

HISTORIC *Translocations*

THE RARE RETURN OF EXTINCTION-THREATENED EAST AFRICAN BLACK RHINO

by Emmanuel Koro in conversation with Thaba Tholo

“Thaba Tholo’s four successful translocations of black rhino species back to Tanzania and Rwanda, where they faced extinction, were rare and historic achievements.”

East African black rhino (*Diceros bicornis michaeli*).

*Saving the life of any species on planet Earth is one of the greatest achievements a human being can accomplish. It's also a challenge that enterprising conservation organisations such as the Thaba Tholo Game Ranch in South Africa, which has the largest population of East African black rhino (*Diceros bicornis michaeli*) outside of its historic home range, love to take on.*

However, for the Limpopo-based Thaba Tholo, keeping the East African black rhino population with the view of translocating some of them back to East Africa where they were being poached to extinction, was a delicate and daunting task.

Thaba Tholo's four successful translocations of these rare rhino species back to Tanzania and Rwanda, where they faced extinction, were rare and historic achievements.

The crowning moment of this little-known, unprecedented and inspirational East African black rhino conservation effort happened on 11 September 2019, when a total of nine black rhino were translocated from South Africa's privately run Thaba Tholo to the Grumeti Conservation area, which forms part of the Greater Serengeti Ecosystem in the north-western part of Tanzania. The four male and five female East African black rhinos originate from a breeding population in South Africa that is renowned for its exceptional breeding success. >>

Origins of East African black rhinos

The East African black rhinos originated from the Kibodo area in Kenya in 1961. Following their first introduction into South Africa in the Addo National Park, the population increased extremely slowly over the initial 18 years – by only four animals. Fortunately, once the population was introduced to and settled in at Thaba Tholo, the success rate of the population escalated.

“Within the following 20 years a total of 107 juveniles were born and the population quadrupled in size,” said Dr Petra Kretzschmar, scientist at the Leibniz Institute for Zoo and Wildlife Research, Germany, who is responsible for the scientific management of the black rhino population.

The high security measures employed at the ranch where the black rhinos were kept, together with the good pastures and scientific management of each animal, led to the project’s success.

“Every animal has a studbook record, which contains the sex and age of the individual, its intercalving intervals, family tree and lineage records (in other words, who the mother and father were and traced back to great- and great-great-grandfathers), fertility tests, pregnancy sonars as well as its genetic profile,” says Dr Kretzschmar. “This enables us to calculate the population growth, the individual intercalving interval, sex and age of each offspring and to carefully select unrelated individuals as well as a sex- and-age structure (population demographics) that would be the most beneficial founder population to the north-western side of the Serengeti.”

The amount of known information for each individual black rhino selected for this relocation project is astonishing.

Forty years ago, an estimated 500-700 East African black rhino freely roamed the Serengeti-Mara ecosystem. Sadly, poaching later drove this black rhino population to near extinction.

Critically endangered

Today, the East African black rhino is critically endangered. An estimated 1 000 individuals remain in the wild. Of the remaining three Management Units (otherwise known as subspecies), the East African black rhino is by far the rarest.

"I am proud that we are in a position to contribute to such a degree to the conservation of this iconic species," said Rubin Els, CEO of Thaba Tholo. "It has taken a lot of vision, effort, planning and finances of various role players to have this nucleus population so well established in this time in history."

Rubin notes that in South Africa the East African black rhino is ironically classified as an alien and invasive species (unwanted species), according to the South African environmental legislation, because their occurrence here is considered to be out of their natural home range.

"To me it was a no-brainer to establish a nucleus of East African black rhino in a place that was safe due to maximum security, intensive monitoring and where they could increase to their full capacity, away from the pressures of humans," he said. "Without all our logistics and scientific advice, we would have never been able to establish such a successful breeding population." >>

The high security measures employed at the ranch where the black rhinos were kept, together with the good pastures and scientific management of each animal, led to the project's success.

Rhinos spend approximately three months after capture in bomas in preparation for the translocation.

Little known behind the scenes work

Wouter Maree, General Manager of Thaba Tholo, said the East African black rhino translocation initiative owes its success to the women and men behind the scenes who continue to give valuable financial, technical and professional support to the project. They include ranger corps, security teams of Thaba Tholo, management team, shareholders and the Grumeti Fund, the veterinarians Drs Andre Uys and Dawid Snyman, Dr Cindy Harper and her special lab team, Conservation Solutions, who provided transport and expertise, and Dr Petra Kretzschmar for years of expert advice.

“Behind the scenes, there are a lot of unsung heroes,” says Wouter. “These are the people who commit their lives and their very existence to the survival of rhinos, which is the cornerstone of success to the Thaba Tholo miracle.”

There are many logistical and administrative tasks involved in the ultimate success of such a mammoth venture. But few people are aware of the crucial role of the rhino keepers, who put their lives on hold to care for the animals whilst they are in captivity.

There is a dedicated team that ensures the welfare of these special animals until they are ultimately released at their final destination.

It starts with this team being involved during the capture operation of each animal. The immobilised rhinos are moved to holding pens (better known as bomas), where they are kept for about three months.

From then onwards, the rhino keepers spend ‘every practical moment’ with the rhino.

Having been naturally from the wild, the black rhinos need to be calmed as quickly as possible. The keepers talk to them, feed them and clean their holding pens on a daily basis. Additionally, they chop branches for them twice daily (as they are browsers and need the food known to them), clean their water troughs and even provide mud baths for them during the heat.

In order to clean the bomas daily, the rhinos need to be taught to move from their boma into an empty adjacent one.

All the dung, uneaten branches and food are carted out on wheelbarrows by hard labour. The water troughs are emptied and meticulously cleaned. When the boma is clean, new branches and feed are placed for further feeding. Thereafter, the rhinos are moved back into the clean boma, where they find fresh food and water prepared for them by their hardworking and caring keepers.

Before long the black rhinos get used to the daily routine. Over time, the keepers develop an intense bond with each rhino. They get to know each rhino personally. Not many people know that black rhinos each have different temperaments and personalities. They even have different moods (some are grumpy throughout, but some become loveable and even like human contact, whilst others remain aloof or neutral) along with different preferences of food (i.e. some will like a specific type of tree, whilst some would prefer the game pellets or thorn tree pods).

The black rhinos are extremely intelligent animals and get bored easily in confinement. To break their monotonous routine and keep them happy, their keepers make great efforts to maintain a daily movement routine and talk to them using loving and lively voices. The black rhinos can be spoilt brats with some of them liking toys such as tyres to keep them occupied.

The whole point of the intense relationships with the rhinos is to ensure they adapt to their new captive environment as quickly as possible, since this ensures they remain in peak physical condition. >>

There is a dedicated team that ensures the welfare of these special animals until they are ultimately released at their final destination.

The keepers who were involved in this relocation success story, deserve to be named: George Kgamanyane, Jankie Sekoboane, Robynne Prinsloo, Ros-Amy Els, Jennifer Conaghan, Kevin Aron and Aiden Perring. They are truly the unknown and unsung heroes.

“After 20 years, all the planning and hard work have finally paid off, paving the way for Thaba Tholo to start relocating meaningful numbers and new founder populations to areas and countries where they have become extinct.”

2019 translocation from Thaba Tholo to the Grumeti Conservation area.

Risk and reward

The transport and translocation/relocation leg of the project is extremely risky and stressful to the black rhinos. They need to be in tip top condition (like an athlete before running a marathon) in order to ensure they travel safely and comfortably and settle successfully on the other side. Some of the keepers travel along with the rhinos on the cargo plane and assist with their acclimatisation in their new country.

“I am both excited and relieved that the animals travelled well during their long journey and that all nine rhinos arrived safely, but at the same time, I am sad for having to part with my special guests,” said Robynne Els, one of the rhino keepers.

After 20 years, all the planning and hard work have finally paid off, paving the way for Thaba Tholo to start relocating meaningful numbers and new founder populations to areas and countries where they have become extinct.

Relocations to date include:

- ① The **first** translocation to Tanzania in **2001** involved a partnership with the South African National Parks (SANParks).
- ② The **second** translocation in **2010** to the Serengeti National Park in Tanzania, in partnership with the Grumeti Fund.
- ③ The **third** translocation in **2017** was the relocation of 18 black rhino from Thaba Tholo to the Akagera National Park in Rwanda. With the newly found population in Akagera, Rwanda became only the fourth African country to have the rare East African black rhino roam its soil.
- ④ The translocation of the nine rhinos to Tanzania in **2019** is the **fourth** consignment of rhino sent from Thaba Tholo to former range states in Africa.

The Grumeti Conservation Fund has been instrumental and a key partner in two of the three translocation events to Tanzania.

"We are incredibly grateful for the willingness and assistance from the Tanzanian government and the Tanzania Wildlife Management Authority in particular," said Stephan Cunliffe, executive director of the Grumeti Fund.

These are indeed exciting times for the successful East African black rhino translocation. ■
