

JRC SCIENTIFIC INFORMATION SYSTEMS AND DATABASES REPORT

Development of EDGAR-POLES JRC platform on historic and projected greenhouse gases and air pollutant emissions

Banja M., Schmitz A.

2022

This publication is a Scientific Information Systems and Databases report by the Joint Research Centre (JRC), the European Commission's science and knowledge service. It aims to provide evidence-based scientific support to the European policymaking process. The contents of this publication do not necessarily reflect the position or opinion of the European Commission. Neither the European Commission nor any person acting on behalf of the Commission is responsible for the use that might be made of this publication. For information on the methodology and quality underlying the data used in this publication for which the source is neither Eurostat nor other Commission services, users should contact the referenced source. The designations employed and the presentation of material on the maps do not imply the expression of any opinion whatsoever on the part of the European Union concerning the legal status of any country, territory, city or area or of its authorities, or concerning the delimitation of its frontiers or boundaries.

Abstract

To support the development and integration of tools and models in line with the European Green Deal priorities using JRC resources, a technical work has been performed towards setting the basis for the development of EDGAR-POLES JRC platform on historic and projected greenhouse gas and air pollutant emissions. To achieve this goal, the work has started from the mapping between Emissions Database for Global Atmospheric Research (EDGAR) database and Prospective Outlook on Long-term Energy Systems (POLES JRC) model having the main aim to provide insights on the level to which the substances, categories, sectors, subsectors, fuels and technologies of both in-house data sources can be equivalent to one-another.

This report is work on progress and will be updated and complemented with the upcoming work under the JRC Work Programme 2023-2024 having in focus the further development of EDGAR-POLES JRC platform in order to provide consistent emissions scenarios use to analyse the impact of climate policies.

Acknowledgements

This Scientific Information Systems and Database report is a product of collaboration between Air and Climate Unit (C.5) and Economics of Climate Change, Energy and Transport Unit (C.6) of the Joint Research Centre, EC under the JRC DETECT (Detecting unexpected and emerging signals from emissions and technologies) Project.

Authors would like to thank colleagues of these units for their support and participation in several discussions and technical meetings.

The report benefited from the comments of Monica Crippa (C.5), Marilena Muntean (C.5), Fabio Monforti-Ferrario (C.5) and Enrico Pisoni (C.5).

Authors would like to thank Diego Guizzardi (C.5) for providing the insights of EDGAR codes used in the mapping process and Federico Pagani (C.5) for elaborating the EDGAR-POLES JRC matrixes in order to provide the required inputs/outputs needed from the EDGAR database.

1 Introduction

Combining results of different databases and models requires a more consistent use of these data sources through a series on assumptions and mapping. Ensuring coherence among in-house data sources requires collaboration work of different teams.

The DETECT project (Detecting unexpected and emerging signals from emissions and technologies) is an example of this collaboration work that involves JRC Units C5, C6 and D1. The project supports the European Green Deal priorities and a stronger Europe in the world strategy. The project is part of JRC Climate and Energy Diplomacy Portfolio, which main objectives are as following:

- Application/development of analytical models and tools
- Policy relevant outputs for international climate negotiations
- Outreach and Capacity building, engage in international research networks

DETECT project main objectives are listed below:

- Support the 'climate ambition strategy' exploring pathways to achieve climate neutrality,
- Support the 'stronger EU in the world' strategy,
- Develop the EDGAR-LULUCF database

Under the framework of the first objective the harmonisation of the JRC Emissions Database for Global Atmospheric Research (EDGAR) and energy-economy model Prospective Outlook on Long-term Energy System (POLES JRC) to develop regional and global scenarios is aimed.

Within the DETECT project this objective is pursued by Task 4 and is coined as "*Development of the EDGAR-POLES platform*".

The main aim of this work is to provide emission time series of greenhouse gases (GHGs) and air pollutants of both EDGAR databases and POLES-JRC model in a consistent way. To this end, the following steps have been accomplished:

- Mapping variables between EDGAR and POLES-JRC in a consistent way,
- Aggregating emission time series corresponding to the mapping series from EDGAR and POLES JRC,
- Making GHG and air pollutant emission time series available in a visualisation tool (e.g. Qlik).

This deliverable aims to document and present the match between EDGAR and POLES JRC allowing to point out and discuss issues arising from the mapping.

The first approach will be to identify for each GHG and air pollutant the lowest¹ available level of granularity of variables matching POLES JRC with EDGAR. In case of GHGs it is needed to specify the Intergovernmental Panel on Climate Change (IPCC) category corresponding to this matching as well as the aggregation of EDGAR sectors, fuels and technologies.

This informative report is organised as follows: in Chapter 2 a description of EDGAR database and POLES JRC is provided, followed by Chapter 3 that describes the basis of mapping methodology between these two in-house data sources. Chapter 4 provides a description on mapping performed in each sector followed by Chapter 5 in which the concept of an EDGAR-POLES JRC platform is provided. Some results of this mapping are showed in Chapter 6 while discussions and conclusions remarks are provided in Chapter 7. This report provides a number of Annexes that includes very detailed description on mapping procedure between EDGAR and POLES JRC for energy, manufacturing industry and transport sector.

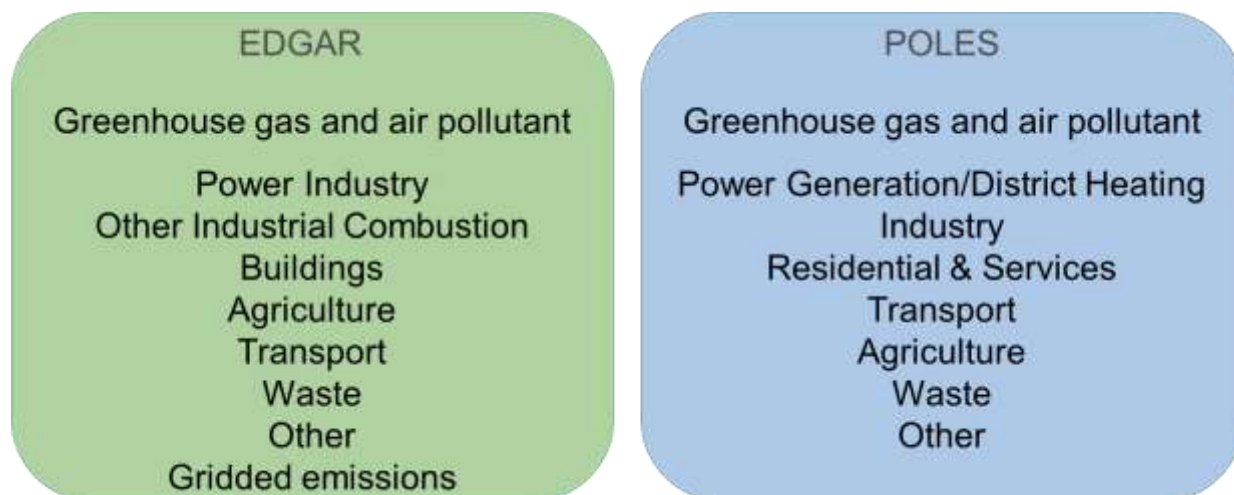

The actual mapping is contained in an Excel document ("Mapping EDGAR-POLES.xlsx") that provides in very detailed way the mapping between these two data sources..

(¹) The "lowest level" we can map EDGAR and POLES JRC is used based on the EDGAR levels (see more in EDGAR database description).

2 Description of EDGAR and POLES JRC

The EDGAR database provides historic emission time series at “t-1” level (the most recent time series covers the period 1970 - 2021), while the POLES-JRC model provides historic and projected emission time series (covering the period 1990 - 2100) for both GHG and air pollutants for the sectors as shown in Figure 1. EDGAR provides also global gridded emissions of both GHG and air pollutants².

Figure 1. Main sectors included in GHG and air pollutant emissions estimation in EDGAR and POLES-JRC

The major difference between EDGAR and POLES-JRC is that the granularity of EDGAR is much finer than in POLES-JRC (see Table 1 and Table 2).

Table 1. EDGAR and POLES JRC mapping granularity levels corresponding to EDGAR structure (levels 1-5)

EDGAR	Type	Main Sector (level 1)	Sub Sector (level 2)	Fuel (level 3)	Technology (level 4)	Controlled Emission Factor (level 5)

2.1 EDGAR database

EDGAR is a global database that provides estimates of country and sector-specific emissions of greenhouse gases (GHGs), including CO₂, and air pollutants implementing a transparent state-of-the-art methodology. EDGAR provides emissions consistently estimated for more than 220 world countries (see Figure 2) based on international statistics and a detailed bottom-up methodology [2], [8], [11], [12] following the IPCC guidelines.

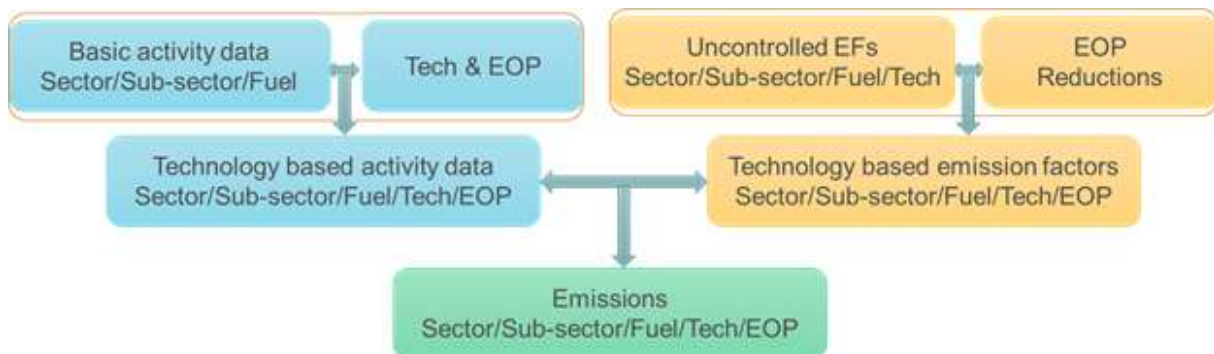

Figure 2. EDGAR database geographical coverage

To achieve this estimation, EDGAR uses four different dimensions shown in the schematic structure in Figure 3.

- sector;
- fuel;
- a general-purpose technology;
- a range of so-called end-of-pipe (EOP) measures

Figure 3. Schematic structure of EDGAR database

The EDGAR methodology used is transparent and in line with the most recent scientific literature and Intergovernmental Panel on Climate Change (IPCC) recommendations. In EDGAR emissions are based on activity

variables at the level of sector, fuel, and general-purpose technology. Emissions are calculated by multiplying activity variables by emission factors (EF) of the EOP measures. The latter calculations are repeated over all kind of GHGs and pollutants.

Regarding fossil CO₂ emissions, all anthropogenic activities leading to climate relevant emissions are included, except biomass/biofuel combustion (short-cycle carbon) in the power, industry, buildings, transport and agricultural sectors, large-scale biomass burning and land use, land-use change and forestry (LULUCF).

Table 3. Main activities included in EDGAR greenhouse gas emission estimation following IPCC categories

Fossil CO ₂	CH ₄ , N ₂ O	F-gases	CO ₂ LULUCF
Power Industry: power and heat generation plants (public and auto-producers)		Non-Ferrous Metal and Electronics Industry	Forest remaining forest Land converted to forest Deforestation Organic soil Fires Other: cropland, grassland and settlements
Other industrial combustion: combustion for industrial manufacturing and fuel production			
Buildings: small scale non-industrial stationary combustion			
Transport: road, non-road, domestic and international aviation, inland waterways and international shipping		Product uses as substitute for ozone depleting substances	
Other sectors: industrial processes, agriculture soils (urea application and lime) and waste	Other sectors: agriculture livestock (enteric fermentation, manure management), agriculture soils (fertilisers, lime application, rice cultivation, bread and paper production), field burning of agricultural residues and waste		

Source: GHG emissions in all world countries [1]

Table 3 shows the main activities included in EDGAR emissions estimation. EDGAR makes use of the IPCC sectorial classification, and a consistent bottom-up emission calculation methodology is applied to all countries, so that emissions of different countries can be compared, considering their respective levels of detail, uncertainties or data limitations [13]. In particular, for developing countries with less robust and systematic statistical data infrastructures and limited experience in reporting their fossil fuel emissions inventories, EDGAR can provide information and support them in complying with their inventory preparation.

Figure 4 and Figure 5 illustrate substances and the schematic view of sectors allocation according to the main processes included in EDGAR. In the following sub-sections, a short description of EDGAR main sectors is provided. In Annex 2 sectors/subsectors codes and names are provided.

Figure 4. Substances included in EDGAR

Figure 5. Allocation of sectors in EDGAR main processes³

⁽³⁾ Refer to Annex 2 for the names of sectors/subsectors that corresponds to the abbreviations in Figure 5.

2.1.1 EDGAR methodology for energy sector

Emissions from the energy sector are included in EDGAR named as “ENE”. Activity data are sourced from the International Energy Agency (IEA) fuel balances. UDI Platts installed capacity is used for the fuel distribution to the different combustion technologies at country level.. Emission factors applied in “ENE” take into consideration the C, N and S content of fuels, the type of combustor device in which the fuel is burned and the internal/downstream installed air pollutant removal processes.

Seven types of sub-sectors are defined within the “ENE” sector for which the IEA fuel balances [4] definitions are applied. The IEA definitions are also applied for the fuel allocation in the “ENE” sector. Below the description and the codes used in EDGAR system for the “ENE” sub-sectors is provided. Combustion technologies included in EDGAR ENE sector are shown in Table 4. Annex 1 provides codes and description of fuels included in “ENE”.

- Auto-produced cogeneration (AHP),
- Public electricity production (PEL),
- Own use in energy industry sector (POW),
- Public district heating (DHE),
- Public cogeneration (CHP),
- Auto-produced electricity (AEL),
- Auto-produced heat plants (AHE).

Table 4. Combustion technologies included in EDGAR “ENE” sector

Main fuel	EDGAR code	Description
Solid Fuels	PDO	Pulverised dry bottom boiler
	GFO	Grate firing
	FBO	Fluidised bed boiler
Gas & Liquid Fuels	BOO	Boiler for gas/liquids (any size)
	GTO	Gas turbine
	ICO	Internal combustion engine

2.1.2 EDGAR methodology for transport sector

Emissions from transport sector are included in EDGAR named as “TRO” for road transport, “TNR” for non-road transport (rail, domestic and international aviation, inland waterways, international shipping and other transportation). Not considered in road transport a) driving cycles as urban, rural or highway and b) cold start conditions. Activity data on fuel consumption are sourced from the IEA energy balances [4]. Statistics on fuel consumption are based on data on fuel sale.

Fuels are distributed to different vehicle categories for which different emission standards may exist applying technology penetration rates based on literature review and commercially available data. Emissions are estimated for buses (BSO), heavy duty vehicles (HDO), light duty vehicles (LDO), passenger cars (PCO), motorcycles (MCO) and mopeds (MPO). Type of fossil fuels included in this sector are described in Table 5.

Table 5. Type of fossil fuels included in EDGAR TRO and TNR sector

Main fuel	EDGAR code	Description
Gas	NGS	Natural gas
	RGS	Refinery gas
Liquid	AVG	Aviation gasoline
	BIT	Bitumen
	DIE	Gas/Diesel oil
	HFO	Residual fuel oil
	JET	Kerosene type jet fuel
	LPG	Liquefied petroleum gases
	LUB	Lubricants
	MOG	Motor gasoline
	NAP	Naphtha
	NGL	Natural gas liquids
	OKE	Kerosene
	OPR	Non specified petroleum products
	WSP	White spirit & SBP

2.1.3 EDGAR methodology for manufacturing industry sector

Emissions from manufacturing industry sector are included in EDGAR named as “IND”. In line with IEA the following industries are included: Chemical, Construction, Food and tobacco, Iron and steel, Machinery, Mining, Non-ferrous metals, Non-metallic minerals, Paper, pulp and print, Transport equipment, Textiles, Wood and wood products and Non-specified industry (see Table 6).

Table 6. EDGARv6.0 codes for industry sector and the respective IPCC 2006 code

Description	EDGARv6.0 code	IPCC 2006 code
Chemical (combustion)	CHE	1.A.2.c
Construction (combustion)	CON	1.A.2.k
Food and tobacco (combustion)	FOO	1.A.2.e
Iron and steel (combustion)	IRO	1.A.2.a
Machinery (combustion)	MAC	1.A.2.h
Mining (combustion)	MIN	1.A.2.i
Non-ferrous metals (combustion)	NFE	1.A.2.b
Non-metallic minerals (combustion)	NMM	1.A.2.f
Paper, pulp and print (combustion)	PAP	1.A.2.d
Transport equipment (combustion)	TEQ	1.A.2.g
Textiles (combustion)	TEX	1.A.2.l
Wood and wood products (combustion)	WOO	1.A.2.j
Non-specified industry	INO	1.A.2.m

2.1.4 EDGAR methodology for the agricultural sector

Emissions from agricultural sector are included in EDGAR named as “ENF”, “MNM”, “AGS” and ‘AWB” respectively for enteric fermentation, manure management, agricultural soil and agricultural waste burning. EDGAR applies the IPCC methodology to estimate emissions from agriculture sector based on Chapter 10 [6] and Chapter 11 [7] of the IPCC 2006 Guideline.

Livestock is the main input for the emission estimation and are allocated in the Animal Waste Management System (AWMS) based on the shares provided in the IPCC 2006 Guideline Chapter 10 Tables 10A-4 up to 10A-9 (for cattle, swine and buffalo) and assumptions on allocation are applied for other livestock. Other activity data such as N excretion, Typical Animal Mass and Carcass weight are taken from the Guideline but also from Common Reporting Format (CRF) tables/ models/literature. In EDGAR the AWMS as Lagoons, Liquid/Slurry, Solid storage, Dry Lot, Dairy Spread, Pit Storage, Poultry Manure, Digesters and Others are included in the “MNM” whereas Pasture/Range/Paddock and Burned for fuel systems are included in the “AGS”.

Unit C5 has developed a web tool - Agricultural Emission Estimation (AgrEE tool)⁴ - to estimate air pollutant and GHG emissions from agricultural activities applying EMEP/EEA 2019 Guidebook and IPCC 2006 Guideline. Both Tier 1 and Tier 2 methods are available. The tool has been developed for the EU Member States inventory compilers.

2.1.5 EDGAR methodology for waste sector

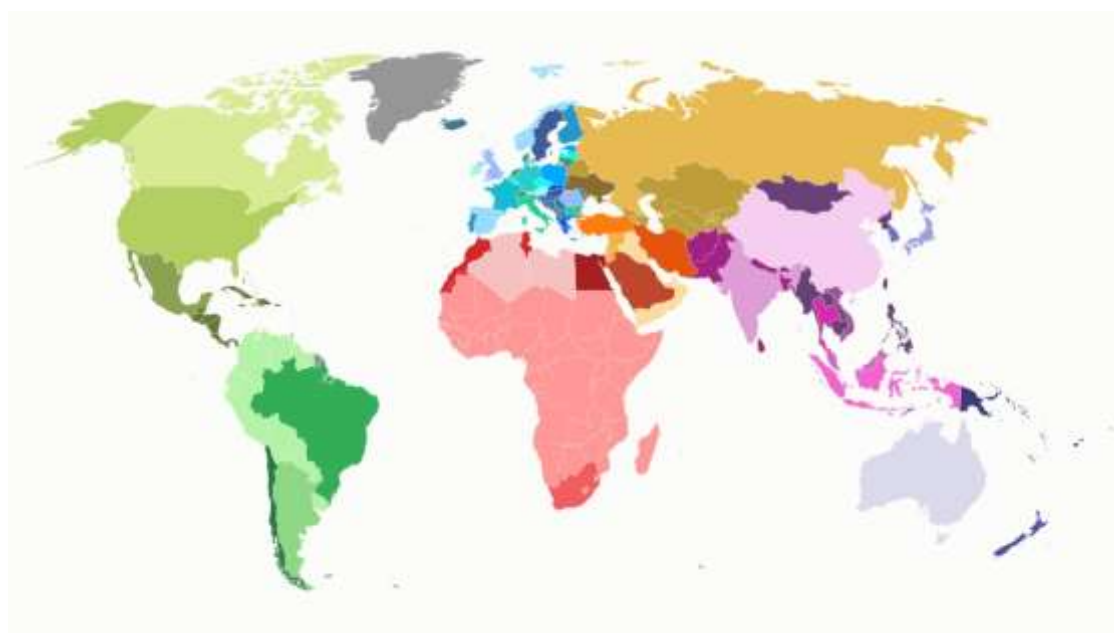

Emissions from the waste sector are included in EDGAR named as “SWD” and ‘WWT” respectively for solid waste disposal (on landfills, incinerated, composted and hazardous solid waste processing/storage) and waste water handling (industrial, domestic and commercial). CO₂ emissions are estimated only for incineration of solid waste process (SWD.INC) that covers waste incineration and open burning without energy recovery. The activities under this subsector are: municipal solid waste (MSW), biogenic waste (BIO), industrial solid waste (industrial waste, solvents, waste oil, hazardous waste) (ISW), industrial sludge (ISL), sewage sludge (SEW), hospital waste and cremation (HOS) and non-specified waste (OTH). Methane (CH₄) is mostly emitted by landfills, while nitrous oxide (N₂O) shows relevant contribution from waste water treatment.

(⁴) https://edgar.jrc.ec.europa.eu/agree_tool

2.2 POLES JRC

POLES⁵ is a partial equilibrium model of the energy system that covers the entire energy balance, from final energy demand, transformation and power production to primary supply and trade of energy commodities across countries and regions. Core of POLES JRC is the detailed modelling of the energy systems and GHG emissions. It allows assessing the contribution to future energy needs of the various energy types (fossil fuels, nuclear, renewables) and energy vectors. The model has been initially developed in 1990 at University of Grenoble (France) to be after transferred to a simulation software by the JRC. The JRC has co-developed the model for some time and has already issued the POLES JRC version. The POLES JRC model is implemented with the Vensim system dynamics software and its domain covers 66 regional entities (see Figure 6) including 12 non EU regions, EU27 and 26 non-EU countries (detailed OECD, G20 and emerging Asia).

Figure 6. POLES JRC model geographical coverage

Source: POLES JRC model documentation [3]

The POLES JRC model can be used for the following analytical support: (i) Assessment of policies related to energy sector; (ii) GHG emissions abatement strategies; (iii) Technology dynamics; (iv) International fuel markets and price feedback. In addition, it calculates the evolution of GHG emissions: endogenously for the energy-industry sectors and through linkage with specialist models for GHG emissions from agriculture and LULUCF, and air pollution. POLES operates on a yearly time step, allowing integrating recent developments. POLES JRC models energy and emission scenarios allowing the selected scenarios to be developed and policies to be translated into quantitative modelling inputs, by sector and region, by 2050 in a standard configuration and up to 2100 for long-term mitigation strategies.

In the climate and energy policies dimension, POLES JRC takes into account the policies in (i) climate and environment e.g cap & pricing for all or selected GHG emissions; (ii) Technology support policies e.g technology availability and purchase, power specific policies, transport specific policies; and (iii) energy consumption policies e.g fiscal policy and subsidies on energy fuels, building specific policies, transport specific policies (fuel and emission standards).

The POLES JRC model uses annual historical data to initialise the projections, typically for the period 1980 to the latest data available. The data needed to run projections are those on (i) socioeconomic and activity variables (e.g population, GDP, sectoral value added etc.); (ii) energy balances (final demand, transformation, supply); (iii) energy prices and taxes; (iv) energy reserves and resources; (v) GHG emissions.

⁽⁵⁾ https://joint-research-centre.ec.europa.eu/poles_en

2.2.1 POLES JRC methodology for CO₂ and non-CO₂ emissions

Energy-related emissions refer to GHG emissions where the primary driver is energy production or consumption. They consist in CO₂ emissions from fossil fuel combustion and non-CO₂ emissions from energy-related activities.

Emission factors by fossil fuels (coal, oil, gas) are applied in POLES JRC for CO and non-CO₂ emissions from combustion. For CO₂ emissions from fossil fuel combustion, emission volumes are obtained directly from the use of individual fossil fuels with an emission factor. Carbon capture and storage (CCS) technology can be developed both in power generation and in industry sectors. Total emissions balances take into account carbon that is captured in CCS (in power plants, synthetic fuel production, hydrogen production and industry) and the uptake of carbon in steelmaking from coking coal. Full energy system in POLES IRC model is shown in Figure 7.

Figure 7. POLES JRC full energy system

For CO₂ and non-CO₂ process emissions, POLES JRC does not apply emission factors. Instead, emissions are based on historic emissions which are then extrapolated by using as driver the main activity data in combination with certain parameters (e.g. elasticities, trend parameters, etc.). Abatement measures (marginal abatement cost curves) might be applied in POLES JR on top of these extrapolation modelling in order to retrieve the actual emissions. Table 7 illustrates the main GHG emissions flows used in POLES JRC model.

Table 7. GHG emissions flows in POLES JRC model

Sector	Category	Substance	Emission activity	Modelling driver
Energy	Fuel combustion	CO ₂	Burning fossil fuel	Fossil fuel combustion
	Oil and gas	CH ₄	Production, transmission & distribution	Oil & gas production Gas transport & use
	Coal production	CH ₄	Underground & surface mining	Coal production (underground and surface)
	Power & heat transport, residential	N ₂ O CH ₄	Combustion by-products	Sectoral final energy consumption
	Power system	SF ₆	Transmission & distribution	Electricity production
Industrial processes	Steel	CO ₂	Iron ore reduction	Steel in thermal processes
	Non-metallic minerals	CO ₂	Carbonate decomposition	Non-metallic mineral industry value added
	Chemicals	CO ₂ N ₂ O	Steam reforming Nitric & adipic acid	Chemicals industry value added
	Aluminium	PFCs	Primary aluminium Semiconductor & PV	"Other" industry value added
	Magnesium, semiconductors	SF ₆	Magnesium refining Semiconductor & PV	Industry value added
	Residential, services, transport	HFCs	Air conditioning, refrigeration, aerosols, foams, solvents	Industry value added
Waste	Waste	CH ₄ , N ₂ O	Solid waste & wastewater Burning waste	Urban population (urban waste) Industry value added (industrial waste)
		CH ₄ , N ₂ O	Enteric fermentation, manure management, soils & rice cultivation	Default emission profile from GLOBIOM (influenced by biomass price as proxy in land use)
Agriculture, forestry and other land use (AFOLU)	Agriculture	CH ₄ , N ₂ O	Deforestation, afforestation, other forestry and land use	Biomass price (derived by GLOBIOM cost curves) as proxy for forestry activity and other land use
	Forestry and land use	CO ₂		

Source: POLES JRC model documentation [3]

Industry is disaggregated into different manufacturing sectors, mining and construction. The industrial energy consumption does not include transport used by industry (which is reported under transport) excluding also the fuel input for auto-production but including the auto-produced electricity.

Additionally, the consumption of fuels for non-energy uses is captured for two types of products: chemical fertilisers, plastics and rubber. The projection of other GHG emissions from energy and industrial processes is based on: (i) a sector-specific economic driver (sectoral value added, energy production or energy consumption); (ii) a trend capturing technology changes; (iii) a marginal abatement cost curve (MACC) that describes the interaction with climate mitigation policies.

In building sector POLES JRC models energy consumption by end-use for residential and services sectors since they are mostly related to building activities and share several common features. Modelling is performed for space heating & cooling and water heating & cooking.

For GHG emissions from agriculture, forestry and land use (AFOLU), baseline emissions and mitigation potential are derived from the specialised International Institute for Applied Statistical Analysis (IIASA) Global Biosphere Management (GLOBIOM) model [5]. Non-energy related emissions (directly related to energy production, transport or consumption) are captured by an emission intensity (with a MACC) applied to the relevant activity.

In waste sector the main drivers used in the estimation are urban population and industrial value added, a technological trend and the abatement potential in case of GHG mitigation policy. The modelling includes the CH₄ emissions from solid waste disposal (municipal and industrial origin) and wastewater treatment and N₂O emissions from processing wastewater due to the de/nitrification processes of the nitrogen present.

2.2.2 POLES JRC methodology for air pollutant emissions

Air pollution modelling in POLES JRC is done by sector and fuel being performed using inputs from specialized sources as GAINS model that provides emission factors per pollutant and sector fuel that are then mapped to time series. The POLES-JRC energy balances are used as inputs to the GAINS model to derive the evolution of air pollutant emissions. Practically 48 flows/pollutant (with respective emission factors considered as direct inputs and recalculated based on historic data) are included in modelling e.g coal in residential and services or diesel & gas use in road transport.

Estimation of pollutants with EFs as direct inputs are included in Power generation (see Table 8), Industry, Buildings, Transport, Agriculture and Other Energy transformation. Estimation with EFs recalculated from historical data are included in Industrial production (see Table 8), Buildings (unattributed), Surface transportation, Agriculture (non-energy), Energy transformation (unattributed)

Table 8. Power generation with EFs as direct inputs and Industrial production with EFs recalculated from historical data

Sector	Source	Activity indicator
Power generation	Biomass	Biomass inputs in power generation (*)
	Coal	Coal inputs in power system for capacity historically installed (conventional coal)
		Coal inputs in newly installed power capacity (conventional coal)
		Coal inputs in newly installed power capacity (advanced coal) (*)
	Gas	Gas inputs in power generation (*)
Oil	Oil inputs in power generation	
Industrial production	Cement	Total energy in non-metallic minerals industry
	Chemicals	Total energy in chemicals industry
	Fertilisers	Total energy in chemical feedstocks industry
	Solvents	Value added of chemicals industry
	Other combustion	Oil in other industry
	Other processes	Total energy in other industry

Source: POLES JRC model documentation [3]

(*) An additional flow is considered when associated to CCS, where a multiplying emission coefficient is applied to the coefficient without CCS.

POLES JRC provides estimation of emissions for SO₂, NO_x, CO, BC, PM₁₀, PM_{2.5}, NH₃ and (NM) VOC. Pollutants resulting from the interaction of the above species with other gases (precursors) such as ozone are not modelled. Results on air pollutants have been used for a cooperation with the model TM5-FASST [10].

The estimation of air pollutant emissions in medium terms takes into account the current legislation adopted by countries in POLES JRC domain. In the longer term, it is assumed that technologies and air pollution policies diffuse across world regions at different speeds depending on per capita income.

3 EDGAR - POLES JRC mapping methodology

Mapping methodology for EDGAR-POLES JRC consist of creating a common matrix for each sector aiming to match at the finest possible granularity taking into account limitations that exist on fuels and technologies. In Table 9 are illustrated issues and cooperation topics between EDGAR and POLES JRC from the point of view of categories, substances, sectors and categories.

Table 9. EDGAR-POLES JRC possible mapping categories

EDGAR			POLES	
Substance & Category		Issues & Cooperation	Categories	Issues & Cooperation
CO ₂ combustion	IPCC	IEA as main data source	CO ₂ emissions by sector & fuel	
CO ₂ process emissions	IPCC	Possibility to map categories and aggregate emissions accordingly	<ul style="list-style-type: none"> Some variables match IPCC categories Other aggregate several IPCC categories 	<ul style="list-style-type: none"> Understand methodology of EDGAR Harmonize POLES Modelling with EDGAR methodology
Non-CO ₂ (CH ₄ , N ₂ O, F-gases)				
Agriculture	IPCC	Possibility to map categories and aggregate emissions accordingly	<ul style="list-style-type: none"> Aggregates for CH₄ & N₂O Higher aggregated than EDGAR 	<ul style="list-style-type: none"> Understand methodology of EDGAR Harmonize POLES Modelling with EDGAR methodology
LULUCF	IPCC	In development, fires not yet included, limited time coverage and no country specific data. Updates foreseen by end 2022	Higher aggregation than EDGAR <ul style="list-style-type: none"> Forest Management Deforestation Afforestation Other 	<ul style="list-style-type: none"> Understand LULUCF methodology of EDGAR

EDGAR database categories for CO₂, CH₄, N₂O and F-gases correspond to the detailed IPCC categories within the sector included in the mapping exercise (see Table 10). In POLES JRC the categories for the estimation of CO₂ emission from combustion also correspond to the IPCC categories. In other sectors and for other substances due to the less detailed structure several categories match the IPCC categories whereas other are aggregated. In the case of CH₄, N₂O and pollutants the POLES emissions are not available at aggregated technology 4 level (see Table 1).

Table 10. Granularity of mapping between EDGAR and POLES JRC

Species	Granularity	Variables Items
CO ₂	highest possible granularity	CO ₂
CH ₄ , N ₂ O	<ul style="list-style-type: none"> high granularity for specific categories (oil & gas, mining) for others merely sum for entire sector (agriculture, energy combustion, transport) 	CH ₄ , N ₂ O
F-gases	<ul style="list-style-type: none"> energy related: SF₆ (switches) industry: aluminium, SF₆ (foundries), HFCs, PFCs 	SF ₆ , PFCs, HFCs: total of species, average GWP
Air pollutants	sectoral level: totals and by fuel	BC, OC, VOC, NO _x , SO ₂ , NH ₃ , CO, PM ₁₀ , PM ₂₅
CO ₂ biomass combustion	highest possible granularity	CO ₂ BIO
Activity Variable	highest possible granularity (usually CO ₂ level) <ul style="list-style-type: none"> final energy consumption (usually) PM tyres & road wear: t*km, km travelled calculation of air pollutants, CH₄/N₂O/F-gases 	Activity Variable (AV)
Additional variables		<ul style="list-style-type: none"> captured CO₂ emissions: CCSCO₂, CCSCO₂BIO activity variables corresponding to captured CO₂ emissions (e.g. energy consumption) activity variable corresponding to CO₂BIO

In case where no match exists (e.g. in power sector the internal combustion and biofuels do not exist in POLES) these are omitted from the matching. Table 11 illustrates the case of technologies in the energy sector for both EDGAR and POLES JRC.

Table 11. Technologies included in EDGAR database and POLES JRC model in ENE sector

EDGAR technologies in ENE	POLES JRC technologies in ENE
Gas turbines	Gas turbines, Combined cycles
Fluidized bed, Pulverized coal dry, bottom boiler, Grate firing	Sub/super coal steam turbine, ultra-critical steam turbine, integrated gasification

In POLES JRC most of the technology development (efficiencies, learning curves, etc.) is usually contained in the activity variable (in most cases energy consumption) which is different to how emission factors/EOP are applied in EDGAR.

In POLES JRC biomass combustion emissions (CO₂BIO) are not accounted as CO₂ emissions in inventories (supposed to be CO₂ neutral). However, an emission factor for biomass combustion is included in order to account for carbon captured when biomass is used in carbon captured and storage (CCS). CCS emissions from biomass combustion are accounted as negative emissions.

In POLES JRC for CH₄ and N₂O high granularity exist for specific categories (e.g oil & gas, mining). For other categories a lump sump for whole sector (e.g agriculture, energy combustion, transport) is provided.

POLES JRC will provide activity variable with the highest possible granularity (usually CO₂ level) and usually for final energy consumption which will allow to calculate emissions of CO₂, air pollutants and CH₄/N₂O at high granularity level.

POLES JRC additional variables will be: (1) captured CO₂ emissions (for CO₂, CO₂BIO); (2) activity variables corresponding to captured CO₂ emissions; (3) activity variable corresponding to CO₂BIO.

For air pollutants mapping will be provided at sectoral level: totals and by fuel. Names of air pollutants in EDGAR and POLES JRC are slightly different in the selection sector/fuel and in the case of non methane volatile organic compounds (NMVOC)

These differences refer to the type of air pollutant emissions that will be provided to EDGAR from POLES JRC. For example if air pollutant emissions coming within a selected sector are fuel based their name will include the ending letter "p". In case of total emissions the names of air pollutants in EDGAR and POLES JRC will remain the same except for NMVOC (see Table 12)..

Table 12. Granularity of mapping between EDGAR and POLES JRC in case of air pollutants⁶

EDGAR	BC	OC	PM ₁₀	PM ₂₅	NMVOC	NOX	CO	SO ₂	NH ₃
sector/subsector/fuel	X	X	X	X	X	X	X	X	X
POLES	BCp	OCp	PM ₁₀	PM _{2.5}	VOCp	NOxp	COp	SO _{2p}	NH ₃
sector/fuel	X	X	X	X	X	X	X	X	X
	BC	OC	PM ₁₀	PM ₂₅	VOC	NOX	CO	SO ₂	NH ₃
sector total	X	X			X	X	X	X	

For POLES JRC and EDGAR the emissions of GHG and air pollutants are always provided in kt. POLES JRC energy consumption is always given in ktoe; whereas for EDGAR energy consumption is always given in TJ.

⁽⁶⁾ In POLES JRC the estimation of PM₁₀ and PM_{2.5} is based in the following equations:
 (1) PM₂₅ = BCp + OCp*x + PM₂₅Op and (2) PM₁₀ = PM₂₅ + PM₁₀Op

4 EDGAR - POLES JRC matrixes

EDGAR-POLES JRC matrixes are grouped following the allocation of sectors in EDGAR main processes as shown in Figure 5. More detailed information about these matrixes and the issues related is provided in Annexes 3 to 7.

4.1 EDGAR-POLES JRC fuel combustion matrix

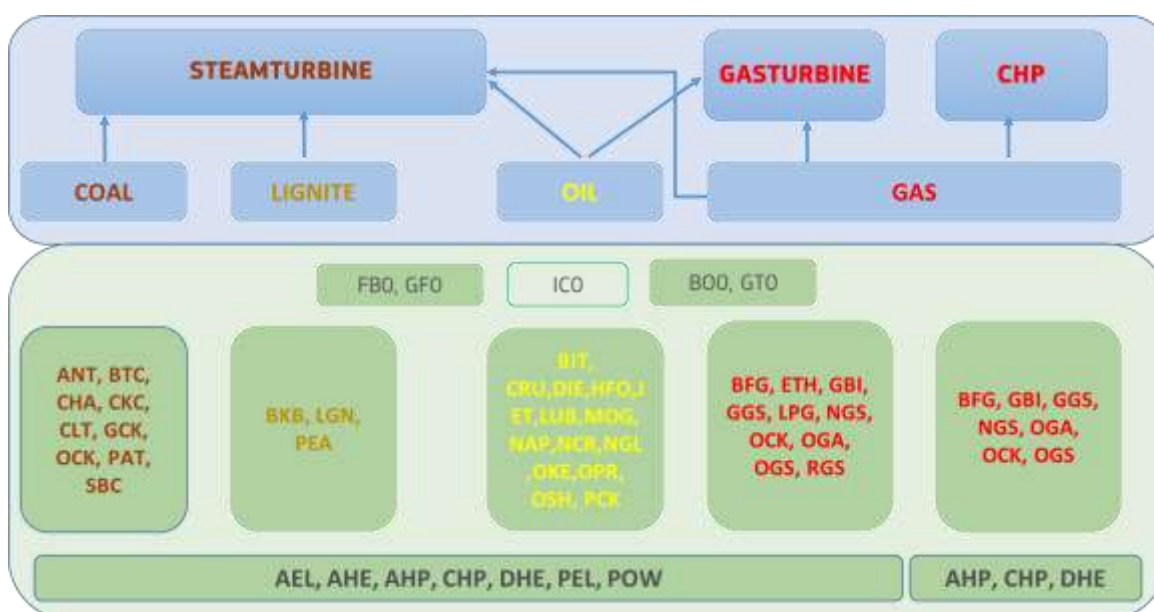

Fuel combustion matrix includes mapping of “ENE”, “IND”, “TRO”, “RCO”, “PRO”, “REF”, “TRF” and “TNR”.

4.1.1 EDGAR-POLES JRC “ENE” matrix

EDGAR-POLES JRC “ENE” matrix is build based on EDGAR level 4 combination of sector/subsector/fuel/technology. Both EDGAR and POLES JRC have the same rank of these levels. EDGAR fuels have been grouped in 4 types of fuels present in POLES JRC: Coal, Lignite, Oil and Gas. POLES JRC will provide total values for CH₄ and N₂O. These totals are the sum of power and industry sectors, which in EDGAR are estimated separately.

Figure 8 illustrates the mapping between EDGAR and POLES JRC for “ENE”, based on the fuel type. POLES JRC main fuels are used as basis for this match. It can be seen that several EDGAR fuels are allocated to each POLES JRC fuel, which is then allocated to one or more technologies.. In POLES JRC model the CHP is applied only to gas fuel

Figure 8. Matching structure for energy sector by technology and fuel type (EDGAR below- POLES JRC above)

More in detail the technologies that are currently included in the matching between EDGAR and POLES JRC in “ENE” matrix are shown in the following tables 13-16. The main issue in mapping is the allocation of internal combustion technology (ICO) which doesn’t exist in POLES JRC. From the literature we can consider gas turbines as a type of internal combustion engine. This can be taken into consideration when allocating the ICO to POLES JRC to gas turbine.

Table 13. EDGAR and POLES JRC technologies included in the “ENE” matrix in Steamturbine - coal category

		POLES	EDGAR
	Fuels	Technologies	Fuels
Steam turbine	Coal	<ul style="list-style-type: none"> Conventional coal (sub-critical & super-critical) Advanced coal (ultra-critical) Integrated gasification combined cycle CCS retrofitted: Conventional coal (sub-critical & super-critical) CCS: Advanced coal (ultra-critical) CCS: Integrated gasification combined cycle 	<ul style="list-style-type: none"> Coke Oven Coke Sub-Bituminous Coal Coal Tar Gas Coke Anthracite Coking Coal Other Bituminous Coal Charcoal Patent Fuel

4.1.2 EDGAR-POLES JRC “TRO” and “TNR”matrix

EDGAR-POLES JRC “TRO” matrix is build based on EDGAR level 4 combination of sector/subsector/fuel/technology. In POLES JRC the ranking of in this combination is sector/subsector/technology/fuel. So the mapping is based on the corresponding technologies and fuels. For CH₄ and N₂O mapping will be only at the sector level whereas for air pollutants mapping will reach the sector and fuel level (see Table 1).

Figure 9 illustrates the mapping structure for road transport sector. EDGAR vehicle types as passenger cars (PCO), motorcycle (MCO) and mopeds (MPO) are aggregated under the POLES JRC cars typology (includes passenger cars and motorcycle POLES JRC categories).

The structure of EDGAR and POLES JRC in transport sector is similar. As shown in Table 17 the EDGAR applies also abatement measures following the development of regional legislations for the relevant air pollutants as SO₂, NO_x, PM₁₀ and PM_{2.5}. In POLES JRC six types of vehicle engines are included.

Table 17. EDGAR abatement standards and POLES JRC engine types in road transport sector

EDGAR	POLES JRC
6 EU standards, 3 US standards	6 engine technologies – Conventional, Plug-in hybrid, Full-electric, Hydrogen fuel cell, Other fuel cell

EDGAR-POLES JRC “TNR” matrix is also build based on EDGAR level 4 combination of sector/subsector/fuel/technology. In POLES JRC three are the main subsectors within non-road transport: Air domestic (AIRDOM), Rail (RAIL) and Navigation (NAV). In POLES JRC category AIRDOM the aggregation of EDGAR subsectors Domestic air transport (DAT) and Road surface wear (RSW) is allocated (see Table 18). Other transport (“TNR.PIP” and TNR.OTH” in EDGAR) does not exist in POLES JRC so no mapping is provided.

POLES JRC does not estimate emissions from road surface wear subsector. However, the model can provide the activity data for this subsector which can be compared with historic EDGAR activity data. POLES JRC will provide the allocation of total value for emissions and activity data for international aviation (IAT) and shipping (SEA).

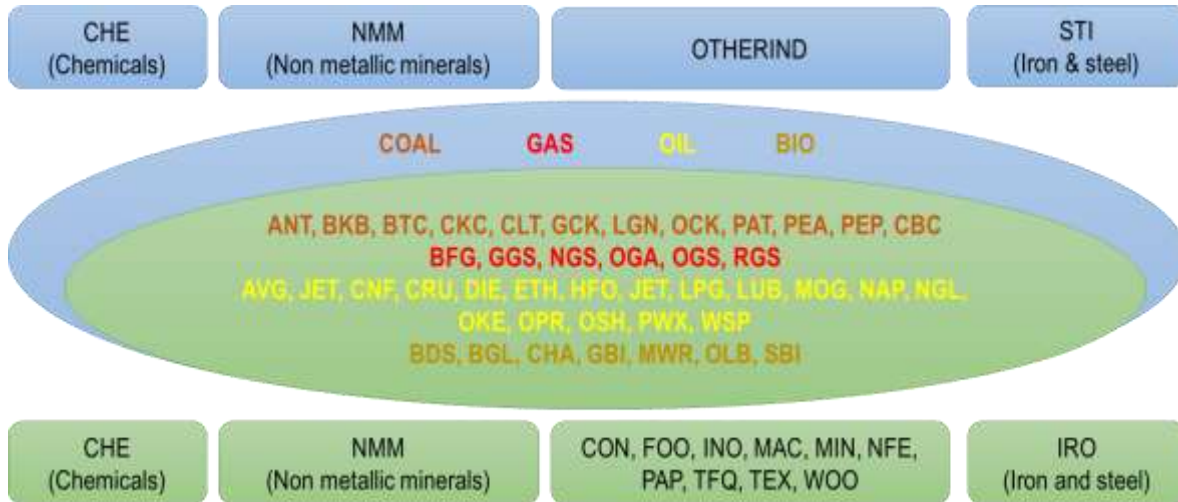

Table 18. EDGAR-POLES JRC mapping structure for non road transport by subsector and fuel

POLES subsector	AIRDOM	RAIL	NAV
POLES fuel	OIL	COAL, OIL	COAL, GAS, OIL, BIO
EDGAR subsector emissions	DAT	RAI	ILW
EDGAR subsector activity data	RSW, DAT

4.1.3 EDGAR-POLES JRC “IND” matrix

EDGAR-POLES JRC “IND” matrix is based on EDGAR level 4 combination of sector/subsector/fuel/technology. As shown in Figure 10 POLES JRC provides the aggregation in four main subsectors: Chemicals (CHE), Non-metallic minerals (NMM), Iron and Steel (STI) and Other industry (OTHERIND). The aggregation of EDGAR subsectors is needed under the POLES JRC subsector “Other industry”. Subsectors as Construction, Food, Machinery. Mining will be aggregated here.

Figure 10. Mapping structure for industry by subsectors and fuel type (EDGAR⁷ below- POLES JRC above)

4.1.4 EDGAR-POLES JRC “RCO” matrix

EDGAR-POLES JRC “RCO” matrix is based on EDGARb level 4 combination of sector/subsector/fuel/technology. Five subsectors are included in EDGAR database for this sector: Residential (RES), Commercial and public services (COM), Agriculture/Forestry (AGR)⁸, Fishing (FSH) and Other not specified (OTH) (see Figure 11).

POLES JRC in the other side responds with Use of fuels in Agriculture (AGR), Residential (RES) and Services (SER). In this mapping work the EDGAR codes on Other not specified (OTH) are not assigned to any of POLES JRC codes. Mapping for “AGR” has been done based on the fuel use. For POLES JRC “RES” and “SER” subsectors the mapping has been done for space heating & cooling (SH) and waster heating & cooking (WH).

Figure 11. Matching structure for residential sector by subsectors/fuel type (EDGAR⁷ below- POLES JRC above)

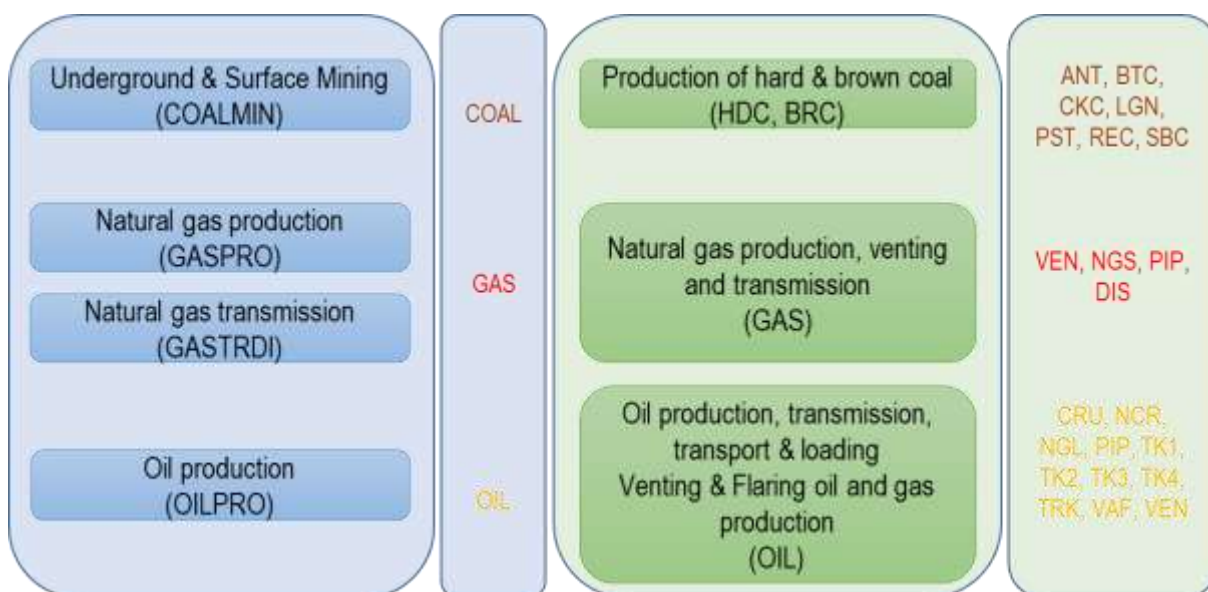

(⁷) Refer to Annex 2 for EDGAR sectors/subsectors codes

(⁸) In EDGAR database the fuel use in agriculture is included in residential sector and not in agriculture sector.

4.1.5 EDGAR-POLES JRC “TRF”, “REF” and “PRO” matrix

EDGAR-POLES JRC “PRO” matrix includes emissions sourced from fuel production and transmissions. In POLES JRC the abatement applied in the estimation of these emissions are already included using MACC curves. From EDGAR side abatement measures included in the estimation of emission from coal production are those applied for methane during the process of recovery in underground mining. Estimation of emissions from fuel transformation does not exist in POLES JRC so this category is omitted when creating the mapping structure showed in Figure 12. In the case of emissions from distribution of losses in transformation process the mapping with IPCC category 1.B.2 of EDGAR was not possible as for POLES JRC more detailed sector categorisation is needed.

Figure 12. EDGAR (right) – POLES JRC (left) mapping structure for fuel production & transmission

EDGAR-POLES JRC “TRF” matrix is splitted in two: one related to fugitive emissions (hereafter “TRF FUG”) and the other related to transformation in industry sector (hereafter “TRF IND”). The mapping in “TRF FUG” includes only CH₄. Regarding the “TRF IND” the mapping includes only the manufacture of solid fuels calculating the emissions from coking process (Table 19). The CO₂ emissions from transformation industry in the “TRF” matrix includes only coking and petroleum refinery.

Table 19. EDGAR-POLES JRC mapping structure for transformation in industry by subsector and fuel

POLES code	MSF COKING
POLES fuel	COAL
EDGAR subsector	EBF, EBF, ECK, EGW, ELO, EMI, ENO, EPA
EDGAR fuel	ANT, BGF, BKB, BTC, CKC, CLT, GCK, GGS, LGN, OCK, OGS, PAT, PEA, SBC

EDGAR-POLES JRC “REF” matrix is splitted in two: one related to fugitive emissions (hereafter “REF FUG”) and the other related to oil refinery in industry sector (hereafter “REF IND”). In POLES JRC the “REF IND” includes mapping only for emissions from petroleum refineries. The respective subsector in EDGAR is that of fuel combustion petroleum refinery (CMB) (see Table 20). CH₄ and N₂O emissions from fuel transformation in petroleum refinery (“REF EVA” in EDGAR) are taken into account as residual category in “ENE” matrix.

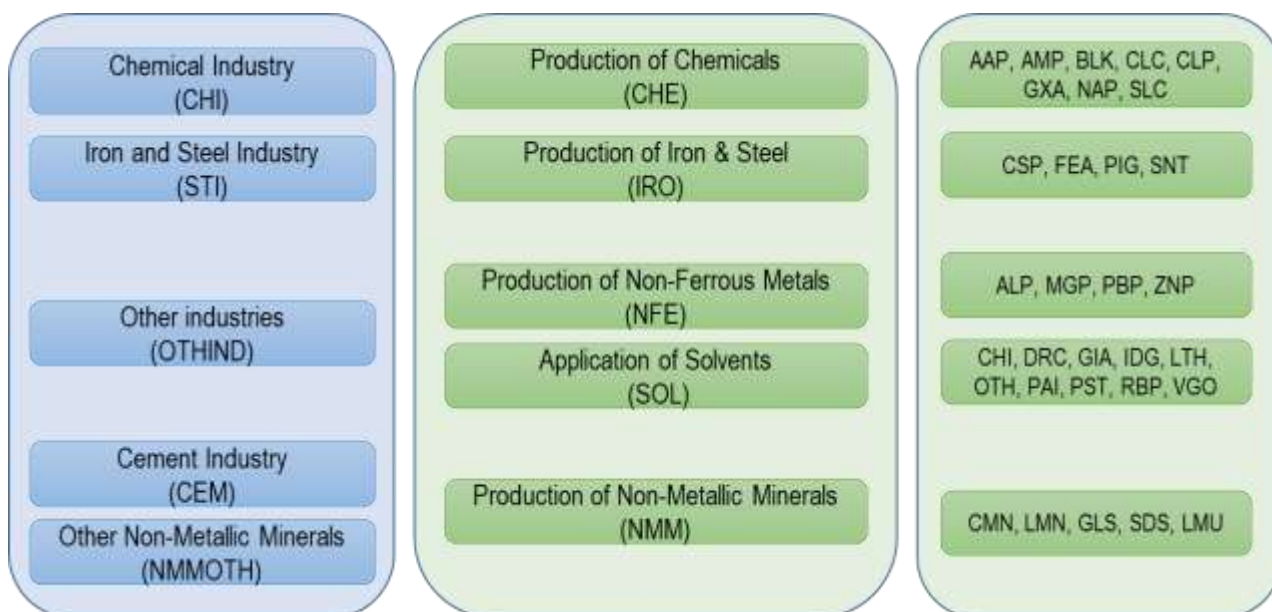

Table 20. EDGAR-POLES JRC mapping structure for oil refinery in industry sector and fuel

POLES code	REF OIL
POLES fuel	OIL
EDGAR subsector	CMB
EDGAR fuel	AVG, BIT, CRU, DIE, ETH, GJE, HFO, JET, LPG, LUBMOG, NAP, NGL, OKE, OPR, PCK, PWX, RFG, RGS, WSP

4.2 EDGAR-POLES JRC process emissions during production matrix

EDGAR-POLES JRC matrixes in process emissions during production are build up to the level of process codes. Here below the mapping structure based on the allocation of respective subsectors process codes. In POLES JRC no use of fuels is included in the respective codes. From EDGAR side as shown in Figure 13 the aggregation of several subsectors and fuels is needed when mapping is done for CO₂, non-CO₂ and air pollutant. Under POLES JRC other industries (OTHIND) emissions and activity data will be provided for the EDGAR subsectors on production of non-metallic metals (NFE) and application of solvents (SOL). The EDGAR subsector production of non-metallic minerals (NMM) will receive inputs on emissions and activity data from POLES JRC cement industry (CEM) and other non-metallic minerals (NMMOTH). Estimation of CO₂ emissions from the non-energy use of fuels (NEU in EDGAR) is not applicable in POLES JRC.

Figure 13. EDGAR-POLES JRC mapping structure for process emissions by process codes and subsectors

For CH₄ the mapping includes production of chemicals and that of iron and steel. However, this estimation is considered as POLES JRC residual category. Mapping of air pollutants in production of chemicals and non-ferrous and solvent application will be only at sector level.

For F-gases the mapping will not include the production of nitrogen trifluoride (NF₃) since this is not available in POLES JRC. For hydrofluorocarbons (HFCs)-all components, the mapping in EDGAR side is done for semiconductors, domestic refrigeration, production and consumption of HFCs, closed and open cell foam, commercial refrigeration, industrial refrigeration, fire protection, consumption in flat panel display production, mobile and stationary air conditioning, use in solvents and transportation of refrigeration.

In case of perfluorocarbons (PFCs)-all components, the EDGAR mapping includes among other subsectors the aluminium production (primary), semiconductors, consumption for accelerators, fire-extinguishers, use in solvent, consumption in flat panel display and solar cells.

In EDGAR the SF₆ mapping includes codes of its production, foundries (aluminium and magnesium, PV solar cells production, consumption for accelerators, production of soundproof windows, consumption in flat panel display production, consumption for electrical equipments manufacturing, consumption for sport shoes and others and consumption for GIS Stock emissions from leakage and maintenance.

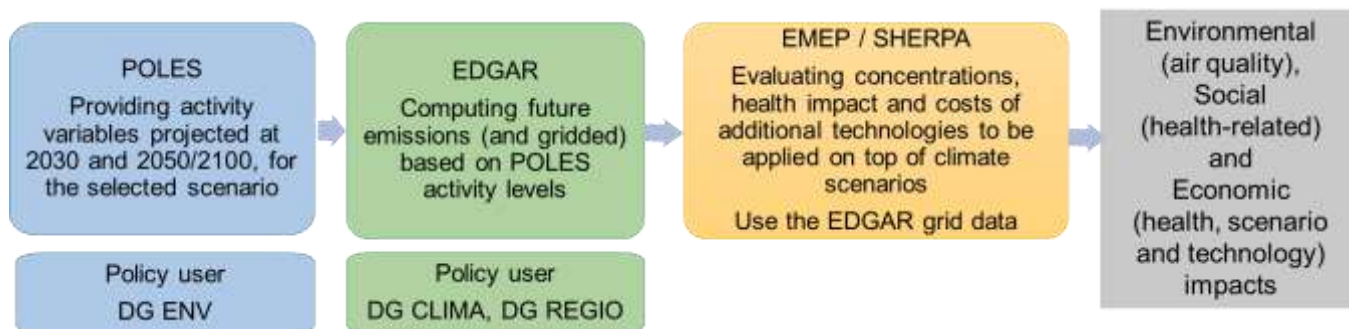

4.3 EDGAR-POLES JRC agriculture and waste matrix

EDGAR-POLES JRC matrix for agriculture sector will provide only the allocation of total value for GHG and air pollutants. In POLES JRC emissions of CH₄ from agriculture includes both manure management (cattle as main livestock) and agricultural soils (rice as main category). N₂O emissions cover both fertilisers use and manure management (cattle). In case of air pollutants the totals of emissions and activity data are provided by POLES JRC which includes in this sector also the emissions of pollutants from wild fires. For waste sector only totals of CO₂, CH₄, N₂O and AP emissions and activity data will be provided.

5 EDGAR - POLES JRC platform

The concept on which the development of an EDGAR-POLES JRC platform proposed is shown in Figure 14. This concept takes into account the role that each of the components of this platform will play when a scenario analysis will be developed either for GHG and air pollutant emissions. POLES JRC will provide activity data following the same matrix structure as those for the emissions.

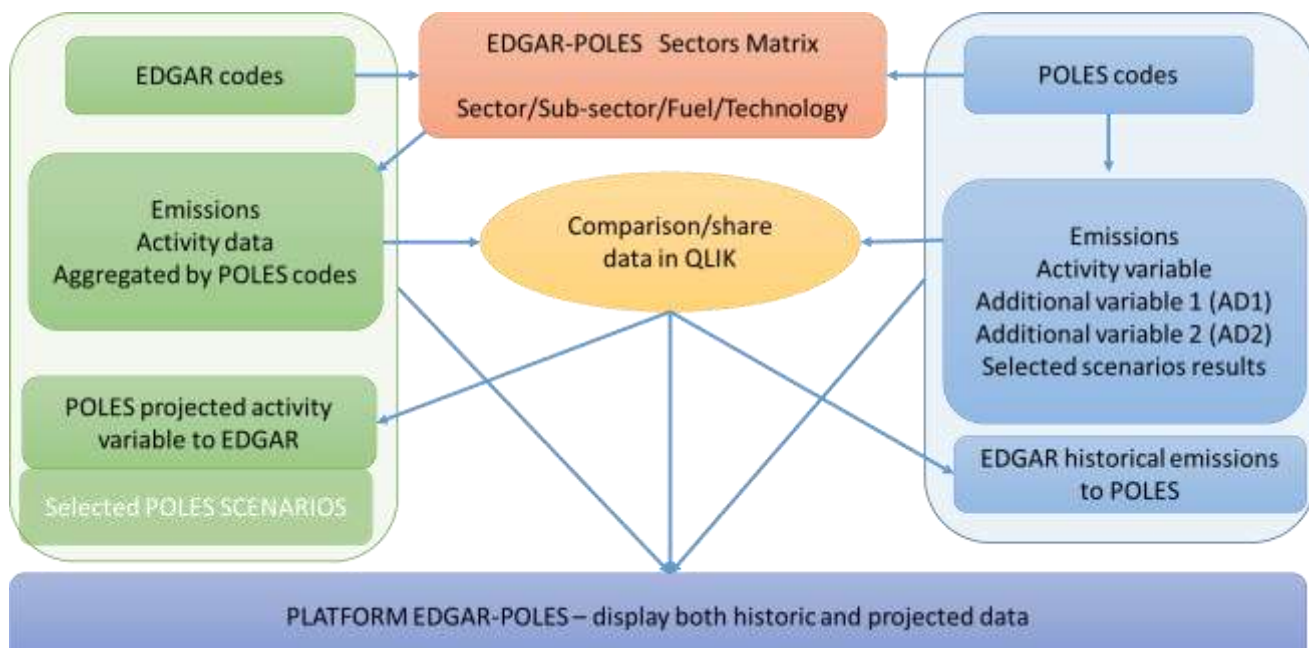

Figure 14. The concept of building an EDGAR-POLES JRC platform

The final aim of the EDGAR-POLES JRC platform is to provide to the users the possibility to visualize the indicators through an interactive and customizable interface using maps, charts, and tables. The EDGAR-POLES JRC platform will serve as an information tool that sustains the analysis of emission trends and future scenarios to identify unexpected and emerging signals in emissions and technologies in all countries/regions included in the EDGAR-POLES JRC matrixes. The platform aims to present comprehensive and comparable greenhouse gas emissions data both historic and projections.

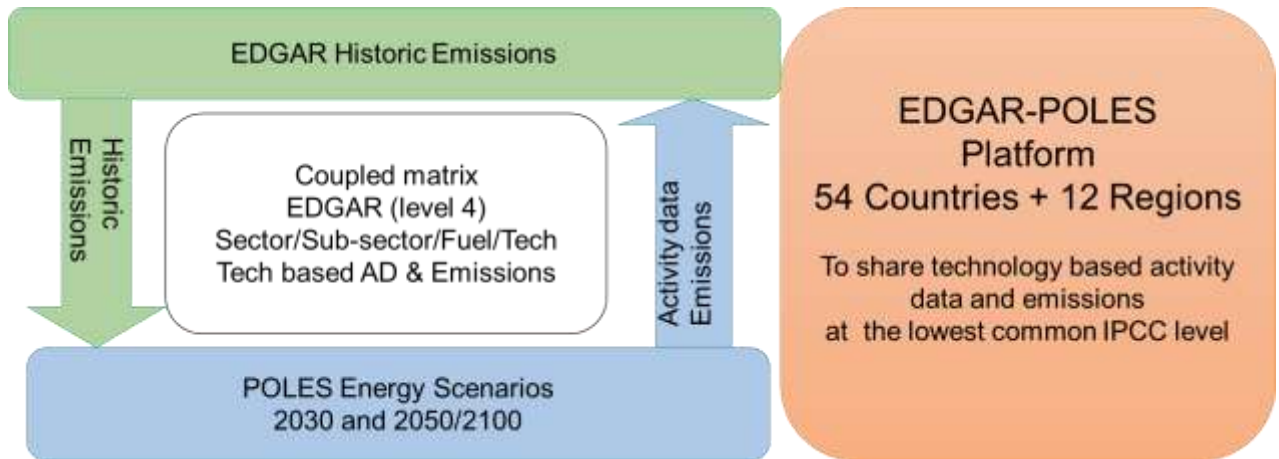

The data sharing/comparison/analysis of emissions and activity data between EDGAR and POLES JRC is based on the in-house QLIK business software (here after as QLIK tool). QLIK tool can manage data structured being useful to implement a data archive. QLIK tool presents data in context discovering significant and meaningful patterns, multi perspective, comparison, multivariate analysis and visualisations can be embedded in the webpage. Figure 15 illustrates the role that QLIK tool will play in the preparation of final output for the EDGAR-POLES JRC platform.

Figure 15. Data sharing/comparison/analysing for EDGAR-POLES JRC within QLIK tool

Selected POLES JRC scenarios results on emissions as well as the projected activity data will be available for EDGAR. For sectors as energy additional activity data will be provided by POLES JRC taking into account the role of carbon capture and storage (CCS) deployment. Figure 16 shows what will be included in QLIK tool that can then be used as an input for the EDGAR-POLES JRC platform.

Figure 16. QLIK tool for EDGAR-POLES JRC platform

A unique EDGAR file will be prepared including all mapped sectors/subsectors/fuels/technologies combinations in order to provide to users the possibility of several visualisations where historic data can be compared, historic data and projections can be visualise.

QLIK tool is expected to provide visualisations that include both historic emissions as estimated by EDGAR and emission projections from POLES JRC model. In Figure 17⁹ an example of QLIK tool output on energy CO₂ emissions (in POLES JRC country domain) as estimated by EDGAR and projected by POLES JRC for period 1990-2050. Scenario data are sourced from JRC GECO 2021¹⁰ report [9]. The NDC-LTS scenario includes the stated Nationally Determined Contributions and the Long-Term Climate Strategies submitted by the UNFCCC parties. In Current Policies scenario it is assumed that all policies in place are already implemented.

Figure 17. Energy CO₂ emissions for 1990-2050: EDGAR historic, POLES JRC, GECO Current Policies & NDC-LTS

⁽⁹⁾ The data from POLES JRC used during the mapping exercise are included in this figure for illustrative purposes.

⁽¹⁰⁾ Scenarios data are sourced from GECO 2021 visualisation https://joint-research-centre.ec.europa.eu/geco-2021/geco-visualisation_en

6 EDGAR-POLES JRC mapping results examples

To illustrate the work done on the mapping between EDGAR and POLES JRC here below some info on the matrixes created as well as some examples of results on emissions and activity data in energy and transport sectors covering period from 1990 to 2019 are shown in this chapter. The data have been processes, analysed, compared and visualized using the in-house QLIK tool.

6.1 EDGAR-POLES JRC matrixes

The aggregation of EDGAR codes to map the POLES JRC codes is shown for some of the matrixes created in “ENE”, “IND” and “TRO” matrixes (see Figure 18).

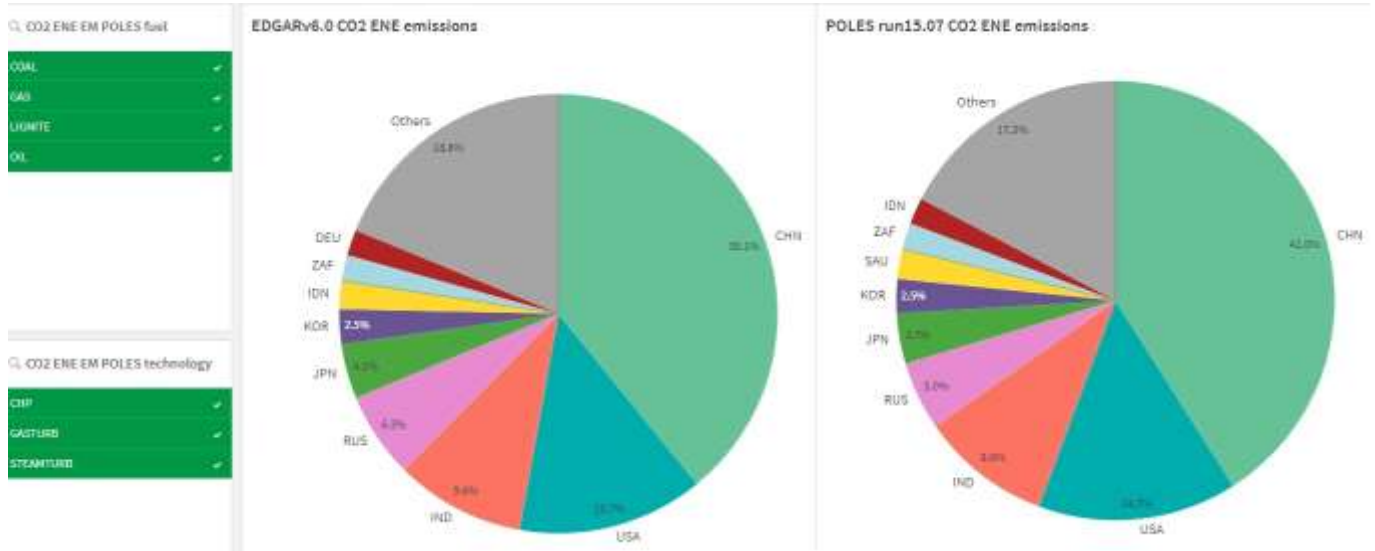

Figure 18. EDGAR codes aggregation by subsector/fuel/technology as in POLES JRC: a) “ENE”, b) “IND” and c) “TRO” matrixes

6.2 Fossil CO₂ and other greenhouse gases

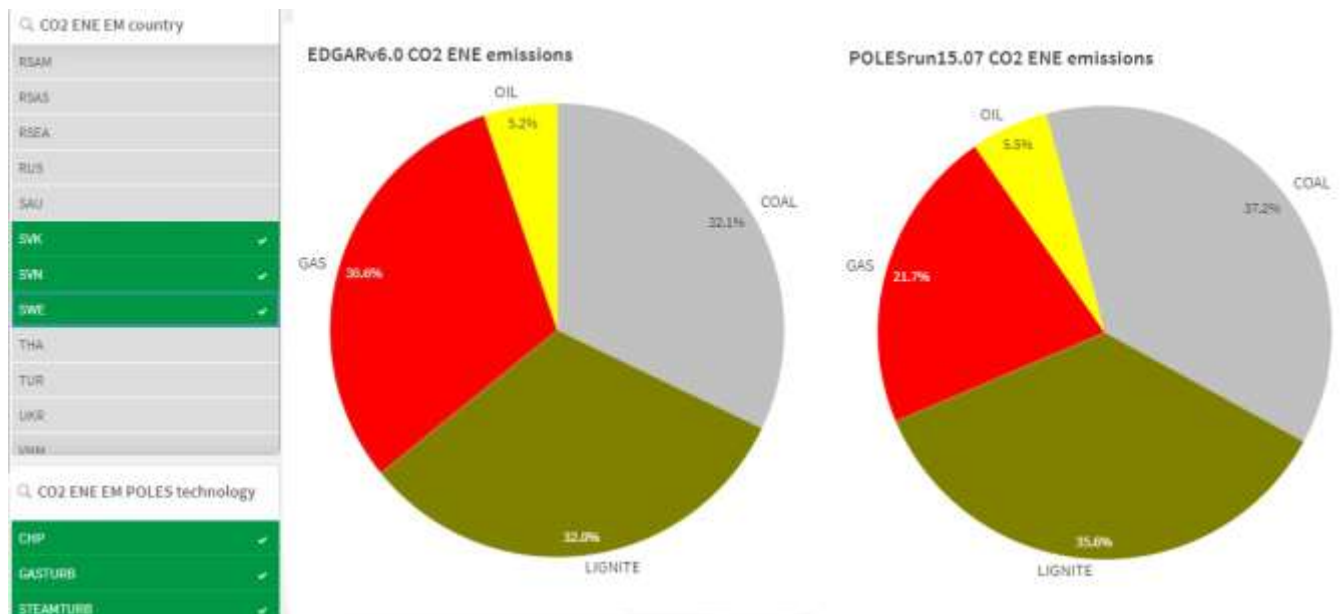

In Figure 19 the 2019 energy fossil CO₂ emissions by country (POLES regions excluded) sourced from both EDGAR and POLES JRC are shown. All fuels and technologies are grouped as in POLES JRC structure.

Figure 19. Energy fossil CO₂ emissions by country as in EDGAR (left) and POLES JRC (right), 2019

In Figure 20 the results of mapping between EDGAR database calculations and POLES JRC modelling for EU27 energy sector in year 2018 are shown. The difference observed is coming due to the fact that internal combustion do not exist in POLES JRC and as such this contribution is not included in EDGAR data used for this comparison.

Figure 20. EU27 energy fossil CO₂ emissions by fuel as in EDGAR (left) and POLES JRC (right), 2018

Time series of EDGAR and POLES JRC for EU27 CO₂ energy emissions from coal and lignite is shown in Figure 21. In the comparison¹¹ of these global CO₂ energy emissions for the solid fuels, the relative¹² differences stay between +4% and -1.5%.

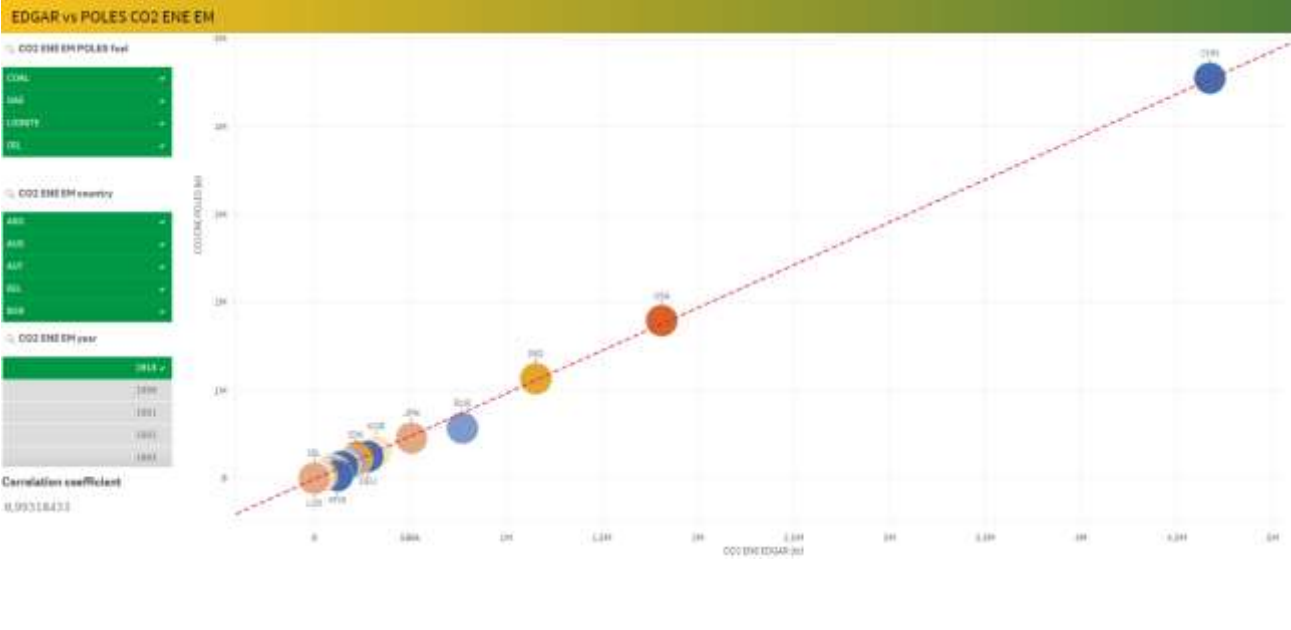

When looking to each fuel separately larger differences are found. In global level differences of CO₂ emissions from coal stand between +5% and -1%. In the case of lignite these differences stand between +5% and -3%. For fossil oil the differences are between +3% and -15%. Larger differences are found for gas fuel due to the issue of ICO. For EU27 the based-fuel differences stands between +8% and -5% for coal, +6% and -3% for lignite, +22% for oil and between +6% and -1%.

Figure 21. EU27 coal and lignite CO₂ energy emissions as in EDGAR and POLES JRC, (1990-2020), in kt

In country basis the correlation between EDGAR and POLES JRC taking all fuel into account is shown in Figure 22. As shown in this figure the correlation factor for the energy CO₂ emissions of EU27 countries between EDGAR and POLES JRC for year 2018 is at 0.993.

Figure 22. Correlation EDGAR - POLES JRC energy CO₂ emissions by country of POLES JRC domain, 2018

(¹¹) EDGAR CO₂ energy emissions versus POLES JRC CO₂ energy emissions.
 (¹²) Uncertainty of emissions is not included when calculating the relative differences between EDGAR and POLES JRC.

The comparison of activity data between EDGAR and POLES JRC (with CCS) over period 1990-2020 is shown in Figures 23 and 24. As explained above the differences between historical trends of EDGAR and POLES JRC activity data for CO₂ emissions in energy sector is due to the issue of internal combustion. Figure 23 illustrates this case showing how the trend of CO₂ energy emissions from coal, lignite and oil compares with the respective historic trend of POLES JRC.

Figure 23. Activity data for CO₂ energy emissions (no gas) - EDGAR (bar) and POLES JRC (line), (1990 – 2020), in TJ

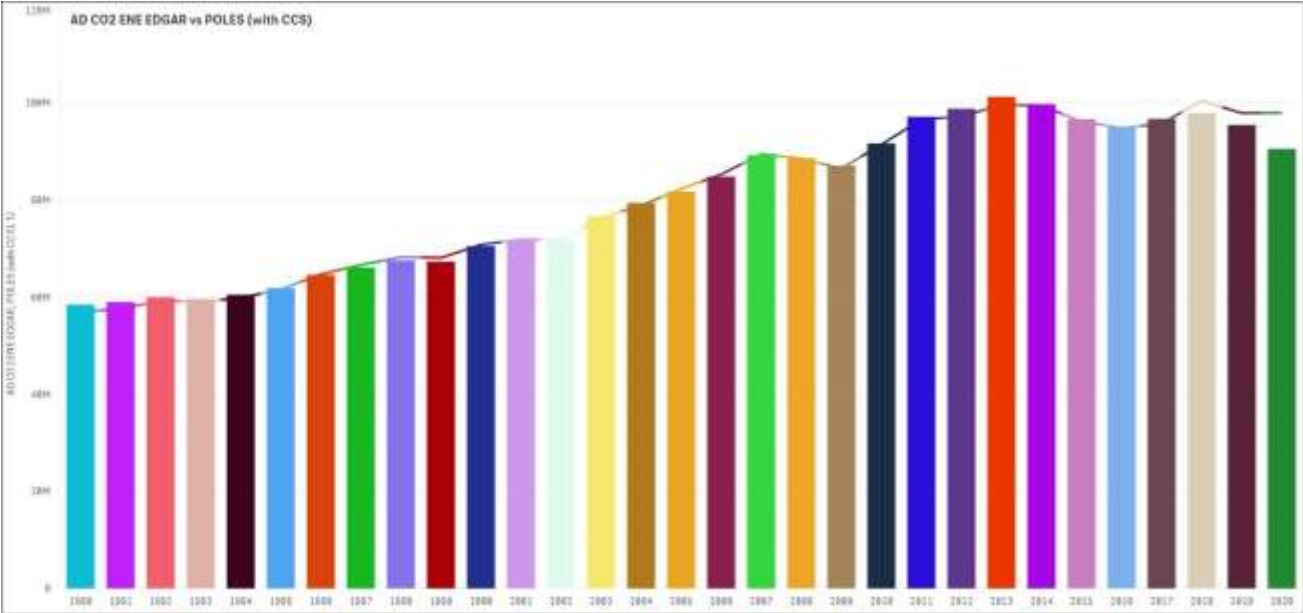

Figure 24 illustrates the case of CCS application in the activity data¹³ provided by POLES JRC for USA, Germany, China, France and Japan. Without the effect of CCS the projected activity data would have been nearly stable up to 2050.

Figure 24. Activity data for energy CO₂ emissions in USA, Germany, China, France, Japan – coal use in steamturbine CCS case, 1990-2040, (in TJ)

Comparison of activity data for the estimation of CO₂ emissions from energy sector (coal, lignite and oil) for POLES JRC country domain is shown in Figure 25. Relative differences for this domain and three fossil fuels (no gas) remain below ±3%. When analysing relative differences for EU27 domain relative differences stay below ±4%. On fuel basis the differences stand between +5% and -1% for coal, to -18% for lignite and oil. For the EU27 the comparison for the three

⁽¹³⁾ The sum of activity data for these five countries is presented since the trend of both activity data with and w/o CCS follows the same trend in each of these countries.

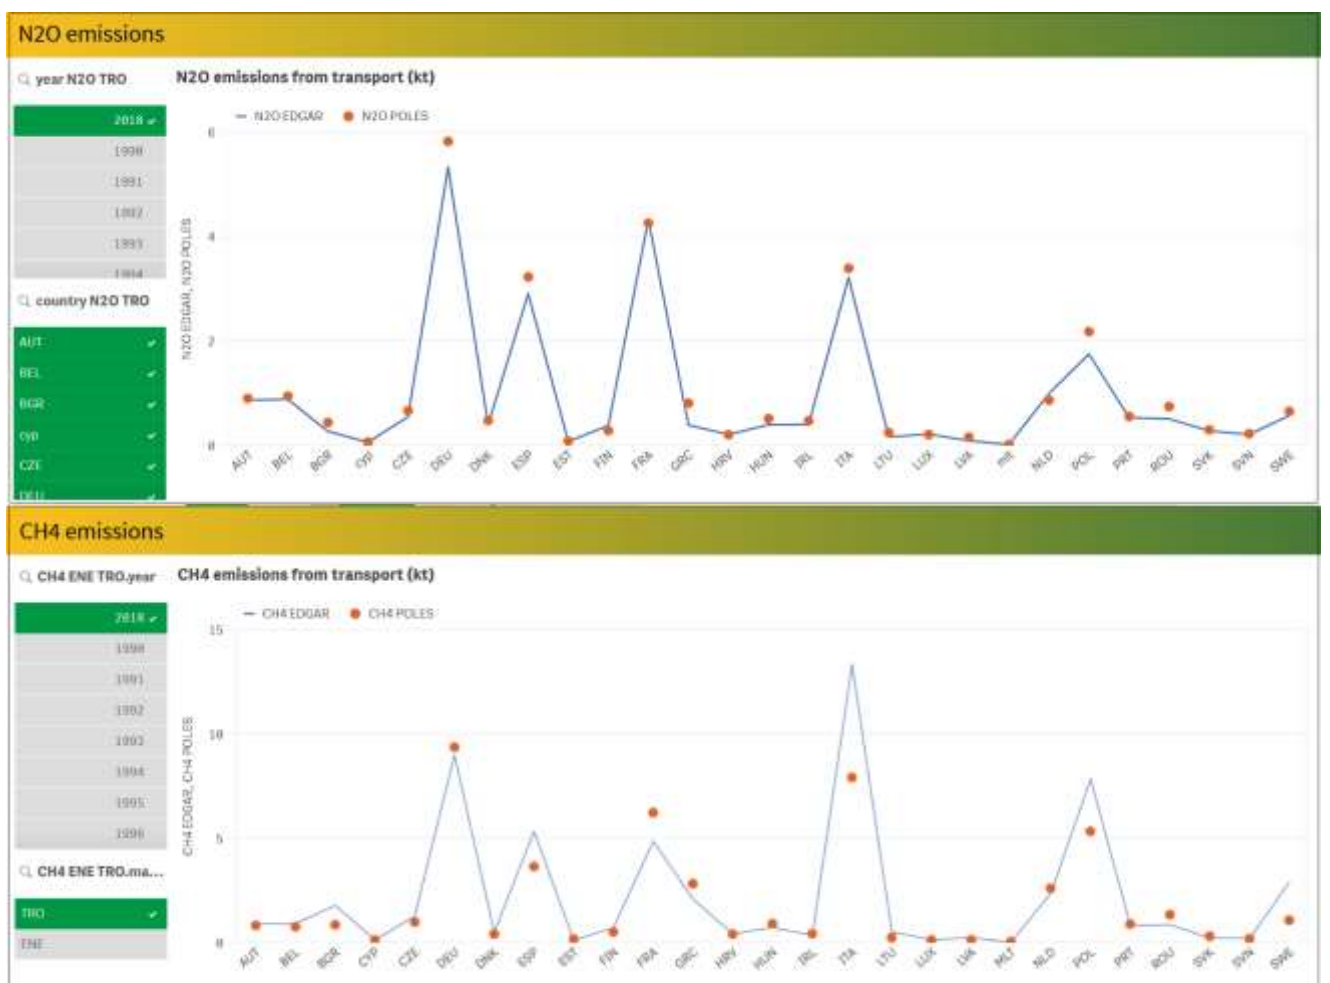

fuels stood at +£% and fuel based comparison reveals that the difference for coal stood between +8% and -5%, for lignite at -8% and for oil between +16% and -5%.

Figure 25. Relative changes in energy activity data (coal, lignite, oil): EDGAR vs POLES (with CCS), 1990-2018, (%)

The comparison by country total values of N₂O and CH₄ emissions in the EU27 transport sector is shown in Figure 26. It can be seen that a good agreement exist in several EU27 countries for both N₂O and CH₄ emissions coming from this sector.

Figure 26. N₂O and CH₄ emissions from transport sector in each EU27 countries, 2018, in kt

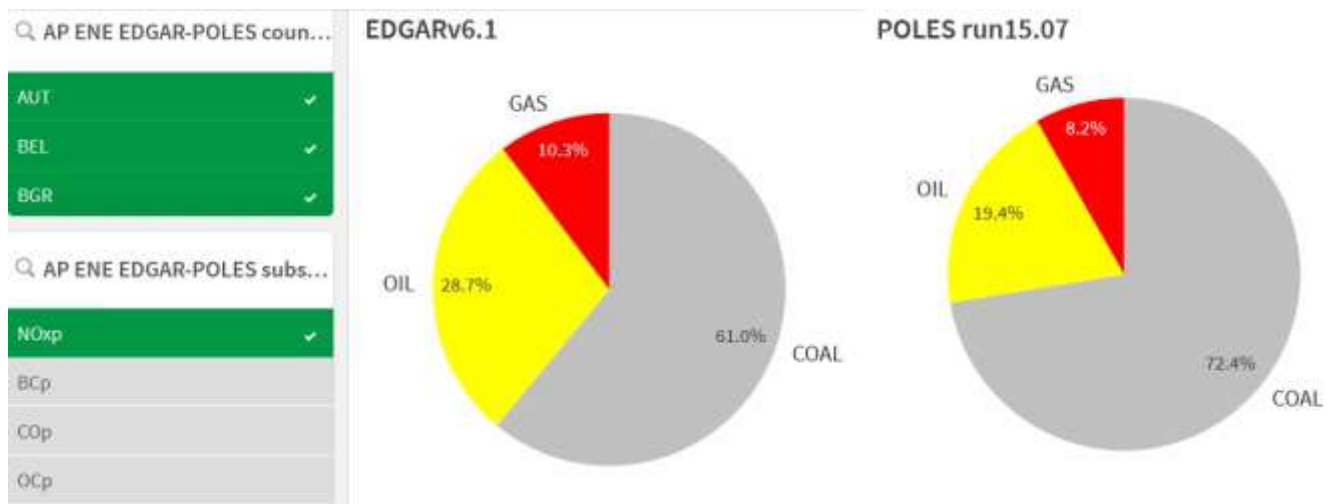

6.3 Air pollutants

Some results on mapping air pollutant emissions between EDGAR and POLES JRC covering energy sector are presented below.

The mapping for air pollutants has been done by total sector and by fuel. In the case of air pollutant larger differences are observed when the comparison is fuel based as well as sector based. These differences are linked with the type of air pollutant and fuel. In the estimation of air pollutant emissions the end of pipe/abatement measures for technologies and emission factors play an important role.

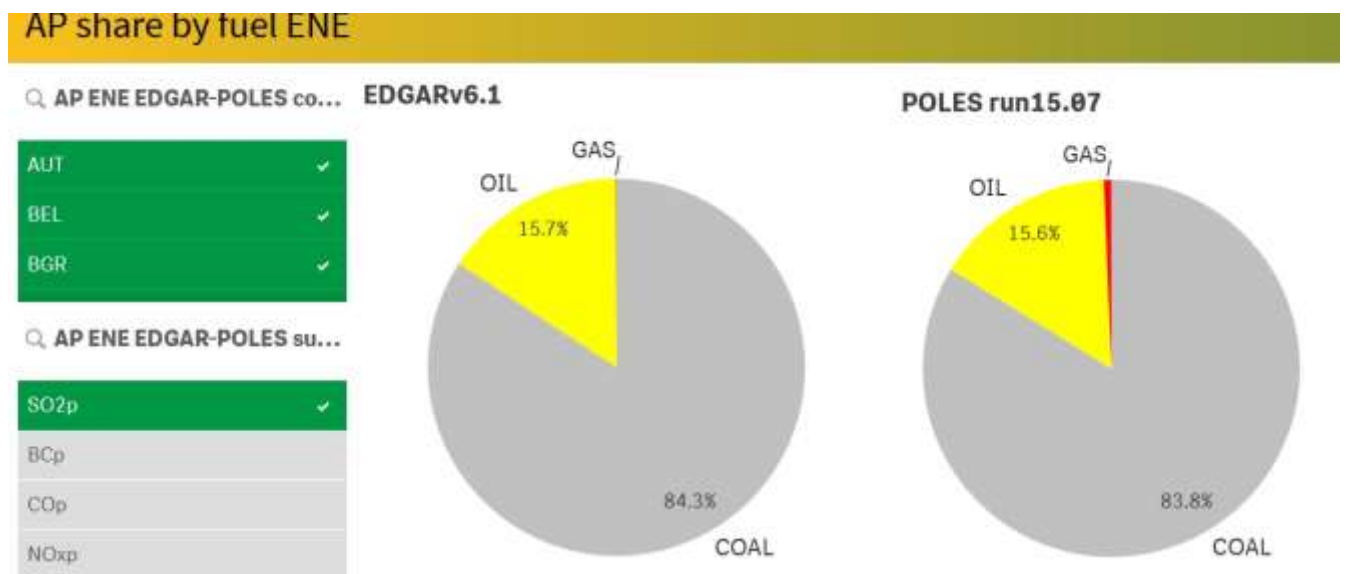

As shown in Figure 27 differences are observed in the contribution of fossil fuels in the NO_x emissions from energy sector in the EU27 domain.

Figure 27. EU27 energy NO_x emissions by fuel as in EDGARv6.1 (left) and POLES JRC (right), 1990

In the case of EU27 SO₂ emissions from energy sector shown in Figure 28 for year 2015, the share of fossil fuels (coal, oil and gas), the differences are not those observed for NO_x energy emissions. However, it was found that moving through years these differences might be considerable. The same was found also for other pollutants.

Figure 28. EU27 energy SO₂ emissions by fuel as in EDGARv6.1 (left) and POLES JRC (right), 2015

In Figure 29 the SO₂ energy missions in each EU27 country as estimated by EDGAR and POLES JRC are shown. As seen in several countries we have found a good match between EDGAR and POLES JRC. However, there are several countries in the EU27 and global domain where the differences exists.

Figure 29. SO₂ emissions from energy sector in each EU27 countries, 1990, in kt

Figure 30 shows how the year-to-year differences of SO₂ energy emissions from oil for both EDGAR and POLES JRC are found for period 1990-2018. It can be seen that in certain years we found nearly the same absolute differences in EDGAR and in POLES JRC as well as different absolute differences in other years.

Figure 30. Year-to-year absolute differences in SO₂ energy emissions from oil: EDGAR and POLES JRC, 1990-2018, in kt

7 Discussions and Conclusions

The objective of this report is to provide the relevant information on the possible mapping between EDGAR and POLES JRC bringing the attention on the harmonisation and issues that exist between these two in-house data sources.

The aim of this work was to map the in-house data sources EDGAR database and POLES JRC model to set the basis for the development of an EDGAR and POLES JRC communication platform. The platform will provide scenarios analysis that will be developed either for GHG and air pollutant emissions.

EDGAR emissions will be associated to POLES JRC projections that will provide energy and emissions results for a Reference, NDC-LTS and 1.5C Scenario. Mapping with EDGAR database has been performed at the possible “lowest” level that combines four EDGAR category combinations sector/subsector/fuel/technology. However, due to the availability of estimation from POLES JRC side this mapping level was not possible to be applied for all sectors in the EDGAR database.

The granularity of mapping in energy sector is more coarse on POLES JRC side since the model makes use of energy balance for three main fossil fuels: coal, gas and oil that are included in three main technologies: steam turbine, gas turbine and combine heat and power. Several EDGAR fuels and subsectors as well are needed to be aggregated. The EDGAR internal combustion technology doesn't exist in POLES JRC. One of the options is to align this technology to the POLES JRC gas turbine technology. On the other side EDGAR lacks of CCS and combined technology.

In manufacturing industry sector again the mapping level is based on EDGAR combination of four levels sector/subsector/fuel/technology. A one-by-one match is possible only for chemical, non-metall and iron & steel subsectors. The remaining ten subsectors should be aggregated.

In residential sector the EDGAR aggregation at subsector level is needed for agriculture and fishing which will be mapped at agriculture subsector of POLES JRC. Other not specified subsector is not assigned to any of the POLES JRC codes as the model do not have it. Several EDGAR fuels are aggregated to the three fuels existing in POLES JRC.

Mapping in transport sector includes mainly that of road transport and non-road transport. We find the same types of vehicles in road transport sector in both EDGAR and POLES JRC. The aggregation of EDGAR fuels in gas, oil and bio fuels of POLES JRC is necessary. For non-road transport three EDGAR subsectors are mapped with the respective POLES JRC. The issue in this subsector is the missing of POLES JRC emissions for road surface wear subsector. The model can provide the activity data for this subsector which can be compared with historic EDGAR activity data. The projected activity data can be used in EDGAR for the emissions estimation. For CH₄ and N₂O POLES JRC will provide only totals by sector whereas for air pollutants mapping will reach the sector and fuel level.

Estimation of emissions from fuel transformation does not exist in POLES JRC so this category is omitted from mapping. In the sector of process emissions during production, mapping is done one-by-one for some of the process codes.

Mapping in agriculture is possible only at sector level since POLES JRC baseline emissions and mitigation potentials are sources from specialized models as IIASA GLOBIOM model.

Some of the conclusions we can make on mapping process between EDGAR and POLES JRC can be summarized as in following:

- Mapping results show that a good alignment of categories, subsectors and fuels can be reached in power, industry, transport and residential sectors. As expected a good alignment can be reached for CO₂ emissions in power sector,
- Mapping for methane and nitrous oxide depends to the fact that the estimation of these GHG in POLES JRC is treated as a residual estimation process. Total values on sector basis are available from POLES JRC model.
- POLES JRC will provide activity data for all EDGAR sectors even in cases when emissions might be not available because the model does not estimate those. POLES JRC activity data for energy sector includes the effect of policies as reported by countries when fulfilling their obligations to UNFCCC,
- Mapping of air pollutants is done only on fuel-based and sector-based providing not the expected result even in the energy sector,

- POLES JRC air pollutant emissions and activity data can be used also as a benchmark for EDGAR emissions trends. More, POLES JRC will provide the projected activity data for each air pollutant by fuel and by sector.
- Mapping is performed for F-gases in the process emissions during production EDGAR main process
- The differences between EDGAR and POLES JRC are found in gas use in energy sector, in totals of CH₄ and N₂O and in the air pollutant estimation.

The way forward

- The work on further development of EDGAR-POLES JRC platform can continue with the aim to refine more the level of mapping between these two in-house data sources when the mapping is on the coarse level. For example on EDGAR side we have gas turbine technology and from POLES we have gas turbine, combined cycle and combined cycle with CCS. This match will require efforts from both sides to improve modelling, alignment and enhancement,
- Application of POLES JRC projections growth rates for both emissions and activity data, to its data in order to produce its own projections. This work will require efforts to define the growth rates for each technology and fuel that under the mapping work has been aggregated due to the coarse structure of POLES JRC model,
- Energy consumption in pipelines (in other transport) could be derived in POLES (a development task),
- Further development of the EDGAR-POLES JRC platform with the aim to develop and provide GHG emission scenario analyses taking into account different policy pathways will contribute to the definition of long-term EU climate targets and their impact assessment.

Annexes

Annex 1. EDGAR fuel codes

Type	Subtype	Fuel name	Code	Carrier group
Solid fuels and products	Hard coal	Anthracite	ANT	Coal
	Hard coal	Other Bituminous Coal	BTC	Bituminous
	Hard coal	Coking Coal	CKC	Bituminous
	Hard coal	Coal Tar	CLT	Coal product (for NEU)
	Hard coal	Gas Coke	GCK	Coal product
	Hard coal	Hard Coal (if no detail)	HDC	Coal
	Hard coal	Coke Oven Coke	OCK	Coal product
	Hard coal	Patent Fuel	PAT	Coal product
	Hard coal	Sub-Bituminous Coal	SBC	Sub-bituminous
	Brown coal	BKB/Peat Briquettes	BKB	Coal product
	Brown coal	Brown Coal (if no detail)	BRC	Brown coal/Peat
	Brown coal	Lignite/Brown Coal	LGN	Brown coal/Peat
	Peat	Peat	PEA	Brown coal/Peat
	Peat	Peat product (Briquettes)	PEP	Brown coal/Peat
	Solid waste	Municipal Waste (non-renew)	MWN	Waste (no biomass)
Oil and oil products	Heavy oils	Bitumen	BIT	Oil product
	Heavy oils	Crude/NGL/Feedstock (if no detail)	CNF	Crude oil subtype
	Heavy oils	Crude Oil	CRU	
	Heavy oils	Gas/Diesel Oil	DIE	
	Heavy oils	Residual Fuel Oil	HFO	
	Heavy oils	Lubricants	LUB	used in NEU
	Heavy oils	Other Hydrocarbons	NCR	
	Heavy oils	Petroleum Coke	PCK	used in NEU
	Heavy oils	Paraffin Waxes	PWX	used in NEU
	Heavy oils	Refinery Feedstock	RFD	Crude oil subtype
	Heavy oils	Orimulsion	ORI	
	Light oils	Additives/Blending Components	ADD	Crude oil subtype
	Light oils	Aviation Gasoline	AVG	
	Light oils	Ethane	ETH	
	Light oils	Gasoline Type Jet Fuel	GJE	
	Light oils	Kerosene Type Jet Fuel	JET	
	Light oils	Liquefied Petroleum Gases (LPG)	LPG	
	Light oils	Motor Gasoline	MOG	
	Light oils	Naphtha	NAP	Used in NEU
	Light oils	Natural Gas Liquids	NGL	Crude oil subtype
	Light oils	Kerosene	OKE	
	Light oils	Non-specified Petroleum Products	OPR	
Light oils	Shale oil	OSH	Light tight oil	
Light oils	White Spirit & SBP	WSP	Used in NEU	
Gaseous fuels and products	Natural gas	Natural Gas	NGS	
	Derived gases	Blast Furnace Gas	BFG	Coal product
	Derived gases	Gas Works Gas	GGG	Coal product
	Derived gases	Elec/Heat Output from Non-spec. Manuf. Gases	MNG	Product of misc. FF
	Derived gases	Coke Oven Gas	OGS	Coal product
	Derived gases	Refinery Gas	RGS	Oil product
	Derived gases	Oxygen Steel Furnace Gas	OGA	
Biomass Fuels (short cycle for CO ₂)	Solid biomass	Charcoal	CHA	Wood product
	Solid biomass	Dung	DNG	
	Solid biomass	Industrial Waste	IWS	Waste
	Solid biomass	Municipal Waste (Renew)	MWR	Waste
	Solid biomass	Non-specified Combust. Renewables + Wastes	NSF	
	Solid biomass	Primary Solid Biomass (non-specified)	SBI	
	Solid biomass	Vegetal waste	VWS	
	Solid biomass	Wood	WOD	
	Liquid biomass	Biodiesel	BDS	
	Liquid biomass	Biogasoline	BGL	
	Liquid biomass	Bagasse	BGS	Sugar cane product
	Liquid biomass	Black Liquor	BLI	Pulp product
	Liquid biomass	Liquid Biomass	LBI	Bioethanol, biodiesel
	Liquid biomass	Other Liquid Biofuels	OLB	
	Gaseous biomass	Biogas	GBI	Landfills, WWTP, digester

GETTING IN TOUCH WITH THE EU

In person

All over the European Union there are hundreds of Europe Direct centres. You can find the address of the centre nearest you online (european-union.europa.eu/contact-eu/meet-us_en).

On the phone or in writing

Europe Direct is a service that answers your questions about the European Union. You can contact this service:

- by freephone: 00 800 6 7 8 9 10 11 (certain operators may charge for these calls),
- at the following standard number: +32 22999696,
- via the following form: european-union.europa.eu/contact-eu/write-us_en.

FINDING INFORMATION ABOUT THE EU

Online

Information about the European Union in all the official languages of the EU is available on the Europa website (european-union.europa.eu).

EU publications

You can view or order EU publications at op.europa.eu/en/publications. Multiple copies of free publications can be obtained by contacting Europe Direct or your local documentation centre (european-union.europa.eu/contact-eu/meet-us_en).

EU law and related documents

For access to legal information from the EU, including all EU law since 1951 in all the official language versions, go to EUR-Lex (eur-lex.europa.eu).

Open data from the EU

The portal data.europa.eu provides access to open datasets from the EU institutions, bodies and agencies. These can be downloaded and reused for free, for both commercial and non-commercial purposes. The portal also provides access to a wealth of datasets from European countries.

The European Commission's science and knowledge service

Joint Research Centre

JRC Mission

As the science and knowledge service of the European Commission, the Joint Research Centre's mission is to support EU policies with independent evidence throughout the whole policy cycle.
