**SlurrySep Floc**

**Concrete Wastewater Solutions**

**SlurrySep Floc** is a proprietary blend of bentonite clay, polymers and pH reducing acids designed for treatment of concrete slurry. As the bentonite clay hydrates, a strong negative charge is produced, causing a flocculation by suspended particles sticking to the clay surface. Results are dramatic as solids quickly settle.

**Features and Benefits**
- Replaces high collection, handling, hauling and disposal costs
- Protects from environmental fines
- Rapid separation of suspended concrete fines in water allowing recycling of water or compliant disposal

**How it Works**

1. Chemical components of the SlurrySep adjust the pH of the water which enhances the precipitation of metals and breaks oil emulsions.
2. Bentonite clay particles attract and encapsulate precipitated metallic ions.
3. The polymeric portion of the formulation attracts remaining oils and suspended solids and forms a floc, which settles to the bottom of the treatment vessel.
4. The bentonite clay and polymer work together to create a strong utterable floc, which will encapsulate and contain heavy metals while allowing the floc to readily release water resulting in a condensed thickened sludge-like material.
5. The entire process is completed in just a few minutes, resulting in clear water that can be discharged directly to a POTW or recycled.
6. The remaining sludge and its encapsulated contaminants are highly resistant to leaching and is prepared to be solidified for compliant land disposal.

**Important Notice**

All wastewater may not be compliant for land II disposal even after treatment methods due to hazardous levels of non-allowed contaminants. Wastewater from plating shops and industrial chemical manufacturing facilities will require wastewater analysis to determine the proper disposal method if applicable. Our laboratories can provide an analysis of sample wastewater taken from a project to determine levels of contaminants and design suggestion for compliant disposal if applicable.
