13-Wind Resource

ECEGR 4530

Renewable Energy Systems

Overview

- Introduction
- Wind Resource Modeling
- Variation with Height
- Power Curve
- Wind Power Modeling

SEATTLEU

Introduction

- Energy from wind has been harnessed for thousands of years:
  - Sailing
  - Milling
  - Pumping water
- Wind turbines operate by converting kinetic energy in the air to electrical energy

Dr. Louie

SEATTLEU

Introduction

- Wind Mill: used to mill grain
- Wind Turbine: used to generate electricity
- Wind Plant (Wind Farm): collection of wind turbines

Wind Resource

- Movement of air on appreciable scales is caused by temperature differentials
  - Higher temperature air is less dense than cold air

- Temperature differentials (gradients) are predominately caused by uneven solar heating
 - Wind is another form of solar energy
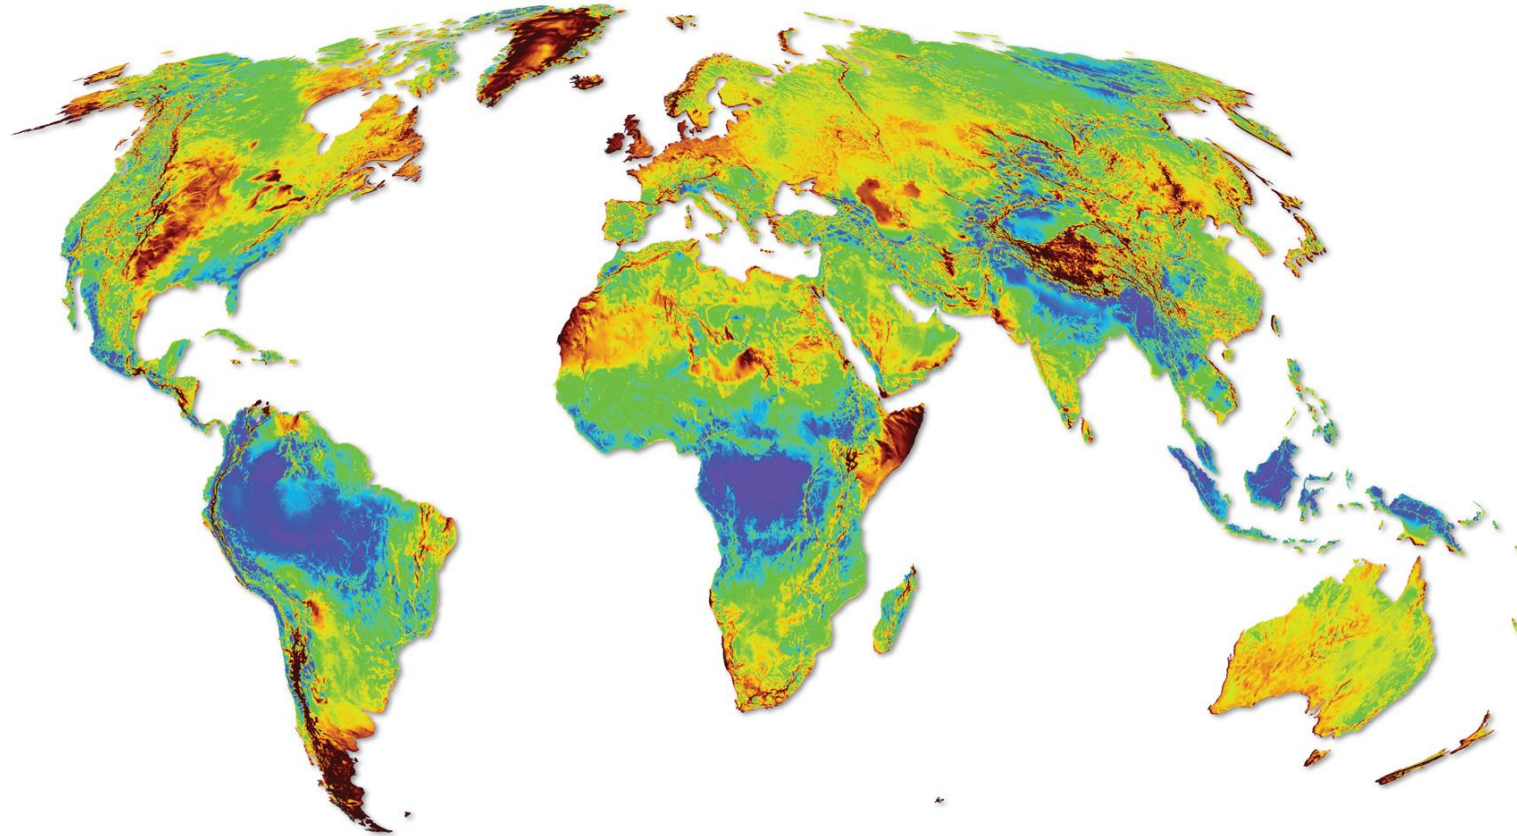

warm air
cool air

Wind Resource (Northern Hemisphere)

- Equatorial regions receive more solar radiation than polar regions

- Warm air rises and moves toward the north
  - Earth's rotation (Coriolis Effect) imparts an east-west direction (westerlies)
  - Around 30° N the air cools and sinks

- This cooler air returns to equatorial region
 - Direction is south west (trade winds)

SEATTLEU

Wind Resource

blue: westerlies
yellow: trade winds (northeasterly)

1: hurricanes
2: cyclones

Dr. Louie

SEATTLEU

5km Global Wind

5km Wind Map at 80m

Wind speed

3　　　6　　　9　m/s

Wind Resource

- At lower levels of the atmosphere, wind is also influenced by frictional forces and obstacles (mountains, etc)
  - Very localized
- Result: wide variation in wind speed and direction
- Wind speed depends on
  - Geographic location
  - Climate
  - Height above ground
  - Terrain

SEATTLEU

Wind Resource

- Localized scale wind regimes

- Examples
  - Shore lines: sea breezes caused by land/water temperature differentials
  - Mountain valleys or gorges: flow channeling
  - Mountain tops/down slope: mountain wave events (Chinook winds)

Dr. Louie

SEATTLEU

Wind Resource

- Wind speed tends to exhibit patterns:
  - Semi-diurnal
  - Diurnal
  - Seasonal
  - Longer-term

SEATTLE**U**

Wind Resource

- Van der Hoven spectrum distribution of kinetic energy in the wind in the frequency domain

4 day
Geostropic winds

diurnal

1 min

Frequency (cycles per hour)

Wind Measurements

- Meteorological (Met) stations/towers contain weather measurement devices
  - Wind speed (anemometer)
  - Wind direction
  - Pressure
  - Other

Variation with Height

- Wind speeds at greater distance from ground level tend to be higher
  - Wind shear
  - Less turbulence caused by ground friction
- Important considering wind turbine hub heights are 80 m, but measurements may be taken at much lower heights

SEATTLE**U**

Variation with Height
Credit: Danielle Isbell

Variation with Height

$$\frac{V_{hub}}{V_{meas}} = \frac{\ln(Z_{hub}/Z_0)}{\ln(Z_{meas}/Z_0)}$$

- Where
  V_{hub}: wind speed at hub height (m/s)
  V_{meas}: measured wind speed (m/s)
  Z_{hub}: height of the wind turbine hub (m)
  Z_{meas}: height of measurement (m)
  Z_0: roughness length (m)

Dr. Louie

SEATTLE U

Variation with Height

Roughness Length

Very smooth, ice or mud	0.00001 m
Calm open sea	0.0002 m
Blown sea	0.0005 m
Snow surface	0.003 m
Lawn grass	0.008 m
Rough pasture	0.010 m
Fallow field	0.03 m
Crops	0.05 m
Few trees	0.10 m
Many trees, few buildings	0.25 m
Forest and woodlands	0.5 m
Suburbs	1.5 m
City center, tall buildings	3.0 m

SEATTLEU

Variation with Height

- Compute the wind speed at a hub height of 90 m if the measurement from a 10 m anemometer is 3 m/s, given the terrain is:
   1. Few trees
    2. City center

Variation with Height

Few trees:

$$\frac{v_{hub}}{v_{meas}} = \frac{\ln(z_{hub}/z_0)}{\ln(z_{meas}/z_0)} \Rightarrow v_{hub} = 3 \times \frac{\ln(90/0.1)}{\ln(10/0.1)} = 4.43 \text{m/s}$$

City Center:

$$\frac{v_{hub}}{v_{meas}} = \frac{\ln(z_{hub}/z_0)}{\ln(z_{meas}/z_0)} \Rightarrow v_{hub} = 3 \times \frac{\ln(90/3)}{\ln(10/3)} = 8.48 \text{m/s}$$

Wind Resource Classes

Class	Mean Wind Speed (m/s) at 50m	Wind Power Density (W/m^2) at 50m
1	<5.6	<200
2	5.6-6.4	200-300
3	6.4-7.0	300-400
4	7.0-7.5	400-500
5	7.5-8.0	500-600
6	8.0-8.8	600-800
7	>8.8	>800

suitable for large-scale development

How do these density values compare with irradiance?

SEATTLEU

Available Power

Kinetic energy in moving air:

$$E_{air} = \tfrac{1}{2}\, mv^2$$

Mass of air

Dr. Louie

SEATTLE**U**
Available Power

- Let the mass of air ℓ meters in length pass through a surface each second
- Mass of air that has passed through a circular cross section 1 m^2 each second
  - m = 1$\ell\rho$
- Where:
  - ρ: is the density of air kg/m^3
    - Usually 1.23 kg/m^3, but may vary

surface

Mass of air

SEATTLE**U**
Available Power

- **Substituting:**
  - $m = \ell\rho$ into
  - $E_{air} = \frac{1}{2}\, mv^2 = \frac{1}{2}\ell\rho v^2$

- **Computing power**
  - $P_{air} = E_{air}/s = \frac{1}{2}\ell\rho v^2/s$ Note: s is seconds
  - Substituting $\ell/s = v$ yields:
   - $P_{air} = \frac{1}{2}\,\rho v^3$

SEATTLEU

Available Power

- Cubic relationship between wind speed and power
  - $P_{air} = \frac{1}{2}\rho v^3$

- Very important to place wind turbines in high wind speed locations

SEATTLEU

Wind Resource

- Wind speeds (and power) tend to exhibit more variability and uncertainty than solar irradiance

wind power

Wind Resource

- To determine if a location is suitable for development (i.e. will be profitable) developers rely on probabilistic models of wind speed

- This usually involves installing temporary anemometers for a period of 6 months – 2years

- Models can be formed based upon the data

SEATTLEU

Probability Density Functions

- Wind speed can be considered a random variable **v**

- We can describe the likelihood that **v** will be within a particular range through its Probability Density Function (PDF), f(**v**)

SEATTLE**U**

Probability Density Functions

- For a random variable x with a Normal (Gaussian) Distribution

$$f(x) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{\frac{-(x-\mu)^2}{2\sigma^2}}$$

- Where
  - μ: mean
  - σ^2: variance

SEATTLEU

Probability Density Functions

- Probability that x will be between x_1 and x_2 is found through integration

$$p[x_1 \leq x \leq x_2] = \int_{x_1}^{x_2} \frac{1}{\sqrt{2\pi\sigma^2}} e^{\frac{-(x-\mu)^2}{2\sigma^2}} dx$$

area = 1
SEATTLEU
Probability Density Functions

- Probability that x will be between 0 and 1 is found through integration
SEATTLEU
Cumulative Distribution Function

- Cumulative Distribution Function (CDF) provides information on the probability that $x \leq x_1$

- Integral of the PDF

$$F(x_1) = p[x \leq x_1] = \int_{-\infty}^{x_1} f(x)dx$$

SEATTLE**U**

Cumulative Distribution Function

- Probability that x will be between 0 and 1 is found by subtracting $F(1) - F(0)$
 - 0.84-0.5=0.34

Wind Speed Modeling

- PDF of the wind resource can be modeled by collecting a number of samples from a met tower

- Normalized histogram of those samples will resemble (hopefully) a common PDF

Wind Speed Modeling

- Histogram of wind speed measurements

- Observations
  - Values > 0
  - Peaked
  - Long tail

Dr. Louie

SEATTLE**U**

Wind Speed Modeling

- Based on empirical observations, wind speed tends to follow a Rayleigh (or Weibull) distribution
$$f\left(v\right) = \frac{2v}{c^2} e^{\frac{-v^2}{c^2}}$$

- Where:
  - c: a parameter of the distribution

$$c = \frac{2\overline{v}}{\sqrt{\pi}}$$

  - $\overline{v}$: is the mean wind speed of the sample

SEATTLEU

Wind Speed Modeling

Dr. Louie

SEATTLE U

Wind Speed Modeling
- Mean wind speed is NOT the most probable

- Most probable wind speed occurs at $0.8\bar{v}$ (if it perfectly follows a Rayleigh Distribution)

SEATTLE**U**

Wind Speed Modeling

- CDF of Rayleigh is:

$$F(v_1) = \int_0^{v_1} \frac{2v}{c^2} e^{\frac{-v^2}{c^2}} dv = 1 - e^{\frac{-v_1^2}{c^2}}$$

mean speed is 7.1 m/s

SEATTLEU

Wind Speed Modeling

- We can judge how well the fitted Rayleigh distribution approximates the measurements in several ways
  - χ^2 goodness-of-fit test (parametric)
  - probability plots (non-parametric)
  - other
- We can refine the model by month, hour, wind direction
SEATTLEU

Wind Speed Modeling

- Data from a 80 m met tower is shown

- Mean wind speed is computed to be: 7.1 m/s

- Write the equation of the best-fit Rayleigh Distribution

SEATTLEU
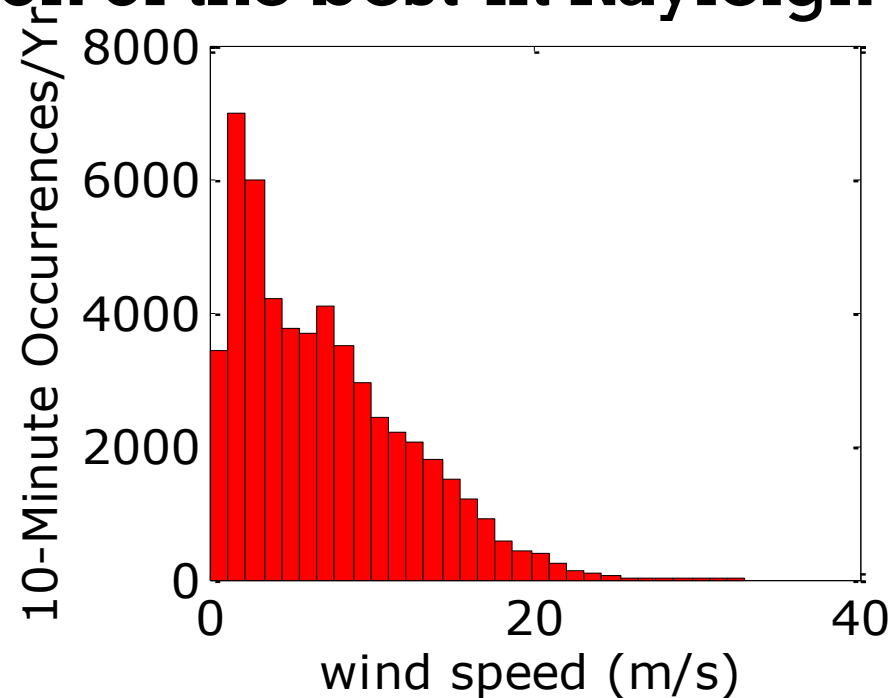

Wind Speed Modeling

$$c = \frac{2\bar{v}}{\sqrt{\pi}} = 8.03$$

$$f(v) = \frac{2v}{8.03^2} e^{\frac{-v^2}{8.03^2}}$$

SEATTLEU

Wind Speed Modeling

Compute the probability that the wind speed will be less than 3 m/s

SEATTLEU

Wind Speed Modeling

- Compute the probability that the wind speed will be less than 3 m/s
$$F(3) = 1 - e^{\frac{-3^2}{8.03^2}} = 0.13$$

$$F(0) = 1 - e^{\frac{-0^2}{8.03^2}} = 0$$
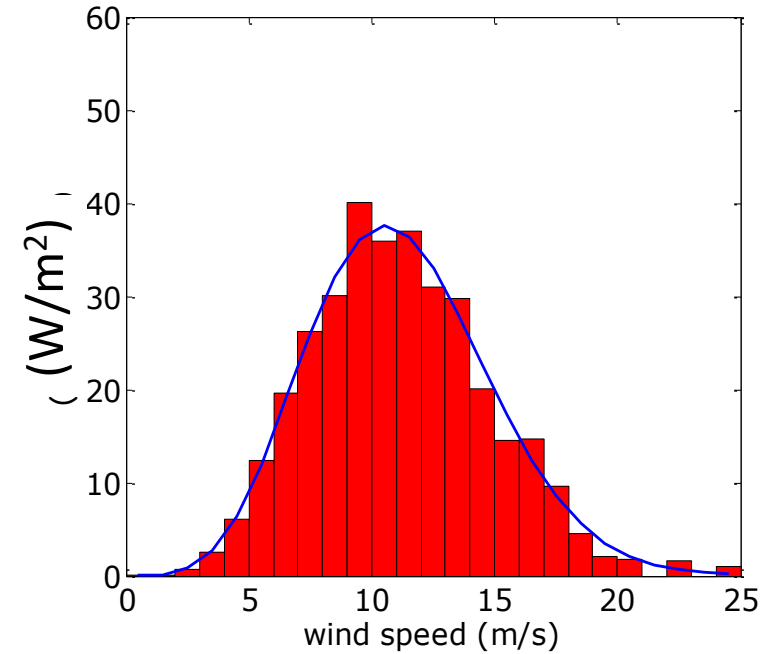

- 13% of the time the wind will be <3 m/s

SEATTLEU

Wind Power Modeling

- Now that we have our wind resource modeled, we need to determine how much energy a wind turbine will produce

- Capacity Factor is an appropriate metric

- CF by:
  - Hour
  - Month
  - Direction

Wind Power Modeling

Distribution of Power in Wind

Cubic relationship between wind speed and wind power

SEATTLE U
