4294967295 where 1 has

the highest precedence. A rule with higher precedence is evaluated at a high priority. It is mandatory to specify precedence when creating a rule in a policy.

qoe-reporting

You can configure the following options for Quality-of-Experience (QoE) reporting.

dest You can configure the following options for destination.

hsl You can configure the following options for hsl publisher.

publisher

Specifies the publisher name.

format-script

Specifies the format script name to format the HSL output string format.

reporting

You can configure the following options for reporting.

dest You can configure the following options for destination.

gx You can configure the following options for gx endpoint.

application-reporting

Specifies whether the application reporting is enabled. When it is enabled, the APPLICATION START and APPLICATION STOP Event-Triggers will be reported when the application start/stop is detected. The default value is disabled.

monitoring-key

Specifies the monitoring-key.

hsl You can configure the following options for hsl endpoint.

publisher

Specifies the publisher.

format-script

Specifies the format script name to format the HSL output string format.

session-reporting-fields

Specifies the session fields and their order based on which messages should be published.

3gpp-parameters

Reports the 3gpp-parameters of the session subscriber.

application-id

Reports the application/category ID that is classified for this session.

called-station-id

Reports the called station ID of the session subscriber.

calling-station-id

Reports the calling station ID of the session subscriber.

concurrent-flows

Reports the number of concurrent flows of this session.

downlink-volume

Reports the aggregate incoming bytes for the traffic associated with this session.

duration-seconds

Reports the total duration of all the flows belonging to the traffic associated with this session.

last-record-sent

Reports the time (seconds) when sending the last record.

new-flows

Reports the number of new flows associated with this session since last record.

observation-time-seconds

Reports the timestamp of the record.

record-reason

Reports the reason for sending the record.

record-type

Reports the reporting record type as
3 : session based record.

report-id
Reports the reporting module ID.

report-version
Reports the format version of this
record.

subscriber-id
Reports the subscriber ID that of
this session.

subscriber-id-type
Reports the ID type of the
subscriber of this session.

successful-transactions
Reports the total number of
successful transactions associated
with this session.

terminated-flows
Reports the total number of
terminated flows during this
session.

timestamp-msec
Reports the time stamp on this
record in milli-seconds.

total-transactions
Reports the total number of
transactions of this session.

uplink-volume
Reports the aggregate outgoing bytes
for the traffic associated with this
session.

flow-reporting-fields
Specifies the flow fields and their order
based on which messages should be
published.

application-id
Reports the application/category ID
that is classified for this flow.

destination-ip
Reports the destination IP address
of the traffic.

destination-transport-port
Reports the destination port of the
traffic.

downlink-volume
Reports the total number of bytes
received for this flow by the
subscriber.

flow-end-milli-seconds
Reports the timestamp (milli-
seconds) in UNIX time format when
the flow ends.

flow-end-seconds
Reports the timestamp (seconds) in
UNIX time format when the flow ends.

flow-start-milli-seconds
Reports the timestamp (milli-
seconds) in UNIX time format when
the flow starts.

flow-start-seconds
Reports the timestamp (seconds) in
UNIX time format when the flow
starts.

observation-time-seconds
Reports the timestamp (seconds) of
the record.

protocol-identifier
Reports the transport layer protocol
of the flow (TCP or UDP).

record-type
Reports the reporting record type of
the flow: 0 - flow start, 1 - flow
end, 2 - flow interim.

report-id
Reports the reporting module ID.

report-version
Reports the format version of this
record.

route-domain
Reports the route domain ID of the

flow.

source-ip
Reports the source IP address of the subscriber that initiates the flow.

source-transport-port
Reports the source port of the subscriber.

subscriber-id
Reports the subscriber ID that initiates this flow.

subscriber-id-type
Reports the ID type of the subscriber that initiates this flow.

timestamp-msec
Reports the timestamp (milliseconds) of the record.

total-transactions
Reports the total number of transactions of this flow.

uplink-volume
Reports the number of bytes sent from the subscriber in this flow.

url-category-id
Reports the ID of the first URL category that is classified for the flow.

vlan-id
Reports the Vlan ID of the flow.

transaction-reporting-fields
Specifies the transaction fields and their order based on which messages should be published.

application-id
Reports the application/category ID that is classified for this transaction.

destination-ip
Reports the destination IP address of the traffic.

destination-transport-port
Reports the destination port of the traffic.

downlink-volume
Reports the number of HTTP response bytes for this transaction.

http-hostname
Reports the HTTP host name of this traffic.

http-hostname-truncated
Reports the truncated HTTP host name due to excessive length.

http-response-code
Reports the HTTP response code of the transaction.

http-url
Reports the HTTP URL of the transaction.

http-url-truncated
Reports the truncated HTTP URL of the transaction due to excessive length.

http-user-agent
Reports the user agent of the HTTP request in this transaction.

http-user-agent-truncated
Reports the truncated user agent of the HTTP request in this transaction due to excessive length.

protocol-identifier
Reports the transport layer protocol of the traffic (TCP or UDP).

record-type
Reports the reporting record type as 10-transactional.

report-id
Reports the reporting module ID.

report-version
Reports the format version of the transaction record.

route-domain
Reports the route domain ID of the traffic.

skipped-transactions
Reports the number of transactional reports skipped within the flow since the last successfully transmission in the transaction.

source-ip
Reports the source IP address of the subscriber.

source-transport-port
Reports the source port of the subscriber.

subscriber-id
Reports the subscriber ID that initiates this transaction.

subscriber-id-type
Reports the subscriber ID type of the subscriber that initiates this transaction.

transaction-classification-result
Reports all the classification tokens from the classification engine.

transaction-end-milli-seconds
Reports the transaction timestamp (milli-seconds) in UNIX time format when the corresponding HTTP response is received.

transaction-end-seconds
Reports the transaction timestamp (seconds) in UNIX time format when the corresponding HTTP response is received.

transaction-number
Reports the sequential number of transaction in this flow (starting from 1).

transaction-start-milli-seconds
Reports the transaction timestamp (milli-seconds) in UNIX time format when an HTTP request is received.

transaction-start-seconds
Reports the transaction timestamp (seconds) in UNIX time format when an HTTP request is received.

uplink-volume
Reports the number of HTTP request bytes for this transaction.

url-category-id
Reports the ID of the first URL category that is classified for the transaction.

vlan-id
Reports the Vlan ID of traffic.

radius-accounting
You can configure the following options for radius-accounting endpoint.

radius-aaa-virtual
Specifies the internal virtual server for radius-accounting endpoint.

sd You can configure the following options for sd endpoint.

application-reporting
Specifies whether the application reporting is enabled. When it is enabled, the APPLICATION_START and APPLICATION_STOP Event-Triggers will be reported when the application start/stop is detected. The default value is disabled.

monitoring-key
Specifies the monitoring-key.

granularity
Specifies the type of reporting will be generated when the policy applies. The options are flow, session and transaction. The default value is session which indicates the session report will be generated if this policy applies.

interval
Specifies the time interval in seconds the report

will be generated. The default value is 0 which indicates this feature is disabled.

transaction

You can configure the following options when the transaction report granularity is selected.

http Specifies the HTTP transaction report options for the following HTTP attributes.

hostname-len

Specifies the maximum HTTP hostname string length to include in the HTTP transaction report. The range is 0 to 65535. The default value is 0.

uri-len

Specifies the maximum HTTP URI string length to include in the HTTP transaction report. The range is 0 to 65535. The default value is 256.

user-agent-max

Specifies the maximum HTTP user agent string length to include in the HTTP transaction report. The range is 0 to 65535. The default value is 0.

volume

You can configure the following options for volume threshold. The report will be generated when any of the following conditions happened. If reporting dest is set, either interval must be set to non-0 or one of volume properties must be set to non-0.

downlink

The report will be generated if the downlink traffic exceeds the threshold. The default value is 0 which indicates this feature is disabled.

total

The report will be generated if the uplink and downlink traffic exceeds the threshold. The default value is 0 which indicates this feature is disabled.

uplink

The report will be generated if the uplink traffic exceeds the threshold. The default value is 0 which indicates this feature is disabled.

quota

You can configure the following options for quota management.

rating-group

Specifies the rating-group name.

reporting-level

Specifies the quota reporting level whether per rating group or per service-id.

qos-rate-pir-downlink

Specifies the configured bandwidth control policy for Peak Information Rate (PIR) to apply to downlink traffic that matches this rule. Use none to reset bwc policy name or category name.

qos-rate-pir-uplink

Specifies the configured bandwidth control policy for Peak Information Rate (PIR) to apply to uplink traffic that matches this rule. Use none to reset bwc policy name or category name.

service-chain

Specifies where to forward the traffic affected by this rule.

tcl-filter

Specifies the tcl expression which uses iRule commands to filter the packet. It is a match if tcl-filter returns TRUE/1 or nomatch if FALSE/0. All configured filters (flow-info-filters, classification-filters, and tcl-filter) must match before rule actions are applied.

url-categorization-filters

Adds, deletes, or replaces a set of url-categorization-filters. You can configure the following options for a url-categorization-filter.

app-service

Specifies the name of the application service to which the url-categorization-filter belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the rule. Only the application service can modify or delete the url-categorization-filter.

url-category

Specifies the name of the url-category of the traffic where the rule applies. The default value is none.

operation

The options match and nomatch indicate the traffic flow must match or not match the condition specified in the classification filter. The default value is match.

status

Specifies the current status of the policy. The options are disabled and enabled. The default value is enabled.

pem profile diameter-endpoint

NAME

diameter-endpoint - Configures a Diameter endpoint profile.

MODULE

pem profile

SYNTAX

Configures the diameter-endpoint profile within the pem profile module using the syntax shown in the following sections.

MODIFY

```
create diameter-endpoint [name]
modify diameter-endpoint [name]
options:
  defaults-from [ [name] | none]
  destination-host [string]
  destination-realm [string]
  fatal-grace-time {
    options:
  enabled [yes | no]
  time [integer]
  }
  msg-max-retransmits [integer]
  msg-retransmit-delay [integer]
  origin-host [string]
  origin-realm [string]
  pem-protocol-profile-gx [ [profile_name] | none]
  pem-protocol-profile-gy [ [profile_name] | none]
  product-name [string]
  supported-apps [Gx | Gy | Sd]
}

edit diameter-endpoint [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

reset-stats diameter-endpoint
reset-stats diameter-endpoint [ [ [name] | [glob] | [regex] ] ... ]
```

DISPLAY

```
list diameter-endpoint
list diameter-endpoint [ [ [name] | [glob] | [regex] ] ... ]
show running-config diameter-endpoint
show running-config diameter-endpoint [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

show diameter-endpoint
show diameter-endpoint [ [ [name] | [glob] | [regex] ] ... ]
options:
  (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
  field-fmt
  global
```

DESCRIPTION

You can use the diameter-endpoint component to modify or display a

diameter-endpoint profile.

EXAMPLES

```
create my_diam_endpt defaults-from diameter-endpoint add { Gx }
```

Creates a custom diameter-endpoint profile name `my_diam_endpt` that inherits its settings from the system default diameter-endpoint profile with Gx capability.

```
modify my_diam_endpt origin-host example-host.example-realm.org origin-realm example-realm destination-host example-peer.peer-realm.org destination-realm peer-realm.org
```

Modifies the origin-host and destination-host of a diameter-endpoint profile named `my_diam_endpt`.

```
modify my_diam_endpt msg-max-retransmits 8 msg-retransmit-delay 10000
```

Modifies the maximum times a message will be retransmitted to 8 and the retransmission delay to 10 seconds of a diameter-endpoint profile named `my_diam_endpt`.

OPTIONS

`defaults-from`

Specifies the name of the object to inherit the settings from.

`destination-host`

Specifies the destination host for diameter messages. This should be a FQDN.

`destination-realm`

Specifies the destination realm for diameter messages. This should be a FQDN.

`fatal-grace-time`

You can configure following options for `fatal-grace-time`. It defines the period that a diameter connection can be down before all sessions associated with that diameter endpoint are terminated. If the connection is re-established before `fatal-grace-time` seconds then the sessions will not be terminated automatically.

`enabled`

Specifies whether `fatal-grace-time` option is enabled or no.

`time`

Specifies the `fatal-grace-time` period in seconds.

`msg-max-retransmits`

Specifies the number of times an outgoing request message will be retransmitted before being dropped.

`msg-retransmit-delay`

Specifies the delay in milliseconds after which an unanswered request will be retransmitted.

`origin-host`

Specifies the origin host for diameter messages. This should be a FQDN.

`origin-realm`

Specifies the origin realm for diameter messages. This should be a FQDN.

`pem-protocol-profile-gx`

Specifies PEM protocol profile to be used when subscriber discovery is enabled. This protocol profile defines mapping of Diameter AVPs to subscriber ID and other PEM subscriber session attributes for Diameter application.

`pem-protocol-profile-gy`

Specifies PEM protocol profile to be used when subscriber discovery is enabled. This protocol profile defines mapping of Diameter AVPs to subscriber ID and other PEM subscriber session attributes for Diameter application.

`product-name`

Specifies the string used in the `product-name` AVP in the capabilities exchange messages.

`supported-apps`

Adds, deletes, or replaces a set of the supported applications. Gx and Sd are mutually exclusive and cannot be added at the same time. When Gx or Sd is added, `pem-protocol-profile-gx` can be specified for the protocol profile. When Gy is added, `pem-protocol-profile-gy` can be specified for the protocol profile.

show radius-aaa [[[name] | [glob] | [regex]] ...]
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
field-fmt
global

DELETE
delete radius-aaa [name]

DESCRIPTION
You can use the radius-aaa component to create, modify, display, or delete a radius-aaa profile.

EXAMPLES
create radius-aaa my_radius_aaa_profile

Creates a custom radius-aaa profile named my_radius_aaa_profile.

list radius-aaa my_radius_aaa_profile

Displays the properties of the radius-aaa profile named my_radius_aaa_profile.

OPTIONS
all Specifies that you want to modify all of the existing components of the specified type.

defaults-from Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile. The default value is radiusaaa.

description User defined description.

retransmission-timeout Specifies the retransmission timeout value of the Radius-AAA profile in seconds.

shared-secret Specifies the shared secret of the Radius-AAA profile when connecting to the RADIUS server.

password Specifies the password of the Radius-AAA profile for authenticating to the RADIUS server.

transaction-timeout

Specifies the transaction timeout value of the Radius-AAA profile in seconds.

partition
Specifies the administrative partition within which the profile resides.

SEE ALSO

create, delete, edit, glob, list, ltm virtual, modify, regex, reset-stats, show, tmsh

pem profile spm

NAME

spm - Configures a Subscriber Policy Manager profile.

MODULE

pem profile

SYNTAX

Configures the spm profile within the pem profile module using the syntax shown in the following sections.

CREATE/MODIFY

create spm [name]

modify spm [name]

options:

app-service [[string] | none]

defaults-from [[name] | none]

description [string]

global-policies-high-precedence [add | delete | replace-all-with] {
[policy_name ...]

global-policies-high-precedence [default | none]

global-policies-low-precedence [add | delete | replace-all-with] {
[policy_name ...]

global-policies-low-precedence [default | none]

unknown-subscriber-policies [add | delete | replace-all-with] {
[policy_name ...]

unknown-subscriber-policies [default | none]

fast-pem [enable | disable]

fast-vs-name [name]

edit spm [[[name] | [glob] | [regex]] ...]

options:

list spm [[[name] | [glob] | [regex]] ...]

show running-config spm

show running-config spm [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

partition

DELETE

delete spm [name]

DESCRIPTION

You can use the spm component to create, modify, display, or delete a spm profile.

EXAMPLES

create spm my_spm_profile

Creates a custom spm profile named my_spm_profile.

list spm my_spm_profile

Displays the properties of the spm profile named my_spm_profile.

OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile. The default value is spm.

description

User defined description.

global-policies-high-precedence

Adds, deletes, or replaces a set of the policies.

global-policies-low-precedence

Adds, deletes, or replaces a set of the policies.

unknown-subscriber-policies

Adds, deletes, or replaces a set of the policies.

fast-pem

Specifies whether fast PEM optimization is enabled or not. The default is enabled.

Specifies whether fast PEM optimization is enabled or not. PEM optimization will use the fast-vs-name virtual server for a portion of the traffic. The default is enabled.

fast-vs-name

Specifies the virtual server which will be used in fast PEM optimization when fast-pem is enabled. The virtual server should have fastL4 profile attached.

partition

Specifies the administrative partition within which the profile resides.

SEE ALSO

`edit`, `glob`, `list`, `ltm virtual`, `modify`, `pem forwarding-endpoint`, `pem interception-endpoint`, `pem listener`, `pem policy`, `pem profile diameter-endpoint`, `pem reporting format-script`, `pem service-chain-endpoint`, `pem subscriber`, `regex`, `reset-stats`, `tms`

pem profile subscriber-mgmt

NAME

subscriber-mgmt - Configures a Subscriber Management profile.

MODULE

pem profile

SYNTAX

Configures the subscriber-mgmt profile within the pem profile module using the syntax shown in the following sections.

CREATE/MODIFY

```
create subscriber-mgmt [name]
modify subscriber-mgmt [name]
options:
  app-service [[string] | none]
  defaults-from [[name] | none]
  description [string]
  dhcp-lease-query {
    options:
  }
  enabled [false | true]
  vs-name [name]
  drop-unknown-traffic-from-server-side [enabled | disabled]
  sess-creation-from-server-side [enabled | disabled]
```

```
edit subscriber-mgmt [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list subscriber-mgmt
list subscriber-mgmt [ [name] | [glob] | [regex] ] ... ]
show running-config subscriber-mgmt
```

```
show running-config subscriber-mgmt [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
  app-service
  description
  dhcp-lease-query {
    options:
  enabled
  vs-name
  }
  drop-unknown-traffic-from-server-side
  sess-creation-from-server-side
```

```
DELETE
delete subscriber-mgmt [name]
```

DESCRIPTION
You can use the subscriber-mgmt component to create, modify, display, or delete a subscriber management profile.

EXAMPLES

```
create subscriber-mgmt my_subscriber_mgmt_profile

Creates a custom subscriber management profile named
my_subscriber_mgmt_profile.

list subscriber-mgmt my_subscriber_mgmt_profile

Displays the properties of the subscriber management profile named
my_subscriber_mgmt_profile.
```

OPTIONS
all Specifies that you want to modify all of the existing components of the specified type.

defaults-from
Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile. The default value is subscriber-mgmt.

description
User defined description.

dhcp-lease-query
Specifies the DHCP lease query attributes to be used for traffic triggered subscribers. The default is disabled

sess-creation-from-server-side
Specifies whether session creation from server side is enabled or not. The default is enabled.

drop-unknown-traffic-from-server-side
Specifies whether drop unknown traffic from server side is enabled or not. The default is disabled.

partition
Specifies the administrative partition within which the profile resides.

SEE ALSO
edit, glob, list, ltm virtual, modify, pem forwarding-endpoint, pem interception-endpoint, pem listener, pem policy, pem profile diameter-endpoint, pem profile spm, pem reporting format-script, pem service-chain-endpoint, pem subscriber, regex, tmsh

BIG-IP 2017-06-26 pem profile subscriber-mgmt(1)

pem protocol diameter-avp

NAME
diameter-avp - Configures diameter AVPs in Policy Enforcement Manager (PEM).

MODULE
pem protocol

SYNTAX
Configure the diameter-avp component within the pem protocol module using the syntax shown in the following sections.

```
CREATE/EDIT/MODIFY
create diameter-avp [name]
modify diameter-avp [name]
options:
  app-service [[string] | none]
  avp-code [integer]
  data-type [address | enumerated | float32 | float64 | grouped | integer32 | integer64 | octetstring | rat-type | t
  description [string]
  length [integer]
  parent-avp [ [diameter_avp_name | none]
  vendor-id [integer]
```

```
edit diameter-avp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```
DISPLAY
list diameter-avp
list diameter-avp [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
DELETE
delete diameter-avp [name]
```

Note: You must remove all references to a diameter-avp before you can delete the diameter-avp.

DESCRIPTION

You can use the diameter-avp component to configure Diameter AVP definitions in Policy Enforcement Manager.

EXAMPLES

```
create diameter-avp user_equipment_value { data-type octetstring avp-code 460 }
```

Creates a PEM diameter-avp user_equipment_value with avp-code 460 and data-type octetstring.

```
delete diameter-avp user_equipment_value
```

Deletes the diameter-avp named user_equipment_value.

```
list diameter-avp user_equipment_value
```

Displays the properties of the diameter-avp named user_equipment_value.

OPTIONS

app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

avp-code
Specifies the avp-code of the Diameter AVP.

data-type
Specifies the data type of the Diameter AVP. The default value is octetstring.

Note: The 'V' bit, known as the Vendor-Specific bit, indicates whether the optional vendor-id field is present in the AVP header. When set, the AVP code belongs to the specific vendor code address space. The 'V' bit is defined as flag-vendor-specific property in pem protocol profile gx.

The options are:

address
The address format is derived from the octetstring AVP base format. It is a discriminated union, representing, for example a 32-bit (IPv4) or 128-bit (IPv6) address, most significant octet first. The first two octets of the address AVP represents the AddressType, which contains in address family. The AddressType is used to discriminate the content and format the remaining octets.

enumerated
Enumerated is derived from the integer32 AVP Base Format. The definition contains a list of valid values and their interpretation and is described in the Diameter application introducing the AVP.

float32
This represents floating point values of single precision. The 32-bit value is transmitted in network byte order. The AVP length field MUST be set to 12 (16 if the 'V' bit is enabled).

float64
This represents floating point values of double precision. The 64-bit value is transmitted in network byte order. The AVP length field MUST be set to 16 (20 if the 'V' bit is enabled).

grouped
The data field is specified as a sequence of AVPs. Each of

these AVPs follows - in the order in which they are specified - including their headers and padding. The AVP length field is set to 8 (12 if the 'V' bit is enabled) plus the total length of all included AVPs, including their headers and padding. Thus the AVP length field of an AVP of type grouped is always a multiple of 4.

integer32
32 bit signed value, in network byte order. The AVP length field MUST be set to 12 (16 if the 'V' bit is enabled).

integer64
64 bit signed value, in network byte order. The AVP length field MUST be set to 16 (20 if the 'V' bit is enabled).

octetstring
The data contains arbitrary data of variable length. Unless otherwise noted, the AVP length field MUST be set to at least 8 (12 if the 'V' bit is enabled). AVP Values of this type that are not a multiple of four-octets in length is followed by the necessary padding so that the next AVP (if any) will start on 32-bit boundary.

rat-type
specifies the value format to be encoded or decoded as the RAT-Type defined in 3GPP TS 29.212.

time The time format is derived from the octetstring AVP base format. The string MUST contain four octets, in the same format as the first four bytes are in the NTP timestamp format.

unsigned32
32 bit unsigned value, in network byte order. The AVP length field MUST be set to 12 (16 if the 'V' bit is enabled).

unsigned64
64 bit signed value, in network byte order. The AVP length field MUST be set to 16 (20 if the 'V' bit is enabled).

utf8string
The utf8string format is derived from the octetstring AVP base format. This is a human readable string represented using the ISO/IEC IS 10646-1 character set, encoded as an octetstring using the UTF-8 transformation format described in RFC 2279.

description
User defined description.

length
Specifies the data length of the Diameter AVP.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

parent-avp
Specifies the name of the parent AVP if it is in a grouped AVP.

vendor-id
Specifies the vendor-id of the Diameter VSA.

SEE ALSO

pem protocol profile gx

NAME
gx - Configures a Diameter Gx protocol profile in Policy Enforcement Manager (PEM).

MODULE
pem protocol profile

SYNTAX
Configure the gx component within the pem protocol profile module using the syntax shown in the following sections.

```

CP/CREATE/EDIT/MODIFY
cp gx [source_name] [ destination_name]
create gx [name]
modify gx [name]
options:
  app-service [[string] | none]
  description [string]
  messages [add | delete | modify | replace-all-with] {
    [ [message-name] ] {
options:
  direction [any | in | out]
  message-type [ccr-i | cca-i | ccr-u | cca-u | ccr-t | rar | raa]
  avps [add | delete | modify | replace-all-with] {
    [ [avp-name] ] {
      options:
        default [string]
        diameter-avp [ [diameter_avp_name] | none]
        flag-mandatory [disabled | enabled]
        flag-protected [disabled | enabled]
        flag-vendor-specific [disabled | enabled]
        interim-message-include [disabled | enabled]
        parent-label [string]
        reporting-message-include [disabled | enabled]
        subscriber-attr [ [subscriber_attribute_name] | none]
      }
    }
  }
}
subscriber-id {
  avp [ [diameter_avp_name] | none]
  type [e164 | imsi | nai | private]
  type-avp [ [diameter_avp_name] | none]
}
edit gx [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

```

```

DISPLAY
list gx
list gx [ [ [name] | [glob] | [regex] ] ... ]
show running-config gx
show running-config gx [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

```

```

DELETE
delete gx [name]

```

Note: You must remove all references to a PEM protocol profile gx before you can delete it.

DESCRIPTION

You can use the gx component to configure PEM protocol profile gx definitions in Policy Enforcement Manager.

EXAMPLES

```

create cust_gx messages add {my_ccr direction out message-type ccr {
avps add {avp1 { subscriber-attr 3gpp_location diameter-avp
user_equipment_value flag-mandatory enabled} } } }

```

Creates a custom PEM Gx protocol profile cust_gx and adds a message. The message is defined as CCR on the egress direction. PEM will insert the Diameter AVP as specified in user_equipment_value with the value stored subscriber attribute 3gpp_location with mandatory flag enabled.

```
delete gx cust_gx
```

Deletes the PEM Gx protocol profile named cust_gx.

```
list gx cust_gx
```

Displays the properties of the PEM Gx protocol profile named cust_gx.

OPTIONS

app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description
User defined description.

messages
Adds, deletes, or replaces a set of messages which specify mapping of Diameter AVPs to subscriber session attribute for specific Gx message. If a message by the specified name does not exist, it will be created. You can configure the following options for a message:

app-service
Specifies the name of the application service to which the message belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the message. Only the application service can modify or delete the message.

direction
Specifies the direction of the message.

The options are:

any PEM will process the message in both ingress and egress directions.

in PEM will process the message in ingress direction.

out PEM will process the message in egress direction.

message-type
Specifies the type of the message.

The options are:

ccr-i
The message is Gx Credit-Control-Request (CCR) Initial.

cca-i
The message is Gx Credit-Control-Answer (CCA) Initial.

ccr-u
The message is Gx Credit-Control-Request (CCR) Update.

cca-u
The message is Gx Credit-Control-Answer (CCA) Update.

ccr-t
The message is Gx Credit-Control-Request (CCR) Terminate.

rar The message is Gx Re-Authorization-Request (RAR).

raa The message is Gx Re-Authorization-Answer (RAA).

avps Adds, deletes, or replaces a set of mapping between Diameter AVPs and PEM subscriber attributes. You can configure the following options.

app-service
Specifies the name of the application service to which the AVP belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the avp. Only the application service can modify or delete the avp.

default
Specifies the Diameter AVP default value. When inserting the AVP, the default value is used if the corresponding subscriber attribute is not defined or is not present.

diameter-avp
Specifies the name of the Diameter AVP. The default value is none.

flag-mandatory
Specifies the value of the mandatory flag in the Diameter AVP when inserting into the message. This flag only applies to Diameter AVP in outgoing message.

flag-protected
Specifies the value of the protected flag in the Diameter AVP when inserting into the message. This flag only applies to Diameter AVP in outgoing message.

flag-vendor-specific
Specifies the value of the vendor-specific flag in the Diameter AVP when inserting into the message. This flag only applies to Diameter AVP in outgoing message.

interim-message-include
Specifies whether this AVP needs to be included in the interim-message (ccr-u only) updates which are generated if there is any change related to session parameters. This flag only applies to Diameter AVP in outgoing message.

parent-label
Specifies how grouped AVPs can be combined. The AVPs with the same parent-label will be combined in the same grouped AVP.

reporting-message-include
Specifies whether this AVP needs to be included in the reporting-message (ccr-u only) updates which are generated for reporting usage information. This flag only applies to Diameter AVP in outgoing message.

subscriber-attr
Specifies the name of the subscriber session attribute to be mapped to Diameter AVP. The default value is none.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

subscriber-id
Specifies how subscriber ID specified by PCRF should be read by PEM.

avp Subscription ID comes with type and data in diameter. This field specifies the avp in the message that should be matched

to get subscriber ID data in raw format.

type Specifies the subscriber ID type (imsi, e164, private) that PEM will use for the session for the ID read by avp.

The options are:

e164 A numbering plan that defines the format of an MSISDN international phone number (up to 15 digits). The number typically consists of three fields: country code, national destination code, and subscriber number.

imsi International Mobile Subscriber Identity. A globally unique code number that identifies a GSM, UMTS, or LTE mobile phone user.

nai Network Access Identifier. A fully qualified network name in the form @; identifies a subscriber and the home network to which the subscriber belongs.

private
The subscriber id type is private for the given deployment.

type-avp
Subscription ID comes with type and data in diameter. type-avp specifies avp in message that should be matched.

BIG-IP 2017-02-17 pem protocol profile gx(1)

pem protocol profile radius

NAME

radius - Configures a RADIUS protocol profile in Policy Enforcement Manager (PEM).

MODULE

pem protocol profile

SYNTAX

Configure the radius component within the pem protocol profile module using the syntax shown in the following sections.

```
CP/CREATE/EDIT/MODIFY
cp radius [source_name] [destination_name]
create radius [name]
modify radius [name]
options:
  app-service [[string] | none]
  description [string]
  messages [add | delete | modify | replace-all-with] {
    [ [message-name] ] {
options:
  direction [any | in | out]
  message-type [acct-req-start | acct-req-stop | acct-req-interim-update]
  avps [add | delete | modify | replace-all-with] {
    [ [avp-name] ] {
options:
  default [string]
  ingress-op [ import | none]
  radius-avp [ [radius_avp_name] | none]
  subscriber-attr [ [subscriber_attribute_name] | none]
}
}
}
  subscriber-id [add | delete | modify | replace-all-with] {
    [ [id-name] ] {
options:
  order [integer]
  prefix [[string] | none]
  radius-avp [[radius_avp_name] | none]
  suffix [[string] | none]
}
}
  subscriber-id-type [e164 | imsi | nai | private]
```

```
edit radius [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties

  DISPLAY
  list radius
  list radius [ [ [name] | [glob] | [regex] ] ... ]
  show running-config radius
  show running-config radius [ [ [name] | [glob] | [regex] ] ... ]
  options:
    all-properties
    non-default-properties
    one-line
    partition
```

```
DELETE
delete radius [name]
```

Note: You must remove all references to a pem protocol profile radius before you can delete it.

DESCRIPTION

You can use the radius component to configure pem protocol profile radius definitions in Policy Enforcement Manager.

EXAMPLES

```
create cust_acct_start messages add { my_acct_start { direction in
message-type acct-req-start avps add { avp1 { subscriber-attr
_sys_attr_3gpp_imeisv radius-avp _sys_radius_3gpp_imeisv ingress-op
import } } } }
```

Creates a custom PEM RADIUS protocol profile `cust_acct_start` and add a message to define how the RADIUS message can be processed. The message is defined as RADIUS accounting on the ingress direction. The mapping action `ingress-op` is to extract RADIUS AVP defined in `_sys_radius_3gpp_imeisv` and store the value into subscriber attribute `_sys_attr_3gpp_imeisv`.

```
delete radius cust_acct_start
```

Deletes the PEM RADIUS protocol profile named `cust_acct_start`.

```
list radius cust_acct_start
```

Displays the properties of the PEM RADIUS protocol profile named `cust_acct_start`.

OPTIONS

app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description
User defined description.

messages
Adds, deletes, or replaces a set of messages which specify mapping of RADIUS AVPs to subscriber session attributes for specific Gx message. If a message by the specified name does not exist, it will be created. You can configure the following options for a message:

app-service
Specifies the name of the application service to which the message belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the message. Only the application service can modify or delete the message.

direction
Specifies the direction of the message.

The options are:

any PEM will process the message in both ingress and egress directions.

in PEM will process the message in ingress direction.

out PEM will process the message in egress direction.

message-type
Specifies the type of the message.

The options are:

acct-req-start
The message is RADIUS accounting with the value of `Acct-Status-Type` AVP set to 1 (Start).

acct-req-stop
The message is RADIUS accounting with the value of `Acct-Status-Type` AVP set to 2 (Stop).

acct-req-interim-update
The message is RADIUS accounting with the value of `Acct-Status-Type` AVP set to 3 (Interim-Update).

avps Adds, deletes, or replaces a set of mapping between RADIUS AVPs and PEM subscriber attributes. You can configure the following options.

app-service

Specifies the name of the application service to which the avp belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the message. Only the application service can modify or delete the avp.

default

Specifies the RADIUS AVP default value. When inserting the AVP, the default value is used if the corresponding subscriber session attribute is not defined or is not present.

ingress-op

Specifies the ingress operation applied when processing the RADIUS AVP. The default value is none.

The options are:

import

Specifies that the RADIUS AVP will be parsed and the value will be stored in the subscriber attribute.

none Specifies that there is no ingress operation applied to the RADIUS AVP.

radius-avp

Specifies the name of the RADIUS AVP. The default value is none.

subscriber-attr

Specifies the name of the subscriber session attribute to be mapped to RADIUS AVP. The default value is none.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

subscriber-id

Adds, deletes, or replaces a set of RADIUS AVPs to form PEM subscriber ID. You can configure the following options:

order

Specifies the order of RADIUS AVPs when constructing the subscriber ID.

prefix

Specifies the prefix string when constructing subscriber ID with the value of the RADIUS AVP.

radius-avp

Specifies the value of RADIUS AVP which will be used to construct the subscriber ID.

suffix

Specifies the suffix string when constructing subscriber ID with the value of the RADIUS AVP.

subscriber-id-type

Specifies the subscriber ID type session attribute value for the session created.

The options are:

e164 A numbering plan that defines the format of an MSISDN international phone number (up to 15 digits). The number typically consists of three fields: country code, national destination code, and subscriber number.

imsi International Mobile Subscriber Identity. A globally unique code number that identifies a GSM, UMTS, or LTE mobile phone user.

nai Network Access Identifier. A fully qualified network name in the form @; identifies a subscriber and the home network to which the subscriber belongs.

private

The subscriber id type is private for the given deployment.

pem protocol radius-avp

NAME
radius-avp - Configures RADIUS AVPs in Policy Enforcement Manager (PEM).

MODULE
pem protocol

SYNTAX
Configure the radius-avp component within the pem protocol module using the syntax shown in the following sections.

CREATE/EDIT/MODIFY
create radius-avp [name]
modify radius-avp [name]
options:
app-service [[string] | none]
data-type [3gpp-rat-type | 3gpp-user-location-info | integer | ipaddr | ipv6addr | ipv6prefix | octet | string | t
description [string]
max-length [integer]
min-length [integer]
type [integer]
vendor-id [integer]
vendor-type [integer]

edit radius-avp [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties

DISPLAY
list radius-avp
list radius-avp [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties
one-line
partition

DELETE
delete radius-avp [name]

Note: You must remove all references to a radius-avp before you can delete the radius-avp.

DESCRIPTION
You can use the radius-avp component to configure RADIUS AVP definitions in Policy Enforcement Manager.

EXAMPLES
create radius-avp imeisv { data-type string type 26 vendor-id 10415 vendor-type 20 }

Creates a PEM radius-avp imeisv which is an Vendor Specific Attribute of 3GPP with type value 26.

delete radius-avp imeisv

Deletes the radius-avp named imeisv.

list radius-avp imeisv

Displays the properties of the radius-avp named imeisv.

OPTIONS
app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

data-type
Specifies the data type of the RADIUS AVP. The default value is string.

The options are:

3gpp-rat-type
specifies the value format to be encoded or decoded as the 3GPP-RAT-Type defined in 3GPP TS 29.061.

3gpp-user-location-info
specifies the value format to be encoded or decoded as the 3GPP-User-Location-Info defined in 3GPP TS 29.061.

integer
32-bit unsigned integer in network byte order.

ipaddr
IPv4 address in network byte order.

ipv6addr
IPv6 address in network byte order.

ipv6prefix
IPv6 prefix data format is defined in RFC 3162.

octet
UTF-8 text [RFC3629], totaling 253 octets or less in length.

string
string (i.e., binary data), totaling 253 octets or less in length. This includes the opaque encapsulation of data structures defined outside of RADIUS.

time
time as a 32-bit unsigned value in network byte order and in seconds since 00:00:00 UTC, January 1, 1970.

description
User defined description.

max-length
Specifies the maximum data length of the RADIUS AVP/VSA. It doesn't include the AVP/VSP header. The default value is 253.

min-length
Specifies the minimum data length of the RADIUS AVP/VSA. It doesn't include the AVP/VSP header. The default value is 1.

name
Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

type
Specifies the type of the RADIUS AVP. 26 is for vendor specific attribute (VSA).

vendor-id
Specifies the vendor-id of the RADIUS VSA. This property is mandatory if type is 26.

vendor-type
Specifies the vendor-type of the RADIUS VSA. This property is mandatory if type is 26.

pem quota-mgmt rating-group

NAME
rating-group - Configures a rating-group for quota management in Policy Enforcement Manager (PEM).

MODULE
pem quota management

SYNTAX
Modify the rating-group component within the pem quota-mgmt module using the syntax shown in the following sections.

```
CREATE/MODIFY
create rating-group [name]
modify rating-group [name]
options:
  app-service [[string] | none]
  rating-group-id [integer]
  description [string]
  request-on-install [yes | no]
  default-threshold [integer]
  default-validity-time [integer]
  default-quota-holding-time [integer]
  initial-quota-request {
interval [integer]
volume {
  input-octets
  output-octets
  total-octets
}
  default-quota {
interval [integer]
```

```

volume {
  input-octets
  output-octets
  total-octets
}
time {
usage-time
consumption-time
}
default-breach-action [terminate | allow | redirect]
default-forwarding-endpoint [name]

```

```

edit rating-group [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

```

```

DISPLAY
list rating-group
list rating-group [ [ [name] | [glob] | [regex] ] ... ]
show running-config rating-group
show running-config rating-group [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

```

```

DELETE
delete rating-group [name]

```

Note: You must remove all references to a rating-group object before you can delete it.

EXAMPLES

```

create rating-group rg1 {
  rating-group-id 1
  initial-quota-request {
    volume {
      input-octets 1000  output-octets 1000
      total-octets 2000
    }
  }
  default-quota {
    volume {
      input-octets 1000      output-octets 1000
      total-octets 2000
    }
  }
  request-on-install yes }

```

Creates a PEM rating-group named rg1.

```
delete rating-group rg1
```

Deletes the rating-group named rg1.

```
list rating-group rg1
```

Displays the properties of the rating-group named rg1.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

rating-group-id

Specifies the rating-group-id that will be used by quota managing endpoint. For instance, this could be the rating group in case of Gy endpoint.

request-on-install

Specifies whether quota has to be requested from the quota managing endpoint (Eg : Gy) when policy referring to this rating-group is installed for a subscriber or later when flow is initiated.

default-threshold

Specifies the default threshold if the quota managing endpoint does not specify threshold.

default-validity-time

Specifies the default validity time for the quota in seconds if OCS did not specify it.

default-quota-holding-time

Specifies the default quota holding time in seconds for which quota is valid without any usage if not specified by OCS.

initial-quota-request

Specifies the initial quota, that will be requested from the quota managing endpoint. Could be either time or volume.

time Specifies the time in seconds.

volume

You can configure the following options for volume initial quota.

output-octets

Specifies the initial quota for downlink traffic.

total-octets
Specifies the initial quota for total uplink and downlink traffic.

input-octets
Specifies the initial quota for uplink traffic.

default-quota
Specifies the default quota, that will be used if quota managing endpoint does not respond. Could be either time or volume.

time Specifies the quota in time.

usage-time
Specifies the usage time in seconds.

consumption-time
Specifies the quota consumption time in seconds.

volume
You can configure the following options for volume default quota.

output-octets
Specifies the default quota for downlink traffic.

total-octets
Specifies the default quota for total uplink and downlink traffic.

input-octets
Specifies the default quota for uplink traffic.

SEE ALSO
create, delete, edit, glob, list, modify, pem policy, show, tmsh

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2016-01-07 pem quota-mgmt rating-group(1)

pem reporting format-script

NAME
format-script - Configures format scripts for the Policy Enforcement Manager (PEM).

MODULE
pem reporting

SYNTAX
Modify the format-script component within the pem reporting module using the syntax shown in the following sections.

CREATE/MODIFY
create format-script [name]
modify format-script [name]
options:
app-service [[string] | none]
definition [string]
description [string]

edit format-script [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties

DISPLAY
list format-script
list format-script [[[name] | [glob] | [regex]] ...]
show running-config format-script
show running-config format-script [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties
one-line
partition

DELETE
delete format-script [name]

Note: You must remove all references to a format script object before you can delete it.

DESCRIPTION

You can use the format-script component to create scripts for HSL reporting. The scripts use TCL syntax and define a custom format that is applied in an enforcement policy rule. The format and fields available differ depending on whether the rule specifies session-based or flow-based reporting.

EXAMPLES

```
create format-script fml { definition { return "(flow app_id[PEM::flow
stats reported app-id], bytes-in:[PEM::flow stats reported bytes-in])"
} }
```

Creates a PEM reporting format script named fml.

```
delete format-script fml
```

Deletes the format script named fml.

```
list format-script fml
```

Displays the properties of the format script named fml.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

definition

Specifies a script using TCL syntax that defines a custom format for HSL reporting applied in an enforcement policy rule. The format and fields available differ depending on whether you are using session-based or flow-based reporting in the rule.

Session-based formats:

The options are:

app-id

Specifies the application id of the session record.

bytes-in

Specifies the aggregate incoming bytes of the session.

bytes-out

Specifies the aggregate outgoing bytes of the session.

calling-station-id

Specifies the calling station Id.

called-station-id

Specifies the called station Id.

flows-concurrent

Specifies the number of concurrent flows in the session.

flows-duration

Specifies the duration of the flow in the session.

flows-ended

Specifies the number of flows ended in the session.

flows-new

Specifies the number of new flows in the session.

last-sent-sec

Specifies the value of seconds of the timestamp since the previous record was sent.

param-3gpp

Specifies the comma-separated string of the value of imsi, imeisv, tower-id, and user-name.

record-reason

Specifies the reason for sending report. The values are 1: period time, 2: volume threshold, 3: subscriber logout, 4: inactivity.

record-type

Specifies the type of the session-based record (always 3).

report-id

Specifies the report Id.

report-version

Specifies the report version.

subscriber-id

Specifies the subscriber id.

subscriber-id-type

Specifies the subscriber id type (e164, imsi, nai, or private).

timestamp

Specifies the seconds value of the timestamp when the record was generated. The Unix epoch is 1970-01-01T00:00:00Z.

timestamp-milliseconds

Specifies the milliseconds value of the timestamp when

the record was generated.

Note: Recommend not to use the following options. They are available for backward compatibility.

last-send-usec
Specifies the value of microseconds of the timestamp since the previous record was sent.

rec-reason
Specifies the reason for sending report. The values are 1: period time, 2: volume threshold, 3: subscriber logout, 4: inactivity.

rec-type
Specifies the type of the session-based record (always 3).

subs-id
Specifies the subscriber id.

subs-id-type
Specifies the subscriber id type (e164, imsi, nai, or private).

timestamp-sec
Specifies the seconds value of the timestamp when the record was generated. The Unix epoch is 1970-01-01T00:00:00Z.

timestamp-usec
Specifies the microseconds value of the timestamp when the record was generated.

Flow-based formats:
The options are:

app-id
Specifies the application id of the flow record.

bytes-in
Specifies the aggregate incoming bytes of the flow.

bytes-out
Specifies the aggregate outgoing bytes of the flow.

dst-ip
Specifies the destination ip address of the flow.

dst-port
Specifies the destination port of the flow.

flow-start-milli-seconds
Specifies the milliseconds value of the timestamp when the flow starts.

flow-start-time-sec
Specifies the seconds value of the timestamp when the flow starts. The Unix epoch is 1970-01-01T00:00:00Z.

flow-end-milli-seconds
Specifies milliseconds value of the timestamp when the flow ends.

flow-end-time-sec
Specifies the seconds value of the timestamp when the flow ends. The Unix epoch is 1970-01-01T00:00:00Z.

proto
Specifies the protocol of the flow.

record-type
Specifies the type of the flow-based record. The value is 0: flow init, 1: flow interim, and 2: flow end.

report-id
Specifies the report Id.

route-domain
Specifies the route domain Id of the traffic.

report-version
Specifies the report version.

src-ip
Specifies the source ip address of the flow.

src-port
Specifies the destination port of the flow.

subscriber-id
Specifies the subscriber id.

subscriber-id-type
Specifies the subscriber id type (e164, imsi, nai, or private).

timestamp
Specifies the of seconds value of the timestamp when the record was generated. The Unix epoch is 1970-01-01T00:00:00Z.

timestamp-milliseconds
Specifies the milliseconds value of the timestamp when

the record was generated.

transactions

Specifies the number of transactions in the flow.

urlcat-id

Specifies the unique number that represents the first (most relevant) URL category that is classified for the flow.

vlan-id

Specifies the vlan Id of the traffic.

Note: Recommend not to use the following options. They are available for backward compatibility.

flow-start-time-usec

Specifies microseconds value of the timestamp when the flow starts.

flow-end-time-usec

Specifies microseconds value of the timestamp when the flow ends.

rec-type

Specifies the type of the flow-based record. The value is 0: flow init, 1: flow interim, and 2: flow end.

subs-id

Specifies the subscriber id.

subs-id-type

Specifies the subscriber id type (e164, imsi, nai, or private).

timestamp-sec

Specifies the of seconds value of the timestamp when the record was generated. The Unix epoch is 1970-01-01T00:00:00Z.

timestamp-usec

Specifies the microseconds value of the timestamp when the record was generated.

description

Specifies a user-defined description.

pem service-chain-endpoint

NAME

service-chain-endpoint - Configures service chain endpoints for the Policy Enforcement Manager (PEM).

MODULE

pem

SYNTAX

Modify the service-chain-endpoint component within the pem module using the syntax shown in the following sections.

CREATE/MODIFY

```
create service-chain-endpoint [name]
modify service-chain-endpoint [name]
options:
  app-service [[string] | none]
  service-endpoints [add | delete | modify | replace-all-with] {
[service endpoint name ... ] {
  options:
  app-service [[string] | none]
  forwarding-endpoint
  to-endpoint [forwarding endpoint name]
  from-vlan [vlan name]
  http-adapt-service
```

```

    internal-virtual [internal virtual server | none]
    icap-type [request | response | both | none]
    order [integer]
    service-option [optional | mandatory]
    steering-policy [policy name | none]
}
}

edit service-chain-endpoint [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list service-chain-endpoint
list service-chain-endpoint [ [ [name] | [glob] | [regex] ] ... ]
show running-config service-chain-endpoint
show running-config service-chain-endpoint [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

DELETE
delete service-chain-endpoint [name]

```

Note: You must remove all references to a service-chain-endpoint before you can delete the service-chain-endpoint.

DESCRIPTION

You can use the service-chain-endpoint component to configure service-chain-endpoint definitions for the Policy Enforcement Manager (PEM). Each service-chain-endpoint consists of one or more service-endpoints, where a service-endpoint consists of a non-zero integer order, existing from-vlan a valid fwd-endpoint or a http-adaptation-service endpoint. When you configure a BIG-IP that has a service-chain-endpoint with multiple service-endpoints, traffic will pass through different endpoints chosen dynamically.

Note: You must create a valid forwarding-endpoint and a valid vlan before you can create a service-endpoint. If you are enabling http-adapt-service, you must create Request Adapt and Response Adapt profiles and attach to the traffic virtual. Also create an internal-virtual and enable icap profile. You must also give each service-endpoint an order from 1 up to 2³²-1. The lower the service-endpoint order is, the higher its precedence is (i.e., traffic will pass through it before other higher order service-endpoints). Each service-endpoint has a boolean (true/false) service-option that defines what would happen if the service-endpoint is down. If service-option is mandatory, the traffic flow is dropped if the service-endpoint is down. If service-option is optional, the traffic flow will be bypassed to the next available service-endpoint.

For more information about how to create a vlan, please refer to net vlan. Also please refer to pem forwarding-endpoint for more information about how to create a pem forwarding-endpoint.

EXAMPLES

```

create service-chain-endpoint chain1 service-endpoints add { ser_ep1 {
order 10 from-vlan vlan1 forwarding-endpoint { to-endpoint fw_ep1 }
service-option optional } ser_ep2 { order 5 from-vlan vlan2 http-adapt-
service {internal-virtual iv1} service-option mandatory } }

```

Creates a PEM service-chain-endpoint named chain1 that has two service-endpoints: ser_ep1 and ser_ep2. The first ser_ep1 has an order of 10 and is optional and has forwarding-endpoint with to-endpoint fw_ep1, type transparent and vlan1 as a from-vlan. The second ser_ep2 has an order of 5 is mandatory and has http-adapt-service enabled with ivs1 as internal-server and vlan2 as a from-vlan. Note that ser_ep2 will precede ser_ep1 because the lower the service-endpoint order is, the higher its precedence is.

```
delete service-chain-endpoint chain1
```

Deletes the service-chain-endpoint named chain1.

```
list service-chain-endpoint chain1
```

Displays the properties of the service-chain-endpoint named chain1.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

service-endpoints

Adds, deletes, or replaces a set of the service endpoints by specifying a series of service-endpoint names. If any of these names did not exist before, then new names will be created. Each service-endpoint is identified by a vlan and a forwarding-endpoint.

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

forwarding-endpoint

Specifies the forwarding endpoint attributes to be set. The below attributes can be set:

to-endpoint

This is a default endpoint that will be chosen if steering policy is not configured. You have to create a valid PEM forwarding-endpoint before you can add to-endpoint to a service-endpoint.

from-vlan

Specifies the vlan that the traffic will come from toward the service-endpoint. Note: The vlan has to exist before you can create a from-vlan field.

http-adapt-service

Specifies the option to set attributes for http adapt services. Below are the attributes that can be set.

internal-virtual

This is the internal virtual on which icap is enabled. You have to create the internal-virtual and assign icap profile before adding here.

icap-type

Defines the ICAP adaptation type: request only adaptation, request and response adaptation or both types of adaptations combined.

order

Specifies the order of the service-endpoint among other service-endpoints. The lower the service-endpoint's order is, the more precedence it has (i.e., the traffic will go through the lowest-ordered service-endpoint first, then through higher order service-endpoint, ... etc.).

service-option

Specifies the behavior when a service-endpoint is not available (i.e., is down). This option is limited when ICAP is defined as the service-endpoint and will not apply if the ICAP service is unavailable. You can configure the following options:

mandatory

If the service-endpoint is down, the traffic flow is dropped.

optional

If the service-endpoint is down, the traffic flow will be bypassed to the next available service-endpoint.

steering-policy

If the steering policy is configured, the policy is evaluated and if steering is enabled the flow will be steered to the corresponding endpoint.

BIG-IP 2016-01-07 pem service-chain-endpoint(1)

pem sessiondb

NAME

sessiondb - Displays, deletes, modifies, and reset-stats a PEM subscriber session record on the BIG-IP(r) system.

MODULE

pem

DESCRIPTION

You can use the sessiondb component to display session record on the BIG-IP system. Additionally, you can delete, reset-stats and modify a specified session record. The subscriber-id or session-ip or all and/or the filtering arguments can be specified as the query key. session-state must be specified in modify command.

When specifying an IP address in show/delete/modify/reset-stats sessiondb session-ip commands, the route domain ID may be optionally included. The route domain ID follows the IP address and is separated

by '%'. For example, 10.10.10.100%5 is an IP address in route domain 5.

Note: show and reset-stats commands apply to both static and dynamic subscribers. Delete and modify commands only apply to dynamic subscribers. The session of static subscribers cannot be deleted. The session-state of static subscribers cannot be changed. To delete a static subscriber session you have to delete the static subscriber configuration in pem subscriber.

SHOW command
SYNTAX

```
show sessiondb subscriber-id []  
show sessiondb session-ip /[] []  
show all
```

options:
all-properties
field-fmt

DESCRIPTION

Used to display the session information.

subscriber-id can either be the complete subscriber-id or a wildcard.

session-ip be either the complete IP address, or a subnet, by specifying the prefix.

all is used to display all the sessions. Due to existing limitations, some of the arguments cannot be used with the 'all' option. In this case, 'subscriber-id *' can be used.

all-properties options enables the per-IP traffic statistics in case of sessions with multiple IP addresses.

field-fmt option provides a structured output. This option is used for REST API compatibility.

args is an optional list of arguments, which can contain the following-

- filtering arguments: These specify the criteria for selecting sessions to display. The filtering arguments can be one or more of the following

- . imsi
- . imeisv
- . calling-station-id
- . called-station-id
- . user-name
- . session-origin
- . session-state
- . device-name
- . device-os
- . user-location-info

This can either be the user location as a hex string, or the location info broken down into individual fields as name value pairs. The values can be combined using '&' or '|' and can have only one of the operators, not both. The key value pairs allowed are as follows ('D' stands for a decimal value and 'H' for hex digit) -

```
- type=[CGI | SAI | RAI | TAI | TAI+ECGI] - mcc=DD[D] -  
mnc=DD[D] - lac=[0x]HHHH - ci=[0x]HHHH - sac=[0x]HHHH -  
rac=[0x]HHHH - tac=[0x]HHHH - eci=[0x]HHHHHHH
```

For e.g.

```
user-location-info 0x1234567 user-location-info  
type=CGI&mcc=123 user-location-info  
type=TAI+ECGI|ecc=123|lac=0x3f5d
```

This is not allowed -

```
user-location-info type=CGI&mcc=123|ecc=456
```

. attr

This is the list of custom attribute key-value pairs. Multiple attributes can be combined with either '&' or '|'. (cannot have a mix of '&' and '|' operators). There can be a maximum of 30 custom attributes.

. policy

List of policy names. This can again be combined using the '&' or '|' operators. There can be maximum of 30 policies.

. blade

. tmm

- include-deleted: This specifies whether to include sessions marked for deletion in the output.
- view-mode: This specifies the format of the output and can be one of extended, table or count. The extended view mode is the default and gives a formatted output of all the session attributes and flow statistics. In the table mode, the user can select the information to be displayed by selecting the list of columns. In this mode, the 'columns' argument HAS to be specified containing the list of columns to display. Column names should be separated by ':' and should be from the following list -

. subscriber_id

. tmm_number

- . blade_number
- . session_state_str
- . session_origin_str
- . ppe_session_id
- . qpe_session_id
- . imsi
- . imeisv
- . called_station_id
- . calling_station_id
- . user_name
- . device_name
- . device_os
- . tower_id
- . ip_info.ip_address
- . policy_info.policy_name
- . any custom attribute e.g. _sys_attr_3gpp_rat_type.

Any unknown column name is considered to be a custom attribute name.

If the view-mode is set to count, then only a count of the number of sessions matching the specified criteria is displayed.

- max-count: This is used to specify an upper limit on the number of matching sessions to be considered for the command.
- resume-from: This argument is used to get a page-by-page listing of the sessions, and can be used only with the field-fmt option.

DELETE command

SYNTAX

```
delete sessiondb subscriber-id []
delete session-ip [ip address>/[] []]
delete all
```

DESCRIPTION

Used to delete sessions.

The optional arguments here can specify the filtering arguments, as explained in the show command above.

All the sessions matching the criteria are deleted.

MODIFY command

SYNTAX

```
modify sessiondb subscriber-id [] session-state
[marked-for-deletion | not-provisioned | provisioned | provisioning-
pending ]
modify session-ip [ip address>/[] []] session-state
[marked-for-deletion | not-provisioned | provisioned | provisioning-
pending ]
```

DESCRIPTION

Used to modify the session state.

The optional arguments here can specify the filtering arguments, as explained in the show command above.

The state of all the matching sessions are modified to the value specified.

session-state

Specifies the new subscriber session state.

The options are:

marked-for-deletion

Specifies that the subscriber session should be scheduled for deletion.

provisioned

Specifies that the subscriber session state should be marked as provisioned, regardless of whether the policies have been assigned or not. The unknown subscriber policies are not applied to the subscriber flows, even if no subscriber policies are provisioned.

not-provisioned

Specifies that the subscriber session state should be marked as not-provisioned. No further attempts to provision the session are made. The unknown subscriber policies are applied to the subscriber flows.

provisioning-pending
Specifies that the subscriber session state should be marked as being in the process of provisioning. This will trigger a session provisioning request (e.g. Gy CCR request) immediately. If no response is received, or the provisioning process fails for any reason, another request will be sent after the retry timeout, until the session is provisioned successfully, or the number of retries is reached.

RESET-STATS command
SYNTAX

```
reset-stats sessiondb subscriber-id []  
reset-stats session-ip [ip address>/[] []  
reset-stats all
```

DESCRIPTION

Used to reset the session statistics.

The optional arguments here can specify the filtering arguments, as explained in the show command above.

The statistics for all the sessions matching the criteria are reset.

EXAMPLES

```
show sessiondb subscriber-id 4085551212
```

Displays the session record of subscriber id 4085551212.

```
show sessiondb subscriber-id 408*
```

Displays the session record of all subscribers with id beginning with '408'.

```
show sessiondb subscriber-id *
```

Displays the session records of all subscribers.

```
show sessiondb session-ip 10.10.10.100
```

Displays the session record of session ip address 10.10.10.100.

```
show sessiondb session-ip 10.10.10.100%5
```

Displays the session record of session ip address 10.10.10.100 in route domain 5.

```
show sessiondb session-ip 10.10.10.10/24
```

Displays the session records of session ip addresses in the 10.10.10.0 subnet.

```
show sessiondb subscriber-id 4085551212 all-properties
```

Displays the session record of subscriber id 4085551212, and statistics for each IP.

```
show sessiondb session-ip 10.10.10.100 all-properties
```

Displays the session record of session ip address 10.10.10.100, and statistics for each IP.

```
show sessiondb session-ip 10.10.10.10/24 view-mode count
```

Displays the count of the number of session records with session ip address in the 10.10.10.0 subnet.

```
show sessiondb subscriber-id 408* session-state provisioned
```

Displays the count of the number of sessions whose id begins with '408' and are in the provisioned state.

```
delete sessiondb subscriber-id 4085551212
```

Deletes the session record of subscriber id 4085551212.

```
delete sessiondb session-ip 10.10.10.100
```

Deletes the session record of IP address 10.10.10.100.

```
delete sessiondb session-ip 10.10.10.100%5
```

Deletes the session record of IP address 10.10.10.100 in route domain 5.

```
delete sessiondb session-ip session-state provisioning-pending
```

Deletes all sessions that are in the provision pending state.

```
reset-stats sessiondb subscriber-id 4085551212
```

Reset the session statistics of subscriber id 4085551212. Flows Current specifies the active flows and it cannot be reset.

```
modify sessiondb subscriber-id 4085551212 session-state provisioned
```

Modifies the session state of subscriber id 4085551212 to provisioned.

```
modify sessiondb subscriber-id 408* session-state provisioned
```

Modifies the session state of sessions with subscriber id starting with 408 to state provisioned.

pem stats action

NAME
action - Displays and resets PEM policy action statistics.

MODULE
pem stats

SYNTAX
Display statistics for the action component within the pem stats module using the syntax in the following section.

DISPLAY
show action
option:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION
You can use the action component to display PEM policy action statistics. The statistics details are described below:

- Pass Specifies the number of flows that are passed (gate enabled).
- Drop Specifies the number of flows that are dropped (gate disabled).
- Clone
Specifies the number of flows to which clone actions apply.
- HTTP Redirect
Specifies the number of flows to which redirection actions apply.
- ICAP Request
Specifies the number of flows to which ICAP actions apply on the request direction.
- ICAP Response
Specifies the number of flows to which ICAP actions apply on the response direction.
- Steering
Specifies the number of flows to which steering actions apply.
- Service Chain
Specifies the number of flows to which steering endpoint actions apply.
- Steering on Response
Specifies the number of flows to which steering actions apply on the response direction.
- QoS Uplink
Specifies the number of uplink flows to which QoS actions apply. Uplink means to network.
- QoS Downlink
Specifies the number of downlink flows to which QoS actions apply. Downlink means to subscriber.
- DSCP Marking Uplink
Specifies the number of uplink flows with DSCP action applies.
- DSCP Marking Downlink
Specifies the number of downlink flows with DSCP action applies.
- HTTP Headers Modify
Specifies the number of HTTP Headers Modify actions.
- Insert Content
Specifies the number of Insert Content actions.
- iRule
Specifies the number of iRule actions.

L2 Marking Uplink
Specifies the number of uplink flows to which L2 Marking actions apply.

L2 Marking Downlink
Specifies the number of downlink flows to which L2 Marking actions apply.

Flow Reporting
Specifies the number of actions of flow reporting record generation applied.

Session Reporting
Specifies the number of actions of session record generation applied.

Transaction Reporting
Specifies the number of actions of transaction record generation applied.

Policy Re-evaluation Rate (count/min)
Specifies the number of successful policy reevaluations per minute.

Policy Re-evaluation Rate Maximum
Specifies the maximum number of policy reevaluations overall for all subscribers and flows.

Media Quality-of-experience (QoE)
Specifies the number of actions of media Quality-of-experience (QoE) record generation applied.

You can reset the PEM policy action statistics using reset-stats command.

EXAMPLES

show action

Displays the PEM policy action statistics.

reset-stats action

Resets the PEM policy action statistics.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

pem stats dtos

NAME
dtos - Displays and resets PEM dtos statistics.

MODULE
pem stats

SYNTAX
Display statistics for the dtos component within the pem stats module using the syntax in the following section.

DISPLAY
show dtos
option:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION
You can use the dtos component to display PEM dtos statistics. The statistics details are described below:

TAC Database
Specifies the number of TAC database queries and successful lookups since the last reset of the counter.

Customdb

Specifies the number of custom TAC database queries and successful lookups since the last reset of the counter.

Default/Licensed

Specifies the number of default/licensed TAC database queries and successful lookups since the last reset of the counter.

TCP Fingerprint

Specifies the number of TCP fingerprint queries and successful OS identification since the last reset of the counter.

User-agent

Specifies the number of user-agent queries and successful OS identification since the last reset of the counter.

You can reset the PEM dtos statistics using `reset-stats` command.

EXAMPLES

`show dtos`

Displays the PEM dtos statistics.

`reset-stats dtos`

Resets the PEM dtos statistics.

OPTIONS

For information about the options that you can use with the command `show`, see `help show`.

pem stats gx

NAME

`gx` - Displays and resets PEM gx statistics.

MODULE

`pem stats`

SYNTAX

Display statistics for the `gx` component within the `pem stats` module using the syntax in the following section.

DISPLAY

`show gx`

option:

(`default` | `exa` | `gig` | `kil` | `meg` | `peta` | `raw` | `tera` | `yotta` | `zetta`)

DESCRIPTION

You can use the `gx` component to display PEM `gx` statistics. The `Current` column represents count of Gx sessions that exist at the moment. The `Max` column represents maximal count of Gx sessions that ever existed at the same time. The `Total` column represents total count of Gx sessions that existed or messages that were sent or received since the start or the last statistics reset. The `Retries` column represents total count of retransmitted Gx messages. The `Errors` column represents total count of received Gx messages that were invalid or outgoing Gx messages that could not be sent. The statistics details are described below:

Gx sessions

Specifies the number of all Gx sessions established.

Provisioned Gx sessions

Specifies the number of provisioned Gx sessions.

Provisioning pending Gx sessions

Specifies the number sessions for which provisioning or creation over Gx has been initiated.

Not provisioned Gx sessions

Specifies the number of not provisioned Gx sessions, i.e. all existing Gx sessions that have not been provisioned.

Provisioning failed Gx sessions

Specifies the number of inactive Gx sessions for which provisioning or creation error happened.

Termination pending Gx sessions
Specifies the number of Gx sessions for which close is initiated.

Terminated Gx sessions
Specifies the total number of Gx sessions terminated since the last reset of the counter.

CCR Sent
Specifies the number of Credit-Control-Request (CCR) requests of all types sent.

CCR Initial Sent
Specifies the number of Credit-Control-Request (CCR) Initial requests sent since the last reset of the counter.

CCR Update Sent
Specifies the number of Credit-Control-Request (CCR) Update requests sent since the last reset of the counter.

CCR Usage Monitoring Sent
Specifies the number of Credit-Control-Request (CCR) requests with usage monitoring report sent.

CCR Application Start Sent
Specifies the number of Credit-Control-Request (CCR) requests with application start report sent.

CCR Application Stop Sent
Specifies the number of Credit-Control-Request (CCR) requests with application stop report sent.

CCR Termination Sent
Specifies the number of Credit-Control-Request (CCR) Termination requests sent since the last reset of the counter.

CCA Received
Specifies the number of Credit-Control-Answer (CCA) responses of all types received.

CCA Initial Received
Specifies the number of Credit-Control-Answer (CCA) Initial responses received since the last reset of the counter.

CCA Update Received
Specifies the number of Credit-Control-Answer (CCA) Update responses received since the last reset of the counter.

CCA Usage Monitoring Received
Specifies the number of Credit-Control-Answer (CCA) responses with usage monitoring report ack received.

CCA Termination Received
Specifies the number of Credit-Control-Answer (CCA) Termination responses received since the last reset of the counter.

RAR Received
Specifies the number of Re-Auth-Request (RAR) requests received.

RAA Sent
Specifies the number of Re-Auth-Answer (RAA) responses sent.

You can reset the PEM gx statistics using reset-stats command.

EXAMPLES

```
show gx
```

Displays the PEM gx statistics.

```
reset-stats gx
```

Resets the PEM gx statistics.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

BIG-IP 2015-11-10 pem stats gx(1)

NAME
gy - Displays and resets PEM gy statistics.

MODULE
pem stats

SYNTAX
Display statistics for the gy component within the pem stats module using the syntax in the following section.

DISPLAY
show gy
option:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION
You can use the gy component to display PEM gy statistics. The Current column represents count of Gy sessions that exist at the moment. The Max column represents maximal count of Gy sessions that ever existed at the same time. The Total column represents total count of Gy that existed or messages that were sent or received since the start or the last statistics reset. The Retries column represents total count of retransmitted Gy messages. The Errors column represents total count of received Gy messages that were invalid or outgoing Gy messages that could not be sent. The statistics details are described below:

Gy sessions
Specifies the number of all Gy sessions established.

Provisioned Gy sessions
Specifies the number of provisioned Gy sessions.

Provisioning pending Gy sessions
Specifies the number sessions for which provisioning or creation over Gy has been initiated.

Not provisioned Gy sessions
Specifies the number of not provisioned Gy sessions, i.e. provisioning pending and provisioning failed Gy sessions.

Provisioning failed Gy sessions
Specifies the number of inactive Gy sessions for which provisioning or creation error happened.

Termination pending Gy sessions
Specifies the number of Gy sessions for which close is initiated.

Terminated Gy sessions
Specifies the total number of Gy sessions terminated since the last reset of the counter.

CCR Sent
Specifies the number of Credit-Control-Request (CCR) requests of all types sent.

CCR Initial Sent
Specifies the number of Credit-Control-Request (CCR) Initial requests sent since the last reset of the counter.

CCR Update Sent
Specifies the number of Credit-Control-Request (CCR) Update requests sent since the last reset of the counter.

CCR Termination Sent
Specifies the number of Credit-Control-Request (CCR) Termination requests sent since the last reset of the counter.

CCA Received
Specifies the number of Credit-Control-Answer (CCA) responses of all types received.

CCA Initial Received
Specifies the number of Credit-Control-Answer (CCA) Initial responses received since the last reset of the counter.

CCA Update Received
Specifies the number of Credit-Control-Answer (CCA) Update responses received since the last reset of the counter.

CCA Termination Received
Specifies the number of Credit-Control-Answer (CCA) Termination responses received since the last reset of the counter.

RAR Received
Specifies the number of Re-Auth-Request (RAR) requests received.

RAA Sent
Specifies the number of Re-Auth-Answer (RAA) responses sent.

You can reset the PEM gy statistics using reset-stats command.

EXAMPLES
show gy
Displays the PEM gy statistics.
reset-stats gy
Resets the PEM gy statistics.

OPTIONS
For information about the options that you can use with the command

show, see help show.

BIG-IP 2015-03-22 pem stats gy(1)

pem stats hsl

NAME

hsl - Displays and resets PEM hsl statistics.

MODULE

pem stats

SYNTAX

Display statistics for the hsl component within the pem stats module using the syntax in the following section.

DISPLAY

show hsl

option:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION

You can use the hsl component to display PEM hsl statistics. The statistics details are described below:

Session Records

Specifies the number of Session-based records sent to each HSL endpoint since the last reset of the counter.

Flow Start Records

Specifies the number of Flow Start records sent to each HSL endpoint since the last reset of the counter.

Flow Interim Records

Specifies the number of Flow Interim records sent to each HSL endpoint since the last reset of the counter.

Flow Stop Records

Specifies the number of Flow Stop records sent to each HSL endpoint since the last reset of the counter.

Transaction Records

Specifies the number of HTTP Transaction records sent to each HSL endpoint since the last reset of the counter.

Records Skipped

Specifies the number of reporting records skipped from being sent the HSL endpoint since the last reset of the counter.

Media Quality-of-Experience (QoE) Records

When Media Quality-of-Experience (QoE) reporting is configured, specifies the number of QoE Records records sent to each HSL endpoint since the last reset of the counter.

Media Quality-of-Experience (QoE) Records Skipped

When Media Quality-of-Experience (QoE) reporting is configured, specifies the number of QoE reporting records skipped (not real media) from being sent the HSL endpoint since the last reset of the counter.

You can reset the PEM hsl statistics using reset-stats command.

EXAMPLES

show hsl

Displays the PEM hsl statistics.

reset-stats hsl

Resets the PEM hsl statistics.

OPTIONS

For information about the options that you can use with the command show, see help show.

pem stats hudnode-opt

NAME
hudnode-opt - Resets PEM hudnode-opt statistics.

MODULE
pem stats

SYNTAX
Reset statistics for the hudnode-opt component within the pem stats module using the syntax in the following section.

DESCRIPTION
You can use the hudnode-opt component to reset PEM hudnode-opt statistics.

EXAMPLES
reset-stats hudnode-opt

Resets the PEM hudnode-opt statistics.

OPTIONS
For information about the options that you can use with the command reset-stats, see help reset-stats.

SEE ALSO
reset-stats, pem stats action, tmsh, pem stats gx

pem stats multiple-ip

NAME
multiple-ip - Displays and resets PEM multiple IP statistics.

MODULE
pem stats

SYNTAX
Display statistics for the multiple-ip component within the pem stats module using the syntax in the following section.

DISPLAY
show multiple-ip
option:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION
You can use the multiple-ip component to display PEM multiple IP statistics. The Total column represents total count of packets received. The Processed column represents total count of packets processed, i.e. packets that were successfully parsed, validated and initiated session creation, deletion or update. The Processed column is incremented regardless of success or failure of session creation, deletion or update and is incremented for retransmitted packets. The Retransmitted column represents total count of packets that were

discarded, because they were retransmissions of already processed packets. The Error column represents total count of packets that could not be parsed or validated. The statistics details are described below:

Forwarded Flows
Specifies the number of flows that have been forwarded.

Sessions Merged
Specifies the number of sessions have been merged due to multiple IP.

You can reset the PEM multiple IP statistics using reset-stats command.

EXAMPLES

```
show multiple-ip
```

Displays the PEM multiple IP statistics.

```
reset-stats multiple-ip
```

Resets the PEM multiple IP statistics.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, pem stats action, pem stats gx, pem stats gy, pem stats hsl, pem stats subscriber, tmsh

pem stats persistence

NAME

persistence - Displays and resets PEM persistence statistics.

MODULE

pem stats

SYNTAX

Display statistics for the persistence component within the pem stats module using the syntax in the following section.

DISPLAY

```
show persistence
```

option:

```
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
```

DESCRIPTION

You can use the persistence component to display PEM persistence statistics. The statistics details are described below:

Source IP

Number of times CARP persistence is based on source IP address.

Destination IP

Number of times CARP persistence is based on destination IP address.

HASH URI

Number of times CARP persistence is based on URI of the HTTP transaction.

HASH TCL

Number of times CARP persistence is based on TCL script.

Fallback Source IP

Number of times CARP persistence is based on fallback source IP address.

Fallback Destination IP

Number of times CARP persistence is based on fallback destination IP address.

You can reset the PEM persistence statistics using reset-stats command.

EXAMPLES

```
show persistence
```

Displays the PEM persistence statistics.

reset-stats persistence

Resets the PEM persistence statistics.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

pem stats radius

NAME

radius - Displays and resets PEM radius statistics.

MODULE

pem stats

SYNTAX

Display statistics for the radius component within the pem stats module using the syntax in the following section.

DISPLAY

show radius

option:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION

You can use the radius component to display PEM radius statistics. The Total column represents total count of packets received. The Processed column represents total count of packets processed, i.e. packets that were successfully parsed, validated and initiated session creation, deletion or update. The Processed column is incremented regardless of success or failure of session creation, deletion or update and is incremented for retransmitted packets. The Retransmitted column represents total count of packets that were discarded, because they were retransmissions of already processed packets. The Error column represents total count of packets that could not be parsed or validated. The statistics details are described below:

Accounting-Request START

Specifies the number of Accounting-Start packets.

Accounting-Request STOP

Specifies the number of Accounting-Stop packets.

Accounting-Request INTERIM_UPDATE

Specifies the number of Accounting-Interim packets.

Accounting-Request ACCOUNTING_ON

Specifies the number of Accounting-On packets.

Accounting-Request ACCOUNTING_OFF

Specifies the number of Accounting-Off packets.

You can reset the PEM radius statistics using reset-stats command.

EXAMPLES

show radius

Displays the PEM radius statistics.

reset-stats radius

Resets the PEM radius statistics.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

pem stats sd

NAME
sd - Displays and resets PEM sd statistics.

MODULE
pem stats

SYNTAX
Display statistics for the sd component within the pem stats module using the syntax in the following section.

DISPLAY
show sd
option:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION
You can use the sd component to display PEM sd statistics. The Current column represents count of Sd sessions that exist at the moment. The Max column represents maximal count of Sd sessions that ever existed at the same time. The Total column represents total count of Sd sessions that existed or messages that were sent or received since the start or the last statistics reset. The Retries column represents total count of retransmitted Sd messages. The Errors column represents total count of received Sd messages that were invalid or outgoing Sd messages that could not be sent. The statistics details are described below:

Sd sessions
Specifies the number of all Sd sessions established.

Provisioned Sd sessions
Specifies the number of provisioned Sd sessions.

Provisioning pending Sd sessions
Specifies the number sessions for which provisioning or creation over Sd has been initiated.

Not provisioned Sd sessions
Specifies the number of not provisioned Sd sessions, i.e. all existing Sd sessions that have not been provisioned.

Provisioning failed Sd sessions
Specifies the number of inactive Sd sessions for which provisioning or creation error happened.

Termination pending Sd sessions
Specifies the number of Sd sessions for which close is initiated.

Terminated Sd sessions
Specifies the total number of Sd sessions terminated since the last reset of the counter.

CCR Sent
Specifies the number of Credit-Control-Request (CCR) requests of all types sent.

CCR Initial Sent
Specifies the number of Credit-Control-Request (CCR) Initial requests sent since the last reset of the counter.

CCR Update Sent
Specifies the number of Credit-Control-Request (CCR) Update requests sent since the last reset of the counter.

CCR Usage Monitoring Sent
Specifies the number of Credit-Control-Request (CCR) requests with usage monitoring report sent.

CCR Application Start Sent
Specifies the number of Credit-Control-Request (CCR) requests with application start report sent.

CCR Application Stop Sent
Specifies the number of Credit-Control-Request (CCR) requests with application stop report sent.

CCR Termination Sent
Specifies the number of Credit-Control-Request (CCR) Termination requests sent since the last reset of the counter.

CCA Received
Specifies the number of Credit-Control-Answer (CCA) responses of

all types received.

CCA Initial Received
Specifies the number of Credit-Control-Answer (CCA) Initial responses received since the last reset of the counter.

CCA Update Received
Specifies the number of Credit-Control-Answer (CCA) Update responses received since the last reset of the counter.

CCA Usage Monitoring Received
Specifies the number of Credit-Control-Answer (CCA) responses with usage monitoring report ack received.

CCA Termination Received
Specifies the number of Credit-Control-Answer (CCA) Termination responses received since the last reset of the counter.

RAR Received
Specifies the number of Re-Auth-Request (RAR) requests received.

RAA Sent
Specifies the number of Re-Auth-Answer (RAA) responses sent.

You can reset the PEM sd statistics using reset-stats command.

EXAMPLES

```
show sd
```

Displays the PEM sd statistics.

```
reset-stats sd
```

Resets the PEM sd statistics.

OPTIONS

For information about the options that you can use with the command show, see help show.

BIG-IP 2016-03-14 pem stats sd(1)

pem stats subscriber

NAME
subscriber - Displays and resets PEM subscriber statistics.

MODULE
pem stats

SYNTAX
Display statistics for the subscriber component within the pem stats module using the syntax in the following section.

DISPLAY
show subscriber
option:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION

You can use the subscriber component to display PEM subscriber statistics. The Current column represents count of sessions or other objects that exist at the moment. The Max column represents maximal count of sessions or other objects that ever existed at the same time. The Total column represents total count of sessions or other objects that existed since the start or the last statistics reset. Some entries support only the Total column. The statistics details are described below:

Active subscriber sessions
Specifies the number of all subscriber sessions. Note that you can use the db component in the sys module to configure tmm.pem.spm.maxsessionlimit to set the number of subscribers supported per processing unit (TMM). Then, the max number of the subscribers per device is set accordingly.

Subscriber sessions marked for deletion
Specifies the number of sessions that were marked for deletion,

but not yet deleted.

Dynamic subscriber sessions without data from RADIUS
Specifies the number of sessions related to non-static subscribers that were neither created by RADIUS accounting start message nor updated by RADIUS accounting interim message. This counter is not incremented for a session related to static subscriber, even if this session is created dynamically.

Subscriber sessions by state/Waiting for provisioning
Specifies the number of sessions that are pending for provision.

Subscriber sessions by state/Waiting for provisioning Hold Timeout
Specifies the number of sessions that are within the provisioning hold time period.

Subscriber sessions by state/Provisioned
Specifies the number of provisioned sessions.

Subscriber sessions by state/Failed provisioning
Specifies the number of sessions, which provisioning failed. Usually this state is temporary and these sessions will try to be reprovisioned.

Subscriber sessions by origin/Sessions discovered via RADIUS
Specifies the number of sessions, which were created by RADIUS accounting start message.

Subscriber sessions by origin/Sessions discovered via DHCP
Specifies the number of sessions, which were created by DHCP message.

Subscriber sessions by origin/Sessions discovered from traffic
Specifies the number of sessions, which were created by client traffic that doesn't correspond to any existing session.

Subscriber sessions by origin/Sessions discovered via iRules
Specifies the number of sessions, which were created by iRules using PEM::session create or other command.

Subscriber sessions by origin/Pre-configured Static Subscriber Sessions
Specifies the number of sessions, which were created for static subscriber with pre-configured IP-addresses.

Subscriber sessions provisioning source/Sessions provisioned via Gx
Specifies the number of sessions, which were provisioned from PCRF via Gx interface.

Subscriber sessions provisioning source/Sessions provisioned via Sd
Specifies the number of sessions, which were provisioned from PCRF via Sd interface.

Subscriber sessions provisioning source/Sessions provisioned via iRules
Specifies the number of sessions, which were provisioned by iRule command.

Subscriber sessions provisioning source/Sessions provisioned from static subscriber database
Specifies the number of sessions which policies were defined on creation of the corresponding static subscriber.

Subscriber sessions provisioning source/Sessions not provisioned (pending and failed)
Specifies the number of not provisioned sessions.

Subscriber session update statistics/Session updates received
Specifies total count of session update attempts, e.g. by RADIUS accounting interim message, Gx Credit-Control-Request (CCR) Update request or iRule command.

Subscriber session update statistics/Session updates applied successfully
Specifies total count of session update attempts that were successful.

Subscriber session update statistics/Session updates received via RADIUS
Specifies total count of session update attempts by RADIUS accounting interim message.

Subscriber session update statistics/Session updates received via Gx
Specifies total count of session update attempts by Gx Credit-Control-Request updates (CCR-U) or Re-Auth-Requests updates (RAR).

Subscriber session update statistics/Session updates received via Sd
Specifies total count of session update attempts by Sd Credit-Control-Request updates (CCR-U) or Re-Auth-Requests updates (RAR).

Subscriber session update statistics/Session updates received via iRules
Specifies total count of session update attempts by iRule command.

Subscriber session deletion statistics/Total sessions fully deleted
Specifies total count of completely deleted sessions.

Subscriber session deletion statistics/Sessions replaced
Specifies total count of sessions that were deleted because they were replaced by other sessions.

Subscriber session deletion statistics/Provisioned sessions deleted
Specifies total count of deleted sessions that had been provisioned at the moment of deletion.

Subscriber session deletion statistics/Waiting for provisioning

sessions deleted
Specifies total count of deleted sessions that were pending for provisioning at the moment of deletion.

Subscriber session deletion statistics/Failed provisioning sessions deleted
Specifies total count of deleted sessions that were in provisioning failed state at the moment of deletion.

Subscriber session deletion statistics/Sessions deleted via RADIUS
Specifies total count of sessions deleted by RADIUS accounting stop message.

Subscriber session deletion statistics/Sessions deleted via Gx
Specifies total count of sessions deleted by Gx RAR-t message.

Subscriber session deletion statistics/Sessions deleted due to Gx connectivity problems
Specifies total count of sessions deleted by the Fatal Grace Time timer associated with a diameter endpoint.

Subscriber session deletion statistics/Sessions deleted via Sd
Specifies total count of sessions deleted by Sd RAR-t message.

Subscriber session deletion statistics/Sessions deleted due to Sd connectivity problems
Specifies total count of sessions deleted by the Fatal Grace Time timer associated with a diameter endpoint.

Subscriber session deletion statistics/Sessions deleted via DHCP
Specifies total count of sessions deleted by DHCP release message.

Subscriber session deletion statistics/Sessions deleted due to Inactivity
Specifies total count of sessions deleted due to inactivity for time configured in the tmm.pem.session.inactivitytimeout variable.

Subscriber session deletion statistics/Sessions deleted via iRules
Specifies total count of sessions deleted by iRule command.

Subscriber session deletion statistics/Sessions deleted administratively
Specifies total count of sessions deleted interactively by operator.

Subscriber session deletion statistics/Sessions deleted due to static subscriber removal
Specifies total count of sessions deleted due to deletion of the corresponding static subscriber. This includes sessions that were created by RADIUS accounting start message, but deleted by deletion of static subscriber.

Subscriber session deletion statistics/Pre-configured static subscriber sessions deleted
Specifies total count of deleted sessions, which policies were defined on creation of the corresponding static subscriber. This includes sessions that were configured in static subscriber, but created and deleted by RADIUS accounting messages.

Multiple IP address subscriber sessions/Active sessions with single IP address
Specifies the number of sessions, which are associated with one IP address.

Multiple IP address subscriber sessions/Active sessions with multiple IP addresses
Specifies the number of sessions, which are associated with more than one IP address.

Multiple IP address subscriber sessions/Active sessions with both IPv4 and IPv6 addresses
Specifies the number of sessions, which are associated with one or multiple IPv4 addresses and one or multiple IPv6 addresses

Multiple IP address subscriber sessions/Active sessions with more than one IPv4 address
Specifies the number of sessions, which are associated with more than one IPv4 address.

Multiple IP address subscriber sessions/Active sessions with more than one IPv6 address
Specifies the number of sessions, which are associated with more than one IPv6 address.

Multiple IP address subscriber sessions/Total session IPv4 addresses
Specifies the number of IPv4 addresses associated with existing sessions. IP address uniqueness is not checked, so if the same IP address is added and removed several times, the total counter is incremented the each time address is added.

Multiple IP address subscriber sessions/Total session IPv6 addresses
Specifies the number of IPv6 addresses associated with existing sessions. IP address uniqueness is not checked, so if the same IP address is added and removed several times, the total counter is incremented the each time address is added.

Multiple IP address subscriber sessions/Sessions provisioned after hold timeout
Specifies the number of sessions, which were put on provision hold and were provisioned after the provision hold period finished.

Multiple IP address subscriber sessions/Session IP addresses added after session is provisioned
Specifies the total number of IP addresses that were added to

already provisioned sessions. IP address uniqueness is not checked, so if the same IP address is added and removed several times, this counter is incremented the each time address is added.

Multiple IP address subscriber sessions/Session IP addresses removed without session delete
Specifies the total number of IP addresses that were removed from existing sessions without session deletion. This is possible for sessions associated with multiple IP addresses.

Exceptions, Errors, Other Statistics/Failed provisioning attempts
Specifies the aggregated number of failed provisioning attempts for all subscribers in the system since the last reset of the counter. For example, a provisioning attempt fails if a policy server (PCRF) returns an error, or does not respond for any reason.

Exceptions, Errors, Other Statistics/Subscriber Limit Exceeded
Specifies the count of the session creation failures, which are caused by exceeding the max number of subscribers supported by one processing unit (TMM).

Exceptions, Errors, Other Statistics/Session IP address limit exceeded
Specifies the count of the session creation or update failures, which are caused by exceeding the max number of IP addresses per session.

Exceptions, Errors, Other Statistics/Attempts to remove non-existent session via RADIUS
Specifies the count of attempts to remove session by RADIUS accounting stop message, which failed because the session was not found.

Exceptions, Errors, Other Statistics/Attempts to remove non-existent session via DHCP
Specifies the count of attempts to remove session by DHCP release message, which failed because the session was not found.

Exceptions, Errors, Other Statistics/Attempts to remove non-existent session via Gx
Specifies the count of attempts to remove session by Gx RAR-t message, which failed because the session was not found.

Exceptions, Errors, Other Statistics/Attempts to remove non-existent session via Sd
Specifies the count of attempts to remove session by Sd RAR-t message, which failed because the session was not found.

Exceptions, Errors, Other Statistics/Attempts to remove non-existent session via iRules
Specifies the count of attempts to remove session by iRule command, which failed because the session was not found.

Exceptions, Errors, Other Statistics/Subscriber sessions with activity log enabled
Specifies the number of sessions for which the activity log was enabled.

You can reset the PEM subscriber statistics using reset-stats command.

EXAMPLES

```
show subscriber
```

Displays the PEM subscriber statistics.

```
reset-stats subscriber
```

Resets the PEM subscriber statistics.

OPTIONS

For information about the options that you can use with the command show, see help show.

pem stats tethering

tethering - Displays and resets PEM tethering statistics.

MODULE

pem stats

SYNTAX

Display statistics for the tethering component within the pem stats module using the syntax in the following section.

DISPLAY

show tethering

option:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION

You can use the tethering component to display PEM tethering statistics. The statistics details are described below:

Subscribers Monitored

Specifies the number of subscribers being monitored for tethering since the last reset of the counter.

Subscribers Tethering

Specifies the number of subscribers tethering since the last reset of the counter.

Subscribers Tethering Maximum

Specifies the maximum number of subscribers that were found to be tethering at any point since the last reset of the counter.

You can reset the PEM tethering statistics using reset-stats command.

EXAMPLES

show tethering

Displays the PEM tethering statistics.

reset-stats tethering

Resets the PEM tethering statistics.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, pem stats action, pem stats gx, pem stats gy, pem stats radius, pem stats subscriber, pem stats hsl, tmsh

pem subscriber-attribute

NAME

subscriber-attribute - Configures subscriber attributes in Policy Enforcement Manager (PEM).

MODULE

pem

SYNTAX

Configure the subscriber-attribute component within the pem module using the syntax shown in the following sections.

CREATE/EDIT/MODIFY

create subscriber-attribute [name]

modify subscriber-attribute [name]

options:

app-service [[string] | none]

description [string]

export [disabled | enabled]

import [disabled | enabled]

well-known-attr-id [called-station-id | calling-station-id | imeisv | imsi | ipaddr | not-defined | subs-id | user]

edit subscriber-attribute [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

DISPLAY

list subscriber-attribute

list subscriber-attribute [[[name] | [glob] | [regex]] ...]

```
show running-config subscriber-attribute
show running-config subscriber-attribute [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
```

```
DELETE
delete subscriber-attribute [name]
```

Note: You must remove all references to a subscriber-attribute before you can delete the subscriber-attribute.

DESCRIPTION
You can use the subscriber-attribute component to configure subscriber attribute definitions in Policy Enforcement Manager.

EXAMPLES

```
create subscriber-attribute 3gpp_imsi { import enabled export enabled
well-known-attr-id imsi}

Creates a PEM subscriber attribute 3gpp_imsi with import enabled,
export enabled, and well-known attribute id 'imsi'.

delete subscriber-attribute 3gpp_imsi

Deletes the PEM subscriber attribute named 3gpp_imsi.

list subscriber-attribute 3gpp_imsi

Displays the properties of the PEM subscriber attribute named
3gpp_imsi.
```

OPTIONS

app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description
User defined description.

export
Specifies whether the subscriber attribute can be exported (inserted) to the outgoing messages defined in pem protocol profile. This configuration is not applicable when referenced in pem protocol profile radius. It is applicable when referenced in pem protocol profile gx. The default value is enabled.

import
Specifies whether the subscriber attribute can be imported (parsed) from the incoming messages defined pem protocol profile. The default value is enabled.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition
Displays the name of the administrative partition within which the subscriber attribute resides.

well-known-attr-id
Specifies an identifier of a well-known (build-in) subscriber attribute. The system provides a special handling for well-known subscriber attributes. For instance, most of the well-known attributes are included into session reporting records by default.

The options are:

called-station-id
The well-known subscriber attribute ID is called-station-id.

calling-station-id
The well-known subscriber attribute ID is calling-station-id.

imeisv
The well-known subscriber attribute ID is imeisv.

imsi The well-known subscriber attribute ID is imsi.

ipaddr
The well-known subscriber attribute ID is ipaddr. It can be ipv4 or ipv6 address.

not-defined
The well-known subscriber attribute ID is not defined. This is the default value.

subs-id
The well-known subscriber attribute ID is subs-id.

user-location-info
The well-known subscriber attribute ID is user-location-info.

username
The well-known subscriber attribute ID is username.

SEE ALSO

BIG-IP 2016-03-14 pem subscriber-attribute(1)

pem subscriber

NAME
subscriber - Configures subscribers for the Policy Enforcement Manager (PEM).

MODULE
pem

SYNTAX
Modify static subscriber component within PEM module using the syntax shown in the following sections.

```
CREATE/MODIFY
create subscriber [name]
modify subscriber [name]
options:
  app-service [[string] | none]
  ip-address-list [add | delete | replace-all-with] {
    [ip address ...]
  }
  policies [add | delete | replace-all-with] {
    [policy_name ...]
  }
  policies [default | none]
  subscriber-id-type [dhcp | dhcp-custom | e164 | imsi | mac-address | mac-dhcp | nai | private ]

edit subscriber [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list subscriber
list subscriber [ [ [name] | [glob] | [regex] ] ... ]
show running-config subscriber
show running-config subscriber [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

DELETE
delete subscriber [name]
```

Note: You must remove all references to a subscriber before you can delete the subscriber.

DESCRIPTION

You can use the subscriber component to configure subscriber definitions for the Policy Enforcement Manager. Subscriber session IP addresses may optionally include a route domain ID. When specified, the route domain ID follows the IP address, after '%' separator. For example, 10.10.10.100%5 is an IP address in route domain 5. A subscriber session may have multiple IP addresses in different route domains.

EXAMPLES

```
create subscriber 4085551212 { ip-address-list add { 10.10.10.2
10.10.10.3 } policies add { policy1 } subscriber-id-type imsi }
```

Creates a PEM subscriber 4085551212 with IP addresses 10.10.10.2 and 10.10.10.3, subscriber id type imsi, and a policy policy1.

```
create subscriber 4085551212 { ip-address-list add { 10.10.10.2%5
10.10.10.3%77 } policies add { policy1 } subscriber-id-type imsi }
```

Creates a PEM subscriber 4085551212 with IP addresses 10.10.10.2 and 10.10.10.3 in route domains 5 and 77 respectively, subscriber id type imsi, and a policy policy1.

```
create subscriber 4085551212 { ip-address-list add { 10.10.10.2%5
10.10.10.2%77 } policies add { policy1 } subscriber-id-type imsi }
```

Creates a PEM subscriber 4085551212 with two IP address entries that consist of the same IP address 10.10.10.2 and different route domain IDs: 5 and 77, subscriber id type imsi, and a policy policy1.

delete subscriber subl

Deletes the subscriber named subl.

list subscriber subl

Displays the properties of the subscriber named subl.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

name Specifies a unique subscriber identifier (up to 64 characters). This option is required for the commands create, delete, and modify.

ip-address-list

Adds, deletes, or replaces a list of the ip address to associate with the subscriber.

policies

Adds, deletes, or replaces a set of the policies to associate with the subscriber.

subscriber-id-type

Specifies the format to use for the subscriber id. The default value is imsi.

The options are:

dhcp For subscribers discovered via DHCP: an identifier comprises either Relay Option (option 82) for DHCPv4 based subscriber IDs or REMOTE-ID and SUBSCRIBER-ID Options (options 37 and 38) for DHCPv6, as configured in the corresponding DHCP profile.

dhcp-custom

For subscribers discovered via DHCP: an identifier created using a custom TCL snippet.

e164 A numbering plan that defines the format of an MSISDN international phone number (up to 15 digits). The number typically consists of three fields: country code, national destination code, and subscriber number.

imsi International Mobile Subscriber Identity. A globally unique code number that identifies a GSM, UMTS, or LTE mobile phone user.

mac-address

For subscribers discovered via DHCP: subscriber MAC address in a standard IEEE 802 format for MAC-48 (six groups of two hexadecimal digits, separated by colons ':').

mac-dhcp

For subscribers discovered via DHCP: a concatenation of mac-address and dhcp identifier as configured in the corresponding DHCP profile.

nai Network Access Identifier. A fully qualified network name in the form @; identifies a subscriber and the home network to which the subscriber belongs.

private

The subscriber id type is private for the given deployment.

BIG-IP 2016-03-14 pem subscriber(1)

NAME
subscribers - Loads static subscribers for the Policy Enforcement Manager (PEM) from a file.

MODULE
pem

SYNTAX
Loads static subscribers from a file within the pem module using the syntax shown in the following sections.

LOAD
load subscribers file [filename]

DESCRIPTION
You can use the command load pem subscribers to load static subscribers definitions for the Policy Enforcement Manager (PEM). The maximum number of static subscribers allowed is (2 * sys db variable tmm.pem.spm.maxsessionlimit) or 100000, whichever is the lesser.

The static subscribers file is a csv file with the following fields: ,,[,]*[,]+. Each record can have zero IP address but must have at least one policy.

The maximum number of IP addresses per subscriber is set by sys db variable tmm.pem.session.ip.addr.max.

The maximum number of IPv4 addresses per subscriber is set by sys db variable tmm.pem.session.ipv4.addr.max.

The maximum number of IPv6 addresses per subscriber is set by sys db variable tmm.pem.session.ipv6.addr.max.

For example, these are the examples from such file:

```
subscriber1,e164,2,11.1.1.1,11.1.1.2,bronze,gold,silver
subscriber2,imsi,0,gold
```

The filename either absolute file name or just the base file name under folder: /var/local/pem/subscribers/

For more information about static subscriber, please refer to pem subscriber module.

EXAMPLES
load subscribers file my_ss_file

Loads static subscribers from file "my_ss_file" under the folder: /var/local/pem/subscribers/.

load subscribers file /shared/tmp/new_ss_file

Loads static subscribers from file "new_ss_file" under the folder: /shared/tmp/.

security

security analytics settings

NAME
settings - Configure global settings for security (AFM) analytics.

MODULE
security analytics

SYNTAX
Configure the settings component within the security analytics module using the syntax shown in the following sections.

MODIFY
modify settings
options:

```

acl-rules {
  collect-client-ip [enabled | disabled]
  collect-client-port [enabled | disabled]
  collect-dest-ip [enabled | disabled]
  collect-dest-port [enabled | disabled]
  collect-server-side-stats [enabled | disabled]
}
collected-stats-internal-logging [enabled | disabled]
collected-stats-external-logging [enabled | disabled]
dns {
  collect-client-ip [enabled | disabled]
}
dos-12-14 {
  collect-client-ip [enabled | disabled]
}
13-14-errors {
  collect-client-ip [enabled | disabled]
  collect-dest-ip [enabled | disabled]
}
publisher [name]
smtp-config [name]
stale-rules {
  collect [enabled | disabled]
}

```

```

DISPLAY
list settings

```

DESCRIPTION
 Use the settings component to modify the settings for analytics entity collection for the AFM (advanced firewall) module.

EXAMPLES
 modify settings acl-rules { collect-client-ip disabled }
 Disables source/client IP analytics collection for ACL rules.
 list settings
 Displays analytics settings for AFM.

OPTIONS

acl-rules
 Firewall (ACL) security statistics collection options.

collect-client-ip
 Specifies whether source/client IP address should be collected for ACL rule matching.

collect-client-port
 Specifies whether source/client port should be collected for ACL rule matching.

collect-dest-ip
 Specifies whether the destination IP address should be collected for ACL rule matching.

collect-dest-port
 Specifies whether the destination port should be collected for ACL rule matching.

collect-server-side-stats
 Specifies whether server side statistics (source address translation information, self IP address and pool member address) should be collected for ACL rule matching.

collected-stats-internal-logging
 Enables or disables the internal logging of the collected statistics.

collected-stats-external-logging
 Enables or disables the external logging of the collected statistics.

dns DNS security statistics collection options.

collect-client-ip
 Specifies whether source/client IP address should be collected for DNS security.

dos-12-14
 Network DoS security statistics collection options.

collect-client-ip
 Specifies whether source/client IP address should be collected for network layer's DoS security.

13-14-errors
 Firewall errors statistics collection options.

collect-client-ip
 Specifies whether source/client IP address should be collected for firewall errors.

collect-dest-ip
 Specifies whether the destination IP address should be collected for firewall errors.

publisher
 Specifies the external logging publisher used to send statistical data to one or more destinations.

smtp-config
 Specifies the default SMTP configuration used for exporting CSV or

PDF security analytics reports.

```
    stale-rules
collect
Specifies whether statistics about all firewall rules should
be collected in order to present information regarding rule
staleness.
```

security anti-fraud engine-update

NAME

engine-update - Runs or loads an Anti-fraud engine update.

MODULE

security anti-fraud

SYNTAX

Run or load the engine-update component within the security anti-fraud module using the syntax in the following sections:

LOAD

```
load engine-update
options:
file [filename]
```

If optional parameter file filename is specified in the load command, the command loads and installs engine update from local file instead of the cloud.

RUN

```
run engine-update
```

DISPLAY

```
list engine-update
options:
all-properties
current-version-create-datetime
download-available
install-datetime
install-user
message
non-default-properties
one-line
partition
progress-status
progress-status-datetime
last-update-check-datetime
readme
```

DESCRIPTION

You can use the engine-update component to run, load or display status of engine update.

EXAMPLES

```
list security anti-fraud engine-update
```

Displays the status of engine update.

OPTIONS

```
current-version-create-datetime
Displays the creation time of currently installed engine update
version.
```

```
download-available
Displays whether new engine version is available for download from
the cloud.
```

```
file Specifies the file name from which the engine update is going to
be installed when using the load command. A full path should be
specified.
```

```
install-datetime
Displays the time when engine update was installed.
```

```
install-user
Displays the name of the user who installed the last engine
```

update.

message
Displays the message describing the failure status of engine update.

partition
Displays the administrative partition within which this object resides.

progress-status
Displays the engine update progress status.

progress-status-datetime
Displays the time when engine update progress status was last changed.

last-engine-check-datetime
Displays the time when last checked for engine update.

readme
Displays the Readme content for the current engine update.

DESCRIPTION
You can use the profile component to create, modify, display, or delete an Anti-Fraud profile.

Note: The users property may be specified only for the commands modify, edit, and list and only when no other properties are specified. By default, users are not displayed.

Note: The first-login-time property of user modes may be specified only for the list command.

EXAMPLES
create profile my_antifraud_profile

Creates a custom Anti-Fraud profile named my_antifraud_profile with default parameters.

list profile

Displays the properties of all Anti-Fraud profiles.

OPTIONS

alert-client-side-caching
Specifies whether or not to cache the sent alerts in order to prevent multiple alerts from being sent to the dashboard.

alert-identifier
Specifies the ID of the customer in the dashboard.

alert-path
Specifies the BIG-IP URL path where the alert is sent. This path cannot be none and must start with '/'.
/

alert-pool
Specifies the name of the pool used when the system sends alerts.

alert-publisher
Specifies the name of the log publisher used for sending alerts originating from the BIG-IP. If only DPS is licensed, this publisher is used for reporting encryption failures.

alert-token-header
Specifies the name of the custom HTTP header in alerts for exchanging a random token between the client side and the BIG-IP.

app-service
Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

auto-transactions
Specifies how the system differentiates between human and automatic (bot) transactions. You can configure the following options for automatic transactions:

bot-score
Deprecated since v13.0.0. Please use bot-score in auto-transactions under urls instead. Specifies the score added to an alert that is triggered if the system determines that the client is a bot and not a human. The default is a score of 50.

click-score
Deprecated since v13.0.0. Please use click-score in auto-transactions under urls instead. Specifies the score added to an alert that is triggered if the min-mouse-over-count and min-mouse-move-count conditions are not met. The default is a score of 40.

integrity-fail-score
Deprecated since v13.0.0. Please use integrity-fail-score in auto-transactions under urls instead. Specifies the score added to an alert that is triggered if the system detects a difference between the actual parameter value and the expected value of a protected parameter sent after a user clicks a web form's Submit button. The default is a score of 40.

min-mouse-move-count
Deprecated since v13.0.0. Please use min-mouse-move-count in auto-transactions under urls instead. Specifies the minimum number of mouse movements necessary per page load in order for the system to consider the transaction to be of human

origin. The default is 5 movements.

min-mouse-over-count
Deprecated since v13.0.0. Please use `min-mouse-over-count` in `auto-transactions` under `urls` instead. Specifies the minimum number of times the client's mouse is positioned over the Submit button in a web form in order for the system to consider the transaction to be of human origin. The default is 2 button interactions.

min-report-score
Deprecated since v13.0.0. Please use `min-report-score` in `auto-transactions` under `urls` instead. Specifies the lowest score necessary for the system to send an alert. The default value is 50.

min-time-to-request
Deprecated since v13.0.0. Please use `min-time-to-request` in `auto-transactions` under `urls` instead. Specifies the minimum amount of time (in seconds) permitted between when a web form is opened and the Submit button is clicked. The default is 2 seconds.

not-human-score
Deprecated since v13.0.0. Please use `not-human-score` in `auto-transactions` under `urls` instead. Specifies the score added to an alert that is triggered if the system only suspects that the client is a bot and not a human. The default is a score of 25.

strong-integrity
Specifies how the system performs strong integrity. You can configure the following options for strong integrity:

hide-encrypted-parameters
Specifies, when enabled, that JavaScript does not add the expected value of encrypted parameters to strong integrity parameter.

parameter
Specifies the name of the HTTP parameter in POST requests added by JavaScript with the expected user-input data verified with physical input events.

tampered-cookie-score
Deprecated since v13.0.0. Please use `tampered-cookie-score` in `auto-transactions` under `urls` instead. Specifies the score added to an alert that is triggered if the system detects that the transaction-data cookie was tampered with. The default is a score of 50.

time-fail-score
Deprecated since v13.0.0. Please use `time-fail-score` in `auto-transactions` under `urls` instead. Specifies the score added to an alert that is triggered if the `min-time-to-request` condition is not met. The default is a score of 20.

before-load-function
Specifies the implementation of additional function to be run before JavaScript load, in the following format: `function(configs){...}`. Note: For certain advanced configurations, F5 support may provide relevant code to be entered here, please do not use it on your own.

blocking-page
Specifies information to display when the profile blocks a user account. You can configure the following options for blocking page:

response-body
Specifies the HTML code the system sends to the user whose account is blocked.

response-headers
Specifies the set of response headers that the system sends to the user whose account is blocked. Separate each header with a new line (Ctrl-V followed by Ctrl-J).

[`case-sensitive` | `case-insensitive`]
Specifies whether the profile treats protected URL paths as case sensitive, or not. The default value is `case-insensitive`. Note: If you create a profile, you can use either property, thereafter it becomes read only. If the profile is case insensitive, the system stores protected URL paths in lowercase in the profile configuration.

cloud-service-pool
Specifies the name of the pool used by the system for various internal purposes, like signing Forensics tool.

config-location
Specifies the BIG-IP URL directory where the configuration for the injected JavaScript is located. The path here does not include the actual filename of the configuration for the injected JavaScript. This path cannot be none and must start with `'/'`.

cookies
Specifies names and lifetimes for the cookies that the system uses to optimize its detection of malware, data transactions, and phishing attacks on the web application. If you do not assign a name to a cookie, a random name is assigned. You can configure the following cookies:

application

Adds, deletes, or replaces a set of application cookies that will be removed if at least one of the protected cookies is missing.

base-domain

Specifies base domain settings for the cookies. You can configure the following options for base domain:

apply

Specifies, when enabled, that the system applies the cookies to the base domain.

exceptions

Adds, deletes, or replaces a set of exceptional base domains that take precedence when the system resolves the base domain from a host header.

client-side

Specifies the name of the cookie in which the system inserts plain text with a record about client side alerts already sent. This is done in order to prevent flooding the system with additional alerts if the page reloads.

client-side-lifetime

Specifies whether the client-side cookie is persistent, and if so, after how many minutes it expires.

components-state

Specifies the name of the cookie that verifies that the system's expected JavaScript can run successfully, and whether the system successfully decrypted configuration data arriving from server.

components-state-lifetime

Specifies whether the components-state cookie is persistent, and if so, after how many minutes it expires.

components-state-removal-protection

Enables or disables protection of the secure-alert cookie from removal.

encryption-disabled

Specifies the name of the cookie that the system adds if the system fails to decrypt a password (to restore the original password as the user typed it), and the system forwards a request to the server and waits for a login failure response. In this case, the cookie does not encrypt the password on the next login attempt. This is used in situations where Application layer encryption is not possible (for example, if the user is using an old browser that cannot encrypt passwords).

encryption-disabled-lifetime

Specifies whether the encryption-disabled cookie is persistent, and if so, after how many minutes it expires.

encryption-disabled-removal-protection

Enables or disables protection of the encryption-disabled cookie from removal.

fingerprint

Specifies the name of the cookie that contains fingerprint data.

fingerprint-lifetime

Specifies whether the fingerprint cookie is persistent, and if so, after how many minutes it expires.

fingerprint-removal-protection

Enables or disables protection of the fingerprint cookie from removal.

html-field-obfuscation

Specifies the name of the cookie that the system sets to identify the fields that were created by HTML field obfuscation, in order to remove them from the request before sending it back to the web application, and to know which field names to decrypt.

html-field-obfuscation-lifetime

Specifies whether the html-field-obfuscation cookie is persistent, and if so, after how many minutes it expires.

malware-forensic

Specifies the name of the cookie that stores the essential response header values from the web application to be sent to the user after he finishes or skips downloading and running Forensics tool on his host.

malware-forensic-lifetime

Specifies whether the malware-forensic cookie is persistent, and if so, after how many minutes it expires.

malware-guid

Specifies the name of the cookie set by JavaScript to a random string (12 chars long, not encrypted). The system sends this cookie value in a special alert to the dashboard in order to associate it with the logged in user.

malware-guid-lifetime

Specifies whether the malware-guid cookie is persistent, and if so, after how many minutes it expires.

malware-guid-removal-protection

Enables or disables protection of the malware-guid cookie from removal.

rules

Specifies the name of the cookie that the system sets in order to perform the actions block-user, forensic, inspection, remediation, or redirect.

rules-lifetime

Specifies whether the rules cookie is persistent, and if so, after how many minutes it expires.

rules-removal-protection

Enables or disables protection of the rules cookie from removal.

secure-alert

Specifies the name of the cookie that secures arrival of alerts originating from JavaScript to the dashboard.

secure-alert-lifetime

Specifies whether the secure-alert cookie is persistent, and if so, after how many minutes it expires.

secure-alert-removal-protection

Enables or disables protection of the secure-alert cookie from removal.

secure-channel

Specifies the name of the cookie that the system sets when the system provides JavaScript with a public key for encryption operations. This cookie is used for the system to correlate incoming encrypted data with the private key when a request comes from the client.

secure-channel-lifetime

Specifies whether the secure-channel cookie is persistent, and if so, after how many minutes it expires.

secure-channel-removal-protection

Enables or disables protection of the secure-channel cookie from removal.

transaction-data

Specifies the name of the cookie that contains information (such as mouse movement, clicks, and events) in encrypted format and sends that information to the system.

transaction-data-lifetime

Specifies whether the transaction-data cookie is persistent, and if so, after how many minutes it expires.

user-inspection

Specifies the name of cookie that is set once a user is identified in a web form submitted by the client and this user is enforced in inspection mode.

user-name

Specifies the name of the cookie with the username value after a username is identified in a request. This ensures that further transactions from the client are still associated with that user even if they do not include the username field.

user-name-lifetime

Specifies whether the user-name cookie is persistent, and if so, after how many minutes it expires.

user-name-removal-protection

Enables or disables protection of the user-name cookie from removal.

debug

Specifies troubleshooting settings to add and filter debug logs of the system. Note: Only F5 support should configure this section, please do not use it on your own. F5 support can configure the following debug options:

console-log

Specifies when the system add prints to browser console. TMM logs are also enabled in such cases. F5 support can configure the following options for console log:

client-ips

Adds, deletes, or replaces a set of client IP addresses for which the system adds prints to browser console.

user-agents

Adds, deletes, or replaces a set of strings contained in user-agent header for which the system adds prints to browser console.

fingerprints

Adds, deletes, or replaces a set of strings contained in fingerprint data for which the system adds prints to browser console.

send-alert

Specifies when the system sends debug alerts to the dashboard. TMM logs are also enabled in such cases. F5 support can configure the following options for sending alerts:

client-ips

Adds, deletes, or replaces a set of client IP addresses for which the system sends debug alerts to the dashboard.

user-agents

Adds, deletes, or replaces a set of strings contained in user-agent header for which the system sends debug alerts to the dashboard.

fingerprints

Adds, deletes, or replaces a set of strings contained in fingerprint data for which the system sends debug alerts to the dashboard.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified.

description

User defined description.

encryption-staging-mode

Specifies, when enabled, that the system activates Anti-fraud encryption staging mode. If decrypted data differs from original data, an alert will be sent and original data will be used.

fingerprint

Specifies how the system collects fingerprint data. You can configure the following fingerprint options:

collect

Specifies, when enabled, that the system collects fingerprint data.

location

Specifies the BIG-IP URL location of the fingerprint JavaScript. This path cannot be none and must start with '/'.

forensic

Specifies how the system enforces scanning client host for malware (Forensics) and its removal (remediation). You can configure the following options for Forensics and remediation:

alert-path

Specifies the BIG-IP URL path for alerts from Forensics tool. This path cannot be none and must start with '/'.

client-domains

Adds, deletes, or replaces a set of client domains to be resolved by Forensics tool.

cloud-config-path

Specifies the BIG-IP URL path for requests from Forensics tool to cloud-service-pool. This path cannot be none and must start with '/'.

cloud-forensics-mode

Specifies the numeric value sent to cloud-service-pool to download Forensics tool.

cloud-remediation-mode

Specifies the numeric value sent to cloud-service-pool to download Forensics tool in remediation mode.

continue-element

Specifies the HTML element with continue option that replaces %SKIP_PART% in the entire html, when enforce-policy is enforce. Note: This property may be modified only when the DB variable antifraud.forensic.showgui has value enable.

exe-location

Specifies the BIG-IP URL path to download Forensics tool that also replaces %EXE_LOCATION% in the entire html. This path cannot be none and must start with '/'.

html Specifies the HTML code the system sends to the user after successful login with option to download Forensics tool. Note: This property may be modified only when the DB variable antifraud.forensic.showgui has value enable.

self-post-location

Specifies the BIG-IP URL path for self POST page opened by Forensics tool during scanning. This path cannot be none and must start with '/'.

skip-element

Specifies the HTML element with skip option that replaces %SKIP_PART% in the entire html, when enforce-policy is not enforce. Note: This property may be modified only when the DB variable antifraud.forensic.showgui has value enable.

skip-path

Specifies the BIG-IP URL path for skip / continue option that also replaces %SKIP_PATH% in both continue-element and skip-element (before their replacement in the entire html). This path cannot be none and must start with '/'.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

javascript-grace-threshold

Specifies the maximum amount of time (in seconds) permitted between when a protected web page is loaded and its injected

JavaScript activates.

javascript-location
Specifies the BIG-IP URL directory where the injected JavaScript is located. The path here does not include the actual filename of the injected JavaScript. This path cannot be none and must start with '/'.

javascript-removal-location
Specifies the BIG-IP URL location of the JavaScript removal detection location. This path cannot be none and must start with '/'.

inject-main-javascript
Deprecated since v12.1.3 (excluding v13.0.0). Please use same configuration in a specific URL instead. Specifies where the system injects the main JavaScript. You can configure the following options for main JavaScript injection position:

[after | before]

Deprecated since v12.1.3 (excluding v13.0.0). Please use same configuration in a specific URL instead. Specifies whether the system injects the main JavaScript after an opening tag or before a closing tag.

tag Deprecated since v12.1.3 (excluding v13.0.0). Please use same configuration in a specific URL instead. Specifies the HTML tag for injection of the main JavaScript. This tag cannot be none.

local-syslog-publisher
DPS mode only. Specifies the name of the log publisher used for reporting encryption failures.

malware
Specifies how the system detects a malware attack on the web application. You can configure the following options for Malware protection:

allowed-domains
Adds, deletes, or replaces a set of whitelisted domains. The system does not send alerts on requests for URLs from these domains, even if the system detects malware injection on these domains.

bait-check-generic
Specifies, when enabled, that the system checks predefined baits. Note: The configured baits are checked anyway.

bait-location
Specifies the BIG-IP URL location of a file that acts as bait for attackers. This path cannot be none and must start with '/'.

blacklist-words
Deprecated since v13.0.0. Please use **blacklist-js-words** and **blacklist-words** in **detected-malware** instead. Adds, deletes, or replaces a set of words that are blacklisted if they appear in the web application's HTML or JavaScript code. If the system detects these words, the system generates a malware alert.

detected-malware
Adds, deletes, or replaces a set of malware detected by the system. You can configure the following options for each malware:

baits
Adds, deletes, or replaces a set of baits for this malware. You can configure the following options for each bait:

data-before
Specifies the HTML code that the malware searches and injects data-inject after it.

data-inject
Specifies the malicious code that the malware injects after data-before.

trigger-url
Specifies trigger URL settings for this bait. You can configure the following options for trigger URL:

name Specifies the URL pattern that triggers the malware to inject malicious code.

position
Specifies the position of this URL pattern in the query string of a bait request.

alone
Specifies that this trigger URL must be alone in the query string of a bait request.

any Specifies that the this trigger URL can be anywhere in the query string of a bait request. This is the default value.

last Specifies that the this trigger URL must be last in the query string of a bait request.

blacklist-functions
Adds, deletes, or replaces a set of regular expression patterns to detect functions that this malware can use when executing AJAX requests.

blacklist-js-words
Adds, deletes, or replaces a set of words that are blacklisted if they appear in the JavaScript code. If the system detects these words, the system generates a malware alert.

blacklist-urls
Adds, deletes, or replaces a set of regular expression patterns to detect URLs that this malware can use for AJAX requests and external scripts.

blacklist-words
Adds, deletes, or replaces a set of words that are blacklisted if they appear in the web application's HTML code. If the system detects these words, the system generates a malware alert.

browser-cache
Specifies how the system checks client network connection as targeted method. You can configure the following options for Browser cache:

blacklist-urls
Adds, deletes, or replaces a set of resources that are loaded by the malware.

whitelist-urls
Adds, deletes, or replaces a set of non-existent resources.

domain-availability
Specifies how the system checks client network connection as generic method. You can configure the following options for Domain availability:

blacklist-urls
Adds, deletes, or replaces a set of URLs that are not blocked by the malware.

whitelist-urls
Adds, deletes, or replaces a set of URLs that are blocked by the malware.

generic-whitelist-words
Adds, deletes, or replaces a set of generic blacklisted words that are ignored.

domain-availability-urls
Deprecated since v13.0.0. Please use **blacklist-urls** and **whitelist-urls** in **domain-availability** under **detected-malware** instead. Specifies a JSON object containing URLs for which client network connectivity should be checked.

external-sources-targets
Adds, deletes, or replaces a set of HTML element types and their attributes for which external injections should be checked.

flash-cookie-content
Specifies the flash file (in hexadecimal format) used to allow JavaScript to access the Flash object on the client side. The default content is none. The length is limited to 64k.

flash-cookie-location
Specifies the BIG-IP URL location of the SWF file that JavaScript requests to get the Flash file. This path cannot be none and must start with '/'.

flash-cookies
Specifies, when enabled, that the system may use a Flash shared object (FSO) as a place to store an alternative malware cookie. This cookie tells the system, after a login attempt, that this user has malware, and the system sends an alert.

generic-whitelist-words
Deprecated since v13.0.0. Please use **generic-whitelist-words** in **detected-malware** instead. Adds, deletes, or replaces a set of generic blacklisted words that are ignored.

inline-scripts-whitelist-signatures
Adds, deletes, or replaces a set of signatures for allowed inline scripts. In case a signature appears as part of JavaScript inline script, the system does not count this script in the source integrity feature.

removed-scripts
Specifies how the system detects self-removed malicious scripts. You can configure the following options for removed scripts detection:

blacklist-functions
Adds, deletes, or replaces a set of functions that are used for detecting self-removed malicious scripts.

whitelist-functions
Adds, deletes, or replaces a set of functions that are

NOT used for detecting self-removed malicious scripts.

same-domain-scripts-validation-header

Specifies the name of the custom HTTP header used to identify PING-PONG requests between JavaScript and BIG-IP for same-domain scripts validations. This name cannot be none.

self-bait-header

Specifies the name of the custom HTTP header used to identify self-bait requests from JavaScript to BIG-IP for malicious injections scan. This name cannot be none.

source-integrity-location

Specifies the BIG-IP URL path where the system collects information about the HTML source from multiple users. This path cannot be none and must start with '/'.

web-rootkit

Specifies how the system detects Web-RootKit malware. You can configure the following options for Web-RootKit detection:

blacklist-functions

Adds, deletes, or replaces a set of additional functions to be checked.

whitelist-functions

Adds, deletes, or replaces a set of native functions that are allowed to be overwritten.

mobilesafe

Specifies how the system detects and prevents phishing, Trojan, and pharming attacks on mobile devices in real time. You can configure the following options for mobile security:

alert-custom-config

Specifies alert custom configuration for SDK forward compatibility. Note: For certain advanced configurations, F5 support may provide a relevant string to be entered here, please do not use it on your own.

alert-threshold

Specifies the minimal score for sending alerts from mobile devices.

app-integrity

Specifies how the system checks if the application on the mobile device has been tampered with. You can configure the following options for Application integrity:

custom-config

Specifies custom configuration of Application integrity for SDK forward compatibility. Note: For certain advanced configurations, F5 support may provide a relevant string to be entered here, please do not use it on your own.

[enabled | disabled]

Enables or disables Application integrity.

android

Specifies Application integrity settings for Android platform. You can configure the following options for Android Application integrity:

score

Specifies Application integrity score for Android platform.

signature

Specifies signature of Android application (in hexadecimal format).

ios Specifies Application integrity settings for iOS platform. You can configure the following options for iOS Application integrity:

hashes

Adds, deletes, or replaces a set of iOS Application hashes (in base64-encoded format). You can configure the following options for iOS Application hash:

version

Specifies iOS Application version for this hash.

score

Specifies Application integrity score for iOS platform.

general-custom-config

Specifies general custom configuration for SDK forward compatibility. Note: For certain advanced configurations, F5 support may provide a relevant string to be entered here, please do not use it on your own.

malware

Specifies how the system checks for malicious applications on the customer's mobile devices. You can configure the following options for Malware detection:

android

Specifies Malware detection settings for Android platform. You can configure the following options for

Android Malware detection:

custom-malware

Adds, deletes, or replaces a custom set of checked malware for Android platform. You can configure the following options for each Android malware:

package

Specifies package of checked Android malware.

score

Specifies score for checked Android malware.

custom-whitelist

Adds, deletes, or replaces a custom set of whitelist applications for Android platform. You can configure the following options for each whitelist Android application:

package

Specifies package of whitelist Android application.

check-custom

Enables or disables custom malware check.

check-generic

Enables or disables generic malware check.

custom-config

Specifies custom configuration of Malware detection for SDK forward compatibility. Note: For certain advanced configurations, F5 support may provide a relevant string to be entered here, please do not use it on your own.

[enabled | disabled]

Enables or disables Malware detection.

ios Specifies Malware detection settings for iOS platform. You can configure the following options for iOS Malware detection:

custom-malware

Adds, deletes, or replaces a custom set of checked malware for iOS platform. You can configure the following options for each iOS malware:

path Specifies path of checked iOS malware.

score

Specifies score for checked iOS malware.

custom-whitelist

Adds, deletes, or replaces a custom set of whitelist applications for iOS platform. You can configure the following options for each whitelist iOS application:

path Specifies path of whitelist iOS application.

behaviour-analysis

Specifies how the system checks for suspicious behavior and characteristics on all applications on the customer's mobile devices. You can configure the following options for behavior analysis:

run Enables or disables behaviour analysis run.

score

Specifies score for behavior analysis.

mitm Specifies how the system checks the defined domains for DNS Spoofing and Certificate Forging on customer devices. You can configure the following options for Man-in-the-middle detection:

certificate-custom-config

Specifies custom configuration of Certificate forging detection for SDK forward compatibility. Note: For certain advanced configurations, F5 support may provide a relevant string to be entered here, please do not use it on your own.

dns-custom-config

Specifies custom configuration of DNS spoofing detection for SDK forward compatibility. Note: For certain advanced configurations, F5 support may provide a relevant string to be entered here, please do not use it on your own.

domains

Adds, deletes, or replaces a set of domains for Man-in-the-middle detection. You can configure the following options for a MITM domain:

dns Specifies DNS spoofing detection settings for this domain. You can configure the following options for DNS spoofing detection:

ip-ranges

Adds, deletes, or replaces a set of IP address ranges for DNS spoofing detection.

spoofing-score

Specifies score for DNS spoofing detection.

certificate
Specifies Certificate forging detection settings for this domain. You can configure the following options for Certificate forging detection:

forging-score
Specifies score for Certificate forging detection.

hash Specifies certificate hash.

[enabled | disabled]
Enables or disables Man-in-the-middle detection.

os-security
Specifies how the system checks the customer's mobile devices for old, unsupported, and unpatched operation system (OS) versions. You can configure the following options for OS security:

android
Specifies OS security settings for Android platform. You can configure the following options for Android OS security:

versions
Adds, deletes, or replaces an ordered set of version ranges for Android platform. You can configure the following options for Android version range:

from Specifies Android version number from which OS is unpatched.

priority
Specifies a unique ordinal number for Android version range in the set. This option is required for the operations add, delete, modify, and replace-all-with.

score
Specifies score for Android version range.

to Specifies Android version number to which OS is unpatched.

custom-config
Specifies custom configuration of OS security for SDK forward compatibility. Note: For certain advanced configurations, F5 support may provide a relevant string to be entered here, please do not use it on your own.

[enabled | disabled]
Enables or disables OS security.

ios Specifies OS security settings for iOS platform. You can configure the following options for iOS OS security:

versions
Adds, deletes, or replaces an ordered set of version ranges for iOS platform. You can configure the following options for iOS version range:

from Specifies iOS version number from which OS is unpatched.

priority
Specifies a unique ordinal number for iOS version range in the set. This option is required for the operations add, delete, modify, and replace-all-with.

score
Specifies score for iOS version range.

to Specifies iOS version number to which OS is unpatched.

untrusted-apps-score
Specifies score for untrusted applications.

rooting-jailbreak
Specifies how the system checks customer's mobile devices to determine if they are rooted / jailbroken. You can configure the following options for Rooting / Jailbreak detection:

custom-config
Specifies custom configuration of Rooting / Jailbreak detection for SDK forward compatibility. Note: For certain advanced configurations, F5 support may provide a relevant string to be entered here, please do not use it on your own.

[enabled | disabled]
Enables or disables Rooting / Jailbreak detection.

jailbreak-score
Specifies score for jailbreak on iOS platform.

rooting-score
Specifies score for rooting on Android platform.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition
Displays the administrative partition within which the component resides.

phishing
Specifies how the system detects a phishing attempt. You can configure the following options for phishing site detection:

alert-path
Specifies the BIG-IP URL path for alerts from the phishing inline script. This path cannot be none and must start with '/'.

allowed-elements
Adds, deletes, or replaces a set of URLs in requests for which the system does not verify (check) the referrer header value.

allowed-referrers
Adds, deletes, or replaces a set of domain names that are allowed to appear in the referrer header when requesting protected resources.

application-css
Specifies, when enabled, that the system injects the CSS content to the existing application CSS files.

application-css-locations
Adds, deletes, or replaces a set of server URL locations of the application CSS files, used when application-css is enabled.

css-attribute-name
Specifies the attribute name as part of the CSS content. This name cannot be none.

css-location
Specifies the BIG-IP URL location of the CSS file, used when application-css is disabled. Injecting JavaScript protects the web application against phishing attempts because even if an attacker removes the injected JavaScript from the copied web page, the CSS element is not modified, and this triggers an alert. This path cannot be none and must start with '/'.

expiration-checks
Specifies, when enabled, that the system sends an alert if expired JavaScript engine files are used, as this is an indication of a phishing attack.

image-location
Specifies the BIG-IP URL location of the 1x1 pixel image file. If an attacker copies a web page with this image, it most likely lacks the JavaScript, and this triggers an alert. This path cannot be none and must start with '/'.

inject-css-element
Deprecated since v12.1.3 (excluding v13.0.0). Please use same configuration in a specific URL instead. Specifies where the system injects the CSS element. You can configure the following options for CSS element injection position:

[after | before]
Deprecated since v12.1.3 (excluding v13.0.0). Please use same configuration in a specific URL instead. Specifies whether the system injects the CSS element after an opening tag or before a closing tag.

tag
Deprecated since v12.1.3 (excluding v13.0.0). Please use same configuration in a specific URL instead. Specifies the HTML tag for injection of the CSS element. This tag cannot be none.

inject-css-link
Deprecated since v12.1.3 (excluding v13.0.0). Please use same configuration in a specific URL instead. Specifies where the system injects the CSS link, when application-css is disabled. You can configure the following options for CSS link injection position:

[after | before]
Deprecated since v12.1.3 (excluding v13.0.0). Please use same configuration in a specific URL instead. Specifies whether the system injects the CSS link after an opening tag or before a closing tag.

tag
Deprecated since v12.1.3 (excluding v13.0.0). Please use same configuration in a specific URL instead. Specifies the HTML tag for injection of the CSS link. This tag cannot be none.

inject-inline-javascript
Deprecated since v12.1.3 (excluding v13.0.0). Please use same configuration in a specific URL instead. Specifies where the system injects the phishing inline script and image. You can configure the following options for phishing inline script and image injection position:

[after | before]
Deprecated since v12.1.3 (excluding v13.0.0). Please use same configuration in a specific URL instead. Specifies whether the system injects the phishing inline script

and image after an opening tag or before a closing tag.

tag Deprecated since v12.1.3 (excluding v13.0.0). Please use same configuration in a specific URL instead. Specifies the HTML tag for injection of the phishing inline script and image. This tag cannot be none.

protected-elements

Adds, deletes, or replaces a set of URLs in requests for which the system verifies (checks) the referrer header value. You can use wildcards, for example *.gif.

referrer-checks

Specifies, when enabled, that the system verifies (checks) requests coming to the web application for resources from different domains.

referrer-info-header

Specifies the name of the custom HTTP header used by client side to communicate referrer and view identifier to BIG-IP.

risk-engine-publisher

Specifies the name of the log publisher used for reports to a Risk engine.

rules

Adds, deletes, or replaces a set of rules used by the system to perform actions upon detected events. You can configure the following options for each rule:

action

Specifies the type of the action that the system performs when this event is detected. The options are:

block-user

Specifies that the system adds the user with block mode to be enforced from the next login.

forensic

Specifies that the system adds the user with forensic mode to be enforced from the next login.

inspection

Specifies that the system adds the user with inspection mode to be enforced from the next login.

redirect

Specifies that the system redirects the next request to a specific web page.

remediation

Specifies that the system adds the user with remediation mode to be enforced from the next login.

route

Deprecated in v13.1.0. Specifies that the system routes to a specific pool all subsequent requests for a specific time.

web-service

Specifies that the system sends a POST request to a specific Web service.

duration

Specifies number of minutes during which the system performs the action block-user, forensic, inspection, remediation or route.

enforce-policy

Specifies enforcement policy for the action block-user, forensic, inspection or remediation. The options are:

enforce

Specifies that the system adds the user mode with the enforce policy.

time-limited

Specifies that the system adds the user mode with the time-limited policy.

unlimited

Specifies that the system adds the user mode with the unlimited policy.

event

Specifies a unique event for the rule. This option is required for the operations create, delete, modify, and replace-all-with. The options are:

auto-transaction

Specifies that the action is performed when the system detects automatic (bot) transaction.

client-network-connection

Specifies that the action is performed when the system detects that client network connectivity is blocked.

client-side-missing-components

Specifies that the action is performed when the system detects missing components on the client side.

encryption-failure

Specifies that the action is performed when the system fails to decrypt a password.

generic-malware
Specifies that the action is performed when the system detects generic malware.

mandatory-words
Specifies that the action is performed when the system detects that mandatory words are changed in the page.

phishing
Specifies that the action is performed when the system detects a phishing attempt.

phishing-user
Specifies that the action is performed when the system detects a user attacked by a phishing attempt.

rat-detection
Specifies that the action is performed when the system detects a Remote Access Trojan (RAT) on a client web browser.

referrer-checks
Specifies that the action is performed when the system detects a request from a different domain by the referrer header.

server-side-missing-components
Specifies that the action is performed when the system detects missing components on the BIG-IP.

source-integrity
Specifies that the action is performed when the system detects a mismatch of the URL's HTML source code.

web-injection
Specifies that the action is performed when the system detects an attempt to inject malware.

min-score
Specifies the lowest score of this event necessary for the system to perform the action.

payload
Specifies the payload for the web-service action.

pool Specifies the name of the pool for the route action.

publisher
Specifies the name of the log publisher for the web-service action.

url Specifies the URL for the action redirect or web-service.

suggested-username-header
Specifies the name of the custom HTTP header in AJAX requests added by JavaScript with a username value identified on the client side.

trigger-irule
Specifies, when enabled, that the system activates Anti-fraud iRule events. The default value is disabled.

urls Adds, deletes, or replaces a set of URLs in the web application that are protected by the system. You can configure the following options for a protected URL:

app-layer-encryption
Specifies when the system performs Application layer encryption. With Application layer encryption, the system detects an attempt to steal and tamper with end-user passwords (or other protected information), and also prevents it by encrypting the protected information. You can configure the following options for Application layer encryption:

add-decoy-inputs
Specifies, when enabled, that the system randomly and continuously generates and removes decoy fields that are added to the web page, thus making it harder for an attacker to identify sensitive information with either JavaScript or a proxy. In order to enable it, you must first enable `html-field-obfuscation`.

custom-encryption-function
Specifies the name or implementation of custom encryption function to be run instead of built-in encryption.

[enabled | disabled]
Specifies whether the system protects this URL with Application layer encryption, and sends an alert if an attacker attempts to breach Application layer encryption for this URL, or not.

fake-strokes
Specifies, when enabled, that the system protects against in-browser key loggers by generating fake keyboard events.

full-ajax-encryption
Specifies, when enabled, that the system encrypts the full AJAX payload.

hide-password-revealer

Specifies, when enabled, that the system hides the password revealer icon found in web pages.

html-field-obfuscation

Specifies, when enabled, that the system encrypts the names of defined fields on the client, and then decrypts them back to the original names on the BIG-IP.

real-time-encryption

Specifies, when enabled, that the system encrypts passwords as they are typed (even before the user clicks the Submit button in a web form).

remove-element-ids

Specifies, when enabled, that the system removes the ID attribute from the fields in a web form. In order to enable it, you must first enable html-field-obfuscation.

remove-event-listeners

Specifies, when enabled, that the system removes event listeners from the encrypted fields in a web form.

stolen-creds

Specifies, when enabled, that the system examines whether the user was trying to use a fabricated password.

substitute-value-function

Specifies a JavaScript function that receives the real password as an argument and returns a fake value.

auto-transactions

Specifies how the system protects this URL from automatic (bot) transactions. You can configure the following options for Automated transactions detection:

bot-score

Specifies the score added to an alert that is triggered if the system determines that the client is a bot and not a human. The default is a score of 50.

browser

Specifies, when enabled, that the system looks for bot automation performed within the browser.

click-score

Specifies the score added to an alert that is triggered if the min-mouse-over-count and min-mouse-move-count conditions are not met. The default is a score of 40.

[enabled | disabled]

Specifies whether the system protects this URL against non-human transactions, and sends an alert if the system detects a non-human transaction attempt for this URL, or not.

full-ajax-integrity

Specifies, when enabled, that the system verifies whether the full AJAX payload was changed by malware when it left the browser for the server.

integrity-fail-score

Specifies the score added to an alert that is triggered if the system detects a difference between the actual parameter value and the expected value of a protected parameter sent after a user clicks a web form's Submit button. The default is a score of 40.

min-mouse-move-count

Specifies the minimum number of mouse movements necessary per page load in order for the system to consider the transaction to be of human origin. The default is 5 movements.

min-mouse-over-count

Specifies the minimum number of times the client's mouse is positioned over the Submit button in a web form in order for the system to consider the transaction to be of human origin. The default is 2 button interactions.

min-report-score

Specifies the lowest score necessary for the system to send an alert. The default value is 50.

min-time-to-request

Specifies the minimum amount of time (in seconds) permitted between when a web form is opened and the Submit button is clicked. The default is 2 seconds.

non-browser

Specifies, when enabled, that the system looks for bot automation performed not within the browser.

not-human-score

Specifies the score added to an alert that is triggered if the system only suspects that the client is a bot and not a human. The default is a score of 25.

strong-integrity

Specifies, when enabled, that the system detects a difference between the actual parameter value and the

expected value of a protected parameter verified with physical input events.

submit-buttons

Adds, deletes, or replaces a set of non-standard Submit buttons found in forms of the web application. You can specify the name, or the CSS syntax (ID, class, or tagname) for each button.

tampered-cookie-score

Specifies the score added to an alert that is triggered if the system detects that the transaction-data cookie was tampered with. The default is a score of 50.

time-fail-score

Specifies the score added to an alert that is triggered if the min-time-to-request condition is not met. The default is a score of 20.

custom-alerts

Adds, deletes, or replaces a set of user-defined alerts sent by the system upon searches in different parts of the request. You can configure the following options for each user-defined alert:

component

Specifies the alert component that the system sends in this alert. Select either: malware (the default value), phishing, auto-transactions, or mobilesafe.

header-name

Specifies a header name in which the system searches for the value when search-in is header.

malware-name

Specifies the malware detected by this alert when component is malware.

message

Specifies the user-defined message that the system sends in this alert.

search-in

Specifies the part of the request where the system must find the value to send this alert. Note: If you create a user-defined alert, you can use either request part, thereafter it becomes read only.

client-ip

Specifies that the systems sends this alert if the client IP address equals to the value.

header

Specifies that the systems sends this alert if the header-name header contains the value.

payload

Specifies that the systems sends this alert if the request payload contains the value.

query-string

Specifies that the systems sends this alert if the URL query string contains the value.

value

Specifies a value that the system searches for in the search-in part of the request. The default value is none, which means that the system searches for any value.

before-load-function

Specifies the implementation of additional function to be run before JavaScript load, in the following format: function(configs){...}. Note: For certain advanced configurations, F5 support may provide relevant code to be entered here, please do not use it on your own.

description

Specifies an optional description of this URL.

destination-urls

Specifies a list of destination URLs for requests from SPA URLs/Views.

fallback-to-base-url

Specifies if a request to a non-configured view should use same configuration as the base URL or disable FPS for that request.

include-query-string

Specifies, when enabled, that the system includes query string of URLs to match this wildcard expression. The default value is disabled.

inject-javascript

Enables or disables JavaScript injection into responses to this URL. The default value is enabled.

inject-main-javascript

Specifies where the system injects the main JavaScript. You can configure the following options for main JavaScript injection position:

[after | before]

Specifies whether the system injects the main JavaScript after an opening tag or before a closing tag.

tag Specifies the HTML tag for injection of the main JavaScript. This tag cannot be none.

inject-javascript-removal

Specifies where the system injects the JavaScript removal detection image. You can configure the following options for JavaScript removal detection image injection position:

[after | before]

Specifies whether the system injects the JavaScript removal detection image after an opening tag or before a closing tag.

tag Specifies the HTML tag for injection of the JavaScript removal detection image. This tag cannot be none.

login-response

Specifies validation criteria on the response of this URL when it is Login page. You must configure at least one of them. If you configure more than one validation criteria, then all the criteria must be fulfilled for successful login. You can configure the following Login page properties:

status-code

Specifies an HTTP response status code that the server must return to the user upon successful login.

domain-cookie

Specifies a defined domain cookie that the successful response to the login URL must include.

exclude-string

Specifies a string that should NOT appear in the successful response to the login URL.

header

Specifies a header name and value that the successful response to the login URL must match.

include-string

Specifies a string that should appear in the successful response to the login URL.

validation

Enables or disables successful login validation.

malware

Specifies when the system detects attempts of attackers to inject malware in the URL. You can configure the following options for Malware detection:

attach-html-to-alerts

Specifies, when enabled, that the system attaches forensics information along with the alerts.

auto-learn-form-tags

Specifies, when enabled, that the system learns the number of HTML form tags that appear in the URL. In order to enable it, you must first enable source-integrity.

auto-learn-input-tags

Specifies, when enabled, that the system learns the number of HTML input tags that appear in the URL. In order to enable it, you must first enable source-integrity.

auto-learn-script-tags

Specifies, when enabled, that the system learns the number of HTML script tags that appear in the URL. In order to enable it, you must first enable source-integrity.

blocked-enter-key-detection

Specifies, when enabled, that the system detects blocked "Enter" key.

deferred-execution

Specifies, when enabled, that the system detects deferred execution attack.

domain-availability

Specifies, when enabled, that the system checks that client network connectivity is not blocked by malware.

enable-symbols

Specifies, when enabled, that the system looks for malware strings (signatures) within JavaScript.

[enabled | disabled]

Specifies whether the system protects this URL against injected malware, and sends an alert if this URL is detected to have malware, or not.

external-injection

Specifies, when enabled, that the system detects malicious scripts injected from domains not in the profile's allowed-domains.

generic-malware

Specifies, when enabled, that the system applies the

detection of generic malware, using honeypots.

manual-count-form-tags

Specifies the number of HTML forms that appear in the URL.

manual-count-input-tags

Specifies the number of HTML inputs that appear in the URL.

manual-count-script-tags

Specifies the number of HTML scripts that appear in the URL.

rat-detection

Specifies, when enabled, that the system checks for Remote Access Trojans (RATs) on clients' web browsers.

removed-scripts-detection

Specifies, when enabled, that the system detects malicious scripts that removed their own injection from the DOM.

same-domain-scripts-validation

Specifies, when enabled, that the system detects malicious responds to same-domain scripts.

self-bait

Specifies, when enabled, that the system scans the original source code of the page for malicious injections.

source-integrity

Specifies, when enabled, that the system verifies that the URL's HTML source code matches the HTML code sent from the server. The source integrity feature counts script tags that are external (with src) and inline (without src).

vbklip-detection

Specifies, when enabled, that the system checks for VBKlip malware.

visibility-check

Specifies, when enabled, that the system searches HTML pages for words from visibility-check-items.

visibility-check-items

Adds, deletes, or replaces a set of words that must appear in the web site's HTML pages and may not be changed. If these words are changed, the system sends an alert.

web-rootkit-detection

Specifies, when enabled, that the system detects malware that overwrites native browser functions.

whitelist-words

Adds, deletes, or replaces a set of words that are permitted to appear in requests for this URL, even though they are otherwise blacklisted by the system for other URLs.

mobilesafe-encryption

Specifies, when enabled, that the system protects requests for this URL from mobile devices with Application layer encryption.

parameters

Adds, deletes, or replaces a set of sensitive parameters protected by the system. You can configure the following options for each parameter:

ajax-mapping

Specifies the mapping between the parameter name and its location in AJAX payload.

attach-to-vtoken-report

Specifies, when enabled, that the system adds the parameter value data to the alerts.

check-integrity

Specifies, when enabled, that the system verifies whether the user-input data was changed by malware when it left the browser for the server.

encrypt

Specifies, when enabled, that the system encrypts the parameter's value attribute.

identify-as-username

Specifies, when enabled, that the system considers this parameter a username. Note: There may be only one such parameter per URL, and its value is used only when login is successful (according to the URL's login-response).

method

Specifies the method of the request from which the systems gets the parameter data. Select either: POST (the default value) or GET.

mobilesafe-encrypt

Specifies that this parameter contains the encrypted fields from mobile devices. Note: There may be only one

such parameter per URL (usually called auth), it cannot have other settings enabled and its method must be POST.

mobilesafe-entangle

Specifies that this parameter must be encrypted by mobile devices. The system replaces its value in the request payload and sends an alert if the mobilesafe-encrypt parameter does not contain this field.

obfuscate

Specifies, when enabled, that the system encrypts the parameter's name attribute.

priority

Specifies a unique ordinal number for this parameter in the set of wildcard parameters.

substitute-value

Specifies, when enabled, that the system substitutes the parameter's value with asterisks [*] in the web application while the form is being filled. In order to enable it, you must first enable encrypt.

type Specifies a type of the parameter. Note: If you create a parameter, you can use either type, thereafter it becomes read only. The options are:

explicit

Specifies that the parameter has an exact path. This is the default value.

wildcard

Specifies that any parameter that matches this wildcard expression is considered protected.

phishing

Specifies when the system detects phishing attempts by attackers who set up a fake URL that imitates the real URL. You can configure the following options for Phishing detection:

capture-users

Specifies, when enabled, that the system logs the usernames and text fields (not passwords) of users attacked by a phishing attempt.

copy-detection

Specifies, when enabled, that the system detects copied web pages.

css-protection

Specifies, when enabled, that the system activates the CSS module, which is part of the system's phishing detection backup mechanism.

[enabled | disabled]

Specifies whether the system protects this URL against phishing, and sends an alert if the system detects this URL to be under a phishing attempt, or not.

field-types-to-send

Adds, deletes, or replaces a set of HTML input types whose values should be included in phishing alerts.

inject-css-element

Specifies where the system injects the CSS element. You can configure the following options for CSS element injection position:

[after | before]

Specifies whether the system injects the CSS element after an opening tag or before a closing tag.

tag Specifies the HTML tag for injection of the CSS element. This tag cannot be none.

inject-css-link

Specifies where the system injects the CSS link, when application-css is disabled. You can configure the following options for CSS link injection position:

[after | before]

Specifies whether the system injects the CSS link after an opening tag or before a closing tag.

tag Specifies the HTML tag for injection of the CSS link. This tag cannot be none.

inject-inline-javascript

Specifies where the system injects the phishing inline script and image. You can configure the following options for phishing inline script and image injection position:

[after | before]

Specifies whether the system injects the phishing inline script and image after an opening tag or before a closing tag.

tag Specifies the HTML tag for injection of the phishing inline script and image. This tag cannot be none.

priority
Specifies a unique ordinal number for this URL in the set of wildcard URLs.

type Specifies a type of the URL. Note: If you create a URL, you can use either type, thereafter it becomes read only. The options are:

explicit
Specifies that the URL has an exact path. This is the default value.

wildcard
Specifies that any URL that matches this wildcard expression is considered protected.

users
Adds, deletes, or replaces a set of users enforced by the system upon successful login. You can configure the following options for an enforced user:

modes
Adds or deletes a single mode in the set of existing user modes.

mode Specifies a unique mode for the user. This option is required for the operations add and delete. The options are:

block
Specifies that the system blocks the user account by displaying blocking-page.

forensic
Specifies that the system enforces the user to run Forensics tool on his host by displaying forensic html.

inspection
Specifies that the system turns on verbose activity logging for this user, i.e. collects all HTML and JS sources from sessions and sends this data to the dashboard.

remediation
Specifies that the system enforces the user to run Forensics tool in remediation mode that deploys Anti-malware client on his host by displaying forensic html.

duration
Specifies number of minutes during which the user is enforced in this mode since its first login, when enforce-policy is time-limited. After their expiration the user mode will be removed automatically.

enforce-policy
Specifies enforcement policy for this user mode. The options are:

enforce
Specifies that the user must download and run Forensics tool in order to continue online actions. Note: This policy may be specified only for the modes forensic and remediation.

time-limited
Specifies that the user is enforced in this mode for a limited time, namely until first-login-time + duration minutes. When this policy is specified for the modes forensic and remediation, the user may skip downloading and running Forensics tool every time.

unlimited
Specifies that the user is enforced in this mode for unlimited time. When this policy is specified for the modes forensic and remediation, the user may skip downloading and running Forensics tool every time.

first-login-time
Displays time when the user firstly logged in being in this mode. A new user mode is added with value none and it is updated automatically during traffic, when enforce-policy is time-limited.

whitelist-custom-alerts
Specifies a list of predefined alerts that are ignored.

security anti-fraud signatures-update

NAME
signatures-update - Runs or loads an Anti-fraud signatures update.

MODULE
security anti-fraud

SYNTAX
Configure, run or load the signatures-update component within the security anti-fraud module using the syntax in the following sections:

MODIFY
modify security anti-fraud signatures-update
options:
 update-automatically [enabled | disabled]

edit security anti-fraud signatures-update
options:
 all-properties
 non-default-properties

LOAD
load signatures-update
options:
 file [filename]

RUN
run signatures-update

DISPLAY
list signatures-update
options:
 all-properties
 current-version-create-datetime
 download-available
 install-datetime
 install-user
 message
 non-default-properties
 one-line
 partition
 progress-status
 progress-status-datetime
 last-update-check-datetime
 readme
 update-automatically

DESCRIPTION
You can use the signatures-update component to run, load, configure or display status of signatures update.

EXAMPLES
list security anti-fraud signatures-update

Displays the status of signatures update.

OPTIONS
 current-version-create-datetime
Displays the creation time of currently installed signatures update version.

 download-available
Displays whether new signatures version is available for download from the cloud.

 file Specifies the file name from which the signatures update is going to be installed when using the load command. A full path should be specified.

 install-datetime
Displays the time when signatures update was installed.

 install-user
Displays the name of the user who installed the last signatures update.

 message
Displays the message describing the failure status of signatures update.

 partition
Displays the administrative partition within which this object resides.

 progress-status
Displays the signatures update progress status.

 progress-status-datetime
Displays the time when signatures update progress status was last

changed.

last-update-check-datetime
Displays the time when last checked for signatures update.

readme
Displays the Readme content for the current signatures update.

update-automatically
Enables or disables automatic nightly update.

security blacklist-publisher all-blacklist-publisher

NAME

all-blacklist-publisher - Show command for blacklist publisher for use by firewall. An all-blacklist-publisher shows all the category records and their associated profiles.

MODULE

security blacklist-publisher

SYNTAX

Shows the category component within the security blacklist-publisher module using the syntax in the following sections.

show all-blacklist-publisher

EXAMPLES

show all-blacklist-publisher

Displays all the blacklist publisher records. Each record displays its category, profile association, route domain, traffic group, next hop, advertised count, and deadadvertised count.

FIELDS

category name
Specifies the category which is associated with the profile.

profile name
Specifies the profile which is associated with the category.

route domain
Specifies the route domain in the route advertisement.

traffic group
Specifies the traffic group which will be utilized in route injection fault tolerance.

next hop
Specifies the next-hop address which will be utilized in route advertisement in blackhole routes.

advertised count
Specifies the number of times this route has been advertised.

deadadvertised count
Specifies the number of times this route has been dropped.

SEE ALSO

show, profile category, security, security blacklist-publisher, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

security blacklist-publisher blacklist-publisher-stats

NAME

blacklist-publisher-stats - Show/reset-stats command for blacklist publisher for use by firewall. A blacklist-publisher-stats shows all the category records and their associated profiles.

MODULE

security blacklist-publisher

SYNTAX

Shows the category component within the security blacklist-publisher module using the syntax in the following sections.

```
show blacklist-publisher-stats
show blacklist-publisher-stats category-name [name]
show blacklist-publisher-stats profile-name [name]
show blacklist-publisher-stats category-name [name] profile-name [name]
```

Reset-Stats the category component within the security blacklist-publisher module using the syntax in the following sections.

```
reset-stats blacklist-publisher-stats
reset-stats blacklist-publisher-stats category-name [name]
reset-stats blacklist-publisher-stats profile-name [name]
reset-stats blacklist-publisher-stats category-name [name] profile-name [name]
```

SHOW EXAMPLES

```
show blacklist-publisher-stats
```

Displays all the blacklist publisher records. Each record displays its category, profile association, advertised count, and deadadvertised count.

FIELDS

`category_name`
Specifies the category which is associated with the profile.

`profile_name`
Specifies the profile which is associated with the category.

`advertise_it`
Specifies the number of times this route has been advertised.

`deadadvertise_it`
Specifies the number of times this route has been dropped.

RESET_STATS EXAMPLES

```
reset-stats blacklist-publisher-stats
```

Reset stats for all the blacklist publisher records.

```
reset-stats blacklist-publisher-stats category_name <\Common\botnets
```

Reset stats of all blacklist publisher records that are associated with "\Common\botnets" category.

```
reset-stats blacklist-publisher-stats profile_name
<\Common\botnets-profile
```

Reset stats of all blacklist publisher records that are associated with "\Common\botnets-profile" profile.

```
reset-stats blacklist-publisher-stats category_name <\Common\botnets
profile_name <\Common\botnets-profile>
```

Reset stat of all the blacklist publisher records that are associated with "\Common\botnets" category and "\Common\botnets-profile" profile.

BIG-IP security blacklist-publisher blacklist-publisher-stats(1)

NAME
by-addr - Show command for blacklist publisher for use by firewall. A by-addr shows all the category records and their associated profiles for the specified shun address.

MODULE
security blacklist-publisher

SYNTAX
Shows the shun-ip component within the security blacklist-publisher module using the syntax in the following sections.

show by-addr [enter IP address, IP address/prefix, or IP address range (two addresses separated by a hyphen).]

EXAMPLES
show by-addr 8.8.8.8
show by-addr 8.8.8.8/24
show by-addr 8.8.8.8-8.8.8.10
Displays all the blacklist publisher records for the specified shun address.

FIELDS
IP Address
Specifies the shun ip to be advertised.
category name
Specifies the category which is associated with the profile.
profile name
Specifies the profile which is associated with the category.
route domain
Specifies the route domain in the route advertisement.
traffic group
Specifies the traffic group which will be utilized in route injection fault tolerance.
next hop
Specifies the next-hop address which will be utilized in route advertisement in blackhole routes.
time-to-live
Specifies the amount of time left until this route will be dropped.

SEE ALSO
show, profile category, security, security blacklist-publisher, tmsh

COPYRIGHT

BIG-IP 2017-security blacklist-publisher by-addr(1)

security blacklist-publisher by-category

NAME
by-category - Show command for blacklist publisher for use by firewall. A by-category shows all the category records and their associated profiles for the specified category name.

MODULE
security blacklist-publisher

SYNTAX
Shows the category component within the security blacklist-publisher module using the syntax in the following sections.

show by-category category-name [[name] | all]

EXAMPLES
show by-category category-name /Common/botnets show by-category category-name all
Displays all the blacklist publisher records for the specified category.

FIELDS
category name
Specifies the category which is associated with the profile.

profile name
Specifies the profile which is associated with the category.

route domain
Specifies the route domain in the route advertisement.

traffic group
Specifies the traffic group which will be utilized in route injection fault tolerance.

next hop
Specifies the next-hop address which will be utilized in route advertisement in blackhole routes.

shun-ip
Specifies the shun ip to be advertised.

time-to-live
Specifies the amount of time left until this route will be dropped.

advertised
Specifies whether this record is currently being advertised.

SEE ALSO

BIG-IP 2security8blacklist-publisher by-category(1)

security blacklist-publisher category

NAME

category - Configures a blacklist publisher category for use by firewall. A category enables a user to advertise shuns based on the route-advertisement-nexthop value(s) in the category's associated profile(s).

MODULE

security blacklist-publisher

SYNTAX

Configure the category component within the security blacklist-publisher module using the syntax in the following sections.

CREATE/MODIFY

```
create category [name]
modify category [name]
options:
  profile-names [add | default | delete | none | replace-all-with] {
    [name]
  }
```

```
edit category [[name] | all]
```

```
options:
  all-properties
  non-default-properties
```

```
list category [[name] | all | [property]]
show running-config profile [[name] | all | [property]]
```

```
options:
  all-properties
  non-default-properties
  one-line
```

DELETE

```
delete category [[name] | all | recursive]
```

Note: If the category is referencing any profile the delete will fail.

DESCRIPTION

You can use the category component to create, modify, display, or delete a blacklist-publisher category.

EXAMPLES

```
create category botnets profile-names add { botnets-profile }
```

Creates the above category and adds the profile (botnets-profile).

```
modify category botnets profile-names delete { botnets-profile }
```

Modifies the above category by deleting the profile (botnets-profile).

delete category botnets

Deletes the above category.

list category botnets

Displays the properties of the above category.

OPTIONS

profile-names

Specifies the profiles referenced in the category.

SEE ALSO

create, delete, edit, modify, list, profile, security, security
blacklist-publisher, tmsb

COPYRIGHT

BIG-IP 2015security blacklist-publisher category(1)

security blacklist-publisher profile

NAME

profile - Configures a publisher profile for use by firewall. A profile specifies the network path and method (how and where) the IP-Intelligence Blacklist data will be advertised.

MODULE

security blacklist-publisher

SYNTAX

Configure the profile component within the security blacklist-publisher module using the syntax in the following sections.

CREATE/MODIFY

```
create profile [name]
modify profile [name | all]
options:
  description [string]
  route-domain [name]
  traffic-group [name]
  route-advertisement-nextthop [IP address]
  route-advertisement-nextthop-v6 [IP address]
```

```
edit profile [[name] | all]
options:
  all-properties
  non-default-properties
```

```
list profile [[name] | all | [property]]
show running-config profile [[name] | all | [property]]
options:
  all-properties
  non-default-properties
  one-line
```

DELETE

```
delete profile [[name] | all | recursive]
```

Note: If the profile is referenced in a category the delete will fail.

DESCRIPTION

You can use the profile component to create, modify, display, or delete a blacklist-publisher profile.

EXAMPLES

```
create profile botnets-profile { route-domain 0 route-advertisement-
nextthop 10.10.10.1 }
```

Creates the above profile with the specified route-domain, and route-advertisement-nextthop.

```
modify profile botnets-profile description "this profile is used for
botnets category"
```

Modifies the above profile with a description.

```
delete profile botnets-profile
```

Deletes the above profile.

list profile botnets-profile

Displays the properties of the above profile.

OPTIONS

description

User defined description.

route-advertisement-nexthop

Specifies the next-hop v4 address which will be utilized in route advertisement in blackhole routes.

route-advertisement-nexthop-v6

Specifies the next-hop v6 address which will be utilized in route advertisement in blackhole routes.

route-domain

Specifies the route-domain in the route advertisement.

traffic-group

Deprecated since v13.1.0. Specifies the traffic group which will be utilized in route injection fault tolerance.

security datasync background-tasks

NAME

background-tasks - Configure the Schedule of the Datasync Background Tasks

MODULE

security datasync

SYNTAX

Manage the background-tasks component within the security datasync module using the syntax shown in the following sections.

MODIFY

modify background-tasks [task_name]

options:

daily-start-time [time]

edit background-tasks [task_name]

options:

all-properties

non-default-properties

DISPLAY

list background-tasks

list background-tasks [task_name]

show running-config background-tasks

show running-config background-tasks [[[name] | [glob] | [regex]] ...]

options:

all-properties

non-default-properties

one-line

show background-tasks

show background-tasks [[[name] | [glob] | [regex]] ...]

options:

field-fmt

DESCRIPTION

You can use the background-tasks component to modify or display the Schedule of the Datasync Background Tasks. This controls the Daily Start Time of each task.

The objects cannot be created or deleted, but only modified and displayed. All of the times displayed and configured are in local time. However, they are stored as UTC, so changing the timezone of the BIG-IP will change the display of the configured time.

There is a limitation on the time which can be configured: the new configuration cannot be within 2 hours of the active time. The configured daily-start-time must be before the value of daily-start-time-must-be-before, OR after the value of daily-start-time-must-be-after, inclusive.

These objects are synchronized via the datasync-global-dg device-group.

Use the show command to display the current task schedule. This shows the start time of each task.

OPTIONS

daily-start-time
Specifies the time of day in which the generation will start.

daily-start-time-must-be-before
Displays the upper limitation: daily-start-time must be before this displayed time.

daily-start-time-must-be-after
Displays the lower limitation: daily-start-time must be after this displayed time.

error-msg
Displays the configuration error message which causes daily-start-time to be non-configurable, or "none" if there is no error.

BIG-IP 2017-08security datasync background-tasks(1)

security datasync device-stats

NAME

device-stats - Display the Datasync Framework device stats.

MODULE

security datasync

SYNTAX

Display the device-stats component within the security datasync module using the syntax shown in the following sections.

DISPLAY

```
list device-stats
list device-stats [ [ [name] | [glob] | [regex] ] ... ]
show running-config device-stats
show running-config device-stats [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
  recursive
```

DESCRIPTION

You can use the device-stats component to display the datasync device-stats for that are updated by the Datasync Framework.

OPTIONS

device
Displays the device name reflected by the stats.

table
Displays the table type reflected by the stats.

profile-chksum
Displays the checksum of the current active profile.

activation-epoch
Displays the activation epoch of the current active generation.

rows-available
Displays the number of available rows in the current active buffer.

rows-in-use
Displays the number of rows that are in use in the current active buffer.

SEE ALSO

create, delete, edit, glob, list, modify, regex, show, tmsh, trust-domain

COPYRIGHT

BIG-IP 2014-07-10 security datasync device-stats(1)

security datasync global-profile

NAME

global-profile - Manage the Datasync Framework settings that are globally synced across devices.

MODULE

security datasync

SYNTAX

Manage the global-profile component within the security datasync module using the syntax shown in the following sections.

CREATE/MODIFY

```
create global-profile [name]
modify global-profile [name]
options:
  table [name]
  activation-epoch [ auto | [integer] ]
  deactivation-epoch [ deactivated | always-active | [integer] ]
  min-rows [ default | [integer] ]
  max-rows [ default | [integer] ]
  regen-time-offset [ default | [integer] ]
  regen-interval [ default | none | [integer] ]
  grace-time [ default | [integer] ]
  master-key [string]
  scramble-alg [string]
  hash-alg [string]
  mac-alg [string]
  mode-of-op [string]
  rsa-exp [ none | rsa-3 | rsa-f4 | default ]
  rsa-bits [ default | none | [integer] ]
  params [string]
```

```
edit global-profile [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list global-profile
list global-profile [ [ [name] | [glob] | [regex] ] ... ]
show running-config global-profile
show running-config global-profile [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
  recursive
```

DELETE

```
delete global-profile [name]
```

DESCRIPTION

You can use the global-profile component to create, modify, display, or delete a datasync global-profile for use with the Datasync Framework. All global-profiles must reside in the automatically created /Common/datasync-global folder. These profiles are synced across all of the devices in the trust domain using the manually-synced device-group datasync-global-dg.

Warning: Creating, modifying or deleting global-profiles may result in the system being offline, in the case of a bad configuration.

EXAMPLES

```
create global-profile /Common/datasync-global/my_global_profile table
table_name
```

Creates a custom datasync global-profile named my_global_profile for table table_name with initial settings, a random master-key, and an activation-epoch 30 minutes in the future.

```
list global-profile /Common/datasync-global/*
```

Displays the properties of all datasync global-profiles.

OPTIONS

table
Specifies the table to which the profile belongs.

activation-epoch

Specifies the epoch at which the profile becomes active, in UNIX-time.

deactivation-epoch

Specifies the epoch at which the profile becomes inactive, in UNIX-time.

create-timestamp

Displays the timestamp at which the profile was created, in UNIX-time.

min-rows

Specifies the minimum number of rows to generate before going online.

max-rows

Specifies the maximum number of rows to generate.

regen-time-offset

Specifies the time offset at which regeneration will be done, in seconds.

regen-interval

Specifies the time interval at which regeneration will be done, in seconds.

grace-time

Specifies the grace time during which new buffers are supported, but not yet activated, in seconds.

master-key

Specifies the secured master key upon which all cryptography is based. Use \"auto\" to generate a random key.

scramble-alg

Specifies the scrambling algorithm to use.

hash-alg

Specifies the hashing algorithm to use.

mac-alg

Specifies the MAC algorithm to use.

mode-of-op

Specifies the scrambling mode-of-operation to use.

rsa-exp

Specifies the RSA exponent.

rsa-bits

Specifies the number of bits to use for RSA keys.

params

Specifies additional internal parameters.

SEE ALSO

create, delete, edit, glob, list, modify, regex, show, tmsh, trust-domain

BIG-IP 2014-07-1security datasync global-profile(1)

security datasync local-profile

NAME

local-profile - Manage the Datasync Framework settings that are local, and not synced across devices.

MODULE

security datasync

SYNTAX

Manage the local-profile component within the security datasync module using the syntax shown in the following sections.

MODIFY

```
modify local-profile [table_name]
options:
  buf-size [integer]
  ds-area [ none | asm | fps ]
  rows-bulk [integer]
  gen-timeout-sec [integer]
  min-mem-mb [integer]
```

```

min-cpu-percent [integer]
max-gen-rows [ infinite | [integer] ]
keep-conf-files [integer]
gen-pause-sec [integer]
offline-until-gen [ enable | disable ]

edit local-profile [table_name]
options:
  all-properties
  non-default-properties

DISPLAY
list local-profile
list local-profile [table_name]
show running-config local-profile
show running-config local-profile [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
  recursive

DESCRIPTION
  You can use the local-profile component to modify or display a datasync
  local-profile for use with the Datasync Framework. Each profile is for
  a single table. The profiles cannot be created or deleted, only
  modified. These profiles are local; they are not synced across
  devices.

OPTIONS
  buf-size
  Specifies the size of each buffer in the table, in bytes.

  ds-area
  Specifies the memory area on which the table will be allocated.

  rows-bulk
  Specifies the number of rows to generate in each bulk.

  gen-timeout-sec
  Specifies the timeout of running the external generator per single
  bulk.

  min-mem-mb
  Specifies the minimum available memory in MB to start generator in
  non-urgent mode.

  min-cpu-percent
  Specifies the minimum available CPU percent to start generator in
  non-urgent mode.

  max-gen-rows
  Specifies the maximum rows to generate.

  keep-conf-files
  Specifies the number of configuration files to keep when rolling
  old ones.

  gen-pause-sec
  Specifies the time in seconds to pause between each bulk
  generation when in non-urgent mode.

  offline-until-gen
  Specifies if the system should be offline until the table is
  generated.

SEE ALSO
  edit, list, modify, show, tmsh

security debug drop-redirect-stats

```

NAME
  drop-redirect-stats - Configures Debuggability drop redirect mode.

MODULE
  security firewall

SYNTAX
  Configure drop redirect feature or display stats using the following

```

syntax.

DISPLAY
show drop-redirect-stats

MODIFY
reset-stats drop-redirect-stats

DESCRIPTION
This command displays size and number of packets that were drop redirected.

EXAMPLES
show security debug drop-redirect-stats

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2009-2017. All rights reserved.

BIG-IP 2017-07security debug drop-redirect-stats(1)

security debug matcher

NAME
debug - Configures Debuggability drop redirect mode.

MODULE
security firewall

SYNTAX
Configure drop redirect feature or display stats using the following syntax.

```
MODIFY
modify debug
matcher {
  drop-redirect {
    drop-redirect-mode {
      disable
      redirect-all
      redirect-hw-only
      redirect-sw-only
    }
  }
}
```

DISPLAY
show debug
drop-redirect-stats

DESCRIPTION
Debuggability drop redirection feature redirects HW dropped packets to a specified interface. This interface may be set using sys db variable debug.hwdropredirect.interface. The feature can also redirect only certain types of drops. This can be done by using sys db variable debug.doshwdropredirect.disables.

Full List of HW Redirect Modes # Disable GlobalDoSVector drop redirects
bit-0 # Disable sPVADoSVector drop redirects bit-1 # Disable
sPVAIPBlacklist drop redirects bit-2 # Disable sPVAIPRateLimit
drop redirects bit-3 # Disable NeuronBlacklist drop redirects
bit-4 # Disable DuplicateSYN drop redirects bit-5

Once an interface is set-up, redirect-hw-only mode can be enabled as the following example.

EXAMPLES
modify security debug matcher drop-redirect drop-redirect-mode
redirect-hw-only

Configures dropped packets to be redirected to a specified interface.

BIG-IP 2018-01-10 security debug matcher(1)

security device-id attribute

NAME device-id - Configures Device-ID collected attributes.

MODULE security

SYNTAX Configure the device-id component within the security module using the syntax shown in the following sections.

MODIFY
modify attribute [name]
options:
collect {
[enabled | disabled]
}

DISPLAY
list device-id

DESCRIPTION
You can use the device-id component to modify or display a Device-ID attribute collection.

EXAMPLES
modify device-id attribute att05 {collect disabled}

Disables collection of att05 by Device-ID JavaScript.

list device-id

Displays the properties of all device-id attributes.

OPTIONS
attribute
Specifies the Device-ID category to be configured.

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

security device device-context

NAME device-context - Configures the security device context policies.

MODULE security device

SYNTAX
MODIFY
modify device-context
options:
description [string]
nat-policy [[policy_name] | none]

edit device-context
options:
all-properties
non-default-properties

reset-stats device-context
nat-rules { [rule name] }

DISPLAY
list device-context
show running-config device-context nat-rules

show device-context nat-rules

DESCRIPTION
You can use the device-context component to configure device level (a.k.a global) policies.

EXAMPLES
modify device-context nat-policy policy1

Configures nat policy named policy1 to be used as the device level nat policy.

list device-context

```
security device device-context {
    nat-policy /Common/policy1
}
```

Displays the current list of policies at device context level.

OPTIONS

description
Specifies nat policies on device context level.

nat-policy
Specifies a NAT policy. This is the policy used to match incoming traffic to a virtual server and perform source/destination translations (as per the matched NAT rule) if and only if: virtual server does not have a NAT policy configured (see ltm virtual) AND virtual server has nat-policy.use-route-domain-policy disabled OR virtual server has nat-policy.use-route-domain-policy enabled but the route domain does not have a NAT policy configured AND virtual server has nat-policy.use-device-policy enabled.

nat-rules
Specifies security nat rules enforced on device context level via referenced nat-policy.

SEE ALSO

edit, list, modify, security firewall address-list, security firewall port-list, security nat policy, security log profile, security nat source-translation, security nat destination-translation, ltm virtual, show, tmsh

security dos autodos-file-object

NAME
autodos-file-object - autodos internal file object.

MODULE
security

SYNTAX
Configure autodos-file-object within security dos module using the syntax shown in the following sections.

CREATE/MODIFY
create autodos-file-object [name]
modify autodos-file-object [name]
options:
app-service [[string] | none]
source-path [file name]

DELETE
delete autodos-file-object [name]

DESCRIPTION
autodos file object is used internally for synchronization of dos module data across HA (high availability) or Cluster setup.

EXAMPLES
create name source-path /var/dos/file.json

Creates a file object named name, that gets its contents from source file /var/dos/file.json.

delete filename

Deletes the file object named filename.

OPTIONS

app-service

Specifies the name of the application service to which the file object belongs. The default value is none.

source-path

The name of the source file from which the contents are copied to create the file object.

SEE ALSO

create, delete, edit, modify, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

security dos behavioral-signature

NAME

behavioral-signature - Configures a Behavioral Bot Signature.

This component has been deprecated and replaced by dos-signature in 13.1.0.

MODULE

security dos

SYNTAX

Configure the behavioral-signature component within the security dos module using the syntax shown in the following sections.

MODIFY

```
modify behavioral-signature [name]
options:
  alias [name]
  status [approved | new | revoked ]
```

DISPLAY

```
list behavioral-signature
```

DELETE

```
delete behavioral-signature [name]
```

DESCRIPTION

You can use the behavioral-signature component to modify, display, or delete a Behavioral Signature.

EXAMPLES

```
list behavioral-signature
```

Displays the properties of all Behavioral Signatures.

OPTIONS

alias

Specifies the behavioral signature user defined alias.

status

Specifies the behavioral signature status.

SEE ALSO

edit, list, modify, security, security dos, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

security dos bot-signature-category

NAME
bot-signature-category - Configures the Bot Signature Categories.

MODULE
security dos

SYNTAX
Configure the bot-signature-category component within the security dos module using the syntax shown in the following sections.

CREATE/MODIFY
create bot-signature-category [string]
modify bot-signature-category [name]
options:
type [benign | malicious]

DISPLAY
list bot-signature-category

DELETE
delete bot-signature-category [name]

DESCRIPTION
You can use the bot-signature-category component to create, modify, display, or delete a Bot Signature Category.

EXAMPLES
create bot-signature my_signature_category

Creates a custom Bot Signature Category named my_signature_category with initial settings.

list bot-signature-category

Displays the properties of all Bot Signature Categories.

OPTIONS
type Specifies the bot signature type. The possible values are benign or malicious.

SEE ALSO
edit, list, modify, security, security dos, tmsh

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

security dos bot-signature

NAME
bot-signature - Configures the Bot Signatures.

MODULE
security dos

SYNTAX
Configure the bot-signature component within the security dos module using the syntax shown in the following sections.

CREATE/MODIFY
create bot-signature [string]
modify bot-signature [name]
options:
category [name]
domains [none | add | delete | replace-all-with] { [string] ... }
risk [high | low | medium]
rule [string]
signature-references [string]
url {
match-type [contains | regexp]
search-string [string]
}
user-agent {
match-type [contains | regexp]
search-string [string]

```

}

DISPLAY
list bot-signature

DELETE
delete bot-signature [name]

DESCRIPTION
You can use the bot-signature component to create, modify, display, or
delete a Bot Signature.

EXAMPLES
create bot-signature my_signature

Creates a custom Bot Signature named my_signature with initial
settings.

list bot-signature

Displays the properties of all Bot Signatures.

OPTIONS
category
Specifies the bot signature category.

domains
Specifies the bot signature domain names.

risk Specifies the bot signature risk. The possible values are high,
low and medium.

rule Specifies the bot signature rule.

signature-references
Specifies the bot signature references.

url Specifies the bot signature's url matching rule. The following
options are available:

match-type
Specifies the bot signature's url rule match type. The
possible values are contains or regexp.

search-string
Specifies the bot signature's url string that should be
matched.

user-agent
Specifies the bot signature's user-agent matching rule. The
following options are available:

match-type
Specifies the bot signature's user-agent rule match type. The
possible values are contains or regexp.

search-string
Specifies the bot signature's user-agent string that should
be matched.

SEE ALSO
edit, list, modify, security, security dos, tmsh

```

DESCRIPTION

This component is used to modify or display the global device DoS profile and statistics for use with network DoS Protection functionality.

EXAMPLES

```
modify device-config ...
```

Modifies the global DoS profile settings.

list device-config

Displays all the properties of the device DoS profile.

run device-config dos-device-config auto-threshold-relearn

Clears the auto-threshold history for all the device auto-threshold vectors.

run device-config dos-device-config dns-nxdomain-relearn

Clears the dns-nxdomain history for all the device dns-nxdomain vectors.

run device-config dos-device-config dynamic-signatures-history-relearn

Clears the dynamic-signatures history for all the device dynamic-signatures vectors.

show device-config dos-device-config dns-nxdomain-stat

Displays the dns-nxdomain statistics for the device.

reset-stats device-config dos-device-config dns-nxdomain-stat

Resets the dns-nxdomain statistics for the device.

OPTIONS

auto-threshold-sensitivity

This option is deprecated in version 13.0.0.

dos-device-vector

Configures attack detection thresholds and rate limit parameters for network DoS vectors.

log-publisher

Specifies the name of the log publisher which logs translation events. See help sys log-config for more details on the logging sub-system.

ip-uncommon-protolist

Specifies the name of an IP uncommon protocol list component. The default is /Common/ip-uncommon-protolist. This is ready-only field.

threshold-sensitivity

Specifies the guidance on how aggressively (how much to pad) to adjust the "Detection/Rate-limit Threshold". Available settings are low, medium and high. This setting is used for Autodos and Behavioral DoS features. Default is set to medium.

dynamic-signatures

Specifies options related to L4-L7 Behavioral DoS (Dynamic Signatures) feature that is applicable at the global/device level. These settings are used to learn the characteristic of the traffic at the device level (across all domains and virtual servers) and generate dynamic signatures as applicable to detect and mitigate anomalous traffic.

Following options are configurable for this feature at global/device level:

network

detection

Specifies the mode for detection of anomalies in traffic for the purpose of dynamic signature generation. Following modes are supported: disabled, enabled and learn-only.

Mode learn-only is same as enabled except that the system does not generate any logs (or alerts the user). It is used mainly to learn the baseline thresholds for the traffic.

Default is disabled.

mitigation

Specifies the mode for mitigation of anomalous traffic (specified in form of dynamic signatures). Following modes are supported: none, low, medium and high.

Each mode represents the severity (or aggressiveness) at which the system should try to mitigate the anomalous traffic.

Default is none.

scrubber-enable

Specifies the configuration mode for enabling or disabling the feature to scrub the attack traffic upon dynamic signature match. Default is no.

scrubber-category

Specifies the IP Intelligence category used for scrubbing the attack traffic upon dynamic signature match that constitutes destination IP address component. Default category is attacked_ips.

scrubber-advertisement-period

Specifies the advertisement period for which the attack traffic is scrubbed. Default is 300 seconds.

dns

detection

Specifies the mode for detection of anomalies in traffic for the purpose of dynamic signature generation. Following modes are supported: disabled, enabled and learn-only.

Mode learn-only is same as enabled except that the system does not generate any logs (or alerts the user). It is used mainly to learn the baseline thresholds for the traffic.

Default is disabled.

mitigation

Specifies the mode for mitigation of anomalous traffic (specified in form of dynamic signatures). Following modes are supported: none, low, medium and high.

Each mode represents the severity (or aggressiveness) at which the system should try to mitigate the anomalous traffic.

Default is none.

VECTOR TYPES

arp-flood

ARP Flood.

bad-ext-hdr-order

IPv6 extension headers in packet are out of order.

bad-icmp-chksum

Bad ICMP checksum.

bad-icmp-frame

Bad ICMP frames. To see the various reasons why ICMP frames are classified as bad, please refer to the written documentation.

bad-igmp-frame

Bad IGMP frames. To see the various reasons why IGMP frames are classified as bad, please refer to the written documentation.

bad-ip-opt

IPv4 option with illegal length.

bad-ipv6-hop-cnt

Bad IPv6 hop count. Terminated packet (cnt==0). Dropped when the rate hits rate limit.

bad-ipv6-ver

Bad IPv6 version. IP Version in the IPV6 packet is not 6.

bad-sctp-chksum

Bad SCTP Checksum type.

bad-tcp-chksum

Bad TCP checksum.

bad-tcp-flags-all-clr

Bad TCP flags (all TCP header flags cleared).

bad-tcp-flags-all-set

Bad TCP flags (all flags set).

bad-ttl-val

Bad IP TTL value (TTL == 0 for IPv4).

bad-udp-chksum

Bad UDP checksum.

bad-udp-hdr

Bad UDP header. To see the various reasons why UDP headers are classified as bad, please refer to the written documentation.

bad-ver

Bad IP version 4. IPv4 version in IP header is not 4.

dns-a-query

DNS A query packet.

dns-aaaa-query

DNS AAAA query packet.

dns-any-query

DNS any query packet.

dns-axfr-query

DNS AXFR query packet.

dns-cname-query

DNS CNAME query packet.

dns-ixfr-query

DNS IXFR query packet.

dns-malformed

DNS Malformed packet.

dns-mx-query

DNS MX query packet.

dns-ns-query

DNS NS query packet.

dns-nxdomain-query
DNS NXDOMAIN query packet.

dns-other-query
DNS OTHER query packet.

dns-oversize
DNS packet with size > . This sys db tunable is configurable with Dos.MaxDNSframeSize.

dns-ptr-query
DNS PTR query packet.

dns-qdcount-limit
DNS QDCOUNT LIMIT query packet.

dns-response-flood
DNS RESPONSE FLOOD query packet.

dns-soa-query
DNS SOA query packet.

dns-txt-query
DNS TXT query packet.

dns-srv-query
DNS SRV query packet.

dup-ext-hdr
Duplicate IPv6 extension headers.

ether-brdcst-pkt
Ethernet broadcast packet.

ether-mac-sa-eq-da
Ethernet MAC SA == DA.

ether-multicast-pkt
Ethernet multicast packet.

ext-hdr-too-large
IPv6 extension header size too large. The max IPv6 extension header size is configurable via the sys db variable dos.maxipv6extsize.

fin-only-set
TCP header with only the FIN flag set.

flood
A Flood is an attack where multiple (typically many) endpoints initiate network traffic to a single subnet or receiving endpoint.

hdr-len-gt-l2-len
Header length > L2 length. No room in L2 packet for IPv4 header (including options).

hdr-len-too-short
Header length too short. IPv4 header length in IP header is less than 20 bytes.

hop-cnt-leq-one
IPv6 hop count <= and the packet needs to be forwarded. This sys db tunable is configurable by the sys db variable tm.minipv6hopcnt.

host-unreachable
ICMP packets of type "Host Unreachable".

icmp-frag-flood
ICMP fragments flood.

icmp-frame-too-large
Packets larger than the maximum ICMP frame size. The max ICMP frame size is configurable via the sys db variable dos.maxicmpframesize.

icmpv4-flood
ICMPv4 Flood.

icmpv6-flood
ICMPv6 Flood.

igmp-flood
IGMP Flood.

igmp-frag-flood
IGMP Fragment Flood.

ip-bad-src
IP addr is a broadcast or multicast address.

ip-err-chksum
IP error checksum. IPv4 header checksum error.

ip-frag-flood
IPv4 fragment flood.

ip-len-gt-l2-len
IP length > L2 length. Total length in IPv4 header is greater than the L3 part length in L2 packet.

ip-overlap-frag
IPv4 overlapping fragments.

ip-short-frag
IPv4 fragments whose payload size is less than the minimum IPv4 Fragment size. The minimum size is configurable via the db variable `tm.minipfragsize`.

ip-unk-prot
IP Unknown Protocol type.

ip-opt-frames
IP option frames. IPv4 packets with options. db variable `tm.acceptipoptions` must be enabled to receive IP options.

ip-other-frag
The total IPv4 fragments' size has exceeded the reassembly queue or the maximum IP packet size.

ipv6-atomic-frag
IPv6 frame with frag extension hdr, but the MF and offset fields are both 0.

ipv6-bad-src
IPv6 src address is a multicast address or IPv6 src or destination address is a IPv4 mapped IPv6 address.

ipv6-ext-hdr-frames
IPv6 extended header frames.

ipv6-frag-flood
IPv6 fragment flood.

ipv6-len-gt-l2-len
IPv6 length > L2 length.

ipv6-other-frag
The total IPv6 fragments' size has exceeded the reassembly queue or the maximum IP packet size.

ipv6-overlap-frag
IPv6 overlapping fragments.

ipv6-short-frag
IPv6 fragments whose payload size is less than the minimum IPv6 Fragment size. The minimum size is configurable via the db variable `tm.minipv6fragsize`.

ipv4-mapped-ipv6
IPv4 mapped IPv6 addresses.

land-attack
Land Attack. IP Src Address equals IP Dst Address. Both V4 and V6 are counted.

l2-len-ggt-ip-len
L2 length >> IP length. L2 packet length is much greater than payload length in IPv4 (L2 length > IP length and L2 length > minimum packet size).

l4-ext-hdrs-go-end
No L4 (extended headers go to or past the end of frame).

no-l4
No L4. No L4 payload for IPv4.

opt-present-with-illegal-len
TCP Option present with illegal length.

payload-len-ls-l2-len
Payload length < L2 length. Payload length in IPv6 header is less than L3 part length in L2 packet.

routing-header-type-0
Routing header type 0 present.

sip-malformed
SIP malformed packet

sip-invite-method
SIP INVITE method packet.

sip-ack-method
SIP ACK method packet.

sip-options-method
SIP OPTIONS method packet.

sip-bye-method
SIP BYE method packet.

sip-cancel-method
SIP CANCEL method packet.

sip-register-method
SIP REGISTER method packet.

sip-publish-method
SIP PUBLISH method packet.

sip-notify-method
SIP NOTIFY method packet.

sip-subscribe-method
SIP SUBSCRIBE method packet.

sip-message-method
SIP MESSAGE method packet.

 sip-prack-method
SIP PRACK method packet.

 sip-uri-limit
Limit SIP URI length.

 sip-other-method
SIP OTHER method packet.

 sweep
A Sweep is an attack where a single endpoint initiates network traffic to a large number of receiving endpoints or subnets.

 syn-and-fin-set
SYN && FIN set.

 tcp-ack-flood
TCP packets with the ACK flag set (for non-existing flows).

 tcp-bad-urg
TCP packets with the URG flag set but URG pointer is 0.

 tcp-hdr-len-gt-l2-len
TCP header length > L2 length. No room in packet for TCP header (including options).

 tcp-hdr-len-too-short
TCP header length too short (length < 5). The offset field in TCP header is less than 20 bytes.

 tcp-opt-overruns-tcp-hdr
TCP option overruns TCP header.

 tcp-syn-flood
TCP header with only the SYN flag set.

 tcp-synack-flood
TCP header with only the SYN and ACK flags set.

 tcp-rst-flood
TCP header with only the RST flag set.

 tcp-psh-flood
TCP header with PUSH flag set.

 tcp-window-size
TCP non-RST pkt with window size < . This sys db tunable is configurable with Dos.TcpLowWindowSize.

 tidcmp
ICMP source quench packets.

 too-many-ext-hdrs
Too many extended headers. The IPv6 extended headers are more than 4. This number can be set through db variable dos.maxipv6exthdrs.

 tcp-syn-oversize
TCP data-SYN with pktlength > dos.maxsynsize which is 128 bytes by default.

 ttl-leq-one
TTL <= . For IPv4 forwarding. This sys db tunable is configurable by tm.minipttl.

 unk-tcp-opt-type
Unknown TCP option type.

 udp-flood
UDP Flood.UDP flood vector counts any UDP packets that either match the UDP Port InclusionList or do not match the UDP Port ExclusionList. "tmsh modify security dos udp-portlist" can be used to configure the udp port list.For more info about udp portlist and how to configure it use "help security dos udp-portlist"

 unk-ipopt-type
Unknown IP option type.

 ip-uncommon-PROTO
ip-uncommon-PROTO vectors counts packets whose protocol is specified in configured ip-uncommon-protolist.

PARAMETERS

 allow-advertisement
Enables allow advertisement. The default is disabled.

 allow-upstream-scrubbing
Enables allow upstream scrubbing. The default value is disabled.

 attacked-dst
Enables attacked-destination. The default value is disabled.

 auto-blacklisting
Enables automatic blacklisting of offending source IPs. The default value is disabled.

 auto-scrubbing
Enables specifying destination IP scrubbing. The default value is disabled.

 auto-threshold

This option is deprecated in version 13.1.0 and is replaced by threshold-mode. Enables the auto threshold mode for dos detection and dos mitigation. The default value is disabled.

bad-actor
Enables per-source IP based bad actor detection. The default value is disabled.

blacklist-category
Blacklist category (of IP intelligence) to which this IP should be added. The default value is none.

blacklist-detection-seconds
Duration in seconds for which the IP has been offending. The default value is 60.

blacklist-duration
Duration in seconds for which this IP should be blocked. The default value is 14400.

ceiling
Option to set a maximum value ("ceiling") for the default-internal-rate-limit for this vector. The range is from 0 to infinity.

default-internal-rate-limit
This parameter is programmed in hardware to limit the traffic to BIG-IP software. If the hardware DoS support does not exist software uses default-internal-rate-limit to limit the good traffic (most of them are flood) to external servers. Bad packets are always dropped.

If the rate limit value is infinite the rate limit is disabled. The default value is 100000.

detection-threshold-percent
This parameter specifies relative threshold that uses dynamically learned 1-hour average rate to detect attacks. If the current rate (1-minute average) increases the specified percent over the 1-hour average rate, attack is detected.

If the threshold value is infinite the detection is disabled. The default value is 500.

detection-threshold-pps
This parameter specifies absolute threshold value. If the current rate (1-minute average) is equal or above the threshold value, attack is detected.

If the threshold value is infinite the detection is disabled. The default value is 100000.

enforce
This option is deprecated in version 13.1.0 and is replaced by state. Enable or disable the packet drop action of DOS detection for this attack type.

floor
Option to set a minimum value ("floor") for the detection-threshold-pps for this vector. The range is from 0 (no-floor) to infinity (no-detection). The default value is 5000.

packet-types
This parameter is used to specify type of packets that will be classified as Sweep/Flood attacks. There are various types of packet types that can be specified. The default value is none.

per-dst-ip-detection-pps
Specifies the attack detection threshold (pps) per destination IP. The default value is infinite.

per-dst-ip-limit-pps
Specifies the attack mitigation threshold (pps) per destination IP. The default value is infinite.

per-source-ip-detection-pps
Specifies the attack detection threshold (pps) per source IP. The default value is infinite.

per-source-ip-limit-pps
Specifies the attack mitigation threshold (pps) per source IP. The default value is infinite.

scrubbing-category
Specifies per-DstIP scrubbing category. The default value is none.

scrubbing-detection-seconds
Specifies duration in seconds for which the destination IP has been offended/attacked. The default value is 10.

scrubbing-duration
Specifies duration in seconds for which this IP should be scrubbed. The default value is 900.

simulate-auto-threshold
Option to enable/disable auto-threshold simulation by generating logs if auto-threshold based detection/mitigation would have kicked in. Only valid in manual mode. The default value is disabled.

state
Specifies the run time state of this signature. The default value is mitigate.

The options are:

disabled

Do not learn, do not collect stats.

learn-only

Learn/Collect stats, but do not "detect" ("alarm" in ASM-speak) any attacks,

detect-only

Learn/Collect stats/detect, but do not mitigate (rate-limit/drop, challenge, etc.) any attacks.

mitigate

Learn/Collect stats/detect/mitigate (using whichever mitigations are configured).

suspicious

Specifies if the vector considers all packets or only unsolicited packets. The default value is false.

threshold-mode

Enables the threshold mode for DoS detection and DoS mitigation. The default value is manual.

The options are:

manual

Specifies the manual thresholds.

stress-based-mitigation

Specifies the manual detection ("alarm") threshold, but mitigation threshold is stress-based.

fully-automatic

Specifies both the detection ("alarm") and mitigation thresholds are automatically computed.

valid-domains

Adds, deletes, modifies, or replaces a set of valid fully qualified domain names (FQDNs).

security dos dns-nxdomain-stat

NAME

dns-nxdomain-stat - Displays and resets dos dns-nxdomain statistics of the specified context on the BIG-IP(r) system.

MODULE

security dos

SYNTAX

Manage the virtual component within the security dos module using the syntax in the following sections.

DISPLAY

show dns-nxdomain-stat

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
field-fmt

MODIFY

reset-stats dns-nxdomain-stat

DESCRIPTION

You can use the dns-nxdomain-stat component to display or reset dos dns-nxdomain statistics.

EXAMPLES

show dns-nxdomain-stat

Displays the dns-nxdomain's statistics in the system default units.

show dns-nxdomain-stat raw

Displays the raw dns-nxdomain's statistics.

```
reset-stats dns-nxdomain-stat
```

Resets the dns-nxdomain statistics.

SEE ALSO

```
reset-stats, show, tmsh
```

security dos dos-signature

NAME

dos-signature - Configures DoS Behavioral Signature(s).

MODULE

security dos

SYNTAX

Configure the dos-signature component within the security dos module using the syntax shown in the following sections.

CREATE/MODIFY

```
create dos-signature [name]
modify dos-signature [name]
```

options:

```
alias [string]
app-service [string | none]
approval-state [ unapproved | manually-approved ]
parent-context-type [device | virtual-server | device-netflow]
parent-context [string]
parent-profile [string]
description [string]
family [dns| network | http]
manual-detection-threshold [integer]
manual-mitigation-threshold [integer]
origin [dynamic-bdos | user-defined]
predicates [list of struct(string, string, string)]
shareability-state [not-shareable | fully-shareable ]
state [disabled | learn-only | detect-only | mitigate]
tags [list of string]
threshold-mode [manual | stress-based-mitigation | fully-automatic]
type [dynamic | persistent]
```

DISPLAY

```
list dos-signature [name]
```

DELETE

```
delete dos-signature [name]
```

DESCRIPTION

You can use the dos-signature component to modify or display a DoS signature.

EXAMPLES

```
create security dos dos-signature Sig_Device_ToS type persistent family
http origin user-defined state disabled
```

This example shows how to create a DoS signature named Sig_Device_ToS

```
list security dos dos-signature Sig_Device_ToS
```

This example shows how to display a DoS signature named Sig_Device_ToS

```
modify dos-signature Sig_Device_TTL manual-detection-threshold 10000
manual-mitigation-threshold 4294967295
```

This examples show how to modify the manual detection and mitigation threshold of a DoS signature named Sig_Device_TTL

```
delete security dos dos-signature Sig_Device_ToS
```

This example shows how to delete a DoS signature named Sig_Device_ToS

OPTIONS

alias

Specifies the alias name of a signature. The default is empty string.

app-service

Specifies the application service that the object belongs to.

approval-state
Specifies whether or not the signature has been reviewed for quality/correctness. The default is unapproved.

User can't modify approval-state for a signature with dns or network family.

The options are:

unapproved
Specifies the signature is not approved.

manually-approved
Specifies the signature has been reviewed for quality/correctness.

parent-context-type
Specifies the type of the context for which this signature has been generated. The available options:

device
Specifies the context type is a DoS device.

virtual-server
Specifies the type of the context is a Virtual Server.

device-netflow
Specifies the context type is Netflow device.

For a dynamic type signature, it is required field and it is not allowed to be modified once specified. For persistent type signature, it can't be reset once it is set. The default is unspecified.

parent-context
Specifies the context for which this signature has been generated. This field is based on parent-context-type. If parent-context-type is device, it must be constant "Device". For a dynamic type signature, it can't be empty and it is not allowed to be modified once specified. For persistent type signature, it can't be reset once it is set. The default is empty string.

parent-profile
Specifies the profile for which this signature has been generated. This field is based on parent-context-type. If parent-context-type is device, it must be constant "/Common/dos-device-config". For a dynamic type signature, it can't be empty and it is not allowed to be modified once specified. For persistent type signature, it can't be reset once it is set. The default is empty string.

description
Specifies user defined description for this signature.

family
Specifies the family this signature belongs to. This is a require field for creation. The options are dns, network, http

It is not allowed to be modified once it is created. User can't create a signature with dns or network family.

manual-detection-threshold
Specifies the manual threshold (Events Per Second) above which the traffic is declared as an attack. The default is infinite(4294967295).

This field is taken effective only when threshold-mode attribute is set to manual. For a signature with http family, it should be always 0.

manual-mitigation-threshold
Specifies the manual threshold (Events Per Second) above which the system rate limits (drops) the traffic that matches this signature. The default is infinite(4294967295).

This field is taken effective only when threshold-mode attribute is set to manual. For a signature with http family, it should be always 0.

origin
Specifies the origin where this signature is generated from. The options are dynamic-bdos and user-defined. The default is user-defined.

It is not allowed to be modified once it is created.

predicates
Specifies list of predicates that constitutes this signature. Each predicate contains 3 string fields: metric, operator, and arguments. It is required field.

User can not add/modify predicates for a signature with dns or network family.

shareability-state
Specifies whether or not the signature can be used by Contexts (Virtual Servers) other than the one that created the signature. The default is not-shareable.

User can't modify shareability-state for a signature with dns or network family. Only not-shareable signature can be deleted.

not-shareable
Specifies the signature can only be used by context which

created it.

fully-shareable
Specifies the signature can be used by contexts other than the one that created it.

state
Specifies the deployment state of this signature. The default is disabled.

The options are:

disabled
Do not learn, do not collect stats.

learn-only
Learn/Collect stats, but do not "detect" ("alarm" in ASM-speak) any attacks,

detect-only
Learn/Collect stats/detect, but do not mitigate (rate-limit/drop, challenge, etc.) any attacks.

mitigate
Learn/Collect stats/detect/mitigate (using whichever mitigation(s) are configured).

tags Specifies list of tags of this signature. The default is empty.

threshold-mode
Specifies the threshold mode for DoS detection and mitigation. The default is manual.

The options are:

manual
Specifies the manual thresholds.

stress-based-mitigation
Specifies the manual detection ("alarm") threshold, but mitigation threshold is stress-based. This option is not available for a signature with http family or for a signature with parent-context-type being device-netflow.

fully-automatic
Specifies both the detection ("alarm") and mitigation thresholds are automatically computed. This option is not available for a signature with http family or for a signature with parent-context-type being device-netflow.

type Specifies the type of this signature. The options are dynamic and persistent. The default is persistent.

It is not allowed to be changed from persistent to dynamic. User can't create dynamic signature but can modify and delete it.

BIG-IP 2017-08-05 security dos dos-signature(1)

security dos dynamic-signatures

NAME

dynamic-signatures - Configures the dynamic signature(s) generated by L4 BDoS (or Dynamic Signature) AFM feature based on traffic characterization and anomaly detection.

This component has been deprecated and replaced by dos-signature in 13.1.0.

MODULE

security dos

SYNTAX

Configure the dynamic-signatures component within the security dos module using the syntax shown in the following sections.

CREATE

Currently this option is not supported for dynamic signatures.

MODIFY

```
modify dynamic-signatures [name]
options:
  context-name [name]
  detection-threshold [integer]
  dynamic-vectors
  enforce [disabled | enabled]
  mitigation-threshold [integer]
  partition [name]
  status [disabled | enabled]
```

```
DISPLAY
list dynamic-signatures
```

```
DELETE
Currently this option is not supported for dynamic signatures.
```

DESCRIPTION

You can use the dynamic-signatures component to modify or display a dynamic signature.

EXAMPLES

```
modify dynamic-signatures Sig_Device_ToS status disabled
```

This example shows how to disable a dynamic signature named Sig_Device_ToS

```
modify dynamic-signatures Sig_Device_TTL detection-threshold 10000
mitigation-threshold 4294967295
```

This examples show how to modify the detection and mitigation threshold of a dynamic signature named Sig_Device_TTL

OPTIONS

context-name
Specifies the context for which the dynamic signature has been generated. This is a read-only field and possible values are 'Device' or 'Virtual server Name'.

detection-threshold
Specifies the threshold value above which the traffic is declared as 'anomalous' (or an attack). When the system generates a dynamic signature (based on traffic anomaly characterization), it assigns a value for detection threshold (based on various factors such as sensitivity, anomaly percent, confidence level etc.)

User can override this value by modifying the signature and specify a new value to be used for detection mechanism.

dynamic-vectors
Specifies the list of metrics and the corresponding values/ranges that constitutes a dynamic signature. This is a read-only field.

enforce
Specifies the run time behavior of the dynamic signature in the datapath with respect to enforcement. Possible values are: disabled or enabled.

If set to disabled, the system does not enforce the signature to rate limit traffic but only collect statistics. If set to enabled, in addition to collecting stats, system also enforces the signature to detect an attack and limit traffic as per the mitigation threshold.

mitigation-threshold
Specifies the threshold above which the system rate limits (drops) the traffic that matches this generated dynamic signature. When the system generates a dynamic signature, it assigns a value for mitigation threshold based on certain factors such as mitigation configuration, detection threshold etc.

User can override this value by modifying the signature and specify a new value to be used for mitigating traffic that matches this dynamic signature.

status
Specifies the run time status of the generated signature. Possible values are: disabled or enabled.

By default, the status is set to enabled when the system generates a dynamic signature. User can disable detection and mitigation for this dynamic signature by setting this field to disabled.

security dos ip-uncommon-protolist

NAME
ip-uncommon-protolist - Configures the DoS IP uncommon protocol list component within the security dos module using the syntax shown in the following sections.

MODULE
security dos

SYNTAX
CREATE/MODIFY
modify ip-uncommon-protolist [name]
options:
description [string]
entries [add | delete | none | replace-all-with]

DISPLAY
list ip-uncommon-protolist
list ip-uncommon-protolist [name]

DESCRIPTION
You can use the ip-uncommon-protolist component to configure a DoS IP uncommon protocol list. These DoS IP uncommon protocol entries are used to rate limit the PPS (Packet per second) rate for IP protocols (identified by the IP protocol number) that are not expected to be common in the customer deployment.

EXAMPLES
create ip-uncommon-protolist plistA entries add { 20 tcp } Creates a plistA IP uncommon protocol list with entries protocol 20 and tcp.

modify ip-uncommon-protolist plistA entries add { udp } Modifies the plistA to add udp protocol to the list.

modify ip-uncommon-protolist plistA entries delete { 20 } Modifies the plistA to add protocol 20 from the list.

list ip-uncommon-protolist plistA Displays the current list of plistA entries.

OPTIONS
description
Specified user defined description for a DoS ip-uncommon--protolist.

entries
Specified contexts of a DoS ip-uncommon--protolist. The default is none.

The options are:
add Add a protocol entry to the specified IP uncommon protocol list.
delete
Remove a protocol entry from the specified IP uncommon protocol list.
none Remove all protocols from the specified IP uncommon protocol list.
replace-all-with
Replace all protocols in the specified IP uncommon protocol list.

name Specified name of a DoS ip-uncommon--protolist. This is required during creation.

"ip-uncommon-protolist" is the system ip-uncommon--protolist. It can't be deleted.

SEE ALSO

BIG-IP 2017-05security dos ip-uncommon-protolist(1)

NAME
l4bdos-file-object - L4 BDoS internal file object.

MODULE
security

SYNTAX
Configure l4bdos-file-object within security dos module using the syntax shown in the following sections.

CREATE/MODIFY
create l4bdos-file-object [name]
modify l4bdos-file-object [name]
options:
 app-service [[string] | none]
 context-name [string]
 source-path [file name]

DELETE
delete l4bdos-file-object [name]

DESCRIPTION
l4bdos file object is used internally for synchronization of bdos module data across HA (high availability) or Cluster setup.

EXAMPLES
create name source-path /var/bdos/file.json context-name /Common/VS1

Creates a file object named name, that gets its contents from file object /var/bdos/file.json and is created for ltm virtual /Common/VS1.

delete filename

Deletes the file object named filename.

OPTIONS
app-service
Specifies the name of the application service to which the file object belongs. The default value is none.

source-path
The name of the source file from which the contents are copied to create the file object.

context-name
The name of the virtual server to which this file object belongs.

SEE ALSO

security dos network-whitelist

NAME
network-whitelist - Configures the DoS network whitelist component within the security dos module using the syntax shown in the following sections. These DoS network whitelist entries are applied to all packets except those going through the management interface.

MODULE
security dos

SYNTAX
MODIFY
modify network-whitelist dos-network-whitelist
options:
 address-list
 description [string]
 entries | extended-entries [add | delete | modify | replace-all-with] {
 [[name]] {
 options:
 description [string]
 destination {
 address [ip_address/prefixlen]
 port [port]
 }
 ip-protocol [any | icmp | igmp | tcp | udp]
 source {
 address [ip_address/prefixlen]]

```

vlangs [vlan name | vlanid/mask]
}
}
}

```

```

DISPLAY
list network-whitelist

```

DESCRIPTION

You can use the network-whitelist component to configure two types of DoS network whitelists: 1) standard whitelist, up to eight entries; 2) extended whitelist, up to the the number of entries specified by DB variable dos.maxewlsize (range from 0 to 1024). Whitelists configured this way can be applied to all traffic except those from the management interface. Along with that you can use address-list to configure the srcIP Global whitelist. To this address-list you need to attach the address list objects. This address-list can be a nested list of fully qualified address. Subnets and IP address ranges and geo-locations are not allowed.. The HSB hardware compares all incoming traffic to the network-whitelist entries. If a match is found then it does not do DoS vector checks for those packets. If a match is not found then DoS vector checks are done on those packets. The network software does its regular DoS vector checks on the incoming packets as usual. If a DoS vector is hit then it compares that packet with the DoS network-whitelist entries. If the packet matches an entry, then the system does not increment the DoS vector that matched. If the packets does not match a DoS network-whitelist entry then the matched DoS vector is incremented and appropriate action is taken.

If an entry specifies more than one of the above items, a packet must pass all of the items to successfully match. For example, if an entry specifies a source subnet and a destination port, a packet must originate from the given subnet and must also have the specified destination port.

Either destination ip_address/prefixlen or source ip_address/prefixlen can be specified in a network-whitelist entry. An ip_address/prefixlen for both source and destination cannot be specified for an entry.

EXAMPLES

```

modify network-whitelist dos-network-whitelist description "bad
interfaces" entries add { re_telnet { ip-protocol tcp destination {
port telnet } } }

```

Creates a new entry called re_telnet. It matches any TCP packet whose destination port is telnet.

```

modify network-whitelist dos-network-whitelist entries add { internal-
net { source { address 172.27.0.0/16 } } }

```

Creates an entry that matches traffic from the 172.27.0.0 network.

```

list network-whitelist
security dos network-whitelist dos-network-whitelist {
  entries {
    re_telnet {
      ip-protocol tcp
      destination {
        port telnet
      }
    }
    internal-net {
      source {
        address 172.27.0.0/16
      }
    }
  }
}

```

Displays the current list of DoS whitelist entries.

```

modify network-whitelist dos-network-whitelist entries delete {
internal-net }

```

Removes the "internal-net" entry from the list of network-whitelist entries.

```

modify security dos network-whitelist dos-network-whitelist extended-
entries add { netwl { source { address 10.0.0.0/8 } destination {
address 20.20.20.0/24 } ip-protocol udp }}

```

Creates a new extended entry called netwl. It matches any UDP packet matches source network address 10.x.x.x and destination network address 20.20.20.x.

```

list security dos network-whitelist dos-network-whitelist extended-entries { netwl }
security dos network-whitelist dos-network-whitelist {
  extended-entries {
    netwl {
      description none
      ip-protocol udp
      destination {
        address 20.20.20.0/24
      }
      port any
    }
    source {
      address 10.0.0.0/8
      vlans any
    }
  }
}

```

Displays the extended whitelist entry just configured.

OPTIONS

description
Your description for the DoS network-whitelist entries.

entries
Adds, deletes, or replaces a standard network-whitelist entry.

extended-entries
Adds, deletes, or replaces an extended network-whitelist entry.

add Creates a new entry, which you specify next with a unique string in curly braces ({}).

delete
Deletes the entry that you specify next, in curly braces ({}). You can use delete {all} to empty the list of network-whitelist entries, which has the same effect as using none (see below).

modify
Modifies the existing entry that you specify next, in curly braces ({}). After the entry name, enter the new configuration settings for the entry inside a nested set of curly braces.

replace-all-with
Replaces the current set of network-whitelist entries with the entry(s) that you specify next, in curly braces ({}).

none Empties the list of network-whitelist entries.

Enter the name of a entry to be added or modified, then enter an open curly brace {}, one or more of the following options, and a closed curly brace {}.

description
Your description for the current entry.

destination
Matches against each packet's destination IP and/or destination port.

address
Specifies an IP address and network to compare against the packet's destination address.

The format for an IPv4 address is a.b.c.d[/prefix]. The general format for an IPv6 address is a:b:c:d:e:f:g:h[/prefix]; you can shorten this by eliminating leading zeros from each field (for example, you can shorten "2001:0db7:3f4a:09dd:ca90:ff00:0042:8329" to "2001:db7:3f4a:9dd:ca90:ff00:42:8329"), and/or by removing the longest contiguous field of zeros (for example, you can shorten "2001:0:0:0:c34a:0:23ff:678" to "2001::c34a:0:23ff:678"). TMSH accepts any valid text representation of IPv6 addresses, as defined in RFC 2373 (see).

port Specifies a port to compare against the packet's destination port.

ip-protocol
Specifies the IP protocol to compare against the packet. This could be any, icmp, igmp, tcp or udp. If you specify this option, a packet only matches if it uses the chosen protocol.

source
Matches against each packet's source IP, and/or source VLANs.

address
Specifies an IP address and network to compare against the packet's source address.

The format for an IPv4 address is a.b.c.d. The general format for an IPv6 address is a:b:c:d:e:f:g:h.

vlan
Specifies either a vlan name or a range of vlanids to compare against the packet. The range is specified as vlanid/mask. For example if you specify "3200/8" then the vlanid range will be 3200-3327.

EXAMPLES

```
modify security dos network-whitelist dos-network-whitelist address-list [name]
```

It adds list1 objects to the global address-list. For configuring the address list objects (list1) you can use the following examples:

```
create security firewall address-list list1 addresses [add | delete] { 30.30.30.30 45:56:567:234:456::0 }
```

```
list security firewall address-list list1
```

```
security firewall address-list list1 {  
  addresses {  
    30.30.30.30 { }  
    45:56:567:234:456:: { }  
  }  
}
```

This is how you can list the address-list objects that you configured for global whitelists list security dos network-whitelist address-list

```
security dos network-whitelist dos-network-whitelist {
  address-list list1 }
```

SEE ALSO

```
edit, list, modify, security, security dos, tmsh security firewall

DESCRIPTION

You can use the profile component to create, modify, display, or delete a DoS profile for use with DoS Protection functionality.

EXAMPLES

```
create profile my_dos_profile
```

Creates a custom DoS profile named my_dos_profile with initial settings.

```
list profile
```

Displays the properties of all DoS profiles.

OPTIONS

app-service
Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

application
Adds, deletes, or replaces a single Application Security sub-profile. You can configure the following options for Application Security:

bot-defense
Specifies properties of proactive bot defense in Application Security. You can configure the following options for Proactive Bot Defense:

collect-stats
Enables or disables domain statistics collection.

cross-domain-requests
Specifies a cross-domain requests handling mode. The options are:

allow-all
Allows all cross-domain requests. This is the default value.

validate-bulk
System validates domains in bulk: the cookies for the related domains are created together with the cookie for the current domain, by generating challenges in iframes - one per each domain.

validate-upon-request
System validates domains upon request: the cookie for the related domain is generated when a request arrives to an unqualified URL without a cookie.

external-domains
Configures a list of external domains that are allowed to link to resources of this website.

grace-period
Specifies the length of grace period (in seconds) in which only the Simple Bot Prevention is enforced.

mode Specifies a mode of proactive bot defense. The options are:

always
Specifies that the proactive bot defense is always enabled.

disabled
Specifies that the proactive bot defense is disabled. This is the default value.

during-attacks
Specifies that the proactive bot defense is enabled only during attacks.

site-domains
Configures a list of domains that are part of the website.

url-whitelist
Configures a list of URLs to exclude from the proactive bot defense.

browser-legit-enabled
Enables or disables the proactive bot defense validation of browser legitimacy and blocking of requests from suspicious clients.

browser-legit-captcha
Enables or disables the browser legitimacy detection improvement using CAPTCHA. In order to enable it, you must first enable browser-legit-enabled.

bot-signatures
Specifies settings of Bot Signatures in Application Security. You can configure the following options for Bot Signatures:

categories
Specifies the action for each Bot Signature Category. You can configure the following options for each Bot Signature Category:

action
Specifies the action for the Bot Signature Category. The possible actions are none, block and report.

check
Enables or disables the checking of Bot Signature, allowing bots to be detected.

disabled-categories
Configures a list of disabled Bot Signatures.

captcha-response
Specifies properties of the CAPTCHA response in Application Security. You can configure the following options for CAPTCHA Response Settings:

failure
Specifies properties of a failed CAPTCHA response. You can configure the following options for a failed CAPTCHA response:

body Configures a failed CAPTCHA response body.

type Configures a type of a failed CAPTCHA response body. You can configure the following options for a failed CAPTCHA response type:

custom
Configures a custom failed CAPTCHA response type.

default
Configures a default failed CAPTCHA response type.

first
Specifies properties of the first CAPTCHA response. You can configure the following options for the first CAPTCHA response:

body Configures the first CAPTCHA response body.

type Configures a type of the first CAPTCHA response body. You can configure the following options for the first CAPTCHA response type:

custom
Configures a custom first CAPTCHA response type.

default
Configures a default first CAPTCHA response type.

geolocations
Configures a list of blacklisted/whitelisted Geolocations. You can configure the following options for each Geolocation:

[black-listed | white-listed]
Specifies a type of Geolocation.

heavy-urls
Specifies heavy URL protection in Application Security. You

can configure the following options for heavy URL protection:

automatic-detection

Enables or disables automatic heavy URL detection. In order to enable it, you must first enable protection.

exclude

Configures a list of URLs (or wildcards) to exclude from the heavy URLs.

include

(Deprecated, use include-list) Configures a list of URLs to include in the heavy URLs.

include-list

Configures a list of URLs to include in the heavy URLs.

latency-threshold

Specifies the latency threshold for automatic heavy URL detection (in milliseconds).

protection

(Deprecated, use stress/tps.url-enable-heavy) Enables or disables heavy URL protection. To enable it, you must additionally enable one of the following DoS URL-based prevention policy methods: url-client-side-defense or url-rate-limiting. This can be done for either tps-based or stress-based anomaly protection.

ip-whitelist

Attribute ip-whitelist is deprecated in version 13.0.0; consider using http-whitelist instead. Adds, deletes, or replaces a set of IP addresses and subnets in the whitelist of Application Security.

name Specifies a dummy name for enabled Application Security. This option is required for the operations create, delete, modify, and replace-all-with.

stress-based

Specifies Stress-based anomaly in Application Security. You can configure the following options for Stress-based anomaly:

de-escalation-period

Specifies the de-escalation period (in seconds) in Stress-based anomaly.

escalation-period

Specifies the escalation period (in seconds) in Stress-based anomaly.

geo-captcha-challenge

Enables or disables Geolocation-based CAPTCHA challenge in Stress-based anomaly.

geo-client-side-defense

Enables or disables Geolocation-based client side integrity defense in Stress-based anomaly.

geo-minimum-share

Specifies the minimum traffic share for detection in Geolocation detection criteria of Stress-based anomaly.

geo-rate-limiting

Enables or disables Geolocation-based rate limiting in Stress-based anomaly.

geo-request-blocking-mode

Specifies a Geolocation-based request blocking mode of Stress-based anomaly. The options are:

block-all

Specifies that the system blocks all requests from the respective Geolocation.

rate-limit

Specifies that the system blocks requests from the respective Geolocation based on the traffic share ratio. This is the default value.

geo-share-increase-rate

Specifies the percentage by which TPS increased in Geolocation detection criteria of Stress-based anomaly.

ip-captcha-challenge

Enables or disables Source IP-based CAPTCHA challenge in Stress-based anomaly.

ip-client-side-defense

Enables or disables Source IP-based client side integrity defense in Stress-based anomaly.

ip-maximum-tps

Specifies the amount which TPS reached in IP detection criteria of Stress-based anomaly.

ip-minimum-tps

Specifies the minimum TPS threshold for detection in IP detection criteria of Stress-based anomaly.

ip-rate-limiting

Enables or disables Source IP-based rate limiting in Stress-based anomaly.

ip-request-blocking-mode
Specifies a Source IP-based request blocking mode of Stress-based anomaly. The options are:

- block-all**
Specifies that the system blocks all requests from the respective Source IP address.
- rate-limit**
Specifies that the system blocks requests from the respective Source IP address based on the traffic share ratio. This is the default value.

ip-tps-increase-rate
Specifies the percentage by which TPS increased in IP detection criteria of Stress-based anomaly.

mode Specifies an operation mode of Stress-based anomaly. The options are:

- off** Specifies that the system does not check for DoS attacks. This is the default value.
- transparent**
Specifies that when the system detects an attack, it displays the attack data on the Reporting DoS Attacks screen. In transparent mode the system does not drop requests either from the attacking IP address, or to attacked URLs.
- blocking**
Specifies that when the system detects an attack, in addition to displaying the attack data on the Reporting DoS Attacks screen, the system also drops either connections from the attacking IP address, or requests to attacked URLs.

site-captcha-challenge
Enables or disables Site-wide CAPTCHA challenge in Stress-based anomaly.

site-client-side-defense
Enables or disables Site-wide client side integrity defense in Stress-based anomaly.

site-maximum-tps
Specifies the amount which TPS reached in Site-wide detection criteria of Stress-based anomaly.

site-minimum-tps
Specifies the minimum TPS threshold for detection in Site-wide detection criteria of Stress-based anomaly.

site-rate-limiting
Enables or disables Site-wide rate limiting in Stress-based anomaly.

site-tps-increase-rate
Specifies the percentage by which TPS increased in Site-wide detection criteria of Stress-based anomaly.

static-url-mitigation
Enables or disables Static URL mitigation in Stress-based anomaly.

url-captcha-challenge
Enables or disables URL-based CAPTCHA challenge in Stress-based anomaly.

url-client-side-defense
Enables or disables URL-based client side integrity defense in Stress-based anomaly.

url-maximum-tps
Specifies the amount which TPS reached in URL detection criteria of Stress-based anomaly.

url-minimum-tps
Specifies the minimum TPS threshold for detection in URL detection criteria of Stress-based anomaly.

url-rate-limiting
Enables or disables URL-based rate limiting in Stress-based anomaly.

url-tps-increase-rate
Specifies the percentage by which TPS increased in URL detection criteria of Stress-based anomaly.

behavioral
Specifies properties of Behavioral Detection in Stress-based anomaly. You can configure the following options for Behavioral Detection:

- dos-detection**
Enables or disables the Behavior Based Detection.
- mitigation-mode**
Specifies mitigation impact on suspicious bad actors/requests. None: Learns and monitors traffic behavior, but no action is taken. Conservative protection: If enabled, slows down and rate limits requests from anomalous IP addresses based on its anomaly detection confidence

and the server's health. If enabled, blocks requests that match the attack signatures. Standard protection:If enabled, slows down requests from anomalous IP addresses based on its anomaly detection confidence and the server's health. Rate limits requests from anomalous IP addresses and, if necessary, rate limits all requests based on the servers health. Limits the number of concurrent connections from anomalous IP addresses and, if necessary, limits the number of all concurrent connections based on the server's health. If enabled, blocks requests that match the attack signatures. Aggressive protection:If enabled, slows down requests from anomalous IP addresses based on its anomaly detection confidence and the server's health. Rate limits requests from anomalous IP addresses and, if necessary, rate limits all requests based on the servers health. Limits the number of concurrent connections from anomalous IP addresses and, if necessary, limits the number of all concurrent connections based on the server's health. Proactively performs all protection actions (even before an attack). Increases the impact of the protection techniques. If enabled, blocks requests that match the attack signatures. Increases the impact of blocked requests.

signatures
Enables or disables signature usage and mitigation.

signatures-approved-only
Allows to use only manually approved signatures.

accelerated-signatures
Enables or disables signatures detection before the connection establishment. Automatically enables syn-cookie mechanism during attack.

tcp-dump
Specifies properties of traffic recording during attacks in Application Security. You can configure the following options for Record Traffic During Attacks:

maximum-duration
Specifies the TCP dump maximum duration (in seconds).

maximum-size
Specifies the TCP dump maximum size (in megabytes).

record-traffic
Enables or disables traffic recording during attacks.

repetition-interval
Specifies the TCP dump repetition interval (in seconds).

tps-based
Specifies TPS-based anomaly in Application Security. You can configure the following options for TPS-based anomaly:

de-escalation-period
Specifies the de-escalation period (in seconds) in TPS-based anomaly.

escalation-period
Specifies the escalation period (in seconds) in TPS-based anomaly.

geo-captcha-challenge
Enables or disables Geolocation-based CAPTCHA challenge in TPS-based anomaly.

geo-client-side-defense
Enables or disables Geolocation-based client side integrity defense in TPS-based anomaly.

geo-minimum-share
Specifies the minimum traffic share for detection in Geolocation detection criteria of TPS-based anomaly.

geo-rate-limiting
Enables or disables Geolocation-based rate limiting in TPS-based anomaly.

geo-request-blocking-mode
Specifies a Geolocation-based request blocking mode of TPS-based anomaly. The options are:

block-all
Specifies that the system blocks all requests from the respective Geolocation.

rate-limit
Specifies that the system blocks requests from the respective Geolocation based on the traffic share ratio. This is the default value.

geo-share-increase-rate
Specifies the percentage by which TPS increased in Geolocation detection criteria of TPS-based anomaly.

ip-captcha-challenge
Enables or disables Source IP-based CAPTCHA challenge in TPS-based anomaly.

ip-client-side-defense
Enables or disables Source IP-based client side integrity defense in TPS-based anomaly.

ip-maximum-tps
Specifies the amount which TPS reached in IP detection criteria of TPS-based anomaly.

ip-minimum-tps
Specifies the minimum TPS threshold for detection in IP detection criteria of TPS-based anomaly.

ip-rate-limiting
Enables or disables Source IP-based rate limiting in TPS-based anomaly.

ip-request-blocking-mode
Specifies a Source IP-based request blocking mode of TPS-based anomaly. The options are:

- block-all**
Specifies that the system blocks all requests from the respective Source IP address.
- rate-limit**
Specifies that the system blocks requests from the respective Source IP address based on the traffic share ratio. This is the default value.

ip-tps-increase-rate
Specifies the percentage by which TPS increased in IP detection criteria of TPS-based anomaly.

mode Specifies an operation mode of TPS-based anomaly. The options are:

- off** Specifies that the system does not check for DoS attacks. This is the default value.
- transparent**
Specifies that when the system detects an attack, it displays the attack data on the Reporting DoS Attacks screen. In transparent mode the system does not drop requests either from the attacking IP address, or to attacked URLs.
- blocking**
Specifies that when the system detects an attack, in addition to displaying the attack data on the Reporting DoS Attacks screen, the system also drops either connections from the attacking IP address, or requests to attacked URLs.

site-captcha-challenge
Enables or disables Site-wide CAPTCHA challenge in TPS-based anomaly.

site-client-side-defense
Enables or disables Site-wide client side integrity defense in TPS-based anomaly.

site-maximum-tps
Specifies the amount which TPS reached in Site-wide detection criteria of TPS-based anomaly.

site-minimum-tps
Specifies the minimum TPS threshold for detection in Site-wide detection criteria of TPS-based anomaly.

site-rate-limiting
Enables or disables Site-wide rate limiting in TPS-based anomaly.

site-tps-increase-rate
Specifies the percentage by which TPS increased in Site-wide detection criteria of TPS-based anomaly.

static-url-mitigation
Enables or disables Static URL mitigation in TPS-based anomaly.

url-captcha-challenge
Enables or disables URL-based CAPTCHA challenge in TPS-based anomaly.

url-client-side-defense
Enables or disables URL-based client side integrity defense in TPS-based anomaly.

url-maximum-tps
Specifies the amount which TPS reached in URL detection criteria of TPS-based anomaly.

url-minimum-tps
Specifies the minimum TPS threshold for detection in URL detection criteria of TPS-based anomaly.

url-rate-limiting
Enables or disables URL-based rate limiting in TPS-based anomaly.

url-tps-increase-rate
Specifies the percentage by which TPS increased in URL

detection criteria of TPS-based anomaly.

trigger-irule

Specifies, when enabled, that the system activates an Application DoS iRule event. The default value is disabled.

single-page-application

Specifies, when enabled, that the system supports a Single Page Applications. The default value is disabled.

fastl4-acceleration-profile

Specifies a fastL4 profile that used for DOS acceleration. None - if disable acceleration.

scrubbing-enable

Specifies whether to enable Traffic Scrubbing during attacks by advertising BGP routes. This requires configuration of security scrubber profile, and will function even when the mode is set to transparent.

scrubbing-duration-sec

Specifies the duration of the Traffic Scrubbing BGP route advertisement, in seconds. This is used when scrubbing-enable is enabled.

rtbh-enable

Specifies whether to enable Remote Triggered Black Hole (RTBH) of attacking IPs by advertising BGP routes. This requires configuration of security blacklist-publisher, and will function even when the Operation Mode is set to transparent.

rtbh-duration-sec

Specifies the duration of the RTBH BGP route advertisement, in seconds. This is used when rtbh-enable is enabled.

description

User defined description.

protocol-dns

Adds, deletes, or replaces a single Protocol DNS Security sub-profile. You can configure the following options for Protocol DNS Security:

name Specifies a dummy name for enabled Protocol DNS Security. This option is required for the operations create, delete, modify, and replace-all-with.

dynamic-signatures

Specifies options related to DNS Behavioral DoS (Dynamic Signatures) feature per virtual server by virtue of attaching a dos profile to a virtual server. Following options are configurable for this feature:

detection

Specifies the mode for detection of anomalies in traffic for the purpose of dynamic signature generation. Following modes are supported: disabled, enabled and learn-only.

Mode learn-only is same as enabled except that the system does not generate any logs (or alerts the user). It is used mainly to learn the baseline thresholds for the traffic.

Default is disabled.

mitigation

Specifies the mode for mitigation of anomalous traffic (specified in form of dynamic signatures). Following modes are supported: none, low, medium and high.

Each mode represents the severity (or aggressiveness) at which the system should try to mitigate the anomalous traffic.

Default is none.

dns-query-vector

Adds, deletes, or replaces Protocol DNS DoS vectors. You can configure the following options for DNS query vectors:

query-type

Specifies the vector (DNS query) type for DoS attack detection.

enforce

This option is deprecated in version 13.1.0 and is replaced by state. Enable or disable the packet drop action of DOS detection for this attack type.

auto-threshold

This option is deprecated in version 13.1.0 and is replaced by threshold-mode. Enables the auto threshold mode for dos detection and dos mitigation. The default value is disabled.

bad-actor

Enables per-source IP based bad actor detection

per-source-ip-detection-pps

Bad actor detection rate (for single IP address) of this vector

per-source-ip-limit-pps

Bad actor allowed rate (for single IP address) of this vector

rate-increase

Specifies the rate increase for DoS attack detection.

rate-limit

Specifies the rate limit for DoS attack detection. If the value is infinite the detection is disabled.

rate-threshold

Specifies the rate threshold for DoS attack detection. If the value is infinite the detection is disabled.

state

Specifies the run time state of this signature. The options are the same as those in network-attack-vector.

threshold-mode

Enables the threshold mode for dos detection and dos mitigation. The default value is manual. The options are the same as those in network-attack-vector.

prot-err-attack-detection

Specifies if protocol errors attack detection is enabled or not. Eg: Malformed, Malicious DoS attacks.

prot-err-atck-rate-incr

Specifies the protocol errors rate increase for DoS attack detection.

protocol-sip

Adds, deletes, or replaces a single Protocol SIP Security sub-profile. You can configure the following options for Protocol SIP Security:

name Specifies a dummy name for enabled Protocol SIP Security. This option is required for the operations create, delete, modify, and replace-all-with.

prot-err-atck-rate-increase

Specifies the protocol errors rate increase for DoS attack detection.

prot-err-atck-rate-threshold

Specifies the protocol errors rate threshold for DoS attack detection.

prot-err-attack-detection

Specifies if protocol errors attack detection is enabled or not. Eg: Malformed packets DoS attacks.

sip-attack-vector

Adds, deletes, or replaces Protocol SIP DoS vectors. You can configure the following options for SIP method vectors:

type Specifies the vector type (SIP method) for DoS attack detection.

enforce

This option is deprecated in version 13.1.0 and is replaced by state. Enable or disable the packet drop action of DOS detection for this attack type.

auto-threshold

This option is deprecated in version 13.1.0 and is replaced by threshold-mode. Enables the auto threshold mode for dos detection and dos mitigation. The default value is disabled.

bad-actor

Enables per-source IP based bad actor detection

per-source-ip-detection-pps

Bad actor detection rate (for single IP address) of this vector

per-source-ip-limit-pps

Bad actor allowed rate (for single IP address) of this vector

rate-increase

Specifies the rate increase for DoS attack detection.

rate-limit

Specifies the rate limit for DoS attack detection. If the value is infinite the detection is disabled.

rate-threshold

Specifies the rate threshold for DoS attack detection. If the value is infinite the detection is disabled.

state

Specifies the run time state of this signature. The options are the same as those in network-attack-vector.

threshold-mode

Enables the threshold mode for dos detection and dos mitigation. The default value is manual. The options are the same as that in network-attack-vector.

dos-network

Adds, deletes, or replaces a single Network DoS Security sub-profile. You can configure the following options for Network DoS Security:

name Specifies a dummy name for enabled Network DoS Security. This option is required for the operations create, delete, modify, and replace-all-with.

dynamic-signatures
Specifies options related to L4 Behavioral DoS (Dynamic Signatures) feature per virtual server by virtue of attaching a dos profile to a virtual server. Following options are configurable for this feature:

detection
Specifies the mode for detection of anomalies in traffic for the purpose of dynamic signature generation. Following modes are supported: disabled, enabled and learn-only.

Mode learn-only is same as enabled except that the system does not generate any logs (or alerts the user). It is used mainly to learn the baseline thresholds for the traffic.

Default is disabled.

mitigation
Specifies the mode for mitigation of anomalous traffic (specified in form of dynamic signatures). Following modes are supported: none, low, medium and high.

Each mode represents the severity (or aggressiveness) at which the system should try to mitigate the anomalous traffic.

Default is none.

scrubber-enable
Specifies the configuration mode for enabling or disabling the feature to scrub the attack traffic upon dynamic signature match. Default is no.

scrubber-category
Specifies the IP Intelligence category used for scrubbing the attack traffic upon dynamic signature match that constitutes destination IP address component. Default category is `attacked_ips`.

scrubber-advertisement-period
Specifies the advertisement period for which the attack traffic is scrubbed. Default is 300 seconds.

network-attack-vector
Adds, deletes, or replaces Network Attack DoS vectors. You can configure the following options for Network Attack vectors:

attack-type
Specifies the vector type (Network Attack) for DoS attack detection.

enforce
This option is deprecated in version 13.1.0 and is replaced by `state`. Enable or disable the packet drop action of DOS detection for this attack type.

auto-threshold
This option is deprecated in version 13.1.0 and is replaced by `threshold-mode`. Enables the auto threshold mode for dos detection and dos mitigation. The default value is disabled.

rate-increase
Specifies the rate increase for DoS attack detection.

rate-limit
Specifies the rate limit for DoS attack detection. If the value is infinite the detection is disabled.

rate-threshold
Specifies the rate threshold for DoS attack detection. If the value is infinite the detection is disabled.

packet-types
Specifies the packet types for Sweep attack vector.

bad-actor
Enables per-source IP based bad actor detection

per-source-ip-detection-pps
Bad actor detection rate (for single IP address) of this vector

per-source-ip-limit-pps
Bad actor allowed rate (for single IP address) of this vector

state
Specifies the run time state of this signature.

The options are:

disabled
Do not learn, do not collect stats.

learn-only
Learn/Collect stats, but do not "detect" ("alarm" in ASM-speak) any attacks,

detect-only
Learn/Collect stats/detect, but do not mitigate

(rate-limit/drop, challenge, etc.) any attacks.

mitigate
Learn/Collect stats/detect/mitigate (using
whichever mitigations are configured).

threshold-mode

Enables the threshold mode for dos detection and dos
mitigation. The default value is manual.

The options are:

manual
Specifies the manual thresholds.

stress-based-mitigation
Specifies the manual detection ("alarm") threshold,
but mitigation threshold is stress-based.

fully-automatic
Specifies both the detection ("alarm") and
mitigation thresholds are automatically computed.

whitelist
Specifies the Dos srcIP whitelist configuration.

http-whitelist
Specifies the IP addresses and subnets whitelist configuration for
Application Security (Overrides the global whitelist).

glob Displays the items that match the glob expression. See help glob
for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required
for the commands create, delete, and modify.

partition
Displays the administrative partition within which the component
resides.

regex
Displays the items that match the regular expression. The regular
expression must be preceded by an at sign (@[regular expression])
to indicate that the identifier is a regular expression. See help
regex for a description of regular expression syntax.

security dos spva-stats

NAME
spva-stats - Shows the Configuration and Data path stats for sPVA.

MODULE
security dos

SYNTAX
Displays the sPVA stats

DISPLAY
show security dos spva-stats

DESCRIPTION
This module shows the sPVA related configuration and data path stats.
sPVA stats are relevant only in case the Hardware is sPVA capable.

EXAMPLES
show security dos spva-stats

Displays the below sPVA related stats

Total SW entry
Total sPVA entry count present in SW

Total HSB entry
Max number of sPVA entries in HSB

Used HSB entry
Total number of sPVA entries present in HSB

Global white list SW entry
Global whitelist entries present in SW

Global white list HSB entry
Global Whitelist entries present in HSB.

Global white list total entry
Total number of Global white list entries present in SW and HSB

Global black list SW entry
Total number of global back list sPVA entries present in SW

Global black list HSB entry
Total number of global black list sPVA entries present in HSB

Global black list total entry
Total number of global black list entry count present in SW and HSB

VS white list SW entry
Total whitelist SW entry count for virtual server with port as wildcard.

VS white list HSB entry
Total whitelist HSB entry count for virtual server with port as wildcard.

VS white list total entry
Total count of white list entries present in SW and HSB for virtual server with port as wildcard.

VS black list SW entry
Total black list SW entry count for virtual server with port as wildcard.

VS black list HSB entry
Total black list HSB entry count for virtual server with port as wildcard.

VS black list total entry
Total count of black list entries present in SW and HSB for virtual server with port as wildcard.

App white list SW entry
Total whitelist SW entry count for application virtual server.

App white list HSB entry
Total whitelist HSB entry count for application virtual server.

App white list total entry
Total count of white list entries present in SW and HSB for application virtual server

App black list SW entry
Total black list SW entry count for application virtual server

App black list HSB entry
Total black list HSB entry count for application virtual server.

App black list total entry
Total count of black list entries present in SW and HSB for application virtual server

Global white list SW hit
Total packets hits for global white list in SW

Global white list HSB hit

BIG-IP 2016-01-07 security dos spva-stats(1)

security dos udp-portlist

NAME

udp-portlist - Configures the DoS udp portlist component within the
security dos module using the syntax shown in the following sections.
These DoS udp portlist entries are applied to all udp packets except
those going through the management interface.

MODULE

security dos

SYNTAX

```
MODIFY
modify udp-portlist dos-udp-portlist
options:
  description [string]
  list-type [exclude-listed-ports | include-listed-ports]
  entries [modify | replace-all-with] {
    [entry] {
      options:
      description [string]
      match-direction [both | dst | none | src]
      port-number [number]
    }
  }
}
```

DISPLAY

```
list udp-portlist
```

DESCRIPTION

You can use the udp-portlist component to configure a DoS UDP portlist
of upto eight entries for all UDP traffic except the management
interface. The HSB hardware compares all incoming UDP traffic to the

udp-portlist entries. There are 2 types of behavior, depending upon whether the udp port list is configured as a white list or as a black list. White list and black list are mutually exclusive properties of a UDP port list.

If the udp port list is configured as a list-type of exclude-listed-ports, and if a match is found on an incoming packet, then we do not increment the UDP Flood DoS vector. If a match is not found, then the UDP Flood DoS vector checks are done on those packets.

If the udp port list is configured as a list-type of include-listed-ports, and if a match is found on an incoming packet, then we increment the UDP Flood DoS vector. If a match is not found, then the UDP Flood DoS vector checks are not done on the packets.

Either destination port or source port or both can be specified in a udp-portlist entry.

EXAMPLES

```
modify udp-portlist dos-udp-portlist description "bad ports" list-type
include-listed-ports Modifies the udp-portlist dos-udp-portlist to a
blacklist.
```

```
modify udp-portlist dos-udp-portlist list-type exclude-listed-ports
Modifies the udp-portlist dos-udp-portlist to a white-list.
```

```
modify udp-portlist dos-udp-portlist description "bad ports" entries
modify { entry1 { match-direction src port-number 161 } } Modifies an
entry. The new entry is for source UDP port 161. It matches any UDP
packet whose source port is 161.
```

```
modify udp-portlist dos-udp-portlist entries modify { 161 { match-
direction both } }
```

Modifies the entry for destination UDP port 161 to source and destination port 161. It matches any UDP packet whose destination or source port is 161.

```
security dos udp-portlist dos-udp-portlist {
  entries {
    entry1 {
      match-direction both
      port-number snmp
    }
    entry2 { }
    entry3 { }
    entry4 { }
  }
  white-list
}
```

Displays the current list of DoS UDP portlist entries.

OPTIONS

description
Your description for the DoS udp-portlist.

list-type
Sets the list type to be either exclude-listed-ports or include-listed-ports

include-listed-ports
Sets the property of the dos-udp-portlist list to include-listed-ports (Blacklist).

exclude-listed-ports
Sets the property of the dos-udp-portlist list to exclude-listed-ports (Whitelist).

entries
Modifies a udp-portlist entry.

modify
Modifies the existing entry that you specify next, in curly braces {}. After the entry name, enter the new configuration (port mode and port number) settings for the entry inside a nested set of curly braces.

replace-all-with
Replaces the current set of udp-portlist entries with the entry(s) that you specify next, in curly braces {}.

Enter the name of a entry to be modified, then enter an open curly brace {}, one or more of the following options, and a closed curly brace {}.

description
Your description for the current entry.

match-direction
Set the mode of matching (source, destination or both).

port-number
Set the port number for matching.

BIG-IP 2016-03-14 security dos udp-portlist(1)

security dos virtual

NAME
virtual - Displays and resets dos per-virtual statistics, or run dos per-virtual command on the BIG-IP(r) system.

MODULE
security dos

SYNTAX
Manage the virtual component within the security dos module using the syntax in the following sections.

DISPLAY
show virtual name [vs_name]
options:
 dns-nxdomain-stat
 field-fmt
 query-valid-domain [fqdn]

MODIFY
reset-stats virtual name [vs_name]
options:
 dns-nxdomain-stat

RUN
run virtual name [vs_name]
options:
 auto-threshold-relearn
 dns-nxdomain-relearn
 dynamic-signatures-history-relearn

DESCRIPTION
You can use the virtual component to display and reset dos per-virtual statistics, or run dos per-virtual commands.

EXAMPLES
show virtual name my_virtual query-valid-domain www.f5.com

Displays if a FQDN(Fully Qualified Domain Name) is present in the per-virtual learned valid domains.

show virtual name my_virtual dns-nxdomain-stat

Displays the dns-nxdomain statistics on the specified virtual server.

reset-stats virtual name my_virtual dns-nxdomain-stat

Resets the dns-nxdomain-stat statistics on the specified virtual server.

run virtual name my_virtual auto-threshold-relearn

Clears the auto-threshold history on the specified virtual server auto-threshold vector.

run virtual name my_virtual dns-nxdomain-relearn

Clears the dns-nxdomain history on the specified virtual server.

run virtual dns-nxdomain-relearn

Clears the dns-nxdomain history on all virtual servers.

run virtual name my_virtual dynamic-signatures-history-relearn

Clears the dynamic-signatures history on the specified virtual server dynamic-signatures vector.

OPTIONS
name Apply the command to the specified virtual server. It can be optional in some commands/options. In these cases, the command will be applied to all virtual servers.

show command: options are
dns-nxdomain-stat: name is required.
field-fmt: only work with dns-nxdomain-stat.
query-valid-domain [fqdn]: name is required.
run command: options are
auto-threshold-relearn: name is required
dns-nxdomain-relearn: name is optional. The command applies to all virtual servers if name is not specified.
auth-threshold-relearn: name is required.
reset-stats command: options are
dns-nxdomain-stat: name is required.

SEE ALSO
reset-stats, run, show, tmsh

security firewall address-list

NAME
address-list - Configures an address-list for use by firewall rules. An address list is a list of IP-address prefixes to compare against the source-IP address and/or destination-IP address in an IP packet.

MODULE
security firewall

SYNTAX
CREATE/MODIFY
create address-list [name]
modify address-list [[name] | all]
options:
addresses [add | delete | modify | replace-all-with] {
[[ip address]]
}
fqdns [add | delete | replace-all-with] {
[fully qualified domain names]
}
fqdns none
geo [add | default | delete | replace-all-with] {
[[country_code[:state_name/city_name]]]
}
geo none
app-service [name]
description [string]

edit address-list [[name] | all]
options:
all-properties
non-default-properties

DISPLAY
list address-list [[name] | all | [property]]
show running-config address-list [[name] | all | [property]]

DELETE
delete address-list [[name] | all]

DESCRIPTION
You can use the address-list component to define reusable lists of addresses. You can use an address list in any of the following firewalls and firewall rule lists: net self, net route-domain, security firewall global-rules, security firewall rule-list, security firewall management-ip-rules, and ltm virtual. A firewall rule compares all of the addresses in the list to either the source or destination IP in the packet, depending on how you apply the list. If there is a match, the firewall rule takes an action, such as accepting or dropping the packet.

EXAMPLES
create address-list alist1 addresses add { 10.10.1.1 10.10.1.2
192.168.24.0/24 }

Creates a new address list, "alist1," with two IPv4 addresses and one IPv4 subnet.

modify address-list alist1 addresses modify { 10.10.1.1 { description
"management IP at wmed site3" } }

Modifies the above address list with a description for the first address.

modify alist1 geo add { TR:Istanbul }

Modifies the above address list with an addition of a country:city/state.

modify address-list alist1 addresses add { 2001:DB8:a::/64 }

Modifies the same address list by adding an IPv6 subnet.

list address-list alist1

```

security firewall address-list alist1 {
  addresses {
    10.10.1.1 {
      description "management IP at wmed site3"
    }
    10.10.1.2 { }
    192.168.24.0/24 { }
    2001:db8:a::/64 { }
  }
}

```

Shows the modified address list.

```
create address-list xyz fqdns add { xyz.com }
```

Creates a new address list, "xyz" with a single fully qualified domain 'xyz.com'.

```
modify address-list xyz addresses add { 2001:DB8:a::/64 } fqdns add {
abc.com }
```

Modifies the same address list by adding an IPv6 subnet and another fully qualified domain 'abc.com'.

```
list address-list xyz
security firewall address-list xyz {
  addresses {
    2001:db8:a::/64 { }
  }
  fqdns {
    abc.com { }
    xyz.com { }
  }
}

```

Shows the above address list 'xyz'.

OPTIONS

addresses

Specifies a list of IP addresses and/or subnets to compare against a packet's source or destination address. The format for an IPv4 address is a.b.c.d[/prefix]. The general format for an IPv6 address is a:b:c:d:e:f:g:h[/prefix]; you can shorten this by eliminating leading zeros from each field (for example, you can shorten "2001:0db7:3f4a:09dd:ca90:ff00:0042:8329" to "2001:db7:3f4a:9dd:ca90:ff00:42:8329"), and/or by removing the longest contiguous field of zeros (for example, you can shorten "2001:0:0:0:c34a:0:23ff:678" to "2001::c34a:0:23ff:678"). TMSH accepts any valid text representation of IPv6 addresses, as defined in RFC 2373 (see).

The next keyword specifies the action to take with the addresses (add, delete, modify, or replace the current set of addresses).

add Creates a new address list, which you specify next with IP addresses and/or prefixes in curly braces ({}).

delete

Deletes the address(es) that you specify next, in curly braces ({}).

modify

Makes it possible to replace the optional description(s) for the address(es). You can specify a description in a nested set of curly braces after each address.

replace-all-with

Replaces the current set of IP addresses with the address(es) that you specify next, in curly braces ({}).

fqdns

Specifies a list of fully qualified domain names to compare against packet's destination IP address domain.

The next keyword specifies the action to take with the fqdns (add, delete, or replace the current set of fqdns).

geo Specifies a list of geographic locations that the packet will be compared against.

app-service

Associates this address list with a particular Application Service. An Application Service is a major component of an iApp, an advanced configuration tool for creating and maintaining similar applications on multiple servers. The asm module (see asm) has components for working with iApps.

description

Is your description for this address list.

security firewall config-change-log

NAME
config-change-log - Configures firewall configuration change log setting.

MODULE
security firewall

SYNTAX
Modify the config-change-log component within the security firewall module using the syntax shown in the following sections.

MODIFY
modify config-change-log log-changes [automatic | on | off]
modify config-change-log log-publisher [none | [name]]

DISPLAY
list config-change-log
show running-config config-change-log

DESCRIPTION
You can use the config-change-log component to configure if changes to the firewall rules should be logged or not. The default is to automatically determine if log is needed based on the mode of the on-demand-compilation. If the mode of the on-demand-compilation is 'enabled', the changes will be logged. If change log is enabled, a publisher need to be configured too.

EXAMPLES
modify config-change-log log-changes on log-publisher local-db-publisher

COPYRIGHT

F5 Networks and BIG-IP (c) Copyright 2014. All rights reserved.

security firewall container-stat

NAME
container-stat - Show the compilation result of firewall rules.

MODULE
security firewall

SYNTAX
show container-stat

DESCRIPTION
You can use the container-stat component to display the compilation result of firewall rules for each container. For firewall rules, a container is uniquely identified by the combination of context type, context name and policy type. The outputs of the command include: the time it takes to compile the rules and to perform overlapping check for each container, the number of micro-rules, the size of the containers in bytes, the amount of memory used for compilation, and the time the container is activated.

EXAMPLES
show security firewall container-stat

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2015-03-1security firewall container-stat(1)

security firewall context-stat

NAME
context-stat - Displays and resets firewall statistics of the specified context on the BIG-IP(r) system. You can only use the show and reset-stats command with this component.

MODULE
security firewall

SYNTAX
show context-stat
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
field-fmt
reset-stats context-stat

DESCRIPTION
You can use the context-stat component to display or reset firewall statistics of the specified context.

EXAMPLES
show context-stat
Displays firewall rule's statistics in the system default units.
show context-stat raw
Displays raw firewall rule's statistics.
reset-stats context-stat
Resets firewall statistics for all contexts.

SEE ALSO
show, reset-stats, tmsh

security firewall current-state

NAME
current-state - Show the current state of firewall rules compilation.

MODULE
security firewall

SYNTAX
show current-state

DESCRIPTION
You can use the current-state component to display the current system-wide state of firewall rules compilation. The outputs of the command includes: the mode of on-demand compilation and on-demand rule deploy (enabled or disabled), the rule compiler status (quiescent, pending-compilation, being-compiled, pending-deployment, being-deployed, failed-compilation, failed-deployment, pccd-failed), compilation start time, compilation end time, deployment start time, deployment end time, aggregate number of micro-rules, active blob name, blob creation time, and if the blob MD5 is verified or not.

EXAMPLES

```
show security firewall current-state
```

security firewall fqdn-entity

NAME

fqdn-entity - Perform on-demand refresh to query IP mappings for one (or all) configured FQDNs in firewall rules.

MODULE

security firewall

SYNTAX

Use the fqdn-entity component within the security firewall module to perform on-demand refresh to query IP mappings for a specific FQDN (or all FQDNs) configured in firewall rules using the following syntax:

DISPLAY

```
load fqdn-entity [all | name]
```

DESCRIPTION

You can use the fqdn-entity component to perform on-demand refresh to query IP mappings for one or all configured FQDNs in firewall rules.

BigIP will periodically refresh IP mappings for each FQDN upon previous mappings expiry time or after refresh-interval as configured in security firewall global-fqdn-policy whichever is greater. fqdn-entity component can be used to refresh the IP mappings irrespective of either the expiry time or the refresh-interval.

EXAMPLES

```
load fqdn-entity all
```

Perform on-demand refresh for all the configured FQDNs in firewall rules.

```
load fqdn-entity f5.com
```

Perform on-demand refresh for fqdn 'f5.com' configured in one of the firewall rules.

SEE ALSO

```
security firewall address-list, security firewall policy, security  
firewall rule-list, security firewall fqdn-info, security firewall  
global-fqdn-policy
```

COPYRIGHT

```
BIG-IP      2015-07-22 security firewall fqdn-entity(1)
```

security firewall fqdn-info

NAME

fqdn-info - Query run time information for one (or all) configured FQDNs in firewall rules.

MODULE
security firewall

SYNTAX
Use the fqdn-info component within the security firewall module to query run time information for one (or all) configured FQDNs in firewall rules using the following syntax:

DISPLAY
show fqdn-info fqdn [all | name]

DESCRIPTION
You can use the fqdn-info component to query run time information for one or all configured FQDNs in firewall rules. Use option fqdn to query information regarding a specific FQDN or all FQDNs configured in firewall rules.

Following information related to each FQDN is queried using fqdn-info component:

- a) Last Refresh time.
- b) Next Refresh time.
- c) Last Successful Refresh.
- d) DNS Records valid until
- e) IP Addresses

OPTIONS
fqdn Specifies the name of a FQDN. Use 'all' to query information for all configured FQDNs.

EXAMPLES
show fqdn-info fqdn all
Query information for all the configured FQDNs in firewall rules.

show fqdn-info fqdn f5.com
Query information for fqdn 'f5.com' configured in one of the firewall rules.

SEE ALSO
security firewall address-list, security firewall policy, security firewall rule-list

security firewall global-fqdn-policy

NAME
global-fqdn-policy - Configures the global fqdn policy which is used to resolve FQDN names to IP Address mappings for the FQDN names that are specified in the firewall rules.

MODULE
security firewall

SYNTAX
Modify the global-fqdn-policy component within the security firewall module using the syntax shown in the following sections.

MODIFY
modify global-fqdn-policy
options:
app-service [name]
description [string]
dns-resolver [[resolver name] | none]
refresh-interval [integer]

edit global-fqdn-policy
options:
all-properties
non-default-properties
one-line
partition
recursive

DISPLAY
list global-fqdn-policy
show running-config global-fqdn-policy
options:

DESCRIPTION

You can use the global-fqdn-policy component to configure a net dns-resolver that will be used by firewall to resolve FQDN names to IP Address mappings. These mappings in turn will be used to match firewall rules (across all policies on all contexts) based on FQDN constraints.

EXAMPLES

```
modify global-fqdn-policy dns-resolver xyz
```

Modifies the global-fqdn-policy to use dns resolver object named 'xyz'. Default refresh-interval is 60 minutes.

```
modify global-fqdn-policy dns-resolver xyz refresh-interval 120
```

Modifies the global-fqdn-policy to use dns resolver object named 'xyz' and specify periodic refresh rate of 120 minutes (2 hours) to re-resolve FQDN-to-IP mappings.

```
list global-fqdn-policy
```

Displays the current list of global-fqdn-policy contents.

OPTIONS

app-service

Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

description

User defined description.

dns-resolver

Specifies an existing net dns-resolver. This will be used by firewall to obtain FQDN-to-IP Address mappings which will be used to match firewall rules based on FQDN constraints. Note dns-resolver none can be used to remove the object from global-fqdn-policy if and only if there are no AFM rules with (non empty) FQDN constraints.

refresh-interval

Specifies refresh interval to be used to re-resolve FQDN-to-IP mappings. Unit is in minutes and default is 60 minutes. Minimum allowed is 10 minutes and maximum is 46080 minutes.

  enforced-policy-rules
  staged-policy-rules
```

```
options:
  fw-context-stat
  port-misuse
  overlapping-status
```

DESCRIPTION

You can use the global-rules component to configure network firewall policy which is enforced or staged on all IP and ICMP traffic except traffic on the management IP.

EXAMPLES

```
list global-rules
```

```
security firewall global-rules {
  enforced-policy /Common/policy1
}
```

Displays the current list of global rules.

OPTIONS

description
Your description for the global list of firewall rules.

enforced-policy
Specifies an enforced firewall policy. enforced-policy rules are enforced globally.

enforced-policy-rules
Specifies firewall rules enforced on traffic globally via referenced enforced-policy.

overlapping-status
Display detail overlapping information

port-misuse
Used to show or reset global port misuse policy statistics.

fw-context-stat
Used to show or reset firewall statistics for the global rules.

staged-policy
Specifies a staged firewall policy. staged-policy rules are not enforced while all the visibility aspects namely statistics, reporting and logging function as if the staged-policy rules were enforced globally.

staged-policy-rules
Specifies firewall rules staged on traffic globally via referenced staged-policy.

service-policy
Specifies a service policy that would apply to traffic globally. The service policy is applied to all flows, provided if there are no other context specific service policy configuration that overrides the global service policy. For example, when a service policy is configured both at a global level, as well as on a firewall rule, and a flow matches the rule, the more specific service policy configuration in the rule will override the service policy setting at the global level. The service policy associated here can be created using net service-policy command.

DISPLAY
list management-ip-rules
show running-config management-ip-rules

DESCRIPTION
You can use the management-ip-rules component to configure network firewall rules that are applied to all management interface traffic. The network software compares IP packets to the criteria specified in these rules. If a packet matches the criteria then the system takes the action specified by the rule. If a packet does not match a rule then the software compares the packet against the next rule. If a packet does not match any rule the packet is accepted.

For configuration sync management-ip-rules are synced to the devicegroup that has a type field of sync-failover. See "cm config-sync".

MATCHING AN IP PACKET

You can use this TMSH component to match against any or all of the

following properties of an IP packet:

- source address
- source port
- the packet's source VLAN
- destination address
- destination port
- the higher-level protocol in the packet's payload

If you match against more than one of these items, a packet must pass all of your tests to successfully match. For example, if you match against a source subnet and several destination ports, a packet must originate from the given subnet and must also have one of the specified destination ports.

RULE ORDER

Rules are evaluated in the order that you specify. You can use the `list management-ip-rules` command to see the current rule order. As you add or modify rules in this component, you can use the `place-before rule-name` or `place-after rule-name` option to choose the rule's place in the sequence.

Rule order can determine whether or not a packet is dropped. Consider the following rules:

- `rule_a`, matches source addresses against 172.16.0.0 and ACCEPTS all packets that match.
- `rule_d`, matches source addresses against 172.16.39.0 and DROPS all packets that match.

Also consider a packet from a host at 172.16.39.55. If `rule_a` appears before `rule_d` in the rule list, the packet's source address matches `rule_a` first and the software accepts it. The software never reaches `rule_d` for comparison. If `rule_d` appears first instead, the packet's source address now matches `rule_d`; in this case, the software drops the packet.

EXAMPLES

```
modify management-ip-rules rules add { reject-internal-net { source {  
addresses replace-all-with { 172.27.0.0/16 } } action reject place-  
before first } }
```

Creates a rule entry at the beginning of the list that rejects traffic from the 172.27.0.0 network.

```
modify management-ip-rules rules add { reject-insecure-ports { rule-  
list block_bad_mgmt place-before first } }
```

Adds a sub rule list to the management-IP firewall. Use the "security firewall rule-list" component to create a custom rule list.

```
list management-ip-rules  
security firewall management-ip-rules {  
  rules {  
    reject-insecure-ports {  
      rule-list block_bad_mgmt  
    }  
    reject-internal-net {  
      action reject  
      source {  
        addresses {  
          172.27.0.0/16 { }  
        }  
      }  
    }  
  }  
}
```

Displays the current list of management-firewall rules.

```
modify management-ip-rules rules delete { reject-internal-net }
```

Removes the `reject-internal-net` rule from the management-IP firewall.

OPTIONS

`description`
Your description for the management-firewall rules.

`rules`
Adds, deletes, or replaces a firewall rule.

`add` Creates a new rule, which you specify next with a unique string in curly braces (`{}`). Use the `place-before` or `place-after` option inside the curly braces to determine the order of the rule. If this is the first rule, use the `replace-all-with` option instead of `add`.

`delete`
Deletes the rule that you specify next, in curly braces (`{}`).

`modify`
Modifies the existing rule that you specify next, in curly braces (`{}`). After the rule name, enter the new configuration settings for the rule inside a nested set of curly braces.

`replace-all-with`
Replaces the current set of global rules with the rule(s) that you specify next, in curly braces (`{}`). Use this option for the first management rule.

`none` Empties the list of management-firewall rules. This implicitly accepts all packets on the management interface.

Enter the name of a rule to be added or modified, then enter an

open curly brace {}, one or more of the following options, and a closed curly brace {}).

action

Specifies the action that the system takes when a packet matches the rule.

accept

Specifies that a matching packet should be accepted. The security software stops comparing a matching packet to any other management-firewall rules.

accept-decisively

This option is functionally the same as accept.

drop

Specifies that a matching packet should be silently dropped. The security software sends nothing back to the packet source, and it does not compare the packet to any other management-firewall rules.

reject

Specifies that a matching packet should be dropped. For TCP-based protocols, the security software sends a TCP reset (with the RST flag raised) back to the source. For other protocols, reject is equivalent to drop.

app-service

Associates the management-rule list with a particular Application Service. An Application Service is a major component of an iApp, an advanced configuration tool for creating and maintaining similar applications on multiple servers. The asm module has components for working with iApps.

description

Your description for the current rule.

destination

Matches against each packet's destination IP and/or destination port. The next options choose the matching criteria.

address-lists

Specifies a list of IP-address lists (see "security firewall address-list") to compare against the packet's destination address.

This list uses the same add, delete, none, and replace-all-with options described above for rules, as well as a default option.

addresses

Specifies a list of IP addresses and/or subnets to compare against the packet's destination address.

The format for an IPv4 address is a.b.c.d[/prefix]. The general format for an IPv6 address is a:b:c:d:e:f:g:h[/prefix]; you can shorten this by eliminating leading zeros from each field (for example, you can shorten "2001:0db7:3f4a:09dd:ca90:ff00:0042:8329" to "2001:db7:3f4a:9dd:ca90:ff00:42:8329"), and/or by removing the longest contiguous field of zeros (for example, you can shorten "2001:0:0:0:c34a:0:23ff:678" to "2001::c34a:0:23ff:678"). TMSH accepts any valid text representation of IPv6 addresses, as defined in RFC 2373 (see).

To edit this list, use the same add, delete, modify, none, and replace-all-with options described above for rules.

port-lists

Specifies a collection of port lists (see "security firewall port-list") to compare against the packet's destination port. If you use this option to specify a port list, a packet only matches if its destination port matches a port on these lists.

This list uses the same add, delete, none, and replace-all-with options described above for rules, as well as a default option.

ports

Specifies a list of ports and port ranges to compare against the packet's destination port.

To edit this list, use the same add, delete, modify, none, and replace-all-with options described above for rules.

icmp Specifies a list of ICMP types and codes to compare against the packet. You must set the ip-protocol option to "icmp" for this option to function. If you use this option, the current rule only matches ICMP packets that have the ICMP properties you specify here. You can add, delete, or modify (that is, change the description of) any entry in the list, or replace-all-with a new set of entries that you specify between curly braces {}).

Use the standard integer identifiers to specify an ICMP type. For example: 3 is destination unreachable and 3:1 is destination unreachable with a code of host unreachable. The official list of ICMP types and codes is here:

ip-protocol
Specifies the IP protocol to compare against the packet. This could be a layer-3 protocol (such as ipv4 or ipv6), or a higher-level protocol like ospf, rdp, or icmp. If you specify this option, a packet only matches if it uses the chosen protocol. Press the key for a full list of valid protocols.

log Specifies whether the security software should write a log entry for all packets that match this rule. You must also enable network filter logging in the "security log profile" component for this option to have any effect. Note that the security software always increments the statistics counter when a packet matches a rule, no matter how you set this option.

place-after [first | last | rule-name]
Specifies that a new rule should be placed after the first rule, the last rule, or the rule-name you specify. If you are adding individual rules (as opposed to specifying replace-all-with), then you must use place-before or place-after to specify the rule's position in the list.

place-before [first | last | rule-name]
Specifies that a new rule should be placed before the first rule, the last rule, or the rule-name you specify. If you are adding individual rules (as opposed to specifying replace-all-with), then you must use place-before or place-after to specify the rule's position in the list.

rule-list
Specifies a full rule list instead of a customized rule that you might define with the other options. See "security firewall rule-list". If you use this option, then only the schedule and status options are valid; the tmsh software rejects any other options that you attempt to use with rule-list.

schedule
Specifies a schedule for the rule. See "security firewall schedule". If you omit this option, the rule or rule list is enabled all the time.

If the rule refers to a rule-list, the rule-list is enabled according to the schedule. When the rule list is enabled, the security software then honors the schedules defined within the rule-list.

source
Matches against each packet's source IP, source port, and/or source VLAN. The next options choose the matching criteria.

address-lists
Specifies a list of address lists (see "security firewall address-list") to compare against the packet's source address.

This list uses the same add, delete, none, and replace-all-with options described above for rules, as well as a default option.

addresses
Specifies a list of IP addresses and networks to compare against the packet's source address.

The format for an IPv4 address is a.b.c.d. The general format for an IPv6 address is a:b:c:d:e:f:g:h.

To edit this list, use the same add, delete, modify, none, and replace-all-with options described above for rules.

port-lists
Specifies a collection of port lists (see "security firewall port-list") to compare against the packet's source port. If you use this option to specify a port list, a packet only matches if its source port matches a port on these lists.

This list uses the same add, delete, none, and replace-all-with options described above for rules, as well as a default option.

ports
Specifies a list of ports and port ranges to compare against the packet's source port.

To edit this list, use the same add, delete, modify, none, and replace-all-with options described above for rules.

vlan
Specifies a list of VLANs, VLAN groups, and tunnels to compare against the packet.

This list uses the same add, delete, none, and replace-all-with options described above for rules, as well as a default option.

status
Specifies whether the rule is enabled, disabled or scheduled. A rule that is enabled is always checked. A rule that is

disabled is never checked. A rule that is scheduled is checked according to the corresponding schedule configuration. A rule that is scheduled must have an associated schedule configuration.

BIG-IP 2016security firewall management-ip-rules(1)

security firewall matching-rule

NAME

matching-rule - Shows the best match firewall rule amongst all the admin configured Network Firewall rules in different contexts (global, route-domain, VIP/SelfIP) given source/destination IP address and port, protocol and user configured vlan name. You can only use the show command with this component.

MODULE

security firewall

SYNTAX

```
show matching-rule
  dest-addr [IP address]
  source-addr [IP address]
  dest-port [TCP/UDP port]
  source-port [TCP/UDP port]
  protocol [protocol]
  vlan [vlan name]
```

DESCRIPTION

With user provided VLAN, source/destination IP addresses, TCP/UDP ports and protocol, the command will try to match these parameters against user configured ACL rules in global, route domain, VIP/SelfIP context, and return the best match rules. Both IPv4 and IPv6 addresses and all possible protocols are supported. This command can be used as a diagnostic tool to trouble-shoot BigIP firewall configuration problem. It provides a faster way to identify which ACL rule will have impact to the specified packet stream.

EXAMPLES

```
# show security firewall matching-rule dest-addr 1.1.1.1 dest-port 140
  source-addr 2.2.2.2 source-port 141 protocol 10 vlan /Common/internal
```

Firewall Matching Rule:

```
-----
Context Type Context Name Policy Name Rule Name Action
-----
Global      globalrule  Accept
```

Total records returned: 1

```

DESCRIPTION

You can use the policy component to configure a shareable and reusable set of network firewall rules which can be associated as enforced or staged with a number of configuration objects of the following types: net self, ltm virtual, security firewall global-rules, net route-domain.

EXAMPLES

```

modify policy rules add {
reject-internal-net {
place-before first
action reject
source {
addresses replace-all-with { 172.27.0.0/16 }
} }
} }

```

Creates a rule entry at the beginning of the list that rejects traffic from the 172.27.0.0 network.

```
modify policy rules delete reject-internal-net
```

Removes the rule reject-internal-net from the list of rules.

```
create security firewall policy pl rules add { r1 { source { geo add {
US } } action reject place-after first } } Creates a policy with a
single rule that rejects all packets from the US.
```

```
create security firewall policy xyz rules add { r1 { destination {
fqdns add { f5.com } } action accept place-after first } } Creates a
policy named 'xyz' with a single rule (named 'r1') that accepts all
packets with destination IP address in domain 'f5.com'.
```

```
list policy
```

Displays the current list of policy rules.

```
create policy "New Policy" copy-from "/Common/Existing Policy"
```

Creates a new policy New Policy by copying existing policy /Common/Existing Policy.

OPTIONS

```
description
User defined description.
```

```
copy-from
(CREATE)Specifies the name of an existing policy from which to
copy all configuration options.
```

```
rules
Adds, deletes, or replaces a firewall rule.
```

```
action
Specifies the action that the system takes when a rule is
matched.
```

```
accept
Specifies that the current packet should be accepted.
```

```
accept-decisively
Specifies that the current packet should be accepted and
that packet will not be compared to any other firewall
rules in any other context.
```

```
drop
Specifies that the current packet should be silently
dropped. Nothing is sent back to the packet source. The
packet is not compared to any other firewall rules.
```

reject
Specifies that the current packet should be dropped. For TCP based protocols a TCP reset is sent to the source. For other protocols reject is equivalent to drop.

description
User defined description.

destination
address-lists
Specifies a list of address lists (see security firewall address-list) against which the packet will be compared.

addresses
Specifies a list of addresses and networks against which the packet will be compared.

fqdns
Specifies a list of fully qualified domain names to compare against packet's destination IP address domain.

geo
Specifies a list of Geo Locations that the packet will be compared against.

port-lists
Specifies a list of port lists (see security firewall port-list) against which the packet will be compared.

ports
Specifies a list of ports and port ranges against which the packet will be compared.

icmp
Specifies a list of ICMP types and codes against which the packet will be compared. The standard integer identifiers are used to specify an ICMP type Example: 3 is destination unreachable and 3:1 is destination unreachable with a code of host unreachable. The list of ICMP types and codes can be found here
<http://www.iana.org/assignments/icmp-parameters/icmp-parameters.xml>.

ip-protocol
Specifies the IP protocol against which the packet will be compared.

irule
Specifies the name of the iRule that will be triggered when a packet matches this firewall rule. The firewall rule match raises a FLOW_INIT iRule event.

irule-sample-rate
Specifies the rate at which an iRule specified by irule option will be triggered when a packet matches this firewall rule. The rate is an integer value in the range 0-65535 and specifies how many packets must match this firewall rule before the iRule is triggered. The default value is 1 and causes the iRule to be triggered for every packet that matches this firewall rule. A value of 0 disables iRule triggering.

log
Specifies whether the packet will be logged if it matches the rule. Logging must also be enabled in the corresponding logging configuration. (e.g. security log profile global-network when policy assigned to global-rules). Note that the statistics counter is always incremented when a packet matches a rule.

place-after
Specifies that a new rule should be placed after another rule, first or last. If individual rules are being added (as opposed to specifying replace-all-with) then place-before or place-after must be specified.

place-before
Specifies that a new rule should be placed before another rule, first or last. If individual rules are being added (as opposed to specifying replace-all-with) then place-before or place-after must be specified.

rule-list
Specifies a list of rules to evaluate. See security firewall rule-list. If a rule-list is specified then only the schedule and status properties effect the rule.

schedule
Specifies a schedule for the rule. See security firewall schedule. If the rule refers to a rule-list the rule-list will be enabled according to the schedule. When the rule list is enabled, the schedules defined within the rule-list will be honored.

source
address-lists
Specifies a list of address lists (see security firewall address-list) against which the packet will be compared.

addresses
Specifies a list of addresses and networks against which the packet will be compared.

fqdns
Specifies a list of fully qualified domain names to compare against packet's source IP address domain.

geo Specifies a list of Geo Locations against which the packet will be compared.

port-lists
Specifies a list of port lists (see security firewall port-list) against which the packet will be compared.

ports
Specifies a list of ports and port ranges against which the packet will be compared.

vlangs
Specifies a list of vlangs, vlang groups and tunnels against which the packet will be compared.

status
Specifies whether the rule is enabled, disabled or scheduled. A rule that is enabled is always checked. A rule that is disabled is never checked. A rule that is scheduled is checked according to the corresponding schedule configuration. A rule that is scheduled must have an associated schedule configuration.

service-policy
Specifies the service policy configuration to use. (see "net service-policy"). The service policy can be used to set specific policy based configurations like flow timers, which applies to the flows that matches the rule.

virtual-server
Specifies the virtual server name that will be used for further traffic processing. Option is valid only for global and/or route domain contexts.

security firewall port-list

NAME

port-list - Configures a port-list for use by firewall rules. A firewall rule can match a packet's source port or destination port against one of the ports in a port list, and can take some action (such as ACCEPT or DROP) for a matching packet.

MODULE

security firewall

SYNTAX

```
CREATE/MODIFY
create port-list [name]
modify port-list [[name] | all]
options:
  app-service [name]
  description [string]
  ports [add | delete | modify | replace-all-with] {
    [ [port] | [port] - [port] ]
  }
edit port-list [[name] | all]
options:
  all-properties
  non-default-properties

DISPLAY
list port-list [[name] | all | [property]]
show running-config port-list [[name] | all | [property]]

DELETE
delete port-list [[name] | all]
```

DESCRIPTION

You can use the port-list component to define reusable lists of ports for various firewall rules. The network software compares a packet's source port and/or destination port against ports in this list. You can assign a port list to the firewall rules in net self, net route-domain, security firewall global-rules, security firewall rule-list, sys

management-ip, and ltm virtual firewall rules.

EXAMPLES

```
create port-list p-list1 ports add { 80 }
```

Creates a new port list with one entry.

```
list port-list
security firewall port-list _sys_self_allow_tcp_defaults {
  ports {
    domain { }
    f5-iquery { }
    https { }
    snmp { }
    ssh { }
  }
}
security firewall port-list _sys_self_allow_udp_defaults {
  ports {
    520 { }
    cap { }
    domain { }
    f5-iquery { }
    snmp { }
  }
}
security firewall port-list p-list1 {
  ports {
    http { }
  }
}
```

Shows all the port lists, including the one created in the previous example.

OPTIONS

app-service

Associates this port list with a particular Application Service. An Application Service is a major component of an iApp, an advanced configuration tool for creating and maintaining similar applications on multiple servers. The asm module has components for working with iApps.

description

Your description for the port list.

ports

Specifies a list of ports to compare against a packet's source or destination port. Use one of the keywords below and then specify the port(s) to add or delete. Specify ranges of ports with a dash between the two ends of the range (for example, 80-88).

add Creates a new port list, which you specify next with port numbers in curly braces ({}).

delete

Deletes the port(s) that you specify next, in curly braces ({}).

modify

Is not supported for this component.

replace-all-with

Replaces the current set of ports with the port(s) that you specify next, in curly braces ({}).

list port-misuse-policy
show running-config port-misuse-policy
options:
  all-properties
  non-default-properties
  one-line

DELETE
delete port-misuse-policy [[name] | all]
```

DESCRIPTION

You can use the port-misuse-policy component to configure a shareable and reusable set of network port misuse policies which can be associated with a service policy objects. A port misuse policy has one or more rules that match connections by IP transport layer (L4) protocol and port number. Each rule must have a unique L4 protocol and port combination within the policy. When connection matches a policy rule (i.e. L4 protocol/port pair) the first data packet of the connection is tested to conform to application (L7) protocol specified in the rule. If data conforms to the L7 protocol (or test is inconclusive) the policy stops. The connection is allowed to proceed normally and data is processed as if no policy is in use. If data definitely does not conform to the specified L7 protocol the connection is treated according to configuration of the matched rule or the policy if rule uses policy defaults. In this case the rule or policy can drop the connection or allow it to proceed, and can also log an event about L7 protocol mismatch.

Port misuse policy (via service policy) can be associated with objects of the following types: ltm virtual, net route-domain, global. Several port misuse policies can be associated with objects of each type. In addition to service policy specified in the object itself, service policies could be associated with ACL rules of the security firewall policy, if it is associated with the object. When more than one policy is associated with the object the most specific port misuse rule is used. For example, if connection matches an ACL rule which has a service policy with port misuse policy also having a rule matching the connection, that port misuse rule is applied. Otherwise the port misuse rule associated via virtual's service policy is applied, if such rule exists and matches the connection. See also net service-policy.

Port misuse policies could be specified for both virtual server and route domain objects associated with the connection. In this case all policies are applied. If a policy has a matching rule that drops the connection, and connection fails to pass L7 protocol test, the connection is terminated and remaining policies are not applied.

EXAMPLES

```
create security firewall port-misuse-policy web-ports-policy
drop-on-l7-mismatch no log-on-l7-mismatch yes rules add { p80 { ip-
protocol tcp port 80 l7-protocol http drop-on-l7-mismatch yes } p8080 {
ip-protocol tcp port 8080 l7-protocol http } }

list security firewall port-misuse-policy web-ports-policy
security firewall port-misuse-policy web-ports-policy {
  drop-on-l7-mismatch no
  log-on-l7-mismatch yes
  rules {
p80 {
  drop-on-l7-mismatch yes
  l7-protocol http
  port http
}
p8080 {
  l7-protocol http
  port webcache
}
}
}
```

Creates port misuse policy with rules for tcp ports 80 and 8080 that test if first data packet looks like HTTP. The rule p80 tests all connections that have destination port TCP 80 and drops them if the

first data packet does not look like HTTP. The rule p8080 tests all connections that have destination port TCP 8080 and logs an event if the first data packet does not look like HTTP (because of policy defaults).

```
modify security firewall port-misuse-policy web-ports-policy { rules
add { p8888 { port 8888 drop-on-l7-mismatch yes }}}
```

Adds a new rule p8888 to port misuse policy web-ports-policy that tests all connections to TCP port 8888 and drops them and logs an event when the first data packet does not look like HTTP.

```
list security firewall port-misuse-policy
```

Displays the current port misuse policy configuration list.

OPTIONS

description

User defined description.

drop-on-l7-mismatch

Indicates if the connection should be dropped when there is a matching rule in the policy that has drop-on-l7-mismatch set to use-policy-setting and connection that matches that rule fails L7 protocol test. The default is yes.

log-on-l7-mismatch

Indicates if a port misuse event should be logged when there is a matching rule in the policy that has log-on-l7-mismatch set to use-policy-setting and connection that matches that rule fails L7 protocol test. The default is no.

rules

Adds, deletes, or replaces a named port misuse policy rule.

description

User defined description.

drop-on-l7-mismatch

Indicates if the connection should be dropped when it matches this rule but fails L7 protocol test. Allowed values are yes, no, and use-policy-setting. The default is use-policy-setting.

ip-protocol

Specifies the transport layer (L4) IP protocol for matching the connection. The valid protocols are sctp, tcp, and udp. A port and L4 protocol combination must be unique for the policy. The default is tcp.

l7-protocol

Specifies the application layer (L7) protocol for the rule. When the connection matches the rule the first data packet is tested to conform to this protocol. If the test is negative the rule can drop the connection and/or log a port misuse event depending on other options. If the test is positive or inconclusive (not enough data) the connection is handled as if there was no port misuse policy associated with the given object (virtual server or route domain), and policies at other objects are applied. Press the key for a full list of valid protocols. The default protocol is http.

log-on-l7-mismatch

Indicates if a port misuse event should be logged when the connection matches this rule but fails L7 protocol test. Allowed values are yes, no, and use-policy-setting. The default is use-policy-setting.

port Specifies the destination port number for matching the connection. The valid values are 1-65535. A port and L4 protocol combination must be unique for the policy.

DESCRIPTION

You can use the rule-list component to configure network firewall rules to be applied to multiple firewalls. The network software compares IP packets to the criteria specified in these rules. If a packet matches the criteria then the system takes the action specified by the rule. If a packet does not match any rule in the list, the software accepts the packet or passes it to the next rule or rule-list (for example, the system compares the packet to net self-ip rules if the packet is destined for a network associated with a self-ip that has firewall rules defined).

MATCHING AN IP PACKET

You can use this TMSH component to match against any or all of the following properties of an IP packet:

```
source address
source fqdn
source geo
source port
the packet's source VLAN
destination address
destination fqdn
destination geo
destination port
the higher-level protocol in the packet's payload
```

If you match against more than one of these items, a packet must pass all of your tests to successfully match. For example, if you match against a source subnet and several destination ports, a packet must originate from the given subnet and must also have one of the specified destination ports.

RULE ORDER

The network software evaluates firewall rules in the order that you specify. You can use the list management-ip-rules command to see the current rule order. As you add or modify rules in this component, you can use the place-before rule-name or place-after rule-name option to choose the rule's place in the sequence.

Rule order can determine whether or not a packet is dropped. Consider the following rules:

```
rule_a, matches source addresses against 172.16.0.0 and ACCEPTS all
packets that match.
rule_d, matches source addresses against 172.16.39.0 and DROPS all
packets that match.
```

Also consider a packet from a host at 172.16.39.55. If rule_a appears before rule_d in the rule list, the packet's source address matches rule_a first and the software accepts it. The software never reaches rule_d for comparison. If rule_d appears first instead, the packet's source address now matches rule_d; in this case, the software drops the packet.

EXAMPLES

```
create rule-list block_bad_mgmt description "ports to be blocked on our
management interfaces" rules replace-all-with { reject_telnet { ip-
protocol tcp destination { ports add { telnet } } action reject } }
```

Creates a new rule list called block_bad_mgmt. It matches and rejects any TCP packet whose destination port is telnet. The description indicates that the rule is intended for the management-IP firewall.

```
modify rule-list block_bad_mgmt rules add { reject_http { ip-protocol
tcp destination { ports add { http } } action reject place-after last }
}
```

Modifies the above rule list by blocking HTTP traffic, too.

```
list rule-list block_bad_mgmt
security firewall rule-list block_bad_mgmt {
  description "ports to be blocked on our management interfaces"
  rules {
    reject_telnet {
      action reject
      destination {
        ports {
          telnet { }
        }
      }
    }
    ip-protocol tcp
  }
  reject_http {
    action reject
    destination {
      ports {
        http { }
      }
    }
  }
  ip-protocol tcp
}
}
```

Shows the above rule list, with both rules.

```
modify rule-list rules add { reject-internal-net { place-before first
action reject source { addresses replace-all-with { 172.27.0.0/16 } } }
}
```

Creates a rule entry at the beginning of the list that rejects traffic from the 172.27.0.0 network.

```
create security firewall rule-list r11 description "Geo Locations to be
blocked" rules add { r1 { source { geo add { US } } place-after first
action drop } }
```

Creates a new rule list "r11", which matches and rejects any packet with a US source. The description explains the purpose of the rule list.

```
modify security firewall rule-list r12 rules add { r2 { source { geo
add { CA } } place-before last action drop } }
```

```
security firewall rule-list r12 {
description "Geo Locations to be blocked"
rules {
  r2 {
action drop
source {
  geo {
CA {
state none
}
}
}
r1 {
action drop
source {
  geo {
US {
state none
}
}
}
}
}
}
```

Shows the above rule list, with both rules.

```
create security firewall rule-list r11 description "domains to be
blocked" rules add { r1 { destination { fqdns add { xyz.com} } place-
after first action drop } }
```

Creates a new rule list "r11", which matches and rejects any packet with destination IP addresses in domain 'xyz.com'. The description explains the purpose of the rule list.

```
modify security firewall rule-list r11 rules modify { r1 { destination
{ fqdns add { abc.com } } } }
```

Modifies the above rule list by blocking destination IP addresses in domain 'abc.com' too.

```
list rule-list r11
security firewall rule-list r11 {
description "domains to be blocked"
rules {
  r1 {
action drop
destination {
  fqdns {
abc.com { }
xyz.com { }
}
}
}
}
}
```

Shows the above rule list, with the single rule r1.

OPTIONS

app-service

Associates the rule list with a particular Application Service. An Application Service is a major component of an iApp, an advanced configuration tool for creating and maintaining similar applications on multiple servers. The asm module has components for working with iApps.

description

Your description for this list of firewall rules.

rules

Adds, deletes, or replaces a firewall rule.

add Creates a new rule, which you specify next with a unique string in curly braces ({}). Use the place-before or place-after option inside the curly braces to determine the order of the rule. If this is the first rule, use the replace-all-with option instead of add.

delete

Deletes the rule that you specify next, in curly braces ({}).

modify

Modifies the existing rule that you specify next, in curly braces ({}). After the rule name, enter the new configuration settings for the rule inside a nested set of curly braces.

none Empties the list of rules. An empty rule list implicitly accepts all packets. The security software skips this context and assesses packets against the next layer of firewall rules, if there is one (such as those defined for net self-

ip, net route-domain or ltm virtual)

replace-all-with
Replaces the current list of rules with the rule(s) that you specify next, in curly braces ({}). Use this option for the first rule in the list.

Enter the name of a rule to be added or modified, then enter an open curly brace {}, one or more of the following options, and a closed curly brace {}).

action
Specifies the action that the system takes when a rule is matched.

accept
Specifies that a matching packet should be accepted. The security software stops comparing a matching packet to any other rules in the list. The software continues comparing the packet to rules in the next appropriate context (such as net self-ip, net route-domain or ltm virtual).

accept-decisively
Specifies that a matching packet should be accepted and should not be compared to any other firewall rules in any other context.

drop
Specifies that a matching packet should be silently dropped. The security software sends nothing back to the packet source. The security software does not compare the packet to any other firewall rules in any other context.

reject
Specifies that a matching packet should be dropped. For TCP-based protocols, the security software sends a TCP reset (with the RST flag raised) back to the source. For other protocols, reject is equivalent to drop.

description
Your description for the current rule.

destination
Matches against each packet's destination IP and/or destination port. The next options choose the matching criteria.

address-lists
Specifies a list of IP-address lists (see "security firewall address-list") to compare against the packet's destination address.

This list uses the same add, delete, none, and replace-all-with commands described above for rules, as well as a default command.

addresses
Specifies a list of IP addresses and/or subnets to compare against the packet's destination address.

The format for an IPv4 address is a.b.c.d[/prefix]. The general format for an IPv6 address is a:b:c:d:e:f:g:h[/prefix]; you can shorten this by eliminating leading zeros from each field (for example, you can shorten "2001:0db7:3f4a:09dd:0a90:ff00:0042:8329" to "2001:db7:3f4a:9dd:a90:ff00:42:8329"), and/or by removing the longest contiguous field of zeros (for example, you can shorten "2001:0:0:0:c34a:0:0:678" to "2001::c34a:0:0:678"). TMSH accepts any valid text representation of IPv6 addresses, as defined in RFC 2373 (see).

To edit this list, use the same add, delete, modify, none, and replace-all-with commands described above for rules.

fqdns
Specifies a list of fully qualified domain names to compare against packet's destination IP address domain.

To edit this list, use the same add, delete, none, and replace-all-with commands described above for rules.

geo
Specifies a list of Geo Locations to compare a packet's source or destination Geo Location.

The format for a Geo Location is a 2 character string for the country code and a string for the state.

To edit this list, use the same add, delete, modify, none, and replace-all-with options described above for rules.

port-lists
Specifies a collection of port lists (see "security firewall port-list") to compare against the packet's destination port. If you use this option to specify a port list, a packet only matches if it's destination port matches a port on these lists.

If you combine address lists and port lists in the same rule, a packet must have a matching port and a matching

address to fully match the rule.

This list uses the same add, delete, none, and replace-all-with commands described above for rules, as well as a default command.

ports

Specifies a list of ports and port ranges to compare against the packet's destination port.

To edit this list, use the same add, delete, modify, none, and replace-all-with commands described above for rules.

icmp Specifies a list of ICMP types and codes to compare against the packet. You must set the ip-protocol option to "icmp" for this option to function. If you use this option, the current rule only matches ICMP packets that have the ICMP properties you specify here. You can add, delete, or modify (that is, change the description of) any entry in the list, or replace-all-with a new set of entries that you specify between curly braces ({}).

Use the standard integer identifiers to specify an ICMP type. For example: 3 is destination unreachable and 3:1 is destination unreachable with a code of host unreachable. The official list of ICMP types and codes is here:

.

ip-protocol

Specifies the IP protocol to compare against the packet. This could be a layer-3 protocol (such as ipv4 or ipv6), or a higher-level protocol like ospf or rdp. If you specify this option, a packet only matches if it uses the chosen protocol. Press the key for a full list of valid protocols.

irule

Specifies the name of the iRule that will be triggered when a packet matches this firewall rule. The firewall rule match raises a FLOW_INIT iRule event.

irule-sample-rate

Specifies the rate at which an iRule specified by irule option will be triggered when a packet matches this firewall rule. The rate is an integer value in the range 0-65535 and specifies how many packets must match this firewall rule before the iRule is triggered. The default value is 1 and causes the iRule to be triggered for every packet that matches this firewall rule. A value of 0 disables iRule triggering.

log Specifies whether the security software should write a log entry for all packets that match this rule. You must also enable network filter logging in the "security log profile" component for this option to have any effect. Note that the security software always increments the statistics counter when a packet matches a rule, no matter how you set this option.

place-after [first | last | rule-name]

Specifies that a new rule should be placed after the first rule, the last rule, or the rule-name you specify. If you are adding individual rules (as opposed to specifying replace-all-with), then you must use place-before or place-after to specify the rule's position in the list.

place-before [first | last | rule-name]

Specifies that a new rule should be placed before the first rule, the last rule, or the rule-name you specify. If you are adding individual rules (as opposed to specifying replace-all-with), then you must use place-before or place-after to specify the rule's position in the list.

rule-list

Specifies a full rule list instead of a customized rule that you might define with the other options. If you use this option, then only the schedule and status options are valid; the tmsh software rejects any other options that you attempt to use with rule-list.

schedule

Specifies a schedule for the rule. See "security firewall schedule". If you omit this option, the rule or rule list is enabled all the time.

If the rule refers to a rule-list, the rule-list is enabled according to the schedule. When the rule list is enabled, the security software then honors any schedules defined within the rule-list.

source

Matches against each packet's source IP, source port, and/or source VLAN. The next options choose the matching criteria.

address-lists

Specifies a list of address lists (see "security firewall address-list") to compare against the packet's source address.

This list uses the same add, delete, none, and replace-all-with commands described above for rules, as well as a default command.

addresses

Specifies a list of IP addresses and networks to compare against the packet's source address.

The format for an IPv4 address is a.b.c.d. The format for an IPv6 address is a:b:c:d:e:f:g:h.

To edit this list, use the same add, delete, modify, none, and replace-all-with commands described above for rules.

fqdns

Specifies a list of fully qualified domain names to compare against packet's source IP address domain.

To edit this list, use the same add, delete, none, and replace-all-with commands described above for rules.

geo Specifies a list of Geo Locations to compare a packet's source or destination Geo Location.

The format for a Geo Location is a 2 alphabet string for the country code and a string for the state.

To edit this list, use the same add, delete, modify, none, and replace-all-with options described above for rules.

port-lists

Specifies a collection of port lists (see "security firewall port-list") to compare against the packet's source port. If you use this option to specify a port list, a packet only matches if its source port matches a port on these lists.

This list uses the same add, delete, none, and replace-all-with commands described above for rules, as well as a default command.

ports

Specifies a list of ports and port ranges to compare against the packet's source port.

To edit this list, use the same add, delete, modify, none, and replace-all-with commands described above for rules.

vlangs

Specifies a list of VLANs, VLAN groups, and tunnels to compare against the packet.

This list uses the same add, delete, none, and replace-all-with commands described above for rules, as well as a default command.

status

Specifies whether the rule is enabled, disabled or scheduled. A rule that is enabled is always checked. A rule that is disabled is never checked. A rule that is scheduled is checked according to the corresponding schedule configuration. A rule that is scheduled must have an associated schedule configuration.

service-policy

Specifies the service policy configuration to use. (see "net service-policy"). The service policy can be used to set specific policy based configurations like flow timers, which applies to the flows that matches the rule.

virtual-server

Specifies the virtual server name that will be used for further traffic processing. Option is valid only for global and/or route domain contexts.

ips-profile

Specifies IPS profile name used for signature matching and/or protocol compliance checks for flows matching the rule.

classification-policy

Specifies the Classification Policy name that will be enforced.

security firewall rule-stat

NAME
rule-stat - Displays statistics of firewall rules on the BIG-IP(r) system. You can only use the show command with this component.

MODULE
security firewall

SYNTAX
show rule-stat
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
field-fmt

DESCRIPTION
You can use the rule-stat component to display statistics of firewall rules.

EXAMPLES
show rule-stat

Displays firewall rule's statistics in the system default units.

show rule-stat raw

Displays raw firewall rule's statistics.

SEE ALSO
show, tmsh

BIG-IP 2013-03-21 security firewall rule-stat(1)

security firewall schedule

NAME
schedule - Create a schedule that you can apply to firewall rules.

MODULE
security firewall

SYNTAX
CREATE/MODIFY
create schedule [name]
modify schedule [[name] | all]
options:
app-service [name]
daily-hour-end [hour:minute]
daily-hour-start [hour:minute]
date-valid-end [MM/DD/YYYY]
date-valid-start [MM/DD/YYYY]
description [text]
days-of-week [[monday | tuesday | wednesday | thursday | friday | saturday | sunday] ...]

edit schedule [[name] | [glob] | [regex]] ...]

DISPLAY
list schedule [[name] | all | [property]]

DELETE
delete schedule [[name] | all]
show running-config schedule [[name] | all | [property]]

DESCRIPTION
You use the schedule component to specify when to apply a firewall rule. You can specify a start time and an end time, some days of the week, a date when the schedule first starts, and/or a date when the schedule ends forever.

To apply the schedule to a firewall rule or rule list, edit the firewall or rule-list component. These are the firewalls and rule lists where you can apply schedules:

"security firewall global-rules"

```
"security firewall management-ip-rules"  
"net self"  
"net route-domain"  
"ltm virtual"  
"security firewall rule-list"
```

By default, all firewall rules are continuously active. By applying a schedule to a firewall rule, you reduce the time that the rule is running.

If you create a schedule without any scheduling specifications (such as `daily-hour-start`), the schedule is always active.

Note you may not delete a schedule that is being used by any firewall rule or rule list.

EXAMPLES

```
create schedule my_schedule1 date-valid-start now date-valid-end  
12/31/2016 daily-hour-start 8:00 daily-hour-end 17:00
```

Creates a new schedule which is active between 8am and 5pm every day until December 31, 2016.

```
list schedule>  
security firewall schedule my_schedule1 {  
  daily-hour-end 17:00  
  daily-hour-start 8:00  
  date-valid-end 2016-12-31:00:00:00  
  date-valid-start 2012-12-12:08:40:01  
}  
security firewall schedule workHours {  
  daily-hour-end 18:00  
  daily-hour-start 8:00  
  days-of-week { monday tuesday wednesday thursday friday }  
}
```

Lists two user-configured schedules, including the one that you created above.

```
modify schedule my_schedule1 days-of-week { monday tuesday wednesday }
```

Modifies the schedule named "my_schedule1." This limits the schedule to running only on Mondays, Wednesdays, and Fridays.

OPTIONS

`app-service`

Associates this schedule with a particular Application Service. An Application Service is a major component of an iApp, an advanced configuration tool for creating and maintaining similar applications on multiple servers. The asm module has components for working with iApps.

`description`

Describes the schedule.

`daily-hour-end`

Specifies the time of day this schedule stops. This end hour must be after the `daily-hour-start` value. The default is 24:00 (midnight).

A schedule may not contain hours that go past midnight (24:00): for example, a `daily-hour-start` of 20:00 and `daily-hour-end` of 02:00 is not allowed. If you need to cover both the late hours and early hours of the day, please create two schedules.

`daily-hour-start`

Specifies the time of day this schedule starts. This start hour must be before the `daily-hour-end` value. The default is 0:00 (midnight at the start of the day).

`date-valid-end`

Specifies the final date for this schedule. The schedule stops firing as of this date. You may specify just the specific date, or a specific date and time for the schedule to end. The date must be after the `date-valid-start` value. The default is 19:14 1/18/2038 (the latest date expressible with a 32-bit integer).

`date-valid-start`

Specifies the start date for this schedule. The schedule does not fire before this date and time. You may specify just the specific date, or a specific date and time for the schedule to start. You must specify a date before the `date-valid-end` value. The default is midnight 1/1/1970 (Unix epoch).

`days-of-week`

Specifies which days of the week the schedule fires. You must specify at least one day of the week, and you cannot specify any day of the week more than once. The default is all seven days.

security firewall user-domain

NAME
user-domain - Configures a user-domain for use by firewall rules.

MODULE
security firewall

SYNTAX

```
CREATE/MODIFY
create user-domain [name]
modify user-domain [[name] | all]
options:
  domain string
  ifmap-service [add | delete | modify | replace-all-with] {
    [ip]
    [port]
    [login]
    [password]
  }
  app-service [name]
  description [string]

edit user-domain [[name] | all]
options:
  all-properties
  non-default-properties

DISPLAY
list user-domain [[name] | all | [property]]
show running-config user-domain [[name] | all | [property]]

DELETE
delete user-domain [[name] | all]

RUN
run user-domain [[name] | all] clear-cache
```

DESCRIPTION
A user-domain object holds attributes to reach services that provide more information about a user. This information includes the domain for which the service is defined, the identity service that can be used to validate this user and the ifmap service that can be used to obtain more information about the user. User domains also have associated cache data which is utilized by user identity feature for performance improvements. You can use the user-domain component to define reusable configuration that is used to learn about more users used in the firewall rules or clear their associated cache data on demand.

EXAMPLES

```
create user-domain gladiators identity-server add { felix-legions { ip
1.1.1.1 login maximus password meridius port 10002 } }

Creates a new user-domain object that defines a new identity-server for
domain gladiators with an identity service felix-legions

modify user-domain gladiators ifmap-server add { rome { ip 10.10.10.10
login marcus password aurelius port 10002 } }

Modifies the above user domain to add an ifmap server.

run user-domain grumpy cat clear-cache

Clears the user identity cache associated with a specified user domain
name.

run user-domain all clear-cache

Clears the user identity cache for all available user domains.
```

OPTIONS

domain
Specifies a domain for which the identity and ifmap services are defined.

app-service
Associates this user domain with a particular Application Service. An Application Service is a major component of an iApp, an advanced configuration tool for creating and maintaining similar applications on multiple servers. The asm module (see asm) has components for working with iApps.

description
User-defined description for this user domain.

clear-cache
Invokes clear-cache functionality for the given user-domain name.

SEE ALSO

BIG-IP 2016-03-14 security firewall user-domain(1)

security firewall user-list

NAME

user-list - Configures a user-list for use by firewall rules. A firewall rule can match a packet sourced from a particular user against one of the users or user-groups in a user list, and can take some action (such as ACCEPT or DROP) for a matching packet. An incoming packet's source IP address is matched in user identity database to get the user and group properties which are then used to perform the rule match.

MODULE

security firewall

SYNTAX

```
CREATE/MODIFY
create user-list [name]
modify user-list [[name] | all]
options:
  app-service [name]
  description [string]
  user-groups [add | delete | modify | replace-all-with] {
    [ [user group names...] ]
  }
  users [add | delete | modify | replace-all-with] {
    [ [user names...] ]
  }

edit user-list [[name] | all]
options:
  all-properties
  non-default-properties

DISPLAY
list user-list [[name] | all | [property]]

DELETE
delete user-list [[name] | all]
```

DESCRIPTION

You can use the user-list component to define reusable lists of user or user-group names for various firewall rules. The network software compares a packet's source user (mapped by incoming source IP address) and group that user belong to, against users (or user-groups) in this list. You can assign a user list to the firewall rules in net self, net route-domain, security firewall global-rules, security firewall rule-list, and ltm virtual firewall rules.

EXAMPLES

```
create user-list u-list1 users add { olympus\xyz }

Creates a new user list named u-list1 with one user named xyz in domain olympus.

create user-list u-list2 user-groups add { olympus\eng }

Creates a new user list named u-list2 with one group named eng in domain olympus.

list user-list

Shows all the user lists configured in the system.
```

OPTIONS

```
app-service
Associates this user list with a particular Application Service. An Application Service is a major component of an iApp, an advanced configuration tool for creating and maintaining similar applications on multiple servers. The asm module has components for working with iApps.

description
Your description for the user list.

user-groups
```

Specifies a list of user groups to compare against the groups a user belongs to (which is mapped from the source IP address).

users

Specifies a list of users to compare against a packet's source user (which is mapped from the source IP address).

SEE ALSO

edit, list, modify, net self, net route-domain, security firewall address-list, security firewall rule-list, security firewall global-rules, tmsh

security flowspec-route-injector flowspec-advertised-route-info

NAME

flowspec-advertised-route-info - Display FlowSpec routes that are currently being advertised.

MODULE

security flowspec-route-injector

SYNTAX

Display flowspec-advertised-route-info component within the security flowspec-route-injector module using the syntax in the following section.

DISPLAY

show flowspec-advertised-route-info route-domain-id

DESCRIPTION

Show flowspec-advertised-route-info displays FlowSpec routes that are currently being advertised per route domain instance.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP security flowspec-route-injector flowspec-advertised-route-info(1)

security flowspec-route-injector profile

NAME

profile - Configures a Security FlowSpec Route Injector profile

MODULE

security flowspec-route-injector

SYNTAX

Manage profile component within the security flowspec-route-injector module using the syntax shown in the following sections.

CREATE/MODIFY

create profile [name]

```

modify profile [name]
options:
  app-service [[string] | none]
  description [string]
  max-flowspec-routes-limit [integer]
  neighbor [add | delete | modify | none | replace-all-with] {
    [IP Address] {
      adj-out [disabled | enabled]
      bgp-multiple-instance [disabled | enabled]
      extended-asn-cap [disabled | enabled]
      graceful-restart [disabled | enabled]
      graceful-restart-time [integer]
      hold-time [integer]
      local-address [IP Address]
      local-as [integer]
      remote-as [integer]
      router-id [IPv4 Address]
    }
  }
route-domain [name]
peer-group {
  adj-out [disabled | enabled]
  bgp-multiple-instance [disabled | enabled]
  extended-asn-cap [disabled | enabled]
  graceful-restart [disabled | enabled]
  graceful-restart-time [integer]
  hold-time [integer]
  local-address [IP Address]
  local-as [integer]
  remote-as [integer]
  router-id [IPv4 Address]
}

edit profile
options:
  all-properties
  non-default-properties

DISPLAY
list profile
show running-config profile

```

DESCRIPTION

profile component under security flowspec-route-injector is used to manage a Security FlowSpec Route Injector profile (unique per route domain instance). Security FlowSpec route injector profile is used by AFM/DHD module to advertise routes based on Source/Destination IP, Source/Destination Port, Protocol etc. for blackholing and scrubbing use cases using BGP FlowSpec mechanism (RFC 5575).

EXAMPLES

```

create profile p1
neighbor add {
  10.128.10.128 {
    local-address 10.128.10.169
  }
}
peer-group {
  local-as 60000
  remote-as 60000
  router-id 1.1.1.1
}
route-domain 0 }

```

Create a security flowspec-route-injector profile p1 for route-domain 0 and add 1 peer neighbor 10.128.10.128. Common attributes that are shared by all neighbors in the profile (unless overridden) are defined using peer-group settings.

```

modify profile p1 peer-group { graceful-restart enabled graceful-
restart-time 120 }

```

Modify profile p1 and update graceful-restart and graceful-restart-time peer-group attributes.

```
list policy
```

Displays the current list of configured security flowspec-route-injector profiles.

OPTIONS

description
User defined description.

max-flowspec-routes-limit
Specifies the maximum number of FlowSpec routes that can be advertised simultaneously per FlowSpec profile (or route domain) instance. Minimum allowed value is 100, Maximum allowed value is 10,000 (which is default value too).

neighbor
Add, modify, delete BGP peer neighbor configuration. Each neighbor is uniquely identified / configured using IP Address as the name.

description
User defined description.

adj-out
Enable/Disable BGP adj-rib-out feature. Default is enabled.

bgp-multiple-instance
Enable/Disable BGP multiple instance capability. Default is disabled.

extended-asn-cap
Enable/Disable Extended ASN capability (i.e. send 4-byte ASN). Default is enabled.

graceful-restart
Enable/Disable graceful restart capability. Default is disabled.

graceful-restart-time
Specifies graceful restart time (max time needed for Neighbor(s) to restart).

hold-time
Specifies the hold time (max time that can elapse between messages from peer). Default is 90 seconds.

local-address
Specifies the Local Address (on BigIP) to be used for initiating BGP connection(s) with peers.

local-as
Specifies the BGP Local AS number.

remote-as
Specifies the BGP Remote AS number.

router-id
Specifies the BGP Router ID to be used in BGP OPEN message when initiating BGP connection with peers. Router ID is an IPv4 address.

route-domain
Specifies name of the route domain to be used by the Security FlowSpec Route Injector profile. This is required field at the time of profile creation and is non-mutable after policy creation.

peer-group
Specifies peer group settings that are inherited by each neighbor unless overridden specifically for that neighbor.

adj-out
Enable/Disable BGP adj-rib-out feature. Default is enabled.

bgp-multiple-instance
Enable/Disable BGP multiple instance capability. Default is disabled.

extended-asn-cap
Enable/Disable Extended ASN capability (i.e. send 4-byte ASN). Default is enabled.

graceful-restart
Enable/Disable graceful restart capability. Default is disabled.

graceful-restart-time
Specifies graceful restart time (max time needed for Neighbor(s) to restart).

hold-time
Specifies the hold time (max time that can elapse between messages from peer). Default is 90 seconds.

local-address
Specifies the Local Address (on BigIP) to be used for initiating BGP connection(s) with peers.

local-as
Specifies the BGP Local AS number.

remote-as
Specifies the BGP Remote AS number.

router-id
Specifies the BGP Router ID to be used in BGP OPEN message when initiating BGP connection with peers. Router ID is an IPv4 address.

security http file-type

NAME
file-type - Lists the available file types that can be used in the context of HTTP Protocol Security.

MODULE
security http

SYNTAX
Retrieve the list of the file-type values using the syntax shown in the following sections.

DISPLAY
list file-type
list file-type [[[name] | [glob] | [regex]] ...]
options:
all
app-service
one-line

DESCRIPTION
Use this command to display the possible values of the file-type object to be used in the context of HTTP Protocol Security. These possible values include predefined and user-defined file types that you can select to have the security profiles allow or disallow.

EXAMPLES
list file-type

Displays all the file types supported by HTTP Protocol Security.

OPTIONS
app-service
Displays the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

SEE ALSO
glob, list, regex, security http profile, tmsh

COPYRIGHT

BIG-IP 2013-06-12 security http file-type(1)

security http mandatory-header

NAME
mandatory-header - Lists the available mandatory headers that can be used in the context of HTTP Protocol Security.

MODULE
security http

SYNTAX
Retrieve the list of the mandatory-header values using the syntax shown in the following sections.

DISPLAY
list mandatory-header
list mandatory-header [[[name] | [glob] | [regex]] ...]
options:
all
app-service
one-line

DESCRIPTION
Use this command to display the possible values of the mandatory-header object to be used in the context of HTTP Protocol Security. These possible values include predefined and user-defined HTTP headers that you can select to be required by the security profiles.

EXAMPLES
list mandatory-header

Displays all the mandatory headers supported by HTTP Protocol Security.

OPTIONS

app-service
Displays the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

SEE ALSO

glob, list, regex, security http profile, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

security http profile

NAME

profile - Configures an HTTP security profile.

MODULE

security http

SYNTAX

Configure the profile component within the security http module using the syntax shown in the following sections.

```
CREATE/MODIFY
create profile [name]
modify profile [name]
options:
  app-service [[string] | none]
  [case-sensitive | case-insensitive]
  defaults-from [[name] | none]
  description [[string] | none]
  evasion-techniques {
    options:
    alarm [disabled | enabled]
    block [disabled | enabled]
  }
  file-types {
    options:
    alarm [disabled | enabled]
    [allowed | disallowed]
    block [disabled | enabled]
    values [add | delete | none | replace-all-with] { [string] ... }
  }
  http-rfc {
    options:
    alarm [disabled | enabled]
    bad-host-header [disabled | enabled]
    bad-version [disabled | enabled]
    block [disabled | enabled]
    body-in-get-head [disabled | enabled]
    chunked-with-content-length [disabled | enabled]
    content-length-is-positive [disabled | enabled]
    header-name-without-value [disabled | enabled]
    high-ascii-in-headers [disabled | enabled]
    host-header-is-ip [disabled | enabled]
    maximum-headers [[integer] | disabled]
    null-in-body [disabled | enabled]
    null-in-headers [disabled | enabled]
    post-with-zero-length [disabled | enabled]
    several-content-length [disabled | enabled]
    unparseable-content [disabled | enabled]
  }
  mandatory-headers {
    options:
    alarm [disabled | enabled]
    block [disabled | enabled]
    values [add | delete | none | replace-all-with] { [string] ... }
  }
  maximum-length {
    options:
    alarm [disabled | enabled]
    block [disabled | enabled]
    post-data [[integer] | any]
    query-string [[integer] | any]
    request [[integer] | any]
    uri [[integer] | any]
  }
  methods {
    options:
    alarm [disabled | enabled]
    block [disabled | enabled]
```

```
values [add | delete | none | replace-all-with] { [string] ... }
}
response {
  options:
body [[string] | none]
headers [[new line separated headers] | none]
type [custom | default | redirect | soap-fault]
url [[string] | none]
}
```

```
edit profile [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

```
DISPLAY
list profile
list profile [ [ [name] | [glob] | [regex] ] ... ]
show running-config profile
show running-config profile [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition
  recursive
```

```
DELETE
delete profile [name]
```

DESCRIPTION

You can use the profile component to create, modify, display, or delete an HTTP security profile for use with HTTP Protocol Security functionality.

EXAMPLES

```
create http my_http_profile defaults-from http_security
```

Creates a custom HTTP security named my_http_profile that inherits its settings from the system default HTTP security profile.

```
list profile
```

Displays the properties of all HTTP security profiles.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

[case-sensitive | case-insensitive]

Specifies whether the security profile treats file types as case sensitive, or not. The default value is case-sensitive. Note: If you create a profile, you can use either property, thereafter it becomes read only. If the security profile is case insensitive, the system stores file types in lowercase in the security profile configuration.

defaults-from

Specifies the profile that you want to use as the parent profile. Your new profile inherits all settings and values from the parent profile specified. The default value is none.

description

User defined description.

evasion-techniques

Specifies what action the system takes when it detects an evasion technique. Evasion techniques are methods used by attackers to avoid detection of their attack. You can configure the following options for evasion technique checks:

alarm

Specifies, when enabled, that the system logs the request data and displays it in the Protocol Security Statistics screen whenever the system detects an evasion technique. The default value is enabled.

block

Specifies, when enabled, that the system stops requests whenever the system detects an evasion technique. The default value is disabled.

file-types

Specifies which file types the security profile considers legal, and specifies what action the system takes when it detects a request for an illegal file type. You can configure the following options for file types:

alarm

Specifies, when enabled, that the system logs the request data and displays it on the Protocol Security Statistics screen whenever the system detects a request for an illegal file type. The default value is enabled.

[allowed | disallowed]

Indicates whether the values property lists file types that the security profile permits or prohibits. Note: For each security profile you may define either allowed file types or disallowed file types.

block

Specifies, when enabled, that the system stops requests for an illegal file type. The default value is disabled.

values

Adds, deletes, or replaces a set of file types considered either legal or illegal by the security profile. You can either select an available file-type or add a new one.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

http-rfc

Specifies which validations the system should check and what action the system takes when it detects a request that is not formatted properly. You can configure the following options for HTTP protocol checks:

alarm

Specifies, when enabled, that the system logs the request data and displays it in the Protocol Security Statistics screen whenever a request fails one of the enabled HTTP protocol checks. The default value is enabled.

bad-host-header

Specifies, when enabled, that the system inspects requests to see whether they contain a non RFC compliant header value. The default value is enabled.

bad-version

Specifies, when enabled, that the system inspects requests to see whether they request information from a client using an HTTP protocol version 1.0 or higher. The default value is enabled.

block

Specifies, when enabled, that the system stops requests whenever the system detects an evasion technique. The default value is disabled.

body-in-get-head

Specifies, when enabled, that the system examines requests that use the HEAD or GET methods to see whether the requests contain data in their bodies, which is considered illegal. The default value is disabled.

chunked-with-content-length

Specifies, when enabled, that the system examines chunked requests for a content-length header, which is not permitted. The default value is enabled.

content-length-is-positive

Specifies, when enabled, that the system examines requests to see whether their content length value is greater than zero. The default value is enabled.

header-name-without-value

Specifies, when enabled, that the system checks requests for valueless header names, which are considered illegal. The default value is enabled.

high-ascii-in-headers

Specifies, when enabled, that the system inspects request headers for ASCII characters greater than 127, which are not permitted. The default value is disabled.

host-header-is-ip

Specifies, when enabled, that the system verifies that the request's host header value is not an IP address. The default value is disabled.

maximum-headers

Specifies whether the system compares the number of headers in the requests against the maximum number, and if so, how many headers are allowed. The default value is a maximum of 20 headers.

null-in-body

Specifies, when enabled, that the system inspects request bodies to see whether they contain a Null character, which is not allowed. The default value is disabled.

null-in-headers

Specifies, when enabled, that the system inspects request headers to see whether they contain a Null character, which is not allowed. The default value is enabled.

post-with-zero-length

Specifies, when enabled, that the system examines POST method requests for no content-length header, and for a content length of 0. The default value is disabled.

several-content-length

Specifies, when enabled, that the system examines each request to see whether it has more than one content-length header, which is considered illegal. The default value is enabled.

unparsable-content

Specifies, when enabled, that the system examines requests for content that the system cannot parse, which is not permitted. The default value is enabled.

mandatory-headers

Specifies which headers must appear in requests, and specifies what action the system takes when it detects a request without a mandatory header. You can configure the following options for mandatory headers:

alarm

Specifies, when enabled, that the system logs the request data and displays it on the Protocol Security Statistics screen whenever a request does not include a mandatory header. The default value is enabled.

block

Specifies, when enabled, that the system stops requests that do not include a mandatory header. The default value is disabled.

values

Adds, deletes, or replaces a set of headers that must appear in requests to be considered legal by the security profile. You can either select an available mandatory-header or add a new one. Note: The system stores mandatory headers in lowercase in the security profile configuration, regardless of whether it is case sensitive or not.

maximum-length

Specifies the default maximum length settings that the security profile considers legal, and specifies what action the system should take when it detects a request using an illegal length. You can configure the following options for length checks:

alarm

Specifies, when enabled, that the system logs the request data and displays it on the Protocol Security Statistics screen whenever a request fails one of the length checks. The default value is enabled.

block

Specifies, when enabled, that the system stops requests that fail one of the length checks. The default value is disabled.

post-data

Indicates whether there is a maximum acceptable length, in bytes, for the POST data portion of a request, and if so, specifies it. The default value is any (no restriction).

query-string

Indicates whether there is a maximum acceptable length, in bytes, for the query string portion of a request, and if so, specifies it. The default value is 1024 bytes.

request

Indicates whether there is a maximum acceptable length, in bytes, of a request, and if so, specifies it. The default value is any (no restriction).

uri Indicates whether there is a maximum acceptable length, in bytes, for a URL, and if so, specifies it. The default value is 1024 bytes.

methods

Specifies which HTTP methods the security profile considers legal, and specifies what action the system takes when it detects a request using an illegal method. You can configure the following options for methods:

alarm

Specifies, when enabled, that the system logs the request data and displays it on the Protocol Security Statistics screen whenever a request uses an illegal method. The default value is enabled.

block

Specifies, when enabled, that the system stops requests that use an illegal method. The default value is disabled.

values

Adds, deletes, or replaces a set of HTTP methods considered legal by the security profile. You can either select an available asm http-method or add a new one. Note: HTTP methods are case sensitive even if the security profile is case insensitive.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

response

Specifies information to display when the security profile blocks a client request. You can configure the following options for blocking page:

body Specifies the HTML code the system sends to the client in response to an illegal blocked request. Only if the response type is custom, you can edit this text.

headers
Specifies the set of response headers that the system sends to the client in response to an illegal blocked request. Only if the response type is custom, you can edit this text. Separate each header with a new line (Ctrl-V followed by Ctrl-J).

type Specifies which content, or URL, the system sends to the client in response to an illegal blocked request.

custom
Specifies a modified response text. You can edit the response header and HTML code in the properties headers and body.

default
Specifies the system-supplied response text written in HTML. You cannot edit that text. This is the default value.

redirect
Specifies that the system redirects the user to a specific web page instead of viewing a blocking page. You can edit the redirect web page in the url property.

soap-fault
Specifies the system-supplied response written in SOAP fault message structure. You cannot edit that text. Use this type when a SOAP request is blocked due to an XML related violation.

url Specifies the particular URL to which the system redirects the user. Only if the response type is redirect, you can edit this text. The web page should include a full URL path, for example, <http://www.myredirectpage.com>.

security ip-intelligence blacklist-category

NAME

blacklist-category - Global list of ip-intelligence blacklist categories. These ip-intelligence blacklist categories are used to configure ip-intelligence policies.

MODULE

security ip-intelligence

SYNTAX

Configure the blacklist-category component within the security ip-intelligence module using the syntax shown in the following sections.

CREATE/MODIFY

```
create blacklist-category [name]
modify blacklist-category [[name] | all]
options:
  app-service [name]
  description [string]
  bl-match-direction [destination | source | source-and-destination]
```

```
edit blacklist-category
```

options:

```
all-properties
non-default-properties
one-line
partition
recursive
```

DISPLAY

```
list blacklist-category
show running-config blacklist-category
options:
  all-properties
  non-default-properties
  one-line
  partition
  recursive
```

DESCRIPTION

You can use the blacklist-category component to configure a shareable and reusable blacklist category which can be configured with specific enforcement and logging settings under ip-intelligence policies.

EXAMPLES

modify blacklist-category Malware description "A variety of forms of hostile or intrusive software."

Modifies the blacklist-category description.

list blacklist-category

Displays the current list of blacklist categories.

OPTIONS

app-service

Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

description

User defined description.

bl-match-direction

Indicates whether to match source IPs, destination IPs, or both.

partition

Displays the administrative partition within which the component resides.

SEE ALSO

create, edit, list, modify, security ip-intelligence feed-list, security ip-intelligence policy, tmsh

COPYRIGHT

BIG-IP security7ip-intelligence blacklist-category(1)

security ip-intelligence feed-list

NAME

feed-list - Configures a feed-list for use by firewall. A feed-list is a list of URL feeds from where files are downloaded and the contents (IP-address prefixes) are compared against the source-IP address and/or destination-IP address in an IP packet by DWBL (Dynamic White/Black lists) by IP-Intelligence.

MODULE

security ip-intelligence

SYNTAX

Configure the feed-list component within the security ip-intelligence module using the syntax in the following sections.

CREATE/MODIFY

create feed-list [name]

modify feed-list [[name] | all]

options:

feeds [add | delete | modify | replace-all-with] {
name [string] {

options:

default-blacklist-category [string]

default-list-type [whitelist | blacklist]

poll {

interval [integer]

user [string]

url [string]

password [string]

}

}

app-service [name]

description [string]

edit feed-list [[name] | all]

options:

all-properties

non-default-properties

```
load feed-list [[name] | all] feeds { name [string] }
```

```
DISPLAY
list feed-list [[name] | all | [property]]
show running-config feed-list [[name] | all | [property]]
options:
  all-properties
  non-default-properties
  one-line
  partition
  recursive
```

```
DELETE
delete feed-list [[name] | all]
```

DESCRIPTION

You can use the feed-list component to define reusable lists of feeds. You can use a feed list in a security ip-intelligence policy. A policy compares all of the addresses in the list (downloaded from a file at the specified url) to either the source or destination IP in the packet, depending on how you apply the list. If there is a match, the ip-intelligence policy takes an action, such as accepting or dropping the packet.

EXAMPLES

```
create feed-list alist1 feeds add { poll { url http://f5.com/bl.txt }
```

Creates a new feed list, "alist1," with IPv4/IPv6 addresses in the file downloaded from the specified url.

```
modify feed-list alist1 feeds modify { description "DWBL file from f5.com" }
```

Modifies the above feed list with a description.

```
modify feed-list alist1 feeds modify { poll { url https://f5.com/bl.txt }
```

Modifies the same feed by changing the protocol.

```
list feed-list alist1
security ip-intelligence feed-list alist1 {
  feeds {
    url2 {
      poll {
        url https://f5.com/bl.txt
        user user1
        password user1_pwd
      }
    }
    description "DWBL file from f5.com"
  }
}
```

Shows the modified feed list.

```
load feed-list alist1 alist2 feeds { feed1 feed2 }
```

Immediately downloads and updates feeds feed1 and feed2 of feed lists alist1 and alist2.

OPTIONS

feeds

Adds, deletes, or replaces feeds. You can configure the following options for a feed:

name Specifies a name for a feed. This option is required for the operations create, delete, modify, and replace-all-with.

add Creates a new feed list.

delete

Deletes the feed list that you specify next, in curly braces ({}).

modify

Makes it possible to replace the optional description(s) for the feed list.

replace-all-with

Replaces the current set of feed list with the a new one that you specify next, in curly braces ({}).

default-list-type

Specifies a default type for this specific entry whether it is a blacklist or whitelist

whitelist

Specifies that this entry is a whitelist.

blacklist

Specifies that this entry is a blacklist.

default-blacklist-category

Default blacklist category type for all blacklist entries that do not have a corresponding category string (eg. Botnet, Spyware, Malware)

poll You can configure the following options under this:

interval

Specifies the frequency at which the url needs to be polled.

user Specifies the user which is used when downloading the url.

url Specifies the URL from where the white/black list will be downloaded. Note: Route domains are not supported when specifying the url.

password
Password for the user.

default-list-type
Specifies a default type for this specific entry whether it is a blacklist or whitelist

whitelist
Specifies that this entry is a whitelist.

blacklist
Specifies that this entry is a blacklist.

app-service
Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

default-blacklist-category
Default blacklist category type for all blacklist entries that do not have a corresponding category string (eg. Botnet, Spyware, Malware)

description
User defined description for this feed list.

partition
Displays the administrative partition within which the component resides.

SEE ALSO

BIG-IP 2016-03security ip-intelligence feed-list(1)

security ip-intelligence global-policy

NAME

global-policy - Configures the global ip-intelligence policy. These ip-intelligence policy contents/filters are applied to all packets except those going through the management interface. They are applied first, before any firewall rules for the packet's virtual server, route domain.

MODULE

security ip-intelligence

SYNTAX

Modify the global-policy component within the security ip-intelligence module using the syntax shown in the following sections.

MODIFY

```
modify global-policy
options:
  app-service [name]
  description [string]
  ip-intelligence-policy [ [policy_name] | none ]
```

edit global-policy

```
options:
  all-properties
  non-default-properties
  one-line
  partition
  recursive
```

reset-stats global-policy

```
options:
  ip-intelligence-categories
```

DISPLAY

```
list global-policy
show running-config global-policy
options:
  all-properties
  non-default-properties
  one-line
  partition
  recursive

show global-policy
options:
  ip-intelligence-categories
```

DESCRIPTION

You can use the global-policy component to configure a shareable and reusable set of network firewall DWBL (Dynamic White/Black lists) which can be enforced globally at the system level and the enforcement happens before the route-domain or virtual server level.

EXAMPLES

```
modify global-policy policy poll

Modifies the global-policy with policy poll.

list global-policy

Displays the current list of global-policy contents.
```

OPTIONS

```
app-service
Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

description
User defined description.

policy
Specifies an existing policy. policy contents are enforced at a global level.

partition
Displays the administrative partition within which the component resides.

ip-intelligence-categories
Used to show/ reset statistics on IP intelligence white/ black lists categories.
```

SEE ALSO

```
create, edit, list, modify, security ip-intelligence feed-list,
security ip-intelligence policy, tmsh
```

```

security ip-intelligence info

NAME info - Query IP Intelligence information about specified IP Address.

MODULE security ip-intelligence

SYNTAX Use the info component within the security ip-intelligence module to query IP Intelligence information about the IP address using the following syntax.

```
DISPLAY
show info address [IP address]
options:
  virtual-server [name]
  route-domain [name]
```

DESCRIPTION

You can use the info component to query IP Intelligence information about an IP Address using IP Intelligence policy attached to the selected context. Global context is the default when the command is used without options. To select the virtual server or the route domain

context use virtual-server or route-domain option. Only one option can be used. If the IP Address is listed in any of the DWBL (Dynamic White/Black List) feeds used by the selected IP Intelligence policy the query shows the list of categories and policy action (drop or allow) for the address. If the policy is configured to query legacy IP Reputation database, that information is also used in the query.

EXAMPLES

```
show info address 10.123.1.12
```

Query IP Intelligence information for IP address 10.123.1.12 using global IP Intelligence policy.

```
show info address 10.123.1.12 virtual-server /Common/vs
```

Query IP Intelligence information for IP address 10.123.1.12 using IP Intelligence policy configured for virtual server /Common/vs.

OPTIONS

virtual-server

Specifies the name of the virtual server configured with IP Intelligence policy to use in the query. This option cannot be used with the route-domain option.

route-domain

Specifies the name of the route domain configured with IP Intelligence policy to use in the query. This option cannot be used with the virtual-server option.

SEE ALSO

BIG-IP 2015-10-22 security ip-intelligence info(1)

security ip-intelligence policy

NAME

policy - Configures an ip-intelligence policy. It's comprised of three logical groups of settings: list of feed lists, enforcement and logging settings per blacklist category, and default enforcement and logging settings for blacklist categories.

MODULE

security ip-intelligence

SYNTAX

Configure the policy component within the security ip-intelligence module using the syntax in the following sections.

CREATE/MODIFY

```
create policy [name]
```

```
modify policy [name]
```

options:

```
app-service [name]
```

```
description [string]
```

```
blacklist-categories [add | default | delete | replace-all-with] {
```

```
  [name] {
```

```
    action [accept | drop | use-policy-setting]
```

```
    app-service none
```

```
    description none
```

```
    log-blacklist-hit-only [no | yes | use-policy-setting]
```

```
    log-blacklist-whitelist-hit [no | yes | use-policy-setting]
```

```
    match-direction-override [match-destination | match-source | match-source-and-destination]
```

```
  }
```

```
}
```

```
feed-lists [add | default | delete | replace-all-with] { [name] }
```

```
default-action [accept | drop]
```

```
default-log-blacklist-hit-only [ no | yes ]
```

```
default-log-blacklist-whitelist-hit [ no | yes ]
```

```
edit policy
```

options:

```
all-properties
```

```
non-default-properties
```

DISPLAY

```
list policy [ [ [name] | [glob] | [regex] ] ... ]
```

```
show running-config policy
```

```
show running-config policy [ [ [name] | [glob] | [regex] ] ... ]
```

options:

all-properties
non-default-properties
one-line
partition
recursive

DESCRIPTION

You can use the policy component to configure a shareable and reusable enforcement and logging settings on Dynamic White/Black lists of IPs coming from downloaded feeds. The policy can then be enforced on a number of configuration objects of the following types: ltm virtual, security ip-intelligence global-policy, net route-domain.

EXAMPLES

```
create policy poll {  
  blacklist-categories add {  
    Spyware {  
      action use-policy-setting  
      app-service none  
      description none  
      log-blacklist-hit-only use-policy-setting  
      log-blacklist-whitelist-hit yes  
    }  
  }  
  feed-lists add { alist1 alist2 }  
  default-action drop  
  default-log-blacklist-hit-only yes  
  default-log-blacklist-whitelist-hit no  
  description none  
  feed-lists none  
  partition Common }
```

Creates a policy poll with feeds from alist1 and alist2 feed lists, specific enforcement and logging settings for Spyware blacklist category and policy default settings for other categories.

```
modify policy poll { feed-lists delete { alist2 } }
```

Removes the feed-list alist2 from the policy poll.

```
list policy
```

Displays the current list of ip-intelligence policies contents.

OPTIONS

app-service

Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

description

User defined description.

partition

Displays the administrative partition within which the component resides.

blacklist-categories

Adds, deletes, or replaces blacklist categories.

action

Specifies what enforcement action will be applied if the packet is categorized with this blacklist category. If the packet is categorized with more than one blacklists the most restrictive action will be applied.

log-blacklist-hit-only

Specifies if a log message will be generated if the packet is categorized with this blacklist and the packet's IP listed in no whitelists.

match-direction-override

Overrides the current IP match direction setting for a category. If this value has not been overridden, it will be set to the value of the parent category's bl-match-direction at the time that the category was added to the policy.

log-blacklist-whitelist-hit

Specifies if a log message will be generated if the packet is categorized with this blacklist and the packet's IP is listed in a whitelist.

feed-lists

Adds, deletes, or replaces a feed list. Specifies a list of feed lists (see security ip-intelligence feed-list) against which the packet will be compared.

default-action

Specifies a default enforcement action which will be performed on the matched packet unless an implicit action specified for one of the blacklist categories the packet's IP is categorized with. If the packet's IP is listed in a white list the action is always accept.

default-log-blacklist-hit-only

Specifies a default blacklist hit only logging action which will be performed on the matched packet unless an implicit action specified for one of the blacklist categories the packet's IP is categorized with.

default-log-blacklist-whitelist-hit

Specifies a default blacklist and whitelist hit logging action

which will be performed on the matched packet unless an implicit action specified for one of the blacklist categories the packet's IP is categorized with.

security log network-storage-field

NAME

network-storage-field - Lists the available storage format fields that can be used in the context of Network Security Logging.

MODULE

security log

SYNTAX

Retrieve the list of the network-storage-field values using the syntax shown in the following sections.

DISPLAY

```
list network-storage-field
list network-storage-field [ [ [name] | [glob] | [regex] ] ... ]
options:
  all
  all-properties
  one-line
  app-service
```

DESCRIPTION

Use this command to display the possible values of the network-storage-field object to be used in the context of Network Security Logging. These possible values are predefined traffic items available for the server to log in context of Network event logging (for example, ACL events, TCP Open/Close, TCP/IP error events).

EXAMPLES

```
list network-storage-field
```

Displays all the storage fields supported by Network Security Logging.

OPTIONS

app-service

Displays the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

SEE ALSO

DELETE
delete profile [name]

```

DESCRIPTION

You can use the profile component to create, modify, display, or delete a Security log profile for use with Security Logging functionality.

EXAMPLES

```
create profile my_log_profile
```

Creates a custom Security log profile named my_log_profile with initial settings.

```
list profile
```

Displays the properties of all Security log profiles.

OPTIONS

app-service

Specifies the name of the application service to which the profile belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the profile. Only the application service can modify or delete the profile.

application

Adds, deletes, or replaces a single Application Security sub-profile. You can configure the following options for Application Security:

facility

Specifies the facility category of the logged traffic in Application Security. Select between local0 and local7.

filter

Adds, deletes, or replaces a set of request filters in Application Security. You can configure the following options for a request filter:

key Specifies a unique key for the request filter. This option is required for the operations create, delete, modify, and replace-all-with. The options are:

request-type

Specifies which kind of requests the system, or

server, logs.

protocol
Specifies whether request logging is dependent on the protocol.

response-code
Specifies whether request logging is dependent on the response status code.

http-method
Specifies whether request logging is dependent on the HTTP method.

search-all, search-in-headers, search-in-post-data, search-in-query-string, search-in-request, search-in-uri
Specifies whether the request logging is dependent on a specific string, and if so, the part of the request where the system must find the string. You can select only one of these filters, the default is search-all, which means that the system logs all requests, regardless of string.

values
Adds, deletes, or replaces a set of values in the request filter.

format
Specifies a storage format in Application Security. You can configure the following options for the storage format:

field-delimiter
Specifies a field delimiter in the predefined storage format. You may not use the % character. The default delimiter is the comma character, for CSV.

field-format
Specifies a field format (for each key/value pair) in the predefined storage format. Use %k for key and %v for value. The default format is empty that is interpreted as "%v", for CSV.

fields
Replaces a set of fields in the predefined storage format. The order in the set is important - the server displays the selected traffic items in the log sequentially according to it.

type Specifies a type of the storage format. The options are:

predefined
Specifies that the log displays only the predefined items you select in the fields.

user-defined
Specifies that the log displays any free text that you type in the user-string which can include the predefined items.

user-string
Specifies a user string in the user-defined storage format.

guarantee-logging
Indicates whether to guarantee local logging in Application Security.

guarantee-response-logging
Indicates whether to guarantee local response logging in Application Security. In order to enable it, you must first enable guarantee-logging, and set response-logging to either illegal or all.

local-storage
Enables or disables local storage in Application Security.

logic-operation
Specifies the logic operation on the associated filters in Application Security. The options are:

and Specifies that requests must pass all filters in order for the system, or server, to log the requests.

or Specifies that requests must meet at least one filter in order for the system, or server, to log the requests. This is the default value.

maximum-entry-length
Specifies the maximum entry length in Application Security. The options are:

1k This is the possible length for remote servers that support the udp protocol.

2k This is the default length for remote servers that support the tcp, udp and tcp-rfc3195 protocols.

10k, 64k
These are possible lengths for remote servers that support the tcp and udp protocol.

maximum-header-size
Specifies the maximum headers size in Application Security.

maximum-query-size
Specifies the maximum query string size in Application Security.

maximum-request-size
Specifies the maximum request size in Application Security.

name Specifies a dummy name for enabled Application Security. This option is required for the operations create, delete, modify, and replace-all-with.

protocol
Specifies the protocol supported by the remote server in Application Security. Select either: tcp (the default value), udp, or tcp-rfc3195.

remote-storage
Specifies a remote storage type in Application Security. The options are:

none Specifies that the system does not store traffic on any remote logging server.

remote
Specifies that the system stores all traffic on a remote logging server, like a syslog.

splunk
Specifies that the system stores all traffic on a reporting server (Splunk) using a preconfigured storage format. Key/value pairs are used in the log messages.

arcsight
Specifies that the system stores all traffic on a remote logging server using the predefined ArcSight settings for the logs. The log messages are in Common Event Format (CEF).

report-anomalies
Indicates whether to report detected anomalies in Application Security.

response-logging
Specifies a response logging type in Application Security. The options are:

none Specifies that the system does not log responses. This is the default value.

illegal
Specifies that the system logs responses to illegal requests.

all Specifies that the system logs all responses if the associated request-type filter has the all value.

servers
Adds, deletes, or replaces a set of remote servers in Application Security, by specifying an IP address and service port in the format [IPv4:port] or [IPv6.port].

built-in
Displays whether this profile is predefined or user-defined.

description
User defined description.

dos-application
Adds, deletes, or replaces a single DoS (Application) Protection sub-profile. You can configure the following options for DoS (Application) Protection:

local-publisher
Specifies the name of the local log publisher used for Application DoS attacks. Note: This publisher should have a single local-database destination.

name Specifies a dummy name for enabled DoS (Application) Protection. This option is required for the operations create, delete, modify, and replace-all-with.

remote-publisher
Specifies the name of the remote log publisher used for Application DoS attacks. Note: This publisher should have arcsight or splunk destinations.

bot-defense
Adds, deletes, or replaces a single Bot Defense sub-profile. You can configure the following options for Bot Defense:

name Specifies a dummy name for enabled Bot Defense. This option is required for the operations create, delete, modify, and replace-all-with.

local-publisher
Specifies the name of the local log publisher used for Bot Defense log messages. Note: This publisher should have a single local-database destination.

remote-publisher
Specifies the name of the remote log publisher used for Bot Defense log messages. Note: This publisher should have only splunk destinations.

filter

Following options are available which enable or disable the logging of Bot Defense log messages:

log-illegal-requests

This option is used to enable or disable the logging of illegal requests.

log-challenged-requests

This option is used to enable or disable the logging of challenged requests.

log-legal-requests

This option is used to enable or disable the logging of legal requests.

log-captcha-requests

This option is used to enable or disable the logging of captcha challenged requests.

log-bot-signature-matched-requests

This option is used to enable or disable the logging of reported bot signature requests. =back

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

ip-intelligence

You can configure the following options under this:

aggregate-rate

This option is used to set the aggregate rate limit that applies to any ip intelligence log message.

log-publisher

Specifies the name of the log publisher used for IP Intelligence events.

log-translation-fields

This option is used to enable or disable the logging of translated (i.e server side) fields in IP Intelligence log messages. Translated fields include (but not limited to) Source Address/Port, Destination Address/Port, IP Protocol, Route Domain and Vlan.

log-shun

This option is used to enable or disable the logging of shun IP Intelligence events.

log-rtbh

This option is used to enable or disable the logging of rtbh IP Intelligence events.

log-scrubber

This option is used to enable or disable the logging of scrubber IP Intelligence events.

port-misuse

You can configure the following options under this:

log-publisher

Specifies the name of the log publisher used for port misuse events.

aggregate-rate

This option is used to set the rate limit that applies to any port misuse log messages.

traffic-statistics

You can configure the following options under this:

log-active-flows

This option is used to enable and disable the logging of number of active flows on client side. The number of flows are logged globally, per virtual server and per route domain periodically if number of active flows increased or decreased.

log-publisher

Specifies the name of the log publisher used for Traffic Statistics logs.

log-reaped-flows

This option is used to enable and disable the logging of number of reaped flows on client side. The number of flows are logged globally, per virtual server and per route domain periodically if number of active flows increased or decreased.

log-missed-flows

This option is used to enable and disable the logging of number of TCP packets (non SYN/ACK) were dropped because of the flow table lookup failed. The number of packets are logged globally, and per route domain periodically.

log-syncookies

This option is used to enable and disable the logging of number of syncookies generated, accepted and rejected in the context globally and per virtual server. These log messages will be generated periodically.

log-syncookies-whitelist

This option is used to enable and disable the logging of number of syncookies whitelist hits, accepted and rejected in

the context globally and per virtual server. These log messages will be generated periodically.

network

Add, delete, modify or replace a single Network Security sub-profile. You can configure the following options under this:

filter

Following options are available which enable or disable the logging of corresponding Network events:

log-acl-match-accept

This option is used to enable or disable the logging of packets that match ACL rules configured with action = Accept or action = Accept Decisively.

log-acl-match-drop

This option is used to enable or disable the logging of packets that match ACL rules configured with action = Drop.

log-acl-match-reject

This option is used to enable or disable the logging of packets that match ACL rules configured with action = Reject.

log-ip-errors

This option is used to enable or disable the logging of IP error packets.

log-tcp-errors

This option is used to enable or disable the logging of TCP error packets.

log-tcp-events

This option is used to enable or disable the logging of TCP events on client side. Only 'Established' and 'Closed' states of a TCP session are logged if this option is enabled.

log-translation-fields

This option is used to enable or disable the logging of translated (i.e server side) fields in ACL match and TCP events. Translated fields include (but not limited to) Source Address/Port, Destination Address/Port, IP Protocol, Route Domain and Vlan.

log-geo-always

This option is used to enable or disable the logging of Geographic IP Location information fields in ACL match and TCP logging. Geographic information includes the country code of Source Address and Destination Address.

rate-limit

Following options are available to set throttling rate limits for the corresponding logging network events:

acl-match-accept

This option is used to set rate limits for the logging of packets that match ACL rules configured with action = Accept or action = Accept Decisively. This option is effective only if logging of this message type is enabled.

acl-match-drop

This option is used to set rate limits for the logging of packets that match ACL rules configured with action = Drop. This option is effective only if logging of this message type is enabled.

acl-match-reject

This option is used to set rate limits for the logging of packets that match ACL rules configured with action = Reject. This option is effective only if logging of this message type is enabled.

ip-errors

This option is used to set rate limits for the logging of IP error packets. This option is effective only if logging of this message type is enabled.

tcp-errors

This option is used to set rate limits for the logging of TCP error packets. This option is effective only if logging of this message type is enabled.

tcp-events

This option is used to set rate limits for the logging of TCP events on client side. This option is effective only if logging of this message type is enabled.

aggregate-rate

This option is used to set the aggregate rate limit that applies to any network logging message.

format

Specifies the Storage format in Network Security sub-profile. These settings are only used to format the log messages destined to a Remote Syslog server. You can configure the following options for the storage format:

field-list

Specifies a set of fields to be logged. This option is valid when storage format type is field-list. The order

in the set is important - the server displays the selected traffic items in the log sequentially according to it. User can pick fields from the following list: acl_policy_name, acl_policy_type, acl_rule_name, action, bigip_hostname, context_name, context_type, date_time, dest_fqdn, dest_geo, dest_ip, dest_port, drop_reason, management_ip_address, protocol, route_domain, sa_translation_pool, sa_translation_type, source_fqdn, source user, src_geo, src_ip, src_port, translated_dest_ip, translated_dest_port, translated_ip_protocol, translated_route_domain, translated_src_ip, translated_src_port, translated_vlan, vlan.

field-list-delimiter

Specifies the delimiter string in field-list storage format type. The default delimiter is the comma character, for CSV. This option is valid when storage format type is field-list. Special character \$ should not be used in delimiter string as it is reserved for internal usage. Also, the maximum length allowed for field-list-delimiter is 31 characters (excluding NUL terminator).

type Specifies a type of the storage format. The options are:

field-list

Specifies that the log displays only the items you specify in the field-list with field-list-delimiter as the delimiter between the items.

none Default format type. With this option, the messages will be logged in the following format:

```
"management_ip_address","bigip_hostname","context_type","context_name","src_geo","src_ip", "dest_geo","dest_ip",
```

user-defined

Specifies that the log displays the message as per the user-defined string format.

user-defined

Specifies the format of log message in form of user defined string. This option is valid when storage format type is user-defined. Maximum configurable length is 512 characters. Any of the following items, if wrapped within \${ }, will be substituted with the actual value when generating the log: acl_policy_name, acl_policy_type, acl_rule_name, action, bigip_hostname, context_name, context_type, date_time, dest_fqdn, dest_geo, dest_ip, dest_port, drop_reason, management_ip_address, protocol, route_domain, sa_translation_pool, sa_translation_type, source_fqdn, source user, src_geo, src_ip, src_port, translated_dest_ip, translated_dest_port, translated_ip_protocol, translated_route_domain, translated_src_ip, translated_src_port, translated_vlan, vlan.

publisher

Specifies the name of the log publisher used for Network events.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

nat This section is used to configure log settings related to events applicable to firewall NAT feature. Following options are available under this section:

end-inbound-session

Event for end of incoming connection to a translated address. Inbound connections are supported only for dynamic-pat source translation. Following options can be configured for logging this event:

backup-allocation-only

Enable logging this event when translation is done using backup address in the source translation object configured in dynamic-pat mode. This is only applicable when lsn-legacy-mode is enabled.

disabled

Disables logging this event.

enabled

Enables logging this event when translation is done using primary address or backup address in the source translation object.

errors

Event for errors encountered while attempting source or destination translation.

disabled

Disables logging for this event.

enabled

Enables logging for this event.

log-publisher

Specifies the name of log publisher used to log NAT related events to one (or more) remote or local destinations.

lsn-legacy-mode

Specifies whether translation events (and other NAT events) are logged in existing CGNAT/LSN formats (for backward compatibility with LSN events).

log-subscriber-id

When enabled, the subscriber ID associated with a subscriber IP address will be printed in the logs.

quota-exceeded

Event for when client exceeded allocated resource limit.

disabled

Disables logging for this event.

enabled

Enables logging for this event.

rate-limit

Following options are available to set throttling rate limits for the corresponding logging FW NAT events:

aggregate-rate-limit

This option is used to set the aggregate rate for all the FW NAT log events that can be logged per second.

end-inbound-session

This option is used to rate limit the end inbound session log events per second.

end-outbound-session

This option is used to rate limit the end outbound session log events per second.

errors

This option is used to rate limit the errors to be logged per second.

start-inbound-session

This option is used to rate limit the start inbound session log events per second.

start-outbound-session

This option is used to rate limit the start outbound session log events per second.

quota-exceeded

This option is used to rate limit the quota exceeded log events per second.

start-inbound-session

Event for start of incoming connection to a translated address. Inbound connections are supported only for dynamic-pat source translation. Following options can be configured for logging this event:

backup-allocation-only

Enable logging this event when translation is done using backup address in the source translation object configured in dynamic-pat mode.

disabled

Disables logging this event.

enabled

Enables logging this event when translation is done using primary address or backup address in the source translation object.

end-outbound-session

Event for end of outbound translation session, when outbound flow is deleted.

action

Specifies what action is taken at the time of logging the event. Possible options are: backup-allocation-only, disabled and enabled.

elements

Optional elements that can be logged for the event. This is applicable only if lsn-legacy-mode is enabled.

destination

Optional element, if selected, is used to log destination address and port in the applicable log event.

start-outbound-session

Event for start of outbound translation session, when outbound flow is created.

action

Specifies what action is taken at the time of logging the event. Possible options are: backup-allocation-only, disabled and enabled.

elements

Optional elements that can be logged for the event. This is applicable only if lsn-legacy-mode is enabled.

destination

Optional element, if selected, is used to log destination address and port in the applicable log event.

protocol-dns

Add, delete, modify or replace a single Protocol (DNS) Security sub-profile. You can configure the following options under this:

filter

Following options are available which enable or disable the logging of corresponding Network events:

log-dns-drop

This option is used to enable or disable the logging of dropped DNS packets.

log-dns-filtered-drop

This option is used to enable or disable the logging of DNS packets that are dropped due to filtering.

log-dns-malformed

This option is used to enable or disable the logging of malformed DNS packets.

log-dns-malicious

This option is used to enable or disable the logging of malicious DNS packets.

log-dns-reject

This option is used to enable or disable the logging of rejected DNS packets.

format

Specifies the Storage format in Protocol (DNS) Security sub-profile. These settings are only used to format the log messages destined to a Remote Syslog server. You can configure the following options for the storage format:

field-list

Specifies a set of fields to be logged. This option is valid when storage format type is field-list. The order in the set is important - the server displays the selected traffic items in the log sequentially according to it. User can pick fields from the following list: action, attack_type, context_name, date_time, dest_ip, dest_port, dns_query_name, dns_query_type, src_ip, src_port, vlan.

field-list-delimiter

Specifies the delimiter string in field-list storage format type. The default delimiter is the comma character, for CSV. This option is valid when storage format type is field-list. Special character \$ should not be used in delimiter string as it is reserved for internal usage. Also, the maximum length allowed for field-list-delimiter is 31 characters (excluding NUL terminator).

type Specifies a type of the storage format. The options are:

field-list

Specifies that the log displays only the items you specify in field-list with field-list-delimiter as the delimiter between the items.

none Default format type. With this option, the messages will be logged in the following format:

```
"date_time", "context_name", "vlan",  
"dns_query_type", "dns_query_name", "attack_type",  
"action", "src_ip", "dest_ip", "src_port",  
"dest_port", "route_domain"
```

user-defined

Specifies that the log displays the message as per the user-defined string format.

user-defined

Specifies the format of log message in form of user defined string. This option is valid when storage format type is user-defined. Maximum configurable length is 512 characters. Any of the following items, if wrapped within \${ }, will be substituted with the actual value when generating the log: action, attack_type, context_name, date_time, dest_ip, dest_port, dns_query_name, dns_query_type, route_domain, src_ip, src_port, vlan.

name Specifies a dummy name for enabled Protocol (DNS) Security. This option is required for the operations create, delete, modify, and replace-all-with.

publisher
Specifies the name of the log publisher used for DNS events.

protocol-dns-dos-publisher
Specifies the name of the log publisher used for DNS DoS events.

dos-network-publisher
Specifies the name of the log publisher used for DoS Network events.

protocol-sip
Add, delete, modify or replace a single Protocol (SIP) Security sub-profile. You can configure the following options under this:

filter
Following options are available which enable or disable the logging of corresponding protocol sip events:

log-sip-drop
This option is used to enable or disable the logging of dropped SIP packets.

log-sip-global-failures
This option is used to enable or disable the logging of SIP packets that resulted in global failures.

log-sip-malformed
This option is used to enable or disable the logging of malformed SIP packets.

log-sip-redirectation-responses
This option is used to enable or disable the logging of SIP packets that resulted in sending redirection response.

log-sip-request-failures
This option is used to enable or disable the logging of SIP request failures.

log-sip-server-errors
This option is used to enable or disable the logging of SIP packets that resulted in server errors.

format
Specifies the Storage format in Protocol (SIP) Security sub-profile. These settings are only used to format the log messages destined to a Remote Syslog server. You can configure the following options for the storage format:

field-list
Specifies a set of fields to be logged. This option is valid when storage format type is field-list. The order in the set is important - the server displays the selected traffic items in the log sequentially according to it. User can pick fields from the following list: `action`, `attack_type`, `context_name`, `date_time`, `dest_ip`, `dest_port`, `dns_query_name`, `dns_query_type`, `src_ip`, `src_port`, `vlan`.

field-list-delimiter
Specifies the delimiter string in field-list storage format type. The default delimiter is the comma character, for CSV. This option is valid when storage format type is field-list. Special character `$` should not be used in delimiter string as it is reserved for internal usage. Also, the maximum length allowed for field-list-delimiter is 31 characters (excluding NUL terminator).

type Specifies a type of the storage format. The options are:

field-list
Specifies that the log displays only the items you specify in the field-list with field-list-delimiter as the delimiter between the items.

none Default format type. With this option, the messages will be logged in the following format:

```
"date_time", "context_name", "vlan",  
"sip_method_type", "sip_caller", "sip_callee",  
"attack_type", "action", "src_ip", "dest_ip",  
"src_port", "dest_port", "route_domain"
```

user-defined
Specifies that the log displays the message as per the user-defined string format.

user-defined
Specifies the format of log message in form of user defined string. This option is valid when storage format type is user-defined. Maximum configurable length is 512 characters. Any of the following items, if wrapped within `{ }`, will be substituted with the actual value when generating the log: `action`, `attack_type`, `context_name`, `date_time`, `dest_ip`, `dest_port`, `dns_query_name`, `dns_query_type`, `route_domain`, `src_ip`, `src_port`, `vlan`.

name Specifies a dummy name for enabled Protocol (SIP) Security. This option is required for the operations create, delete, modify, and replace-all-with.

publisher

Specifies the name of the log publisher used for SIP events.

`protocol-sip-dos-publisher`
Specifies the name of the log publisher used for SIP DoS events.

`protocol-transfer`
Adds, deletes, or replaces a single Protocol (Transfer) Security sub-profile. You can configure the following options for Protocol (Transfer) Security:

`name` Specifies a dummy name for enabled Protocol (Transfer) Security. This option is required for the operations `create`, `delete`, `modify`, and `replace-all-with`.

`publisher`
Specifies the name of the log publisher used for Protocol Security log messages. Note: This publisher should have either `local-database`, `local-syslog`, `remote-syslog`, `arcsight` or `splunk single destination`.

`regex`
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

security log protocol-dns-storage-field

NAME

`protocol-dns-storage-field` - Lists the available storage format fields that can be used in the context of Protocol DNS Security Logging.

MODULE

`security log`

SYNTAX

Retrieve the list of the `protocol-dns-storage-field` values using the syntax shown in the following sections.

DISPLAY

```
list protocol-dns-storage-field
list protocol-dns-storage-field [ [ name ] | [ glob ] | [ regex ] ] ... ]
options:
  all
  all-properties
  one-line
  app-service
```

DESCRIPTION

Use this command to display the possible values of the `protocol-dns-storage-field` object to be used in the context of Protocol DNS Security Logging. These possible values are predefined traffic items available for the server to log in the context of DNS event logging (for example, Malformed, Malicious, or Dropped DNS packets).

EXAMPLES

```
list protocol-dns-storage-field
```

Displays all the storage fields supported by Protocol DNS Security Logging.

OPTIONS

`app-service`
Displays the application service to which the object belongs. The default value is none. Note: If the `strict-updates` option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

SEE ALSO

`glob`, `list`, `regex`, `security log profile`, `tmsh`

BIG-IP 20security log protocol-dns-storage-field(1)

security log protocol-sip-storage-field

NAME
protocol-sip-storage-field - Lists the available storage format fields that can be used in the context of Protocol SIP Security Logging.

MODULE
security log

SYNTAX
Retrieve the list of the protocol-sip-storage-field values using the syntax shown in the following sections.

DISPLAY
list protocol-sip-storage-field
list protocol-sip-storage-field [[name] | [glob] | [regex]] ...]
options:
all
all-properties
one-line
app-service

DESCRIPTION
Use this command to display the possible values of the protocol-sip-storage-field object to be used in the context of Protocol SIP Security Logging. These possible values are predefined traffic items available for the server to log in the context of SIP event logging (e.g Dropped SIP packets).

EXAMPLES
list protocol-sip-storage-field

Displays all the storage fields supported by Protocol SIP Security Logging.

OPTIONS
app-service
Displays the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

SEE ALSO

BIG-IP 20security log protocol-sip-storage-field(1)

security log remote-format

NAME
remote-format - Lists the log format for different remote destinations (such as ArcSight, Splunk etc.) used by various Firewall events (such as Network, IP Intelligence, DoS etc.).

MODULE
security log

SYNTAX
Retrieve the list of the remote-format using the syntax shown in the following sections.

DISPLAY
list remote-format
list remote-format [[name] | [glob] | [regex] ...]
options:
all
all-properties
app-service
format
one-line

DESCRIPTION
Use this command to display the actual log format used to send firewall event logs to remote destinations such as ArcSight, Splunk and Syslog. These log formats are used by the log destinations of log publisher configured in different sub-profiles (for example Network, IP Intelligence, DNS, DNS DoS etc.) of a security log profile.

EXAMPLES
list remote-format
Displays the log format for all firewall events.
list remote-format network-arcsight
Displays the format for Network log events (such as ACL matches, TCP events etc.) sent to an ArcSight destination.
list remote-format network-dos-splunk
Displays the format for Network DoS log events sent to a Splunk destination.
list remote-format ip-intelligence-syslog-default
Displays the format for IP Intelligence log events sent to a remote syslog destination.

OPTIONS
app-service
Displays the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.
format
Displays the remote log format used by the object.

SEE ALSO
glob, list, regex, security log profile, tmsh

COPYRIGHT

BIG-IP 2013-02-20 security log remote-format(1)

security log storage-field

NAME
storage-field - Lists the available storage format fields that can be used in the context of Application Security Logging.

MODULE
security log

SYNTAX
Retrieve the list of the storage-field values using the syntax shown in the following sections.

DISPLAY
list storage-field
list storage-field [[name] | [glob] | [regex] ...]
options:
all
app-service
format
id
one-line

DESCRIPTION
Use this command to display the possible values of the storage-field

object to be used in the context of Application Security Logging. These possible values are predefined traffic items available for the server to log. The traffic items appear in the final format string as arguments in the printf() function, i.e. "%\$", therefore each storage field has its fixed format (specifier) and id (position).

EXAMPLES

list storage-field

Displays all the storage fields supported by Application Security Logging.

OPTIONS

app-service

Displays the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

format

Displays a format of the field (s - string, d - decimal). It corresponds to the conversion specifier in the printf() function.

id Displays an order ID of the field (starting from 1). It corresponds to the position in the argument list of the desired argument in the printf() function.

SEE ALSO

glob, list, regex, security log profile, tmsh

detail
field-fmt

DELETE
delete destination-translation [name | all]

DESCRIPTION

A destination-translation NAT object is a set of IP Address(es) and port numbers that the BIG-IP system uses as public-side addresses and ports. When this object is assigned to a Security NAT Policy rule (which is associated to a virtual server), any incoming traffic to this virtual server that matches the rule, will have their private destination addresses (and/or ports) translated to a public address and/or port from this destination-translation object.

EXAMPLES

```
create destination-translation d1 type static-pat addresses add {  
10.10.10.0/24 } ports add { 7000-8000 }
```

Creates the destination-translation object d1 that contains the translation addresses in the range of 10.10.10.0/24, translation port range 7000-8000 and uses static-pat as the translation algorithm.

```
delete destination-translation d1
```

Deletes the destination-translation named d1.

OPTIONS

addresses

Specifies the set of translation IP addresses available. This is a collection of either one (or more) IP Address, one (or more) IP prefixes with their prefix lengths and/or IP Address range. All public-side (destination) addresses come from the subnets you enter in this property.

app-service

Specifies the name of the application service to which this object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this object. Only the application service can modify or delete this object.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the destination-translation component. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

ports

Specifies the range of port numbers available for use with translation IP addresses.

type Specifies which kind of translation is performed. Available options are static-nat and static-pat.

static-nat

Using this translation type in the destination-translation, only (destination) IP Address translation is performed (and no port translation) for the incoming client traffic that matches the NAT Policy Rule using this translation object. There is a static (pre-defined) 1:1 mapping between the untranslated IP Address(es) and the translated IP Address(es) specified in this object.

static-pat

Using this translation type in the destination-translation, (destination) port translation is performed for the incoming client traffic that matches the NAT Policy Rule using this translation object. There is a static (pre-defined) 1:1 mapping between the untranslated port(s) and the translated port(s) specified in this object. In addition, if translation address(es) are specified in the destination-translation, it also performs IP Address translation (in the same fashion as done for static-nat).

            [ [port] | [port1-port2] ]
          }
          ports none
          vlans [add | default | delete | replace-all-with] {
            [vlan names...]
          }
          vlans none
        }
        translation {
          destination [name | none]
          source [name | none]
        }
      }
    }
  }
  rules none
edit policy
options:
  all-properties
  non-default-properties
```

```
DISPLAY
list policy
show running-config policy
options:
  all-properties
  non-default-properties
  one-line
```

DESCRIPTION

You can use the policy component to configure a shareable and reusable set of nat rules which can be associated with a number of configuration objects of the following types: ltm virtual, security device-context, net route-domain.

EXAMPLES

```
create policy p1 rules add {
  r1 {
    place-before first
    ip-protocol tcp
    source {
      addresses replace-all-with { 192.168.10.0/24 }
      ports replace-all-with { 10000-19999 }
    }
    destination {
      addresses replace-all-with { 10.10.10.0/24 }
      ports replace-all-with { 80 443 }
    }
    translation {
      destination my_dest_nat
      source my_src_nat
    }
  }
}
```

Creates a rule entry at the beginning of the policy that matches incoming TCP traffic with source address in the range 192.168.10.0/24, source port in the range 10000-19999, destination address in the range 10.10.10.0/24, destination port 80 or 443 and if matches, performs the source translation as per source-translation object named my_src_nat and destination translation as per destination-translation object named my_dest_nat.

```
modify policy p1 rules delete r1
```

Removes the rule r1 from the policy p1.

```
list policy
```

Displays the current list of policy rules.

OPTIONS

description
User defined description.

rules
Adds, deletes, or replaces a NAT rule.

description
User defined description.

destination
address-lists
Specifies a list of address lists (see security firewall address-list) against which the packet will be compared.

addresses
Specifies a list of addresses and networks against which the packet will be compared.

port-lists
Specifies a list of port lists (see security firewall port-list) against which the packet will be compared.

ports
Specifies a list of ports and port ranges against which the packet will be compared.

proxy-arp
Enable or disable proxy arp for pre-translation destination addresses.

route-advertisement
Enable or disable route advertisements for pre-translation destination addresses.

ip-protocol
Specifies the IP protocol against which the packet will be compared.

log-profile
Specifies the name of the log profile (see security log profile) that is used to log the translation events triggered by this NAT rule.

place-after
Specifies that a new rule should be placed after another rule, first or last. If individual rules are being added (as opposed to specifying replace-all-with) then place-before or place-after must be specified.

place-before
Specifies that a new rule should be placed before another rule, first or last. If individual rules are being added (as opposed to specifying replace-all-with) then place-before or

place-after must be specified.

source
address-lists
Specifies a list of address lists (see security firewall address-list) against which the packet will be compared.

addresses
Specifies a list of addresses and networks against which the packet will be compared.

port-lists
Specifies a list of port lists (see security firewall port-list) against which the packet will be compared.

ports
Specifies a list of ports and port ranges against which the packet will be compared.

vlans
Specifies a list of vlans, vlan groups and tunnels against which the packet will be compared.

status
Specifies whether the rule is enabled or disabled. A rule that is enabled is always checked. A rule that is disabled is never checked.

translation
Specifies the translation objects.

destination
Specifies the name of destination translation object (see security nat destination-translation). If specified, it is used to perform the destination address/port translation as per it's settings. If not specified, the matching traffic's destination address/port are not translated.

source
Specifies the name of source translation object (see security nat source-translation). If specified, it is used to perform the source address/port translation as per it's settings. If not specified, the matching traffic's source address/port are not translated.

DESCRIPTION

A source-translation NAT object is a set of IP Address(es) and port numbers that the BIG-IP system uses as public-side addresses and ports. When this object is assigned to a Security NAT Policy rule (which is associated to a virtual server), any incoming traffic to this virtual server that matches the rule, will have their private source addresses (and/or ports) translated to a public address and/or port from this source-translation object.

EXAMPLES

```

create source-translation s1 type dynamic-pat pat-mode napt mapping {
mode endpoint-independent-mapping timeout 600 } addresses add {
10.10.20.0/24 } ports add { 4000-5000 } client-connection-limit 100

```

Creates the source-translation object named s1 that contains the translation addresses in the range of (addresses) 10.10.20.0/24, translation port range 4000-5000, with a client connection limit of 100 connections per client. The translated address and port are persisted for 600 seconds. This object operates in NAPT mode (Network Address and Port Translation mode), which is the default mode if not specified when type is dynamic-pat.

```

delete source-translation s1

```

Deletes the source-translation object named s1.

OPTIONS

app-service
Specifies the name of the application service to which this object belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this object. Only the application service can modify or delete this object.

addresses
Specifies the set of translation IP addresses available in the pool. This is a collection of IP prefixes with their prefix lengths. All public-side addresses come from the subnets you enter in this property.

backup-addresses
Specifies translation IP addresses available in the backup pool which is used by DNAT translation mode if DNAT mode translation fails and falls back to NAPT mode. This is a collection of IP prefixes with their prefix lengths.

client-connection-limit

The maximum number of simultaneous translated connections a client or subscriber is allowed to have. This attribute is applicable only if type is set to dynamic-pat.

description
User defined description.

egress-interfaces
The set of interfaces on which the source address translation is allowed or disallowed. If egress-interfaces-enabled is specified, the source address translation is allowed only on the specified set of interfaces. If egress-interfaces-disabled is specified, source address translation is disabled on specified interfaces.

egress-interfaces-disabled
Source address translation is not allowed on the interfaces specified in the egress-interfaces set.

egress-interfaces-enabled
Source address translation is allowed on the interfaces specified in the egress-interfaces set.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

hairpin-mode
This attribute is applicable only if type is set to dynamic-pat.

Enable or disable hairpinning for incoming connections.

When a client sends a packet to another client in the same private network, hairpin mode sends the packet directly to the source client's private address; the BIG-IP system immediately translates the packet's public-side source address. Rather than going out to the public network and coming back later for translation, the packet takes a hairpin turn at the BIG-IP device.

icmp-echo
Enable or disable ICMP echo on translated addresses.

inbound-mode
This attribute is applicable only if type is set to dynamic-pat.

Modifies the inbound-connection mode for incoming connections to translation endpoints. A translation endpoint is the public-side address and port (X':x') for a private-side address (X:x). You can allow one of the following two algorithms for managing inbound connections:

endpoint-independent-filtering
creates inbound mappings automatically from outbound traffic and allows inbound connections. Consider an outbound mapping from X:x to X':x'. If a connection comes from X:x through X':x', the BIG-IP system automatically creates a reverse mapping from X':x' back to X:x. A public-side station can respond through the X':x' address. This allows the BIG-IP system to provide Endpoint Independent Filtering (EIF) as defined in section 5 of RFC 4787
().

explicit
Allows inbound connections if and only if there exists an inbound mapping to translate public-side source address X':x' to client's private address X:x. Users can create Inbound mappings via iRules or PCP.

none disables inbound connections to translation end-points (X':x'). If there is a mapping of X (a private-side IP address) to X' (a public-side IP), connections can only go out from X through X'. If a public-side recipient tries to answer at the client's public-side X' address, the BIG-IP system does not map X' back to X. The inbound connection never happens.

Port Control Protocol (PCP) is not supported if you use this setting.

pat-mode
Specifies which kind of translation address mapping is performed when type is specified as dynamic-pat. Available options are NATP, Deterministic, and PBA.

NAPT (Network Address Port Translation) assigns translation addresses and ports in round-robin fashion. The algorithm first cycles through translation addresses and then through translation ports.

Deterministic
(DNAT) is a reversible translation method. A given client address and port always translates to a particular public address and port from the source-translation pool. This method has the following restrictions:

it is only available for NAT44 translations,
it does not support connections through DS-Lite tunnels,
subscriber connections must be received over a VLAN with the property, cmp-hash, set to "source ip,"
the egress to the Internet must be over a VLAN with the property, cmp-hash, set to "dest ip,"
any security NAT rule ("security nat policy") that uses this must have a source property set to an IP prefix containing fewer than 231 addresses. For example, the source cannot be 0.0.0.0/0.

PBA (Port Block Allocation) assigns 'blocks' of the translation

addresses and ports to individual clients. All client connections are restricted to the allocated port blocks. Only block allocations and deallocations are logged in order to reduce the volume of logs.

subscriber connections must be received over a VLAN with the property, `cmp-hash`, set to "source ip," the egress to the Internet must be over a VLAN with the property, `cmp-hash`, set to "dest ip,"

You can access your VLAN configurations through the "net vlan" component. You can find the VLANs used by your virtual server by showing or listing the "ltm virtual" component.

`name` Specifies a unique name for the source-translation component. This option is required for the commands `create`, `delete`, and `modify`.

`mapping`

These settings are applicable only if `type` is set to `dynamic-pat`.

Configure the mapping settings for translation entries. It is the preservation of a public-side IP address for a client from session to session.

`mapping.mode`

Configure the mapping mode for translation entries. You can enter `address-pooling-paired`, `endpoint-independent-mapping`, or `none`.

`address-pooling-paired`

causes the BIG IP software to attempt to keep the IP address persistent but not necessarily the port. If a client's private IP address:port combination is X:x, it's public-side address may be X:a in one session, X:b in the next session, X:c in a third session, and so on.

`endpoint-independent-mapping`

causes the BIG IP software to attempt to keep the IP address and port persistent. If a client's private IP address:port combination is X:x, and it's public-side address is X':x' in the first session, it remains X':x' in all future sessions.

This is called "Endpoint Independent Mapping" in RFC 4787 ().

This is the only supported setting for PCP, which you configure with the `pcp` property.

`none` prevents the BIG IP software from attempting any IP address or port mapping. An address:port combination of X:x is never guaranteed to have the same public-side address or port in two sessions.

`mapping.timeout`

After the most-recent session where address:port X:x translated to X':x' on the public side, a timer begins. If the timer expires before X:x has another session, X' or x' may be used as the public side of another address:port. Use this parameter to set the timeout (in seconds) for address and port mapping.

`pcp` A Port Control Protocol (PCP) client can set (or at least learn) its own translation (public-side) IP address and/or port. It can also set the address and/or port of a third-party client. PCP is defined in RFC 6887 (see).

`pcp.profile`

Specifies the PCP profile to use for this LSN pool. This PCP profile defines the settings to use for communication with PCP clients. Use the `create ltm profile pcp` command to create a new PCP profile.

PCP requires a profile (defined with this property) and either a `pcp.selfip` or a `pcp.dslite` tunnel where clients can send their PCP requests.

If you remove this profile option, you must specifically remove any `pcp.selfip` or `pcp.dslite` tunnel, too.

`pcp.selfip`

Specifies the PCP Server self-IP address for this LSN pool. The virtual server's clients send their PCP packets to this address. Use the `create net self` command to create a self-IP address, then use that address for this parameter. Choose a self-IP address in a VLAN that is reachable by the virtual server's clients.

`pcp.dslite`

Specifies a DS-LITE tunnel for PCP packets. Whenever a client sends a PCP packet through this tunnel, the BIG-IP device uses the PCP profile you choose with the `pcp.profile` property.

A DS-LITE tunnel places each IPv4 packet into the payload of an IPv6 packet. The IPv6 packet carries the IPv4 packet between customer equipment and the BIG-IP system, which then removes the IPv4 packet, uses NAT to translate its IPv4 addresses, and sends it to its destination.

You cannot use this property if the `pat-mode` property is set to `Deterministic`.

`port-block-allocation`

Configures the port block settings for PBA mode.

`port-block-allocation.block-idle-timeout`

Configures the time after the last connection using the block is freed that the block assignment expires. The default value is 3600

seconds.

port-block-allocation.block-lifetime
Configures the timeout after which the block is no longer used for new port allocations. The block becomes a zombie block. The default is 0 which corresponds to an infinite timeout.

port-block-allocation.block-size
Configures the number of ports in a block. The default value is 64.

port-block-allocation.client-block-limit
Configures the number of blocks that can be assigned to a single subscriber IP address. The default value is 1.

port-block-allocation.zombie-timeout
Configures the timeout after which connections using the zombie block are killed. After connections are killed zombie block is freed after **port-block-allocation.block-idle-timeout**. This parameter is unused unless the **port-block-allocation.block-lifetime** is set. The default value is 0 which corresponds to infinite timeout.

proxy-arp
Enable or disable proxy arp for the translated source IP addresses.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

ports
Specifies the range of port numbers available for use with translation IP addresses.

route-advertisement
Enable or Disable Route Advertisement for the translated source IP addresses.

type Specifies which kind of translation is performed. Available options are: **static-nat**, **static-pat**, and **dynamic-pat**.

dynamic-pat
Using this type, BigIP translates a group of private (internal) IP Addresses to a pool of (one or more) public (external) IP Addresses and also translates ports to reuse the pool of public addresses. BigIP supports 3 different modes for **dynamic-pat** which can be specified using option **pat-mode** as described above.

static-nat
Using this translation type in the source-translation, only (source) IP Address translation is performed (and no port translation) for the incoming client traffic that matches the NAT Policy Rule using this translation object. There is a static (pre-defined) 1:1 mapping between the untranslated IP Address(es) and the translated IP Address(es) specified in this object (i.e same translation address (X') is used for all connections originating from the client with untranslated address (X)).

static-pat
Using this translation type in the source-translation, (source) port translation is performed for the incoming client traffic that matches the NAT Policy Rule using this translation object. There is a static (pre-defined) 1:1 mapping between the untranslated port(s) and the translated port(s) specified in this object. In addition, if translation address(es) are specified in the source-translation, it also performs IP Address translation (in the same fashion as done for **static-nat**).

DISPLAY
list security protocol-inspection compliance

DESCRIPTION
Use this command to get default information about compliance checks. This command does not allow you to create/modify compliance checks.

EXAMPLES
list security protocol-inspection compliance
Displays all compliance inspections.
list security protocol-inspection compliance ftp_malformed_param
Displays compliance inspection "ftp_malformed_param".

PROPERTIES
accuracy
Specifies the accuracy of the compliance inspection.
description
Specifies the description of the compliance inspection. Also this parameter is used in logging when compliance inspection is matched.
service
Specifies target-based service.
action
Specifies enforcement action for matched compliance inspection.
direction
Specifies the flow direction for which this compliance inspection will be applied.
log
Specifies whether the inspection will be logged if it matches the compliance inspection.
app-service
Specifies app service.
documentation
Specifies compliance inspection documentation.
performance-impact
Specifies performance impact of this compliance inspection.
systems
Specifies systems where this compliance inspection can be matched.
attack-type
Specifies compliance inspection attack type.
id
Specifies compliance inspection identifier.
protocol

Specifies transport protocol where this compliance inspection can be matched (udp, tcp, any).

risk Specifies compliance inspection risk.

value
Specifies value for specific compliance check depending on field (see below).

value-type
Specifies value type for specific compliance check.

SEE ALSO

security protocol-inspection profile

NAME

profile - Configures the protocol inspection profiles.

MODULE

security protocol-inspection profile

SYNTAX

```
CREATE/MODIFY
modify security protocol-inspection profile
create security protocol-inspection profile
properties:
  app-service [string]
  auto-add-new-inspections [bool]
  auto-publish-suggestion [bool]
  avr-stat-collect [bool]
  compliance-enable [bool]
  defaults-from [string]
  description [string]
  signature-enable [bool]
  services { ... }
  staging-period [integer]
```

DISPLAY

```
list security protocol-inspection profile
```

DESCRIPTION

Use this command to create/modify protocol inspection profile.

EXAMPLES

```
create security protocol-inspection profile new_http_profile { default-
from protocol_inspection_http }
```

Create profile "new_http_profile" and clone all configuration from predefined profile protocol_inspection_http.

```
list security protocol-inspection profile
```

Displays all protocol inspection profiles.

```
list security protocol-inspection profile new_http_profile
```

Displays protocol inspection profile with name new_http_profile.

PROPERTIES

app-service [string]
Specifies app service.

auto-add-new-inspections [bool]
If set, new inspections arrived via IPS IM pkg will be automatically added to this profile for configured service.

auto-publish-suggestion [bool]
If set, after the learning period(staging-period) the action for the inspections will automatically be updated to the suggested action, if exists.

avr-stat-collect [bool]
Specifies if AVR collects data from IPS.

compliance-enable [bool]
Specifies whether the compliance checks will be enabled for this profile.

signature-enable [bool]
Specifies whether the signature checks will be enabled for this profile.

defaults-from [string]
Specifies parent profile (in time of creating). If this parameter is assigned then new profile will be cloned from parent profile.

description [string]
Specifies profile description.

services
Specifies services for this profile. ...

staging-period
If auto-publish-suggestion is set, this value defines the time period after which inspection action will be automatically updated to suggested action.

BIG-IP 2017-security protocol-inspection service(1)

security protocol-inspection signature

NAME

signature - Configures the signature inspections.

MODULE

security protocol-inspection signature

SYNTAX

CREATE/MODIFY

```
modify security protocol-inspection signature
create security protocol-inspection signature
properties:
  accuracy [high | low | medium]
  description [string]
  last-updated [date in format %y-%m-%d:%H:%M:%S]
  reference-links [string]
  service [string]
  action [accept | drop | reject]
  direction [any | to-client | to-server]
  log [yes | no]
  references [string]
  sig [string - signature in snort format]
  app-service [string]
  documentation [string]
  performance-impact [high | low | medium]
  revision [integer]
  systems [string]
  attack-type [string]
  id [integer]
  protocol [any | tcp | udp]
  risk [critical | high | low | medium]
  user-defined [yes | no]
```

DISPLAY

```
list security protocol-inspection signature
```

DESCRIPTION

Use this command to create/modify custom signatures in snort format.

EXAMPLES

```
create security protocol-inspection signature new_sig { log yes action
drop sig "content:\"GET\"; content:\"HTTP\"; description "Signature
match" }
```

Create signature "new_sig" which find "GET" and "HTTP" in payload (see details about snort signatures in related documentation). Following actions are applied if signature is matched: drop flow and write message "Signature match".

```
modify security protocol-inspection signature new_sig { log no action
accept sig }
```

Modify action and logging of previous signature "new_sig". Following actions are applied if signature is matched: accept flow.

```
list security protocol-inspection signature new_sig
```

Displays signature new_sig.

```
list security protocol-inspection signature
```

Displays all signatures.

PROPERTIES

accuracy

Specifies the accuracy of the signature.

description

Specifies the description of the signature. Also this parameter is used in logging when signature is matched.

last-updated

Specifies date/time when signature has been updated last time.

reference-links

Specifies external references (url) to signature.

references
Specifies external industrial references (cve and bugtraq) to signature.

service
Specifies target-based service.

action
Specifies enforcement action for matched signature.

direction
Specifies flow direction for signature. Signature search will apply only for payload in this direction.

log Specifies whether the inspection will be logged if it matches the signature.

app-service
Specifies app service.

documentation
Specifies signature documentation.

performance-impact
Specifies performance impact of this signature.

revision
Specifies signature revision. For custom signatures, this parameter will be incremented each time you modify this signature.

systems
Specifies systems where this signature can be matched.

attack-type
Specifies signature attack type.

id Specifies signature identifiers.

protocol
Specifies transport protocol where this signature can be matched (udp, tcp, any).

risk Specifies signature risk.

sig Specifies snort signature.

user-defined
Specifies if signature is created by user.

deprecated
Specifies if inspection is now deprecated and will not be matched anymore.

security protocol-inspection updates

NAME

updates - Configures updates.

MODULE

security protocol-inspection updates

SYNTAX

INSTALL
install security protocol-inspection updates
options:
file [string]

DISPLAY

show security protocol-inspection updates

DESCRIPTION

Use this command to install and see all available IM packages.

EXAMPLES

install security protocol-inspection updates file file_name

Install new update from file "file_name".

show security protocol-inspection updates

Show all available updates.

OPTIONS

file Specifies IM package file.

SEE ALSO

show, install, security, tmsh

security scrubber dwbl-scrubber-category-stats

NAME

dwbl-scrubber-category-stats - Show the list of IPs that are associated with a scrubbed category.

MODULE

security scrubber

SYNTAX

show dwbl-scrubber-category-stats

DESCRIPTION

You can use the dwbl-scrubber-category-stats component to display the list of IPs that are associated with a scrubbed category.

EXAMPLES

show security scrubber dwbl-scrubber-category-stats category-name [name] profile-name scrubber-profile-default

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2016. All rights reserved.

BIG-IP security6scrubber dwbl-scrubber-category-stats(1)

security scrubber dwbl-scrubber-stat

NAME

dwbl-scrubber-stat - Show scrubber's Dwbl related stats.

MODULE

security scrubber

SYNTAX

Run the show dwbl-scrubber-stat within the security scrubber module using the syntax shown in the following sections.

SHOW

show dwbl-scrubber-stat
options:
destination
expire-time
monitors
observed-rate-bps
observed-rate-cps
observed-rate-pps
route-domain

scrubber-status
scrubber-type
silverline-status
silverline-url
threshold-bps
threshold-cps
threshold-pps
ttl
under-attack

DESCRIPTION

You can use the dwbl-scrubber-stat component to display the threshold, observed rate, under attack, time to live, and expire time for each monitor. Each row displays stats related per a monitor. Scrubber module monitors selected virtual servers, categories, route domains, and netflow protected servers.

EXAMPLES

```
show security scrubber dwbl-scrubber-stat show security scrubber dwbl-  
scrubber-stat monitors show security scrubber dwbl-scrubber-stat  
scrubber-status show security scrubber dwbl-scrubber-stat silverline-  
url silverline-status expire-time under-attack
```

OPTIONS

destination
Show the column for the destination configured on the scrubber.

expire-time
Show the column for the current expiration time on the scrubber.

monitors
Show the columns related to the monitor configuration: threshold-bps, observed-rate-bps, threshold-cps, observed-rate-cps, threshold-pps, observed-rate-pps.

observed-rate-bps
Show the column for the current observed BPS on the monitor.

observed-rate-cps
Show the column for the current observed CPS on the monitor.

observed-rate-pps
Show the column for the current observed PPS on the monitor.

route-domain
Show the column for the Route Domain configured on the monitor.

scrubber-status
Show the columns related to the current status of the scrubber: under-attack, expire-time, silverline-status.

scrubber-type
Show the column for the type of monitor configured for the scrubber.

silverline-status
Show the column for the current status of Silverline.

silverline-url
Show the column for the URL configured for Silverline.

threshold-bps
Show the column for the BPS threshold configured for the scrubber.

threshold-cps
Show the column for the CPS threshold configured for the scrubber.

threshold-pps
Show the column for the PPS threshold configured for the scrubber.

ttl Show the column for the TTL configured for the scrubber.

under-attack
Show the column for whether an attack has been detected.

COPYRIGHT

BIG-IP 2018-security scrubber dwbl-scrubber-stat(1)

security scrubber profile

NAME

profile - Configures a scrubber profile for use by firewall. A scrubber-profile-default specifies monitors and method (how and where)

to be monitored and scrubbed.

MODULE
security scrubber

SYNTAX
Configure the scrubber-profile-default component within the security scrubber profile module using the syntax in the following sections.

```
MODIFY
  modify profile [name]
options:
  advertisement-ttl [integer]
  scrubber-categories action [add | delete | modify | none |
    replace-all-with] {
    [name] { advertisement-method [bgp-flowspec-method | bgp-method
      | none-method | silverline-method] | blacklist-category [string] |
    next-hop [IPv4 address] | next-hop-v6 [IPv6 address] | route-domain-
    name [string] | app-service [[string] | none]}
  }
  scrubber-rt-domain action [add | delete | modify | none |
    replace-all-with] {
    [name] { absolute-threshold [integer] | advertisement-method
      [bgp-flowspec-method | bgp-method | none-method | silverline-method]
    next-hop [IPv4 address] | next-hop-v6 [IPv6 address] | percentage-
    threshold [integer] | route-domain [string] |
  scrubber-rd-network-prefix action [add | delete | modify |
    none | replace-all-with] {
    [name] { dst-ip [IP address] | mask [integer] | next-hop
      [IP address] | app-service [[string] | none] }
  }
  excluded-vlans action [add | delete | none |
    replace-all-with] {
    [name]
  }
}
scrubber-virtual-server action [add | delete | modify | none |
  replace-all-with] {
  [name] { absolute-threshold [integer] | advertisement-method
    [bgp-flowspec-method | bgp-method | none-method | silverline-method] |
  next-hop [IP address] | percentage-threshold [integer] | vs-name
    [string] app-service [[string] | none]}
}
silverline { url [string] user-id [string] user-passwd [string] }
app-service [[string] | none]

list profile [[name] | all | [property]]
show running-config profile [[name] | all | [property]]
options:
  all-properties
  non-default-properties
  one-line
  recursive
```

OPTIONS

app-service
Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

description
User defined description.

advertisement-ttl
Defines the scrubbing duration for all monitored entities in seconds.

scrubber-categories
Defines how a blacklist-category to be scrubbed.

advertisement-method
Defines a method to use to scrub a blacklist-category.

blacklist-category
Identifies a blacklist-category to be scrubbed.

next-hop
Defines the nexthop to be used for scrubbing/redirecting traffic for IPv4 shuns.

next-hop-v6
Defines the nexthop to be used for scrubbing/redirecting traffic for IPv6 shuns.

route-domain-name
Identifies a route-domain to be used for route advertisement.

absolute-threshold
Defines bandwidth threshold which triggers scrubbing for selected route domain.

advertisement-method
Defines a method to use to scrub a route domain.

percentage-threshold
Defines bandwidth threshold which triggers scrubbing for selected route domain. The percentage is calculate based on route-domain bandwidth value.

next-hop
Defines the nexthop to be used for scrubbing/redirecting IPv4 traffic.

next-hop-v6
Defines the nexthop to be used for scrubbing/redirecting IPv6 traffic.

route-domain-name
Identifies a route-domain to be used for route advertisement.

excluded-vlans
Identifies VLANs to be excluded from traffic monitoring.

scrubber-rd-network-prefix
Defines subnets which to be used for scrubbing/redirecting traffic. If is defined than the scrubbing for parent route-domain would be ignored.

OPTIONS

dst-ip
Defines subnet to be used for redirection.

mask
Defines subnet mask to be used for redirection.

next-hop
Defines the nexthop to be used for scrubbing/redirecting traffic.

app-service
Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

scrubber-virtual-server
Defines how and when a virtual server to be scrubbed.

OPTIONS

absolute-threshold
Defines a bandwidth threshold which triggers scrubbing for a selected virtual server.

advertisement-method
Defines a method to use to scrub a virtual server.

percentage-threshold
Defines bandwidth threshold which triggers scrubbing for selected route domain. The percentage is calculate based on defined virtual server bandwidth value.

next-hop
Defines the nexthop to be used for scrubbing/redirection traffic.

vs-name
Identifies a virtual server to be used for route advertisement.

app-service
Specifies the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the Application Service that owns the object, you cannot modify or delete the object. Only the Application Service can modify or delete the object.

OPTIONS

url
Used to communicate with Silverline system.

user-id
Defines silverline user's user identification.

user-passwd
Defines silverline user's password.

COPYRIGHT

BIG-IP 2017-09-01 security scrubber profile(1)

security scrubber unredirect

NAME

unredirect - Stop scrubbing for a monitored entity. A unredirect

command enables a user to stop redirection (scrubbing) for a selected monitored entity such as category, virtual server, or route domain.

MODULE
security scrubber

SYNTAX
Configure the redirect component within the security scrubber module using the syntax shown in the following sections.

```
RUN
run security scrubber unredirect
options:
  profile [scrubber-profile-default]
  unredirect-category [string]
  unredirect-netflow-protected-server [string]
  unredirect-route-domain [string]
  unredirect-virtual-server [string]
```

DESCRIPTION
You can use the unredirect component to stop traffic redirection (scrubbing) for a selected monitored entity.

EXAMPLES
run security scrubber unredirect scrubber-profile scrubber-profile-default unredirect-category
run security scrubber unredirect scrubber-profile scrubber-profile-default unredirect-virtual-server
run security scrubber unredirect scrubber-profile scrubber-profile-default unredirect-route-domain
run security scrubber unredirect scrubber-profile scrubber-profile-default unredirect-netflow-protected-server

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2017-06-20 security scrubber unredirect(1)

security ssh profile

NAME
profile - Configures ssh profile.

MODULE
security ssh

SYNTAX
Modify the profile component within the security ssh module using the syntax shown in the following sections.

```
CREATE/MODIFY
create profile [name]
modify profile [name]
options:
  description [string]
  rules [add | delete | modify | replace-all-with] {
    [ [name] ] {
      options:
    actions [add | delete | modify] {
      [ [name] ] {
        shell-action { control [allow | disallow | terminate] log [no | yes] }
        sub-system-action { control [allow | disallow | terminate] log [no | yes] }
        sftp-up-action { control [allow | disallow | terminate] log [no | yes] }
        sftp-down-action { control [allow | disallow | terminate] log [no | yes] }
        scp-up-action { control [allow | disallow | terminate] log [no | yes] }
        scp-down-action { control [allow | disallow | terminate] log [no | yes] }
        rexec-action { control [allow | disallow | terminate] log [no | yes] }
        local-forward-action { control [allow | disallow | terminate] log [no | yes] }
        remote-forward-action { control [allow | disallow | terminate] log [no | yes] }
        x11-forward-action { control [allow | disallow | terminate] log [no | yes] }
        agent-action { control [allow | disallow | terminate] log [no | yes] }
        other-action { control [allow | disallow | terminate] log [no | yes] }
      }
    }
  }
  description [string]
  identity-users [add | delete | replace-all-with] {
    [identity user list names...]
  }
  identity-groups [add | delete | replace-all-with] {
    [identity group list names...]
  }
}
rules none
actions [add | delete | modify] {
  [ [name] ] {
    options:
  shell-action { control [allow | disallow | terminate] log [no | yes] }
  sub-system-action { control [allow | disallow | terminate] log [no | yes] }
```

```

sftp-up-action { control [allow | disallow | terminate] log [no | yes] }
sftp-down-action { control [allow | disallow | terminate] log [no | yes] }
scp-up-action { control [allow | disallow | terminate] log [no | yes] }
scp-down-action { control [allow | disallow | terminate] log [no | yes] }
rexec-action { control [allow | disallow | terminate] log [no | yes] }
local-forward-action { control [allow | disallow | terminate] log [no | yes] }
remote-forward-action { control [allow | disallow | terminate] log [no | yes] }
x11-forward-action { control [allow | disallow | terminate] log [no | yes] }
agent-action { control [allow | disallow | terminate] log [no | yes] }
other-action { control [allow | disallow | terminate] log [no | yes] }
}
}
auth-info [add | delete | modify] {
  [ [name] ] {
    options:
    proxy-server-auth {
      private-key [string]
      public-key [string]
    }
    proxy-client-auth {
      private-key [string]
      public-key [string]
    }
    real-server-auth {
      public-key [string]
    }
  }
}
timeout [integer]
lang-env-tolerance [any | common | default-value | none]

```

```

edit profile
options:
  all-properties
  non-default-properties

```

```

DISPLAY
list profile
show running-config profile
options:
  all-properties
  non-default-properties
  one-line

```

DESCRIPTION

You can use the profile component to configure a shareable and reusable set of ssh profile rules.

EXAMPLES

```

create profile profile1 auth-info add {
  auth1 {
    proxy-server-auth {
      private-key "abcd"
      public-key "1234"
    }
    proxy-client-auth {
      private-key "efgh"
      public-key "5678"
    }
  }
}

```

Creates a ssh profile with auth-info of client facing auth and server facing auth.

```

modify profile profile1 actions add {
  action1 {
    sftp-up-action {
      control disallow log yes
    }
    shell-action {
      control terminate log yes
    }
  }
}

```

Modify existing profile by adding default actions of shell action and sftp action.

```

modify profile profile1 rules add {
  rule1 {
    actions add {
      action1 {
        sftp-up-action {
          control disallow log yes
        }
        shell-action {
          control terminate log yes
        }
      }
    }
    identity-groups add {
      "grp1" "grp2"
    }
    identity-users add {
      "usr1" "usr2"
    }
    description "rule1 and action1"
  }
}

```

Modify existing profile by adding rule1 to it with command actions and user and group identity info.

```
list profile
```

Displays the current list of profile rules.

OPTIONS

description
User defined profile description.

timeout
User defined timeout value.

lang-env-tolerance
Set the tolerance level for LANG environment variable settings.
Only applicable when "other-action" is set to "disconnect" or
"terminate". "common" allows only "en_US.UTF-8", while "any"
allows any standard locale.

rules
Adds, deletes, or replaces a profile rule.

description
User defined rule description.

actions
Specifies the rule actions that the system takes when a
profile is applied.

shell-action
Specifies the rule shell action info.

sub-system-action
Specifies the rule sub system info.

sftp-up-action
Specifies the rule sftp up action info.

sftp-down-action
Specifies the rule sftp up action info.

scp-up-action
Specifies the rule scp up action info.

scp-down-action
Specifies the rule scp up action info.

rexec-action
Specifies the rule rexec action info.

local-forward-action
Specifies the rule local forward action info.

remote-forward-action
Specifies the rule local forward action info.

x11-forward-action
Specifies the rule x11 forward action info.

agent-action
Specifies the rule agent action info.

other-action
Specifies the rule other action info.

identity-users
Specifies the rule users identity.

identity-groups
Specifies the rule groups identity.

actions
Specifies the profile default actions that the system takes when a
profile is applied.

shell-action
Specifies the rule shell action info.

sub-system-action
Specifies the rule sub system info.

sftp-up-action
Specifies the rule sftp up action info.

sftp-down-action
Specifies the rule sftp up action info.

scp-up-action
Specifies the rule scp up action info.

scp-down-action
Specifies the rule scp up action info.

rexec-action
Specifies the rule rexec action info.

local-forward-action
Specifies the rule local forward action info.

remote-forward-action
Specifies the rule local forward action info.

x11-forward-action
Specifies the rule x11 forward action info.

agent-action
Specifies the rule agent action info.

other-action

Specifies the rule other action info.

auth-info

Specifies the authentication info of public key and private key for this profile.

proxy-server-auth

Specifies a set of private/public keys that can be used to authenticate proxy (BigIP) host server to the real clients during the initial key exchange of the SSH session between real clients and BigIP acting as a proxy server. A SSH Profile MUST have at least 1 set of private/public key configured for proxy server authentication.

private-key

Specifies the private key of the authentication algorithm (RSA, DSS etc) used for the proxy server authentication.

public-key

Specifies the public key of the authentication algorithm (RSA, DSS etc) used for the proxy server authentication.

proxy-client-auth

Specifies a set of private/public keys that can be used to support 'publicKey' based client authentication as defined in RFC 4252 (The Secure Shell (SSH) Authentication Protocol). Note that this is optional in a SSH profile and is only required to support 'publicKey' based client authentication (as defined in section 7 of the above mentioned RFC).

private-key

Specifies the private key of the authentication algorithm (RSA, DSS etc) used for the proxy client authentication.

public-key

Specifies the public key of the authentication algorithm (RSA, DSS etc) used for the proxy client authentication.

real-server-auth

Specifies public key that can be used to authenticate real host server to the proxy (BigIP) client during the initial key exchange of the SSH session between BigIP acting as a proxy client and a real ssh (backend) server. If user does not configure any public key for the real server authentication in a SSH profile, all (backend) real servers are always trusted.

public-key

Specifies the public key of the authentication algorithm (RSA, DSS etc) used for the real server authentication.

sys

sys air-filter-reset

NAME

air-filter-reset - Resets the air filter alert timer

MODULE

sys

SYNTAX

Reset the air filter alert timer air-filter-reset component within the sys module using the following syntax.

DISPLAY

run air-filter-reset

DESCRIPTION

You can use the air-filter-reset component to reset the air filter alert time. The primary usage of this command is to reset the timer after the air filter has been replaced.

EXAMPLES

run air-filter-reset

Resets the air filter alert timer.

SEE ALSO
tmsh

BIG-IP 2017-03-07 sys air-filter-reset(1)

sys alert lcd

NAME
alert - Manages outstanding alerts.

MODULE
sys

SYNTAX
Manages the outstanding alerts on the system when used with the syntax below.

DISPLAY
show alert lcd

MODIFY
reset-stats alert lcd
reset-stats alert lcd [priority { alert | critical | emergency | error | info | warning }]

DESCRIPTION
You can use the lcd component to display or clear the lcd alerts for the system. The clear lcd alerts can be issued with the priority option followed by the priority value in which case only alerts with matching priority are cleared.

EXAMPLES
show alert lcd

Displays lcd alerts.

reset-stats alert lcd

Clears all lcd alerts.

SEE ALSO
reset-stats, show, sys alert lcd, tmsh

sys aom

NAME
aom - Manages Always On Management subsystem

MODULE
sys

SYNTAX
Manages the Always On Management(AOM) subsystem when used with the syntax below.

DISPLAY

aom list

MODIFY

aom [readonly | webui | media-redirectation | vkvm | ipmi] [enabled | disabled]

DESCRIPTION

You can use the aom component to manage the AOM access for the system. All AOM controls are disabled by default. These commands are not supported on all platforms.

readonly reduces the AOM menu to status only, the AOM cannot be used to change the system.

webui controls access to the AOM web services, when enabled this opens port 443 on the AOM for HTTPS. This option is not available on all platforms.

media-redirectation controls if the AOM can access a virtual media server to allow the user to mount a file or iso image from a remote system to the AOM. Only allowed when webui is enabled. Media-redirectation opens up ports 5120/5124(CDMEDIA) 5122/5126(FDMEDIA) and 5123/5127(HDMEDIA) on the AOM. This option is not available on all platforms.

vkvm controls AOM webui Virtual Keyboard, Video and Mouse redirection. Only allowed when webui is enabled. This opens up port 7578/7582. This option is not available on all platforms.

ipmi controls ipmi access over LAN. When enabled ipmi commands into the AOM over the network port 623(IPMI) and 52123(SSHSOL) are allowed.

EXAMPLES

list sys aom all-properties

Displays aom configuration.

modify sys aom ipmi enabled

Allows IPMI access into the Always On Management subsystem.

SEE ALSO

sys appiq config

NAME

config - Configures this BIG-IP for AppIQ feature.

MODULE

sys appiq

SYNTAX

Automatically configures AppIQ feature on this box with given ECM host IP.

MODIFY

modify config

options:

host-ip [ip address]

DISPLAY

list config

options:

all-properties

DESCRIPTION

When run for the first time, this command automatically creates necessary configuration objects to establish communication between BIG-IP and ECM cluster. The command can be reused to change the configured host IP of the ECM cluster.

OPTIONS

host-ip

Specifies an IPv4/6 address for the ECM host. By default, this value is "any6" and AppIQ is disabled. Upon setting this value, the feature is enabled.

User can later delete automatically created and configured AppIQ logging profiles under System configuration to disable the feature. Please note that the command needs to be re-run to enable

the feature if the configuration is manually removed/changed.

SEE ALSO

list, modify, tmsh

COPYRIGHT

sys application apl-script

NAME

apl-script - Provides scripts that can be included by an application template.

MODULE

sys application

SYNTAX

Configure the apl-script component within the sys application module using the syntax in the following sections.

EDIT

```
create apl-script [name]
modify apl-script [name]
options:
  apl-checksum [[string] | none]
  apl-signature [[string] | none]
  description [[string] | none]
  ignore-verification [true | false]
edit apl-script [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
```

DISPLAY

```
list apl-script
list apl-script [ [name] | [glob] | [regex] ] ... ]
```

DELETE

```
delete apl-script [name]
```

GENERATE

Note: generate cryptographic signature or checksum based on apl script text.

```
generate sys application apl-script [name]
options:
  checksum
  signature
```

DESCRIPTION

An APL script contains APL that can be directly included into application templates. APL scripts provide a convenient way to build libraries of common presentation elements. For detailed description of application presentation language elements, See help page of sys application template

EXAMPLES

The following is a fairly simple example of an APL script and a template that makes use of the APL script. The APL script defines a user type that can then be used multiple times in different templates.

```
sys application apl-script com.f5.apl.example {
  define string port validator "PortNumber"
}

sys application template example_template {
  actions {
  definition {
    presentation {
      include "com.f5.apl.example"
      section my_section {
        string address1
        port portnum1
        string address2
        port portnum2
      }
    }
  }
}

generate my_script checksum
```

Generate a checksum for the script text and add the checksum as a property.

```
generate my_script signature signing-key my_key
```

Generate a signature for the script text using the specified private key and add the signature as a property.

Note: For a script which includes a checksum or signature to successfully load, the script text contents must match the stored checksum or signature.

To temporarily stop the verification of signature or checksum and still retain the checksum or signature, the ignore-verification attribute must be set to true. This is done by editing the script and adding the ignore-verification attribute.

To completely clear the signature or checksum, simply set the attribute script-signature or script-checksum to empty string "". By doing so, the script will be processed as if it was never signed or checksummed.

```
modify apl-script my_script {
description none
script {
}
ignore-verification true
script-checksum 74778e7b13016e0b9329a17f8d2da601
total-signing-status checksum
verification-status checksum-verified }
```

OPTIONS

You can use these options with the apl-script command:

checksum

Generate a checksum for the script text and add the checksum to the script as a property. Only for use with the generate command.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

script

Contains the APL text that can be imported into application templates.

signature

Generate a signature for the script text using the specified private key and add the signature to the script as a property. Only for use with the generate command.

signing-key

The private key to use for signing the script. Only for use with the signature option.

SEE ALSO

create, delete, edit, glob, list, modify, regex, sys application template and generate.

COPYRIGHT

BIG-IP 2016-03-14 sys application apl-script(1)

sys application custom-stat

NAME

custom-stat - Provides derived statistics for iStats.

MODULE

sys application

SYNTAX

Configure the custom-stat component within the sys application module

using the syntax in the following sections.

```
EDIT
create custom-stat [key]
modify custom-stat [key]
options:
  app-service [[string] | none]
  keyspace [string]
  formula [string]
  measure [string]
edit custom-stat [ [key] | [glob] | [regex] ] ... ]
options:
  all-properties

DISPLAY
list custom-stat
list custom-stat [ [key] | [glob] | [regex] ] ... ]

DELETE
delete custom-stat [key]
```

DESCRIPTION
Statistics are derived for objects in the given keyspace based on the given formula, producing the given measure.

EXAMPLES
create sys application custom-stat myKey
keyspace sys.application.service
measure conns_per_min
formula "rate counter conns 60"

Creates a derived iStat.

OPTIONS
You can use these options with the custom-stat component:

app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

formula
Specifies the first token in the formula indicates the computation to be made. Currently only rates are supported.

rate

rate computes the rate of change of the source measure over the last seconds. This is applicable only to numeric measures. The derived measure is of type gauge.

keyspace
Specifies that a derived iStat will be computed for all objects in the given keyspace for which the formula is computable (the source measure of the correct type exists).

measure
Specifies the name of the derived measure to be created. The type of the derived measure is dependent on the formula.

SEE ALSO
create, modify, sys application service

COPYRIGHT

sys application service

NAME
service - Configures traffic management application services.

MODULE
sys application

SYNTAX
Modify the service component within the sys application module using the syntax shown in the following sections.

CREATE/MODIFY
create service [name]

```

modify service [name]
options:
  description [string]
  device-group [[string] | default | non-default | none]
  execute-action [name]
  lists [add | delete | modify | replace-all-with] {
    [name] {
      options:
    }
  value { [string]... }
  value none
  encrypted [yes | no]
}
lists none
strict-updates [disabled | enabled]
tables [add | delete | modify | replace-all-with] {
  [name] {
    options:
  }
  column-names { [name] ... }
  encrypted-columns { [name] ... }
  rows { row { [value] ... } row { [value] ... } ... } }
  rows none
}
tables none
template [name]
traffic-group [[string] | default | non-default | none]
variables [add | delete | modify | replace-all-with] {
  [name] {
    options:
  }
  value [string]
  encrypted [yes | no]
}
variables none

metadata
  [add | delete | modify] {
    [metadata name ... ] {
      value [ "value content" ]
      persist [ true | false ]
    }
  }
}

```

```

edit service [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list service
list service [ [ [name] | [glob] | [regex] ] ... ]
show running-config service
show running-config service [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
  partition

```

Note: Application Service objects are always created in a subfolder of the current folder. Make sure the correct path is used to display the service. E.G list myapplication.app/myapplication

```

DELETE
delete service [name]

```

OPTIONS

You can use these options with the service component:

description
User defined description.

device-group
Specifies the name of the device group to which the application service is assigned. If this property is modified with the default keyword, the value of the parent folder or partition will be used and the inherited-devicegroup property will be set to true.

execute-action
Runs the specified template action associated with the service.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

lists
Provides the set of list variables and values that are passed to template scripts.

metadata
Associates user defined data, each of which has name and value pair and persistence. The default value is persistent, which means the data will be saved into the config file.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

strict-updates
Specifies whether configuration objects contained in the application service can be directly modified outside the context of the system's application service management interfaces.

tables
Provides the set of table variables and values that are passed to template scripts.

template
The template defines the configuration for the application service. Generic application service has no template associated with it. This can be changed after the service has been created to move the service to a new template. A templated application service can be converted to a generic application service by setting new template to none or empty string. Similarly a generic application service can be made templated by associating it with the existing template.

template-modified
Indicates that the application template used to deploy the service has been modified. The application service should be updated to make use of the latest changes.

template-prerequisite-errors
Indicates any missing prerequisites associated with the template that defines this application.

traffic-group
The name of the traffic group that the application service is assigned to. If this property is modified with the "default" keyword, the value of the parent folder or partition will be used and the inherited-trafficgroup property will be set to true.

variables
The set of atomic variables and values that are passed to template scripts.

SEE ALSO

sys application template

NAME
template - Enables the creation of user-defined templates.

MODULE
sys application

SYNTAX
Configure the template component within the sys application module using the syntax in the following sections.

```
CREATE/EDIT/MODIFY
create template [name]
modify template [name]
options:
  actions [add | delete | modify | replace-all-with] {
    definition {
      options:
        html-help [string]
        implementation { [string] }
        presentation { [string] }
        role-acl [add | delete | modify | replace-all-with] {
          [role]
        }
        role-acl none
        run-as [string]
      }
    }
  }
description [string]
requires-modules [add | delete | modify | replace-all-with] {
  [string]
}
requires-bigip-version-max [string]
requires-bigip-version-min [string]
metadata
  [add | delete | modify] {
    [metadata_name ... ] {
      value [ "value content" ]
      persist [ true | false ]
    }
  }
}
```

edit template [name]

DISPLAY
list template
list template [name]

DELETE
delete template [name]

GENERATE

Note: generate cryptographic signature or checksum based on template fields - html-help, implementation, macro and presentation in definition section.

generate template [name]
options:
checksum
signature

SAVE/LOAD

save template [name] file [filename]
load template [filename]

DESCRIPTION

Application templates allow a user to define a custom interface for easily creating complex configurations. The user can create multiple templates for various types of configurations. Once built, the user can use a template to create an application, which is a specific set of configuration objects (such as Virtual IP addresses, pools, and so forth), that work together to perform some task.

The template is composed of two primary parts, the presentation and the implementation.

The presentation section describes a form (a set of questions and user interface elements) that the user must fill out in order to create an application.

The implementation section describes how the values collected from the user (the form variables) are used to generate the actual configuration objects which are part of the application.

The presentation section of the template is written in a simple language called Application Presentation Language or APL. The implementation section of the template is written in TCL and provides access to tmsh scripting commands.

APPLICATION LIFECYCLE

Before describing in detail how a template is written, it is important to explain how the resulting template will be used. Since templates are used to create and edit applications, it makes sense to review the application lifecycle.

Application Creation

The user selects which template to use for his application. The system presents an empty form, based on the template's presentation script that the user fills out and submits. The system collects and stores the form variables in a newly created application object. Configuration objects are generated based on the form variables by the template's implementation script.

Application Editing

The user selects an existing application that he would like to change. The system reloads the form associated with the template that was used to create the application and refills all form variables using the previous user input, which is gathered from the application object. The user edits the form and submits it. The template's implementation script is run again to compute a new set of configuration objects for the application. The system alters the current configuration objects associated with the application to match the newly computed set of configuration objects, including creating, modifying, and deleting objects as needed.

Application Deletion

The user selects an application to delete. All configuration objects associated with the application are removed.

APPLICATION TEMPLATE LANGUAGE

The application template language describes the user interface presented to a user making a new application, or editing an existing application. It describes what questions to ask, how the questions are presented (for example, a free form field or a list of options), and the names of the variables used to store the values the user inputs.

It consists of a set of primitive form elements (string, choice, etc), a set of grouping and organization constructs (section, table, etc), methods for hiding or displaying portions of the form based on the values of other portions (optional), a method to associate human-readable text with various form elements (text) and methods for creating user defined types(define group, define section, etc) for reuse of application presentation language elements.

Primitive Elements

Primitive elements represent the actual user interface components. The system displays each primitive element as part of the form, and associates it with a form variable. The following lists the basic primitive types:

choice

A list of options from which the user can select (a drop-down menu).

```
choice [default ""] [display ""] {"", "", ...}
```

editchoice

Multiple choices are available that the user can select, or a new value can be entered if the choices are not acceptable.

```
choice [default ""] [display ""] {"", "", ...}
```

multichoice

Similar to a basic choice element except that multiple items may be selected from the available choices.

```
choice [default ""] [display ""] {"", "", ...}
```

password

Similar to a string element except the contents may be obscured to prevent others from seeing the value.

```
password [default ""] [display ""] [required]
```

string

A basic text box into which the user can enter an arbitrary string.

```
string [default ""] [display ""] [required] [validator ""]
```

Each primitive element is associated with a variable name, which defines where the value collected by the form is stored. In addition, primitive elements can have additional parameters such as a default value, a validation method that provides for additional requirements (for example, the string must be an IP address).

The following defines the format for the string primitive values, using normal BNF syntax:

- o default - A sensible default value to which the string is initialized when a new application is created.
- o display - Directs the renderer how to display the element. This can be small, medium, large, xlarge, or xxlarge.
- o required - If present, a valid value must be entered before the application can be created.
- o validator - The name of a well known validation method.

Section

The section construct is used to group form variables (primitives) into logical sections for display.

Each section is named, and header text can be defined for a section using the text construct.

Every variable must be inside a section. The format for a section is:

```
section { }
```

For example, to represent the data associated with a virtual IP:

```
section vip
{
  string address
  string port default "80" display "small"
}
```

Table

The table construct is similar to section, except that it represents a grouping of elements that can be repeated zero or more times. The syntax for table and section are identical.

```
table { }
```

For example, to collect a list of nodes from a user to populate a pool, you can add any number of nodes, each of which has an address and port:

```
section pool
{
  table members
  {
    string address
    string port default "80" display "small"
  }
}
```

The table above is displayed using a JavaScript-editing widget that enables you to add and remove pool members. Each member contains two form variables: address and port.

Optional

The optional construct allows the form elements to be hidden or shown based on the state of other form elements. The syntax of the optional construct is:

```
optional ( ) { }
```

The expression in the optional construct is evaluated during the display of the form. The content section is displayed or hidden, based on its value.

To dynamically hide parts of the presentation based on the answer to a earlier question, use the variable name in the expression:

```
section chooseopts {
  choice show_section_1 {"yes", "no"}
}
section section1
{
```

```
optional (chooseopts.show_section_1 == "yes")
{
  string str
}
}
```

User defined types

The define construct allows the creation of user-defined types out of primitive types. The defined type can then be used multiple times independently at different places. This is especially useful in conjunction with the include element because types can be defined in the included application presentation language script and then used where necessary in the template. For more details on application presentation language script, See help sys application apl-script.

For example, user defined choice type can be defined as below and can be reused at multiple sections:

```
define choice yesno {
  "Yes", "No"
}
section ssl_section {
  yesno use_ssl
}
section optimizations {
  yesno use_wa
  yesno offload_ssl
}
```

The define group construct allows the creation of user-defined type to allow the user to group multiple elements of existing types together. The defined type can be reused multiple times independently similar to the above.

For example IPAddress and port can be grouped into a user-defined type and reused in multiple sections:

```
define group addrport {
  string addr required validator "IPAddress"
  string port
}
section http_section {
  addrport server
}
section sip_section {
  addrport client
  addrport server
}
```

Localization

The text element lets you define the localized text labels for sections, table, row and other sub-elements. For message element, body text can be localized in addition to the label. Similarly for the choice, editchoice and multichoice element, display text associated with each choice value can be localized. The syntax for the text element is:

```
text [""] {
""
. ""
. "" ""
. "" { "" => "", "" => "", ... }
}
```

Depending on the locale used (setting in the browser), particular text label, body text or choice display text will be shown to the user.

For example, string, message and choice display texts can be localized as below.

```
section http
{
  message intro
  string address
  string port default "80" display "small"
  choice pools default "pool1" { "pool1", "pool2", "pool3" }
  choice profile default "http" tcl {
    set choices "no\n"
    append choices "http\n"
    append choices [tmsh::run_proc f5.app_utils:get_items ltm profile http]
    return $choices
  }
}
```

```
text {
vs "HTTP Application"
vs.intro "Introduction" "This template supports simple web server implementations"
vs.address "What IP address do you want to use for this virtual server?"
vs.port "What port do you want to use for this virtual server?"
vs.pools "Use pool.." {"Internal" => "pool1", "Public cloud" => "pool2", "Private data center" => "pool3" }
vs.profile "Use profile.." { "Do not use profile" => "no", "Use F5's recommended profile" => "http" }
}
```

```
text "de_AU" {
vs "HTTP-Anwendung"
vs.intro "Einführung "Diese vorlage unterstützt einfache web-server-implemientierungen"
vs.address "Welche ip-adresse mochten Sie für diesen virtuellen Server zu verwenden?"
vs.port "Welchen port willst du für diesen virtuellen Server zu verwenden?"
vs.pools "Verwenden pool.." {"intern" => "pool1", "Privat Rechenzentrum" => "pool3", "Öffentliche Cloud" => "pool2" }
vs.profile "Mit profil.." { "Verwenden sie kein profil" => "no", "Verwenden von F5 empfohlen profil" => "http" }
}
```

}

A user from Austria will see the german text, all other locales will see the default (locale-less) text.

While localizing choice value display text, users are allowed to use different ordering of choice values in each locale. If TCL is used to populate the choices, then best effort is made to match what is returned in the TCL to the given localized choice value. In the above example, the embedded TCL script for profile will return two static choices (no and http) followed by the list of all http profiles. These static choices are localized, but not the other results. When the TCL results contain a mix of localized and non-localized choices, the localized choices will always be listed first in the order specified in the text element.

With the localization, message body and static choices will become optional in the declaration. If the message body is provided in both the declaration and in text element, the body in the text element will override the body in the variable declaration. Same applicable for the display text of choice value provided in declaration. The recommended syntax for choice, editchoice and multichoice element is to give just the choice values in the variable declaration, and give the display text of the choices in the text element.

TMSH SCRIPTING SUPPORT

Once the user finishes editing an application, the form variables are saved, and the implementation section of the associated template is run. The implementation section is an ordinary TCL script and can use the standard set of tmsh scripting extensions. In addition, there are a few template-specific additions.

First, access to the form variable is done using the syntax, where

is the name of the section to which the variable belongs, and
is the name of the form variable:

```
$::
```

Next, a table can be iterated over, and for each list element, the components of the list can be gathered using the `tmsh::get_field_value` command. For example, for the pool member example described in the section regarding the list, you can use the following syntax:

```
foreach member $::pool_members {  
  set the_addr [tmsh::get_field_value $member address]  
  set the_port [tmsh::get_field_value $member port]  
  # Do something with the_addr and the_port  
}
```

This means for variable access can also be used within a script macro. Expansion of a macro is done using the `tmsh::expand_macro` command. Usage:

```
tmsh::expand_macro [macro] [name_value_pair_list]
```

The variables defined in the presentation are automatically available from within the macro. If additional variables are needed from within the macro, they can be specified via `name_value_pair_list`. Variables defined this way will take precedence over duplicate variables defined in the presentation.

TMSH BUILT-IN VARIABLES

Specific details on application and application template is provided to implementation section using built-in variables. Following are the variables available for use.

`tmsh::app_name`
Stores the user-provided application name string.

`tmsh::app_name_path`
Stores the path name of application in configuration database.

`tmsh::app_template_name`
Stores the user-provided application template name including the path in configuration database.

`tmsh::app_template_action`
Stores the application template action name.

EXAMPLES

The following template example shows both the presentation and implementation sections. (It lacks some features, such as use of optional, defaults, validators, etc.)

```
presentation {  
  section basic  
  {  
    choice ssl_enabled { "true", "false" }  
    string addr  
    string more_stuff  
    table servers  
    {  
      string addr  
      string port  
      string ratio  
    }  
  }  
}  
text  
{  
  basic "Some example questions"  
  basic.ssl_enabled "Should SSL be enabled?"  
  basic.addr "What address should we use for the VIP?"
```

```

    basic.servers.addr "Address"
    basic.servers.port "Port"
}
}
implementation {
if { $::basic_ssl_enabled }
{
set profile_name [format "%s_%s" $tmsh::app_name clientssl]
tmsh::create ltm profile client-ssl $profile_name
append profile_name " http"

set destination "$::basic_addr:https"
set monitor https
}
else
{
set profile_name http
set destination "$::basic_addr:http"
set monitor http
}
}

set pool_name [format "%s_%s" $tmsh::app_name pool]

set members \{
foreach server $::basic_servers {
append members [tmsh::get_field_value $server addr]
append members ":"
append members [tmsh::get_field_value $server port]
append members " { ratio "
append members [tmsh::get_field_value $server ratio]
append members "}"
append members " "
}
}
append members \}

tmsh::create ltm pool $pool_name \
members replace-all-with $members \
monitor $monitor

set vs_name [format "%s_%s" $tmsh::app_name virtual]
tmsh::create ltm virtual $vs_name \
destination $destination \
profiles replace-all-with "{ $profile_name }" \
snat automap \
pool $pool_name \
http-class none
}

```

generate my_app checksum

Generate a checksum for the template definition and add the checksum as a property.

generate my_app signature signing-key my_key

Generate a signature for the template definition using the specified private key and add the signature as a property.

Note: For a template which includes a checksum or signature to successfully load, the definition contents must match the stored checksum or signature.

To temporarily stop the verification of signature or checksum and still retain the checksum or signature, the ignore-verification attribute must be set to true. This is done by editing the script and adding the ignore-verification attribute.

To completely clear the signature or checksum, simply set the attribute script-signature or script-checksum to empty string "". By doing so, the script will be processed as if it was never signed or checksummed.

```

sys application template my_tmpl {
actions {
definition {
html-help {

}
}
implementation {
# insert tmsh script
}
presentation {
# insert apl script
}
role-acl none
run-as none
}
description "This is my template"
ignore-verification true

```

OPTIONS

actions
Adds, deletes, or replaces a set of template actions. You can configure the following options for an action:

html-help
The help for the application template action formatted as HTML.

implementation

The script that is run to create the configuration objects associated with the application.

name The name of the application template action.

presentation
The questions that must be answered to create an application from the template.

role-acl
The list of roles that are allowed to run the action.

run-as
The user account that will be used to run the implementation script. If no account is specified, the script is run as the calling user.

checksum
Generate a checksum for the template definition and add the checksum to the template as a property. Only for use with the generate command.

signature
Generate a signature for the template definition using the specified private key and add the signature to the template as a property. Only for use with the generate command.

signing-key
The private key to use for signing the template. Only for use with the signature option.

description
User defined description.

metadata
Associates user defined data, each of which has name and value pair and persistence. The default value is persistent, which saves the data into the config file.

partition
Displays the administrative partition within which the application template resides.

prerequisite-errors
A message indicating if there are any errors with the prerequisites for the template on the current BIG-IP system. If there are errors no applications can be created from this template. If there are no errors then the template is valid.

requires-modules
Adds, deletes, or replaces the list of modules that are required to be provisioned for this template to work.

requires-bigip-version-max
Specifies the maximum version of BIG-IP software required by this template.

requires-bigip-version-min
Specifies the minimum version of BIG-IP software required by this template.

THIRD PARTY TCL LIBRARY USAGE

A selection of third party libraries have been tested to work within the CLI script environment. These include MD5, BASE64, SHA1/SHA256, HTTP, TLS, TCL Perl, LDAP client, and XML parser. The TCL packages can only reside in the /use/share/compat-tcl8.4 directory.

Important: Only these tested packages are supported currently.

The following example shows how the Tcl package command can make use of the XML parser:

```
cli script /Common/use_xml {
proc script::EStart {tag attlist args} {
    array set attr $attlist
    puts "Element \"$tag\" started with [array size attr] attributes"
}

proc script::PCData text {
    incr ::count [string length $text]
}

proc script::run {} {
    namespace eval :: {
        set count 0
    }
    puts "running use_xml...\n"
    set pkg_name xml
    if {[catch {package require $pkg_name 3.2}]} {
        puts "No package found: $pkg_name!\n"
    }
    else {
        puts "Found package: $pkg_name!\n"
        set parser [xml::parser]
        $parser configure -elementstartcommand script::EStart -characterdatacommand script::PCData
        set fp [open "/shared/test.xml" r]
        set text [read $fp]
        $parser parse $text
        puts "The document contains $::count characters"
        close $fp
    }
}
```

Here are some additional examples:

```
cli script /Common/use_shal {
proc script::run {} {
  set pkg_name shal
  if {[catch {package require $pkg_name}]} {
    puts "No package found: $pkg_name!\n"
  }
  else {
    puts "Found package: $pkg_name!\n"
    puts "TCL does SHA1 now:"
    puts [shal::shal -hex "TCL does SHA1"]
  }
}

cli script /Common/use_base64 {
proc script::run {} {
  set pkg_name base64
  if {[catch {package require $pkg_name}]} {
    puts "No package found: $pkg_name!\n"
  }
  else {
    puts "Found package: $pkg_name!\n"
    set chemical [encoding convertto utf-8 "C\u2088H\u2081\u2080N\u2084O\u2082"]
    set encoded [base64::encode $chemical]
    set caffeine [encoding convertfrom utf-8 [base64::decode $encoded]]
    puts "Caffeine: $caffeine"
  }
}
}
```

BIG-IP 2016-03-14 sys application template(1)

sys autoscale-group

NAME

autoscale-group - Configure autoscale group ID for BIG-IP VE Autoscale Service on Amazon Web Services(AWS).

MODULE

sys

SYNTAX

Configure the autoscale-group component within the sys module using the syntax in the following sections.

CREATE/MODIFY

modify sys autoscale-group

Properties:

autoscale-group-id [[string] | none]
description [string]

edit sys autoscale-group

Options:

all-properties
non-default-properties

DISPLAY

list sys autoscale-group

Options:

all-properties
non-default-properties
one-line

Properties:

autoscale-group-id
description

DESCRIPTION

Specifies Amazon Web Services (AWS) Auto-Scaling Group ID to which given BIG-IP-VE belongs to. These settings will be used for Auto Scaling BIG-IP instances based on user specified policy by Amazon Web Services(AWS).

OPTIONS

autoscale-group-id

Specifies autoscale-group id as reported by Amazon Web Services(AWS).

description

User defined description.

SEE ALSO

edit, list, modify, sys autoscale-group, tmsh

BIG-IP 2017-08-15 sys autoscale-group(1)

sys clock

NAME

clock - Displays the current date and time.

MODULE

sys

SYNTAX

```
DISPLAY
show clock
options:
  field-fmt
modify clock
options:
  time [time]
```

DESCRIPTION

You can use the clock component to display the system date and time.

EXAMPLES

```
show clock
```

Display the current date and time.

```
modify clock time 2012-12-11:12:30:45
```

Set the system clock to the specified time.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, tmsh

BIG-IP 2013-03-22 sys clock(1)

sys cluster

NAME

cluster - Configures a cluster in a VIPRION(r) system.

MODULE

sys

SYNTAX

Configure the cluster component within the sys module using the syntax in the following sections.

MODIFY

```

modify cluster [name]
  options:
    address [IP address/Netmask | none]
    alt-address [IP address/Netmask | none]
    members {
      [ 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 ] {
    options:
      address [IP address | none]
      alt-address [IP address | none ]
      [disabled | enabled]
      priming [disabled | enabled]
    }
  }
  min-up-members [integer]
  min-up-members-enabled [no | yes]

```

```

edit cluster default
  options:
    all-properties
    non-default-properties

```

```

DISPLAY
list cluster
  options:
    all-properties
    non-default-properties
    one-line

```

```

show running-config cluster
show running-config cluster [option name]
  options:
    one-line

```

```

show cluster
show cluster [option name]
  options:
    all-properties
    field-fmt

```

DESCRIPTION

You can use the cluster component to modify the configuration of the primary blade in a cluster. When you do this, the system automatically propagates the changes to the other blades in the cluster. This is known as cluster synchronization.

EXAMPLES

```
modify cluster default address 192.168.217.44/24
```

Sets the floating management IP address for the cluster default to an IP address of 192.168.217.44.

```
list cluster my_cluster
```

Displays the properties of the cluster named my_cluster.

OPTIONS

address

Specifies an IP address for the cluster or cluster member. The default value is none.

alt-address Specifies an optional, additional IP address for the cluster or cluster member in support of dual-stack addressing. The default value is none. Note: The IP address specified must compliment the family of the IP address held in address. I.e. Without loss of generality, if address holds an IPv6 address, then alt-address must hold an IPv4 address or none at all. Symmetrically, if address holds an IPv4 address, then alt-address must hold an IPv6 address or none at all.

disabled

Disables the specified cluster member. The default value is enabled.

enabled

Enables the specified cluster member. This is the default value.

members

Specifies the cluster members to be acted on by the command. A cluster member is a slot into which you insert a blade. The cluster member is identified by the number assigned to the slot.

min-up-members

Specifies the minimum number of cluster members that must be up for the cluster to remain Active. The default value is 0.

min-up-members-enabled

When set to yes, specifies that when the number of cluster members that are active is below the value of the option min-upmembers, the cluster fails over to its peer. The default value is no.

Enable this parameter when you configure a redundant pair.

Important: Make sure that you modify the value of the min-up-members option appropriately when you take blades down in a cluster. Otherwise, you can get into the condition where disabling a cluster member brings the cluster below the value of the option min-up-members, which can cause the cluster to fail over to its peer.

name

Specifies a name for the cluster. This option defaults to the value default.

priming

Prevents a cluster member from proceeding to the RUNNING cluster quorum state, which is useful when a blade is in a reboot loop. The default value is disabled.

SEE ALSO

sys config-diff

NAME

config-diff - Displays the differences between two specified single configuration files (SCFs).

MODULE

sys

SYNTAX

Display information using the config-diff component within the sys module with the syntax in the following section.

DISPLAY

show config-diff [file name] [file name]

DESCRIPTION

You can use the config-diff component to display the differences between two previously created SCF files.

EXAMPLES

show config-diff my.scf your.scf

Displays information about the differences between two specified files.

OPTIONS

file name

Specifies the name of an SCF file that you want to compare to another SCF file.

SEE ALSO

show, tmsh

COPYRIGHT

BIG-IP 2010-03-11 sys config-diff(1)

sys config

NAME

config - Manages the BIG-IP(r) system configuration.

MODULE

sys

SYNTAX

Save the running configuration or load the system configuration files within the sys module using the following syntax.

MODIFY

save config

options:

- base
- binary
- current-partition
- exclude-gtm
- file
- gtm-only
- no-passphrase
- one-line
- passphrase
- partitions
- tar-file
- time-stamp
- user-only
- wait

load config

options:

- base
- current-partition
- default
- exclude-gtm
- file
- files-folder
- from-terminal
- gtm-only
- merge
- passphrase
- partitions
- tar-file
- user-only
- verify

delete config file [file name]

DISPLAY

list config file

DESCRIPTION

The system applies all configuration changes that you make from within tmsb to the running configuration. To save the running configuration to the system configuration files, use the command sequence save config. Additionally, you can replace the running configuration with the configuration in the system configuration files using the command sequence load config.

If any of these options are not specified, save/load config will save or load the configuration in all partitions on this system:

- o binary
- o default
- o file
- o from-terminal
- o partitions

EXAMPLES

save config

Saves the running configuration in all partitions by overwriting the system configuration files.

In Virtual Editions with f5-swap-eth installed, saves the mapping of Ethernet device names and MAC addresses to /etc/ethmap to make the working BIG-IP still work after adding/deleting virtual NIC(s). It also works for save config partitions all.

save config base

Saves the running base configuration in all partitions by overwriting the system base configuration files.

save config binary

Saves all running configuration by overwriting the system binary configuration database file.

save config current-partition

Saves the running configuration in current update partition by overwriting the system configuration files.

save config wait

Save request waits if another save operation is in progress.

save config file my_file tar-file my_tar_file no-passphrase

Saves all running configuration to the specified file, my_file, and all the user provided disk files referred to by the configuration into my_tar_file. From v12.1.0 onwards the no-passphrase option should be explicitly specified for saving the unencrypted SCF and SCF.tar.

save config file my_file passphrase my_password

Saves all running configuration to the specified file, `my_file` and encrypt it with `my_password`.

```
save config partitions { my_partition }
```

Saves the running configuration in `my_partition` by overwriting the system configuration files.

```
save config partitions all
```

Saves the running configuration in all partitions by overwriting the system configuration files.

```
save config user-only
```

Saves only user account configuration by overwriting the system configuration files.

```
load config
```

Replaces the running configuration in all partitions with the configuration in the system configuration files.

```
load config base
```

Replaces the running base configuration in all partitions with the configuration in the system base configuration files.

```
load config current-partition
```

Replaces the running configuration in current update partition with the configuration in the system configuration files.

```
load config merge file my_file
```

Loads the specified configuration from `my_file`, which modifies the running configuration.

```
load config verify file my_file
```

Validates the specified configuration in `my_file` to see whether they are valid to replace the running configuration. The running configuration will not be changed.

```
load config verify merge file my_file
```

Validates the specified configuration in `my_file` to see whether they are valid to be merged into the running configuration. The running configuration will not be changed.

```
load config default
```

Sets system configuration back to factory default settings.

```
load config file my_file tar-file my_tar_file
```

Replaces all running configurations with the configuration in the specified file, `my_file` and the disk files referred to by the configuration are retrieved from `my_tar_file`.

```
load config file my_file files-folder my_files_folder
```

Replace all running configuration with the configuration in the specified file, `my_file` and the disk files referred to by the configuration is taken from the directory tree under `my_files_folder`.

```
load config file my_file passphrase my_password
```

Replaces all running configuration with the configuration in the specified encrypted file, `my_file` and decrypt it with `my_password`.

While searching for disk files under the specified folder, the order of search is first by file name as in `cache-path`, and then by object-name. If more than one file is found for a name, then the relative path in the `cache-path` is used to make the selection.

That is, while looking for

Looks for file(s) named B.

If none are found, looks for file(s) named "xxx"

When more than one file is found, looks for a copy that matches paths in the order:

```
B>
```

```
B>
```

```
load config partitions { x }
```

Replace the running configuration in partition x with the configuration in the system configuration files.

```
load config partitions all
```

Replace the running configuration in all partitions with the configuration in the system configuration files.

```
load config from-terminal
```

Replace the running configuration with what is entered from the terminal.

1. Type the initial command. 2. The system responds with a confirmation prompt, type Y to confirm.

Replace the running configuration? (y/n) y

3. Type in the replacement configuration entries.

```
net self-allow {
  defaults {
    igmp:any
    ospf:any
    pim:any
    tcp:161
    tcp:22
    tcp:4353
    tcp:443
    tcp:53
    udp:1026
    udp:161
    udp:4353
    udp:520
    udp:53
  }
}
net stp-globals {
  config-name 00-01-D7-B5-67-00
}
sys management-ip 172.27.41.70/24 { }
sys management-route default {
  gateway 172.27.41.254
}
sys provision ltm {
  level nominal
}
....
ltm pool pool1 {
  slow-ramp-time 200
}
.....
^D
```

4. Use Ctrl+D to submit the changes or Ctrl+C to cancel the changes.

delete config file myfile

Delete myfile in default directory, /var/local/scf/.

list config file

Display files in default directory, /var/local/scf/.

OPTIONS

base Indicates the base configuration. This option cannot be specified with the binary, default, gtm-only, and user-only options.

binary

Indicates binary configuration. This option may not be specified with any other options.

default

Indicates factory default configuration. This option cannot be specified with any other options.

file Loads or saves a configuration from the specified file. For save, a file with a relative path is saved in the default directory, /var/local/scf. For load, in shell mode, the default directory, /var/local/scf, is used for a file with a relative path. In bash mode, for a file with a relative path, the current directory is searched first. If the file can't be found in the current directory, /var/local/scf is searched.

This option can be used with binary, default, from-terminal and partitions options.

passphrase

Specifies a password to save or load an encrypted configuration file. This option can only be used with option file.

tar-file

Loads or saves disk files referred to by the configuration from the specified tar file. A file with a relative path is looked up, relative to the current directory.

files-folder

Loads disk files referred to by the configuration from the folder tree under the specified folder. Disk files by name are searched for recursively. When there is more than one file with the same name, the relative path of the file from the cache-path is used for selection.

from-terminal

Specifies that the configuration will be input from the terminal in the same format as the system configuration files in . Use Ctrl+D to submit the changes and Ctrl+C to cancel the changes.

This option cannot be specified with default, file and partitions.

gtm-only

Indicates the Global Traffic Manage (GTM) configuration. This option cannot be specified with the base, exclude-gtm, and user-only options.

exclude-gtm

Indicates the BIG-IP configuration, excluding GTMs. This is only valid with the file option. This option cannot be specified with

the base, gtm-only, and user-only options.

merge

Loads the configuration from the specified file or from the terminal, which modifies the running configuration. If merging from the terminal, it requires Ctrl+D to complete the operation. This option is only valid with the file or from-terminal options.

partitions

Indicates the partitions in which configuration components reside. This option cannot be specified with the default, file, from-terminal, or merge options.

user-only

Indicates the configuration including user account information only. This option cannot be specified with the base, default, exclude-gtm, or gtm-only options.

time-stamp

Inserts a time-stamp in a file name. This is only valid with the file option.

verify

Validates the specified configuration from file(s) or from the terminal without changing the running configuration.

wait Specifies that tmsh should wait for another instance of tmsh to finish saving the configuration before proceeding. If wait is not specified and another instance of tmsh is in the process of saving the configuration, the command exits tmsh immediately (because the other instance of tmsh is already saving the configuration).

SEE ALSO

BIG-IP 2016-12-15 sys config(1)

sys connection

NAME

connection - Sets idle timeout for, displays, and deletes active connections on the BIG-IP(r) system.

MODULE

sys

SYNTAX

Use the connection component within the sys module to manage connections using the following syntax.

MODIFY

modify connection

options:

idle-timeout [integer]

DISPLAY

show connection

option:

all-properties

age [integer]

cs-client-addr [IP address/prefixlen]

cs-client-port [[integer] | [service]]

cs-server-addr [IP address/prefixlen]

cs-server-port [[integer] | [service]]

connection-id [integer]

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

protocol [name]

save-to-file [filename]

ss-client-addr

ss-client-port [[integer] | [service]]

ss-server-addr

ss-server-port [[integer] | [service]]

type [any | mirror | self | mptcp]

DELETE

delete connection

option:

age [integer]

cs-client-addr [IP address]

cs-client-port [[integer] | [service]]

cs-server-addr [IP address]

```
cs-server-port [ [integer] | [service] ]
connection-id [ integer ]
protocol [name]
ss-client-addr [IP address]
ss-client-port [ [integer] | [service] ]
ss-server-addr [IP address]
ss-server-port [ [integer] | [service] ]
type [any | mirror | self | mptcp]
```

DESCRIPTION

You can use the connection component to set the idle timeout for or delete active connections to the BIG-IP system based on a specified filter. Additionally, you can display information about the active connections to the system.

You can specify the option using either a number or a service (80 or http).

Important: If you do not specify a port or service, the system deletes all connections that match just the IP address. If you do not specify an IP address, the system deletes all connections including mirrored connections.

EXAMPLES

```
show connection all-properties
```

Displays information about all active connections to the system.

```
modify connection idle-timeout 300
```

Changes the amount of idle time before a connection is disconnected to five minutes (300 seconds).

OPTIONS

age Specifies, in seconds, the minimum idle time of the active connections that you want to display or delete.

cs-client-addr/prefixlen
Specifies the client-side remote IP address of the active connections that you want to display or delete. Subnet addresses are allowed with prefix lengths up to /24 and /56 for IPv4 and IPv6 respectively.

cs-client-port
Specifies the clientside remote port of the active connections that you want to display or delete.

cs-server-addr/prefixlen
Specifies the clientside local IP address of the active connections that you want to display or delete. Subnet addresses are allowed with prefix lengths up to /24 and /56 for IPv4 and IPv6 respectively.

cs-server-port
Specifies the clientside local port of the active connections that you want to display or delete.

connection-id
Specifies the MPTCP connection ID of the active connections that you want to display or delete.

idle-timeout
Specifies the interval, in seconds, that a connection can remain idle before the system closes the connection.

protocol
Specifies the protocol of the active connections that you want to display or delete.

save-to-file
Specifies the file which connection information can be save to. With this option, it can write a file larger than 2GB.

ss-client-addr
Specifies the serverside local IP address of the active connections that you want to display or delete.

ss-client-port
Specifies the serverside local port of the active connections that you want to display or delete.

ss-server-addr
Specifies the serverside remote IP address of the active connections that you want to display or delete.

ss-server-port
Specifies the serverside remote port of the active connections that you want to display or delete.

type Specifies the type of active connections that you want to display or delete. The possible values are:

any Specifies all active connections.

mirror
Specifies only mirrored connections.

self Specifies the connection with which you are accessing the system.

mptcp
Specifies the MPTCP type of connections.

sys console

NAME

console - Configures the serial console for the BIG-IP(r) system.

MODULE

sys

SYNTAX

Configure the console component within the sys module using the syntax in the following section.

MODIFY

modify console
options:
 baud-rate [integer]

DISPLAY

show console

DESCRIPTION

You can use the console component to configure the serial console on the BIG-IP system.

OPTIONS

 baud-rate
Specifies the baud rate for the serial console. Select from the following options:

- o 9600
- o 19200 (default)
- o 57600
- o 115200

For information about the options that you can use with the command show, see help show.

sys cpu

NAME

cpu - Displays statistics about the Traffic Management Microkernel (TMM) service, specifically, CPU cycles.

MODULE

sys

SYNTAX

Display statistics for the cpu component within the sys module using the syntax in the following section.

DISPLAY

show cpu

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
global

DESCRIPTION

You can use the cpu component to display the CPU cycles for the system. You can also specify the unit value in which the system displays statistics.

EXAMPLES

show cpu

Displays TMM processor statistics in the system default units.

show cpu raw

Displays raw TMM processor statistics.

SEE ALSO

show, tmsh

sys crypto ca-bundle-manager

NAME

ca-bundle-manager - Certificate Authority (CA) certificate bundle manager on the BIG-IP(r) system.

MODULE

sys crypto

SYNTAX

A ca-bundle-manager manages cryptographic ca-bundles using the syntax given in the following sections.

CREATE/MODIFY

create ca-bundle-manager [name]

modify ca-bundle-manager [name]

options:

```

description [string]
exclude_bundle
  [add | delete | replace-all-with] ] {
[cert file obj] ...
}
exclude_url
  [add | delete | replace-all-with] ] {
[url] ...
}
include_bundle
  [add | delete | replace-all-with] ] {
[cert file obj] ...
}
include_url
  [add | delete | replace-all-with] ] {
[url] ...
}
proxy-server [ [hostname] | [ipv4] | [ipv6] ]
proxy-port [ port number ]
trusted-ca-bundle [certificate file object]
update-interval [days]
time-out [seconds]
update-now [yes | no]

```

LIST

```

list ca-bundle-manager [name]
options:
  -hidden

```

DELETE

```

delete ca-bundle-manager [name]

```

DESCRIPTION

You can use the `ca-bundle-manager` component to automatically update and install CA-bundles on the system from two sources - local certificate file objects and remote URL resources, using set include/exclude operations. The set include/exclude operations are equivalent to mathematical set addition/subtraction operations. For example, the user may use `include-bundle` and `include-url` options to combine CA-certificates from various sources, and use `exclude-bundle` and `exclude-url` options to remove certain CA-certificates from the final CA-bundle file. The generated CA-bundle file will be installed as a `certificate-file-object` on the system, and used as `trusted-ca-bundle` by other modules. Additionally, the user may set the update frequency of the CA-bundle, or use web proxy for downloading the remote URL resources. By default, a newly created CA-bundle manager does not create or update the managed CA-bundle object unless it has a positive update interval or being explicitly told to do so by the `update-now` option. Additionally, the calculated CA-bundle must contain at least two CA certificates to be installed on the system.

EXAMPLES

```

modify sys crypto ca-bundle-manager bmgr include-bundle add {
ca-bundle.crt } include-url add { https://ca.f5net.com/ca-bundle.crt }
trusted-ca-bundle trusted-ca-chain.crt update-interval 30

```

Creates a `ca-bundle-manager` `bmgr` from two sources, one is a locally installed certificate file object `ca-bundle.crt`, and the other is from remote URL resource `https://ca.f5net.com/ca-bundle.crt` using `trusted CA bundle`. `bmgr` is refreshed from the two sources every 30 days.

```

modify sys crypto ca-bundle-manager bmgr update-now yes

```

Extending from above example, this command triggers an immediate update of the generated `ca-bundle` from its sources.

```

list sys crypto ca-bundle-manager bmgr -hidden

```

Shows all the properties of the `ca-bundle-manager` `bmgr`, including the hidden fields.

```

delete sys crypto ca-bundle-manager bmgr

```

Deletes the `ca-bundle-manager` `bmgr` from the system. Note that the generated `ca-bundle` certificate file object is not removed, and can still be used.

OPTIONS

`description`
Specifies user defined description.

`include-bundle`
Specifies a list of certificate file objects to include for generating the new `ca-bundle`.

`include-url`
Specifies a list of remote `ca-bundles` at the URLs to include for generating the new `ca-bundle`.

`exclude-bundle`
Specifies a list of certificate file objects to exclude from the new `ca-bundle`.

`exclude-url`
Specifies a list of remote `ca-bundles` at the URLs to exclude from the new `ca-bundle`.

`partition` Displays the administrative partition within which this `ca-bundle-manager` resides.
`proxy-server` Specifies the host name or IP address of the proxy server for accessing remote URL resources. Only HTTP proxy is supported. Optional `http://` may be prepended.
`proxy-port` Specifies the port number of the proxy server for accessing

remote URL resources. Default is 3128.
trusted-ca-bundle
Specifies the trusted CA certificate bundle when downloading ca-bundles from the other URLs.

update-interval
Specifies the update interval in days to refresh the remote ca-bundles at the URLs. Default value is 0, which means the generated ca-bundle is not dynamically updated.

time-out
Specifies the time-out period in seconds to download the remote ca-bundles at the URLs. The value ranges between 1 and 3600 (1 hour). The default value is 8 seconds.

update-now
Specifies whether the ca-bundle-manager should immediately refresh its generated ca-bundle from all its sources and recalculate its certificate contents. The default value is no.

updated-by
Specifies a read-only attribute from which this ca-bundle-manager was last updated.

managed-bundle
Specifies a read-only attribute, which indicates the ca-bundle certificate file object name, managed by this ca-bundle-manager.

sys crypto cert-validation-response ocspl

NAME

ocsp - Manages the OCSPl response of a certificate when it has OCSPl validation enabled.

MODULE

sys crypto cert-validation-response

SYNTAX

Use the ocspl component within the sys.crypto.cert-validation-response module to manage the cached OCSPl response of a given certificate.

DELETE

```
delete ocspl
options:
certificate [name]
```

DESCRIPTION

You can use the ocspl component to delete the cached OCSPl response of a given certificate. The response is automatically re-fetched, and the certificate status is updated subsequently.

OPTIONS

certificate
Specifies the name of the certificate whose OCSPl response you want to delete.

SEE ALSO

delete, tmsh

COPYRIGHT

BIG-IP 2sys-crypto cert-validation-response ocspl(1)

sys crypto cert-validator crl

NAME
crl - Configures a CRL cert-validator.

MODULE
sys crypto cert-validator

SYNTAX
Configure the crl component using the syntax shown in the following sections.

CREATE/MODIFY
create crl [name]
modify crl [name]
options:
 internal-proxy [none | [string]]
 strict-revocation-check [disabled | enabled]
reset-stats crl [name]

DISPLAY
list crl [name]
show crl [name]

DELETE
delete server-ssl [all | [name]]
options:
 recursive

DESCRIPTION
You can use the crl component to create, modify, display or delete a custom CRL cert-validator.

EXAMPLES
create cert-validator crl my_crl internal-proxy my_intp

Creates a CRL cert-validator named my_crl using the internal proxy named my_intp.

OPTIONS
internal-proxy
Specifies the internal proxy to define the route for reaching CRL distribution points to fetch CRL files.

strict-revocation-check
If enabled, the certificate status won't be checked until the CRL fetching and caching is complete. If disabled, the certificate status will be immediately considered as unknown if the CRL fetching and caching is not complete yet. The default value is disabled.

SEE ALSO
sys crypto cert-validator ocsf, sys internal-proxy

COPYRIGHT

BIG-IP 2017-12-11 sys crypto cert-validator crl(1)

sys crypto cert-validator ocsf

NAME
ocsf - Configuration of the OCSF cert-validator.

MODULE
sys crypto

SYNTAX
Configure the ocsf component within the sys.crypto.cert-validator.ocsf module using the syntax shown in the following sections. This object is associated with a certificate object to enable an OCSF request for updating the certificate status.

CREATE/MODIFY
create ocsf [name]
modify ocsf [name]
options:

```
cache-error-timeout [integer]
cache-timeout [indefinite | [integer] ]
concurrent-connections-limit [integer]
clock-skew [integer]
description [string]
dns-resolver [name]
proxy-server-pool [name]
responder-url [none | [string] ]
route-domain [name]
sign-hash [sha1 | sha256]
signer-cert [name]
signer-key [name]
signer-key-passphrase [none | [string] ]
status-age [integer]
strict-resp-cert-check [disabled | enabled]
timeout [indefinite | [integer] ]
trusted-responders [none | [name] ]
```

DISPLAY

```
list oosp [name]
```

DELETE

```
delete [all | [name]]
options:
  recursive
```

DESCRIPTION

You can use the oosp component to create, modify, display or delete a custom OOSP cert-validator.

The OOSP cert-validator is associated with a certificate object.

EXAMPLES

```
create cert-validator my_oosp dns-resolver name
```

Creates an OOSP cert-validator named my_oosp using the DNS resolver specified by name.

OPTIONS

cache-error-timeout

Specifies the lifetime of an error response in the cache, in seconds. The default value is 3600 seconds.

cache-timeout

Specifies the lifetime of the OOSP response in the cache, in seconds. The actual time period for which the response is cached is the minimum of the response validity period and the cache-timeout. The default value is indefinite, indicating that the response validity period takes precedence.

concurrent-connections-limit

Specifies the maximum number of connections per second allowed for the OOSP cert-validator.

clock-skew

Specifies the tolerable absolute difference in the clocks of the responder and the BIG-IP, in seconds. The default value is 300.

description

User defined description.

dns-resolver

Specifies the DNS resolver object used for fetching the OOSP response.

partition

Displays the administrative partition within which this validator resides.

proxy-server-pool

Specifies the proxy server pool used for fetching the OOSP response.

responder-url

Specifies the absolute URL that overrides the OOSP responder URL obtained from the certificate's AIA extension(s). This should be an HTTP-based URL.

route-domain

Specifies the route domain for fetching an OOSP response using HTTP forward proxy.

sign-hash

Specifies the hash algorithm used for signing the OOSP request. The default value is sha256.

signer-cert

Specifies the certificate corresponding to the key used for signing the OOSP request.

signer-key

Specifies the key used for signing the OOSP request.

signer-key-passphrase

Specifies the passphrase of the key used for signing the OOSP request.

status-age

Specifies the maximum allowed lag time for the 'thisUpdate' time in the OOSP response that the BIG-IP accepts. If this maximum is exceeded, the response is dropped. If this value is set to 0, this validation is skipped. The default value is 86400 seconds.

strict-resp-cert-check

If enabled, the responder's certificate is checked for an OCSF signing extension. The default value is disabled.

timeout

Specifies the time interval (in seconds) that the BIG-IP waits for before ending the connection to the OCSF responder. The default value is 8.

trusted-responders

Specifies the certificates used for validating the OCSF response when the responder's certificate has been omitted from the response.

BIG-IP 2017-01-20 sys crypto cert-validator ocsf(1)

sys crypto cert

NAME

cert - Manage cryptographic certificates on the BIG-IP(r) system.

MODULE

sys crypto

SYNTAX

Manage cryptographic certs using the syntax in the following section.

CREATE

```
create cert [name]
options:
  city [string]
  common-name [string]
  consumer
    [enterprise-manager | iquery | iquery-big3d | ltm | webserver]
  country [string]
  email-address [string]
  key [string]
  lifetime [days]
  organization [string]
  ou [string]
  state [string]
  subject-alternative-name [string]
```

INSTALL

```
install cert [name]
options:
  cert-validation-options [none | ocsf]
  cert-validators [none | [cert_validator_name]]
  consumer
    [enterprise-manager | iquery | iquery-big3d | ltm | webserver]
  from-editor
  from-local-file [filename]
  from-url [URL]
  issuer-cert [none | [issuer_cert_name]]
  no-overwrite
```

MODIFY

```
modify cert [name]
options:
  cert-validation-options [none | ocsf]
  cert-validators [none | [cert_validator_name]]
  issuer-cert [none | [issuer_cert_name]]
```

DELETE

```
delete cert [name]
```

DESCRIPTION

You can use the cert component to create, install, and delete cryptographic certificates, and bundles.

EXAMPLES

```
create cert example key testkey.key common-name "My Company Inc."
country "US"
```

Generates a self signed certificate named "example.crt". A key with the specified name "testkey.key" in this case must be installed on the system in order for this operation to succeed. The cert extension (".crt") will be appended to the created cert name if it is not already provided in the name.

```
create cert /myfolder/example key testkey.key common-name "My Company Inc." country "US"
```

Similar to above, but creates the cert "example.crt" in the folder "/myfolder" instead of the default "/Common". The specified folder "/myfolder" must already exist in order for this operation to succeed.

```
create cert server2 key server2.key common-name "My Company Inc." country "US" consumer webserver
```

Generates a self-signed certificate named server2.crt. The consumer attribute, "webserver", is used to cause the files to be placed directly in the path which can be found by the BIG-IP system httpd. A pre-existing key named "server2.key" must exist in the web server's key path in order for this operation to succeed. Please note that for non LTM consumer's key and cert names must be the same.

```
install cert example from-editor
```

Opens an interactive editor session into which can be pasted a certificate for import into the BIG-IP system. A certificate file-object will be created with the name example which contains the contents saved from the editor session.

```
install cert example from-local-file /tmp/example.crt
```

Obtains a certificate from the file located at /tmp/example.crt.

```
install cert example from-url http://example.com/example.crt
```

Obtains a certificate from a remote host, based on the URI specified.

```
modify sys crypto cert leaf.crt issuer-cert issuer.crt cert-validators add { my_ocsp1 } cert-validation-options { ocsp }
```

Assigns issuer certificate issuer.crt to the certificate leaf.crt, associates the OCSF certificate validator my_ocsp to the certificate, and enables the OCSF certificate validator for this certificate.

```
delete cert example.crt
```

Deletes the certificate "example.crt" from the system.

OPTIONS

cert-validation-options

Specifies the option used for validating the certificate status.

cert-validators

Specifies the name of the cert-validators used for validating the certificate status. Each cert-validation type can only have one cert-validator.

city Specifies the x509 city field to be used in creation of the certificate.

common-name

Specifies the x509 common-name to be used in creation of the certificate.

consumer

Specifies the system component by which a certificate will be consumed. The default behavior is to create file-objects for use by ltm components. This is the same as specifying "ltm" for this property. If a component other than "ltm" is specified then files will be installed/created in locations where the specified components can find them. For example, for component "webserver", certificates will be placed in the webserver's ssl directories.

country

Specifies the x509 country to be used in creation of the certificate. The country must be a 2 letter country code.

email-address

Specifies the x509 email-address to be used in creation of the certificate.

fingerprint

Displays the SHA-256 fingerprint of the certificate.

from-editor

Specifies that the certificate should be obtained from a text editor session. This allows certificates to be imported via cut-n-paste from another location as long as they are in a text representation.

from-local-file

Specifies a local file path from which a certificate is to be copied.

from-url

Specifies a URI which is to be used to obtain a certificate for import into the system.

The URL syntax is protocol dependent. Supported schemes are "HTTP", "HTTPS", "FTP", "FTPS" & "FILE."

issuer-cert

Specifies the name of the issuer certificate for this certificate.

no-overwrite

Specifies option of not overwriting a certificate if it is in the scope.

key Specifies a key from which a certificate should be generated when

using the create command.

organization
Specifies the x509 organization to be used in creation of the certificate.

ou Specifies the x509 organizational unit to be used in creation of the certificate.

state
Specifies the x509 state or province of the certificate.

subject-alternative-name
Specifies standard X.509 extensions as shown in RFC 2459. Allowed values e.g. DNS:example.com, IP:192.168.1.1, IP:12:34, email:user@example.com, URI:http://www.example.com

BIG-IP 2017-05-01 sys crypto cert(1)

sys crypto check-cert

NAME

check-cert - Examines certificates and displays or logs any that have expired on the BIG-IP(r) system.

MODULE

sys crypto

SYNTAX

Run a check on the expiration date of LTM certificates, in the sys crypto module by using the syntax below.

RUN

```
run check-cert [certificate-file-name]
options:
  ignore-large-cert-bundles [enabled | disabled]
  log [enabled | disabled]
  stdout [enabled | disabled]
  verbose [enabled | disabled]
```

DESCRIPTION

You can use the check-cert command to check the expiration date of certificate(s) and print the results to the screen and/or log them to /var/log/ltm.

OPTIONS

ignore-large-cert-bundles
Specifies whether or not to ignore large certificate bundles which contain more than 20 certificates. By default it will not be ignored, i.e., it will still check every certificate bundle if this option is not specified.

log Specifies whether results should be logged or not. By default they will be logged.

stdout
Specifies whether results should be printed to STDOUT or not. By default they will be printed.

verbose
Specifies whether verbose output should be emitted or not, such as information about all certificates being checked rather than just those which return unfavorable results. By default verbose output is disabled.

EXAMPLES

```
run check-cert
```

Checks all certificate file-objects known by MCPD, and displays information about any certificates which have expired or which are close to expiration. By default this information is printed to the screen and logged to /var/log/ltm.

```
run check-cert default.crt
```

Runs the check on the specific certificate "default.crt"

```
run check-cert verbose
```

Displays expiration information about all certificates, not just those that have expired or have impending expirations.

run check-cert ignore-large-cert-bundles enabled

Ignore the certificate bundles with large size (the ones containing more than 20 certificates).

run check-cert log disabled

Prints the results to screen but does not log them.

run check-cert stdout disabled

Logs the results to /var/log/ltn, but does not print them to the screen.

SEE ALSO

BIG-IP 2016-03-14 sys crypto check-cert(1)

sys crypto client

NAME

client - Manage remote crypto clients.

MODULE

sys crypto

SYNTAX

Manage crypto clients using the syntax in the following section.

CREATE/MODIFY

```
create client [name]
modify client [name]
options:
  addr [ip address]
  connection-reset
  [disabled | enabled]
  heartbeat [integer]
  max-retries [integer | infinite]
  port [integer]
  profiles [add | delete | replace-all-with] { [profile_name ...] }
  profiles [none]
  req-timeout [integer]
  retry-interval [integer]
```

DISPLAY

```
list client
list client [ [name] | [globl] | [regex] ] ... ]
show client
show client [ [name] | [globl] | [regex] ] ... ]
```

DELETE

```
delete client [name]
```

DESCRIPTION

You can use the client component to manage remote crypto clients.

EXAMPLES

```
create client example addr 10.1.1.1 port 12100 profiles add { serverssl
tcp }
```

Creates a remote crypto client named "example" that will use a remote crypto server with the IP address "10.1.1.1" on port "12100". The remote crypto client will use SSL over a TCP connection to communicate with the remote crypto server.

OPTIONS

addr Specifies the IP address of the remote crypto server.

connection-reset

Resets the connection to the remote crypto server.

(enabled | disabled)

Specifies the state of the remote crypto client. The default value is enabled.

heartbeat

Specifies the number of seconds to wait before sending a heartbeat

request. A value of 0 disables the sending of heartbeat requests. The default value is 30 seconds.

max-retries
Specifies the maximum number of times to retry connecting to the remote crypto server.

If the maximum retries value is infinite, the crypto client retries connecting until a connection is made.

The default value is infinite.

port Specifies the port used by the remote crypto server.

profiles
Specifies a list of profiles that the remote crypto client will use to communicate with remote the remote crypto server.

req-timeout
Specifies the timeout in milliseconds for crypto requests to complete. The default value is 5000 milliseconds.

retry-interval
Specifies the interval in seconds between attempts to connect to the remote crypto server. The default value is 10 seconds.

SEE ALSO

BIG-IP 2015-01-16 sys crypto client(1)

sys crypto crl

NAME

crl - Manage certificate revocation lists on the BIG-IP(r) system.

MODULE

sys crypto

SYNTAX

Manage crls using the syntax in the following section.

INSTALL

```
install crl [name]
options:
ca-file [filename]
consumer
[enterprise-manager | iquery | iquery-big3d | ltm | webserver]
from-editor
from-local-file [filename]
from-url [URL]
```

DELETE

```
delete crl [name]
```

DESCRIPTION

You can use the crl component to install, and delete certificate revocation lists. The file-objects created by these operations can be used in other BIG-IP system configuration blocks such as ssl profiles.

EXAMPLES

```
install crl example from-editor
```

Opens an interactive editor session into which can be pasted a crl for import into the BIG-IP system. A crl file-object will be created with the name example which contains the contents saved from the editor session.

```
install crl example from-local-file /tmp/example.crl
```

Obtains a crl from the file located at /tmp/example.crl and installs it as example.crl. The crl extension (".crl") will be appended to the installed crl name if it is not already provided in the name.

```
install crl /myfolder/myexample from-local-file /tmp/example.crl
```

Similar to above, but installs the crl "myexample.crl" in folder "/myfolder" instead of the default "/Common". The specified folder "/myfolder" must already exist in order for this operation to succeed.

```
install crl example from-url http://example.com/example.crl
```

Obtains a `crl` from a remote host, based on the URI specified.

```
delete crl example.crl
```

Deletes the certificate revocation list "example.crl" from the system.

OPTIONS

consumer

Specifies the system component by which the certificate revocation list will be consumed. The default behavior is to create file-objects for use by ltm components. This is the same as specifying "ltm" for this property. If a component other than "ltm" is specified then files will be installed/created into locations where the specified components can find them. For example, for component "webserver", crls will be placed in the webserver's ssl directories.

from-editor

Specifies that the `crl` should be obtained from a text editor session. This allows crls to be imported via cut-n-paste from another location as long as they are in a text representation.

from-local-file

Specifies a local file path from which the `crl` is to be copied.

from-url

Specifies a URI which is to be used to obtain the `crl` for import into the configuration of the system.

The URL syntax is protocol dependent. Supported schemes are "HTTP", "HTTPS", "FTP", "FTPS" & "FILE."

SEE ALSO

BIG-IP 2013-03-21 sys crypto crl(1)

sys crypto csr

NAME

`csr` - Manage cryptographic certificate signing requests on the BIG-IP(r) system.

MODULE

`sys crypto`

SYNTAX

Manage cryptographic CSRs using the syntax in the following section.

CREATE

```
create csr [name]
options:
  challenge-password [string]
  admin-email-address [string]
  city [string]
  common-name [string]
  consumer
    [enterprise-manager | iquery | iquery-big3d | ltm | webserver]
  country [string]
  email-address [string]
  key [string]
  organization [string]
  ou [string]
  state [string]
  subject-alternative-name [string]
```

SHOW

```
show csr
```

LIST

```
list csr [name]
```

DELETE

```
delete csr [name]
```

DESCRIPTION

You can use the `csr` component to create, show, list and delete cryptographic certificate signing requests.

EXAMPLES

```
create csr example key testkey.key common-name "My Company Inc."
country "US" challenge-password "abcd"
```

Generates a certificate signing request named "example.csr" with provided common-name, country and challenge-password attributes. A key with the specified name "testkey.key" in this case must be installed on the system in order for this operation to succeed. The csr extension (".csr") will be appended to the created csr name if it is not already provided in the name.

```
create csr /myfolder/example key testkey.key common-name "My Company Inc." country "US" challenge-password "abcd"
```

Similar to above, but creates the csr "example.csr" in the folder "/myfolder" instead of the default "/Common". The specified folder "/myfolder" must already exist in order for this operation to succeed.

```
create csr server2 key server2.key common-name "My Company Inc." country "US" consumer webservers
```

Generates a certificate signing request named "server2.csr". The consumer attribute, "webservers", is used to cause the files to be placed directly in the path which can be found by the BIG-IP system httpd. A pre-existing key named "server2.key" must exist in the web server's key path in order for this operation to succeed.

```
show csr
```

Shows the number of certificate signing requests installed in the system.

```
list csr example.csr
```

Lists all details of the certificate signing request "example.csr". A csr with the specified name "example.csr" in this case must already be installed on the system in order for this operation to succeed. Because only one certificate signing request name is specified in the list command, it will also display the contents of the certificate signing request file.

```
list csr example1.csr example2.csr
```

Lists all details of the certificate signing requests "example1.csr" and "example2.csr". Because more than one certificate signing request name is specified in the list command, it will not display the contents of the certificate signing request files.

```
list csr
```

Lists details of all certificate signing requests that are configured in the system. This command does not display the contents of the certificate signing request files.

```
delete csr example.csr
```

Deletes the certificate signing request "example.csr" from the system.

OPTIONS

challenge-password

Specifies the PKCS#9 challenge-password field to be used in creation of the certificate signing request.

admin-email-address

Specifies the administrator email-address to be used in creation of the certificate signing request.

city Specifies the x509 city field to be used in creation of the certificate signing request.

common-name

Specifies the x509 common-name to be used in creation of the certificate signing request.

consumer

Specifies the system component by which a certificate signing request will be consumed. The default behavior is to create file-objects for use by ltm components. This is the same as specifying "ltm" for this property. If a component other than "ltm" is specified then files will be installed/created in locations where the specified components can find them. For example, for component "webservers", certificate signing requests will be placed in the webservers ssl directories.

country

Specifies the x509 country to be used in creation of the certificate signing request. The country must be a 2 letter country code.

email-address

Specifies the x509 email-address to be used in creation of the certificate signing request.

key Specifies a key from which a certificate signing request should be generated when using the create command.

organization

Specifies the x509 organization to be used in creation of the certificate signing request.

ou Specifies the x509 organizational unit to be used in creation of the certificate signing request.

state

Specifies the x509 state or province to be used in creation of the certificate signing request.

subject-alternative-name
Specifies standard X.509 subject alternative extensions as shown in RFC 2459 to be used in creation of the certificate signing request. Examples of allowed types are : DNS:example.com, IP:192.168.1.1, IP:12:34, email:user@example.com, URI:http://www.example.com

BIG-IP 2016-07-20 sys crypto csr(1)

sys crypto encrypted-attributes

NAME

encrypted-attributes - Displays all objects in the MCP binary database that contain items encrypted with the master key for the BIG-IP(r) system.

MODULE

sys crypto

SYNTAX

Display a list of objects with attributes encrypted with the master-key in the binary database using the syntax in the following section.

DISPLAY

show encrypted-attributes
options:
field-fmt

DESCRIPTION

You can use the encrypted-attributes command to help diagnose master-key problems in the BIG-IP(r) system. Only users with the Administrator role or the Resource Administrator role can view the list of objects with encrypted attributes.

EXAMPLES

show encrypted-attributes

Displays, in a table, information about the system's objects with encrypted-attributes including type, object name, attribute name, and whether or not the encrypted value in the binary database can be decrypted with the current master-key.

show master-key field-fmt

Displays, in field format, information about the system's objects with encrypted-attributes.

OPTIONS

For information about the options that you can use with the command show, see help show.

sys crypto fips external-hsm

NAME
external-hsm - Configures parameters for external HSM FIPS hardware.

MODULE
sys crypto fips

DESCRIPTION
You can use the external-hsm command to set parameters about the HSM vendor name and the password to login to the external HSM hardware.

SYNTAX
Configures FIPS external-hsm within the sys crypto fips module using the syntax in the following section.

CREATE
create external-hsm
modify external-hsm vendor [thales | safenet | none]
modify external-hsm password [password]
modify external-hsm num-threads [no. of threads]

DISPLAY
list external-hsm
list external-hsm vendor
list external-hsm password

sys crypto fips key

NAME
key - Manage FIPS keys

MODULE
sys crypto fips

SYNTAX
Manage cryptographic keys within the sys crypto fips module using the syntax in the following section.

SHOW
show key [key ID]
options:

field-fmt
all-properties
include-public-keys

DELETE
delete key [key ID]

DESCRIPTION
You can use the key component to show and delete cryptographic keys contained in the FIPS hardware.

EXAMPLES

show key

Displays the list of all private keys stored in the FIPS hardware and their meta-data.

show key bef8221fd25a27cda51b3904bc2f5fb8

Displays information specifically about the FIPS key with the key ID "bef8221fd25a27cda51b3904bc2f5fb8".

show key field-fmt

Displays, in field format, information about private keys stored in the FIPS hardware.

show key all-properties

Displays all information about the FIPS contained private keys, including: handle, a numerical value used by the FIPS hardware to identify individual keys; modulus-length, the cryptographic modulus length of the key; and modulus, the modulus associated with the key, displayed as a string of hex octets separated by colons.

show key include-public-keys

Displays the list of all private and public keys stored in the FIPS hardware and their meta-data. Note that public keys are not displayed by default and need not exist for normal operation of FIPS hardware.

delete key bef8221fd25a27cda51b3904bc2f5fb8

Deletes the FIPS key with the key ID "bef8221fd25a27cda51b3904bc2f5fb8" from the system.

OPTIONS

include-public-keys

Specifies that public keys should be selected for output in addition to private.

For information about the options that you can use with the command show, see help show.

SEE ALSO

sys crypto key

NAME

key - Manage cryptographic keys and related objects on the BIG-IP(r) system.

MODULE

sys crypto

SYNTAX

Manage cryptographic keys and related objects of the sys crypto module using the syntax in the following section.

CREATE

create key [name]

options:

challenge-password [string]

admin-email-address [string]

city [string]

common-name [string]

consumer

[enterprise-manager | iquery | iquery-big3d | ltm | webserver]

```
country [string]
curve-name [prime256v1 | secp384r1 | secp521r1]
email-address [string]
key-size [512 | 1024 | 2048 | 4096]
key-type [dsa-private | ec-private | rsa-private]
lifetime [days]
organization [string]
ou [string]
passphrase [passphrase]
prompt-for-password
security-type [fips | normal | password | nethsm]
state [string]
subject-alternative-name [string]
```

SHOW

```
show key
```

LIST

```
list key
list key [name]
```

INSTALL

```
install key [name]
options:
  consumer
    [enterprise-manager | iquery | iquery-big3d | ltm | webserver]
  from-editor
  from-local-file [filename]
  from-url [URL]
  from-nethsm
  no-overwrite
```

DELETE

```
delete key [name]
```

DESCRIPTION

You can use the key component to create, show, list, install, and delete cryptographic keys, and associated cryptographic objects. The file-objects created by these operations can be used in other BigIP configuration blocks such as ssl profiles.

EXAMPLES

```
create key mykey
```

Generates a 2048-bit (default-sized) RSA key file object named "mykey.key". The appropriate extension will be added to the generated key/cert if not already a part of the provided name.

```
create key mykey key-type ec-private curve-name prime256v1
```

Generates a prime256v1 curve name EC private key file object named "mykey.key". The appropriate extension will be added to the generated key/cert if not already a part of the provided name.

```
create key /myfolder/mykey
```

Similar to above, but creates the key "mykey.key" in folder "/myfolder" instead of the default "/Common". The specified folder "/myfolder" must already exist in order for this operation to succeed.

```
create key example gen-cert gen-csr common-name "My Company Inc."
country "US"
```

Generates a 2048-bit (default-sized) RSA key file object named "example.key" and a self signed certificate named "example.crt". Also, a certificate signing request will be printed to the console for use in obtaining a signed certificate from a certificate authority if desired.

```
create key my gen-cert gen-csr prompt-for-password common-name "My
Company Inc." country "US"
```

Similar to above, creates key "my.key" but also prompts for a password to be used as a challenge password in the certificate authority signing procedure.

```
create key server2 gen-cert gen-csr common-name "My Company Inc."
country "US" consumer webserver
```

Generates a key and self signed certificate identified by server2. The consumer attribute, "webserver", is used to cause these files to be placed directly in the paths which can be found by the BigIP's httpd.

```
show key
```

Shows the number of keys installed in the system.

```
list key example.key
```

Lists all details of the key named "example.key". A key with the specified name "example.key" in this case must already be installed on the system in order for this operation to succeed.

```
list key
```

Lists all details of all keys installed in the system.

```
install key example from-editor
```

Opens an interactive editor session into which can be pasted a key for import into the BigIP system. A key file-object will be created with the name example which contains the contents saved from the editor session.

```
install key example from-local-file /tmp/example.key
```

Obtains a key from the file located at /tmp/example.key.
install key example from-url http://example.com/my.key
Obtains a key from a remote host, based on the URI specified.
delete key example.key
Deletes the key "example.key" from the system.

OPTIONS

challenge-password

Specifies the challenge password to create the certificate request key.

admin-email-address

Specifies the administrator email-address to be used in creation of the certificate request associated with the given key.

city Specifies the x509 city field to be used in creation of the certificate associated with the given key.

common-name

Specifies the x509 common-name to be used in creation of the certificate associated with the given key.

consumer

Specifies the system component by which a key and/or associated cryptographic file will be consumed. The default behavior is to create file-objects for use by ltm components. This is the same as specifying "ltm" for this property. If a component other than "ltm" is specified then files will be installed/created into locations where the specified components can find them. For example, for component "webserver", keys and certs will be placed in the webserver's ssl directories.

country

Specifies the x509 country to be used in creation of the certificate associated with the given key. The country must be a 2 letter country code.

curve-name

Specifies the curve name to be used in creation of elliptic curve (EC) key. This options applies only when generating EC keys. Default value is prime256v1.

email-address

Specifies the x509 email-address to be used in creation of the certificate associated with the given key.

from-editor

Specifies that the key should be obtained from a text editor session. This allows keys to be imported via cut-n-paste from another location as long as they are in a text representation.

from-local-file

Specifies a local file path from which a key is to be copied.

from-url

Specifies a URI which is to be used to obtain a key for import into the configuration of the system.

The URL syntax is protocol dependent. Supported schemes are "HTTP", "HTTPS", "FTP", "FTPS" & "FILE."

from-nethsm

Specifies an option to import an existing key from network-HSM to BIG-IP config. The key label is specified as the key name to identify the key to be imported from network-HSM.

no-overwrite

Specifies option of not overwriting a key if it is in the scope.

gen-certificate

Specifies that in addition to generating a key, a self-signed certificate will also be created. If this option is specified then x509 attributes should also be specified. Minimally, you must also specify a common-name.

gen-csr

Specifies that a certificate signing request should be generated along with the key. The CSR will be displayed to the terminal for the purposes of use in getting a certificate signed by an outside authority. X509 attributes must also be specified.

key-size

Specifies the size, in bits, of the key to be generated. This option does not apply when generating EC keys.

key-type

Specifies the type of cryptographic key to be generated. Default is rsa-private.

lifetime

Specifies the certificate life time to be used in creation of the certificate associated with the given key.

organization

Specifies the x509 organization to be used in creation of the certificate associated with the given key.

ou Specifies the x509 organizational unit to be used in creation of the certificate associated with the given key.

prompt-for-password
Specifies that a password should be prompted for and then used as a challenge password in generation of the CSR (Certificate Signing Request).

security-type
Specifies the level of security used in storing the key in question. For example a security-type of FIPS means that the key should be stored on a FIPS card if one is available.

state
Specifies the x509 state or province of the certificate associated with the given key.

passphrase
Specifies an optional passphrase with which the key has been protected. It may be used by consumers of the key in the data-plane or control-plane to decrypt it.

subject-alternative-name
Specifies standard X.509 extensions as shown in RFC 2459. Allowed values e.g. DNS:example.com, IP:192.168.1.1, IP:12:34, email:user@example.com, URI:http://www.example.com

BIG-IP 2017-08-28 sys crypto key(1)

sys crypto master-key

NAME

master-key - Displays the configuration of the master key for the BIG-IP(r) system.

MODULE

sys crypto

SYNTAX

Display the configuration of the master-key component within the sys crypto module using the syntax in the following section.

DISPLAY

show master-key
options:
field-fmt

MODIFY

modify master-key
options:
prompt-for-password

RUN

run master-key diagnostic

DESCRIPTION

You can use the master-key command to manipulate the system master key. Users with the Administrator role or the Certificate Manager role can set the key to a value of their choosing by using the 'prompt-for-password' option during a modify operation. All other roles, including Resource Administrators, are prohibited from setting the master key.

Use the 'diagnostic' option of the run command to test the key integrity.

EXAMPLES

show master-key

Displays, in a table, information about the system's master key.

show master-key field-fmt

Displays, in field format, information about the system's master key.

run master-key diagnostic

Loads the device key. Uses the device key to decrypt the master key file to test the integrity of the keys. On success, there is no output. There will be a response only if there is an error.

modify master-key prompt-for-password

Create a master-key based on a word or phrase of your choosing. You can use this to manually synchronize several devices without having to copy keys between them.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, tmsh

BIG-IP 2016-03-14 sys crypto master-key(1)

sys crypto pkcs12

NAME

pkcs12 - Install pkcs12 keys and certificates on the BIG-IP(r) system.

MODULE

sys crypto

SYNTAX

Install keys and certificates from pkcs12 files using the syntax in the following section.

INSTALL

```
install pkcs12 [name]
options:
  consumer
  [enterprise-manager | iquery | iquery-big3d | ltm | webserver]
  from-local-file [filename]
  from-url [URL]
  key-passphrase
  key-security-type
  [fips | password | normal]
  passphrase [passphrase]
  no-overwrite
```

DESCRIPTION

You can use the pkcs12 component to install cryptographic keys and certificates from pkcs12 formatted files. The file-objects created by these operations can be used in other BigIP configuration blocks such as ssl profiles.

EXAMPLES

```
install pkcs12 example from-local-file /tmp/example.p12
```

Obtains a pkcs12 from the file located at /tmp/example.p12, and installs the key and certificate from that file as file-objects named "example.key" and "example.crt" respectively.

```
install pkcs12 /myfolder/example from-local-file /tmp/example.p12
```

Similar to above, but installs the key "example.key" and cert "example.crt" in folder "/myfolder" instead of the default "/Common". The specified folder "/myfolder" must already exist in order for this operation to succeed.

```
install pkcs12 example prompt-for-password from-local-file
/tmp/example.p12
```

Same as above but also prompts for a password which is to be used to decrypt the pkcs12 file.

```
install pkcs12 my from-url http://example.com/my.p12
```

Obtains a pkcs12 file from a remote host, based on the URL specified.

```
install pkcs12 server consumer webserver from-local-file
/tmp/example.p12
```

Obtains a pkcs12 file from /tmp/example.p12 and installs the key and certificate from that file as file-objects that can be used by the "webserver". The consumer attribute, "webserver", is used to cause these files to be placed directly in the paths which can be found by the BigIP's httpd.

OPTIONS

consumer

Specifies the system component by which a key and associated certificate from a PKCS12 file will be consumed. The default behavior is to create file-objects for use by ltm components. This is the same as specifying "ltm" for this property. If a component other than "ltm" is specified then files will be installed/created into locations where the specified components can find them. For example, for component "webserver", keys and certs will be placed in the webserver's ssl directories.

from-local-file

Specifies a local file path from which the contents of the PKCS12 are to be read.

from-url

Specifies a URI which is to be used to obtain a PKCS12 for import into the configuration of the system.

The URL syntax is protocol dependent. Supported schemes are "HTTP", "HTTPS", "FTP", "FTPS" & "FILE."

key-passphrase

Specifies the passphrase to be used to encrypt the key.

key-security-type

Specifies the security type of the key. Default is set to "normal".

passphrase

Specifies the passphrase to be used to decrypt the PKCS12 file.

no-overwrite

Specifies option of not overwriting key/certificate if they are in the scope.

SEE ALSO

install, tmsh

BIG-IP 2013-07-17 sys crypto pkcs12(1)

sys crypto server

NAME

server - Manage remote crypto servers.

MODULE

sys crypto

SYNTAX

Manage crypto servers using the syntax in the following section.

CREATE/MODIFY

```
create server [name]
modify server [name]
options:
  addr [ip address]
  clients [add | delete | replace-all-with] { [ip_addr/prefixlen ...] }
  clients [none]
  [disabled | enabled]
  port [integer]
  profiles [add | delete | replace-all-with] { [profile_name ...] }
  profiles [none]
```

DISPLAY

```
list server
list server [ [name] | [globl] | [regex] ] ... ]
show server
show server [ [name] | [globl] | [regex] ] ... ]
```

DELETE

```
delete server [name]
```

DESCRIPTION

You can use the server component to manage remote crypto servers.

EXAMPLES

```
create server example addr 10.1.1.1 port 12100 profiles add { clientssl
tcp }
```

Creates a remote crypto server named "example" that will listen for remote crypto clients on IP address "10.1.1.1" and port "12100". The remote crypto server will use SSL over a TCP connection to communicate

with remote crypto clients.

OPTIONS

addr Specifies the IP address of the remote crypto server.

clients

Specifies a list of allowed client IP addresses and subnets. An empty list allows all clients.

(enabled | disabled)

Specifies the state of the remote crypto server. The default value is enabled.

port Specifies the port used by the remote crypto server.

profiles

Specifies a list of profiles that the remote crypto server will use to communicate with remote crypto clients.

SEE ALSO

BIG-IP 2016-03-14 sys crypto server(1)

sys daemon-ha

NAME

daemon-ha - Configures high availability for a BIG-IP(r) system.

MODULE

sys

SYNTAX

Configure the daemon-ha component within the sys module using the syntax in the following sections.

MODIFY

modify daemon-ha [name]

options:

heartbeat [enabled | disabled]
heartbeat-action [go-offline | go-offline-downlinks-restart |
go-offline-restart | reboot | restart | restart-all]
running [enabled | disabled]

edit daemon-ha [[name] | [glob] | [regex]] ...]

options:

all-properties
non-default-properties

DISPLAY

list daemon-ha

list daemon-ha [[name] | [glob] | [regex]] ...]

show running-config daemon-ha

show running-config daemon-ha [[name] | [glob] | [regex]] ...]

options:

all-properties
non-default-properties
not-running-action
one-line
running-timeout

DESCRIPTION

You can use the daemon-ha component to configure the daemons on the system that handle high availability for the BIG-IP system.

EXAMPLES

modify daemon-ha bigd running disabled

Disables the bigd daemon.

list daemon-ha bigd running-timeout

Displays the running timeout of the bigd daemon.

OPTIONS

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

heartbeat

Specifies whether heartbeat monitoring is enabled for the specified daemon. If monitoring is enabled and the daemon does not

maintain its heartbeat the action specified by the value of the heartbeat-action option is taken.

The default value is enabled for all daemons, except the named daemon, which is disabled by default.

heartbeat-action

Specifies the action the system takes if the specified daemon does not maintain its heartbeat.

The default value is dependent on the specified daemon, the most common default value is restart.

name Specifies a unique name for the component. This option is required for the command modify.

not-running-action

Specifies the action that the system takes if the daemon is not running. This option is read-only.

The default value is dependent on the specified daemon, the most common default value is go-offline-downlinks.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

running

Specifies whether the running-timeout and non-running-action options are enabled. The default value is dependent on the specified daemon, the most common default value is enabled.

Note: This feature is implemented only for the daemons: tmm, mcpd, bcm56xxd, bigd, gtmd, clusterd, tmrouted, bd, datasyncd and tmrouted.

running-timeout

Specifies the amount of time (in seconds) that must elapse before the specified daemon is considered to be not running. This option is read-only.

The default value is dependent on the specified daemon.

SEE ALSO

edit, glob, list, modify, regex, show, tmsh

sys daemon-log-settings clusterd

NAME

clusterd - Changes the log-level of or displays information about the daemon clusterd.

MODULE

sys daemon-log-settings

SYNTAX

Configure the clusterd component within the sys daemon-log-settings module using the syntax in the following sections.

MODIFY

modify clusterd

options:

log-level [critical | debug | error | informational | notice | warning]

edit clusterd

options:

all-properties
non-default-properties

DISPLAY

list clusterd

options:

all-properties
non-default-properties
one-line

DESCRIPTION

You can use the clusterd component to change the level of the messages about the clusterd daemon that appear in the system logs. Additionally, you can display information about the daemon.

EXAMPLES

```
list clusterd
```

Displays information about the clusterd daemon.

```
modify clusterd log-level critical
```

Changes the level of the messages about the clusterd daemon that display in the system log to critical.

OPTIONS

```
log-level
```

Specifies the level of log messages for the specified daemon that you want to display in the system log.

SEE ALSO

edit, list, modify, tmsh

COPYRIGHT

sys daemon-log-settings csyncd

NAME

csyncd - Changes the log-level of or displays information about the daemon csyncd.

MODULE

sys daemon-log-settings

SYNTAX

Configure the csyncd component within the sys daemon-log-settings module using the syntax in the following sections.

MODIFY

```
modify csyncd
```

```
options:
```

```
log-level [critical | debug | error | informational | notice | warning]
```

```
edit csyncd
```

```
options:
```

```
all-properties  
non-default-properties
```

DISPLAY

```
list csyncd
```

```
options:
```

```
all-properties  
non-default-properties  
one-line
```

DESCRIPTION

You can use the csyncd component to change the level of the messages about the csyncd daemon that appear in the system logs. Additionally, you can display information about the daemon.

EXAMPLES

```
list csyncd
```

Displays information about the csyncd daemon.

```
modify csyncd log-level critical
```

Changes the level of the messages about the csyncd daemon that display in the system log to critical.

OPTIONS

```
log-level
```

Specifies the level of log messages for the specified daemon that you want to display in the system log.

BIG-IP 2010-03-31 sys daemon-log-settings csyncd(1)

sys daemon-log-settings icr-eventd

NAME
icr-eventd - Changes the log level of the daemon icr-eventd.

MODULE
sys daemon-log-settings

SYNTAX
Configure the icr-eventd component within the sys daemon-log-settings module using the syntax in the following sections.

MODIFY
modify icr-eventd
options:
log-level [critical | debug | error | informational | notice | warning]

edit icr-eventd
options:
all-properties
non-default-properties

DISPLAY
list icr-eventd
options:
all-properties
non-default-properties
one-line

DESCRIPTION
You can use the icr-eventd component to change the ltm log level of the icr-eventd daemon.

EXAMPLES
list icr-eventd

Displays log level of the icr-eventd daemon.

modify icr-eventd log-level warning

Changes the log level of the icr-eventd daemon to warning.

OPTIONS
log-level
Specifies the level of log messages for the icr-eventd daemon in the ltm logs.

SEE ALSO
edit, list, modify, tmsh

COPYRIGHT

BIG-IP 2016-08sys daemon-log-settings icr-eventd(1)

sys daemon-log-settings icrd

NAME
icrd - Changes or displays the audit level of the daemon icrd.

MODULE
sys daemon-log-settings

SYNTAX
Configure the icrd component within the sys daemon-log-settings module using the syntax in the following sections.

MODIFY
modify icrd
options:
audit [none | modifications | all]

edit icrd
options:
all-properties
non-default-properties

DISPLAY
list icrd
options:
all-properties
non-default-properties
one-line

DESCRIPTION
You can use the icrd component to change the audit level of the icrd daemon.

EXAMPLES
list icrd
Displays audit log level of the icrd daemon.
modify icrd audit all
Changes the audit level of the icrd daemon to all. This means that all commands executed by the icrd daemon get audited

OPTIONS
audit
Specifies the audit level of log messages for the icrd daemon in the audit logs.

SEE ALSO
edit, list, modify, tmsh

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2015-01-22 sys daemon-log-settings icrd(1)

sys daemon-log-settings lind

NAME
lind - Changes the log-level of or displays information about the daemon lind.

MODULE
sys daemon-log-settings

SYNTAX
Configure the lind component within the sys daemon-log-settings module using the syntax in the following sections.

MODIFY
modify lind
options:
log-level [critical | debug | error | informational | notice | warning]

edit lind
options:
all-properties
non-default-properties

DISPLAY
list lind
options:
all-properties
non-default-properties
one-line

DESCRIPTION
You can use the lind component to change the level of the messages about the lind daemon that appear in the system logs. Additionally, you can display information about the daemon.

EXAMPLES

list lind

Displays information about the lind daemon.

modify lind log-level critical

Changes the level of the messages about the lind daemon that display in the system log to critical.

OPTIONS

log-level

Specifies the level of log messages for the specified daemon that you want to display in the system log.

SEE ALSO

edit, list, modify, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

sys daemon-log-settings mcpd

NAME

mcpd - Changes the log-level of or displays information about the daemon mcpd.

MODULE

sys daemon-log-settings

SYNTAX

Configure the mcpd component within the sys daemon-log-settings module using the syntax in the following sections.

MODIFY

modify mcpd

options:

audit [all | disabled | enabled | verbose]
log-level [alert | critical | debug | emergency | error | informational | notice | panic | warning]

edit mcpd

options:

all-properties
non-default-properties

DISPLAY

list mcpd

options:

all-properties
non-default-properties
one-line

DESCRIPTION

You can use the mcpd component to change the level of the messages about the mcpd daemon that appear in the system logs. Additionally, you can display information about the daemon.

EXAMPLES

list mcpd

Displays information about the mcpd daemon.

modify mcpd log-level critical

Changes the level of the messages about the mcpd daemon that display in the system log to critical.

OPTIONS

audit

Enables or disables auditing for the mcpd daemon, and specifies verbose or all as the auditing level. The default is disabled.

log-level

Specifies the level of log messages for the specified daemon that you want to display in the system log.

SEE ALSO

edit, list, modify, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any

purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2010-03-31 sys daemon-log-settings mcpd(1)

sys daemon-log-settings tmm

NAME

tmm - Changes the log-level of or displays information about the Traffic Management Microkernel (tmm).

MODULE

sys daemon-log-settings

SYNTAX

Configure the tmm component within the sys daemon-log-settings module using the syntax in the following sections.

MODIFY

modify tmm

options:

arp-log-level [debug | error | informational | notice | warning]
http-compression-log-level [debug | error | informational | notice | warning]
http-log-level [debug | error | informational | notice | warning]
ip-log-level [debug | informational | notice | warning]
irule-log-level [debug | error | informational | notice | warning]
layer4-log-level [debug | informational | notice]
net-log-level [critical | debug | error | informational | notice | warning]
os-log-level [alert | critical | debug | emergency | error | informational | notice | warning]
pva-log-level [debug | informational | notice]
ssl-log-level [alert | critical | debug | emergency | error | informational | notice | warning]

edit tmm

options:

all-properties
non-default-properties

DISPLAY

list tmm

options:

all-properties
non-default-properties
one-line

DESCRIPTION

You can use the tmm component to change the level of the messages about the tmm that appear in the system logs. Additionally, you can display information about the tmm.

EXAMPLES

list tmm

Displays information about the tmm.

modify tmm http-compression-log-level critical

Changes the level of the messages about HTTP compression that display in the system log to warning.

OPTIONS

arp-log-level

Specifies the lowest level of ARP messages from the tmm daemon to include in the system log. The default value is warning.

http-compression-log-level

Specifies the lowest level of HTTP compression messages from the tmm daemon to include in the system log. The default value is error.

http-log-level

Specifies the lowest level of HTTP messages from the daemon to include in the system log. The default value is error.

ip-log-level

Specifies the lowest level of IP address messages from the tmm daemon to include in the system log. The default value is warning.

irule-log-level

Specifies the lowest level of iRule messages from the tmm daemon to include in the system log. The default value is warning.

layer4-log-level

Specifies the lowest level of Layer 4 messages from the tmm daemon to include in the system log. The default value is notice.

net-log-level

Specifies the lowest level of network messages from the tmm daemon to include in the system log. The default value is warning.

os-log-level

Specifies the lowest level of operating system messages from the tmm daemon to include in the system log. The default value is notice.

pva-log-level

Specifies the lowest level of PVA messages from the tmm daemon to include in the system log. The default value is informational.

ssl-log-level

Specifies the lowest level of SSL messages from the tmm daemon to include in the system log. The default value is warning.

SEE ALSO

edit, list, modify, tmsh

BIG-IP 2010-03-31 sys daemon-log-settings tmm(1)

sys datastor

NAME

datastor - Configures the data storage used for optimization.

MODULE

sys

SYNTAX

Configure the datastor component within the sys module using the syntax in the following sections.

MODIFY

modify datastor

options:

dedup-cache-weight [integer]
description [string]
disk [disabled | enabled]
high-water-mark [integer]
low-water-mark [integer]
web-cache-weight [integer]

DISPLAY

list datastor

show running-config datastor

options:

all-properties
cache-size
non-default-properties
one-line
store-size

DESCRIPTION

You can use the datastor component to configure disk I/O operations and optimized page cache for frequently accessed sectors. Note that symmetric data deduplication is one consumer of this storage space.

EXAMPLES

list datastor all-properties

Displays the data storage settings.

modify datastor disk disabled

Disables data storage on the disk.

OPTIONS

cache-size

Displays the size of the data storage in megabytes (MB).

dedup-cache-weight

Specifies the relative weight of the dedup cache for the Acceleration Manager module. The default value is 10.

description

User defined description.

disk Enables or disables the use of the disk (in addition to memory) for data storage.

If you enable or disable data storage on the disk, you must then restart the datastor service from the command line using the command sequence `bigstart restart datastor`.

high-water-mark
Specifies the percentage of full cache above which pruning starts. The valid range is 60 - 100 percent. The default value is 92.

low-water-mark
Specifies the percentage of full cache below which pruning stops. The valid range is 10 - 90 percent. The default value is 80.

store-size
Displays the amount of space for each disk path specified.

web-cache-weight
Specifies the relative weight of the web cache for the Acceleration Manager module. The default value is 10.

SEE ALSO

wom deduplication, list, modify, show, tmsh

COPYRIGHT

BIG-IP 2012-12-06 sys datastor(1)

sys db

NAME

db - Displays or modifies bigdb database entries.

MODULE

sys

SYNTAX

Configure the db component within the sys module using the syntax in the following sections.

MODIFY

```
modify db [name] value [database variable value]
modify db [name] reset-to-default
```

DISPLAY

```
list db
list db [ [ [name] | [glob] | [regex] ] ...]
options:
  all-properties
  default-value
  non-default-properties
  one-line
  value
  value-range
```

```
show running-config db
show running-config db [ [ [name] | [glob] | [regex] ] ...]
options:
  all-properties
```

DESCRIPTION

You can use the db component to modify and retrieve the data that is stored in the bigdb configuration database.

Important: After you change a bigdb database variable using the db component, you must run the command sequence `save config`. If you do not, the next time that you run the command sequence `load [config base | config]`, the value of the bigdb database variable may be reset to the value in the stored configuration.

Note that tmsh only displays bigdb database entries when you explicitly request them.

EXAMPLES

```
modify db Connection.SynCookies.Threshold value 16384
```

Sets the database entry, SYN Check(tm) Activation Threshold, to the given value.

```
modify db Connection.SynCookies.Threshold reset-to-default
```

Sets the database entry, SYN Check(tm) Activation Threshold, back to the default value.

list log.mcpd.level

Displays the properties of the database entry log.mcpd.level:

OPTIONS

default-value

Displays the system-supplied default value of the database entry.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies the unique name of the database variable. This option is required for the command modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reset-to-default

Resets the database variable back to its default value.

value

Specifies the value to which you want to set the specified database entry.

value-range

Displays the type of data that you can use with the value option. The options are:

integer

IP address

list of valid values

management IP address

string

unsigned integer

SEE ALSO

glob, list, modify, regex, show, tmsh

sys default-config

NAME

default-config - Loads the default configuration of the BIG-IP(r) system stored in the configuration files to the running configuration of the system.

MODULE

sys

SYNTAX

Configure the default-config component within the sys module using the following syntax.

MODIFY

load default-config

DESCRIPTION

You can use the default-config component to load the default system configuration to the running configuration. This results in the user-defined configuration being removed from the running configuration.

EXAMPLES

load default-config

Loads the default configuration stored on the system to the running configuration of the system.

SEE ALSO

load, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2010-03-11 sys default-config(1)

sys diags ihealth-request

NAME
ihealth-request - Displays the BIG-IP(r) iHealth qkview upload request status, errors and progress.

MODULE
sys diags

SYNTAX
Display the ihealth-request component within the sys diags module using the syntax in the following section.

DISPLAY
list sys diags ihealth-request
 all-properties
 one-line

show sys diags ihealth-request
 raw

DESCRIPTION
You can use the ihealth-request component to display the status of the iHealth upload feature.

EXAMPLES
list ihealth-request

Displays iHealth upload request status.

OPTIONS
ihealth-start-time
This is the start time of the ihealth request in seconds since 1970-01-01 00:00:00 UTC.

ihealth-finish-time
This is the finish time of the ihealth request in seconds since 1970-01-01 00:00:00 UTC.

error
This is the error status of the ihealth request: (one of none, creds, qkview-error, qkview-timeout, ihealth-unreach, ihealth-process, ihealth-sr-format, ihealth-timeout, ihealth-resolv, ihealth-invalid-opts, ihealth-missing-user-password, ihealth-login-failed, ihealth-missing-qkview-file, qkview-invalid-opts, ihealth-miscellaneous-error).

status
This is the status of the ihealth upload process (one of none, running, analyzing or uploading).

progress
This is the progress in percent of the upload process.

type This is the type of the diagnostics request (one of none, ihealth, qkview or tcpdump).

qk-progress
This is the percent complete of a qkview in the process of being generated.

qkview-filename
This is the filename of the last qkview file generated, if there is one.

qkview-date
This is the date of the last qkview file generated, if there is one.

qkview-size
This is the file size of the last qkview file generated, if there is one.

qkview-user
This is the user name of the account that created the last qkview file generated, if there is one.

tcpdump-filename
This is the filename of the last tcpdump file generated, if there is one.

tcpdump-date
This is the date of the last tcpdump file generated, if there is one.

tcpdump-size
This is the file size of the last tcpdump file generated, if there

is one.

For information about the options that you can use with the command list, see help list.

SEE ALSO

list, tmsh, qkview

sys diags ihealth-result

NAME

ihealth-result - Displays the BIG-IP(r) iHealth qkview upload results.

MODULE

sys diags

SYNTAX

Display the ihealth-result component within the sys diags module using the syntax in the following section.

DISPLAY

list ihealth-result
options:
all-properties
one-line

show ihealth-result
options:
field-fmt

DESCRIPTION

You can use the ihealth-result component to display the result history of the iHealth upload feature.

EXAMPLES

list ihealth-result

Displays iHealth upload result history for the system.

OPTIONS

time-checked
This is the date and time that the qkview was uploaded to iHealth.

check-user
This is the iHealth user name (email address) used to access the iHealth service.

result
This is the result returned from iHealth.

sr This is the Support Request number uploaded to the iHealth service with the qkview file.

description
This is the description uploaded to the iHealth service with the qkview file.

size This is the size of the qkview file uploaded to the iHealth service.

id This is the iHealth ID number returned from the iHealth service for the qkview file.

warnings
This is the the total number of warnings returned by the iHealth service.

criticals
This is the the total number of critical warnings returned by the iHealth service.

For information about the options that you can use with the command list, see help list.

SEE ALSO

list, tmsh, qkview

BIG-IP 2017-01-16 sys diags ihealth-result(1)

sys diags ihealth

NAME
ihealth - Displays the BIG-IP(r) iHealth qkview upload settings.

MODULE
sys diags

SYNTAX
Display and modify the ihealth component within the sys diags module using the syntax in the following section.

MODIFY
modify ihealth
options:
user
password
expiration
options

DISPLAY
list ihealth
options:
all-properties
one-line

show ihealth
options:
field-fmt

DESCRIPTION
You can use the ihealth component to display or modify the configuration of the iHealth upload feature.

EXAMPLES
list ihealth

Displays iHealth upload configuration information for the system.

modify ihealth expiration 180

Modify the expiration of iHealth upload history to 180 days.

modify ihealth options "-t 180"

Add a time limit of 180 seconds for qkview module execution.

OPTIONS
user This is the iHealth user name (email address) used to access the iHealth service.

password
This is the iHealth password used to access the iHealth service.

expiration
This is the number of days to retain iHealth upload history. The default is 30, and the maximum is 365.

options
This is a command line string to specify qkview options.

For information about the options that you can use with the command list, see help list.

SEE ALSO
list, tmsh, qkview

BIG-IP 2017-01-20 sys diags ihealth(1)

sys disk application-volume

NAME
application-volume - Configures an application volume instance.

MODULE
sys disk

SYNTAX
Configure the application-volume component in the sys disk module using the syntax shown in the following sections.

DISPLAY
show application-volume [name]
list application-volume [name]

DELETE
delete application-volume [name]

DESCRIPTION
The application-volume component provides better granularity for managing disks. Physical disks can now be shared by several application-volumes. An application-volume is physically confined to one logical disk. The visibility of the application-volume can be confined to a particular software volume set or it can be global. No application-volume properties are allowed to be modified through tmsh or iControl(r) interfaces.

EXAMPLES
delete application-volume mysqlpdb_MD1.3

Deletes an application-volume named mysqlpdb_MD1.3.

show application-volume mysqlpdb_MD1.3

Displays the configuration details of the application-volume mysqlpdb_MD1.3 in a table.

OPTION
logical-disk [name]
Specifies the name of the logical disk in which the application-volume will be created.

owner [unassigned/datastor/mysql/vcmp]
Specifies the owner for which this application-volume is assigned. unassigned - is the default option and means the volume is not in use and nobody owns it.

preservability [discardable/precious]
Specifies the if application-volume can be discarded by software (for example, during module provisioning). discardable - is the default option.

resizeable [false/true]
Specifies the if application-volume can potentially be resized. false - is the default option.

size [integer]
Specifies the size of the application-volume.

volume-set-visibility-restraint [name]
Specifies the name of the volume set to which the application-volume is constrained, if any.

SEE ALSO
delete, show, list, tmsh, sys provision, sys disk logical-disk

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2009-2013, 2016. All rights reserved.

BIG-IP 2016-03-14 sys disk application-volume(1)

NAME
directory - Manages resizing of system directories.

MODULE
sys disk

SYNTAX
Configure the directory component in the sys disk module using the syntax shown in the following sections.

MODIFY
modify directory [directory_name]
options:
 new-size [new_size]

SHOW
show directory

DESCRIPTION
The directory component assists in resizing system directories. It allows system administrators to increase the size of 4 system directories (/config, /shared, /var, /var/log). This allows more flexible management of the system resources and path for growing the directory sizes on case per case basis.

EXAMPLES
modify directory /shared new-size 35000

Increases the size of /shared system directory to 35 MiB.

show directory

Displays a table with currently scheduled directories for resizing. If there are no such directories the output is empty.

SEE ALSO
modify, show, tmsh

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2009-2013. All rights reserved.

BIG-IP 2013-11-20 sys disk directory(1)

sys disk logical-disk

NAME
logical-disk - Manages logical disks.

MODULE
sys disk

SYNTAX
Configure the logical-disk component in the sys disk module using the syntax shown in the following sections.

MODIFY
modify logical-disk [name]
options:
 vg-reserved [integer]
 mode [none/mixed/datastor]

DISPLAY
list logical-disk [name]

DESCRIPTION
The logical-disk component provides better granularity for managing disks. A physical disk can now be shared by one or more logical disks. A logical disk is physically confined to one physical disk.

EXAMPLES
modify logical-disk foo mode mixed vg-reserved 200

Modifies the logical disk foo mode property to mixed and the vg-reserved property size to 200 MiB.

list logical-disk foo

Displays the configuration details of the logical disk named foo.

OPTION
mode [none/mixed/datastor/control]
Specifies the current mode of the logical disk. The options are:

control - Indicates that the logical disk is part of a RAID array.

datastor - Indicates that the entire disk is committed to the datastor module.
mixed - Indicates that the disk contains multiple volumes for software and/or multiple volumes for application data.
none - Indicates that the disk is not in use. This is the default option.

size [integer]
Specifies the size (MiB) of the logical disk.

vg-free [integer]
Specifies the usable free space (MiB) available in the logical disk.

vg-in-use [integer]
Specifies the total logical disk space (MiB) in use.

vg-reserved [integer]
Specifies the reserved logical disk space (MiB). This space is NOT available for provisioning.

SEE ALSO

modify, list, tmsh, sys provision, sys disk logical-disk

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2016-03-14 sys disk logical-disk(1)

sys dns

NAME
dns - Configures the Domain Name System (DNS) for the BIG-IP(r) system.

MODULE
sys

SYNTAX
Modify the dns component within the sys module using the syntax shown in the following sections.

MODIFY
modify dns
options:
description [string]
include [string]
name-servers [add | delete | replace-all-with] {
 [IP address] ...
}
name-servers none
number-of-dots [integer]
search [add | delete | replace-all-with] {
 [domain] ...
}
search none

edit dns
options:
all-properties
non-default-properties

DISPLAY
list dns
list dns [option]
show running-config dns
show running-config dns [option]
options:
all-properties
non-default-properties
one-line

DESCRIPTION
You can use the dns component to manage configurations by server grouping, in this case, DNS servers.

EXAMPLES
modify dns name-servers add { 192.168.10.20 192.168.10.22 }
Adds DNS name servers with the IP addresses, 192.168.10.20 and 192.168.10.22, to the BIG-IP system.

modify dns search add { siterequest.com store.siterequest.com london.siterequest.com }
Adds the host names, siterequest.com, store.siterequest.com, and london.siterequest.com, to the DNS search configuration for the BIG-IP system.

Note: When DNS searches for the host, siterequest, which is not a fully qualified domain name, it uses the IP address of the first match, in this case, siterequest.com.

`show running-config dns`
Displays the running configuration of the dns component.

OPTIONS

`description`
User defined description.

`include`
Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using the include option. If you use this option incorrectly, you put the functionality of the system at risk.

`name-servers`
Configures a group of DNS name servers for the BIG-IP system.

`number-of-dots`
Configures the number of dots needed in a name before an initial absolute query will be made.

`search`
Configures a list of domain names in a specific order. DNS uses that order when searching for host names that are not fully qualified. You can use this option to delete domain names in the list.

sys dynad instrumentation

NAME

instrumentation - Display and configure the instrumentation available for the BIG-IP(r) DynaD feature.

MODULE

sys dynad

SYNTAX

Display and modify the instrumentation component within the sys dynad module using the syntax in the following section.

MODIFY

```
modify sys dynad instrumentation [name]
options:
    active
```

DISPLAY

```
list sys dynad instrumentation
list sys dynad instrumentation [name]
options:
    all-properties
    one-line
    active
```

DESCRIPTION

You can use the instrumentation component to display or modify the configuration of the DynaD feature.

EXAMPLES

```
list sys dynad instrumentation
```

Display all the instrumentation available for use by the DynaD feature.

```
list sys dynad instrumentation [name]
```

Display a specific instrumentation available for use by the DynaD feature.

```
modify sys dynad instrumentation [name] active true
```

Activate the specified instrumentation.

OPTIONS

active
Indicates the state of the instrumentation. The system will be instrumented when set to 'true'.

For information about the options that you can use with the command list, see help list.

SEE ALSO
list, tmsh, dynad

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2016. All rights reserved.

BIG-IP 2016-11-22 sys dynad instrumentation(1)

sys dynad key

NAME
key - Encryption key used for the BIG-IP(r) DynaD feature.

MODULE
sys dynad

SYNTAX
Display the key component within the sys dynad module using the syntax in the following section.

DISPLAY
list sys dynad instrumentation
list sys dynad instrumentation key
options:
all-properties
one-line
key
blob

DESCRIPTION
You can use the key component to display the encryption key used by the DynaD feature.

EXAMPLES
list sys dynad key
Display the entire key component.

OPTIONS
key Display the encryption key used to load DynaD instrumentation.
blob Display the encrypted blob used by F5 support to prepare DynaD instrumentation.
For information about the options that you can use with the command list, see help list.

SEE ALSO
list, tmsh, dynad

COPYRIGHT

BIG-IP 2017-09-05 sys dynad key(1)

sys dynad rpm

NAME

rpm - Display and install instrumentation rpms for the BIG-IP(r) DynaD feature.

MODULE

sys dynad

SYNTAX

Manage instrumentation with the rpm component within the sys dynad module using the syntax in the following section.

INSTALL

install sys dynad rpm [package]

DISPLAY

list sys dynad rpm
list sys dynad rpm [package]

options:

- all-properties
- one-line
- force
- arch
- description
- path
- release
- version

show sys dynad rpm
show sys dynad rpm [package]

DESCRIPTION

You can use the rpm component to view and install DynaD instrumentation packages. DynaD instrumentation packages must be placed in the /shared/rpm directory to be used by the BIG-IP(r) system.

Note that installation can only occur when the DynaD feature is inactive.

EXAMPLES

list sys dynad rpm

Display all the rpms available for installation.

list sys dynad rpm [package]

Display a specific rpm available for installation.

install sys dynad rpm [package]

Install the specified instrumentation rpm.

install sys dynad rpm force [package]

Forcibly install the specified instrumentation rpm.

show sys dynad rpm

Display all previously installed instrumentation rpms.

OPTIONS

force

Forcibly install the specified package irregardless of most errors. This option is useful if an RPM needs to be reinstalled.

arch Displays the architecture of the instrumentation contained in the package.

description

Displays the description of the instrumentation contained in the package.

path Displays the local path to the package.

release

Displays the release number of the package.

version

Displays the version number of the package.

For information about the options that you can use with the command list, see help list.

SEE ALSO

list, tmsh, dynad

sys dynad settings

NAME
Settings - Display and configure global settings for the BIG-IP(r) DynaD feature.

MODULE
sys dynad

SYNTAX
Display and modify the settings component within the sys dynad module using the syntax in the following section.

MODIFY
modify sys dynad settings
options:
development-mode

DISPLAY
list sys dynad settings
options:
all-properties
one-line
development-mode

DESCRIPTION
You can use the settings component to display or modify the global settings for the DynaD feature.

EXAMPLES
list sys dynad settings

Display all the settings available to the DynaD feature.

modify sys dynad settings development-mode true

Enable development mode.

OPTIONS
development-mode
Development-mode can be used to place the DynaD feature into a promiscuous operating mode. Allowing it to bypass various validation checks performed on installed scripts.

For information about the options that you can use with the command list, see help list.

SEE ALSO
list, tmsh, dynad

COPYRIGHT

sys dynad status

NAME
status - Displays the status of the BIG-IP(r) DynaD feature.

MODULE
sys dynad

SYNTAX
Display the status component within the sys dynad module using the syntax in the following section.

DISPLAY
show sys dynad status

DESCRIPTION
You can use the status component to display the overall state of the DynaD feature.

EXAMPLES
show sys dynad status

Displays status of the DynaD feature.

For information about the options that you can use with the command show, see help show.

SEE ALSO
show, tmsh, dynad

COPYRIGHT

BIG-IP 2017-05-19 sys dynad status(1)

sys ecm config

NAME
config - Configures Elastic Compute Manager cluster.

MODULE
sys ecm

SYNTAX
Modify the configuration for ECM module using the syntax shown in the following sections.

MODIFY
modify config
options:
seed-ip [string]
dns-resolver [string]

edit config
options:
all-properties
non-default-properties

DISPLAY
list config
options:
auth [string]
seed-ip [string]
dns-resolver [string]
status [string]

OPTIONS
You can use these options with the config component:

auth Displays the authorization credentials to access ECM cluster. Authorization credentials are obtained by registering the BIG-IP with the ECM cluster. Refer to register command within the ECM module.

seed-ip
Specifies the host name or IP address of the seed node of the ECM cluster.

dns-resolver
Specifies the BIG-IP DNS resolver to use for host name resolution.

status
Displays the status

SEE ALSO

BIG-IP 2017-05-24 sys ecm register(1)

sys failover

NAME failover - Configures failover for a BIG-IP(r) unit in a redundant system configuration.

MODULE sys

SYNTAX Change the failover state within the sys module using the syntax in the following section.

MODIFY
run failover
options:
device [string]
no-persist
offline
online
persist
standby
traffic-group [[string] | default | non-default | none]

DISPLAY
show failover
options:
cable

DESCRIPTION
Failover is the process where a standby unit in a redundant system configuration takes over when a software or hardware failure is detected on the active unit.

EXAMPLES
run failover standby

Causes the active unit or cluster to go into the standby state forcing the other unit or cluster in the redundant system configuration to become active.

run failover offline

Causes the active unit or cluster to go into the Forced Offline state.

run failover online

Changes the status of a unit or cluster from Forced Offline to either Active or Standby, depending upon the status of the other unit or cluster in a redundant system configuration.

show failover

Displays the failover state of the BIG-IP system (active, standby, offline, forced_offline) and how long it has been in that state.

run failover standby device my_bigip

Specifies that the my_bigip device should become the active device for all traffic groups currently active on this device.

run failover standby traffic-group traffic_grp01

Specifies that the traffic group named traffic_grp01 should fail over to the Standby state. The traffic group will then become Active on another device.

run sys failover offline no-persist

Changes the status of a unit to Forced Offline and indicates that the change will not be persisted after a system restart.

run sys failover offline persist

Changes the status of a unit to Forced Offline and indicates that the change will be persisted after a system restart.

OPTIONS

Use these options to control failover of the system:

device

Specifies the device that should next become the active device for the specified traffic group or all traffic groups (if a traffic group is not specified). This option may only be specified with the standby option.

no-persist

Does not persist the change in status of a unit. The option is valid only with the offline state.

offline

Changes the status of a unit or cluster to Forced Offline. If persist or no-persist options are not specified, the default action is to persist the offline status of the unit between system restarts.

online

Changes the status of a unit or cluster from Forced Offline to either Active or Standby, depending upon the status of the other unit or cluster in a redundant system configuration.

persist

Persists the change in status of a unit. The option is valid only with the offline state.

standby

Specifies that the active unit or cluster fails over to a Standby state, causing the standby unit or cluster to become Active.

traffic-group

Specifies the traffic-group that should fail over to the Standby state, the traffic-group will become Active on another device. This option may only be specified with the standby option.

Use this option to display the failover cable status of the system:

cable

Displays the status that the failover daemon detects on the serial cable from its failover peer. It also shows what the failover peer detects on the serial cable. An active BIG-IP system will see a zero from its failover peer. A standby BIG-IP system will see a one from its failover peer.

SEE ALSO

run, tmsh

BIG-IP 2017-03-13 sys failover(1)

sys feature-module

NAME

feature-module - Enables or disables a feature module on the BIG-IP(r) system.

MODULE

sys

SYNTAX

Configure the feature-module component within the sys module using the syntax in the following sections.

MODIFY

```
modify feature-module
modify feature-module [ [all] | [cgnat] ]
options:
  enabled | disabled

edit feature-module
[ [ [cgnat] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties

DISPLAY
list feature-module
list feature-module
[ [ [cgnat] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

DESCRIPTION

You can use the feature-module component to modify the availability of any licensed feature modules on your system.

EXAMPLES

```
modify feature-module cgnat enabled
Enables the BIG-IP Carrier Grade NAT module.

modify feature-module cgnat disabled
Disables the BIG-IP Carrier Grade NAT module.

list feature-module
Displays the current feature module of the system.
```

OPTIONS

all Specifies that you are enabling or disabling all of the available modules.

cgnat Specifies that you are enabling or disabling the BIG-IP Carrier Grade NAT module.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

regex Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

edit, glob, list, modify, regex, show, tmsh, provision

sys file apache-ssl-cert

NAME apache-ssl-cert - Manages an Apache SSL certificate file.

MODULE sys file

SYNTAX Configure the apache-ssl-cert component within the sys file module using the syntax shown in the following sections.

CREATE
create apache-ssl-cert [name]
options:
 source-path [URL]

DISPLAY
list apache-ssl-cert
list apache-ssl-cert [[[name] | [glob] | [regex]] ...]

DELETE
delete apache-ssl-cert [name]

DESCRIPTION

You can use the apache-ssl-cert component to create, delete, or list an

SSL certificate.

EXAMPLES

```
create apache-ssl-cert new-cert source-path
http://cert-server/cert_store/certs/cert1.crt
```

Downloads the certificate from the given URL into file-store, creates an SSL certificate file named new-cert, and saves the given URL in the source-path attribute.

```
create apache-ssl-cert new-cert source-path file://shared/save/cert1.crt
```

Specifies the location of the file on the local disk (use this when the file has already been created on the local disk).

SUPPORTED URL FORMAT

Supported URL schemes are HTTP, HTTPS, FTP, FTPS, and FILE.

OPTIONS

bundle-certificates

Lists data about all the certificates in the bundle, if the certificate file is a bundle. This option must be explicitly specified; otherwise, this field will be none.

certificate-key-curve-name

Specifies the Elliptical Curve name of the cryptographic key associated with this certificate. This field will be set to none if an Elliptical Curve key is not present.

certificate-key-size

Specifies the number of bits in the key associated with this certificate.

checksum

Specifies a cryptographic hash or checksum of the file contents for use in verification of file integrity.

create-time

Specifies the time at which the file-object was created.

created-by

Specifies the user who originally created the file-object.

expiration-date

Specifies the date at which this certificate expires. Stored as a POSIX time.

expiration-string

Specifies a string representation of the expiration date of the certificate.

fingerprint

Displays the SHA-256 fingerprint of the certificate.

is-bundle

Specifies whether the certificate file is a bundle (that is, whether it contains more than one certificate).

issuer

Specifies X509 information of the certificate's issuer. If the cert is a bundle, this displays the issuer information for the primary (first) cert in the bundle.

key-type

Specifies the type of cryptographic key associated with this certificate.

last-update-time

Specifies the last time at which the file-object was updated/modified.

mode Specifies the UNIX file permissions mode for the file associated with this file-object as a numerical value.

partition

Specifies the administrative partition where the certificate resides.

revision

Identifies the latest revision of the file. The revision starts with 1 and gets incremented on each update.

serial-number

Specifies the certificate's serial number.

size Specifies the size (in bytes) of the file associated with this file object.

source-path [URL]

This attribute takes a URL, for example:

```
source-path http://cert-server/cert_store/certs/vs_132.crt
```

```
source-path https://cert-server/cert_store/certs/vs_132.crt
```

```
source-path
```

```
ftp://username:password@server/cert_store/certs/vs_132.crt
```

subject

Specifies X509 information of the certificate's subject. If the cert is a bundle, this displays the subject information for the primary (first) cert in the bundle.

subject-alternative-name

Specifies a standard X.509 extension as shown in RFC 2459.

updated-by
Specifies the user who last updated the file-object.

version
Specifies the X509 version of the certificate.

SEE ALSO

create, delete, glob, list, ltm profile client-ssl, ltm profile server-ssl, modify, regex, tmsh

sys file browser-capabilities-db

NAME
browser-capabilities-db - Manages a browser capabilities DB file.

MODULE
sys file

SYNTAX
Configure the browser-capabilities-db component within the sys file module using the syntax shown in the following sections.

CREATE/MODIFY
create browser-capabilities-db [name]
modify browser-capabilities-db [name]
options:
source-path [URL]

DISPLAY
list browser-capabilities-db
list browser-capabilities-db [[[name] | [glob] | [regex]] ...]

DELETE
delete browser-capabilities-db [name]

DESCRIPTION
You can use the browser-capabilities-db component to create, delete, list or modify an browser capabilities DB file.

EXAMPLES
create browser-capabilities-db dcdb source-path
file:/shared/images/dcdb

Loads the browser capabilities file from the given path on the local disk into file-store and creates an file named dcdb.

OPTIONS
checksum
A cryptographic hash or checksum of the file contents for use in verification of file integrity.

create-time
Specifies the time at which the file-object was created.

created-by
Specifies the user who originally created the file-object.

last-update-time
Specifies the last time at which the file-object was updated/modified.

mode Specifies the UNIX file permissions mode for the file associated with this file-object as a numerical value.

revision
Specifies the latest revision of the file. The revision starts with 1 and gets incremented on each update.

size Specifies the size (in bytes) of the file associated with this file object.

source-path [path]
This attribute takes an absolute path on the local disk, for example:

source-path file:/shared/images/filename

updated-by

Specifies the user who last updated the file-object.

SEE ALSO

create, delete, glob, list, modify, regex, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

sys file data-group

NAME

data-group - Manages an external data group file.

MODULE

sys file

SYNTAX

Manage the data-group component within the sys file module using the syntax shown in the following sections.

CREATE/MODIFY

create data-group [name]

modify data-group [name]

options:

app-service [[string] | none]
data-group-description [string]
data-group-name [name]
separator [string]
source-path [URL]
type [integer | ip | string]

edit data-group [[[name] | [glob] | [regex]] ...]

DISPLAY

list data-group

list data-group [[[name] | [glob] | [regex]] ...]

DELETE

delete data-group [name]

DESCRIPTION

You can use the data-group component to create, edit, delete, list or modify an external data group file.

EXAMPLES

```
create data-group new-dg source-path  
http://file-server/data-groups/acl.class type string
```

Downloads the data-group file from the given URL into file-store, creates an external-data-group file named new-dg, and saves the given URL in the source-path attribute.

```
create data-group new-dg source-path  
http://file-server/data-groups/acl.class type string data-group-name dg  
data-group-description "created for rule xyz"
```

Downloads the data-group file from the given URL into file-store, creates an external-data-group file named new-dg, saves the given URL in the source-path attribute, and creates an external data group within the ltm data-group module named dg with the given description.

```
create data-group new-dg source-path file:/shared/save/Test.cls type ip
```

Specifies the location of the file on the local disk (use this when the file has already been created on the local disk).

SUPPORTED URL FORMAT

Supported URL schemes are HTTP, HTTPS, FTP, FTPS, and FILE.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

checksum

Specifies a cryptographic hash or checksum of the file contents for use in verification of file integrity.

created-by

Specifies the user who originally created the file-object.

create-time
Specifies the time at which the file-object was created.

data-group-description
Specifies the description of the external data group that will be created within the ltm data-group module and reference the given data group file. This is optional in the create command.

data-group-name
Specifies the name of the external data group that will be created within the ltm data-group module and reference the given data group file. This is optional in the create command.

last-update-time
Specifies the last time at which the file-object was updated/modified.

mode Specifies the UNIX file permissions mode for the file associated with this file-object as a numerical value.

revision
The latest revision of the file. The revision starts with 1 and gets incremented on each update.

separator
Specifies a separator to use when defining the data group. The default value is :=.

size Specifies the size (in bytes) of the file associated with this file object.

source-path [URL]
This attribute takes a URL, for example:

source-path http://file-server/data-groups/AUL_1.cls

source-path https://file-server/data-groups/CNN.x

source-path
ftp://username:password@server/data-groups/latest.class

source-path file:/shared/save/Test.dat

type Specifies the kind of data in the group. This option is required by the create command.

Possible values for type are:

- o integer
- o ip
- o string

updated-by
Specifies the user who last updated the file-object.

SEE ALSO

create, delete, edit, glob, list, ltm data-group external, modify, regex, tmsh

sys file device-capabilities-db

NAME
device-capabilities-db - Manages a device capabilities DB file.

MODULE
sys file

SYNTAX
Configure the device-capabilities-db component within the sys file module using the syntax shown in the following sections.

CREATE/MODIFY
create device-capabilities-db [name]
modify device-capabilities-db [name]
options:
source-path [file:/PATH/FILE]

DISPLAY
list device-capabilities-db
list device-capabilities-db [[[name] | [glob] | [regex]] ...]

DELETE
delete device-capabilities-db [name]

DESCRIPTION
You can use the device-capabilities-db component to create, delete, list or modify an device capabilities DB file.

EXAMPLES
create device-capabilities-db dcdb source-path file:/shared/images/dcdb

Loads the device capabilities file from the given path on the local disk into file-store and creates an file named dcdb.

OPTIONS

checksum
A cryptographic hash or checksum of the file contents for use in verification of file integrity.

create-time
Specifies the time at which the file-object was created.

created-by
Specifies the user who originally created the file-object.

last-update-time
Specifies the last time at which the file-object was updated/modified.

mode Specifies the UNIX file permissions mode for the file associated with this file-object as a numerical value.

revision
Specifies the latest revision of the file. The revision starts with 1 and gets incremented on each update.

size Specifies the size (in bytes) of the file associated with this file object.

source-path [path]
This attribute takes an absolute path on the local disk, for example:
source-path file:/shared/images/filename

updated-by
Specifies the user who last updated the file-object.

sys file external-monitor

NAME
external-monitor - Manages an external monitor file.

MODULE
sys file

SYNTAX
Manage the external-monitor component within the sys file module using the syntax shown in the following sections.

CREATE/MODIFY
create external-monitor [name]
modify external-monitor [name]
options:
app-service [[string] | none]
source-path [URL]

edit external-monitor [[[name] | [glob] | [regex]] ...]

DISPLAY
list external-monitor
list external-monitor [[[name] | [glob] | [regex]] ...]

DELETE

delete external-monitor [name]

DESCRIPTION

You can use the external-monitor component to create, edit, delete, list or modify an external-monitor file.

EXAMPLES

```
create external-monitor new-mon source-path
http://file-server/external-monitors/mon_app1
```

Downloads the monitor file from the given URL into file-store, creates an external-monitor file named new-mon, and saves the given URL in the source-path attribute.

```
create external-monitor new-mon source-path file:/shared/save/Test.mon
```

Specifies the location of the file on the local disk (use this when the file has already been created on the local disk).

SUPPORTED URL FORMAT

Supported URL schemes are HTTP, HTTPS, FTP, FTPS, and FILE.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

checksum

Specifies a cryptographic hash or checksum of the file contents for use in verification of file integrity.

created-by

Specifies the user who originally created the file-object.

create-time

Specifies the time at which the file-object was created.

last-update-time

Specifies the last time at which the file-object was updated/modified.

mode Specifies the UNIX file permissions mode for the file associated with this file-object as a numerical value.

revision

The latest revision of the file. The revision starts with 1 and gets incremented on each update.

size Specifies the size (in bytes) of the file associated with this file object.

source-path [URL]

This attribute takes a URL, for example:

source-path

```
http://file-server/external-monitors/monitor_service
```

source-path

```
https://file-server/external-monitors/custom_mon.1
```

source-path

```
ftp://username:password@server/external-monitors/tested.mon
```

updated-by

Specifies the user who last updated the file-object.

SEE ALSO

create, delete, edit, glob, list, ltm monitor external, modify, regex, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

sys file ifile

NAME

ifile - Manages an iFile file.

MODULE

sys file

SYNTAX

Manage the ifile component within the sys file module using the syntax shown in the following sections.

CREATE/MODIFY

```
create ifile [name]
modify ifile [name]
options:
  app-service [[string] | none]
  source-path [URL]

edit ifile [ [name] | [glob] | [regex] ] ... ]
```

DISPLAY

```
list ifile
list ifile [ [name] | [glob] | [regex] ] ... ]
```

DELETE

```
delete ifile [name]
```

DESCRIPTION

You can use the ifile component to create, edit, delete, list or modify an iFile file.

EXAMPLES

```
create ifile new-ifile source-path http://tmp/text.txt
```

Downloads the iFile file from the given URL into file-store and creates an iFile file named new-ifile. Saves the given URL in the source-path attribute.

Supported URL schemes are "HTTP", "HTTPS", "FTP", "FTPS" & "FILE"

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

checksum

A cryptographic hash or checksum of the file contents for use in verification of file integrity.

created-by

Specifies the user who originally created the file-object.

create-time

Specifies the time at which the file-object was created.

last-update-time

Specifies the last time at which the file-object was updated/modified.

mode Specifies the UNIX file permissions mode for the file associated with this file-object as a numerical value.

revision

The latest revision of the file. The revision starts with 1 and gets incremented on each update.

size Specifies the size (in bytes) of the file associated with this file object.

source-path [URL]

This attribute takes a URL, for example:

```
source-path http://file-server/ifiles/AUL_1.cls
```

```
source-path https://file-server/ifiles/CNN.x
```

source-path

```
ftp://username:password@server/ifiles/latest.class
```

updated-by

Specifies the user who last updated the file-object.

SEE ALSO

create, delete, edit, glob, list, ltm ifile, modify, regex, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

sys file lwtunneltbl

NAME
lwtunneltbl - Manages an lwtunneltbl file.

MODULE
sys file

SYNTAX
Manage the lwtunneltbl component within the sys file module using the syntax shown in the following sections.

CREATE/MODIFY
create lwtunneltbl [name]
modify lwtunneltbl [name]
options:
app-service [[string] | none]
source-path [URL]

edit lwtunneltbl [[[name] | [glob] | [regex]] ...]

DISPLAY
list lwtunneltbl
list lwtunneltbl [[[name] | [glob] | [regex]] ...]

DELETE
delete lwtunneltbl [name]

DESCRIPTION
You can use the lwtunneltbl component to create, edit, delete, list or modify an lwtunneltbl file.

EXAMPLES
create lwtunneltbl new-ifile source-path http://tmp/text.txt

Downloads the lwtunneltbl file from the given URL into file-store and creates an lwtunneltbl file named new-ifile. Saves the given URL in the source-path attribute.

Supported URL schemes are "HTTP", "HTTPS", "FTP", "FTPS" & "FILE"

OPTIONS
app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

checksum
A cryptographic hash or checksum of the file contents for use in verification of file integrity.

created-by
Specifies the user who originally created the file-object.

create-time
Specifies the time at which the file-object was created.

last-update-time
Specifies the last time at which the file-object was updated/modified.

mode
Specifies the UNIX file permissions mode for the file associated with this file-object as a numerical value.

revision
The latest revision of the file. The revision starts with 1 and gets incremented on each update.

size
Specifies the size (in bytes) of the file associated with this file object.

source-path [URL]
This attribute takes a URL, for example:
source-path http://file-server/ifiles/AUL_1.cls
source-path https://file-server/ifiles/CNN.x
source-path
ftp://username:password@server/ifiles/latest.class

updated-by
Specifies the user who last updated the file-object.

SEE ALSO
create, delete, edit, glob, list, ltm ifile, modify, regex, tmsh

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

sys file rewrite-rule

NAME
rewrite-rule - Manages a HTML content rewrite rule.

MODULE
sys file

SYNTAX
Configure the rewrite-rule component within the sys file module using the syntax shown in the following sections.

CREATE/MODIFY
create rewrite-rule [name]
modify rewrite-rule [name]
options:
 local-path [URL]

edit rewrite-rule [[[name] | [glob] | [regex]] ...]

DISPLAY
list rewrite-rule
list rewrite-rule [[[name] | [glob] | [regex]] ...]

DELETE
delete rewrite-rule [name]

DESCRIPTION
You can use the rewrite-rule component to create, edit, delete, list or modify a HTML content rewrite rule.

EXAMPLES
create rewrite-rule new-rule local-path /shared/tmp/my_rewrite_rule

Creates a new HTML content rewrite rule using file located by local-path and saves path in the local-path attribute.

OPTIONS

checksum
Specifies a cryptographic hash or checksum of the file contents for use in verification of file integrity.

created-by
Specifies the user who originally created the file-object.

create-time
Specifies the time at which the file-object was created.

last-update-time
Specifies the last time at which the file-object was updated/modified.

mode
Specifies the UNIX file permissions mode for the file associated with this file-object as a numerical value.

revision
Specifies the latest revision of the file. The revision starts with 1 and gets incremented on each update.

size
Specifies the size (in bytes) of the file associated with this file object.

local-path [path]
This attribute takes a path, for example:
local-path /shared/tmp/my_rewrite_rule

updated-by
Specifies the user who last updated the file-object.

SEE ALSO
create, delete, edit, glob, list, ltm profile html, modify, regex, tmsh

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2013-04-12 sys file rewrite-rule(1)

sys file ssl-cert

NAME
ssl-cert - Manages a SSL certificate file.

MODULE
sys file

SYNTAX
Configure the ssl-cert component within the sys file module using the syntax shown in the following sections.

CREATE/MODIFY
create ssl-cert [name]
options:
app-service [[string] | none]
source-path [URL]

modify ssl-cert [name]
options:
app-service [[string] | none]
cert-validation-options [none | ocsf]
cert-validators [none | [cert_validator_name]]
issuer-cert [none | [issuer_cert_name]]
source-path [URL]

edit ssl-cert [[[name] | [glob] | [regex]] ...]

DISPLAY
list ssl-cert
list ssl-cert [[[name] | [glob] | [regex]] ...]

DELETE
delete ssl-cert [name]

DESCRIPTION
You can use the ssl-cert component to create, edit, delete, list or modify an SSL certificate.

EXAMPLES
create ssl-cert new-cert source-path
http:/cert-server/cert_store/certs/cert1.crt

Downloads the certificate from the given URL into file-store, creates an SSL certificate file named new-cert, and saves the given URL in the source-path attribute.

create ssl-cert new-cert source-path file:/shared/save/cert1.crt

Specifies the location of the file on the local disk (use this when the file has already been created on the local disk).

SUPPORTED URL FORMAT
Supported URL schemes are HTTP, HTTPS, FTP, FTPS, and FILE.

OPTIONS

app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

bundle-certificates
Lists data about all the certificates in the bundle, if the certificate file is a bundle. This option must be explicitly specified; otherwise, this field will be none.

cert-validation-options
Specifies the option used for validating the certificate status.

cert-validators
Specifies the name of the cert-validators used for validating the certificate status. At most one cert-validator can be configured for each cert-validation type.

certificate-key-size
Specifies the number of bits in the key associated with this certificate.

checksum
Specifies a cryptographic hash or checksum of the file contents for use in verification of file integrity.

create-time
Specifies the time at which the file-object was created.

created-by
Specifies the user who originally created the file-object.

expiration-date
Specifies the date at which this certificate expires. Stored as a POSIX time.

expiration-string
Specifies a string representation of the expiration date of the certificate.

fingerprint
Displays the SHA-256 fingerprint of the certificate.

is-bundle

Specifies whether the certificate file is a bundle (that is, whether it contains more than one certificate).

issuer

Specifies X509 information of the certificate's issuer. If the cert is a bundle, this displays the issuer information for the primary (first) cert in the bundle.

issuer-cert

Specifies the name of the issuer certificate for this certificate.

key-type

Specifies the type of cryptographic key associated with this certificate.

last-update-time

Specifies the last time at which the file-object was updated/modified.

mode Specifies the UNIX file permissions mode for the file associated with this file-object as a numerical value.

revision

Specifies the latest revision of the file. The revision starts with 1 and gets incremented on each update.

serial-number

Specifies the certificate's serial number.

size Specifies the size (in bytes) of the file associated with this file object.

source-path [URL]

This attribute takes a URL, for example:

source-path http://cert-server/cert_store/certs/vs_132.crt

source-path https://cert-server/cert_store/certs/vs_132.crt

source-path

ftp://username:password@server/cert_store/certs/vs_132.crt

subject

Specifies X509 information of the certificate's subject. If the cert is a bundle, this displays the subject information for the primary (first) cert in the bundle.

subject-alternative-name

Specifies a standard X.509 extension as shown in RFC 2459.

updated-by

Specifies the user who last updated the file-object.

version

Specifies the X509 version of the certificate.

SEE ALSO

create, delete, edit, glob, list, ltm profile client-ssl, ltm profile server-ssl, modify, regex, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2017-05-05 sys file ssl-cert(1)

sys file ssl-crl

NAME

ssl-crl - Manages a SSL CRL file.

MODULE

sys file

SYNTAX

Configure the ssl-crl component within the sys file module using the syntax shown in the following sections.

CREATE/MODIFY

create ssl-crl [name]

modify ssl-crl [name]

options:

app-service [[string] | none]

source-path [URL]

```
edit ssl-crl [ [ [name] | [glob] | [regex] ] ... ]
```

DISPLAY

```
list ssl-crl  
list ssl-crl [ [ [name] | [glob] | [regex] ] ... ]
```

DELETE

```
delete ssl-crl [name]
```

DESCRIPTION

You can use the `ssl-crl` component to create, edit, delete, list or modify an SSL CRL file.

EXAMPLES

```
create ssl-crl new-crl source-path  
http://cert-server/cert_store/CRLs/latest.crl
```

Downloads the CRL file from the given URL into `file-store`, creates an SSL CRL file named `new-crl`, and saves the given URL in the `source-path` attribute.

```
create ssl-crl new-crl source-path file:/shared/save/copy_10.crl
```

Specifies the location of the file on the local disk (use this when the file has already been created on the local disk).

SUPPORTED URL FORMAT

Supported URL schemes are HTTP, HTTPS, FTP, FTPS, and FILE.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

checksum

Specifies a cryptographic hash or checksum of the file contents for use in verification of file integrity.

created-by

Specifies the user who originally created the file-object.

create-time

Specifies the time at which the file-object was created.

last-update-time

Specifies the last time at which the file-object was updated/modified.

`mode` Specifies the UNIX file permissions mode for the file associated with this file-object as a numerical value.

revision

Specifies the latest revision of the file. The revision starts with 1 and gets incremented on each update.

`size` Specifies the size (in bytes) of the file associated with this file object.

source-path [URL]

This attribute takes a URL, for example:

```
source-path http://cert-server/cert_store/CRLs/backup_10.crl
```

```
source-path https://cert-server/cert_store/CRLs/jan_2010.crl
```

source-path

```
ftp://username:password@server/cert_store/CRLs/latest.crl
```

updated-by

Specifies the user who last updated the file-object.

SEE ALSO

`create`, `delete`, `edit`, `glob`, `list`, `ltm profile client-ssl`, `ltm profile server-ssl`, `modify`, `regex`, `tmsh`

COPYRIGHT

F5 Networks and BIG-IP (c) Copyright 2008-2013. All rights reserved.

BIG-IP 2013-04-12 sys file ssl-crl(1)

NAME ssl-key - Manages a SSL certificate key file.

MODULE sys file

SYNTAX Configure the ssl-key component within the sys file module using the syntax shown in the following sections.

CREATE/MODIFY

```
create ssl-key [name]
modify ssl-key [name]
options:
  app-service [[string] | none]
  source-path [URL]
  passphrase [passphrase]

edit ssl-key [ [ [name] | [glob] | [regex] ] ... ]
```

DISPLAY

```
list ssl-key
list ssl-key [ [ [name] | [glob] | [regex] ] ... ]
```

DELETE

```
delete ssl-key [name]
```

DESCRIPTION

You can use the ssl-key component to create, edit, delete, list or modify an SSL certificate key file.

EXAMPLES

```
create ssl-key new-key source-path
http:/cert-server/cert_store/certs/cert1.key
```

Downloads the certificate-key file from the given URL into file-store and creates an SSL certificate key file named new-key. Saves the given URL in the source-path attribute.

```
create ssl-key new-key source-path file:/shared/save/cert1.key
```

Specifies the location of the file on the local disk. Use this when the file has already been created on the local disk.

SUPPORTED URL FORMAT

Supported URL schemes are HTTP, HTTPS, FTP, FTPS, and FILE.

OPTIONS

app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

checksum
A cryptographic hash or checksum of the file contents for use in verification of file integrity.

create-time
Specifies the time at which the file-object was created.

created-by
Specifies the user who originally created the file-object.

key-size
Specifies the size of the cryptographic key associated with this file object, in bits.

key-type
Specifies the cryptographic type of the key in question. That is, which algorithm this key is compatible with.

The options are:

rsa-private
The key is an RSA private key.

dsa-private
The key is a DSA based private key.

last-update-time
Specifies the last time at which the file-object was updated/modified.

mode Specifies the UNIX file permissions mode for the file associated with this file-object as a numerical value.

passphrase [passphrase]
Specifies an optional passphrase with which the key has been protected. It may be used by consumers of the key in the data-plane or control-plane to decrypt it.

revision
Specifies the latest revision of the file. The revision starts with 1 and gets incremented on each update.

security-type
Specifies the type of security used to handle or store the key.

The options are:

normal
The key resides in a standard form on the file-system. This

is the default value.

fips The key is protected by a FIPS device on the system and is only applicable to devices with FIPS support.

password
Specifies that the key is protected by a passphrase and stored in encrypted form.

nethsm
The key is protected by a FIPS device outside the system.

size Specifies the size (in bytes) of the file associated with this file object.

source-path [URL]
This attribute takes a URL, for example:

source-path http://cert-server/cert_store/certs/vs_132.key

source-path https://cert-server/cert_store/certs/vs_132.key

source-path
ftp://username:password@server/cert_store/certs/vs_132.key

updated-by
Specifies the user who last updated the file-object.

SEE ALSO

sys fix-connection

NAME
fix-connection - Displays FIX connection statistics.

MODULE
sys

SYNTAX
DISPLAY
show fix-connection
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
all-properties
save-to-file

DESCRIPTION
You can use the **fix-connection** component to display statistics about FIX connections.

EXAMPLES
show fix-connection

Displays FIX connection statistics in the system default units.

OPTIONS
For information about the options that you can use with the command **show**, see **help show**.

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2014-05-19 sys fix-connection(1)

sys folder

NAME
folder - Configure folders (directory structure) on the BIG-IP(r) system.

MODULE
sys

SYNTAX
Configure the folder component within the sys module using the syntax in the following sections.

CREATE/MODIFY
create folder [name]
modify folder [name]
options:
app-service [[string] | none]
description [string]
device-group [[string] | default | non-default | none]
no-ref-check [false | true]
traffic-group [[string] | default | non-default | none]

DISPLAY
list folder
list folder [[name] | [glob] | [regex] | [recursive]]

DELETE
delete folder [name]

DESCRIPTION
The folder system enables users to create logical containers for the purpose of granular control of synchronization to other devices in a device group.

The folder system is hierarchical, with folders and sub-folders, in a parent-to-child relationship. The highest level folder in the system is called root. For every administrative partition on the BIG-IP system, there is a top-level folder. Top-level folders always have root as the parent. Users can create sub-folders to any folder in the system.

EXAMPLES
create sys folder sub-folder1 device-group dgl traffic-group none

Creates a new sub-folder to the current working folder called sub-folder1, associates the folder with a device-group called dgl, and sets the traffic-group to no association.

modify sys folder /Common/sub-folder1/subfolder2 description "store pools for the B2 server configuration"

Changes the description property of the folder indicated by its full name.

OPTIONS
app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description
User defined description.

device-group
Adds this folder and all configuration items in this folder to a device group for device failover or config-sync purposes. The options are:

default
Indicates that this folder should use the device group setting of its parent folder. If the parent folder's associated device group is changed, this folder's device group will change as well.

non-default
Disassociates this folder from its parent folder's device group setting. This folder's device group field can then be set independently of the parent folder's field.

hidden
Folders may be hidden by setting this property to true. The -hidden command-line option will allow you to view hidden folders, but is not required to use or modify a folder. The -hidden command-line option only affects output from the list command and the results of tab completing a configuration item. If set to false, the folder will always be visible as long as the user has the appropriate permissions.

inherited-devicegroup
Specifies, when set to true, that this folder uses the device group setting of its parent folder. If the parent folder's associated device group is changed then this folder's device group will change as well. This field is read-only.

inherited-traffic-group
Specifies, when set to true, that this folder uses the traffic

group setting of its parent folder. If the parent folder's associated traffic group is changed then this folder's traffic group will change as well. This field is read-only.

no-ref-check

Specifies whether strict device group reference validation is performed on configuration items in the folder. The options are:

false

Requires configuration items in the folder to sync to a super-set of the devices that are associated with any configuration that refers to configuration items in the folder. This is the default value.

true Disables this check. It is then assumed that any dependent configuration items contained in the folder will be created locally on the other devices.

traffic-group

Adds this folder and its configuration items to an existing traffic group. The values default and non-default work as they do for the device-group option.

SEE ALSO

create, delete, glob, list, modify, regex, tmsh

sys fpga firmware-config

NAME
firmware-config - Configures the FPGA firmware to be used by the system.

MODULE
sys fpga

SYNTAX
Configure the firmware-config component within the sys fpga module using the syntax shown in the following sections.

MODIFY
modify firmware-config
options:
type [14-performance-fpga | 17-intelligent-fpga | standard-balanced-fpga | traffic-acceleration-fpga]

DISPLAY
list firmware-config
options:
all-properties
non-default-properties
one-line

DESCRIPTION
You can use the firmware-config component to configure the FPGA firmware type to use.

EXAMPLES
list firmware-config
Displays properties of the current FPGA firmware configuration.
modify firmware-config type
Modify the type of the current FPGA firmware configuration. The default is standard-balanced-fpga.

OPTIONS
type The type for FPGA firmware current used on the system.
14-performance-fpga: High throughput fpga firmware.
17-intelligent-fpga: eFAD and L7 intelligent fpga firmware.
standard-balanced-fpga: The balanced standard fpga firmware.
traffic-acceleration-fpga: traffic acceleration fpga firmware.

SEE ALSO

BIG-IP 2017-09-05 sys fpga turboflex-profile(1)

sys geoip

NAME

geoip - Loads the GeoIP data files.

MODULE

sys

SYNTAX

Use the geoip component within the gtm module to load the GeoIP data files using the syntax in the following sections.

LOADING

load geoip

DESCRIPTION

The BIG-IP system ships with three default database files that are stored in the /usr/share/GeoIP/v2 directory. The three files are: F5GeoIP.dat, F5GeoIPISP.dat, and F5GeoIPv6.dat.

You can download and install updated GeoIP database files using the procedure available from the F5 download site. The installation places the updated database files in the share/GeoIP/v2 directory.

When you run the load geoip command sequence, the system loads the GeoIP files from disk into the running configuration. If you have downloaded and installed updated database files, those files are loaded from the /shared/GeoIP/v2 directory. Otherwise, the default database files are loaded from the /usr/share/GeoIP/v2 directory. Note that if both directories contain the same files, the files in shared/GeoIP/v2 are loaded.

EXAMPLES

load geoip

Loads the GeoIP files from disk into the running configuration.

sys global-settings

NAME

global-settings - Configures the global system settings for a BIG-IP(r) system.

MODULE

sys

SYNTAX

Configure the global-settings component within the sys module using the syntax in the following sections.

MODIFY

modify global-settings

options:

```
aws-access-key [string]
aws-secret-key [string]
aws-api-max-concurrency [integer]
file-blacklist-path-prefix [string]
file-blacklist-read-only-path-prefix [string]
file-whitelist-path-prefix [string]
console-inactivity-timeout [integer]
custom-addr [IP address]
description [string]
failsafe-action [go-offline | reboot | restart-all |
  go-offline-restart-tm | failover-restart-tm]
file-local-path-prefix [local path prefix]
gui-audit [disabled | enabled]
gui-security-banner [disabled | enabled]
gui-security-banner-text [string]
gui-setup [disabled | enabled]
host-addr-mode [custom | management | state-mirror]
hostname [string]
hosts-allow-include [string]
lcd-display [disabled | enabled]
net-reboot [disabled | enabled]
password-prompt [string]
mgmt-dhcp [disabled | enabled]
quiet-boot [disabled | enabled]
remote-host [add | delete | replace-all-with] {
  [name]... {
```

options:

```
addr [IP address]
hostname [string]
}
}
remote-host none
username-prompt [string]
```

edit global-settings

options:

```
all-properties
non-default-properties
```

DISPLAY

list global-settings

list global-settings [option]

show running-config global-settings

show running-config global-settings [option]

options:

```
all-properties
non-default-properties
one-line
```

DESCRIPTION

You can use the global-settings component to set up the BIG-IP system.

EXAMPLES

```
modify system remote-host add { bigip151 {addr 172.27.226.151 hostname
bigip151.saxon.net} }
```

Sets up a remote host named bigip151 with an IP address of 172.27.226.151 and a hostname of bigip151.saxon.net.

```
list global-settings all-properties
```

Displays all of the properties of the global system settings.

OPTIONS

aws-access-key

Amazon Web Services (AWS) supplied access key needed to make secure requests to AWS. The default value is none.

aws-secret-key

Amazon Web Services (AWS) supplied secret key needed to make secure requests to AWS. The default value is none.

aws-api-max-concurrency

Maximum concurrent connections allowed while making Amazon Web Service (AWS) api calls. The default value is 1.

file-blacklist-path-prefix

Specifies the path prefixes that are disallowed for certain commands. The blacklist takes precedence over the whitelist. It is used by the tmsh save/load sys config file command to disallow saving or loading configuration. Example: The path prefix /shared/tmp/ is included both in the whitelist and blacklist. Since, it is present in the blacklist, the configuration cannot be saved or loaded from the /shared/tmp/ location. The paths are specified in braces separated by spaces in quotes. ex: "{/shared/3dns} {/shared/bin}".

file-blacklist-read-only-path-prefix

Specifies the read-only path prefixes that are disallowed for certain commands. It is used by the tmsh save/load sys config file command to disallow saving or loading configuration. It is a read-only attribute with value "{/etc/shadow}".

file-whitelist-path-prefix

Specifies the path prefixes that are valid for certain commands.

It is used by the tmsb save/load sys config file command for saving or loading configuration. The paths are specified in braces separated by spaces in quotes. ex: "{/var/local/scf/} {/tmp/} {/shared/} {/config/}".

console-inactivity-timeout

Specifies the number of seconds of inactivity before the system logs off a user that is logged on. The default value is 0 (zero), which means that no timeout is set. The valid range is 0 - 2147483647.

custom-addr

Specifies an IP address for the system. The default value is ::. The host-addr-mode option must be set to custom in order for this setting to take effect.

description

Specifies a user defined description. The default value is no description.

failsafe-action

Specifies the action that the system takes when the switch board fails. The default value is go-offline-restart-tm.

failover-restart-tm

Specifies that when the switch board fails the system restarts the traffic management system and fails over to the other unit in a redundant pair.

go-offline

Specifies that when the switch board fails the system goes offline.

go-offline-restart-tm

Specifies that when the switch board fails the system goes offline and restarts the traffic management system.

reboot

Specifies that after the active cluster fails over to its peer, it reboots while the peer processes the traffic.

restart-all

Specifies that when the switch board fails the system restarts all system services.

file-local-path-prefix

Specifies a list of folder prefixes that can be applied for file objects. This is a space separated list of folder prefixes, contained in curly braces. Example: "{file:///shared/}" or "{file:///fileobjectfolder/} {/shared/}". By default the folders are "/shared/" and "/tmp/", represented as "{/shared/} {/tmp/}".

gui-audit

Specifies whether or not system GUI log audit messages. If you disable this option, system GUI will not log audit messages. The default value is disabled.

gui-security-banner

Specifies whether the system presents on the login screen the text you specify in the gui-security-banner-text option. If you disable this option, the system presents an empty frame in the right portion of the login screen. The default value is enabled.

gui-security-banner-text

Specifies the text to present on the login screen when the gui-security-banner option is enabled. The default value is Welcome to the BIG-IP Configuration Utility.

Note: To enter a carriage return in the text type Ctrl-V followed by Ctrl-J. Additionally, you must escape special characters, such as a question mark(?), with a back slash.

gui-setup

Enables or disables the Setup utility in the browser-based Configuration utility. The default value is enabled.

Note: When you configure a system using tmsb, disable this option. Disabling this option allows the system administrators to use the browser-based Configuration utility without having to run the Setup utility.

host-addr-mode

Specifies the type of host address you want to assign to the system. The default value is management. The options are:

custom

Use this value to specify a custom IP address for the system using the custom-addr option.

management

Indicates that the host address is the management port of the system.

state-mirror

Use this value when the host address of the system is shared by the other system in a redundant pair. In case of system failure, the traffic to the other system is routed to this system.

hostname

Specifies a local name for the system. The default value is bigip1.

hosts-allow-include

Warning: Do not use this parameter without assistance from the F5 Technical Support team. The system does not validate the commands issued when you use the `hosts-allow-include` option. If you use this option incorrectly, you put the functionality of the system at risk.

`lcd-display`

Enables or disables the LCD display on the front of the system. The default value is enabled.

`net-reboot`

Enables or disables the network reboot feature. The default value is disabled.

If you enable this feature and then reboot the system, the system boots from an ISO image on the network, rather than from an internal media drive. Use this option only when you want to install software on the system, for example, for an upgrade or a re-installation.

Note: An enabled value reverts to disabled after you reboot the system a second time.

`password-prompt`

Specifies the text to present above the password field on the system's login screen.

`mgmt-dhcp`

Specifies whether the system uses DHCP client for acquiring the management interface IP address. If this option is enabled, manually specified IP addresses for the management interface may be overwritten if the network also contains a DHCP server. If this option is disabled, no DHCP server will be applied to the management interface, however any previously acquired address will still be used. The default value is enabled for VE and disabled for all other platforms. When this option is enabled, manual changes like `create/delete` on `management-ip` will not be allowed.

`quiet-boot`

Enables or disables the quiet boot feature. The default value is enabled. When enabled, the system suppresses informational text on the console during the boot cycle.

`remote-host`

Configures a remote host in the `/etc/hosts` file. The default value is none. You must enter both an IP address and a fully qualified domain name (FQDN) or alias for each host that you want to add to the file.

`username-prompt`

Specifies the text to present above the user name field on the system's login screen.

    app-service [[string] | none]
    attribute percent-up-members
    threshold [integer]
    minimum-threshold [integer]
    sufficient threshold [integer]
    weight [integer]
  }
}
}

```

DISPLAY

```

list ha-group
list ha-group [name]
options:
  all
  all-properties
  current-module
  one-line

```

DELETE

```

delete ha-group [name]

```

DESCRIPTION

You can use the ha-group component to configure a high availability (HA) group that determines the HA scoring mechanism for a unit in a traffic group. This mechanism compares the relative health of the two or more units in the traffic group and the system with the highest score becomes the active unit. Note Use the attribute ha-group of the traffic group to make the association.

EXAMPLES

```

create ha-group group1 pools add { ftp_pool { attribute percent-up-
members weight 70 } }

```

Creates a HA group, named group1, that includes the pool named ftp_pool, and uses the attribute percent-up-members and a weight of 70 to determine the HA score for a unit in a traffic group.

```

list ha-group group1

```

Displays the configuration of the HA group, group1.

OPTIONS

active-bonus

Specifies a number to add to the unit's HA score when the unit is active. This option ensures that the state of a unit is dependent upon the history of its state. The default value is 10 (ten). The range is 0 - 100.

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

attribute

Specifies an attribute of the component that you want to use for the HA scoring mechanism. Percent-up-members is the only available attribute for HA scoring for the clusters, pools, and trunks options.

clusters

Specifies the clusters that you want to configure for the HA group. You can only configure a cluster on a chassis.

description

User defined description.

[disabled | enabled]

Enables or disables the HA group in the HA table. The default value is enabled.

name Specifies the name of the component that you want to configure. This option is required when you create, modify, or delete a HA group. This option is also required when you configure clusters, pools, or trunks for the HA group.

pools

Specifies the pools that you want to configure for the HA group.

threshold

Deprecated. Use minimum-threshold instead.

minimum-threshold
Specifies the minimum number of up interfaces in a trunk, up pool members in a pool, or up cluster members in a cluster below which the specified component does not contribute to the HA score for the unit. The default value is 0 (zero), which indicates this option is disabled. The value may not exceed the number of members of the trunk, pool, or cluster.

sufficient-threshold
Specifies the sufficient number of up interfaces in a trunk, up pool members in a pool, or up cluster members in a cluster above which the specified component is considered at 100% for its contribution to the HA score for the unit. The default value is all (or 0). The value may not exceed the number of members of the trunk, pool, or cluster.

trunks
Specifies the trunks that you want to configure for the HA group.

weight
The value of this option is multiplied by the percent of up cluster, pool, or trunk members, and is added to the HA score. The default value is 10. The range is 10 - 100.

sys ha-status

NAME

ha-status - Displays information about the high availability (HA) status of a unit in a redundant pair.

MODULE

sys

SYNTAX

Display information about the ha-status component within the sys module using the following syntax.

DISPLAY

show ha-status

options:

all-properties
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
failure
field-fmt

DESCRIPTION

You can use the ha-status component to display information about the high availability status of a unit in a redundant pair.

EXAMPLES

show ha-status

Display information about the HA status of the unit.

OPTIONS

failure

Display only the objects that present a failure condition.

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, tmsh

sys host-info

NAME
host-info - Displays statistics about the host.

MODULE
sys

SYNTAX
Configure the host-info component within the sys module using the syntax in the following sections.

DISPLAY
show host-info
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
global

DESCRIPTION
You can use the host-info component to display statistics about the host, including CPU count, active CPU count, processor mode, memory usage, and more.

EXAMPLES
show host-info

Displays host statistics in the system default units.

show host-info raw

Displays raw host statistics.

ssl-ocsp-response-max-age [integer]
ssl-ocsp-response-time-skew [integer]
```

edit httpd

options:

```
all-properties
non-default-properties
```

DISPLAY

list httpd

list httpd [option name]

show running-config httpd

show running-config httpd [option name]

options:

```
all-properties
non-default-properties
one-line
```

DESCRIPTION

You can use the httpd component to configure the HTTP daemon for the system.

Important: F5 Networks recommends that users of the Configuration utility exit the utility before changes are made to the system using the httpd component. This is because making changes to the system using this component causes a restart of the httpd daemon. Additionally,

restarting the httpd daemon creates the necessity for a restart of the Configuration utility.

EXAMPLES

```
modify httpd { ssl-certfile [string] ssl-certkeyfile [string] }
```

Changes the SSL certificate and the SSL key. Note that when you change the SSL key, you must also change the SSL certificate.

```
modify httpd auth-pam-idle-timeout 43200
```

Sets the PAM idle timeout to half a day (in seconds).

```
modify httpd allow replace-all-with {172.27.0.0/255.255.0.0}
```

Replaces the existing list of hosts that can connect to the httpd daemon with the hosts in the range, 172.27.0.0/255.255.0.0.

OPTIONS

allow

Configures IP addresses and hostnames for the HTTP clients from which the httpd daemon accepts requests. The default value is All.

Warning: Using the value none resets the httpd daemon to allow all HTTP clients access to the system; therefore, F5 Networks recommends that you do not use the value none.

auth-name

Specifies the name for the authentication realm. The default value is BIG-IP.

auth-pam-dashboard-timeout

Specifies whether idle timeout while viewing the dashboard is enforced or not. The default value is off.

auth-pam-idle-timeout

Specifies the number of seconds of inactivity that can elapse before the GUI session is automatically logged out. The default value is 1200 seconds.

auth-pam-validate-ip

Specifies whether the check for consistent inbound IP for the entire web session is enforced or not. The default value is on.

description

User defined description.

fast-cgitimeout

Specifies, in seconds, the timeout for FastCGI. The default value is 300 seconds.

fips-cipher-version

Read-only field for internal use. Non-zero value indicates that ssl-ciphersuite has been set to FIPS 140-2 compliant defaults. The value 1 indicates that the ciphersuite is "ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384:ECDHE-RSA-AES128-SHA:ECDHE-RSA-AES256-SHA:ECDHE-RSA-AES128-SHA256". User changes to ssl-ciphersuite will not affect this field. This field is relevant only when FIPS 140-2 compliance is enabled in the license.

hostname-lookup

The default value is off.

include

The default value is none.

Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using this option. If you use the include option incorrectly, you put the functionality of the system at risk.

log-level

Specifies the minimum httpd message level to include in the system log. The default value is warn.

redirect-http-to-https

Specifies whether the system should redirect HTTP requests targeted at the configuration utility to HTTPS. The default value is disabled.

request-header-max-timeout

Specifies, in seconds, the maximum time allowed to receive all of the request headers, if the request-header-min-rate option is used, in which case the timeout is extended as more data arrives. Ignored if request-header-min-rate is not used. A value of 0 means no limit. The default value is 40.

request-header-min-rate

Specifies, in bytes per second, the minimum average rate at which the request headers must be received. A value of 0 means no limit. The default value is 500.

request-header-timeout

Specifies, in seconds, the time allowed to receive all of the request headers. A value of 0 means no limit. If you use the request-header-min-rate option, this represents the initial value for the timeout, which will be extended as more data arrives. The default value is 20.

Warning: This includes the time needed to complete the initial SSL handshake. If the user's browser is configured to query certificate revocation lists and the CRL server is not reachable, the initial SSL handshake may take a significant time until the browser gives up waiting for the CRL.

request-body-max-timeout

Specifies, in seconds, the maximum time allowed to receive all of the request body, if the request-body-min-rate option is used, in which case the timeout is extended as more data arrives. Ignored if request-body-min-rate is not used. A value of 0 means no limit. The default value is 0.

request-body-min-rate

Specifies, in bytes per second, the minimum average rate at which the request body must be received. A value of 0 means no limit. The default value is 500.

request-body-timeout

Specifies, in seconds, the time allowed for reading all of the request body. This includes the time needed to do any SSL renegotiation. A value of 0 means no limit. If you use the request-body-min-rate option, this represents the initial value for the timeout, which will be extended as more data arrives. The default value is 60.

ssl-ca-cert-file

Specifies the name of the file that contains the SSL Certificate Authority (CA) certificate file. The default value is none.

ssl-certchainfile

Specifies the name of the file that contains the SSL certificate chain. The default value is none.

ssl-certfile

Specifies the name of the file that contains the SSL certificate. The default value is /etc/httpd/conf/ssl.crt/server.crt.

Note that the path to the file must start with either /etc/httpd/conf/ssl.crt/ or /config/httpd/conf/ssl.crt/, unless the path is a relative path. If the path is a relative path, then it must start with conf/ssl.crt/.

ssl-certkeyfile

Specifies the name of the file that contains the SSL certificate key. The default value is /etc/httpd/conf/ssl.key/server.key.

Note that the path to the file must start with either /etc/httpd/conf/ssl.key/ or /config/httpd/conf/ssl.key/, unless the path is a relative path. If the path is a relative path, then it must start with conf/ssl.key/.

When you change the key file, you must also change the certificate file. For example, use the following command sequence to change the key: modify httpd { ssl-certfile [string] ssl-certkeyfile [string] }

ssl-ciphersuite

Specifies the ciphers that the system uses. The default value is "ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384:ECDHE-RSA-AES128-SHA:ECDHE-RSA-AES256-SHA:ECDHE-RSA-AES128

ssl-include

The default value is none.

Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using this option. If you use the ssl-include option incorrectly, you put the functionality of the system at risk.

ssl-protocol

The list of SSL protocols to accept on the management console. A space-separated list of tokens in the format accepted by the Apache mod_ssl SSLProtocol directive.

The default value is all -SSLv2 -SSLv3.

ssl-port

The SSL port to run the management console. It is a number in the range of 1 and 65535.

The default value is 443.

ssl-ocsp-default-responder

Specifies the default responder URI for OCSP validation. The default is http://localhost.localdomain. The value for the default responder should always be preceded with http://.

ssl-ocsp-enable

Specifies OCSP validation of the client certificate chain. The default is off.

ssl-ocsp-override-responder

Specifies the force use of default responder URI for OCSP validation. The default is off.

ssl-ocsp-responder-timeout

Specifies the maximum allowable time in seconds for OCSP response. The default is 300 seconds.

ssl-ocsp-response-max-age

Specifies the maximum allowable age ("freshness") for OCSP responses. The default value (-1) does not enforce a maximum age, which means that OCSP responses are considered valid as long as their nextUpdate field is in the future.

ssl-ocsp-response-time-skew

Specifies the maximum allowable time skew in seconds for OCSP response validation. The default is 300 seconds.

ssl-verify-client
Specifies if the client certificate needs to be verified for SSL session establishment. The default is no.

ssl-verify-depth
Specifies maximum depth of CA certificates in client certificate verification. The default is 10.

sys hypervisor-info

NAME

hypervisor-info - Used inside of a vCMP guest to display proposed configuration information passed in from the vCMP hypervisor.

MODULE

sys

SYNTAX

Access the hypervisor-info component within the sys module using the syntax in the following sections.

DISPLAY

show hypervisor-info
options:
field-fmt

DESCRIPTION

You can use the hypervisor-info component to display vCMP guest configuration information proposed by the vCMP hypervisor. Note that this component will only display information when used from inside a vCMP guest. On any other BIG-IP system, the show command will produce no output.

These values will override the default values for any of the corresponding configuration items inside the guest:

Proposed Address - The management IP, as configured via tmsh sys management-ip on appliances and via tmsh sys cluster on clusters.

Proposed Gateway - The default gateway, as configured via tmsh sys management-route.

Proposed Hostname - The hostname, as configured via tmsh sys global-settings.

Proposed Netmask - The management netmask. See "Proposed Address" above.

EXAMPLES

show hypervisor-info

Displays hypervisor configuration information in default units.

OPTIONS

For information about the options that you can use with the command show, see help show.

BIG-IP 2016-03-14 sys hypervisor-info(1)

sys icall event

NAME

event - Generate an Event on the BIG-IP(r) system.

MODULE

sys icall

SYNTAX

Generate the event component within the sys icall module using the syntax shown in the following sections.

GENERATE

```
generate event
options:
  name [string]
  context {
    {
      name [string]
      value [string]
    }
  }
}
```

DESCRIPTION

You may use the generate event command to construct a free-form Event in the system which will be sent to interested Event Handlers.

EXAMPLES

```
generate event name EMPLOYEE context { { first_name Sam } { last_name
Shepard } }
```

Construct an event named "EMPLOYEE" that contains two pieces of information as name/value pairs. An Event Handler must be subscribed to the event by the name "EMPLOYEE" or by both event name and all the contexts in a context group.

OPTIONS

context

Specifies a set of name/value pairs that convey the information of the Event.

name The Events name; does not have to be unique, but may not be empty.

SEE ALSO

create, delete, edit, list, modify, show, sys icall event-handler, sys icall script, tmsh

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2016-03-14 sys icall event(1)

sys icall handler periodic

NAME

periodic - Make or configure a periodic handler for the BIG-IP(r) system.

MODULE

sys icall handler

SYNTAX

Modify the periodic component within the sys icall handler module using the syntax shown in the following sections.

CREATE/MODIFY

```
create periodic [name]
modify periodic [name]
options:
  arguments {
    {
      name [string]
      value [string]
    }
    ...
  }
}
```

```
description [string]
first-occurrence [date/time]
interval [integer]
last-occurrence [date/time]
script [script name]
status [active | inactive]
```

```
mv periodic [ [ [source-name] [destination-name] ] |
[ [name] to-folder [folder-name] ] |
[ [name...name] to-folder [folder-name] ] ]
options:
to-folder
```

```
DISPLAY
list periodic
list periodic [ [ [name] | [glob] | [regex] ] ... ]
show periodic
show periodic [ [ [name] | [glob] | [regex] ] ... ]
```

```
DELETE
delete periodic [name]
```

DESCRIPTION

You can create a periodic handler to run scripts automatically based on clock time.

EXAMPLES

```
create periodic my_handler1 script script1 first-occurrence now+1h
interval 45 arguments { { name user value j.han } { name role value
manager } }
```

Create a new periodic handler that will execute script1 every 45 seconds. The handler will wait one hour before beginning, but continue to execute indefinitely. Each 45 seconds, when the script executes, the provided arguments will be passed into the script as `EVENT::context()` data.

```
mv periodic /Common/my_periodic to-folder /Common/my_folder
```

Moves a periodic icall handler named `my_periodic` to a folder named `my_folder`, where `my_folder` has already been created and exists within `/Common`.

OPTIONS

arguments

Specifies a set of name/value pairs that will be passed to the script at the start of each execution on each interval.

The use of arguments is optional and may be changed at any time.

description

A user defined description of the item.

first-occurrence

A specific date and time for this handler to begin executing. If not specified, the current date and time of creation will be used.

interval

The number of seconds between each time this handler should execute.

last-occurrence

A specific date and time for this handler to stop executing. If not specified, the script will run indefinitely.

script

The iCall Tcl script the handler when execute at each time interval. Note that this script must be an object in `sys icall script`; a `cli script` will not work.

status

Specify either active or inactive. Active is the default value.

When the handler status is active, the handler accepts events and executes the script as expected. However, when the status is inactive, the handler will no longer accept incoming events and the script will not execute. Use the inactive status when you wish to keep the handler as a configuration item and do not wish to delete it, but also do not wish the handler to run.

to-folder

A periodic icall handler can be moved to any folder under `/Common`, but configuration dependencies may restrict it from moving out of `/Common`.

SEE ALSO

`create`, `delete`, `edit`, `list`, `modify`, `mv`, `show`, `sys icall event`, `sys icall script`, `tmsb`

sys icall handler perpetual

NAME
perpetual - Make or configure a perpetual handler for the BIG-IP(r) system.

MODULE
sys icall handler

SYNTAX
Modify the perpetual component within the sys icall handler module using the syntax shown in the following sections.

CREATE/MODIFY
create perpetual [name]
modify perpetual [name]
options:
description [string]
script [script name]
status [active | inactive | suspend]
subscriptions [add | delete | modify | replace-all-with] {
[subscription name] {
options:
event-name [event name]
filters [add | delete | modify | replace-all-with] {
[filter name] {
options:
value [string]
match-algorithm [accept-all | exact | glob | regex | subnet]
}
}
}
}
restart perpetual [name]
start perpetual [name]
stop perpetual [name]

mv perpetual [[[source-name] [destination-name]] |
[[name] to-folder [folder-name]] |
[[name...name] to-folder [folder-name]]]
options:
to-folder

DISPLAY
list perpetual
list perpetual [[[name] | [glob] | [regex]] ...]
show perpetual
show perpetual [[[name] | [glob] | [regex]] ...]

DELETE
delete perpetual [name]

DESCRIPTION
You can create a perpetual handler to run continuously executing code and to receive events by specifying subscriptions.

EXAMPLES
create perpetual my_handler1 script script1 subscriptions add { sub1 {
event-name LTM_POOL_UP } }

Creates a new perpetual handler run the program defined in "script1". Anytime an event called "LTM_POOL_UP" is generated in the system, a copy will be sent to my_handler1.

mv perpetual /Common/my_perpetual to-folder /Common/my_folder

Moves a perpetual icall handler named my_perpetual to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS
description
A user defined description of the item.

script
The iCall Tcl script the handler will execute upon creation. The user is responsible for creating a script with perpetual execution. If the script is changed, the handler will not change its executing code until the handler is restarted or put into inactive and then active status.

Note that this script must be an object in sys icall script; a cli script will not work.

status
Specify active, inactive, or suspend. Active is the default value.

Inactive status indicated that the handler is to no longer execute and to no longer receive events. The handler's state is lost and all pending events are deleted. Use this status to eliminate a handler in the system but to keep its information stored.

The handler may also be set to suspend which will keep the handler

script executing, but the system will send no new events to the handler. Events waiting to be processed remain in queue.

subscriptions

Create one or more subscription items to specify the conditions of this handler's execution. The handler subscribes generally to events by the event name, and specifically to data by using filters. The use of filters is optional.

The handler will be sent events by the system as defined by the subscription property, but the code inside the handler must use `EVENT::get_next` function in order to receive the data into the handler. See `sys icall script` for more information.

to-folder

A perpetual `icall` handler can be moved to any folder under `/Common`, but configuration dependencies may restrict it from moving out of `/Common`.

SEE ALSO

`create`, `delete`, `edit`, `list`, `modify`, `mv`, `show`, `sys icall event`, `sys icall script`, `tmsb`

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2016-03-14 `sys icall handler perpetual(1)`

sys icall handler triggered

NAME

`triggered` - Make or configure an event-triggered handler for the BIG-IP(r) system.

MODULE

`sys icall handler`

SYNTAX

Modify the `triggered` component within the `sys icall handler` module using the syntax shown in the following sections.

CREATE/MODIFY

```
create triggered [name]
modify triggered [name]
options:
  description [string]
  script [script name]
  status [active | inactive]
  subscriptions [add | delete | modify | replace-all-with] {
    [subscription name] {
      options:
        event-name [event name]
        filters [add | delete | modify | replace-all-with] {
          [filter name] {
            options:
              value [string]
            match-algorithm [accept-all | exact | glob | regex | subnet]
          }
        }
      }
    }
  }
```

```
mv triggered [ [ [source-name] [destination-name] ] |
  [ [name] to-folder [folder-name] ] |
  [ [name...name] to-folder [folder-name] ] ]
options:
  to-folder
```

DISPLAY

```
list triggered
list triggered [ [ [name] | [glob] | [regex] ] ... ]
show triggered
show triggered [ [ [name] | [glob] | [regex] ] ... ]
```

DELETE

```
delete triggered [name]
```

DESCRIPTION

You can create a `triggered` handler to automatically run a script when a specified event occurs.

EXAMPLES

```
create triggered my_handler1 script script1 subscriptions add { pools {
  event-name LTM_POOL_UP filters add { pool_name { value pool1 }
}
```

```
node_name { value node1 } } }
```

Creates a new triggered handler that will execute the script called "script1" when an event called "LTM_POOL_UP" is generated in the system and contains the contexts { pool_name, pool1 } and { node_name, node1 }.

```
mv triggered /Common/my_triggered to-folder /Common/my_folder
```

Moves a triggered icall handler named my_triggered to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

description

A user defined description of the item.

script

The iCall Tcl script the handler will execute when invoked by an appropriate event. Note that this script must be an object in sys icall script; a cli script will not work.

status

Specify either active or inactive. Active is the default value.

When the handler status is active, the handler accepts events and executes the script as expected. However, when the status is inactive, the handler will no longer accept incoming events and the script will not execute. Use the inactive status when you wish to keep the handler as a configuration item and do not wish to delete it, but also do not wish the handler to run.

subscriptions

Specify one or more subscriptions to define the conditions of this handler's execution. The handler subscribes generally to events by the event name, and specifically to data by using filters. The use of filters is optional.

A handler that specifies more than one subscription will execute when any one subscription is matched to an event.

to-folder

A triggered icall handler can be moved to any folder under /Common, but configuration dependencies may restrict it from moving out of /Common.

SEE ALSO

create, delete, edit, list, modify, mv, show, sys icall event, sys icall script, tmsh

COPYRIGHT

BIG-IP 2016-03-14 sys icall handler triggered(1)

sys icall istats-trigger

NAME

istats-trigger - Configure an iStats trigger to generate a user defined event for the iCall feature on the BIG-IP(r) system.

MODULE

sys icall

SYNTAX

Modify the istats-trigger component within the sys icall module using the syntax shown in the following sections.

CREATE/MODIFY

```
create istats-trigger [name]
modify istats-trigger [name]
```

options:

```
description [string]
duration [integer]
event-name [string]
istats-key [string]
range-max [integer]
range-min [integer]
repeat [integer]
```

```
mv istats-trigger [ [ [source-name] [destination-name] ] |
  [ [name] to-folder [folder-name] ] |
  [ [name...name] to-folder [folder-name] ] ]
options:
```

to-folder

DISPLAY

list istats-trigger
list istats-trigger [[name] | [glob] | [regex]] ...]

DELETE

delete istats-trigger [name]

DESCRIPTION

You can create an istats-trigger to automatically generate a Control Plane iRules event under the conditions specified in the properties.

EXAMPLES

```
mv istats-trigger /Common/my_istats_trigger to-folder /Common/my_folder
```

Moves an istats-trigger named my_istats_trigger to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

description

A user defined description of the item.

duration

Duration in seconds. The value "0" means trigger instantly when in range.

event-name

The name of the event that will be generated.

istats-key

Specify the items and thresholds to define when this istats-trigger will generate an event.

range-max

Trigger event only if value is less-than-or-equal to range-max.

range-min

Trigger event only if value is greater-than-or-equal to range-min. Note that if 0 is included in the specified range, then the iStats key must be explicitly initialized with "istats set [key] 0" in order for the trigger to fire.

repeat

Repeat interval in seconds. The value "none" means do not resend the event unless the value falls outside the range and then re-enters it.

to-folder

An istats-trigger can be moved to any folder under /Common, but configuration dependencies may restrict it from moving out of /Common.

SEE ALSO

create, delete, edit, list, modify, mv, show, sys icall event, sys icall event-handler, sys icall script, tmsh

BIG-IP 2016-03-14 sys icall istats-trigger(1)

sys icall publisher

NAME

publisher - Show the services publishing events on a BIG-IP(r) system

MODULE

sys icall

SYNTAX

Show the available publishers within the sys icall module using the syntax shown in the following sections.

DISPLAY

show publisher [field-fmt]
show publisher [[name] | [glob] | [regex]] ...] [field-fmt]

DESCRIPTION

This command lets you display the publishers on the system, as well as the events that they publish and the contexts that those events are guaranteed to contain.

By default these are shown in a tabular form; use the field-fmt option to show them in a format similar to listing other objects in tmsh.

If a published event includes no contexts, then a single line will be shown with a - in the context column. If a publisher publishes no events, then a single line will be shown with a - in the event column.

OPTIONS

field-fmt

By default, the events will be shown in a tabular format. This overrides the command to print the publishers in object format like the list command does for other objects.

SEE ALSO

show, tmsh, sys icall event, sys icall handler periodic, sys icall handler perpetual, sys icall handler triggered, sys icall istats-trigger, sys icall script

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2014-06-27 sys icall publisher(1)

sys icall script

NAME

script - Manage a Tcl script used by handlers during execution on the BIG-IP(r) system.

MODULE

sys icall

SYNTAX

Manage the script component within the sys icall module using the syntax shown in the following sections.

```
CREATE/MODIFY/EDIT
create script [name]
modify script [name]
edit script [name]
options:
  definition
  description [string]
  events [add | delete | modify | replace-all-with] {
    [event name] {
      contexts [add | delete | modify | replace-all-with] {
        [context name]
      }
    }
  }
}

mv script [ [ [source-name] [destination-name] ] |
  [ [name] to-folder [folder-name] ] |
  [ [name...name] to-folder [folder-name] ] ]
options:
  to-folder

DISPLAY
list script
list script [name]

DELETE
delete script [name]
```

Note: You must remove all references to the icall script before deletion.

DESCRIPTION

You can use this script component to manage Tcl scripts which are used by event handlers upon execution.

Caution: if you add a handler to a shared configuration on a set of BIG-IP appliances, then care must be used in making changes to configuration items. A handler's script which makes config changes on more than one device may cause inconsistencies that must be manually resolved.

EXAMPLES

```
create script my_script1
```

Create a new icall script item called "my_script1". Upon pressing enter, the user will enter the text editor in order to edit the Tcl script. Note that this configuration item may only be modified while in the edit view.

```
mv script /Common/my_script to-folder /Common/my_folder
```

Moves an icall script named my_script to a folder named my_folder, where my_folder has already been created and exists within /Common.

OPTIONS

definition

Holds the Tcl code.

description

User defined description.

events

Register events with the system that this script creates.

to-folder

An icall script can be moved to any folder under /Common, but configuration dependencies may restrict it from moving out of /Common.

EVENT ACCESSORS

In addition to all the tmsch:: commands provided by the system to use in the Tcl scripts (please see help cli script), the commands below are provided to access event specific information.

Hint: When you use a tmsch:: command, call it inside of Tcl catch to receive any error messages returned, and to allow the script to exit gracefully if needed. Without Tcl catch, the script may crash and end the process.

The following Tcl variables may be used in triggered handlers. (The \$ is not part of the variable name but is the lookup operator for the Tcl variable.):

`$EVENT::context([name])`

An array variable containing the value of each context, keyed by the context name.

`$EVENT::creation_time`

The date and time the event was generated.

`$EVENT::event_name`

The name of the event that was generated.

`$EVENT::handler_name`

The name of the event handler that matched the event being handled.

`$EVENT::script_name`

The name of the currently running script.

For use in perpetual handlers:

`EVENT::get_next [-timeout [milliseconds]]`

The timeout parameter is optional. If the timeout is set, then `EVENT::get_next` will return 0 if no event matches before the timeout hits. Otherwise, the `EVENT::get_next` will return 1, and the above variables in the `EVENT::` namespace will be replaced with the data from the new event.

SCRIPT EXAMPLES

The following script will print out all the information of an event.

```
puts "*** start of event ***"
```

```
foreach var [info vars EVENT::*] {
  set varname [namespace tail $var]
  if { [array exists $var] } {
    puts "$varname: "
    foreach { k v } [array get $var] { ;#k = key v = value
      puts "$k:$v"
    }
  } else {
    puts "$varname: [set $var]"
  }
}
```

The next script will allow events to hold bash commands and have the script execute them. The script would be required to run inside an event handler that subscribed to the appropriate event and filtered on the words "utility" and "arguments".

```
set bash_cmd $EVENT::context(utility) append bash_cmd " "
$EVENT::context(arguments)
```

```
if { [catch { exec /bin/bash -c $bash_cmd } result] } {
  puts "error executing bash command: $bash_cmd" } else {
  puts $result }
```

sys icmp-stat

NAME
icmp-stat - Displays and resets ICMP statistics on the BIG-IP system.

MODULE
sys

SYNTAX
Configure the icmp-stat component within the sys module using the syntax in the following section.

MODIFY
reset-stats icmp-stat

DISPLAY
show icmp-stat
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION
You can use the icmp-stat component to display and reset ICMP statistics. The statistics you can view are standard ICMP statistics, including ICMPv4 packets and errors, and ICMPv6 packets and errors.

OPTIONS
For information about the options that you can use with the command show, see help show.

For information about the options that you can use with the command reset-stats, see help reset-stats.

SEE ALSO
reset-stats, show, sys icmp-stat, tmsh

BIG-IP 2011-04-25 sys icmp-stat(1)

sys icontrol-soap

NAME
icontrol-soap - Configures the iControl SOAP daemon for the BIG-IP(r) system.

MODULE
sys

SYNTAX
Configure the icontrol-soap component within the sys module using the following syntax.

CREATE/MODIFY
modify icontrol-soap
options:
allow [add | delete | none | replace-all-with] {
All or IP address ...
}

edit icontrol-soap
options:
all-properties
non-default-properties

DISPLAY

```
list iconcontrol-soap
list iconcontrol-soap [option name]
show running-config iconcontrol-soap
show running-config iconcontrol-soap [option name]
options:
  all-properties
  non-default-properties
  one-line
```

DESCRIPTION

You can use the iconcontrol-soap component to configure the iControl SOAP for the system.

Important: F5 Networks recommends that users of the Configuration utility exit the utility before changes are made to the system using the iconcontrol-soap component. This is because making changes to the system using this component causes a restart of the iconcontrol-soap daemon. Additionally, restarting the iconcontrol-soap daemon creates the necessity for a restart of the Configuration utility.

EXAMPLES

```
modify iconcontrol-soap allow replace-all-with {9.9.9.9}
```

Reduces the allowed IP address that can access iControl SOAP to 9.9.9.9

OPTIONS

allow

Configures IP addresses for iControl SOAP clients from which the iconcontrol-soap daemon accepts requests. The value may be either a full IP address or a Perl Compatible Regular Expression to allow connections from a specific subnet. The default value is All.

Warning: Using the value none resets the iconcontrol-soap daemon to allow all iControl SOAP clients access to the system; therefore, F5 Networks recommends that you do not use the value none.

SEE ALSO

sys integrity status-check

NAME

status-check - Checks and verifies the integrity of the BIG-IP BIOS and kernel using the tpm-status utility.

MODULE

sys crypto

SYNTAX

Run a check on the system's integrity status in the sys integrity module by using the syntax below.

RUN

```
run status-check
```

options:

-h Print help for the tpm-status command.

-c Attempt to continue after reaching an error.

-o Output the PCR measurements to a given file after measurement. The file will be overwritten if pre-existing.

-a Append the PCR measurements to a given file after measurement.

-v [0|1|2|3] Modify the verbosity of the tpm-status utility from 0 (not verbose) to 3 (very very verbose). Default

Note: Options -o and -a are mutually exclusive. Files may only be written to areas allowed by tmsh.

DESCRIPTION

You can use the status-check command to check the system's integrity status.

EXAMPLES

```
run status-check
```

Runs the tpm-status utility and returns the integrity status. It shall be one of VALID, INVALID, UNAVAILABLE, or PENDING.

```
run status-check -v 3
```

Runs the tpm-status utility with very very verbose output then returns the integrity status.

SEE ALSO

run, tmsh

sys internal-proxy

NAME

internal-proxy - Configuration of the internal proxy.

MODULE

sys

SYNTAX

Configure the internal-proxy component within the sys.internal-proxy module using the syntax shown in the following sections. This object is used by other services such as CRL cert-validator, for defining how to send/receive the outbound traffic for the service.

CREATE/MODIFY

```
create internal-proxy [name]
modify internal-proxy [name]
options:
  description [string]
  dns-resolver [name]
  proxy-server-pool [name]
  route-domain [name]
```

DISPLAY

```
list internal-proxy [name]
```

DELETE

```
delete [all | [name]]
options:
  recursive
```

DESCRIPTION

You can use the internal-proxy component to configure a custom internal proxy.

EXAMPLES

```
create sys internal-proxy my_intp dns-resolver my_dnsr

Creates an internal proxy named my_intp using the DNS resolver my_dnsr.
```

OPTIONS

```
dns-resolver
Specifies the DNS resolver object used for sending out the traffic.

proxy-server-pool
Specifies the proxy server pool used for reaching servers.

route-domain
Specifies the route domain for for reaching servers using HTTP forward proxy.
```

SEE ALSO

sys crypto cert-validator crl

sys ip-address

NAME
ip-address - Displays the IP addresses currently associated with a configuration object on a BIG-IP(r) system.

MODULE
sys

SYNTAX
Display the IP addresses associated with a BIG-IP system configuration object using the syntax in the following section.

DISPLAY
show ip-address
options:
[all-properties | field-fmt]

DESCRIPTION
You can use the ip-address component to display the location on the BIG-IP system of the IP addresses associated with a configuration object. The system displays the following information:

Entry
Displays the IP address and any associated configuration. For example, for a Local Traffic Manager pool member, the entry is the member's IP address and port number, 10.1.1.1:80.

Component
Displays the type of component associated with the IP address. For example, for a Local Traffic Manager pool, the entry is ltm pool.

Object-ID
Displays the name of a configuration object associated with the IP address. For example, for a Local Traffic Manager pool named my_pool, the entry is my_pool.

Property
When you specify the all-properties option, displays the name of the property that contains the IP address value. Note that if the IP address is an object identifier the system displays n/a.

EXAMPLES
show ip-address

Displays the IP addresses currently associated with a BIG-IP system configuration object.

OPTIONS
For information about the options that you can use with the command show, see help show.

SEE ALSO
show, tmsh

BIG-IP 2010-03-11 sys ip-address(1)

sys ip-stat

NAME
ip-stat - Displays and resets IP statistics on the BIG-IP system.

MODULE
sys

SYNTAX
Configure the ip-stat component within the sys module using the syntax in the following section.

MODIFY
reset-stats ip-stat

DISPLAY
show ip-stat
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION

You can use the ip-stat component to display and reset IP statistics. The statistics you can view are standard IP statistics, including IPv4 and IPv6 packets, fragments, fragments reassembled, and errors.

OPTIONS

For information about the options that you can use with the command show, see help show.

For information about the options that you can use with the command reset-stats, see help reset-stats.

SEE ALSO

reset-stats, show, sys ip-stat, tmsb

BIG-IP 2011-04-25 sys ip-stat(1)

sys ipfix destination

NAME

destination - Displays or resets statistics for IPFIX log destinations.

MODULE

sys ipfix

SYNTAX

Specify the destination within the sys ipfix module using the syntax in the following section.

MODIFY

reset-stats destination [name]

DISPLAY

show destination [name]

DESCRIPTION

You can use the destination component to display IPFIX destination statistics, like Templates and Data Record counts. You can also reset the IPFIX destination statistics to zero at any time.

OPTIONS

For information about the options that you can use with the command show, see help show.

For information about the options that you can use with the command reset-stats, see help reset-stats.

SEE ALSO

reset-stats, show, sys log-config destination ipfix, sys ipfix irules, sys ipfix element, tmsb

COPYRIGHT

BIG-IP 2014-05-27 sys ipfix destination(1)

sys ipfix element

NAME

element - Configures element for IPFIX logging.

MODULE

sys ipfix

SYNTAX

Configure the IPFIX component within the sys ipfix module using the syntax shown in the following sections.

CREATE/MODIFY

```
create element [name]
modify element [name]
options:
  all
  app-service [[string] | none]
  data-type
    [ boolean | datetime-microseconds |
      datetime-milliseconds | datetime-nanoseconds |
      datetime-seconds | float32 | float64 |
      ipv4-address | ipv6-address | macaddress |
      octetarray | signed16 | signed32 | signed64 |
      signed8 | string |
      unsigned16 | unsigned32 |
      unsigned64 | unsigned8 ]
  description [string]
  enterprise-id [integer]
  id [integer]
  size [integer]
```

DISPLAY

```
list element
list element [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

DELETE

```
delete element [name]
```

Note: Default elements loaded at boot time may not be deleted.

DESCRIPTION

You can use the element component to configure elements for the IPFIX logging interface.

EXAMPLES

```
create element myelement id 345 enterprise-id 543 data-type string size
128
```

Creates a element named myelement with element id 345, enterprise-id 543, data-type string and data size of 128.

```
delete element myelement
```

Deletes the element named myelement.

```
list element myelement
```

Displays properties of the element named myelement.

OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

app-service

Specifies the name of the application service to which the element belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the element. Only the application service can modify or delete the element.

data-type

Specifies the data type of the element.

description

User defined description.

enterprise-id

Specifies the enterprise-id for the IPFIX element being configured between 0 and 4294967295. An enterprise id value of 0 is used to define standardized IANA Information Elements.

id

Specifies the element id for the IPFIX element being configured between 1 and 65535. Values greater than 32767 will be considered NETFLOW-only Information Elements; since the high bit of the 16-bit value is set for those values.

size

Specifies the IPFIX element data size between 1 and 1900 for data-types octetarray and string. The default is 0; and means variable for these two data-types.

glob

Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name

Specifies a unique alphanumeric name for the component. Preferably camel casing. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

create, delete, glob, list, modify, regex, tmsh

COPYRIGHT

BIG-IP 2014-05-28 sys ipfix element(1)

sys ipfix irules

NAME

irules - Displays or resets statistics for irules that use IPFIX logging destinations.

MODULE

sys ipfix

SYNTAX

Specify the irules component within the sys ipfix module using the syntax in the following section.

MODIFY

reset-stats irules

DISPLAY

show irules

DESCRIPTION

You can use the irules component to display a global set of statistics for the iRules that use IPFIX destinations, like memory allocation and outstanding counts for templates, messages and destinations. You can also reset the IPFIX iRules statistics to zero at any time.

OPTIONS

For information about the options that you can use with the command show, see help show.

For information about the options that you can use with the command reset-stats, see help reset-stats.

SEE ALSO

reset-stats, show, sys log-config destination ipfix, sys ipfix destination, sys ipfix element, tmsh

COPYRIGHT

BIG-IP 2014-05-27 sys ipfix irules(1)

sys iprep-status

NAME

iprep-status - Displays the status of an IP reputation database. In the BIG-IP(R) Configuration Utility, this database is referred to as the IP Address Intelligence database.

MODULE

sys

SYNTAX

Display information about the iprep-status component within the sys module using the following syntax.

DISPLAY

show iprep-status
options:
current-module
field-fmt

running-config

DESCRIPTION

You can use the `iprep-status` component to display status information about the IP reputation database. The reputation database (referred to as IP Address Intelligence in the Config Utility) is available from third-party vendors. An IP intelligence database is a list of IP addresses that have a questionable reputation. The status information returned includes:

- the date and time that the BIG-IP system last contacted the vendor server
- the date and time that the BIG-IP system last received an update
- the total number of IP address in the database
- the number of IP addresses in the most recent update

Note: When the system has an IP Intelligence license and the database variable `db iprep.autoupdate` is enabled (default), the database is automatically downloaded and stored in the binary file:

`/var/IpRep/F5IpRep.dat`

The database contains information that maps IP addresses or ranges of IP addresses to one or more reputation categories. After every update, the `IpRep` data file is loaded from disk into the running configuration.

EXAMPLES

```
show iprep-status
```

Displays current status information for the IP reputation database.

OPTIONS

For information about the options that you can use with the command `show`, see `help show`.

SEE ALSO

`show`, `tmsh`

COPYRIGHT

BIG-IP 2016-03-14 sys iprep-status(1)

sys license

NAME

`license` - Manage the BIG-IP(r) system licensing information.

MODULE

`sys`

SYNTAX

Manage the `license` component within the `sys` module using the syntax in the following section.

INSTALL

```
install license
```

options:

```
add-on-keys { [key] ... }
license-server [ [host name] | [IP address] ]
license-server-port [number]
no-certificate-update
registration-key [key]
show-difference
verbose
```

DISPLAY

```
show license
```

options:

```
detail
```

REVOKE

```
revoke license
```

options:

```
license-server [ [host name] | [IP address] ]
license-server-port [number]
verbose
```

DESCRIPTION

You can use the `license` component to do the following:

Display detailed licensing and version information for the system, including the registration key, licensing dates, platform ID, suggested service check date, and the installed active modules.

Install and update the system license.

Revoke the existing license (only for VE instances; the registration key may subsequently be re-used to relicense this or another VE instance).

EXAMPLES

show license

Displays the system software licensing information.

show license detail

Displays the system software licensing information, including optional modules and active features.

install license

Reactivate an existing license.

revoke license

System returns to an unlicensed state; the previous registration key may be re-used on this or another VE.

OPTIONS

add-on-keys

Specifies additional feature modules to be included in the license. If add-on keys are not specified the system will use the add-on keys in the current license file.

license-server

Specifies the host name or IP address of the license server. The default value is 65.61.115.202 (activate.f5.com).

license-server-port

Specifies the IP port of the license server. The default value is 443.

no-certificate-update

Do not perform the certificate update check when contacting the Licensing Server.

registration-key

Specifies the license registration key. If the registration key is not specified the system will use the registration key in the current license file.

show-difference

Displays a comparison between the existing license and the pending license, and prompts to allow the user to keep the existing license or install the pending license.

verbose

Display status as the license is being installed.

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, tmsh

COPYRIGHT

BIG-IP 2017-04-05 sys license(1)

sys log-config destination alertd

NAME

alertd - Modify the AlertD destination.

MODULE

sys log-config destination

SYNTAX

Modify the AlertD component within the sys log-config destination module using the syntax shown in the following sections.

MODIFY

```
modify alertd [name]
options:
  all
  description [string]
```

```
DISPLAY
list alertd
list alertd [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

Note: There is only one AlertD destination, alertd; this destination cannot be created or deleted.

DESCRIPTION

You can use this destination component to modify the AlertD destination for the common logging interface. There is only one AlertD destination; it cannot be deleted. You can use this destination to send logs directly to the AlertD daemon, bypassing syslog-ng.

EXAMPLES

```
list alertd alertd
```

Displays properties of the AlertD destination.

OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

description
User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the modify command.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

glob, list, modify, regex, tmsb

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2014-07-sys log-config destination alertd(1)

sys log-config destination arcsight

NAME

arcsight - Formats incoming logs into the ArcSight format for delivery by a forwarding destination.

MODULE

sys log-config destination

SYNTAX

Configure the ArcSight component within the sys log-config destination module using the syntax shown in the following sections.

```
CREATE/MODIFY
create arcsight [name]
modify arcsight [name]
options:
  all
  app-service [[string] | none]
  description [string]
  forward-to [string]
```

```
DISPLAY
list arcsight
list arcsight [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

```
DELETE
delete arcsight [name]
```

Note: You must remove all references to a destination before you can delete the destination. Default destinations may not be deleted.

DESCRIPTION

You can use this destination component to create ArcSight formatting destinations for the common logging interface. ArcSight log destinations currently only deliver log messages from the Network Firewall Module or the Application Security Module.

EXAMPLES

```
create arcsight my_dest forward-to another_dest
```

Creates an ArcSight destination named `my_dest` which forwards to another destination `another_dest`. `another_dest` must be a Local Syslog, Local Database, Remote Syslog, or Remote High Speed Log destination.

```
delete arcsight my_dest
```

Deletes the destination named `my_dest`. Destinations cannot be deleted when in use by a publisher.

```
list arcsight my_dest
```

Displays properties of the destination named `my_dest`.

OPTIONS

`all` Specifies that you want to modify all of the existing components of the specified type.

app-service

Specifies the name of the application service to which the destination belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the destination. Only the application service can modify or delete the destination.

description

User defined description.

forward-to

Specifies a Local Syslog, Local Database, Remote Syslog, or Remote High Speed Log destination. This is required for the create and modify commands.

`glob` Displays the items that match the glob expression. See help `glob` for a description of glob expression syntax.

`name` Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

SEE ALSO

`create`, `delete`, `glob`, `list`, `modify`, `regex`, `tmsh`

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2013-0sys2log-config destination arcsight(1)

sys log-config destination ipfix

NAME

`ipfix` - Formats log messages into IPFIX messages and sends them to a specified pool of IPFIX Collectors

MODULE

`sys log-config destination`

SYNTAX

CREATE/MODIFY

```
create ipfix [name]
modify ipfix [name]
```

options:

```
all
app-service    [[string] | none]
description    [string]
pool-name      [string]
protocol-version [ipfix | netflow-9]
template-delete-delay [integer]
template-retransmit-interval [integer]
transport-profile [profile name]
```

serverssl-profile [profile name]

DISPLAY

```
list ipfix
list ipfix [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

DELETE

```
delete ipfix [name]
```

Note: You must remove all references to a destination before you can delete the destination. Default destinations may not be deleted.

DESCRIPTION

You can use this destination component to create IPFIX forwarding destinations for the common logging interface.

The IPFIX protocol is designed for logging IP-transmission events. RFC 5101 () specifies the protocol, and RFC 5102 () describes the information model for IPFIX logs. IPFIX logs are raw, binary-encoded strings with their fields and field lengths defined by IPFIX templates. IPFIX collectors are external devices that can receive IPFIX templates and use them to interpret IPFIX logs.

EXAMPLES

```
create ipfix my_dest pool-name my_pool
```

Creates a destination named my_dest which sends IPFIX messages to the pool named my_pool.

```
delete ipfix my_dest
```

Deletes the destination named my_dest. Destinations cannot be deleted when in use by a publisher or another destination.

```
list ipfix my_dest
```

Displays properties of the destination named my_dest.

OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

app-service

Specifies the name of the application service to which the destination belongs. The default value is none.

Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the destination. Only the application service can modify or delete the destination.

description

A user defined description for this logging destination.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

pool-name

Specifies the LTM pool that receives messages from the IPFIX destination. This option is required for the create command. The pool should contain one or more IPFIX collectors; use the "ltm pool" component to set up an LTM pool.

protocol-version

Specifies the protocol version used to encode IPFIX messages sent by this logging destination. The possible values are ipfix and netflow-9. The default is ipfix.

template-delete-delay

This feature is not implemented.

template-retransmit-interval

Specifies the time interval, in seconds, after which this IPFIX logging destination must resend all active IPFIX Templates to the pool of IPFIX collectors.

The logging destination periodically retransmits all of its IPFIX templates at the interval you set in this property. These retransmissions can be helpful if the transport-profile is UDP, a lossy transport mechanism. They can also be useful for debugging a network session with a network analyzer, such as Wireshark.

The default value is 30 seconds.

transport-profile

Specifies the name of a profile for the transport protocol to be used by this IPFIX logging destination. You can use any existing TCP-based or UDP-based profile. The default value is the default udp profile.

You can use the ltm profile tcp command (see "ltm profile tcp") to create a TCP profile, or ltm profile udp (see "ltm profile udp") to create a UDP profile.

serverssl-profile

Specifies the name of a server-side SSL profile to be used by this

IPFIX Log Destination. The default is not to use a server-side SSL profile. If one is specified, the IPFIX Log Destination must be configured to use TCP as the transport protocol, and will use SSL over TCP to communicate with the configured IPFIX collectors.

You can use the ltm profile server-ssl command (see "ltm profile server-ssl") to create a server-side SSL profile.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

ltm pool, ltm profile tcp, ltm profile udp, create, delete, glob, list, modify, regex, tmsh

BIG-IP 2016-03-1sys log-config destination ipfix(1)

sys log-config destination local-database

NAME

local-database - Modify the Local Database destination.

MODULE

sys log-config destination

SYNTAX

Modify the Local Database component within the sys log-config destination module using the syntax shown in the following sections.

MODIFY

```
modify local-database [name]
options:
  all
  description [string]
```

DISPLAY

```
list local-database
list local-database [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

Note: There is only one Local Database destination, local-db. This destination cannot be created or deleted.

DESCRIPTION

You can use this destination component to modify the Local Database destination for the common logging interface. There is only one Local Database destination that cannot be deleted.

EXAMPLES

```
list local-database local-db
```

Displays properties of the Local Database destination.

OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

description
User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the modify command.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

glob, list, modify, regex, tmsh

BIG-IP sys3log-config destination local-database(1)

sys log-config destination local-syslog

NAME local-syslog - Configures the Local Syslog destination.

MODULE sys log-config destination

SYNTAX Modify the Local Syslog component within the sys log-config destination module using the syntax shown in the following sections.

MODIFY
modify local-syslog [name]
options:
all
default-facility [local0 | local1 | local2 | local3 | local4 | local5 | local6 | local7]
default-severity [alert | crit | debug | emerg | err | info | notice | warn]
description [string]

DISPLAY
list local-syslog
list local-syslog [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties
one-line

Note: There is only one Local Syslog destination, local-syslog. This destination cannot be created or deleted.

DESCRIPTION
You can use this destination component to modify the Local Syslog destination for the common logging interface. There is only one Local Syslog destination which cannot be deleted.

EXAMPLES
list local-syslog local-syslog

Displays properties of the Local Syslog destination.

OPTIONS
all Specifies that you want to modify all of the existing components of the specified type.

default-facility
Specifies the facility given to log messages received that do not already have one. The default value is local0. The options are local0, local1, local2, local3, local4, local5, local6, and local7.

default-severity
Specifies the severity given to log messages received that do not already have one. The default value is info. The options are debug, info, notice, warn, err, crit, alert, and emerg.

description
User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the modify command.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

BIG-IP 20sys0log-config destination local-syslog(1)

sys log-config destination management-port

NAME

management-port - Sends received messages to a specified IP address and port through the management interface.

MODULE

sys log-config destination

SYNTAX

Configure the Management Port Log component within the sys log-config destination module using the syntax shown in the following sections.

CREATE/MODIFY

```
create management-port [name]
modify management-port [name]
options:
  all
  app-service [[string] | none]
  description [string]
  ip-address [ ip address ]
  port [ port ]
  protocol [ tcp | udp ]
```

DISPLAY

```
list management-port
list management-port [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

DELETE

```
delete management-port [name]
```

Note: You must remove all references to a destination before you can delete the destination. Default destinations may not be deleted.

DESCRIPTION

You can use this destination component to create Management Port Log forwarding destinations for the common logging interface.

EXAMPLES

```
create management-port my_dest ip-address 1.2.3.4 port 99 protocol udp
```

Creates a destination named my_dest which forwards to the address 1.2.3.4:99 using the UDP protocol.

```
delete management-port my_dest
```

Deletes the destination named my_dest. Destinations cannot be deleted when in use by a publisher or another destination.

```
list management-port my_dest
```

Displays properties of the destination named my_dest.

OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

app-service

Specifies the name of the application service to which the destination belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the destination. Only the application service can modify or delete the destination.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

ip-address

Specifies the IP address that will receive messages from the specified destination.

port Specifies the port of the IP address that will receive messages from the specified destination.

protocol
Specifies the protocol used to send messages to the specified destination. The default value is tcp. The options are tcp and udp.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

BIG-IP syslog-config destination management-port(1)

sys log-config destination remote-high-speed-log

NAME

remote-high-speed-log - Sends received messages to a specified pool.

MODULE

sys log-config destination

SYNTAX

Configure the Remote High Speed Log component within the sys log-config destination module using the syntax shown in the following sections.

CREATE/MODIFY

```
create remote-high-speed-log [name]
modify remote-high-speed-log [name]
options:
  all
  app-service [[string] | none]
  description [string]
  distribution [ adaptive | balanced | replicated ]
  pool-name [ string ]
  protocol [ tcp | udp ]
```

DISPLAY

```
list remote-high-speed-log
list remote-high-speed-log [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

DELETE

```
delete remote-high-speed-log [name]
```

Note: You must remove all references to a destination before you can delete the destination. Default destinations may not be deleted.

DESCRIPTION

You can use this destination component to create Remote High Speed Log forwarding destinations for the common logging interface.

EXAMPLES

```
create remote-high-speed-log my_dest pool-name my_pool
```

Creates a destination named my_dest which forwards to the pool my_pool.

```
delete remote-high-speed-log my_dest
```

Deletes the destination named my_dest. Destinations cannot be deleted when in use by a publisher or another destination.

```
list remote-high-speed-log my_dest
```

Displays properties of the destination named my_dest.

OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

app-service

Specifies the name of the application service to which the destination belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the destination. Only the application service can modify or delete the destination.

description
User defined description.

distribution
Specifies the distribution method used by the Remote High Speed Log destination to send messages to pool members. The default method is adaptive: connections to pool members will be added as required to provide enough logging bandwidth. This can have the undesirable effect of logs accumulating on only one pool member when it provides sufficient logging bandwidth on its own. **balanced** sends each successive log to a new pool member, balancing the logs among them according to the pool's load balancing method. **replicated** replicates each log to all pool members, for redundancy.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

pool-name
Specifies the ltm pool that receives messages from the Remote High Speed Log destination. This option is required for the create command.

protocol
Specifies the protocol used to send messages to the specified pool. The default value is tcp. The options are tcp and udp.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

BIG-IP sys log-config-destination remote-high-speed-log(1)

sys log-config destination remote-syslog

NAME

remote-syslog - Configures Remote Syslog destinations to format log messages into Syslog format and forward them to a Remote High-Speed Log destination.

MODULE

sys log-config destination

SYNTAX

Configure the Remote Syslog component within the sys log-config destination module using the syntax shown in the following sections.

CREATE/MODIFY

create remote-syslog [name]
modify remote-syslog [name]

options:

all
app-service [[string] | none]
default-facility [local0 | local1 | local2 | local3 | local4 | local5 | local6 | local7]
default-severity [alert | crit | debug | emerg | err | info | notice | warn]
description [string]
format [legacy-bigip | rfc3164 | rfc5424]
remote-high-speed-log [string]

DISPLAY

list remote-syslog
list remote-syslog [[[name] | [glob] | [regex]] ...]
options:
all-properties
non-default-properties
one-line

DELETE

delete remote-syslog [name]

Note: You must remove all references to a destination before you can delete the destination. Default destinations may not be deleted.

DESCRIPTION

You can use this destination component to create Remote Syslog formatting destinations for the common logging interface.

EXAMPLES

```
create remote-syslog my_dest remote-high-speed-log another_dest
```

Creates a destination named `my_dest` which forwards to another destination `another_dest`. `another_dest` may not be another Remote Syslog destination.

```
delete remote-syslog my_dest
```

Deletes the destination named `my_dest`. Destinations cannot be deleted when in use by a publisher or another destination.

```
list remote-syslog my_dest
```

Displays properties of the destination named `my_dest`.

OPTIONS

`all` Specifies that you want to modify all of the existing components of the specified type.

`app-service`

Specifies the name of the application service to which the destination belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the destination. Only the application service can modify or delete the destination.

`default-facility`

Specifies the facility given to log messages received that do not already have a facility listed. The default value is `local0`. The options are `local0`, `local1`, `local2`, `local3`, `local4`, `local5`, `local6`, and `local7`.

`default-severity`

Specifies the severity given to log messages received that do not already have a severity listed. The default value is `info`. The options are `debug`, `info`, `notice`, `warn`, `err`, `crit`, `alert`, and `emerg`.

`description`

User defined description.

`format`

Specifies the syslog format received messages are formatted into. The default value is `rfc3164`. The options are `legacy-bigip`, `rfc3164`, and `rfc5424`. For more information, see the respective RFCs.

`glob` Displays the items that match the glob expression. See `help glob` for a description of glob expression syntax.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@`[regular expression]) to indicate that the identifier is a regular expression. See `help regex` for a description of regular expression syntax.

`remote-high-speed-log`

Specifies the forwarding destination to send logs in the syslog format. This option is required for the `create` command. It may only be a remote high speed log destination or a management port destination.

SEE ALSO

`create`, `delete`, `glob`, `list`, `modify`, `regex`, `tmsh`

BIG-IP `2sys-log-config destination remote-syslog(1)`

sys log-config destination splunk

NAME

`splunk` - Configures Splunk formatting destinations to format incoming log messages into the Splunk format.

MODULE

sys log-config destination

SYNTAX

Configure the Splunk component within the sys log-config destination module using the syntax shown in the following sections.

CREATE/MODIFY

```
create splunk [name]
modify splunk [name]
options:
  all
  app-service [[string] | none]
  description [string]
  forward-to [string]
```

DISPLAY

```
list splunk
list splunk [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

DELETE

```
delete splunk [name]
```

Note: You must remove all references to a destination before you can delete the destination. Default destinations may not be deleted.

DESCRIPTION

You can use this destination component to create Splunk formatting destinations for the common logging interface.

EXAMPLES

```
create splunk my_dest forward-to another_dest
```

Creates a destination named `my_dest` which forwards to another destination `another_dest`. `another_dest` must be a Local Syslog, Local Database, Remote Syslog, or Remote High Speed Log destination.

```
delete splunk my_dest
```

Deletes the destination named `my_dest`.

```
list splunk my_dest
```

Displays properties of the destination named `my_dest`. Destinations cannot be deleted when in use by a publisher.

OPTIONS

`all` Specifies that you want to modify all of the existing components of the specified type.

app-service

Specifies the name of the application service to which the destination belongs. The default value is `none`. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the destination. Only the application service can modify or delete the destination.

description

User defined description.

forward-to

Specifies a Local Syslog, Local Database, Remote Syslog, or Remote High Speed Log destination to receive Splunk formatted log messages. This is required for the creation of a Splunk destination.

`glob` Displays the items that match the glob expression. See help `glob` for a description of glob expression syntax.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

SEE ALSO

```

```
options:
```

```
all-properties
```

```
non-default-properties
```

```
one-line
```

DELETE

```
delete filter [name]
```

DESCRIPTION

You can use the filter component to configure the filters for the common logging interface.

EXAMPLES

```
create filter my_filter publisher my_pub
```

Creates a filter named my_filter with the publisher my_pub.

```
delete filter my_filter
```

Deletes the filter named my_filter.

```
list filter my_filter
```

Displays properties of the filter named my_filter.

OPTIONS

all Specifies that you want to modify all of the existing components of the specified type.

app-service

Specifies the name of the application service to which the filter belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the filter. Only the application service can modify or delete the filter.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

level

The minimum severity level of logs to be filtered. The severity levels in increasing order are debug, info, notice, warn, err,

crit, alert, and emerg. The default value is debug.

message-id

A refinement for filtering out specific logs. The default value is none. This is an eight digit hex number. The proper hex value can be obtained from an existing log message by extracting the eight digit value.

For example, the message-id for the example log message below is highlighted.

```
Oct 9 15:38:20 bigip1 notice mcpd[21498]: 01070410:5: Removed
subscription with subscriber id logstatd
```

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

publisher

A publisher to send filtered log messages. The default value is none.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

source

The stream of log messages that will be filtered by the created/modified filter. The default value is all.

SEE ALSO

create, delete, glob, list, modify, regex, tmsh

COPYRIGHT

BIG-IP 2018-03-20 sys log-config filter(1)

sys log-config publisher

NAME

publisher - Configures lists of destinations for the common logging interface.

MODULE

sys log-config

SYNTAX

Configure the publisher component within the sys log-config module using the syntax shown in the following sections.

CREATE/MODIFY

```
create publisher [name]
modify publisher [name]
options:
  all
  app-service [[string] | none]
  description [string]
  destinations [add | delete | none | replace-all-with] {
    [ [destinations] ]
  }
}
```

DISPLAY

```
list publisher
list publisher [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  one-line
```

DELETE

```
delete publisher [name]
```

Note: You must remove all references to a publisher before you can delete the publisher. Default publishers may not be deleted.

DESCRIPTION

You can use the publisher component to configure publishers for the common logging interface.

EXAMPLES

```
create publisher my_pub destinations add {
  destination_1
```

```
destination_2
```

```
}
```

Creates a publisher named `my_pub` with two destinations, `destination_1` and `destination_2`.

```
delete publisher my_pub
```

Deletes the publisher named `my_pub`.

```
list publisher my_pub
```

Displays properties of the publisher named `my_pub`.

OPTIONS

`all` Specifies that you want to modify all of the existing components of the specified type.

`app-service`

Specifies the name of the application service to which the publisher belongs. The default value is none. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the publisher. Only the application service can modify or delete the publisher.

`description`

User defined description.

`destinations`

Adds, deletes, or replaces a set of destinations.

`glob` Displays the items that match the glob expression. See help `glob` for a description of glob expression syntax.

`name` Specifies a unique name for the component. This option is required for the commands `create`, `delete`, and `modify`.

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@`[regular expression]) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

SEE ALSO

`create`, `delete`, `glob`, `list`, `modify`, `regex`, `tmsh`

BIG-IP 2013-04-10 sys log-config publisher(1)

sys log-rotate

NAME

`log-rotate` - Configures log rotation for the BIG-IP(r) system.

MODULE

`sys`

SYNTAX

Configure the `log-rotate` component within the `sys` module using the syntax in the following sections.

MODIFY

```
modify log-rotate
```

```
options:
```

```
common-backlogs [integer]
```

```
common-include [string]
```

```
description [string]
```

```
ilx-include [string]
```

```
ilx-rotations [string]
```

```
ilx-schedule [string]
```

```
ilx-size [string]
```

```
include [string]
```

```
max-file-size [integer]
```

```
mysql-include [string]
```

```
syslog-include [string]
```

```
tomcat-include [string]
```

```
wa-include [string]
```

```
edit log-rotate
```

```
options:
```

```
all-properties
```

```
non-default-properties
```

DISPLAY

```
list log-rotate
list log-rotate [option]
show running-config log-rotate
show running-config log-rotate [option]
options:
  all-properties
  non-default-properties
  one-line
```

DESCRIPTION

You can configure the system to rotate the log files after a specified length of time. This helps to clear the hard drive of unneeded log files.

EXAMPLES

```
modify log-rotate common-backlogs 7
```

Specifies that the system saves seven copies of the common log files.

```
list log-rotate all-properties
```

Displays the configuration of the log-rotate component.

OPTIONS

common-backlogs

Specifies the number of logs that you want the system to save. Select a number from the valid range of 1 - 100. The default value is 24.

common-include

The default value is none.

Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using this option. If you use the common-include option incorrectly, you put the functionality of the system at risk.

description

User defined description.

ilx-include

The default value is none.

Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using this option. If you use the include option incorrectly, you put the functionality of the system at risk.

ilx-rotations

The default value is 10.

Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using this option. If you use the include option incorrectly, you put the functionality of the system at risk.

ilx-schedule

The default value is daily.

Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using this option. If you use the include option incorrectly, you put the functionality of the system at risk.

ilx-size

The value is specified in kilobytes. The default value is 10240 kilobytes.

Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using this option. If you use the include option incorrectly, you put the functionality of the system at risk.

include

The default value is none.

Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using this option. If you use the include option incorrectly, you put the functionality of the system at risk.

max-file-size

The max size of rotated log files in kB. The default value is 1024000.

syslog-include

The default value is none.

Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using this option. If you use the syslog-include option incorrectly, you put the functionality of the system at risk.

tomcat-include

The default value is none.

Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using this option. If you use the tomcat-include option incorrectly, you put the functionality of the system at risk.

wa-include
The default value is none.

Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using this option. If you use the wa-include option incorrectly, you put the functionality of the system at risk.

sys log

NAME
log - Displays various system log files.

MODULE
sys

SYNTAX
Configure the log component within the sys module using the syntax in the following sections.

DISPLAY
show log
show log [audit | daemon | gtm | kernel | ltm | mail | messages | security | tmm | user | webui]
options:
lines [integer]
range [date range]

DESCRIPTION
You can use the log component to display various logs.

EXAMPLES
show log
Displays a list of logs that you can view.
show log gtm
Displays the Global Traffic Manager log.
show log gtm lines 100 range 2/19/2006:15:04:00--epoch
Displays no more than 100 lines of the Global Traffic Manager log that were logged before the 19th of February 2006 at 3:04 pm.

OPTIONS
audit
Displays a log of configuration changes.
daemon
Displays the Unix daemon logs.
gtm Displays the Global Traffic Manager logs.
kernel
Displays Linux Kernel messages.
lines
Specifies how many lines of the log that you want the system to display at one time.
ltm Displays Local Traffic Manager logs.
mail Displays mail daemon logs.
messages
Displays application messages.
range
Specifies the date range of the log information that you want the system to display.
security
Displays security-related messages.
tmm Displays Traffic Manager Micro-kernel logs.

user Displays various user process logs.

webui
Displays Configuration utility logs.

SEE ALSO

BIG-IP 2013-04-12 sys log(1)

sys mac-address

NAME
mac-address - Displays all MAC addresses currently associated with a configuration object on a BIG-IP(r) system, including all dynamically-discovered MAC addresses.

MODULE
sys

SYNTAX
Display the MAC addresses associated with a BIG-IP system configuration using the syntax in the following section.

DISPLAY
show mac-address
options:
field-fmt

DESCRIPTION
You can use the mac-address component to display the location on the BIG-IP system of the MAC addresses associated with a configuration object. The system displays the following information, which identifies the location of the MAC address in the configuration.

Entry
Displays the MAC address.

Component
Displays the type of component associated with the MAC address, for example, net interface.

Object-ID
Displays the name of a configuration object associated with the MAC address, for example, 2.1.

Property
Displays the name of the property that contains the MAC address value. Note that if the MAC address is an object identifier the system displays n/a.

EXAMPLES
show mac-address

Displays all MAC addresses currently associated with a BIG-IP system configuration object.

OPTIONS
For information about the options that you can use with the command show, see help show.

SEE ALSO
show, tmsh

sys management-dhcp

NAME

management-dhcp - Configures dhcp settings for the management interface (MGMT). The changes in this object are reflected in dhclient's next lease renewal cycle and doesn't effect the current lease. User can force the changes to take effect right away by restarting dhclient.

MODULE

sys

SYNTAX

Configure the management-dhcp component within the sys module using the syntax in the following sections.

MODIFY

```
modify management-dhcp [name]
options:
  client-id [string]
  description [string]
  hostname [string]
  request-options [add | delete | modify | replace-all-with]
  send-options [add | delete | modify | replace-all-with]
  supersede-options
    [add | delete | modify | replace-all-with] {
      [name] ... {
        value
      }
    }
  supersede-options none
```

```
edit management-dhcp [name]
```

```
options:
  all-properties
```

DISPLAY

```
list management-dhcp
list management-dhcp [name]
show running-config sys management-dhcp
show running-config sys management-dhcp [name]
options:
  all-properties
  one-line
```

DESCRIPTION

Specifies DHCP client settings for the management interface. These settings will be used to retrieve an IP address for the management interface if mgmt-dhcp is enabled.

EXAMPLES

```
modify management-dhcp default request-options add ntp-servers
```

Adds ntp-servers to the lists of options requested by the management interface DHCP client.

OPTIONS

client-id
Specifies the client identifier to send to the DHCP server.

description
User defined description.

hostname
Specifies the hostname to send to the DHCP server.

request-options
Specifies the options to request from the DHCP server. Adding or removing an option will be reflected at next lease renewal with dhcp server or upon restarting DHCP client.

send-options
Specifies the options to send to the DHCP server.

supersede-options
Specifies dhclient options for which BIG-IP should always use a locally-configured value or values rather than whatever is provided by the DHCP server in the lease.

SEE ALSO

sys management-ip

NAME
management-ip - Configures the ip address and netmask for the management interface (MGMT).

MODULE
sys

SYNTAX
Configure the management-ip component within the sys module using the syntax in the following sections.

CREATE/MODIFY
create management-ip [ip address/netmask]
create management-ip [ip address/prefixlen]
modify management-ip [ip address/prefixlen]
options:
description

DISPLAY
list management-ip
show running-config management-ip
options:
all-properties
one-line

DELETE
delete management-ip [ip address/netmask]
delete management-ip [ip address/prefixlen]

DESCRIPTION
Specifies network settings for the management interface.

The management interface is available on all switch platforms and is designed for management purposes. You can access the browser-based Configuration utility and command line configuration utility through the management port. You cannot use the management interface in traffic management VLANs. You can configure only one IP address on the management interface.

After you make any changes using the management-ip component, issue the following command sequence to save the changes to the bigip_base.conf file: save sys config.

To configure management-ip firewall rules, see security firewall management-ip-rules.

Note: modify only allows modification of the description field. If you wish to change the IP address of the management interface, please see the example below.

EXAMPLES
create management-ip 10.2.3.4/255.255.0.0
Creates the IP address 10.2.3.4 on the management interface.
create management-ip 10.2.3.4/16
Creates the IP address 10.2.3.4 on the management interface.
delete sys management-ip 10.2.3.4/25; create sys management-ip 10.2.3.5/25
Changes the IP address of the management interface. Note: modify does not allow a user to change the IP address directly.

OPTIONS
[ip address/netmask]
Specifies the IPv4 address and netmask.
[ip address/prefixlen]
Specifies the IPv6 address and prefix length.
description
User defined description.
dhcp-enabled
Specifies if the ip address has been configured by DHCP.

sys management-ovsdb

NAME

management-ovsdb - Configures the OVSDB server.

MODULE

sys

SYNTAX

Configure the management-ovsdb component within the sys module using the syntax in the following sections.

MODIFY

modify management-ovsdb

options:

bfd-disabled
bfd-enabled
bfd-route-domain [route-domain]
ca-cert-file [filename]
cert-file [filename]
cert-key-file [filename]
controller-addresses [IP address(es)]
description [string]
disabled
enabled
flooding-type [multipoint | replicator]
log-level [level]
logical-routing-type [none | backhaul]
port [port number]
tunnel-floating-addresses [IP address(es)]
tunnel-local-address [IP address]
tunnel-maintenance-mode [active | passive]

DISPLAY

list management-ovsdb

show running-config management-ovsdb

options:

all-properties
one-line
bfd-disabled
bfd-enabled
bfd-route-domain
ca-cert-file
cert-file
cert-key-file
controller-addresses
description
disabled
enabled
flooding-type
log-level
logical-routing-type
port
tunnel-floating-addresses
tunnel-local-address
tunnel-maintenance-mode

DESCRIPTION

Specifies the configurations for the OVSDB server.

EXAMPLES

modify management-ovsdb controller-addresses add { 10.0.0.1 }

Specifies 10.0.0.1 as the controller address.

list management-ovsdb all-properties

Displays the OVSDB server configurations.

OPTIONS

bfd-disabled

Disable the BFD sessions between the BIG-IP and replicators.

bfd-enabled

Enable the BFD sessions between the BIG-IP and replicators.

bfd-route-domain

Specifies the route-domain on which the VXLAN tunnel of VNI 0 is created for the BFD sessions between the BIG-IP and replicators.

ca-cert-file

Specifies the name of the CA certificate file.

cert-file

Specifies the name of the certificate file.

cert-key-file

Specifies the name of the certificate key file.

controller-addresses
Specifies the IP address(es) of the controller.

disabled
Disables OVSDB management.

enabled
Enables OVSDB management.

flooding-type
Specifies the flooding type to use to transmit unknown destination frames.

log-level
Specifies the log level for OVSDB management. The log file is located at /var/log/vxland.log.

logical-routing-type
Specifies the logical routing type.

port Specifies the OVSDB connection port. The default port is 6640.

tunnel-floating-addresses
Specifies the floating endpoint address(es) for the tunnels. The addresses need to be a self IP address associated with a floating traffic-group.

tunnel-local-address
Specifies the local endpoint address for the tunnels created by the controller. A valid IP address for the tunnel local endpoint is required when OVSDB management is enabled.

tunnel-maintenance-mode
Specifies whether the tunnels are created automatically (active) or manually (passive).

description
User defined description.

sys management-proxy-config

NAME
management-proxy-config - Configures proxy configuration for database download.

MODULE
sys

SYNTAX
Configure a management-proxy-config component within the sys module using the syntax shown in the following sections.

CREATE/MODIFY
create management-proxy-config [name]
modify management-proxy-config [name]
options:
description [string]
proxy-ip-addr [ip address]
proxy-port [port]
username [string]
password [string]

edit management-proxy-config [name]
options:
all-properties
non-default-properties

DISPLAY
list management-proxy-config [name]
options:
all-properties
non-default-properties
one-line

DELETE
delete management-proxy-config [name]

DESCRIPTION

Configures proxy configuration for database download. The management-proxy-config consists of the object name, proxy ip address (proxy-ip), proxy port (proxy-port), username and password. You can have only one proxy configuration specified.

EXAMPLES

```
create management-proxy-config test-proxy { proxy-ip-addr 10.10.10.10
proxy-port 1010 username test password test }
```

Creates the proxy configuration with name test-proxy and uses the specified proxy-ip-addr 10.10.10.10 and proxy-port 1010 with supplied credentials username/password test/test for database download.

```
modify management-proxy-config test-proxy { proxy-port 1012 }
```

Modify the proxy configuration for database download to use proxy port 1012.

```
delete management-proxy-config test-proxy
```

Delete the test-proxy configuration for database download.

OPTIONS

description

User defined description.

proxy-ip-addr

Specifies proxy IP to be used for database download.

proxy-port

Specifies proxy port to be used for database download (default value is 3128).

username

Specifies username for proxy configuration to be used for database download.

password

Specifies password for proxy configuration to be used for database download.

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2017-01-26 sys management-proxy-config(1)

sys management-route

NAME

management-route - Configures route settings for the management interface (MGMT).

MODULE

sys

SYNTAX

Configure the management-route component within the sys module using the syntax in the following sections.

CREATE/MODIFY

```
create management-route [name | default | default-inet6]
options:
```

```
description [string]
```

```
gateway [ip address]
```

```
mtu [number]
```

```
network [ip address/netmask]
```

```
type [interface | blackhole]
```

```
modify management-route [name | default | default-inet6]
options:
```

```
description [string]
```

```
gateway [ip address]
```

```
mtu [number]
```

```
type [interface | blackhole]
```

```
edit management-route [ [ [name | default | default-inet6]
| [glob] | [regex] ] ... ]
```

```
options:
```

```
all-properties
```

DISPLAY

```
list management-route
```

```
list management-route [ [ [name | default | default-inet6]
| [glob] | [regex] ] ... ]
show running-config management-route
show running-config management-route [ [ [name | default
| default-inet6] | [glob] | [regex] ] ... ]
options:
all-properties
one-line
```

```
DELETE
delete management-route [name]
```

DESCRIPTION

Specifies route settings for the management interface. You must configure a route on the management interface if you want to access the management network on the BIG-IP(r) system by connecting from another network.

The management interface is available on all switch platforms and is designed for management purposes. You can access the browser-based Configuration utility and command line configuration utility through the management port. You cannot use the management interface in traffic management VLANs.

EXAMPLES

```
create management-route default gateway 10.10.10.254
```

Sets the management interface default gateway IP address to 10.10.10.254.

```
create management-route myMgmtRoute network 10.10.10.0/24 gateway
10.10.10.254
```

Creates a management route named myMgmtRoute for the subnet 10.10.10.0/24 whose gateway IP address is 10.10.10.254.

```
modify management-route 10.10.10.0/24 gateway 172.24.74.62
```

Changes the management interface to subnet 10.10.10.0/24, and the gateway to 172.24.74.62.

OPTIONS

default
Specifies that the system forwards packets to the destination through the default IP address and netmask, 0.0.0.0 0.0.0.0.

default-inet6
Specifies that the system forwards packets to the destination through the default version 6.0 IP address and netmask.

description
User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

[ip address/netmask]
Specifies the IP address and netmask through which the system forwards packets to the destination. You can use either of these formats: 0.0.0.0/0 or 0.0.0.0 0.0.0.0.

gateway
Specifies that the system forwards packets to the destination through the gateway with the specified IP address.

mtu Specifies the maximum transmission unit (MTU) for the management interface. The value of the MTU is the largest size that the BIG-IP system allows for an IP datagram passing through the management interface.

network
The subnet and netmask to be used for the route. This is an optional field; if empty the name should be of the form [ip address/netmask].

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

type Specifies that traffic should be delivered to the management interface (interface) or be dropped by the system (blackhole).

sys mcp-state

NAME
mcp-state - Displays information about the mcpd daemon.

MODULE
sys

SYNTAX
Display information about the mcpd daemon using mcp-state component within the sys module using the syntax in the following section.

DISPLAY
show mcp-state
options:
field-fmt

DESCRIPTION
You can use the mcp-state component to display the current state of the mcpd daemon.

EXAMPLES
show mcp-state

Displays, in a table, information about the state of the mcpd daemon.

show mcp-state field-fmt

Displays, in field format, information about the state of the mcpd daemon.

OPTIONS
For information about the options that you can use with the command show, see help show.

SEE ALSO
show, tmsh

COPYRIGHT

sys memory

NAME
memory - Displays system memory information and statistics.

MODULE
sys

SYNTAX
Configure the memory component within the sys module using the syntax in the following sections.

DISPLAY
show memory
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
global

DESCRIPTION
You can use the memory component to display information about the system memory.

EXAMPLES
show memory gig

Displays memory statistics in gigabytes.

show memory raw

Displays raw memory statistics.

OPTIONS
For information about the options that you can use with the command show, see help show.

sys nethsm async-queue-stat

NAME
async-queue-stat - Display or reset Network HSM pkcs11d daemon async queue statistics

MODULE
sys

SYNTAX
Display and reset the async-queue-stat component within the sys nethsm module using the syntax in the following section.

MODIFY
reset-stats async-queue-stat

DISPLAY
show async-queue-stat
options:
(default | field-fmt)

DESCRIPTION
You can use the async-queue-stat component to display Network HSM pkcs11d async-queue statistics like queued operations and queue times. You can also reset the Network HSM pkcs11d async-queue statistics to zero at any time.

OPTIONS
For information about the options that you can use with the command show, see help show.

For information about the options that you can use with the command reset-stats, see help reset-stats.

SEE ALSO

sys ntp

NAME

ntp - Configures the Network Time Protocol (NTP) daemon for the BIG-IP(r) system.

MODULE

sys

SYNTAX

Configure the ntp component within the sys module using the following syntax.

MODIFY

```
modify ntp
options:
  description [string]
  include [string]
  restrict [add | delete | replace-all-with] {
    [string] {
      address [IP address]
      default-entry [enabled | disable]
      description [string]
      ignore [enabled | disable]
      kod [enabled | disable]
      limited [enabled | disable]
      low-priority-trap [enabled | disable]
      mask [IP address]
      no-modify [enabled | disable]
      non-ntp-port [enabled | disable]
      no-peer [enabled | disable]
      no-query [enabled | disable]
      no-serve-packets [enabled | disable]
      no-trap [enabled | disable]
      no-trust [enabled | disable]
      ntp-port [enabled | disable]
      version [enabled | disable]
    }
  }
  restrict none
  servers [add | delete | replace-all-with] {
    [hostname | IP address] ...
  }
  servers none
  timezone [string]
```

edit ntp

```
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list ntp
list ntp [option]
show running-config ntp
show running-config ntp [option]
options:
  all-properties
  non-default-properties
  one-line
```

DESCRIPTION

You can use this component to configure the NTP servers for the system.

EXAMPLES

```
modify ntp servers add {192.168.1.245}
```

Adds the NTP server with the IP address, 192.168.1.245, to the system.

```
modify ntp servers replace-all-with {time.f5net.com}
```

Replaces the existing list of NTP servers with a single host, time.f5net.com.

```
modify ntp timezone "America/Los_Angeles"
```

Sets the system time to Pacific Standard Time.

```
modify ntp restrict add { basicrestrict { default-entry enable ignore
enable } }
```

Adds a default restriction denying all packets.

OPTIONS

description
User defined description.

include

Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using the include option. If you use this option incorrectly, you put the functionality of the system at risk.

restrict

Specifies a set of access restrictions.

address

The address for the entry. See also, the mask option. The

default value is 0.0.0.0.

default-entry
Specifies whether the entry is the default entry. The default value is disabled.

description
User defined description.

ignore
Specifies whether all packets will be ignored. The default value is disabled.

kod Specifies whether a kod (kiss of death) packet will be sent when an access violation occurs. The default value is disabled.

limited
Specifies whether service will be denied if packet spacing limits are violated. The default value is disabled.

low-priority-trap
Specifies whether lower priority traps will be overridden by normal priority traps. The default value is disabled.

mask The mask for the entry. See also, the address option. The default value is 0.0.0.0.

no-modify
Specifies whether ntpq and ntpdc queries that attempt to modify the server are allowed. The default value is disabled.

non-ntp-port
When enabled, the restrict entry will be matched only if the source port is not the standard NTP UDP port (123). The default value is disabled.

no-peer
Specifies whether packets will be denied if they mobilize a new association. The default value is disabled.

no-query
Specifies whether ntpq and ntpdc queries will be denied. The default value is disabled.

no-serve-packets
Specifies whether all queries except ntpq and ntpdc will be denied. The default value is disabled.

no-trap
Specifies whether to decline the mode 6 control message trap service to matching hosts. The default value is disabled.

no-trust
Specifies whether to reject packets that are not cryptographically authenticated. The default value is disabled.

ntp-port
When enabled, the restrict entry will be matched only if the source port is the standard NTP UDP port (123). The default value is disabled.

version
Specifies whether packets will be rejected if they do not match the local NTP version. The default values is disabled.

servers
Configures NTP servers for the BIG-IP system.

timezone
Specifies the time zone that you want to use for the system time.

sys outbound-smtp

NAME

outbound-smtp - Configures outgoing email for the BIG-IP(r) system.

MODULE
sys

SYNTAX
Configure the outbound-smtp component within the sys module using the following syntax.

MODIFY
modify outbound-smtp
options:
description [string]
from-line-override [string]
mailhub [string]
rewrite-domain [string]

edit outbound-smtp
options:
all-properties
non-default-properties

DISPLAY
list outbound-smtp
list outbound-smtp [option]
show running-config outbound-smtp
show running-config outbound-smtp [option]
options:
all-properties
non-default-properties
one-line

DESCRIPTION
You can use this component to configure the outgoing SMTP server that the system will use to send automated email.

EXAMPLES
modify outbound-smtp mailhub smtp.yoursite.com:587

Configures the TMOS system to send outgoing email through the specified SMTP server.

OPTIONS
description
User defined description.

from-line-override
Specify whether From field's domain can be overridden.

mailhub
The SMTP server to use to send outgoing automated email.

rewrite-domain
The domain name in the From address to use when sending outgoing automated email.

SEE ALSO

sys performance all-stats

NAME
all-stats - Resets or displays all performance statistics.

MODULE
sys performance

SYNTAX
Reset or display all performance statistics for the system within the sys_performance module using the syntax in the following sections. On VIPRION(r) systems, displaying performance statistics on a secondary blade is not supported.

MODIFY
reset-stats all-stats

DISPLAY
show all-stats
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

(detail | historical)

DESCRIPTION

You can use the all-stats component to reset or display all system performance statistics.

Note that tmsh only displays performance statistics when you explicitly request them.

EXAMPLES

show all-stats detail

Displays detailed information about system performance in the system default units.

reset-stats all-stats

Resets all performance statistics for the system.

OPTIONS

For information about the options that you can use with the command show, see help show.

For information about the options that you can use with the command reset-stats, see help reset-stats.

SEE ALSO

reset-stats, show, sys performance connections, sys performance gtm, sys performance ramcache, sys performance system, sys performance throughput, tmsh

BIG-IP 2012-10-19 sys performance all-stats(1)

sys performance connections

NAME

connections - Displays connection performance information.

MODULE

sys performance

SYNTAX

Display statistics for the connections component within the sys performance module using the syntax in the following section. On VIPRION(r) systems, displaying performance statistics on a secondary blade is not supported.

DISPLAY

show connections

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

(detail | historical)

DESCRIPTION

You can use the connections component to display information about system performance, including details about new and active connections and HTTP requests.

You can reset the connection performance statistics using the all-stats component.

EXAMPLES

show connections gig detail

Displays detailed information about connection performance in gigabytes.

show connections historical

Displays historical performance information about connections.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, sys performance all-stats, sys performance gtm, sys performance ramcache, sys performance system, sys performance throughput, tmsh

BIG-IP 2012-03-26 sys performance connections(1)

sys performance dnsexpress

NAME
dnsexpress - Displays performance information for the DNS-Express.

MODULE
sys performance

SYNTAX
Display statistics for the dnsexpress component within the sys performance module using the syntax in the following section. On VIPRION(r) systems, displaying performance statistics on a secondary blade is not supported.

DISPLAY
show dnsexpress
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
(historical)

DESCRIPTION
You can use the dnsexpress component to display information about system performance, including the number of queries, responses, zone transfer messages, and NOTIFYs.

EXAMPLES
show dnsexpress historical

Displays historical performance information for DNS-Express.

OPTIONS
For information about the options that you can use with the command show, see help show.

SEE ALSO
show, sys performance all-stats, sys performance connections, sys performance ramcache, sys performance system, sys performance throughput, tmsh

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2014-10-22 sys performance dnsexpress(1)

sys performance dnssec

NAME
dnssec - Displays performance information for the DNSSEC signing.

MODULE
sys performance

SYNTAX
Display statistics for the dnssec component within the sys performance module using the syntax in the following section. On VIPRION(r) systems, displaying performance statistics on a secondary blade is not supported.

DISPLAY
show dnssec
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

(historical)

DESCRIPTION

You can use the dnssec component to display information about system performance, including the number of queries for specific DNSSEC types and zone transfer signing.

EXAMPLES

show dnssec historical

Displays historical performance information for DNSSEC signing.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, sys performance all-stats, sys performance connections, sys performance ramcache, sys performance system, sys performance throughput, tmsb

BIG-IP 2014-10-22 sys performance dnssec(1)

sys performance gtm

NAME

gtm - Displays performance information for the Global Traffic Manager.

MODULE

sys performance

SYNTAX

Display statistics for the gtm component within the sys performance module using the syntax in the following section. On VIPRION(r) systems, displaying performance statistics on a secondary blade is not supported.

DISPLAY

show gtm

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
(detail | historical)

DESCRIPTION

You can use the gtm component to display information about system performance, including details about the Global Traffic Manager, including number of requests, resolutions, persisted connections, and those returned to DNS.

You can reset the Global Traffic Manager performance statistics using the all-stats component.

EXAMPLES

show gtm detail

Displays detailed performance information about the Global Traffic Manager in the system default units.

show gtm historical

Displays historical performance information about the Global Traffic Manager.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, sys performance all-stats, sys performance connections, sys performance ramcache, sys performance system, sys performance throughput, tmsb

COPYRIGHT

F5 Networks and BIG-IP (c) Copyright 2008-2010. All rights reserved.

sys performance ramcache

NAME
ramcache - Displays RAM cache performance information.

MODULE
sys performance

SYNTAX
Display statistics for the ramcache component within the sys performance module using the syntax in the following section. On VIPRION(r) systems, displaying performance statistics on a secondary blade is not supported.

DISPLAY
show ramcache
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
historical

DESCRIPTION
You can use the ramcache component to display RAM cache utilization information.

You can reset the RAM cache performance statistics using the all-stats component.

EXAMPLES
show ramcache default

Displays ramcache performance information in the system default units.

show ramcache historical

Displays historical ramcache performance information.

OPTIONS
For information about the options that you can use with the command show, see help show.

SEE ALSO
show, sys performance all-stats, sys performance connections, sys performance gtm, sys performance system, sys performance throughput, tmsh

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

sys performance system

NAME
system - Displays system performance information.

MODULE
sys performance

SYNTAX
Display statistics for the system component within the sys performance module using the syntax in the following section. On VIPRION(r) systems, displaying performance statistics on a secondary blade is not supported.

DISPLAY
show system
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
(detail | historical)

DESCRIPTION

You can use the system component to display CPU and memory usage information.

You can reset the system performance statistics using the all-stats component.

EXAMPLES

show system detail

Displays detailed system performance information in the system default units.

show system historical

Displays historical system performance information.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, sys performance all-stats, sys performance connections, sys performance gtm, sys performance ramcache, sys performance throughput, tmsh

BIG-IP 2012-03-26 sys performance system(1)

sys performance throughput

NAME

throughput - Displays performance information about traffic throughput.

MODULE

sys performance

SYNTAX

Display statistics for the throughput component within the sys performance module using the syntax in the following section. On VIPRION(r) systems, displaying performance statistics on a secondary blade is not supported.

DISPLAY

show throughput

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
(detail | historical)

DESCRIPTION

You can use the throughput component to display information about traffic throughput, including client, server, compression, and SSL transactions.

You can reset the throughput performance statistics using the all-stats component.

EXAMPLES

show throughput gig detail

Displays detailed throughput performance information in gigabits per second.

show throughput historical

Displays historical throughput performance information.

OPTIONS

For information about the options that you can use with the command show, see help show.

SEE ALSO

show, sys performance all-stats, sys performance connections, sys performance gtm, sys performance ramcache, sys performance system, tmsh

sys pfman consumer

NAME
consumer - Manage the state of pfman health status consumers.

MODULE
sys pfman

SYNTAX
Manage pfman administered consumers using the syntax in the following section.

MODIFY
modify consumer [guest-name]
parameter:
state [up|down|reset]

DISPLAY
list consumer
list consumer [guest-name]

DESCRIPTION
You can use the consumer component to manage the state of guest access to device health status services.

EXAMPLES
modify consumer tesseract-guest down

Transitions to 'down' the communication link between the hypervisor and guest pfmand daemons. When 'down', the guest is unable to send requests to the hypervisor, nor will it receive status updates.

modify consumer tesseract-guest up

Transitions to 'up' the communication link between the hypervisor and guest pfmand daemons. When 'up', the guest can send requests to the hypervisor, and receive status updates.

modify consumer tesseract-guest reset

Transitions to 'down', then to 'up', the communication link between the hypervisor and guest pfmand daemons.

list consumer tesseract-guest

Lists the current status of the guest called "tesseract-guest".

list consumer

Lists the current status of all guests.

SEE ALSO
list, modify, tmsh

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

sys pfman device

NAME
device - Manage the state of a pfman controlled device status.

MODULE
sys pfman

SYNTAX
Manage pfman administered devices using the syntax in the following section.

MODIFY
modify device [pci_device]
parameter:
state [up|down|reset]

DISPLAY
list device
list device [pci_device]

DESCRIPTION
You can use the device component to manage the state of device reset and health status reporting.

EXAMPLES
modify device 04:00.0 down

This will cause pfmand to "down" the device. A device in the "down" state will not return to use until the device returns to "up" status. All associated tmm instances will be informed of the device status change to "down".

modify device 86.00.0 up

This causes pfmand to attempt to bring a "down" device back to the "up" status. When successful, all associated tmm instances will be informed of the device status change to "up".

modify device 86:00.0 reset

Instructs pfmand to issue a reset of device 86:00.0.

list device 85:00.0

Lists the status of device 85:00.0.

list device

Lists the status of all devices.

SEE ALSO
list, modify, tmsh

BIG-IP 2016-04-21 sys pfman device(1)

sys proc-info

NAME
proc-info - Display CPU and memory usage for each process.

MODULE
sys

SYNTAX
Display proc-info component within the sys module using the syntax in the following section.

DISPLAY
show proc-info
show proc-info process_name
options:
(default | field-fmt | all | kil | meg | gig | raw | exa | peta | tera | zetta | yotta)

DESCRIPTION
Show proc-info displays CPU and memory usage for each process and the process associated module name. This can be used to debug which process or module uses more resource.

OPTIONS
For information about the options that you can use with the command show, see help show.

SEE ALSO
show, tmsh

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying,

recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2008-2011. All rights reserved.

BIG-IP 2011-02-16 sys proc-info(1)

sys provision

NAME
provision - Configures provisioning on the BIG-IP(r) system.

MODULE
sys

SYNTAX
Configure the provision component within the sys module using the syntax in the following sections.

MODIFY
modify provision [afm | am | apm | asm | avr | fps | gtm | ilx | lc | ltm | pem | swg | urldb | sslo | vcmp]
options:
cpu-ratio [integer]
disk-ratio [integer]
level [custom | dedicated | minimum | nominal | none]
memory-ratio [integer]

edit provision
[[[afm | am | apm | asm | avr | fps | gtm | ilx | lc | ltm | pem | swg | urldb | sslo | vcmp] [glob] | [regex]] ...]
options:
all-properties
non-default-properties

DISPLAY
list provision
[[[afm | am | apm | asm | avr | fps | gtm | ilx | lc | ltm | pem | swg | urldb | sslo | vcmp] [glob] | [regex]] ...]
show running-config provision
[[[afm | am | apm | asm | avr | fps | gtm | ilx | lc | ltm | pem | swg | urldb | sslo | vcmp] [glob] | [regex]] ...]
options:
all-properties
non-default-properties
one-line

DESCRIPTION
You can use the provision component to modify the allocation of resources to the licensed modules on your system.

EXAMPLES
modify provision asm level minimum
Provisions the minimum amount of resources for the BIG-IP Application Security Manager.

list provision
Displays the current provisioning of the system.

Using Transactions
1. create / cli transaction
2. modify / sys provision ltm level minimum
3. modify / sys provision gtm level nominal
4. submit / cli transaction

The previous four steps create a transaction to modify the provisioning of a unit to provision the Local Traffic Manager at the minimum level and the Global Traffic Manager at the nominal level.

1. create / cli transaction
2. modify / sys provision ltm level none
3. modify / sys provision gtm level dedicated
4. submit / cli transaction

The previous four steps create a transaction to modify the provisioning of a unit to dedicate all of the unit's resources to the Global Traffic Manager when currently only the Local Traffic Manager is provisioned.

OPTIONS
afm Specifies that you are provisioning the BIG-IP Advanced Firewall Manager. When the Advanced Firewall Manager is provisioned, the tmsh module security is enabled.

am Specifies that you are provisioning the BIG-IP Acceleration Manager. When the Acceleration Manager is provisioned, the tmsh module wam is enabled and more tmsh components under wom are available.

apm Specifies that you are provisioning the BIG-IP Access Policy Manager. When the Access Policy Manager is provisioned, the tmsh module **apm** is enabled.

asm Specifies that you are provisioning the BIG-IP Application Security Manager. When **asm** is provisioned the tmsh module **asm** is enabled.

avr Specifies that you are provisioning the BIG-IP Application Visibility and Reporting. When Application Visibility and Reporting is provisioned the tmsh module **analytics** is enabled.

cpu-ratio
Use this option only when the level option is set to custom. F5 Networks recommends that you do not modify this option. The default value is none.

disk-ratio
Use this option only when the level option is set to custom. F5 Networks recommends that you do not modify this option. The default value is none.

fps Specifies that you are provisioning the BIG-IP Fraud Protection Service. When **fps** is provisioned the tmsh module **security anti-fraud** is enabled.

glob Displays the items that match the glob expression. See help **glob** for a description of glob expression syntax.

gtm Specifies that you are provisioning the BIG-IP Global Traffic Manager. When **gtm** is provisioned the tmsh module **gtm** is enabled.

ilx Specifies that you are provisioning BIG-IP iRules Language Extensions.

lc Specifies that you are provisioning the BIG-IP Link Controller. When Link Controller is provisioned the tmsh module **gtm** is enabled.

level
Specifies the level of resources that you want to provision for a module. The options are:

custom
F5 Networks does not recommend that you specify this level.

dedicated
Specifies that all resources are dedicated to the module you are provisioning. For all other modules, the level option must be set to none.

minimum
Specifies that you want to provision the minimum amount of resources for the module you are provisioning.

nominal
Specifies that you want to share all of the available resources equally among all of the modules that are licensed on the unit.

none Specifies that you do not want to provision any resources for this module.

ltm Specifies that you are provisioning the BIG-IP Local Traffic Manager.

memory-ratio
Use this option only when the level option is set to custom. F5 Networks recommends that you do not modify this option. The default value is none.

pem Specifies that you are provisioning the BIG-IP Policy Enforcement Manager. When Policy Enforcement Manager is provisioned the tmsh module **pem** is enabled.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help **regex** for a description of regular expression syntax.

swg Specifies that you are provisioning the BIG-IP Secure Web Gateway. When Secure Web Gateway is provisioned, the assumption is that Access Policy Management is already provisioned and tmsh component **apm url-filter** is enabled;

urldb
Specifies that you are provisioning the BIG-IP Secure Web Gateway with minimum resource mode. Mainly used for SSL orchestration use cases. The tmsh module **urldb** cannot be provisioned in BIG-IP when the tmsh module **swg** is already provisioned and vice-versa.

sslo Specifies that you are provisioning the BIG-IP SSL Orchestrator.

vcmp Specifies that you are provisioning the BIG-IP Virtual CMP. When Virtual CMP is provisioned the tmsh module **vcmp** is enabled.

SEE ALSO

edit, glob, list, modify, regex, show, tmsh

sys pva-traffic

NAME
pva-traffic - Displays and resets Packet Velocity(r) ASIC (PVA) traffic statistics for the system.

MODULE
sys

SYNTAX
Configure the pva-traffic component within the sys module using the following syntax.

MODIFY
reset-stats pva-traffic

DISPLAY
show pva-traffic
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
global

DESCRIPTION
You can use the pva-traffic component to display traffic statistics, including bits in and out, packets in and out, current, maximum, and total connections, and other miscellaneous statistics.

The BIG-IP(r) system has one PVA accelerator; however, when you run the command show pva-traffic, the system displays a PVA statistics entry for each Traffic Management Microkernel (TMM).

EXAMPLES
show pva-traffic

Displays PVA traffic statistics for the system.

show pva-traffic raw

Displays PVA traffic statistics for the system in raw data form.

OPTIONS
For information about the options that you can use with the command show, see help show.

For information about the command reset-stats, see help reset-stats.

SEE ALSO
reset-stats, show, sys tmm-traffic, sys traffic, tmsh

BIG-IP 2011-04-25 sys pva-traffic(1)

sys raid array

NAME
array - Configures an array of hard disks on the BIG-IP(r) system.

MODULE
sys raid

SYNTAX
Configure the array component within the sys raid module using the

syntax in the following sections.

```
MODIFY
modify array [name] [ [add | remove] [hard disk name] ]

DISPLAY
show array
show array [name]
options:
field-fmt

DESCRIPTION
You can use the array component to add a hard disk to or remove a hard
disk from an array of disks, or to display information about an array
of disks.

EXAMPLES
show array

Displays information about all of the arrays that are configured on the
system.

modify array MD1 remove HD2

Removes hard disk, HD2 from array, MD1.

OPTIONS
hard disk name
Specifies the name of the hard disk that you want to add to or
remove from the array. This option is required for the command
modify.

name Specifies the name of the array. This option is required for the
command modify.

SEE ALSO
modify, show, tmsh

BIG-IP      2010-03-11      sys raid array(1)
```

sys raid bay

```
NAME
bay - Manages a BIG-IP(r) system disk drive bay.

MODULE
sys raid

SYNTAX
Manage the bay component within the sys raid module using the syntax in
the following sections.

MODIFY
modify bay [1 | 2]
options:
flash-led
no-flash-led

DISPLAY
show bay [1 | 2]
options:
field-fmt

DESCRIPTION
You can use the bay component to display information about a system
bay, signal the LED on a bay to flash, or signal the LED on a bay to
stop flashing. The LED is helpful for identifying the location of a
specific disk, see sys raid disk.

EXAMPLES
modify bay 1 flash-led

Signal the system to make the LED on bay 1 flash.

show bay

Displays information about the system bay.

show bay field-fmt

Displays information about the system bay in a field format.
```

OPTIONS

flash-led
Signal the LED on the bay to flash.

no-flash-led
Signal the LED on the bay to stop flashing.

For information about the field-fmt option, see help show.

SEE ALSO

BIG-IP 2011-08-29 sys raid bay(1)

sys raid disk

NAME

disk - Displays information about the BIG-IP(r) system disks.

MODULE

sys raid

SYNTAX

Display information about the disk component within the sys raid module using the syntax in the following sections.

DISPLAY

```
show disk [name]
options:
  field-fmt
  all-properties
```

DESCRIPTION

You can use the disk component to display information about the system disks including name, serial number, and whether the disk is a member of an array of disks. When "all-properties" option is specified, the media wear-out information of the disk is also shown. This include the wear-out indicator, space available, power-on hours, and estimated remaining life.

EXAMPLES

```
show disk
```

Displays information about all of the system disks.

```
show disk HD1 field-fmt
```

Displays information, in a field format, about disk, HD1.

```
show disk SSD1 all-properties
```

Displays all information (including the media wear-out information) about disk, SSD1.

OPTIONS

name Specifies the name of the disk for which you want to display information.

SEE ALSO

show, tmsh

COPYRIGHT

sys ready

NAME
ready - Display the ready status for processing config/license/provision commands.

MODULE
sys

SYNTAX
Display the ready status for processing config/license/provision commands using the syntax in the following section.

DISPLAY
show ready
options:
field-fmt

DESCRIPTION
You can use the ready component to display whether or not the BIG-IP is ready to handle actions such as:

config
Adding or modifying the system's configuration, such as adding a pool member.

license
Apply or update licensing.

provision
Modify resource provisioning, such as enabling or disabling modules

EXAMPLES
show ready

```
-----  
Sys::BIG-IP Ready:  
-----  
config      yes  
license     yes  
provision   yes  
  
show ready field-fmt  
  
sys bigip-ready {  
  config-ready yes  
  license-ready yes  
  provision-ready yes  
}
```

OPTIONS
For information about the options that you can use with the command show, see help show.

SEE ALSO
show, tmsh

COPYRIGHT

BIG-IP 2017-05-18 sys ready(1)

sys scriptd

NAME
scriptd - Configure the scriptd daemon

MODULE
sys

SYNTAX
Configure the scriptd daemon within the sys module using the syntax in the following sections.

MODIFY
modify scriptd
options:
log-level [alert | crit | debug | emerg | err | info | notice | warn]
max-script-run-time [seconds]

DISPLAY

```
list scriptd
show running-config scriptd
options:
  all-properties
```

DESCRIPTION

You can use the scriptd component to configure the scriptd daemon. The scriptd daemon runs app application template implementation scripts when an application service is created or updated (see sys application template and sys application service).

EXAMPLES

```
list scriptd

Displays scriptd configuration.

modify scriptd max-script-run-time 120

Updates the maximum time, in seconds, that a script is allowed to run.
```

OPTIONS

log-level
Specifies the syslog level at which scriptd will generate log messages.

max-script-run-time
Specifies, in seconds, the maximum amount of time that a script is allowed to run before scriptd will kill the script. The default value is 300. The minimum value is 5.

SEE ALSO

list, modify, show, sys application template, sys application service, tmsh

BIG-IP 2012-04-19 sys scriptd(1)

sys service

NAME

service - Manages services on the BIG-IP(r) system.

MODULE

sys

SYNTAX

Configure the service component within the sys module using the syntax in the following sections.

MODIFY

```
modify service [name]
options:
  [add | disable | enable | reinit | remove]
```

```
restart service [name]
```

```
start service [name]
```

```
stop service [name]
```

```
options:
```

```
  force
```

DISPLAY

```
list service
```

```
list service [name]
```

```
show running-config service
```

```
show running-config service [name]
```

```
options:
```

```
  all-properties
```

```
show service
```

```
options:
```

```
  memstat
```

DESCRIPTION

You can use the service component to add, disable or enable, start, stop, restart, reinitialize, remove, or display information about a service.

Note that the tmsh connection to mcpd will be dropped if you stop or restart the mcpd service. The next tmsh command will prompt you to try again. Alternatively you can quit tmsh and login again.

EXAMPLES

```
list service
```

Displays information about the services available on the BIG-IP system.

restart service mcpd

Restarts the mcpd daemon.

OPTIONS

add Adds the specified service.

disable

Disables the specified service.

enable

Enables the specified service.

memstat

Displays memory usage statistics for the specified service.

reinit

Reinitializes the specified service.

remove

Removes the specified service.

SEE ALSO

list, modify, restart, show, start, stop, tmsh

sys sflow data-source http

NAME

http - Displays the status of all HTTP sFlow data sources on the BIG-IP system.

MODULE

sys sflow data-source

SYNTAX

Display the status of http component within the sys sflow data-source module using the syntax shown in the following sections.

DISPLAY

show http

options:

all-properties

field-fmt

DESCRIPTION

You can use the http component to display the current status of all HTTP sFlow data sources on the BIG-IP system.

EXAMPLES

show http

Displays the current status of all HTTP sFlow data sources.

SEE ALSO

sys sflow global-settings http

NAME
http - Manages the global HTTP sFlow configuration on the BIG-IP system.

MODULE
sys sflow global-settings

SYNTAX
Configure the http component within the sys sflow global-settings module using the syntax shown in the following sections.

MODIFY
modify http
options:
description [string]
poll-interval [integer]
sampling-rate [integer]

DISPLAY
list http
options:
all-properties
non-default-properties
one-line

DESCRIPTION
You can use the http component to modify or list the global HTTP sFlow configuration on the BIG-IP system.

Note: You can modify the global HTTP sFlow configuration on the BIG-IP system, only if you are assigned either the Resource Administrator or Administrator user role.

EXAMPLES
modify http poll-interval 60 sampling-rate 1500

Sets the poll-interval to 60 seconds and the sampling-rate to 1500 packets for all monitored HTTP data sources on the BIG-IP system.

OPTIONS

description
User defined description.

poll-interval
Specifies the maximum interval in seconds between polling by the sFlow agent of all monitored HTTP data sources on the BIG-IP system. The default value is 10.

sampling-rate
Specifies the ratio of packets observed at all HTTP data sources to the samples generated. For example, a sampling rate of 2000 specifies that 1 sample will be randomly generated for every 2000 packets observed. The default value is 1024.

sys sflow receiver

NAME
receiver - Manages sFlow receivers configured on the BIG-IP system.

MODULE
sys sflow

SYNTAX
Configure the receiver component within the sys sflow module using the syntax shown in the following sections.

```
CREATE/MODIFY
create receiver [name]
modify receiver [name]
options:
  address [ip address]
  app-service [[string] | none]
  description [string]
  max-datagram-size [integer]
  port [ip port]
  state [disabled | enabled]
```

```
DISPLAY
list receiver
list receiver [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  one-line
```

DELETE

delete receiver [name]

DESCRIPTION

You can use the receiver component to create, delete, list, or modify an sFlow receiver object on the BIG-IP system.

Note: You can add an sFlow receiver to the BIG-IP system, only if you are assigned either the Resource Administrator or Administrator user role.

EXAMPLES

```
create receiver my_receiver address 10.10.10.10
```

Creates an sFlow receiver object named `my_receiver` with an IP address of 10.10.10.10, where the port, max-datagram-size, and state options are set to default values.

```
create receiver my_receiver address 10.20.10.20 port 1234 state enabled
```

Creates an sFlow receiver object named `my_receiver` with an IP address of 10.20.10.20, a port of 1234, and the max-datagram-size option set to default value. The state of the receiver is enabled.

```
modify receiver my_receiver state enabled
```

Changes the state of sFlow receiver object named `my_receiver` to enabled.

OPTIONS

address

Specifies the IP address on which the sFlow receiver listens for UDP datagrams. This option is required for the create command.

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

max-datagram-size

Specifies the maximum size in bytes of the UDP datagram the sFlow receiver accepts. The default value is 1400.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

port Specifies the port on which the sFlow receiver listens for UDP datagrams. The default value is the standard sFlow port, 6343.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

state

Specifies the state of the receiver. The sFlow samples will be collected and sent to the receiver when enabled. The default value is disabled.

sys smtp-server

NAME

smtp-server - Configure the SMTP server connection.

MODULE

sys

SYNTAX

Create or modify an SMTP server access configuration using the syntax

in the following sections.

```
CREATE / MODIFY
modify smtp-server [name]
create smtp-server [name]
options:
  app-service [[string] | none]
  [authentication-enabled | authentication-disabled]
  encrypted-connection [none | tls | ssl]
  local-host-name [string]
  smtp-server-host-name [string]
  smtp-server-port [integer]
  from-address [string]
  username [string]
  password [string]
```

```
DISPLAY
list smtp-server
show running-config smtp-server
options:
  all-properties
```

DESCRIPTION
You can use the smtp-server component to configure an SMTP server connection.

EXAMPLES
list smtp-server

Displays the SMTP configuration.

```
modify smtp-server smtp1 authentication-enabled encrypted-connection
ssl local-host-name example.f5.com from-address example@f5.com smtp-
server-host-name mail.server.com username user password pass
```

Configures SMTP server connection with username=user and password=pass to be authenticated against the SMTP server mail.server.com. SSL encryption will be used for all communication with the SMTP server. Email messages will be sent out with the address example@f5.com in the "Reply-To" address.

OPTIONS

app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

[authentication-enabled | authentication-disabled]
Enables or disables authentication against the configured SMTP server.

encrypted-connection
Specifies which type of encrypted connection the SMTP server requires in order to send mail. The default value is none.

local-host-name
Specifies the host name used in SMTP headers in the format of a fully qualified domain name. This setting does not refer to the BIG-IP system's Hostname.

smtp-server-host-name
Specifies the SMTP server host name in the format of a fully qualified domain name.

smtp-server-port
Specifies the SMTP port number. The default value is 25.

from-address
Specifies the email address that the email is being sent from. This is the "Reply-to" address that the recipient sees.

username
Specifies the user name that the SMTP server requires when validating a user.

password
Specifies the password that the SMTP server requires when validating a user. This password is stored in an encrypted form.

  non-default-properties
  one-line

```

DESCRIPTION

You can use the snmp component to configure the snmpd daemon for the BIG-IP system.

Important: F5 Networks recommends that users of the Configuration utility exit the utility before changes are made to the system using the command sequence `tmsch sys snmp`. This is because making changes to the system using this command causes a restart of the snmpd daemon. Likewise, restarting the snmpd daemon creates the necessity for a restart of the Configuration utility.

EXAMPLES

```
modify snmp sys-contact admin@company.com
```

Modifies the configuration to indicate that the person who administers the snmpd daemon for the system can be reached using the email address, `admin@company.com`.

```
modify snmp sys-location "central office"
```

Modifies the configuration to indicate that the physical location of the system is the central office.

```
modify snmp snmpv1 disabled
```

Disables snmpV1 agent support.

```
modify snmp snmpv2c disabled
```

Disables snmpV2c agent support.

```
modify snmp agent-trap disabled
```

Disables agent traps.

```
modify snmp allowed-addresses add {10.10.0.0/255.255.240.0}
```

Adds a range of SNMP clients to the `/etc/hosts.allow` file.

```
modify snmp traps add { tv1 { version 1 community public host
192.168.1.240 port 162 } }
```

Adds an SNMP version 1 trapsess, `tv1`, to the system. The destination IP address of `tv1` is `192.168.1.240`, the port is `162`, and the community that has access to `tv1` is `public`. The default port is `162`.

```
modify snmp traps add { tv2 {version 2c community public host
192.168.1.241 port 162} }
```

Adds an SNMP version 2 trapsess, `tv2`, to the system. The destination IP address of `tv2` is `192.168.1.241`, the port is `162`, and the community that has access to `tv2` is `public`. The default port is `162`. The default version is `2c` (version 2).

```
modify snmp traps add { trap_v3_1 { version 3 host 192.168.1.242 port
162 security-level auth-no-privacy security-name mySecurityName auth-
protocol md5 auth-password myAuthPassword } }
```

Adds an SNMP version 3 trapsess, trap_v3_1, with authentication capabilities to the system. The destination IP address of trap_v3_1 is 192.168.1.242, the port is 162, the security level is the authentication without privacy, the security name is mySecurityName, the authentication protocol is MD5, and the authentication password is myAuthPassword. The default port is 162.

```
modify snmp traps add { trap_v3_2 { version 3 host 192.168.1.243 port 162 security-level auth-privacy security-name mySecurityName auth-protocol sha auth-password myAuthPassword privacy-protocol aes privacy-password myPrivacyPassword } }
```

Adds an SNMP version 3 trapsess, trap_v3_2, with authentication and privacy capabilities to the system. The destination IP address of trap_v3_2 is 192.168.1.243, the port is 162, the security level is the authentication and privacy, the security name is mySecurityName, the authentication protocol is SHA, the authentication password is myAuthPassword, the privacy protocol is AES, and the privacy password is myPrivacyPassword. The default port is 162.

```
modify snmp v1-traps add { ts { community public host 10.20.5.11 port 162 } }
```

Adds an SNMP version 1 trapsink, ts, to the system. The destination IP address of ts is 10.20.5.11, the port is 162, and the community that has access to ts is public. The default port is 162.

```
modify snmp v2-traps add { t2s { community public host 10.20.5.12 port 162 } }
```

Adds an SNMP version 2 trap2sink, t2s, to the system. The destination IP address of t2s is 10.20.5.12, the port is 162, and the community that has access to t2s is public. The default port is 162.

```
modify snmp users add { myUser1 { username myUser1 access ro security-level auth-no-privacy auth-protocol md5 auth-password myAuthPassword privacy-protocol } }
```

Adds an SNMP version 3 user with the user name, myUser1, to the system. The access to the management information base (MIB) of myUser1 is read-only, the security level is the authentication without privacy, the authentication protocol is MD5, and the authentication password is myAuthPassword.

```
modify snmp users add { myUser2 { username myUser2 oid-subset .1.3.6.1.4.1.3375 auth-protocol md5 auth-password myAuthPassword privacy-protocol none } }
```

Adds an SNMP version 3 user with the user name, myUser2, to the system. The access to the management information base (MIB) of myUser2 is read-only (by default) and restricted to every object below .1.3.6.1.4.1.3375 object identifier in the MIB tree, the security level is the authentication without privacy, the authentication protocol is MD5, and the authentication password is myAuthPassword.

```
modify snmp users add { myUser3 { username myUser3 access ro security-level auth-privacy auth-protocol sha auth-password myAuthPassword privacy-protocol des privacy-password myPrivacyPassword } }
```

Adds an SNMP version 3 user with the user name, myUser3, to the system. The access to the management information base (MIB) of myUser3 is read-only, the security level is the authentication and privacy, the authentication protocol is SHA, the authentication password is myAuthPassword, the privacy protocol is DES, and the privacy password is myPrivacyPassword.

```
modify snmp users add { myUser4 { username myUser4 access ro security-level no-auth-no-privacy auth-protocol none privacy-protocol none } }
```

Adds an SNMP version 3 user with the user name, myUser4, to the system. The access to the management information base (MIB) of myUser4 is read-only without the authentication and privacy settings.

```
modify snmp communities add { community1 { community-name mycommunity access ro source 192.168.1.246 oid-subset 5 ipv6 disabled } }
```

Creates a community specification named community1 for the BIG-IP system. community1 includes a community, named mycommunity, that provides read-only access to the host at 192.168.1.246. This host cannot be an IPv6 address. The oid for this community is 5.

```
modify snmp communities add { new-name { community-name public source default oid-subset 1 access ro } }
```

Replaces the default community specification for the BIG-IP system. Using this command, the default community includes a community, named public, that provides read-only access to the default host. The oid for this community is 1.

```
modify snmp communities delete { mycommunity }
```

Deletes the community named mycommunity.

```
modify snmp load-max1 0 load-max5 0 load-max15 0
```

Disables monitoring of snmpd load average on the BIG-IP system.

OPTIONS

snmpv1
Specifies, when enabled, that the snmpd daemon supports snmpV1 queries. The default value is enabled.

snmpv2c
Specifies, when enabled, that the snmpd daemon supports snmpV2c

queries. The default value is enabled.

agent-addresses

Indicates that the SNMP agent is to listen on the specified address. F5 Networks recommends that you do not change this setting without fully understanding the impact of the change.

agent-trap

Specifies, when enabled, that the snmpd daemon sends traps, for example, start and stop traps. The default value is enabled.

allowed-addresses

Configures the IP addresses of the SNMP clients from which the snmpd daemon accepts requests. An SNMP client is a system that runs the SNMP manager software for the purpose of remotely managing the BIG-IP system. The default value is 127.

auth-trap

Specifies, when enabled, that the snmpd daemon generates authentication failure traps. The default value is disabled.

bigip-traps

Specifies, when enabled, that the BIG-IP system sends device warning traps to the trap destinations. The default value is enabled.

community

Configures a community for the snmpd daemon. Note that you must include a community key, and you must enclose the attributes in braces.

The options are additive and include:

access

Specifies the community access level to the MIB. The access options are ro (read-only) or rw (read-write). The default value is ro.

community name

Specifies the name of the community that you are configuring for the snmpd daemon. This option is required. The default value is public.

description

User defined description.

ipv6 Specifies to enable or disable IPv6 addresses for the community that you are configuring. The default value is disabled.

oid-subset

Specifies to restrict access by the community to every object below the specified object identifier (OID).

source

Specifies the source addresses with the specified community name that can access the management information base (MIB). The default value is default, which means allow any source address to access the MIB.

description

User defined description.

disk-monitors

Checks the disks mounted at the specified path for available disk space.

The options are:

description

User defined description.

minspace

Specifies the minimum disk space threshold in either kB or percentage based on the value of the minspace-type option. If the available disk space is less than this amount, the associated entry in the 1.3.6.1.4.1.2021.9.1.100 MIB table is set to (1) and a descriptive error message is returned to queries of 1.3.6.1.4.1.2021.9.1.101.

minspace-type

Specifies a minimum disk space measurement type of either size in kB, or percent. Note that the value of the minspace option is based on the value of this option.

path Specifies the path to the disk that the system checks for disk space. This option is required.

include

Warning: Do not use this parameter without assistance from the F5 Technical Support team. The system does not validate the commands issued using the include parameter. If you use this parameter incorrectly, you put the functionality of the system at risk.

l2forward-vlan

Specifies the VLANs for which you want the snmpd daemon to expose Layer 2 forwarding information. Layer 2 forwarding is the means by which frames are exchanged directly between hosts, with no IP routing required. The default value is none.

The options are:

all The snmpd daemon exposes Layer 2 forwarding information for all VLANs.

Warning: When you set this option to all, the system can create a very large table of statistics and potentially affect system performance.

none Indicates that this option is not set.

Important: The default is not the same as setting this option to the string "none," which indicates that you do not want the snmpd daemon to expose Layer 2 forwarding for any VLAN.

VLAN name

Specifies the names of the VLANs for which the snmpd daemon exposes Layer 2 forwarding information. The snmpd daemon overwrites the value of the sysL2ForwardAttrVlan object identifier (OID) with the specified VLAN names. Once you set this parameter, users cannot change the value of the sysL2ForwardAttrVlan OID using the SNMP set method.

load-max1

Specifies the maximum 1-minute load average of the machine. If the load exceeds this threshold, the associated entry in the 1.3.6.1.4.1.2021.10.1.100 MIB table is set to (1) and a descriptive error message is returned to queries of 1.3.6.1.4.1.2021.10.1.101.

Note that when you specify a 0 (zero) for all three of the load-max1, load-max5, and load-max15 options, the system does not monitor the load average.

load-max5

Specifies the maximum 5-minute load average of the machine. If the load exceeds this threshold, the associated entry in the 1.3.6.1.4.1.2021.10.1.100 MIB table is set to (1) and a descriptive error message is returned to queries of 1.3.6.1.4.1.2021.10.1.101.

Note that when you specify a 0 (zero) for all three of the load-max1, load-max5, and load-max15 options, the system does not monitor the load average.

load-max15

Specifies the maximum 15-minute load average of the machine. If the load exceeds this threshold, the associated entry in the 1.3.6.1.4.1.2021.10.1.100 MIB table is set to (1) and a descriptive error message is returned to queries of 1.3.6.1.4.1.2021.10.1.101.

Note that when you specify a 0 (zero) for all three of the load-max1, load-max5, and load-max15 options, the system does not monitor the load average.

process-monitors

Specifies to check the machine to determine if the specified process is running. An error flag (1) and a description message are passed to the 1.3.6.1.4.1.2021.2.1.100 and 1.3.6.1.4.1.2021.2.1.101 MIB columns (respectively) if the specified program is not found in the process table as reported by /bin/ps -e.

F5 Networks recommends that you do not modify or delete system processes; however, you can add, modify, or delete user-defined processes.

The options are:

description

User defined description.

max-processes

Specifies the maximum number of instances of the process that can run. The default value is 1.

If you do not specify values for the min-processes and max-processes options, the max-processes option is 1 by default.

min-processes

Specifies the minimum number of instances of the process that can run. The default value is 1.

If you do not specify a value for the max-processes option, and the min-processes option is not specified, the min-processes option is 0 (zero) by default.

process

Specifies the name of the monitored process. The maximum length for a process name is 16 characters. This option is required.

sys-contact

Specifies the name of the person who administers the snmpd daemon for this system. The default value is "Customer Name"

sys software block-device-hotfix

NAME
block-device-software-hotfix - Manages F5 Networks block device software hotfixes.

MODULE
sys software

SYNTAX
Install or display information about a block-device-hotfix using the syntax in the following sections.

INSTALL
install block-device-hotfix [name] volume [name]
options:
create-volume
reboot

DISPLAY
list block-device-hotfix
list block-device-hotfix [[[name [/slot_id]] | [glob] | [regex]] ...]
options:
build
checksum
device-agent
id
one-line
product
title
resource-id
verified
version

DESCRIPTION
You can use the block-device-hotfix component to install a block-device-hotfix onto a volume, or view information about available block-device-hotfixes.

Use the create-volume option with the block-device-hotfix component to create new volumes.

Note: You use the slot_id option only for chassis systems and only when displaying the values for the options of a specific block-device-hotfix. You do not use the slot_id option when installing or deleting a block-device-hotfix, because these commands operate on all blades or the entire system.

EXAMPLES
list block-device-hotfix Hotfix-BIGIP-11.4.0-2419.0-HF3.iso
Displays information about the specified block-device-hotfix, BIGIP-9.6.1-824.0-HF3.im.
list block-device-hotfix */1
Displays information about the all the block-device-hotfixes on the first slot.
install block-device-hotfix Hotfix-BIGIP-11.4.0-2419.0-HF3.iso volume HD1.1 reboot
Attempts to install the specified block-device-hotfix, Hotfix-BIGIP-11.4.0-2419.0-HF3.iso, onto HD1.1.
Note: If the installation is successful, and you used the reboot option, as in this example, the machine reboots into the newly installed block-device-hotfix.

OPTIONS
build
Displays the build number of the block-device-hotfix.
checksum
Displays the checksum of the block-device-hotfix.
create-volume
Create a new volume using the name specified with the volume option. Mirrored volume names must begin with the prefix MD1.. Mirrored volumes are available only on systems that support RAID, see sys raid.
device-agent
Displays the name of the service which is responsible for managing the type of block device on which a give hotfix is available. vcmp-virtual-cdrom is the device-agent which allows VCMP guests to install hotfixes that reside in the host system, via a virtual cdrom device.
glob
Displays the items that match the glob expression. See help glob for a description of glob expression syntax.
name
Specifies the name and sequential ID of the block-device-hotfix that you want to install or delete.
product
Displays the F5 Networks product this block-device-hotfix contains.
reboot
Specifies that the system reboots immediately after a successful

installation.

resource-id

Displays the resource-id string corresponding to software block-device-hotfix in question. This string is used to identify the image for use in interacting with the device agent that is responsible for management of the resource. In the case of the vcmp-virtual-cdrom device-agent the resource-id is used by the live installation daemon when requesting that the hypervisor make hotfixes available before the installation can proceed.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

slot id

Specifies the number of the slot on a chassis system that contains the block-device-hotfix about which you want to display information.

title

Displays a textual description of the block-device-hotfix.

verified

When set to yes, indicates that the block-device-hotfix is authentic.

version

Displays the version number of the product the block-device-hotfix contains.

volume

Specifies the name of the volume on which you want to install the block-device-hotfix, or from which you want to delete the block-device-hotfix.

DESCRIPTION

You can use the block-device-image component to install images from block devices onto a volume, or view information about available block-device-images.

INSTALLING A SOFTWARE BLOCK-DEVICE-IMAGE

Before you begin installing a block-device-image, the image must be made available to the system. As of this writing, block device images are only available from within a VCMP guest via a virtual cdrom service. A VCMP host administrator must have provided the images for use by the guest as part of their administration of the VCMP host.

From tmsb, you can use show sys software status to see all of the available disk volumes where you can install the image. You can install the image file in any volume that is not active.

Then use the install command with this component to install the image to an unused volume. You can use the create-volume option if you want to create a new volume. The installation takes some time; you can use show sys software status repetitively to watch the progress of the installation. To put the newly installed software into active service, use the reboot option in the install command, or use the reboot volume vol-name command after the install command completes.

Note: You use the slot_id option only for chassis systems and only when displaying the values for the options of a specific block-device-image. You do not use the slot_id option when installing or deleting a block-device-image, because these commands operate on all blades or the entire system.

CONFIRMING AN BLOCK-DEVICE-IMAGE INSTALLATION

You can use show sys version to confirm that the system is running the new software version. If this is a new module for the current system, you may need to use show sys license and/or install sys license to update your license. For a new module, you may also need to provision CPU, memory, and disk space for the module with the sys provision component.

EXAMPLES

```
install block-device-image BIGIP-11.4.1.608.0.iso volume HD1.1 reboot
```

Attempts to install the specified block-device-image, BIGIP-11.4.1.608.0.iso, onto HD1.1. Note: If the installation is successful, the machine reboots into the newly installed block-device-image.

```
list block-device-image BIGIP-11.4.1.608.0.iso
```

Displays information about the specified block-device-image, build 608.0 of BIG-IP version 11.4.1.

```
list block-device-image */1
```

Displays information about all of the block-device-images located on the first slot.

OPTIONS

build

Displays the build number of the block-device-image.

build-date

Displays the date on which the block-device-image was built.

checksum

Displays the checksum of the block-device-image. You can use this option to verify the integrity of the block-device-image.

create-volume

Creates a new volume using the name specified with the volume option. Mirrored volume names must begin with the prefix MD1.. Mirrored volumes are available only on systems that support RAID, see sys raid.

device-agent

Displays the name of the service which is responsible for managing the type of block device on which a give image is available. vcmp-virtual-cdrom is the device-agent which allows VCMP guests to install images that reside in the host system, via a virtual cdrom device.

file-size

Displays the size of the block-device-image file in megabytes.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

last-modified

Displays the date the file was last modified.

name Specifies the name of the block-device-image that you want to install or delete.

product

Displays the F5 Networks product the block-device-image contains.

reboot

Specifies that the system reboots immediately after a successful installation.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression])

to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

resource-id

Displays the resource-id string corresponding to software image in question. This string is used to identify the image for use in interacting with the device agent that is responsible for management of the resource. In the case of the vcmp-virtual-cdrom device-agent the resource-id is used by the live installation daemon when requesting that the hypervisor make images available, before the installation can proceed.

verified

When set to yes, indicates that the block-device-image is authentic.

version

Displays the version number of the product this block-device-image contains.

volume

Specifies the name of the volume on which you want to install the block-device-image, or from which you want to delete the block-device-image.

Note: You cannot install software on the active volume.

DESCRIPTION

You can use the hotfix component to install a hotfix onto a volume, view information about available hotfixes, or delete unwanted hotfixes.

Use the create-volume option with the hotfix component to create new volumes.

Note: You use the slot_id option only for chassis systems and only when

displaying the values for the options of a specific hotfix. You do not use the slot_id option when installing or deleting a hotfix, because these commands operate on all blades or the entire system.

EXAMPLES

```
list hotfix Hotfix-BIGIP-9.6.1-824.0-HF3.im
```

Displays information about the specified hotfix, BIGIP-9.6.1-824.0-HF3.im.

```
list hotfix */1
```

Displays information about the all the hotfixes on the first slot.

```
install hotfix Hotfix-BIGIP-9.6.1-824.0-HF3.im volume HD1.1 reboot
```

Attempts to install the specified hotfix, BIGIP-9.6.1-824.0-HF3.im, onto HD1.1.

Note: If the installation is successful, and you used the reboot option, as in this example, the machine reboots into the newly installed hotfix.

OPTIONS

build

Displays the build number of the hotfix.

checksum

Displays the checksum of the hotfix. You can use this option to verify the integrity of the hotfix.

create-volume

Create a new volume using the name specified with the volume option. Mirrored volume names must begin with the prefix MD1.. Mirrored volumes are available only on systems that support RAID, see sys raid.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies the name and sequential ID of the hotfix that you want to install or delete.

product

Displays the F5 Networks product this hotfix contains.

reboot

Specifies that the system reboots immediately after a successful installation.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

slot_id

Specifies the number of the slot on a chassis system that contains the hotfix about which you want to display information.

title

Displays a textual description of the hotfix.

verified

When set to yes, indicates that the hotfix is authentic.

version

Displays the version number of the product the hotfix contains.

volume

Specifies the name of the volume on which you want to install the hotfix, or from which you want to delete the hotfix.

SEE ALSO

 version

DELETE
 delete image [[[name] ...] | [all]]

DESCRIPTION
 You can use the image component to install images onto a volume, view information about available images, or delete unwanted images.

INSTALLING A SOFTWARE IMAGE
 Before you begin installing an image, you must download the image file into the /shared/images directory. You can find new software images at <http://downloads.f5.com>. We recommend downloading both the .iso file and the .md5 file. Download the file (or files) to your local machine, then transfer it to the /shared/images directory on the BIG-IP(r). Use the Manager (GUI) interface to make this transfer, or quit tmsh to the Unix command line and use scp or a similar Unix command.

If you downloaded the .md5 file, you can use the Unix md5sum command to check the MD5 hash of the .iso file, and you can compare it to the contents of the .md5 file. They should match. If they do not, retry the download and/or transfer of the .iso file.

From tmsh, you can use show sys software status to see all of the available disk volumes where you can install the .iso file. You can install the .iso file in any volume that is not active.

Then use the install command with this component to install the .iso file to an unused volume. You can use the create-volume option if you want to create a new volume. The installation takes some time; you can use show sys software status repetitively to watch the progress of the installation. To put the .iso file into active service, use the reboot option in the install command, or use the reboot volume vol-name command after the install command completes.

Note: You use the slot_id option only for chassis systems and only when displaying the values for the options of a specific image. You do not use the slot_id option when installing or deleting an image, because these commands operate on all blades or the entire system.

CONFIRMING AN IMAGE INSTALLATION
 You can use show sys version to confirm that the system is running the new software version. If this is a new module for the current system, you may need to use show sys license and/or install sys license to update your license. For a new module, you may also need to provision CPU, memory, and disk space for the module with the sys provision component.

EXAMPLES
 install image BIGIP-10.0.0.5376.0.iso volume HD1.1 reboot

Attempts to install the specified image, BIGIP-10.0.0.5376.0.iso, onto HD1.1. Note: If the installation is successful, the machine reboots into the newly installed image.

list image BIGIP-10.0.0.5376.0.iso

Displays information about the specified image, build 5376.0 of BIG-IP version 10.0.0.

list image */1

Displays information about all of the images located on the first slot.

OPTIONS
 build
 Displays the build number of the image.

build-date
 Displays the date on which the image was built.

checksum

Displays the checksum of the image. You can use this option to verify the integrity of the image.

create-volume

Creates a new volume using the name specified with the volume option. Mirrored volume names must begin with the prefix MD1.. Mirrored volumes are available only on systems that support RAID, see sys raid.

file-size

Displays the size of the image file in megabytes.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

last-modified

Displays the date the file was last modified.

name Specifies the name of the image that you want to install or delete.

product

Displays the F5 Networks product the image contains.

reboot

Specifies that the system reboots immediately after a successful installation.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

verified

When set to yes, indicates that the image is authentic.

version

Displays the version number of the product this image contains.

volume

Specifies the name of the volume on which you want to install the image, or from which you want to delete the image.

Note: You cannot install software on the active volume.

SEE ALSO

BIG-IP 2016-03-14 sys software image(1)

sys software signature

NAME

signature - Manages F5 Networks software signatures.

MODULE

sys software

SYNTAX

Display information about, or delete a signature using the syntax in the following sections.

DISPLAY

list signature
list signature [[[name [/slot_id]] | [glob] | [regex]] ...]
options:
one-line

DELETE

delete signature [[name] ...]
options:
all

DESCRIPTION

You can use the signature component to view information about available

signatures, or delete unwanted signatures.

Note: You use the `slot_id` option only for chassis systems and only when displaying the values for the options of a specific signature. You do not use the `slot_id` option when deleting a signature, because these commands operate on all blades or the entire system.

EXAMPLES

```
list signature BIGIP-11.5.0.0.135.iso.sig
```

Displays information about the specified signature, `BIGIP-11.5.0.0.135.iso.sig`.

```
list signature */1
```

Displays information about the all the signatures on the first slot.

OPTIONS

`regex`

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (`@[regular expression]`) to indicate that the identifier is a regular expression. See help `regex` for a description of regular expression syntax.

`slot_id`

Specifies the number of the slot on a chassis system that contains the hotfix about which you want to display information.

SEE ALSO

`delete`, `glob`, `list`, `regex`, `sys software image`, `tmsh`

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2013-11-18 sys software signature(1)

sys software status

NAME

`status` - Displays the status of a BIG-IP(r) system software installation.

MODULE

`sys software`

SYNTAX

Display information about the status component within the `sys software` module using the following syntax.

DISPLAY

```
show status
options:
  field-fmt
```

DESCRIPTION

You can use the `status` component to display the status of the software installation, including whether the system is active, the name of the product being installed, the software version and build number of the software, and the slot and volume on which the software is installed.

After you use the `install sys software image` command (see `install` and "`sys software image`") to install a new software image, you can use this command to monitor the progress of the installation. A percentage meter appears in the `Status` column.

EXAMPLES

```
show status
```

Displays the status of the software installation in a table.

```
show status field-fmt
```

Displays the status of the software installation separately for each volume on the system.

```
root@(big-ip1)(cfg-sync Standalone)(Active)(/Common)(tmsh)# quit
[root@big-ip1:Active:Standalone] images # watch tmsh show sys software status
```

Launches the Unix `watch` command from the Unix command line. The command produces auto-updating output similar to this:

```
-----  
Sys::Software Status  
Volume Product Version Build Active Status  
-----  
HD1.1 EM 3.2.0 222.0 no installing 6.000 pct  
HD1.2 EM 3.2.0 150.0.465 yes complete  
HD1.3 EM 3.2.0 67.0 no complete
```

Where the "installing 6.000 pct" status increases until it eventually changes to "complete." It changes to a specific failure message if there is an issue.

OPTIONS

field-fmt
Specifies to display the software status for each volume in a field format, rather than in a table.

SEE ALSO

show, tms

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2016-03-14 sys software status(1)

sys software update-status

NAME

update-status - Displays the BIG-IP(r) update check results.

MODULE

sys software

SYNTAX

Display the results of an update check contained in the update-status component within the sys software module using the syntax in the following section.

DISPLAY

```
list update-status  
options:  
  all-properties  
  one-line  
  [update type] (e.g. RELEASE)  
  
show update-status  
options:  
  field-fmt  
  [update type] (e.g. RELEASE)
```

DESCRIPTION

You can use the update-status component to display the results of the update check feature.

EXAMPLES

```
list update-status  
  
Displays all update check information for the system.  
  
show update-status RELEASE  
  
Displays update check information for the RELEASE update type for the system in a formatted output.  
  
list update-status GEOLOC all-properties one-line  
  
Displays all update check information for the GEOLOC update type on one line.  
  
list update-status last-checked-version  
  
Displays the last checked version for all update types.
```

OPTIONS

app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates

option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

available
This is the file name of the available update.

check-user
This is the system user that last executed the update check.

label
This is the label used when displaying the status on the GUI.

last-checked
This is the last time this update type was checked.

last-checked-auto-mode
This is false if the last time this update type was checked was performed manually.

last-checked-version
This is the version found at the last time this update type was checked.

progress-status
This is the state of the update check.

supplement
This is the file name of the supplemental file.

url This is the URL linking to the available update.

url-supplement
This is a URL linking to a file supplemental to the available update.

BIG-IP 2016-03-14 sys software update-status(1)

sys software update

NAME
update - Displays the BIG-IP(r) update check and phone home schedule settings.

MODULE
sys software

SYNTAX
Display and modify the update component within the sys software module using the syntax in the following section.

MODIFY
modify update
options:
auto-check
auto-phonehome
frequency

DISPLAY
list update
options:
all-properties
one-line

show update
options:
field-fmt

DESCRIPTION
You can use the update component to display or modify the configuration of the update check and phone home feature.

EXAMPLES

`list update`

Displays update check and phone home configuration information for the system.

`show update`

Displays update check and phone home configuration information for the system formatted for easy viewing.

`modify update frequency monthly`

Modify the frequency of update checks to monthly.

`modify update auto-check disabled`

Disable the auto update check feature.

`modify update auto-phonehome disabled`

Disable the auto phone home feature.

OPTIONS

`auto-check`

Set this to enabled in order to turn on the auto update check feature. disabled turns the feature off.

`auto-phonehome`

Set this to enabled in order to turn on the auto phone home feature. disabled turns the feature off.

`check-status`

This read-only field displays the result of the last update check.

`errors`

This read-only field displays the number of consecutive errors detected by update checking.

`frequency`

The frequency of update checks can be one of daily, weekly, or monthly.

For information about the options that you can use with the command `list`, see `help list`.

SEE ALSO

`list`, `show`, `tmsh`

BIG-IP 2016-03-14 sys software update(1)

sys software volume

NAME

`volume` - Manages software volumes on the BIG-IP(r) system.

MODULE

`sys software`

SYNTAX

Delete, reboot into, or display information about a hard drive volume using the syntax in the following sections.

REBOOT

`reboot volume [name]`

DISPLAY

`list volume`

`list volume [[[name].[slot_id]] | [glob] | [regex]] ...]`

`show running-config`

`show running-config [[[name].[slot_id]] | [glob] | [regex]] ...]`

options:

`active`

`active-requested`

`all-properties`

`basebuild`

build
edition
media [media] [size] [default-boot-location]
one-line
product
status
version

DELETE

delete volume [name]

DESCRIPTION

You can use the volume component to view information about configured volumes, delete unwanted volumes, and reboot the device to a specific volume.

Volumes are created using the install command. See help sys software image and the option create-volume.

Deleting or rebooting into a volume on a VIPRION system affects the entire chassis; therefore, you do not need to specify the slot number.

EXAMPLES

list volume */1

Displays the details of all the volumes located on the first slot in a chassis.

delete volume HD1.5

Deletes the volume named HD1.5.

reboot volume HD1.1

Boots into volume HD1.1 if that volume is not already active. If the volume has an image actively being installed on it, the reboot occurs when the installation is complete.

OPTIONS

active

Specifies if this volume is being run.

active-requested

Specifies if this volume should be active once its status is complete. The system associates this setting with either the active volume or the volume that is going to become active when its status is complete. If active-requested is set on a volume that is not presently active, the system reboots into the volume when the volume status is complete. As an example, install sys software image BIGIP-10.1.0.3341.0.iso volume HD1.2 reboot will cause active-requested to be set on volume HD1.2, and the system will reboot into volume HD1.2 when the installation is complete. This value is read-only.

basebuild

Displays the build number of either the hotfix presently applied to the system or the original build.

build

Displays the original build number (before any hotfixes).

edition

Displays a textual description of the image. You can use this option to specify the hotfix you want to install.

media

Displays a description of the physical media on which the volume exists. The options are:

media

The type of physical device on which the volume exists, for example, hard drive (hd) or compact flash (cf).

size The space on the slot reserved for the volume.

default-boot-location

Specifies the volume into which the system boots if the slot resets.

name Specifies the name of the volume you are configuring. Volume names are in the format HDX.Y, CFX.Y, or MDX.Y, where X is the hard drive index (HDX), compact flash index (CFX), or RAID index (MDX) (on systems that support RAID), and Y is the volume number on that drive.

product

Displays the F5 Networks product that is installed on the volume.

reboot

Reboots the system into the specified volume.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

status

Displays the installation status of the volume. The options are complete or installing.

version

Displays the version number of the software installed on the volume.

SEE ALSO

delete, glob, install, list, reboot, regex, sys software hotfix, sys software image, sys raid, tmsh

BIG-IP 2013-03-21 sys software volume(1)

sys sshd

NAME

sshd - Configures the Secure Shell (SSH) daemon for the BIG-IP(r) system.

MODULE

sys

SYNTAX

Configure the sshd component within the sys module using the syntax in the following sections.

MODIFY

modify sshd

options:

```
allow [add | delete | replace-all-with] {
  [ [hostname] | [IP address] ] ...
}
allow none
banner [disabled | enabled]
banner-text [string]
inactivity-timeout [integer]
include [string]
login [disabled | enabled]
log-level [debug | debug1 | debug2 | debug3 | error | fatal |
  info | quiet | verbose]
port [integer]
```

edit sshd

options:

```
all-properties
non-default-properties
```

DISPLAY

list sshd

list sshd [option]

show running-config sshd

show running-config sshd [option]

options:

```
all-properties
non-default-properties
one-line
```

DESCRIPTION

You can use the sshd component to configure a secure channel between the BIG-IP system and other devices.

F5 Networks recommends that users of the Configuration utility exit the utility before changes are made to the system using the sshd component. This is because making changes to the system using this component causes a restart of the sshd daemon. Likewise, restarting the sshd daemon creates the necessity for a restart of the Configuration utility.

EXAMPLES

```
modify sshd allow add {192.168.0.0/255.255.0.0}
```

Creates an initial range of IP addresses (192.168.0.0 with a netmask of 255.255.0.0) that are allowed to log in to the system.

```
modify sshd allow add {192.168.1.245}
```

Adds the IP address, 192.168.1.245, to the existing list of IP addresses that are allowed to log in to the system.

```
modify sshd login enabled
```

Enables SSH login to the system.

```
modify sshd inactivity-timeout 3600
```

Sets an inactivity timeout of 60 minutes for SSH logins to the system.

modify sshd log-level error

Sets the sshd message log level to ERROR.

modify sshd banner enabled banner-text "NOTICE: Improper use of this computer may result in prosecution!"

Creates a banner that displays when a user attempts to log in to a system using SSH.

Note that you must enclose the banner text in double quotation marks, and then type single quotation marks outside the double quotation marks. You can also use the backslash character to escape each quotation mark as well as any other special characters that the system might process (for example, exclamation point !).

OPTIONS

allow

Configures servers in the /etc/hosts.allow file. The default value is all.

Warning: Using the value none resets the sshd daemon to allow all servers access to the system. F5 Networks recommends that you do not use the value none with the sshd component.

banner

Enables or disables the display of the banner text field when a user logs in to the system using SSH. The default value is disabled.

banner-text

When the banner option is enabled, specifies the text to include in the banner that displays when a user attempts to log on to the system.

fips-cipher-version

Read-only field for internal use. Non-zero value indicates that the list of ciphers has been set to FIPS 140-2 compliant defaults. The value 1 indicates that the list of ciphers is "aes128-cbc,aes256-cbc". User changes to the list of ciphers will not affect the value of this field. This field is relevant only when FIPS 140-2 compliance is enabled in the license.

inactivity-timeout

Specifies the number of seconds before inactivity causes an SSH session to log out. The default value is 0 (zero) seconds, which indicates that inactivity timeout is disabled.

include

Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using the include option. If you use this option incorrectly, you put the functionality of the system at risk.

login

Enables or disables SSH logins to the system. The default value is enabled.

log-level

Specifies the minimum sshd message level to include in the system log. The possible values are:

debug - debug3

Indicates that the minimum sshd message level that the system logs is the specified debugging level of messages.

error

Indicates that the minimum sshd message level that the system logs is error.

fatal

Indicates that the minimum sshd message level that the system logs is fatal.

info Indicates that the minimum sshd message level that the system logs is informational.

quiet

Indicates that the system does not log sshd messages.

verbose

Indicates that the system logs all sshd messages.

port Specifies the TCP port to run SSHD. It is a number in the range of 1 and 65535.

The default value is 22.

sys state-mirroring

NAME

state-mirroring - Configures connection mirroring for a BIG-IP(r) system that is part of a redundant pair in a high availability system.

MODULE

sys

SYNTAX

Configure the state-mirroring component within the sys module using the syntax in the following sections.

MODIFY

modify state-mirroring

options:

addr [IP address]
peer-addr [IP address]
secondary-addr [IP address]
secondary-peer-addr [IP address]
state [enabled | disabled]

edit state-mirroring

options:

all-properties
non-default-properties

DISPLAY

list state-mirroring

list state-mirroring [option]

show running-config state-mirroring

show running-config state-mirroring [option]

options:

all-properties
non-default-properties
one-line

DESCRIPTION

You can use this component to configure connection mirroring on a system that is part of a redundant pair in a high availability system.

Connection mirroring is the process of duplicating connections from the active system to the standby system. Enabling this setting ensures a higher level of connection reliability, but it may also have an impact on system performance.

EXAMPLES

```
modify state-mirroring state enabled addr 192.168.10.10 peer-addr
192.168.10.20
```

Enables and configures connection mirroring for a high availability system in which one BIG-IP system has an IP address of 192.168.10.10, and its peer has an IP address of 192.168.10.20.

```
modify state-mirroring state enabled
```

Re-enables connection mirroring for a system for which connection mirroring was disabled.

OPTIONS

addr Specifies the primary self-IP address on this unit to which the peer unit in this redundant pair mirrors its connections. The default value is ::.

peer-addr

Specifies the primary self-IP address on the peer unit to which this unit mirrors its connections. The default value is ::.

secondary-addr

Specifies another self-IP address on this unit to which the peer unit mirrors its connections when the primary address is unavailable. The default value is ::.

secondary-peer-addr

Specifies another self-IP address on the peer unit to which this unit mirrors its connections when the primary peer address is unavailable. The default value is ::.

state

Enables or disables connection mirroring. The default value is enabled.

DISPLAY
list syslog
list syslog [option]
show running-config syslog
show running-config syslog [option]
options:
all-properties
non-default-properties
one-line

```

DESCRIPTION

You can use the syslog component to configure the system log.

EXAMPLES

```
modify syslog auth-priv-from warning
```

Resets the lowest level of messages about user authentication that are included in the system log to messages with a level of warning, error, critical, alert, and emergency.

```
modify syslog auth-priv-to warning
```

Resets the highest level of messages about user authentication that are included in the system log to messages with a level of warning, error, critical, alert, and emergency.

OPTIONS

auth-priv-from

Specifies the lowest level of messages about user authentication to include in the system log. The default value is notice.

auth-priv-to

Specifies the highest level of messages about user authentication to include in the system log. The default value is emerg.

clustered-host-name

When enabled, the slash-separated slot ID of the blade that originated the log is prepended to the hostname field. The default value is enabled.

clustered-message-slot

When enabled, the space-separated slot ID of the blade that originated the log is prepended to the message text. The default value is disabled.

cron-from

Specifies the lowest level of messages about time-based scheduling to include in the system log. The default value is warning.

cron-to

Specifies the highest level of messages about time-based scheduling to include in the system log. The default value is emerg.

daemon-from

Specifies the lowest level of messages about daemon performance to include in the system log. The default value is notice.

daemon-to

Specifies the highest level of messages about daemon performance to include in the system log. The default value is emerg.

description

User defined description.

host Specifies the IP address of a remote server to which syslog sends messages. The default value is none.

include

Warning: Do not use this option without assistance from the F5 Technical Support team. The system does not validate the commands issued using the include options. If you use this option incorrectly, you put the functionality of the system at risk.

iso-date

Enables or disables the ISO date format for messages in the log files. The default value is disabled.

console-log

Enables or disables logging emergency syslog messages to the console. The default value is enabled.

kern-from

Specifies the lowest level of kernel messages to include in the system log. The default value is notice.

kern-to

Specifies the highest level of kernel messages to include in the system log. The default value is emerg.

local-ip

Specifies the IP address of the interface syslog binds with in order to log messages to a remote host. For example, if you want syslog to log messages to a remote host that is connected to a VLAN, you set this parameter to the self IP address of the VLAN.

local6-from

Specifies the lowest error level for messages from the local6 facility to include in the log. The default value is notice.

local6-to

Specifies the highest error level for messages from the local6 facility to include in the log. The default value is emerg.

mail-from

Specifies the lowest level of mail log messages to include in the system log. The default value is notice.

mail-to

Specifies the highest level of mail log messages to include in the system log. The default value is emerg.

messages-from

Specifies the lowest level of messages about user authentication to include in the system log. The default value is notice.

messages-to

Specifies the highest level of system messages to include in the system log. The default value is warning.

remote-port

Specifies the port number of a remote server to which syslog sends messages. The default value is 514.

remote-servers

Configures the remote servers, identified by IP address, to which syslog sends messages. The default value is none.

user-log-from

Specifies the lowest level of user account messages to include in the system log. The default value is notice.

user-log-to

Specifies the highest level of user account messages to include in the system log. The default value is emerg.

sys turboflex profile-config

NAME

profile-config - Configures the TurboFlex profile chosen by users.

MODULE

sys turboflex

SYNTAX

Configure the profile-config component within the sys turboflex module using the syntax shown in the following sections.

MODIFY

```
modify profile-config
```

options:

```
type [ turboflex-adc | turboflex-highspeed-layer4 | turboflex-security | turboflex-base | turboflex-low-latency |
```

DISPLAY

```
list profile-config
```

options:

```
all-properties
```

DESCRIPTION

You can use the profile-config component to configure the TurboFlex profile type to use.

EXAMPLES

```
list profile-config
```

Displays properties of the current TurboFlex profile configuration.

```
modify profile-config type
```

Modify the type of the active TurboFlex profile configuration. The default is turboflex-adc.

OPTIONS

type The type for TurboFlex profile currently chosen on the system.

turboflex-base: The Standard basic profile.

turboflex-adc: The Application Delivery Controller (ADC) profile provides the HW acceleration features normally associated with the ADC use cases. In order to enable this profile, the LTM module must be provisioned.

turboflex-ultrafast-layer4: The Ultra Fast L4 CPS profile provides HW acceleration features normally associated with fast L4 LBing. In order to enable this profile, the LTM module must be provisioned. For full capability, the TAM module must be provisioned after selecting this profile.

turboflex-security: The Security profile provides the HW acceleration features normally associated with the security use cases. In order to enable this profile, the LTM modules must be provisioned. For full capability, the AFM module must be provisioned after selecting this profile.

turboflex-low-latency: The Low Latency FIX profile provides the HW acceleration features normally associated the FIX use case. In order to enable this profile, the Advanced Protocol or FIX-LL add-ons must be licensed and the LTM module must be provisioned.

turboflex-private-cloud: The Private Cloud (PC) profile provides the HW acceleration features normally associated with the PC use cases. In order to enable this profile, the LTM module must be

provisioned.

BIG-IP 2017-03-03 sys turboflex profile feature(1)

sys turboflex warning

NAME

warning - Displays all warnings for a TurboFlex profile configuration.

MODULE

sys turboflex

SYNTAX

Displays current warning component within the sys turboflex module using the syntax in the following section.

DISPLAY
show features
options:
all-properties
field-fmt
current-module

DESCRIPTION

You can use the warning component to display the active TurboFlex profiles and its feature set.

EXAMPLES

show warning

Displays the warnings after a TurboFlex profile is configured.

SEE ALSO

show, tmsh, turboflex

BIG-IP 2017-03-29 sys turboflex warning(1)

SYS UCS

NAME
ucs - Loads or saves a UCS (.ucs) file.

MODULE
sys

SYNTAX
Configure the ucs component within the sys module using the syntax in the following sections.

MODIFY

save ucs [file name]
options:
no-private-key
passphrase

load ucs [file name]
options:
include-chassis-level-config
no-license
no-platform-check
passphrase
platform-migrate
reset-trust

delete ucs [file name]

DISPLAY
list ucs
show ucs [file name]

DESCRIPTION
You can use the ucs component to save the running configuration of the system into a UCS file. Additionally, you can modify the running configuration of the system by loading an existing UCS file.

When you save a UCS file, the file is saved to the default directory, /var/local/ucs.

When you load a UCS file in shell mode, the system searches for the file using the relative path to the default directory (/var/local/ucs). When you load a UCS file in bash mode, the system searches the current directory first. If the file is not found in the current directory, the default directory is then searched.

EXAMPLES

save ucs myucs

Saves the running configuration of the system into the file myucs.ucs.

load ucs myucs

Modifies the running configuration of the system by loading the configuration contained in the myucs.ucs file.

delete ucs myucs

Delete myucs.ucs in the default directory, /var/local/ucs/.

list ucs

Displays existing UCS files in the default directory, /var/local/ucs/.

OPTIONS

include-chassis-level-config
During restore of the UCS file, include chassis level configuration that is shared among boot volume sets. For example, cluster default configuration.

no-license
Performs a full restore of the UCS file and all the files it contains, with the exception of the license file. The option must be used to restore a UCS on RMA devices (Returned Materials Authorization).

no-platform-check
Bypasses the platform check and allows a UCS that was created using a different platform to be installed. By default (without this option), a UCS created from a different platform is not allowed to be installed.

no-private-key
Indicates that the UCS file can be saved without private key information.

passphrase
Specifies the passphrase that is necessary to load the specified UCS file.

platform-migrate
Ignore the configuration items specific to a particular platform. The platform-specific objects already present on the device are not removed or modified. The ones included in the UCS archive are not loaded.

This option is not valid for UCS archives from systems provisioned with modules other than LTM and GTM. If the UCS comes from a system running any release of TMOS version 10, only LTM (not GTM) is supported.

This option implies no-license and no-platform-check.

reset-trust

When specified, the device and trust domain certs and keys are not loaded from the UCS. Instead, a new set is regenerated.

sys url-db download-result

NAME

download-result - Lists download result for URL Master and RTSU DB.

MODULE

sys url-db

SYNTAX

List download-result component within the module using the syntax shown in the following sections.

DISPLAY

The download-result consists of the object name (/Common/masterdb or /Common/rtsudb), and version. These objects are created by BIGIP and cannot be modified or deleted.

list url-db download-result [masterdb | rtsudb] /slot_number

options:

all-properties
non-default-properties
one-line

list url-db download-result masterdb /slot_number

db-version [integer]
ret-code 0

list url-db download-result rtsudb /slot_number

db-version [integer]
ret-code 0

DESCRIPTION

Lists download result for Master URL database and Real-Time Security Update (RTSU). These objects are created after the first successful download and updated after every download. For cluster environments the slot number will be shown after the name of the database.

OPTIONS

db-version

Specifies database version for URL Master or Real-Time Security Update DB.

ret-code

Specifies the download result status and always zero now.

SEE ALSO

sys url-db download-schedule sys url-db url-category

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2017-01-19 sys url-db download-result(1)

sys url-db download-schedule

NAME
download-schedule - Configures download schedule for URL Master DB.

MODULE
sys url-db

SYNTAX
Configure a download-schedule component within the module using the syntax shown in the following sections.

MODIFY
The download-schedule consists of the object name (/Common/urldb), download start time (start-time), download end time (end-time) and status. You can have only one download schedule and the download occurs daily.

```
modify url-db download-schedule urldb
start-time [HH:MM]
end-time [HH:MM]
download-now [true | false]
status [true | false]
use-proxy [true | false]
```

DISPLAY
list url-db download-schedule urldb
options:
all-properties
non-default-properties
one-line

DESCRIPTION
Configures download schedule for Master URL database.

EXAMPLES
modify download-schedule urldb { start-time 2:00 end-time 4:00 }

Modify the download schedule for Master DB download schedule between 2:00 AM and 4:00 AM. Other downloads such as RTSU (Real-Time Security Update) and ACE (Advanced Classification Engine) DB download occurs at regular intervals.

modify download-schedule urldb { start-time 20:00 end-time 22:00 }

Modify the download schedule for Master DB download schedule between 8:00 PM and 10:00 AM.

modify download-schedule urldb { download-now true }

Master DB Download starts in few minutes after issuing this command. The download-now will be set to false after successful download.

modify download-schedule urldb { status false }

By setting the status flag to false, download (Master and other DB) will not occur any more.

modify download-schedule urldb { use-proxy true }

DB Download uses proxy configuration after issuing this command.

OPTIONS
download-now
Specifies to start download in few minutes and no need to wait for the scheduled window.

end-time
Shows download end time. Download will start between scheduled start time and end time.

start-time
Shows download start time. Download will start between scheduled start time and end time.

status
Shows the download status is enabled. By turning to false, download will not occur.

use-proxy
Specifies to use proxy configuration for database download.

SEE ALSO

BIG-IP 2016-02-25 sys url-db download-schedule(1)

sys url-db url-category

NAME
url-category - Configures URL categories for URL classification and filtering

MODULE
sys url-db

SYNTAX
Configure a url-category component within the module using the syntax shown in the following sections.

CREATE/MODIFY

Each url-category consists of the object name (/Common/Business_and_Economy), a display-name ("Business and Economy") which is a more user-friendly category name, and a category number. The hundreds and thousands of URLs under a url-category are stored in a database. You can create your own url-category (custom category) and you can add more URLs to an existing category (reategorization).

```
create url-db url-category [name]
options:
display-name [string]
description [string]
initial-disposition [integer]
is-security-category [string]
parent-cat-number [integer]
severity-level [integer]
urls [add | delete | modify | replace-all-with] {
[string]
}
```

```
modify url-db url-category [name]
initial-disposition [integer]
is-security-category [string]
parent-cat-number [integer]
severity-level [integer]
urls [add | delete | modify | replace-all-with] {
[string]
}
```

DISPLAY

```
list url-category
list url-category [ [ [name] | [glob] | [regex] ] ... ]
options:
all-properties
non-default-properties
one-line
partition
```

DESCRIPTION
Configures a url-category

NOTE: When you create a new url-category, you must provide a display-name. However, after creation it cannot be changed to another value. The system will provide a cat-number for your newly created url-category. The number is an integer greater than 1900. The url-category you create is considered to be a custom URL category, and so the is-custom flag will be set to true.

NOTE: The only change you can make to a system provided url-category is to add one or more URLs to its list of URLs. This is called reategorization, and the is-recategory flag will be set to true. You need to do this if the URL does not already exist in the database.

EXAMPLES

```
create url-category my-own-url-cat display-name "My Own URL Category"
urls add { http://a.url.com http://www.another.url.org }
```

Creates a new url-category. The new url-category you create is known as a custom category, as opposed to a system provided url-category. In this case, you must specify the display-name and at least one URL.

```
modify url-category my-own-url initial-disposition 4 parent-category 0
```

Modify the initial-disposition and parent-category in a customized url-category.

```
modify url-category Business_and_Economy urls add {
http://www.theneomarxist.com }
```

Modify a system provided url-category by adding a URL to it. This

action is called recategorization. The url-category is recategorized.

OPTIONS

cat-number

Shows a unique category number. Custom URL categories have numbers greater than 1900. This is a read-only attribute.

description

Specifies a unique description for the URL category.

display-name

Specifies a user-friendly name that describes what the URL category represents. This attribute cannot be changed after creation.

initial-disposition

Specifies the action to be taken when a certain URL category is not listed in any url-filter.

is-custom

This flag is set by the system when you create your own URL category. This attribute is read-only.

is-security-category

This flag is not being used. This attribute is read-only.

parent-cat-number

Specifies the category number of a parent url-category. 0 denotes no parent.

severity-level

Specifies the severity level.

sys version

NAME

version - Displays software version information for the BIG-IP(r) system.

MODULE

sys

SYNTAX

Display statistics for the version component within the sys module using the syntax in the following section.

DISPLAY

show version
options:
detail

DESCRIPTION

You can use the version component to display the software version running on the system, including a list of hotfixes that you have applied to the system.

EXAMPLES

show version

Displays software version information.

show version detail

Displays more extensive software version information about the system, including the operating system kernel information, and details about each hotfix that you have applied to the system.

OPTIONS

For information about the options that you can use with the command show, see help show.

BIG-IP 2013-07-26 sys version(1)

util

util ccmode

NAME

ccmode - Set Common Criteria mode and a subset of configuration defaults required for a Common-Criteria-compliant BIGIP system.

MODULE

util

SYNTAX

ccmode

DESCRIPTION

Use this command to set a subset of defaults that are required for a Common-Criteria-compliant system.

Run this command **ONLY** if you are creating a Common-Criteria-compliant BIG-IP system, or have otherwise determined that all of the changes are desirable for your BIG-IP configuration. Note that there are runtime changes triggered by this command.

Running the ccmode command is an essential part of the configuration changes required to configure a BIG-IP system as Common-Criteria-compliant. This command changes the base configuration in several ways, including:

- o Defining the minimum required password policy.
- o Defining the allowed cipher sets for SSL/TLS.
- o Disabling some features excluded from the evaluation and therefore not permitted to be used in a compliant system.
- o Setting several DB variables, including the Security.CommonCriteria variable, an indicator from which other runtime changes are triggered.

While running this script is essential to creating a Common-Criteria-compliant system, it is not sufficient. Customers wishing to configure compliant systems must consult the configuration Guidance documentation provided when the evaluation is complete, and follow its instructions to completely configure the BIG-IP.

This command has no facility for "undoing" the changes it makes. Instead, the administrator must reverse or revise all of the individual commands, reset the DB variables to their defaults, save the new configuration, and restart the BIG-IP.

BIG-IP 2015-06-26 util clientssl-ciphers(1)

util diadb

NAME
diadb - Run the diadb command to display, filter or delete dia persistence entries.

MODULE
util

SYNTAX
run util diadb

util dnatutil

NAME
dnat - Command providing reverse and forward mapping for deterministic NAT (DNAT).

MODULE
util

SYNTAX
Run the dnat utility from within the util module using the following syntax:
run util dnat [] [
[:]]

DESCRIPTION
The dnat utility allows the calculation of forward and reverse source address and port mapping for the deterministic mode of Large Scale NAT.

EXAMPLES
dnat 10.0.0.1 --action forward Shows a list of translation address/port pairs that might be used for a subscriber at 10.0.0.1, using the DNAT states contained in /var/log/ltn.
dnat 173.240.102.139:5678 Performs a reverse mapping back to the subscriber address for the connection from 173.240.102.139:5678, using

the DNAT states contained in /var/log/ltn.

`dnat --start_time '2012-09-27 06:30:00' --end_time '2012-09-27 12:10:00' 173.240.102.139:5678` Same as the previous example, but only shows the subscriber addresses that used the translation within the specified time range.

`dnat --start_time '2012-09-27 06:30:00' --end_time '2012-09-27 12:10:00' --file /var/log/test 173.240.102.139:5678` Same as the previous example, but use the DNAT states contained in /var/log/test

`dnat --file /var/log/test` Shows summary information, using the DNAT states contained in /var/log/test

`dnat --action summary --start_time '2012-09-27 06:30:00' --end_time '2012-09-27 12:10:00'` Shows summary information, using the DNAT states within the specified time range.

OPTIONS

`client_addr` or `--client_addr`

Used to provide the subscriber address for forward mappings (`--action forward`), and the translation address for reverse mappings (`--action reverse`).

`client_port` or `--client_port`

Used to provide the subscriber port for forward mappings (`--action forward`), and the translation port for reverse mappings (`--action reverse`).

`end_time` or `--end_time`

End time of search range. User can specify the time format via the `--time-format` switch. The time format defaults to 'YYYY-MM-DD HH:MM:SS.'

`start_time` or `--start_time`

Start time of search range. User can specify the time format via the `--time-format` switch. The time format defaults to 'YYYY-MM-DD HH:MM:SS.'

`--action`

Specify the action to be taken: `summary`, `forward`, `reverse`, `reverse_addr`. Default: `reverse` when supplied with `client_addr`, `summary` otherwise.

`summary`

Provides summary information on the parsed deterministic NAT configuration snippet.

`reverse`

Returns possible subscriber address for the provided client address and client port (as translation end-point).

`forward`

Returns possible translation end-points for the provided client address (as subscriber address).

`forward_compact`

Returns possible subscriber addresses for the provided client address (as translation address), in a compact format with address and port-range.

`reverse_addr`

Returns possible subscriber addresses for the provided client address (as translation address).

`--file /var/log/ltn`

Read DNAT state from file (default: /var/log/ltn)

`--time_format`

Timestamp parse format for `--start_time` or `--end_time` (default: '%F %T %Z', this yields 'YYYY-MM-DD HH:MM:SS', with timezone being optional.)

`--flags`

DAGLIB flags parameter.

`--flags_v2or`

DAGLIB flags override parameter, apply when deterministic NAT state is from log version 2 or lower only.

`--all`

Display all entries, even if there are duplicates (default disabled).

`--version`

Display version and DAG information.

SEE ALSO

`run`, `tmsh`, `date`

util establish adfs trust

NAME
establish-adfs-trust - Establish trust with ADFS server.

MODULE
util

SYNTAX
establish-adfs-trust --vs [--cert] --username
[--password]
- Virtual server name. It should have the "adfs_proxy"
profile attached.
- Certificate object name for new trust certificate. If the
option is not provided, existing trust certificate will be updated.
/ - Credentials of a local administrator account on the
ADFS server. The command will prompt for password if it's not provided
on the command line.

DESCRIPTION
The establish-adfs-trust utility allows users to establish trust with
ADFS server. During trust establishment, APM generates a self signed
certificate and registers it with ADFS. On success, APM adds the newly
generated certificate and key to the server SSL profile of given
virtual server. Any previously attached certificate and key are
detached from the server SSL profile, but remain on the system.

EXAMPLES
establish-adfs-trust --vs adfs_vs --cert adfs_cert --username
Administrator
The above command will prompt for password.
establish-adfs-trust --vs adfs_vs --cert adfs_cert --username
Administrator --password secret

util finalize custom ami

NAME
finalize-custom-ami - Utility to clean-up and prepare the custom AMI
for Autoscaling on AWS. Deprecated since 14.0.0.

MODULE
util

SYNTAX
Run the finalize-custom-ami utility from within the util module using
the following syntax:
run util finalize-custom-ami

DESCRIPTION
The finalize-custom-ami utility runs the final clean-up steps to
prepare the instance for being packaged as a custom AMI that could be
autoscaled in AWS. This is a BIG-IP VE on AWS specific utility tool
that shouldn't be run on other platforms. This should be used

according to supporting documentation provided by F5.

All the output is reported on standard output.

EXAMPLES

```
run util finalize-custom-ami
```

util ihealth

NAME

ihealth - Run the ihealth utility for the purpose of uploading a new or existent qkview file to ihealth.

MODULE

util

SYNTAX

```
run util ihealth [ -f ] [ -e ] [ -l ] [ -a ] [ -u ] [ -p ] [ -s ] [ -d ] [ -n ] [ -h ] [ -C ] [ -x ]
```

or

```
run util ihealth [ --file= ] [ --existing= ] [ --auth-url= ] [ --api-url= ] [ --user= ] [ --password= ] [ --sr= ] [ --
```

DESCRIPTION

The ihealth utility runs a menu that allows users to select qkview files or creating a new qkview file for uploading to ihealth using DevCentral userid.

OPTIONS

- file**
This is the name of the local diagnostics file to use or create.
- existing**
This flag can be used to specify to use an existing diagnostics file, rather than create one.
- auth-url**
This is an over-ride of the DevCentral login server URL used for connecting to the iHealth diagnostic service.
- api-url**
This is an over-ride of the iHealth API service used for storing and processing qkviews.
- user**
This is an over-ride of the DevCentral user name stored for connecting to the iHealth diagnostic service.
- password**
This is an over-ride of the DevCentral password stored for connecting to the iHealth diagnostic service.
- description**
This is a description that is attached to the diagnostics file when uploaded to the iHealth diagnostic service.
- sr** This is a service request number that is attached to the diagnostics file when uploaded to the iHealth diagnostic service.
- exclude**
This is an over-ride of the stored exclude settings for limiting files collected by qkview. See qkview for the possible values.
- exclude-cores**
This directs qkview to exclude core files from it's data collection.
- no-upload**
This directs the iHealth command to skip uploading to the iHealth service.
- help**
Displays the usage for this command.

SEE ALSO
run, tmsh, qkview

util ipsecalgdb

NAME
ipsecalgdb - Run the ipsecalgdb command to view IPsecALG translation, and pending IKE connection count entries.

MODULE
util

SYNTAX
run util ipsecalgdb
Commands:
delete
list

Objects:
all
tran[slation] entries
pend[ing] IKE connection count entries

DESCRIPTION
The ipsecalgdb utility allows users to view IPsecALG translation, and pending IKE connection count entries, as well as deleting those entries using this utility.

EXAMPLES
run util ipsecalgdb delete all

Delete all IPsecALG translation, and pending IKE connection count entries.

run util ipsecalgdb delete trans

Delete all IPsecALG translation entries.

run util ipsecalgdb delete pend

Delete all IPsecALG pending IKE connection count entries.

run util ipsecalgdb list all

Shows all IPsecALG translation, as well as pending IKE connection count entries.

OPTIONS
delete
Delete all objects of the specified type.

list Display all objects of the specified type.

all = all available object types.
trans = IPsecALG translation entries.
pend = IPsecALG pending IKE connection count entries.

SEE ALSO
run, tmsh

COPYRIGHT

BIG-IP 2016-08-02 util ipsecalgdb(1)

util lsndb

NAME

lsndb - Run the lsndb command to view Large Scale NAT persistence entries, inbound mappings, client connection counts, and PCP mappings.

MODULE

util

SYNTAX

run util lsndb

Commands:

del[ete]

list

summary

Objects:

all

client

inbound[-mapping]

pba

pcp

filters

persist[ence]

all

DESCRIPTION

The lsndb utility allows users to view LSN persistence mappings, inbound mappings, PCP mappings, client connection counts and port block entries. Persistence, inbound and PCP mappings can also be deleted using this utility.

EXAMPLES

```
run util lsndb delete all
```

Delete all LSN persistence mappings, inbound mappings and PCP mappings.

```
run util lsndb del inbound
```

Delete all LSN inbound mappings.

```
run util lsndb delete pcp
```

Delete all PCP mappings.

```
run util lsndb delete persist
```

Delete all LSN persistence entries.

```
run util lsndb list all
```

Shows all LSN persistence mappings, inbound mappings, PCP mappings, client connection counts and port block entries.

```
run util lsndb list client
```

Shows all LSN client connection counts. Each line will display the client IP address and the number of connections used by the client. Connection counts are only available for LSN pools with a non-zero client connection limit.

```
run util lsndb list inbound
```

Shows all LSN inbound mappings. Each line will display the translation IP address, the client IP address, the DS-Lite tunnel (if configured) and the age of the mapping.

```
run util lsndb list pba
```

Shows all LSN port block entries. Each line will display the client IP address, the port block used and the time that the entry will persist in the database (TTL).

```
run util lsndb list pcp
```

Shows all PCP mappings. PCP clients send MAP requests to map their private IP address and port to a public IP address and port. The BIG IP system uses those mappings as NAT entries. Each line will display the client IP address, the external address used and the age of the mapping.

```
run util lsndb list filters
```

Shows all LSN filters for inbound mappings. Each line will display the inbound mappings along with filter's remote peer IP address and prefix length.

```
run util lsndb list persist
```

Shows all LSN persistence entries. Each line will display the client IP address, the translation address used and the time that the entry will persist in the database (TTL).

```
run util lsndb summary all
```

Show summary for all LSN persistence mappings, inbound mappings and port block entries.

```
run util lsndb summary inbound
```

Show summary for all LSN inbound mapping entries.

```
run util lsndb summary pba
```

Show summary for all LSN port block entries.

```
run util lsndb summary persist
```

Show summary for all LSN persistence entries.

OPTIONS

delete

Delete all objects of the specified type. Client connection counts and port block entries cannot be deleted.

list Display all objects of the specified type.

summary

Display summary information of the specified type.

Object types are:

all = all available object types.

client = LSN client counts (list only).

inbound = LSN inbound mapping entries.

pba = LSN port block entries.

pcp = PCP mappings entries.

persist = LSN translation persist entries.

util platform check

NAME

platform_check - Runs platform checks available on an active system.

MODULE

util

SYNTAX

Run the platform_check utility from within the util module using the following syntax:

```
run util platform_check
```

DESCRIPTION

The platform_check utility runs diagnostics available on an active system to verify correct functionality of platform components. This should be used according to supporting documentation provided by F5.

Output is provided on standard output as well as /var/log/platform_check. Running platform_check with the -h argument will produce available argument listing. Running platform_check with the -l argument will list the available test suites.

EXAMPLES

```
run util platform_check
```

Runs all diagnostics available for an active system.

```
run util platform_check drive
```

Runs only the drive suite of diagnostics.

SEE ALSO

run, tmsh

util platform diag

NAME

platform_diag - Runs platform diagnostics available on an inactive system

MODULE

util

SYNTAX

Run the platform_diag utility from within the util module using the following syntax:

```
run util platform_diag
```

DESCRIPTION

The platform_diag utility runs the diagnostics on an inactive system to verify correct functionality of platform components. This should not be used on an active system. This should be used according to supporting documentation provided by F5.

Output is provided on standard output as well as /var/log/platform_diag. Running platform_diag with the -h argument will produce available argument listing. Running platform_diag with the -l argument will list the available test suites.

EXAMPLES

```
run util platform_diag
```

Runs all appropriate diagnostics for this platform.

```
run util platform_diag hwaccel
```

Runs only the hwaccel suite of diagnostics.

util serverssl-ciphers

NAME

serverssl-ciphers - Display the Server SSL ciphers that match a given cipher string.

MODULE

util

SYNTAX

```
serverssl-ciphers string
```

DESCRIPTION

Use this command to display all Server SSL ciphers that match the given string.

EXAMPLES

run util serverssl-ciphers default

COPYRIGHT

No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2015-06-26 util serverssl-ciphers(1)

util sipdb

NAME

sipdb - Run the sipdb command to view SIP persistence entries.

MODULE

util

SYNTAX

run util sipdb

util ssh keyswap

NAME

ssh-keyswap - Run the ssh-keyswap command to manage SSH keys on the BIG-IP.

MODULE

util

SYNTAX

run util ssh-keyswap

util test-monitor

NAME

test-monitor - Runs an external monitor and displays the inputs to and output from the monitor.

MODULE

util

SYNTAX

Run the test-monitor utility from within the util module using the following syntax:

run util test-monitor address port

DESCRIPTION

The test-monitor utility runs a single instance of a monitor against the specified ip-address:port. The utility output shows the environment, command-line arguments, and resulting messages on stdout and stderr.

Internal monitors are not supported.

EXAMPLES

```
run util test-monitor monitorA address 10.10.10.4 port 80
```

Runs a monitor on the IP address 10.10.10.4 and port 80.

util verify encryption

NAME

verify-encryption - Runs the encrypted attributes diagnostics utility

MODULE

util

SYNTAX

Run the verify-encryption utility from within the util module using the following syntax:

```
run util verify-encryption
run util verify-encryption
```

DESCRIPTION

The verify-encryption runs the /usr/sbin/lssa utility that diagnoses issues with encrypted attributes.

When running this utility, it looks through the files /config/bigip.conf, /config/bigip_base.conf, /config/profile_base.conf, /config/bigip_user.conf and returns lines that match the regular expression of keys, but can't actually be decrypted by the master key. Optionally, a file list can be provided as parameters. Only the specified files will be searched in this case.

EXAMPLES

```
run util verify-encryption
```

Runs the lssa utility for the files /config/bigip.conf, /config/bigip_base.conf, /config/profile_base.conf, /config/bigip_user.conf.

```
run util verify-encryption /config/partitions/partA/bigip.conf
run util verify-encryption /config/partitions/partB/bigip.conf
```

Runs the lssa utility for the space separated file-list.

vcmp

vcmp global

NAME
global - Display global vCMP system statistics.

MODULE
vcmp

SYNTAX
Configure the global component within the vcmp module using the following syntax.

DISPLAY
show global
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION
Use the global component within the vcmp module to display high-level vCMP system statistics on a per-slot basis. These are statistics that are not associated with any particular vCMP guest or virtual-disk.

EXAMPLES
show vcmp global

Display all global vCMP system statistics.

OPTIONS
For information about the options that you can use with the show command, see help show.

SEE ALSO
tmsh, show, vcmp guest, vcmp virtual-disk

COPYRIGHT

vcmp guest

NAME
guest - Configures a cluster of virtual machines (VMs) that run on one or all slots. This cluster is known as a vCMP guest.

MODULE
vcmp

SYNTAX
Configure the guest component within the vcmp module using the syntax in the following sections.

CREATE
create guest [name]
modify guest [name]
options:
 hostname [hostname]
 app-service [[string] | none]
 boot-priority [integer]
 initial-hotfix [hotfix-filename]
 initial-image [image-filename]
 management-gw [ip-address]
 management-ip [ip-address/netmask | ip-address/prefixlen]
 management-network [bridged | isolated]
 slots [integer]
 traffic-profile [vcmp-traffic-profile-name]
 min-slots [integer]
 allowed-slots {
 [slot ID] ...
 }

```
cores-per-slot [integer]
state [configured | provisioned | deployed]
virtual-disk [filename]
vlans [add | delete | replace-all-with] {
[VLAN name] ...
}
capabilities [add | delete | modify | replace-all-with] {
[capability Id] [ { value [integer] } ]
}
```

DISPLAY
list guest
show guest

options:
all-properties
status

DELETE
delete guest [name]

DESCRIPTION
Manage vCMP guests running on this host.

EXAMPLES

list vcmp guest

Lists the current configuration of all guests.

show vcmp guest

Displays detailed information regarding the state and progress of all guests.

show vcmp guest status

Displays the running state of all guests, including each guest's prompt status.

show vcmp guest all-properties

Displays greater detailed statistics and information on all guests.

```
create vcmp guest my_guest slots 4 min-slots 2 management-ip
192.168.45.12/24 management-gw 192.168.45.254 initial-image
BIGIP-11.0.0.2400.0.iso
```

Creates a guest that should span four slots, but must span at least two, with the given management IP and gateway, and with the image file BIGIP-11.0.0.2400.0.iso, which is used to install TMOS on the guest's virtual disks. By default, this guest is in the configured state and has a management network in Bridged mode.

```
modify vcmp guest my_guest state provisioned
```

Moves the guest into the provisioned state, which causes the host to assign the guest to slots, allocate hardware resources to the guest from those slots, and create virtual disks for the guests on those slots.

Moves the guest into the deployed state, which causes the host to start and maintain VMs on each slot that the guest has been assigned to.

```
modify vcmp guest my_guest state configured
```

Moves the guest back to the configured state, which causes all of its VMs to shut down and the hardware to be deallocated. The guest is unassigned from all slots. The guest's virtual disks will remain on the host.

```
modify vcmp guest my_guest traffic-profile fiftyMbpsSLAProfile
```

Adds a traffic-profile named fiftyMbpsSLAProfile to the guest in question, which is configured under vcmp traffic-profile.

OPTIONS

app-service

Specifies the name of the application service to which the guest belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the guest. Only the application service can modify or delete the guest.

boot-priority

Specifies the boot priority of a guest. Lower values mean higher boot priorities. The default value is 65535. Note: Boot priority is only applied when multiple guests start and hardware resources constrain the number of guests starting.

hostname

Assigns the specified host name to the guest. The host name must be a FQDN. If none is given, the default of ".localdomain" is used. If the guest's name contains characters that are not allowed in a FQDN, then "localhost.localdomain" is used.

This is only a suggested value and may be changed on the guest itself. If the guest ever reverts to the default host name, this suggested host name is used instead of the normal system default.

initial-hotfix

Specifies which hotfix image to install on newly created virtual

disks for this guest. This image is only used when initially creating the virtual disks. After initial creation, the typical live-install process should be used on the guest to manage software upgrades. The image filename must match a verified software image file that exists in the /shared/images directory, otherwise the guest will sit in a wait state on any slot that is missing the hotfix image until that image is added.

This field is required if the guest state is provisioned or deployed, otherwise it can be left blank.

initial-image

Specifies which software image to install on newly created virtual disks for this guest. This image is only used when initially creating the virtual disks. After initial creation, the typical live-install process should be used on the guest to manage software upgrades. The image filename must match a verified software image file that exists in the /shared/images directory, otherwise the guest will sit in a wait state on any slot that is missing the software image until that image is added.

This field is required if the guest state is provisioned or deployed, otherwise it can be left blank.

management-gw

Specifies the IP address of the default gateway for the management network. This IP address is only a suggested value and can be changed on the guest itself. If the guest ever reverts to the default management gateway, the suggested gateway is used instead of the normal system default.

This field is required if the guest's management-network is bridged, otherwise it can be left blank.

management-ip

Specifies the management IP address and netmask to assign to the guest. This address floats to the primary slot of the guest.

This is only a suggested value and can be changed on the guest itself. If the guest ever reverts to the default management IP address, the suggested IP address is used instead of the normal system default.

This field is required if the guest's management-network is bridged, otherwise it can be left blank.

management-network

Specifies the management network mode for this guest. When in Bridged mode, the management interfaces on the guest's VMs are bridged to the physical management interfaces on the host blades. This enables the guest to communicate with networks attached to these physical interfaces, the host itself, and other guests in Bridged mode.

In Isolated mode, the management interfaces of the guest's VMs are completely disconnected. The only way to manage such a guest is by connecting to the console on each of the guest's VMs by using the /usr/bin/vconsole utility or by connecting through a configured self IP on a guest's VLAN.

The default value is Bridged.

ssl-mode

Specifies the SSL mode for this guest. When in shared mode the guest shares the available non-dedicated ssl resources with other guests that are in shared mode. when in dedicated mode the guest receives dedicated SSL hardware resources proportional to number of vcpu cores. When in none mode the guest receives no hardware ssl resources. The default value is shared.

slots

Specifies the number of slots to which this guest should be assigned. This number must be greater than zero and no bigger than the cluster size. The host will attempt to assign the guest up to this number of slots.

Note that this property can be changed while the guest is in any state. While in the configured state, modifying the slots property has no effect, since the guest has not yet been assigned to any slots. While in the provisioned state, decreasing this field will cause the guest to be unassigned from enough slots to honor the new value. The host will unassign the guest first from slots that have the most allocated resources. When a guest's slots value is increased, the host attempts to assign the guest to as many slots as possible, up to the new slots value. This same behavior occurs when modifying the property while the guest is in the deployed state, except that running VMs are shut down on any slots that the guest is unassigned from, and new VMs are deployed on any slots to which the guest has been newly assigned.

The default value is 1.

traffic-profile

Specifies a traffic-profile to be used in defining characteristics of traffic which transits the guest's data-plane. For instance a traffic-profile with a color-policer on it that limits the network throughput of the guest may be applied to enforce service agreements between a host admin and a guest user, or to help mitigate network level DOS of other guests in the system.

min-slots

This field dictates the number of slots that the guest must be assigned to. If at the end of any allocation attempt the guest is not assigned to at least this many slots, the attempt fails and

the change that initiated it is reverted. A guest's min-slots value cannot be greater than its slots value.

The default value is 1.

allowed-slots

This list contains those slots that the guest is allowed to be assigned to. When the host determines which slots this guest should be assigned to, only slots in this list will be considered. This is a good way to force guests to be assigned only to particular slots, or, by configuring disjoint allowed-slots lists on two guests, that those guests are never assigned to the same slot.

By default this list includes every available slot in the cluster. This means by default the guest is allowed to be assigned to any slot.

cores-per-slot

This value dictates how many cores a guest is allocated from each slot that it is assigned to. Possible values are dependent on the type of blades being used in this cluster. Use tab-completion to see a list of possible values on the current system.

The default cores-per-slot value depends on the type of blades being used in this cluster.

state

Guests are put into the configured state by default. In this state, the configuration for the guest exists on the host, but none of the guest's VMs are running and no hardware resources (for example: CPU cores, memory) are allocated to it. When the guest moves to the provisioned state, hardware resources are allocated to it, and if not already present, virtual disks are created, and the initial-image is installed onto them. In the deployed state, the vcmpd daemon on the host blades use the allocated resources to launch the VMs. Note that moving from the configured state to the deployed state implies the actions that occur in the provisioned state. To shut down a guest's VMs without de-allocating its hardware resources, move the guest from the deployed state to the provisioned state. Moving a guest to the configured state causes its hardware resources to be deallocated. This does not cause the guest's virtual disks to be deleted. They persist on disk and are reused when the vCMP moves back to the provisioned/deployed states.

virtual-disk

Specifies the filename of the virtual disk to use for this guest's VMs. If the filename does not end in .img, it is appended. When the guest moves to a state in which virtual disks need to be provisioned (provisioned or deployed), a new virtual disk image will be created for the guest with this given filename on each slot that the guest is assigned to and does not already have a virtual disk image. The initial-image is used when creating and installing new virtual disk images. If this field is left blank when virtual disk images need to be provisioned for this guest, a default value of ".img" is assigned. If a virtual disk by that name already exists, then an error is thrown. This prevents virtual disks from accidentally being reused by this assigning of default virtual disk filenames.

capabilities

This list contains the various capability flags and an optional value associated with the guest. The possible capability flags are: appliance-mode, stats-isolated-mode, and host-software-only-mode. The value attributes for these capability flags are currently ignored and may be omitted. The capabilities may be added or removed from a vCMP guest in any state.

The appliance-mode capability disables root and bash access to the guest.

The stats-isolated-mode capability prevents some guest statistics from being sent to the hypervisor.

The host-software-only-mode capability prevents the guest from installing images and hotfixes other than those provided by the hypervisor.

vcmp health ha-status

NAME
ha-status - Display vCMP guest high availability (HA) status.

MODULE
vcmp health

SYNTAX
Display guest HA status using the following syntax.

DISPLAY
show ha-status

DESCRIPTION
Use the ha-status component within the vcmp health module to display HA status information about the vCMP guests deployed on this system. This is similar to running tms show sys ha-status inside of a guest.

EXAMPLES
show vcmp health ha-status
Display HA status status for all guests.
show vcmp health ha-status my_guest
Display HA status status for a single guest; "my_guest".

OPTIONS
For information about the options that you can use with the show command, see help show.

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.
F5 Networks and BIG-IP (c) Copyright 2014. All rights reserved.

BIG-IP 2015-11-05 vcmp health ha-status(1)

vcmp health module-provision

NAME
module-provision - Display vCMP guest module provisioning status.

MODULE
vcmp health

SYNTAX
Display guest module provisioning status using the following syntax.

DISPLAY
show module-provision

DESCRIPTION
Use the module-provision component within the vcmp health module to display module provisioning status information about the vCMP guests deployed on this system. This will show you which modules are provisioned in a guest and at what level.

EXAMPLES
show vcmp health module-provision
Display module provisioning status for all guests.
show vcmp health module-provision my_guest
Display module provisioning status for a single guest; "my_guest".

OPTIONS
For information about the options that you can use with the show command, see help show.

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2015-11-05 vcmp health module-provision(1)

vcmp health prompt

NAME
prompt - Display vCMP guest prompt status.

MODULE
vcmp health

SYNTAX
Display guest prompt status using the following syntax.

DISPLAY
show prompt

DESCRIPTION
Use the prompt component within the vcmp health module to display the per-slot command-line prompts for the vCMP guests deployed on this system. These are the same prompts that one would see when logging into a guest via SSH. Example:
"bigip.mydomain.com:/S1-green-P:Active:Standalone"

EXAMPLES
show vcmp health prompt
Display prompt status for all guests.
show vcmp health prompt my_guest
Display prompt status for a single guest; "my_guest".

OPTIONS
For information about the options that you can use with the show command, see help show.

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

BIG-IP 2015-11-05 vcmp health prompt(1)

vcmp health software

NAME
software - Display vCMP guest software status.

MODULE
vcmp health

SYNTAX
Display guest software status using the following syntax.

DISPLAY
show software

DESCRIPTION
Use the software component within the vcmp health module to display software status information about the vCMP guests deployed on this system. This is similar to running tmsh show sys software inside the guest.

EXAMPLES

```
show vcmp health software
```

Display software status for all guests.

```
show vcmp health software my_guest
```

Display software status for a single guest; "my_guest".

OPTIONS

For information about the options that you can use with the show command, see help show.

COPYRIGHT

```
BIG-IP      2015-11-05      vcmp health software(1)
```

vcmp traffic-profile

NAME

traffic-profile - Configures a traffic-profile, which can be applied to a vCMP guest to control characteristics of data-plane network traffic to the guest.

MODULE

vcmp

SYNTAX

Configure the traffic-profile component within the vcmp module using the syntax in the following sections.

CREATE

```
create traffic-profile [name]
modify traffic-profile [name]
options:
  color-policer [color-policer-name]
```

DISPLAY

```
list traffic-profile
```

options:

```
  all-properties
```

DELETE

```
delete traffic-profile [name]
```

DESCRIPTION

Manage vCMP traffic-profiles running on this host.

EXAMPLES

```
list vcmp traffic-profile
```

Lists the current configuration of all traffic-profiles.

```
create vcmp traffic-profile fiftyMbpsSLAProfile color-policer
fiftyMbpsLimiter
```

Creates a traffic-profile which makes use of the color-policer fiftyMbpsLimiter.

OPTIONS

color-policer

Specifies the color based policer for metering and shaping traffic destined to a guests data-plane.

SEE ALSO

create, delete, edit, glob, list, modify, regex, show, tmsh

COPYRIGHT

BIG-IP      2015-05-12      vcmp traffic-profile(1)
```

vcmp virtual-disk-template

NAME
virtual-disk-template - Manages the vCMP virtual disk templates available on this hypervisor.

MODULE
vcmp

SYNTAX
Configure the virtual-disk-template component within the vcmp module using the syntax in the following sections.

DISPLAY
list virtual-disk-template

options:
all-properties

DELETE
delete virtual-disk-template [name]

DESCRIPTION
The virtual-disk-template component is used to list and delete virtual disk templates that are used to create new virtual disk images for vCMP guests. Virtual disk templates are automatically created by vcmpd when guests move to the Provisioned state and a virtual disk template with the version being installed to the guest's virtual disk image doesn't already exist. This is the only way that virtual disk templates are created. Deleting virtual disk templates frees up space but will slow down future virtual disk image installs of that version; the virtual disk template will need to be first re-created.

EXAMPLES

```
list vcmp virtual-disk-template
```

Lists all virtual disk templates currently available.

```
delete vcmp virtual-disk-template my_vdisk
```

Deletes the virtual disk template named my_vdisk. Note that this is only valid if the virtual-disk-template is not currently attached to any vCMP guest.

SEE ALSO
tmsh vcmp virtual-disk

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

F5 Networks and BIG-IP (c) Copyright 2010-2014. All rights reserved.

BIG-IP 2015-01-14 vcmp virtual-disk-template(1)

vcmp virtual-disk

NAME
virtual-disk - Manages the vCMP virtual disks available on this hypervisor.

MODULE
vcmp

SYNTAX
Configure the virtual-disk component within the vcmp module using the syntax in the following sections.

DISPLAY
list virtual-disk

show virtual-disk

options:
all-properties

show virtual-disk

DELETE
delete virtual-disk [name]

DESCRIPTION

The virtual-disk component is used to list and delete virtual disks that are used by vCMP guests. Virtual disks are automatically created by vcmpd when guests move to the Provisioned state and do not already have virtual disks attached to them. This is the only way that virtual disks are created. Virtual disks that are not attached to any guest can be deleted. Virtual disks not already in use can be explicitly attached to vCMP guests.

EXAMPLES

list vcmp virtual-disk

Lists all virtual disks currently available.

delete vcmp virtual-disk my_vdisk

Deletes the virtual disk named my_vdisk. Note that this is only valid if the virtual-disk is not currently attached to any vCMP guest.

SEE ALSO

create, delete, list, modify, tmsh

BIG-IP 2014-05-08 vcmp virtual-disk(1)

wam

wam ad-policy

NAME
ad-policy - Configures an ad policy for WebAccelerator for use in ad insertion.

MODULE
wam

SYNTAX
Configure the ad-policy within the wam module using the syntax shown in the following sections.

CREATE/MODIFY
create ad-policy [name]
modify ad-policy [name]
options:
ad-insertion-order [random | sequential]
ads [add | delete | modify] {
[name] {
options:
url [url]
preroll [yes | no]
}
}
description [string]

DISPLAY
list ad-policy [name ...]

DELETE
delete ad-policy [name ...]

DESCRIPTION

You can use the ad-policy component to manage the WebAccelerator ad policies. An ad policy defines how the ad insertion is to be performed while processing video resources. Individual ad urls can be configured in the ad-policy along with the insertion order.

EXAMPLES

create wam ad-policy my_ad_policy ads add { my_ad1 { preroll yes url http://www.example.com/ad1.m3u8 } }

Creates an ad policy named `my_ad_policy` with an ad named `my_ad1` for the url `http://www.example.com/ad1.m3u8` and as a preroll candidate.

```
list wam ad-policy my_ad_policy
```

Displays properties of the ad policy named `my_ad_policy`.

```
delete wam ad-policy my_ad_policy
```

Deletes the ad policy named `my_ad_policy`.

OPTIONS

`ad-insertion-order`
Specifies whether the ads are to be inserted randomly or in the order specified in the policy.

`ads` Specifies the collection of ads.

`description`
User defined description of an ad policy.

AD OPTIONS

`url` Specifies the url of the ad.

`preroll`
Specifies that the ad is a candidate for preroll insertion. Preroll ad is inserted at the beginning of the playlist.

SEE ALSO

wam application

NAME

`application` - Configures application for WebAccelerator.

MODULE

`wam`

SYNTAX

Configure the application component within the `wam` module using the syntax shown in the following sections.

CREATE/MODIFY

```
create application [name]
```

```
modify application [name]
```

options:

```
app-service [[string] | none]
```

```
code [number]
```

```
content-expiration-time [date and time]
```

```
description [string]
```

```
hosts [add | delete | modify | replace-all-with] {  
  [ [host name] | [glob] ] {
```

options:

```
app-service [[string] | none]
```

```
code [number]
```

```
subdomain-number-of-http [number]
```

```
subdomain-number-of-https [number]
```

```
subdomain-prefix [string]
```

```
}
```

```
ibr-adaptive-lifetime [number]
```

```
ibr-default-lifetime [number]
```

```
ibr-prefix [string]
```

```
info-header [none | standard | debug]
```

```
multibox [disabled | farm | symmetric]
```

```
policy [name]
```

```
perf-monitor [enabled | disabled]
```

```
perf-monitor-data-retention-period [number]
```

```
collect-roi-statistics [ enabled | disabled ]
```

```
send-metadata [never | always | uncompressed]
```

```
roi-report-email-addresses { string }
```

```
roi-report-frequency [ every-month | every-week ]
```

```
roi-report-name [string]
```

```
roi-report-next-time [date and time]
```

```
roi-report-smtp-config [ smtp configuration object name ]
roi-report-collect-statistics { caching-bytes-saved | client-ibred-links |
    compression-bytes-saved | icc-refed-links | inlined-links |
    caching-requests-saved | client-ibred-links-recd | icc-inlined-links |
    image-opt-bytes-saved | minification-bytes-saved }

edit application [ [ [name] | [glob] | [regex] ] ... ]
options:
    all-properties
    non-default-properties

reset-stats application
reset-stats application [ [ [name] | [glob] | [regex] ] ... ]
```

```
DISPLAY
list application [name ...]
show running-config application [name ...]
options:
    all-properties
    non-default-properties
    partition
    predefined
```

```
show application
show application [name]
options:
    all-properties
    (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
```

```
DELETE
delete application [name ...]
```

Note: You must remove all references to an application before you can delete it.

DESCRIPTION

You can use the application component to configure the host map, select policies, and set application wide parameters that affect WebAccelerator behavior.

EXAMPLES

```
create application my_app hosts add { host1.com host2.com } policy
my_local_policy
```

Creates a WebAccelerator application with a host map consisting of two hosts, host1.com and host2.com, and a local policy set to my_local_policy.

```
modify application my_app remote-policy my_remote_policy
```

Sets my_remote_policy as the remote policy for application my_app.

```
modify application my_app modify hosts { host1.com { subdomain-number-
of-http 3 subdomain-prefix abcd } }
```

Sets the number of subdomain hosts to 3 and the subdomain prefix to abcd for host host1.com of WebAccelerator application my_app.

```
modify application my_app roi-report-name "my_report" roi-report-
frequency monthly roi-report-next-time now roi-report-email-addresses
add { someone@domain.com } roi-report-smtp-config smtp-config roi-
report-collect-statistics add { caching_bytes_saved
caching_requests_saved }
```

Sets the ROI report name to my_report. The ROI report is set to be sent monthly, and the next time to send the report is set to now. The ROI report will be mailed to someone@domain.com. The SMTP configuration used to send the ROI report will be the predefined configuration of name smtp-config. The ROI report will contain the statistics specified by roi-report-collect-statistics, which in this case would be caching_bytes_saved and caching_requests_saved.

```
delete application my_app
```

Deletes WebAccelerator application my_app.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

code Specifies a numeric non-zero code of the application or application host, which is used for troubleshooting and performance reporting. Each application or application host must have a unique code. If not supplied, it will be generated by the system. Use the keyword generate to specify that the system generate a new unique code.

content-expiration-time

Specifies the date and time that limits how old cached documents can be to still be served from the cache. All documents older than this date and time are considered expired. For example, the following example expires all cached documents of the application my_app:

```
modify application my_app content-expiration-time now
```

description

Specifies the object type description.

hosts

Specifies the list of domain names (host names) that might appear in HTTP requests for your Web application. These are the same host names that DNS has mapped to the server machine on which your WebAccelerator system is running. To map a group or range of requested host names to a single destination host, you can use an asterisk (*) as a wildcard for the first part of the host name.

ibr-adaptive-lifetime

Specifies the adaptive lifetime for Intelligent Browser Referencing in seconds. The default value is 864000 (10 days).

ibr-default-lifetime

Specifies the lifetime for Intelligent Browser Referencing in seconds. The default value is 15724800 (6 months).

ibr-prefix

Specifies a prefix for the Intelligent Browser Referencing tag. The default value is ";wa".

info-header

Enables and controls the appearance of HTTP header X-WA-Info: in responses from WebAccelerator. This header can be used for troubleshooting the WebAccelerator system and for tuning policies. The possible values are:

debug

HTTP header X-WA-Info: is included into responses with standard information, with some additional values to aid WebAccelerator troubleshooting.

none HTTP header X-WA-Info: is not included into responses.

standard

HTTP header X-WA-Info: is included into responses with standard information, such as S-code, policy, and node codes, etc.

multibox

Specifies which type of multibox support is required for this application, if any. Options are disabled, for deployments with an independent WebAccelerator; farm, for farm deployments; and symmetric, for symmetric deployments. When this is not disabled, the application should be shared by a config sync device group containing all devices in the deployment. It enables the broadcast of invalidation messages to other devices in the device group, and, when set to symmetric, also enables symmetric processing of traffic.

partition

Displays the administrative partition within which the application resides.

perf-monitor

Specifies whether performance monitoring for this application is enabled. Enabling performance monitoring on many applications may affect the overall performance of WebAccelerator. The default value is disabled.

perf-monitor-data-retention-period

Specifies the time period in days for how long the performance data must be preserved. The default value is 30 days.

collect-roi-statistics

Specifies whether ROI statistics collection for this application is enabled. The default value is disabled.

roi-report-name

Specifies the name of ROI statistics report if the statistics collection is enabled and report generation is desired.

roi-report-frequency

Specifies the frequency of ROI statistics report, if the statistics collection is enabled and report generation is desired. The options are every week or month.

roi-report-email-addresses

Specifies the email-addresses to which ROI statistics report will be sent.

roi-report-next-time

Specifies the next time when the ROI statistics report will be sent.

roi-report-smtp-config

Specifies the smtp configuration that will be used to send the scheduled ROI report over email.

roi-report-collect-statistics

Specifies which statistics are to be included in the ROI statistics report.

policy

Specifies the acceleration policy to which you want to assign the new Web application.

predefined

Displays if this application is predefined.

send-metadata

Specifies when Etag HTTP headers will be included into responses. The default value is always.

always

Etag HTTP headers will always be included into responses.

never
Etag HTTP headers will not be included into responses.

uncompressed
Metadata HTTP headers will be included only if response is uncompressed.

subdomain-number-of-http
Specifies the number of HTTP subdomains that you want the WebAccelerator system to generate. The WebAccelerator system uses these additional subdomains only on embedded URLs or links that request images or scripts. The default value is 0.

subdomain-number-of-https
Specifies the number of HTTPS subdomains that you want the WebAccelerator system to generate. The WebAccelerator system uses these additional subdomains only on embedded URLs or links that request images or scripts. The default value is 0.

subdomain-prefix
Specifies the prefix that you want the system to assign to the subdomains. The default value is wa.

For example, if the Requested Host is `www.siterequest.com`, and you select 2 from the HTTP Subdomains box and type `wa` in the Subdomain Prefix box, the WebAccelerator system changes the domain on qualifying embedded URLs and links to use the following domains:

```
wal.www.siterequest.com
wa2.www.siterequest.com
```

Note: You must configure DNS with these entries, and they must map to the same IP address as the base origin server (`www.siterequest.com` in this example).

wam domain list

NAME
`domain-list` - Configures a list of domains for WebAccelerator for use in inserting DNS prefetch tags.

MODULE
wam

SYNTAX
Configure the `domain-list` component within the `wam` resource module using the syntax shown in the following sections.

```
CREATE/MODIFY
create domain-list [name]
modify domain-list [name]
options:
  app-service [[string] | none]
  description [[string] | none]
  domains
    [add | delete | none | replace-all-with] {
    [string] ...
  }
}
```

```
DISPLAY
list domain-list [name ...]
```

```
DELETE
delete domain-list [name ...]
```

DESCRIPTION
You can use the `domain-list` component to manage the domain list

resources used by the WebAccelerator DNS prefetching feature. A domain-list must be created, then added to the appropriate domain-lists on a WebAccelerator policy node in order for the domains within the domain list to be inserted into a document.

EXAMPLES

```
create domain-list my_domain_list domains add {example.com
example2.com}
```

Creates a domain list resource for the domains example.com and example2.com for use in inserting DNS prefetch tags.

```
list domain-list my_domain_list
```

Displays properties of the domain-list resource named my_domain_list.

```
delete domain-list my_domain_list
```

Deletes the domain-list resource named my_domain_list.

OPTIONS

app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

domains
Specifies the domains described by the domain list resource.

SEE ALSO

create, delete, edit, list, modify, show, tmsh

wam object-type

NAME

object-type - Configures object types for WebAccelerator.

MODULE

wam

SYNTAX

Configure the object-type component within the wam module using the syntax shown in the following sections.

CREATE/MODIFY

```
create object-type [name]
modify object-type [name]
options:
  app-service [[string] | none]
  code [ [number] | generate]
  compression [disabled | policy-controlled]
  description [string]
  extensions [add | delete | modify | replace-all-with] {
    [document extension]
    ...
  }
  mime-types [add | delete | modify | replace-all-with] {
    [MIME type]
    ...
  }
  symmetric-compression [ disabled | enabled ]
```

```
edit object-type [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
```

DISPLAY

```
list object-type [ [ [name] | [glob] | [regex] ] ... ]
show running-config object-type [ [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  non-default-properties
  group
```

partition
predefined

DELETE
delete object-type [name ...]

DESCRIPTION

You can use the object-type component to manage recognized types of objects. These object types are used to classify documents processed by WebAccelerator. A document can be classified by its file extension or MIME type.

EXAMPLES

```
create object-type documents.abcd extensions add { abc abcd } mime-  
types add { text/abcd text/x-abcd }
```

Creates a WebAccelerator object type named documents.abcd that includes all documents with extensions .abc or .abcd, and MIME types text/abcd or text/x-abcd.

```
delete object-type documents.abcd
```

Deletes the pool named documents.abcd.

```
list object-type documents.abcd
```

Displays properties of the object-type named documents.abcd.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

code Specifies the numeric non-zero code of the object type, which is used troubleshooting and performance reporting. Each object type must have unique code. If not supplied, it will be generated by the system. Use keyword generate to have the system generate a new unique code.

compression

Specifies if this object type supports compression and when it can be enabled. The default value is disabled.

Valid values are:

disabled

Never compresses the response. If you use this option, be aware that it overrides any compression setting configured for the assembly rule that the WebAccelerator system matches to the specified object type. You should use this option only if you want the WebAccelerator system to ignore assembly rules for the specified object type.

policy-controlled

Specifies that compression is controlled by WebAccelerator policy. The compression setting is specified in the assembly rule that the WebAccelerator system matched for this object type. In most cases, you should use this option.

description

Specifies the object type description.

extensions

Specifies the extension the WebAccelerator system should find in the file name or Content-Disposition header of the response, in order to match to the specified object type.

group

Displays the group portion of the name.

mime-types

Specifies the MIME-types that the WebAccelerator system should find in the Content-Type header of the response, in order to match to the specified object type.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify. The name of the object type must be in form group.type where group is used to organize object type based on common usage pattern. for example, documents, binary, pages. The type is used to uniquely identify the object type within a group.

partition

Displays the administrative partition within which the object type resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

symmetric-compression

Specifies whether this object type will be compressed on the WAN link in a symmetric multibox deployment.

SEE ALSO

create, delete, edit, list, modify, show, tms

publish-build [integer]
publish-comment [string]
published-on [date]

```

Note: Policies can be created only in the Drafts folder. This is required to support publishing functionality. You may create multiple Drafts folders, one for each folder where published policies are going to reside.

DISPLAY

```

list policy [name ...]
show running-config policy [name ...]
options:
  all-properties
  non-default-properties
  partition
  predefined
  state

```

DELETE

```
delete policy [name ...]
```

SAVE/LOAD

```

save policy [name]
load policy [name]
options:
  overwrite
  file [filename]

```

PUBLISH

```

publish policy [name]
options:
  publish-comment [string]
  publish-build [integer]

```

Note: Published policies can be deleted, but cannot be modified. The only way to update a published policy is to edit and then publish its development version.

DESCRIPTION

You can use the policy component to manage WebAccelerator acceleration policies. An acceleration policy is a collection of defined rule parameters that dictate how the WebAccelerator system handles HTTP requests and responses. The WebAccelerator system uses two types of rules to manage content: matching rules and acceleration rules. Matching rules are used to classify requests by object type and match the request to a specific acceleration policy. Once matched to an acceleration policy, the WebAccelerator system applies the associated acceleration rules to manage the requests and responses. There are multiple types of acceleration rules: variation, proxy, proxy override, parameter value substitution, and invalidation. The WebAccelerator system ships with several predefined acceleration policies that are optimized for specific Web applications, in addition to several non-application specific policies for general delivery and one for an optional symmetric deployment.

EXAMPLES

Note: For the following examples, the current folder is assumed to be set to /Common.

```
create policy "Drafts/My Policy"
```

Creates a new empty policy named My Policy in the folder /Common/Drafts.

```
create policy "Drafts/My Policy" copy-from "/Common/Generic Policy - Complete"
```

Creates a new policy My Policy in the folder /Common/Drafts by copying standard system policy /Common/Generic Policy - Complete.

```
modify policy "Drafts/My Policy" copy-from "/Common/Generic Policy - Complete"
```

Modifies the policy My Policy by overwriting it with standard system policy /Common/Generic Policy - Complete.

```
modify policy "Drafts/My Policy" nodes add { "My Node" { default-from Site }}
```

Adds a new node My Node as the child node of the node Site.

```
modify policy "Drafts/My Policy" nodes modify { "My Node" { matching add { content-type { values add { pages.other }}}}}
```

Adds a new matching rule into the node My Node. The rule will match content type of the requests to WAM object type pages.other.

```
publish policy "Drafts/My Policy" publish-comment "Added new node My Node"
```

Publishes the policy My Policy.

```
modify policy "Drafts/My Policy" nodes delete { "My Node" }
```

Deletes the node My Node from the policy My Policy.

delete policy "My Policy"

Deletes the policy My Policy.

save policy "My Policy" file policy.txt

Saves the policy My Policy into the file /var/local/wam/policy.txt.

load policy "Drafts/My Policy" overwrite file /tmp/policy.txt

Loads the policy My Policy from the file /tmp/policy.txt and overwrites the policy if it already exists.

POLICY OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

code Specifies a numeric non-zero code of the policy that is used for troubleshooting and performance reporting. Each policy must have a unique code. If not supplied, it will be generated by the system. Use the keyword generate to specify that the system generate a new unique code.

copy-from

Specifies the name of an existing policy from which to copy all configuration options. If this field is used in the modify command, the configuration options of the existing policy will be replaced with the new ones. The code, state, publish-build, publish-comment, and published-at options are not updated.

description

User defined description of a policy.

nodes

Specifies the collection of policy nodes. Matching rules and acceleration rules for acceleration policies are organized on the Policy Tree, which consists of nodes. The structure of the Policy Tree supports a parent-child relationship. This enables you to easily randomize rules. That is, because a leaf node in a Policy Tree inherits all the rules from its root node and branch node, you can quickly create multiple leaf nodes that contain the same rule parameters by creating a branch with multiple leaf nodes. If you override or create new rules at the branch node level, the WebAccelerator system reproduces those changes to the associated leaf nodes.

partition

Displays the administrative partition within which the policy resides.

publish-build

Specifies the policy build version that was used during policy publishing. If not specified, this number is automatically incremented by the WebAccelerator system.

publish-comment

Specifies the user supplied comment that describes the changes in the policy that is being published.

published-on

Specifies the date and time when this policy was last published.

file Specifies the file name where the policy is going to be saved or loaded from. If a full path is not specified, it is set to /var/local/wam directory.

overwrite

Specifies that the policy file for the save command or the policy component for the load command can be overwritten if it exists.

NODE OPTIONS

always-proxy

Specifies that all requests matching this node must be proxied. If it enabled, proxy rules are not used, even if configured. proxy-override rules still apply.

app-service

Specifies the name of the application service to which this node belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete this node. Only the application service can modify or delete this node.

assembly-compression

Specifies, when enabled, that the WebAccelerator system compresses content for responses, using gzip-encoding. Note that to use this feature, you must set the compress value for the response's object type in the corresponding object-type component, and the client must be able to accept gzip-encoded content. The default value is enabled.

assembly-compression-ows

Specifies, when enabled, that the WebAccelerator system requests gzip-encoded or deflate-encoded content from the origin Web server. Note that the origin Web server will comply only if it supports compression, otherwise it will reply with uncompressed content. The default value is disabled.

assembly-concatenation

Specifies, when enabled, that the WebAccelerator system will perform JavaScript/CSS concatenation in HTML documents. The URLs that may be concatenated are specified using the assembly-concatenation-sets option. See the WebAccelerator documentation for more details. The default value is disabled.

assembly-concatenation-sets

Specifies the concatenation sets that are active for this node. If a URL in the HTML document that belongs to one of the enabled sets is found, it will be transformed with concatenation using the URL of the configured set. This is an ordered set, and if the URL exists in multiple active concatenation sets, the first set specified by this option will be used. See the WebAccelerator documentation for more details.

assembly-css-inlining

Specifies, when enabled, that the WebAccelerator system will inline CSS URLs in HTML documents. The CSS URLs that may be inlined are specified using the assembly-css-inlining-urls option. See the WebAccelerator documentation for more details. The default value is disabled.

assembly-css-inlining-urls

Specifies the CSS URLs that may be inlined.

assembly-css-reorder

Specifies, when enabled, that the WebAccelerator system will reorder CSS URLs to the HEAD section of HTML documents. The CSS URLs that may be reordered are specified using the assembly-css-reorder-urls option. See the WebAccelerator documentation for more details. The default value is disabled.

assembly-css-reorder-cache-size

Specifies the size of the intermediate cache used to store CSS URLs being reordered. Increasing the size of this cache allows more CSS URLs to be reordered. The default value is 8kB. The maximum value is 8kB.

assembly-css-reorder-urls

Specifies the CSS URLs that may be reordered. The URLs must be fully-qualified and whitespace used to separate URLs. The URLs must correspond to WebAccelerator URL resources created by the command create wam resource url. See the help for wam resource url.

assembly-dns-prefetch

Specifies, when enabled, that the WebAccelerator system manipulates an HTML document to add DNS prefetch tags at the end of the head. The DNS prefetch tags added are the combined list of domain lists specified in assembly-dns-prefetch-domain-lists. DNS prefetch tags will not be inserted in the following conditions: when DNS prefetching is explicitly disabled in the document, either by an HTTP header or by a meta-tag in the head of the HTML document; when the connection is served over HTTPS without assembly-dns-prefetch-https-enable enabled; or when the connection is to a client browser that does not support DNS prefetching.

In a document, most browsers will perform DNS prefetching on all domains linked with an HREF. This will speed up performance by having the browser cache possible DNS resolutions before a client clicks on a link, but DNS prefetching cannot automatically occur when a link is created through other means (such as javascript). Inserting DNS prefetch tags addresses this issue.

The default value is disabled.

assembly-dns-prefetch-domain-lists

Specifies the lists of domains that will be inserted into a document. The domain lists must correspond to WebAccelerator domain list resources created by the command create wam resource domain-list. See the help for wam resource domain-list.

assembly-dns-prefetch-https-enable

Specifies, when enabled, that the WebAccelerator system manipulates an HTML document to add DNS prefetch tags at the end of the head when a document is served over HTTPS when the client browser supports DNS prefetching. By default, most browsers that support DNS prefetching will not do any DNS prefetching on pages served over HTTPS. Enabling assembly-dns-prefetch-https-enable will insert a meta-header that will turn on DNS prefetching on the page and a meta-header turning off DNS prefetching for the rest of the page. DNS prefetching cannot be turned on for the rest of an HTML document once the meta-header turning off DNS prefetching is reached.

DNS prefetching is turned off on most browsers serving pages over HTTPS by default as a security measure. DNS prefetching can be used to track which pages are seen over HTTPS by watching the domain resolution requests sent out by the client. According to DNS prefetch standards currently, turning on DNS prefetching on a page will cause all links in the page to have their domains prefetched. This is mitigated by this option with the insertion of an HTTP meta-header turning off DNS prefetching after the DNS tags inserted by the WebAccelerator system. Turning on DNS prefetching for the rest of the page in a request served over HTTPS can be done with the assembly-dns-prefetch-https-automatic option.

The default value is disabled.

assembly-dns-prefetch-https-automatic

Specifies, when enabled, that the WebAccelerator system will not insert a meta-tag into an HTML document served over HTTPS turning

off DNS prefetching for the rest of a page. By default, most browsers that support DNS prefetching will not do any DNS prefetching on pages served over HTTPS. `assembly-dns-prefetch-https-enable` must be enabled for this option to work.

The default value is disabled.

`assembly-ibr`

Specifies, when enabled, that the WebAccelerator system manipulates the Web browser cache to reduce requests to your site for relatively static content, such as images and style sheet (CSS) files. The default value is enabled.

`assembly-image-inlining`

Specifies, when enabled, that the WebAccelerator system will inline image URLs in CSS documents. The image URLs that may be inlined are specified using the `assembly-image-inlining-urls` option. See the WebAccelerator documentation for more details. The default value is disabled.

`assembly-image-inlining-max-size`

Specifies the maximum size of the image that is allowed to be inlined. The default value is 2kB. The maximum value is 8kB.

`assembly-image-inlining-urls`

Specifies the image URLs that may be inlined.

`assembly-js-inlining`

Specifies, when enabled, that the WebAccelerator system will inline JS URLs in HTML documents. The JS URLs that may be inlined are specified using the `assembly-js-inlining-urls` option. See the WebAccelerator documentation for more details. The default value is disabled.

`assembly-js-inlining-urls`

Specifies the JS URLs that may be inlined.

`assembly-js-reorder`

Specifies, when enabled, that the WebAccelerator system will reorder JavaScript URLs to the end of HTML documents. The JavaScript URLs that may be reordered are specified using the `assembly-js-reorder-urls` option. See the WebAccelerator documentation for more details. The default value is disabled.

`assembly-js-reorder-cache-size`

Specifies the size of the intermediate cache used to store JavaScript URLs being reordered. Increasing the size of this cache allows more JavaScript URLs to be reordered. The default value is 8kB. The maximum value is 8kB.

`assembly-js-reorder-urls`

Specifies the JavaScript URLs that may be reordered. The URLs must be fully-qualified and whitespace used to separate URLs. The URLs must correspond to WebAccelerator URL resources created by the command `create wam resource url`. See the help for `wam resource url`.

`assembly-intelligent-client-cache`

Specifies, when enabled, that the WebAccelerator system will Intelligent Client Cache HTML documents. See the WebAccelerator documentation for more details. The default value is disabled.

`assembly-icc-force`

Specifies, when enabled, that the WebAccelerator system will Intelligent Client Cache HTML documents, even if the client does not support HTML5 localStorage. See the WebAccelerator documentation for more details. The default value is disabled.

`assembly-icc-image-max-size`

Specifies the maximum size of the image that is allowed to be inlined as part of Intelligent Client Caching. The default value is 32kB. The maximum value is 50kB.

`assembly-icc-css-max-size`

Specifies the maximum size of the CSS that is allowed to be inlined as part of Intelligent Client Caching. The default value is 50kB. The maximum value is 1024kB.

`assembly-icc-js-max-size`

Specifies the maximum size of the JS that is allowed to be inlined as part of Intelligent Client Caching. The default value is 50kB. The maximum value is 1024kB.

`assembly-icc-max-num-urls`

Specifies the maximum number of links in an HTML document that are allowed to be inlined as part of Intelligent Client Caching. The default value is 10. The maximum value is 100.

`assembly-icc-min-client-expiry`

Specifies the minimum client expiry of a resource that is allowed to be inlined as part of Intelligent Client Caching. The default value is 2days.

`assembly-minification`

Specifies, when enabled, that the WebAccelerator system will minify JavaScript and CSS.

`assembly-multiconnect`

Specifies, when enabled, that the WebAccelerator system modifies embedded URLs with unique sub-domains that prompt the browser to open more persistent connections for each supported protocol (HTTP or HTTPS). To use this feature, you must configure DNS with the additional domains and map those domains to the same IP address as the base origin server. The default value is enabled.

assembly-on-proxies

Specifies, when enabled, that the WebAccelerator system applies the Content Compression and Intelligent Browser Referencing features (if enabled) to content served to clients, even if the content is not served from the WebAccelerator system's cache. Enable this option if you are using the Content Compression or Intelligent Browser Referencing features. The default value is enabled.

assembly-pdf-linearization

Specifies, when enabled, that the WebAccelerator system applies linearization on PDF documents, if the documents match the node matching rules. PDF linearization transforms the document to include the index of the pages in the beginning. This allows Web browsers to load and show specific pages rather than a whole document. See the WebAccelerator documentation for more details. The default value is disabled.

optimize-image

Specifies whether image optimization should be applied and the format conversion to use. Each of the 4 supported formats (JPEG, PNG, GIF, TIFF) can be converted to any of the others. Images using a capability unique to one format may lose that feature when converted to a format that does not support it. (For example, animated GIFs or multipage-TIFFs will have only the first image when converted to PNG or JPEG). Transparency will be lost when converting from GIF or PNG to JPEG. TIFF is a container for many different image formats so the results will be best-effort and may not list completely.

A converted image will likely have a different number of bytes after conversion. Some conversions are likely to produce fewer bytes; however, a requested conversion will be done even if it results in more bytes (for consistency). For example, you may want to offer multiple formats of an image without storing them all on a server.

A correct Content-Type header will be generated for converted images, but HTML files will not be rewritten.

`optimize-for-client` Specifies whether to allow conversion to a format and/or size which is optimum for the specific client making the request but which, if saved by that client and later sent elsewhere, might not be appropriate.

`webp-quality` WebP is a "lossy" compression format. This means when you convert an image to a WebP and then convert it back, you will not get back exactly the same image you started with. Compression changes the amount of information stored (and therefore the number of bytes), but not the image dimensions (the number of pixels). The `webp-quality` attribute represents the absolute quality of the WebP produced. Compression (quality) is represented as a number between 1-100 where 1 is minimal quality, but small, and 100 is high-quality, but large. For most images, useful values of quality will be from about 30-70.

`jpegxr-quality` JPEG-XR is a "lossy" compression format. This means when you convert an image to a JPEG-XR and then convert it back, you will not get back exactly the same image you started with. Compression changes the amount of information stored (and therefore the number of bytes), but not the image dimensions (the number of pixels). The `jpegxr-quality` attribute represents the absolute quality of the JPEG-XR produced. Compression (quality) is represented as a number between 1-100 where 1 is minimal quality, but small, and 100 is high-quality, but large. For most images, useful values of quality will be from about 5-30.

`jpeg-quality-is-relative` =item `jpeg-quality`

JPEG is a "lossy" compression format. This means when you convert an image to a JPEG and then convert it back, you will not get back exactly the same image you started with. Compression changes the amount of information stored (and therefore the number of bytes), but not the image dimensions (the number of pixels). When `jpeg-quality-is-relative` is set to no, the `jpeg-quality` attribute represents the absolute quality of the JPEG produced. Compression (quality) is represented as a number between 1-100 where 1 is minimal quality, but small, and 100 is high-quality, but large. For most images, useful values of quality will be from about 30-100. Because information once lost cannot be regained, converting a low-quality JPEG to a higher quality is pointless and image optimization will prevent that (by not changing the original to a higher JPEG quality).

You might be unable to choose a specific absolute quality for JPEG images. When `jpeg-quality-is-relative` is set to yes, the relative JPEG quality setting is enabled. In this case, `jpeg-quality` is a percentage (a number between 1-100) that when multiplied by each JPEG's original quality, becomes its optimized quality.

`jpeg-strip-exif`

JPEG files have a header (called EXIF) that contains optional data such as a date, time, camera model, exposure settings, and so on. The EXIF header can also contain a color profile, which is required when included. EXIF headers can be small or large. Unless they contain a color profile, they do not affect displaying the image, and so can be removed if the loss of the information they contain is acceptable. There are four options for this setting:

`no` Leaves any EXIF headers alone.

`yes` Always strips EXIF headers.

`if-safe`

Only strips EXIF headers if they do not have color profiles (ensures that images display properly).

`make-safe`

Applies the color profile and then strips the EXIF header (typically decreases image file size). Applying a color profile requires additional CPU time.

jpeg-strip-keeps-copyright This setting affects the meaning of `jpeg-strip-exif`. If it is set, stripping the EXIF header will strip everything except the Copyright notice (if one is present).

jpeg-sampling-factor
Sets the sampling factor to be used when producing JPEG images. The default value is `preserve`, which matches the original file. You can also explicitly specify this option, as it can sometimes improve compression.

jpeg-progressive-encoding
When enabled, progressive encoding will be used in JPEG images. For large JPEG files, this can improve compression. When this is enabled, it will be applied only if the file is large enough to improve compression.

png-256-colors
It is often possible to significantly reduce the size of PNG files without changing their appearance very much by reducing the number of colors to 256 optimally selected values. This optimization is enabled when `png-256-colors` is set to `yes`.

cache-complete-only
Specifies, when enabled, that the WebAccelerator system caches HTML pages only if the HTML code within the page contains begin and end tags. When disabled, the WebAccelerator system reviews HTTP response headers to determine if the information contained on the page is complete. The default value is `enabled`.

cache-first-hit
Specifies that the first response should be cached according to the policy caching settings. When this is off, the response is cached when more than one request for the document has been seen. Turning this on can reduce cache churn for unpopular documents. The default value is `no`.

cache-mode
Specifies how where the cached documents will be stored. The default value is `memory-and-disk`. Possible values are:

memory-and-disk
The cached documents will be stored in memory or on disk.

memory-only
The cached documents will be stored in memory only.

cache-priority
Specifies the cache admission priority of documents matching the policy node. Documents with high priority are more likely to be admitted into the cache. The default value is `medium`. Possible values are:

low Documents will have low priority.

medium
Documents will have medium priority.

high Documents will have high priority.

cache-stand-in-period
Specifies the amount of time that the WebAccelerator system continues to serve content from cache if the origin Web server does not respond to the WebAccelerator system's requests for fresh content. The default value is 0 (zero), which means the WebAccelerator system responds to requests for expired content with a HTTP 404 error.

code Specifies a numeric non-zero code for the node that is used for troubleshooting and performance reporting. All nodes must have unique codes within the policy. If not supplied, the code will be generated by the system. Use the keyword `generate` to specify that the system generate a new unique code.

coherency
Specifies if the WebAccelerator system will attempt to keep content matching the associated node in sync across the blades of a cluster. The default behavior is to keep content in sync.

blade
The cached documents will not be kept coherent across blades. This causes each blade to have its own copy of a given cached document.

cluster
The cached documents will be kept coherent across blades. This causes the cluster to have single version of a given cached document.

defaults-from
Specifies the node that you want to use as the parent node. Your new node inherits all options and values from the parent node specified. The default value is `none`, which means this is a root node.

description
User defined description of a node.

invalidations
Specifies the collection of invalidations rules. Invalidations rules enable you to expire cached content before it has reached its time-to-live (TTL) value. This is useful when content updates

are event-driven, such as when an item is added to a shopping cart, a request contains a new auction bid, or a poster has submitted content on a forum thread. Invalidations rules can be created only on leaf nodes.

lifetime-cache-control-extensions

Enables you to configure extension tokens to be added to the cache-control header of HTTP response. The WebAccelerator system does not process any of these extensions. It is possible that the origin Web server will send cache-control extensions as well. You can choose whether to preserve them by including the custom-extension in the lifetime-preserve-response-values list.

lifetime-cache-max-age

Specifies the amount of time that the WebAccelerator system serves content from the cache before requesting fresh content from the origin Web server. The default value is 4 hours.

lifetime-honor-ows

Specifies, if enabled, that the WebAccelerator system honors certain cache-control directives from the origin Web server response to determine cache lifetime. The default value is disabled.

lifetime-honor-ows-values

Specifies which Cache-Control directive from the origin Web server response will determine cache lifetime. Available directives are all-values, private, no-cache, no-store, must-revalidate, proxy-revalidate, max-age, s-maxage, and expires. This option is only effective if lifetime-honor-ows is enabled.

lifetime-honor-request

Specifies, if enabled, that the WebAccelerator system honors certain Cache-Control directives from the client's browser request to determine cache lifetime. The default value is enabled.

lifetime-honor-request-values

Specifies which cache-control directive from client's browser request will determine cache lifetime. Available directives are all-values, no-cache, no-store, max-age, max-stale, and min-fresh. This option is only effective if lifetime-honor-request is enabled. The default values are max-age, max-stale, and min-fresh.

lifetime-http-heuristic

Specifies the percentage, based on the HTTP Last-Modified header, that the WebAccelerator system uses to compute TTL values for cached content. For example, if content was modified 30 days ago and the lifetime-http-heuristic option is set to 50%, the WebAccelerator system caches the content for 15 days. This option is applicable only if you use the HTTP Last-Modified headers to identify content lifetime. The default value is 50%. This option is effective only if lifetime-use-heuristic is enabled.

lifetime-insert-no-cache

Specifies, when enabled, that the WebAccelerator system inserts a no-cache directive into the HTTP Cache-Control header, which stops the client's browser from locally caching content. This value overrides the HTTP Cache-Control header cache directives sent to the client by the origin Web server.

lifetime-preserve-response

Specifies, if enabled, that the WebAccelerator system preserves certain Cache-Control directives from the origin Web server and includes them into client's browser response. The default value is enabled.

lifetime-preserve-response-values

Specifies which Cache-Control directive from the origin web server response will be preserved in response to the client's web browser. Available directives are all-values, private, no-cache, no-store, must-revalidate, proxy-revalidate, max-age, s-maxage, expires, and custom-extension. This option is only effective if lifetime-preserve-response is enabled. The default value is all-values.

lifetime-response-max-age

Specifies, when enabled, the amount of time that the client's browser should locally store content. This value overrides the max-age and expires the directives in the HTTP Cache-Control header that are sent to the client by the origin web server, only if the new value for the max-age is greater than the value supplied by the origin web server. Modify this value only if there is an acceptable trade off between the freshness of the content served to clients and overall site performance.

lifetime-response-s-maxage

Specifies, when enabled, the amount of time that the client's browser should locally store shared content. This value overrides the s-maxage and expires the directives in the HTTP Cache-Control header that are sent to the client by the origin web server, only if the new value for the s-maxage is greater than the value supplied by the origin web server. Modify this value only if there is an acceptable trade off between the freshness of the shared content served to clients and overall site performance.

lifetime-stand-in-codes

Specifies that the WebAccelerator system is allowed to serve stale content from the cache if it is not able to re-validate its freshness with the origin web server. The WebAccelerator system serves invalid content to the downstream proxies or clients if the response code from the origin web server matches one of codes specified with this option. This option is effective only if cache-stand-in-period has a non-zero value. The default values are 404, 500, and 504.

lifetime-use-heuristic

Specifies, when enabled, that the WebAccelerator system uses the percentage from lifetime-use-heuristic option to compute TTL values for cached content. The default value is no.

matching

Specifies the collection of matching rules. The rules consist of the HTTP request data type parameters that the WebAccelerator system uses to match an incoming HTTP request to a specified node. The following types of HTTP parameters are available for matching rules: host, path, extension, query-param, unnamed-query-param, path-segment, cookie, user-agent, referrer, protocol, method, header, client-ip, and content-type.

object-min-size

Specifies the minimum object size required in order for content matching the associated node to be eligible for caching. The default behavior is to use the minimum object size specified by the associated web-acceleration profile.

object-max-size

Specifies the maximum object size allowed for content matching the associated node in order to be eligible for caching. The default behavior is to use the maximum object size specified by the associated web-acceleration profile.

order

Specifies the order of the node in the Policy Tree. All nodes in the policy must have an order. The order numbers are sequential, starting from 2. Orders 0 and 1 are reserved for internal use. The child node orders must be greater than the order of their parent node. You can change the order of the nodes by updating the order option of the node that you would like to move. The system honors the specified order if it falls within the range of sibling node orders. Otherwise, the system picks the closest valid order number. The remaining nodes are automatically re-ordered to free requested order number. The node order is also used as a last resort to determine which node to use when multiple nodes match the request. The node with a lower order wins. New nodes have their order assigned automatically to make them last among their siblings.

proxy

Specifies the collection of proxy rules. In general, proxy rules options are relevant to only requests that match their node, rather than to matched responses. The following types of HTTP parameters are available for proxy rules: host, query-param, unnamed-query-param, path-segment, cookie, user-agent, referrer, protocol, method, header, and client-ip.

proxy-override

Specifies the collection of proxy override rules. You can define proxy override rules and associated conditions under which the WebAccelerator system should ignore proxying rules options. The following types of HTTP parameters are available for proxy override rules: host, query-param, unnamed-query-param, path-segment, cookie, user-agent, referrer, protocol, method, header, and client-ip.

request-queueing

Specifies, when enabled, that the WebAccelerator system will queue requests for expired or new documents and proxy fewer requests to the origin web server (OWS). If the response is cachable, the response will be served to all waiting requests; if not, the waiting requests will proxy normally.

response-codes-cached

Specifies the collection of HTTP response codes that determine whether the WebAccelerator system should cache the content. The valid codes are 300, 301, 302, 307, and 410. The codes 200, 201, 203, and 207 are included into the list implicitly. The default values are 300 and 301.

substitutions

Specifies the collection of parameter value substitution rules. Some requested pages include hyperlinks that require that specific information appear in the response. You can configure parameter value substitution so that when a query parameter contains identification information for a sites visitors, it prompts the WebAccelerator system to serve different content for the request, based on the specific visitor. Conversely, if parameter value substitution is not configured, the WebAccelerator system uses the value that it cached for the original request, for all subsequent requests after the first, even if the subsequent requests have different values that should be used in the response.

If you configure parameter value substitution, the WebAccelerator system changes the targeted parameters value on the page served from the cache, so that the parameter you specify appears on the URL embedded in that page.

variation

Specifies the collection of variation rules. When the WebAccelerator system caches responses from the origin web server, it uses certain HTTP request parameters to create a Unique Content Identifier (UCI). The WebAccelerator system stores the UCI in the form of a compiled response and uses the UCI to easily match future requests to the correct content in its cache. You can configure variation rules to add or modify the parameters on which the WebAccelerator system bases its caching process. If the WebAccelerator system receives two requests that are identical except for the value of a query parameter defined in the variation rule, it creates a different UCI for each, and caches each

response under its unique UCI. The following types of HTTP parameters are available for variation rules: host, query-param, unnamed-query-param, path-segment, cookie, user-agent, referrer, protocol, method, header, and client-ip.

viewstate-cache
Specifies, when enabled, that the WebAccelerator system accelerates requests and responses for Web form objects that are generated by ASP.NET web applications. Because the file size of forms can be significant, the WebAccelerator system is able to cache and substitute values, thus reducing the file size and achieving faster performance.

viewstate-cache-size
Specifies the size of the ViewState object cache in kilobytes. The default value is 100 kilobytes.

viewstate-tag
Specifies the name of the web form field where the ViewState object is stored. The default value is `__VIEWSTATE`.

video-optimization-fast-start
Specifies when enabled, that the WebAccelerator system optimizes video by prefetching.

video-optimization-max-bitrate
Specifies, the maximum bitrate of video that can be allowed in kilobits per sec. The default value is 0.

video-optimization-insert-ad
Specifies, when enabled, that the WebAccelerator system can insert ad into the video.

video-optimization-preroll-ad
Specifies, when enabled, that the WebAccelerator system can insert ad at the beginning of the video.

video-optimization-ad-frequency
Specifies the frequency of ad insertion. Units in seconds.

video-optimization-ad-policy
Specifies the ad policy applicable when processing the video.

type Displays the node type. The possible types are:

branch

The branch nodes exist only for the purpose of propagating rule parameters to leaf nodes. The WebAccelerator system does not perform matching against branch nodes. Branch nodes can have multiple leaf (child) nodes, as well as child branch nodes.

leaf A leaf node inherits rule parameters from its parent branch node. The WebAccelerator system performs matching only against leaf nodes, and then applies the leaf nodes corresponding acceleration rules to the request.

HTTP PARAMETERS

Both matching and acceleration rules are identified by the type, and optionally, by the name of HTTP parameters that are used inside the rules. The following types of HTTP parameters are available:

content-type

A rule that uses the content-type parameter is based on type definitions in the object-type components. Unlike the HTTP request data types, a matching rule based on content type is specific to the content type parameter that the WebAccelerator system generates for a response. You specify the regular expression that you want a response's content type to match.

client-ip

A rule that uses the client IP parameter is based on the IP address of the client making the request. The IP address, however, may not always be the address of the client that originated the request. For example, if the client goes through a proxy server, the IP address is the IP address of the proxy server, rather than the client IP address that originated the request. If several clients use a specific proxy server, they all appear to come from the same IP address.

cookie:[name]

A rule that uses the cookie parameter is based on a particular cookie that you identify by name, and for which you provide a value to match against. This value is usually literal and must appear on the cookie in the request or in a regular expression that matches the request's cookie that appears on the cookie HTTP request headers. These are the same names you use to set the cookies, using the HTTP Set-Cookie response headers. The HTTP request can contain multiple cookies, and the rule identifier must include the name of the cookie separated with colon (:).

extension

A rule that uses the extension parameter is based on the value that follows the far-right period, in the far-right segment key of the URL path.

header:[name]

A rule that uses the header parameter is based on a particular header that you identify by name and for which you provide a value to match against. You can use an HTTP request data type header parameter to create rules based on any request header other than one of the recognized HTTP request data types. The HTTP request can contain multiple headers, and the rule identifier must include the name of the header separated with colon (:).

host A rule that uses the host parameter is based on the value provided for the HTTP Host request header field. This header field describes the DNS name that the HTTP request is using.

method

A rule that uses the method parameter is based on whether the request uses the GET or POST method.

query-param:[name]

A rule that uses the query parameter is based on a particular query parameter that you identify by name and for which you provide a value to match against. The value is usually literal and must appear on the query parameter in the request, or in a regular expression that matches the request's query parameter value. The query parameter can be in a request that uses GET or POST methods. The HTTP request can contain multiple query parameters, and the rule identifier must include the name of the header separated with colon (:).

path A rule that uses the path parameter is based on the path portion of the URI. The path is defined as everything in the URL after the host and up to the end of the URL, or up to the question mark (whichever comes first).

path-segment:[name]

A segment is the portion of a URI path that is delimited by a forward slash (/). For example, in the path: /apps/search/full/complex.jsp, apps, search, full, and complex.jsp all represent path segments. The path can contain multiple segments so the rule identifier must include the name of the segment separated with colon (:). The name can be a segment ordinal or some other string to distinguish it from other segments rules in the same node.

protocol

A rule that uses the protocol parameter is based on whether the request uses the HTTP or HTTPS protocol.

referrer

A rule that uses the referrer parameter is based on the value provided for the HTTP Referer in the request header. (Note the misspelling of Referer. This spelling is defined for this request header in all versions of the HTTP specification.) This header provides the URL location that referred the client to the page that the client is requesting. You do not typically base rules on the Referer request header, unless you want your sites behavior to be dependent on the specific referrer. For example, one implementation would be for sites that provide different branding for their pages based on the user's web portal or search engine.

unnamed-query-param:[name]

An unnamed query parameter is a query parameter that has no equal sign. That is, only the query parameter value is provided in the URL of the request. The HTTP request may contain multiple unnamed query parameters so the rule identifier must include the name of it separated with colon (:). The name can be the ordinal of unnamed query parameter or some other string that can make it distinguishable from other unnamed query parameter rules in the same node.

user-agent

A rule that uses the user agent parameter is based on the value provided for the HTTP User-Agent in the request header, which identifies the browser that sent the request.

RULE OPTIONS

active

Specifies, when enabled, that the invalidation trigger rule is enabled. You can use this option to disable a specific invalidation trigger rule temporary, without removing it from the policy.

arg-all

Specifies, when enabled, that the rule matches all HTTP parameters of this type rather than one identified by arg-name or arg-ordinal. This option is applicable to variation rules query-param, unnamed-query-param, path-segment, cookie, and header. Such rules serve as a fallback case for defining document variation. All root nodes must include one variation rule of each type with this option enabled. The default value is disabled.

arg-alias

src-alias

dst-alias

request-data-alias

Specifies the user supplied alias for rules that use ordinals to identify HTTP request data. These include the unnamed-query-param and path-segment rules. The src-alias and dst-alias options are used in parameter value substitution rules to define aliases for the source and target definitions correspondingly. The request-data-alias option defines an alias for the invalidation trigger rules.

arg-direction

src-direction

dst-direction

request-data-direction

Specifies the direction that the WebAccelerator system uses to count the ordinal of path-segment. The src-direction and dst-direction options are used in parameter value substitution rules to define the ordinal direction for the source and target definitions correspondingly. The request-data-direction option defines the ordinal direction for the invalidation trigger rules.

The default value is left-to-right. The possible values are:

left-to-right

The path segment is counted form left to right.

right-to-left

The path segment is counted form right to left.

arg-name
src-name
dst-name
request-data-name

Specifies the name of the parameter type for query-param, cookie, and header. If not specified, arg-name option is initialized from the rule name. This option is not effective if arg-all is enabled. The src-name and dst-dst options are used in parameter value substitution rules to define the parameter name for the source and target definitions correspondingly. The request-data-name option defines the parameter name for the invalidation trigger rules.

arg-ordinal
src-ordinal
dst-ordinal
request-data-ordinal

Specifies, in the form of a number, the location of a parameter for unnamed-query-param and path-segment rules. The numbering starts at 1 and follows the direction specified in the corresponding direction option. This option is not effective if arg-all is enabled. The src-ordinal and dst-ordinal options are used in parameter value substitution rules to define the parameter ordinal for the source and target definitions correspondingly. The request-data-ordinal option defines the parameter ordinal for the invalidation trigger rules.

broadcast

Specifies whether a triggered invalidation rule is broadcast to other members of a multibox deployment. This option is only effective when the application using this policy has multibox set to farm or symmetric.

cache-content

Specifies the parameter for which the WebAccelerator system must obtain fresh content when the invalidations rule is triggered. The available request types are: host, path, extension, query-param, unnamed-query-param, path-segment, cookie, user-agent, referrer, protocol, method, header, and client-ip.

Note: You must select and configure the path parameter for the cached content to invalidate, or the invalidations rule will fail to trigger. All other parameters are optional.

description

User-defined description of a rule.

dst-type

Specifies the HTTP parameter type to use as target definition for the request value substitution rule. A target definition contains a value in the embedded URL that you want the WebAccelerator system to replace with the value that you specified for the source definition, during assembly. The possible values are:

path-segment

Specifies that the WebAccelerator system targets the URL parameter, as specified by the dst-ordinal and dst-direction you define.

query-param

Specifies that the WebAccelerator system targets the URL parameter, as specified by the dst-name you define.

unnamed-query-param

Specifies that the WebAccelerator system substitutes the URL parameter, as specified by the dst-ordinal you define.

dst-urls

Specifies the collection of URLs in the request for which you want the WebAccelerator system to replace content.

request

Specifies a parameter in the request that triggers the invalidations rule. The available request types are: host, path, extension, query-param, unnamed-query-param, path-segment, cookie, user-agent, referrer, protocol, method, header, and client-ip.

Note: You must select and configure the path parameter for the request header criteria, or the invalidations rule will fail to trigger. All other parameters are optional.

request-data-type

Specifies the HTTP request parameter value that the WebAccelerator system should find in its cache and for which it should request updated content from the origin Web server. The default value is undefined.

The following types of HTTP parameters are available:

host
query-param
unnamed-query-param
path-segment
cookie
user-agent
referrer
header

client-ip

Specifies that the WebAccelerator system should use the corresponding value from the request that triggered the invalidation. Additional data, if required to identify the value, must be specified in the request-data-name, request-data-ordinal, and request-data-direction options. The values option is ignored.

undefined

Specifies that the WebAccelerator system should not use any values from the request that triggered the invalidation. You must add a value into the values option with which to compare the cached content.

src-type

Specifies the HTTP parameter type to use as source definition for the request value substitution rule. A source definition contains the value that the WebAccelerator system embeds in the URL, in place of the cached (target definition) value, during substitution. Typically, the source definition is a specific request element, such as a particular query parameter; however, you can specify another source type, such as a random number. The possible values are:

path-segment

Specifies that the WebAccelerator system substitutes the URL parameter, as specified by the src-ordinal and src-direction options you define.

query-param

Specifies that the WebAccelerator system substitutes the URL parameter, as specified by the src-name option you define.

randomizer

Specifies that the WebAccelerator system generates a random number and places that number on the targeted location in an embedded URL.

request-url

Specifies that the WebAccelerator system is limited to target-specific URLs embedded in a page, as defined in the prefix that an embedded URL must match before the WebAccelerator system performs substitution. If you use the request URL as the source, the WebAccelerator system uses the entire request URL as the value to substitute.

unnamed-query-param

Specifies that the WebAccelerator system substitutes the URL parameter, as specified by the src-ordinal option you define.

src-url

Specifies whether the request URL is a relative URL or an absolute URL. The default value is absolute.

value-case-sensitive

Specifies, when enabled, that the HTTP parameter must be matched against supplied value(s) in case sensitive manner. The default value is no.

values

Values are a collection of rule parameters that enable you to specify different parameter values for the same rule. Most rules allow only one value, while variation rules support multiple values. Each value can prompt a different behavior by the WebAccelerator system. All variation rules must include at least one value with match-all option enabled. A value can be represented by actual string, regex, or multiple strings, or regexes separated by space ().

RULE VALUE OPTIONS

can-be-empty

Specifies, when enabled, that the defined HTTP request parameter is included in the request, but has no value (is an empty string). The default value is no.

can-be-missing

Specifies, when enabled, that the defined HTTP request parameter is absent from the request. The default value is no.

invert-match

Specifies, when enabled, that the defined HTTP request parameter does not match the associated regular expression that you defined. The default value is no.

match-all

Specifies, when enabled, that the defined HTTP request parameter matches all possible values. This option is available only for variation rule values as a fallback case. Each variation rule must have at least one value with this option enabled. The default value is no.

cache-as

Specifies whether the associated value should prompt the WebAccelerator system to reply to matched requests with the same or different content. This option is available only for variation rule values.

wam resource concat-set

NAME
concat-set - Configures concatenation sets for WebAccelerator for use in JavaScript/CSS concatenation

MODULE
wam resource

SYNTAX
Configure the concat-set within the wam resource module using the syntax shown in the following sections.

CREATE/MODIFY
create concat-set [name]
modify concat-set [name]
options:
 app-service [[string] | none]
 url [url]
 type [css|js]
 members [string] ...

DISPLAY
list concat-set [name ...]

DELETE
delete concat-set [name ...]

DESCRIPTION
You can use the concat-set component to manage the concatenation sets used by the WebAccelerator JavaScript and CSS concatenation feature. A concatenation set must be created, then enabled and activated in the configuration on a WebAccelerator policy node.

EXAMPLES
create concat-set testSet url http://www.example.com/concatSet.css type css

Creates a set whose URL will be http://www.example.com/concatSet.css for use in concatenation.

list concat-set testSet

Displays properties of the concatenation set named testSet.

delete concat-set testSet

Deletes concatenation set named testSet.

OPTIONS
app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

url Specifies the URL that will be used to generate the concatenated link.

type Either "css" or "js". Specifies whether the set is to be used for CSS or JavaScript concatenation.

members
Specifies the members of this set. The set members are the URL resources that are defined by the wam resource url.

SEE ALSO
create, delete, edit, list, modify, tmsh

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

wam resource domain-list

NAME
domain-list - Configures a list of domains for WebAccelerator for use in inserting DNS prefetch tags.

MODULE
wam resource

SYNTAX
Configure the domain-list component within the wam resource module using the syntax shown in the following sections.

```
CREATE/MODIFY
create domain-list [name]
modify domain-list [name]
options:
  app-service [[string] | none]
  description [[string] | none]
  domains
    [add | delete | none | replace-all-with] {
    [string] ...
    }
```

```
DISPLAY
list domain-list [name ...]
```

```
DELETE
delete domain-list [name ...]
```

DESCRIPTION
You can use the domain-list component to manage the domain list resources used by the WebAccelerator DNS prefetching feature. A domain-list must be created, then added to the appropriate domain-lists on a WebAccelerator policy node in order for the domains within the domain list to be inserted into a document.

EXAMPLES
create domain-list my_domain_list domains add {example.com example2.com}

Creates a domain list resource for the domains example.com and example2.com for use in inserting DNS prefetch tags.

```
list domain-list my_domain_list
```

Displays properties of the domain-list resource named my_domain_list.

```
delete domain-list my_domain_list
```

Deletes the domain-list resource named my_domain_list.

OPTIONS
app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description
User defined description.

domains
Specifies the domains described by the domain list resource.

SEE ALSO
create, delete, edit, list, modify, show, tmsh

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

wam resource url

NAME

url - Configures a URL resource for WebAccelerator for use in reordering whitelists

MODULE

wam resource

SYNTAX

Configure the url component within the wam resource module using the syntax shown in the following sections.

CREATE/MODIFY

```
create url [name]
modify url [name]
options:
  app-service [[string] | none]
  url [url]
  type [css|js]
```

DISPLAY

```
list url [name ...]
```

DELETE

```
delete url [name ...]
```

DESCRIPTION

You can use the url component to manage the URL resources used by the WebAccelerator JavaScript and CSS reordering features. A URL resource must be created, then added to the appropriate whitelist on a WebAccelerator policy node in order for the corresponding URL to be reordered.

EXAMPLES

```
create url test.css url http://www.example.com/test.css type css
```

Creates a URL resource for the URL `http://www.example.com/test.css` for use in CSS reordering whitelists.

```
list url test.css
```

Displays properties of the URL resource named `test.css`.

```
delete url test.css
```

Deletes the URL resource named `test.css`.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is `none`. Note: If the `strict-updates` option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

`url` Specifies the URL described by the URL resource.

`type` Either `"css"` or `"js"`. Specifies whether the URL resource is to be used for CSS or JavaScript reordering.

SEE ALSO

`create`, `delete`, `edit`, `list`, `modify`, `show`, `tmsh`

COPYRIGHT

wam roi-statistics

NAME roi-statistics - Provides ROI statistics for WAM application.

MODULE
wam

SYNTAX
Provides ROI statistics for configured application within the wam module.

DISPLAY
show roi-statistics
show roi-statistics [application-name]
options:
 (default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)
 field-fmt

DESCRIPTION
You can use the roi-statistics component to view the ROI statistics of configured WAM application.

EXAMPLES
show roi-statistics my_application

The show command will display ROI statistics for the configured WAM application.

SEE ALSO
show, tmsh

COPYRIGHT
No part of this program may be reproduced or transmitted in any form or by any means, electronic or mechanical, including photocopying, recording, or information storage and retrieval systems, for any purpose other than the purchaser's personal use, without the express written permission of F5 Networks, Inc.

WOM

wom advertised-route

NAME
advertised-route - Configures a route advertised by the local endpoint to remote endpoints for WAN optimization.

MODULE
wom

SYNTAX
Configure the advertised-route component within the wom module using the syntax in the following sections.

CREATE/MODIFY
create advertised-route [name]
modify advertised-route [name | all]
options:
 app-service [[string] | none]
 description [string]
 dest [ip address/netmask]
 include [disabled | enabled]
 label [value]
 metric [integer]
 origin [configured | discovered | manually-saved | persistable]

DISPLAY
list advertised-route
show advertised-route
options:
 running-config

DELETE
delete advertised-route [name]

DESCRIPTION
You can use the advertised-route component to configure a subnet that the system can reach through the local endpoint. You can specify a netmask or use slash format.

Routes are advertised to all connected WAN Optimization Managers. The remote endpoints use the subnet configuration information to determine peer routing and optimization actions.

EXAMPLES

```
list advertised-route all
```

Displays all endpoint advertised routes for the local WAN Optimization Manager.

```
delete advertised-route adv_rt2
```

Deletes the advertised route adv_rt2.

OPTIONS

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

dest Specifies the IP address and netmask of the advertised route.

include

Enables or disables the inclusion of this route in the optimization of traffic. This option allows you to define a subset of IP addresses to exclude from optimization within a larger included subnet. An excluded endpoint advertised route must be a valid address range subset of an included endpoint advertised route. The default is enabled.

label

Specifies an optional descriptive label for this route.

metric

Specifies a routing number to select between WAN Optimization Manager pairs. The higher the number, the more expensive the route in terms of resources. Not currently implemented.

origin

Specifies whether the route was discovered automatically or configured manually. You can change the origin from discovered to persistable, if you want to save the route to the file bigip_local.conf when you use the command save config. After you run the command save config, this attribute changes to manually saved. Endpoints that have the attribute discovered are not saved to the file bigip_local.conf.

The options are:

configured

Indicates that you manually configured this route. The system automatically sets this value, and you cannot change it.

discovered

Indicates that the system automatically discovered this route. Note that route for which the value of the origin property is discovered are not saved to the file bigip_local.conf.

manually-saved

After you run the command save / sys config, the value of the origin property that was set to persistable changes to manually-saved. Note that after the system changes the value to manually-saved, you cannot change it again.

persistable

Change the origin from discovered to persistable, if you want to save the route to the file bigip_local.conf when you use the command save / sys config.

BIG-IP 2017-03-31 wom advertised-route(1)

NAME
deduplication - Configures symmetric data deduplication for WAN optimization.

MODULE
wom

SYNTAX
Configure the deduplication component within the wom module using the syntax in the following sections.

MODIFY
modify deduplication
options:
 codec [sdd-v2 | sdd-v3]
 [disabled | enabled]
 max-endpoint-count [integer]

DISPLAY
list deduplication
show running-config deduplication
options:
 dictionary-size
 one-line

DESCRIPTION
You can use the deduplication component to configure symmetric data deduplication, which compresses data over the WAN by identifying and removing repetitive data patterns.

EXAMPLES
list deduplication

Displays all the deduplication settings.

modify deduplication max-endpoint-count 4

Sets the maximum number of remote endpoints to 4.

OPTIONS
 codec
 Specifies which algorithm the system uses for deduplication.

 The options are:

 sdd-v2
 Used for low number of spokes, such as for data center to data center replication.

 sdd-v3
 Used for high number of spokes, such as for connecting multiple remote sites or mesh topologies.

 dictionary-size
 Displays the current size of the dictionary, which deduplication uses to look up byte patterns.

 [disabled | enabled]
 Enables or disables deduplication. The default value is enabled. Note that if you enable or disable deduplication, you must then restart the BIG-IP WOM system using bigstart restart, or the change takes effect the next time the BIG-IP device reboots.

 max-endpoint-count
 Specifies the maximum number of concurrent remote endpoints supported by symmetric data deduplication. For codec sdd-v3, the system sets the value at 128.

SEE ALSO

BIG-IP 2012-04-10 wom diagnose-conn(1)

wom endpoint-discovery

NAME
endpoint-discovery - Configures automatic discovery of remote endpoints for WAN optimization.

MODULE
wom

SYNTAX
Configure the endpoint-discovery component with the wom module using the syntax in the following sections.

MODIFY
modify endpoint-discovery
options:
auto-save [disabled | enabled]
description [string]
discoverable [disabled | enabled]
discovered-endpoint [disabled | enabled]
icmp-max-requests [integer]
icmp-min-backoff [integer]
icmp-num-retries [integer]
max-endpoint-count [integer]
mode [disable | enable-all | enable-icmp | enable-tcp]

reset-stats endpoint-discovery

DISPLAY
list endpoint-discovery
show running-config endpoint-discovery
options:
all-properties
non-default-properties
one-line

show endpoint-discovery
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DESCRIPTION
You can use the endpoint-discovery component to specify parameters for automatically discovering remote endpoints for WAN optimization. These endpoints are configured WAN Optimization Managers on remote BIG-IP(r) systems that advertise themselves to the configured WAN Optimization Manager on the local BIG-IP system.

EXAMPLES
modify endpoint-discovery max-endpoint-count 10

Limits the number of remote endpoints that can be discovered to ten. After discovering ten remote endpoints, the WOM stops sending probe messages.

list endpoint-discovery all-properties

Displays the configuration parameters for the discovery of remote endpoints.

OPTIONS
auto-save
Specifies whether the system automatically saves remote endpoints

that it discovers. The default value is enabled.

description
User defined description.

discoverable
Specifies whether the WAN Optimization Manager responds to probe messages it receives from WAN Optimization Managers on remote BIG-IP systems. The default value is enabled.

discovered-endpoint
Specifies whether the WAN Optimization Manager sends out probe messages to discover other WAN Optimization Managers on remote BIG-IP systems in the network. The default value is enabled.

icmp-max-requests
Specifies the maximum number of ICMP probe message requests, after which the system stops sending probe message requests until at least one message is cleared from the queue by either a timeout or a response. The default value is 1024.

icmp-min-backoff
Specifies the maximum number of seconds to wait before abandoning an ICMP probe message request and resending it. The range is from 0 to 255. The default value is 5.

icmp-num-retries
Specifies the maximum number of times the system sends an ICMP probe message request for a single flow. The range is from 0 to 255. The default value is 10.

max-endpoint-count
Specifies the highest number of endpoints for the system to discover before it stops sending probe messages. The range is from 0 to 255. The default value is 0, which indicates no limit.

mode Specifies the type of probe messages the system should send. The default value is enable-all.

The options are:

disable
Turns off probe messages.

enable-icmp
Sends only ICMP probe messages.

enable-tcp
Sends only TCP probe messages.

enable-all
Sends both ICMP and TCP probe messages.

BIG-IP 2012-04-10 wom endpoint-discovery(1)

wom local-endpoint

NAME
local-endpoint - Configures the local endpoint for the WAN Optimization Manager.

MODULE
wom

SYNTAX
Configure the local-endpoint component within the wom module using the following syntax.

CREATE/MODIFY
create local-endpoint
modify local-endpoint
options:
addresses [add | delete | replace-all-with] {
[ip address]

```
}
addresses none
allow-nat [disabled | enabled]
description [string]
endpoint [disabled | enabled]
internal-forwarding [disabled | enabled]
ip-encap-mtu [unsigned integer]
ip-encap-profile [none | profile name]
ip-encap-type [gre | ipip | ipsec | none]
no-route [drop | passthru]
server-ssl [none | profile name]
snat [local | none | remote]
tunnel-port [unsigned integer]
```

DISPLAY

```
list local-endpoint
show local-endpoint
show running-config local-endpoint
options:
  all-properties
  non-default-properties
  one-line
```

DELETE

```
delete local-endpoint
```

DESCRIPTION

You can use the local-endpoint component to modify the settings for the local endpoint for the WAN Optimization Manager on the local BIG-IP(r) system.

EXAMPLES

```
modify local-endpoint allow-nat disabled
```

Disables the allow-nat option, specifying that the system does not accept connections for traffic behind a Network Address Translation (NAT) device.

```
list local-endpoint all-properties
```

Displays all of the properties of the local-endpoint component.

OPTIONS

addresses

Specifies a single IP address the system uses for the local endpoint. The IP address must be in the same subnet as a self IP address on the BIG-IP(r) system.

allow-nat

When enabled, specifies that the system accepts connections for traffic behind a Network Address Translation device. The default value is enabled.

description

User defined description.

endpoint

When enabled, specifies that the local endpoint is available for initiating and receiving optimized traffic. The default value is enabled.

To turn off WAN optimization on this endpoint, use disabled.

internal-forwarding

When enabled, specifies that the local endpoint is available for forwarding internal traffic to remote endpoints. The default value is disabled.

This parameter works only if internal-forwarding for remote-endpoint is set to default.

ip-encap-mtu

Specifies the maximum transfer unit for IP encapsulated traffic.

ip-encap-profile

Specifies the name of the profile with the encapsulation settings. This profile must be of the type specified for the setting ip-encap-type.

ip-encap-type

Specifies the type of IP layer encapsulation to perform on iSession(tm) traffic.

The default value is none. The options are:

gre The system uses the Generic Routing Encapsulation (GRE) tunneling protocol.

ipip The system uses the IP over IP (IPIP) tunneling protocol.

ipsec

The system uses IP security (IPsec) encapsulation.

none No IP encapsulation takes place.

no-route

Specifies what the system does with traffic for which there is no remote endpoint to complete the iSession connection.

The default value is passthru. The options are:

drop The system terminates the traffic flow.

passthru

The traffic flow continues without an iSession connection.

server-ssl
Specifies the default server SSL profile the system uses for all encrypted outbound connections. The default value is none.

snat Specifies the IP address the system uses for incoming traffic as the source IP address of the TCP connection between the WAN Optimization Manager and the server.

The default value is none. The options are:

local
The system uses the endpoint IP address closest to the destination. Use this setting to make sure the return route also goes through the BIG-IP system, so that both sides of the connection can be optimized. This setting is useful if responses returning from the server to the client would not normally pass through the BIG-IP system.

none The system uses the original connecting client IP address.

remote
The system uses the source IP address of the incoming iSession connection. Use this setting when an appliance that uses NAT is located between the WAN Optimization endpoints.

tunnel-port
Specifies the number of the port on the local endpoint that the WAN Optimization Manager uses for control connections. The port must have access through the firewall. The range is from 1 to 65535. The default value is 443.

BIG-IP 2014-05-08 wom local-endpoint(1)

wom profile cifs

NAME
cifs - Configures a Common Internet File System (CIFS) profile.

MODULE
wom profile

SYNTAX
Configure the cifs component within the wom profile module using the syntax shown in the following sections.

CREATE/MODIFY

```
create cifs [name]
modify cifs [name]
options:
  app-service [[string] | none]
  defaults-from [ [name] | none]
  description [string]
  fast-close [disabled | enabled]
  fast-set-file-info [disabled | enabled]
  office-2003-extended [disabled | enabled]
  read-ahead [disabled | enabled]
  record-replay [disabled | enabled]
  write-behind [disabled | enabled]
```

DISPLAY

```
list cifs
list cifs [ [name] | [glob] | [regex] ] ... ]
show running-config cifs
show running-config cifs [ [name] | [glob] | [regex] ] ... ]
options:
  all-properties
  app-service
  non-default-properties
  one-line
  partition

show cifs
show cifs [ [name] | [glob] | [regex] ] ... ]
```

options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DELETE
delete cifs [name]

DESCRIPTION
You can use the cifs component to manage a CIFS profile.

EXAMPLES
create cifs my_cifs_profile
Creates a CIFS profile named my_cifs_profile using the system defaults.
modify cifs my_cifs_profile fast-close disabled
Turns off fast-close for the CIFS profile named my_cifs_profile.

OPTIONS

app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from
Specifies the profile that you want to use as the parent profile. The new profile inherits all settings and values from the parent profile specified. The default value is cifs.

description
User defined description.

fast-close
Specifies whether the system speeds up file close operations by fulfilling them through the WAN Optimization Manager closer to the request initiator. The default value is enabled.

fast-set-file-info
Specifies whether the system speeds up file metadata change requests by fulfilling the requests through the WAN Optimization Manager closer to the request initiator. The default value is enabled.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

office-2003-extended
Specifies whether the system performs read-ahead operations based on parsing the Microsoft CDF file and understanding its structure. The default value is enabled.

partition
Displays the administrative partition within which the component resides.

read-ahead
Specifies whether the system speeds up CIFS file downloads by prefetching the file data on the WAN Optimization Manager closer to the request initiator. The default value is enabled.

record-replay
Specifies whether the system opens CIFS files faster by performing more intelligent read-ahead operations. The default value is enabled.

regex
Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

write-behind
Specifies whether the system speeds up CIFS file uploads to the server by fulfilling write requests through the WAN Optimization Manager closer to the request initiator. The default value is enabled.

SEE ALSO

app-service

non-default-properties

one-line

partition

show isession

show isession [[[name] | [glob] | [regex]] ...]

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

field-fmt

global

DELETE

delete isession [name]

DESCRIPTION

You can use the isession component to manage an iSession profile.

EXAMPLES

```
create isession my_isession_profile defaults-from isession
```

Creates an iSession profile named my_isession_profile using the system defaults.

```
modify isession my_isession_profile deduplication disabled
```

Turns off deduplication for the iSession profile named my_isession_profile.

OPTIONS

adaptive-compression

Enables or disables the automatic selection of the optimal compression algorithm for the current traffic, based on link speed. The system can use only compression algorithms that are specified. The default value is enabled.

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

compression

Enables or disables the compression of data according to the methods you select for the attribute compression-codecs. The default value is enabled.

compression-codecs

Specifies the codecs to use for compression. The following codecs are available:

bzip2

Specifies the use of the bzip2 compression algorithm, which improves compression ratios on low-bandwidth data links.

deflate

Specifies the use of the Deflate data compression algorithm.

lzo Specifies the use of the Lempel-Ziv-Oberhumer (LZO) data compression algorithm.

data-encryption

Enables or disables encryption of the traffic on the outbound connection. If you select enabled, the system uses the SSL profiles specified on the local and remote endpoints of the iSession connection. The default value is disabled.

deduplication

Enables or disables data deduplication, which replaces previously transmitted data with references, thus reducing the amount of bandwidth needed to transfer data over the WAN. The default value is enabled.

defaults-from

Specifies the profile that you want to use as the parent profile. The new profile inherits all settings and values from the parent profile specified. The default value is isession.

deflate-compression-level

Specifies the level of compression, if deflate-compression is specified and adaptive-compression is disabled. The range is 1 to 9. A higher value causes the CPU to spend more time looking for matches, which may result in better compression. The default value is 1.

description

User defined description.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

mode Enables or disables the use of this profile for WAN optimization traffic. The default value is enabled.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

partition

Displays the administrative partition within which the component resides.

port-transparency

Enables or disables the preservation of the destination port specified by the client over the WAN. The default value is enabled.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

reuse-connection

Enables or disables the saving and reuse of connections between the local and remote WAN Optimization Managers. The default value is enabled.

target-virtual

For terminated iSession traffic, specifies the matching criteria that a client-side BIG-IP system uses to select a target virtual server on the server-side BIG-IP system.

The default value is virtual-match-all. The options are:

none Specifies that the system sends the terminated iSession traffic directly to the server.

host-match-all

Specifies that the system selects the closest match from all the host virtual servers.

host-match-no-isession

Specifies that the system matches only host virtual servers with no iSession profile.

virtual-match-all

Specifies that the system selects the closest match from all the virtual servers.

SEE ALSO

wom profile mapi

NAME
mapi - Configures a Messaging Application Program Interface (MAPI) profile.

MODULE
wom profile

SYNTAX
Configure the mapi component within the wom profile module using the following syntax.

CREATE/MODIFY
create mapi [name]
modify mapi [name]
options:
app-service [[string] | none]
defaults-from [[name] | none]
description [string]
discover-exchange-servers [disabled | enabled]
native-compression [disabled | enabled]

DISPLAY
list mapi
list mapi [[[name] | [glob] | [regex]] ...]
show running-config mapi
show running-config mapi [[[name] | [glob] | [regex]] ...]
options:
all-properties
app-service
non-default-properties
one-line
partition

show mapi
show mapi [[[name] | [glob] | [regex]] ...]
options:
(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DELETE
delete mapi [name]

DESCRIPTION
You can use the mapi component to manage a MAPI profile.

EXAMPLES
create mapi my_mapi_profile

Creates a MAPI profile named my_mapi_profile using the system defaults.

modify mapi my_mapi_profile native-compression enabled

Turns on native-compression for the MAPI profile named my_mapi_profile.

OPTIONS
app-service
Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

defaults-from
Specifies the profile that you want to use as the parent profile. The new profile inherits all settings and values from the parent profile specified. The default value is mapi.

description
User defined description.

discover-exchange-servers
Enables or disables the automatic discovery of the Microsoft Exchange servers in the network and creation of a virtual server for each one discovered. The default value is disabled.

glob Displays the items that match the glob expression. See help glob for a description of glob expression syntax.

name Specifies a unique name for the component. This option is required for the commands create, delete, and modify.

native-compression
Enables or disables native Microsoft Exchange compression. The default value is disabled.

partition

Displays the administrative partition within which the component resides.

regex

Displays the items that match the regular expression. The regular expression must be preceded by an at sign (@[regular expression]) to indicate that the identifier is a regular expression. See help regex for a description of regular expression syntax.

SEE ALSO

BIG-IP 2012-05-22 wom profile mapi(1)

wom remote-endpoint

NAME

remote-endpoint - Configures one or more remote endpoints for the WAN Optimization Manager.

MODULE

wom

SYNTAX

Configure the remote-endpoint component within the wom module using the following syntax.

CREATE/MODIFY

create remote-endpoint [name]

modify remote-endpoint [name]

options:

address [ip address]

allow-routing [disabled | enabled]

app-service [[string] | none]

dedup-action [none | cache-refresh]

description [string]

endpoint [disabled | enabled]

internal-forwarding [default | disabled | enabled]

ip-encap-mtu [unsigned integer]

ip-encap-profile [none | profile name]

ip-encap-type [default | gre | ipip | ipsec | none]

origin [configured | discovered | manually-saved | persistable]

server-ssl [none | profile name]

snat [default | local | none | remote]

tunnel-encrypt [disabled | enabled]

tunnel-port [unsigned integer]

reset-stats remote-endpoint

DISPLAY

list remote-endpoint

list remote-endpoint [name]

show running-config remote-endpoint

show running-config remote-endpoint [name]

options:

all-properties

dedup-codec

non-default-properties

one-line

show remote-endpoint

show remote-endpoint [name]

options:

(default | exa | gig | kil | meg | peta | raw | tera | yotta | zetta)

DELETE

delete remote-endpoint [name]

Note: If you delete a remote endpoint without also disabling the endpoint-discovery component, the remote endpoint may reappear as it is rediscovered. To remove a remote endpoint from traffic initiated by this WAN Optimization Manager, set the endpoint option of the remote-endpoint component to disabled.

DESCRIPTION

You can use the remote-endpoint component to create, modify, or delete a remote endpoint for traffic from the local WAN Optimization Manager.

EXAMPLES

modify remote-endpoint 13.16.0.5 endpoint disabled

Disables the WAN optimization connection to the remote endpoint that is named 13.16.0.5.

list remote-endpoint all-properties

Displays all the properties of all the remote endpoints for traffic from the local WAN Optimization Manager.

OPTIONS

allow-routing

Specifies whether there is a route from the local endpoint to this remote endpoint through which the local endpoint can establish connections. The default value is enabled.

address

Specifies the IP address of the remote endpoint.

app-service

Specifies the name of the application service to which the object belongs. The default value is none. Note: If the strict-updates option is enabled on the application service that owns the object, you cannot modify or delete the object. Only the application service can modify or delete the object.

description

User defined description.

dedup-action

Clears the cache used for symmetric data deduplication on the specified remote endpoint and immediately resets the value to none.

dedup-codec

Displays the deduplication codec used by the remote endpoint: `sdd-v2` or `sdd-v3`.

endpoint

When enabled, specifies that traffic can be optimized between the local and remote endpoints. The default value is enabled.

Note: Disabling a remote endpoint affects only the connection between the local endpoint and this remote endpoint.

internal-forwarding

When enabled, specifies that the remote endpoint is available for forwarding internal traffic.

When disabled, specifies that the remote endpoint is NOT available for forwarding internal traffic.

When default, specifies that forwarding internal traffic is managed by the local-endpoint.internal-forwarding setting.

The default value is default.

ip-encap-mtu

Specifies the maximum transfer unit for IP encapsulated traffic. The default value is 0.

ip-encap-profile

Specifies the name of a profile with encapsulation settings. This profile must be of the type specified for the setting `ip-encap-type`.

ip-encap-type

Specifies the type of IP layer encapsulation performed on iSession traffic.

The default value is default. The options are:

default

The system uses the `ip-encap-type` value set for the local endpoint.

gre The system uses the Generic Routing Encapsulation (GRE) tunneling protocol.

ipip The system uses the IP over IP (IPIP) tunneling protocol.

ipsec

The system uses IP security (IPsec) encapsulation.

none No IP encapsulation takes place.

origin

Specifies whether the remote endpoint was discovered automatically or configured manually.

The options are:

configured

Indicates that you manually configured this remote endpoint. The system automatically sets this value, and you cannot change it.

discovered

Indicates that the system automatically discovered this remote endpoint. Note that endpoints for which the value of the origin property is discovered are not saved to the file `bigip_local.conf`.

manually-saved

After you run the command `save / sys config`, the value of the origin property that was set to `persistable` changes to `manually-saved`. Note that after the system changes the value to `manually-saved`, you cannot change it again.

`persistable`

Change the origin from `discovered` to `persistable`, if you want to save the endpoint to the file `bigip_local.conf` when you use the command `save / sys config`.

`server-ssl`

Specifies the server SSL profile the system uses to connect to this remote endpoint. This setting overrides the `server-ssl` setting for the local-endpoint component. The default value is `none`.

`snat` Specifies the IP address the system uses as the source IP address of the TCP connection between the WAN Optimization Manager and the server.

The default value is `default`. The options are:

`default`

The system uses the `snat` value set for the local-endpoint component.

`local`

The system uses the endpoint IP address closest to the destination. Use this setting to make sure the return route also goes through the BIG-IP system, so that both sides of the connection can be optimized. This setting is useful if responses returning from the server to the client would not normally pass through the BIG-IP system.

`none` The system uses the original connecting client IP address.

`remote`

The system uses the source IP address of the incoming `iSession` connection. Use this setting when an appliance that uses NAT is located between the WAN Optimization Manager endpoints.

`tunnel-encrypt`

Enables or disables encryption of traffic passing between the two WAN Optimization Managers. The default value is `enabled`

`tunnel-port`

Specifies whether to use a specific port for traffic optimized to this endpoint or to use port transparency (0). The default value is 443.

BIG-IP 2014-05-08 `wom remote-endpoint(1)`

wom remote-route

NAME

`remote-route` - Displays the destination routes learned from the remote endpoints.

MODULE

`wom`

SYNTAX

Display the `remote-route` component within the `wom` module using the syntax in the following section.

DISPLAY

`show remote-route`

options:

(`default` | `exa` | `gig` | `kil` | `meg` | `peta` | `raw` | `tera` | `yotta` | `zetta`)
`detail`

DESCRIPTION

You can use the `remote-route` component to view the subnets that the

system can reach through the remote endpoint(s). The system can optimize traffic destined for these subnets.

EXAMPLES

```
show remote-route
```

Displays the subnets reachable through the remote endpoint(s) configured on the WAN Optimization Manager.

```
show remote-route detail
```

Displays detailed information about the remote endpoint(s) through which the displayed subnets can be reached.

SEE ALSO

```
show, tmsh, wom advertised-route, wom remote-endpoint, wom server-

wom server-discovery

NAME

server-discovery - Configures the dynamic discovery of servers that can be reached through the local endpoint and the routes to reach them.

MODULE

wom

SYNTAX

Configure the server-discovery component within the wom module using the syntax in the following sections.

MODIFY

```
modify server-discovery  
options:  
  auto-save [disabled | enabled]  
  description [string]  
  filter-mode [exclude | include]  
  idle-time-limit [integer]  
  ip-ttl-limit [integer]  
  max-server-count [integer]  
  min-idle-time [integer]  
  min-prefix-length-ipv4 [integer]  
  min-prefix-length-ipv6 [integer]  
  mode [disabled | enabled]  
  rtt-threshold [integer]  
  subnet-filter [add | delete | none | replace-all-with] {  
    [ip address]  
  }  
  time-unit [days | hours | minutes]
```

DISPLAY

```
list server-discovery  
show running-config server-discovery  
options:  
  all-properties  
  auto-save  
  current-module  
  description  
  filter-mode  
  idle-time-limit  
  ip-ttl-limit  
  max-server-count  
  min-idle-time  
  min-prefix-length-ipv4  
  min-prefix-length-ipv6  
  mode  
  non-default-properties  
  one-line  
  rtt-threshold  
  subnet-filter  
  time-unit
```

DESCRIPTION

You can use the server-discovery component to configure the dynamic discovery of servers and the routes to reach them through the local endpoint. The local endpoint advertises these routes to any remote

endpoints to which it is connected.

EXAMPLES

`list server-discovery all-properties`

Displays the settings for dynamic discovery of advertised routes.

`modify server-discovery mode disabled`

Disables the dynamic discovery of advertised routes.

OPTIONS

`auto-save`

Specifies whether the system automatically saves the subnets that it discovers that can be reached through the local endpoint. The default value is enabled.

`description`

User defined description.

`filter-mode`

Specifies whether the subnets you add using the attribute `subnet-filter` are excluded from or included in the discovery of advertised routes. If you specify `include`, and do not specify any IP addresses, no subnets are discovered. The default is `exclude` with no IP addresses specified, which means that all advertised routes that conform to the specified attributes are discovered.

`idle-time-limit`

Specifies the maximum length of time a route can be idle without being removed from discovery. The default value is 0. Use the attribute `time-unit` to set the unit of measure. Use the attribute `min-idle-time` to set the minimum length of idle time.

`ip-ttl-limit`

Specifies the number of network segments on which a packet is allowed to travel before the route is removed from discovery. The more routers a packet travels through, the smaller the `ip ttl` value is. The range is 0 to 255. The default value is 5.

`max-server-count`

Specifies the highest number of servers the system discovers before it stops looking. The default value is 50.

`min-idle-time`

Specifies the minimum length of time a route must be idle before being removed from discovery. The default value is 0, which indicates that idle time is not considered in discovery. Use the attribute `time-unit` to set the unit of measure. Use the attribute `idle-time-limit` to set the maximum length of idle time.

`min-prefix-length-ipv4`

Specifies the minimum prefix length for route aggregation in IPv4 networks. The range is 0 to 32. The default value is 32.

`min-prefix-length-ipv6`

Specifies the minimum prefix length for route aggregation in IPv6 networks. The range is 0 to 128. The default value is 128.

`mode` Enables or disables the dynamic discovery of servers that can be reached through the local endpoint. For server discovery to take place, the setting of the component `wom endpoint-discovery` must not be set to disabled.

`rtt-threshold`

Specifies that the system does not add servers it discovers with a round-trip time greater than this value, in milliseconds. The default value is 10.

`subnet-filter`

Specifies the IP addresses of the subnets to include in or exclude from the discovery of advertised routes, depending on the setting you selected for the attribute `filter-mode`. The default is none. If you selected `include` for the attribute `filter-mode`, and do not specify any IP addresses, no subnets are discovered.

`time-unit`

Specifies the unit of measure (days, hours, or minutes) for the length of idle time specified using the attributes `idle-time-limit` and `min-idle-time`.

wom verify-config

NAME
verify-config - Checks the WAN Optimization Manager configuration.

MODULE
wom

SYNTAX
run verify-config

DESCRIPTION
You can use the verify-config component within the wom module to display configuration information about the WAN Optimization Manager that can be used for troubleshooting.

SEE ALSO
run, tmsh, wom diagnose-conn
