# 06-Solar Resource Part 2 

ECEGR 4530
Renewable Energy Systems

## Overview

- Angle of Incidence Components
- Effect of Declination
- Effect of Latitude
- Effect of Tilt
- Effect of Hour Angle
- Hours of Day Light

## Introduction

- Last lecture we determined that the angle of incidence affects the irradiance received by a surface
- We now investigate the variables that affect the angle of incidence

## Introduction

- Angle of incidence depends on many factors, including:
- Tilt of the surface (already discussed)
- Latitude ( $\phi$ )
- Declination angle ( $\delta$ )
- Surface azimuth angle ( $\gamma$ )
- Hour angle ( $\omega$ )

## Introduction

Normal to tilted surface C

## Effect of Day of Year (Declination)

## Effect of Declination Angle

- Earth is tilted on an axis, which causes seasons
- Axis is tilted at $23.5^{\circ}$
- Declination ( $\delta$ ): angular position of the sun at solar noon wrt the plane of the equator (degrees)

## Effect of Declination Angle

For Northern Hemisphere

## Effect of Declination Angle

- Declination angle is zero during the equinoxes

viewed from the sun
viewed from the sun

## Effect of Declination Angle

- Declination is computed as:
$\delta=\delta_{0} \sin \left(\frac{360^{\circ}(284+d)}{365}\right) \quad$ (where does the 284 come from?)
- where
- $\delta_{0}=23.5^{\circ}$

## Effect of Declination Angle

- Summer solstice: $\delta=\delta_{0}=23.5^{\circ}$
- Winter solstice: $\delta=-\delta_{0}=-23.5^{\circ}$
- Spring equinox: $\delta=0$
- Autumn equinox: $\delta=0$

## Effect of Declination Angle

- Northern Hemisphere: the axial tilt increases the daylight hours in March-September
- Southern Hemisphere: the axial tilt increases the daylight hours in the September-March
- More daylight hours means more daily insolation

## Effect of Declination Angle

- Daylight on April 9th, 2012 at 13:57:25

Source: time.gov

## Effect of Declination Angle

- Daylight on January 17 ${ }^{\text {th }}, 2017$ at 7:27:25

## Effect of Declination Angle

- Daylight on March 14 ${ }^{\text {th }}, 2017$ at 1:10:00

## Effect of Declination Angle

- Declination affects zenith angle
- Assume solar noon (sun due south)
- Assume the surface is at the equator (latitude $=0^{\circ}$ )
- spring and autumn equinox: $\theta_{z}=0^{\circ}$
- summer solstice: $\theta_{z}=23.5^{\circ}$
- winter solstice: $\theta_{z}=-23.5^{\circ} \hat{\jmath}$

## Effect of Latitude

## Effect of Latitude

- Let
- $\phi$ : latitude of the surface (degrees)
- Assume North is positive, South is negative
- $-90 \leq \phi \leq 90$

## Effect of Latitude

- Assume:
- declination $=0^{\circ}$ (i.e. Spring/Autumn Equinox)
- Sun directly due south (solar noon)
- Horizontal surface is at latitude $\phi$ (degrees)
- It follows that $\theta=\theta_{\mathrm{z}}=\phi$ and $\mathbf{G}_{0}=\mathbf{G}_{0 \mathrm{n}} \mathbf{\operatorname { c o s }}(\phi)$

## Effect of Latitude

- Combining the effects of declination and latitude
- Assume solar noon (sun due south)
- Assume the surface is horizontal $\left(\theta=\theta_{z}\right)$
- Using trigonometry:

$$
\begin{aligned}
\theta=\theta_{z} & =\phi-\delta \\
\cos (\theta) & =\cos \left(\theta_{z}\right)=\sin (\delta) \sin (\phi) \lambda+\cos (\delta) \cos (\phi)
\end{aligned}
$$

equator

## Example

- What is the irradiance for a horizontal surface at the top of the atmosphere (extraterrestrial) above Seattle, Washington (latitude $47.6^{\circ}$ ) on January 23 at solar noon? Account for intrayear irradiance variation.

## Example

- What is the irradiance for a horizontal surface at the top of the atmosphere (extraterrestrial) above Seattle, Washington (latitude $47.6^{\circ}$ ) on January 23 at solar noon?

$$
\begin{aligned}
& d=23 \\
& G_{o n}(d)=G_{s c}\left[1+0.034 \cos \left(2 \pi\left(\frac{d}{365}\right)\right)\right]=1408.6 \\
& \delta=\delta_{0} \sin \left(\frac{360^{\circ}(284+d)}{365}\right)=23.5^{\circ} \sin \left(\frac{360^{\circ}(284+23)}{365}\right)=-19.75^{\circ}
\end{aligned}
$$

## Example

- What is the irradiance for a horizontal surface at the top of the atmosphere (extraterrestrial) above Seattle, Washington (latitude $47.6^{\circ}$ ) on January 23 at solar noon?

$$
\begin{aligned}
& \theta_{z}=47.6--19.75=67.4^{\circ} \\
& G=G_{0 n} \cos \theta_{z} \Rightarrow 1408.6 \times 0.385=542 \mathrm{~W} / \mathrm{m}^{2}
\end{aligned}
$$

## Effect of Declination Angle

- At large values of ( $\phi-\delta$ ), the angle of incidence is large (cosine effect is significant)
- How can we compensate for this?

## Surface Orientation

- Tilt the surface
- Want the surface to be normal to the irradiance
- $\beta=(\phi-\delta)$ (Northern Hemisphere)
- Want angle of incidence to be zero

## Effect of Surface Orientation

## Surface Orientation

- Tilt should equal latitude during equinox
- As $\delta$ increases, less tilt needed
- At solar noon: $\cos (\theta)=\cos (\phi-\delta-\beta)$
- In the southern hemisphere:
- $\cos (\theta)=\cos (-\phi+\delta-\beta)$

## Surface Orientation

Surface is normal to $G$ when $\beta=\phi-\delta$

## Surface Orientation

- General rule of thumb: tilt a PV panel at the latitude
- Normal to irradiance on equinoxes
- Too much tilt in summer
- Too little tilt in winter

Where in the world are these PV panels?

## Surface Orientation

- $\cos (\theta)=\cos (\phi-\delta-\beta)$
- Note: $\cos (w+z)=\cos (w) \cos (z)-\sin (w) \sin (z)$
- Note: $\sin (\mathrm{w}+\mathrm{z})=\sin (\mathrm{w}) \cos (\mathrm{z})+\cos (\mathrm{w}) \sin (\mathrm{z})$
- $\cos (\phi-\delta-\beta)=\cos (\theta+x)[$ set $x=-\delta-\beta]$
$-\cos (\phi+x)=\cos (\phi) \cos (x)-\sin (\phi) \sin (x)$

## Surface Orientation

$\cos (\phi-\delta-\beta)=\cos (\phi) \cos (x)-\sin (\phi) \sin (x)$
[back substituting for the first $x=-\delta-\beta$ ]
$=\cos (\phi) \cos (-\delta-\beta)-\sin (\phi) \sin (x)$
[Now use $\cos (w+z)=\cos (w) \cos (z)-\sin (w) \sin (z)]$
$=\cos (\phi)[\cos (-\delta) \cos (-\beta)-\sin (-\delta) \sin (-\beta)]-\sin (\phi) \sin (x)$
$[u \sin g \cos (-u)=\cos (u)$ and $\sin (-u)=-\sin (u)]$
$=\cos (\phi)[\cos (\delta) \cos (\beta)-\sin (\delta) \sin (\beta)]-\sin (\phi) \sin (x)$

## Surface Orientation

$=\cos (\phi)[\cos (\delta) \cos (\beta)-\sin (\delta) \sin (\beta)]-\sin (\phi) \sin (x)$
[back substituting for the remaining $x=-\delta-\beta]$
$=\cos (\phi)[\cos (\delta) \cos (\beta)-\sin (\delta) \sin (\beta)]-\sin (\phi) \sin (-\delta-\beta)$
$[\mathrm{using} \sin (\mathrm{w}+\mathrm{z})=\sin (\mathrm{w}) \cos (\mathrm{z})+\cos (\mathrm{w}) \sin (\mathrm{z})$ ]
$=\cos (\phi)[\cos (\delta) \cos (\beta)-\sin (\delta) \sin (\beta)]$
$-\sin (\phi)[\sin (-\beta) \cos (-\delta)+\cos (-\beta) \sin (-\delta)]$

## Surface Orientation

$=\cos (\phi)[\cos (\delta) \cos (\beta)-\sin (\delta) \sin (\beta)]$
$-\sin (\phi)[\sin (-\beta) \cos (-\delta)+\cos (-\beta) \sin (-\delta)]$
[multiplying out]
$=\cos (\phi) \cos (\delta) \cos (\beta)-\cos (\phi) \sin (\delta) \sin (\beta)$
$-\sin (\phi) \sin (-\beta) \cos (-\delta)-\sin (\phi) \cos (-\beta) \sin (-\delta)$
[using $\cos (-u)=\cos (u)$ and $\sin (-u)=-\sin (u)]$
$\cos (\theta)=\cos (\phi) \cos (\delta) \cos (\beta)-\cos (\phi) \sin (\delta) \sin (\beta)$
$+\sin (\phi) \sin (\beta) \cos (\delta)+\sin (\phi) \cos (\beta) \sin (\delta)$

## Surface Orientation

- Extraterrestrial irradiance accounting for the tilt, latitude and declination of a surface at solar noon:

$$
\begin{aligned}
& \mathbf{G}_{0 \mathrm{~T}}=\mathbf{G}_{0 \mathrm{n}} \cos (\theta)= \mathbf{G}_{0 \mathrm{n}} \cos (\phi-\delta-\beta) \\
&=\mathbf{G}_{0 \mathrm{n}}[\cos (\phi) \cos (\delta) \cos (\beta) \\
&-\cos (\phi) \sin (\delta) \sin (\beta) \\
&+\sin (\phi) \sin (\beta) \cos (\delta) \\
&+\sin (\phi) \cos (\beta) \sin (\delta)] \quad \text { Important result }
\end{aligned}
$$

## Surface Orientation

- Compute the extraterrestrial irradiance on a vertical surface above $30^{\circ} \mathrm{N}$ on April 15 at solar noon.
- Hint: April 15 is the $105^{\text {th }}$ day of the year

## Surface Orientation

- Compute the extraterrestrial irradiance on a vertical surface above $30^{\circ} \mathrm{N}$ on April 15 at solar noon.
- Hint: April 15 is the $105^{\text {th }}$ day of the year

$$
\begin{aligned}
& \phi=30^{\circ} \\
& \beta=90^{\circ}
\end{aligned}
$$

## Surface Orientation

- Compute the extraterrestrial irradiance on a vertical surface above $30^{\circ} \mathrm{N}$ on April 15 at solar noon.
- Hint: April 15 is the $105^{\text {th }}$ day of the year

$$
\begin{aligned}
& \phi=30^{\circ} \\
& \beta=90^{\circ}
\end{aligned}
$$

$$
\begin{aligned}
& G_{o n}(d)=G_{s c}\left[1+0.033 \cos \left(2 \pi\left(\frac{105}{365}\right)\right)\right]=1356.4 \mathrm{~W} / \mathrm{m}^{2} \\
& \delta=\delta_{0} \sin \left(\frac{360^{\circ}(284+d)}{365}\right)=23.5^{\circ} \sin \left(\frac{360^{\circ}(284+105)}{365}\right)=9.4^{\circ}
\end{aligned}
$$

## Surface Orientation

$$
\begin{aligned}
& \mathbf{G}_{0 T}=\mathbf{G}_{0 \mathrm{n}}[\cos (\phi) \cos (\delta) \cos (\beta) \\
&-\cos (\phi) \sin (\delta) \sin (\beta) \\
&+\sin (\phi) \sin (\beta) \cos (\delta) \\
&+\sin (\phi) \cos (\beta) \sin (\delta)]=476 \mathrm{~W} / \mathrm{m}^{2}
\end{aligned}
$$

Or

- $\mathbf{G}_{0 \mathrm{~T}}=\mathrm{G}_{0 \mathrm{n}} \cos (\phi-\delta-\beta)=476 \mathrm{~W} / \mathrm{m}^{2}$

## Effect of Time

## Effect of Hour Angle

- We want to relate this angle to time
- How many degrees does the Earth rotate each hour?

$$
\frac{360^{\circ}}{24}=15^{\circ}
$$

## Effect of Hour Angle

- We define the hour angle, $\omega$, as:

$$
\omega=15^{\circ}(h-12)+\left(\lambda-\lambda_{\text {zone }}\right)
$$

- $h$ local civil time (hours)
- $\lambda$ longitude (degrees)
- $\lambda_{\text {zone }}$ longitude of the meridian defining the local time (degrees)
- $\omega$ : angle that the Earth has rotated since solar noon

## Effect of Hour Angle

- UTC (Coordinated Universal Time) is defined at $0^{\circ}$ longitude
- Seattle is 8 hours behind UTC during standard time
- $\lambda_{\text {zone }}$ is then $8 \times 15^{\circ}=120^{\circ} \mathrm{W}$
- During Day Light Savings Time (roughly March - Nov) we are 7 hours behind UTC
- $\lambda_{\text {zone }}$ is then $7 \times 15^{\circ}=105^{\circ} \mathrm{W}$
- For a more accurate calculation use the Equation of Time
- We will assume that solar time = civil time
- $\left(\lambda-\lambda_{\text {zone }}=0\right)$

## Effect of Hour Angle

- Hour Angle is:
- negative in the morning (before solar noon)
- positive in the evening (after solar noon)

## Effect of Hour Angle

- If $\phi=\delta=0$ and $\beta=0$, then
- $\cos (\theta)=\cos (\omega)$

## Angle of Incidence

## Angle of Incidence

- Derivation of the angle of incidence is more difficult, so the result is provided
- $\cos (\theta)=\sin (\delta) \sin (\phi) \cos (\beta)$

$$
-\sin (\delta) \cos (\phi) \sin (\beta)
$$

$+\cos (\delta) \cos (\phi) \cos (\beta) \cos (\omega)$
$+\cos (\delta) \sin (\phi) \sin (\beta) \cos (\omega) \quad$ Important result

## Simplifications

- If $\beta=0$ (no tilt), then $\theta_{z}=\theta$ and
- $\cos (\theta)=\sin (\delta) \sin (\phi)+\cos (\delta) \cos (\phi) \cos (\omega)$
- For surfaces tilted at their latitude
- $\cos (\theta)=\cos (\delta) \cos (\omega)$
- For surfaces at solar noon
- $\cos (\theta)=\cos (\phi-\delta-\beta)$

## Angle of Incidence

- Note: $\cos (\theta)$ must be greater than or equal to 0 , otherwise the sun is shining on the rear of the surface (set the value to 0 )
- Note: angle of incidence equations do not account for the Earth blocking the sun's irradiance
- Try: $\omega=180, \beta=90, \phi=0$ and $d=1$ (sunny at midnight!)
- Only use the angle of incidence for daylight hours

## Hours of Daylight

## Astronomy Trivia

- How many hours of daylight are there in Seattle during the spring equinox?
A. 6
B. 10
C. 12
D. 14
E. 16
F. 18

## Astronomy Trivia

- How many hours of daylight are there in Seattle during the spring equinox?
A. 6
B. 10
C. 12
D. 14
E. 16
F. 18

## Hours of Day Light

- Daylight hours vary depending on latitude and declination
- For a horizontal surface the sun sets $(\mathbf{G}=0)$ when $\theta=90^{\circ}$
- Find $\omega$ such that:
- $\cos (\theta)=\sin (\delta) \sin (\phi)+\cos (\delta) \cos (\phi) \cos (\omega)=0$
- Solving yields:
- $\cos \left(\omega_{\mathrm{s}}\right)=-\tan (\delta) \tan (\phi)$
- $\omega_{\mathrm{s}}$ : sunset angle

## Hours of Day Light

- Since every $15^{0}$ is one hour:
- Hours of daylight is:

$$
N=\frac{2}{15} \cos ^{-1}(-(\tan \delta) \times(\tan \phi))
$$

## Effect of Hour Angle

- Visualization

## Hours of Sunlight on a Surface

- If a surface is tilted, it may receive fewer hours of sunlight than the number of daylight hours
- To compute the sunset hour angle for a titled panel, set $\cos (\theta)$ $=0$ and solve for $\omega$

$$
\begin{aligned}
\cos (\theta)= & 0=\sin (\delta) \sin (\phi) \cos (\beta) \\
& -\sin (\delta) \cos (\phi) \sin (\beta) \\
& +\cos (\delta) \cos (\phi) \cos (\beta) \cos (\omega) \\
& +\cos (\delta) \sin (\phi) \sin (\beta) \cos (\omega)
\end{aligned}
$$

- If the computed hour is earlier than sunrise for a horizontal surface, then use the angle for the horizontal surface as the sun will still be below the horizon (it is still night time)

## Hours of Sunlight on a Surface

- Whenever $\cos (\theta)<0$, the sun is not shining on the panel (but the sun perhaps has not yet set)
- For example, the sun will stop shining on a vertical surface facing south in the summer before the sun sets (i.e. the sun is "behind" the face of the surface)

## Side Note

How did Eratosthenes estimate the circumference in the third century BCE?

$8$

June 21

From another angle

North

- Therefore, Syene and Alexandria are $7.2^{\circ}$ of latitude apart
- Syene: $24^{\circ} \mathrm{N}, 33^{\circ} \mathrm{E}$
- Alexandria: $31^{\circ} \mathrm{N}, 30^{\circ} \mathrm{E}$
- Distance between Syene and Alexandria: 500 miles
- (7.2/360) C = 500 miles
- => C = 25,000
- Actual circumference: $\sim 24,900$ miles
