

Natural Oxytocin during Induced Labour

Intravenous infusion of Syntocinon[®] aims to prompt 'a contraction pattern similar to that of normal labour', thus coaxing the woman's natural oxytocin to be released in response to those contractions.

Natural oxytocin therefore adjusts for the stature of individuals, and by default, for their blood volume.

IF Syntocinon infusion[®] can be reduced once labour is established, and ceased before the end of labour, natural oxytocin is available to fulfil its normal role.
